- Infectious and neoplastic etiologies often cause significant pain, anterior uveitis (miosis, aqueous flare, fibrin, iridal hyperemia and swelling), chorioretinitis with retinal detachment, and possible secondary glaucoma.

CAUSES
See Table 1.

RISK FACTORS
- Ophthalmic—hypermature cataract, retinal detachment, chronic anterior uveitis.
- Systemic—any disease or disorder predisposing to the systemic diseases known to cause uveitis or direct vascular damage

Table 1

Causes of hyphema.

Primary Ophthalmic Etiologies	*Systemic Disease Etiologies*
Trauma (blunt or perforating)	Hypertension
Extraocular vascular compression (choking, chest compression)	Hyperviscosity syndrome
PIFM	Thrombocytopenia
Retinal detachment	Coagulopathy
Primary intraocular neoplasia (iris melanoma, ciliary body adenoma/adenocarcinoma)	Metastatic neoplasia (especially lymphoma)
Golden retriever pigmentary uveitis	Rickettsial disease
Patent anomalous congenital blood vessels (persistent pupillary membranes, tunica vasculosa lentis, hyaloid artery)	FIP
	Fungal disease
	Prototheca
	Parasitic (aberrant intraocular larval migration)

HYPHEMA (CONTINUED)

(e.g., chronic renal disease, hyperthyroidism, systemic hypertension); living in geographic areas with endemic tick-borne disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Deep corneal vascularization, along the ventral limbus, can be mistaken for hyphema.

CBC/BIOCHEMISTRY/URINALYSIS
Abnormal findings may help support a diagnosis of systemic disease.

OTHER LABORATORY TESTS
Based on history and physical examination findings, coagulation profile and serology (rickettsial, fungal) may be indicated if systemic disease is suspected.

IMAGING
- Ocular ultrasound is indicated to evaluate for retinal detachment or uveal tumors when not visible on the ophthalmic examination.
- Based on history and physical examination findings, thoracic radiographs, abdominal radiographs, and abdominal ultrasound may be indicated if systemic disease is suspected.

DIAGNOSTIC PROCEDURES
- Systemic arterial blood pressure measurement using Doppler ultrasonic flow probe or oscillometric techniques, if hypertension is suspected.
- Lymph node aspirates if lymphadenopathy is present or if neoplasia or fungal disease is suspected.

PATHOLOGIC FINDINGS
Gross hemorrhage in the anterior chamber.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient medical care is appropriate unless an underlying systemic disease is identified that requires hospitalization.

ACTIVITY
No restricted activity is required unless the patient is blind (restrict environment to fenced yards, no in-ground pools, leash walks, etc.) or the hyphema is due to thrombocytopenia or coagulopathy (avoid rough play, unrestricted running, etc.).

CLIENT EDUCATION
- Hyphema itself, although it appears dramatic, is not painful.
- It is very important to identify the underlying cause of the hyphema, as some etiologies pose a serious health threat.
- Ophthalmic treatment should be initiated immediately to try to prevent painful and sometimes irreversible and blinding sequelae like glaucoma.

SURGICAL CONSIDERATIONS
- Hyphema secondary to a perforating corneal laceration or ulceration should be surgically repaired by direct suturing of the cornea (laceration) or corneal graft (perforated ulcer) when a visual outcome is expected; for a severe perforation with extensive iris prolapse and loss of the pupil, enucleation is recommended.
- Permanently blind and painful eyes should be enucleated (with histopathology) for permanent comfort.
- Surgical irrigation/removal of the hyphema is not successful, as the trauma of the surgery results in exacerbation of the hyphema and intraocular inflammation.

MEDICATIONS

DRUG(S) OF CHOICE
- Topical prednisolone acetate 1% or dexamethasone 0.1% q4–8h to help stabilize the blood–aqueous barrier; *do not use if a corneal ulcer or perforation is present.*
- Atropine 1% q6–24h to help prevent posterior synechia; *atropine is contraindicated if secondary glaucoma is present.*
- Systemic nonsteroidal anti-inflammatory drug (NSAID—carprofen, meloxicam, deracoxib) for analgesia in patients with perforating trauma; may help stabilize blood–aqueous barrier.
- Systemic prednisone/prednisolone with known or suspected choroidal/retinal involvement, *depending on the underlying cause*; anti-inflammatory dose (0.5–1.0 mg/kg PO q24h) can be used for blunt trauma, feline infectious peritonitis (FIP), and rickettsial and fungal disease with proper antimicrobial therapy.
- Topical carbonic anhydrase inhibitors (dorzolamide 2%, brinzolamide 1%, q8h), beta blocker (timolol 0.5% q8–12h), and/or sympathomimetic (dipivefrin 0.1% q8–12h) can be used if secondary glaucoma is present.

CONTRAINDICATIONS
- Topical NSAIDs (flurbiprofen, diclofenac, ketorolac, etc.) are generally considered contraindicated with hyphema.
- Topical prostaglandin analogues (latanoprost, travoprost, bimatoprost) are contraindicated in secondary glaucomas.

FOLLOW-UP

PATIENT MONITORING
- Tonometry should be used to monitor for secondary glaucoma, which lowers the prognosis for a visual outcome.
- Perform tonometry every 1–2 days if the intraocular pressure (IOP) is high normal or greater, or if risk factors such as fibrin and/or posterior synechia are present.
- Perform tonometry weekly if the IOP is low, or if the hyphema and anterior uveitis are mild to moderate in severity.
- *Tonometry is contraindicated with a corneal perforation.*

POSSIBLE COMPLICATIONS
Secondary glaucoma, posterior synechia/dyscoria, cataract formation, loss of vision, possible loss of the eye if the eye becomes permanently blind and painful.

EXPECTED COURSE AND PROGNOSIS
- If the underlying cause of the hyphema can be successfully treated, such as repair of a corneal laceration or control of hypertension, and intraocular damage is not extensive, the prognosis is good for complete resolution of the hyphema.
- If trauma to the eye is severe or if the underlying disease is not controlled, the hyphema will persist and blindness can result; no improvement in hyphema after 2 weeks following blunt trauma has a poor prognosis for return of vision; enucleation should be performed in any cat with permanent blindness from trauma due to the risk of developing traumatic ocular sarcoma.
- Hyphema caused by bleeding from PIFMs usually does not resolve or will resolve and recur.
- If the eye is painful due to a perforated globe or secondary glaucoma, with no reasonable hope of regaining vision, enucleation is recommended.

MISCELLANEOUS

ABBREVIATIONS
- FIP = feline infectious peritonitis.
- IOP = intraocular pressure.
- NSAID = nonsteroidal anti-inflammatory drug.
- PIFM = pre-iridal fibrovascular membrane.

Consulting Editor Kathern E. Myrna

HYPOADRENOCORTICISM (ADDISON'S DISEASE)

BASICS

DEFINITION
- Endocrine disorder resulting from deficient production of glucocorticoids and, usually, mineralocorticoids.
- Primary hypoadrenocorticism (Addison's disease) is due to destruction of the adrenal cortices resulting in glucocorticoid and mineralocorticoid deficiency.
- The term atypical hypoadrenocorticism has been applied to the subset of dogs with primary hypoadrenocorticism and normal electrolyte concentrations.
- Secondary hypoadrenocorticism results from pituitary adrenocorticotropic hormone (ACTH) insufficiency, resulting in inadequate glucocorticoid production by the adrenal cortices.

PATHOPHYSIOLOGY
- Mineralocorticoid (aldosterone) deficiency results in a diminished ability to excrete potassium and retain sodium, disrupting sodium and potassium balance in the body.
- Sodium loss leads to diminished effective circulating volume; this contributes to pathophysiologic changes and clinical abnormalities, including prerenal azotemia, hypotension, dehydration, weakness, and depression.
- Hyperkalemia can result in weakness, lethargy, and anorexia; it may result in bradyarryhthmias.
- Glucocorticoid (cortisol) deficiency contributes to anorexia, vomiting, diarrhea, melena, lethargy, and weight loss; due to its role in glucose homeostasis, hypocortisolemia predisposes to hypoglycemia.

SYSTEMS AFFECTED
- Gastrointestinal.
- Musculoskeletal.
- Cardiovascular.
- Renal/urologic.

GENETICS
A genetic basis has been determined in standard poodles, bearded collies, Nova Scotia duck tolling retrievers, and Leonbergers.

INCIDENCE/PREVALENCE
Unknown; considered uncommon in dogs and very rare in cats.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- Great Danes, Rottweilers, Portuguese water dogs, standard poodles, bearded collies, Leonbergers, West Highland white terriers, Novia Scotia duck tolling retrievers and soft coated wheaten terriers have increased relative risk; golden retrievers and Chihuahuas have decreased relative risk.
- No predilection in cats.

Mean Age and Range
- Dogs—range: <1 to >12 years; median: 4 years; young to middle-aged.
- Cats—range: 1–9 years; middle-aged.

Predominant Sex
Female dogs at increased relative risk; no predilection in cats.

SIGNS

General Comments
- Signs vary from mild in patients with chronic hypoadrenocorticism to severe and life-threatening in an acute Addisonian crisis.
- Multiple organ systems may be involved; type and extent of involvement vary with case.

Historical Findings
- Dogs—lethargy, anorexia, vomiting, weakness, weight loss, diarrhea, waxing/waning course, previous response to therapy, polyuria/polydipsia (PU/PD), melena.
- Cats—lethargy, anorexia, weight loss, vomiting, waxing/waning course, previous response to therapy, PU/PD.

Physical Examination Findings
- Dogs—depression, weakness, hypovolemia, dehydration, collapse, hypothermia, melena, hypotension, bradycardia, painful abdomen, hair loss.
- Cats—dehydration, hypovolemia, weakness, hypothermia, depression, hypotension, bradycardia, collapse.

CAUSES
- Primary hypoadrenocorticism—idiopathic (immune-mediated), mitotane or trilostane overdose, granulomatous disease, metastatic tumors, fungal disease, coagulopathy, adrenal hemorrhage or necrosis.
- Secondary hypoadrenocorticism—iatrogenic following withdrawal of long-term glucocorticoid administration, ACTH deficiency, panhypopituitarism, pituitary or hypothalamic lesions.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Signs are nonspecific and often mimic gastrointestinal and renal diseases; differential diagnoses for gastrointestinal distress include intestinal obstruction (e.g., foreign body, intussusception, neoplasia), gastrointestinal perforation, pancreatitis, infectious disease, and others (see Acute Vomiting).
- Differential diagnoses for hyperkalemia include acute kidney injury, urinary tract obstruction, third-space fluid loss (e.g., peritoneal or pleural effusion, uroabdomen), and Trichuriasis.
- Although no signs are pathognomonic, a waxing and waning course and previous response to nonspecific medical intervention should alert the clinician.

CBC/BIOCHEMISTRY/URINALYSIS
- Hematologic abnormalities may include anemia, eosinophilia, and lymphocytosis.
- The absence of a stress leukogram in a sick patient should prompt consideration of hypoadrenocorticism.
- Serum biochemical findings may include hyperkalemia, azotemia, hyponatremia, hypochloremia, hyperphosphatemia, hypercalcemia, hypoalbuminemia, increased alanine aminotransferase (ALT) activity, and hypoglycemia.
- Urinalysis often reveals impaired urine-concentrating ability and in some cases isothenuria; some patients with isothenuria are also azotemic, potentially causing confusion with primary renal disease.
- Some patients with hypoadrenocorticism exhibit normal electrolyte levels (so-called atypical hypoadrenocorticism).

OTHER LABORATORY TESTS
- Definitive diagnosis is by demonstration of undetectable to low (<2 µg/dL) baseline serum cortisol concentrations that fail to increase above 2 µg/dL following ACTH administration.
- Cortisol concentrations should be measured before and 1 hour after administration of synthetic ACTH (1 µg/kg, IV in dogs and 5 µg/kg, IV in cats).
- The ACTH stimulation test can be performed during initial stabilization and treatment if dexamethasone is used (does not cross-react with the cortisol assay).
- If prednisone, prednisolone, or hydrocortisone has been administered, the treatment must be discontinued, and the ACTH stimulation test performed at least 24 hours after changing the glucocorticoid to dexamethasone (do not withhold corticosteroids from a patient in acute crisis).
- A low resting cortisol does not confirm hypoadrenocorticism; an ACTH stimulation test is required.
- Plasma ACTH concentration can be measured in patients with normal electrolyte concentrations to differentiate primary from secondary hypoadrenocorticism; must collect sample before initiating therapy, especially glucocorticoids; carefully follow sample handling instructions from the laboratory; plasma ACTH concentrations are high with primary hypoadrenocorticism and undetectable to low with secondary hypoadrenocorticism.

IMAGING
- Radiographs may reveal microcardia, narrowed vena cava or descending aorta, hypoperfused lung fields, less commonly microhepatica, and very rarely megaesophagus.

HYPOADRENOCORTICISM (ADDISON'S DISEASE) (CONTINUED)

• Abdominal ultrasound may reveal small adrenal glands.
• Imaging is not usually necessary for diagnosis, but is often performed during the diagnostic workup in patients with gastrointestinal signs.

PATHOLOGIC FINDINGS
• Gross examination—atrophy of the adrenal glands.
• Microscopically—lymphocytic-plasmocytic adrenalitis and/or adrenocortical atrophy; other abnormalities may be present depending on etiology (neoplasia, fungal disease, etc.).

TREATMENT

APPROPRIATE HEALTH CARE
• An acute Addisonian crisis is a medical emergency requiring intensive therapy and 24-hour observation and care; the diagnostic workup is performed while initial treatment and stabilization are ongoing; cats often respond more slowly than dogs.
• The intensity of treatment for patients with chronic hypoadrenocorticism depends on the severity of clinical signs; usually initial stabilization and therapy are conducted on an inpatient basis.

NURSING CARE
• Treat acute Addisonian crisis with rapid correction of hypovolemia and restoration of volume status using isotonic fluids, preferably Plasma-Lyte® or lactated Ringer's solution; although normal saline (0.9% NaCl) was historically recommended, it can exacerbate existing acidosis, but can be used in the absence of other isotonic crystalloid fluids.
• Do not increase sodium concentration by more than 12 mEq/L every 24 hours to prevent CNS myelinolysis; this is more likely to occur when the initial sodium concentration is <120 mEq/L; lactated Ringer's solution has a sodium content of 130 mEq/L and will increase the sodium concentration more slowly than Plasma-Lyte (140 mEq/L) and 0.9% saline (154 mEq/L).
• Although most cases respond to fluid resuscitation alone, severe hyperkalemia (>8.5–9.0 mEq/L and/or bradycardia or other ECG abnormalities) may require additional therapy; see Hyperkalemia.
• If necessary, a colloid fluid also can be given to treat hypotension and hypovolemia.
• Treat hypoglycemia, if present, with IV dextrose; due to hyperosmolarity, 50% dextrose should be diluted a minimum of 1 : 3 prior to IV administration.
• Monitor hydration status, blood pressure, urine output, rectal temperature, and heart rate and rhythm.

ACTIVITY
Avoid unnecessary stress and exertion during an Addisonian crisis.

DIET
No need to alter.

CLIENT EDUCATION
• Lifelong glucocorticoid and/or mineralocorticoid replacement therapy is required.
• Increased dosages of glucocorticoid (above maintenance requirements) are required during periods of stress such as travel, boarding, hospitalization, and surgery.

MEDICATIONS

DRUG(S) OF CHOICE
• In an Addisonian crisis, parenteral administration of a rapidly acting glucocorticoid such as dexamethasone sodium phosphate is indicated; dexamethasone sodium phosphate is given at a dose of 0.25 mg/kg IV on the first day, and 0.15 mg/kg on the second day; glucocorticoid is gradually tapered and changed to oral prednisone or prednisolone as the condition improves.
• Alternatively, hydrocortisone (0.5–0.625 mg/kg/h) has both mineralocorticoid and glucocorticoid properties, and prednisolone sodium succinate (2 mg/kg IV initially, and then 0.5 mg/kg IV q12h) is also an option; since both of these cross-react with cortisol assays (dexamethasone does not), they should be administered after the ACTH stimulation test is complete, or ACTH stimulation testing should be delayed at least 24 hours after administration.
• During an Addisonian crisis, supportive therapy, including gastroprotectants and anti-emetics, is often necessary.
• Chronic primary hypoadrenocorticism—most patients will need daily glucocorticoid replacement (prednisone 0.1–0.2 mg/kg/day PO), as well as mineralocorticoid replacement (desoxycorticosterone [DOCP], 2.2 mg/kg IM/SC, typically given monthly and adjusted as needed on the basis of serial electrolyte determinations); the initial monthly DOCP dose for an average-sized cat is 12.5 mg IM/SC; though not preferred, an alternative means of administering glucocorticoid replacement to cats is Depo-Medrol® (10 mg IM monthly).
• Prednisone dose is adjusted based on clinical signs and side effects; the dose is decreased if PU/PD, polyphagia, and muscle wasting are present, but increased if vomiting, diarrhea, or lethargy occurs; some dogs, particularly large breeds, require less than 0.1 mg/kg/day, but all dogs with hypoadrenocorticism require some prednisone, but all dogs with hypoadrenocorticism require some glucocorticoid.
• The label dose of DOCP is 2.2 mg/kg, but this author routinely begins at 1.5 mg/kg with owner consent to use an off-label dose.
• Alternatively, an oral mineralocorticoid replacement can be used (fludrocortisone acetate 5–10 µg/kg PO q12h, adjusted by 0.05–0.1 mg increments on the basis of serial electrolyte determinations); fludrocortisone has some glucocorticoid activity and the maintenance dose of prednisone for patients receiving fludrocortisone may be lower than for dogs receiving DOCP; a few dogs develop PU/PD and/or polyphagia from fludrocortisone.
• Patients with confirmed atypical and secondary hypoadrenocorticism require only glucocorticoid supplementation (prednisone 0.1–0.2 mg/kg/day PO), adjusted as described above.

PRECAUTIONS
N/A

ALTERNATIVE DRUG(S)
See Hyperkalemia; Hyponatremia.

FOLLOW-UP

PATIENT MONITORING
• Depending on clinical presentation, patients hospitalized for treatment of hypoadrenocorticism may require intensive monitoring and frequent laboratory evaluations; monitor clinical status, urine output, CBC, blood chemistry, and ECG as needed; blood glucose and electrolytes may need to be evaluated several times daily during initial therapy; arterial or venous blood gas analysis may be of benefit.
• Monitor for melena, as some dogs experience severe gastrointestinal blood loss during and following a crisis, sometimes requiring blood transfusion.
• Measure electrolyte concentrations 2 and 4 weeks following the first injection of DOCP, to determine whether the dose (2 weeks) and the dosing interval (4 weeks, prior to next injection) are appropriate; recheck electrolytes prior to next injection and each time the dose or dosing interval is adjusted; then check electrolyte concentrations every 6 months, or when the patient is sick.
• DOCP is usually required at monthly intervals; rare patients need injections as often as every 3 weeks; some dogs may require DOCP less than every 28–30 days; however, the author prefers to adjust the dose instead of extending the dosing interval, and does not decrease the dose (as directed below) and extend the dosing interval in the same dog.
• The majority of dogs with hypoadrenocorticism will be well controlled on a maintenance DOCP dose of 1.5 mg/kg/injection every month; if necessary based on expense, the DOCP dosage can be sequentially decreased by 10% each month

(CONTINUED) # HYPOADRENOCORTICISM (ADDISON'S DISEASE)

based on electrolyte determinations, as some dogs can be controlled on a monthly dosage that is less than 1.5 mg/kg; make sure that the owner is aware that this is off-label use.
- Adjust the daily dose of fludrocortisone by 0.05–0.1 mg increments as needed, based on serial electrolyte determinations; following initiation of therapy, check electrolyte levels weekly until they stabilize in the normal range; thereafter, check electrolyte concentrations monthly for the first 3–6 months and then every 3–12 months.
- In many dogs given fludrocortisone, the daily dose required to control the disorder increases incrementally, usually during the first 6–24 months of therapy; in most dogs, the final fludrocortisone dosage needed is 20–30 µg/kg/day PO; very few can be controlled on 10 µg/kg/day or less.
- In patients that were initially azotemic, monitor creatinine concentrations as needed following discharge from the hospital.

PREVENTION/AVOIDANCE
- Continue hormone replacement therapy for the lifetime of the patient.
- Increase the dosage of replacement glucocorticoid during periods of stress such as travel, boarding, hospitalization, and surgery.

POSSIBLE COMPLICATIONS
- PU/PD may occur from prednisone administration, but this usually resolves with a decrease in dosage; rarely, it is necessary to try an alternative glucocorticoid, such as methylprednisolone, when the dog's clinical signs are not controlled on a dose of prednisone that is low enough to eliminate side effects.
- PU/PD may occur from fludrocortisone administration.
- Side effects from DOCP are uncommon; rarely weight gain and PU/PD are seen.

EXPECTED COURSE AND PROGNOSIS
- Except for patients with primary hypoadrenocorticism caused by granulomatous or metastatic disease and secondary hypoadrenocorticism caused by a pituitary mass, the vast majority of patients have a good to excellent prognosis following proper stabilization, treatment, and monitoring.
- Owners must be reminded that they should not skip DOCP injections, as this could precipitate a potentially fatal, and inevitably costly, Addisonian crisis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Concurrent endocrine gland failure occurs in up to 5% of dogs—hypothyroidism, diabetes mellitus, and/or hypoparathyroidism.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
None

SYNONYMS
Addison's disease.

SEE ALSO
- Hyperkalemia.
- Hyponatremia.

ABBREVIATIONS
- ACTH = adrenocorticotropic hormone.
- ALT = alanine aminotransferase.
- DOCP = desoxycorticosterone.
- PU/PD = polyuria/polydipsia.

HYPOALBUMINEMIA

BASICS

DEFINITION
Hypoalbuminemia defined as measured serum albumin value less than reference range.

PATHOPHYSIOLOGY
• Albumin—constitutive protein exclusively synthesized in liver. • Provides 75–80% of plasma colloid oncotic pressure. • Low oncotic pressure due to serum albumin <1.5 g/dL permits fluid extravasation into interstitial and third-space compartments, causing edema and body cavity effusion.

SYSTEMS AFFECTED
Cardiovascular and respiratory—transudative effusions (pleural effusion, ascites); peripheral edema; pulmonary edema.

INCIDENCE/PREVALENCE
Accompanies many primary diseases that cause hepatic insufficiency, protein-losing enteropathy (PLE), protein-losing nephropathy (PLN), hemorrhage, negative acute-phase response in chronic disease.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Underlying disease may have breed predilection.

Mean Age and Range
Varies with syndrome association.

Predominant Sex
N/A

SIGNS

General Comments
• Reflect primary disease leading to hypoalbuminemia. • Hypoalbuminemia influences metabolite and xenobiotic protein binding, plasma oncotic pressure, third-space fluid distribution, acid-base balance, and ability to maintain intravascular perfusion pressure.

Historical Findings
• Vary with underlying disease. • Increased drug-related effects due to reduced protein binding.

Physical Examination Findings
• Vary with underlying primary disease. • Serum albumin ≤1.5 g/dL often associated with pitting edema, decreased heart/lung sounds, and/or abdominal fluid wave.

CAUSES

Decreased Albumin Production
• Chronic hepatic insufficiency—chronic hepatitis; cirrhosis; idiopathic hepatic fibrosis; granulomatous hepatitis; congenital portosystemic shunt (PSS; dogs). • Inadequate nutritional intake/absorption (modest effect).

Extracorporeal Albumin Loss
• PLN—amyloidosis; glomerulonephritis. • PLE—lymphangiectasia; lymphoma; severe inflammatory bowel disease (IBD); histoplasmosis; pythiosis; chronic intussusception; Addison's disease. • Severely exudative cutaneous lesions. • Chronic severe blood loss—usually enteric. • Repeated large-volume paracentesis of abdominal or pleural effusion.

Sequestration: Body Cavities/Tissues
• Inflammatory effusions—pancreatitis; septic or aseptic peritoneal or pleural effusions; chylous effusions (modest effect). • Vasculopathies—immune-mediated (systemic lupus erythematosus [SLE]); infectious (Ehrlichia, Rocky Mountain spotted fever); sepsis syndrome; other (modest effect).

Miscellaneous
Downregulated albumin synthesis—hyperglobulinemia, negative acute-phase response, negative nitrogen intake, catabolism (modest effect).

RISK FACTORS
• Diseases of the liver, kidney, intestines, and blood vessels. • Negative nitrogen balance; poor nutrition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Severe hepatic disease—may see jaundice; hepatic encephalopathy (HE); ascites. • PLE—diarrhea common but inconsistent. • Cutaneous lesions—must be severe and exudative (burns, toxic epidermal necrolysis [TEN], vasculitis, tumors, trauma). • External blood loss—hemorrhage (enteric, urinary, other). • Malnutrition—mild hypoalbuminemia. • Aggressive fluid therapy—exacerbates low albumin.

CBC/BIOCHEMISTRY/URINALYSIS

CBC
• Depends on underlying disease. • Severe hepatic disease—red blood cell (RBC) microcytosis suggests PSS. • Severe blood loss—regenerative anemia or microcytic/hypochromic anemia.

Biochemistry
• Chronic hepatic disease—low albumin; normal to high globulin. • PLE—low albumin; variable globulin. • PLN—low albumin; globulin usually normal but may be low with severe PLN. • Exudative losses—low albumin; variable globulin. • Malnutrition—low albumin; normal globulin. • Severe blood loss—low albumin; low to normal globulin. • Cholesterol—low with chronic hepatic disease, severe PLE, Addison's disease, and severe malnutrition; high with PLN and pancreatitis. • Hepatic enzymes—alanine aminotransferase (ALT) may be high with chronic hepatitis, IBD causing PLE; high alkaline phosphatase (ALP) often seen with systemic inflammation as well as hepatic disease. • Bilirubin—sometimes high with hepatic disease. • Blood urea nitrogen (BUN)—often low with hepatic insufficiency or patients undergoing diuresis; high with reduced renal function or dehydration. • Hyperkalemia and hyponatremia—suggest hypoadrenocorticism, third-space effusions, or pseudohypoadrenocorticism (endoparasitism). • Spurious hypocalcemia—due to low protein.

Urinalysis
• Rules out PLN and urologic blood loss. • Obtain urine by cystocentesis to avoid lower-tract contamination; *caution*: beware cystocentesis-induced microhematuria. • Proteinuria—confirm dipstick detection with chemical determination. • Urine protein : creatinine (UP : UCr) ratio—important; >3.0 compatible with nephrotic range proteinuria; must evaluate urine sediment: spurious positive values with active sediment (i.e., substantial pyuria, macroscopic hematuria, bacteriuria); many dogs with glomerulonephritis have hyaline, waxy, or granular casts; bacterial culture of urine necessary to rule out bacteriuria as cause of increased urine protein. • Microalbuminuria—not helpful. • Ammonium biurate crystalluria—hepatic insufficiency, PSS, or acquired portosystemic shunt (APSS).

OTHER LABORATORY TESTS
• Total serum bile acids (TSBA)—usually high with severe hepatic disease; sometimes spurious low values with PLE (fat malabsorption). • Physicochemical evaluation of effusion—transudate (usually pure) if hypoalbuminemia is the major causal factor. • Antithrombin (AT)—may be low with PLE, PLN, and hepatic synthetic failure. • Protein C (PC)—may be low with severe hepatic disease/failure, PSS, sepsis.

IMAGING
• Thoracic radiography—pleural effusion; pulmonary edema; lymphadenopathy, metastatic disease, cardiac or pulmonary disorders. • Abdominal radiographs—effusion; altered hepatic size; mass lesions; pancreatic disease. • Abdominal ultrasonography—small liver, lymphangiectasia in intestinal wall/mucosa, mass lesions, fluid pockets, altered portal blood flow, mesenteric lymphadenopathy, biliary tree abnormalities, renal abnormalities.

DIAGNOSTIC PROCEDURES
• Hepatic biopsy—after evaluating coagulation (mucosal bleeding time, platelet count) status. • Renal biopsy—differentiates

amyloidosis from glomerulonephritis; submit samples for special renal panel staining and electron microscopy. • Intestinal biopsy—endoscopic or surgical.

PATHOLOGIC FINDINGS
Depend on underlying causal disease.

TREATMENT

APPROPRIATE HEALTH CARE
• Diverse, depends on cause. • Pleural/peritoneal effusion restricting ventilation—perform centesis.

NURSING CARE
Provide physical therapy and walk patient to improve mobilization of peripheral edema.

DIET
• Achieve positive energy and nitrogen balance. • HE—control protein intake (see Hepatic Encephalopathy). • PLE with IBD component—novel/hydrolyzed protein (see Inflammatory Bowel Disease). • PLE due to lymphangiectasia—feed ultra-low-fat diet. • PLN – feed high-quality/reduced-protein diet.

SURGICAL CONSIDERATIONS
Severe hypoalbuminemia delays healing, anesthetic drug metabolism, body cavity effusions may complicate drug dosing and dispersal, surgical approach, patient ventilation.

MEDICATIONS

DRUG(S) OF CHOICE
• Depend on underlying disease.
• Glucocorticoids—for some types of chronic hepatitis and some PLEs; prednisolone is preferred if it is effective; dexamethasone lacks mineralocorticoid effects that lessens sodium and water retention, but has greater potential for ulceration/erosion. • Diuretics—furosemide (1–4 mg/kg IV/IM/PO q4–12h) in combination with spironolactone (1–4 mg/kg q12h) in patients with hepatic or cardiac disease, combine with low-salt diet, use judiciously to avoid intravascular volume contraction; for body cavity effusion mobilization, taper diuretic dose after initial positive response; diuretics may be used intermittently to mobilize recurring ascites.
• Antithrombotic treatment (low AT, PC, evidence of thrombi)—clopidogrel (0.5–1.0 mg/kg PO q24h), especially in PLN.
• Enalapril (0.5 mg/kg PO q12–24h)—for dogs with PLN; alternatives are benazepril or the angiotensin receptor blocker telmisartan (1 mg/kg PO q24h).

CONTRAINDICATIONS
Synthetic colloids—avoid with anuria, renal failure, congestive heart failure, severe coagulopathy, or von Willebrand disease.

PRECAUTIONS
• Fluid therapy—avoid overdosing crystalloid fluids, especially when administered with synthetic colloids as these are rapidly distributed into interstitial spaces (70% volume within 1 hour), aggravating antecedent pulmonary or limb edema, and body cavity effusions; restrict maintenance fluid volume of crystalloids to one-third normal (depending on contemporary losses) when used with colloids.
• Transfusion of canine plasma or human albumin—may be complicated by transfusion or allergic reactions; plasma and albumin transfusions of dubious value if severe ongoing protein loss due to PLN, PLE, vasculitis.
• Diuretic therapy—high doses may cause severe intravascular volume contraction leading to azotemia, hypotension, and electrolyte and acid-base derangements. • Unanticipated drug side effects—due to reduced albumin drug binding. • Use of 1 desamino-8-darginine vasopressin (DDAVP) for bleeding—may aggravate fluid retention and associated complications. • Glucocorticoids—mineralocorticoid effects of some drugs may worsen fluid accumulation; prefer synthetic glucocorticoids without mineralocorticoid effects.

POSSIBLE INTERACTIONS
Inadvertent overdosing of drugs with high-protein binding.

FOLLOW-UP

PATIENT MONITORING
• Bodyweight—especially during fluid therapy; monitors fluid retention. • Vital signs, thoracic auscultation for crackles—monitor for pulmonary edema. • Sequential serum albumin concentrations. • Blood pressure—monitors vascular expansion. • Abdominal girth—monitors ascites. • Central venous pressure—unreliable; potentially dangerous in patients with bleeding or thrombotic tendencies.

PREVENTION/AVOIDANCE
Limit glucocorticoid exposure as much as possible; use alternative medications to control primary illness if possible.

POSSIBLE COMPLICATIONS
• PLN/PLE—may be complicated by thromboembolism; minimize IV catheterization and trauma. • Hypovolemia—from dehydration, Addisonian crisis, blood loss, or diuretic overdose predisposes to acute renal failure, disseminated intravascular coagulation (DIC), or HE.

EXPECTED COURSE AND PROGNOSIS
Depend on underlying cause.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Numerous diverse diseases or syndromes.

PREGNANCY/FERTILITY/BREEDING
Condition complicates pregnancy.

HYPOCALCEMIA

BASICS

DEFINITION
Serum total and ionized calcium concentration below the reference range.

PATHOPHYSIOLOGY
- Of total circulating serum calcium, 40–50% is protein-bound, 40–50% is ionized, and 10% is complexed with other substances. Protein-bound and complexed calcium are unavailable for use by tissues. Only ionized calcium is available to tissues and is responsible for clinical problems (hypo and hypercalcemia).
- Mechanisms of hypocalcemia include:
  - Low concentrations of binding proteins—hypoalbuminemia.
  - Reduced intestinal absorption—deficient vitamin D (renal disease, severe intestinal disease, rickets, chronic glucocorticoid treatment).
  - Reduced renal and bone resorption—hypoparathyroidism.
  - Inadequate dietary intake.
  - Excessive loss—lactation (eclampsia).
  - Sequestration—saponification (acute pancreatitis).
  - Binding/complexing with administered, ingested, or endogenous chemicals—phosphate-containing enemas, citrate toxicosis (multiple citrate-containing anticoagulant transfusions), ethylene glycol toxicosis, oxalate toxicosis, low calcium/high phosphorus diet (nutritional secondary hyperparathyroidism), acute tumor lysis syndrome (hyperphosphatemia from cancer therapy-induced rapid destruction of tumor cells).
  - Impaired synthesis or refractoriness to parathyroid hormone (PTH)—hypomagnesemia.
  - Target organ calcitriol (vitamin D) resistance (vitamin D–dependent rickets type 2).
  - Multifactorial—ionized hypocalcemia in critically ill patients.

SYSTEMS AFFECTED
- Cardiovascular—ECG changes and bradycardia.
- Gastrointestinal—anorexia and vomiting (especially cats).
- Nervous/neuromuscular—seizures, tetany, ataxia, and weakness.
- Ophthalmic—posterior lenticular cataracts.
- Respiratory—panting.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
Small-breed bitches predisposed to eclampsia.

Mean Age and Range
Variable

Predominant Sex
Variable

SIGNS
General Comments
Signs of underlying disease may occur without clinical signs of hypocalcemia, because the latter do not occur until total serum calcium falls below 6.7 mg/dL. Severity of signs at a given calcium concentration are also dependent on rate of decrease; dogs with chronic hypocalcemia are less likely to show signs than dogs with acute hypocalcemia.

Historical Findings
- Facial rubbing.
- Muscle trembling, twitching, or fasciculations.
- Seizures.
- Ataxia or stiff gait.
- Weakness.
- Panting.
- Vomiting.
- Anorexia.

Physical Examination Findings
- Ataxia, stiff gait, weakness, muscle fasciculation, trembling, twitching.
- Hyperthermia.
- Posterior lenticular cataracts in patients with primary hypoparathyroidism.

CAUSES
Nonpathologic Hypocalcemia
- Laboratory error—confirm true hypocalcemia, especially if clinical signs are not present.
- Hypoalbuminemia—most common cause (>50% of patients); reduction of protein-bound calcium but not ionized calcium; not associated with clinical signs.
- Alkalosis—causes a reduction in ionized calcium while total can remain normal; not associated with clinical signs except in cases of borderline low serum ionized calcium concentrations.

Pathologic Hypocalcemia
- Primary hypoparathyroidism.
- Hypoparathyroidism secondary to bilateral thyroidectomy (or other corrective hyperthyroid therapies) causing parathyroid damage.
- Posthyperparathyroid correction due to prolonged negative feedback–induced hypofunction of normal parathyroid glands.
- Renal disease—acute or chronic.
- Ethylene glycol toxicosis.
- Oxalate toxicosis (lily, philodendron, etc.).
- Acute pancreatitis.
- Puerperal tetany—eclampsia.
- Phosphate-containing enemas.
- Nutritional secondary hyperparathyroidism.
- Hypomagnesemia.
- Intestinal malabsorption.
- Citrate toxicosis—multiple blood transfusions or improper citrate–blood ratio.
- Rickets (rare)–hypovitaminosis D, decreased plasma calcitriol, target organ calcitriol receptor resistance (vitamin D–dependent rickets type 2).
- Acute tumor lysis syndrome.
- Ionized hypocalcemia in critically ill patients. Multifactorial: parathyroid dysfunction; cytokine suppression of parathyroid function; vitamin D deficiency; hypomagnesemia; calcium chelation; accumulation of calcium in soft tissues, body fluids, and cells.

RISK FACTORS
- Puerperal tetany—small-breed bitches during first 21 days of nursing, but can affect large breeds. Preparturient eclampsia reported in cats, rarely in dogs.
- Postcorrective procedures for hyperthyroidism and hyperparathyroidism.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Clinical signs of hypocalcemia—primary or secondary hypoparathyroidism, eclampsia, intoxication leading to rapid calcium binding/complexing (e.g., phosphate-containing enemas, ethylene glycol); other causes rarely lower serum calcium enough to cause clinical signs.
- Neurologic signs—ethylene glycol toxicosis, primary neurologic disease.
- Vomiting—acute pancreatitis, intestinal malabsorption, renal failure, ethylene glycol toxicosis.
- Bone pain or fractures—nutritional secondary hyperparathyroidism, neoplasia.

LABORATORY FINDINGS
Drugs That May Alter Laboratory Results
- Sodium bicarbonate causes alkalosis and lowers ionized calcium concentration.
- Samples collected in or contaminated by EDTA or citrate will be hypocalcemic.

Disorders That May Alter Laboratory Results
Hypoalbuminemia can lower total calcium concentration and is generally not associated with decreased ionized calcium. Patients with concurrent hypoalbuminemia and ionized hypocalcemia likely have a concurrent condition causing ionized hypocalcemia.

CBC/BIOCHEMISTRY/URINALYSIS
- Hypocalcemia.
- Hypoalbuminemia with conditions causing protein loss, translocation, or decreased production.
- High total CO_2 with metabolic alkalosis.
- Azotemia—with acute and chronic kidney injury.
- Hyperphosphatemia with acute and chronic kidney injury, primary or secondary hypoparathyroidism, acute tumor lysis syndrome, or in

patients receiving phosphate-containing enemas.
• High amylase and lipase in many, but not all, patients with acute pancreatitis or renal disease.
• Mild to moderate anemia possible with chronic renal failure, nutritional secondary hyperparathyroidism, or intestinal malabsorption.
• Leukocytosis possible with acute pancreatitis.
• Isosthenuria with chronic kidney injury, moderate to advanced acute kidney injury.
• Glucosuria in some patients with acute kidney injury, diabetes with acute pancreatitis, ethylene glycol toxicosis, or oxalate toxicosis.

OTHER LABORATORY TESTS
• Ionized calcium—helps determine if clinical signs are due to hypocalcemia.
• Ethylene glycol test—in patients suspected of ingesting ethylene glycol within previous 12–16 hours (questionable reliability).
• Pancreatic lipase immunoreactivity—in patients suspected of having acute pancreatitis (questionable reliability if only test used).
• Intact PTH assay—if primary hypoparathyroidism is suspected.
• Serum magnesium concentration—hypomagnesemia is rare cause of hypocalcemia.
• Plasma calcitriol (vitamin D, 1,25 dihydroxycholecalciferol) concentration—to screen for rickets or vitamin D–dependent rickets type 2 (rare).

IMAGING
• Radiography usually normal.
• Small kidneys with chronic renal disease and large kidneys with acute kidney injury.
• Osteopenia and pathologic fractures with nutritional secondary hyperparathyroidism.
• Ultrasound—hyperechoic renal parenchyma with ethylene glycol or oxalate toxicosis, may identify pancreatitis or abdominal effusion.

DIAGNOSTIC PROCEDURES
ECG—prolongation of ST and QT segments; sinus bradycardia and wide T waves or T wave alternans in some patients.

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient treatment for clinical hypocalcemia.
• Emergency treatment indicated for primary or secondary hypoparathyroidism, eclampsia, hyperphosphatemia, citrate and ethylene glycol toxicosis.
• Long-term treatment for primary hypoparathyroidism and sometimes post-thyroidectomy-associated PTH deficiency.
• Eclampsia—remove puppies from bitch and hand-nurse until weaned.

DIET
Diet change recommended for nutritional secondary hyperparathyroidism (to a balanced diet) and renal failure (see Chronic Kidney Disease).

MEDICATIONS

DRUG(S) OF CHOICE
Emergency Treatment
• Calcium gluconate 10% solution—5–15 mg/kg (0.5–1.5 mL/kg); give IV slowly to effect over 10 min; monitor heart rate and stop temporarily if bradycardia occurs; if ECG monitoring is possible, QT interval shortening is an indication to temporarily stop administration. Vomiting can indicate excessive calcium administration.
• Calcium chloride 10% solution—also effective but not recommended in small animals because it is extremely caustic if administered extravascularly. Three times more potent than calcium gluconate; mg/kg dosage is the same, but only one-third the volume is needed (0.15–0.5 mL/kg).

Short-Term Treatment Immediately after Correction of Tetany for Hypoparathyroidism
• Relapse of clinical signs can be prevented by use of IV CRI of calcium gluconate 10% solution (60–90 mg/kg/day [6.5–9.75 mL/kg/day]) added to fluids that do not contain bicarbonate. Rarely necessary for postparturient eclampsia.
• Subcutaneous calcium gluconate 10% diluted 2–4 times with saline can be administered 3 or 4 times daily for initial control of tetany (reported to be safe in most patients, but there have been reports of marked and disabling inflammatory calcinosis cutis associated with subcutaneous use).

Long-Term Treatment
See Hypoparathyroidism.

CONTRAINDICATIONS
Avoid bicarbonate, as alkalinization may further decrease serum ionized calcium levels.

POSSIBLE INTERACTIONS
Calcium salts may precipitate if added to solutions containing bicarbonate, lactate, acetate, or phosphates.

FOLLOW-UP

PATIENT MONITORING
• For patients requiring long-term therapy, serum calcium should be assessed 4–7 days following initial treatment, then (if normocalcemic) monthly for first 6 months, then every 2–4 months.
• Goal—maintain serum calcium concentration between 8 and 10 mg/dL.

EXPECTED COURSE AND PROGNOSIS
• Vary dependent on underlying cause.
• Recurrence of hypocalcemia following calcium administration for primary hypoparathyroidism is common if calcitriol is not also administered; monitoring is advised.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
• Hypocalcemia can lead to weakness and dystocia.
• Eclampsia in dogs is usually seen in first 21 days of nursing a litter.

SEE ALSO
• Acute Kidney Injury.
• Chronic Kidney Disease.
• Eclampsia.
• Ethylene Glycol Toxicosis.
• Hypoalbuminemia.
• Hypomagnesemia.
• Hypoparathyroidism.
• Lily Toxicosis.
• Pancreatitis—Cats.
• Pancreatitis—Dogs.

ABBREVIATIONS
• PTH = parathyroid hormone.

HYPOCHLOREMIA

BASICS

DEFINITION
Serum chloride concentration below the lower limit of reference interval—dogs: <105 mEq/L; cats: <117 mEq/L (reference intervals may vary from laboratory to laboratory).

PATHOPHYSIOLOGY
- Chloride is the most abundant anion in the extracellular fluid.
- Chloride concentration is controlled by electrochemical gradients resulting from the active transport of sodium.
- In general, chloride concentration varies directly with sodium concentration and inversely with bicarbonate concentration.

SYSTEMS AFFECTED
Depends on underlying disorder.

GENETICS
N/A

INCIDENCE/PREVALENCE
N/A

SIGNALMENT
Species
Dog and cat.

Breed Predilections
N/A

Predominant Sex
N/A

SIGNS
Depends on underlying disorder.

CAUSES
- Gastric vomiting.
- Hypoadrenocorticism.
- Metabolic alkalosis.
- Chronic respiratory acidosis.
- Excessive nasogastric suctioning.
- Excess total body water.
- Salt-losing nephropathy.
- Diuretic therapy (especially loop and thiazide diuretics).
- Treatment with bicarbonate.
- Treatment with laxatives.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
If the degree of hypochloremia exceeds that of hyponatremia, it suggests selective chloride loss, as seen in patients with gastric vomiting or metabolic alkalosis.

LABORATORY FINDINGS
Drugs That May Alter Laboratory Results
Potassium bromide therapy can cause pseudohyperchloremia, as many chemistry analyzers cannot differentiate bromide from chloride.

Disorders That May Alter Laboratory Results
Lipemia and hyperproteinemia can falsely lower chloride concentration if ion-specific electrodes are not used.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Low chloride.
- Other abnormalities depend on underlying disorder, possibly hyponatremia, hypokalemia, and high bicarbonate concentration.

OTHER LABORATORY TESTS
- Measurement of urine fractional excretion of chloride may demonstrate high excretion.
- Blood gas measurement may reveal metabolic alkalosis.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
- Depends on underlying disorder.
- When choosing IV fluids, 0.9% NaCl has 154 mEq/L of chloride, Normosol®-R and Plasma-Lyte-148® have 98 mEq/L of chloride, and lactated Ringer's solution has 109 mEq/L of chloride; if fluid administration is indicated, 0.9% NaCl may increase chloride faster than the others; if both sodium and chloride concentrations are low due to excess free water, intravenous fluids may be contraindicated.
- If performing frequent nasogastric suctioning and removing large volumes of gastric residual volume, reinstallation of 2–3 mL/kg of aspirated volume may be considered. One study in dogs receiving routine nasogastric suctioning every 4 hours (average of 0.9 ± 1.2 mL/kg/h of gastric volume removed) did not identify the development of hypochloremia over the course of 36 hours.

NURSING CARE
N/A

DIET
No need to alter.

CLIENT EDUCATION
Depends on underlying disorder.

HYPOGLYCEMIA

BASICS

DEFINITION
Blood glucose concentration below the lower reference interval (generally <60 mg/dL).

PATHOPHYSIOLOGY
Mechanisms responsible for hypoglycemia:
- Excess insulin or insulin-like factors (e.g., insulinoma, extrapancreatic paraneoplasia [insulin-like growth factor-2 (IGF-2)], xylitol toxicosis, iatrogenic insulin overdose).
- Reduced hepatic gluconeogenesis and glycogenolysis (e.g., hepatic disease, glycogen storage diseases, hypoadrenocorticism, sepsis).
- Excessive metabolic use of glucose (e.g., in hunting dogs, pregnancy, neoplasia, polycythemia, and sepsis).
- Reduced intake or underproduction of glucose (e.g., in puppies and kittens, toy breeds, glycogen storage disease, and severe malnutrition or starvation).

SYSTEMS AFFECTED
- Musculoskeletal.
- Nervous.

SIGNALMENT
- Dog and cat.
- Variable, depending on the underlying cause.

SIGNS
- Seizures.
- Posterior paresis.
- Weakness.
- Collapse.
- Muscle fasciculations.
- Abnormal behavior.
- Lethargy and depression.
- Ataxia.
- Polyphagia.
- Weight gain.
- Exercise intolerance.
- Some animals appear normal aside from findings associated with underlying disease.
- Many animals have episodic signs.
- Polyneuropathy.

CAUSES

Endocrine
- Insulinoma.
- Extrapancreatic neoplasia associated with IGF-2 overproduction (e.g., hepatocellular carcinoma, hepatocellular adenoma, intestinal leiomyoma or leiomyosarcoma).
- Iatrogenic insulin overdose.
- Hypoadrenocorticism.
- Islet cell hyperplasia (nesidioblastosis).

Hepatic Disease
- Portosystemic shunt.
- Cirrhosis.
- Severe hepatitis (e.g., toxic and inflammatory).
- Glycogen storage diseases.

Overuse
- Hunting dog (exertional) hypoglycemia.
- Pregnancy.
- Polycythemia.
- Neoplasia.
- Sepsis—increased glucose utilization induced by cytokine production in macrophage-rich tissues.

Reduced Intake/Underproduction
- Young puppies and kittens.
- Toy-breed dogs.
- Severe malnutrition or starvation.
- In sepsis there is also cytokine-induced inhibition of gluconeogenesis in the setting of nutritional glycogen depletion.

Toxicosis
- Iatrogenic insulin overdose.
- Xylitol toxicosis.
- Antihyperglycemic agent toxicosis (e.g., sulfonylureas).

RISK FACTORS
- Low energy intake predisposes to hypoglycemia in patients with conditions causing overuse and underproduction.
- Fasting, excitement, exercise, and eating may or may not increase the risk of hypoglycemic episodes in patients with insulinoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Patients with hyperinsulinism—signs of hypoglycemia or a normal physical examination.
- Patients with hypoadrenocorticism—waxing, waning, nonspecific signs (e.g., vomiting, diarrhea, melena, weakness); Addisonian patients that present in a crisis usually display hypovolemia and hyperkalemia rather than hypoglycemia (e.g., shock, bradycardia, dehydration).
- Patients with portosystemic shunts—usually young to middle-aged; often thin or appear to have stunted growth; rarely, they have ascites or edema.
- Patients with cirrhosis and severe hepatitis usually have other signs of their disease (e.g., gastrointestinal abnormalities, icterus, and ascites or edema).
- Patients with sepsis—critical; usually in shock; pyrexia or hypothermia revealed by examination; may have gastrointestinal abnormalities.
- Glycogen storage diseases—rare; usually younger animals.
- Extrapancreatic neoplasia and large neoplastic processes (hepatoma) that cause hypoglycemia may be detected by physical examination.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
None

Procedures That May Alter Laboratory Results
Delayed separation of serum causes falsely low serum glucose values; if serum cannot be separated within 30 minutes of collection, it should be collected in a sodium fluoride (gray-stoppered) tube. Polycythemia may result in false hypoglycemia if measured on a point-of-care glucometer.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Patients with hyperinsulinism may have normal results.
- Patients with hypoadrenocorticism may have hypocholesterolemia, hypoalbuminemia, lymphocytosis, eosinophilia, hyperkalemia, hyponatremia, azotemia, or hypercalcemia.
- Patients with congenital portosystemic shunts may have microcytosis, hypoalbuminemia, low blood urea nitrogen, slightly elevated liver enzyme activities, ammonium biurate crystalluria, and hyposthenuria. Serum bilirubin concentration sometimes increased.
- Patients with cirrhosis, severe hepatitis, and hepatic neoplasia may have anemia associated with chronic disease, high liver enzyme activities, hyperbilirubinemia, hypoalbuminemia, bilirubinuria, and hyposthenuria.
- Patients with xylitol toxicosis may have hypokalemia and later signs of hepatic failure.

OTHER LABORATORY TESTS
- Simultaneous fasting glucose/insulin determination—indicated when insulinoma is suspected; plasma insulin concentration within the upper end or above reference range in the face of hypoglycemia (glucose <60 mg/dL) suggests insulinoma.
- Baseline cortisol ± adrenocorticotropic hormone stimulation test—to diagnose hypoadrenocorticism.
- Fasting and postprandial serum bile acids—diagnose portosystemic shunt or functional hepatic disease.
- Free abdominal fluid should be collected and analyzed.
- Fructosamine—chronic hypoglycemia will result in low fructosamine concentrations.

IMAGING
- Abdominal radiography and ultrasonography—useful in patients with extrapancreatic neoplasia and large neoplastic processes (may see organomegaly or masses), as well as portosystemic shunt (microhepatica), cirrhosis (microhepatica, hyperechogenicity), and severe hepatopathy. Not very sensitive nor specific for detecting insulinoma. Abdominal CT more accurately detects pancreatic endocrine tumors.

HYPOGLYCEMIA (CONTINUED)

• Ultrasound-guided, laparoscopic, or surgical hepatic biopsy—useful to evaluate hepatic parenchymal disease.
• Technetium-99m quantitative hepatic scintigraphy—to detect portosystemic shunt.
• Mesenteric portography—to detect portosystemic shunt (requires surgery).

DIAGNOSTIC PROCEDURES
Ultrasound-guided or surgical tissue biopsy—useful to evaluate hepatic parenchymal disorders and extrapancreatic neoplasia.

TREATMENT
• Animals with clinical hypoglycemia should be treated as inpatients.
• If able to eat (i.e., responsive, no vomiting), feeding should be part or all of initial treatment.
• If unable to eat, start continuous IV fluid therapy with 2.5–5% dextrose solution.
• Surgery is indicated if a portosystemic shunt or neoplasia is the cause of hypoglycemia.

MEDICATIONS
DRUG(S) OF CHOICE
Emergency/Acute Treatment
• In hospital—administer 50% dextrose 0.5 g/kg IV, diluted 1 : 3 as slow bolus. Glucagon as IV CRI at 5–10 ng/kg/min is transiently effective in cases of insulin-secreting tumors.
• At home—client should not administer medication orally during a seizure; hypoglycemic seizures usually abate within 1–2 min; if a seizure is prolonged, recommend transport to hospital; if a short seizure has ended or other signs of a hypoglycemic crisis exist, recommend rubbing corn syrup or 50% dextrose on the buccal mucosa, followed by 2 mL/kg of the same solution orally once the patient can swallow; then seek immediate attention.
• Owners of diabetic animals can be taught to inject prescribed glucagon 0.03 mg/kg IM.
• Initiate frequent feeding of a diet low in simple sugars or, if patient is unable to eat, continuous fluid therapy with 2.5 or 5% dextrose solution.

Long-Term Treatment
• See Insulinoma for treatment considerations.
• Hunting dog hypoglycemia—feed moderate meal of fat, protein, and complex carbohydrates a few hours before hunting; can feed snacks (e.g., dog biscuits) every 3–5 hours during the hunt.
• Toy-breed hypoglycemia—increase frequency of feeding.
• Puppy and kitten hypoglycemia—increase frequency of feeding.
• Other causes of hypoglycemia require treating the underlying disease and do not usually need long-term treatment (exception: glycogen storage disease type 1).

CONTRAINDICATIONS
• Insulin.
• Barbiturates and diazepam do not treat cause in patients with hypoglycemic seizures; may potentially worsen hepatoencephalopathy in patients with hepatic disease.

PRECAUTIONS
• 50% dextrose causes tissue necrosis and sloughing if given extravascularly; may cause phlebitis at concentrations above 5%.
• Administration of a dextrose bolus without subsequent frequent feedings or IV fluids with dextrose can predispose to hypoglycemic episodes.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP
PATIENT MONITORING
• Based on underlying disease.
• At home—for return or progression of clinical signs of hypoglycemia; assess serum glucose if signs recur.
• Single, intermittent serum glucose determinations may not reflect true glycemic status of patient because of counter-regulatory hormones.
• If due to insulin overdose in the diabetic (or postinsulinoma resection diabetes), reassess response to insulin with a blood glucose curve and adjust the insulin dose accordingly. Check for metastatic insulinoma.

POSSIBLE COMPLICATIONS
Recurrent, progressive episodes of hypoglycemia.

MISCELLANEOUS
ASSOCIATED CONDITIONS
Prolonged hypoglycemia can cause transient (hours to days) to permanent dementia and blindness.

AGE-RELATED FACTORS
Neonatal animals have poor glycogen storage capacity and reduced capacity for gluconeogenesis; thus, short periods of fasting (6–12 hours) can cause hypoglycemia. Important to remember when fasting prior to and following anesthesia.

PREGNANCY/FERTILITY/BREEDING
Hypoglycemia can lead to weakness and dystocia.

HYPOKALEMIA

BASICS

DEFINITION
Serum potassium concentration <3.5 mEq/L (normal range: 3.5–5.5 mEq/L).

PATHOPHYSIOLOGY
- Potassium is primarily an intracellular electrolyte (98% of total body potassium is intracellular); serum levels, however, may not accurately reflect total body stores.
- It is predominantly responsible for the maintenance of intracellular fluid volume and required for normal function of many enzymes.
- Resting cellular membrane potential is determined by the ratio of intracellular to extracellular potassium concentration and maintained by the Na^+/K^+–adenosine triphosphate (ATPase) pump. Conduction disturbances in susceptible tissues (cardiac, nerve, muscle) are caused by rapid shifts in this ratio causing myoneural membrane hyperpolarization.
- Hypokalemia can be caused by decreased intake, loss (via the gastrointestinal tract or kidneys), or translocation of potassium from the extracellular to the intracellular fluid space.

SYSTEMS AFFECTED
- Neuromuscular—muscle weakness, including skeletal and muscles of respiration.
- Cardiac—electrocardiac changes and arrhythmias.
- Renal—hyposthenuria, nephropathy, and renal failure.
- Metabolic—acid-base balance (metabolic alkalosis); glucose homeostasis.

SIGNALMENT
- Dogs and cats with predispositions to increased potassium loss, translocation of potassium, or decreased intake of potassium.
- Young Burmese cats with recurrent hypokalemic periodic paralysis episodes.

SIGNS
- Generalized muscle weakness or paralysis.
- Muscle cramps.
- Lethargy and confusion.
- Vomiting.
- Anorexia.
- Carbohydrate intolerance and weight loss.
- Polyuria (PU).
- Polydipsia (PD).
- Decreased bowel motility (humans; maybe dogs and cats).
- Hyposthenuria.
- Ventroflexion of the neck.
- Respiratory muscle failure.

CAUSES

Decreased Intake
- Anorexia or starvation.
- Potassium deficient diet.
- Administration of potassium-deficient or potassium-free intravenous fluids.
- Bentonite clay ingestion (e.g., clumping cat litter).

Gastrointestinal Loss
- Vomiting.
- Diarrhea.
- Both upper and lower gastrointestinal obstruction, especially pyloric outflow obstruction.

Urinary Loss
- Chronic kidney disease (CKD).
- Renal tubular acidosis.
- Hypokalemic nephropathy.
- Postobstructive diuresis.
- Dialysis (hemodialysis or peritoneal).
- Intravenous fluid diuresis.
- Hyperaldosteronism.
- Hypochloremia.
- Drugs (loop diuretics, amphotericin B, penicillins, fludrocortisone, desoxycorticosterone pivalate).

Translocation (Extracellular to Intracellular Fluid)
- Glucose administration.
- Insulin administration or release.
- Sodium bicarbonate administration.
- Catecholamines.
- Alkalemia.
- Beta2-adrenergic agonist overdose (e.g., albuterol, terbutaline).
- Hypokalemic periodic paralysis (Burmese cats).
- Rattlesnake envenomation (presumably from catecholamine release).

RISK FACTORS
- Acidifying diets with negligible potassium.
- Diuresis or dialysis with potassium-deficient fluids.
- Chronic illness (sustained anorexia and muscle wasting).
- Hypomagnesemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- PU/PD, hyperglycemia, and glucosuria—rule out diabetes mellitus.
- PU/PD, azotemia, and isosthenuria—rule out CKD and nephropathy, especially in cats.
- Vomiting, metabolic alkalosis, and hypochloremia—rule out upper gastrointestinal obstruction.
- Metabolic acidosis with urine pH >6.5—rule out renal tubular acidosis.
- Urethral obstruction—rule out postobstructive diuresis.
- Hypertension with or without azotemia—rule out hyperaldosteronism
- Young Burmese cat with episodic muscle weakness—rule out hypokalemic periodic paralysis.

LABORATORY FINDINGS

Chemicals That May Alter Laboratory Results
Falsely elevated potassium measurement can be caused by excessive K_3EDTA relative to the blood sample, as found in "purple-top" blood tube for hematology; not a problem with additive-free "red-top" tubes for serum).

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Hyperglycemia, glucosuria, ± ketonuria, ± ketoacidosis in patients with diabetes mellitus.
- Normocytic, normochromic, nonregenerative anemia in patients with CKD.
- Elevated blood urea nitrogen (BUN) and creatinine concentrations, with isosthenuria in patients with CKD or hypokalemic nephropathy.
- Low total CO_2 or HCO_3^-—in patients with renal tubular acidosis (RTA) or renal failure.
- Normal anion gap metabolic acidosis in RTA.
- Urine pH >6.5 in patients with distal tubular acidosis.
- High total CO_2 or HCO_3^-—in patients with metabolic alkalosis.
- High PCO_2 with hypoventilation.

OTHER LABORATORY TESTS
- Increased aldosterone and decreased renin in patients with primary hyperaldosteronism.
- Elevated urinary fractional excretion of potassium in patients with CKD, hypokalemic nephropathy, and primary hyperaldosteronism.
- Adrenocorticotropic hormone (ACTH) stimulation tests are used to diagnose adrenal gland disorders.

IMAGING
- Radiography, ultrasonography are helpful to diagnose gastrointestinal tract obstructions (mass or foreign bodies), pancreatitis, CKD workup, adrenal gland diseases (adrenocortical hyperplasia, adrenocortical neoplasia).
- Upper gastrointestinal barium study to additionally diagnose gastrointestinal obstructions (anatomic or functional).
- CT to further diagnose adrenal gland, renal, and gastroenteric disorders.

DIAGNOSTIC PROCEDURES
Upper gastrointestinal endoscopy to diagnose upper gastrointestinal disorders.

TREATMENT
- Mild hypokalemia (3.0–3.5 mEq/L) can be treated by oral supplementation.
- Moderate hypokalemia (2.5–3.0 mEq/L) is best treated by inpatient administration of oral ± intravenous supplementation and carefully monitored.
- Patients with severe hypokalemia (<2.5 mEq/L) should be hospitalized for intensive intravenous potassium supplementation.

HYPOKALEMIA (CONTINUED)

Table 1

Patient's K^+ Concentration	*KCl/L (mEq)*	*Dosage (mEq K^+/kg/h, IV)*
3.5–4.5	20	0.05–0.1
3.0–3.5	30	0.1–0.2
2.5–3.0	40	0.2–0.3
2.0–2.5	60	0.3–0.4
<2.0	80	0.5–1.5

Note: do not exceed an intravenous supplementation rate of 0.5 mEq/kg/h unless continually monitoring and on the verge of ventilator muscle failure. With severe life-threatening hypokalemia (serum potassium <2.0 mEq/L), potassium chloride can be administered at a rate of 1.0–1.5 mEq/kg/h with ECG monitoring.

Patients, especially cats, should be carefully monitored for cardiac arrhythmias, rhabdomyolysis and impaired ventilation.

MEDICATIONS

DRUG(S) OF CHOICE

- Oral supplementation with potassium gluconate (e.g., Tumil-K®) is effective in mildly affected patients. The initial dosage is 2 mEq/4.5 kg bodyweight in food twice daily.
- Parenteral supplementation is required in anorectic or vomiting patients or in patients with moderate to severe hypokalemia (<3.0 mEq/L). Potassium chloride is added to intravenous fluids and delivered according to Table 1, best administered via infusion pump or with a pediatric fluid administration set (60 drops/mL). Monitor and taper accordingly.
- Provide magnesium sulfate, if hypomagnesemic; 1.0 mEq/kg/24h by CRI, or a 0.25 mEq/kg slow IV bolus.

CONTRAINDICATIONS

- Glucose supplementation.
- Insulin administration.
- Sodium bicarbonate administration.
- Untreated hypoadrenocorticism.
- Hyperkalemia.
- Oliguric or anuric renal failure or severe renal impairment.
- Rapid rehydration to correct severe dehydration (i.e., potassium-supplemented fluids should not be bolused IV).

PRECAUTIONS

Administer with caution, avoid over-supplementation, do not bolus, monitor frequently.

POSSIBLE INTERACTIONS

Concurrent potassium supplementation with angiotensin-converting enzyme (ACE) inhibitors (e.g., enalapril), potassium-sparing diuretics (e.g., spironolactone), prostaglandin inhibitors (e.g., nonsteroidal anti-inflammatory drugs), beta blockers (e.g., atenolol), or cardiac glycosides (e.g., digoxin) can cause adverse effects.

ALTERNATIVE DRUG(S)

Potassium phosphate can be used in patients with concurrent hypophosphatemia where one-half of the potassium dose (in mEq) is administered in the form of potassium phosphate solution.

FOLLOW-UP

PATIENT MONITORING

Check serum potassium every 6–24 hours based on severity of hypokalemia.

POSSIBLE COMPLICATIONS

Electrolyte disturbances and severe bradyarrhythmias. It is essential to close the IV fluid outflow valve and thoroughly mix the fluid contents when adding potassium chloride solution to the parenteral fluid bag.

HYPOMAGNESEMIA

BASICS

DEFINITION
- Dogs—serum magnesium <1.89 mg/dL, ionized magnesium <0.43 mmol/L.
- Cats—serum magnesium <1.75 mg/dL, ionized magnesium <0.48 mmol/L.

PATHOPHYSIOLOGY
- Magnesium is the second most abundant intracellular cation, found primarily in bone (60%) and soft tissues (38%).
- Hypomagnesemia has many causes; incidence rates >50% have been reported in critically ill humans.
- Serum magnesium is present in three forms—protein-bound form (approximately 25–30%) and chelated and ionized forms (together 70–75%).
- Serum magnesium concentration does not always reflect whole-body magnesium status.
- Magnesium absorption occurs primarily in the ileum as well as the jejunum and colon.
- Kidneys maintain magnesium balance, with 10–15% reabsorbed in the proximal tubule, 60–70% in the thick ascending limb of the loop of Henle, and 10–15% reabsorbed in the distal convoluted tubule. Reabsorption within the distal convoluted tubule is under hormonal and neurohormonal control and determines the final urine concentration of magnesium.
- Magnesium is an important cofactor in the sodium–potassium adenosine triphosphate (ATPase) pump that maintains a membrane electrical gradient. Magnesium is also important in the production and elimination of acetylcholine; hypomagnesemia can increase acetylcholine at motor endplates and cause tetany.
- Interference with membrane potentials can result in neuromuscular and cardiac abnormalities.
- Magnesium regulates calcium movement into smooth muscle cells and is important for cardiac contractile strength, conduction, and peripheral vascular tone.
- Hypomagnesemia alters function of skeletal muscle, resulting in tetany and myopathies.
- Magnesium depletion affects membrane pumps on cardiac cells, resulting in depolarization and tachyarrhythmias; cardiac arrhythmias associated with hypomagnesemia include ventricular arrhythmias, torsades de pointes, QT prolongation, ST segment shortening, and widening of T waves; hypomagnesemia increases the risk of digoxin toxicity because both inhibit the membrane pump.
- Hypomagnesemia causes resistance to the effects of parathyroid hormone (PTH) and can increase the uptake of calcium into bone.

SYSTEMS AFFECTED
- Cardiovascular.
- Endocrine.
- Gastrointestinal.
- Neuromuscular.
- Renal.

INCIDENCE/PREVALENCE
Reported in 28–54% of critically ill dogs and cats, may have increased incidence in bulldogs.

SIGNALMENT
Dog and cat.

SIGNS
- Weakness.
- Muscle fibrillation.
- Ataxia and depression.
- Hyperreflexia.
- Tetany.
- Behavior changes.
- Cardiac arrhythmias.

CAUSES
- Gastrointestinal—severe malnutrition or significant intestinal malabsorptive disease, following excessive loss of body fluids (e.g., severe, prolonged diarrhea), secretory large-bowel diarrhea.
- Renal—nephrotoxic drugs (e.g., cisplatin, aminoglycosides, amphotericin B), osmotic diuresis (e.g., with diabetes mellitus), loop diuretics, chronic thiazide diuretic therapy, hypercalciuria, postobstructive diuresis, and renal tubular acidosis.
- Other drugs associated with hypomagnesemia include cyclosporine, ticarcillin, carbenicillin, and proton pump inhibitors.
- Endocrine diseases associated with hypomagnesemia include hyperaldosteronism, hyperthyroidism, and primary hypoparathyroidism. Hypomagnesemia is found in 32% of dogs and 85% of cats with hypoparathyroidism, and can be seen following surgical parathyroidectomy.
- Lactation, pancreatitis, insulin administration, and catecholamine excess can cause excessive magnesium loss.
- Magnesium can be redistributed by refeeding after starvation and insulin therapy in diabetic patients.
- Causes of hypomagnesemia in the critically ill include decreased intake, lack of magnesium in parenteral fluids (long-term fluid therapy or hemodialysis), use of a total parenteral nutrition formulation with inadequate magnesium content, excessive gastrointestinal loss, redistribution, and sequestration.
- Hypomagnesemia is associated with diabetes mellitus in humans, with nearly 25% of human diabetic outpatients having low serum magnesium, and may occur during therapy for diabetic ketoacidosis in dogs and cats.

RISK FACTORS
- Gastrointestinal malabsorption syndromes.
- Polyuric renal disease.
- Diuretic administration.
- Diabetes mellitus and diabetic ketoacidosis.
- Total parenteral nutrition.
- Peritoneal dialysis.
- Lactation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Signs of hypomagnesemia are vague and multisystemic; therefore, other causes of neuromuscular abnormalities, especially other electrolyte abnormalities, must be investigated.
- Consider cardiac abnormalities, intoxications, and renal diseases.

LABORATORY FINDINGS
Note: 12 mg of magnesium = 1 mEq of magnesium; to convert from mg/dL to mEq/L, divide by 1.2.

Drugs That May Alter Laboratory Results
- Serum is favored over plasma because EDTA, sodium fluoride-oxalate, and sodium citrate anticoagulants used for plasma samples can contain citrate or other ions that bind magnesium. Heparinized whole blood or plasma may be used to determine ionized magnesium concentration
- Intravenous calcium gluconate can falsely decrease serum magnesium values.

Disorders That May Alter Laboratory Results
- Hemolysis can falsely elevate serum magnesium.
- Hypercalcemia (>16 mg/dL) and hyperproteinemia (>10 g/dL) can falsely elevate serum magnesium.
- Hyperbilirubinemia and lipemia can falsely decrease serum magnesium.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Low serum magnesium.
- If patient is azotemic, consider renal causes.
- Tubular casts in urinary sediment might indicate nephrotoxicity.
- Hypokalemia, hyponatremia, and hypocalcemia are common findings with hypomagnesemia and should alert the clinician to the possibility of hypomagnesemia.

OTHER LABORATORY TESTS
- Diagnosis of magnesium depletion can be difficult since <1% of total body magnesium is located in serum; only 55% of the magnesium in plasma is in the active (ionized) form; 33% is bound to plasma proteins and 12% is chelated with divalent anions such as phosphate and sulfate; magnesium assays (spectrophotometry) measure all three fractions.
- Ionized magnesium can be measured with an ion-selective electrode or by ultrafiltration of plasma; alternative methods of evaluating magnesium status include measurement of

HYPOMAGNESEMIA (CONTINUED)

mononuclear blood cell magnesium levels or quantifying retention from a loading dose.
• Urinary magnesium determination might help differentiate conditions associated with high urinary magnesium loss from conditions of low intake or absorption.
• Human studies suggest that retention of >40–50% of an administered magnesium load indicates magnesium depletion, while retention of <20% indicates adequate magnesium stores.

DIAGNOSTIC PROCEDURES
• Electrodiagnostics (e.g., electromyelography and electrocardiography) might reveal effects of hypomagnesemia, but will not differentiate the cause.
• Hypomagnesemia can cause prolongation of the PR interval, widening of the QRS complex, depression of the ST segment, and peaking of the T wave, in addition to ventricular arrhythmias.

TREATMENT

APPROPRIATE HEALTH CARE
• Treatment depends on underlying cause and severity.
• Management includes treatment of the underlying condition(s) and magnesium replacement.
• Mild hypomagnesemia might resolve with treatment of the underlying disorder; however, if hypomagnesemia is severe, intensive care and magnesium replacement are needed.

NURSING CARE
Hypomagnesemia is a common finding in critically ill, hospitalized veterinary patients. Nursing should focus on the underlying disorder(s).

ACTIVITY
Based on concurrent conditions.

DIET
A balanced diet that takes into account all concurrent problems is appropriate.

MEDICATIONS

DRUG(S) OF CHOICE
• Magnesium sulfate or magnesium chloride.
  ◦ Emergency loading—0.15–0.3 mEq/kg IV over 15–60 min.
  ◦ Rapid replacement—0.75–1 mEq/kg/day (0.03 mEq/kg/h) IV.
  ◦ Slow replacement—0.3–0.5 mEq/kg/day (0.013–0.02 mEq/kg/h) IV.
• Magnesium sulfate can be diluted in 5% dextrose in water or 0.9% saline; the solution of magnesium salts should be <20% and should use a separate IV port to minimize drug interactions

CONTRAINDICATIONS
• Hypomagnesemia potentiates nephrotoxicity of aminoglycosides.
• Avoid cisplatin chemotherapy.

PRECAUTIONS
• Discontinue digoxin if possible.
• Use diuretics with caution.
• Hypermagnesemia is possible with overzealous supplementation.
• Azotemic patients should receive a lower dose of magnesium and more frequent monitoring than patients with normal kidney function.

POSSIBLE INTERACTIONS
• Magnesium sulfate is incompatible with sodium bicarbonate, hydrocortisone, and dobutamine HCl.
• Calcium-containing compounds lower serum magnesium concentration.
• Additive CNS depression can occur when parenteral magnesium is used with CNS depressant sedatives, neuromuscular blocking agents, and anesthetics.
• Combined use of parenteral magnesium sulfate and nondepolarizing neuromuscular blocking agents is contraindicated.
• Use magnesium supplementation cautiously with digitalis compounds to avoid conduction disturbances.
• Calcium supplements might negate the effects of parenteral magnesium.

FOLLOW-UP

PATIENT MONITORING
• Measure serum magnesium and calcium concentrations daily.
• Continuous ECG and blood pressure monitoring, especially during magnesium infusion.

POSSIBLE COMPLICATIONS
• Severe hypomagnesemia can be fatal.
• Magnesium is inversely associated with fibroblast growth factor 23 (FGF23), an important prognostic factor in CKD in cats.

EXPECTED COURSE AND PROGNOSIS
Outcome is dependent on resolution of the underlying disease(s).

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Hyperthyroidism.
• Hypocalcemia.
• Hypokalemia.
• Hyponatremia.
• Hypoparathyroidism.
• Hypophosphatemia.

PREGNANCY/FERTILITY/BREEDING
Effects on fetus are identical to effects on the dam.

SEE ALSO
Hypocalcemia

ABBREVIATIONS
• ATP = adenosine triphosphate.
• PTH = parathyroid hormone.

Consulting Editor Patty A. Lathan

HYPOMYELINATION

BASICS

OVERVIEW

• Also known as "shaking puppies." • Congenital deficit in myelin deposition caused by either delayed myelination or a permanent lack of myelin at birth. • Axons >1–2 mm in diameter have a myelin cover produced by oligodendrocytes in the central nervous system (CNS) and Schwann cells in the peripheral nervous system (PNS); myelin insulates axons and facilitates propagation of action potentials. • Affected axons with deficit in myelin deposition can alter impulse conduction or trigger spontaneous discharges and then generate tremors; the degree of tremor is usually correlated with the severity of the abnormal myelin deposition.

SIGNALMENT

CNS

• Clinical signs appear at birth or when the puppy starts to ambulate. • Dog—springer spaniel, Samoyed, chow chow, Weimaraner, Bernese mountain dog, Dalmatian, Catahoula, rat terrier, border terriers, and lurcher. • Cat—Siamese and presumed in domestic shorthair and Birman cats. • Predominant sex (X-linked)—springer spaniel and Samoyed male puppies clinically affected, whereas females remain largely asymptomatic carriers; no sex differences reported in other breeds.

PNS

• Dog. • Golden retriever—reported in both sexes.

SIGNS

CNS

• Action-related repetitive myoclonus—rapid contractions and relaxation of diffuse skeletal muscles manifested as generalized body tremors that worsen with exercise and subside during rest or sleep; some affected dogs and cats appear to be "bouncing." • The tremors diminish with time in the majority of affected dogs and usually resolve by 12 months of age or earlier; however, some dogs can retain a persistent fine tremor of the pelvic limbs. • Some dogs also present with head bobbing and nystagmus. • In rat terriers, associated with goiter and clinical signs of congenital hypothyroidism. • Springer spaniels and Samoyeds are usually affected for life.

PNS

• Clinical signs appear at 5–7 weeks of age. • Generalized weakness, pelvic limb ataxia and paresis, muscle wasting, and hyporeflexia that improve with age. • Tremors are not present.

CAUSES & RISK FACTORS

• Genetic—X-linked recessive condition for CNS disease in springer spaniels and autosomal recessive gene in rat terriers, Weimaraners, and border terriers. • Genetic basis speculative for other breeds. • Mutation identified in Weimaraners and rat terriers. • The carrier frequency in Weimaraners has been estimated to be 4.3%. • Viral or toxic—possible in some breeds. • PNS—undetermined; possibly genetic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

CNS

• Cerebellar hypoplasia or abiotrophy—tremors in neonates; but cerebellar ataxia (hypermetric gait) and intention tremors more prominent. • Storage diseases—associated with tremors; neonates are normal. • Generalized tremor syndrome in dogs (historically identified as "white shakers" but other hair coat colors can be affected)—affected dogs are usually >8 months old. • Metabolic diseases (hypocalcemia, hypernatremia, hyponatremia, hypoglycemia). • Feline polioencephalomyelitis—young to middle-aged cats; other neurologic signs are present (paresis, seizures, hyperesthesia). • Toxic—organophosphates, permethrins, mycotoxins: history of exposure to a toxic product.

PNS

• Muscular dystrophy—serum creatine kinase highly elevated. • Congenital myasthenia gravis. • Other polyneuropathies or myopathies.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

IMAGING

MRI—may detect white matter changes on CNS form.

DIAGNOSTIC PROCEDURES

CNS

• Presumed diagnosis based on signalment, clinical signs, and evolution. • Histopathology (necropsy). • DNA test for causative genetic mutation (currently available for Weimaraners and rat terriers).

PNS

• Electromyography—usually normal to mild diffuse spontaneous activity. • Motor nerve conduction velocity—small or no evoked potentials and slowed conduction. • Nerve biopsy—insufficient myelin surrounding peripheral axons.

TREATMENT

None effective for either form.

MEDICATIONS

DRUG(S) OF CHOICE

N/A

FOLLOW-UP

PREVENTION/AVOIDANCE

Avoid breeding from affected animals in which a genetic cause is suspected.

EXPECTED COURSE AND PROGNOSIS

• CNS—Springer spaniels and Samoyeds affected for life; other breeds usually improve by 1 year of age. • PNS—dogs have normal lifespan.

MISCELLANEOUS

ABBREVIATIONS

• CNS = central nervous system.
• PNS = peripheral nervous system.

Author Elsa Beltran

HYPONATREMIA

BASICS

DEFINITION
Serum sodium concentration below the lower limit of the reference range.

PATHOPHYSIOLOGY
Sodium is the most abundant cation in the extracellular fluid. Hyponatremia usually reflects hypo-osmolality and is typically associated with a decreased total body sodium content. Either water retention or solute loss can cause hyponatremia. Most solute loss occurs in iso-osmotic solutions (e.g., vomit and diarrhea) and, as a result, water retention in relation to solute is the underlying cause in almost all patients with hyponatremia. In general, hyponatremia occurs only when a defect in renal water excretion is present.

SYSTEMS AFFECTED
- Nervous—severe neurologic dysfunction is not usually seen until serum sodium concentration falls below 110–115 mEq/L. Clinical signs may be more related to the rate of decline in serum sodium concentration than the actual nadir. Dogs with chronic hyponatremia often have mild, if any, clinical signs.
- Overly rapid correction of hyponatremia can also cause neurologic damage.

SIGNALMENT
Species
Dog and cat.

SIGNS
- Lethargy.
- Weakness.
- Confusion.
- Nausea/vomiting.
- Seizures.
- Obtundation.
- Coma.
- Other signs depend on the underlying cause.

CAUSES
Normal Osmolar Hyponatremia
- Hyperlipidemia (pseudohyponatremia).
- Hyperproteinemia (pseudohyponatremia).

Hyperosmolar Hyponatremia
- Hyperglycemia.
- Mannitol administration.

Hypo-osmolar Hyponatremia
Normovolemic
- Primary polydipsia.
- Hypothyroid myxedema coma.
- Hypotonic fluid infusion.
- Syndrome of inappropriate antidiuretic hormone secretion (SIADH).

Hypervolemic
- Congestive heart failure.
- Hepatic cirrhosis.
- Nephrotic syndrome.
- Severe renal failure.

Hypovolemic
- Gastrointestinal losses.
- Renal failure.
- Third-space losses.
- Cutaneous losses (e.g., burns).
- Diuresis.
- Hypoadrenocorticism.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hypoadrenocorticism.
- Severe gastrointestinal disease.
- Metabolic or respiratory acidosis.
- Congestive heart failure.
- Primary polydipsia.

LABORATORY FINDINGS
Drugs That May Alter Lab Results
Mannitol can cause pseudohyponatremia by solvent drag.

Disorders That May Alter Lab Results
Hyperlipidemia and hyperproteinemia can cause pseudohyponatremia on analyzers that use indirect potentiometry or flame photometry. Hyperglycemia can cause pseudohyponatremia through solvent drag, and serum sodium concentration normalizes with correction of hyperglycemia (e.g., with IV fluid or insulin therapy in patients with diabetes mellitus).

Valid if Run in a Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Low serum sodium concentration.
- Other abnormalities may point to the underlying cause.

OTHER LABORATORY TESTS
- Plasma osmolality is usually low; if plasma osmolality is normal or high, exclude hyperlipidemia, hyperglycemia, hyperproteinemia, and mannitol administration.
- Urine osmolality <100–150 mOsmol/kg indicates primary polydipsia or reset osmostat. Urine osmolality >150–200 mOsmol/kg indicates impaired renal water excretion.
- Urine sodium concentration <15–20 mEq/L indicates low effective circulating volume, pure cortisol deficiency, or primary polydipsia with high urine output. Urine sodium concentration >20–25 mEq/L indicates SIADH, adrenal insufficiency, renal failure, reset osmostat, diuretic administration, or vomiting with marked bicarbonate loss.

TREATMENT
Generally inpatient, depending on severity of hyponatremia, associated neurologic dysfunction, and underlying disorder.

MEDICATIONS

DRUG(S) OF CHOICE
- Treatment consists of addressing the underlying cause and increasing the serum sodium concentration if necessary. Overly rapid normalization (>10-12 mEq/L in 24 hours) of chronic hyponatremia can have potentially severe neurologic sequelae (myelinolysis) and may be more detrimental than the hyponatremia itself. Therefore, an isotonic crystalloid is the fluid of choice in most cases. More aggressive correction of serum sodium with hypertonic or normal saline in patients with chronic hyponatremia is not recommended.
- Acute hyponatremia (occurring over 24–48 hours) can be corrected more quickly, but is rare in small animals. Unless an acute cause of hyponatremia can be identified, or severe clinical signs of hyponatremia are present (seizures, cerebral edema), slower correction is recommended.
- Hypervolemic (edematous) patients are typically managed with diuretics and salt restriction, or hemodialysis if necessary (e.g., acute renal failure).
- Hypovolemic patients are managed by replacing the volume deficit with isotonic crystalloids. Isotonic (0.9%) saline, Normosol®-R, and lactated Ringer's solution (LRS) may be used. LRS has a sodium concentration of 130 mEq/L and is helpful in slowly increasing sodium concentrations in dogs with severe hyponatremia (<120 mEq/L).
- Other therapeutic interventions are dictated by the underlying cause of the hyponatremia.

PRECAUTIONS
Overly rapid correction of hyponatremia can result in neurologic damage (demyelination); avoid increasing serum sodium concentration by more than 10–12 mEq/L/day (0.5 mEq/L/h).

FOLLOW-UP

PATIENT MONITORING
- Serial serum sodium determinations (generally q4–6h) to avoid overly rapid correction of the serum sodium concentration and to assure appropriate response to other therapies.
- Monitor hydration status.
- Monitor other serum electrolyte concentrations as indicated by the patient's clinical condition and underlying disorder.

PREVENTION/AVOIDANCE
Depends on the underlying disorder.

POSSIBLE COMPLICATIONS
Depends on the underlying disorder.

EXPECTED COURSE AND PROGNOSIS
Depends on the underlying disorder.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other electrolyte and acid-base abnormalities are often associated with the clinical disorders that cause hyponatremia.

HYPOPARATHYROIDISM

BASICS

DEFINITION
Absolute or relative deficiency of parathyroid hormone (PTH) secretion leading to hypocalcemia.

PATHOPHYSIOLOGY
• Dogs—most commonly idiopathic immune-mediated parathyroiditis, rarely following bilateral thyroidectomy or following severe cervical trauma. • Cats—most commonly iatrogenic secondary to damaged or removed parathyroid glands during thyroidectomy; idiopathic atrophy and immune-mediated parathyroiditis uncommon.

SYSTEMS AFFECTED
• Cardiovascular—ECG changes and bradycardia. • Gastrointestinal—anorexia and vomiting, possibly (altered gastrointestinal muscular activity). • Nervous/neuromuscular—seizures, tetany, ataxia, weakness (diminished neuronal membrane stability). • Ophthalmic—posterior lenticular cataracts. • Respiratory—panting (neuromuscular weakness, anxiety).

INCIDENCE/PREVALENCE
• Dog—uncommon. • Cat—common (10–82%) following bilateral thyroidectomy; spontaneous occurrence rare.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Toy poodle, miniature schnauzer, German shepherd dog, Labrador retriever, terrier breeds; mixed-breed cats.

Mean Age and Range
• Dogs—mean 4.8 years; range: 6 weeks–13 years. • Cats—secondary to thyroidectomy, mean 12–13 years; range: 4–22 years. • Cats—spontaneous, mean 2.25 years; range: 6 months–7 years.

Predominant Sex
Dogs—female (60%); cats—male (64%).

SIGNS

Historical Findings
Dogs
• Seizures (49–86%). • Ataxia/stiff gait (43–62%). • Facial rubbing (62%). • Muscle trembling, twitching, and fasciculations (57%). • Growling (57%). • Panting (35%). • Weakness. • Vomiting. • Anorexia.

Cats
• Lethargy, anorexia, and depression (100%). • Seizures (50%). • Muscle trembling, twitching, and fasciculations (83%). • Panting (33%). • Bradycardia (17%).

Physical Examination Findings
Dogs
• Tense, splinted abdomen (50–65%). • Ataxia/stiff gait (43–62%). • Fever (30–70%). • Muscle trembling, twitching, and fasciculations (57%). • Panting (35%). • Posterior lenticular cataracts (15–32%). • Weakness. • Normal physical examination (20%).

Cats
• Muscle trembling, twitching, and fasciculations (83%). • Panting (33%). • Posterior lenticular cataracts (33%). • Bradycardia (17%). • Fever (17%). • Hypothermia (17%).

CAUSES
See Pathophysiology.

RISK FACTORS
Dogs, cats—bilateral thyroidectomy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Seizures
• Cardiovascular—syncope. • Metabolic—hepatoencephalopathy, hypoglycemia, other causes of hypocalcemia. • Neurologic—epilepsy, neoplasia, toxin, inflammatory disease.

Weakness
• Cardiovascular—congenital defects, arrhythmias, heart failure, pericardial effusion. • Metabolic—hypoadrenocorticism, hypoglycemia, anemia, hypokalemia (especially cats), hypothyroidism. • Neurologic/neuromuscular—myasthenia gravis, polymyositis, polyradiculoneuropathy, spinal cord disease. • Toxic—tick paralysis, botulism, chronic organophosphate exposure, snake envenomation (Eastern coral snake and other elapids, Mojave and certain other pit vipers), lead poisoning.

Muscle Trembling, Twitching, and Fasciculations
• Metabolic—puerperal tetany (i.e., eclampsia), other causes of hypocalcemia. • Toxic—tetanus, strychnine, permethrin, snake envenomation.

CBC/BIOCHEMISTRY/URINALYSIS
• Hemogram and urinalysis usually normal; perform to rule out other differential diagnoses. • Hypocalcemia (usually <6.5 mg/dL) and normal or mild to moderate hyperphosphatemia. • Evaluate serum albumin carefully in all patients with hypocalcemia; hypoalbuminemia is most common asymptomatic cause of hypocalcemia (assuming ionized fraction is adequate). • The only other intrinsic disease process besides hypoparathyroidism that reduces serum calcium and raises serum phosphorus is renal failure, which is easily distinguished from hypoparathyroidism by presence of azotemia; highly concentrated phosphate enema solutions can also cause hyperphosphatemia and hypocalcemia, as can excessive potassium phosphate parenteral fluid supplementation.

OTHER LABORATORY TESTS
Serum PTH—undetectable or very low PTH concentration; patients with other processes causing hypocalcemia (e.g., renal failure) have normal to high serum PTH concentration.

IMAGING
Atrophic parathyroid glands will not be visible with ultrasonography (normally 2–3 mm).

DIAGNOSTIC PROCEDURES
• ECG changes from hypocalcemia include prolongation of ST and QT segments; sinus bradycardia and wide T waves; occasionally T wave alternans. • Cervical surgical exploration reveals absence or atrophy of parathyroid glands.

PATHOLOGIC FINDINGS
• Dogs—normal or diminished tissue with mature lymphocytes, plasma cells, and fibrous connective tissue along with chief cell degeneration. • Cats—parathyroid gland atrophy more common, although histopathologic findings similar to dogs also found.

TREATMENT

APPROPRIATE HEALTH CARE
• Hospitalize for medical management of hypocalcemia until clinical signs of hypocalcemia are controlled and serum total calcium concentration is >7 mg/dL. • See Hypocalcemia for emergency inpatient management and appropriate fluid therapy

NURSING CARE
No specific care other than seizure watch.

DIET
Avoid calcium-poor diets; for dogs, puppy diets generally higher in calcium than adult dog food.

CLIENT EDUCATION
• Naturally occurring primary hypoparathyroidism requires lifelong therapy and monitoring. • Most cases of iatrogenic hypoparathyroidism (e.g., bilateral thyroidectomy) will recover over days to months and only require transient management and monitoring.

MEDICATIONS

DRUG(S) OF CHOICE

Emergency/Acute Therapy
See Hypocalcemia.

Short-Term Post-tetany Therapy
See Hypocalcemia.

(CONTINUED) HYPOPARATHYROIDISM

Table 1

Vitamin D preparations.

Preparation	*Dose*	*Maximal Effect*	*Size*
1,25 Dihydroxycholecalciferol (active vitamin D_3, calcitriol)	0.03–0.06 µg/kg/day	1–4 days	0.25 and 0.5 µg capsules, 1.0 µg/mL oral solution, and 1 and 2 µg/mL injectable
Dihydrotachysterol	Initial—0.02–0.03 mg/kg/day Maintenance—0.01–0.02 mg/kg/24–48h	1–7 days	Currently unavailable in United States; formerly available as 0.125 mg, 0.2 mg, 0.4 mg tablets and 0.2 mg/mL syrup
Ergocalciferol (vitamin D_2)	Initial—4000–6000 U/kg/day Maintenance—1000–2000 U/kg/day–week	5–21 days	25,000 and 50,000 U capsules and 8000 U/mL syrup

Table 2

Calcium preparations.

Preparation	*Dose of Elemental Calcium*	*Available Calcium*	*Size Available (Needs to Be Converted to Elemental Calcium)*
Calcium carbonate	Canine—1–4 g/day Feline—0.5–1 g/day	40%	Tablets—500, 600, 650, 1250, 1500 mg Chewable tablets—400, 420, 500, 750, 50, 1000, 1250 mg Capsules—1250 mg Oral suspension—250 mg/mL
Calcium gluconate	Canine—1–4 g/day Feline—0.5–1 g/day	10%	Tablets—500, 650, 975 mg Chewable tablets—500 mg Capsules—500, 700 mg Powder for suspension—70 mg/mL
Calcium lactate	Canine—1–4 g/day Feline—0.5–1 g/day	13%	Tablets—650, 770 mg Capsules—500 mg
Calcium acetate	Canine—1–4 g/day Feline—0.5–1 g/day	25%	Tablets, gelcaps, and capsules—667 mg
Calcium citrate	Canine—1–4 g/day Feline—0.5–1 g/day	21%	Tablets—950, 1150 mg Effervescent tablets—2,380 mg Capsules—850, 1070 mg Powder for oral suspension—725 mg/mL
Calcium glubionate	Canine—1–4 g/day Feline—0.5–1 g/day	30%	Syrup—360 mg/mL

Long-Term Therapy

• Vitamin D administration is needed indefinitely for primary hypoparathyroidism and total parathyroidectomy; dosage should be adjusted based on serum calcium concentration. • Shorter-acting preparations of vitamin D are preferred so that overdosage (causing hypercalcemia) can be quickly corrected (see Table 1). • A more economical approach to treatment is to maximize oral administration of calcium and reduce oral administration of vitamin D (see Table 2); calcium is usually less expensive than vitamin D; dosage is influenced by each product's available elemental calcium content.

CONTRAINDICATIONS

Hypercalcemia

PRECAUTIONS

All calcium preparations given orally can cause nausea and constipation; calcium carbonate may be less irritating because of its high calcium availability and lower dosage requirement.

POSSIBLE INTERACTIONS

• Injectable and sometimes oral calcium solutions and tablets are incompatible with tetracycline drugs, cephalothin, methylprednisolone sodium succinate, dobutamine, metoclopramide, and amphotericin B. • Thiazide diuretics used in conjunction with large doses of calcium may cause hypercalcemia. • Patients on digitalis are more likely to develop arrhythmias if calcium is administered intravenously. • Calcium administration may antagonize effects of calcium channel blocking agents.

FOLLOW-UP

PATIENT MONITORING

• Hypocalcemia and hypercalcemia are both concerns with long-term management. • Once serum calcium is stable and normal, assess

HYPOPARATHYROIDISM (CONTINUED)

serum calcium concentration monthly for the first 6 months, then every 2–4 months; goal is to maintain serum total calcium between 8 and 10 mg/dL. • Inform clients about clinical signs of hypo- and hypercalcemia.

POSSIBLE COMPLICATIONS

• Hypocalcemia if undertreated. • Hypercalcemia, which can lead to nephrocalcinosis and kidney injury (see Hypercalcemia) and resistance to antidiuretic hormone.

EXPECTED COURSE AND PROGNOSIS

• With close monitoring of serum calcium and client dedication, the prognosis for long-term survival is excellent. • Adjustments in vitamin D and oral calcium administration can be expected during the course of management, especially during the initial 2–6 months. • Cats with hypoparathyroidism secondary to thyroidectomy usually require only transient treatment because they typically regain normal parathyroid function within 4–6 months, often within 2–3 weeks.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Excess muscular activity can lead to hyperthermia, which may necessitate treatment.

PREGNANCY/FERTILITY/BREEDING

Hypocalcemia can lead to weakness and dystocia.

SEE ALSO

- Hypercalcemia.
- Hyperthyroidism.
- Hypocalcemia.

HYPOPHOSPHATEMIA

BASICS

DEFINITION
Serum phosphorus concentration <2.5 mg/dL.

PATHOPHYSIOLOGY
- Control of phosphorus is influenced by the actions and interactions of PTH and vitamin D with the gastrointestinal tract, bone, kidneys, and parathyroid glands.
- Decreased serum phosphorus concentration can be caused by translocation of phosphorus from the extracellular fluid into cells, decreased renal reabsorption, or decreased intestinal absorption of phosphorus.
- Low serum phosphorus can lead to adenosine triphosphate (ATP) depletion, which affects cells with high ATP energy demands (skeletal muscle, cardiac muscle, nerve tissue, and red blood cells).
- Many important enzyme systems are dependent on adequate phosphorus levels, including glycolysis, ammoniagenesis, 1-hydroxylation of 25(OH)-cholecalciferol, and 2,3-diphosphoglycerate, which are essential for energy production, acid excretion, calcium balance, and tissue oxygenation, respectively.
- Phosphorus is also required for maintenance of cell membrane integrity, playing an essential role in the production of ATP, guanosine triphosphate, cyclic adenosine monophosphate (AMP), and phosphocreatinine.
- Diabetic (ketotic and nonketotic) patients are at increased risk for hypophosphatemia due to depleted phosphorus stores, lost muscle mass, and urinary losses. Insulin administration yields ATP from glycolysis, causing translocation of phosphorus.

SYSTEMS AFFECTED
- Hemic/lymphatic/immune—hemolysis, impaired oxygen delivery to tissues, impaired leukocyte and platelet function.
- Neurologic—impaired glucose uptake leads to encephalopathy, seizures, and coma.
- Musculoskeletal—rhabdomyolysis, weakness, pain, ventilatory failure, and gastrointestinal ileus.
- Cardiac—impaired contractility.

SIGNALMENT
- Older dog and cat.
- Diabetic patient.
- Keeshonden have genetic predisposition to hyperparathyroidism.

SIGNS
Historical Findings
Usually consistent with the primary condition responsible for the hypophosphatemia; however, evidence of severe hypophosphatemia (e.g., hemolysis) is usually not observed unless serum concentrations decrease to 1.0 mg/dL or less.

Physical Examination Findings
- Hemolytic anemia (especially in cats) causes pallor, tachypnea, dyspnea, and/or hemoglobinuria.
- Skeletal and respiratory muscle weakness.
- Mental dullness.

CAUSES
- Maldistribution (translocation)—treatment of diabetic ketoacidosis, insulin administration or carbohydrate load, total parenteral nutrition or nutritional recovery, hyperventilation or respiratory alkalosis.
- Reduced renal reabsorption (increased renal loss)—primary hyperparathyroidism, renal tubular disorders (e.g., Fanconi syndrome), proximal tubule diuretics (e.g., carbonic anhydrase inhibitors), eclampsia (puerperal tetany), hyperadrenocorticism (corticosteroids promote renal phosphate loss), sodium bicarbonate administration.
- Reduced intestinal absorption (decreased intake)—phosphorus-deficient diets, vitamin D deficiency, malabsorption disorders, phosphate binders.
- Laboratory error—hemolysis, icterus, osmotic diuretic administration.

RISK FACTORS
- Phosphorus-deficient diets or parenteral nutrition (refeeding syndrome).
- Diabetes mellitus.
- Prolonged anorexia, malnutrition, or starvation.
- Primary hyperparathyroidism.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Concurrent hyperglycemia, glucosuria, ketonuria, and high anion gap metabolic acidosis—rule out diabetic ketoacidosis.
- Concurrent glucosuria, normoglycemia, isosthenuria with or without azotemia—rule out renal tubular defects.
- Concurrent hypercalcemia and proteinuria, hematuria, with or without bacteria—rule out primary hyperparathyroidism with cystic calculi or nephroliths.
- Concurrent hypocalcemia—rule out puerperal tetany.
- Concurrent panhypoproteinemia—rule out intestinal malabsorption.

LABORATORY FINDINGS
Drugs That May Alter Laboratory Results
Liposomal amphotericin B (depending on assay).

Disorders That May Alter Laboratory Results
Monoclonal gammopathy may falsely lower serum phosphorus concentrations by binding to inorganic phosphorus.

Valid If Run In Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Serum phosphorus <2.5 mg/dL.
- Hyperglycemia, glucosuria, ketonuria, and high anion gap metabolic acidosis with diabetic ketoacidosis.
- Glucosuria, normoglycemia, isosthenuria, or azotemia with renal tubular defects.
- Hypercalcemia with primary hyperparathyroidism.
- Hypocalcemia with puerperal tetany.
- High serum alkaline phosphatase, proteinuria with hyperadrenocorticism.
- Panhypoproteinemia with intestinal malabsorption.

OTHER LABORATORY TESTS
- Serum fructosamine, ketone concentration—to diagnose or rule out diabetes mellitus or diabetic ketoacidosis, respectively.
- Parathyroid hormone (PTH) assay—to diagnose or rule out hyperparathyroidism.
- PTH-related peptide (PTH-rp)—for hypercalcemia of malignancy.
- Vitamin D metabolite measurement—to diagnose or rule out vitamin D deficiency.

IMAGING
- Radiography may reveal urolithiasis in cases of primary hyperparathyroidism or poor bone quality/pathologic fractures with disorders of vitamin D metabolism.
- Ultrasonography or CT may reveal parathyroid mass.

DIAGNOSTIC PROCEDURES
Surgical exploration of the cervical area may reveal a parathyroid mass. Urine anion gap can reveal renal tubular secretory defect.

TREATMENT
- Prevention is preferred.
- Asymptomatic patients with low (1.5–2.5 mg/dL), but not depleted, phosphorus concentrations may not need phosphate treatment. Cats are more likely to have hemolysis with marked hypophosphatemia.
- If caused by insulin administration or hyperalimentation, administer supplemental phosphorus.
- Severe hypophosphatemia (<1.5 mg/dL)—patients need hospitalization and monitoring for hemolysis or hemolytic crisis. Administer isotonic crystalloid solution without calcium, IV, supplemented with potassium phosphate.
- Packed red blood cell transfusion for severe hemolytic crisis.

HYPOPHOSPHATEMIA (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

- Phosphate—0.01–0.12 mMol/kg/h IV. Monitor serum phosphorus every 6–8 hours.
  - Potassium phosphate (3 mMol phosphate/mL and 4.4 mEq potassium/mL) IV.
  - Sodium phosphate (3 mMol phosphate/mL and 4 mEq sodium/mL) IV.
- Discontinue therapy when serum phosphorus concentration reaches 2 mg/dL in order to avoid iatrogenic hyperphosphatemia and hypocalcemia.

CONTRAINDICATIONS

- Hyperphosphatemia.
- Hypocalcemia.
- Hypercalcemia.
- Renal failure.
- Hyperkalemia.

PRECAUTIONS

- Concurrent diuretic administration, especially carbonic anhydrase inhibitors.
- Renal disease.
- Iatrogenic hyperphosphatemia causes hypocalcemia and soft tissue (especially blood vessels) mineralization.

POSSIBLE INTERACTIONS

- Potassium phosphate may precipitate in IV line if coadministered with calcium-containing fluids, dobutamine, fluoroquinolones.
- Angiotensin-converting enzyme (ACE) inhibitor (e.g., enalapril) administration.
- Cardiac glycoside (e.g., digoxin) administration.
- Potassium-sparing diuretics (e.g., spironolactone).

ALTERNATIVE DRUG(S)

Oral phosphate supplement (e.g., phospho-soda) if not vomiting.

FOLLOW-UP

- Measure serum phosphorus levels every 6–8 hours until within normal range.
- Monitor patients for hyperphosphatemia and discontinue treatment immediately.
- Check serum potassium level daily until stable.

POSSIBLE COMPLICATIONS

- Hemolysis.
- Respiratory depression and failure.
- Cardiac arrest.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Concurrent hypokalemia is common in patients with diabetic ketoacidosis.

AGE-RELATED FACTORS

Usually presents in older dogs.

PREGNANCY/FERTILITY/BREEDING

Concurrent hypocalcemia in the periparturient animal increases PTH-promoted renal excretion of phosphorus, causing hypophosphatemia.

SEE ALSO

- Diabetes Mellitus with Ketoacidosis.
- Hyperparathyroidism.

HYPOPITUITARISM

BASICS

OVERVIEW
- A condition resulting from a defect in pituitary hormone synthesis; most frequently due to a genetic mutation.
- Associated with low production of pituitary hormones including thyroid-stimulating hormone (TSH), luteinizing hormone, follicle-stimulating hormone, and growth hormone (GH). Adrenocorticotropic hormone (ACTH) synthesis is usually preserved in dogs with congenital hyposomatotropism (pituitary dwarfism).
- Hypopituitarism due to transsphenoidal hypophysectomy to treat pituitary-dependent hypercortisolism can result in hypothyroidism, hypocortisolism, and possible GH deficiency.

SIGNALMENT
- Dogs.
- Age—2–6 months.
- Breeds—German shepherd dog, Karelian bear dog, Saarloos wolfhound, spitz, miniature pinscher, and Weimaraner.
- Simple autosomal recessive in German shepherd dog and Karelian bear dog; mutation of the *LHX3* gene.

SIGNS

Historical Findings
- Mental retardation manifested as difficulty in housebreaking.
- Slow growth noticed in first 2–3 months of life.
- Proportionate dwarfism.

Physical Examination Findings
- Retained puppy hair coat.
- Thin, hypotonic skin.
- Shrill bark.
- Truncal alopecia.
- Cutaneous hyperpigmentation.
- Infantile genitalia.
- Delayed dental eruption.

CAUSES & RISK FACTORS

Congenital
- Mutation of *LHX3* gene.
- Isolated GH deficiency.

Acquired
- Pituitary tumor.
- Trauma.
- Radiotherapy.
- Hypophysectomy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hypothyroid dwarfism.
- Portosystemic shunt, diabetes mellitus, hyperadrenocorticism, malnutrition, parasitism (all result in stunted growth).

CBC/BIOCHEMISTRY/URINALYSIS
- Mild anemia.
- Hypophosphatemia.
- Azotemia.

OTHER LABORATORY TESTS
- GH and insulin-like growth factor (IGF) assays; GH assay not currently available in the United States; recommend measurement of IGF-1, which is low.
- Adrenal function is usually preserved in dogs with the *LHX3* mutation.
- TSH response test; subnormal response to TSH.
- Ghrelin-stimulation test—monitors changes in GH levels in response to ghrelin; requires GH assay.
- DNA testing.

IMAGING
Radiography may reveal epiphyseal dysgenesis and abnormal retention of physeal growth plates.

TREATMENT
Manage medically on an outpatient basis.

MEDICATIONS

DRUG(S) OF CHOICE
- GH—porcine GH, if available; has the same structure as canine GH: 0.1 IU/kg SC three times weekly for 4–6 weeks. Dose adjustments based on IGF-1 measurements every 4–6 weeks initially.
- The author is currently using the following source for porcine GH in the United States: http://www.humc.edu/hormones/material.html. This is not an FDA-approved drug in any species and requires client consent and special preparation and handling by a veterinary pharmacist.
- Medroxyprogesterone acetate (2.5–5 mg/kg IM q3 weeks, then q6 weeks after normal stature is achieved).
- Treat hypothyroidism with levothyroxine (22 µg/kg PO q24h).
- Glucocorticoids (e.g., prednisone: 0.2 mg/kg PO q24h) if ACTH response test results are consistent with hypoadrenocorticism; higher dosage of steroids is needed during periods of stress.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Hypersensitivity reactions and carbohydrate intolerance may develop with growth hormone supplementation.

FOLLOW-UP

PATIENT MONITORING
- IGF-1 every 4–6 weeks initially, and then less frequently.
- Blood and urinary glucose concentration.
- Stop GH supplementation if glucosuria develops or blood glucose is >150 mg/dL.

POSSIBLE COMPLICATIONS
Acromegaly and diabetes mellitus; pyometra in female dogs treated with progestins.

EXPECTED COURSE AND PROGNOSIS
- Skin and hair coat improve within 6–8 weeks of initiating GH and thyroid supplementation.
- Generally no increase in stature because growth plates have usually closed by the time of diagnosis.
- Dogs often die at a young age (3–4 years) because of neurologic complications, renal failure, or infections.
- Poor long-term prognosis.

MISCELLANEOUS

SEE ALSO
- Hypoadrenocorticism (Addison's Disease).
- Hypothyroidism.

ABBREVIATIONS
- ACTH = adrenocorticotropic hormone.
- GH = growth hormone.
- IGF-1 = insulin-like growth factor-I.
- TSH = thyroid-stimulating hormone.

HYPOPYON AND LIPID FLARE

BASICS

OVERVIEW

Hypopyon

Accumulation of white blood cells in anterior chamber of eye; inflammatory breakdown of blood–aqueous barrier allows entry of cells into anterior chamber; chemoattractants mediate influx; cells settle in ventral anterior chamber due to gravity.

Lipid Flare

Resembles hypopyon but turbidity of anterior chamber is caused by lipids in aqueous humor; requires breakdown of blood–aqueous barrier and concurrent hyperlipidemia.

SIGNALMENT

Dogs and cats; no age or sex predilection.

SIGNS

Hypopyon

• White to yellow opacity within anterior chamber—may be a ventral accumulation of cells or may completely fill anterior chamber; fibrin accumulation in anterior chamber may prevent discrete settling of white blood cells, resulting in cells suspended within fibrin matrix. • Concurrent ophthalmic signs include blepharospasm, epiphora, diffuse corneal edema, aqueous flare, miosis, iridal swelling, and vision loss.

Lipid Flare

• Diffuse milky appearance to anterior chamber. • Concurrent ophthalmic signs may include vision loss, mild blepharospasm, and mild to moderate diffuse corneal edema.

CAUSES & RISK FACTORS

Hypopyon

Any cause of uveitis can result in hypopyon—most commonly associated with severe uveitis. Hypopyon can also result from neoplastic cell accumulation in ocular lymphoma.

Lipid Flare

Lipid flare results from hyperlipidemia and concurrent uveitis; hyperlipidemia may also destabilize blood–aqueous barrier directly. Postprandial lipemia may occasionally result in lipemic aqueous if uveitis is present.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hypopyon

Fibrin in anterior chamber—generally forms an irregular clot, not ventral horizontal line.

Lipid Flare

• Severe aqueous flare—does not appear as milky white as lipid flare; animals with aqueous flare generally exhibit more ocular pain. • Diffuse corneal edema—severe corneal edema may be confused with anterior chamber opacity, but corneal stromal thickening, keratoconus, and corneal bullae are noted with the former.

CBC/BIOCHEMISTRY/URINALYSIS

Hypopyon

Often normal; abnormalities relate to underlying cause of uveitis.

Lipid Flare

Elevated serum triglycerides and cholesterol; abnormalities reflect underlying metabolic disorder(s).

OTHER LABORATORY TESTS

Hypopyon

None if hypopyon is related to obvious corneal disease; if related to uveitis, look for underlying cause of uveitis (e.g., anterior uveitis).

Lipid Flare

See Hyperlipidemia.

DIAGNOSTIC PROCEDURES

Anterior chamber centesis indicated with suspicion of neoplastic hypopyon; otherwise unrewarding.

TREATMENT

• Hypopyon requires aggressive treatment for uveitis and underlying cause.
• Lipid flare requires treatment for uveitis and underlying metabolic disorder.

MEDICATIONS

DRUG(S) OF CHOICE

Hypopyon

Corticosteroids

• *Topical*—prednisolone acetate 1% or dexamethasone 0.1%: apply 2–6 times daily, depending on disease severity; taper medication as condition resolves.
• *Subconjunctival*—triamcinolone acetonide (dog: 4–6 mg; cat: 4 mg) or methylprednisolone (dog: 3–10 mg; cat: 4 mg) by subconjunctival injection; one-time injection followed by topical and/or systemic anti-inflammatories. • *Systemic*—prednisone (dog: 0.5–2.2 mg/kg/day; cat: 1–3 mg/kg/day); taper dose after 7–10 days; only if infectious causes of uveitis have been ruled out.

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

• *Topical*—flurbiprofen, diclofenac, or kerorolac: 2–4 times daily, depending on severity of disease; less effective than corticosteroids. • *Systemic*—carprofen (dog: 2.2 mg/kg PO q12h); meloxicam (dog: 0.2 mg/kg PO q24h); robenacoxib (cat: 1 mg/kg PO q24h; limit duration of use to 3 days); meloxicam (cat: 0.2 mg/kg IV/SC/PO once, then 0.05 mg/kg IV/SC/PO q24h for 2 days, then 0.025 mg/kg q24–48h; limit duration of use to 4 days); do not use NSAIDs concurrently with systemic corticosteroids.

Topical Mydriatic/Cycloplegic

Atropine sulfate 1%—1–4 times daily, depending on severity of disease; use ointment instead of solution in cats to minimize salivation.

Lipid Flare

Topical Corticosteroids

Prednisolone acetate 1% or dexamethasone 0.1%—2–4 times daily, depending on severity of disease; taper medication as condition resolves.

Topical Mydriatic/Cycloplegic

Atropine sulfate 1%—1–2 times daily, for ocular discomfort.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Avoid topical miotic medications. • Topical and subconjunctival corticosteroids contraindicated if ulcerative keratitis present. • Out of concern for secondary glaucoma, topical atropine should be used judiciously with intraocular pressure (IOP) monitoring.

FOLLOW-UP

PATIENT MONITORING

Recheck in 2–3 days. IOP should be monitored to detect secondary glaucoma. Frequency of subsequent rechecks dictated by response to treatment.

EXPECTED COURSE AND PROGNOSIS

• Hypopyon—prognosis guarded to good; depends on underlying disease and response to treatment. • Lipid flare—prognosis good; generally responds quickly (within 24–72 hours) to moderate anti-inflammatory therapy; recurrence possible.

MISCELLANEOUS

ABBREVIATIONS

• IOP = intraocular pressure.
• NSAID = nonsteroidal anti-inflammatory drug.

Author Ian P. Herring
Consulting Editor Kathern E. Myrna

HYPOREXIA

BASICS

OVERVIEW
- Spontaneous decrease in food intake, and implies inadequate caloric intake.
- Triggered by numerous conditions and reflects a derangement in hypothalamic processes that govern satiety and hunger.
- Prolonged hyporexia results in weight loss and contributes to sarcopenia and cachexia.

SIGNALMENT
Dogs and cats of all ages; no breed or sex predilections.

SIGNS
- Patients may refuse all food (anorexia) or consume a portion of their caloric needs.
- Preferential appetite may be reported for treats or highly desirable foods, but not a balanced diet.
- Signs suggesting nausea (e.g., drooling or gagging) may be reported, and severely affected animals may avoid food or try to hide it.
- Sustained hyporexia results in weight loss, and may be accompanied by a decrease in lean muscle mass as well as fat.

CAUSES & RISK FACTORS
- Any metabolic derangement (endocrine, renal, hepatic) or organic compromise (e.g., respiratory or cardiovascular or gastrointestinal disease).
- Systemic inflammation (infectious, sterile, neoplastic).
- Medications, pain/discomfort, or psychologic issues (fear, anxiety).
- Lesions in the hypothalamus or affecting smell.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Must be differentiated from 'pseudo-inappetence', i.e., limited intake due to oral pathology, prehension disorders or palatability issues.

CBC/BIOCHEMISTRY/URINALYSIS
- Influenced by underlying cause(s), but can be normal despite inadequate intake.
- Sustained and severe hyporexia in cats may result in hepatic lipidosis, characterized by an increase in alkaline phosphatase activity and hyperbilirubinemia.

OTHER LABORATORY TESTS
As necessary to identify underlying cause(s).

IMAGING
As necessary to identify underlying cause(s).

DIAGNOSTIC PROCEDURES
As necessary to identify underlying cause(s).

TREATMENT
- Underlying disorders, vomiting/nausea, pain, and anxiety should be addressed promptly.
- Medications contributing to poor intake should be withdrawn if possible.
- Offering warmed food or more palatable options may be helpful.
- Sustained hyporexia should be addressed with an enteral feeding device (e.g., esophageal feeding tube) or parenterally in patients with substantial gastrointestinal compromise.

MEDICATIONS
- Numerous medications are anecdotally reported to improve food intake in companion animals, but most are not licensed for this purpose and there are limited efficacy and safety data.
- Practitioners are encouraged to use FDA-approved appetite stimulants before considering alternative approaches.
- The administration of an appetite stimulant should not delay efforts to identify and address the underlying cause(s) of hyporexia.

DRUG(S) OF CHOICE
- Capromorelin—dogs: 3 mg/kg PO q24h; a ghrelin receptor agonist, FDA-approved as an appetite stimulant for dogs (feline product under development).
  - Mimics actions of ghrelin, the "hunger hormone," a peptide secreted by gastric mucosa.
  - Receptors located in hypothalamus; activation promotes feelings of hunger and food-seeking behavior.
  - Ghrelin also triggers release of growth hormone, increasing muscle mass and lean weight gain.
- Mirtazapine—dogs: 3.75–30 mg/dog PO q24h; cats: 1.9 mg/cat PO q48h; used off-label for many years as an appetite stimulant; mechanism is likely related to increased central norepinephrine levels. Transdermal formulation approved for cats (2 mg/cat q24h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Mirtazapine has relatively narrow therapeutic window; should be dosed cautiously in small patients and those with renal compromise. Side effects can include vocalization, behavior changes, and tremors.
- Serotonin syndrome may occur with concurrent administration of monoamine oxidase inhibitors, metoclopramide, ondansetron, or tramadol.

FOLLOW-UP

PATIENT MONITORING
Monitor food intake and bodyweight carefully, and modify therapy for both underlying disease and hyporexia as necessary.

PREVENTION/AVOIDANCE
Prompt recognition and management of conditions that may impact food intake.

POSSIBLE COMPLICATIONS
- Cats with sustained, substantial hyporexia may develop hepatic lipidosis.
- Hyporexia impacts outcome and mortality in hospitalized people and it likely has a similar impact in companion animals.

EXPECTED COURSE AND PROGNOSIS
- Response to appetite stimulants is variable; some animals require enteral feeding devices.
- Underlying cause(s) of hyporexia ultimately determines prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Sarcopenia (i.e., age-related loss of muscle) and cachexia (i.e., rapid/extreme weight loss and muscle wasting) are associated with or exacerbated by hyporexia.

AGE-RELATED FACTORS
None (unless related to underlying cause).

HYPOSTHENURIA

BASICS

DEFINITION
Urine specific gravity (USG) between 1.000 and 1.006.

PATHOPHYSIOLOGY
The ability to concentrate urine normally (dogs: >1.030; cats: >1.035) depends on a complex interaction between antidiuretic hormone (ADH), the protein receptor for ADH on the renal tubule, and a hypertonic renal medullary interstitium; interference with the synthesis, release, or actions of ADH, damage to the renal tubule, or altered tonicity of the medullary interstitium (medullary washout) can cause hyposthenuria.

SYSTEMS AFFECTED
Depends on the underlying disorder.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
None

Predominant Sex
None

SIGNS
- Polyuria and polydipsia.
- Urinary incontinence—occasional.
- Other signs depend on the underlying disorder.

CAUSES
Any disorder or drug that interferes with the release or action of ADH, damages the renal tubule, causes medullary washout, or causes a primary thirst disorder (see Differential Diagnosis).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Central diabetes insipidus (little or no ADH produced).
- Nephrogenic diabetes insipidus (resistance to ADH).
- Pyometra.
- Pyelonephritis.
- Hyperadrenocorticism.
- Hypoadrenocorticism.
- Hyperthyroidism.
- Hypercalcemia.
- Primary liver disease.
- Hypokalemia.
- Primary polydipsia—compulsive water drinking.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
Cortisone, lithium, demeclocycline, methoxyflurane, thiazide diuretics, and intravenous administration of fluids can all lower USG into the hyposthenuric range.

Valid if Run in a Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Low USG (1.000–1.006); other abnormalities may point to the underlying cause.
- High serum alkaline phosphatase (ALP) enzyme activity suggests hyperadrenocorticism or primary liver disease.
- High cholesterol common in patients with hyperadrenocorticism.
- Leukocytosis with a left shift in some patients with pyometra or pyelonephritis.
- Hyperkalemia and hyponatremia suggest hypoadrenocorticism.
- Low serum potassium concentration confirms hypokalemia.
- Inflammatory sediment or bacteriuria and positive urine culture consistent with pyelonephritis.
- Proteinuria common in patients with pyelonephritis, pyometra, and hyperadrenocorticism.

OTHER LABORATORY TESTS
- Adrenocorticotropic hormone (ACTH) stimulation test to screen for hyperadrenocorticism and hypoadrenocorticism.
- Low-dose dexamethasone suppression test and urine : cortisol creatinine test to screen for hyperadrenocorticism.
- Serum bile acids concentration to evaluate liver function (*note*: dogs with hyperadrenocorticism often have mild elevations of bile acid concentration).

IMAGING
- Radiography to assess renal size and shape and to detect calcified adrenal tumor or large uterus.
- Ultrasonography to assess adrenal size, renal and hepatic size and architecture, and uterine size. Dilated renal pelves may indicate pyelonephritis or be an artifact of IV fluid therapy.
- MRI or CT may identify pituitary or hypothalamic mass that may be the cause of central diabetes insipidus or hyperadrenocorticism.

DIAGNOSTIC PROCEDURES
- Desmopressin response test to differentiate primary central diabetes insipidus from primary nephrogenic diabetes insipidus.
- Reassessment of USG following change of environment in a dog suspected of having primary polydipsia. For example, some dogs hospitalized with free access to water will drink less and concentrate urine by the end of the day, suggesting a diagnosis of primary polydipsia.

TREATMENT
- Depends on the underlying disorder.
- Do not restrict patient's water intake unless appropriate to the definitive diagnosis.
- Depends on the underlying disorder.

MEDICATIONS

DRUG(S) OF CHOICE
Depend on the underlying disorder.

FOLLOW-UP

PATIENT MONITORING
USG, hydration status, renal function, and electrolytes.

POSSIBLE COMPLICATIONS
Dehydration

MISCELLANEOUS

ASSOCIATED CONDITIONS
See Differential Diagnosis.

ZOONOTIC POTENTIAL
None

SEE ALSO

HYPOTHERMIA

BASICS

Due to limited clinical literature in veterinary science, much of the information below has been extrapolated from human medical literature and experimental animal studies.

DEFINITION

• Core body temperature drops below that required for normal metabolism. In primary hypothermia, the healthy individual's compensatory responses to heat loss are overwhelmed by exposure, whereas secondary hypothermia complicates many systemic diseases. • Stage I—90–95 °F (32–35 °C). • Stage II—82–90 °F (28–32 °C). • Stage III—75–82 °F (24–28 °C). • Stage IV—<75 °F (24 °C).

PATHOPHYSIOLOGY

• Normal thermoregulation balances heat gained or lost to the environment with heat produced via central thermogenesis; it is controlled by the hypothalamus with input from thermoreceptors; heat can be gained or lost to the environment via four mechanisms: evaporation, radiation, convection, and conduction; central thermogenesis generates heat via basal metabolism, muscle activity, and uncoupling of brown fat (neonates). • Heat production can be augmented via shivering and increased basal metabolic rate; activation of both sympathetic nervous and endocrine systems results in increased circulating levels of thyroid-releasing hormone, catecholamines, growth hormone, and glucocorticoids, which all contribute to increased glucose utilization and basal metabolic rate. • Adaptations to minimize heat loss include cutaneous vasoconstriction, piloerection, and behavioral responses such as curling up, sharing body heat, and seeking shelter.

SYSTEMS AFFECTED

• Cardiovascular—in mild hypothermia, sympathetic stimulation induces tachycardia and peripheral vasoconstriction with normal or elevated cardiac output (CO) and BP; as the patient becomes colder, cardiac pacemaker cell depolarization is slowed, resulting in bradycardia resistant to treatment with atropine; the resultant fall in CO is balanced by increased systemic vascular resistance; at lower temperatures, bradycardia becomes progressively extreme and systemic vascular resistance falls as catecholamine release and adrenergic receptor responsiveness are blunted. • Endocrine—sympathetic activation and release of counter-regulatory hormones trigger increased glycogenolysis, gluconeogenesis, and lipolysis as well as inhibit the release and uptake of insulin resulting in hyperglycemia; when hypothermia develops slowly or is longlasting, glycogen stores become depleted and hypoglycemia develops. • Gastrointestinal—increased gastric acid production and reduced duodenal bicarbonate secretion may predispose to gastrointestinal ulceration; ileus is common. • Hemic—plasma shifts and consequent hemoconcentration may lead to hyper- and hypocoagulopathy; depressed enzymatic activity of clotting factors and platelet hyporeactivity may exacerbate hypocoagulability. • Hepatobiliary/pancreatic—hypoxia leads to hepatocellular damage and pancreatitis. • Musculoskeletal—increased joint fluid viscosity and muscle stiffness. • Nervous—CNS metabolism and level of consciousness decrease and nerve conduction velocity progressively slows; mild incoordination is followed by lethargy, obtundation, and coma. • Renal—peripheral vasoconstriction increases renal blood flow and glomerular filtration rate resulting in increased urine production; progressive tubular dysfunction and antidiuretic hormone resistance contribute further to cold diuresis; later, urine output decreases as result of falling CO; acute kidney injury may ensue. • Respiratory—initial tachypnea replaced by decreased respiratory rate and tidal volume and increased airway secretions; as temperature falls, protective airway reflexes are reduced; below 93.2 °F (34 °C) ventilatory drive is attenuated and increased pulmonary vascular resistance leads to ventilation–perfusion mismatch; progressive hypoventilation, apnea, and, more rarely, pulmonary edema may develop; hypothermia shifts the oxyhemoglobin dissociation curve to the left; this may be masked by concurrent lactic and respiratory acidosis that may become so profound the overall result is a right shift. • Skin—edema secondary to increased vascular permeability.

GENETICS

Unknown

INCIDENCE/PREVALENCE

Varies with geographic location.

GEOGRAPHIC DISTRIBUTION

Most common in cold climates.

SIGNALMENT

Species

Dog and cat.

Breed Predilections

Smaller breeds with increased surface area.

Mean Age and Range

More common in neonates and geriatrics.

Predominant Sex

None

SIGNS

General Comments

A thorough search should be made to find precipitating, comorbid conditions.

Historical Findings

• Known prolonged exposure to cold ambient temperatures. • Possibly, disappearance from home or a history of trauma.

Physical Examination Findings

Stage I: 90–95 °F (32–35 °C)

• Lethargy and weakness. • Vigorous shivering (variable). • Variable heart rate, rhythm, and BP. • Light pink to pale mucous membranes. • Confusion, agitation, or obtundation. • Variable respiratory rate.

STAGE II: 82–90 °F (28–32 °C)

• Collapse. • Reduced shivering (variable). • Bradyarrhythmia with hypotension. • Pale mucous membranes. • Muscle and joint stiffness. • Obtundation, stupor, or coma. • Ataxia and hyporeflexia. • Reduced depth and rate of respiration.

STAGE III: 75–82 °F (24–28 °C)

• Moribund with cold, edematous skin. • Loss of shivering (variable). • Bradyarrhythmia with hypotension. • Pale mucous membranes. • Muscle and joint stiffness. • Coma with fixed, dilated pupils. • Areflexia. • Reduced depth and rate of respiration or respiratory arrest. • Pulmonary edema.

STAGE IV: <75 °F (<24 °C)

• No vital signs. • Cardiac arrest.

CAUSES

• Inadequate thermogenesis: ○ Normal thermogenesis is overwhelmed. ○ Serious illness. • Extreme heat loss: ○ Excessive evaporation, conduction, convection, and radiation. ○ Inability to vasoconstrict blood vessels or piloerect hair. ○ Loss of behavioral adaptations. • Thermoregulatory center failure: ○ Hypothalamic injury or disease.

RISK FACTORS

• Extremes of age. • Low body fat and glycogen stores. • Burn injury. • Intracranial injury or disease. • Hypothyroidism. • Diabetic ketoacidosis. • Sepsis. • Trauma. • General anesthesia. • Medications including but not limited to beta blockers, barbiturates, narcotics, phenothiazines.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Primary CNS disease, hypoglycemia, anemia, hepatic encephalopathy, myxedema, electrolyte disturbances, sepsis, intoxication, neoplasia, and death. • Bradyarrhythmia—cardiac disease, medication side effects, and toxicities.

CBC/BIOCHEMISTRY/URINALYSIS

• Results depend on severity and presence of comorbidities. • CBC—hemoconcentration, leukopenia, and thrombocytopenia. • Biochemistry—azotemia, hyper- and hypoglycemia, variable electrolyte abnormalities, elevated liver enzyme activity, hyperbilirubinemia. • Urinalysis—isosthenuria and glucosuria.

HYPOTHERMIA (CONTINUED)

OTHER LABORATORY TESTS
• Blood gas—variable; metabolic and respiratory acidosis is common. • Hyperlactatemia—shivering, reduced tissue perfusion, and impaired hepatic clearance. • Coagulation—hyperfibrinogenemia and disseminated intravascular coagulation; in vivo prolongation of clotting times may not be reflected by in vitro assays and should correct with rewarming. • Thyroid hormone evaluation may confirm underlying hypothyroidism.

IMAGING
To investigate recovery complications or comorbid conditions.

DIAGNOSTIC PROCEDURES

ECG
Classic findings include presence of Osborn or J-waves, atrial and ventricular dysrhythmias, and prolongation of PR, QRS, and QT intervals with progression from sinus bradycardia through atrial fibrillation to ventricular fibrillation and ultimately asystole.

PATHOLOGIC FINDINGS
• Findings in patients who succumb to primary hypothermia are variable and nonspecific; if body cooling and death occur rapidly, necropsy findings are minimal but may include reddish discoloration of skin, hemorrhagic gastric erosions, and lipid deposits in epithelial cells of renal proximal tubules and other organs. • Patients who die from secondary hypothermia may have similar findings; however, they will also have evidence of a separate and significant disease process.

TREATMENT

APPROPRIATE HEALTH CARE
Emergency inpatient intensive care until normothermic and stable.

NURSING CARE
• Warming: ○ Active external rewarming using warm blankets, heating pads, radiant heat, forced warm air, and administration of warm parenteral fluids (stage II) is used in patients with stage I–II hypothermia; complications include core temperature after-drop whereby return of cold blood from periphery to central circulation causes further core cooling; rewarming of the trunk should be performed before the extremities to minimize this risk. ○ Techniques to warm patients with stage III–IV hypothermia include administration of warm humidified oxygen, warmed IV fluids, and bladder or gastric lavage with warm saline; more invasive and technically demanding methods include closed thoracic and peritoneal lavage, and extracorporeal rewarming. ○ Whole-body immersion in hot water is contraindicated, as it will cause massive vasodilatation and hypotension and is likely to provoke dysrhythmias and cardiovascular collapse. • Fluid therapy: ○ IV crystalloid fluids warmed to 104 °F (40 °C). ○ During rewarming, these patients have significant IV fluid requirements as vasoconstriction relaxes and cold diuresis is reversed. ○ Patients must be closely monitored for volume overload during resuscitation. • Consider inotropic drugs in patients unresponsive to volume resuscitation. • Mechanically ventilate patients with respiratory failure.

ACTIVITY
Minimally affected patients should be encouraged to be active, as muscle activity will generate more endogenous body heat.

DIET
Withhold oral intake until patient is alert.

CLIENT EDUCATION
Prevention of exposure to cold temperatures is imperative in preventing primary hypothermia. Clients with very young and very old patients as well as those with serious medical conditions or taking medications that inhibit thermoregulatory ability should be counseled to keep their pets indoors and to take protective measures if they are to be exposed to cold temperatures.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Hypoglycemic patients warrant dextrose supplementation. • Antiarrhythmic agents generally not warranted as most arrhythmias will resolve with rewarming.

CONTRAINDICATIONS
No evidence to support routine use of steroids or antibiotics.

PRECAUTIONS
Systemic clearance of metabolized drugs is slowed proportionally—consider dose reduction to minimize likelihood of unanticipated toxicity.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Continuous core body temperature. • Continuous ECG and frequent BP during rewarming. • Frequent assessment (q6–12h) of electrolytes, acid-base status, packed cell volume, total protein, and blood glucose. • Daily monitoring of blood urea nitrogen, urine specific gravity, coagulation indices, and liver enzymes in severely affected patients.

PREVENTION/AVOIDANCE
• Avoid prolonged exposure to cold. • Monitor and maintain body temperature in anesthetized animals.

POSSIBLE COMPLICATIONS
• Peripheral vasodilation during rewarming may further drop BP and body temperature. • Iatrogenic burns. • Return of cool peripheral blood to the heart may precipitate cardiac arrhythmias. • Cardiac arrest. • Gastric lavage increases the risk of aspiration pneumonia and fluid and electrolyte shifts. • Thoracic and/or peritoneal lavage increases the risk for hemorrhage, lung or bowel trauma, and fluid and electrolyte shifts. • Extracorporeal rewarming techniques have increased risk for local vascular complications, air embolism, hypotension, hemorrhage, thrombosis, and hemolysis.

EXPECTED COURSE AND PROGNOSIS
Variable—depend on severity, underlying cause, and patient health status.

HYPOTHYROIDISM

BASICS

DEFINITION
Clinical manifestations that result from inadequate production of thyroxine (T_4) and 3,5,3′-triiodothyronine (T_3) by the thyroid gland. Characterized by a generalized decrease in cellular metabolic activity.

PATHOPHYSIOLOGY

Acquired Hypothyroidism
- In dogs, acquired hypothyroidism can be primary, secondary, or tertiary.
- Primary hypothyroidism is associated with a defect localized to the thyroid gland. The thyroid tissue has been destroyed or replaced and thus becomes less responsive to thyroid-stimulating hormone (TSH). T_3 and T_4 levels gradually decline, with a compensatory increase in TSH.
  - Lymphocytic thyroiditis is an immune-mediated process characterized by chronic and progressive lymphocytic infiltration and destruction of the thyroid gland. This process is gradual and accounts for the slow onset of clinical signs associated with hypothyroidism. The immune-mediated process is associated with production of autoantibodies, predominantly against thyroglobulin; however, autoantibodies against T_3 and T_4 have been reported.
  - Idiopathic thyroid atrophy does not demonstrate an inflammatory component and is caused by the replacement of normal thyroid tissue with adipose tissue.
  - Together, these processes account for 95% of the clinical cases of hypothyroidism in dogs; each accounts for 50% of reported cases.
  - Rare causes of primary hypothyroidism include neoplastic destruction of thyroid tissue, iodine deficiency, infection, and iatrogenic destruction secondary to drugs, surgery, or radioiodine treatment.
- Secondary acquired hypothyroidism is rare. The defect is localized to the pituitary, where the ability to synthesize and secrete TSH is impaired. Secondary hypothyroidism may be caused by pituitary tumors, congenital malformation of the pituitary, infection, or TSH suppression. Drugs, hormones, or concurrent illness can cause TSH suppression.
- Tertiary hypothyroidism (not reported in the veterinary literature) is hypothalamic in origin, and production of thyrotropin-releasing hormone (TRH) is either decreased or nonexistent.
- Hypothyroidism may occur following radioactive iodine (I-131) therapy for hyperthyroidism in cats.

Congenital Hypothyroidism
- Congenital hypothyroidism is a rare disease that is categorized as goitrous or nongoitrous. Goiter (enlargement of the thyroid gland) develops when there is increased release of TSH, along with an intact thyroid TSH receptor.
- An autosomal recessive form of congenital hypothyroidism has been reported in specific dog and cat breeds. Affected animals have a thyroid peroxidase deficiency.
- Congenital hypothyroidism is also noted as an element of panhypopituitarism.

SYSTEMS AFFECTED
- Behavioral.
- Cardiovascular.
- Endocrine/metabolic.
- Gastrointestinal (GI).
- Nervous.
- Neuromuscular.
- Ophthalmic.
- Reproductive.
- Skin/exocrine.

GENETICS
- No known genetic basis for heritability associated with adult-onset primary hypothyroidism in dogs, although some breeds appear to be predisposed to thyroiditis.
- An autosomal recessive form of congenital hypothyroidism has been reported in toy fox terriers, giant schnauzers, Tenterfield terriers, and Abyssinian cats.

INCIDENCE/PREVALENCE
- Primary hypothyroidism is the most common endocrinopathy in dogs. Prevalence appears to average about 1 : 250.
- Hypothyroidism is rare in cats.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dog, rarely cat.

Breed Predilections
Larger-breed dogs are more likely to develop hypothyroidism (golden retriever, Doberman pinscher, Great Dane, Irish setter), though several smaller-breed dogs do appear to also be predisposed (miniature schnauzer, cocker spaniel, poodle, dachshund).

Mean Age and Range
Most commonly seen in middle-aged dogs, with the average age of onset being 7 years.

Predominant Sex
None

SIGNS

General Comments
Clinical signs associated with hypothyroidism are vague and involve many different systems.

Historical Findings
- Lethargy, weight gain, and hair loss are the most common signs (40–50% of all cases).
- Pyoderma (often recurrent), hyperpigmentation of the skin, and a dry, brittle hair coat (10% of cases).
- Rarely (<5% of cases), facial paralysis, weakness, or conjunctivitis.

Physical Examination Findings
- Most changes appear to be secondary to decreased metabolism due to a lack of circulating thyroid hormones.
- The most common findings include dermatologic abnormalities (88% of hypothyroid dogs):
  - Bilateral symmetric nonpruritic truncal alopecia; hair loss is noted in areas of increased wear and usually includes the ventral thorax and neck, ventral abdomen, elbows, and tail. Loss of primary hair is most common, with retention of guard hairs, resulting in a short, fine hair coat.
  - Dry, lackluster hair coat.
  - Seborrhea is common and may be localized or have a more generalized distribution pattern.
  - Pyoderma is noted in 14% of hypothyroid dogs and may be recurrent in nature. Generalized demodicosis and *Malassezia* spp. infections are common. Though primary dermatologic conditions are nonpruritic, pruritis may accompany secondary parasitic, yeast, or bacterial infections. Chronic changes to the skin can result in thickening and hyperpigmentation.
- Otitis externa.
- Weight gain.
- Decreased activity/lethargy.
- Most neurologic signs are associated with polyneuropathy and include weakness, facial nerve paralysis, vestibular signs (usually peripheral), and hyporeflexia. No data support a direct association between megaesophagus or laryngeal paralysis and hypothyroidism.
- CNS signs, including seizures, ataxia, and coma (myxedema coma), are rare.
- In females, hypothyroidism is associated with increased periparturient mortality and lower birth rate in pups. In males, decreased fertility has been reported, but not confirmed, in hypothyroid dogs.
- Cardiovascular abnormalities are rare. Bradycardia, arrhythmias, decreased conduction, decreased contractility, and diastolic dysfunction have been reported.
- Ocular changes including corneal cholesterol deposits, keratoconjunctivitis sicca (KCS), and conjunctivitis are seen in less than 1% of hypothyroid dogs.

Congenital Hypothyroidism
- Lethargy and general inactivity.
- Dwarfism.
- Alopecia.
- Constipation (more common in cats).

CAUSES
- Lymphocytic thyroiditis.
- Idiopathic thyroid atrophy.
- Neoplasia.
- Pituitary disease.
- Congenital abnormalities.

HYPOTHYROIDISM (CONTINUED)

- Iodine deficiency (dietary).
- Iatrogenic (secondary to surgery or radiation).

RISK FACTORS

- Surgical removal (bilateral) of the thyroid gland.
- I-131 therapy for hyperthyroidism in cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary dermatologic disease.
- Other endocrinopathies (hyperadrenocorticism, diabetes mellitus, growth hormone deficiency).
- Pancreatitis.
- Nephrotic syndrome.
- Hepatobiliary disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Useful to rule out nonthyroidal illness.
- Normochromic, normocytic, and nonregenerative anemia is a common finding (28–32% of hypothyroid dogs).
- Hyponatremia.
- Hypercholesterolemia (present in over 75% of hypothyroid dogs).
- Hypertriglyceridemia.
- Elevated levels of cholesterol and triglycerides have been associated with atherosclerosis in dogs, although this is rare.
- No specific changes are noted on urinalysis.

OTHER LABORATORY TESTS

- Diagnosing hypothyroidism is complex. The TSH stimulation test is a reliable single test used to diagnose hypothyroidism and is considered the gold standard. However, there is limited access to test reagents and the cost is often prohibitive.
- Several tests are available to assess thyroid function, thyroid hormone levels, and antithyroglobulin antibody levels. These tests include total T_4, free T_4, endogenous TSH, antithyroglobulin antibodies, anti-T_3 antibodies, anti-T_4 antibodies, total T_3, reverse T_3, and free T_3.
- Combination testing will yield a reliable result.

Total T_4

- Initial screening (high sensitivity) test of thyroid function.
- This test measures both protein-bound and free T_4 levels.
- The test is a direct assessment of the ability of the thyroid gland to produce hormone.
- A decreased total T_4 level is a common finding in hypothyroid animals, but is not diagnostic of hypothyroidism as concurrent illness can cause an artificial decrease in total T_4 level.

Free T_4

- Measures metabolically active portion of total T_4 level.
- Hypothyroid animals would be expected to have a low free T_4 level.
- Concurrent illness has less effect on the free T_4 level compared with the total T_4 level.
- Measurement by equilibrium dialysis (fT_4ED) has been demonstrated to be more reliable than radioimmunoassay, because it mitigates the influence of antithyroglobulin antibodies.
- Newer methods of free T_4 analysis utilize chemiluminescent technology with comparable sensitivity and specificity to fT_4ED, but the effect of antibodies on this assay is unclear, and the fT_4ED is still the gold standard.

Endogenous TSH Level

- Measurement of canine endogenous TSH is available.
- Cross-reactivity allows this assay to be used in cats; however, it may be accurate only 50% of the time in cats.
- This test has high specificity and low sensitivity; best used as a confirmatory test and not as a screening test.
- TSH level is expected to be elevated in primary hypothyroid animals due to loss of negative feedback, however, 20–40% of hypothyroid dogs have TSH values in the reference range.
- Interpretation of the TSH level requires knowledge of the total or free T_4 level.
- Methods of assessing TSH levels are less sensitive at low levels and evaluation of endogenous TSH cannot be used to diagnose secondary hypothyroidism.

Antithyroglobulin Antibodies

- Antithyroglobulin antibodies include antithyroglobulin, anti-T_3, and anti-T_4 antibodies.
- A positive titer is predictive of immune-mediated thyroiditis, and suggestive of hypothyroidism, but only 20% of euthyroid dogs with antibodies develop hypothyroidism within 1 year.
- Anti-T_3 and -T_4 antibodies are similar to T_3 and T_4 and can cross-react to falsely elevate these assay levels. In animals who are slightly hypothyroid (as measured by total T_4), the presence of anti-T_4 antibodies may make it appear as if these animals are euthyroid, leading to a delay in the diagnosis and treatment of hypothyroidism.

TSH Stimulation Test

- Historically considered the gold standard for diagnosing hypothyroidism.
- Pharmaceutical-grade bovine TSH was used to conduct this test; however, this is no longer available.
- Recombinant human TSH can be used safely in both dogs and cats to effectively conduct the test, but is expensive. Therefore, this test is unlikely to become routine.

Total T_3, Reverse T_3, and Free T_3

- Total T_3 measurement is an unreliable indicator of thyroid function.
- The total T_3 level has been demonstrated to be normal in up to 90% of hypothyroid dogs.
- The reverse T_3 level has not been validated in companion animals.
- Evaluation of total T_3, reverse T_3, and free T_3 levels is not recommended to assess thyroid function.

Nonthyroid Factors That Alter Thyroid Function Tests

- In addition to sick euthyroid syndrome, other factors alter the results of thyroid function tests, which may result in a misdiagnosis.
- Most nonthyroid factors cause an artificial *decrease* in thyroid hormone levels.
- Some drugs can decrease thyroid hormone levels, but do not usually result in an animal developing clinical signs of hypothyroidism. Glucocorticoids, phenobarbital, and nonsteroidal anti-inflammatory drugs (NSAIDs) can decrease circulating thyroid hormone levels.
- Sulfonamides can decrease thyroid hormone levels and lead to clinical disease. This effect is noted to occur within weeks of initiation of therapy and disappears 2 weeks after therapy has been discontinued.
- Glucocorticoids inhibit the entire hypothalamic-pituitary-thyroid axis and have a direct effect against thyroid hormone.
- Phenobarbital causes a decrease in thyroid levels only in animals receiving long-term treatment. Phenobarbital should not be administered for 4 weeks prior to thyroid function testing.
- The influence of NSAIDs is variable and evaluation of thyroid function should be made with caution, and preferably after stopping NSAIDs well in advance of testing.
- Well-conditioned and athletic dogs consistently have lower total and free T_4 levels. Certain breeds have normal ranges of thyroid hormones that are different from other breeds. The greyhound, Scottish deerhound, saluki, and whippet have total T_4 concentrations that are well below the mean concentrations for other dogs. Alaskan sled dogs have serum T_4, T_3, and free T_4 concentrations below the normal reference range.
- Vaccination causes a transient increase in circulating autoantibody levels, which may cause a truly hypothyroid animal to appear euthyroid. Thyroid function testing should not be conducted if a patient has been vaccinated within the previous 2 weeks.

IMAGING

Radiographic Findings

Developmental bone problems (delayed epiphyseal ossification or dysgenesis) are usually noted with congenital hypothyroidism.

Ultrasonographic Findings

- Significant differences in thyroid gland volume and echogenicity exist between hypothyroid and euthyroid patients, but interpretation is highly user dependent.
- No significant difference is noted between euthyroid and sick euthyroid subjects.

(CONTINUED) HYPOTHYROIDISM

PATHOLOGIC FINDINGS

- Lymphocytic thyroiditis is characterized by chronic and progressive lymphocytic infiltration and destruction of the thyroid gland. Cytotoxic T cells initiate inflammation, leading to thyrocyte destruction and parenchymal fibrosis.
- Idiopathic thyroid atrophy is characterized by the replacement of normal thyroid parenchyma with adipose and connective tissue.
- Many cutaneous changes are nonspecific. However, certain findings, including dermal thickening, myxedema, and vacuolation of arrector pili muscles, are most characteristic.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient medical management.

CLIENT EDUCATION

- Lifelong therapy required.
- Easily managed with oral thyroid hormone supplementation.
- Dose adjustments are common in the early stages of treatment.
- Most clinical signs will resolve over time with appropriate thyroid hormone supplementation.

MEDICATIONS

DRUG(S) OF CHOICE

- Synthetic thyroid hormone supplementation easily treats hypothyroidism.
- Levothyroxine sodium is available as both human and veterinary products.
- Generic forms of the drug should be avoided, as human studies have demonstrated wide variability in the bioavailability of generic forms. If a generic form is used, always prescribe the same formulation.
- Hormone supplementation is initiated at 0.02 mg/kg PO q12h.
- Supplementation can often eventually be decreased to once daily after proper control is achieved.
- Levothyroxine doses for dogs exceed those for humans and may confuse pharmacists or human endocrinologists.
- Humans are instructed to take the medication on an empty stomach and proton pump inhibitors can impede absorption. This should be considered if a dog is difficult to regulate.

PRECAUTIONS

Patients with concurrent metabolic conditions (hepatic disease, endocrinopathies, renal disease, cardiac disease) should have supplementation started slowly (about 25% of recommended dose) and slowly increased over time (3 months) to the recommended maintenance level.

POSSIBLE INTERACTIONS

- Glucocorticoids, NSAIDs, furosemide may increase metabolism of levothyroxine.
- GI protectants can decrease absorption and administration should be separated from thyroid hormone supplementation by 2 hours.

ALTERNATIVE DRUG(S)

- If T_4 levels do not normalize after attempting monitoring and treatment, treatment can be attempted with liothyronine (4–6 mg/kg PO q8–12h).
- Monitoring is based on T_3 levels. However, there is no reliable method by which to measure T_3.

FOLLOW-UP

PATIENT MONITORING

- Assessment of clinical signs, weight, and thyroid function testing is recommended 6–8 weeks after therapy has begun, 2–4 weeks after each dose change, and then once to twice yearly. Patients should also be monitored if signs of thyroid toxicosis (e.g., polyuria/polydipsia [PU/PD], polyphagia) occur.
- The total T_4 level should be monitored and timed so that blood is taken 4–6 hours after pill administration.
- Once stable and well controlled, the total treatment dose may be given once daily in some dogs.
- For animals receiving supplementation once daily, blood should be taken immediately before the medication is given and then again 4–6 hours later, to measure trough and peak concentrations.
- When supplementation therapy is appropriate, the total postdose T_4 level should be in the upper half of the reference range, or slightly above it.
- If the total T_4 level is significantly increased above normal, the medication dose should be decreased or the frequency of administration reduced.
- If the total T_4 level is low, an increase in the dose may be necessary.
- Before increasing dose, assess client compliance, evaluate GI status to ensure there is no impact on absorption, and confirm there has been no change in the levothyroxine formulation.

PREVENTION/AVOIDANCE

Adequate hormone supplementation with routine monitoring should avoid recurrence of this condition.

POSSIBLE COMPLICATIONS

- If untreated hypothyroid animals are at increased risk of developing myxedema, myxedema coma, and atherosclerosis.
- Oversupplementation of thyroid hormone can result in iatrogenic hyperthyroidism.

EXPECTED COURSE AND PROGNOSIS

- Primary hypothyroidism can be easily and successfully controlled; the prognosis for affected animals, when appropriately treated, is excellent. Resolution of clinical signs is an important predictor of adequate supplementation therapy.
- Significant improvement in attitude, activity level, and alertness should occur within 1 week of starting therapy.
- Dermatologic abnormalities improve slowly, with complete resolution taking up to 3 months.
- Polyneuropathies usually begin improving quickly; complete resolution may take several months.
- Anemia and serum cholesterol levels gradually resolve in the first weeks of therapy.
- Life expectancy usually normal.
- Congenital hypothyroidism has a guarded to poor prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

May rarely be associated with other endocrinopathies.

PREGNANCY/FERTILITY/BREEDING

Increased periparturient mortality and lower birthweight pups.

SEE ALSO

Myxedema and Myxedema Coma

HYPOXEMIA

BASICS

DEFINITION
- A decrease in partial pressure of arterial oxygen (PaO_2), resulting in marked desaturation of hemoglobin.
- PaO_2 at sea level ranges from 80 to 100 mmHg in normal animals.

PATHOPHYSIOLOGY
Six physiologic causes:
- Low partial pressure of inspired oxygen (PIO_2).
- Hypoventilation (increase in partial pressure of carbon dioxide in arterial blood [$PaCO_2$]).
- Mismatching of alveolar ventilation and perfusion so that areas of the lung that are not ventilated properly are still perfused adequately.
- Alveolar–capillary membrane diffusion defect.
- Right-to-left cardiac or pulmonary shunting.

SYSTEMS AFFECTED
- All organs—oxygen essential for normal cellular function; individual tissue oxygen requirements vary by organ.
- Cardiovascular—can result in focal or global ischemia; if prolonged, can develop arrhythmias and cardiac failure.
- Nervous—brain and CNS most important; hypoxemia can result in irreversible brain damage because there are no large oxygen stores in brain tissue.

SIGNALMENT
Any breed, age, and sex of dog and cat.

SIGNS

Historical Findings
- Breathing problems—especially open-mouth breathing.
- Trauma.
- Episodes of coughing.
- Gagging.
- Exercise intolerance.
- Cyanosis.
- Collapse.

Physical Examination Findings
- Tachypnea.
- Dyspnea.
- Orthopnea.
- Pale mucous membranes.
- Cyanosis.
- Coughing.
- Open-mouth breathing.
- Tachycardia.
- Poor peripheral pulse.
- Abnormal thoracic auscultation.

CAUSES
- Low PIO_2—high altitude (the higher the elevation, the lower the barometric pressure, which results in a decrease in PIO_2; fraction of oxygen in inspired air (FIO_2) is fixed at 0.21); suffocation; enclosure in small areas with improper ventilation.
- Hypoventilation—result of inadequate alveolar ventilation; muscular paralysis; upper airway obstruction; air or fluid in the pleural space; restriction of the thoracic cage, diaphragmatic hernia; CNS disease; anesthetics.
- Mismatching of alveolar ventilation and perfusion—most common cause of hypoxemia and occurs with virtually any lung disease: pulmonary thromboembolism; pulmonary parenchymal disease (infectious or neoplastic); lower airway disease; pneumonia; pulmonary contusions; pulmonary edema; also during anesthesia or prolonged recumbency when a large region of lung becomes atelectatic.
- Alveolar–capillary membrane diffusion impairment—rarely clinically important.
- Right-to-left cardiac or pulmonary shunting—tetralogy of Fallot; ventricular septal defect; reversed patent ductus arteriosus; intrapulmonary arteriovenous shunt.

RISK FACTORS
- Move to higher elevation.
- Trauma.
- Bronchopneumonia of any cause.
- Pleural disease.
- Anesthesia.
- Cardiac disease.
- Bronchial disease—chronic bronchitis, feline asthma.
- Diseases associated with risk of embolization, e.g., immune-mediated hemolytic anemia, hyperadrenocorticism, neoplasia, pancreatitis, sepsis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Signs of tachypnea and/or dyspnea.
- Excitement or anxiety.
- Hyperthermia.
- Pyrexia.
- Head trauma.
- Pain.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
N/A

Disorders That May Alter Laboratory Results
- Air bubbles in the arterial blood sample—falsely high PaO_2 values.
- Improper packaging of the arterial blood sample—falsely high PaO_2 values after approximately 30 min at room temperature.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Packed cell volume (PCV)—can be high with chronic condition; can be low if inflammatory or neoplastic.
- Liver enzyme elevation common with organ hypoxia.

OTHER LABORATORY TESTS

Arterial Blood Gases
- Collect arterial blood sample in an anaerobic manner, as follows: use enough heparin to coat the needle and the inside of the syringe; collect sample from femoral or dorsal pedal artery; place a rubber stopper on the needle or covering the hub of the syringe, to prevent room air from entering the sample; analyze sample within 15 min if left at room temperature; place sample on ice to extend safe time for analysis to 2–4 hours.
- Bedside or portable blood gas analyzers—several models available; make analysis more convenient.

IMAGING
Thoracic radiographs and echocardiography— evaluate intrathoracic disease; differentiate pulmonary and cardiac disease.

DIAGNOSTIC PROCEDURES

Pulse Oximetry
- Indirectly determines saturation of arterial blood with oxygen (SaO_2); relation between PaO_2 and SaO_2 based on oxyhemoglobin dissociation curve: SaO_2 >90% when PaO_2 >60 mmHg.
- SaO_2 <95%—considered abnormal, indicates PaO_2 <80 mmHg.
- Best results when probe used on animal's tongue; thus may be limited to anesthetized, heavily sedated, or seriously ill patients with low level of consciousness; keep tongue moistened for most accurate readings.
- Other potentially successful probe sites—lip, ear; vulva (female), prepuce (male); skin between toes; thin skin in the flank area. Interpret values with caution.
- Poor results—using sites that have hair or poor perfusion; least accurate in low-flow states such as hypotension (global low flow) or hypothermia (low flow to skin); falsely low values (usually <85%) during carboxyhemoglobinemia (smoke inhalation).
- Rectal probes will allow readings in awake patients.

Endoscopy or Lung Biopsy
Airway sampling often required to determine primary abnormality resulting in hypoxemia.

(CONTINUED) HYPOXEMIA

TREATMENT

Must identify and correct the primary cause.

Oxygen Therapy

- Most common supportive treatment.
- Corrects low-inspired oxygen, hypoventilation, and alveolar–capillary membrane diffusion defects; may not fully correct mismatching of ventilation and perfusion; does not correct right-to-left cardiac or pulmonary shunts and low cardiac output.
- May not be completely beneficial until adequate blood volume is established or alveolar contents are removed (e.g., pulmonary edema, purulent material).
- Delivery—directly from an oxygen source from the anesthetic machine via a face mask placed securely around the muzzle or from an E-tank fitted with an oxygen regulator through a face mask, intranasal catheter placed in the oropharynx, or oxygen cage.
- Increase in FIO_2—determined by the oxygen flow rate and the amount of oxygen mixed with room air.
- Positive pressure ventilation—may be needed for severe hypoxemia of any cause.
- High flow oxygen therapy (HFOT) has been shown to increase arterial oxygen in dogs with severe hypoxemia.

Fluid Therapy

- Low cardiac output—fluid administration and inotropic support (e.g., pimobendan, dobutamine, or dopamine) important.
- Cardiac failure—requires aggressive medical treatment; diuretics; afterload and preload reduction; inotropic support; oxygen administration; cautious amounts of fluids may be indicated after institution of primary treatment; use caution with type and rate of fluids after initial stabilization.
- Hypovolemic, hemorrhagic, traumatic, or septic shock—requires end point fluid administration; crystalloids (20–30 mL/kg), hypertonic solutions (7% NaCl, 4 mL/kg), or blood products (packed red blood cells [pRBC], whole blood, plasma), or a combination.
- Severe pulmonary contusion—hypertonic fluids or low dose crystalloids (5–10 mL/kg).

MEDICATIONS

DRUG(S) OF CHOICE

For bronchospasm—bronchodilators; terbutaline (0.01 mg/kg SC/IM/IV q8h) or albuterol inhaler.

CONTRAINDICATIONS

- Aggressive fluid administration—not indicated for cardiac failure and pulmonary edema.
- Diuretics—not indicated for shock, low PIO_2, alveolar–capillary membrane diffusion defects, mismatching of alveolar ventilation and perfusion, and right-to-left shunts.

PRECAUTIONS

- Inotropic drugs—arrhythmias may develop.
- Oxygen toxicity—prolonged (>12 hour) exposure to high-concentration (>70%) oxygen can result in pulmonary edema, seizures, and death.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Decrease in respiratory effort and decrease in cyanosis (if initially noted)—check efficacy of treatment and support.
- Arterial blood gas—determine resolution.
- Pulse oximetry—alternative; interpret results cautiously with hypotension, hypothermia, smoke inhalation, and non-tongue probe site. Trend in the actual number being produced is important.

POSSIBLE COMPLICATIONS

- Brain damage—depends on severity and duration of hypoxemia; partial or complete loss of neuronal function; dementia; seizures; loss of consciousness.
- Arrhythmias—may develop secondary to myocardial hypoxia; may be very difficult to treat effectively.
- Respiratory arrest requiring intubation and positive pressure ventilation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

PREGNANCY/FERTILITY/BREEDING

May adversely affect fetuses, especially during first trimester of pregnancy.

SEE ALSO

Author Thomas K. Day
Consulting Editor Elizabeth Rozanski

ICTERUS

BASICS

DEFINITION
Increased total bilirubin concentration causing yellow tissue discoloration.

PATHOPHYSIOLOGY
• Bilirubin—derived from degradation of heme-containing proteins; most (80%) from senescent erythrocytes; remainder from other heme-containing proteins (e.g., P450 cytochromes, myoglobin). • Unconjugated bilirubin—transported in plasma bound to albumin; diglucuronide conjugated after hepatocellular uptake. • Conjugated bilirubin—transported in bile, expelled into intestines where most converted to other products, e.g., urobilinogen can undergo enterohepatic circulation, stercobilin colors feces brown. • Hyperbilirubinemia—caused by increased bilirubin production (increased red blood cell [RBC] destruction; *hemolytic jaundice*); heme exceeding hepatic capacity for uptake, conjugation, or biliary excretion (*hepatic jaundice*), or interrupted biliary elimination (*posthepatic jaundice*). • Nonhemolytic jaundice caused by hepatobiliary disease or bile peritonitis.

SYSTEMS AFFECTED
• Skin/exocrine—skin discoloration (jaundice) reflects serum bilirubin >2.5 mg/dL. • Hepatobiliary—retained bile acids and markedly increased bilirubin may contribute to hepatocellular injury. • Renal/urologic—extreme hyperbilirubinemia may cause renal tubular injury. • Nervous—extreme unconjugated hyperbilirubinemia may cause degenerative brain lesions (rare, kernicterus).

SIGNALMENT

Species
Dog and cat.

Mean Age and Range
• Most causes—diseases of adult animals. • Young, unvaccinated dogs—at risk for infectious canine hepatitis.

Predominant Sex
Adult female pure-bred dogs—at risk for immune-mediated hemolytic anemia.

SIGNS

Historical Findings

Increased Formation: Hemolysis
• Vague signs—lethargy, weakness. • Gastrointestinal (GI) signs—anorexia, constipation, vomiting, weight loss. • Jaundice. • Recent blood transfusion. • Severe trauma—bleeding into muscle, abdomen, or hematoma formation. • Rhabdomyolysis (rare cause).

Decreased Elimination: Cholestasis
• Vague GI signs—anorexia, vomiting, diarrhea, change in fecal color: nonobstructive jaundice green, orange; obstructed jaundice acholic. • Jaundice. • Change in urine color—orange. • Abdominal enlargement—if ascites. • Polyuria and polydipsia. • Altered mentation—if hepatic encephalopathy (HE).

Physical Examination Findings

Increased Formation: Hemolysis
• Pallor, tachycardia, tachypnea, weakness, bounding femoral pulses, anemic heart murmur. • Jaundice. • Hepatomegaly/splenomegaly—extramedullary hematopoiesis, reticuloendothelial hyperplasia. • Lymphadenopathy. • Bleeding tendencies—if thrombocytopenic. • Orange feces. • Fever. • "Gelatinous" feel to skin (vasculopathy). • Rhabdomyolysis—weakness, pain.

Decreased Elimination: Cholestasis
• Weight loss. • Jaundice. • Hepatomegaly/splenomegaly. • Abdominal effusion/mass/pain. • Melenic, orange, green, or acholic feces. • Fever.

CAUSES

Prehepatic Jaundice
• Hemolytic disorders—immune-mediated hemolysis; certain drugs (propylene glycol carriers in cats, trimethoprim sulfa); systemic lupus erythematosus; infectious disorders; toxins (e.g., oxidative injury: zinc, onions; phenols); severe hypophosphatemia. • Incompatible blood transfusion. • Infections—feline leukemia virus (FeLV); *Mycoplasma haemofelis*; heartworm; *Babesia*; *Ehrlichia*; *Cytauxzoon*. • Large-volume blood resorption—hematomas, body cavities (e.g., hemangiosarcoma, warfarin).

Hepatic Jaundice
• Chronic idiopathic or familial hepatitis. • Adverse drug reactions—e.g., anticonvulsants; acetaminophen; trimethoprim sulfate; carprofen; stanozolol (cats); benzodiazepines (cats); see Hepatotoxins. • Cholangitis/cholangiohepatitis. • Infiltrative neoplasia—lymphoma. • Cirrhosis (dogs). • Hepatic lipidosis (cats). • Massive liver necrosis—e.g., aflatoxin, cycad, nonsteroidal anti-inflammatory drugs (carprofen), copper associated injury. • Systemic illnesses with hepatic involvement—leptospirosis (dogs); histoplasmosis; feline infectious peritonitis; hyperthyroidism (cats); toxoplasmosis (cats). • Bacterial sepsis—originating anywhere in body; may elaborate bacterial products that impair hepatic bilirubin processing/elimination.

Posthepatic Jaundice
Transient or persistent mechanical bile duct obstruction—pancreatitis (transient obstruction); neoplasia: bile duct, pancreas, duodenum; intraluminal duct occlusion: cholelithiasis, sludged bile, liver flukes (cats), immune-mediated duct destruction (sclerosing cholangitis in cats), gall bladder mucocele (dogs); ruptured biliary tree causing bile peritonitis.

RISK FACTORS
• Young unvaccinated dogs—infectious disease, canine infectious hepatitis. • Breed predisposition for familial hepatic disease—Labrador retriever, Doberman pinscher, Bedlington terrier, cocker spaniel, Dalmatian. • Middle-aged, obese dogs—pancreatitis. • Anorectic, obese cats—hepatic lipidosis. • Hepatotoxic drugs. • Blunt abdominal trauma, chronic biliary tract disease, gallbladder mucocele—bile peritonitis. • Hemolytic anemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Prehepatic jaundice—usually abrupt onset; mucous membrane pallor; mild to moderate jaundice; weakness; tachypnea; cardiac murmur with severe anemia. • Hepatic jaundice—breed risk for familial hepatitis; variable jaundice; otherwise normal mucous membranes; alteration in liver size (large or small); abdominal effusion (pure or modified transudate); polyuria and polydipsia; behavioral abnormalities of HE; coagulopathy. • Posthepatic jaundice—chronic and/or recurrent bouts of apparent GI signs or pancreatitis with cholelithiasis; moderate or marked jaundice; otherwise normal mucous membranes; diffuse or cranial abdominal pain; cranial abdominal mass; abdominal effusion (septic, nonseptic, or bile peritonitis); bleeding tendencies; acholic feces unless melena.

LABORATORY FINDINGS
• Bilirubin assay—based on diazo reaction; assesses direct-reacting and total serum bilirubin; most yield reasonable total bilirubin results; values for direct bilirubin vary. • Higher readings in heparinized plasma. • Sample management—important; total bilirubin may decrease by 50% per hour with direct exposure to sunlight or artificial lighting. • Hemolysis—variable effects on total bilirubin measured by spectrophotometry. • Lipemia—falsely increases total bilirubin values measured by endpoint assays. • Fractionation into conjugated and unconjugated—*unable to define causes of jaundice*, contrary to dogma.

CBC/BIOCHEMISTRY/URINALYSIS

Prehepatic Jaundice
• CBC—severe anemia (usually regenerative); blood smear may reveal autoagglutination, spherocytes, Heinz bodies, parasites; hemoglobinemia with intravascular hemolysis, normal to low platelets, normal to high WBCs, with left shift. • Biochemistry—normal to high alanine aminotransferase (ALT) and alkaline phosphatase (ALP) activity, blood urea nitrogen (BUN) concentration; normal to low albumin; normal to high globulin; normal glucose and cholesterol; high bilirubin.

Hepatic Jaundice
• CBC—mild nonregenerative anemia; low mean corpuscular volume (MCV) with chronic liver disease and portosystemic shunting; variable

white blood cell (WBC) count. • Biochemistry—mildly to markedly high ALT ± ALP; normal to low albumin, BUN, glucose, cholesterol. • Urinalysis—normal to dilute urine; bilirubinuria precedes hyperbilirubinemia; bilirubinuria important in cats.

Posthepatic Jaundice

• CBC—± mild nonregenerative anemia; variable WBC count. • Biochemistry—increased ALT, moderate to markedly increased ALP; usually normal albumin, BUN, glucose concentrations; normal to high cholesterol.

OTHER LABORATORY TESTS

• In-saline autoagglutination slide test—with suspected RBC agglutination; may have reported high MCV. • Direct Coombs' test—submit if no evidence of autoagglutination. • Osmotic fragility test—detects likelihood of RBC hemolysis tonicity challenge. • Blood smears—hemoparasites, spherocytes, schistocytes, anisocytosis (regenerative). • Plasma zinc—if hemolytic anemia. • Antinuclear antibodies—with hemolytic anemia. • Serum bile acids—redundant if nonhemolytic jaundice already suspected. • Serology—for infectious diseases (e.g., FeLV, leptospirosis, mycoses) with signs of multisystemic illness and hepatic jaundice. • PCR for acute leptospirosis—within first few days, urine and/or serum; before appropriate antibiotic therapy. • Abdominal effusion—characterize cell and protein content. • Coagulation tests—prolonged values, esp. proteins invoked by vitamin K absence or antagonism and prothrombin time, with bile duct occlusion; vitamin K_1 responsive. • Microbial culture and sensitivity—blood ± other specimens if inflammatory leukon and suspected bacterial infection (e.g., urinary tract, biliary tract, liver).

IMAGING

• Abdominal radiography—obscured by effusion; may reveal hepatomegaly, mass effect, mineral or gas interface in liver (emphysematous cholecystitis, choleliths); splenomegaly (hemolytic anemia, portal hypertension, abdominal neoplasia); metallic foreign body with zinc-induced hemolysis. • Thoracic radiography—may reveal metastatic disease; sternal lymphadenopathy (reflecting abdominal disease); general lymphadenopathy (lymphosarcoma, systemic infection [fungal]). • Abdominal US—may distinguish parenchymal liver disease from extrahepatic biliary obstruction; characterizes hepatic parenchymal lesions; may disclose abdominal neoplasia; may determine cause of abdominal effusion; used to target lesions, fluid, or cystocentesis sampling (aspirates or needle biopsy).

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration—cytology of mass, lymph node, hepatic parenchyma, bile. • Liver biopsy—bacterial culture of liver, bile, other specimens obtained via celiotomy, blind percutaneous, keyhole, laparoscopic, or US-guided techniques. • Surgical intervention—required for diagnosis and treatment of posthepatic disorders.

TREATMENT

• Depends on underlying cause. • Inpatient—for initial medical care. • Cage rest—to facilitate liver regeneration or reduce oxygen requirements if severe anemia. • Diet—important for hepatic and posthepatic jaundice; nutritionally balanced with maximum protein tolerated; carbohydrate based (dogs) with restricted protein for hepatic encephalopathy; restrict sodium if ascites. • Vitamin supplementation—water-soluble vitamins in all patients; parenteral vitamin K_1 for bile duct obstruction or severe cholestasis.

MEDICATIONS

DRUG(S) OF CHOICE

• Prehepatic jaundice—eliminate inciting cause; see Anemia, Immune-Mediated; whole blood transfusion for life-threatening anemia. • Hepatic/posthepatic jaundice—treat specific disorders based on imaging, biopsy, culture.

CONTRAINDICATIONS

• Avoid known hepatotoxic drugs. • Avoid tetracyclines unless clearly indicated—suppress hepatic protein synthesis, promote hepatic lipidosis. • Avoid analgesics, anesthetics, barbiturates—with hepatic failure.

PRECAUTIONS

• Sedatives—may precipitate HE. • Corticosteroids—for nonseptic inflammation; increase risk for infection; may aggravate ascites (water and sodium retention), promote vacuolar hepatopathy (dogs) and hepatic lipidosis (cats).

POSSIBLE INTERACTIONS

Consider influence of altered hepatic metabolism on drug therapy; hypoalbuminemia influences potency of protein-bound drugs, enhancing effects (may lead to toxicity).

FOLLOW-UP

PATIENT MONITORING

• Prehepatic jaundice—recheck packed cell volume and blood smears as needed; may require repeat transfusions; taper immunosuppressive drugs. • Hepatic and posthepatic jaundice—recheck serum biochemical profile as dictated by underlying disease; continue symptomatic and specific treatments until remission, varies with disease process.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Patients with immune-mediated hemolysis treated with immunosuppressive doses of corticosteroids predisposed to thromboembolism, GI ulcers, and infection. • Patients in hepatic failure susceptible to infections, enteric bleeding, ascites. • Patients with reconstructive biliary surgery have risk of recurrent bacterial cholangitis.

SYNONYMS

IDIOVENTRICULAR RHYTHM

BASICS

DEFINITION
If conduction of sinus node pacemaker impulses to the ventricles is blocked or the impulses decrease in frequency, the lower regions of the heart automatically take over the role of pacemaker for the ventricles, which results in ventricular escape complexes (Figure 1) or an idioventricular rhythm (Figure 2).

ECG Features
- P waves may be absent or may precede, be hidden within, or follow the ectopic QRS complex.
- P waves are unrelated to the QRS complexes.
- QRS configuration—wide and bizarre; similar to that of a ventricular premature complex.

PATHOPHYSIOLOGY
- May be hemodynamically important with slow ventricular rates.
- Does not occur in healthy animals.
- Subsidiary pacemakers seem to discharge more rapidly in cats than in dogs.

SYSTEMS AFFECTED
Cardiovascular

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- Atrial standstill in English springer spaniels and Siamese cats.
- Pugs, miniature schnauzers, and Dalmatians prone to conduction abnormalities.

Mean Age and Range
N/A

Predominant Sex
N/A

SIGNS

Historical Findings
- Some animals asymptomatic.
- Weakness.
- Lethargy.
- Exercise intolerance.
- Syncope.
- Heart failure.

Physical Examination Findings
- Irregular rhythm associated with pulse deficits.
- Variation in heart sounds.
- Possible intermittent "cannon" waves in the jugular venous pulses (with atrioventricular [AV] block).

CAUSES
- Not a primary disease—a secondary result of a primary disease.
- The escape rhythm is a safety mechanism to maintain cardiac output.

Causes of Sinus Bradycardia and Sinus Arrest
- Increased vagal tone (high intracranial pressure, high ocular pressure).
- Drugs—digoxin, tranquilizers, propranolol, quinidine, and anesthetics.
- Addison's disease.
- Hypoglycemia.
- Renal failure.
- Hypothermia.
- Hyperkalemia.
- Hypothyroidism.

Causes of AV Block
- Congenital.
- Neoplasia.
- Fibrosis.
- Lyme disease.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- A series of ventricular escape beats with a heart rate <65 bpm in dogs and <100 bpm in cats; heart rates of 65–160 bpm in dogs and 100–180 bpm in cats are often termed accelerated idioventricular rhythms.
- Ventricular tachycardia—dogs have a cardiac rate >160 bpm; cats >180 bpm.
- Slow heart rate in animals with right bundle branch block, left bundle branch block, or left anterior fascicular block; animals with these disturbances have the P waves associated with the QRS complexes.

CBC/BIOCHEMISTRY/URINALYSIS
- No specific findings.
- Complete blood testing may suggest a metabolic abnormality.

OTHER LABORATORY TESTS
- Drug toxicity.
- Lyme titer in animals with complete AV block.

IMAGING
Echocardiogram may show structural heart disease.

DIAGNOSTIC PROCEDURES
ECG

PATHOLOGIC FINDINGS
Depend on underlying cause.

TREATMENT

APPROPRIATE HEALTH CARE
- Rhythm is an escape or safety mechanism for maintaining cardiac output; do *not* direct treatment toward suppressing this escape rhythm, but toward the primary disease process that allows the escape rhythm to assume pacemaker control of the heart.
- Symptomatic treatment is directed toward increasing the heart rate.

NURSING CARE
May be required for underlying disease.

ACTIVITY
Symptomatic animals may require cage rest.

DIET
No modifications or restrictions unless required for management of the underlying condition.

CLIENT EDUCATION
Inform of the need to seek and specifically treat an underlying cause.

SURGICAL CONSIDERATIONS
Pacemaker implantation may be necessary.

MEDICATIONS

DRUG(S) OF CHOICE
- Atropine or glycopyrrolate usually indicated to block vagal tone or increase the heart rate.
- If those drugs are ineffective, isoproterenol, dopamine, dobutamine, or artificial pacing may be needed.

CONTRAINDICATIONS
Lidocaine, procainamide, quinidine, propranolol, diltiazem, or any other drug that slows the cardiac rate or reduces contractility.

PRECAUTIONS
Atropine is briefly vagotonic immediately post injection and can temporarily exacerbate the condition.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
- Serial ECG may show clearing of the lesion or progression to complete heart block.
- Serial blood profiles may be needed to monitor progress of the primary disease process.

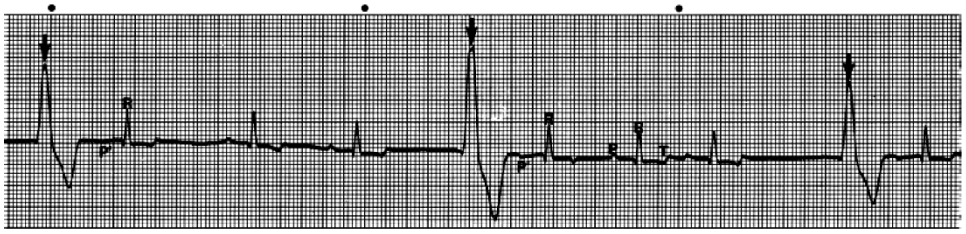

Figure 1.

Ventricular escape complexes (arrows) during various phases in the dominant sinus rhythm in a dog during anesthesia. The sinus rate increased (not shown) after anesthesia was stopped; ½ cm–1 mv. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore, MD: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

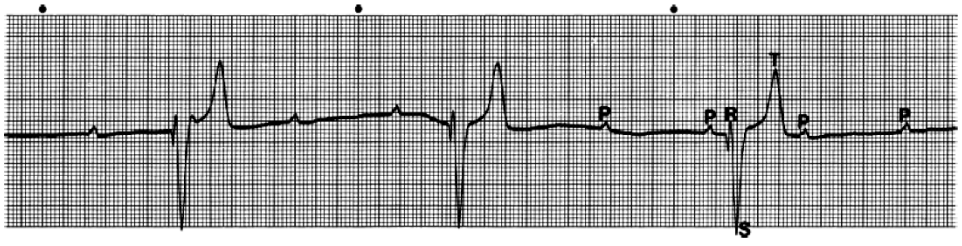

Figure 2.

Complete heart block. The P waves occur at a rate of 120, independent of the ventricular rate of 50. The QRS configuration is a right bundle branch block pattern. The heart rate and QRS shape suggest that the rescuing focus is probably near the AV junction. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore, MD: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

• Serial echocardiograms may show improvement or progressive changes in cardiac structure.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Prolonged bradycardia may cause secondary congestive heart failure or inadequate renal perfusion.

EXPECTED COURSE AND PROGNOSIS
• Arrhythmia may abate when the primary disorder is corrected.
• Guarded if condition is associated with cardiac or metabolic disorder; poor if the rate is not increased pharmacologically or if underlying cause cannot be identified and treated.

MISCELLANEOUS

ASSOCIATED CONDITIONS

ILEUS

BASICS

OVERVIEW

- Adynamic (paralytic, functional) ileus is defined as a transient and reversible intestinal obstruction resulting from inhibition of bowel motility.
- Lack of peristalsis of stomach, small bowel, or large bowel causes functional obstruction, as intestinal contents accumulate in the dependent areas of the gastrointestinal tract instead of being propelled in an aborad direction.
- Ileus is not a primary disease but a secondary complication of a number of disorders.
- Adynamic ileus is thought to occur secondary to electromechanical dissociation of the intestinal musculature due to increased sympathetic tone, release of humoral inhibitory factors (catecholamines, vasopressin, endogenous opiates), impaired release of prokinetic hormones (neurotensin, motilin), or hypokalemia.
- Secondary causes of intestinal pseudo-obstruction have been subclassified into developmental, infectious, inflammatory, autoimmune, metabolic, paraneoplastic, endocrine, and toxic etiologies.
- Lymphocytic leiomyositis represents a visceral myopathic form of chronic intestinal pseudo-obstruction that has been described in humans, dogs, horses, and cats; it is defined as lymphocytic infiltration of the muscularis propria and is thought to represent an autoimmune response to the myofibers of the muscularis propria layer of the bowel by T lymphocytes.
- Systems affected—gastrointestinal; autonomic nervous system.

SIGNALMENT

Cat and dog.

SIGNS

- Anorexia.
- Vomiting.
- Regurgitation.
- Lethargy.
- Diarrhea.
- Weight loss.
- Coughing secondary to aspiration pneumonia from gastroesophageal reflux.
- Mild abdominal distention or discomfort secondary to accumulation of gas in hypomotile bowel.
- Failure to auscultate gut sounds after 2–3 minutes suggests ileus.
- Gut sounds can be increased during initial state (partial loss of motility).

CAUSES & RISK FACTORS

- Surgery (especially gastrointestinal surgery).
- Pain.
- Electrolyte imbalance (hypokalemia, hypomagnesemia, hypocalcemia).
- Acute inflammatory lesions of bowel, peritoneal cavity, pancreas, or other abdominal organs.
- Unrelieved mechanical obstruction.
- Intestinal ischemia.
- Gram-negative sepsis.
- Endotoxemia.
- Shock.
- Retroperitoneal injury.
- Uremia.
- Autonomic neuropathies (dysautonomia, spinal cord injury).
- Visceral myopathies associated with autoimmune disease.
- Use of anticholinergic drugs.
- Intestinal overdistension (aerophagia).
- Lead poisoning.
- Stress (cold and noise).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Adynamic ileus must be differentiated from mechanical obstruction caused by:

- Intestinal foreign bodies.
- Inflammatory bowel disease.
- Intussusception.
- Intramural abscess.
- Incarcerated or strangulated hernia.
- Volvulus.
- Mesenteric infarction.
- Parasites.
- Adhesions.
- Postoperative stricture.
- Impaction.
- Congenital malformation.
- Inflammatory or traumatic lesions.
- Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- Hemogram changes depend on primary cause of ileus.
- Serum chemistry profiles and urinalysis help assess electrolyte disturbances (especially hypokalemia) and presence of azotemia.

OTHER LABORATORY TESTS

- Measurement of pancreatic lipase concentration (Spec or SNAP cPL or fPL) to assess for pancreatitis.
- Fecal parvovirus ELISA test in puppies with ileus and diarrhea.

IMAGING

Abdominal Radiographic Findings

- Stomach and/or intestinal loops are distended with gas and fluid.
- Common radiographic patterns include:
  - Generalized gas ileus—consider aerophagia, smooth muscle paralyzing drugs, generalized peritonitis, or enteritis.
  - Generalized fluid ileus—consider enteritis, diffuse intestinal neoplasia.
  - Localized gas ileus—consider localized peritonitis (pancreatitis), early bowel obstruction, disruption of arterial supply.
  - Localized fluid ileus—consider foreign body, neoplastic obstruction, intussusception.

Ultrasonography

- Differentiate adynamic ileus from mechanical intestinal obstructions.
- Identify pancreatitis or peritonitis.
- Ultrasound has been used to assess frequency and contraction of pyloric antrum in dogs.
- Careful evaluation of intestinal layers for loss of normal layering associated with infiltrative neoplasia, thickening of muscularis propria layer and/or submucosal layer associated with inflammatory bowel disease or small cell lymphoma, and attenuation of muscularis layer associated with fibrosis secondary to leiomyositis.

DIAGNOSTIC PROCEDURES

Barium-Impregnated Polyethylene Spheres (BIPS)

- Confirm adynamic ileus.
- Delayed gastrointestinal transit along with retention of BIPS in the stomach.
- Scattering of BIPS throughout the upper gastrointestinal tract.

Upper Gastrointestinal Series

- Upper gastrointestinal series can be performed to help assess for presence of partial intestinal obstructions or delayed gastric and intestinal motility.
- Gastric and intestinal transit times must be interpreted cautiously following administration of liquid barium in light of marked variation in emptying times from animal to animal, and the stress of hospitalization can delay gastric and intestinal transit times.

Other Procedures to Consider

- Noninvasive electrogastrography is used experimentally to assess gastric myoelectrical activity in dogs.
- Abdominocentesis with peritoneal effusion to confirm peritonitis.
- Gastrointestinal endoscopy or exploratory laparotomy to rule out mechanical obstruction.
- Full-thickness intestinal biopsies are necessary to diagnose intestinal leiomyositis because the disorder affects the muscularis propria layer of the bowel, which is typically not accessible via endoscopic biopsy.
- Spinal radiographs, myelogram, spinal MRI, CT, cerebrospinal fluid (CSF) analysis to identify spinal cord injury.
- Ocular response test with 0.1% pilocarpine and 0.25% physostigmine for dysautonomia.

TREATMENT

- Identify and treat primary underlying cause.
- Correct electrolyte abnormalities (especially hypokalemia) if present.

• Use of prokinetic drugs such as cisapride, metoclopramide, or erythromycin should be considered, depending on underlying cause.
• Gastrointestinal decompression of stomach via nasogastric tube is beneficial in select cases.
• Fat-restricted diets should be implemented in dogs with delayed gastric emptying because higher-fat diets can delay gastric emptying in this species.

MEDICATIONS

DRUG(S) OF CHOICE

• Metoclopramide is most effective when administered as CRI (1–2 mg/kg/24h); bolus injections (0.4 mg/kg IV q6h) are less effective in light of relatively short half-life (90 min) in dogs; metoclopramide does not affect colonic motility and should be avoided in animals with colonic ileus or megacolon.
• Cisapride (0.5–0.75 mg/kg q8–12h) is a far more potent and effective prokinetic compared to metoclopramide and affects gastric, small intestinal, and colonic motility.
• Erythromycin (1–2 mg/kg PO q12h) has prokinetic activity in stomach and small intestine.
• Cyclosporine (5 mg/kg q12–24h) can be administered for management of intestinal leiomyositis or other immune-mediated disorders affecting intestinal tract.
• Prednisone (1 mg/kg q12h with progressive tapering over 10–12 weeks) can be administered for management of leiomyositis or inflammatory bowel disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Anticholinergic drugs (e.g., atropine, glycopyrrolate).
• Opiates (e.g., morphine, hydromorphone, oxymorphone, butorphanol).
• Opiate antidiarrheals (e.g., paregoric, diphenoxylate hydrochloride/atropine sulfate, loperamide hydrochloride).

FOLLOW-UP

PATIENT MONITORING

• Monitor and correct electrolyte imbalance if present.
• Abdominal auscultation to evaluate gastrointestinal motility.
• Survey abdominal radiographs to evaluate gastric and intestinal distension.

PREVENTION/AVOIDANCE

Avoid anticholinergic drugs and opiates if not indicated.

POSSIBLE COMPLICATIONS

Animals with adynamic ileus are predisposed to development of intestinal dysbiosis, bacterial translocation, and sepsis.

EXPECTED COURSE AND PROGNOSIS

Prognosis depends on successful resolution of primary disease process.

MISCELLANEOUS

SYNONYMS

• Adynamic ileus—functional ileus, paralytic ileus.
• Pseudo-obstruction—chronic, more segmental adynamic ileus.
• Mechanical ileus—generally addressed in current literature as mechanical obstruction.

PREGNANCY/FERTILITY/BREEDING

Ileus has been reported in a lactating bitch with hypomagnesemia and hypocalcemia.

ABBREVIATIONS

• BIPS = barium-impregnated polyethylene spheres.
• CSF = cerebrospinal fluid

ILLICIT/CLUB DRUG TOXICOSIS

BASICS

OVERVIEW

Intoxication with illicit/club drugs includes various pharmaceuticals—barbiturates, benzodiazepines, cocaine, gamma hydroxybutyric acid (GHB), lysergic acid diethylamide (LSD), marijuana, methylenedioxymethamphetamine (MDMA: ecstasy), methamphetamine and other designer amphetamines, opioids, and phencyclidine (PCP).

Pathophysiology

• Barbiturates—sedative hypnotics causing CNS depression. • Cocaine—myocardial stimulant and increases catecholamine and serotonin levels, causing CNS stimulation. • GHB—synthetic γ-aminobutyric acid (GABA) derivative causing CNS depression. • LSD—CNS stimulation and hallucinations by increasing serotonin and glutamate in CNS, binds dopamine and α-adrenergic receptors. • MDMA—increases serotonin and catecholamines in CNS, leading to CNS stimulation and hallucinations. • Opioids—bind to opioid receptors causing CNS depression. • PCP—inhibits glutamate and stimulates α-adrenergic receptors; potentiates effects of norepinephrine, epinephrine, and serotonin; sympathomimetic and hallucinogen.

Systems Affected

• Cardiovascular—cocaine, GHB, LSD, MDMA, PCP: arrhythmias, hypertension; barbiturates, opioids: arrhythmias, hypotension. • Musculoskeletal—cocaine, PCP: tremors. • Nervous—cocaine, LSD, MDMA: stimulation; barbiturates, GHB: depression; opioids, PCP: sedative to stimulatory effects, ataxia. • Ophthalmic—cocaine, LSD, MDMA: mydriasis; opioids: miosis. • Respiratory—barbiturates, opioids: respiratory depression (rare).

SIGNS

• Barbiturates—sedation (rarely agitation), ataxia, bradycardia, hypotension, respiratory depression (rare), coma. • Cocaine—agitation, mydriasis, tachycardia, hypertension, tremors, seizures. • GHB, opioids—lethargy, weakness, coma, respiratory depression. • LSD—mydriasis, disorientation, hallucinations, agitation (rarely sedation), tachycardia. • MDMA—agitation, mydriasis, hyperthermia, tachycardia, tremors, hallucinations, seizures. • PCP—depression to agitation, hypertension, tachycardia, tremors, seizures.

CAUSES & RISK FACTORS

Ingestion of club drugs may occur in animals that live with people who take these pharmaceuticals or in police dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Barbiturates, GHB, opioids—meningitis, hepatic encephalopathy, ethanol, ethylene glycol, phenothiazines. • Cocaine—amphetamines, caffeine, metaldehyde, MDMA. • LSD, MDMA, PCP—meningitis, hepatic encephalopathy, amphetamines, cocaine, ketamine, psilocybin, serotoninergic medications (selective serotonin reuptake inhibitors, etc.).

CBC/BIOCHEMISTRY/URINALYSIS

No direct abnormalities. May see creatine kinase and K elevation (rhabdomyolysis) and myoglobinuria secondary to tremors.

OTHER LABORATORY TESTS

Over-the-counter illicit urine drug screens available; not approved for use in animals, but appear to be reliable except for marijuana (false negative). GC/MS can detect all, but turnaround time decreases usefulness.

TREATMENT

• Inpatient care in dark quiet place; thermoregulation and fluid therapy to maintain body temperature and BP; fluids will also help to protect kidneys from myoglobinuria. • Monitor for respiratory depression (barbiturates, opioids); intubate and ventilate if needed. • Emesis (if asymptomatic and recent ingestion) or gastric lavage (if large amount ingested).

MEDICATIONS

DRUG(S) OF CHOICE

• Activated charcoal (1–2 g/kg PO) with cathartic (if severe signs expected). • Agitation—phenothiazines (acepromazine 0.025–0.05 mg/kg IV, titrate up as needed); cyproheptadine (dog: 1.1 mg/kg; cat: 2–4 mg PO q4–6h or can be given rectally if vomiting). • Agitation, seizures—benzodiazepines (diazepam 0.5–2 mg/kg IV); see Contraindications. • Tremors—methocarbamol (50–150 mg/kg IV). • Tachycardia—propranolol (0.02 mg/kg IV). • Naloxone—reversal for opioids (0.01–0.1 mg/kg IV).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Do not use diazepam with MDMA (increases dysphoria and morbidity).

FOLLOW-UP

PATIENT MONITORING

BP, heart rate, urine color—q1h, then less frequently if patient remains stable.

EXPECTED COURSE AND PROGNOSIS

Signs occur within minutes. Most will have a good prognosis if treated and recover in 24–36 hours.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

• Barbiturates, LSD, cocaine, and MDMA have been associated with severe birth defects. • Opioids and PCP have been associated with fetal intoxication and low birthweight.

SEE ALSO

• Amphetamine and ADD/ADHD Medication Toxicosis. • Antidepressant Toxicosis—SSRIs and SNRIs. • Benzodiazepine and Other Sleep Aids Toxicosis. • Marijuana Toxicosis.

ABBREVIATIONS

• GABA = γ-aminobutyric acid. • GHB = gamma hydroxybutyric acid. • LSD = lysergic acid diethylamide. • MDMA = methylenedioxymethamphetamine, ecstasy. • PCP = phencyclidine.

IMIDAZOLINE TOXICOSIS

OVERVIEW

• Sympathomimetic drugs used for topical vasoconstrictive effects in ophthalmic anti-redness drops and nasal decongestant sprays.
• Oxymetazoline, naphazoline, tetrahydrozoline, brimonidine, and xylometazoline are imidazolines commonly used in prescription and over-the-counter ophthalmic and nasal products.

Pathophysiology

• Central and peripheral alpha$_2$ adrenergic agonist activity. In overdose, central activity predominates, resulting in norepinephrine release and clinical signs of hypotension, bradycardia, and sedation.
• Companion animal pharmacokinetic data limited. Imidazolines considered to have narrow margin of safety, with no known therapeutic dose in veterinary medicine.
• Absorption rapid and nearly complete when ingested.
• Imidazolines partially metabolized in liver and eliminated mostly unchanged in urine.

Systems Affected

• Cardiovascular—early transient tachycardia and hypertension followed by prolonged bradycardia and hypotension, arrhythmias, pallor, slow capillary refill time.
• Gastrointestinal—vomiting.
• Nervous—sedation, lethargy, ataxia, weakness, tremors, rare seizures, rare paradoxical agitation, coma.
• Ophthalmic—miosis.

SIGNALMENT

Dogs primarily; cats rarely.

SIGNS

• Lethargy and sedation.
• Early transient hypertension and tachycardia transitioning to prolonged bradycardia and hypotension.
• Pallor with prolonged capillary refill time.
• Ataxia.
• Hyperactivity.
• Arrhythmias.
• Vomiting.
• Weakness.
• Miosis.
• Tremors.
• Seizures.
• Coma.
• Death.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other alpha agonist drugs—clonidine, tizanidine, medetomidine, dexmedetomidine, xylazine, amitraz.
• Marijuana, methanol, ethanol.
• Beta adrenergic blocker toxicosis—metoprolol, atenolol, propranolol.
• Calcium channel blocker toxicosis—diltiazem, amlodipine, verapamil.
• Primary cardiac disease with signs of bradycardia and hypotension.

CBC/CHEMISTRY/URINALYSIS

Consider monitoring blood glucose and electrolytes in symptomatic patients.

OTHER LABORATORY TESTS

N/A

DIAGNOSTIC PROCEDURES

• ECG monitoring—arrhythmias, bradycardia vs. tachycardia depending on stage of presentation.
• Blood pressure monitoring—early hypertension vs. later prolonged hypotension.

PATHOLOGIC FINDINGS

N/A

TREATMENT

• Emergency care with any exposure—narrow margin of safety, signs develop at low doses.
• Decontamination—emesis induction is *not* recommended: rapid absorption and early onset of clinical signs; activated charcoal only in asymptomatic animals presenting early.
• IV fluid therapy to correct dehydration and hypotension; IV fluid diuresis not expected to enhance excretion; colloids if no response to crystalloid IV fluid therapy.

MEDICATIONS

DRUG(S) OF CHOICE

• Activated charcoal (1 g/kg PO) with cathartic × 1 dose in asymptomatic patients presenting early (<1–2 hours after ingestion); avoid use in symptomatic patients.
• Alpha$_2$ adrenergic antagonists—atipamezole 50 µg/kg IV/IM may be used to reverse severe sedation and bradycardia; give ¼ dose IV and remainder IM to avoid worsening hypotension; administer additional doses PRN based on clinical signs; alternatively, yohimbine 0.1 mg/kg IV may be used.
• Bradycardia—atropine 0.01–0.02 mg/kg IV PRN; avoid use if hypertensive.
• Hyperactivity—diazepam (0.5–1 mg/kg IV) or butorphanol (0.2–0.8 mg/kg IM/IV) PRN.
• Seizures—diazepam (0.5–1 mg/kg IV) PRN.
• Tremors—diazepam (0.5–1 mg/kg IV) or methocarbamol (50–220 mg/kg IV slowly, up to a daily dose of 330 mg/kg)
• Vomiting—maropitant (1 mg/kg SC/IV q24h) PRN.

Alternative Drugs

Naloxone 0.011–0.022 mg/kg IV/IM PRN may be tried if atipamezole and yohimbine are unavailable. Mechanism of action is unknown, and results may be variable.

FOLLOW-UP

PATIENT MONITORING

Monitor heart rate, blood pressure, ECG, and temperature closely.

PREVENTION/AVOIDANCE

Keep imidazoline medications secured out of reach to prevent dogs from chewing and ingesting them.

EXPECTED COURSE AND PROGNOSIS

• Expected course—up to 24–36 hours depending on specific product ingested.
• Prognosis is good with appropriate treatment; successfully treated patients are expected to make a full recovery.

MISCELLANEOUS

AGE-RELATED FACTORS

• Animals with decreased renal function may experience prolonged duration of signs.
• Neonates and geriatric pets may be more sensitive.

PREGNANCY/FERTILITY/BREEDING

• Limited data available, but some imidazolines have been shown to pass into milk.
• Very high doses of oxymetazoline have resulted in fetal abnormalities in rats.

Consulting Editor Lynn R. Hovda

IMMUNODEFICIENCY DISORDERS, PRIMARY

BASICS

DEFINITION
Diminished ability to mount an effective immune response due to heritable defects in the immune system.

PATHOPHYSIOLOGY
- Defects in the cell-mediated, humoral, complement, and phagocytic systems have all been described.
- Defects involving the humoral immune response—associated with a high susceptibility to bacterial infection.
- Defects involving the cell-mediated immune response—associated with a high susceptibility to viral, fungal, and protozoal infections.
- Defects in the phagocytic or complement system—associated with disseminated infection.

SYSTEMS AFFECTED
- Hemic/lymphatic/immune—defect in a specific cell population in lymphoid tissue.
- Skin/exocrine/respiratory/gastrointestinal—chronic or recurrent infections.
- Other organ systems—dissemination of infection, failure to thrive.

GENETICS
Typically breed specific with variable modes of inheritance.

INCIDENCE/PREVALENCE
Rare

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- X-linked severe combined immunodeficiency—basset hounds, Cardigan Welsh corgis.
- Severe combined immunodeficiency disease—Parson Russell terriers.
- Immunoglobulin (Ig) A deficiency—beagles, German shepherd dogs, and Chinese Shar-Peis.
- IgM deficiency—Doberman pinschers
- Thymic hypoplasia—dwarfed Weimaraners.
- Cyclic hematopoiesis—gray collies.
- Chediak-Higashi syndrome—Persian cats.
- Leukocyte adhesion deficiency—Irish setters.
- Complement deficiency—Brittanys.
- Bactericidal defect—Doberman pinschers.
- Transient hypogammaglobulinemia—Samoyeds.

Mean Age and Range
Primary immunodeficiency diseases typically expressed in the first year of life.

Predominant Sex
X-linked recessive severe combined immunodeficiency disease of basset hounds—males affected and females are carriers.

SIGNS

General Comments
Depends on the level at which the immune response is defective; ranges from chronic respiratory and gastrointestinal signs and skin infections to life-threatening conditions.

Historical Findings
- High susceptibility to infection and failure to respond to appropriate conventional antibiotic therapy.
- Lethargy.
- Anorexia.
- Skin infection.
- Failure to thrive.
- Signs often appear when maternal antibody concentrations decline.
- Vaccine-induced disease by modified live virus preparation.

Physical Examination Findings
- Hallmark—failure to thrive.
- Clinical signs attributable to infections.

CAUSES
Congenital

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Patients must be rigorously evaluated for underlying disease process that may cause secondary (acquired) immunodeficient state (e.g., hyperadrenocorticism, feline leukemia virus [FeLV], feline immunodeficiency virus [FIV]).

CBC/BIOCHEMISTRY/URINALYSIS
CBC may indicate deficiencies in specifically affected cell lines or show chronic inflammation.

OTHER LABORATORY TESTS
- Serum protein electrophoresis—demonstrate gross deficiency in immunoglobulin concentration.
- Serum immunoglobulin quantitation—evaluate humoral immune system, identify selective immunoglobulin deficiency, support diagnosis of agammaglobulinemia.
- Lymphocyte transformation test—evaluate the cell-mediated immune system and identify animals with T-lymphocyte deficiency.
- Bactericidal assays—evaluate neutrophil function.
- Serum concentration of complement components—diagnose complement deficiency.
- Enumeration of lymphocyte subsets by immunofluorescence with monoclonal antibodies—identify deficiency of specific cell lines.
- Other more specific tests to evaluate immune function in veterinary species are available, but obtaining reliable results generally requires access to research laboratories that perform these tests.

DIAGNOSTIC PROCEDURES
In some patients, bone marrow and lymph node biopsy aids in classifying the type of immune deficiency.

PATHOLOGIC FINDINGS
- Lesions vary depending on the specific defect; most are the result of recurrent or opportunistic infection involving the skin, ear canal, and respiratory and gastrointestinal systems.
- Septicemia common in animals with severe defects.
- T-lymphocyte defects—hypoplastic or dysplastic lesions of the thymus and T-lymphocyte-dependent areas of secondary lymphoid tissues.
- B-lymphocyte defects—hypoplastic or dysplastic lesions of the bone marrow or B-lymphocyte-dependent areas of secondary lymphoid tissues.
- Lymphoid hypoplasia or hyperplasia may be seen, depending on the overall defect and the occurrence of infection.

TREATMENT

APPROPRIATE HEALTH CARE
- Hospitalization may be necessary to control life-threatening infection.
- Outpatient management possible for some patients.

NURSING CARE
Supportive care appropriate to the nature of the infection.

ACTIVITY
Determined largely by the severity of the defect and the occurrence of infection.

DIET
- Dietary management may be required to ensure that the patient is maintained at an adequate level of nutrition.
- Potential sources of infectious agents such as raw meat diets must be avoided.

CLIENT EDUCATION
- Inform client that the condition is incurable.
- Discuss why the patient has high susceptibility to infection.
- Discuss and advise as to the heritability of the disease.
- Discuss the possibility of littermates being affected.
- Avoid/limit exposure to animals with infections or kennel situations.

MEDICATIONS

DRUG(S) OF CHOICE
- Antibiotics to control infections; culture and sensitivity testing important in patients with chronic recurrent infections.

• γ-globulin or plasma preparations can be used in conjunction with antibiotics to control infection in patients with humoral defect.
• Symptomatic treatment for secondary diseases.

CONTRAINDICATIONS

γ-globulin or plasma preparations should not be administered to patients with selective IgA deficiency because many affected patients have high concentrations of anti-IgA antibodies and may develop anaphylaxis.

PRECAUTIONS

Modified live virus vaccines should not be administered to patients with suspected T-lymphocyte deficiencies because they may induce disease in these patients.

FOLLOW-UP

PATIENT MONITORING

• For clinical signs of secondary infection.
• Routine physical examination to assess efficacy of antibiotic therapy.

PREVENTION/AVOIDANCE

• Do not breed affected animals.
• Pedigree analysis to determine the mode of inheritance and prevent propagating the defect.

POSSIBLE COMPLICATIONS

Infection

EXPECTED COURSE AND PROGNOSIS

• The severity of the defect determines the course and prognosis.
• Patients with minor defects can be successfully managed.

MISCELLANEOUS

ABBREVIATIONS

• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• Ig = immunoglobulin.

IMMUNOPROLIFERATIVE ENTEROPATHY OF BASENJIS

BASICS

OVERVIEW
• Immune-mediated disease characterized by progressive, chronic intermittent diarrhea, anorexia, and weight loss, associated with intense lymphoplasmacytic, infiltrative gastroenteritis or enteritis and concurrent evidence of protein-losing enteropathy, malabsorption, and maldigestion. • Hypergammaglobulinemia present due to increased concentrations of serum immunoglobulin (Ig) A. • Systems affected include gastrointestinal, immune, skin, renal, endocrine.

SIGNALMENT
• Young to middle-aged Basenji—usually <3 years of age. • No sex predilection. • Related dogs often affected.

SIGNS
Historical Findings
• Chronic intermittent diarrhea. • Severe progressive weight loss. • Anorexia often preceding diarrhea. • Variable vomiting.

Physical Examination Findings
• Attitude—usually bright and alert. • Bilaterally symmetric alopecia, ulceration of pinna. • Decreased body condition score. • Ascites, peripheral edema with severe disease.

CAUSES & RISK FACTORS
• Pathogenesis unclear, but interaction between abnormal immune regulation, genetic predisposition, and possibly contribution by environmental factors is hypothesized. • Mode of inheritance not known, but autosomal recessive is suspected. • Stressful events may exacerbate clinical signs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Lymphangiectasia. • Lymphoplasmacytic enteritis. • Intestinal lymphoma. • Eosinophilic enteritis. • Antibiotic-responsive diarrhea. • Diet-responsive enteropathy. • Histoplasmosis. • Intestinal parasitism. • Giardiasis. • Exocrine pancreatic insufficiency. • Hypoadrenocorticism. • Hepatobiliary disease.

CBC/BIOCHEMISTRY/URINALYSIS
• Severe hypoalbuminemia. • Hyperglobulinemia. • Decreased albumin : globulin ratio. • Mature neutrophilia—more severe with advanced disease. • Mild, nonregenerative anemia of chronic disease. • Moderately increased hepatic enzymes (alanine transaminase [ALT] and aspartate transaminase [AST]) due to reactive hepatopathy.

OTHER LABORATORY TESTS
• Hypergammaglobulinemia due to increased serum IgA. • May have hypergastrinemia and hyperchlorhydria. • May see changes in serum folate or hypocobalaminemia. • No one test or histologic finding definitive or pathognomonic.

IMAGING
Abdominal ultrasound may demonstrate generalized small bowel thickening (4–6 mm) with abnormal gastrointestinal wall layering and a lack of other visceral abnormalities.

DIAGNOSTIC PROCEDURES
• Endoscopic appearance of small bowel usually abnormal, but may be normal; biopsies always required for accurate diagnosis. • Genetic testing (DNA) not available at this time.

PATHOLOGIC FINDINGS
• Consistent pathologic lesions include uniform thickening of small bowel, generalized lymphoplasmacytic infiltration of intestinal lamina propria, lacteal dilation, crypt abscesses, and blunting and fusion of villous tips. • May be gastric rugal fold hypertrophy, lymphocytic gastritis, oxyntic gland hyperplasia, and/or gastric mucosal atrophy. • Presence and severity of gastric lesions do not correlate with severity of intestinal lesions. • Other associated lesions include thyroid parafollicular cell atrophy, ulceration of pinna, gastric acinar atrophy, and glomerulonephritis.

TREATMENT
• Outpatient medical management unless dehydration or other severe complications exist. • Advise clients not to breed affected dogs or their littermates. • Minimize stressful episodes. • Use dietary trials (ideally fat-restricted, highly digestible diets) to determine what diet is best tolerated.

MEDICATIONS

DRUG(S) OF CHOICE
Immunosuppressive/Anti-inflammatory Drugs
• Variable success reported, but considered mainstay of treatment. • Prednisone—2 mg/kg PO q24h for 2–4 weeks, then slowly taper over 3–4 months to achieve 0.5–1 mg/kg PO q48h or lowest effective dose.
• Chlorambucil—0.25 mg/kg PO q72h with monitoring for adverse effects, or other immunosuppressive medications can be tried.

Antibiotics
• Trials of antibiotics are variably helpful for affected individuals that may have antibiotic-responsive diarrhea.
• Metronidazole—10 mg/kg PO q12h.
• Tylosin—10–20 mg/kg PO q12h.

Nutritional Supplements/Adjunctive Treatment
Use of probiotics is commonly advised and may favor reduced risk of dysbiosis and lowered state of inflammatory responses by gut-associated lymphoid tissues, but no specific data available to support this hypothesis.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Anticholinergics contraindicated.

FOLLOW-UP
• Diarrhea and weight loss usually show initial improvement with treatment, but recurrence of signs is common. • Long-term prognosis is poor over course of months to a few years.

MISCELLANEOUS

ABBREVIATIONS
• ALT = alanine transaminase.
• AST = aspartate transaminase.
• Ig = immunoglobulin.

Consulting Editor Mark P. Rondeau

INCONTINENCE, FECAL

BASICS

DEFINITION
Inability to retain feces or generate a coordinated and appropriate act of defecation.

PATHOPHYSIOLOGY
• The colon, rectum, and anus are primary sites of function in normal defecation. • Coordinated contractions of the circular and longitudinal smooth muscle of the colon result in orderly accumulation of fecal matter, which is stored in the descending colon. • Intense propulsive activity down the length of the colon, called mass movement, is stimulated by the autonomic nervous system and moves fecal matter toward the anus. • The internal anal sphincter is composed of smooth muscles while the external anal sphincter is composed of striated muscle; parasympathetic innervation to the internal sphincter is provided by the pelvic nerves via the sacral segments (S1–S3); sympathetic innervation is provided by the hypogastric nerves via the lumbar segments (L1–L4); parasympathetic stimulation leads to relaxation of the internal sphincter and contraction of the rectum, whereas sympathetic stimulation leads to contraction of the internal sphincter and relaxation of the rectum; the striated muscles of the external anal sphincter are under conscious control via the caudal rectal nerve (a branch of the pudendal nerve). • Neurogenic sphincter incompetence can be caused by damage or denervation of the pudendal nerve, lesions that cause lumbar or sacral spinal segment dysfunction, autonomic dysfunction, or generalized peripheral neuropathy or myopathy. • Non-neurogenic sphincter incompetence is caused by damage to the anal sphincters. • Damage to, or degeneration of, the levator ani and coccygeus muscles may also contribute to fecal incontinence. • Reservoir fecal incontinence develops when disease processes reduce the capacity or compliance of the rectum; the patient is aware of the need to defecate, but sphincter control is overwhelmed by fecal volume or spastic colorectal/anal disease.

SYSTEMS AFFECTED
• Gastrointestinal (GI). • Neurologic.

GENETICS
N/A

Increased incidence in older patients.

Predominant Sex
N/A

SIGNS
Historical Findings
• Reservoir incontinence—urge to defecate; frequent, conscious defecation; defecation may be associated with tenesmus or dyschezia. • Sphincter incontinence—involuntary expulsion or dribbling of fecal material, especially during excitement or barking and coughing. • History of neurologic signs, anorectal surgery, and/or trauma. • Concurrent urinary incontinence suggests neurogenic sphincter incontinence.

Physical Examination Findings
• Reservoir incontinence—anorectal sensitivity or pain on digital palpation, rectal mass or thickening of rectal mucosa; external anal sphincter tone and perineal reflex are normal. • Non-neurogenic sphincter incontinence—evidence of perineal trauma or perianal fistulae; anal reflex is present, but external anal sphincter may not be completely closed if sphincter has been anatomically disrupted. • Neurogenic sphincter incontinence—loss of tone to external anal sphincter; perineal reflex is absent or diminished. • Neurologic examination findings may include lumbosacral pain, paraparesis, paraplegia, decreased postural reactions, hopping, paw placements, normal to decreased reflexes (patellar, withdrawal, perineal reflex), or absent nociception in perineum or tail. • Diffuse lower motor neuron (LMN) signs suggest generalized peripheral neuropathy or myopathy; these are rare causes of fecal incontinence in small animals.

CAUSES
Reservoir Incontinence
• Colorectal disease—colitis, irritable bowel syndrome, and neoplasia. • Diarrhea—large volumes of feces from any cause can overwhelm the absorptive and storage capacity of the colon.

Non-neurogenic Sphincter Incontinence
• Traumatic anal injuries. • Neoplasia. • Iatrogenic—complication of anorectal surgery. • Anorectal or perianal diseases—e.g., perianal fistulae. • Mucocutaneous diseases—e.g., immune-mediated, infectious.

Neurogenic Sphincter Incontinence
• Iatrogenic—traumatic nerve injury as postoperative complication. • Diseases affecting dorsal funiculus (L4 and cranial). • Spinal cord—arachnoid diverticulum, arachnoid cysts, spinal malformations, syringomyelia, trauma, intervertebral disc disease, neoplasia, infectious or inflammatory meningomyelitis, fibrocartilaginous embolism, myelomalacia. • Degenerative lumbosacral stenosis—L6–L7 or L7–S1, intervertebral disc disease, severe spondylosis deformans, synovial cysts, ligamentous hypertrophy, lumbosacral instability, neoplasia. • Peripheral neuropathy—infectious, endocrine/metabolic, immune-mediated, drug-induced (e.g., vincristine), dysautonomia, idiopathic. • Diffuse neuromuscular diseases—neuropathies, junctionopathies, myopathies (LMN unit). • Degeneration (aging)—multiple factors likely involved, including atrophy of muscles involved in fecal continence, weakness, degenerative neuropathy, cognitive dysfunction.

RISK FACTORS
• Colonic disease. • Anorectal disease and surgery. • Neurologic disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Primary GI disease can increase urge to defecate; these animals typically attempt to go outside to defecate, or posture to defecate. • Behavioral disorders (e.g., separation anxiety) often associated with destructive activities or excessive vocalization. • Inadequate house training usually occurs in young dogs or dogs recently introduced to indoor environment or in cats with litter box aversion.

CBC/BIOCHEMISTRY/URINALYSIS
Usually unremarkable.

OTHER LABORATORY TESTS
• Thyroid testing. • If junctionopathy suspected, consider submitting acetylcholine receptor antibody titers. • If polymyositis suspected, submit *Toxoplasma* and *Neospora* titers. • Rectal scraping for cytology is indicated in regions where *Heterobilharzia*, histoplasmosis, or pythiosis is endemic; rectal cytology may also indicate presence of neoplasia. • Zinc sulfate flotation tests and fecal PCR, ELISA, or culture to detect *Giardia* sp., *Tritrichomonas* (cats), and other parasitic, bacterial, viral, and protozoal infections. • Serum trypsin-like immunoreactivity to rule out exocrine pancreatic insufficiency. • Serum cobalamin and folate concentrations to investigate small intestinal malabsorptive disease.

IMAGING
• Lateral and ventrodorsal survey radiography of lumbosacral spine may show evidence of intervertebral disc extrusion, spondylosis deformans, discospondylitis, vertebral neoplasia, lumbosacral trauma, or vertebral malformations. • Abdominal ultrasound, barium radiographic studies, and CT may help identify masses or intestinal lining abnormalities. • MRI is optimum diagnostic tool to demonstrate specific spinal cord and brain lesions. • CT with IV contrast or CT with myelography may also demonstrate compressive lesions within spinal canal.

INCONTINENCE, FECAL (CONTINUED)

DIAGNOSTIC PROCEDURES
• Full-thickness or endoscopic GI biopsies if diarrhea present. • Colonoscopy and colorectal mucosal biopsy if reservoir incontinence suspected. • Electromyography/nerve conduction studies. • Muscle and nerve biopsy for myopathy and peripheral neuropathy. • Analysis of cerebrospinal fluid (CSF) may reveal evidence of CNS infectious or inflammatory process, neoplasia, or trauma.

PATHOLOGIC FINDINGS
Dependent on underlying disease.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient vs. outpatient depends on underlying disease.

NURSING CARE
• In recumbent patients or patients with difficulty ambulating and fecal incontinence, nursing care is of paramount importance. • To prevent decubital ulcers, rotate recumbency every 2–4 hours and utilize a water bed. • Soiled bed should be changed immediately, and soiled hair coat and skin should be washed with gentle soap and warm water and dried thoroughly. • Occasional warm water enemas will diminish volume of feces in colon and may decrease incidence of inappropriate defecation. • Reflex defecation may be stimulated by applying warm washcloth to anus or perineum. • Physical therapy options include massage, passive range of motion exercises, and assisted walking; hydrotherapy, thermal therapies, and acupuncture may be considered when appropriate.

ACTIVITY
Animal should be encouraged to go outside to urinate and defecate every 4–6 hours. Sling walking may be necessary.

DIET
Fecal volume can be reduced by feeding low-residue commercial diets or foods such as cottage cheese and rice. Feed pet at established times to better control times needed to defecate.

CLIENT EDUCATION
• Prognosis for recovery of function is poor if underlying cause cannot be identified and successfully corrected; discuss prognosis with client early in evaluation to avoid unrealistic expectations. • Environmental changes (e.g., providing designated area that is easy to clean) may increase client satisfaction and thus avoid euthanasia of otherwise healthy animal.

SURGICAL CONSIDERATIONS
Fascial slings, silicone elastomer slings, and other surgical techniques to repair external anal sphincter or improve anorectal angulation have been attempted with low success rates.

MEDICATIONS

DRUG(S) OF CHOICE
• Diphenoxylate (0.1–0.2 mg/kg PO q12h) and loperamide (0.1–0.2 mg/kg PO q8–12h) are opiate motility-modifying drugs; they inhibit GI motility, thus increasing the amount of water absorbed from the feces. • Anti-inflammatory agents, such as glucocorticoids, metronidazole, and sulfasalazine (dogs only), may benefit patients with suspected reservoir incontinence due to inflammatory bowel disease or colitis. • Improvement in signs may be achieved if specific therapy for perianal fistulae, colitis, or other reservoir or non-neurogenic causes of incontinence can be given, but there are no specific drugs effective in patients with neurogenic incontinence.

CONTRAINDICATIONS
• Do not use motility-modifying drugs in patients if infectious or toxigenic cause of diarrhea is suspected. • Do not use opiate motility modifiers in debilitated patients, or patients with impaired liver or renal function. • Do not use diets containing high concentrations of insoluble fibers as this will produce large, bulky stool that is difficult to pass or may cause obstipation.

PRECAUTIONS
• Opiate motility-modifying drugs may cause sedation. • Use loperamide with caution in patients with p-glycoprotein defects.

POSSIBLE INTERACTIONS
Increased sedation and respiratory depression are possible when opiates are used concurrently with other CNS depressants (e.g., barbiturates, tranquilizers).

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• If fecal incontinence is due to underlying neurologic cause, use serial neurologic examinations to monitor patient progress. • Radiographic procedures, electromyography, CSF analysis, and MRI can also be used to follow progress. • Check fecal consistency and volume and make sure pet does not become constipated or obstipated. • Examine perianal skin and hair coat to ensure there is no fecal matter and secondary inflammation or infection. • Adjust diet to find appropriate therapy for each individual patient.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Neurogenic sphincter incontinence is often unresponsive despite appropriate dietary, medical, and surgical treatment.

EXPECTED COURSE AND PROGNOSIS
50% of pets with fecal incontinence were euthanized in a recent study.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
• Exposure to animal feces increases risk of exposure to zoonotic parasites. • Advise clients about zoonotic diseases (e.g., salmonellosis, cutaneous and visceral larval migrans, and toxoplasmosis).

INCONTINENCE, URINARY

BASICS

DEFINITION
Loss of voluntary control of micturition, usually observed as involuntary urine leakage.

PATHOPHYSIOLOGY
Most commonly a disorder of the storage phase of micturition, resulting from impaired urethral sphincter mechanism, detrusor hyperreflexia, or poor bladder compliance. Congenital malformations such as ectopic ureters or urethral malformation can also cause incontinence. Overflow incontinence can result from partial or complete functional urethral obstruction or bladder atony.

SYSTEMS AFFECTED
- Renal/urogenital.
- Nervous.
- Skin—urine scald, perineal and ventral dermatitis.

INCIDENCE/PREVALENCE
Urinary incontinence may affect up to 20% of female spayed dogs and up to 30% of those weighing over 20 kg.

SIGNALMENT
- Dog and rarely cat.
- Most common in spayed female dogs.
- More common in dogs >20 kg.
- Overflow incontinence most common in young to middle-aged, large- to giant-breed male dogs.

CAUSES

Anatomic
- Congenital abnormality of the urethral sphincter mechanism.
- Ectopic ureters that terminate in the bladder neck, urethra, vestibule, or vagina.
- Shortened (hypoplastic) urethra.
- Ureterovaginal hypoplasia/aplasia (cats).
- Cystic hypoplasia.
- Patent urachal remnant.
- Intrapelvic bladder interfering with abdominal pressure transmission to the proximal urethra.
- Vestibular or vulvar conformational abnormalities contributing to urine pooling and leakage.

Neurologic
- Central or peripheral lower motor neuron injury to the sacral spinal cord and pudendal nerve leading to weak urethral closure and flaccid bladder.
- Overflow incontinence secondary to upper motor injury of the thoracolumbar spinal cord and loss of inhibitory signaling to the urethral sphincter.
- Dysautonomia leading to urine retention and overflow incontinence.
- Damage to local reflex arc allowing for relaxation of the urethral sphincter when the detrusor contracts.
- Lesions of the cerebellum or cerebral micturition center affecting inhibition and voluntary control of voiding, resulting in frequent involuntary urination or leakage of small amounts of urine.
- Feline leukemia virus–associated myelopathy leading to progressive paresis or paralysis.

Urinary Bladder Dysfunction
- Bladder atony leading to incomplete voiding and overflow incontinence.
- Bladder overdistension with loss of cellular tight junctions and incomplete contractile signal transmission.
- Bladder fibrosis leading to poor compliance and decreased storage capacity.
- Detrusor hyperreflexia (overactive bladder) and poor compliance.

Urethral Disorders
- Congenital or acquired urethral sphincter mechanism incompetence (most common).
- Functional outlet obstruction leading to overflow incontinence (detrusor urethral dyssynergia).
- Mechanical outflow obstruction from enlarged prostate, benign or malignant neoplasia, urolith, foreign body, or external compression.

Urine Retention
Overflow incontinence when intravesicular pressure exceeds outlet resistance.

Mixed Urinary Incontinence
Any combination of factors in dogs and cats leading to involuntary urine loss. Not typically defined in the way human mixed urinary incontinence is (overactive bladder and stress incontinence).

RISK FACTORS
- Large-breed (>20 kg) spayed female dog.
- Early spay (<12 weeks).
- Breed predispositions are possible.
- Intrapelvic bladder.
- Urogenital conformational abnormalities affecting bladder neck, urethral length, or vestibule.
- Other possible risk factors include obesity, tail-docking, and polyuria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Voluntary inappropriate urination.
- Pollakiuria.
- Prostatic or vaginal discharge.
- Polyuria—may worsen minor incontinence because of increased pressure on already weakened urethral sphincter mechanism.

CBC/BIOCHEMISTRY/URINALYSIS
- Hematology and serum biochemistry are indicated in patients with polyuria and polydipsia.
- CBC and serum biochemistry are usually normal unless comorbidities exist.
- Urinalysis frequently normal.
- Urine sediment may indicate urinary tract infection or polyuria.

OTHER LABORATORY TESTS
- Urine culture may be indicated if clinical signs (straining to urinate, pollakiuria) and urine sediment (pyuria, bacteriuria, hematuria) are consistent with urinary tract infection.
- Cats should be tested for feline leukemia virus.
- Additional testing for causes of polyuria and polydipsia may be indicated based on serum biochemistry and urinalysis results.

IMAGING

Radiographic Findings
- Plain radiography may identify a pelvically placed bladder.
- Intravenous contrast excretory urography may identify dilated or ectopic ureters; however, careful attention must be paid to proper technique and the sensitivity of the imaging is inferior to other methods.
- Retrograde contrast vaginourethrography may reveal congenital abnormalities of the vagina, urethra, and vestibule, and occasionally ectopic ureters.
- Single- or double-contrast cystourethrography allows for accurate assessment of bladder position and urethral length.
- Imaging of the dog or cat with acquired urethral sphincter mechanism incompetence, the most common cause of acquired urinary incontinence, is usually normal.

Ultrasonographic Findings
- Ultrasound assessment may detect ureteral dilation or ectopic ureters; however, the sensitivity is very operator dependent.
- Allows for evaluation of kidneys, bladder, and prostate.

CT Findings
CT excretory urography is currently the imaging modality of choice to diagnose ectopic ureters.

DIAGNOSTIC PROCEDURES
- Neurologic examination—tail tone, anal tone, perineal reflexes and sensation, and bulbospongiosus reflexes.
- Orthopedic examination—determination of pain or difficulty posturing to urinate, which can lead to urine retention.
- Urethral catheterization—to determine patency of urethra and residual urine volume in patients with suspected urine retention and overflow incontinence.
- Cystoscopy—evaluates urethra and bladder as well as visualization of position and shape of ureteral openings.
- Urodynamic assessment—may document decreased urethral pressure or detrusor hyperreflexia; limited availability at some specialty clinics.

INCONTINENCE, URINARY (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

- Usually outpatient.
- Medical therapy is primary treatment for patients with urethral sphincter mechanism incompetence.
- Urinary tract infection should be treated appropriately if identified.
- Address partial urethral obstructive and neurologic disorders if identified.
- Ectopic ureters should be corrected either by cystoscopic laser ablation if intramural (common) or surgery if extramural (rare).
- Anatomic disorders should be identified and corrected if possible.
- Functional abnormalities of the bladder or urethra may require medical treatment.
- Bulking agents such as bovine cross-linked collagen may be injected into urethral submucosa, or surgical salvage procedures such as placement of urethral hydraulic occluder if urethral sphincter incompetence not responsive to medical therapy.

MEDICATIONS

DRUG(S) OF CHOICE

Urethral Sphincter Mechanism Incompetence

- Alpha-adrenergic agonist treatment (e.g., phenylpropanolamine 1–2 mg/kg PO q8–12h) or estrogen compounds (e.g., estriol 2 mg/dog PO q24h for 2 weeks, then decrease dose q2 weeks to lowest effective dose; diethylstilbestrol 0.1–1 mg/dog PO q24h for 5–7 days, then 0.1–1 mg/dog q5–7 days PRN).
- Phenylpropanolamine and estrogens may be used in combination in spayed females and may have a synergistic effect.
- Imipramine (5–15 mg/dog PO q12h), a tricyclic antidepressant with cholinergic and alpha-agonist effects, may be of use if other medical therapy fails, especially if detrusor hyperreflexia is suspected as well.
- Testosterone cypionate (2.2 mg/kg IM q30–45 days) may be used in males with urethral sphincter mechanism incompetence; however, its efficacy is far below phenylpropanolamine.

Detrusor Hyperreflexia

Antimuscarinic agents (oxybutynin chloride 0.2–0.3 mg/kg PO q8–12h or 1.25–5 mg/dog PO q8–12h; imipramine 5–15 mg/dog PO q12h).

Functional Outflow Obstruction

See Urinary Tract Obstruction.

CONTRAINDICATIONS

- Do not use estrogens in males or intact females.
- Do not use alpha agonists in patients with hypertension, and use with caution in patients with conditions that predispose to hypertension.
- Do not use anticholinergics in patients with glaucoma or cardiac disease.

PRECAUTIONS

- Adrenergic agonists can cause hypertension, changes in appetite, and restlessness.
- Adverse effects of estrogen use include vulvar swelling, mammary development, and attractiveness to males; these are usually dose dependent and will subside with dose reduction; always use the lowest effective dose.
- Bone marrow suppression is extremely rare secondary to estrogen use at the recommended doses.
- Testosterone use can lead to signs of aggression and increased libido in males.
- Anticholinergic agents can cause nausea, vomiting, and constipation.

POSSIBLE INTERACTIONS

- Do not administer tricyclic antidepressants concurrently with monoamine oxidase inhibitors (e.g., amitriptyline, clomipramine, imipramine).
- Hypertensive risk increases with concurrent use of alpha agonists and tricyclic antidepressants.

FOLLOW-UP

PATIENT MONITORING

- Monitor blood pressure periodically in patients receiving alpha agonists.
- Monitor vulvar and mammary swelling in patients receiving estrogen treatment.
- Monitor prostate size in males receiving testosterone.
- Once continence is achieved, gradually reduce to lowest effective dose.
- Perform urine cultures to guide treatment and prevent resistance of symptomatic urinary tract infections.

POSSIBLE COMPLICATIONS

- Hypertension.
- Recurrent and resistant urinary tract infections.
- Urine scald and perineal (females) or ventral abdominal (males) dermatitis.
- Refractory incontinence.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Urinary tract infection.
- Hydroureter and hydronephrosis in some ectopic ureter patients, even after correction.

PREGNANCY/FERTILITY/BREEDING

Dogs with congenital anomalies such as ectopic ureters should be removed from the breeding population.

SYNONYMS

- Hormone-responsive incontinence.
- Enuresis.

SEE ALSO

- Polyuria and Polydipsia.
- Urinary Retention, Functional.
- Urinary Tract Obstruction.

Client Education Handout available online

INFERTILITY, FEMALE—DOGS

BASICS

DEFINITION
Abnormal cycling, copulation failure, conception failure, or pregnancy loss in bitches.

PATHOPHYSIOLOGY
- Normal fertility—requires normal estrous cyclicity with ovulation of normal ova into a patent, healthy reproductive tract; fertilization by normal spermatozoa; implantation of the conceptus into the endometrium; formation of the normal placenta; and maintenance of pregnancy in the presence of high progesterone concentration throughout the approximately 2-month gestation.
- Breakdown in any of these processes causes infertility.

SYSTEMS AFFECTED
Reproductive

SIGNALMENT
- Animals of all ages; more common in old animals.
- Dogs >6 years old—more likely to have underlying cystic endometrial hyperplasia; may be predisposed to uterine infection and failure of conception or implantation.
- Breeds predisposed to hypothyroidism—may have higher prevalence; include golden retrievers, Doberman pinschers, dachshunds, Irish setters, miniature schnauzers, Great Danes, poodles, and boxers.

SIGNS

Historical Findings
- Failure to cycle.
- Failure to cycle normally—shortened interestrous interval (interval of 4 months or less).
- Failure to copulate, poor semen quality, or lack of functional spermatozoa in the male.
- Failure to become pregnant and/or maintain pregnancy after normal copulation.
- Persistent estrus (>3 weeks).

Physical Examination Findings
- Negative pregnancy exam after mating.
- Positive pregnancy with no subsequent parturition.

CAUSES
- Insemination at the improper time in the estrous cycle—most common.
- Subclinical uterine infection.
- Cystic endometrial hyperplasia.
- Male infertility factors.
- Hypothyroidism.
- Hypercortisolism.
- Anatomic abnormality.
- Chromosomal abnormality.
- Abnormal ovarian function.
- Previous ovariectomy, hysterectomy, or ovariohysterectomy.
- *Brucella canis* infection.
- Silent estrus.

RISK FACTORS
- *B. canis*.
- Hypothyroidism.
- Hypercortisolism—endogenous or exogenous.
- Systemic viral infection—canine herpesvirus.
- Any chronic, debilitating disease.
- Congenital vaginal anomaly.
- Old age.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Historical Information
- Extremely useful in distinguishing causes.
- Is the patient cycling?
  - Primary anestrus = no overt estrous cycle by 2 years of age.
  - Secondary anestrus = no overt estrous cycle within 1 year of a normal cycle.
- Has the patient conceived or given birth in the past? If so, how recently? Litter size? Percentage of stillbirths? Percentage of litter weaned?
- Is the patient free of systemic viral or protozoal infection?
- Is the patient capable of normal copulation?
- Was the patient bred to a male of proven fertility (i.e., litter whelped within previous 6 months) at the proper time of the estrous cycle?
- Did the patient ovulate during the estrous cycle and maintain progesterone concentration consistent with pregnancy during the entire gestation?
- Is the bitch euthyroid?

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS

Serologic Test for *B. canis* (Dogs)
- Rapid slide agglutination test—used as a screen; sensitive but not specific.
- If positive results—recommend recheck by an agar gel immunodiffusion test, bacterial culture, or PCR of whole blood or lymph node aspirate.

Serum Progesterone Measurement
- Should remain high throughout gestation.
- If concentration <2 ng/mL in mid-gestation and pregnancy loss occurs, insufficient luteal function indicated (hypoluteodism); see Abortion, Spontaneous (Early Pregnancy Loss)—Dogs, and Premature Labor.
- Concentration >2 ng/mL—may indicate diestrus, silent heat (estrus with no overt behavioral or physical changes), or pathologic production of progesterone from a luteal ovarian structure, functional ovarian neoplasm, or the adrenal gland.
- Quantitative (chemiluminescence, fluorescence, enzyme immunoassay) progesterone assay is important to detect levels <2.0 ng/mL; rapid in-hospital assays are least accurate between 2 and 5 ng/mL.
- Progesterone may be measured during proestrus and estrus to predict ovulation time and optimize breeding management.
- Concentration and ovulation:
  - 1–1.9 ng/mL, probable ovulation in 3 days (recheck).
  - 2–2.9 ng/mL, ovulation in 2 days.
  - 3–3.9 ng/mL, ovulation in 1 day.
  - 4–10 ng/mL, ovulation that day.
- Optimal breeding day for single breeding to produce maximum litter size—2 days after ovulation.
- Day of ovulation from onset of proestrus or estrus extremely variable; not well correlated with standing behavior (see Breeding, Timing).

Other Tests
- Bacterial culture for uterine organisms—vaginal discharge originating in the uterus during proestrus or estrus is collected directly by hysterotomy or transcervical catheterization, or indirectly from the anterior vagina using a guarded swab.
- Thyroid hormone testing—resting serum concentration of T_3 or T_4 and thyroid stimulating hormone (TSH).
- Serologic testing—canine herpesvirus; see Abortion, Spontaneous (Early Pregnancy Loss)—Dogs.
- Karyotype—performed on patients with primary or persistent anestrus; can identify chromosomal abnormalities that can cause abnormal sexual differentiation.
- Serum cortisol concentration—if the resting serum cortisol is high, the underlying cause should be identified; see Hyperadrenocorticism (Cushing's Syndrome)—Dogs.
- Semen evaluation—direct evaluation to rule out oligospermia or azoospermia; alternatively, may test-breed the male to another female to prove fertility; rule out azoospermia in tomcat by finding spermatozoa in a vaginal flush or swab specimens from the queen or in urine collected by cystocentesis from the tom; see Infertility, Male—Dogs.
- Serum anti-Müllerian hormone/progesterone, luteinizing hormone (LH)/estrogen for determination of ovarian presence; see Ovarian Remnant Syndrome.

IMAGING
- Radiography—normal ovaries and a nongravid uterus usually not visible with radiography; large ovaries may indicate cystic ovarian disease or neoplasia; visible uterus may indicate cystic endometrial hyperplasia.
- Ultrasound—may diagnose pregnancy as early as 20–24 days after ovulation; useful for documenting pregnancy loss; useful for detecting suspected cystic ovarian or neoplastic ovarian disease, cystic endometrial hyperplasia,

INFERTILITY, FEMALE—DOGS (CONTINUED)

and intraluminal fluid; may be difficult to image normal ovaries and nongravid uterus—operator dependent.
• Positive-contrast procedures—vaginography; hysterography; performed prepuberally or when the patient is in estrus; may reveal anatomic abnormality (e.g., abnormal structure and impatency); see Vaginal Malformations and Acquired Lesions.

DIAGNOSTIC PROCEDURES

• Laparotomy—assess anatomy of the tubular tract and gonads.
• Hysterotomy—to obtain a direct uterine culture specimen; biopsy of the uterus or ovaries.

TREATMENT

• Heritable cause (e.g., thyroid insufficiency)—counsel owner regarding removing the patient from the breeding program.
• Surgical resection of vaginal anomalies—may ease natural service and vaginal delivery of pups.
• Surgical repair of impatent tubular tract—difficult procedure; prognosis for future fertility guarded.
• Surgical drainage of ovarian cysts—efficacy unknown.
• Unilateral ovariectomy of neoplastic ovary—future fertility depends on resumption of normal function of the remaining ovary and lack of metastasis.
• Estrus suppression for one to two estrous cycles may benefit bitches with short interestrous interval (4 months or less).
• Better breeding management—good prognosis for future fertility, unless other condition present (more guarded prognosis).

MEDICATIONS

DRUG(S) OF CHOICE

• Antibiotics—for uterine infection; choice depends on bacterial culture and sensitivity of the uterus or of vaginal discharge during proestrus or estrus.
• L-thyroxine—for thyroid insufficiency; dogs: 0.01–0.02 mg/kg PO q12h; prognosis for future fertility with return to euthyroid state guarded.

Gonadotropin Therapy

• For induction of ovulation.
• Gonadotropin-releasing hormone (GnRH), which causes release of endogenous LH from the pituitary, or human chorionic gonadotropin (hCG), which has LH-like activity.
• Ovarian cystic disease—GnRH (50 μg/dog IM) or hCG (1,000 IU/dog half IV/half IM); causes ovulation or luteinization of cystic ovarian tissue.
• Estrus induction—diethylstilbestrol (5 mg PO q24h for 9 days or until signs of proestrus induced); bromocriptine (20 μg/kg PO q12h for 21 days); cabergoline (5 μg/kg PO q24h for up to 30 days or until signs of proestrus induced); deslorelin (2.1 mg implant, Ovuplant®; placed in vestibule): must have serum progesterone <0.5 mg/mL at start; implant removed after ovulation confirmed with serum progesterone >10 ng/mL.
• Estrus suppression—megestrol acetate (2 mg/kg PO q24h for 8 days if begun within first 3 days of proestrus, or 0.5 mg/kg PO q24h for 32 days if begun in anestrus) or mibolerone (dose dependent on bodyweight; 30 μg PO q24h for dogs weighing 0.5–12 kg; 60 μg PO q24h for 12–23 kg; 120 μg PO q24h for weight 23–45 kg; 180 μg PO q24h daily for dogs weighing >45 kg and for German shepherd dogs and related breeds and crossbreds).

CONTRAINDICATIONS

• Treatment with progestins, including megestrol acetate, contraindicated in bitches with cystic endometrial hyperplasia or history of progesterone-dependent disease.
• Treatment with mibolerone contraindicated in Bedlington terriers and other breeds with familial liver disease.
• All hormonal therapies contraindicated in potentially pregnant bitches.

FOLLOW-UP

PATIENT MONITORING

• Hypothyroid dogs—recheck thyroid function after 1 month of supplementation.
• Ultrasonography—to definitively diagnose pregnancy; monitor gestation.
• Progesterone assay.

MISCELLANEOUS

Karotype testing can be performed by Molecular Cytogenetics Laboratory, Texas A&M University, or Veterinary Genetics Laboratory, UC Davis.

ASSOCIATED CONDITIONS

• Infertility caused by endocrinopathy—hypothyroidism, hyperadrenocorticism.
• Bitches with vaginal anatomic abnormality—persistent or recurrent urinary tract disease or vaginitis.

ZOONOTIC POTENTIAL

B. canis infection—organism is less readily shed if affected animals are gonadectomized; stress good hygiene.

SEE ALSO

• Abortion, Spontaneous (Early Pregnancy Loss)—Dogs.
• Breeding, Timing.
• Brucellosis.
• Hyperadrenocorticism (Cushing's Syndrome)—Dogs.
• Hypothyroidism.
• Infertility, Male—Dogs.
• Ovarian Remnant Syndrome.
• Vaginal Hyperplasia and Prolapse.
• Vaginal Malformations and Acquired Lesions.

ABBREVIATIONS

• GnRH = gonadotropin-releasing hormone.
• hCG = human chorionic gonadotropin.
• LH = luteinizing hormone.
• TSH = thyroid-stimulating hormone.

INFERTILITY, MALE—DOGS

BASICS

DEFINITION
- Diminished or absent fertility; does not imply sterility.
- Results from wide range of problems that prevent delivery of sufficient numbers of normal spermatozoa to fertilize ovulated, mature oocytes in the bitch.

PATHOPHYSIOLOGY
- Spermatogenesis—formation and development of spermatozoa from spermatogonia to mature spermatozoa; coordinated, hormonally controlled, cyclic process; testicular problems require at least 70 days for recovery; epididymal problems require up to 10–14 days.
- Azoospermia—no spermatozoa in ejaculate.
- Oligozoospermia—low number of spermatozoa.
- Teratospermia—high number of abnormally shaped spermatozoa.
- Asthenospermia—reduced motility.
- Primary causes—impaired or arrested spermatogenesis, blockage of excurrent ducts, genitourinary inflammation, testicular neoplasia, environmental stress, congenital abnormality, endocrine abnormality.

SYSTEMS AFFECTED
- Reproductive.
- Endocrine/metabolic.
- Musculoskeletal.
- Nervous.

GENETICS
- Heritable component should be considered for autoimmune orchitis as cause of azoospermic infertility.
- Cryptorchidism—heritable, sex-limited polygenic autosomal recessive trait in dogs; associated with increased frequency of inguinal/umbilical hernias, patellar luxation, preputial and penile problems.
- Alpha-L-fucosidase deficiency—storage disorder causing acrosomal dysgenesis.
- Primary ciliary dyskinesia—congenital abnormality of ciliary ultrastructure; absent, irregular, or asynchronous motility patterns of all ciliated cells; diagnosed by electron microscopy of spermatozoa.
- Hypothyroidism—effect on male fertility probably minimal.

INCIDENCE/PREVALENCE
True incidence unknown; likely increased with inbreeding.

SIGNALMENT

Species
Dog

Breed Predilections
Relatively higher prevalence of specific problems in breeds with small genetic pool or intensive inbreeding.

Mean Age and Range
Prevalence increases with age.

SIGNS

General Comments
General complaint—no puppies produced; whelping rate <75% when bred with correct timing to fertile bitches.

Historical Findings
- Age of testicular descent.
- Age at first attempted mating.
- Temperament (high-strung).
- Libido and breeding behavior.
- Frequency and number of matings.
- Method used to time breedings.
- Type of semen used for breeding (fresh, fresh-extended, chilled-extended, frozen).
- Handling of semen and route of insemination.
- Litter size(s).
- Familial history of infertility.
- Coefficient of inbreeding.
- Fertility status of bitches.
- *Brucella canis* status of all breeding animals.
- Current and previous drug and dietary therapies, especially corticosteroids and steroid hormones.
- Previous medical or surgical illnesses.

Physical Examination Findings
- Sheath and penis—palpate to identify masses or adhesions.
- Nonerect penis—exteriorize to identify lesions of superficial mucosa and damage to os penis.
- Testes and epididymides—palpate and examine, note size and symmetry of epididymides relative to testes.
- Internal urethra and prostate—digital rectal palpation to determine location, size, and symmetry.

CAUSES
Incorrect timing of breeding—most common cause.

Congenital
- Chromosomal abnormalities: XXY syndrome and XX disorder of sexual development (see Sexual Development Disorders).
- Germinal cell aplasia—biopsy reveals "Sertoli cell only" syndrome.
- Segmental aplasia of epididymis or vas deferens—oligospermia (unilateral) or azoospermia (bilateral).

Acquired
- Incomplete ejaculation—unfamiliar surroundings; slippery flooring; no estrous bitch; dominant owner or bitch present.
- Obstruction of efferent ducts, epididymides, or ductus deferens—azoospermia if bilateral; sperm granuloma, spermatocele, acute inflammation, chronic inflammatory stenosis, segmental aplasia, neoplasia, vasectomy, attempts to tack testes into scrotal location.
- Hyperthermia/heat stroke.
- Inflammation or infection of testes—especially *Escherichia coli*; requires prompt and aggressive treatment to prevent infertility.
- Hypothyroidism—role unclear; may be associated with decreased libido.
- Hyperprolactinemia—role unclear; associated with azoospermia.
- Hyperadrenocorticism—testicular atrophy and oligospermia; probably reversible.
- Drugs—parasiticides, corticosteroids, anabolic steroids, estrogens, androgens, progestogens, gonadotropin-releasing hormone (GnRH) agonists/antagonists, ketoconazole, amphotericin B: may interfere with or interrupt spermatogenesis.
- Environmental toxins—endocrine-disrupting contaminants can affect hypothalamic-pituitary-gonadal axis and gonadal steroidogenesis.
- Trauma, testicular neoplasia, systemic disease, and ischemia—may cause transient infertility or sterility.
- Prostatic disease—can markedly reduce semen quality and libido.
- Inbreeding—reduces fertility; reduced-fertility lines might only be salvaged by concerted breeding program and out-crosses with highly fertile animals.
- Lymphocytic orchitis—familial in some breeds (e.g., beagle and borzoi); affected animals may be fertile when young; accelerated rate of fertility loss with age.
- Retrograde ejaculation—some retrograde flow into bladder normal.

RISK FACTORS
- Congenital disorders affecting reproductive function—occur in specific breeds.
- Teaser bitches and stud dogs not tested for infectious diseases (e.g., *B. canis* and bacterial culture of genital tract) before clinical use.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Before extensive diagnostic work on male, determine that bitches are fertile (previous litters) and breedings optimally timed (see Infertility, Female—Dogs, and Breeding, Timing).

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Brucellosis or prostatitis—variable changes in leukogram (normal or leukocytosis) and urinalysis (high numbers of leukocytes); depends on time course of infection; false-negative Brucellosis test possible, antibiotic therapy may cause false negative.
- Systemic illness—may impair reproductive function, but infertility usually not primary complaint.

INFERTILITY, MALE—DOGS (CONTINUED)

OTHER LABORATORY TESTS

Endocrine Profile

- Resting testosterone—normal, intact dogs, 0.4–10 ng/mL (1–4 ng/mL common range).
- Primary testicular failure—low testosterone and high follicle-stimulating hormone (FSH) and luteinizing hormone (LH).
- Germinal compartment failure—normal testosterone and high FSH; FSH high due to loss of inhibin secretion from Sertoli cells.
- Hypogonadism—low testosterone, FSH, and LH.
- Thyroid function—evaluated by baseline T_3, T_4, thyroid-stimulating hormone concentration (see Hypothyroidism).
- *B. canis*—screen with 2-mercaptoethanol rapid slide agglutination test (2-ME-RSAT); confirm with agar gel immunodiffusion test (AGID).

IMAGING

Ultrasonography—identify lesions that alter testicular and epididymal architecture (e.g., neoplasia, spermatocele, orchitis, epididymitis); evaluate prostate gland for hyperplasia, chronic prostatitis, cyst, abscess, or neoplasia (see Prostate Disease in the Breeding Male Dog).

DIAGNOSTIC PROCEDURES

Breeding Soundness Examination

- Must always consist of two semen collections.
- Sperm-rich and prostatic portions of ejaculate—collect as separate fractions by use of sterile artificial vagina and sterile, graduated, nontoxic plastic tubes, in presence of estrous bitch.
- Sperm-rich fraction—assess volume, concentration, motility, and morphologic characteristics of sperm cells; qualitative and quantitative cultures.
- Prostatic fraction and urine—cytologic examination; qualitative and quantitative cultures.
- Culture results—must be correlated with clinical and cytologic evidence of active infection; inflammation present if >3–5 white blood cells/hpf observed (especially sperm-rich fraction).
- If prostatic fraction indicates infection—reevaluate by other sampling techniques that avoid contamination from penile mucosa and prepuce; negative cytology possible with chronic prostatitis.
- Azoospermic or oligospermic ejaculate—recollect 1 hour later and again on several occasions before confirming infertility.

Epididymal Markers

Alkaline phosphatase (ALP) activity in seminal fluid—normal 8,000–40,000 U/mL; epididymal in origin; may indicate obstruction if <5,000 U/mL and complete ejaculate obtained; pathologic effects of obstruction more easily seen from ALP concentration if ALP performed on two ejaculates collected 1 hour apart.

PATHOLOGIC FINDINGS

Testicular biopsy—determines degree of spermatogenesis and integrity of blood–testis barrier; differentiates obstruction of efferent ducts from testicular hypoplasia and degeneration; allows informed prognosis.

TREATMENT

ACTIVITY

- Restrict if activity results in hyperthermia.
- No restriction for other causes.

DIET

Ensure adequate diet and mineral supplementation; avoid supplementation of products containing excessive or undefined amounts of steroid hormones, e.g., extracts of testes, ovaries, and adrenals; phytoestrogens.

CLIENT EDUCATION

- Return to function may require at least 70 days from correction of identified cause(s).
- Stress patience and check patient regularly to ensure condition is not worsening.
- Emphasize potential role of heritable infertility.

SURGICAL CONSIDERATIONS

Re-anastomosis of blocked excurrent epididymal ducts (vasectomies) has been successful for reestablishment of sperm production.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics as indicated by culture and sensitivity.
- Pseudoephedrine—to treat retrograde ejaculation (used with limited success in men): 4–5 mg/kg PO q8h, or 1h and 3h before collection.
- Phenylpropanolamine—4–8 mg/kg PO q24h starting 5 days prior to collection.

CONTRAINDICATIONS

- Trimethoprim-sulfas—contraindicated if predisposed to keratoconjunctivitis sicca, can induce thrombocytopenia.
- Chloramphenicol—associated with anorexia and vomiting.

FOLLOW-UP

PATIENT MONITORING

Recheck at intervals that take into account length of spermatogenic cycle (70 days) but frequent enough to allow detection of deteriorating condition.

PREVENTION/AVOIDANCE

Avoid exposure to environmental temperature extremes.

POSSIBLE COMPLICATIONS

50–60% return to fertility after diagnosis and appropriate treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Brucellosis—discospondylitis, polyarthritis, posterior paresis, fever, uveitis.
- Prostatic disease—obstipation, locomotor difficulties, fever, hematuria, pollakiuria, dysuria.
- Lymphocytic orchitis—lymphocytic thyroiditis.

AGE-RELATED FACTORS

- Daily sperm output and morphologically normal sperm cells decline with age.
- Difficult to assess effect of age alone on fertility.
- Most old, infertile dogs have concurrent diseases (e.g., systemic or prostatic disease, testicular neoplasia, osteoarthritis) that have documented effects on fertility or libido.

ABBREVIATIONS

- 2-ME-RSAT = 2-mercaptoethanol rapid slide agglutination test.
- AGID = agar gel immunodiffusion test.
- ALP = alkaline phosphatase.
- FSH = follicle-stimulating hormone.
- GnRH = gonadotropin-releasing hormone.
- LH = luteinizing hormone.

INFLAMMATORY BOWEL DISEASE

BASICS

DEFINITION
A group of chronic enteropathies characterized by persistent or intermittent gastrointestinal (GI) signs with histopathologic evidence of intestinal inflammation. Inflammatory bowel disease (IBD) is generally categorized by the predominant mucosal cellular infiltrate, such as lymphocytic-plasmacytic, eosinophilic, or granulomatous enteritis.

PATHOPHYSIOLOGY
• Poorly understood but likely due to complex interplay between mucosal immunity and environmental factors (i.e., dietary and bacterial antigens) in genetically susceptible dogs; aberrant host immune responses are likely triggered by antigens derived from resident microbiota.
• Damage results from elaboration of cytokines, release of proteolytic and lysosomal enzymes, complement activation secondary to immune complex deposition, and generation of oxygen free radicals. • Host genetic susceptibility involving defects in innate immunity is suspected in dogs, and possibly cats.

SYSTEMS AFFECTED
• GI. • Hepatobiliary. • Hemic/lymphatic/immune—rarely. • Musculoskeletal—rarely.
• Ophthalmic—rarely. • Respiratory—rarely.
• Skin/exocrine—rarely.

GENETICS
Defects in host susceptibility genes have been identified in German shepherd dog, boxer, and soft-coated wheaten terrier.

INCIDENCE/PREVALENCE
IBD is most common histopathologic diagnosis in dogs and cats with chronic GI signs in which other causes have been eliminated through clinical trials and diagnostic testing.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Increased risk in German shepherd, boxer, and soft-coated wheaten terrier, in addition to breed-specific forms described elsewhere.
• Siamese cats may be predisposed.

Mean Age and Range
Most common in middle-aged animals, but younger animals may be affected.

Predominant Sex
N/A

SIGNS

Historical Findings
• Intermittent or persistent chronic GI signs (>3 weeks' duration). • May include vomiting, small/large bowel diarrhea, decreased appetite, and/or weight loss. • Severe IBD may cause protein-losing enteropathy (PLE) in dogs.

Physical Examination Findings
• Vary from apparently healthy to a thin, lethargic animal. • Poor hair coat with chronic disease and nutritional deficiencies. • Abdominal palpation may reveal pain, thickened bowel loops, and mesenteric lymphadenopathy (especially in cats). • Ascites may occur in dogs with PLE. • Hematochezia, fecal mucus, and tenesmus seen with colonic involvement.

CAUSES
Pathogenesis unknown but most likely multifactorial, involving complex interactions between host genetics, mucosal immunity, and environmental (diet, intestinal bacteria) factors.

Infectious Agents
• Adherent and invasive *Escherichia coli* has been associated with granulomatous colitis in dogs.
• *Giardia*, *Salmonella*, *Campylobacter*, and resident microbiota have been implicated.

Dietary Agents
Meat proteins, milk proteins, gluten (wheat), and additives are all proposed causative agents, likely playing an important role.

Genetic Factors
• Some forms of IBD more common in certain breeds. • Defects in innate immunity (e.g., mutations in *TLR2*, *TLR5*, and *nod2* as seen in German shepherd dogs) that perturb mucosal homeostasis may predispose individual to IBD.

RISK FACTORS
Current hypotheses suggest that IBD is multifactorial disorder conditioned by genetic, immunologic, and environmental factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Cats—hyperthyroidism, intestinal neoplasia (especially small cell lymphoma), adverse food reactions, feline infectious peritonitis and other viral infections (e.g., feline leukemia virus [FeLV] and feline immunodeficiency virus [FIV]), renal and hepatic insufficiency, exocrine pancreatic insufficiency, intestinal parasitism, and antibiotic-responsive diarrhea (ARD) are primary differentials.
• Dogs—intestinal neoplasia, motility disorders, adverse food reactions, lymphangiectasia, exocrine pancreatic insufficiency, intestinal parasitism, and ARD are primary differentials.

CBC/BIOCHEMISTRY/URINALYSIS
• Often unremarkable; these tests more often serve to eliminate other differential diagnoses.
• Anemia of chronic disease; mild leukocytosis ± left shift sometimes seen with mucosal disruption (e.g., erosions); mild eosinophilia may be seen with eosinophilic enteritis, food allergy, and intestinal parasites among other causes. • Cats may show alterations in serum total protein (i.e., hyperproteinemia) and albumin concentrations, with increased liver enzyme activities.
• Hypoproteinemia more common in dogs than cats. • Cobalamin deficiency in both dogs and cats with involvement of ileum.

OTHER LABORATORY TESTS
• Useful to eliminate other differentials.
• Dogs—evaluation of exocrine pancreatic function: canine trypsin-like immunoreactivity (cTLI); serology for pancreatitis: canine pancreatic lipase activity (Spec cPL), and serum cobalamin and folate assays to localize small intestinal disease. • Cats—T_4 and FeLV/FIV serology; fasting serum TLI (if exocrine pancreatic insufficiency suspected); serology for pancreatitis (Spec fPL), and serum cobalamin and folate assays to localize small intestinal disease.

IMAGING
• Survey abdominal radiographs—usually unremarkable. • Barium contrast studies—may reveal mucosal abnormalities and thickened bowel loops; normal findings do not eliminate possibility of IBD.
• Ultrasonography—may indicate increased intestinal wall thickness (particularly muscularis propria and submucosal layers) and mesenteric lymphadenopathy; however, these abnormalities not specific for IBD.

DIAGNOSTIC PROCEDURES
• Perform elimination dietary trial to rule out adverse food reactions; if GI signs resolve within 2 weeks, then diagnosis of adverse food reaction is made. • Perform fecal testing for nematode and protozoal parasites; treat for *Giardia* spp. and endoparasitic infection with fenbendazole (50 mg/kg for 5 days). • Definitive diagnosis of IBD requires intestinal biopsy and histopathology, usually obtained via GI endoscopy; WSAVA guidelines should be used to define severity of mucosal inflammation. • Laparotomy indicated if GI endoscopy unavailable or to collect full-thickness mucosal specimens; *always be sure to collect ileal biopsies*. • Use scoring indices (canine inflammatory bowel disease activity index) to define clinical severity and assess response to therapy.

PATHOLOGIC FINDINGS
Morphologic evidence of mucosal inflammation including epithelial changes, architectural distortion (e.g., erosion/ulceration, crypt hyperplasia, fibrosis, loss of colonic goblet cells), and increased lamina propria cellularity. Histopathologic guidelines for defining severity of GI inflammation have been described.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient, unless patient is debilitated from dehydration, hypoproteinemia, or cachexia.

INFLAMMATORY BOWEL DISEASE (CONTINUED)

NURSING CARE
• If patient is dehydrated or must have food restricted because of intractable vomiting, any balanced crystalloid fluid is adequate (for a patient without concurrent disease); otherwise, select fluids on basis of secondary diseases. • If severe hypoalbuminemia from PLE, consider use of colloids.

ACTIVITY
No restrictions.

DIET
• Feed novel intact protein or hydrolysate elimination diet to help reduce intestinal inflammation. • Fiber supplementation (e.g., fermentable fiber such as pumpkin, Metamucil®) suggested in dogs and cats with colitis. • Fish oil (n-3 fatty acids) as free radical scavenger to reduce inflammation. • Probiotics may be of benefit in some animals but clinically unproven at this time; must be given continuously over several weeks for potential benefit to be realized.

CLIENT EDUCATION
• Emphasize that IBD is not cured but is controllable in most instances. • Relapses are common; clients should be patient during the various food and medication trials that are often necessary to control the disease.

SURGICAL CONSIDERATIONS
Surgery only indicated for collection of intestinal biopsies in dogs and intestinal and/or liver, pancreatic and/or mesenteric biopsies in cats.

MEDICATIONS

DRUG(S) OF CHOICE
• Evidence-based data indicate glucocorticoids are effective drugs for inducing remission in majority of dogs and cats; use prednisone or prednisolone in dogs at 1–2 mg/kg PO daily for 21 days to induce remission, then taper dose by 25% every 2 weeks. • Dogs weighing >30 kg will require lower steroid dosage to provide comparable clinical efficacy; this will also reduce adverse effects; *dose large dogs by body surface area*. • Treat cats with oral prednisolone at 1–2 mg/kg for 14–21 days, then taper as above; avoid glucocorticoids in cats with diabetes mellitus and those with history of adverse effects. • Budesonide may be used to minimize adverse steroid effects and maintain remission in some dogs and cats; dosage ranges dogs: 1–3 mg/m^2 daily; cats: 1 mg/day. • Correct hypocobalaminemia by weekly parenteral cobalamin injections for first 6 weeks and thereafter every 2–3 weeks or as needed based on repeat testing of cobalamin concentrations; oral cobalamin therapy requires daily administration; antibiotics (metronidazole, tylosin) generally *not* indicated for treatment of IBD; these drugs may cause significant disruption to gut microbiota even after administration discontinued. • Some evidence that oral cyclosporine is of value in dogs with steroid-refractory disease and PLE; dose at 5 mg/kg PO daily for 4–6 weeks or as needed to induce remission. • Use of other immunosuppressive drugs, including azathioprine, chlorambucil, leflunomide, or mycophenolate, has been reported. • Empirical deworming with fenbendazole (50 mg/kg PO q24h for 5 days). • Fecal microbiota transplant anecdotally effective in cases of refractory IBD; however, clinical trial data yet to be reported.

CONTRAINDICATIONS
Based on concurrent disease.

PRECAUTIONS
See Drug(s) of Choice.

POSSIBLE INTERACTIONS
See Drug(s) of Choice.

ALTERNATIVE DRUG(S)
See Drug(s) of Choice.

FOLLOW-UP

PATIENT MONITORING
• Periodic (q2–4 weeks) physical and laboratory evaluations may be necessary until the patient's condition stabilizes; serum albumin provides important prognostic information in dogs; serum cobalamin deficiency will delay complete clinical recovery in both dogs and cats. • Monitor serum cobalamin concentrations in hypocobalaminemic dogs and cats. • No other follow-up may be required except yearly physical examinations and assessment during relapse.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Dehydration, malnutrition, adverse drug reactions, hypoproteinemia, hypocobalaminemia, anemia, and diseases secondary to therapy.

EXPECTED COURSE AND PROGNOSIS
• Generally good to excellent short-term prognosis. • Poor long-term prognosis in dogs with IBD has been associated with severe clinical disease, marked endoscopic (duodenal) abnormalities, ascites, and hypoalbuminemia; long-term prognosis worse compared to food-responsive diarrhea and ARD, other forms of canine chronic enteropathy.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• See discussion under specific diseases. • Cats may demonstrate concurrent inflammatory lesions in the liver and/or pancreas ("triaditis").

AGE-RELATED FACTORS
Some differentials more likely in younger individuals (i.e., intestinal parasitism vs. neoplasia).

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Counsel clients about breeding and monitoring for appearance of other diseases.

SYNONYMS
None

SEE ALSO
• Colitis, Histiocytic Ulcerative.
• Diarrhea, Chronic—Cats.
• Diarrhea, Chronic—Dogs.
• Food Reactions (Gastrointestinal), Adverse.
• Gastroenteritis, Eosinophilic.
• Immunoproliferative Enteropathy of Basenjis.
• Protein-Losing Enteropathy.
• Small Intestinal Dysbiosis.
• Vomiting, Chronic.

ABBREVIATIONS
• ARD = antibiotic-responsive diarrhea. • cPL = canine pancreatic lipase. • FeLV = feline leukemia virus. • FIV = feline immunodeficiency virus. • fPL = feline pancreatic lipase. • GI = gastrointestinal. • IBD = inflammatory bowel disease. • PLE = protein-losing enteropathy. • TLI = trypsin-like immunoreactivity.

INFLUENZA

BASICS

OVERVIEW

• An acute to subacute contagious viral disease with an almost exclusive respiratory manifestation caused by influenza viruses.
• Canine influenza viruses (CIV) are influenza type A viruses that developed from equine (H3N8, USA) or avian (H3N2; East Asia) influenza viruses. Although the viruses originated in other species, the H3 viruses are considered "canine influenza viruses" as they are now transmissible dog to dog. Influenza H7N2 is an avian influenza A virus that was documented in shelter cats. H1N1 human pandemic influenza is also capable of infecting dogs and cats, but there is no evidence of transmission.
• Natural route of infection is airborne particles or oral contact with contaminated surfaces. Replication of the virus appears to be restricted to epithelial cells of the upper and lower airways, with possible involvement of alveolar macrophages. Antibody response detectable by 8 days post infection and titers remain detectable for >1 year. Protective immune responses have not been defined.
• H3N8 CIV activity was first detected in racing greyhounds in the United States in 2004 and has subsequently been identified in dogs across the country.
• H3N2 CIV was detected in South Korea in 2007, but existed in China several years earlier; genetic lineage is of avian origin and probably arose in East Asia.
• H3N2 CIV infection causes more severe clinical signs, is more easily transmissible, and is shed for a longer period than H3N8 CIV.

SIGNALMENT

• Natural infections of H3N8 CIV currently limited to dogs; H3N2 virus is capable of infecting dogs and cats; H7N2 has infected shelter cats.
• All dogs and cats are susceptible to infection; there are no known age, breed, or sex restrictions on susceptibility.

SIGNS

• 60–80% of infected dogs develop clinical signs.
• Incubation period 2–4 days post infection.
• Modest febrile response 39.4–40 °C (103–104 °F) 3–6 days post infection.
• Clear nasal discharge, which can progress to thick, mucoid discharge, most frequently caused by secondary bacterial colonization.
• More severe form of disease shows higher body temperatures with development of pneumonia and tachypnea 6–10 days post infection.
• Many dogs develop a cough that can last for several weeks.

CAUSES & RISK FACTORS

• Respiratory infection caused by influenza viruses.
• Most cases have a history of group housing in kennels, day care centers, and rescue shelters, or contact with animals that have recently been in group housing or social settings such as dog shows.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• On an individual basis, early signs of influenza are indistinguishable from signs of kennel cough complex.
• Distinction from typical respiratory pathogens of dogs is found in group settings in which 60–80% of dogs can show clinical signs.
• Later in disease course—pneumonia may develop with or without secondary bacterial infections.

CBC/BIOCHEMISTRY/URINALYSIS

• Generally unremarkable.
• CBC may reflect stress initially, then bacterial pneumonia later in disease (leukocytosis, left shift).

OTHER LABORATORY TESTS

N/A

DIAGNOSTIC PROCEDURES

• Matrix gene reverse transcriptase polymerase chain reaction (RT-PCR) test—most reliable and preferred test; can detect agent in acute phase of disease (1–7 days post onset of clinical signs) in nasal swab.
• Viral isolation—possible early (-first 3 days) in infection.
  ◦ PCR and viral isolation can be negative if collected too late in infection.
  ◦ Serologic tests for H3N8 will not detect H3N2 and vice versa; must test for each separately.
• Hemagglutination inhibition test—preferred serologic test; acute and convalescent titers optimal; since most dogs have no circulating CIV antibodies, antibodies detected in serum more than 7 days post onset of clinical signs determine exposure to CIV.
• Antigen-capture ELISA tests gave unacceptable levels of false negatives with H3N8 infections, but higher viral loads with H3N2 give acceptable results if testing done early in course of infection.

PATHOLOGIC FINDINGS

Primary lesion caused by infection is destruction of ciliated epithelial cell layer in upper airways with extension into lungs. Areas of lung consolidation can be found 6–10 days post infection.

TREATMENT

• Infected animals should be isolated to prevent infection of other animals.
• Contagious period for H3N2 CIV extends approximately 2 weeks after onset of clinical signs.
• Continued coughing of affected animal is not a sign of virus shedding.
• Strongly recommend treating uncomplicated cases as outpatients to prevent hospital contamination.
• Only hospitalize those with pneumonia that require IV fluid or oxygen support.
• Enforced rest—for at least 14–21 days (uncomplicated cases); 2 months in cases of pneumonia.

MEDICATIONS

• Antiviral drugs have not been tested for efficacy.
• Antibiotics to control secondary bacterial infections recommended if fever, lethargy, or inappetence accompany mucopurulent nasal discharge—amoxicillin, amoxicillin–clavulanic acid, and doxycycline are empiric first-line options for mild cases.
• Clinical pneumonia—first-line recommendations include parenteral administration of fluoroquinolone and penicillin (ampicillin) or clindamycin initially until antimicrobial culture and sensitivity available.
  ◦ Resistant bacteria—important to culture and establish bacterial sensitivity; consider inherent resistance of Mycoplasma to penicillins and cephalosporins; for organisms resistant to first-choice antibiotic therapies above, consider aminoglycosides (gentamicin or amikacin, contraindicated in animals with renal dysfunction, dehydration), cephalosporins (cephalexin, cefazolin, cefadroxil, cefoxitin, cefovecin); see Suggested Reading.
  ◦ In absence of controlled studies on efficacy, inhalational antimicrobial therapy not recommended.
• In animals treated for pneumonia—recheck patient and radiographs after 10–14 days to decide whether continued antibiotic therapy indicated; optimal duration of therapy for pneumonia unknown; shorter courses of antibiotics (as used in humans with pneumonia) than traditionally recommended 4–6 weeks may be effective.
• Cough suppressants (butorphanol or hydrocodone bitartrate)—often effective in suppressing dry nonproductive cough; cough suppression counterproductive in animals with pneumonia.
• Bronchodilators (theophylline or aminophylline)—may relieve wheezing.

FOLLOW-UP

• If infection established in a kennel, evacuate kennel for 1–2 weeks and disinfect with sodium hypochlorite (1 : 30 dilution), chlorhexidine, or benzalkonium; influenza virus can live on hard surfaces for up to 24 hours.

INFLUENZA (CONTINUED)

• Uncomplicated cases should resolve within 10–14 days; if patient continues to cough beyond 14 days, further diagnostics indicated.
• Mortality rate highly variable and likely linked to degree of secondary bacterial infection, strain of virus, and intensity of veterinary care.
• Currently there are licensed influenza vaccines for use in dogs that cover H3N8, H3N2, or both. There are no licensed vaccines for cats.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Risk thought to be low; however, influenza viruses mutate rapidly and outbreaks in dogs and cats monitored for this potential; one person documented to develop infection with H7N2 working with cats in shelter outbreak.
• Cats can be experimentally infected with H3N8 CIV; H7N2 virus was isolated from cats in an animal shelter.
• H3N2 virus can also infect ferrets, guinea pigs, and mice.

ABBREVIATIONS

• CIV = canine influenza virus.
• RT-PCR = reverse transcriptase polymerase chain reaction.

INSOLUBLE OXALATE PLANT TOXICOSIS

BASICS

OVERVIEW

- Over 200 species of plants contain insoluble oxalate crystals.
- Most houseplants are in the Araceae family; many are found in homes and offices.
- Common names vary; scientific names must be used for accurate identification.
- Insoluble oxalate crystals are not absorbed systemically, and signs are often self-limiting.
- Signs are generally limited to irritation of oral mucosa; other signs occur more rarely.
- *Dieffenbachia* spp. (dumbcane) ingestion by dogs and cats has been associated with more serious outcomes, including death.
- Cats ingesting *Philodendron* spp. may exhibit more severe clinical signs.
- Common plants include:
  - *Aglaonema commutatum* (Chinese evergreen).
  - *Anthurium* spp. (flamingo flower).
  - *Arisaema amurense* (Jack-in-the-pulpit).
  - *Dieffenbachia* spp. (dumbcane).
  - *Epipremnum* spp. (pothos, devil's ivy, variegated philodendron).
  - *Monstera deliciosa* (fruit salad plant).
  - *Philodendron* spp. (sweetheart vine, fiddle leaf).
  - *Schefflera actionphylla* (umbrella plant).
  - *Spathiphyllum* spp. (peace lily).
  - *Syngonium* spp. (arrowhead vine).
  - *Zantedeschia* spp. (calla lily).

SIGNALMENT

- Indoor cats and dogs primarily, although pets may be exposed by houseplants moved outside during summer months.
- Dogs tend to chew and destroy the entire plant; cats nibble on leaves.
- May occur more often in younger pets that are bored or inquisitive.

SIGNS

- Rapid onset, often within minutes of exposure.
- Oral—vocalization, pawing at muzzle, head shaking, hypersalivation, edema of lips, tongue or pharynx; rarely gagging, choking, and vomiting.
- Ocular—pawing at eyes, photophobia, conjunctival swelling.
- Respiratory—*rarely*, dyspnea from pharyngeal swelling and inflammation.

CAUSES & RISK FACTORS

- Plants in environment.
- Insoluble oxalate crystals are arranged in bundles called raphides that are contained in idioblasts within plant stems and leaves.
- Chewing or biting on plant material releases crystals from stems and leaves until idioblast is emptied.
- Crystals act as miniature pins or mechanical irritants to mucous membranes, but are not absorbed systemically.
- Potential for chemical irritation with release of prostaglandins, histamine, proteolytic enzymes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Caustic agents (alkalis and acids in household products; drain cleaners).
- Other agents causing oral irritation (capsaicin, detergents, topical spot-on flea and tick products.
- Quaternary ammonium compounds (>2% in cats).
- Stinging nettle (*Urtica dioica*) ingestion.
- Systemic disease-causing oral lesions.

CBC/BIOCHEMISTRY/URINALYSIS

- Rarely performed unless prolonged vomiting.
- CBC, electrolytes, serum chemistry.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Exam of oral cavity including visualization of pharynx.
- Fluorescein ophthalmic stain if ocular signs are present.

PATHOLOGIC FINDINGS

- Death rarely occurs.
- Few cases with severe erosive, ulcerative glossitis; oropharyngeal edema.

TREATMENT

- Generally limited to supportive care.
- IV fluids if dehydrated from excessive salivation or vomiting.
- Oral—irrigation of oral cavity with copious amounts of cool fluids; small amounts of calcium-containing product (milk, yogurt, etc.) to bind oxalate crystals.
- Ocular—lavage for 15 min with tepid water.
- Respiratory—endotracheal tube or temporary tracheostomy if dyspnea severe.

MEDICATIONS

No specific antidote available.

DRUG(S) OF CHOICE

- Antiemetics as needed:
  - Maropitant 1 mg/kg SC/PO/IV q24h.
  - Ondansetron 0.1–1mg/kg IV q8–12h.
- GI protectants as needed:
  - H2 blockers (famotidine, ranitidine).
  - Omeprazole 0.5–1 mg/kg PO daily.
  - Sucralfate 0.25–1 g PO q8h.
- Pain medication as needed:
  - Butorphanol 0.1–0.5 mg/kg IV/IM/SC.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Corticosteroids—use is controversial, but dexamethasone phosphate 0.125–0.5 mg/kg IV/IM/SC may be useful in severe inflammatory conditions.

FOLLOW-UP

PATIENT MONITORING

Monitor for signs of dyspnea and respiratory difficulty.

PREVENTION/AVOIDANCE

Identify plants in household and keep away from pets.

POSSIBLE COMPLICATIONS

- Corneal abrasion or ulcer from pawing at eyes.
- Erosive ulcers in mouth and gastrointestinal tract.
- Pharyngeal edema and death (rare).

EXPECTED COURSE AND PROGNOSIS

- Most signs are mild to moderate and of short duration, generally lasting 2–4 hours; less often signs last 12–24 hours.
- Excellent prognosis as signs are generally self-limiting.

MISCELLANEOUS

AGE-RELATED FACTORS

Young pets are more frequently represented; likely due to boredom and inquisitive nature.

INSULINOMA

BASICS

DEFINITION
Functional pancreatic islet beta-cell tumor that secretes insulin, independent of systemic glucose concentration.

PATHOPHYSIOLOGY
- Excessive insulin secretion leads to glucose uptake and use by insulin-sensitive tissues and reduced hepatic production of glucose, resulting in hypoglycemia and associated clinical signs.
- Insulinomas can secrete other hormones, such as somatostatin, glucagon, gastrin, pancreatic polypeptide, insulin-like growth factor 1 (somatomedin), and serotonin; however, clinical signs are typically associated with hypoglycemia.
- Nervous system abnormalities are typically the first clinical signs seen due to the brain's dependence on glucose for energy and lack of glycogen stores.
- Hypoglycemia stimulates release of counter-regulatory hormones (e.g., glucocorticoids, growth hormone, catecholamines, and glucagon) that cause adrenal stimulation in an effort to raise plasma glucose levels.
- Release of counter-regulatory hormones and adrenal stimulation can lead to muscle tremors, restlessness, nervousness, and hunger.

SYSTEMS AFFECTED
- Nervous—seizures, disorientation, abnormal behavior, collapse, polyneuropathy/peripheral neuropathy, posterior paresis, ataxia.
- Musculoskeletal—weakness, muscle fasciculations.
- Gastrointestinal—variable appetite and weight.
- Urinary—polyuria, polydipsia.

INCIDENCE/PREVALENCE
- Dogs—uncommon.
- Cats—rare.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- Dogs—Labrador retrievers, standard poodles, boxers, fox terriers, Irish setters, German shepherd dogs, golden retrievers, collies.
- Cats—possibly Siamese.

Mean Age and Range
- Dogs—middle-aged to old; mean: 10 years, range: 3–14 years.
- Cats—mean: 15 years, range: 12–17 years.

SIGNS

General Comments
- Often episodic and vague.
- May be related to fasting, excitement, exercise, and/or eating.

Historical Findings
- Dogs—generalized or focal seizures; historical findings may include weakness, posterior paresis, collapse, muscle fasciculations, bizarre behavior, lethargy and depression, ataxia, polyphagia or inappetance, weight gain or loss, polyuria and polydipsia, and exercise intolerance.
- Cats—seizures, ataxia, muscle fasciculations, weakness, lethargy and depression, anorexia, weight loss, and polydipsia.

Physical Examination Findings
- Usually within normal limits unless in a hypoglycemic crisis.
- Obesity may be noted.
- Polyneuropathy is seen rarely in dogs (paresis to paralysis, muscle atrophy, and/or hyporeflexia).

CAUSES
Many dogs and cats have single insulin-producing beta-islet cell carcinoma or adenocarcinoma of the pancreas, but 50% or more will develop or present with metastasis.

RISK FACTORS
For hypoglycemic episodes—fasting, excitement, exercise, and eating.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Extrapancreatic tumor hypoglycemia—paraneoplastic hypoglycemia has been documented in dogs with tumors including leiomyosarcoma and hepatocellular, mammary, and pulmonary carcinomas, among others; these tumors secrete insulin or insulin-like substances.
- Rule out causes such as insulin overdose, neonatal/toy breed hypoglycemia, ingestion of oral hypoglycemic agents, hepatic failure, sepsis, hypoadrenocorticism, hunting dog (exertional) hypoglycemia, and glycogen storage diseases.
- Seizures and collapse—consider a variety of differentials including cardiovascular, metabolic, and neurologic disease.

CBC/BIOCHEMISTRY/URINALYSIS
- Often within normal limits except for hypoglycemia (<65–70 mg/dL in majority of patients).
- Normoglycemia does not rule out the presence of an insulinoma; a small percentage of patients may be intermittently normoglycemic, which is thought to be due to counter-regulatory hormone production (e.g., epinephrine, glucocorticoids, glucagon).

OTHER LABORATORY TESTS

Simultaneous Fasting Glucose and Insulin Determinations
- Paired glucose and insulin can often be measured without fasting, since hypoglycemia is commonly identified at presentation.
- If a patient presents for hypoglycemia, obtain additional serum for possible insulin level evaluation prior to administering exogenous dextrose.
- If necessary, patients may be fasted (and hospitalized and monitored closely due to the risk for hypoglycemia), and serial (q1–2h) blood samples collected; when serum glucose drops below 60 mg/dL, that sample should be analyzed for simultaneous glucose and insulin concentrations.
  - Elevated insulin concentration (>20 µU/mL) in the face of hypoglycemia—insulinoma highly likely.
  - Insulin concentration within reference range (5–20 µU/mL) in the face of hypoglycemia—insulinoma probable
  - Any insulin concentration within reference range with concurrent hypoglycemia is abnormal; if insulin concentration below normal limits with hypoglycemia then an insulinoma is unlikely, but repeated sampling may be necessary.
- Formulas utilizing simultaneous hypoglycemic glucose and insulin concentrations such as the insulin : glucose ratio and the amended insulin : glucose ratio have poor specificity.

IMAGING
- Thoracic and abdominal radiography—helpful for identification of metastatic disease and/or extrapancreatic tumor-induced causes of hypoglycemia as well as some other differential diagnoses.
- Ultrasonography—30–75% of pancreatic masses are clearly identified through ultrasonography; can be used for screening for metastatic disease, but relatively insensitive.
- CT—superior technique for detection of primary insulinomas in dogs; however, false-positive lymph node metastases are common.
- Scintigraphy and single proton emission computed tomography (SPECT)—intermittently successful in detecting insulinomas.
- Intraoperative ultrasound—widely used for gross occult tumor detection in human insulinomas; rarely reported in veterinary medicine.

DIAGNOSTIC PROCEDURES
Exploratory laparotomy—indicated when insulinoma is suspected based on the aforementioned physical, biochemical, and/or imaging results, but imaging is inconclusive.

PATHOLOGIC FINDINGS
- Histopathologically, primary pancreatic insulinomas in dogs are either beta-islet cell carcinomas or adenocarcinomas and occasionally adenomas, although dogs with adenomas may subsequently develop metastasis.
- In cats, most insulinomas are malignant with metastasis common.

• In both species, metastatic disease is frequently noted in the liver, mesentery, and regional lymph nodes, and appears histopathologically similar to the primary tumor.

TREATMENT

APPROPRIATE HEALTH CARE

• Hospitalize for workup and surgery.
• Outpatient if the owner declines surgery and the patient is not clinically hypoglycemic.

NURSING CARE

Close monitoring for recurrence of signs associated with hypoglycemia is indicated, especially as most hospitalized patients become refractory to glucose supplementation and require increasing dosages.

ACTIVITY

Restricted

DIET

• Feed four to six (or more) small meals a day.
• Food should be high in protein, fat, and complex carbohydrates and low in simple sugars.

CLIENT EDUCATION

Client should be educated about the signs of hypoglycemia and seek immediate attention if they occur.

SURGICAL CONSIDERATIONS

• Surgical management improves prognosis over medical therapy alone.
• Medical management is important before exploratory laparotomy; most patients respond well to frequent small feedings and corticosteroids; in refractory cases, IV fluids containing 2.5–5% dextrose and/or glucagon may be necessary.
• Objectives include confirmation of diagnosis, identification of extrapancreatic metastases or other disease, and removal of as much cancerous tissue as possible.
• At surgery, most insulinomas can be visualized and/or palpated; if a pancreatic mass cannot be found, intraoperative ultrasound may be beneficial.
• Approximately 15% of dogs have multiple primary insulinomas, so always examine the entire pancreas.
• Biopsy regional lymph nodes and carefully evaluate the liver (and other abdominal contents) with biopsy of any abnormalities; 40–50% of dogs will have metastasis; in one study, of 14 dogs suspected to have extrapancreatic metastasis from a primary pancreatic insulinoma, only 8 (57%) had histologic evidence of metastasis; therefore, the presence of what appears to be metastasis should be biopsied and not automatically lead to intraoperative euthanasia.
• Insulinoma can be classified as stage I (confined to the pancreas); stage II (regional lymph node metastasis present); or stage III (distant metastasis present).
• Postoperative complications include pancreatitis, persistent hypoglycemia secondary to incomplete removal of the primary tumor or metastatic disease, and diabetes mellitus (DM). DM is thought to occur secondary to atrophy of remaining normal beta-islet cells.

MEDICATIONS

DRUG(S) OF CHOICE

Emergency/Acute Therapy

• 50% dextrose (0.5 g/kg IV diluted 1 : 3, slowly over 1–3 min)—for emergency control of hypoglycemic episodes; once hypoglycemic signs abate, IV fluid therapy with 2.5–5% dextrose added to an isotonic crystalloid solution should be administered (dextrose may be increased to 7.5% if needed to control clinical signs, but should be administered through a central venous catheter to prevent phlebitis).
• Glucagon (1–5 ng/kg/min IV as CRI) is gluconeogenic and may be used to effect to treat clinical signs associated with severe refractory hypoglycemia, in preparation for surgery.

Long-Term Therapy

• If exploratory laparotomy is pursued and complete excision of the tumor is obtained, long-term therapy may not be needed.
• If dietary therapy is ineffective for controlling hypoglycemia, glucocorticoids (e.g., prednisone 0.25 mg/kg PO q12h, increased as necessary up to 2 mg/kg PO q12h) may be given.
• Diazoxide (Proglycem®) stimulates hepatic gluconeogenesis/glycogenolysis and inhibits insulin secretion—dosage is 5–60 mg/kg PO q12h, starting at the low end and increasing as needed; should be used in addition to dietary modifications and glucocorticoids when they become less effective for controlling clinical signs.
• Streptozotocin is a nitrosourea that semi-selectively targets pancreatic beta-cells; may be given at 500 mg/m^2 slow IV over 2h, after a 3h IV diuresis with isotonic crystalloid and followed by a 2h diuresis; this protocol may be repeated every 3 weeks until normoglycemia is achieved. Streptozotocin is emetogenic and can be hepatotoxic and/or nephrotoxic; it can also cause DM secondary to cytotoxic effects on pancreatic beta-islet cells; is currently difficult to obtain.
• The synthetic somatostatin analogues octreotide (10–20 µg SC q8–12h) or lantreotide (no determined dose in veterinary species) may be utilized to prevent hypoglycemia in dogs refractory to conventional treatments.
• Anecdotal reports of the use of toceranib phosphate (Palladia®) exist for medical management in nonsurgical cases and/or postoperative treatment in patients with metastatic disease.

CONTRAINDICATIONS

Insulin

PRECAUTIONS

• Dextrose boluses, when given alone, may precipitate further hypoglycemic crises.
• Glucocorticoids used at high dosages for prolonged periods can cause iatrogenic hyperadrenocorticism.
• Diazoxide may cause bone marrow suppression, gastrointestinal irritation, aplastic anemia, cataracts, thrombocytopenia, and tachycardia in humans.
• Streptozocin can cause emesis, hepatic failure, renal failure, DM, and pancreatitis.
• Neither diazoxide nor streptozotocin has been evaluated in cats.
• Glucagon is indicated for short-term therapy to stabilize refractory patients, but is not a definitive or long-term therapy.

POSSIBLE INTERACTIONS

Hydrochlorothiazide can potentiate diazoxide.

FOLLOW-UP

PATIENT MONITORING

• Teach client to monitor for return and/or progression of signs of hypoglycemia.
• Serum glucose determinations are important for monitoring for return and/or progression of insulinoma-associated hypoglycemia.
• Abdominal ultrasound may be used for postoperative long-term monitoring.

POSSIBLE COMPLICATIONS

Recurrent or progressive episodes of hypoglycemia.

EXPECTED COURSE AND PROGNOSIS

• Dogs that undergo exploratory laparotomy are more likely to become and remain euglycemic and have longer survivals than dogs managed by medical means.
• Even in the presence of local metastatic disease, any reduction of tumor burden is likely to improve glycemic control with medical therapies; the median length of euglycemic control after surgery is inversely correlated with the stage of disease and varies from 14 months for dogs without evidence of metastasis to 2–3 months for dogs with nodal and/or distant metastasis.
• Median survival time is inversely correlated with the stage of disease and varies from 16–19 months (range: 2–60 months) for dogs without evidence of metastasis to 7–9 months in dogs with evidence of nodal and/or distant metastasis; more recent studies have documented even longer median survival times of

INSULINOMA (CONTINUED)

17–18 months for all dogs with insulinoma and 25–42 months for those dogs undergoing surgery and surgery followed by prednisone therapy at time of relapse, respectively.
• Cats—mean survival time about 6.5 months; range: 0–32 months. Too few cases to accurately predict prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Obesity due to hyperinsulinemia.

AGE-RELATED FACTORS
Younger dogs have shorter survival times.

SYNONYMS
- Beta-cell tumor.
- Hyperinsulinism.
- Insulin-producing pancreatic tumor.
- Insulin-secreting tumor.
- Islet or beta-cell (adeno)carcinoma.
- Islet cell tumor.

INTERSTITIAL CELL TUMOR, TESTICLE

BASICS

OVERVIEW
Benign tumor of the testicle that arises from interstitial (Leydig) cells.

SIGNALMENT
- 33–50% of all testicular tumors in dogs, but rare in cats.
- Median age, 10 years.
- Boxer, German shepherd, Afghan hound, Weimaraner, Shetland sheepdog, collie, and Maltese may be at increased risk.

SIGNS
- Usually incidental finding.
- Fertility issues in breeding dogs.
- May be associated with testosterone secretion and perianal gland hyperplasia or adenomas.
- 4–20% of dogs will have more than one type of testicular tumor. Up to 50% of dogs will have bilateral tumors; only 12% of contralateral tumors will be palpable.

CAUSES & RISK FACTORS
- Generally unknown.
- Cryptorchidism—may predispose.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Sertoli cell tumor.
- Seminoma.
- Hyperadrenocorticism—with feminization.
- Hypothyroidism—with feminization.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal, unless estrogen excess causes bone marrow hypoplasia (rare).
- Various cytopenias—with estrogen excess (rare).

OTHER LABORATORY TESTS
- High serum estradiol concentration.
- Low serum testosterone concentration.
- Immunohistochemical evaluation with inhibin-α and calretinin.

IMAGING
- Testicular sonography may aid in differential diagnoses.
- Abdominal ultrasonography for retained testicles and to evaluate for concurrent malignancies.

DIAGNOSTIC PROCEDURES
N/A

TREATMENT
- Bilateral orchiectomy and scrotal ablation is the treatment of choice; exploratory laparotomy for retained testicles.
- Histopathologic examination of appropriate tissue.
- Immunohistochemistry may be necessary to identify cell of origin in some cases.

MEDICATIONS

DRUG(S) OF CHOICE
None, unless bone marrow hypoplasia induces a dangerous cytopenia.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
None required, unless bone marrow hypoplasia.

POSSIBLE COMPLICATIONS
Cytopenias caused by estrogen excess.

EXPECTED COURSE AND PROGNOSIS
Bilateral orchiectomy and scrotal ablation are often curative; cutaneous and muscle metastases have been reported.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Prostate disease—with testicular tumor.
- Perianal gland hyperplasia/adenomas.

SEE ALSO
- Seminoma.
- Sertoli Cell Tumor.

INTERVERTEBRAL DISC DISEASE—CATS

BASICS

OVERVIEW

• Disc extrusion or protrusion causing myelopathy is more common in dogs; both Hansen's type I and type II disc disease, and acute, noncompressive nucleus pulposus extrusion (ANNPE) are reported in cats. • Type I disc disease is secondary to chondroid metaplasia and mineralization of the nucleus pulposus. • Type II disc disease is secondary to fibroid degeneration and protrusion of the annulus fibrosus. • With ANNPE, normal nucleus pulposus is extruded through a tear in the dorsal annulus, resulting in a concussive or contusive injury, with minimal to no ongoing compression of the spinal cord.

SIGNALMENT

• For all reported cats with myelopathy secondary to disc disease—mean age 8.4 years, range: 1.5–17 years. • Cats with mineralized type I disc disease—mean age 7.3 years, range: 2–13 years. • Predominantly domestic breeds, several purebred (Oriental) breeds reported; rare exotic large cat (tiger) reported. • No sex predisposition.

SIGNS

• Majority of cats have thoracolumbar or lumbosacral disc disease—clinical signs confined to pelvic limbs; cervical disc disease also described, in which case all four limbs may be affected; sacrocaudal disc disease can result in urinary and/or fecal retention or incontinence, lower lumbar pain. • Signs frequently acute or peracute, but may be chronic. • Paresis/paralysis. • Ataxia. • Gait abnormality, lameness, reluctance to jump. • Spinal/back pain. • Urinary/fecal incontinence. • Abnormalities of tail carriage or tone. • Loss of pain perception (if severe lesion). • Hypoventilation (if severe cervical lesion).

CAUSES & RISK FACTORS

• Majority of cats reported had type I disc degeneration, with extrusion of mineralized nucleus pulposus into vertebral canal resulting in spinal cord trauma and compression. • Unlike dogs, where chondrodystrophic breeds (e.g., dachshunds) predisposed to type I disc disease and subsequent extrusion, no obvious risk factors apparent in cats. • Most cats reported had clinically significant disc protrusions or extrusions between T11 and S1; similar to dogs, presence of the intercapital ligament from T1 to T10 may make disc protrusions in that region less likely.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Trauma. • Vascular—ischemic neuromyopathy ("saddle thrombus"), ischemic myelopathy. • Neoplasia, especially lymphoma. • Vascular—ischemia to spinal cord. • Infectious—feline infectious peritonitis (FIP), *Cryptococcus*, etc.

CBC/BIOCHEMISTRY/URINALYSIS

USUALLY NORMAL.

IMAGING

• Vertebral column radiographs—narrowed disc space(s), mineralized discs in situ, mineralized disc material within vertebral canal or overlying intervertebral foraminae. • Myelography—extradural compressive lesion at affected disc. • CT—extradural compression; mineralization of compressive material may be apparent. • MRI—T2 hyperintensity within injured cord; mineralized disc material appears hypointense on all imaging sequences; extradural compression may be apparent; with ANNPE, decreased T2 intensity of nucleus pulposus of likely extruded disc, hyperintensity in overlying spinal cord with minimal to no compressive epidural material.

DIAGNOSTIC PROCEDURES

• Cerebrospinal fluid—unremarkable or contaminated with blood in most cats; neutrophilic pleocytosis noted in three cats. • Histopathology of material removed at surgery—consistent with degenerative disc material (type I or II).

TREATMENT

• Surgical spinal cord decompression likely most effective treatment for compressive disc disease; cats with noncompressive disc extrusions had successful outcomes with physical rehabilitation alone. • Risks of spinal surgery should be discussed with owner—hemorrhage, iatrogenic injury to spinal cord, instability. • Hemilaminectomy, ventral slot, lateral corpectomy, and lumbosacral dorsal laminectomy surgeries are described in the cat. • Postoperative care—good recumbent patient care, pain management, bladder management if incontinent cat (indwelling urinary catheter or manual expression), and appropriate physical therapy. • Fenestration of adjacent mineralized discs should be considered to avoid recurrence. • Medical management (cage rest, pain management) may be considered in ambulatory cats, but more aggressive diagnostics and treatment should be considered in nonambulatory cats and those with progressive neurologic signs.

MEDICATIONS

DRUG(S) OF CHOICE

• Pain management, preferably opiates, if cat tolerates them. • Efficacy of corticosteroids in feline disc disease has not been evaluated.

FOLLOW-UP

• Repeat neurologic examinations (at least 1–2 times/day) during hospitalization to monitor postoperative and medically managed patients for improvement or decline in neurologic status. • Strict cage rest for medically managed and postoperative patients for 4–6 weeks, then gradual increase in activity and physical therapy, as needed. • Unknown whether long-term activity restriction beneficial. • Because disc disease uncommon in cats, possible recurrence rate unknown, but in one cat that recovered well after hemilaminectomy, additional mineralized disc extrusion caused paraplegia and necessitated second surgery (unpublished data). • A few cats had persistent urinary retention in spite of good recovery of ambulation, requiring routine bladder expression by owner. • Majority of cats managed surgically (even two without pain perception) had good to excellent outcome.

MISCELLANEOUS

ABBREVIATIONS

• ANNPE = acute, noncompressive nucleus pulposus extrusion. • FIP = feline infectious peritonitis.

Suggested Reading

Rayward RM. Feline intervertebral disc disease: a review of the literature. Vet Comp Orthop Traumatol 2002, 15:137–144.

Author Marguerite F. Knipe

INTERVERTEBRAL DISC DISEASE, CERVICAL

BASICS

DEFINITION
Degeneration of the cervical intervertebral discs that may result in protrusion or extrusion of disc material into the spinal canal. The protruded or extruded disc material causes spinal cord compression (myelopathy) and/or nerve root compression (radiculopathy), as well as concussive spinal cord injury in varying degrees.

PATHOPHYSIOLOGY
- Traditionally classified as acute disc herniation (Hansen type I disc) or chronic disc protrusion (Hansen type II disc); other types include extrusion of apparently healthy, hydrated nucleus pulposus with or without spinal cord compression, the latter termed acute noncompressive nucleus pulposus extrusion (ANNPE).
- Hansen type I—degeneration of the nucleus pulposus and acute rupture of the annulus fibrosus with extrusion of the nucleus pulposus into the spinal canal.
- Hansen type II—fibrinoid degeneration and protrusion of the dorsal annulus fibrosus into the vertebral canal (can involve a dynamic component).
- Disc extrusion or protrusion into the spinal canal causes focal compression of the spinal cord (myelopathy) and/or focal compression of a nerve root (radiculopathy) in addition to a variable degree of contusion injury; ANNPE primarily results in a contusion injury.
- Consequences of spinal cord compression are ischemia and demyelination.
- Consequences of spinal cord contusion include axonal and vascular injury as well as secondary cellular injury.
- Disc extrusion may be secondary to trauma, but this rarely occurs aside from those patients with hydrated disc herniations.
- Surgical fusion of cervical vertebrae may alter the biomechanics of adjacent vertebral bodies and therefore predispose discs to protrusion or extrusion; this is termed the domino effect.

SYSTEMS AFFECTED
Nervous system—either focal myelopathy or focal radiculopathy.

GENETICS
- Not known.
- Chondrodystrophic breeds (e.g., dachshund) are most commonly affected with Hansen type I disc extrusion.
- Large-breed dogs are most commonly affected with Hansen type II disc extrusion.

SIGNALMENT

Species
Dogs, rarely cats.

Breed Predisposition
- Hansen type I—dachshund, poodle, beagle, cocker spaniel, French bulldog, shih tzu; chondrodystrophic breeds.
- Hansen type II—Doberman pinscher, Labrador retriever.

Mean Age and Range
- Hansen type I—3–6 years of age.
- Hansen type II—8–10 years of age.

Predominant Sex
None recognized.

SIGNS
- Severity of clinical signs and spinal cord injury is dependent on several factors, including the rate and volume of disc protrusion or extrusion, spinal cord diameter relative to vertebral canal diameter, and the velocity of disc material that is extruded.
- Herniation in the cervical region can result in fewer neurologic deficits compared to similar lesions in the thoracolumbar region, because the spinal canal area is greater and can accommodate more disc material before spinal cord compression.

Historical Findings
- Neck pain—most common owner complaint.
- Stiff, stilted gait, lameness, or reluctance to move the head and neck.
- Lowered head stance and muscle spasms of the head, neck, and shoulder.
- Inability to rise or falling forward frequently.

Physical Examination Findings
- Neck pain—elicited upon slow manipulation of the neck or by deep palpation of the cervical muscles.
- Apparent forelimb lameness or nerve root signature (e.g., a thoracic limb that knuckles, appears lame, or is held in partial flexion).
- Paresis with or without general proprioceptive deficits involving one or both thoracic and pelvic limbs may be present.
- Pelvic limb paresis may be more severe than thoracic limb paresis.
- Pelvic limb spinal reflexes may be normal to exaggerated.
- Thoracic limb spinal reflexes may be normal to exaggerated when lesions are located in the C1–C6 spinal cord segment, and may be normal to decreased when the C6–T2 spinal cord segment is affected, although this finding is not reliable in some patients.
- Severity of clinical signs and degree of compression are not always correlated.
- Bladder function may be upper motor neuron in nature or normal.

CAUSES
- Degeneration of the intervertebral disc material and subsequent herniation or protrusion.
- Trauma may lead to extrusion of healthy material or otherwise degenerative material.

RISK FACTORS
Obesity and repeated traumatic events in those breeds predisposed to intervertebral disc disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Neoplasia.
- Atlantoaxial instability.
- Spinal fracture/luxation.
- Discospondylitis.
- Meningitis.
- Fibrocartilaginous embolism.
- Cervical vertebral instability.
- Systemic illness—hypoadrenocorticism, hypothyroidism.
- Spondylomyelopathy.

CBC/BIOCHEMISTRY/URINALYSIS
Often performed in anticipation of medication administration, general anesthesia, and/or surgery.

OTHER LABORATORY TESTS
- Cerebrospinal fluid (CSF) analysis—performed under general anesthesia (prior to myelography if performed).
- CSF analysis reveals nonspecific changes such as mild to moderate elevation in protein levels and mild to moderate pleocytosis, which is more pronounced in Hansen type I disc extrusion.
- Electromyography may be useful if the underlying cause is associated with denervation.

IMAGING

Cross-sectional Imaging
- MRI and CT are most sensitive for diagnosis of cervical intervertebral disc disease and intervertebral disc herniation (IVDH) as well as for surgical planning.
- MRI is the best available method for early recognition of intervertebral disc degeneration (IVDD) in dogs and is capable of the most complete evaluation of the spinal cord parenchyma.
- CT is also useful in diagnosis of spinal cord compression, especially by degenerative disc material; the spinal cord parenchyma is not as well assessed with this modality compared with MRI.

Cervical Spinal Radiography
- Well-positioned lateral and ventrodorsal survey radiographs of the cervical spine aid in excluding other differentials (i.e., discospondylitis, fracture/luxation, atlantoaxial instability, or lytic vertebrae suggestive of a bone tumor), but are not reliable for many patients with IVDH.
- Classic findings include narrowed intervertebral disc space or disc space wedging, collapse of the articular facets, or calcified disc material present in the

INTERVERTEBRAL DISC DISEASE, CERVICAL (CONTINUED)

intervertebral foramen or in the spinal canal, although many of these findings can be seen without clinical signs, especially in over-represented breeds.
• Hansen type II disc disease may be associated with spondylosis deformans.

Myelography

• Survey cervical radiographs may be misleading; therefore, myelography is more sensitive compared to survey radiographs, although cross-sectional imaging has replaced this modality in most practices.
• Lateral radiographs reveal dorsal deviation of the ventral contrast column over the intervertebral disc space consistent with extradural compression; intraforaminal or dorsolateral disc herniation is best seen on an oblique views.
• Acute cases with spinal cord swelling can cause blockage of contrast material and prevent it from flowing past the obstruction, limiting the diagnostic capabilities of the image.

DIAGNOSTIC PROCEDURES

CSF analysis.

PATHOLOGIC FINDINGS

Gross Findings

• Hansen type I disc—white extruded disc material that has a granular consistency and is usually easily removed from the spinal canal.
• Hansen type II disc—firm protrusion of the dorsal annulus fibrosus that is adherent to the floor of the spinal canal and to the dura of the spinal cord; type II discs are much more difficult to remove from the spinal canal.
• Spinal cord—in acute disc extrusion the spinal cord may appear bruised or swollen or may appear grossly normal; in chronic disc protrusion, the spinal cord may appear to be atrophied but is often normal in appearance.

Histopathologic Findings

• Hansen type I disc—shifting concentration of glycosaminoglycans, loss of water and proteoglycan content, and increased collagen content; the disc becomes more cartilaginous and undergoes dystrophic calcification.
• Hansen type II disc—a gradual fibroid metaplasia leaves the disc with increased glycosaminoglycan levels and lower collagen content; the nucleus does not undergo cartilaginous metaplasia.
• Spinal cord—dependent on the severity of the disease and type of disc disease; Hansen type II: demyelination and gliosis are seen; Hansen type I: hemorrhage and edema can be seen; with severe disease, myelomalacia can be observed.

TREATMENT

APPROPRIATE HEALTH CARE

• Conservative or surgical management dependent on patient's history and presenting neurologic status.
• In general, conservative management can be considered with a gradual onset of clinical signs or clinical signs that are limited to hyperpathia or mild ataxia.
• Surgical management is often indicated in patients with repeated episodes of neck pain, severe neck pain and neurologic deficits, or a lack of response to conservative management.
• Patients with hydrated intervertebral disc herniations may perform similarly with conservative and surgical treatment.
• ANNPE is treated conservatively as there is no compression to address surgically.

NURSING CARE

• Level of nursing care needed depends on the severity of the injury; if unable to be cared for at home, patients should be monitored as inpatients.
• Minimal manipulation of the head and neck to avoid worsening discomfort.
• Urination—monitor patients for complete emptying of the bladder; patients may need to have bladder manually expressed or intermittent bladder catheterization; in some cases, indwelling urinary catheter may need to be placed.
• Defecation—patients typically defecate normally, although frequent cleaning and management of any soft stool are important.
• Recumbent patients—should be kept on a well-padded mat and turned frequently (often every 4 hours); should be checked for pressure sores over bony prominences; should be diligently cleaned and kept dry.
• Physical therapy—passive range of motion of all joints should be performed as often as possible to prevent severe muscle atrophy, especially in patients with minimal voluntary motor ability; hydrotherapy can be considered in tetraparetic patients as well.

ACTIVITY

• Activity should be very limited; no running or jumping, and confined to a crate-sized space; when patients are being walked, a harness should be used instead of a collar.
• With conservative or postoperative management, patients should be strictly confined to cage rest for 4 weeks, followed by a gradual return to normal activity over the course of another 4 weeks.

DIET

For obese patients, a decrease in caloric intake should be instituted.

CLIENT EDUCATION

• Appropriate expectations for clinical improvement or signs of worsening should be discussed.
• Confinement is very important for recovery.
• Weight loss if the animal is obese.

SURGICAL CONSIDERATIONS

• The goal of surgery is to remove disc material from the spinal canal and therefore decompress the spinal cord and/or nerve root.
• Surgery usually provides rapid pain relief and significantly improved motor function.
• A ventral cervical slot is the most common surgical approach for the removal of disc material; disc material that has extruded dorsolaterally into the intervertebral foramen or dorsally is removed via a lateral approach or through a dorsal laminectomy.
• Fenestration alone for dogs with neck pain usually does not resolve clinical signs and is no longer recommended.

MEDICATIONS

DRUG(S) OF CHOICE

• Anti-inflammatory therapy (low-dose glucocorticoid or nonsteroidal anti-inflammatory drugs [NSAIDs]) is often beneficial in order to decrease the pain in animals that are being treated conservatively as well as those recovering from surgery; use of high-dose glucocorticoids is not well supported by the literature and is generally not recommended.
• Analgesic medications such as gabapentin and muscle relaxants such as methocarbamol can also be used in conjunction with anti-inflammatories to improve pain control in both conservative as well as surgical treatment.

CONTRAINDICATIONS

Systemic status should be considered when choosing medications.

PRECAUTIONS

Anti-inflammatories or analgesic medications given to animals without simultaneous strict cage confinement could exacerbate disc extrusion by encouraging activity.

POSSIBLE INTERACTIONS

Using glucocorticoids with NSAIDs can cause severe gastrointestinal irritation and possibly intestinal perforation.

FOLLOW-UP

PATIENT MONITORING

• Weekly evaluations should be performed until resolution of clinical signs or until clinical progress plateaus.
• All patients should be fitted with a harness, and neck collars should be avoided.

PREVENTION/AVOIDANCE

• Inherent in particular breeds.
• Keeping patients at an ideal weight may help.

POSSIBLE COMPLICATIONS

• Complications are uncommon.
• Conservative management—continued neck pain, deteriorating motor status.
• Surgical management—hemorrhage, infection, neurologic deterioration,

respiratory compromise, subluxation/luxation of vertebral bodies, collapse of intervertebral disc space, and foraminal collapse.

EXPECTED COURSE AND PROGNOSIS

- Prognosis for patients treated surgically or conservatively depends on neurologic signs at the time of presentation; lack of nociception leads to a poor prognosis for recovery of function long term (<50%) and duration of clinical signs beyond days likely worsens the prognosis.
- Prognosis is generally favorable for most patients; surgical treatment often leads to rapid improvement in pain control, especially in patients undergoing a ventral slot procedure.
- Some patients treated conservatively have recurrence of disease or deterioration and may require surgical intervention.
- Patients who experience IVDH may be predisposed to IVDH at other sites in the future due to the underlying pathology (IVDD).

MISCELLANEOUS

ASSOCIATED CONDITIONS

Animals predisposed to cervical disc disease are also the same breeds that are predisposed to thoracolumbar disc disease.

SEE ALSO

Intervertebral Disc Disease, Thoracolumbar.

ABBREVIATIONS

- ANNPE = acute noncompressive nucleus pulposus extrusion.
- CSF = cerebrospinal fluid.
- IVDD = intervertebral disc degeneration.
- IVDH = intervertebral disc herniation.
- NSAID = nonsteroidal anti-inflammatory drug.

I

INTERVERTEBRAL DISC DISEASE, THORACOLUMBAR

BASICS

DEFINITION

Intervertebral disc disease (IVDD) is an acute traumatic or chronic degenerative condition that causes loss of normal neurologic function to the pelvic limbs, bladder, and anal sphincter. Intervertebral discs chronically degenerate by loss of water, cellular necrosis, and dystrophic calcification. In the chronic condition, biomechanical properties of the disc deteriorate, and subsequently protrusion (Hansen type II) or extrusion (Hansen type I) of disc material occurs.

PATHOPHYSIOLOGY

• Intervertebral disc degeneration is initiated by one or more factors including trauma, chronic overload, decreased spinal mobility, age-related deterioration in collagen and cartilage, and hypermobility. • Hansen type I refers to acute extrusion of nucleus pulposus through the annulus fibrosis into the vertebral canal; Hansen type I lesions typically occur in chondrodystrophic dogs, but may occur in larger nonchondrodystrophic dogs as well; onset of neurologic signs is usually acute and often severe; acute disc extrusion results in extruded material causing direct trauma to the spinal cord and residual disc mass leading to extradural spinal cord compression; trauma and spinal cord compression results in ischemia and spinal cord changes that vary from mild demyelination to necrosis of both gray and white matter; events at the cellular level include release of vasoactive substances, increased intracellular calcium, and increased free radical formation and lipid peroxides. • Hansen type II lesions involve gradual protrusion (bulging) of the dorsal annular fibers into the vertebral canal associated with fibroid degeneration of the disc; Hansen type II lesions typically occur in nonchondrodystrophic dogs; the most common case presentation is of gradual onset of neurologic dysfunction and slow progression. • Hansen type III injuries occur when the nucleus pulposus herniates with such force as to enter the spinal cord by penetration of the dura; Hansen type III injuries are rare, but carry a poor prognosis because they are commonly associated with subsequent myelomalacia and loss of deep pain response.• Affected animals exhibit pain due to dural irritation, nerve root impingement, or possibly discogenic (annular pain receptors) in origin. • Disc herniation is rare between T3 and T10 owing to the barrier of the intercapital ligament between dorsal annulus and spinal cord.

SYSTEMS AFFECTED

• Nervous. • Neuromuscular. • Renal/urologic (loss of voluntary urethral sphincter control). • Digestive (loss of voluntary anal sphincter control). • Musculoskeletal (muscle atrophy in chronic disease).

GENETICS

Early studies suggest a polygenetic model with no dominance or sex linkage.

INCIDENCE/PREVALENCE

• Most common neurologic dysfunction in small animals; affects 2% of the canine population. • Occurs less commonly in cats, but the exact incidence is unknown, and the disease is likely underdiagnosed or reported due to lack of suspicion as a differential diagnosis. • In specific breeds, such as dachshunds, affected prevalence as high as 20% has been reported. • Thoracolumbar disc disease comprises 85% of all disc herniations; 70% occur from T11 to L3.

SIGNALMENT

Species

Dog and occasionally cat.

Breed Predilections

• Type I—dachshund; shih tzu, Lhaso apso; Pekingese, cocker spaniel, Welsh corgi; toy and miniature poodle. • Type II—large breeds, but may occur in any breed. • Type III—active agility, racing, or working breeds; greyhound; border collie; Australian shepherd.

Mean Age and Range

• Type I—3–6 years of age. • Type II—8–10 years of age; cats: mean age of 10 years. • Type III—any age; occurs during exertion or trauma.

SIGNS

General Comments

The severity of clinical signs depends on the type of herniation, velocity of disc contact with the spinal cord, amount and duration of cord compression, location (upper motor neuron [UMN] or lower motor neuron [LMN]), and regional spinal canal/spinal cord diameter ratio (cervical vs. thoracolumbar).

Historical Findings

• Onset may be peracute or acute in chondrodystrophoid dogs (type I disease) and may occur during vigorous activity. • Larger dogs or smaller dogs with type II disease have a more insidious onset and tend to worsen with time. • Dogs with type III disease have a history of active exertion followed by sudden loss of function, or of severe traumatic origin such as vehicular trauma or racing injury.

Physical Examination Findings

• Thoracolumbar pain is a common finding in dogs; reluctant to ambulate and hunched posture; careful palpation of spinous processes and epaxial musculature produces distinct localized pain; often some degree of paraparesis with decreased or absent proprioception or decreased motor ability in the pelvic limbs. • Myotactic spinal reflexes in the pelvic limbs are exaggerated (hyperreflexive) when the lesion is between T3 and L3; reflexes are decreased (hyporeflexive) when lesion is caudal to L3. • Superficial and deep pain perception may be decreased or absent in the pelvic limbs. • Presence of deep pain sensation is the single most reliable prognostic factor for return to acceptable function; pain perception should be conscious in nature and not confused with a withdrawal reflex (local spinal reflex); in animals with diminished conscious deep pain response, observation of mydriasis or tachycardia may be useful in confirming the presence of deep pain. • Forelimb function is normal with thoracolumbar disc rupture; occasionally Schiff–Sherrington phenomena may cause increased muscle tone in the forelimbs, but this clinical sign is location related only and does not indicate a poor prognosis. • Urinary incontinence or retention is common when the lesion affects motor function. • Pain is less obvious in cats; the site of herniation is often lumbar.

CAUSES

• Chondroid or fibroid degeneration of the thoracolumbar intervertebral discs. • Acute trauma that overloads the capacity of the intervertebral disc to absorb force and ruptures the dorsal annulus. • 15% of animals with spinal fractures have been reported to have disc extrusions in addition to the fracture/luxation.

RISK FACTORS

• Type I disease most often affects chondrodystrophic breeds. • Racing and breeds used for agility competition are at risk for Type III disk disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Type I—trauma causing fracture/luxation, neoplasia, discospondylitis, fibrocartilaginous embolism; differentiated by history, survey radiography, myelography, CT, or MRI. • Type II—degenerative myelopathy, spinal neoplasia, discospondylitis, orthopedic disease; differentiated by history, radiographic modalities, and careful orthopedic and neurologic examination. • Type III—trauma causing spinal fracture or subluxation/luxation of vertebrae in the thoracolumbar region, fibrocartilaginous embolism, or Type I disk disease; differentiated by survey radiography, myelography, CT, or MRI.

(CONTINUED) # INTERVERTEBRAL DISC DISEASE, THORACOLUMBAR

CBC/BIOCHEMISTRY/URINALYSIS

• Elevation of liver enzymes is common if the patient has received previous corticosteroids for pain or neurologic disease. • Urine retention/incontinence increases risk of urinary tract infection characterized by leukocytes, protein, and bacteriuria on urinalysis.

OTHER LABORATORY TESTS

Cerebrospinal fluid (CSF) analysis performed routinely in conjunction with myelography if there is high suspicion of another disease process; may be normal, but more typically shows mild to moderate increase in protein with or without pleocytosis when IVDD occurs.

IMAGING

• Thoracolumbar spinal radiography with the patient anesthetized; unanesthetized radiographs can be used to rule out neoplasia and other processes, but can be misleading for thoracolumbar disc disease. • Survey radiographs rule out some other disease processes.
• Diagnostic radiographs taken under general anesthesia may reveal a narrowed or wedged disc space, collapsed articular facet space, and small intervertebral foramen with increased or mineralized density within the spinal canal.
• Accuracy and sensitivity of survey radiographs for determining a specific site of disc herniation are low; in conjunction with careful neurologic examination, the exact location can often be narrowed down to a small vertebral area, but the extent of herniation and pressure on the meninges from herniation of disc material may extend over more than one space.

DIAGNOSTIC PROCEDURES

• MRI is now considered the diagnostic mode of choice when available due to the noninvasive nature and superior information regarding location and extent of disease; presence of a hyperintense spinal cord lesion as long as the body of L2 on a T2-weighted image in deep-pain-negative dogs is associated with a poorer prognosis.
• CT with or without contrast is often diagnostic in chondrodystrophic dogs; dystrophic calcification of extruded material is easily visualized and lateralization can be easily determined; contrast enhancement can different disc disease from neoplastic or granulomatous processes. • Myelography performed with iohexol was previously the method of choice and is still indicated when CT or MRI is not available; the contrast agent is usually introduced at L5–L6; positive diagnosis is an extradural mass lesion causing spinal cord compression adjacent to the affected disc; spinal cord swelling may be evidenced by thinning of contrast columns over several intervertebral spaces.
• Lateralization is more consistent when determined from both oblique and dorsoventral myelogram views. • CSF analysis is an important addition when alternative causes of neuropathy are likely differential diagnoses or when imaging findings are equivocal or nondiagnostic.

PATHOLOGIC FINDINGS

Gross

• Extruded disc material (type I disease)—white to yellow and "toothpaste" consistency seen on laminectomy; if chronic, may be hardened and adhered to surrounding structures; extradural hemorrhage is usually present and mixed with extruded disc material; the ventral sinus may be ruptured and actively bleeding; subdural hemorrhage may be visible. • Protruded disc material (type II disease)—usually firm, grayish-white, and may be adherent to surrounding structures; compression of the spinal cord is apparent, but usually without evidence of recent hemorrhage or trauma visible.
• Extradural or intradural hemorrhage without or with minimal extruded disc material (type III disease); the dural membrane may be penetrated and extruded material may be present within the spinal cord parenchyma; myelomalacia may be detectable as loss of dural and parenchymal integrity at the affected site. • Spinal cord may appear normal or be swollen and discolored in acute severe disease.

Histopathologic

• Degenerated discs have decreased amounts of proteoglycans, glycosaminoglycans, and water; discs may become mineralized or cartilaginous. • Spinal cord lesion depends upon type and severity of disc extrusion or protrusion; acute, severe disease may cause hemorrhage, edema, tissue necrosis; chronic disease demyelination of white and in some cases gray matter.

TREATMENT

APPROPRIATE HEALTH CARE

Guidelines for Therapy Based on Classification of Clinical Condition

• Class 1—back pain only, first episode.
• Class 2—recurrent back pain, ataxia, mild paraparesis, motor ability good. • Class 3—severe paraparesis, proprioceptive deficits, motor ability affected but still present; voluntary control of urination may be diminished; bladder many be easy to manually express or difficult due to detrusor dysfunction. • Class 4A—complete paralysis (no motor ability) with deep pain perception present; voluntary control of urination and defecation absent, bladder usually easy to express manually. • Class 4B—complete paralysis, no deep pain perception present.

Treatment Recommendations Based on Classification of Clinical Condition

• Class 1—treated medically unless pain persists. • Class 2—treated medically initially with serial neurologic exam; surgery is performed if patient remains static or condition declines. • Classes 3 and 4A—immediate surgical decompression recommended; prognosis good. • Class 4B—surgical decompression and fair prognosis if within the first 12–48 hours of occurrence or for slower onset of clinical signs (clinical signs progressive over 12 hours); poor prognosis if deep pain perception has been absent for >48 hours or if the clinical signs progressed rapidly (<6 hours) from normal to loss of deep pain. • Serial neurologic examination important for all affected animals.

NURSING CARE

• Absolute restricted confinement for 2–4 weeks or until ambulatory. • Minimize spinal manipulation and support spine when handling patient. • Ensure ability to urinate or consider bladder expression, intermittent catheterization, or indwelling urinary catheter for patients in classes 3–4B. • Recumbent patients should be kept clean on padded bedding placed on elevated cage racks and turned frequently to prevent formation of decubital ulcers. • Manual evacuation of the bowel or enemas may be necessary to promote defecation. • Physical therapy with passive manipulation of pelvic limbs begun early followed by more intense therapy (hydrotherapy) for animals with neurologic deficits but regaining motor function; rehabilitation protocols are not contraindicated, but recent research suggests that they may not be beneficial in improving the speed of return to function. • Carts useful in many patients in promoting return to function; patient tolerance is limiting factor.

ACTIVITY

• Restricted movement most important part of medical management. • Cage rest in hospital or enforced cage rest as an outpatient for 2–4 weeks for class 1 patients or postoperative animals.

DIET

Weight reduction if patient is obese.

CLIENT EDUCATION

• Some degree of restricted activity may be important for the remainder of the animal's life since it has disc disease. • Most animals in classes 1–4A have a good to excellent prognosis for return to function, i.e., ambulation with bowel and bladder continence; patients in class 4B have a poorer but not hopeless prognosis;

INTERVERTEBRAL DISC DISEASE, THORACOLUMBAR (CONTINUED)

percentages vary, but up to approximately 50% may regain deep pain and some function, especially if appropriate surgical decompression occurs early in the disease process.

SURGICAL CONSIDERATIONS

• Surgery strongly indicated for animals in classes 3 and 4, also within the first 12–48 hours for class 4B dogs; also indicated for static or worsening class 1 and 2 dogs. • Primary surgical goal is to relieve spinal cord compression by disc mass removal via hemilaminectomy, dorsal laminectomy, or pediculectomy; disc fenestration alone is not effective for treating acute disc extrusions, but is frequently recommended as an adjunct to decompression at the primary site. • Hemilaminectomy on the side of predominant disc extrusion is the surgical procedure of choice for most thoracolumbar discs; studies indicate improved return to function, minimized spinal destabilization, and decreased formation of compressive laminectomy scars in the long-term postoperative period. • Foramenotomy and pediculectomy are similar to hemilaminectomy and may allow a more limited approach and decreased cord manipulation. • Dorsal laminectomy is the procedure of choice for disc herniation in the region of the lumbosacral plexus or where extensive examination of the spinal cord is necessary. • Recurrence of clinical signs in animals in the immediate postoperative period may be due to further extrusion of disc from the original site if fenestration is not adjunctively performed at the site of disc disease during hemilaminectomy or dorsal laminectomy; later recurrence of clinical signs after recovery is usually due to protrusion/extrusion at adjacent sites; several studies document approximately 8% long-term recurrence of clinical signs in dogs after initial hemilaminectomy and active site fenestration due to protrusion/extrusion at other sites. • Controversy remains over the efficacy of multiple site prophylactic disc fenestrations performed during the decompressive surgery, because evidence that fenestration prevents recurrence of clinical signs is not definitive and fenestration causes osteoarthritis to form at the intervertebral space of each site of fenestration, leading to potential chronic patient discomfort and pain.

MEDICATIONS

DRUG(S) OF CHOICE

• Nonsteroidal anti-inflammatory drugs (NSAIDs) or narcotics may be used as analgesics in class 1 cases to alleviate patient discomfort during recovery; use of analgesics is not a substitute for the cage rest period required of all patients.
• Narcotic analgesics may be necessary postoperatively; hydromorphone (0.05–0.2 mg/kg IV/IM/SC q4h) or similar narcotic injectable used at appropriate doses are the treatment of choice in the immediate postoperative period; oral narcotics such as codeine (1–2 mg/kg PO q8h) or tramadol (5–8 mg/kg PO q8h) are useful to alleviate patient discomfort within the first week after decompression; transdermal lidocaine or fentanyl may be useful modes of analgesic administration in some animals, particularly those intractable to frequent dosing of injectable or oral agents.
• Gabapentin (5–10 mg/kg PO q12h), an NMDA receptor antagonist in dogs with chronic pain sensitization, is not an appropriate analgesic used alone in the immediate postoperative period.
• Methocarbamol (25–45 mg/kg q8h) may be useful in cases where muscle spasm is contributing to pain; more applicable with cervical disease. • Bethanechol (5–15 mg/dog PO) and phenoxybenzamine (0.25 mg/kg PO q8–12h) or prazosin (1 mg/15 kg PO q8–12h) are variably helpful in managing bladder dysfunction associated with spinal cord lesion. • Previous indications for methylprednisolone sodium succinate for treatment of acute pain are now controversial for efficacy; the high potential for side effects may outweigh the small gains from the drug.
• Corticosteroids are no longer commonly recommended in the treatment of acute intervertebral disc disease due to lack of demonstrated clinical efficacy.

PRECAUTIONS

• Glucocorticoid use is discouraged in cases of IVDD where drug side effects such as gastrointestinal hemorrhage and intestinal perforation often far outweigh benefits; potent glucocorticoids such as dexamethasone should never be used. • Glucocorticoids are contraindicated within 48 hours of using an NSAID in dogs. • Use of glucocorticoids without cage confinement may decrease pain, thereby encouraging excessive activity and leading to further disc herniation and deterioration of clinical condition.

ALTERNATIVE DRUG(S)

Alternative Therapies

• Acupuncture use has been described, but consistent efficacy has not been demonstrated.
• Chiropractic therapy has no proven benefits for IVDD and may potentially be harmful to the animal. • Percutaneous therapeutic lasers do not reach the site of inflammation and are not efficacious; one recent study did demonstrate slightly more rapid recovery from IVDD if laser therapy regimens occurred as an adjunct to surgical decompression procedures. • Discolysis by enzymatic injection or laser ablation has been described but is not proven therapy in dogs.

FOLLOW-UP

PATIENT MONITORING

• Patients treated medically should be reevaluated two to three times daily for worsening neurologic signs for the first 48 hours after onset. • If stable, reevaluate daily, then weekly, until clinical signs have resolved.
• Patients treated surgically are evaluated twice daily until improvement is noted; urinary bladder function or awaiting development of an autonomic bladder are the limiting factors for hospitalization.

POSSIBLE COMPLICATIONS

• Recurrence of signs associated with disc herniation at original or at new site.
• Deterioration of clinical signs with or without surgery; continued inflammatory processes initiated by the initial extrusion may result in myelomalacia or diminished function. • Rarely, development of ascending or descending myelomalacia; occurs in class 4A or 4B dogs 3–5 days following injury and is characterized by variable and progressive neurologic deterioration, possible fever, possible dyspnea, and extreme pain, with the cranial movement of the inflammation; careful monitoring of the anatomic position of detection of the panniculus reflex is recommended; cranial movement of the reflex can indicate ascending myelomalacia and provide early warning of a grave condition; such animals are often euthanized when diagnosed.

EXPECTED COURSE AND PROGNOSIS

• Overall prognosis for dogs in classes 1–4A good to excellent (85–95%); those treated conservatively may experience recurrence of clinical signs. • Recurrence rates of dogs without fenestration at the time of laminectomy range from 5–30%. • Dogs in class 4B have a variable (10–75%) chance of recovery; overall a guarded but seemingly favorable prognosis if surgery is performed within 48 hours and the animal is allowed sufficient time to recover.
• Dogs with type III disc extrusions often exhibit severe initial clinical signs and carry a grave prognosis for full recovery.

MISCELLANEOUS

ABBREVIATIONS

• CSF = cerebrospinal fluid.
• IVDD = intervertebral disc disease.
• LMN = lower motor neuron.
• NSAID = nonsteroidal anti-inflammatory drug.
• UMN = upper motor neuron.

INTUSSUSCEPTION

BASICS

DEFINITION
• Invagination of one gastrointestinal (GI) segment into the lumen of the adjacent segment. • Intussusceptions are classified according to their localization within the GI tract—ileocolic and jejunojejunal intussusceptions are the most common; other types include gastroesophageal, duodenojejunal, and cecocolic.

PATHOPHYSIOLOGY
• The mechanism is unknown—GI irritation and hypermotility may cause the orad segment to invaginate into the aborad segment; uncoupling of coordinated peristaltic rhythm may be a contributing factor. • Intussusception often leads to a partial or complete mechanical obstruction of the GI tract. • Compromise of venous and lymphatic drainage of the affected bowel leads to marked edema and intramural hemorrhage, and, if left untreated, loss of segmental arterial supply and necrosis; full-thickness compromise of the integrity of the bowel may occur leading to septic peritonitis. • The segment entrapped within the lumen is the intussusceptum; the engulfing segment is the intussuscipiens.

SYSTEMS AFFECTED
• GI—partial or complete mechanical obstruction, bowel wall necrosis, hematochezia, melena, hypermotility followed by ileus, vomiting, and diarrhea. • Cardiovascular—distributive and hypovolemic shock (vomiting and diarrhea, intraluminal hemorrhage, peritonitis).

GENETICS
N/A

INCIDENCE/PREVALENCE
Uncommon

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog > cat.

Breed Predilections
• German shepherd—gastroesophageal intussusceptions (60% of reported cases) and other types of intussusceptions. • Siamese cats are overrepresented.

Mean Age and Range
• Most commonly younger animals. • Older affected animals should be evaluated for underlying disease such as chronic enteropathy and intestinal neoplasia.

Predominant Sex
None

SIGNS

General Comments
• Clinical signs depend on the inciting cause, location and type of intussusception, completeness of obstruction, degree of bowel wall compromise and presence of peritonitis. • Gastroesophageal intussusceptions present with the most acute and severe clinical signs compared to more aborad locations.

Historical Findings
• Recent foreign body ingestion. • Previous or current enteropathy. • Vomiting. • Diarrhea. • Hematochezia. • Hematemesis. • Melena. • Abdominal pain. • Abdominal distention. • Decreased appetite or anorexia. • Weight loss. • Historical findings are typically acute in onset, but chronic cases are reported.

Physical Examination Findings
• Abdominal pain. • Palpation of thickened tube of bowel. • Tachycardia from hypovolemia and pain. • Bradycardia if significant vagal nerve stimulation has occurred. • Prolonged or rapid capillary refill time. • Thin body condition. • Fever. • Ileocolic intussusceptions may present with protrusion of the intussusceptum from the rectum; this can be differentiated from a rectal prolapse via probing along the side of the protruding tissue; the presence of a blind-ending fornix indicates the existence of a rectal prolapse.

CAUSES
• Any disease that alters GI motility. • Acute or chronic enteropathy and enteritis. • Recent abdominal surgery. • Intestinal mural disease or intraluminal foreign body. • Intestinal parasitism. • Less common causes include renal allograft transplantation (8–33% incidence) and hematopoietic cell grafts (5% incidence) in dogs. The reason for this relationship is unclear.

RISK FACTORS
Presence of any condition listed under Causes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Any disease that can cause vomiting and diarrhea, including intestinal parasites; viral enteritis; bacterial enteritis; intraluminal foreign bodies; chronic enteropathy; mesenteric volvulus; GI neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
• Leukogram—leukopenia: especially with sepsis or parvoviral infection; leukocytosis: either stress response, acute inflammation, or sepsis. • Hematocrit—elevated if dehydration or underlying hemorrhagic gastroenteritis; decreased: GI hemorrhage. • Biochemical analysis—derangements of electrolytes due to loss through vomiting or diarrhea (may include hyponatremia, hypochloridemia, hypokalemia); azotemia (prerenal) if significantly dehydrated; hypoalbuminemia due to intestinal luminal loss from chronic protein-losing enteropathy or acute changes in bowel wall integrity and permeability. • Urinalysis—may reveal elevated specific gravity in response to dehydration.

OTHER LABORATORY TESTS
• May see hyperlactatemia secondary to vascular compromise to intestinal segment. • Blood gas evaluation may reveal a metabolic acidosis secondary to dehydration and hypoperfusion. • Alternately, if the obstruction results in primarily gastric vomiting (pyloric obstruction), a hypochloremic, hypokalemic, metabolic alkalosis may be present.

IMAGING
• Plain abdominal radiographs may reveal an obstructive intestinal pattern—the degree of intestinal distention may be related to the degree of obstruction; may or may not reveal a soft tissue mass consistent with the intussusception. • With gastroesophageal intussusception, a soft tissue mass may be seen within the lumen of the esophagus near the esophageal hiatus of the diaphragm—may be confused with a hiatal hernia, but the severity of the clinical signs typically associated with a hiatal hernia is less severe compared to the often peracute presentation associated with gastroesophageal intussusception. • Abdominal ultrasound is useful in the diagnosis of intussusceptions—the small intestinal intussusception appears as a target patterned mass on transverse sections, and as a multitude of parallel lines on longitudinal sections. • Upper GI contrast studies or barium enemas can be helpful in supporting the diagnosis of an intussusception.

DIAGNOSTIC PROCEDURES
Upper GI endoscopy will definitively identify gastroesophageal intussusception and differentiate it from hiatal hernia.

PATHOLOGIC FINDINGS
• Gross examination of the intussusception reveals telescoping of a segment of bowel into the adjacent segment. • Histopathologic examination reveals variable degrees of venous and lymphatic congestion, vascular compromise, bowel wall necrosis, and peritonitis.

TREATMENT

APPROPRIATE HEALTH CARE
• Initial efforts should be focused on patient stabilization as well as correction of dehydration and existing electrolyte abnormalities. • GI obstruction caused by intussusception is a surgical emergency; proceed with surgery once patient is stabilized.

(CONTINUED) INTUSSUSCEPTION

NURSING CARE
• IV fluid administration to correct dehydration as well as replace anticipated ongoing losses through vomiting and diarrhea. • Specific rate of administration and choice of fluid type are dictated by patient status and electrolyte derangements.

ACTIVITY
Recommend controlled activity for 10–14 days postoperatively.

DIET
• Postoperative anorexia may be due to pain, nausea, and/or esophagitis. • Nasal-esophageal, esophageal, or gastric feeding tubes may be indicated—enteral nutrition is required for intestinal mucosal healing and is preferred; enteral nutrition should be provided within the first 24 hours after surgery, once the patient is awake from anesthesia, at normal body temperature, and treatment of pain, ileus, nausea, and vomiting have been initiated. • If patient is vomiting, a postpyloric feeding tube may be indicated.

CLIENT EDUCATION
• Communication centered on the importance of the identification and treatment of an underlying cause.
• Complications may include perioperative mortality, septic peritonitis, or protracted hospital stay related to dehydration, hypovolemia, regurgitation, vomiting, blood loss, and peritonitis. • Recurrence rates have been reported to be 6–27%.

SURGICAL CONSIDERATIONS
• Surgical correction should be performed as soon as the patient is stable enough to undergo anesthesia and surgery. • Once identified, all intussusceptions are a surgical emergency. • A full abdominal exploratory is always performed for the identification of any potential underlying causes; full-thickness biopsy of the bowel is recommended.
• Multiple intussusceptions may be present.
• Some intussusceptions can be manually reduced by gently milking the intussusceptum from within the intussuscipiens; upon reduction, the bowel may or may not be viable. • In the event that manual reduction is not possible, or the bowel has questionable viability, an intestinal resection and anastomosis is necessary. • Surgical enteroplication has been proposed as a procedure for preventing recurrence. ○ The rate of side effects and complications associated with enteroplication may be higher than the recurrence rate. ○ It is important to exercise care when performing this procedure. ○ Briefly, the loops created in the bowel should be gentle, and sharp turns in the bowel loops are to be avoided; the submucosal layer of the adjacent loops of bowel should be included in the sutures, but the lumen should not be entered.

MEDICATIONS

DRUG(S) OF CHOICE
• Perioperative antibiotics are recommended—manual reduction of an intussusception is considered a clean surgical procedure, while an intestinal resection and anastomosis is considered a clean contaminated procedure; septic peritonitis is considered a dirty/infected procedure.
• Long-term antibiotic administration is not recommended, except in cases in which septic peritonitis is present either preoperatively or postoperatively.

CONTRAINDICATIONS
Some surgeons believe that drugs with promotility properties are contraindicated postoperatively in patients with intussusception, but reports of such drugs causing recurrence is lacking.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Postoperatively, patients should be maintained on IV fluids. • Pain ileus, nausea, and vomiting should be treated. • Most recurrences occur within the first few days of surgery, but recurrences have been reported up to 3 weeks after surgery. • Intestinal dehiscence typically occurs 3–5 days postoperatively, as collagenase and matrix metalloproteinase levels rapidly increase at the anastomosis site.

PREVENTION/AVOIDANCE
Prevention of many of the underlying causes can be achieved through such actions as vaccination, intestinal parasite control, and limiting situations in which patients can be exposed to dietary indiscretion or foreign body ingestion.

POSSIBLE COMPLICATIONS
• Recurrence—6–27% of patients. • Septic peritonitis—may result from postoperative intestinal dehiscence or intraoperative contamination. • Short bowel syndrome is a rare complication that can occur with massive resections (generally >70% in dogs) of the small intestine.

EXPECTED COURSE AND PROGNOSIS
Highly dependent upon underlying cause, location of intussusception, and condition at presentation. • In general, the prognosis improves as the location of the intussusception moves more aborad. • Gastroesophageal intussusceptions have a grave prognosis with mortality rates approaching 95%, while intestinal intussusceptions have a good prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Intestinal parasites. • Viral enteritis.
• Intestinal mural diseases. • Gastroesophageal intussusceptions are typically associated with an underlying esophageal disorder or gastric motility disorders.

AGE-RELATED FACTORS
• Younger patients are typically affected with underlying enteritis (viral or bacterial) or intestinal parasitism. • Older patients are more commonly affected with intestinal neoplasia.

ZOONOTIC POTENTIAL
Some underlying causes may be zoonotic (parasitic, bacterial, and protozoal causes of enteritis).

I

IRIS ATROPHY

BASICS

OVERVIEW

- Degeneration of iris tissues; both the iris stroma and posterior iris epithelium can be affected, resulting in loss of iris sphincter and dilator muscle function, atrophy of iris vessels, and loss of iris pigment.
- Both the pupillary margin and more peripheral portions of the iris can be affected, resulting in an iris that is thin or has areas of full-thickness tissue loss.
- Senile or secondary change.
- Secondary iris atrophy is usually a result of chronic inflammation (uveitis).
- Iris sphincter muscle is frequently affected by atrophy, resulting in incomplete pupillary constriction, unequal pupil size (anisocoria), and possibly abnormal pupil shape (dyscoria).
- Irregular scalloped, moth-eaten pupil margin is a common manifestation.
- Pupil margin may remain unaffected; peripheral loss of iris tissue can cause large holes in the iris that resemble multiple pupillary openings.
- Vision largely unaffected.

SIGNALMENT

- Dog—common aging change; all breeds, but affects small breeds (e.g., miniature and toy poodles, miniature schnauzers, Chihuahuas) more commonly.
- Cat—uncommon; most common with blue irides.
- Secondary—any breed of dog or cat.

SIGNS

Historical Findings

- Large or dyscoric pupil in one or both eyes.
- Photophobia.
- Previous episodes of uveitis.

Physical Examination Findings

- Incomplete or absent pupillary light reflex accompanied by normal menace response and dazzle reflex.
- Anisocoria may be present with unilateral or asymmetric presentation.
- Irregular, scalloped edge to pupillary margin; dyscoria (see Web Figures 1 and 2).
- Tapetal reflex visible through thin or absent areas of the iris on transillumination—translucent patches or holes within the iris stroma: may resemble additional pupils.
- Strands of iris arising from free pupillary margin occasionally remain, spanning across portions of the pupil (Web Figures 1 and 2).
- Secondary—may be accompanied by any sign associated with chronic uveitis.

CAUSES & RISK FACTORS

- Normal aging.
- Uveitis.
- Glaucoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Must differentiate from congenital iris anomalies:
  - Iris aplasia—rare in dog and cats.
  - Iris hypoplasia—differentiate based on age at first presentation of signs.
  - Iris coloboma—complete, full-thickness area of lack of development of all layers of the iris; frequently associated with the merle condition; may also see associated lack of lens zonules and indentation of the lens posterior to the colobomatous iris area; differentiate based on age and presence of associated abnormalities.
  - Polycoria—more than one pupil, each with ability to constrict due to presence of an iris sphincter.
  - Persistent pupillary membranes—arise from collarette (midportion) of the iris, not from the free pupillary margin.
- Pupil dilation due to glaucoma—elevated intraocular pressure (IOP), corneal edema, conjunctival ± episcleral vascular injection, enlargement of globe may also be present; may also be blind.
- Adhesions of iris to lens or cornea (posterior or anterior synechia) as a result of uveitis or trauma—differentiate based on associated abnormalities consistent with uveitis or perforating trauma (e.g., full-thickness corneal scar).

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Tonometry—low IOP possible if secondary to uveitis; high IOP if secondary to glaucoma or if uveitis has also caused secondary glaucoma; normal IOP if primary senile iris atrophy.

TREATMENT

- Irreversible.
- Secondary—successful treatment aimed at controlling the underlying disease may halt progression of the condition.
- Patient may exhibit photophobia because of inability to constrict the pupil; provide adequate shade.

MEDICATIONS

DRUG(S) OF CHOICE

- Senile—none.
- Secondary—depending on underlying disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Topical atropine—exacerbates pupillary dilation and photophobia.

FOLLOW-UP

- Senile—may continue to progress with age.
- Secondary—usually does not progress once primary disease is controlled.

MISCELLANEOUS

SEE ALSO

- Anterior Uveitis—Cats.
- Anterior Uveitis—Dogs.
- Glaucoma.

ABBREVIATIONS

- IOP = intraocular pressure.

IRON TOXICOSIS

BASICS

OVERVIEW

• Iron is an essential metal for mammals; overdose results in clinical signs and potential death. • Absorption increases with readily ionized and soluble iron. • Oral sources may include dietary supplements (multivitamin, prenatal), snail and slug baits, single-use heat-producing packs (hand warmers), fertilizers, most oxygen absorber packets; overdoses of injectable iron may occur. • Oral overdose leads to disruption of gastrointestinal (GI) mucosa allowing greater iron absorption, resulting in possible systemic toxicity. • Potential organ systems involved include GI, cardiovascular (CV), hepatobiliary, nervous, hemic, and renal. • Tissue damage occurs due to free radical/reactive oxygen species formation resulting in direct or secondary damage through processes such as lipid peroxidation. • Disrupts mitochondrial function and interferes with cellular respiration.

SIGNALMENT

• Predominantly dogs, uncommon in other species. • All ages susceptible.

SIGNS

• History of iron ingestion or injectable overdose. • Initial signs related to GI irritation and mucosal damage; onset of signs occurs within 6–8 hours post ingestion; may include vomiting, diarrhea, mucosal damage (hematemesis, melena), abdominal pain and depression; signs with mild to moderate ingestions may not progress beyond GI. • In absence of significant initial GI signs, systemic toxicity unlikely. • A quiet/latent period may follow initial GI signs and last up to 24 hours post ingestion. • In severe cases, recurrence of clinical signs occurs 12–96 hours post ingestion and can include ongoing vomiting/diarrhea ± mucosal damage, tachycardia, hypotension, CV collapse, metabolic acidosis, shock, hepatic necrosis, coagulopathy/disseminated intravascular coagulation (DIC), acute kidney injury, seizures, death. • Following GI involvement, scarring and stricture formation may occur during healing.

CAUSES & RISK FACTORS

• Ingestion of iron-containing medication or other materials. • Majority of cases due to canine dietary indiscretion. • Elemental/absorbable iron results in mild signs at 20 mg/kg PO and severe signs at 60 mg/kg; other forms of iron including iron salts require conversion to elemental iron for dose calculations. • Metallic iron and iron oxide (rust)not readily ionizable/absorbable and toxicity not expected.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of severe gastroenteritis and shock, viral/bacterial enteritis, caustic/corrosive ingestion, other dietary indiscretion, gastric torsion, heatstroke, snake bite.

CBC/BIOCHEMISTRY/URINALYSIS

• Leukocytosis. • Anemia (blood loss) or hemoconcentration. • Normal to high aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), serum bilirubin.

OTHER LABORATORY TESTS

• Blood gas to monitor for metabolic acidosis. • Serum iron levels ± total iron binding capacity (TIBC); serum iron level more commonly performed and drawn 4–6 hours post ingestion with capsule or tablet ingestion and 2–3 hours post ingestion with liquid or chewable tablets; repeat q2–4h until peak level if able. • Hemolyzed serum samples increase iron content and should be avoided. • ECG/blood pressure. • Coagulation profile for DIC.

IMAGING

Abdominal radiography—iron-containing material may be radiopaque; adherence to mucosa may be visible.

DIAGNOSTIC PROCEDURES

Analysis of GI or stomach contents may aid in documenting high iron exposures.

PATHOLOGIC FINDINGS

• Primary gross lesions—hemorrhage in GI tract and liver; hepatomegaly. • Histopathologic lesions—GI necrosis with potential of hepatocellular and vascular endothelial necrosis.

TREATMENT

• Inpatient monitoring with toxic doses; home monitoring if patient remains asymptomatic during initial 8 hours post ingestion; continue inpatient care if symptomatic. • Correct hypovolemic shock with IV fluids. • Correct severe acidosis with IV sodium bicarbonate. • Feed patient bland diet depending on GI status.

Decontamination

• Oral milk of magnesia or aluminum hydroxide (precipitates iron in GI tract) at 5–30 mL PO q8–12h × 24h; may cause diarrhea. • Induce emesis or gastric lavage (if emesis contraindicated). • Emergency gastrotomy if lavage fails to remove adherent pills or bezoars. • Whole bowel irrigation or enema.

MEDICATIONS

DRUG(S) OF CHOICE

Chelation

• Chelate when serum iron >350–500 μg/dL or serum iron >TIBC. • Deferoxamine mesylate (40 mg/kg IM q4–8h) until urine no longer becomes reddish brown after treatment; IV administration at 15 mg/kg/h CRI reserved for critical patients. • Continue therapy until signs resolved and serum iron below 300 μg/dL.

Other

• Antiemetic (maropitant 1 mg/kg SC/IV q24h). • GI protectant—proton pump inhibitor (omeprazole 1 mg/kg PO q24h); sucralfate (0.5–1 g PO q8–12h). • Ascorbic acid once iron fully removed from GI tract to enhance excretion (10–15 mg/kg q4–6h PO/SC/IM/IV).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Activated charcoal does not bind iron. • Avoid gastric lavage in presence of hematemesis due to increased risk of perforation. • Administer IV deferoxamine slowly or may precipitate cardiac arrhythmias.

FOLLOW-UP

• Liver enzymes—monitor up to 24 hours after excess circulating iron controlled. • Watch for evidence of GI stricture formation/obstruction. • Prognosis generally good with early treatment; decreases once signs of iron toxicosis develop or with very large ingestions.

MISCELLANEOUS

SEE ALSO

Poisoning (Intoxication) Therapy.

ABBREVIATIONS

IVERMECTIN AND OTHER MACROCYCLIC LACTONES TOXICOSIS

BASICS

OVERVIEW

• Ivermectin, milbemycin, moxidectin, selamectin, others. • Toxicity—dogs given large extra-label dosages (>10–15 times recommended dosage). • Ivermectin—binds to glutamate-gated chloride ion channels in invertebrate nerve and muscle cells causing subsequent paralysis and death of the parasite. Also interacts with other ligand-gated chloride channels, including those gated by γ-aminobutyric acid (GABA).
• Sensitivity—collies and certain other breeds are more sensitive to high doses of ivermectin. This sensitivity has been associated with an inherited deletion of the ABCB1-1Δ gene that encodes a transmembrane protein pump called P-glycoprotein. P-glycoprotein is believed to transport ivermectin out of brain tissue and into circulation.

SIGNALMENT

• Dogs. • Collies—most commonly affected.
• Dogs homozygous for the ABCB1-1Δ gene deletion also affected; heterozygous dogs can react at higher doses. The ABCB1-1Δ gene mutation has been found in Shetland sheepdogs, Australian shepherds, Old English sheepdogs, German shepherds, English shepherds, longhaired whippets, silken windhounds, and a variety of mixed-breed dogs.
• No age or sex predilections.

SIGNS

• Mydriasis. • Depression. • Drooling/salivation. • Vomiting. • Ataxia. • Tremors.
• Disorientation. • Weakness, recumbency.
• Nonresponsiveness. • Transient blindness.
• Bradycardia. • Hypoventilation. • Coma.
• Death.

CAUSES & RISK FACTORS

• Extra-label use at high dosage. • Breed sensitivity—see above. • Treating demodicosis with high-dose ivermectin while patient is on spinosad.

DIAGNOSIS

• History and clinical signs. • No specific tests useful.

DIFFERENTIAL DIAGNOSIS

• Overdoses of other insecticides such as pyrethrins, pyrethroids, organophosphorus, and carbamate compounds. • Other toxicants, such as loperamide or diseases affecting CNS.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Arterial blood gases—may reveal high partial pressure of carbon dioxide ($PaCO_2$) and low partial pressure of oxygen (PaO_2) from respiratory depression and hypoventilation.

DIAGNOSTIC PROCEDURES

Physostigmine 1 mg IV; temporary (30–40 min) return to consciousness or resumed alertness and muscle activity after administration supports but does not confirm diagnosis; does not speed recovery; not indicated for treatment; glycopyrrolate administered first may prevent severe bradycardia.

TREATMENT

• Supportive and symptomatic care. • If patient alert and able to swallow, activated charcoal repeated every 6–8 hours; monitor for hypernatremia. • Use of IV lipid emulsion has been successful in ameliorating clinical signs in many cases; recent literature has conflicting data on effectiveness in dogs with ABCB1-1Δ homozygous mutations.
• Important goals—proper fluid therapy, maintenance of electrolyte balance, nutritional support, and prevention of secondary complications. • Nutritional support—institute early, preferably within 2–3 days of exposure; severe CNS depression or coma may last for days or weeks depending on severity of exposure. • Good nursing care for recumbent patient. • Ocular lubricants.
• Mechanical ventilation—may be required with respiratory depression.

MEDICATIONS

DRUG(S) OF CHOICE

• No known reversal agent. • Atropine or glycopyrrolate—may be administered as needed to treat bradycardia. • 20% intravenous lipid emulsions—bolus dose 1.5 mL/kg over 2–3 min; CRI of 0.25 mL/kg/min for 30–60 min; check serum q2h and if not lipemic; repeat as needed; if no clinical improvement after three doses, discontinue.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Other drugs known to cause toxicity in dogs with ABCB1 mutation—loperamide, doxorubicin, vincristine, vinblastine, acepromazine, butorphanol, emopside, and erythromycin. • Do not use ivermectin concurrently with ketoconazole.
• Concomitant extra-label use of ivermectin and spinosad may produce clinical signs.

FOLLOW-UP

• Prognosis and eventual outcome—depends on individual and breed sensitivity, amount of drug ingested or injected, how rapidly clinical signs develop, response to supportive treatment, and overall health of patient.
• Convalescence may be prolonged (several weeks); good supportive care in many seemingly hopeless cases has resulted in complete recovery.

MISCELLANEOUS

SEE ALSO

• Heartworm Disease—Dogs.
• Poisoning (Intoxication) Therapy.

ABBREVIATIONS

• GABA = γ-aminobutyric acid.
• PaCO2 = partial pressure of carbon dioxide.
• PaO_2 = partial pressure of oxygen.

JOINT LUXATIONS

BASICS

DEFINITION
Luxation is the complete disruption of the contiguous articular surfaces of a joint when the supporting structures around the joint are damaged or missing. Subluxation is a partial disruption.

PATHOPHYSIOLOGY
• Synovial joints have a joint capsule that joins the articulating bones together. The fibrous layer of this capsule is a primary stabilizer of the joint. Most joints have additional ligaments that reinforce the joint capsule to improve the resistance to movement outside of the normal range of motion of that joint. All motion joints also have a system of muscles and tendons that exert forces on the joint to control movement and prevent subluxation of the joint. The co-contraction forces around a joint are very influential on the stability of the joint. Instability occurs when the stabilizing system is damaged, disrupted, or does not develop normally. • If laxity is clinically apparent, then the instability is generally described as luxation or subluxation of the joint. • Luxation may occur as a result of traumatic forces causing the joint to move beyond the elastic limits of the supporting tissues. • Secondary changes are set in motion by damage to the tissues that creates early, and then later, more chronic joint damage.

SYSTEMS AFFECTED
• Musculoskeletal—primarily the intra-articular environment and the support structures around the joint, including joint capsule, fibrocartilage, collateral ligaments, and supporting muscle/tendon units.
• Neurologic—neurologic feedback and supply to the support system may also be affected.

GENETICS
• Hyperlaxity syndrome is an inherited trait in humans. Puppies may show temporary hyperlaxity when confined or when housed on poor substrates. • Hip dysplasia is a form of inherited laxity of the coxofemoral joint. • Shoulder luxation is an inherited predisposition in small breeds, such as miniature poodles. • Femoropatellar instability leading to medial patellar luxation is a common inherited disease in small-breed dogs. • Ehlers–Danlos syndrome is a congenital collagen disorder that leads to generalized joint laxity.

INCIDENCE/PREVALENCE
Various forms of laxity/luxation (specifically hip dysplasia and medial patella luxation) are very common. Other forms such as Ehlers–Danlos syndrome are extremely uncommon.

SIGNALMENT

Species
All species.

Breed Predilections
• Traumatic luxation has not been shown to be breed specific in any joint. • Breed predilection for nontraumatic luxations varies with the joint affected. • Hip—large breeds show clinical signs of hip dysplasia more frequently than smaller breeds, but breeds of all sizes can have radiographic signs. • Congenital shoulder luxation occurs most commonly in miniature breeds (miniature poodle). • Medial patella luxation is more common in small-breed dogs.

Mean Age and Range
• Traumatic—any age. • Congenital laxity/luxation is typically seen in the juvenile dog, with secondary degenerative joint disease showing later in life.

SIGNS
• Acute swelling, pain, and non-use of the limb are usually seen with acute luxation. Partial weight-bearing may occur with subluxation or chronic luxation. • Abnormal anatomic position of one bone in relation to the adjoining bone. • Hip luxation is commonly craniodorsal (the displacement of the femoral head in relation to the acetabulum). • Shoulder luxation is commonly medial. • Elbow luxation is commonly proximolateral. • Carpal and tarsal luxations commonly result in varus, valgus, or hyperextension when stressed.

CAUSES
• Traumatic overstress of normal soft tissues beyond their elastic limit. • Fracture of the bone attaching the origin or insertion of a tendon or ligament to the body of the bone. • Minimal stress on abnormally unstable joints of congenital etiology.

RISK FACTORS
• Abnormal congenital conformation, causing altered joint stresses. • Fatigue, causing muscle weakness and incoordination. • Neurologic derangement. • Environments conducive to traumatic events.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Fractures. • Joint disease—immune-mediated, septic, or degenerative.

CBC/BIOCHEMISTRY/URINALYSIS
• No abnormalities expected that are directly related to the luxation. • Trauma-induced abnormalities in traumatic situations.

OTHER LABORATORY TESTS
Arthrocentesis may help to rule out nontraumatic joint disease.

IMAGING
• Radiographs confirm the diagnosis by documenting the anatomic malalignment. • Radiographs to rule out other pathology, such as intra- or extra-articular fractures that could affect the decision to perform closed reduction. • Stress views may be needed in some situations.

DIAGNOSTIC PROCEDURES
• Palpation of the laxity/luxation (ex. ortolani, cranial drawer, medial patella luxation, stress-induced laxity/instability). • Palpation of the position of the displaced bone.

PATHOLOGIC FINDINGS
• Trauma-induced hemorrhage, edema, and disruption of ligaments and joint capsule. • Secondary changes related to degenerative joint disease.

TREATMENT

APPROPRIATE HEALTH CARE

Closed Reduction
• Closed reduction is attempted if: there is no underlying intraarticular pathology (fracture); there is adequate intact support structures to maintain marginal stability immediately after reduction; there is no underlying dysplasia that predisposes the joint to luxation (as this would increase the chance of reduction failure); there is no additional pathology in other limbs that would require immediate weight-bearing of the affected limb. • Closed reduction is often considered the first line of treatment (when appropriate) for hip luxations (craniodorsal and caudoventral), shoulder luxation, and elbow luxations. • Surgical stabilization is often required with carpal, tarsal, and stifle luxations. • Surgical intervention (arthrodesis) or long-term brace (orthotic) are required for palmar or plantar instability due to the excessive stresses placed on palmar and plantar ligaments and fibrocartilage in the dog and cat.

Immobilization
Immobilize the joint with a bandage/splint if the affected joint is distal to the inguinal or axial areas.

External Coaptation (Maintenance Period)
• Craniodorsal hip luxation—ehmer sling (~14 days). • Caudoventral hip luxation—hobbles (~14 days). • Elbow luxation—spica splint (~14 days). • Shoulder luxation (medial)—valpeau sling (~14 days). • Shoulder luxation (lateral)—spica splint (~14–21 days). • Tarsocrural and radiocarpal instability (except palmar and plantar instability)—cast or medial/lateral splint (6–10 weeks depending on degree of injury). • Medial, lateral, or dorsal pes and manus instability caudal spoon splint or cast (6–10 weeks depending on degree of injury).

JOINT LUXATIONS (CONTINUED)

NURSING CARE
• Rest, exercise restriction, pain control, and maintenance of external coaptation. • Cold compresses for 5–10 minutes four or five times a day initially to reduce inflammation.

ACTIVITY
Cage rest for joint stabilization period, then slow return to function to encourage healing and strengthening of soft tissue support of the limb.

DIET
Normal

J

CLIENT EDUCATION
Activity and weight gain increase the likelihood of degenerative changes in the long term.

SURGICAL CONSIDERATIONS
• Surgery is typically required for spinal luxations. • For appendicular skeleton for which closed reduction is ideal, an open surgical approach is preferred if: closed reduction fails; there is evidence of predisposing joint dysplasia; there is evidence of an intra-articular fracture; there is concurrent pathology that requires early stability and weight-bearing on the affected limb. • With open reduction, stabilization via prosthetic ligament placement, ligament reconstruction, or temporary transarticular stabilization is considered. • Salvage procedures include prosthetic joint replacement, surgical removal of bone-to-bone contact points (femoral head and neck ostectomy), arthrodesis, and amputation. Arthrodesis is the first line of treatment for all palmar and plantar luxations of the pes or manus.

MEDICATIONS

DRUG(S) OF CHOICE
• Nonsteroidal anti-inflammatory drugs (NSAIDs) decrease prostaglandin synthesis by inhibiting cyclooxygenase enzymes:
∘ Carprofen 2.2 mg/kg PO or SC q12h, or 4.4 mg/kg PO or SC q24h. ∘ Deracoxib 1–2 mg/kg PO q24h. ∘ Firocoxib 5 mg/kg PO q24h. ∘ Grapiprant 2 mg/kg PO q24h—for canines. ∘ Meloxicam 0.1 mg/kg PO or SC q24h. ∘ Robenacoxib 1–2 tablets PO depending on weight q24h for 3 days—for felines. • Tramadol 1–4 mg/kg PO q8–12h. • Gabapentin 5–10 mg/kg PO q8–12h.

CONTRAINDICATIONS
• NSAIDs and gastrointestinal sensitivity.
• NSAIDs and liver or renal pathology.

PRECAUTIONS
Stop medications if diarrhea or vomiting is seen.

POSSIBLE INTERACTIONS
• Other NSAIDs. • Steroids.

ALTERNATIVE DRUG(S)
• Analgesics (opioids). • Fish oil supplementation to decrease inflammatory mediator production.

FOLLOW-UP

PATIENT MONITORING
• Always take a radiograph after reduction.
• Some clinicians will evaluate reduction 3–5 days after initial stabilization via radiographs to ensure surgical stabilization is not warranted (note—do not remove coaptation for radiographs as this will increase risk of reluxation). • Take follow-up radiographs when the splint/sling is removed (typically 2–10 weeks post stabilization).

PREVENTION/AVOIDANCE
• Fenced-in yards. • Keep pets on a leash when outside. • Keep the sling in place for the duration of planned stabilization (for coaptation that is maintained for <3 weeks).

POSSIBLE COMPLICATIONS
• Reluxation. • Pressure sores from bandages and coaptation. • Clinical osteoarthritis.
• Infection after surgery. • Implant failure of joint prosthetic.

EXPECTED COURSE AND PROGNOSIS
• Return of function is expected unless a complication occurs. • Progressive degenerative joint disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Osteoarthritis

AGE-RELATED FACTORS
None

PREGNANCY/FERTILITY/BREEDING
If patient is pregnant, care should be taken to prescribe appropriate pain management.

SYNONYMS
Dislocation

SEE ALSO
• Arthritis (Osteoarthritis).
• Hip Dysplasia.

ABBREVIATIONS
• NSAID = nonsteroidal anti-inflammatory drug.

KERATITIS, EOSINOPHILIC—CATS

BASICS

OVERVIEW
• Presumed immune-mediated inflammation of the cornea characterized by perilimbal corneal vascularization, white-pink corneal infiltrate, and corneal edema.
• Synonym—proliferative keratitis.

SIGNALMENT
Young adult to middle-aged cats.

SIGNS
• Unilateral or bilateral.
• Variable ocular pain, often minimal.
• Serous to mucoid ocular discharge.
• Limbal superficial corneal vascularization 90–360° (temporal or inferior nasal quadrants are first affected).
• White to pink, flat or raised granular corneal infiltrate.
• Multifocal, small, white gritty corneal deposits.
• Corneal edema.
• Corneal ulceration may be present.
• Conjunctival and third eyelid hyperemia, chemosis, and thickening with possible cobblestone surface texture.

CAUSES & RISK FACTORS
• Feline herpesvirus-1 (FHV-1) may be associated, but exact role is unclear.
• Exact etiopathogenesis unknown; proposed theories are: (1) type I hypersensitivity with IgE-mediated mast cell and eosinophil degranulation, (2) type IV reaction where sensitized T-lymphocytes stimulate eosinophil-mediated corneal damage.
• Bacterial and fungal infection are not consistent etiologic causes, although secondary bacterial keratitis may occur.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Chronic corneal ulceration with secondary corneal vascularization (granulation tissue).
• FHV-1 stromal keratitis—appears similar, but lacks proliferative component, with more severe ocular pain and corneal ulceration.
• Corneal neoplasia: (1) lymphoma—concurrent conjunctival and/or uveal infiltration is common, (2) squamous cell carcinoma—rarely involves cornea in cats.
• *Chlamydia psittaci* or *Mycoplasma felis*—usually conjunctival diseases without corneal involvement.

CBC/BIOCHEMISTRY/URINALYSIS
Peripheral eosinophilia may be present.

OTHER LABORATORY TESTS
• PCR for FHV-1 has limited diagnostic value since healthy cats may have positive results.
• Immunofluorescent antibody test (IFA) testing for *Chlamydia psittaci*.

DIAGNOSTIC PROCEDURES
• Corneal cytology provides definitive diagnosis and should be done first. Typically numerous eosinophils, free eosinophil granules and/or mast cells, neutrophils, lymphocytes, plasma cells, and epithelial cells are seen.
• Cytology helps rule out chlamydia and mycoplasma.
• Fluorescein staining to evaluate for corneal ulceration.
• Keratectomy and histopathology may confirm diagnosis in chronic or nonresponsive cases.

TREATMENT
Outpatient

MEDICATIONS

DRUG(S) OF CHOICE
• Topical corticosteroids—1% prednisolone acetate or 0.1% dexamethasone sodium phosphate q6–12h for 5–7 days, then gradually taper to the lowest effective frequency of application or discontinue.
• Topical 1–2% cyclosporine A q8–12h, then tapered to lowest effective frequency of application or discontinued. Can use in cats in which oral megestrol acetate and topical corticosteroids are contraindicated. May be irritating or cause blepharitis.
• Topical 0.5% megestrol acetate q8–12h initially, then tapered to lowest effective frequency or discontinued.
• Adjunctive topical or systemic antiviral therapy may be warranted in cases with history or clinical signs compatible with FHV-1 infection.
• Subconjunctival corticosteroids—triamcinolone acetonide (0.1–0.2 mL q3–7 days); only in cats that are difficult to treat with topical medications.
• Systemic prednisolone—2.2 mg/kg PO q12h and taper. Use only if a cat will not tolerate topical therapy or oral megestrol acetate.
• Megestrol acetate—2.5 mg PO q24h for 3–5 days, then 2.5 mg PO q48h for 3–5 days, then gradually decrease frequency to the lowest effective frequency or discontinue.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Topical corticosteroid administration may be associated with recrudescence of FHV-1 keratoconjunctivitis and should be used and monitored carefully. Client should be advised to immediately report any adverse change in the condition of the eye (blepharospasm, corneal edema, increased ocular discharge, etc.).
• Megestrol acetate causes adrenal cortical suppression and may result in diabetes mellitus, polyphagia, temperament change, mammary gland hyperplasia, or neoplasia and pyometra. It should not be used in cats with hepatic disease or other illness.

FOLLOW-UP
• Response to therapy is usually rapid.
• Complete resolution may take several days to months. May require long-term therapy.
• Corneal vascularization and infiltrate may resolve completely with minimal corneal scarring.
• Recurrences in both the short and long term are common.

MISCELLANEOUS
Not typically associated with dermatologic eosinophilic granuloma complex.

ABBREVIATIONS
• FHV-1 = feline herpesvirus-1.
• IFA = immunofluorescent antibody test.

Consulting Editor Kathern E. Myrna

KERATITIS, NONULCERATIVE

BASICS

DEFINITION
An inflammatory disorder of the cornea that does not retain fluorescein stain.

PATHOPHYSIOLOGY
A pathologic response resulting in reduced corneal clarity secondary to edema, inflammatory cell infiltration, vascularization, pigmentation, lipid or calcium deposition, or scarring.

SYSTEMS AFFECTED
Ophthalmic

GENETICS
• No proven genetic basis in dogs or cats. • Chronic superficial keratitis (pannus)—inherited predisposition in German shepherd dogs.

INCIDENCE/PREVALENCE
Common in dogs and cats.

GEOGRAPHIC DISTRIBUTION
Chronic superficial keratitis is more common in regions of high UV light exposure.

SIGNALMENT

Species
• Dog—chronic superficial keratitis (pannus); pigmentary keratitis; pigmentary keratopathy of pugs; nodular granulomatous episcleritis (NGE; see Episcleritis); keratoconjunctivitis sicca (KCS; see Keratoconjunctivitis Sicca). • Cat—eosinophilic keratitis (see Keratitis, Eosinophilic—Cats); herpesvirus (stromal form); corneal sequestrum; KCS uncommon, usually secondary to chronic herpesvirus infection.

Breed Predilections
Dogs
• Chronic superficial keratitis (pannus)—highest prevalence in German shepherd dogs and sighthounds. • Pigmentary keratitis—notably brachycephalic breeds with exposure keratopathy from lagophthalmia, tear film deficiencies, and trichiasis. • Pigmentary keratopathy of pugs—suspected genetic condition that results in progressive corneal pigmentation, cause currently unknown. • NGE—prevalent in cocker spaniels, collies, and Shetland sheepdogs. • KCS—brachycephalic breeds, cocker spaniels, English bulldogs, West Highland white terriers, cavalier King Charles spaniels.

Cats
• Eosinophilic keratitis—most prevalent in domestic shorthair. • Corneal sequestration—most prevalent in brachycephalic breeds.

Mean Age and Range
• Dogs: chronic superficial keratitis—any age, usually between 3-6 years (younger in sighthounds); pigmentary keratitis and pigmentary keratopathy of pugs may occur at any age; NGE—any age, mean 3.8 years in Collies; KCS—middle-aged to older dogs. • Cats: herpesvirus, eosinophilic keratitis, and corneal sequestrum—any age.

Predominant Sex
• Dogs—female predisposition reported for pannus and KCS. • Cats—castrated male predisposition reported for eosinophilic keratitis.

SIGNS

Historical Findings
Corneal discoloration and ocular discomfort.

Physical Examination Findings
Dogs
• Chronic superficial keratitis—usually bilateral, corneal vascularization range from superficial vessels to dense granulation tissue with variable pigmentation; lateral or ventrolateral cornea (entire cornea affected in advanced cases); thickened and depigmented third eyelids; white deposits (corneal degeneration) may be present at the leading edge of corneal lesion; may lead to blindness. • Pigmentary keratitis—Focal to diffuse brown discoloration of the cornea; often with corneal vascularization or scarring. • Pigmentary keratopathy of pugs—brown corneal pigmentation originating from medial cornea and progressing towards central cornea. • NGE—bilateral or unilateral; raised, fleshy masses affecting the lateral limbus and cornea; corneal deposits, edema, and vascularization may occur in adjacent corneal stroma; slow to rapidly progressive; third eyelids may appear thickened. • KCS—unilateral or bilateral; mucoid ocular discharge, conjunctival hyperemia, corneal vascularization, pigmentation, and scarring; corneal ulceration may occur.

Cats
• Herpesvirus (stromal form)—unilateral or bilateral; stromal edema, infiltrates, deep vascularization and scarring; ulceration may occur; severe scarring may threaten vision. • Eosinophilic keratitis—usually unilateral; raised vascularized lesion with pink-white infiltrates forming gritty plaques; may retain fluorescein stain at the lesion's periphery. • Corneal sequestrum—usually unilateral (can be bilateral); amber, brown, or black plaques on the central or paracentral cornea; vary in size and depth; edges may appear raised; corneal vascularization is variable; may retain fluorescein at periphery of lesion.

CAUSES

Dogs
• Chronic superficial keratitis—presumed to be immune-mediated; high altitude (increased UV radiation exposure) increases the prevalence and severity of disease. • Pigmentary keratitis—secondary to chronic corneal irritation; evaluate for primary underlying ocular conditions; frequently associated with exposure keratopathy and KCS. • Pigmentary keratopathy of pugs—unknown, may have genetic basis. • NGE—presumed to be immune mediated. • KCS—bilateral: usually immune-mediated or drug-induced; unilateral: congenital, iatrogenic, neurogenic.

Cats
• Herpesvirus (stromal form)—immune-mediated T-cell lymphocyte reaction to herpesvirus antigen (vs. cytopathic effect of the virus). • Eosinophilic keratitis—possible hypersensitivity reaction; high incidence of animals PCR positive for feline herpesvirus type 1 (FHV-1); fewer positive for *Chlamydia*-like agents. • Corneal sequestrum—unknown; likely due to chronic corneal irritation or ulceration; suggested relationship with herpesvirus.

RISK FACTORS
Dogs—chronic superficial keratitis more likely to occur at high altitudes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Infectious keratitis is usually ulcerative and painful; cytology of the cornea reveals white blood cells, infectious organisms. In cats, stromal herpesvirus may be associated with ulcerative keratitis and secondary bacterial infection. • Neoplasia—rare involvement of sclera or cornea; distinguish based on color, age of animal, breed predilection; usually unilateral; lack of response to topical anti-inflammatory therapy. Very rare in cats.

DIAGNOSTIC PROCEDURES

Dogs
• Schirmer tear test—values <15 mm/min suggest KCS but should be interpreted with breed and ocular findings. • Cytologic examination of corneal or conjunctival scrapings—chronic superficial keratitis characterized by lymphocytes, plasma cells, and mast cells. • Biopsy of episcleral nodular mass or cornea (superficial keratectomy)—for NGE diagnosis, can be considered for patients with chronic superficial keratitis.

Cats
• Conjunctival or corneal scraping—PCR most successful for diagnosis for herpesvirus (IFA or viral culture of limited value). Eosinophilic keratitis: eosinophils on cytology. • Superficial keratectomy—consider for diagnosis of eosinophilic keratitis or sequestrum but usually unnecessary.

(CONTINUED) KERATITIS, NONULCERATIVE

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient—generally sufficient.
- Inpatient—cases that warrant surgery due to inadequate response to medical therapy.

CLIENT EDUCATION

Dogs

Typically lifelong treatment; disease is controlled rather than cured.

Cats

- Herpesvirus—ocular discomfort and keratitis often recur. • Eosinophilic keratitis—disease controlled rather than cured. • Corneal sequestrum—may slough spontaneously, however cornea may rupture; clinical course often protracted without surgery; removal of sequestrum by superficial keratectomy may be curative, although recurrence possible.

SURGICAL CONSIDERATIONS

Dogs

- Chronic superficial keratitis—superficial keratectomy for severe disease in which vision is impaired due to corneal pigmentation; patients still require indefinite medical treatment to prevent recurrence; β-irradiation with a strontium-90 probe is noninvasive and may be performed in severe cases.
- Pigmentary keratitis—superficial keratectomy may be performed only after initial underlying cause is corrected; only in severe cases that threaten vision. • Pigmentary keratopathy of pugs—high likelihood of recurrence after superficial keratectomy.
- NGE—superficial keratectomy is diagnostic; medical treatment is still required. • KCS—parotid duct transposition or permanent partial tarsorrhaphy to reduce exposure.

Cats

- Eosinophilic keratitis—superficial keratectomy is diagnostic but not curative; medical treatment is preferred. • Corneal sequestrum—superficial keratectomy may be curative; recurrence is possible.

MEDICATIONS

DRUG(S) OF CHOICE

Dogs

- Chronic superficial keratitis—topical corticosteroids (1% prednisolone or 0.1% dexamethasone q6–12h); topical 0.2–2% cyclosporine, 1% pimecrolimus, or 0.03% tacrolimus q8–12h; agents can be used alone or in combination for more severe cases; subconjunctival corticosteroid injection (triamcinolone acetonide, 2–8 mg) can be used as an adjunct to topical therapy in severe cases. • Pigmentary keratitis—treatment directed at underlying cause; topical corticosteroids if primary cause is inflammatory; lubricants and cyclosporine or tacrolimus if primary condition is KCS; cyclosporine or tacrolimus may reduce pigmentation in all cases. • Pigmentary keratopathy of pugs—topical cyclosporine 0.2–2% or tacrolimus 0.02–0.03% may arrest progression of corneal pigmentation; topical corticosteroids may temporarily reduce density of corneal pigment. • NGE—topical corticosteroids and/or cyclosporine as described above; systemic azathioprine (2 mg/kg/day PO, initially, then gradually reduce) may be effective when used alone or in combination with topical medications.
- KCS—topical 0.2–2% cyclosporine, or 0.02–0.03% tacrolimus q8–12h (see Keratoconjunctivitis Sicca).

Cats

- Herpesvirus—topical antiviral agents recommended: cidofovir 0.5% q12h or trifluridine q4–6h for 2 days, then taper. Systemic antiviral agents include: famciclovir 90 mg/kg PO q12h. For inflammation, topical nonsteroidal anti-inflammatory drugs or cyclosporine q12h may be used.
- Eosinophilic keratitis—topical corticosteroids (1% prednisolone or 0.1% dexamethasone) q6–12h; patient monitored for ulceration or worsening of clinical signs; topical antivirals can be used in combination with corticosteroids if concurrent herpesvirus; use of topical cyclosporine reported (0.2–1.5%) with variable results; megestrol acetate (5 mg PO q24h for 5 days, then 5 mg PO q48h for 1 week, then 5 mg PO weekly for maintenance) is highly effective, but associated with side effects. • Corneal sequestrum—topical antibiotic (terramycin or erythromycin) q8–12h for associated corneal ulceration; artificial tear lubrication may relieve discomfort; topical antivirals can be used if herpesvirus infection is suspected; topical 1% atropine ointment q12–24h for pain from concurrent uveitis if present.

CONTRAINDICATIONS

Topical corticosteroids contraindicated with corneal ulcers; topical atropine contraindicated with KCS, glaucoma, or lens luxation. Topical neomycin and polymixin may cause anaphylactic reactions in cats.

PRECAUTIONS

- Azathioprine may cause gastrointestinal signs, pancreatitis, hepatotoxicity, and myelosuppression. • Megestrol acetate—not FDA-approved for use in cats; possible side effects include polyphagia, diabetes mellitus, mammary hyperplasia, mammary neoplasia, and pyometra. • Famciclovir— anorexia, polydipsia.

FOLLOW-UP

PATIENT MONITORING

Periodic ocular examination recommended to evaluate efficacy of treatment; examine at 1- to 2-week intervals, gradually lengthening the interval with remission or resolution of clinical signs; taper medications based on resolution of clinical signs; complete resolution of pigmentation may not occur. UV light protection (tinted goggles) is recommended for pannus.

POSSIBLE COMPLICATIONS

All of the above may lead to continued ocular discomfort, visual defects, or blindness in severe cases.

K

KERATITIS, ULCERATIVE

BASICS

DEFINITION
Inflammation of the cornea associated with loss of corneal epithelium (corneal erosion) or loss of variable amounts of underlying corneal stroma (corneal ulcer).

PATHOPHYSIOLOGY
• May be caused by any condition (traumatic or nontraumatic) that disrupts corneal epithelium or stroma. • Ulcers—superficial or deep, uncomplicated or complicated: ○ Superficial—involves epithelium and possibly superficial stroma. ○ Deep—involves a greater thickness of stroma and may extend to Descemet's membrane (descemetocele), possibly leading to rupture of globe. ○ Complicated—persistence of underlying/inciting cause, microbial infection, or production of degradative enzymes (melting). • Epithelial wound healing—adjacent corneal epithelial cells loosen and begin migration over the defect within a few hours; mitosis occurs within a few days to restore normal epithelial thickness; healing process complete in 5–7 days in uncomplicated, superficial ulcers. • Stromal wound healing—slower, more complex; can be in an avascular or vascular manner; in shallow wounds, epithelial migration may be sufficient to fill defect; epithelium may cover some deeper ulcers even when epithelium and stromal regeneration are insufficient to restore normal corneal thickness (nonulcerated divot defect is called a facet); stroma usually heals by fibrovascular infiltration, resulting in scarring. • Stromal ulcers—often complicated by microbial infection or enzymatic destruction initiated by microbial organisms, host inflammatory cells, or corneal epithelial or stromal cells; enzymatic destruction may result in gelatinous appearance of corneal stroma ("melting" or "malacic" ulcer).

SYSTEMS AFFECTED
Ophthalmic

GENETICS
• No proven basis; breed predilections exist. • May be secondary to other corneal diseases with breed predispositions and genetic basis, such as corneal epithelial dystrophy in Shetland sheepdogs and corneal endothelial dystrophy in Boston terriers.

INCIDENCE/PREVALENCE
Common

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Dogs—brachycephalic breeds predisposed. • Spontaneous chronic corneal epithelial defects (SCCED)/indolent erosion—any breed. • Cats—Persian, Himalayans, Siamese, and Burmese predisposed to corneal sequestrums (see Corneal Sequestrum—Cats).

Mean Age and Range
• Age of onset—variable; determined by cause. • SCCED—middle-aged and older dogs.

SIGNS

Historical Findings
• May be acute or chronic (SCCED). • Tearing, squinting, rubbing at eyes. • Owners may report a "film" over the eye (often corneal edema); prolapsed third eyelid. • Herpetic ulcers (cats)—may have history of respiratory disease.

Physical Examination Findings
• Nonspecific—serous to mucopurulent ocular discharge, blepharospasm, nictitans prolapse, conjunctival hyperemia. • Superficial—may note one or more circumscribed, linear, or geographic defects in cornea. • Deep stromal ulcer or descemetocele—may appear as a crater-like defect. • Depending on cause and duration—may see neovascularization, pigmentation, scarring, inflammatory cell infiltrate (yellow to cream-colored opacity with indistinct margins, often surrounded by corneal edema), collagenolytic activity (melting) of corneal stroma. • SCCED—loose or redundant epithelial edges; may demonstrate fluorescein stain extending into areas with seemingly intact epithelium (ring of less intense staining). • Reflex anterior uveitis—mild or severe, secondary to ulceration; severe may result in hypopyon; severe suggests concurrent bacterial infection.

CAUSES
• Trauma—blunt; penetrating; perforating. • Adnexal disease—ectopic cilia, entropion, ectropion, eyelid mass, distichiasis. • Lagophthalmos (inability to close eyelids completely)—results in exposure keratitis; may be breed-related in brachycephalic dogs and cats; may be caused by exophthalmos, buphthalmos, or may be neuroparalytic from facial nerve paralysis. • Tear-film abnormality—quantitative tear deficiency (keratoconjunctivitis sicca [KCS]); qualitative tear film deficiency caused by mucin deficiency or some other unidentified tear abnormality. • Infection—usually secondary in dogs; can be primary herpesvirus infection in cats. • Primary corneal disease—endothelial dystrophy; other endothelial disease. • Miscellaneous—foreign body (corneal or conjunctival), chemical burns, neurotrophic keratitis (loss of trigeminal sensation), immune-mediated disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other causes of a red and painful eye—conjunctivitis, uveitis, KCS, glaucoma (see Red Eye). • May develop concurrently with other causes of a red eye (e.g., secondary to KCS).

OTHER LABORATORY TESTS
• Corneal culture and sensitivity—aerobic culture; particularly for complicated, deep, or rapidly progressive corneal ulcers. • Herpesvirus (cats)—PCR or immunofluorescent antibody test (IFA) for herpesvirus available; negative test does not rule out herpesvirus infection.

DIAGNOSTIC PROCEDURES

Fluorescein Staining
• Homogeneous stain uptake—superficial or stromal ulcer; may be circular to geographic, linear, or combination; location and shape may help determine cause (e.g., linear may indicate foreign body or rubbing of ectopic cilia); interpretation of depth subjective. • SCCED—may have leakage of stain under surrounding loose epithelium. • Descemetocele—crater-like defect that retains stain at periphery but is clear at center; may see Descemet's membrane bulging if large defect. • Previous stromal ulcer that has epithelialized (facet)—crater-like defect with transient pooling of stain that is easily rinsed; must distinguish from descemetocele.

Other
• Cytologic evaluation of cornea and Gram, Giemsa, or Wright staining may reveal microbial or fungal organisms and help direct initial antimicrobial therapy. • Schirmer tear test may identify ulceration associated with KCS; contraindicated in very deep ulcers or descemetoceles.

PATHOLOGIC FINDINGS
• Ulcers—suppurative inflammation, possibly neovascularization, loss of epithelium and basement membrane; possibly organisms. • SCCEDs—superficial hylanized zone in stroma; epithelial lipping around erosions; varying degrees and types of leukocytic infiltrate and fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE
Hospitalize deep or rapidly progressive ulcers; these may require surgery and/or frequent medical treatments.

(CONTINUED) KERATITIS, ULCERATIVE

NURSING CARE
Keep facial hair out of eyes and clean.

ACTIVITY
• Restrict with deep stromal ulcer or descemetocele to prevent rupture. • Prevent self-trauma with Elizabethan collar.

CLIENT EDUCATION
• Instruct client to wait at least 5 minutes between medications if more than one ophthalmic drop is prescribed; wait longer between ointments. • Advise client to contact veterinarian if patient appears more painful or the eye markedly changes in appearance. • SCCED—discuss protracted course with client; usually achieve healing within 2–6 weeks but may require weekly rechecks and multiple procedures.

SURGICAL CONSIDERATIONS
• Superficial ulcers do not usually require surgery if inciting cause has been eliminated. • Ulcer that extends one-half or greater corneal thickness and particularly to Descemet's membrane may benefit from surgery. • Descemetocele or full-thickness corneal laceration—surgical emergency, possible referral.

Procedures
• SCCED—debridement of loose epithelium with a dry, sterile, cotton-tipped swab after application of topical anesthesia (50% success rate); punctate or grid keratotomy easily performed after epithelial debridement with topical anesthesia (80% success rate); superficial keratectomy is more invasive and may cause more scarring but has 100% success rate; application of a contact lens or nictitans flap after any of these procedures may improve comfort and aid healing. • Diamond burr keratotomy for SCCED/indolent erosion only; use gently over surface of erosion; may be associated with increased risk of infection. • Rotational pedicle conjunctival flap, corneoscleral transposition, corneal transplant—surgical procedures for ulcers >50% stromal thickness and descemetoceles. • Cyanoacrylate repair (corneal glue)—can be used for deep ulcers; promotes corneal vascularization and stabilizes cornea, but has lower success rate compared to other corneal surgeries.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics
• Topical agents—indicated for all patients. • Frequency of application—determined by severity and preparation; ointments have relatively long contact time and are applied q6–12h; solutions are applied more frequently (q2–6h) in initial treatment of complicated ulcers; solutions probably more appropriate in deep ulcers. • Commonly used agents—erythromycin (cats); triple antibiotic, gentamicin, and tobramycin. • Uncomplicated ulcers or superficial erosions—combination of neomycin, polymyxin B, and bacitracin an excellent first choice; broad spectrum of antimicrobial activity; often used 2–3 times/day for prophylactic therapy. • Complicated ulcers—often use combination therapy of cefazolin (use IV solution to make 33–50 mg solution in saline or artificial tears for topical use) with a fluoroquinolone (ciprofloxacin, ofloxacin); particularly in rapidly progressive, deep, or melting ulcers; frequency depends on severity but usually a minimum of q3–4h.

Atropine
• 1% ointment or solution. • Indicated for reflex anterior uveitis; frequency—usually q8–24h to effect (mydriasis).

Antiviral Agents
• Indicated for herpetic ulcers in cats. • Trifluridine (Viroptic) solution—q4–6h until clinical response is observed; then reduce for 1–2 weeks after clinical signs have subsided. • Famciclovir—90 mg/kg PO q12h for 2–4 weeks.

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)
• Flurbiprofen, diclofenac. • For anti-inflammatory and analgesic properties.

CONTRAINDICATIONS
• Topical corticosteroids—contraindicated with any corneal erosion or ulcer. • Topical NSAIDs—contraindicated with herpetic ulcers. • Topical atropine—contraindicated with glaucoma, KCS.

PRECAUTIONS
• Topical NSAIDs may delay corneal healing, may potentiate corneal melting. • Trifluridine, neomycin—may be irritating. • Topical cyclosporine can be used safely in KCS patients with uncomplicated ulcers.

POSSIBLE INTERACTIONS
Combining antibiotics in solution may inactivate some antibiotics.

ALTERNATIVE DRUG(S)
• Acetylcysteine—anticollagenolytic agent used for treatment of melting ulcers; efficacy is controversial; dilute 20% stock solution to 5–10% with artificial tears; apply q2–4h. • Serum—anticollagenolytic agent; keep refrigerated; avoid contamination; discard after 48 hours.

FOLLOW-UP

PATIENT MONITORING
• Superficial ulcers—repeat fluorescein stain in 3–6 days; if it persists 7 days or longer, either inciting cause has not been eliminated or patient has an SCCED. • Deep stromal or rapidly progressive ulcers—assess every 24 hours initially if outpatient until improvement is seen; many of these patients are hospitalized or undergo surgery; decrease frequency of antibiotic therapy as condition improves.

PREVENTION/AVOIDANCE
• Brachycephalic dogs—lubricant ointment administration, permanent partial tarsorrhaphy surgery, or both may prevent recurrent ulceration. • KCS-related ulcers—lifelong treatment of KCS (cyclosporine) or parotid duct transposition surgery. • Herpesvirus (cats)—oral lysine (250 mg PO q12h) may prevent viral replication; may decrease severity and/or frequency of outbreaks.

POSSIBLE COMPLICATIONS
Progressive corneal ulceration—rupture of globe, endophthalmitis, secondary glaucoma, phthisis bulbi, blindness, blind and painful eye (may require enucleation).

EXPECTED COURSE AND PROGNOSIS
• Uncomplicated superficial ulcer—usually heals in 5–7 days. • SCCED—may persist for weeks to months; may require multiple procedures. • Deep corneal ulcer treated medically—may require several weeks for fibrovascular repair of defect; does not always granulate satisfactorily; continued deterioration of ulcer and globe rupture are possible. • Deep ulcer treated with conjunctival flap—frequently results in more comfort within a few days after surgery; blood supply to flap can be cut in 4–6 weeks to decrease scarring.

MISCELLANEOUS

ABBREVIATIONS
• IFA = immunofluorescent antibody test. • KCS = keratoconjunctivitis sicca. • NSAID = nonsteroidal anti-inflammatory drug. • SCCED = spontaneous chronic corneal epithelial defect.

Consulting Editor Kathern E. Myrna

Client Education Handout available online

K

KERATOCONJUNCTIVITIS SICCA

BASICS

OVERVIEW
- Deficiency of the aqueous layer of precorneal tear film.
- Causes corneal/conjunctival drying and resultant surface inflammation.

SIGNALMENT
- Common in dog; rare in cat.
- Predisposed dog breeds—many brachycephalic and spaniel breeds, miniature schnauzers, poodles, bloodhounds, Samoyeds, West Highland white terriers, and Yorkshire terriers.
- Inheritance—undefined.
- Age of onset—variable and depends on inciting cause.

SIGNS
- Conjunctival hyperemia.
- Mucoid to mucopurulent ocular discharge—intermittent to persistent depending on severity.
- Blepharospasm.
- Corneal changes—dryness, superficial vascularization, pigmentation, fibrosis, ulceration.
- Blepharitis due to ocular exudates.
- Severe disease—impaired vision or blindness.
- Cats are less symptomatic than dogs.

CAUSES & RISK FACTORS
- Immune-mediated/idiopathic—most common, possibly associated with other immune-mediated diseases (e.g., atopy).
- Infectious—canine distemper virus; leishmaniasis; chronic blepharoconjunctivitis (e.g., feline herpesvirus).
- Iatrogenic—removal of third eyelid gland (especially in at-risk breeds), radiation therapy.
- Congenital—Yorkshire terriers overrepresented.
- Neurologic—loss of parasympathetic innervation to lacrimal gland, trigeminal nerve deficit, or dysautonomia; neurogenic parasympathetic loss may have ipsilateral dry nose.
- Traumatic—after ocular proptosis or orbit inflammation.
- Systemic disease—diabetes mellitus, hyperadrenocorticism, hypothyroidism, or any debilitating disease.
- Drug-induced—systemic sulfonamides (e.g., trimethoprim-sulfadiazine).
- Transient—general anesthesia and atropine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Often confused with allergic or bacterial conjunctivitis.
- Dogs with keratoconjunctivitis sicca (KCS) may have concurrent bacterial overgrowth.
- Differentiate with Schirmer tear test.

DIAGNOSTIC PROCEDURES
- Schirmer tear test—normal value at least 9 mm/min (cat) or 15 mm/min (dog) of wetting; symptomatic patients usually <10 mm/min of wetting; lower values combined with clinical signs suggest KCS.
- Fluorescein staining—may show corneal ulcers.
- Conjunctival cytology—may demonstrate bacterial overgrowth.

TREATMENT
- Outpatient—unless severe corneal ulceration.
- Instruct client to use solution(s) before ointment(s) and wait 5 minutes between treatments.
- Advise client to call at once if ocular pain increases (patients are predisposed to corneal ulceration).
- Parotid duct transposition—surgical option for dogs and cats that reroutes parotid duct to deliver saliva to ocular surface if KCS is refractory to lacrimostimulant therapy.
  - More common with congenital KCS.
  - Saliva can irritate cornea and result in mineral deposits; some patients require ongoing topical therapy.
- Episcleral cyclosporine implant—for dogs responsive to topical cyclosporine but with poor owner compliance.

MEDICATIONS

DRUG(S) OF CHOICE
- Lacrimostimulants—cyclosporine 0.2% ointment or 1–2% solution; tacrolimus 0.02–0.03% solution or ointment—therapy q12h recommended (q8h if severe or refractory).
- For neurogenic KCS—pilocarpine 0.1–0.2% topically q8h or very careful oral pilocarpine (narrow therapeutic window; see Suggested Reading).
- For feline KCS—antiviral therapy (see Conjunctivitis—Cats); hyaluronate-based artificial tear in short term; consider lacrimostimulant therapy.
- Lacrimomimetics—artificial tears to moisten ocular surface to improve comfort; use viscous solutions or gels q2–12h depending on severity and ointment before bedtime; can reduce frequency once patient responds to lacrimostimulants.
- Broad-spectrum antibiotics—topical ointment q6–8h for 3–4 weeks; indicated for secondary bacterial overgrowth or concurrent corneal ulceration.
- Ocular cleansing—use eye wash to remove discharge and debris prior to administering medications; if mucoid discharge is very tenacious, 5% *N*-acetylcysteine can be used q6–12h as a mucinolytic agent prior to eye rinsing.
- Corticosteroids—topical; minimize inflammation; can reduce corneal vascularization and pigmentation once aqueous tears improve; not commonly used (corneal ulcer risk).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Topical cyclosporine or tacrolimus—rarely irritating, but if noted consider compounded aqueous preparation.
- Pilocarpine—initially irritating topically; systemic side effect risk.
- Topical corticosteroids—avoid with ulcerative keratitis or severe KCS (corneal ulcer risk).

FOLLOW-UP
- Regular rechecks—monitor response and progress.
- Schirmer tear test—4–6 weeks after initiating cyclosporine or tacrolimus (patient should receive drug as prescribed on day of visit).
- Usually requires life-long treatment.
- Good prognosis but refractory cases may require more aggressive therapy (e.g., up to 1% tacrolimus) or surgery (e.g., parotid duct transposition).

MISCELLANEOUS

ABBREVIATIONS
- KCS = keratoconjunctivitis sicca.

KITTEN BEHAVIOR PROBLEMS

BASICS

DEFINITION
Undesirable behaviors exhibited by kittens between birth and puberty.

PATHOPHYSIOLOGY
• Most pediatric behavior problems are normal, species-typical behaviors. • Lack of appropriate social interactions and environmental stimulation and genetics can contribute to abnormal or unwanted behaviors.

SYSTEMS AFFECTED
Behavioral

GENETICS
Paternal influences on friendliness to people and boldness to unfamiliar or novel objects have been supported.

SIGNALMENT

Species
Cats

Mean Age and Range
Generally 6–48 weeks.

SIGNS

General Comments

Play Aggression
• Elements of predation including stalking, chasing, attacking, pouncing, swatting, and biting. Play can be solitary, with objects, or social to another kitten, animal or person.
• With normal play, bites are inhibited and claws retracted. Vocalizations are rare compared to other forms of feline aggression.
• Inappropriate play behaviors may be uninhibited, leading to bite and scratch injuries.

Excessive Play/Activity and/or Destructive Play
High level of solitary play (running, jumping, climbing, object play) may result in household damage and disruption.

Scratching
• Use of claws to scratch on household items and/or people.
• Scratching is a normal behavior for claw maintenance, territorial marking, and defense but becomes problematic when scratched objects include walls, furniture, carpets, and other household items.

Fearful Behaviors
Includes hiding, hissing, scratching, and unsocial behaviors and can include varying manifestations of aggression to another animal or person.

Historical Findings

Aggressive Play Directed toward People or Other Pets in the Household
• Attacks directed toward people or other pets in the household. • Ambushes are common and lack vocalizations. Bites are generally inhibited but may puncture the skin

Uninhibited Aggressive Play Directed toward People
• Signs similar to above except more intense.
• Bites and scratches are not as inhibited and can break skin.

Play Directed toward Household Objects
• Bursts of solitary play that include intense running, climbing across and up household furnishings. • Knocks or swipes objects from surfaces.

Scratching
Household items and family members.

Fear and Defensive Behaviors Due to Lack of Socialization
• Insufficient exposure to people before 7–9 weeks of age. • Behaviors associated with fear, e.g., dilated pupils, piloerection, defensive postures, hissing, hiding, fleeing, aggression.

Fear and Defensive Behaviors Related to Early Trauma
Normal until experience traumatic event, e.g., abuse, attack by another animal.

Fear and Defensive Behaviors Related to Correction Techniques
• History of punishment by owner(s).
• Kitten shows defensive postures including hissing, fleeing, hiding, dilated pupils, piloerection in presence of owner or in response to corrections.

CAUSES

Aggressive Play Directed toward People or Other Cats in the Household
• Normal species-typical behavior but without appropriate social interaction with conspecifics, the behavior can become uninhibited and injurious. • Owners may encourage inappropriate interactive play by promoting play with human body parts (fingers, hands, feet). • Lack of outlets for appropriate play.

Play Directed toward Objects in the Household
Normal species-typical behavior beginning at 7–8 weeks of age.

Fear and Defensive Behaviors Due to Lack of Early Socialization
No or minimal amount of exposure to people before 7–9 weeks of age.

Fear and Defensive Behaviors Related to Early Trauma
Early traumatic event.

Fear and Defensive Behaviors Related to Correction Techniques
Normal until "corrected" by person, e.g., spanked, swatted, flicked on nose, yelled at, chased.

RISK FACTORS

Aggressive Play Directed toward People
• Only cat in household, hand-reared kitten, or

appropriate outlets for normal play and exploration. • Encouragement of inappropriate play (e.g., with hands, fingers, feet).

Play Directed toward Objects in the Household
• Lack of sufficient/appropriate enrichment including toys and interactive play with people or other animals. • Only pet in household.

Scratching
Lack of appropriate/inadequate scratching outlets.

Fear and Defensive Behaviors
• Lack of appropriate socialization with people, use of punishment and other traumatic experience(s). • Removing kittens less than 2 weeks of age from queen may result in fearful and aggressive kittens towards humans and other cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Play Aggression toward People
Differentiate normal play from the more serious, uninhibited play aggression.

Excessive Play/Destructive Behaviors
None.

Scratching
Nail maintenance, marking, play-related, or defense.

Fearful and Defensive Behaviors
CNS diseases, pain, metabolic disorders, pain.

CBC/BIOCHEMISTRY/URINALYSIS
Frightened kittens may have elevated glucose levels, stress leukogram.

TREATMENT

ACTIVITY
Many kitten behavior problems can be alleviated or reduced by enriching kitten's environment (e.g., provide movable toys, variety of toys, rotating them regularly). Engage the kitten in interactive play directed away from the owner's body parts. Provide access to window sills and perches. Offer a variety of enticing scratching surfaces. Possibly get second kitten.

DIET
Provide multiple small meals. Use food delivery toys.

CLIENT EDUCATION
Most of these problems are normal kitten behaviors that owners perceive as abnormal or excessive and inappropriate for their lifestyle. Most kittens will mature out of these problem behaviors with appropriate management and by providing for behavioral needs.

Aggressive Play Directed toward People
• Owner needs to initiate regular interactive

KITTEN BEHAVIOR PROBLEMS (CONTINUED)

Ensure owners never use hands, fingers, or feet to encourage play. • Effective treatment may be to acquire another kitten, if size and temperament are compatible. • Redirection: Identify situations in which the attacks may occur. Watch for signs of dilated pupils, stalking, crouching, tail swishing. Be prepared to redirect the play to another object (e.g., tossing a wadded piece of paper or chasing a toy) or to cue and reward alternative desirable behaviors that the kitten has learned (e.g., go to mat, sit/watch, let's eat, let's play). • Educate the client to not hit or swat or punish. • Immediately stop any attention or play for inappropriate behaviors. • Interrupt to redirect into alternative acceptable behaviors with trained cues (sit, go to mat) or with a noise to reorient into desirable play. • Frequent trimming of claws helps reduce damage caused by nails. • For humane and welfare reasons declawing is strongly discouraged and prohibited in many countries and jurisdictions. Where legally permissible it should be a last resort only if owners have been fully counselled on behavior management, modification and alternative options.

Aggressive Play Directed toward Other Cats in the Household

• Acquire additional kitten of the same size and temperament as the problem kitten. • Watch for signs and redirect into alternative acceptable behaviors (sit/watch, go to mat). • Problem kitten and other cat should have restricted access to each other at times when problems might arise. • Startling, punitive techniques may aversively affect the other cat and are not recommended. • Provide appropriate outlets for predatory behaviors with the problem kitten on a regular, daily basis using toys or objects.

Play That Is Excessive and/or Destructive, and Scratching

• Put valuable, breakable, or dangerous objects away. • Provide a variety of appropriate toys for batting and food delivery and rotate every few days to maintain novelty and interest. • Interactive play with kitten using toys or objects on a daily basis. • Provide scratching posts using materials that are cat's preferred substrates and assure they are long enough and stable enough for the cat to stretch and scratch. • Place scratching stations in commonly used areas and encourage use with catnip, treats, and integrating perches and resting areas. • Decrease the appeal of the targeted objects, e.g., with sticky tape, unpleasant taste or odor, or less appealing substrate. • Frequent trimming of claws. • Declawing is a humane concern and in many places prohibited.

Fear and Defensive Behaviors Due to Lack of Early Socialization or from Early Trauma

• Gradual exposure to people without forcing interactions, provided no negative outcome/endpoint. • House kitten where it is conditioning generally required. Highly enticing food and treats should be offered. Initially, food can be put in or near hiding area. Gradually food is given with increasing proximity to the people, ending each session at a distance or location where the cat remains calm and will take food. No attempt should be made to grab or hold the kitten. Progress gradually until the kitten takes food that is tossed toward it, given by hand, or given while the kitten is on the person's lap. Counter-conditioning can also include play with toys that can tossed or chased, such as those on wands or ropes. • Important: Let the kitten make the advances—not the person—and avoid any fearful endpoint by forcing interaction, preventing escape, or progressing too quickly.

Fear and Defensive Behaviors Related to Correction Techniques

Identify and cease inappropriate punishment.

MEDICATIONS

DRUG(S) OF CHOICE

• None needed except as indicated for fear and anxiety. See also Fears, Phobias, and Anxieties—Cats. • May consider use of feline pheromones and nutritional supplements with alpha-casozepine or L-theanine for mild fear and anxiety.

FOLLOW-UP

PATIENT MONITORING

• Telephone follow-up support is helpful. • Be sure clients are not using aversive techniques that may induce fear and aggression in the kitten and/or exacerbate intensity of play aggression.

PREVENTION/AVOIDANCE

• Kitten behavior problems are often a result of owner's unrealistic expectations and misunderstanding of normal kitten behavior, as well as lack of enrichment and appropriate predatory play outlets. • Between 3 and 7 weeks of age, kittens should experience positive interactions with people to reduce fear and develop appropriate social bonds with humans. • Between 4 and 18 weeks, it is helpful to have exposure to tolerant (and playful) conspecifics to learn effective bite and play inhibition. • Advise family members to avoid rough-housing and body part play with kittens. • Discourage punitive corrections.

EXPECTED COURSE AND PROGNOSIS

Normal Play Behaviors Directed toward People, Other Cats, and Household Objects

Reduction or resolution of problem when appropriate treatment protocols are followed. Many behaviors may begin to wane with

Uninhibited Aggressive Play Directed toward People

• Guarded prognosis. • Aggression may become more severe with maturity. A better prognosis is given to those cases that are caught early and appropriately counseled or by obtaining a second compatible cat.

Scratching

If measures to prevent, divert, and reward for using appropriate scratching surfaces are successful, the prognosis is good, and as the kitten matures, the behaviors wane. Some cats may need long-term management.

Fear and Defensive Behaviors Due to Lack of Early Socialization or Related to Early Trauma

Kittens vary in the degree to which they acclimate to people; improvement may take months to years; some may never be comfortable around people. • The longer the interval from 3 weeks of age to exposure to people, the poorer the prognosis. • The more intense the early trauma, the poorer the prognosis.

Fear and Defensive Behaviors Related to Correction Techniques

These can resolve if corrections have not been too frequent or too intense, and the clients follow advice to replace these techniques with reward-based, avoidance, and redirection procedures.

MISCELLANEOUS

AGE-RELATED FACTORS

Fear and Defensive Behaviors Due to Lack of Early Socialization

During the sensitive period, between 3 and 7 weeks, the kitten must be exposed to people to prevent fearful and defensive responses to them.

KITTEN SOCIALIZATION AND KITTEN CLASSES

BASICS

OVERVIEW

• Early experiences set the foundation for future behavior, having long lasting effects on social behavior, temperament, and the ability to learn and relate to various stimuli and to cope in various environmental contexts.
• For a kitten to grow up into a well-adjusted adult cat, adequate socialization and environmental exposure is needed during the socialization period and beyond into the first year of life.

Definitions

• Socialization—a process of learning normal behavior, communication, and social skills for appropriate interactions with other individuals in various contexts. • Socialization period—a sensitive window of development whereby a cat learns to communicate and relate to other cats, humans, and the environment. • Kitten classes—also called kitten "kindy" or kindergarten. Allow cats to socialize with other cats, a variety of people, and to be exposed to multiple and varied environmental stimuli in a positive and nonthreatening manner.

Pathophysiology

Potential effects on behavioral and neurological development.

SIGNALMENT

Genetics

Genetics or the paternity of the kittens, with kittens sired from friendly toms being friendlier toward people.

Mean Age

• The sensitive socialization period is between 2 weeks and 7 weeks, yet socialization is a continuous process. During the socialization period, less experience is necessary to produce profound effects on future behavior. Handling only 15 minutes per day from 2 to 6 weeks of age has been shown to produce more friendly kittens. • For kitten classes—healthy dewormed kittens should begin attending group classes 10 days after receiving the first vaccination of their kitten immunization series. Typically begin classes between 8 and 12 weeks and conclude by 14 weeks.

Predominant Sex

• Male kittens play more with objects than females. • No sex differences in social play.

SIGNS

• Lack of adequate socialization experiences during sensitive periods of development.
• Cat-directed fear and/or aggression—lack of early familiarity and positive exposure with other cats. • Human-directed fear and/or aggression—early positive social experiences with humans prior to 7 weeks, otherwise fear, avoidance, aggression, and behaving as if "feral." • Predatory aggression—exposure to future prey species, starting at 4 weeks, can improve predatory behavior and hunting ability, whereas exposure to non-prey species may reduce aggression later in life. • Fear and anxiety in unfamiliar environments.
• Attendance at group kitten classes at an early age can prevent future behavior problems and/or allow for the early identification of abnormal and problematic behavior. • Kitten classes—age-specific (8 and 12 weeks at start and finished by 14 weeks) for group-controlled interactions. Focus is education regarding normal behavior, the prevention of behavior problems, and addressing normal problematic behaviors through management, supervision, and positive reinforcement training.

CAUSES & RISK FACTORS

• Avoiding environmental and social experiences prior to the completion of kitten vaccination series increases the risk of future behavior problems. • The risk of exposure to infectious disease with socialization and environmental exposure needs to be considered along with the risk of being undersocialized and not suitable as a pet because of lifelong fear, anxiety, and aggressive issues. • A clean bill of health and initial vaccinations must have been administered at least 10 days prior to class. • Kittens should be dewormed according to the Companion Animal Parasite Council guidelines. https://capcvet.org/guidelines/general-guidelines/
• Kittens should be screened for contagious diseases, such as upper respiratory infection and ringworm, prior to each class. • Kitten classes "vaccinate" the kitten against behavior problems later in life. • Genetics and a lack of socialization can render some kittens intolerant to human handling and behaving as if feral. • Kittens removed from the queen and exclusively hand raised by humans are more fearful and aggressive toward cats and humans, tend to be hyperactive, have difficulty forming social attachments with other cats, and display poor learning ability.
• Removal from the queen and littermates prior to 10 weeks of age may increase the risk of inter-cat aggression with a lack of learned social skills. • Kittens weaned too early are more likely to perform non-nutritive suckling and kneading of objects. • Experiences at the veterinary clinic should employ Fear Free and/or Low Stress handling techniques.
• Traumatic experiences that induce fear during sensitive fear periods when the kitten is between 6 and 8 weeks of age should be avoided. • Avoiding exposure to other species during socialization may result in fear toward the species, whereas experience with species that might normally have a predator–prey relationship may increase predatory behavior toward that species. • Early exposure of kittens to dogs living within the household improves the likelihood of successful cohabitation. • Kitten socialization with people and cats is only beneficial to behavioral development if the kitten finds human and/or cat contact enjoyable. Continued exposure when it induces fear is unlikely to result in habituation to the stimulus and is likely to exacerbate fear and/or aggression.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Identify abnormal and/or problematic behavior and make a behavioral diagnosis or schedule or refer for a behavior consultation.

Possible Behavioral Manifestations of a Lack of Socialization

• Global fears, encompassing fears of people, cats, other animals, objects, sounds, and environments. • Generalized anxiety and situational anxiety in unfamiliar environments.
• Specific fears, neophobia and failure to habituate to novelty or stimuli. • Noise sensitivity, aversions, and phobias.
• Hyperexcitability and hypervigilance with an inability to settle due to a lack of early environmental enrichment. • Aggression toward people and cats in various contexts with various motivations (e.g., fear, predatory).

TREATMENT

Recommendations for Socialization

• Socialization "vaccinates" the kitten against the development of future behavioral problems and should begin concurrently with the kitten immunization series. • Food treats and social play should be used liberally with new and repeated kitten socialization experiences while keeping the kitten safe.
• Social play and exploration should be encouraged using toys in various contexts and environments while keeping the kitten safe.
• Healthy kittens usually have good appetites. If the kitten is not consuming food treats in specific contexts, it suggests the kitten is fearful and the experience is not positive or beneficial for socialization.
• Healthy and well-adjusted kittens play. If the kitten will not engage in play, it suggests the kitten is fearful and the experience is not positive or beneficial for socialization.
• Socialization by the breeder—gentle handling should occur daily, shortly after birth, and include exposure to multiple

KITTEN SOCIALIZATION AND KITTEN CLASSES (CONTINUED)

people, various smells and different surfaces with mild fluctuations in temperature.
• Socialization at the owner's home—allow the kitten to choose to interact and make exposure positive with the liberal use of food treats. Meet people of different ages, stature, gait and complexion. Meet other pets to potentially prevent fear and aggression.
• Attendance at group kitten classes and social exposure is recommended for all healthy kittens prior to 14 weeks of age and prior to being fully vaccinated.

Recommendations for Kitten Classes

• All healthy kittens between 8 and 12 weeks should be enrolled into group classes.
• Kittens attending are deemed healthy by a veterinary examination, have been dewormed, and have started their vaccination series. The first class might be attended by owners only, particularly if scheduled to begin within the first 10 days after vaccination. • Group classes are often held at veterinary clinics, allowing for positive interactions with other kittens, people, and objects. • Classes are attended by kittens and their owners at least weekly and are typically about an hour in length.
• Rotating classes cover the following topics: ○ Play sessions—controlled and monitored play (5–10 minutes) with other kittens in a secure environment, typically at the start and end of class. ○ Health and handling—instruction and positive handling for routine health and grooming procedures in the veterinary clinic, at the grooming facility, and at home. ○ Sights and sounds—exposure to novel environments, objects, surfaces, and sounds in a positive and fun manner. Various people attending interact with kittens in a positive manner. ○ Rearing advice—education on normal cat body language, learning, behavior problem solving and prevention, and kitten rearing. ○ Basic manners—positive reinforcement training to address mouthing/biting/scratching, jumping on furniture/counters, chewing and scratching objects, stealing objects, carrier, collar/harness/leash, and litterbox training. ○ Kitten classes offered at the veterinary hospital can also insure a focus on positive exposures to the veterinary facility, equipment, and procedures.

MEDICATIONS

DRUG(S) OF CHOICE

• A selective serotonin reuptake inhibitor or tricyclic antidepressant may be indicated for fear, anxiety, and aggression-related problems when combined with behavior and environmental modification for the specific diagnosis. • May "in effect" chemically place the kitten back into its socialization state and aid socialization. • Consider daily or situational behavior medications for cats 12 weeks of age or greater who demonstrate abnormal fear, anxiety, or aggression.

Nutraceuticals/Supplements

• Alpha-casozepine, a bovine-sourced hydrolyzed milk protein, may have calming properties. • L-Theanine, an extract of green tea, may reduce fear, anxiety, and stress.

Pheromones

• Feliway Classic (CEVA), a synthetic cheek gland pheromone, may have calming properties and facilitate adaptation to new environments. • Feliway Multicat (CEVA), a synthetic mammary pheromone, can mediate social tension between cats.
• FeliScratch (CEVA), a synthetic interdigital pheromone, may promote scratching in specific locations.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid selective serotonin reuptake inhibitors and tricyclic antidepressants in combination and use with caution with other serotonin-influencing drugs.

FOLLOW-UP

PATIENT MONITORING

Kitten owners should be questioned during routine heath examinations and encouraged to bring concerns regarding problematic behavior to their veterinarian's attention as soon as the problem is identified.

PREVENTION/AVOIDANCE

• Prevention of problems is preferable and easier than treatment. • Socialization experiences must be positive for the kitten to benefit from those experiences. • Avoid exposure which induces negative emotions as it is difficult to habituate to stimuli that induce fear, anxiety, and stress.
• Preventive counseling at the first kitten visit reduces the risk of undesirable climbing on furniture and curtains, undesirable vocalization, and increases amenability to body handling.

POSSIBLE COMPLICATIONS

• Kittens obtained after their socialization period with little prior socialization and those that have been raised in suboptimal environments may be resistant to socialization.
• Unwillingness to consume treats, explore, and/or play in socialization contexts suggest that the exposure is not positive for the kitten.

EXPECTED COURSE AND PROGNOSIS

Early identification and intervention gives the best prognostic outcome and chance for cure.

LACTIC ACIDOSIS (HYPERLACTATEMIA)

BASICS

DEFINITION
• Blood lactate concentration >1.5 mmol/L in dogs and >1.8 mmol/L in cats.
• Lactic acidosis is hyperlactatemia with concurrent metabolic acidosis.

PATHOPHYSIOLOGY
• Plasma lactate is a late but quantitative indicator of tissue hypoperfusion. Hypoperfusion and tissue hypoxia occur before a rise in blood lactate is detectable.
• Lactic acid is the end product of anaerobic glucose metabolism; at physiologic pH, lactic acid immediately dissociates to lactate and hydrogen ions. Clinically significant lactate accumulation can be due to anaerobic glycolysis occurring during normal physiologic (e.g., exercise) or pathologic processes (e.g., shock, seizures).
• Lactate exists as levorotatory (L-lactate) and dextrorotatory (D-lactate) stereoisomers. L-Lactate predominates in mammalian cells and is the only form detectable by routine analysis.
• Hepatic and renal lactate metabolism maintains a balance between lactate production and clearance.
• In most critically ill or injured patients, hyperlactatemia and lactic acidosis are due to conditions that cause tissue hypoxia, with a shift to anaerobic glycolysis.
• Inadequate perfusion, severe hypoxemia, increased oxygen demand, decreased hemoglobin concentration, or combinations of these factors can cause tissue hypoxia.
• Clinically evident tissue hypoperfusion does not usually occur in patients with hyperlactatemia alone, but hyperlactatemia from "occult" hypoperfusion (not detectable by routine monitoring) might be a precursor to overt hypoperfusion.
• Lactic acidosis can occur secondary to marked tissue hypoxia and hypoperfusion, certain drugs or toxins, or congenital defects in carbohydrate metabolism.
• Blood lactate measurement is a useful tool for assessing severity of tissue hypoxia, response to therapy, and prognosis:
  ◦ In human trauma and shock patients, lactate predicts outcome, and mortality is correlated with severity of lactic acidosis.
  ◦ Lactate concentrations are increased in critically ill and injured dogs; severity of hyperlactatemia is associated with outcome.
• Serial lactate measurement allows the clinician to assess the response of critically ill patients to resuscitative therapy (decreasing lactate concentration indicates restoration of tissue oxygen delivery).

SYSTEMS AFFECTED
• Cardiovascular—persistent lactic acidosis associated with impaired cardiac contractility, impaired pressor response to catecholamines, increased sensitivity of myocardium to ventricular arrhythmias, and reduced cardiac output. These changes may worsen organ hypoperfusion, leading to further tissue hypoxia.
• As acidosis and tissue hypoxia become severe, failure of multiple organ systems and death can occur.

SIGNALMENT
Dog and cat.

SIGNS
General Comments
Signs relate more to underlying disorder than to direct effects of acidosis. As tissue hypoperfusion, hypoxia, and acidosis worsen, signs of dysfunction can occur in any organ system.

Historical Findings
Disorders causing lactic acidosis are common; historical facts should prompt suspicion of an underlying acidosis.

Physical Examination Findings
• Tachypnea is usually present due to attempted respiratory compensation.
• Most patients with acidosis are hypovolemic and demonstrate poor tissue perfusion or dehydration—dark mucous membranes, prolonged capillary refill time, or increased skin turgor.
• Severely acidotic patients might have cardiac dysrhythmias and weak pulses.

CAUSES
• Two types of hyperlactatemia, A and B, based on presence or absence of hypoperfusion or tissue hypoxia.
• Type A hyperlactatemia—more common; due to decreased or inadequate oxygen delivery or increased oxygen demand. Causes of type A hyperlactatemia include shock, regional hypoperfusion, arterial obstruction, severe hypoxemia or anemia, carbon monoxide poisoning, and severe motor seizures.
• Increased oxygen demand can be caused by increased muscle activity (e.g., exercise, tremors, struggling, fever, seizure activity).
• Type B hyperlactatemia—all other causes of lactic acidosis; subdivided into three subsets (B_1, B_2, B_3); characterized by absence of hypoxemia or poor tissue perfusion. Many causes of type B lactic acidosis might be "occult" hypoperfusion not detectable by routine monitoring parameters or possibly combinations of types A and B lactic acidosis.
  ◦ Type B_1 hyperlactatemia is associated with diseases such as sepsis, neoplasia, liver disease and diabetes mellitus.
  ◦ Type B_2 hyperlactatemia is associated with a wide variety of drugs or toxins including corticosteroids, activated charcoal, propofol, lactulose, morphine, terbutaline, theophylline, xylitol, and parenteral nutrition.
  ◦ Type B_3 hyperlactatemias are caused by congenital metabolic diseases, mitochondrial myopathies, and enzyme deficiencies.
• Most common causes of type B lactic acidosis in veterinary medicine include neoplasia, alkalosis, sepsis, renal failure, liver disease, catecholamine use (norepinephrine, epinephrine), and intoxications (strychnine, cyanide, ethylene glycol, salicylates, acetaminophen, propylene glycol).
• Elevated blood lactate has been observed in patients with lymphoma and meningioma. Though the type and cause of hyperlactatemia in these animals is not clearly understood, the presence of a high lactate should prompt the clinician to evaluate other markers of perfusion (heart rate, mucous membrane color, pulse quality, capillary refill, serum creatinine) before attempting aggressive fluid resuscitation.
• Metformin intoxication is associated with severe lactic acidosis and hypoglycemia in people and dogs.

RISK FACTORS
Risk factors for hyperlactatemia are risk factors for specific disorders that cause tissue hypoxia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Differential diagnoses for hyperlactatemia and lactic acidosis include those disorders described under Causes.

LABORATORY FINDINGS
Drugs That May Alter Laboratory Results
• Activated charcoal, catecholamines, salicylates, acetaminophen, terbutaline, nitroprusside, halothane, bicarbonate, and propylene glycol can cause mild-to-moderate hyperlactatemia in the absence of true tissue hypoperfusion and hypoxia.
• Lower lactate concentrations are found in blood samples with sodium citrate anticoagulant than in those with heparin and EDTA.
• Even small amounts of lactate-containing intravenous fluids (e.g., lactated Ringer's solution) can cause false increases in measured blood lactate concentration if not properly cleared from the catheter prior to sampling.

Disorders That May Alter Laboratory Results
• Stress, trembling, resisting restraint, excitement, and venous stasis can increase

LACTIC ACIDOSIS (HYPERLACTATEMIA) (CONTINUED)

lactate to 2.5–5.0 mmol/L, but lactate usually normalizes in ≤2 hours.
• Seizures or extreme muscular exertion can increase lactate to 4–10 mmol/L, but lactate usually normalizes in ≤2 hours.
• Several types of neoplasia increase lactate concentrations because tumor cells preferentially use anaerobic glucose metabolism.
• Alkalosis, sepsis, liver disease, and renal failure can also increase lactate concentrations by mechanisms other than poor tissue perfusion and hypoxia.
• Failure to detect hyperlactatemia does not ensure adequate perfusion to all organs; significant organ hypoperfusion can still exist that might ultimately lead to multiple organ failure.
• Regional hypoperfusion, especially splanchnic, occurs in the absence of, or before, increases in systemic lactate and often despite therapy that successfully maintains blood pressure, cardiac output, and respiratory parameters.
• D-Lactate is not detected by routine analysis. Although D-lactate normally only exists at 1–5% the concentration of L-lactate, D-lactate elevation has been associated with short bowel syndrome and exocrine pancreatic insufficiency in humans. In cats, D-lactate has been associated with gastrointestinal disease, diabetic ketoacidosis, and propylene glycol intoxication.
• D-Lactate hyperlactatemia is a rare cause of high anion gap acidosis.

Valid if Run in Human Laboratory?

• Yes; semiautomated and automated techniques are available for rapid measurement of lactate concentration in microliter samples of whole blood, serum, and plasma.
• Lactate should be sampled from comparable sites (e.g., all venous or arterial) for serial measurement.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC generally reflects underlying cause(s).
• Biochemical and urinalysis findings can help determine underlying cause of acidosis; examples include renal azotemia and increased serum osmolality seen with ethylene glycol intoxication; renal azotemia, hyperkalemia, and tubular casts seen with acute renal failure; and increased total protein and increased hematocrit with hemoconcentration and poor tissue perfusion in a hypovolemic patient.

OTHER LABORATORY TESTS

• Blood gas analysis (arterial preferred to assess blood oxygen) might define extent of a concurrent respiratory disorder or a mixed acid–base disorder.
• Additional tests (e.g., ethylene glycol, serum and urine glucose and ketones) might be helpful, depending on suspected cause.

TREATMENT

• Hyperlactatemia is more important as a marker of severe or developing systemic problems. Aggressive treatment is not recommended for elevated blood lactate in the absence of other signs of circulatory shock. Fluid resuscitation is also not indicated if cardiogenic shock is the cause.
• Hyperlactatemia, with or without acidosis, should drive the clinician to seek causes of hypoperfusion and should focus early therapeutic interventions to improve tissue oxygen delivery.
• If lactic acidosis is severe, aggressive therapy to correct underlying cause(s) and specifically treat acidosis or hypoperfusion is indicated.

MEDICATIONS

DRUG(S) OF CHOICE

• Specific drug and fluid use depends on underlying cause.
• Many causes of hyperlactatemia and lactic acidosis are characterized by hypovolemia; thus, IV fluid therapy is generally first step in treatment (unless cardiogenic).
• Alkalinizing and pH-neutral isotonic crystalloid fluids might be preferred (vs. 0.9% NaCl) in cases of hypovolemic lactic acidosis to more rapidly normalize blood pH.
• Though controversial, sodium bicarbonate therapy to correct blood pH <7.1 might be indicated when the pH fails to increase in response to aggressive fluid resuscitation or when cardiovascular collapse is suspected to be due to low blood pH.

PRECAUTIONS

• Sodium bicarbonate should only be used to correct pH to 7.2. This can be accomplished by calculating the bicarbonate deficit or giving an empirical dose of 1 mEq/kg IV and rechecking blood pH.
• Sodium bicarbonate is more likely to be effective in patients with a normal anion gap metabolic acidosis (normal lactate) than patients with high anion gap metabolic acidosis, as the latter will correct acidemia when organic anions (lactate or ketoacids) are converted to bicarbonate during hemodynamic recovery.
• 10–15% of administered bicarbonate is converted to CO_2; it is important that only patients with adequate ventilation are treated.
• Complications of sodium bicarbonate therapy can include volume overload, paradoxic central nervous system acidosis, hypocalcemic tetany and a left-shift of oxygen–hemoglobin dissociation curve (iatrogenic alkalosis).

FOLLOW-UP

PATIENT MONITORING

• Serial lactate determinations are more valuable than single measurements; monitor lactate over time in critical patients.
• The ability of a patient to clear lactate predicts response to therapy and survival.
• Monitor other parameters that gauge response to therapy of underlying cause.

PREVENTION/AVOIDANCE

Owners should understand early warning signs of condition(s) that led to lactic acidosis in their pet with instructions to seek prompt medical attention should they recur.

POSSIBLE COMPLICATIONS

• Dogs with hyperlactatemia and acidosis have poorer outcomes, similar to humans.
• Lactate >6–6.5 mmol/L suggests tissue hypoperfusion (e.g., shock) or local ischemia (e.g., gastric necrosis in patients with gastric dilatation and volvulus [GDV]).

EXPECTED COURSE AND PROGNOSIS

• Lactic acidosis should correct with resuscitation. Lactic acidosis that fails to respond is a grave prognostic indicator.
• Hypotensive dogs without hyperlactatemia have a better prognosis and chance of survival than do hypotensive dogs with hyperlactatemia.
• Hypotensive, normolactatemic cats in an intensive care unit have a significantly greater chance of survival to hospital discharge than their hyperlactatemic counterparts.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Lactic acidosis can be found with any condition causing tissue hypoxia.
• Hyperlactatemia in patients with lymphoma and meningioma may exist despite normal tissue oxygen delivery. In these patients, other parameters should be used to assess tissue perfusion as blood lactate can remain elevated despite adequate resuscitation.

SEE ALSO

Acidosis, Metabolic.

ABBREVIATIONS

• GDV = gastric dilatation and volvulus.

Consulting Editor Patty A. Lathan

LAMENESS

BASICS

DEFINITION
A disturbance in gait and locomotion in response to pain, anatomic disruption, or injury.

PATHOPHYSIOLOGY
- Severe, sharp pain—limited limb movement during all phases of locomotion, little to no load bearing in motion or at rest.
- Milder, dull, or aching pain—reduced loading and ground contact time during all phases of locomotion.
- Pain produced only during certain phases of movement—patient adjusts its motion and gait to minimize discomfort.
- Anatomic dysfunction resulting in certain normal motions being altered or impossible.

SYSTEMS AFFECTED
- Musculoskeletal.
- Nervous.

SIGNALMENT
- Any age or breed of dog.
- Age, breed, and sex predilection—depend on specific disease.

SIGNS

General Comments
- Unilateral forelimb—head and neck moves upward when the affected limb is placed on the ground and drops when the sound limb loads.
- Unilateral hind limb—pelvis drops when affected leg loads, rises when it unloads.
- Bilateral hind limb—thoracic limbs carried lower and shifted caudally at the stance, to shift weight forward.
- Always assess the patient's neurologic status, especially with a suspected proximal lesion.

Historical Findings
- Complete history—identify known trauma; alterations with weather, exercise tolerance, response to rest, effect of previous treatments.
- Determine speed of onset of lameness.
- Determine progression—static, slow, rapid.
- Determine consistency—intermittent, constant, associations with interventions, rest or activities.
- How does the patient show pain?

Physical Examination Findings
- Perform a complete routine examination.
- Observe posture—standing, getting up or lying down, sitting.
- Observe gait—walking; trotting; climbing stairs; tight turns or figure eights.
- Palpate—asymmetry of muscle mass (measure and compare); note bony prominences.
- Manipulate bones and joints, beginning distally and working proximally.
- Assess—instability; incongruency; pain; range of motion (measure); abnormal sounds or crepitus.
- Examine suspected area of involvement last—by starting with normal limbs, patient may relax, allowing comparison of normal to abnormal reactions.

CAUSES

Forelimb

Growing Dog (<12 Months of Age)
- Osteochondrosis of the shoulder.
- Shoulder luxation or subluxation—congenital.
- Osteochondrosis of the elbow.
- Ununited anconeal process.
- Medial coronoid disease.
- Elbow incongruity.
- Avulsion or calcification of the flexor muscles—elbow.
- Asymmetric growth of the radius and ulna.
- Panosteitis.
- Hypertrophic osteodystrophy.
- Trauma—soft tissue; bone; joint.
- Infection—local; systemic.
- Nutritional imbalances.
- Congenital anomalies.

Mature Dog (>12 Months of Age)
- Degenerative joint disease.
- Bicipital tenosynovitis.
- Calcification or mineralization of supraspinatus or infraspinatus tendon.
- Contracture of supraspinatus or infraspinatus muscle.
- Soft tissue or bone neoplasia—primary; metastatic.
- Trauma—soft tissue; bone; joint.
- Panosteitis.
- Polyarthropathies.
- Polymyositis.
- Polyneuritis.

Hind Limb

Growing Dog (<12 Months of Age)
- Hip laxity (hip dysplasia).
- Avascular necrosis of femoral head—Legg–Calvé–Perthes disease.
- Osteochondritis of stifle.
- Patella luxation—medial or lateral.
- Osteochondritis of hock.
- Panosteitis.
- Hypertrophic osteodystrophy.
- Trauma—soft tissue; bone; joint.
- Infection—local; systemic.
- Nutritional imbalances.
- Congenital anomalies.

Mature Dog (>12 Months of Age)
- Degenerative joint disease (hip dysplasia).
- Cruciate ligament disease.
- Avulsion of long digital extensor tendon.
- Soft tissue or bone neoplasia—primary; metastatic.
- Trauma—soft tissue; bone; joint.
- Panosteitis.
- Polyarthropathies.
- Polymyositis.
- Polyneuritis.

RISK FACTORS
Breed, size, overweight, strenuous activity, metabolic disease (Cushing's, hypothyrodism).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Must differentiate musculoskeletal from neurogenic and metabolic causes.

CBC/BIOCHEMISTRY/URINALYSIS
Muscle injury elevates creatine phosphokinase levels. General inflammatory disease such as infectious inflammatory arthropathies have been associated with elevations of C-reactive protein (CRP).

OTHER LABORATORY TESTS
Depends on suspected cause, however various tests available for infectious or inflammatory diseases.

IMAGING
- Radiographs—recommend two views of region of interest. Stressed views indicated if ligamentous injury is part of the differential list.
- CT, MRI, ultrasound, and nuclear scintigraphy where appropriate.

DIAGNOSTIC PROCEDURES
- Cytologic examination of joint fluid—identify and differentiate intra-articular disease.
- Electromyogram (EMG)—differentiate chronic neuromuscular from musculoskeletal disease.
- Muscle and/or nerve biopsy—reveal and identify neuromuscular disease.

TREATMENT
Depends on underlying cause.

MEDICATIONS

DRUG(S) OF CHOICE

Nonsteroidal Anti-inflammatory Drugs (NSAIDs) and Analgesics
- May be used for symptomatic treatment; minimize pain, decrease inflammation.
- Carprofen 2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h.
- Deracoxib 1–2 mg/kg PO q24h, chewable.
- Firocoxib 5 mg/kg PO q24h.
- Grapiprant 2 mg/kg PO q24h, to animals >3.6 kg.
- Meloxicam—load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid.
- Tepoxalin—load 20 mg/kg, then 10 mg/kg PO q24h.

PRECAUTIONS

NSAIDs—gastrointestinal irritation or renal/hepatic toxicity may preclude use in some patients.

ALTERNATIVE DRUG(S)

- Chondroprotective drugs, such as polysulfated glycosaminoglycans, green-lipped mussel extract, and glucosamine/chondroitin sulfate (limited supportive data), may help limit associated cartilage damage and degeneration.
- Nonspecific anti-inflammatory supplements—e.g. green-lipped muscle extract and omega 3 fatty acid supplementation.

FOLLOW-UP

PATIENT MONITORING

Depends on underlying cause.

MISCELLANEOUS

SEE ALSO

Chapters covering musculoskeletal and neuromuscular disorders.

ABBREVIATIONS

- CRP = C-reactive protein.
- EMG = electromyogram.
- NSAID = nonsteroidal anti-inflammatory drug.

LARYNGEAL AND TRACHEAL PERFORMATION

BASICS

OVERVIEW

Tracheal perforation is a loss of integrity of the tracheal wall, allowing leakage of air to create subcutaneous (SC) emphysema, pneumomediastinum, pneumopericardium, pneumothorax, and pneumoretroperitoneum. Caused by penetrating, intraluminal, or blunt cervical or thoracic trauma. Severity ranges from small perforation to complete avulsion. With complete avulsion, mediastinal tissues can form a pseudomembrane to maintain airway patency. Laryngeal perforation is disruption of laryngeal structures (thyroid, cricoid, and arytenoid cartilages) and can create similar leakage of air and may result in upper airway obstruction.

Systems Affected

- Respiratory—compromise of airway, possible pneumomediastinum and pneumothorax. Laryngeal swelling may result in upper airway obstruction.
- Cardiovascular—pneumothorax and tension pneumothorax can decrease venous return and cardiac output.
- Nervous, musculoskeletal—depends on severity of hypoxia.
- Skin—SC emphysema, initially cervical but can affect entire body.

SIGNALMENT

Dog and cat—no breed, age, or sex predilection.

SIGNS

- Onset: immediate or up to 1 week after injury.
- SC emphysema and respiratory distress are most common.
- Other signs—respiratory distress, may have stridor, anorexia, lethargy, exercise intolerance, gagging, ptyalism, vomiting, coughing, hemoptysis, upper airway obstruction, and shock. May have dysphonia (voice change) and/or dysphagia.

CAUSES & RISK FACTORS

- Access to outside while unsupervised causing increased risk of all types of trauma.
- Exposure to other animals causing increased risk of bite wounds.
- Penetrating cervical wounds—bite wounds, impalement, projectile missiles, foreign bodies.
- Iatrogenic perforation during endotracheal intubation, transtracheal wash, jugular venipuncture, cervical surgery, radiation therapy, tracheal stent fracture, or failure to deflate cuff or to stabilize the tube while repositioning patient. Overinflation of endotracheal cuff can cause a linear tear in the trachealis muscle at thoracic inlet or intrathoracic trachea. Occurs most often with dental procedures.
- Blunt trauma can cause intrathoracic tracheal avulsion.
- Blunt trauma to the cervical region can cause laryngeal avulsion or fracture.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anesthesia—barotrauma resulting in alveolar rupture and pneumothorax.
- Penetrating wounds—perforation of esophagus or cervical bite.
- After blunt trauma—pulmonary contusions, pneumothorax, rib fractures.
- Differentials for tracheal perforation include intrathoracic tracheal compression by mediastinal mass, spontaneous pneumothorax, pleural effusion, and bronchoesophageal fistula.
- Differentials for laryngeal perforation include trauma to caudal pharynx or larynx, pharyngeal or laryngeal mass (such as squamous cell carcinoma, lymphoma, granuloma, other), laryngeal paralysis, abscess, pharyngeal mucocele, foreign body in airway.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

OTHER LABORATORY TESTS

Arterial blood gas analysis can show hypoxemia, hypercarbia, and respiratory acidosis.

IMAGING

- Lateral cervical and thoracic radiographs are essential. SC emphysema, pneumomediastinum, pneumopericardium, and pneumothorax can be seen. Also evaluate for concurrent thoracic trauma (e.g., rib fractures), and noncardiogenic pulmonary edema.
- In cases of tracheal avulsion, site of disruption may be visible.
- In cases of laryngeal trauma may observe disruption of the hyoid apparatus.
- Abdominal radiographs occasionally show pneumoretroperitoneum.
- CT can be useful to identify location and extent of laryngeal and tracheal damage. Laryngeal and hyoid fractures and dislocations can be visualized.

DIAGNOSTIC PROCEDURES

- Laryngoscopy and tracheoscopy used to confirm laryngeal or tracheal perforation or avulsion and characterize severity; false negatives can occur.
- If patient does not have a patent airway, can be stabilized with general anesthesia and a temporary tracheostomy. Laryngoscopy can then be performed.
- Larynx should be evaluated for symmetry and function of laryngeal structures, presence of
- hematomas, exposed cartilage, foreign body, or flaps of laryngeal mucosa.
- Esophagoscopy performed to rule out concurrent esophageal injury.

TREATMENT

- Hospitalization is indicated.
- Oxygen supplementation with 95% O_2 for 4 hours will decrease SC emphysema.
- Minimal handling to reduce stress; most cases of iatrogenic perforation will heal.
- If pneumothorax develops, thoracocentesis ± thoracostomy tubes may be required.
- Intubation if needed.
- If patient decompensates, surgical exploration is indicated.
- Tracheal rupture secondary to blunt trauma or penetrating injury requires surgical repair.
- If tracheal avulsion is present, intubate only the proximal segment using an undersized endotracheal tube. Avoid positive-pressure ventilation to prevent disruption of pseudomembrane.
- Cervical tracheal perforation—approach via ventral midline; may require a partial median sternotomy. Damaged areas of trachea are often on the dorsolateral surface: debride and repair with 3-0 to 5-0 monofilament absorbable suture.
- Tracheal resection and anastomosis indicated for severe tracheal damage or tracheal avulsion.
- Intrathoracic tracheal avulsion—approach via a right lateral 3rd or 4th intercostal thoracotomy. Open the pseudomembrane and intubate the caudal segment. Preplace sutures, guide an endotracheal tube from the cranial segment into the caudal segment, and complete repair.
- If upper airway obstruction or unable to intubate, an emergency temporary tracheostomy is indicated. Temporary tracheostomy is performed at approximately the 4th tracheal ring and tube is sized to about 50% of tracheal lumen.
- Laryngeal repair indicated if avulsed/exposed arytenoid cartilage with debridement or partial arytenoidectomy or tieback procedure. If there is collapse or fracture of the cricothyroid cartilages, laryngeal exploration via ventral laryngotomy may be needed to stabilize laryngeal structures to reduce stenosis.
- Hyoid bone avulsion and laryngotracheal avulsion should be repaired with apposition via ventral approach.
- Mucosal flaps should be trimmed and edges apposed with 4-0 or 5-0 absorbable suture.
- Intraluminal stents can be used for preventing adhesions, collapse, and other complications.
- Stents will require second procedures 3–4 weeks later for removal.
- Unilateral arytenoid lateralization (tieback) if traumatic laryngeal paralysis without fractures or if arytenoid avulsion.

(CONTINUED) LARYNGEAL AND TRACHEAL PERFORATION

- Permanent tracheostomy may be indicated if unable to restore patent airway or with severe laryngeal damage.
- Exercise restriction for 3–4 weeks post trauma and surgical repair.
- No neck leads and harness only when leash walking.

MEDICATIONS

DRUG(S) OF CHOICE

- Broad-spectrum antibiotic therapy if caused by bite wounds.
- Antibiotics after obtaining cultures from contaminated wounds; continue 1–2 weeks in the postoperative period. Empirical selections while awaiting culture results could include:
  - Ampicillin 22 mg/kg IV q8h (both dogs and cats) and enrofloxacin 10–15 mg/kg diluted and given slowly IV or PO q24h in dogs (5 mg/kg q24h in cats).
  - Clindamycin 10 mg/kg IV or PO q8h and either amoxicillin/clavulanic acid 15 mg/kg PO q12h or enrofloxacin, as listed above.
  - Corticosteroids (dexamethasone sodium phosphate 0.1–0.2 mg/kg IV) at time of surgery to reduce inflammation; may repeat at a dose of 0.05–0.1 mg/kg IV q24h for first 24–48 hours.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Sedation—use with caution, can decrease respiratory drive.
- Corticosteroids are not indicated unless there is a large degree of upper airway swelling or concern for postoperative swelling.

FOLLOW-UP

PATIENT MONITORING

- Monitor respiratory rate and effort, mucous membrane color, capillary refill time, pulse quality, and heart rate, and auscult frequently.
- Pulse oximetry and/or arterial blood gases.
- Thoracic radiographs to monitor pneumomediastinum, pneumothorax, and help detect tracheal stenosis. Tracheoscopy required in some cases.
- Tracheostomy care if tracheostomy is needed.
- Respiratory rate and effort, respiratory noise, and exercise tolerance, during and after the recovery stage.

PREVENTION/AVOIDANCE

- Use of 3 mL syringe for cuff inflation for cats and small dogs to prevent overinflation of cuff.
- High-volume low-pressure endotracheal tube cuff may also reduce risk of tracheal damage.
- Disconnect endotracheal tube from anesthetic circuit when repositioning animal during anesthesia.
- Selection of appropriate endotracheal tube and endoscope size along with use of lubrication will reduce iatrogenic tracheal and laryngeal trauma.
- Direct visualization of the larynx for intubation can reduce risk of iatrogenic trauma.
- Long-term intubation for positive-pressure ventilation can be maintained by temporary tracheostomy to prevent laryngeal damage.

POSSIBLE COMPLICATIONS

- Tracheal stricture and stenosis at site of perforation or repair.
- Laryngeal paralysis from damage to recurrent laryngeal nerve.
- Dehiscence of tracheal anastomosis site.
- Stenosis or stricture resulting in airway compromise.
- Infection from trauma, or post operatively.
- Sepsis (rare).
- Obstruction of temporary or permanent tracheostomy with mucus.
- Death, particularly at induction of anesthesia with complete tracheal avulsion, or with complete airway obstruction.

EXPECTED COURSE AND PROGNOSIS

- Most cases respond well to appropriate therapy.
- Complete tracheal avulsion—guarded prognosis. Without surgery—extremely poor prognosis due to stricture formation.
- Prognosis depends on severity of trauma, concurrent injuries, and treatment.
- If severe laryngeal trauma is present and veterinary care can be quickly obtained, permanent tracheostomy can allow for fair to good prognosis (with the exception of cats and very small dogs, where stoma obstruction with mucus may be recurrent and severe).

MISCELLANEOUS

ASSOCIATED CONDITIONS

With tracheal perforation caused by blunt trauma, can have pulmonary contusions, pneumothorax, rib fractures, and hemothorax.

PREGNANCY/FERTILITY/BREEDING

Hypoxia can result in fetal distress and death.

ABBREVIATIONS

- SC = subcutaneous.

LARYNGEAL DISEASES

BASICS

DEFINITION

• The larynx is made of cartilage structures surrounding the rima glottis. The functions of the larynx are to control airflow during respiration, protect the lower airways from aspiration during swallowing, and control phonation. • Laryngeal diseases in dogs and cats include laryngeal paralysis, laryngitis, laryngeal collapse, foreign body obstruction, neoplasia, and trauma.

PATHOPHYSIOLOGY

• Decreased diameter of the laryngeal opening increases resistance to airflow during inspiration and results in stridor on inspiration. The decrease in airflow will lead to hypoxemia, cyanosis, and/or respiratory distress and a decrease in heat exchange (heat intolerance, hyperthermia). • Inflammation or lesions of the vocal cords can lead to aphonia or change in bark/meow.

SYSTEMS AFFECTED

• Respiratory—respiratory distress, often associated with airway obstruction. Aspiration pneumonia may develop. Stridor is common.
• Cardiovascular—hypoxemia/distress may lead to tachycardia; laryngeal stimulation may trigger vagal response (bradycardia).
• Gastrointestinal—retching, regurgitation, vomiting, and/or dysphagia can occur when polyneuropathy causes laryngeal paralysis and esophageal dysfunction; esophagitis is frequently associated with brachycephalic airway syndrome (BAS). • Nervous—depression, stupor, or coma may occur if severe laryngeal obstruction leads to severe hyperthermia. Older dogs with laryngeal paralysis often have geriatric-onset laryngeal paralysis polyneuropathy (GOLPP), which includes hind limb weakness.

GENETICS

• Juvenile laryngeal paralysis in the bouvier des Flandres is transmitted as a dominant trait. • In laryngeal paralysis associated with polyneuropathy in the Leonberger dog, X-linked inheritance is suggested. • No other laryngeal disorder has been proven to be genetic in the dog or cat, but familial conditions and breed predispositions have been reported.

INCIDENCE/PREVALENCE

• More common in dogs than in cats.
• Currently, congenital laryngeal paralysis is only sporadic in the bouvier des Flandres.
• Idiopathic laryngeal paralysis is a common disease of older large-breed dogs; exact prevalence unknown. • BAS is a common syndrome in French and English bulldogs.
• Laryngeal trauma may occur in conjunction with bite wounds; tracheal bite wounds may result in laryngeal paralysis/collapse due to damage to the recurrent laryngeal nerves.
• Neoplasia is rare in dogs, but fairly common in older cats, who are often initially thought to have lower airway disease due to "wheezing" that accompanies laryngeal masses.

SIGNALMENT

Species

Dog and cat.

Breed Predilections

• Familial laryngeal paralysis/polyneuropathy complex occurs in the Dalmatian, Rottweiler, Leonberger, and Pyrenean mountain dog (great Pyrenees). • Congenital laryngeal paralysis is found in bouviers des Flandres, huskies, husky crosses, white German shepherd dogs, and probably bull terriers.
• Idiopathic acquired laryngeal paralysis is most often found in large-breed dogs (especially Labrador and golden retrievers).
• BAS is found in brachycephalic breeds of dogs. • Upper airway obstruction due to laryngeal collapse or narrowed laryngeal opening occurs in Norwich terriers.

Mean Age and Range

• Congenital and familial laryngeal paralysis—onset of signs usually in the first months of life (2 and 8 months). Later in the Leonberger, 1–9 years, and white German shepherd dog, 2 years. • Acquired laryngeal paralysis—possible at any age but more frequent in older dogs.
• Neoplasia—middle-aged to old dogs.

SIGNS

Historical Findings

• Panting. • Exercise and heat intolerance.
• Noisy respiration. • Change of voice.
• Occasional cough. • Severe cases—inspiratory respiratory distress, collapse, syncope, or even sudden death.
• Polyneuropathy, polymyopathy, or myasthenia gravis—regurgitation, weakness, abnormal gait (pattern of abnormalities varies).
• Absence of signs is possible in Norwich terriers with upper airway obstruction.

Physical Examination Findings

• Panting, polypnea, and inspiratory stridor in canine cases. • Respiration is less noisy in cats with laryngeal disease. • Cyanosis.
• Hyperthermia frequent. • Aspiration pneumonia—fever, crackles on respiratory auscultation. • Polyneuropathy, polymyopathy, or myasthenia gravis—paraparesis or tetraparesis with decreased spinal reflexes. • Leonberger with familial polyneuropathy—high-stepping pelvic-limb gait with depressed spinal and cranial nerve reflexes. • Rottweilers with laryngeal paralysis/polyneuropathy complex—cataracts frequently observed. • Normal physical examination in some Norwich terriers with upper airway obstruction.

CAUSES

• Laryngeal paralysis: ○ Congenital—(1) neuronal degeneration of the nucleus ambiguous (bouvier des Flandres and husky); (2) idiopathic. ○ Acquired—(1) polyneuropathy: idiopathic; familial (laryngeal paralysis–polyneuropathy complex); immune-mediated; (2) myasthenia gravis; (3) polymyopathy: idiopathic; immune-mediated; infectious (toxoplasmosis, neosporosis); (4) ventral cervical or cranial thoracic lesion—neoplasia or trauma affecting one or both recurrent nerves; examples include lymphoma of the vagus nerve in the cat and traumatic neuropathy secondary to thyroidectomy. • Acute laryngitis: ○ Cause often not found. ○ Virus—canine parainfluenza virus, feline herpesvirus 1. ○ Bacteria—*Bordetella bronchiseptica*. ○ Gastroesophageal reflux.
• Idiopathic chronic obstructive laryngitis (lymphoplasmacytic, granulomatous).
• Laryngeal neoplasia: ○ Dog—rhabdomyoma, rhabdomyosarcoma, adenocarcinoma, squamous cell carcinoma, lipoma, extramedullary plasmacytoma. ○ Cat—lymphoma, squamous cell carcinoma. • Trauma: injuries caused by foreign bodies. • Neck trauma, bite wounds.
• Laryngeal collapse secondary to BAS.
• Idiopathic laryngeal malformation, collapse in Norwich terriers.

RISK FACTORS

Breed associations. Risk factors for developing severe or fatal clinical signs include obesity, dark coat, hot or humid temperature (especially in a closed environment), and concurrent lower airway or pulmonary disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Pharyngeal diseases—also cause gagging, stridor, and cough. Dysphagia is not seen with laryngeal disease but may be present in the case of pharyngeal lesion. • Tracheal diseases may be confused with laryngeal disease in some cases. Cough is more frequent in tracheal disease than in laryngeal disease, while inspiratory stridor is more frequent in laryngeal disease.

CBC/BIOCHEMISTRY/URINALYSIS

• No specific abnormalities. • Leukocytosis may be present in aspiration pneumonia.
• Mild-to-moderate increase in liver enzymes if chronic hypoxemia. • Hypercholesterolemia may be present if concurrent hypothyroidism is present.

OTHER LABORATORY TESTS

If laryngeal paralysis is secondary to polyneuropathy/polymyopathy, these may be considered, but are low yield:
• Thyroid panel in the dog. • Antibody titers against *Toxoplasma gondii* (dog and cat) and *Neospora caninum* (dog). • Anticholinesterase receptor antibody titer.

IMAGING

• Thoracic radiographs—to rule-out aspiration pneumonia as a complication, other lower airway conditions, and a

mediastinal mass as a cause of laryngeal paralysis. • If vomiting/regurgitation present—barium swallow with fluoroscopy (to identify esophageal dysfunction, reflux esophagitis/hiatal hernia coexisting in some cases of brachycephalic airway syndrome). • Pharynx/larynx radiographs or ultrasonography—to identify potential mass.

DIAGNOSTIC PROCEDURES

Laryngoscopy

• Method of choice to identify laryngeal paralysis, collapse, mass, trauma, foreign body, or laryngitis. • General anesthesia or deep sedation is required. • Laryngeal paralysis: ○ Diagnosis confirmed by loss of abduction of arytenoid cartilages during deep inspiration. ○ Usually bilateral but unilateral paralysis is possible in the early course of the disease. ○ Unilateral paralysis has been described in cats. ○ False-positive result possible because of the influence of general anesthesia on laryngeal function. Intravenous doxapram HCl (1–2 mg/kg) to increase respiratory effort is advised if the diagnosis is in doubt.

Esophagoscopy

When vomiting/regurgitation is observed, to rule out reflux esophagitis or hiatal hernia.

Retrograde Rhinoscopy

When pharyngeal disease is suspected or in the case of BAS.

PATHOLOGIC FINDINGS

• Laryngeal paralysis: ○ Gross findings—redness, swelling, and thickening of the arytenoid cartilages and the vocal folds. ○ Histopathology—nonspecific edema and inflammation of laryngeal mucosa and submucosa; denervation atrophy of laryngeal muscles in the case of neuropathy of recurrent laryngeal nerve(s). • Idiopathic chronic obstructive laryngitis: ○ Histopathology—lymphoplasmacytic, granulomatous, or pyogranulomatous inflammation of the laryngeal submucosa.

TREATMENT

APPROPRIATE HEALTH CARE

• Paralysis: ○ Surgical palliation (arytenoid lateralization) is recommended for dogs with clinical signs but may be associated with postoperative aspiration. ○ If signs are mild, avoidance of triggers is advised (e.g., heat, humidity). • Emergency: ○ Sedation/anesthesia; supplemental oxygen; cooling therapy. ○ Do not sedate to "look" with the thought to do surgery in the future as aspiration may occur on recovery. • Cats with suspected laryngeal masses may be very difficult to intubate; be sure to have surgical supplies for urgent tracheostomy readily available.

NURSING CARE

• Paralysis: ○ Avoid warm, poorly ventilated environments, stress, and intense excitation as these further compromise normal cooling mechanisms and proper air exchange. ○ Avoid cervical collars. ○ Avoid weight gain.

ACTIVITY

Exercise should be severely restricted in animals suffering from laryngeal paralysis, especially in warm temperatures.

DIET

Loss of weight is advocated in overweight patients with any upper airway disorder.

CLIENT EDUCATION

• Paralysis: ○ Discuss the importance of surgery and the risk of not performing surgery (chronic hypoxemia, heat stroke, risk of suffocation, and death) in moderately to severely affected dogs. ○ Discuss potential complications of surgery including aspiration pneumonia. ○ Discuss the potential progression of neuromuscular disease. ○ Discuss the potential heritability of this condition in certain breeds. • Neoplasia: ○ Discuss surgical/chemotherapeutical options.

SURGICAL CONSIDERATIONS

• Paralysis: ○ Surgery (unilateral arytenoid lateralization) is the treatment of choice in both dogs and cats; bilateral surgical correction is not advised because it increases the risk of aspiration pneumonia. ○ Cats that are breathing comfortably but have a voice change alone may be managed medically. • Neoplasia: ○ Surgery, radiation or chemotherapy. ○ Permanent tracheostomy in dogs may improve quality of life if surgical excision is not possible.

MEDICATIONS

DRUG(S) OF CHOICE

• Paralysis—if surgery is declined, anxiolytic may be considered. • Lymphoma (mainly in cats)—chemotherapy (see Lymphoma—Cats).

PRECAUTIONS

Usual safety precautions if chemotherapy is administered.

FOLLOW-UP

PATIENT MONITORING

• Immediate postsurgical period—check rectal temperature (should remain normal). • Monitor for aspiration pneumonia (short and long term). • If surgery is successful, exercise, stridor, and heat intolerance should decrease.

POSSIBLE COMPLICATIONS

• Paralysis—recurrence of clinical signs are uncommon if surgery is correctly performed; aspiration pneumonia is possible as the larynx is placed in a fixed open position; risk of aspiration pneumonia increased if bilateral arytenoid lateralization is performed or if dysphagia due to pharyngeal and/or esophageal dysfunction coexists. • Tumor—recurrence of clinical signs if complete resection is not possible; increased risk of aspiration pneumonia in the postoperative period.

EXPECTED COURSE AND PROGNOSIS

• Idiopathic paralysis—good with surgery; guarded to poor if surgery is declined. • Paralysis associated with esophageal dysfunction—poor. • Tumor—guarded to good in the case of successful resection of a benign tumor; poor in the case of carcinoma, even with radiation therapy; variable in the case of feline lymphoma.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Laryngeal paralysis is sometimes associated with a mass in the anterior mediastinum or the ventral cervical region. • Coexistence of megaesophagus, weakness, or abnormal gait with laryngeal paralysis suggests polyneuropathy, polymyopathy, or myasthenia gravis.

AGE-RELATED FACTORS

Congenital and familial laryngeal paralysis—onset of clinical signs in the first year of life.

PREGNANCY/FERTILITY/BREEDING

Dogs affected with congenital laryngeal paralysis or laryngeal paralysis/polyneuropathy complex should not be bred.

SEE ALSO

• Brachycephalic Airway Syndrome.
• Cyanosis.
• Myasthenia Gravis.

ABBREVIATIONS

• BAS = brachycephalic airway syndrome.
• GOLPP = geriatric-onset laryngeal paralysis polyneuropathy.

L

LEAD TOXICOSIS

BASICS

DEFINITION
Intoxication (blood lead >0.35 ppm, although somewhat variable) owing to acute or chronic exposure to some form of lead.

PATHOPHYSIOLOGY
• Cell damage is due to the ability of lead to substitute for other polyvalent cations (especially divalent cations such as Ca and Zn) important for cell homeostasis. • Diverse biological processes are affected, including metal transport, energy metabolism, apoptosis, ion conduction, cell adhesion, inter- and intracellular signaling, enzymatic processes, protein maturation, and genetic regulation.

SYSTEMS AFFECTED
• Gastrointestinal—unknown mechanism; likely damage to peripheral nerves. • Nervous—capillary damage; alteration of membrane ionic channels and signaling molecules. • Renal/urologic—damage to proximal tubule cells due to enzyme disruption and oxidative damage. • Hemic/lymph/immune—interference with hemoglobin synthesis; increased fragility and decreased survival of red blood cells (RBCs); release of reticulocytes and nucleated RBCs from bone marrow; inhibition of 5′-pyrimidine nucleotidase causing retention of RNA degradation products; aggregation of ribosomes resulting in basophilic stippling.

INCIDENCE/PREVALENCE
• True incidence unknown. • Decreasing prevalence in dogs—owing to elimination of sources. • Steady to increasing prevalence in cats—increased awareness and diagnosis. • Higher prevalence during warmer months. • Higher prevalence in young animals—greater bioavailability of lead and more permeable blood–brain barrier.

GEOGRAPHIC DISTRIBUTION
• Low socioeconomic status of pet-owning family associated with high blood lead concentration in pets. • Areas with older homes/buildings.

SIGNALMENT
Species
Dogs and cats—dogs more commonly than cats.

Breed Predilections
N/A

Mean Age and Range
Mainly dogs <1 year of age.

Predominant Sex
N/A

SIGNS
General Comments
• Primarily gastrointestinal and neurologic. • Gastrointestinal—often precede CNS signs; predominant with chronic, low-level exposure. • CNS—occur more often with acute exposure, more common in younger animals. • Renal—proximal tubular nephropathy has been reported.

Historical Findings
History of renovation of older house or building or ingestion of lead objects.

Physical Examination Findings
• Vomiting. • Diarrhea. • Anorexia. • Abdominal pain. • Regurgitation due to megaesophagus. • Lethargy. • Hysteria. • Seizures. • Blindness. • Cats—central vestibular abnormalities such as vertical nystagmus and ataxia reported.

CAUSES
• Ingestion of some form of lead—paint and paint residues or dust from sanding; car batteries; linoleum; solder; plumbing materials and supplies; lubricating compounds; putty; tar paper; lead foil; golf balls; lead object (e.g., shot, fishing sinkers, drapery weights); leaded glass. • Use of improperly glazed ceramic food or water bowl. • Lead paint or lead-contaminated dust or soil are common sources for exposure; cats ingest lead as a result of self-grooming.

RISK FACTORS
• Age <1 year. • Living in economically depressed areas. • Living in old house or building that is being renovated. • Feeding trimmings from lead-shot game.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Dogs
• Canine distemper. • Infectious encephalitides. • Epilepsy. • Bromethalin, methylxanthine, or tremorgenic mycotoxin toxicosis. • Nonsteroidal anti-inflammatory drug (NSAID) toxicosis. • Heat stroke. • Intestinal parasitism. • Intussusception. • Foreign body. • Pancreatitis. • Infectious canine hepatitis.

Cats
• Degenerative or storage diseases. • Hepatic encephalopathy. • Infectious encephalitides. • Organophosphate, bromethalin, or methylxanthine toxicosis.

CBC/BIOCHEMISTRY/URINALYSIS
• Between 5 and 40 nucleated RBCs/100 white blood cells (WBCs) without anemia. • Absence of nucleated RBCs does not rule out the diagnosis. • Anisocytosis, polychromasia, poikilocytosis, target cells, hypochromasia. • Basophilic stippling of RBCs; often difficult to detect. • Neutrophilic leukocytosis. • Cats—elevated aspartate aminotransferase (AST) and alkaline phosphatase (ALP) reported. • Urinalysis—mild nonspecific renal damage; glucosuria; proteinuria; hemoglobinuria.

OTHER LABORATORY TESTS
Lead Concentration
• Toxic—antemortem whole blood: >0.35 ppm (35 µg/dL); postmortem liver and/or kidney: >5 ppm (wet weight). • Blood lead concentrations fluctuate and do not necessarily correlate with total body burden. • Lower values—must be interpreted in conjunction with history and clinical signs. • No normal "background" blood lead concentrations; typically less than 0.05 ppm. • Blood concentrations—do not correlate with occurrence or severity of clinical signs. • $CaNa_2EDTA$ mobilization test—collect one 24-hour urine sample; administer $CaNa_2EDTA$ (75 mg/kg IM); collect a second 24-hour urine sample; with toxicosis, urine lead increases 10- to 60-fold post-EDTA (succimer could conceivably be substituted for $CaNa_2EDTA$ but this has not been evaluated). • Point-of-care testing is available, but results might underestimate true blood lead concentrations; confirmation of results using other techniques such as GFAAS or ICP-MS is recommended.

IMAGING
May note radiopaque material in gastrointestinal tract; not diagnostic.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Gross—may note paint chips or lead objects in gastrointestinal tract. • Intranuclear inclusion bodies—may be noted in hepatocytes or renal tubular epithelial cells; intracellular storage form of lead; considered pathognomonic. • Cerebrocortical lesions—spongiosis, vascular hypertrophy, gliosis, neuronal necrosis, demyelination.

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient—first course of chelation, depending on severity of clinical signs. • Outpatient—orally administered chelators.

NURSING CARE
• Balanced electrolyte fluids—Ringer's solution; replacement of hydration deficit. • Gastric lavage or whole bowel irrigation—may be indicated.

ACTIVITY
N/A

(CONTINUED) LEAD TOXICOSIS

DIET
N/A

CLIENT EDUCATION
• Inform client of the potential of adverse human health effects of lead. • Notify public health officials. • Determine the source of the lead.

SURGICAL CONSIDERATIONS
Removal of lead objects from the gastrointestinal tract.

MEDICATIONS

DRUG(S) OF CHOICE
• Evacuation of gastrointestinal tract—saline cathartics; sodium or magnesium sulfate (dogs 2–25 g; cats 2–5 g PO as 20% solution or less). • Control of seizures—diazepam (given to effect; dogs and cats 0.5 mg/kg IV) or phenobarbital sodium (administer in increments of 10–20 mg/kg IV to effect). • Alleviation of cerebral edema—mannitol (0.25–2 g/kg of 15–25% IV, slow infusion over 30–60 minutes) and dexamethasone (2.2–4.4 mg/kg IV).
• Some evidence that antioxidants or thiol-containing drugs may be useful—vitamins C and E, α-lipoic acid, *N*-acetylcysteine; optimal doses not determined. • B vitamins, especially thiamine, may also be useful; optimal doses not determined. • Reduction of lead body burden—chelation therapy: ∘ $CaNa_2EDTA$ (dogs and cats, 25 mg/kg SC, IM, IV q6h for 2–5 days); dilute to a 1% solution with D_5W before administration; may need multiple treatment courses if blood lead concentration is high; allow 5-day rest period between treatment courses.
∘ Succimer—alternative to $CaNa_2EDTA$; orally administered chelating agent; 10 mg/kg PO q8h for 5 days followed by 10 mg PO q12h for 2 weeks; allow 2-week rest period between treatments; may administer per rectum if clinical signs such as emesis preclude oral administration; cats successfully treated with 10 mg/kg PO q8h for 17 days. Advantages over other chelators: can be given PO, allowing for outpatient treatment; does not increase lead absorption from the gastrointestinal tract; not reported to be nephrotoxic; chelation of essential elements such as zinc and copper is not clinically significant.

CONTRAINDICATIONS
$CaNa_2EDTA$—do not administer to patients with renal impairment or anuria; establish urine flow before administration; do not administer orally.

PRECAUTIONS
• $CaNa_2EDTA$—safety in pregnancy not established; teratogenic at therapeutic doses although in human medicine is recommended over succimer for pregnant patients.
• Succimer—safety in pregnancy not established; fetotoxic at doses much higher (100–1000 mg/kg) than recommended therapeutic dose.

POSSIBLE INTERACTIONS
$CaNa_2EDTA$—depletion of zinc, iron, and manganese with long-term therapy.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Blood lead—should be <0.1 ppm; assess 10–14 days after cessation of chelation therapy.

PREVENTION/AVOIDANCE
• Test paint, dust, soil prior to animal access if likelihood of lead contamination.
• Determine source of lead and remove it from the patient's environment.

POSSIBLE COMPLICATIONS
Occasionally, permanent neurologic signs (e.g., blindness).

EXPECTED COURSE AND PROGNOSIS
• Signs should dramatically improve within 24–48 hours after initiating chelation therapy.
• Prognosis—favorable with treatment.
• Uncontrolled seizures—guarded prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Dogs <1 year of age—more likely to be affected.

ZOONOTIC POTENTIAL
None; however, humans in the same environment may be at risk for exposure.

PREGNANCY/FERTILITY/BREEDING
• Transplacental passage—may cause neonatal poisoning.
• Lactation—lead mobilized from bones unlikely to poison nursing animals.

SYNONYMS
Plumbism

SEE ALSO
Poisoning (Intoxication) Therapy.

ABBREVIATIONS
• ALP = alkaline phosphatase.
• AST = aspartate aminotransferase.
• GFAAS = graphite furnace atomic absorption spectrometry
• ICP-MS = inductively coupled plasma mass spectrometry.
• NSAID = nonsteroidal anti-inflammatory drug.
• RBC = red blood cell.
• WBC = white blood cell

L

LEFT ANTERIOR FASCICULAR BLOCK

BASICS

DEFINITION
• Conduction delay or block in the anterior fascicle of the left bundle branch (Figures 1 and 2). • Left ventricle activation is altered or delayed toward the blocked fascicle and corresponding papillary muscle.
• Controversial terminology in veterinary cardiology because, in contrast to humans, dogs and cats do not appear to have an anatomic left anterior fascicle.

Electrocardiogram (ECG) Features
• QRS complex—normal duration. • Left axis deviation—dogs, <+40°; cats, <0°: ○ Small q waves and tall R waves in leads I and aVL—small q not essential. • Deep S waves (exceeding the R waves) in leads II, III, and aVF.

PATHOPHYSIOLOGY
• Anatomic basis still speculative—anterior fascicle vulnerable because it has a single blood supply, is long and thin, and is located in the turbulent outflow tract of the left ventricle. • No hemodynamic compromise.

SYSTEMS AFFECTED
Cardiovascular

GENETICS
N/A

INCIDENCE/PREVALENCE
• Most commonly described form of bundle branch block in cats. • Uncommon in dogs.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
N/A

Mean Age and Range
N/A

Predominant Sex
N/A

SIGNS

Historical Findings
• Signs usually associated with the underlying cause. • Usually an incidental ECG finding.

Physical Examination Findings
No associated signs or hemodynamic compromise.

CAUSES
• Hypertrophic cardiomyopathy (cats).
• Left ventricular hypertrophy (e.g., mitral insufficiency, aortic stenosis, aortic body tumor, hypertension, hyperthyroidism).
• Hyperkalemia (e.g., urethral obstruction, acute renal insufficiency, Addison's disease).
• Ischemic cardiomyopathy (e.g., arteriosclerosis of the coronary arteries, myocardial infarction, myocardial hypertrophy that obstructs coronary arteries). • Surgical repair of a cardiac defect (e.g., ventricular septal defect or aortic valvular disease).
• Restrictive cardiomyopathy (cats).
• Fibrosis. • Often noted in otherwise normal individuals.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Left ventricular enlargement—absence of left ventricular enlargement on thoracic radiograph or cardiac ultrasound supports a diagnosis of left anterior fascicular block.
• Right bundle branch block—deep, wide S waves in leads I, II, III, and aVF causing a right axis deviation; in patients with left anterior fascicular block, leads I and aVL are positive and leads II, III, and aVF have deep S waves resulting in a left axis deviation.
• Altered position of the heart within the thorax—thoracic radiographs help identify mass or foreign body that may be displacing the heart. • Suspect hyperkalemia if signs of urethral obstruction, renal insufficiency, or hypoadrenocorticism (Addison's disease); determine serum potassium concentration.

CBC/BIOCHEMISTRY/URINALYSIS
Hyperkalemia possible.

OTHER LABORATORY TESTS
N/A

IMAGING
• Echocardiogram may show structural heart disease. • Thoracic and abdominal radiographs may show mass, pulmonary metastatic lesion, foreign body, or abnormal cardiac position.

DIAGNOSTIC PROCEDURES
• Electrocardiography. • Long-term ambulatory monitoring (Holter) may reveal intermittent bundle branch block.

PATHOLOGIC FINDINGS
Possible lesions or scarring on endocardial surface in the path of the bundle branches; applying Lugol's iodine to the endocardial surface within 2 hours post mortem enables clear visualization of the conduction system.

TREATMENT

APPROPRIATE HEALTH CARE
• Treatment unnecessary. • Treat underlying disease if present.

NURSING CARE
Unnecessary

ACTIVITY
Unrestricted unless indicated by underlying condition.

DIET
No modifications unless indicated by underlying condition.

CLIENT EDUCATION
Fascicular block per se does not cause hemodynamic compromise; combined with right bundle branch block it may develop into second- or third-degree AV block, making treatment essential; need to treat underlying cause if present.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
Treatment directed toward possible underlying primary disease (e.g., drugs to lower the serum potassium in hyperkalemia).

LEFT ANTERIOR FASCICULAR BLOCK

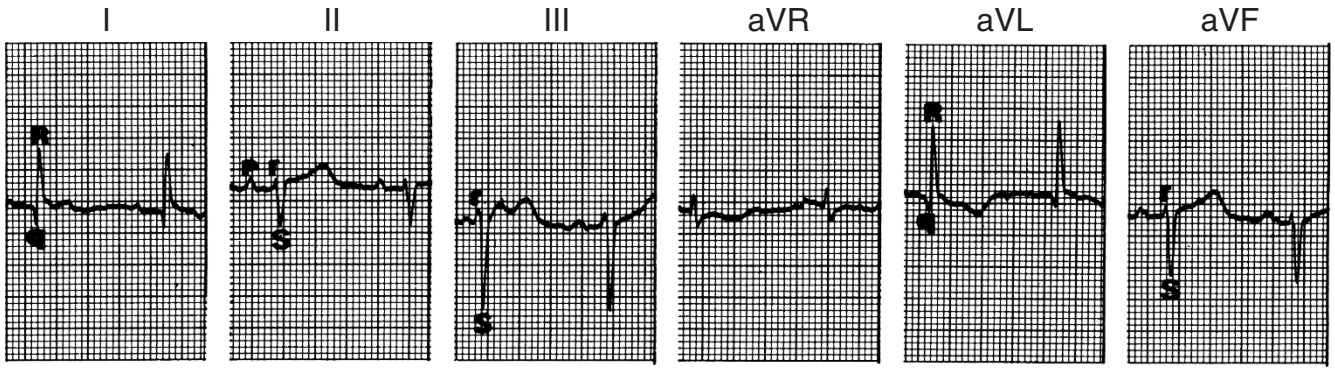

Figure 1.

Left anterior fascicular block in a dog with hyperkalemia (serum potassium, 5.3 mEq/L). There is abnormal left axis deviation (–60°) with a qR pattern in leads I and aVL and an rS pattern in leads II, III, and aVF. The large T waves are compatible with hyperkalemia. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

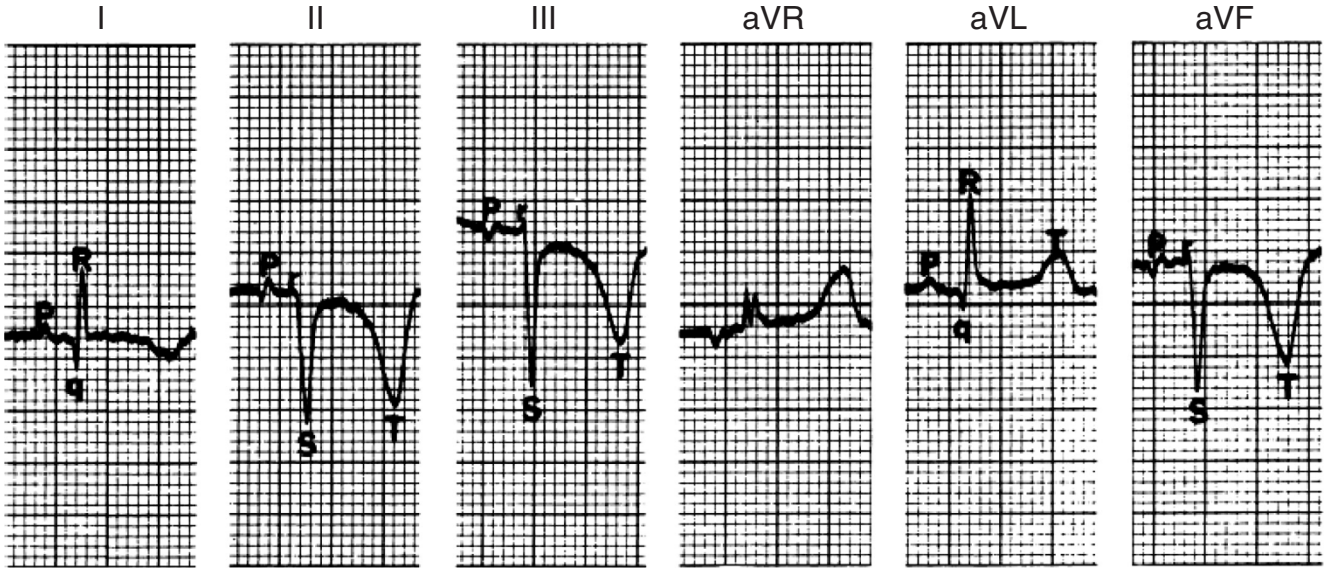

Figure 2.

Left anterior fascicular block in a cat with hypertrophic cardiomyopathy. Severe left axis deviation (–60°) with a qR pattern in leads I and aVL and an rS pattern in leads II, III, and aVF. The QRS complexes are of normal duration. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

LEFT BUNDLE BRANCH BLOCK

BASICS

DEFINITION
Conduction delay or block in both the left posterior and left anterior fascicles of the left bundle (Figures 1 and 2); a supraventricular impulse activates the right ventricle first through the right bundle branch; the left ventricle is activated late, causing the QRS to become wide and bizarre.

Electrocardiogram (ECG) Features
• QRS prolonged—dogs >0.08 seconds; cats >0.06 seconds. • QRS wide and positive in leads I, II, III, and aVF. • Block can be intermittent or constant.

PATHOPHYSIOLOGY
• Because the left bundle branch is thick and extensive, the lesion causing the block is often large. • Usually an incidental ECG finding—does not cause hemodynamic abnormalities.

SYSTEMS AFFECTED
Cardiovascular

GENETICS
N/A

INCIDENCE/PREVALENCE
Uncommon in cats and dogs. In cats with hypertrophic cardiomyopathy, left bundle branch block is not as commonly seen as left anterior fascicular block.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Dog and cat.

Breed Predilections
N/A

Mean Age and Range
N/A

Predominant Sex
N/A

SIGNS
Historical Findings
• Usually an incidental ECG finding—does not cause hemodynamic abnormalities. • Signs may be associated with the underlying condition if present.

Physical Examination Findings
Does not cause signs or hemodynamic compromise.

CAUSES
• Cardiomyopathy. • Direct or indirect cardiac trauma (e.g., hit by car, cardiac needle puncture). • Neoplasia. • Subvalvular aortic stenosis. • Fibrosis. • Ischemic cardiomyopathy (e.g., arteriosclerosis of the coronary arteries, myocardial infarction, myocardial hypertrophy that obstructs coronary arteries).

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Left ventricular enlargement. • No left ventricular enlargement on thoracic radiograph or cardiac ultrasound studies supports diagnosis of isolated left bundle branch block. • Can also be confused with ventricular ectopic beats, but the PR interval is usually constant and left bundle branch block does not result in pulse deficits.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
• Echocardiography may reveal structural heart disease; absence of left heart enlargement supports a diagnosis of left bundle branch block. • Thoracic and abdominal radiographs may show masses or pulmonary metastatic lesions; traumatic injuries could result in localized or diffuse pulmonary densities.

DIAGNOSTIC PROCEDURES
• ECG. • Long-term ambulatory monitoring (Holter) may reveal intermittent left bundle branch block.

PATHOLOGIC FINDINGS
Possible lesions or scarring on endocardial surface in the path of the bundle branches; applying Lugol's iodine to the endocardial surface within 2 hours post mortem enables clear visualization of the conduction system.

TREATMENT

APPROPRIATE HEALTH CARE
Directed toward the underlying cause if applicable.

NURSING CARE
Generally not necessary.

ACTIVITY
Unrestricted unless required for management of underlying condition.

DIET
No modifications unless required for management of underlying condition.

CLIENT EDUCATION
• Left bundle branch block per se does not cause hemodynamic abnormalities. • Lesion causing the block could progress, leading to more serious arrhythmias or complete heart block.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
N/A (unless required for management of underlying condition).

CONTRAINDICATIONS
N/A

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)

(CONTINUED) LEFT BUNDLE BRANCH BLOCK

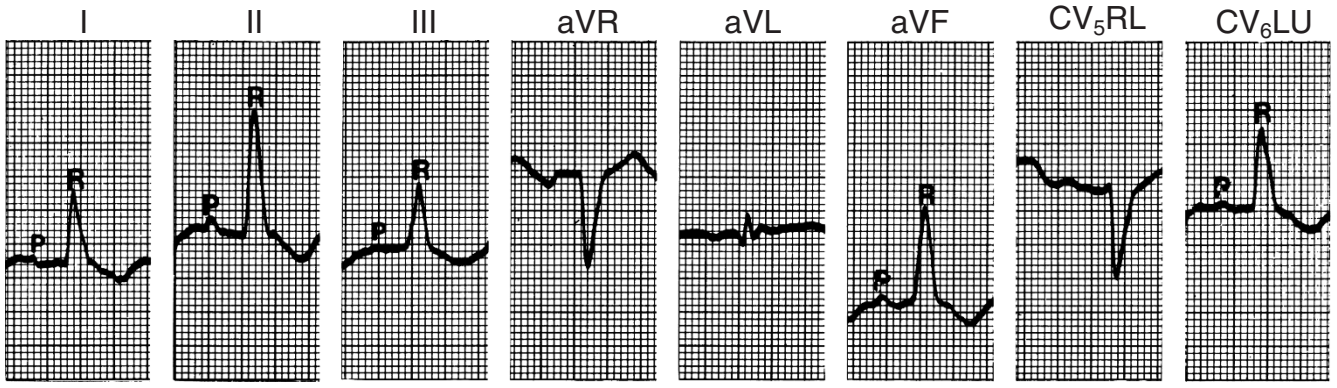

Figure 1.

Intermittent left bundle branch block in a Chihuahua. QRS complexes are wider (0.07–0.08 seconds) in the second, third, and fourth complexes and in the last three complexes. Consistent PR interval confirms a sinus origin for the abnormal-appearing QRS complexes (lead II, 50 mm/s, 1 cm = 1 mV). (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

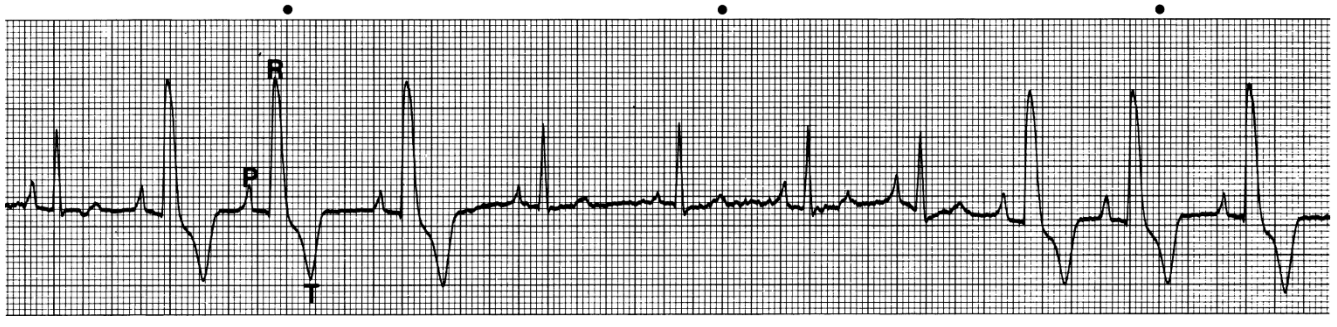

Figure 2.

Left bundle branch block in a cat with hypertrophic cardiomyopathy. The QRS complex is of 0.07-second duration and is positive in leads I, II, III, and aVF. Neither a Q wave nor an S wave occurs in these leads. The QRS complex is inverted in leads aVR. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

LEGG-CALVÉ-PERTHES DISEASE

BASICS

DEFINITION
Spontaneous deterioration of the femoral head and neck, leading to an incongruent, malformed coxofemoral joint and secondary osteoarthritis.

PATHOPHYSIOLOGY
- Precise cause unknown; a specific vascular lesion not identified.
- Histologic evidence points to infarction of vessels supplying the proximal femur.
- Necrosis of subchondral bone leads to collapse of subchondral bone and deformation of the femoral head during normal loading.
- Articular cartilage becomes thickened, develops clefts, and undergoes superficial fraying.
- Simultaneous osseous degeneration and repair is characteristic of ischemia and revascularization of bone.
- No known association with hypercoagulability or other coagulopathy.

SYSTEMS AFFECTED
Musculoskeletal—causes a pelvic limb lameness; insidious in onset.

GENETICS
- Manchester terriers have multifactorial inheritance pattern with a high degree of heritability.
- Probable autosomal recessive inheritance in miniature poodles, West Highland white terriers, Yorkshire terriers, and pugs.
- Hereditary predisposition likely.

INCIDENCE/PREVALENCE
- Most common among adolescent dogs of miniature, toy, and small breeds.
- No accurate estimates available.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog

Breed Predilections
- Toy breeds and terriers are most susceptible.
- Manchester terriers, miniature pinschers, toy poodles, Lakeland terriers, West Highland white terriers, Yorkshire terriers, Cairn terriers, and pugs—higher than expected incidence.

Mean Age and Range
- Most patients are 5–8 months of age.
- Range 3–13 months.

Predominant Sex
None

SIGNS

General Comments
Usually unilateral; only 12–16% of cases are bilateral.

Historical Findings
Progressive pelvic limb lameness that is usually insidious in onset over 2–3 months; ranges from weight-bearing to non-weight-bearing lameness.

Physical Examination Findings
- Pain on manipulation of the hip—common.
- Atrophy of the thigh muscles—common.
- Decreased range of motion of hip—inconsistent.
- Crepitation of hip—inconsistent.
- Patient otherwise normal.

CAUSES
- Unknown.
- Tamponade of the epiphyseal intracapsular subsynovial vessels supplying the femoral head is suggested cause of ischemia leading to the pathologic changes.
- Other proposed causes include abnormal anatomic conformation, increased intracapsular pressure, hormonal influences, and hereditary factors.

RISK FACTORS
- Adolescent small, toy, and miniature breed dogs.
- Trauma to the hip region.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Intracapsular hip trauma (e.g. femoral head or neck fracture).
- Severe hip dysplasia (but atypical breeds).
- Femoral head osteochondrosis.
- Infection and neoplasia considered less likely in patients with classic signalment, clinical findings, and radiographic lesions.
- Medial patellar luxation—differential for pelvic limb lameness in young toy breed dogs.
- Rupture of the cranial cruciate ligament—differential for pelvic limb lameness in older dogs.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
- Early radiographic changes—widening of the joint space; focal decreased or increased bone density of the epiphysis; sclerosis and thickening of the femoral neck.
- Later radiographic changes—lucent areas within the femoral head (apple-core or moth-eaten).
- End-stage radiographic changes—flattening and extreme deformation of the femoral head; severe osteoarthrosis; potential femoral neck fractures.
- Advanced imaging (computed tomography or magnetic resonance imaging) may be more sensitive than radiographs in early stages.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
- Femoral head—removed during femoral head and neck excision (FHNE) or total hip replacement; usually deformed with a thickened, irregular articular surface.
- Early disease—histologically characterized by loss of lacunar osteocytes and necrosis of marrow elements; trabeculae surrounded by granulation tissue.
- Later disease—thickened metaphyseal trabeculae; mixture of necrosis and repair tissue typical of revascularization of bone.
- Advanced disease—osteoclastic activity; new bone formation.

TREATMENT

APPROPRIATE HEALTH CARE
- Rest and analgesics—successful in alleviating lameness in less than 25% of patients.
- Ehmer sling—successful in one patient; maintained for 10 weeks; increased risk of ankylosis. Not widely recommended.
- Insidious onset often prevents early recognition and possibility of successful conservative treatment.
- FHNE with early and vigorous physical therapy after surgery—treatment of choice.
- Micro total hip replacement (THR) has been reported to successfully restore normal ground reaction forces.

NURSING CARE

Post Surgery
- Physical therapy—crucial for rehabilitating the affected limb.
- Analgesics, anti-inflammatory drugs, and cold packing—reduces pain and inflammation to increase limb use.
- Range-of-motion exercises initiated immediately—reduces risk of muscle contraction and limited range of motion.
- Small lead weights attached as ankle bracelets above the hock joint—encourages early use of the treated limb.

ACTIVITY
- Post surgery—early, low-impact activity encouraged to improve leg use.
- Conservative therapy—restricted activity recommended.

DIET
Avoid obesity.

CLIENT EDUCATION
- Warn owners of potential genetic basis of the disease in Manchester terriers, miniature poodles, Yorkshire terriers, West Highland white terriers, and pugs; discourage breeding affected dogs.

• Warn client that recovery after FHNE may take 3–6 months and requires early and vigorous physical therapy.

SURGICAL CONSIDERATIONS
FHNE or micro THR—treatment of choice.

MEDICATIONS

DRUG(S) OF CHOICE
Nonsteroidal anti-inflammatory drugs (NSAIDs)—preoperative or postoperative; minimize joint pain; reduce synovitis; reduce soft tissue pain and inflammation to encourage postsurgery limb use:
• Carprofen 2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h.
• Deracoxib 1–2 mg/kg PO q24h, chewable.
• Etodolac 10–15 mg/kg PO q24h.
• Firocoxib 5 mg/kg PO q24h.
• Grapiprant 2 mg/kg PO q24h, to animals >3.6 kg.
• Meloxicam—load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid.
• Tepoxalin—load 20 mg/kg, then 10 mg/kg PO q24h.

CONTRAINDICATIONS
NSAIDs—gastrointestinal disease, liver disease, or renal disease may preclude use in some patients.

PRECAUTIONS
NSAIDs—can cause gastrointestinal tract ulceration, hepatotoxicity, or nephrotoxicity; inhibition of platelet activity may increase hemorrhage at surgery; discontinue aspirin for at least 1 week before surgery, if possible.

POSSIBLE INTERACTIONS
NSAIDs—do not use in conjunction with glucocorticoids; risk of gastrointestinal tract ulceration; consider appropriate wash-out times when switching from one NSAID to another.

ALTERNATIVE DRUG(S)
Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—minimal benefit in advanced disease; no evidence to suggest that these drugs prevent or reverse the disease process.

FOLLOW-UP

PATIENT MONITORING
• Postsurgical progress checks—1- to 2-week intervals depending on progress with limb use; ensure compliance with exercise recommendations.
• Conservative therapy—reevaluate after 4–6 weeks of strict rest (physical examination, radiographs) to determine if surgery is needed.

PREVENTION/AVOIDANCE
• Discourage breeding of affected animals.
• Do not repeat dam–sire breeding that resulted in affected offspring.

POSSIBLE COMPLICATIONS
Noncompliance with postsurgical physical therapy exercises may result in less than optimal limb function.

EXPECTED COURSE AND PROGNOSIS
• FHNE—good to excellent prognosis for full recovery (84–100% success rate).
• Micro THR—excellent prognosis for full recovery.
• Conservative therapy—reported to alleviate lameness after 2–3 months in less than 25% of patients.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Usually affects juvenile small-breed dogs, but mature dogs may be affected by chronic disease.

ZOONOTIC POTENTIAL

Client Education Handout available online

LEIOMYOMA, STOMACH, SMALL AND LARGE INTESTINE

BASICS

OVERVIEW
Uncommon benign tumor arising from the smooth muscle of the stomach and intestinal tract; with immunohistochemistry these tumors may be reclassified as a gastrointestinal stromal tumor (GIST) or GIST-like.

SIGNALMENT
- Dog more commonly affected than cat.
- Middle-aged to older (>6 years) dogs and cats.
- No breed predisposition.

SIGNS

Historical Findings
- Relate to location in the gastrointestinal tract.
- Stomach—vomiting.
- Small intestine—vomiting; weight loss; borborygmus; flatulence.
- Large intestine and rectum—tenesmus; hematochezia; sometimes rectal prolapse.

Physical Examination Findings
- Stomach—no specific abnormalities; may have melena on rectal exam.
- Small intestine—often no abnormal findings; may feel mid-abdominal mass; occasionally distended, painful loops of small bowel; possible melena on rectal exam.
- Large intestine and rectum—may feel palpable mass per rectum; may have bright red blood on rectal exam.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Foreign body.
- Inflammatory bowel disease.
- Adenocarcinoma.
- Leiomyosarcoma.
- GIST.
- GIST-like.
- Lymphoma.
- Pancreatitis.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Hypoglycemia—occasionally associated with paraneoplastic syndrome.
- Stomach and small intestine—may see microcytic hypochromic anemia (iron-deficiency anemia).

OTHER LABORATORY TESTS
N/A

IMAGING
- Abdominal ultrasonography—may reveal a thickened wall of stomach or bowel; gastric leiomyoma most common at esophageal–gastric junction.
- Contrast radiography (stomach and small intestine)—may reveal a space-occupying mass.
- Double-contrast radiography (large intestine and rectum)—reveals a space-occupying mass.
- Contrast-enhanced CT—highest details of gastrointestinal tract and abdominal lymph node visualization.

DIAGNOSTIC PROCEDURES

Fine-Needle Aspirates
If mass or thickening seen with ultrasound, fine-needle aspirate (FNA) with cytology may be performed to rule out other differentials; for leiomyomas cytology is generally low yield.

Upper Gastrointestinal Tract
Perform upper gastrointestinal tract endoscopy and mucosal biopsy; however, this is frequently nondiagnostic because tumors are deep to the mucosal surface or distal to scope length. Therefore surgical biopsy often required to confirm the diagnosis.

Large Intestine and Rectum
Colonoscopy may reveal a mass; mucosal biopsy may be nondiagnostic because of normal mucosal covering of the tumor; surgical biopsy often required. If mass can be palpated per rectum, transrectal biopsies may be obtained.

TREATMENT
- Surgical resection—treatment of choice; curative if tumor is resectable.
- Even large leiomyomas often can be removed successfully and cured with narrow margins.

MEDICATIONS

DRUG(S) OF CHOICE
If reclassified as a GIST (c-KIT-positive), may consider a tyrosine kinase inhibitor (toceranib phosphate) as follow-up therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
- Complete resection—normal postoperative care; no additional follow-up necessary.
- Monitor blood glucose postoperatively if hypoglycemic prior to surgery.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Hypoglycemia—recognized as an associated paraneoplastic syndrome.

ABBREVIATIONS
- FNA = fine-needle aspirate.
- GIST = gastrointestinal stromal tumor.

LEIOMYOSARCOMA, STOMACH, SMALL AND LARGE INTESTINE

BASICS

OVERVIEW
- Uncommon malignant tumor arising from smooth muscle of stomach or intestines.
- Locally invasive; metastatic rate up to 50%, usually intra-abdominal sites, especially lymph nodes and liver.
- Prognosis fair to guarded.
- In large intestine the cecum is often affected.
- Analyses reclassified many leiomyosarcomas to gastrointestinal stromal tumors (GISTs) or GIST-like tumors; differentiate with immunohistochemistry.
- True leiomyosarcomas (LMS) rare; this chapter discusses GISTs with LMS.

SIGNALMENT
- Dog more commonly affected than cat.
- Mostly middle-aged to older (>6 years).
- No breed predisposition.

SIGNS

Historical Findings
- Relate to GI tract.
- Stomach—vomiting; weight loss.
- Small intestine—vomiting; weight loss; diarrhea; borborygmus; flatulence.
- Large intestine and rectum—tenesmus, may lead to rectal prolapse; hematochezia.

Physical Examination Findings
- Stomach—nonspecific.
- Small intestine—may feel mid-abdominal mass; sometimes distended, painful loops of small bowel.
- Large intestine and rectum—may feel mass per rectum.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Foreign body.
- Inflammatory bowel disease.
- Adenocarcinoma.
- Leiomyoma.
- GIST.
- GIST-like.
- Lymphoma.
- Pancreatitis.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Anemia—may be hypochromic, microcytic (iron-deficiency anemia).
- Leukocytosis.
- Hypoglycemia— paraneoplastic syndrome.

IMAGING
- Abdominal ultrasonography—may reveal mass or mural thickening:
  - GISTs more likely to have abdominal effusion.
  - Contrast-enhanced CT—highest detail for GI tract and abdominal lymph node visualization.

DIAGNOSTIC PROCEDURES

Fine-Needle Aspirates (FNA)
- FNA and cytology of mass or GI thickening may show malignant mesenchymal cells supportive of sarcoma.
- FNA and cytology of intra-abdominal lymph nodes important for metastasis evaluation.

Upper Gastrointestinal Tract
- Endoscopy and mucosal biopsy—often nondiagnostic as tumors are deep to the mucosal surface; mass may be beyond reach of endoscope.
- Surgical biopsy—often required to confirm diagnosis.

Large Intestine and Rectum
- Colonoscopy—may allow a mass to be seen; mucosal biopsy may be nondiagnostic due to normal mucosa covering the tumor.
- Deep biopsy—perform if possible.

Immunohistochemistry on Biopsy
- Perform to differentiate LMS from GIST.
- c-KIT-positive; DOG1 is sensitive and specific marker.

TREATMENT
- Surgical resection—treatment of choice.
- Evaluate for metastasis prior to surgery (e.g., mesenteric lymph nodes, liver, lungs).

MEDICATIONS

DRUG(S) OF CHOICE
- If reclassified as a GIST (c-KIT-positive), consider a tyrosine kinase inhibitor (toceranib phosphate) as follow-up therapy:
  - 5/7 dogs with gross disease had clinical benefit (3 complete response, 1 partial response, 1 stable disease); median progression-free survival = 110 weeks.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- LMS often metastasize to liver and regional lymph nodes.
- Older case series:
  - Small intestine: median survival time (MST) 12 months.
  - Cecum: MST 7.5 months, but most died of other diseases.
  - Gastric: rare, high rate of metastasis, short survival.
- Even dogs with metastasis can have prolonged survivals; MST 21.7 months in one study of dogs with metastatic LMS.
- One report showed similar survival times between dogs with leiomyoma, LMS, GIST, and GIST-like tumors:
  - 42 dogs, small intestinal tumors treated surgically: 1- and 2-year survivals of 62.6% and 52.3%.
  - 19 dogs, cecal tumors treated surgically: 1- and 2-year survivals of 84.2% and 66%.
- Mitotic index <9 and histological grade were prognostic for survival in abdominal visceral soft tissue sarcomas (mostly spleen and small intestine).

MISCELLANEOUS

ASSOCIATED CONDITIONS
Hypoglycemia—reported as paraneoplastic syndrome.

ABBREVIATIONS
- FNA = fine-needle aspirate.
- GIST = gastrointestinal stromal tumor.
- LMS = leiomyosarcomas.
- MST = median survival time.

LEISHMANIOSIS

BASICS

OVERVIEW

• Primary species infecting dogs and cats is protozoan *Leishmania infantum* which is endemic in Mediterranean basin countries, the Middle East, Central Asia, China, and South and Central America. • Dogs in the United States may acquire infection in another country, or part of endemic foxhound population (vertical transmission). • Sand fly vectors transmit flagellated parasites (promastigotes) to skin of host. Other modes of transmission include vertical, venereal, and blood transfusion. • Dogs and cats—clinical manifestations range from subclinical to severe; main systems affected: lymphoid organs, skin, eyes, kidneys, liver; renal failure is most common cause of death.

SIGNALMENT

• Dogs—purebred dogs (except Ibizan hounds) more susceptible; no sex or age predilection. • Cats—no breed, sex, or age predilection.

SIGNS

• Similar in dogs and cats. • Lymphadenomegaly. • Nonpruritic, exfoliative, erosive–ulcerative, nodular, papular, or pustular dermal and mucocutaneous lesions. • Blepharitis, conjunctivitis, keratoconjunctivitis, uveitis. • Polyuria, polydipsia. • Hyporexia, weight loss, vomiting, diarrhea, melena. • Splenomegaly, hepatomegaly. • Lameness. • Epistaxis. • Fever (rare).

CAUSES & RISK FACTORS

• Travel to or acquisition from endemic regions. • Coinfections (e.g., *E. canis*, retroviruses), immunosuppression, or malnutrition predispose.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Scaling and alopecia—infectious (bacterial, parasitic, fungal) or immune-mediated disease (lupus). • Renal disease—infection (pyelonephritis, Lyme nephritis), other glomerulonephropathy.

CBC/BIOCHEMISTRY/URINALYSIS

• Hyperproteinemia, hypergammaglobulinemia (polyclonal). • Hypoalbuminemia. • Nonregenerative normocytic normochromic anemia. • Proteinuria—quantitate with urine protein/creatinine ratio. • Leukocytosis or leukopenia with lymphopenia. • Increased hepatocellular enzyme activities. • Renal azotemia. • Thrombocytopenia.

OTHER LABORATORY TESTS

• Protein electrophoresis—differentiate polyclonal from monoclonal gammopathy. • Serologic diagnosis (IFA or ELISA)—most cross-react to *Trypanosoma cruzi*; differentiate based on clinical signs, history, and likelihood of exposure. In-house immunochromatographic tests available. • PCR—sensitive with aspirates of bone marrow, lymph nodes, spleen, skin; blood is less sensitive.

DIAGNOSTIC PROCEDURES

Fine-needle aspirates or biopsy of relevant tissues.

PATHOLOGIC FINDINGS

• Granulomatous, suppurative, or pyogranulomatous inflammation, lymphoplasmacellular inflammation in skin and hemolymphoid tissues. Reactive hyperplasia in lymphoid organs. • Visualization of amastigotes confirms diagnosis. Absence of amastigotes does not rule out. • Mucosal ulcerations—nasal, oral, gastrointestinal tract.

TREATMENT

• Medical management of infection. • Follow IRIS Guidelines for treatment of renal disease (see Internet Resources). • Diet—high-quality protein; renal diet as indicated.

MEDICATIONS

DRUG(S) OF CHOICE

• Dogs—meglumine antimoniate (100 mg/kg SC q24h or 50–75 mg/kg SC q12h for 1 month) or miltefosine (2 mg/kg PO q24h for 1 month). Best in combination with long-term allopurinol (10 mg/kg PO q12h for 12–24 months). Allopurinol may also be used alone. • Cats—allopurinol (10 mg/kg PO q12–24h) as monotherapy. Short-term meglumine antimoniate (20–50 mg/kg SC q24h) plus allopurinol is optional.

FOLLOW-UP

PATIENT MONITORING

• Monitor clinical signs, laboratory abnormalities, and antibody levels (quantitative serology) at day 30, 90, 180 and then every 6 months. • Relapses (rise in antibody or globulin concentrations and/or reappearance of clinical signs, laboratory abnormalities) may occur months to years after therapy or during therapy if drug resistance develops; recheck at least every 2 months after treatment completion. Drug resistance reported for allopurinol. • Monitor for urolithiasis and renal mineralization in dogs on long-term allopurinol.

PREVENTION/AVOIDANCE

• Topical pyrethroid-based repellents. • Canine vaccines available in Europe, parts of South America; reduces incidence of clinical disease but not subclinical infection.

EXPECTED COURSE AND PROGNOSIS

• Good (lymphadenomegaly, skin lesions) to poor (severe renal insufficiency) outcome, defined by clinical stage (LeishVet system outlines four stages). • Death usually from end-stage glomerulonephritis, nephrotic syndrome, and/or hypertension. • Infection may not be completely eliminated; in long-term treatment, monitoring required to prevent relapses.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Advise client of risk via exposure to sand flies in endemic areas. • Leishmaniosis is reportable in the United States and some other countries.

ABBREVIATIONS

• IFA = immunofluorescence antibody assay.

INTERNET RESOURCES

LEISHMANIOSIS, CUTANEOUS

BASICS

DEFINITION
Leishmaniosis is a group of infectious diseases occurring throughout the Mediterranean region, the Middle East, parts of Asia, and Central and South America. It is caused by parasitic protozoa of the genus *Leishmania*, and *Leishmania infantum* is the most common cause of disease in the dog. It occurs infrequently in the cat.

PATHOPHYSIOLOGY
Infection is transmitted by the bite of female sand flies of the genus *Phlebotomus* in Europe and *Lutzomia* in the New World. Nonvectorial transmission modalities have been demonstrated (venereal, vertical, dog-to-dog, blood transfusion), but are much less common. Following inoculation of a small number of promastigotes into the dermis, the innate immune response (complement, neutrophils, macrophages) and then the adaptive response (T-cell-mediated) attempt to control the infection. A high percentage of dogs develop an effective T helper-1 response, resulting in subclinical infection and becoming seronegative or developing a low anti-*Leishmania* antibody titer. A smaller group of dogs develop a predominantly T helper-2 response, have elevated antibody titers (immunoglobulin G [IgGs]), and allow the progression of the infection causing lesions and clinical signs. Active infection causes lesions by different mechanisms, including an acute inflammatory response (fever, lethargy, asthenia) and granulomatous inflammatory lesions, by generating immunocomplexes that are deposited in different organs causing inflammation and tissue damage (glomerulonephritis, arthritis, uveitis).

SYSTEMS AFFECTED
Infection with *Leishmania infantum* (CanL) is considered systemic. Rarely (papulonodular cutaneous form), the infection is exclusively cutaneous. From the dermis, infection first spreads to the hematopoietic organs (bone marrow, lymph nodes, spleen) and then systemically. The spread of infection and the involvement of numerous organs and systems explains the clinical pleomorphism of the disease.

GENETICS
Several haplotypes, possibly associated with tendency to develop a T helper-2 response, are associated with increased susceptibility to the development of the disease. Some breeds, including German shepherd dog, boxer, Rottweiler, Alaskan Malamutes, appear to be susceptible. Conversely, some autochthonous Mediterranean breeds (e.g., Ibizian hound) respond with an effective cellular response and very rarely develop clinical signs.

INCIDENCE/PREVALENCE
In areas where CanL is endemic, the prevalence of infection is very high (over 50%) with seroprevalences ranging between 5% and 30%. However, less than 5% of dogs develop clinical signs. Isolated cases have been observed in non-endemic areas (Northern Europe, United States), most often in dogs that have visited areas where the disease is endemic.

GEOGRAPHIC DISTRIBUTION
Found in Mediterranean countries, Portugal, the Middle East, Central and South Asia, and Central and South America. Vertical transmission of CanL has been seen in hunting foxhounds in the United States.

SIGNALMENT
No breed or age predisposition.

SIGNS
Historical Findings
- Loss of body weight.
- Decreased or increased appetite.
- Lethargy.
- Polyuria/polydipsia.
- Vomiting.
- Diarrhea.

Physical Examination Findings
- Generalized lymphadenomegaly.
- Skin lesions:
  - Nonpruritic dermatitis.
  - Generalized exfoliative dermatitis with or without alopecia.
  - Erosive–ulcerative dermatitis (planum nasale, distal legs, paw pads).
  - Nodular dermatitis.
  - Pustular dermatitis.
  - Papular dermatitis (ventral pinnae, nose, abdomen).
- Onychogryphosis.
- Lethargy.
- Muscle atrophy.
- Mucous membranes pallor.
- Fever.
- Splenomegaly.
- Epistaxis.
- Arthritis/articular pain/lameness.
- Ocular lesions: keratoconjunctivitis, blepharitis, and uveitis.

CAUSES
Leishmania infantum (syn. *L. chagasi*) zymodeme MON1 is a protozoan parasite with two structural variants: the amastigote form found in mononuclear phagocytes within the mammalian host and the infective flagellated promastigote form found in the sand fly.

RISK FACTORS
Living in an endemic area and outdoors lifestyle. Immunosuppression can trigger disease progression in a previously infected dog.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Any cause of cutaneous granulomatous disease with or without systemic symptoms. Leishmaniosis is considered one of the great imitators.

CBC/BIOCHEMISTRY/URINALYSIS
- Mild to moderate nonregenerative anemia.
- Leukocytosis or leukopenia—lymphopenia, neutrophilia, neutropenia.
- Thrombocytopathy.
- Thrombocytopenia.
- Impaired secondary hemostasis and fibrinolysis.
- Hyperproteinemia.
- Hyperglobulinemia (polyclonal beta- and/or gammaglobulinemia).
- Hypoalbuminemia.
- Decreased albumin/globulin ratio.
- Proteinuria.
- Renal azotemia.
- Elevated liver enzymes.

OTHER LABORATORY TESTS
Cytology—finding *Leishmania* amastigotes in lymph node or bone marrow smears is considered diagnostic with low sensitivity. Serum anti-*Leishmania* antibodies by immunofluorescence antibody test (IFAT) or ELISA. Main diagnostic test—dogs with clinical CanL usually have high antibody titers (>1:80 in IFAT). Biopsies (skin, lymph node) are recommended with low or borderline titers for histopathology and detection of *Leishmania* in the tissue with immunohistochemistry or PCR. Positive PCR for *Leishmania* DNA in sample of bone marrow, lymph node, or ocular conjunctiva is not definitive proof that clinical signs are the consequence of *Leishmania* infection.

IMAGING
Abdominal ultrasonography—splenomegaly.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Granulomatous inflammation in tissues (nodular to diffuse dermatitis, granulomatous colitis, granulomatous nephritis).

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient medical management except in cases with severe organ involvement.

ACTIVITY
N/A

LEISHMANIOSIS, CUTANEOUS (CONTINUED)

DIET
During treatment with allopurinol, a low-purine diet is recommended to avoid xanthinuria and urolithiasis.

CLIENT EDUCATION
Treatment does not completely eliminate infection despite the clinical improvement. Dogs remain infected life-long. Regular examinations for early detection of disease relapses needed. Application of topical insecticides (pyrethroids) are necessary to minimize the risk of transmission to other animals.

SURGICAL CONSIDERATIONS
N/A

L

MEDICATIONS

DRUG(S) OF CHOICE
Meglumine antimoniate 100 mg/kg SC q24h for 4–6 weeks with allopurinol 10 mg/kg PO q12h for at least 6 months. Miltefosine 2 mg/kg PO q24h (with allopurinol) instead of meglumine antimoniate: This combination appears to be less effective. The use of immunostimulants (domperidone, nucleotides) may reduce the risk of disease relapses. Treatment with allopurinol and an immunostimulant (domperidone or nucleotides) alone effective in cases of mild or moderate disease, but it is generally not effective (not recommended) in severe cases.

CONTRAINDICATIONS
Meglumine antimoniate is contraindicated in patients with severe kidney disease due to potential nephrotoxicity.

PRECAUTIONS
Meglumine antimoniate causes pain and inflammation at injection site; vomiting and diarrhea are common side effects. Allopurinol can cause development of xanthine uroliths. Dogs on long treatment with allopurinol should be fed a low-purine diet.

POSSIBLE INTERACTIONS
Allopurinol may decrease the hepatic metabolism of azathioprine. If used concurrently the dosage of azathioprine should be reduced by one-third. Allopurinol may increase serum cyclosporine level.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Follow-up visits: 4–6 weeks after diagnosis, every 3 months during the first year, and then every 6 months. A complete physical examination, CBC, serum biochemistry including serum protein electrophoresis, urine analysis, and serology should be performed at each check-up.

PREVENTION/AVOIDANCE
Topical pyrethroids in collars (deltamethrine, flumethrin) or spot on (permethrin) have been demonstrated to reduce the risk of infection and to reduce the prevalence of the disease. All dogs living in endemic areas should be treated regularly with topical pyrethroids. Three protein vaccines are currently licensed for CanL: two in Europe and one in Brazil. These vaccines are safe and have protection efficacies close to 70%. They do not prevent infection, but reduce the risk of having clinical leishmaniosis if infected. They can be administered to dogs living in endemic areas along with topical insecticides/repellents to increase protection. Dogs visiting endemic areas should be treated with topical pyrethroids.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
Four clinical stages have been defined based on clinical signs, serology, pathologic abnormalities, and renal disease. Prognosis depends on clinical stage: from good in mild disease (stage I) to poor in very severe disease (stage IV). Treatment causes clinical improvement in most dogs. However, dogs remain infected life-long.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Coinfection with other vector-borne diseases (e.g., ehrlichiosis) are frequently diagnosed in dogs with leishmaniosis. It is recommended to test dogs with leishmaniosis for prevalent local vector-borne infectious diseases.

AGE-RELATED FACTORS
N/A.

ZOONOTIC POTENTIAL
Leishmaniosis is a zoonosis and dogs are considered the most important peri-domestic reservoir of *L. infantum* infection for humans. The ownership of an infected dog does not appear to greatly increase the risk of developing leishmaniosis. Dogs diagnosed with leishmaniosis must be treated and monitored, and topical pyrethroids used, to prevent transmission of infection. Reporting of infection to public health authorities is required in some countries.

PREGNANCY/FERTILITY/BREEDING
Leishmaniosis can be transmitted vertically and by venereal route. Infected dogs should not be used as breeders. Allopurinol is considered to be safe during pregnancy. Information regarding the risk of using meglumine antimoniate in pregnant or lactating animals is limited. Use should be avoided. Miltefosine is contraindicated in pregnant and lactating animals. Puppies born to a mother with leishmaniosis should be screened for *Leishmania* infection with serology or PCR of a bone marrow sample at 3–6 months of age.

SYNONYMS
Leishmaniasis.

ABBREVIATIONS
- CanL = canine leishmaniosis caused by *Leishmania infantum*.
- IFAT = immunofluorescence antibody test.

LENS LUXATION

BASICS

OVERVIEW

- Lens luxation—total dislocation of lens from its normal location; occurs when lens capsule separates 360° from the zonules that hold lens in place.
- Anterior—forward displacement through the pupil into anterior chamber.
- Posterior—backward displacement into vitreous.
- Subluxation—partial separation of lens from its zonular attachments; lens remains in a normal or near-normal position in pupil.
- Primary (hereditary) luxation—inherited zonular defect of dogs resulting in bilateral but often asymmetrical clinical signs.
- Congenital luxation—often associated with other congenital ocular anomalies.
- Secondary luxation—due to chronic inflammation, buphthalmia, intraocular neoplasia, senile zonular degeneration, or trauma.

SIGNALMENT

- Primary—usually adult dogs (typically 3–6 years); common breeds include terriers, Chinese crested and Chinese Shar-Pei. Rare in cats.
- Secondary—dog and cat; any age/breed.

SIGNS

- Fibrils of liquefied vitreous in anterior chamber.
- Abnormally shallow (anterior luxation) or deep anterior chamber (posterior luxation).
- Abnormal iris curvature secondary to tilting of lens.
- Phacodonesis (tremor of lens with globe movement).
- Iridodonesis (tremor of iris with globe movement).
- Aphakic crescent (crescent-shaped area of pupil lacking lens).
- Acute or chronic painful eye, episcleral injection, diffuse or central corneal edema.
- Glaucoma more common in anterior lens luxation but can be detected in any stage.
- Uveitis.
- Cataracts.
- Retinal detachment.

CAUSES & RISK FACTORS

- Primary—associated with *ADAMTS17* gene mutation in some canine breeds; inheritance pattern uncertain in others.
- Primary luxation and primary glaucoma—may occur simultaneously in some breeds.
- Chronic uveitis.
- Intraocular neoplasia—secondary to physical luxation or chronic inflammation.
- Trauma—rarely causes a normal lens to luxate without severe ocular injury.
- Cataracts—can cause tension and breakage of lens zonules.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uveitis, glaucoma—painful, red eyes with corneal edema; may be concurrent.
- Buphthalmia may cause lens luxation.
- Corneal endothelial dystrophy or degeneration may also cause corneal edema.
- Diagnosis made by careful ophthalmic examination and history.

CBC/BIOCHEMISTRY/URINALYSIS

Normal, unless systemic disease present.

IMAGING

- Thoracic radiographs, abdominal ultrasonography—may be indicated if intraocular neoplasia.
- Ocular ultrasonography—useful if corneal edema or cloudy ocular media preclude examination.

DIAGNOSTIC PROCEDURES

- Complete ophthalmic examination, including tonometry.
- Genetic test available for some predisposed breeds.

TREATMENT

- Potentially visual eyes—immediate referral to a veterinary ophthalmologist for possible intracapsular lens extraction is indicated.
- Manual trans-corneal reduction of anterior lens luxation and medical management of posterior luxation has been described.
- Topical miotic therapy may be used to keep a posteriorly luxated lens behind pupil and avoid surgery in some cases.
- Irreversibly blind eyes can be enucleated or eviscerated with intrascleral prosthesis; if secondary to neoplasia, enucleation is the best choice (therapeutic and diagnostic).

MEDICATIONS

DRUG(S) OF CHOICE

- Topical miotics—demecarium bromide or prostaglandin analogs (latanoprost) q12h indicated if the lens is primarily subluxated or posteriorly luxated.
- If the pupil is blocked due to anterior lens luxation, tropicamide may allow the pupil to dilate, releasing lens and decreasing risk for pupillary block glaucoma.
- Mannitol: 1 g/kg IV over 20 minutes indicated for intraocular pressure (IOP) >40 mmHg.
- Carbonic anhydrase inhibitors—topical dorzolamide q8h for high IOP.
- Topical anti-inflammatory—0.1% dexamethasone sodium phosphate or 1% prednisolone acetate (q6–24h) if inflammation present.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Topical miotics—contraindicated if lens in anterior chamber.
- Client must verify location of lens prior to applying a miotic
- Mannitol—contraindicated in patients with cardiac disease, dehydration, pulmonary edema, anuria and intracranial bleeding.

FOLLOW-UP

- Medically treated primary posterior luxation—recheck IOP 24 hours after starting treatment and frequently thereafter; once IOP is stable, re-examine patient 3 or 4 times/year.
- Monitor for secondary glaucoma and retinal detachment.
- If only one lens is involved at the time of examination, the other lens may eventually luxate as well; the ophthalmologist may choose to perform prophylactic phacoemulsification in the contralateral eye if not yet luxated.

MISCELLANEOUS

ABBREVIATIONS

- IOP = intraocular pressure.

LEPTOSPIROSIS

BASICS

DEFINITION

• Caused by pathogenic members of genus *Leptospira*; each serovar has own virulence factors, infectious dose, route of exposure. • Acute and chronic diseases of dogs (mainly nephritis and hepatitis) and rarely cats. • Dogs—serovars causing disease vary by geographic area; recent serovars of concern in the United States are *L. grippotyphosa*, *L. autumnalis*, and *L. pomona*; vaccines should include regional serovars.

PATHOPHYSIOLOGY

• *Leptospira* penetrate intact/cut skin/mucous membranes; rapidly invade bloodstream (4–7 days); disseminated spread (2–4 days). • Invasion leads to transient fever, leukocytosis, mild hemolysis and hemoglobinuria, albuminuria. • Capillaries—endothelial cell damage. • Liver—hepatic necrosis. • Kidney—leptospiruria; *Leptospira* localize in damaged renal tubules; organism replicates in tubular epithelium. • Serum antibodies appear as bacteremia decreases. • Death—usually due to interstitial nephritis, vascular damage, renal failure; may result from septicemia, disseminated intravascular coagulopathy (DIC), respiratory failure.

SYSTEMS AFFECTED

• Cardiovascular—endothelial cell damage, hemorrhage. • Hepatobiliary—hepatitis, necrosis. • Nervous—meningitis. • Renal/urologic—focal interstitial nephritis, hemoglobinuric nephrosis, tubular damage/failure. • Respiratory—vasculitis, interstitial pneumonia, leptospiral pulmonary hemorrhage syndrome (LPHS).

Chronic Disease

• Ophthalmic—anterior uveitis. • Renal/urologic—chronic kidney disease. • Reproductive—abortion; weak puppies; linked to feline stillbirth.

INCIDENCE/PREVALENCE

• Reported incidence (dogs)—falsely low due to inapparent and undiagnosed infections. • Prevalence (dogs)—Increasing in urban dogs; hospital prevalence increasing since 1990s.

GEOGRAPHIC DISTRIBUTION

• Worldwide, especially in warm, wet climates. • Standing water, neutral or slightly alkaline soil promote presence in environment. • *L. canicola* most common worldwide; *L. icterohaemorrhagiae* most common in Australia. • *L. bratislava* has yet to be confirmed by culture as a serovar in dogs in the United States.

SIGNALMENT

Species

Dogs, rarely cats.

Mean Age and Range

• Young dogs without maternal antibodies and unvaccinated older dogs more likely to exhibit clincal disease. • Dogs with adequate antibody titers seldom exhibit clinical disease unless exposed to serovar not in vaccine.

Predominant Sex

N/A

SIGNS

General Comments

Signs vary with age/immune status, virulence of infecting serovar, host response.

Historical Findings

Peracute to Subacute Disease

• Fever. • Sore muscles/stiffness. • Weakness, lethargy. • Anorexia, vomiting. • Diarrhea—with/without blood. • Icterus. • Cough, dyspnea. • Polyuria/polydipsia (PU/PD) progressing to anuria. • Death.

Chronic Disease

• No apparent illness. • Fever. • PU/PD.

Physical Examination Findings

Peracute to Acute Disease

• Tachypnea. • Tachycardia, weak pulses. • Hematemesis. • Hematochezia, melena. • Epistaxis. • Injected mucous membranes. • Widespread petechial and ecchymotic hemorrhages. • Reluctance to move, paraspinal hyperesthesia, stiff gait. • Conjunctivitis. • Rhinitis. • Hematuria. • Mild lymphadenopathy.

CAUSES

• Dogs—*L. canicola*, *L. icterohaemorrhagiae*, *L. pomona*, *L. grippotyphosa*, *L. copenhagenii*, *L. australis*, *L. autumnalis*, *L. ballum*, and *L. bataviae*. • Cats—*L. canicola*, *L. grippotyphosa*, *L. pomona*, and *L. bataviae*.

RISK FACTORS

Transmission

• Direct—via urine, post-abortion discharge, fetus, sexual contact (semen). • Indirect—exposure (via urine) to contaminated environment (vegetation, soil, food, water, bedding). • Disease in companion animals is often result of spillover from diseased wildlife maintenance hosts.

Host Factors

• Vaccine—protection is serovar-specific; may not prevent kidney colonization and urine shedding; new vaccines available of "subunit" type; newer panvalent antigen may cross-protect against many serovars. • Outdoor animals, hunting dogs—exposure of abraded or water-softened skin increases risk of infection.

Environmental Factors

• Warm, moist environment (low-lying areas, rainy season of temperate regions). • Temperature range—44.6–50°F (7–10°C) to 93–96°F (34–36°C). • Organism survives best in stagnant water with neutral or slightly alkaline pH: ○ 180 days in wet soil; longer in standing water. • Dense animal population—kennels or urban settings. • Exposure to rodents, other wildlife (e.g., deer).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Subacute to Acute Disease

• Dogs—heartworm disease; hemolytic anemias; septicemia; viral infections (canine hepatitis, canine herpesvirus); neoplasia; trauma; lupus; tick-borne disease; toxoplasmosis; postrenal obstruction; renal toxins (e.g., ethylene glycol, aminoglycosides); causes of pulmonary interstitial/alveolar disease. • Cats—hemotropic mycoplasmosis; toxins (e.g., acetaminophen); septicemia; feline immunodeficiency virus (FIV)- and feline leukemia virus (FeLV)-associated diseases; cholangitis; toxoplasmosis; feline infectious peritonitis (FIP); neoplasia; trauma; postrenal obstruction.

Reproductive/Neonatal Disease

• Dogs—brucellosis, canine distemper, herpesviruses. • Cats—FIP, FeLV, panleukopenia, herpesvirus, toxoplasmosis, salmonellosis.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—leukocytosis with left shift; leukopenia during leptospiremic phase; thrombocytopenia. Hematocrit variable with hemoconcentration, bleeding, or hemolysis. • Chemistry— azotemia; electrolyte alterations—depend on degree of renal and gastrointestinal dysfunction (hyponatremia, hyper/hypokalemia, hypochloremia, hyperphosphatemia); hypoalbuminemia; elevated hepatic enzyme activities; hyperbilirubinemia. • Prolonged prothrombin and partial thromboplastin times; increased d-dimer concentrations. • Urinalysis—isosthenuria; proteinuria; glucosuria.

OTHER LABORATORY TESTS

Serology (Microscopic Agglutination Test [MAT])

• Test serum in acute stage and 3–4 weeks later (convalescent). • Unvaccinated patients—titers initially low (1:100–1:200), higher in convalescent sample (1:800–1:1,600 or higher) if homologous *Leptospira* serovar is tested; several serovars may cross-react in MAT test, especially if high titers to one serovar. • Vaccinated patients—high titers for up to 12–16 weeks post vaccination, then drop to <1:400; new subunit vaccines—titers rise to ≥1:1,600 for

(CONTINUED) LEPTOSPIROSIS

12 weeks for serovars *L. canicola* and *L. icterohaemorrhagiae*; titers for other serovars (*L. pomona* and *L. grippotyphosa*) variable.
• Run acute and convalescent samples at same time, if possible.

Darkfield Microscopy of Urine
Fresh urine, often inconclusive.

Fluorescent Antibody Test of Urine
• *Leptospira* viability not required; submit urine to lab on ice by overnight courier.
• More conclusive than microscopy.

PCR Test of Urine and Tissue
Only indicates genus *Leptospira*; may be useful with refinement and validation.

DIAGNOSTIC PROCEDURES
Culture (body fluids or tissues) not practical due to fastidiousness of leptospiras; require special culture/transport medium.

PATHOLOGIC FINDINGS
• Degree of kidney and liver disease depends on serovar and host immunity. • Cats—generally less severe lesions. • Dogs (acute disease)—lungs may be edematous; kidneys pale and enlarged; liver enlarged, may be friable with multifocal necrosis/hemorrhage; gastrointestinal tract may hemorrhage.
• Warthin–Starry silver stain; immunohistochemistry; fluorescent antibody test on formalin-fixed sections of kidney, liver, fetal/placental tissue.

TREATMENT

NURSING CARE
• Shock—IV, balanced, isotonic replacement solution. • Dehydration—IV or oral maintenance solutions as indicated. • Severe hemorrhage—blood transfusion may be indicated. • Oliguria, anuria—restore circulating volume; then give intravenous osmotic diuretics or tubular diuretics; dialysis may be needed. • LPHS—oxygen supplementation or mechanical ventilation as indicated.

CLIENT EDUCATION
Inform client of zoonotic potential from contaminated urine of affected dogs and environment.

MEDICATIONS

DRUG(S) OF CHOICE
• Doxycycline 5 mg/kg PO or IV q12h for 2 weeks; use alone to clear both leptospiremia and leptospiruria. • Ampicillin 22 mg/kg IV q6–8h (or other penicillins as available); only clears leptospiremia; must be followed by course of doxycyline.

PRECAUTIONS
Doxycycline can cause esophagitis, esophageal stricture.

FOLLOW-UP

PREVENTION/AVOIDANCE
• Vaccine (dogs)—whole-cell bacterin vaccines contain serovars *L. canicola/icterohaemorrhagiae* (newer also include *L. pomona/grippotyphosa*): ○ Promotes immunity to homologous serovars and protection from overt clinical disease; may not prevent colonization of the kidneys, resulting in chronic carrier state. ○ Serovar-specific. ○ Newer subunit vaccine contains *L. pomona*, *L. icterohaemorrhagiae*, *L. grippotyphosa*, and *L. canicola*; possibly provides protection from clinical disease/prevents kidney colonization. ○ Bacteria-induced immunity lasts 6–8 months and is serovar-specific. ○ Revaccinate at least yearly. ○ Vaccinate high-risk dogs (hunter, show dogs, dogs with access to water/ponds) every 4–6 months, especially in endemic areas. • Kennels—strict sanitation to avoid contact with infected urine; control rodents; monitor/remove carrier dogs until treated; isolate infected animals during treatment. • Activity—limit access to marshy/muddy areas, ponds, low-lying areas with stagnant surface water, heavily irrigated pastures; limit access to wildlife. • Environmental contamination—leptospira shedding in urine is intermittent; leptospira survive but do not multiply in environment; cells survive until either drying, UV light exposure, or freeze-thaw has killed the leptospires.

POSSIBLE COMPLICATIONS
• DIC. • Permanent liver/kidney dysfunction. • Uveitis. • Abortion.

EXPECTED COURSE AND PROGNOSIS
• Most infections subclinical or chronic.
• Prognosis guarded for acute severe disease.

MISCELLANEOUS

AGE-RELATED FACTORS
Severe clinical disease in young dogs (nonvaccinated or lacking maternal antibody).

ZOONOTIC POTENTIAL
• High—spreads in urine of infected animals.
• Strict kennel hygiene and disinfection of premises.

PREGNANCY/FERTILITY/BREEDING
• Possible abortion. • Antimicrobial therapy—consider effect of drug on developing fetus.

ABBREVIATIONS
• DIC = disseminated intravascular coagulopathy.
• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.
• LPHS = leptospiral pulmonary hemorrhage syndrome.
• MAT = microscopic agglutination test.
• PU/PD = polyuria/polydipsia.

Client Education Handout available online

L

LEUKEMIA, CHRONIC LYMPHOCYTIC

BASICS

OVERVIEW
• Uncommon, lymphoproliferative disorder. • Slowly progressive over months to years. • Circulating neoplastic lymphocytes are mature and well differentiated. • May originate in spleen or bone marrow.

SIGNALMENT
• More frequent in dog than cat. • No sex predilection reported. • Dogs—mean age 10 years (range 1.5–15 years). • Cats—median age 12.5 years (range 5–20 years).

SIGNS
• Nonspecific, often no clinical signs of illness. • Lethargy, decreased appetite, chronic weight loss. • Lymphadenomegaly, splenomegaly. • Fever. • Polydipsia/polyuria.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Lymphoma—may have a leukemic phase (stage V). • Acute lymphoblastic leukemia. • Immune-mediated hematologic diseases. • Chronic antigenic stimulation (reactive lymphocytosis)—ehrlichiosis. • Acute viral infection-associated lymphocytosis.

CBC/BIOCHEMISTRY/URINALYSIS
• Lymphocytosis—range 5,000 to >500,000 cells/μL; typically small, mature lymphocytes. • Larger size cells (intermediate-size or blasts) may be observed, especially with progression to blast crisis (advanced stage). • Mild-to-moderate normocytic, normochromic anemia (nonregenerative). • Normal-to-low platelet count (uncommon). • Normal-to-low neutrophil count (uncommon). • Normal-to-mildly increased serum globulins.

OTHER LABORATORY TESTS
• Immunophenotyping by flow cytometry (peripheral blood) is becoming more common practice for classification of leukemias (noninvasive)—affords prognostic information. • Immunocytochemical staining (bone marrow samples), flow cytometry of bone marrow aspirates, or PCR for antigen receptor rearrangement (PARR) may be useful for classification of leukemias. • Cytologic examination (bone marrow aspirate or core biopsy) may show high numbers of mature lymphocytes (especially B-cell chronic lymphocytic leukemia [CLL]); crowding out of normal cell lines in advanced stages. • If hyperglobulinemia, serum protein electrophoresis to detect monoclonal gammopathy. • Direct Coombs' test may be positive with secondary immune-mediated hemolytic anemia. • Serology for *Erlichia canis*.

IMAGING
Radiography and ultrasonography may reveal splenomegaly or internal lymphadenomegaly.

DIAGNOSTIC PROCEDURES
• Bone marrow aspiration (cytology) or marrow biopsy (histopathology) may be used for immunophenotyping. • Lymph node and spleen cytology or histopathology may help differentiate CLL from leukemic phase of lymphoma.

TREATMENT
• Usually outpatients treated with oral therapy. • Treatment should be instituted when patient demonstrates clinical signs of illness (including weight loss, lethargy), lymphadenomegaly or organomegaly, cytopenias, or with lymphocyte count above 50,000/μL. • Consult a veterinary oncologist for updates in treatment options and regimens.

MEDICATIONS

DRUG(S) OF CHOICE
• Dogs—chlorambucil 6 mg/m^2 PO q24h for 7–14 days; then 3 mg/m^2 PO q24h; and eventually (maintenance) 2–4 mg/m^2 q48h, adjusted based on response and chronic hematologic tolerability. • Cats—chlorambucil 2 mg/patient regardless of body weight q2–4 days. • Prednisone 2 mg/kg (up to maximum of 60 mg) PO q24h (dogs); 5–10 mg/cat q24h (cats; use prednisolone); in combination with chlorambucil; may be tapered or discontinued when lymphocyte count normalizes. • Alternative chemotherapy agents and protocols to be considered when resistance or blast crisis develops over time—consult with an oncologist.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Chemotherapy may have toxic side effects; seek advice with oncologist before starting treatment if you are unfamiliar with cytotoxic drugs.

FOLLOW-UP

PATIENT MONITORING
Initially, examination of CBC every 2 weeks; response to treatment and disease progression.

POSSIBLE COMPLICATIONS
Chronic chemotherapy-induced myelosuppression; may need to alter dosage, depending on neutrophil and platelet counts.

EXPECTED COURSE AND PROGNOSIS
• Variable course, but eventually progressive to blast crisis or becomes resistant to therapy. • Median survival time with therapy approaches 18 months in dogs with B-cell CLL, and surpasses 24 months in dogs with T-cell CLL. • Median survival time with therapy in cats was >14 months in one study.

MISCELLANEOUS

ABBREVIATIONS
• CLL = chronic lymphocytic leukemia. • PARR = PCR for antigen receptor rearrangement.

LEUKOCYTOSIS

BASICS

DEFINITION
General term—white blood cell (WBC) count increased above reference interval; nonspecific to type of cell. Evaluation of individual leukocyte absolute numbers is needed to discern the cellular population(s) causing the overall increase in WBC count. Neutrophilia is the most common cause of a total WBC increase, and a left shift with toxic changes (e.g., Döhle bodies, cytoplasmic basophilia, foamy cytoplasmic vacuolation, and/or toxic granulation) may be present.

PATHOPHYSIOLOGY
One or more of the following mechanisms:
- Inflammation and increased tissue demand for leukocytes causing myeloid hyperplasia in the bone marrow.
- Translocation of cells from the marginating pool to the circulating pool of large vessels.
- Altered cytokine production resulting in increased release of cells from marrow storage pool.
- Decreased migration to tissues.
- Delayed apoptosis.

SYSTEMS AFFECTED
Chronic inflammation/leukocytosis may lead to nonspecific tissue damage and organ dysfunction.

GENETICS
Leukocyte adhesion deficiency (LAD) is an uncommon, autosomal recessive, primary immunodeficiency resulting in reduced neutrophil adhesion and inability to migrate to tissues.

SIGNALMENT
- Nothing specific for generalized causes.
- LAD reported in Irish setters and a domestic longhair cat.
- Young and nervous/anxious animals with a physiologic response.
- Rottweilers, Alaskan Malamutes, Siberian huskies, and cats with eosinophil dysregulation diseases.

SIGNS
- Animals with leukocytosis may exhibit fever, anorexia, weight loss, organomegaly, and other signs caused by the primary disease process.
- Affected animals with LAD can exhibit persistent marked leukocytosis/neutrophilia, impaired wound-healing, recurrent infections, and/or weight loss.

CAUSES
- Etiologies resulting in increased inflammatory cytokine production include infectious or sterile causes, immune-mediated diseases, paraneoplastic or inflammatory disease.
- Shifting of neutrophils from the marginating pool to the circulating pool (measured) can be caused by stress or fear.
- Increases in circulating leukocytes due to decreased margination to the tissues can be caused by excessive endogenous corticosteroid or in patients with LAD.
- Delayed apoptosis can lead to hypersegmentation of neutrophils.

Neutrophilia
- Mature neutrophil count above reference interval.
- Most common—stress/physiologic response or inflammation caused by infectious or noninfectious conditions.
- Metabolic disease, corticosteroid excess (endogenous or exogenous).
- Physiologic (shift) or stress response.
- Tissue necrosis or trauma (surgical or other).
- Neoplasia—chronic myelogenous leukemia (primary) and secondary to histiocytic sarcoma; leiomyosarcoma; lymphoma; and mammary, pancreatic, squamous cell, bronchogenic, and hepatocellular carcinomas.

Monocytosis
- Monocyte count above reference interval, usually accompanies a neutrophilia.
- Most common—corticosteroid-mediated stress response (dogs), or chronic inflammatory conditions (infectious and noninfectious).
- Metabolic disease, chemotherapeutic drugs.
- Recovery from acute marrow injury.
- Tissue necrosis or trauma.
- Acute or chronic myelomonocytic or monocytic leukemia.

Lymphocytosis
- Lymphocyte count above reference interval.
- Most common—physiologic response or young (<6 months) age.
- Infectious agents and inflammatory conditions.
- Post vaccine.
- Physiologic (epinephrine-mediated) anxiety, excitement, exercise, fright, pain.
- Neoplasia (dogs and cats)—acute or chronic lymphocytic leukemia (primary), and non-hemic, lymphoma, thymoma.

Eosinophilia
- Eosinophil count above reference interval.
- Most common—allergic or hypersensitivity reaction, inflammation in selected tissues, or parasitic infection.
- Infectious agents and inflammatory conditions.
- Hypereosinophilic syndrome.
- Neoplasia—chronic eosinophilic leukemia (primary/uncommon), and paraneoplastic syndrome (common) associated with lymphoma, mast cell tumor, and infrequently other neoplasms.

Basophilia
- Basophil count above reference interval.
- Rare cause of a leukocytosis, may accompany an eosinophilia (same differentials apply).
- Chronic basophilic leukemia (primary/uncommon) and paraneoplastic syndrome associated with chronic myeloid leukemia and essential thrombocythemia.

RISK FACTORS
- Breeds predisposed to hyperadrenocorticism, eosinophilic diseases, or immune-mediated diseases.
- Geographic areas with specific infectious agents.
- Drugs—adenocorticotropic hormone (ACTH); catecholamine injections; corticosteroids; granulocyte colony-stimulating factor (G-CSF); methimazole.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Based upon individual leukocyte population(s) causing the leukocytosis.

Leukogram Patterns
- Inflammatory leukogram resulting from inflammatory cytokines may include one or more of the following: neutrophilia, left shift, toxic change, monocytosis, eosinophilia, and/or basophilia.
- Stress leukogram induced by endogenous or exogenous corticosteroids presents with a neutrophilia without a significant left shift or toxic change, monocytosis, lymphopenia, and/or eosinopenia (dogs).
- Excitement/physiologic (shift) leukogram mediated by catecholamines resulting in a neutrophilia without a significant left shift and toxicity, lymphocytosis, and/or monocytosis.
- Neoplastic leukograms typically involve the uncontrolled proliferation of cells, typically lymphocytes. Leukemias of other origin (neutrophils/monocytes) occur less frequently and inflammation should be excluded first. Some non-hemic neoplasms can cause a paraneoplastic neutrophilia, eosinophilia, and/or basophilia.
- With intense inflammation, the neutrophil count can increase dramatically into a range more commonly seen with leukemia (>50,000/µL), sometimes referred to as a "leukemoid reaction."
- Consider causes of severe inflammation first (e.g., pyometra, peritonitis) as chronic myeloid leukemia comprising mature neutrophils is rare in veterinary medicine.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC with leukocyte differential and absolute numbers with morphology review of a blood smear.
- Biochemical profile.
- Urinalysis with bacterial culture and sensitivity to evaluate for urinary tract infection, if indicated.

LEUKOCYTOSIS (CONTINUED)

Factors That May Erroneously Alter Laboratory Results

Blood smear review may help exclude errors in automated cell counting that can occur in the presence of nucleated erythrocytes or parasites.

OTHER LABORATORY TESTS

- Culture, serology, and/or PCR for infectious agents.
- ACTH stimulation test—if clinical concern for hyperadrenocorticism.
- Coombs' test, saline agglutination test—if suspicion for immune-mediated anemia.
- Flow cytometry—if suspicion for hemic neoplasia, immune-mediated disease.
- PCR for antigen receptor rearrangement (PARR)—if suspicion for lymphoid neoplasia.

IMAGING

Radiography and ultrasonography can aid in identifying occult site(s) of infection or neoplasia.

DIAGNOSTIC PROCEDURES

- Bone marrow aspirate or biopsy if indicated.
- Biopsy any masses.
- Organ evaluation, as indicated.

TREATMENT

APPROPRIATE HEALTH CARE

- Treatment should be based on the identified underlying etiology of the leukocytosis.
- Animals with infectious causes should receive appropriate antimicrobial medications.
- Suitable immunosuppression for immune-mediated diseases.
- Patients with extreme leukocytosis >50,000/µL require intensive management, including the possibility of hospitalization due to increased risk of mortality.

MEDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Determine if leukocytosis is persistent via repeat CBC to exclude physiologic response.
- In patients with extreme leukocytosis, serial CBCs every 24 hours, or as indicated, to assess the leukocyte response to medical therapy.

EXPECTED COURSE AND PROGNOSIS

- Leukocyte counts decrease after treatment of the inciting cause.
- Resolution can vary from a few hours (e.g., lymphocytes post stress) to a few days or weeks (e.g., inflammatory neutrophilia).
- Extreme leukocytosis >50,000/µL is associated with a poor prognosis and high mortality rate; patients with fever and neoplasia have the shortest survival times.

MISCELLANEOUS

AGE-RELATED FACTORS

Young animals (<6 months) have higher lymphocyte counts than adult animals and age-appropriate reference intervals are recommended.

PREGNANCY/FERTILITY/BREEDING

Mild leukocytosis characterized by a mature neutrophilia may be observed in pregnant animals.

SYNONYMS

None

SEE ALSO

LEUKOENCEPHALOMYELOPATHY IN ROTTWEILERS

BASICS

OVERVIEW
- Neurodegenerative disorder that affects the white matter of young adult Rottweilers leading to chronic progressive ataxia of the limbs.
- The clinical signs are primarily associated to involvement of the cervical spinal cord, but white matter lesions are also present in the brainstem, cerebellum, and subcortical white matter.
- Occurs worldwide.
- Probably autosomal recessive inheritance.

SIGNALMENT
Rottweiler—either sex; onset in adult dogs 1.5–4 years old.

SIGNS
- Insidious, nonpainful, progressive onset.
- Cervical spinal cord signs prevail despite widespread demyelinating process.
- Proprioceptive ataxia of the thoracic (delayed protraction with overreaching of the limb) and pelvic limbs, with upper motor neuron weakness.
- Front limbs are more severely affected than hind limbs. Mild asymmetry between right and left limbs may be present.
- Nail scuffing in all limbs.
- Proprioceptive positioning and hopping delayed to absent in all limbs.
- Spinal reflexes normal to exaggerated.

CAUSES & RISK FACTORS
- Autosomal recessive inheritance suspected.
- Inbreeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Cervical compressive lesions such as cervical vertebral spondylomyelopathy (wobbler), cervical subarachnoid diverticula, fibrotic stenosis, spinal cord tumors—difficult to differentiate on clinical signs alone; all can have an insidious onset; MRI necessary for diagnosis.
- Neuroaxonal dystrophy and distal sensorimotor polyneuropathy—neurologic disorders reported in Rottweilers; differentiated on the basis of neurologic deficits; neuroaxonal dystrophy: deficits relate to the cerebellum; distal sensorimotor polyneuropathy: tetraparesis associated with lower motor neuron signs.
- Discospondylitis, fracture/luxation, intervertebral disc disease—neck pain; disc disease rarely seen in large-breed dogs at a young age.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
N/A

IMAGING
- Spinal cervical survey radiographs normal.
- MRI—on T2W transverse images of the cervical spine, bilateral and symmetrical well-demarcated, ovoid in shape, intra-axial hyperintensities in the white matter of the dorsolateral funiculi, extending contiguously from the cervicomedullary junction to the sixth cervical vertebral body. Symmetrical hyperintensities also observed in pyramids and ventral aspect of the crus cerebri in the brain. No contrast enhancement.

DIAGNOSTIC PROCEDURES
Cerebrospinal fluid (CSF) analysis normal.

PATHOLOGIC FINDINGS
- Although the most severe lesion is located in the white matter of the cervical spinal cord, it extends caudally into the thoracic spinal cord and rostrally into the brainstem.
- Macroscopic examination—in the dorsal aspect of the lateral funiculi of the cervical spinal cord and in the pyramidal tracts of the medulla oblongata, presence of well-demarcated whitish opaque foci located bilaterally and symmetrically, corresponding to myelin loss.
- Microscopy—in the cervical spinal cord, the lesion affects the cervical spinal cord white matter in the dorsal portion of the lateral funiculi (dorsal spinocerebellar, lateral corticospinal, reticulospinal, and rubrospinal tracts). In the brain, the lesion affects the pyramidal tracts, crus cerebri, medial lemniscus, caudal cerebellar peduncle, trapezoid body, spinal tracts of the trigeminal nerve, and optic tracts; multifocal lesions are also observed in the cerebellar folia.
- The myelin loss exceeds axon loss with extensive astrogliosis and astrocytosis. Normal-appearing axons observed in areas of severe demyelination.
- Lesion bilateral with some asymmetry.

TREATMENT
- Outpatient, unless the severity of neurologic deficits precludes nursing care at home.
- Activity—whatever can be tolerated.
- Diet—ensure proper intake of food; patient may have difficulty reaching the feeding area.
- Neurologic status—slowly and progressively deteriorates; eventually, the patient is unable to walk or get up.

MEDICATIONS

DRUG(S) OF CHOICE
N/A

FOLLOW-UP
- Neurologic examination—monitor monthly to assess progression.
- Avoid bed sores and urine and fecal scalding by keeping the patient on a clean, dry, and cushioned pad (e.g., synthetic sheepskin).
- Severe tetraparesis—within 6–12 months after onset of clinical signs.
- Euthanasia—because of severe debility.

MISCELLANEOUS

ABBREVIATIONS
- CSF = cerebrospinal fluid.
- T2W = T2-weighted.

Author Joane M. Parent

LILY TOXICOSIS

BASICS

OVERVIEW

• Plants in the *Lilium* and *Hemerocallis* genera—widely used ornamental plants—are very toxic to cats; *Lilium*—Easter lilies, tiger lilies, Japanese show lilies, rubrum lilies, numerous *Lilium* hybrids; *Hemerocallis*—daylilies. • Ingestion of leaves or flowers and, potentially, pollen or vase water—results in a severe nephrotoxic syndrome; as little as 1–2 leaves reported to be lethal. • Toxic principle(s) not elucidated but found to be in the water-soluble plant fraction.

SIGNALMENT

• Cats—systemic poisoning. • Dogs—only mild gastrointestinal upset, even after ingestion of large quantities of plant material. • No age or breed predilections noted.

SIGNS

• Sudden onset of vomiting and drooling—gradually subsides within 4–6 hours. • Depression and anorexia—typically within 12 hours of exposure; both persist throughout the syndrome. • Polyuria and dehydration; azotemia by 12–24 hours; progresses to anuric renal failure by 24–48 hours. • Vomiting—recurs by 36 hours; accompanied by progressive weakness. • Recumbency—by 2–4 days. • Death—by 3–7 days post ingestion. • Severe pancreatitis has also been reported but is rare.

CAUSES & RISK FACTORS

• Plants—Easter lilies, tiger lilies, Asiatic hybrid lilies, Japanese show lilies, *Lilium* hybrids, daylily; primarily when used in cut-flower arrangements or as household potted plants. • All ingestions by cats of plant material from the *Lilium* and *Hemerocallis* genera should be considered potentially lethal. • Primarily indoor cats—predisposed to ingestion of newly introduced flowers or plants.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Nephrotoxins

• Aspirin and other nonsteroidal anti-inflammatory drug (NSAIDs). • Cholecalciferol (vitamin D3); calcipotriene. • Soluble oxalate-containing plants. • Ethylene glycol. • Nephrotoxic antibiotics—aminoglycosides. • Melamine/cyanuric acid poisoning.

Systemic Diseases

• Acute presentation of chronic renal failure. • Urinary obstruction. • Immune-mediated renal disease. • Leptospirosis. • Pyelonephritis. • Lymphoma.

CBC/BIOCHEMISTRY/URINALYSIS

• Stress leukogram. • Increases in BUN, creatinine, phosphorous, and potassium. • Creatinine—may be disproportionately elevated compared to BUN. • Increased aspartate aminotransferase (AST), alanine aminotransferase (ALT), and alkaline phosphatase (ALP) possible late in disease—likely secondary to prolonged anorexia and hepatic stress. • Proteinuria, glucosuria, and isosthenuria; numerous tubular epithelial casts. Early in the syndrome, tubular cell detail can be seen in the casts. • Crystalluria—*not* caused by ingestion of these plants. • Increased amylase and lipase may occur with very large ingestions.

DIAGNOSTIC PROCEDURES

• If possible, examine plant to verify that it has been chewed. • Have plant positively identified by a professional horticulturist or other expert if necessary.

PATHOLOGIC FINDINGS

• Gross—swollen, edematous kidneys; systemic congestion; pancreatic necrosis may be seen. • Histologic—severe acute renal tubular necrosis with intact basement membranes; mild to severe interstitial edema; severe cast formation in the collecting ducts; later in the syndrome may note evidence of mitotic figures in the remaining tubular epithelium.

TREATMENT

• Early decontamination—lessens duration and severity of signs. Inducing emesis may be helpful if vomiting has not already occurred. Endoscopy has been used to remove plant pieces. Bathe cats if pollen is noted on the patient's face or fur. • Fluid therapy—initiation within 18 hours of ingestion typically prevents anuric renal failure; intravenous balanced crystalloids at 2–3 times maintenance for 48–72 hours. • Anuric renal failure—peritoneal or hemodialysis is the only effective treatment; 7 days or more of therapy has resulted in a return of renal function in a few cases but does not guarantee recovery.

MEDICATIONS

DRUG(S) OF CHOICE

Decontamination

• Emetic agents for cats—xylazine 0.44 mg/kg IM or dexmedetomidine 7 µg/kg IM. • Activated charcoal 1–2 g/kg PO. • Cathartic—sorbitol 70% solution 1–2 mL/kg PO.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Avoid fluids containing potassium if hyperkalemic. • Avoid drugs eliminated by renal clearance. • Diuretics (mannitol, hypertonic fluids, furosemide, thiazides) are not effective at initiating urine production once anuric renal failure has occurred.

FOLLOW-UP

PATIENT MONITORING

• Monitor renal values and electrolytes every 12–24 hours during treatment with IV fluids. • Repeat 2–3 days after discharge, then as needed based on results and signs.

EXPECTED COURSE AND PROGNOSIS

• Dehydration from polyuric renal failure is required for the disease to progress to anuria. • Prevention of dehydration (early fluids)—prevents the progression of the syndrome to anuria. • Initiation of IV fluids within 18 hours of exposure and prior to development of renal failure carries a good prognosis. • Without treatment or if treatment is delayed, the mortality rate of lily toxicosis in cats is reportedly as high as 100%.

MISCELLANEOUS

SEE ALSO

• Poisoning (Intoxication) Therapy.

ABBREVIATIONS

• ALP = alkaline phosphatase. • ALT = alanine aminotransferase. • AST = aspartate aminotransferase. • NSAID = nonsteroidal anti-inflammatory drug.

LIPOMA, INFILTRATIVE

BASICS

OVERVIEW
- Invasive, non-encapsulated, lipoma variant that does not metastasize.
- A benign neoplasm that infiltrates soft tissues, particularly muscles, and including fasciae, tendons, nerves, blood vessels, salivary glands, lymph nodes, and joint capsules, and occasionally bones.
- Muscle infiltration typically extensive.
- Surgical cure—possible but difficult to obtain. Radiation therapy has utility to control growth.
- Occurs much less frequently than does lipoma.

SIGNALMENT
- Usually middle-aged dogs.
- No breed predilection definitively demonstrated; Labrador retrievers possibly overrepresented.
- May be more common in females than in males.

SIGNS
- Large, diffuse, soft tissue mass.
- Clinically appears as localized muscle swelling and/or distended abdomen if abdominal component.
- Infiltration of pelvic, thigh, shoulder, sternal, and lateral cervical musculature most common; recent evidence suggests no clear site prediction.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Soft tissue sarcoma, particularly liposarcoma, hemangiopericytoma, myxosarcoma, rhabdomyosarcoma, and fibrosarcoma.
- Lipoma.
- Intermuscular lipoma.
- Mast cell neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
N/A

IMAGING
- Radiography—reveals fat dense tissue between soft tissue dense structures.
- CT or MRI—fat-attenuating lesions allow adequate discrimination of tumor for surgery and/or radiation treatment planning; however, differentiation of normal fat from infiltrative lipoma can be problematic.

DIAGNOSTIC PROCEDURES
- Cytologic examination of aspirate reveals mature adipocytes with no cellular or nuclear atypia, identical to cells that form adult fat.
- Incisional biopsy can provide definitive histologic diagnosis if sufficient tissue representation of adipocytes and myocyte fibers can be identified.

PATHOLOGIC FINDINGS
- Histologic examination—well-differentiated adipocytes; may be indistinguishable from normal adipose tissue.
- Distinctive feature—tumor infiltration into and between muscle bundles and other tissues.

TREATMENT

Surgical Considerations
- Characteristic invasiveness makes excision extremely problematic; difficult to distinguish between tumor and normal adipose tissue.
- Poorly defined tumor margins—may contribute to the observed high recurrence rate after surgical excision.
- 36–50% of patients have recurrence within 3–16 months, except with limb amputation for appendicular tumor.
- Amputation of an affected limb is recommended only when quality of life is affected; tumor causes little inconvenience unless it interferes with movement (mechanical lameness), causes pressure-related pain, or develops in a vitally important anatomic site. However, amputation must be performed before growth of proximal extent of tumor crosses attainable surgical margin.

External Beam Radiotherapy
- Beneficial for long-term tumor control—median survival 40 months in a retrospective study of 13 dogs, with only 1 dog (7.7%) euthanized owing to tumor-related signs (vs. 26.7% with surgery alone).
- Dogs with measurable disease may only have stabilization of the tumor.
- Cytoreductive surgery to microscopic disease prior to radiation may result in long-term disease control.
- Unlikely to kill mitotically inactive mature adipocytes but may inhibit progressive infiltration by damaging tumor microcirculation.

MEDICATIONS

DRUG(S) OF CHOICE
N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
- Therapeutic recommendations— guided by size, anatomic location and quality of life to determine whether and when to recommend surgery and adjunctive radiation therapy for incomplete surgical margins.
- Reevaluations—schedule as dictated by tumor growth and choice of therapy.

POSSIBLE COMPLICATIONS
Temporary acute side effects (e.g., moist dermatitis and alopecia) expected with radiation therapy; consultation with a radiation oncologist is recommended regarding specific, anatomic site-related side effects.

EXPECTED COURSE AND PROGNOSIS
- Surgical cure only possible if all affected tissues can be removed. Long-term control of tumor growth may be attained with external beam radiation therapy alone or in combination with surgery.
- Lack of metastatic potential affords a good prognosis if local tumor growth can be controlled.
- If liposarcoma diagnosed, behavior is similar to other soft tissue sarcomas, therefore consult relevant literature on these tumors.

LIVER FLUKE INFESTATION

BASICS

OVERVIEW

• Flukes reported in cats: *Platynosomum concinnum* (syn. *P. fastosum*, *P. illiciens*) (infection occurs in cats in Florida, Hawaii, Puerto Rico, and other tropical–semitropical areas); *Opisthorchis felineus* (Italy, Eastern Europe); *Opisthorchis viverrini* (southern Vietnam, Thailand, Laos, Malaysia, India); *Amphimerus pseudofelineus* (the Americas); *Clonorchis sinensis* (also known as Oriental liver fluke of people; northern Vietnam, China); *Metorchis albidus, M. conjunctus* (North America, Europe, Russia); *Eurytrema procyonis* (eastern United States). • Flukes reported in dogs: *Heterobilharzia americana* (southeastern United States); *Clonorchis conjunctus*; *Clonorchis sinensis* (China); *Schistosoma japonicum* (Philippines); *Schistosoma haematobium* (Zambia); *Metorchis bilis*, and *Opisthorchis felineus* (Germany) in sled dogs fed a diet including raw fish; *Opisthorchis viverrini* (southern Vietnam, Thailand, Laos, Malaysia, India).
• *Platynosomum concinnum* is the most common fluke infecting cats. One report of infection in a cat from Ohio and one from Illinois. It is the most common trematode infection affecting the liver of companion pets in North America. • Infestation acquired from ingestion of infected intermediate host (e.g., lizard or frog). • Estimated 15–85% of cats with intermediate host access are infected in endemic areas. • *Heterobilharzia americana*—raccoon is the natural definitive host and most important reservoir host; dogs can also serve as the definitive host.

SIGNALMENT

• *Platynosmum concinnum*—young (6–24 months) cat with access to local fauna.
• *Heterobilharzia americana*—dogs swimming or wading in contaminated freshwater sources; young adult dogs more commonly affected.

SIGNS

• Cats (*P. concinnum*)—depends on severity of infection. • Most infected cats lack clinical signs. • With severe infestation—jaundice, emaciation, anorexia, vomiting, mucoid diarrhea, hepatomegaly, abdominal distention, malaise, fever. • Dogs (*H. americana*)—lethargy, weight loss, vomiting, diarrhea, inappetence, hypercalcemia, polyuria/polydipsia (PU/PD), melena.

CAUSES & RISK FACTORS

P. concinnum

• Adults reside in bile ducts and gallbladder; life cycle requires two intermediate hosts and tropical or semitropical climate. • Embryonated eggs pass in cat's feces; ingested by first intermediate host (a land snail). • Miracidia hatch from eggs in the snail penetrating host tissue and develop sporocysts. • Mature daughter sporocysts emerge from the snail and thereafter are ingested by a second intermediate host, usually an anole lizard (but also skinks, geckos, frogs, and toads); enter bile ducts where they reside until host ingested as prey by the cat. • Cercariae released in the upper digestive tract of the cat; migrate to the bile ducts where they mature and shed eggs within 8 weeks. • Risk factors for infection—tropical or subtropical climate; appropriate intermediate hosts; access to an outdoor or indoor/outdoor environment; successful hunting skills; consumption of infected intermediate host.

Metorchis conjunctus

• In cats—may infect the liver and biliary structures initially causing watery blood-tinged diarrhea and later evidence of biliary tree invasion; eggs are passed in feces 17 days from initial infection. • Infection typically associated with increased liver enzyme and may be associated with transient eosinophilia.

Heterobilharzia americana

• Eggs containing fully developed miracidium are passed in feces of definitive (final) host. In fresh water, eggs hatch, release miracidia that penetrate snail hosts, where sporocysts develop. Cercaria released from snail host 25 days after infection; these infect vertebrate host (dog, human) by skin penetration.
• Adult flukes develop in liver and migrate to mesenteric veins where eggs disseminate to various viscera, including liver, pancreas, mesenteric lymph nodes, spleen, and intestines; there they initiate granulomatous inflammation and sclerotic vascular lesions.
• Healing leads to scar formation and organ injury that can result in liver failure and gastrointestinal malabsorption. • Eggs appear in feces 68 days after infection.

Schistosoma haematobium

Adult fluke and eggs disperse to splanchnic organs, including liver and pancreas; in portal or hepatic veins eggs and adults associate with encapsulated fibrotic granulomatous foci.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Cholangiohepatitis; hepatic lipidosis; bile duct carcinoma; hepatic lymphoma; choleliths and any disorder causing major bile duct occlusion. • In dogs, primary gastrointestinal diseases and neoplasia (lymphoma) may be suspected. • Identified by finding trematode eggs in feces, rarely observing anechoic ovoid structures with echoic center in biliary tree by ultrasound, cytologic examination of bile or hepatic aspirates; most definitively from histopathology of biopsied liver, biliary structures, or pancreas.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—cats: variable; eosinophilia beginning 3 weeks after infection; persists for months; not all infected cats demonstrate eosinophilia; dogs: most common findings are lymphopenia and mild to marked thrombocytopenia; anemia; eosinophilia is uncommon.
• Biochemistry—cats: high liver enzyme activities, especially alanine aminotransferase (ALT) and aspartate aminotransferase (AST); alkaline phosphatase (ALP) may be normal or only slightly increased initially; bilirubin usually increased, markedly high in advanced cases; dogs: variable elevation in liver enzyme activities; hypercalcemia thought to be secondary to granulomatous inflammation; hypernatremia, hypercholesterolemia, hypo- or hyperalbuminemia, hyperglobulinemia, azotemia. • Bilirubin—cats: increased; markedly high in advanced severe disease; dogs: usually normal, may be increased.
• Urinalysis—cats: bilirubinuria.

OTHER LABORATORY TESTS

• Fasting/postprandial bile acid—increased.
• Fecal examination in cats—noninvasive definitive diagnostic test: *P. concinnum* eggs detected in only 25% of infected cats. • Fecal egg retrieval—cats: sedimentation most successful; formalin-ether or sodium acetate most reliable (demonstrates eightfold more eggs than direct fecal examination); dogs: sedimentation with saline recommended as miracidium will hatch in fresh water making identification difficult. Direct saline smear of feces may identify eggs. • Feline patients with few parasites (one to five flukes) may shed only 2–10 eggs/g of feces; eggs may not be discovered by fecal testing. • Serial fecal examinations may be necessary.
• Coagulation testing—dogs: prothombin time/partial thromboplastin time (PT/PTT) may be prolonged; antithrombin III (ATIII) decreased. • Parathyroid hormone/parathyroid-related hormone (PTH/PTHrp)—dogs: PTHrp may be elevated in hypercalcemic patients.

IMAGING

• Abdominal radiography—cats: may show mild hepatomegaly; dogs: may show hepatosplenomegaly, lymphadomegaly.
• Abdominal ultrasonography—cats: differentiates biliary obstruction from hepatocellular disease; shows one or more of the following: (1) biliary obstruction: dilated

gallbladder, common bile duct (>2 mm), and intrahepatic ducts; (2) gallbladder sediment with flukes (oval hypoechoic structures with echoic center), mildly thick gallbladder wall with a double-layered appearance (cholecystitis); (3) hypoechoic hepatic parenchyma with prominent hyperechoic portal areas (ducts) associated with cholangiohepatitis; dogs: heterogeneous parenchyma, ascites, splenomegaly, lymphadomegaly, thickened gastric and intestinal walls.

DIAGNOSTIC PROCEDURES

• Fecal examination for trematode eggs. • Cholecystocentesis—discloses fluke eggs in cats. • Liver biopsy (cats and dogs)—reveals signs of infection, ova.

PATHOLOGIC FINDINGS

Cats

• Gross—liver may appear large and yellow-green with dilated bile ducts; may see flukes in bile ducts or gallbladder; increased size and tortuosity of bile ducts on cut section. • Histologic lesions—depend on the number of flukes and duration of infestation; *early stage* (4–6 weeks): enlarged bile ducts and periductal areas infiltrated with inflammatory cells, especially eosinophils; *mid-stage* (4 months): severe adenomatous hyperplasia of bile duct epithelium and coincident periductal inflammation; *late stage* (6 months): extensive peribiliary fibrous connective tissue that may cause bile duct stenosis.

Dogs

• Gross—ulcerative gastritis, submucosal edema, red mucosal discoloration along intestinal tract, dystrophic mineralization of multiple organs. • Histologic lesions—trematode eggs in multiple organs; granulomatous inflammation and fibrosis throughout multiple organs; dystrophic mineralization of multiple organs.

TREATMENT

Outpatient vs. inpatient—depends on severity of illness.

Inpatient

• Balanced polyionic fluids with supplemental potassium chloride 20–40 mEq/L; as appropriate; based on serum electrolytes. • Nutritional support—avoid development of hepatic lipidosis; feed high-protein calorically dense food and ensure food intake; use feeding tubes if needed to ensure adequate food intake in inappetent cats; rarely, severe clinical signs may require parenteral nutrition; rarely hepatic encephalopathy necessitates protein restriction. • B vitamin supplementation—important for anorectic and ill cats on fluid therapy; 2 mL B-soluble vitamins/L fluids.

MEDICATIONS

DRUG(S) OF CHOICE

• Praziquantel 20 mg/kg SC q24h for 3–5 days is treatment of choice for cats; eggs may pass in feces for up to 2 months after treatment. For dogs, varying dosages have been reported. Praziquantel at 30 mg/kg PO once and 50 mg/kg SC once cleared a dog symptomatic for *H. americana*; more recently 25 mg/kg TID for 2 days and 3 days either orally or SQ, or 15–20 mg/kg PO q8h for 1–2 days is also reported. Some dogs were also treated concurrently with fenbendazole at 50 mg/kg PO q24h for 10 days. • Prednisolone—initial dose for cats showing eosinophilia, significant inflammation on biopsy or having severe clinical signs: 1–2 mg/kg/day for 2–4 weeks; then tapered in 50% decrements every 2 weeks. • Ursodeoxycholic acid 10–15 mg/kg q24h PO; tablet form and divided dose administered with feeding achieves best bioavailability; avoid if evidence of extrahepatic bile duct obstruction. • Broad-spectrum antibiotic coverage to protect against retrograde biliary tree infection with enteric organisms introduced by parasite; infection encouraged by fluke death in tissues. • Antioxidant therapy—suggested by necro-inflammatory tissue injury; vitamin E (10 IU/kg day PO) and *S*-adenosyl-L-methionine (SAMe; Denosyl-SD4 has proven bioavailability in cats as a glutathione [GSH] donor): 20 mg/kg PO daily, enteric coated tablets, until liver enzymes normalize. • Antiemetic—metoclopramide (0.2–0.4 mg/kg PO, SC q6–8h or by constant rate infusion 1–2 mg/kg/day); ondansetron (0.5 mg/kg q12h IV or PO 30 minutes before feeding); maropitant (1.0 mg/kg [5 mg/cat] IV, SC or PO once per day; maximum of 5 days).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Pregnancy—use caution with drug use.

FOLLOW-UP

PATIENT MONITORING

• Monitor clinical signs, appetite, body condition and weight, liver enzymes, bilirubin, and fecal sedimentation. • Hypercalcemia in dogs usually resolves within 36–48 hours after praziquantel administration. • Watch for signs of biliary tree occlusion after administration of praziquantel. • Monitor fecal saline sedimentation for clearance of ova in dogs.

PREVENTION/AVOIDANCE

• Restrict outdoor access if endemic parasite. • Praziquantel prophylaxis—every 3 months; for outdoor cats in endemic, tropical climates.

POSSIBLE COMPLICATIONS

• Death from liver failure; untreated symptomatic disease. • Biliary tree obstruction. • Pancreatitis. • Pancreatic exocrine insufficiency—with chronic infection. • Cholangitis/cholangiohepatitis (suppurative or nonsuppurative).

EXPECTED COURSE AND PROGNOSIS

Uncomplicated recovery with treatment expected in most patients.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None

LOWER URINARY TRACT INFECTION, BACTERIAL

BASICS

DEFINITION

• Urinary tract infection (UTI)—bacterial adherence, replication, and persistence within the urinary tract associated with clinical signs and/or inflammation. • Sporadic cystitis (uncomplicated UTI): lower UTI that occurs no more than once every 6 months.
• Recurrent UTI—UTI that occurs ≥3 times in a year, or ≥2 times in 6 months. Subcategories include: ○ Persistent—UTI that fails to resolve after appropriate antimicrobial therapy. ○ Relapse—UTI that appears to resolve; however, subsequent urine cultures confirm persistence of the original bacterial isolate. ○ Reinfection—UTI resolves with appropriate therapy but abnormal urinary defenses allow for recolonization of different bacterial species.
• Subclinical bacteriuria (asymptomatic bacteriuria)—bacterial presence within the urinary tract not associated with detectable clinical signs and/or inflammation.

PATHOPHYSIOLOGY

UTI development is dependent on the interplay between bacterial virulence factors and impairment of the anatomical, functional, environmental, and immunologic competency of the host. Most commonly, uropathogenic bacteria originate from the enteric flora and ascend from the distal urogenital tract into the proximal urethra and urinary bladder. Colonization may elicit a mucosal inflammatory response resulting in dysuria, pollakiuria, pyuria, and hematuria.

SYSTEMS AFFECTED

Renal/urologic.

INCIDENCE/PREVALENCE

• Bacteriuria is not equivalent to UTI. Current data identifies UTI prevalence given predisposing conditions. • Prevalence of bacteriuria in dogs: ○ With subclinical bacteriuria: 2.1–8.9%. ○ With diabetes mellitus: 37%. ○ With hyperadrenocorticism, at diagnosis: 46%. ○ With thoracolumbar intervertebral disc extrusion: 20.0–38.5%. ○ With indwelling urinary catheters: 63.8%.
• Prevalence of bacteriuria in cats: ○ With subclinical bacteriuria: 0.9–28.8%. ○ With lower urinary tract-associated clinical signs: 3.4–12.0%. ○ With ureteral calculi: 8.4%. ○ With chronic kidney disease: 16.9–29.1%. ○ With diabetes mellitus: 12.2–12.8%. ○ With perineal urethrostomies: 22%.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

More common in dogs than cats.

Breed Predilections

Breed-associated conditions (hyperadrenocorticism, urolithiasis, etc.) may promote bacteriuria.

Mean Age and Range

• UTIs occur at any age, but are more common in older dogs and cats. • Dogs—female: mean 7.7 ± 0.1 years; male: mean 8.0 ± 0.1 years. • Cats—female: mean 11.8 ± 4.4 years; male: mean 9.8 ± 4.8 years.

Predominant Sex

• Dogs—female dogs more commonly affected.
• Cats—female cats are slightly overrepresented.

SIGNS

Historical Findings

• Patients may be asymptomatic. • Pollakiuria, dysuria, hematuria, stranguria, inappropriate elimination, and excessive licking at or discharge from the genitalia may be present.
• Systemic clinical signs (anorexia, fever) are infrequent and suggest complicating factors (e.g., pyelonephritis).

Physical Examination Findings

• Unremarkable in most animals. • Abnormalities occasionally noted with urinary bladder palpation: ○ Stimulation of micturition. ○ Pain reactions.

CAUSES

• Uropathogenic bacteria commonly originate from enteric flora with rare hematogenous origins. • *Escherichia coli* is the most common bacterial isolate in dogs (45–55%) and cats (37.3%). • Eight species of bacteria (*E. coli*, *Staphylococcus*, *Proteus*, *Streptococcus*, *Klebsiella*, *Enterococcus*, *Pseudomonas*, and *Corynebacterium*) account for approximately 95% of UTIs.

RISK FACTORS

• Immune dysfunction/suppression (e.g., hyperadrenocorticism, feline leukemia virus [FeLV], feline immunodeficiency virus [FIV]).
• Nidus for bacterial adherence and harboring (e.g., indwelling urinary catheters, uroliths).
• Altered urine composition (e.g., persistently dilute urine, glucosuria). • Abnormal micturition/urine retention (e.g., loss of urethral tone, neurologic disease, urethral obstruction).
• Abnormal anatomy (e.g., ectopic ureters, hooded vulva). • Disrupted urinary tract mucosal defenses (e.g., mucosal trauma).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• UTI cannot be diagnosed or excluded based on the presence/absence of clinical signs. • Dysuria, pollakiuria, hematuria, and stranguria occur with lower urinary tract diseases including cystolithiasis, urinary tract neoplasia, prostatitis, obstructive uropathy, and feline idiopathic cystitis.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC and biochemistry are unremarkable.
• Urinalysis: ○ Proteinuria and hematuria indicate inflammation. ○ Urine pH >7.5 may indicate the presence of urease-producing bacteria (*Proteus* spp., *Staphylococcus* spp., *Ureaplasma* spp., or *Corynebacterium* spp.). ○ Pyuria is present in most animals with UTI but is not synonymous with infection. ○ Bacteriuria identification increases UTI suspicion. Using a modified Wright–Giemsa stain (Diff-Quik) or Gram stain can improve bacterial detection.

OTHER LABORATORY TESTS

Urine Culture

• Definitive diagnosis requires aerobic urine culture. • In female dogs with limited antibiotic exposure forgoing a urine culture can be justified for uncomplicated UTI if the pathogen and local susceptibility patterns are known. In male dogs, cats, and animals with recurrent UTI urine culture is recommended. • Cystocentesis is the gold standard method for collecting urine culture specimens. Bacterial growth >10^3 cfu/mL is diagnostic. • Urine samples obtained by catheterization are often contaminated by the normal flora of the distal urethra. Bacterial growth >10^4 cfu/mL in male dogs, >10^5 cfu/mL in female dogs, and >10^3 cfu/mL in cats is diagnostic. Indwelling catheters may be colonized without concurrent UTI; therefore, sample collection from indwelling urinary catheters should be avoided. • Culturing voided midstream urine samples should be avoided unless other urine collection techniques are contraindicated or not possible. • Urine collected from nonsterile surfaces should not be cultured.

Antibiotic Sensitivity Testing

Antibiotic sensitivity is accurately predicted by use of the isolate's "susceptible" vs. "resistant" profiles.

IMAGING

Rarely is imaging necessary for uncomplicated infections. Radiographs, contrast studies, and ultrasound may help to identify recurrent UTI-predisposing causes.

DIAGNOSTIC PROCEDURES

Cystoscopy is used in patients with recurrent UTI to visualize abnormalities within the urinary bladder and urethra including uroliths, masses, polyps, ectopic ureters, etc.

PATHOLOGIC FINDINGS

N/A

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient treatment is appropriate; inpatient treatment may be necessary with UTI complications or associated conditions (e.g., acute pyelonephritis).

CLIENT EDUCATION
N/A

SURGICAL CONSIDERATIONS
Management of uroliths, polypoid cystitis, and infection niduses may require surgical intervention.

MEDICATIONS

DRUG(S) OF CHOICE
• Given the morbidity associated with sporadic cystitis, empiric antimicrobial treatment is commonly started before receiving urine culture results. • When susceptibility data is available, the lowest tier antimicrobial should be selected. • "First-line" antimicrobials—should be selected when possible: ◦ Amoxicillin (11–15 mg/kg PO q8h). ◦ Trimethoprim-sulfadiazine (TMS) (15 mg/kg PO q12h). ◦ Amoxicillin/clavulanic acid (12–25 mg/kg PO q12h). • "Second-line" antimicrobials—reserved for resistant isolates based on culture and sensitivity or when patient factors prohibit the use of "first-line" therapies: ◦ Floroquinolones (e.g., marbofloxacin 2.7–5.5 mg/kg PO q24h; enrofloxacin; ciprofloxacin). ◦ Cefovecin (8 mg/kg SC). ◦ Nitrofurantoin (4.4–5.0 mg/kg PO q8h). • "Third-line" antimicrobials—reserved for multidrug resistant infections necessitating therapeutic intervention: ◦ Amikacin (dogs 15–30 mg/kg IV or SC q24h; cats 10–14 mg/kg IV or SC q24h). ◦ Chloramphenicol (dogs 40–50 mg/kg PO q8h; cats 12.5–20 mg/kg [not exceeding 50 mg/cat] PO q12h). • Antibiotic treatment of uncomplicated infections is recommended for 3–10 days. • Recurrent UTI treatment requires a urine culture and sensitivity. • Treatment durations are extended for persistent and relapse infections (up to 4 weeks). • Reinfections are treated as multiple uncomplicated infections, however an attempt to identify an abnormality in host defenses should be pursued.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Pyelonephritis or prostatitis necessitates therapies able to penetrate the respective tissues (see Pyelonephritis; Prostatitis and Prostatic Abscess).

POSSIBLE INTERACTIONS
N/A

ALTERNATE DRUGS
Nonsteroidal anti-inflammatory drugs (NSAIDs) may be used cautiously to reduce clinical signs in dogs with cystitis while awaiting urine culture results. They should not be used in dehydrated patients.

FOLLOW-UP

PATIENT MONITORING
• For uncomplicated UTIs clinical improvement should occur within 48 hours. If clinical signs remain for >48 hours, complicating factors should be investigated. • Complicated UTIs—continue therapy for 7–10 days beyond resolution of clinical signs, pyuria, and bacteriuria. Confirm resolution via urine culture 7–10 days after end of therapy.

PREVENTION/AVOIDANCE
• Diagnosis and control of predisposing conditions is the most effective method for preventing UTIs. • Ancillary therapies can be considered to prevent recurrence: ◦ Cranberry extract may inhibit *E. coli* attachment to the bladder mucosa. ◦ Methenamine—converted into formalin when urine pH is <7.0. Concurrent administration of ascorbic acid (vitamin C) promotes urinary acidification. ◦ Prophylactic antibiotics—once-daily administration of antibiotics may lengthen infection-free intervals; however, multidrug resistance is likely in subsequent isolates.

POSSIBLE COMPLICATIONS
UTIs may lead to pyelonephritis, struvite urolith formation, or polypoid cystitis.

EXPECTED COURSE AND PROGNOSIS
Prognosis for patients with uncomplicated UTIs is excellent. The prognosis for patients with complicated infections is determined by successful control or resolution of predisposing conditions.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Struvite urolithiasis. • Polypoid cystitis.
• Pyelonephritis. • Prostatitis.
• Emphysematous cystitis.

AGE-RELATED FACTORS
Juvenile animals with recurrent UTIs should be evaluated for urolithiasis or urinary tract malformations.

BASICS

OVERVIEW

• Funguria is usually due to ascending infection of normal commensal flora of the skin and mucosa, or environmentally ubiquitous organisms (primary funguria).
• *Candida albicans* is the most common isolate; other *Candida* spp. are less common, and non-*Candida* spp. fungi are rare.
• Urinary shedding may occur with systemic fungal infections (secondary funguria).
• Organ system affected—renal/urologic.

SIGNALMENT

• Dog and cat.
• German shepherd dogs and female dogs are overrepresented in systemic aspergillosis.

SIGNS

• Dysuria, stranguria, and pollakiuria; gross hematuria is rare.
• Many animals are asymptomatic.

CAUSES & RISK FACTORS

• Fungal urinary tract infections (UTIs) are associated with immunosuppression or immunocompromised disease states.
• Suspected risk factors—diabetes mellitus, urinary tract stomata (perineal urethrostomy, cystotomy tubes, indwelling urinary catheters), lower urinary tract disease (transitional cell carcinoma, chronic bacterial UTI), recent or chronic antibiotic or immunosuppressive therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Causes of lower urinary tract disease including bacterial UTI, cystolithiasis, sterile cystitis, urethritis, and bladder and urethral neoplasia.
• Primary funguria must be differentiated from systemic infections with secondary funguria.
• Contamination of urine samples during collection may occur in animals with cutaneous or mucocutaneous yeast overgrowth.

CBC/BIOCHEMISTRY/URINALYSIS

• Yeast/fungal elements are often visible within urine sediment. *Candida* spp. may appear as both budding yeast and filamentous structures.
• CBC and biochemistry usually unremarkable. With renal or systemic involvement, abnormalities will reflect those organs involved.

IMAGING

• Chest radiographs and abdominal ultrasound screen for diseases causing immunocompromise.
• Spinal radiographs may show diskospondylitis in cases of systemic aspergillosis.

DIAGNOSTIC PROCEDURES

Urine Culture

• *Candida* spp. grow within 3 days on standard blood agar.
• Other fungi grow more slowly and thus will not be detected by standard urine culture protocols.
• If fungal UTI is suspected or confirmed, fungal culture should be requested.

Antifungal Sensitivity Testing

• *C. albicans* is usually susceptible to fluconazole; antifungal sensitivity testing is typically unnecessary.
• Non-*albicans* species of *Candida* are more commonly resistant to fluconazole, and thus susceptibility testing should be considered.
• Susceptibility testing should be performed on non-*Candida* spp. and with persistent *Candida* spp. UTI despite 4–6 weeks of appropriate antifungal therapy.

TREATMENT

• Identify and correct any risk factors.
• Patients with asymptomatic funguria and no risk factors for disease should have a repeat urine culture performed prior to starting therapy.

MEDICATIONS

DRUG(S) OF CHOICE

• Fluconazole 5–10 mg/kg PO q12h is the initial treatment of choice for *C. albicans*.
• Antifungal therapy for non-*C. albicans* spp. should be based on susceptibility testing.
• Drugs with poor urinary excretion of active drug, such as itraconazole, ketoconazole, posaconazole, and voriconazole, are not recommended.
• Patients with persistent infection after 4–8 weeks of fluconazole may benefit from intravesicular infusion of 1% clotrimazole.
• Amphotericin B (intravenous or intravesicular) can be used, but efficacy is unknown. Intravenous therapy is primarily used for systemic disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Intravesicular clotrimazole should be avoided in animals with recent bladder surgery or urethral trauma.

FOLLOW-UP

• Repeat urine sediment and urine culture every 2–3 weeks to confirm treatment efficacy. Treatment should be continued for a minimum of 4–6 weeks.
• Urine sediment analysis and culture should be performed 1 and 2 months after cessation of therapy.
• 25% of dogs and cats with candiduria may have persistent and asymptomatic infections. Treatment should be reserved for symptomatic episodes in these patients.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Diabetes mellitus.
• Transitional cell carcinoma.

SEE ALSO

• Aspergillosis, Disseminated Invasive.
• Aspergillosis, Nasal.
• Cryptococcosis.
• Immunodeficiency Disorders, Primary.

ABBREVIATIONS

• UTI = urinary tract infection.

LUMBOSACRAL STENOSIS AND CAUDA EQUINA SYNDROME

BASICS

DEFINITION
• Lumbosacral stenosis refers to narrowing of the lumbosacral vertebral canal and/or L7–sacral intervertebral foramina, causing compression of L7, sacral, or caudal nerves.
• Cauda equina syndrome implies pain or other clinical signs related to dysfunction of these nerves.

PATHOPHYSIOLOGY
• Congenital—abnormal vertebral development causing narrowing of the lumbosacral vertebral canal. Transitional vertebrae and other malformations are common at this site and may contribute to (early) disease progression.
• Acquired—bony and soft tissue degenerative changes, most commonly affecting the L7 intervertebral disc, that cause stenosis of the vertebral canal and/or intervertebral foramina. Specific syndrome of sacral osteochondrosis dissecans is recognized in young German shepherd dogs and other breeds.

SYSTEMS AFFECTED
Nervous—specifically nerves from L7 caudally.

GENETICS
No known genetic basis.

INCIDENCE/PREVALENCE
Unknown

SIGNALMENT
Species
• Reasonably common in dogs.
• Uncommonly reported in cats but suspected with increasing frequency.

Breed Predilections
• Congenital—small to medium dogs; border collies.
• Acquired—any medium–large dog; often suspected in working dogs, so frequently German shepherd dogs and Malinois but also common in boxers, Rottweilers.

Mean Age and Range
• Congenital—3–8 years.
• Acquired—mean age at onset 6–7 years. Sacral osteochondrosis signs often appear ~1 year old.

Predominant Sex
• Congenital—none.
• Acquired—male.

SIGNS
• Lumbosacral pain—salient feature; may be the only clinical sign; may be evident in reluctance to jump or climb stairs. Pain on pressure on, or dorsiflexion of, the lumbosacral vertebral column (often also induced during extension of hip joints).
• Pelvic limb lameness—caused by lumbar 7th and/or sacral nerve dysfunction; may progress to pelvic limb weakness, muscle wasting, and postural reaction deficits.
• Urinary and/or fecal incontinence—caused by S1–3 nerve dysfunction.
• Abnormal tail carriage, tail weakness or paralysis—results from dysfunction of caudal nerves.
• Self-inflicted lesions—most often associated with congenital lesions or cauda equina inflammation.

CAUSES
• Congenital vertebral malformation, including transitional vertebrae, or osteochondrosis of the cranial sacrum.
• Intervertebral disc herniation (types I and II).
• Hypertrophy or hyperplasia of the interarcuate ligament.
• Proliferation of the articular facets and/or periarticular soft tissues.
• Subluxation at the lumbosacral junction.
• Inflammatory or neoplastic disease of the vertebral canal can produce identical clinical signs (hence "cauda equina syndrome").

RISK FACTORS
Dogs with lumbosacral transitional vertebrae, especially German shepherd dogs, have increased risk to develop the syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Hip dysplasia or other orthopedic disease (notably iliopsoas injury)—distinguish via thorough orthopedic examination ± imaging.
• Chronic discospondylitis, osteomyelitis, neoplastic disease—cannot be differentiated by clinical signs alone.
• Vertebral fractures and subluxations—acute; characterized by more bilateral signs.
• Localized meningomyelitis or radiculoneuritis—usually more diffuse pain.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually normal.
• Urinalysis—may reveal lower urinary tract infection secondary to urinary incontinence, or associated with discospondylitis.

OTHER LABORATORY TESTS
If images suggest the need, cerebrospinal fluid (CSF) analysis may aid in diagnosing inflammatory (or infectious or neoplastic) disease.

IMAGING
• Radiology—commonly exhibit spondylosis at the lumbosacral junction; narrowing of the L7–S1 disc space; ventral displacement of the sacrum relative to the lumbar vertebrae; *but* interpret with caution because all these can be observed in clinically normal animals.
• CT and MRI—modalities of choice. Apparent abnormalities must be interpreted with regard to the whole clinical picture because many are also observed in normal animals.

DIAGNOSTIC PROCEDURES
• Electromyography—denervation may be detected in muscles innervated by the nerves L7 to caudal; denervation confirms localization of the lesion but is not specific for compressive lesions.
• Slowed sciatic–tibial nerve conduction or prolongation of F wave latencies may be detected.

PATHOLOGIC FINDINGS
• May see one or more of the following features:
  ◦ Type II disc disease with bulging of dorsal annulus.
  ◦ Hypertrophy of the interarcuate ligament.
  ◦ Stenosis of the intervertebral foramen by soft tissue or bony proliferation compressing L7 nerve(s) or as a congenital lesion.
  ◦ Ventral displacement of the sacrum in relation to lumbar vertebrae.
  ◦ Proliferation of articular facets and hypertrophy of joint capsule.
  ◦ Congenitally shortened pedicles.
  ◦ Thickened and sclerotic laminae and articular processes.
  ◦ Various vertebral malformations (not only transitional vertebrae).
• Cauda equina syndrome can also be associated with neoplasia, inflammation, infection.

TREATMENT

APPROPRIATE HEALTH CARE
Urinary incontinence—inpatient for initial management.

NURSING CARE
Urinary incontinence—manual expression or catheterize the bladder until adequate voluntary control returns; monitor for urinary tract infection and administer appropriate antibiotics following culture and sensitivity.

ACTIVITY
• Nonsurgical treatment—confinement and restricted leash walks, alone or combined with systemic anti-inflammatory drugs or analgesics, or epidural injection of corticosteroids, frequently alleviate pain; clinical signs may return with increasing levels of exercise.
• If treated surgically, restrict for 6–12 weeks; then gradual return to athletic function.

LUMBOSACRAL STENOSIS AND CAUDA EQUINA SYNDROME (CONTINUED)

DIET
Avoid obesity; excess weight increases biomechanical stress on the spine.

CLIENT EDUCATION
- Inform client that there may be progressive neurologic impairment of the pelvic limbs, urinary and fecal incontinence, and paralysis of the tail.
- Inform client that pelvic limb lameness and self-inflicted lesions result from pain associated with nerve root irritation and/or compression.
- Discuss surgical treatment, which is appropriate for cases with severe pain and may be suitable for cases with neurologic deficits (especially incontinence, which may be difficult to reverse).
- Medical management is frequently successful for animals with mild pain and/or mild neurologic deficits only.

SURGICAL CONSIDERATIONS
Several options, each focused on alleviating the specific source of the problems defined by imaging; dorsal laminectomy, lateral foraminotomy, or fixation–fusion may all be effective in specifically selected cases.

MEDICATIONS

DRUG(S) OF CHOICE
- NSAIDs—e.g., carprofen 2 mg/kg q12h for 5–7 days then reducing doses until PRN.
- Gabapentin—frequently used at ~20–30 mg/kg q8h and may be effective (side effect: sedation; dizziness reported in humans).
- Epidural corticosteroid—methylprednisolone actetate 1 mg/kg (<0.5 mL total volume).

CONTRAINDICATIONS
N/A

FOLLOW-UP

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
- Syndrome progression, increasingly severe neurologic signs.
- Seroma formation—frequent sequela to surgery; can be effectively managed by cage rest and surgical drainage. Prevent by careful soft tissue closure.
- Adhesions between nerves and surrounding soft tissues after surgery.
- Recurrence of clinical signs following medical (commonly) or surgical (less commonly) intervention.
- Failure of fixation–fusion implant.
- Fracture of articular process after excessive lateral bone excision at surgery.
- Infection (especially if an implant is used for surgery).

EXPECTED COURSE AND PROGNOSIS
- Vary with the severity of neurologic injury.
- Majority are successfully managed medically, but need to ensure outcome matches requirements for dog's way of life; surgery remains an option.
- If low lumbar pain and mild neurologic deficits—good prognosis after surgery; 70–80% have an excellent or good outcome.
- If fecal and urinary incontinence—guarded prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Lower urinary tract infections frequently accompany urinary incontinence.

AGE-RELATED FACTORS
- If a lumbosacral transitional vertebra is present, syndrome may develop 1–2 years earlier than the average dog.
- Older large-breed dogs may have concomitant diseases that also cause neurologic deficits: type II disc protrusions at other sites, degenerative peripheral nerve disease (especially Labrador retrievers), degenerative myelopathy (especially German shepherd dogs).

SYNONYMS
- Lumbosacral instability.
- Lumbosacral malarticulation or malformation.
- Lumbosacral spondylolisthesis.
- Lumbosacral spondylopathy.

SEE ALSO
- Discospondylitis.
- Intervertebral Disc Disease—Cats.
- Intervertebral Disc Disease, Thoracolumbar.

ABBREVIATIONS
- CSF = cerebrospinal fluid.
- NSAID = nonsteroidal anti-inflammatory drug.

LUNG LOBE TORSION

BASICS

OVERVIEW
• Twisting of lung lobe(s) at the hilus with occlusion or narrowing of the bronchus, lymphatics, vein, and (finally) arteries. • Affected lobes—right middle lobe most commonly affected (especially in large dogs) with preexisting pleural effusion; other lobes can twist singly or in pairs. Occasionally torsion occurs in midlobar area. Pugs are very commonly affected, with the left cranial lobe most common. • Initially, the lobe becomes engorged with blood and enlarges; infarction and necrosis may follow; hemorrhagic pleural effusion typically develops.

SIGNALMENT
• Dogs and less commonly cats. • Pugs are most commonly affected, although any dog may be affected. • Large-breed dogs more commonly have pleural effusion first, and then develop torsion. • Afghan hounds were initially reported as commonly affected due to chylothorax, but this is rarely seen. • Any age. • More common in males.

SIGNS
• Tachypnea, acute or chronic respiratory distress. • Lethargy. • Anorexia. • Fever. • Pain. • Orthopnea. • Cough, hemoptysis. • Retching. • Tachycardia. • Pale mucous membranes. • Cyanosis.

CAUSES & RISK FACTORS
• Inconsistently found with preexisting conditions (e.g., trauma, neoplasia, and chylothorax; asthma/bronchitis in the cat). Atelectasis and or pleural effusion seem to be predisposing factors. • Thoracic or diaphragmatic surgery. • Spontaneous or idiopathic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Pulmonary contusion or atelectasis. • Diaphragmatic hernia. • Pulmonary abscess or infarction. • Neoplasia. • Coagulopathy. • Pneumonia, embolization, or thrombosis. • Congestive heart failure. • Pleural effusion and compression atelectasis. • Fungal or foreign body granuloma. • Lobar consolidation or bronchial obstruction from a foreign body.

CBC/BIOCHEMISTRY/URINALYSIS
Nonspecific abnormalities.

OTHER LABORATORY TESTS
Fluid analysis—pleural effusion can be hemorrhagic; with chronicity or preexisting effusions; the effusion may be a modified transudate or chylous.

IMAGING
Radiography
• Opacification of affected lobe with loss of visible lobar vessels and truncation of bronchus. • Initially may reveal air bronchograms with proximal narrowing or disorientation of the torsed bronchus. Small gas bubbles with "sponge appearance" can be scattered throughout affected lobe (vesicular gas pattern); seen in 87% of one series. • Progressive pleural effusion—suggested by ventral leafing and interlobar fissure lines. • Consolidation and occasional swelling of the torsed lobe with possible displacement or rotation of the heart, trachea, or carina. Mediastinal shift can be contralateral or ipsilateral. Other lobes can be displaced. • Thoracentesis provides therapeutic benefits and can improve visualization of intrathoracic structures.

Ultrasonography
• Thoracic ultrasound prior to fluid removal often allows better resolution of internal structures. • Hypoechoic periphery with scattered reverberating foci (bronchial cartilage) centrally. • Rounded edges of lobes.

CT
Very useful for confirmation of diagnosis.

DIAGNOSTIC PROCEDURES
• Thoracentesis—obtain pleural fluid for analysis (modified transudate, exudate, hemorrhage, or chylous effusion possible). • Bronchoscopy—may reveal occlusion or twist of the associated bronchus. • Surgical exploration—for definitive diagnosis and treatment.

TREATMENT
• Thoracentesis or chest tube placement as needed. • Intravenous fluid administration for support. • Administer oxygen and treat for shock—when indicated. • Anesthesia—requires adequate ventilatory support; carefully monitor patient. • Surgical removal of the involved lobe(s)—only effective treatment; do not untwist lobe and attempt to salvage—may lead to recurrence or necrosis; in situ ligation of the vessels or clamping with noncrushing forceps has been advocated to avoid reperfusion problems such as acidosis; consider use of surgical stapling device; closely inspect remaining thoracic structures for any abnormalities; perform culture and pathologic examination of excised specimen. • Post surgery—monitoring; supportive care; tube drainage. Torsion of a second lung lobe may occur.

MEDICATIONS

DRUG(S) OF CHOICE
• Antibiotics—perioperatively. • Pain control.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
• Observe for recurrence of pleural effusion. • Reexpansion pulmonary edema—can be a serious problem (especially in cats) if large volumes of pleural fluid are withdrawn quickly or if chronically compressed lungs are acutely inflated at surgery. • Thoracic radiographs—before discharge; as needed thereafter. • Prognosis—fair to good if no underlying abnormality remains.

LUPUS ERYTHEMATOSUS, CUTANEOUS (DISCOID)

BASICS

OVERVIEW
• Considered to be a relatively benign variant of systemic lupus erythematosus (SLE). • Divided into facial discoid lupus erythematosus (FDLE) and generalized DLE (GDLE). • FDLE is one of the most common immune-mediated skin diseases in dogs. • FDLE predominantly involves the nasal planum, face, and ears. • GDLE—lesions progress beyond the head.

SIGNALMENT
• Dogs and cats. • Very uncommon in cats. • FDLE—collie, German shepherd dog, Siberian husky, Shetland sheepdog, Alaskan Malamute, chow chow, and their crosses. • GDLE—German shepherd dog and Chinese crested (predominantly). • FDLE—no age predilection; GDLE—older dogs.

SIGNS
FDLE
• Initial depigmentation of nasal planum and/or lips progresses to erosions and ulcerations. • Loss of normal "cobblestone" architecture of the nasal planum. • Tissue loss and scarring can occur. • Chronic lesions are fragile and may easily bleed; severe hemorrhage associated with arteriole damage. • May involve pinnae and periocular region.

GDLE
• Lesion behind the neck and/or on mucocutaneous junctions. • Initial lesion—annular hyperpigmented plaques with adherent crust, follicular plugging and central alopecia. • Advanced lesions—reticulated patterns of hyperpigmentation or hypertrophic scars.

CAUSES & RISK FACTORS
• Actinic radiation may alter antigenic nature of keratinocytes. • Seasonal and geographic exacerbation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Major Considerations
• Other immune-mediated diseases (pemphigus foliaceus, pemphigus erythematosus, SLE, ischemic dermatitis, vasculitis). • Drug reaction. • Dermatomyositis. • Nasal dermatophytosis. • Mucocutaneous pyoderma. • Insect bite hypersensitivity.

Other (Rare) Considerations
• Contact allergy. • Zinc-responsive dermatosis. • Trauma. • Superficial necrolytic dermatitis. • Epitheliotropic lymphoma. • Squamous cell carcinoma.

CBC/BIOCHEMISTRY/URINALYSIS
Normal unless due to an underlying cause.

OTHER LABORATORY TESTS
Antinuclear antibody (ANA), LE preparation, and Coombs' tests—usually normal or negative except in SLE.

DIAGNOSTIC PROCEDURES
• Biopsy and histopathology will differentiate DLE from most other disorders; may be complicated by untreated mucocutaneous pyoderma. • Biopsy early lesions—depigmented areas, mild erosions, or mildly crusted lesions.

PATHOLOGIC FINDINGS
Interface-lichenoid dermatitis with prominent basal cell apoptosis, varying degrees of epidermal atrophy, and pigment incontinence;. chronic lesions may include scarring.

TREATMENT
• FDLE—good prognosis; may be disfiguring. • GDLE—guarded prognosis; depends on response to therapy. • Avoid sunlight/apply sunblock.

MEDICATIONS

DRUG(S) OF CHOICE
• Topical therapy (FDLE):
◦ Glucocorticosteroids—potent fluorinated product initially; less potent product later if possible (q24h for 14 days; then q48–72h).
◦ Tacrolimus ointment (0.1%) q12–24h initially then taper to q24–72h once in remission. ◦ Use a soft muzzle for 10 minutes after applying topical therapy to prevent medication removal by the patient.
• Systemic therapy (GDLE; severe FDLE):
◦ Tetracycline and niacinamide—250 mg each PO q8h for dogs <10 kg; 500 mg PO q8h for larger dogs (alternatives include doxycycline 10 mg/kg PO q24h and minocycline 5 mg/kg PO q12h).
◦ Prednisolone—2–4 mg/kg/day either solely or in combination with azathioprine 2 mg/kg PO q48h; taper prednisone to 0.5–1 mg/kg PO q48h for long-term maintenance.
◦ Cyclosporine—5–10 mg/kg PO q24h as alternative immunosuppressive therapy.
• Systemic antibiotic treatment for 3–4 weeks prior to systemic immunosuppressive therapy to differentiate from mucocutaneous pyoderma. • Vitamin E—10–20 IU/kg PO q12h may help reduce inflammation and protect the skin. • Hydroxychloroquine—5 mg/kg q24h; antimalarial drug that has been used in human cases.

FOLLOW-UP

PATIENT MONITORING
• Recheck 4 weeks after initiating treatment to evaluate for clinical response. • CBC and biochemistry—every 12 months (topical therapy); every 3–6 months (systemic therapy). • Azathioprine—CBC and platelet counts every 2 weeks for the first month, then every 3–6 months.

PREVENTION/AVOIDANCE
Affected animals should avoid UV light exposure.

POSSIBLE COMPLICATIONS
• Scarring. • Secondary pyoderma. • Hemorrhage. • Disfigurement.

EXPECTED COURSE AND PROGNOSIS
• FDLE—progressive but not usually life-threatening if left untreated. • With proper treatment, expect remission in majority of cases. • GDLE—prognosis is more guarded.

MISCELLANEOUS

ABBREVIATIONS
• ANA = antinuclear antibody.
• FDLE = facial discoid lupus erythematosus.
• GDLE = generalized discoid lupus erythematosus.
• LE = lupus erythematosus.
• SLE = systemic lupus erythematosus.

LUPUS ERYTHEMATOSUS, SYSTEMIC (SLE)

BASICS

DEFINITION
A systemic autoimmune disease characterized by the formation of antibodies against a wide array of self-antigens. Pathogenic antibodies, circulating immune complexes, and autoreactive T-cells are the primary mediators of tissue injury.

PATHOPHYSIOLOGY
- Antigen–antibody complexes are formed and deposited in a variety of sites, including blood vessels, glomeruli, synovial membranes, choroid plexus, and skin (type III hypersensitivity).
- Antibodies directed against a broad range of membrane, cytoplasmic, and nuclear antigens are produced, resulting in direct cytotoxic damage (type II hypersensitivity).
- Production of autoreactive T-cells causes cell-mediated damage (type IV hypersensitivity).
- Tissue injury is caused by immune-complex mediated activation of complement, infiltration of inflammatory cells, and direct cytotoxicity of autoantibodies against membrane-bound antigens.
- Clinical manifestations depend on localization of the immune complexes and specificity of the autoantibodies.
- Genetic, environmental, pharmacologic, and infectious factors may be triggers.

SYSTEMS AFFECTED
- Musculoskeletal—deposition of immune complexes in synovial membranes.
- Skin/exocrine—deposition of immune complexes in the skin.
- Renal/urologic—immune-complex glomerulonephritis.
- Hemic/lymphatic/immune—autoantibodies against red blood cells (RBCs), leukocytes, platelets, and bone marrow precursors.
- Other organ systems—associated with deposition of immune complexes or antibodies.

GENETICS
- In dogs, SLE has been positively associated with the presence of dog leukocyte antigen (DLA) A7 and negatively associated with the presence of DLA A1 and B5. Decreased serum IgA has been reported as a predisposing factor for SLE in dogs.
- An immune-mediated disease in the Nova Scotia duck tolling retriever characterized by immune-mediated arthropathy and steroid-responsive meningitis–arteritis has been reported and is termed SLE-related disease in this breed.

INCIDENCE/PREVALENCE
Uncommon in dog, rare in cat.

SIGNALMENT
Species
Dog and cat—male dogs overrepresented.

Breed Predilections
- Medium to large breeds; breed predispositions reported for the Finnish spitz, German Shepherd dog, Shetland sheepdog, collie, beagle, and poodle.
- Purebred cats, particularly Siamese and Persians, may be at increased risk.

Mean Age and Range
Mean age 5 years; range 6 months to 13 years.

SIGNS
Historical Findings
- Onset of clinical signs may be acute or insidious with waxing and waning course, and different clinical manifestations may occur sequentially:
  - Lethargy/weakness.
  - Anorexia.
  - Shifting-leg lameness.
  - Skin lesions.

Physical Examination Findings
- Swollen and/or painful joints are the major presenting sign. Joints are swollen but not deformed (nonerosive).
- Symmetric or focal skin lesions—erythema, scaling, ulceration, depigmentation, vesicles, ulcerated or draining nodules, and/or alopecia.
- Ulceration of mucocutaneous junctions and oral mucosa.
- Persistent or cyclic fever—especially in the acute phase.
- Lymphadenopathy.
- Hepatosplenomegaly.
- Muscle pain or atrophy.

CAUSES
Definitive cause not identified. T suppressor cells may be defective.

RISK FACTORS
Exposure to UV light may exacerbate cutaneous lesions.

DIAGNOSIS
- Major signs—polyarthritis, glomerulonephritis, consistent dermatologic lesions, hemolytic anemia, thrombocytopenia, polymyositis, leukopenia.
- Minor signs—fever of unknown origin, oral ulcers, peripheral lymphadenopathy, pleuritis, pericarditis, myocarditis, neurologic abnormalities.
- Definitive diagnosis—positive antinuclear antibody (ANA) or lupus erythematosus (LE) test (or both), and two major signs or one major *and* two minor signs.
- Probable diagnosis—positive ANA or LE test (or both), and one major sign *or* two minor signs.

DIFFERENTIAL DIAGNOSIS
- Neoplasia.
- Infectious diseases (e.g., tick-borne disease, septic arthritis).
- Immune-mediated polyarthropathy.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC—anemia, leukopenia, leukocytosis, or thrombocytopenia; anemia may be moderate and nonregenerative or severe and regenerative (hemolytic).
- Biochemistry—results vary widely, depending on the organ(s) affected.
- Urinalysis—repeatable elevated protein:creatinine ratio (>1) with benign sediment and negative culture.

OTHER LABORATORY TESTS
- ANA test—detects antibodies directed against nuclear antigens. False positive and false negatives occur.
- LE test on synovial fluid—identifies phagocytized nuclear material within neutrophils and macrophages; time-consuming.
- Direct antiglobulin (Coombs') test—identifies complement or antibody on the surface of RBCs; test should only be run in patients with anemia.

IMAGING
- Radiographs of affected joints reveal soft-tissue swelling consistent with nonerosive arthritis.
- Thoracic and abdominal radiographs may demonstrate hepatomegaly or splenomegaly.

DIAGNOSTIC PROCEDURES
- Arthrocentesis—high cell count with nondegenerate neutrophils and monocytes and low viscosity are characteristic findings.
- Bacterial culture of synovial fluid—negative.
- Blood culture in animals with fever—negative.
- Skin biopsy—in patients with skin lesions; save specimen in 10% buffered formalin (for histologic examination) and Michel's solution (for immunofluorescence).

PATHOLOGIC FINDINGS
- Nonerosive polyarthritis with infiltrations of synovial membrane by neutrophils and lymphocytes; no pannus formation.
- Membranous or membranoproliferative glomerulonephritis.
- Mononuclear interface dermatitis with hydropic degeneration of keratinocytes and eosinophilic round bodies representing apoptotic basal keratinocytes.
- Vasculitis and panniculitis in some patients.
- Deposition of immune complexes along the basement membrane of the dermal–epidermal junction (detected by immunofluorescence).
- Vasculitis may be seen in any organ.

LUPUS ERYTHEMATOSUS, SYSTEMIC (SLE) (CONTINUED)

• Reactive lymphoid hyperplasia in the lymph nodes and spleen.

TREATMENT

APPROPRIATE HEALTH CARE
• Hospitalization—may be necessary for initial management.
• Outpatient management—often possible.

NURSING CARE
Supportive care varies with systems affected.

ACTIVITY
• Enforced rest—during episodes of acute polyarthritis.
• Avoid sunlight if photosensitization suspected.

DIET
Restricted protein, high-quality protein diet with *n*-3 fatty acid supplementation in animals with glomerulonephritis.

CLIENT EDUCATION
• Progressive, unpredictable disease course .
• Need for long-term, immunosuppressive therapy and its side effects.
• Heritability of the disease.

MEDICATIONS

DRUG(S) OF CHOICE
• Corticosteroids—to control the abnormal immune response and reduce inflammation (e.g., prednisone 1–2.2 mg/kg/day PO). Consider alternative steroids (equivalent doses) in cats; e.g., prednisolone, dexamethasone, triamcinolone, methylprednisolone.
• Cytotoxic immunosuppressive drugs—add when prednisone fails to improve the condition after 7–10 days or if the patient is steroid intolerant.
• Azathioprine (dogs only) 2 mg/kg PO q24h until remission, then q48h.
• Chlorambucil (cats and dogs) 0.1–0.2 mg/kg PO q24h initially, then q48h.
• Cyclosporine – microemulsion (e.g., Atopica); dogs: 5–10 mg/kg/day PO, divided twice daily; cats: 0.5–3 mg/kg PO q12h.
• Mycophenolate mofetil (dogs) 10 mg/kg PO q12h until remission, then taper.
• Gradually taper doses (no more often than every 3–4 weeks) once remission is achieved.

PRECAUTIONS
• Azathioprine should be avoided in cats.
• Azathioprine and chlorambucil may cause bone marrow suppression.
• Cyclosporine may cause gastrointestinal upset, papillomatosis, and gingival hyperplasia.
• Mycophenolate mofetil may cause GI upset, lymphopenia.
• Treatment with immunosuppressive drugs can increase the risk of severe infection.

POSSIBLE INTERACTIONS
• Concurrent use of aspirin (or other nonsteroidal anti-inflammotory drugs) and prednisone is contraindicated.
• Cyclosporine may have multiple drug interactions due to inhibition of cytochrome P450 enzymes.

ALTERNATIVE DRUG(S)
• Levamisole: dogs, 2–5 mg/kg PO, EOD for 4 months (maximum 150 mg per patient) combined with prednisone 0.5–1.0 mg/kg PO q12h. The prednisone is tapered over 1–2 months and the levamisole continued for 4 months.
• Other immunosuppressive drugs can be considered depending upon the clinical manifestations exhibited (leflunomide for immune-mediated hemolytic anemia, polyarthritis, and myasthenia gravis, topical tacrolimus for skin lesions).

FOLLOW-UP

PATIENT MONITORING
• Physical examination – weekly.
• CBC and biochemical analysis—to monitor for side effects of therapeutics; day 7 then every 2–4 weeks.
• ANA—often remains elevated during remission but may fall as patient improves.

PREVENTION/AVOIDANCE
Do not breed affected animals.

POSSIBLE COMPLICATIONS
• Renal failure and nephrotic syndrome secondary to glomerulonephritis.
• Bronchopneumonia, urinary tract infection, or sepsis secondary to immunosuppression.

EXPECTED COURSE AND PROGNOSIS
Prognosis is guarded. The presence of hemolytic anemia and glomerulonephritis and the development of bacterial infection warrant a poor prognosis. In up to 40% of cases, death occurs during the first year of treatment as a result of renal failure, poor response to therapy, drug complications, or secondary systemic infections.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
The use of cytotoxic immunosuppressive drugs in pregnant animals is contraindicated.

SEE ALSO
• Anemia, Immune-Mediated.
• Glomerulonephritis.
• Polyarthritis, Nonerosive, Immune-Mediated, Dogs.
• Thrombocytopenia, Primary Immune-Mediated.

ABBREVIATIONS
• ANA = antinuclear antibody.
• DLA = dog leukocyte antigen.
• LE = lupus erythematosus.
• RBC = red blood cell.
• SLE = systemic lupus erythematosus.

LYME BORRELIOSIS

BASICS

DEFINITION
• One of the most common tick-transmitted zoonotic diseases in the world.
• Caused by spirochetes of the *Borrelia burgdorferi* (*Bb*) sensu lato complex.
• Most seropositive dogs are nonclinical; 5% may show Lyme arthritis (LA), 1–2% may show Lyme nephritis (LN).
• Reported in humans, dogs, horses, and, sporadically, in cats.

PATHOPHYSIOLOGY
• Experimentally, 2–5 months incubation period.
• LA—self-limiting episodic arthritis/anorexia/fever due to interstitial migration of organisms and host immune responses.
• LN—associated with glomerular deposition of *Bb*-specific antigen–antibody complexes.
• In dogs, cardiac involvement rare.

SYSTEMS AFFECTED
• Organisms persist associated with collagen and fibroblasts in skin, joints, tendons, pericardium, peritoneum, meninges, muscle, heart, and lymph nodes; rarely found in body fluids.
• Pathologic changes—with few exceptions restricted to joints, draining lymph nodes; rarely, immune-complex glomerulonephritis (ICGN).

GENETICS
Genetic predisposition for infection (not illness) in beagles and Bernese mountain dogs. Labrador and golden retrievers are predisposed to LN, but it remains rare (proteinuria is not associated with seropositivity).

INCIDENCE/PREVALENCE
• Seroprevalence in dogs varies with exposure to infected ticks in endemic areas (5–30%). In some areas before tick control was common, seroprevalence was 70–90% in healthy dogs.
• Clinical Lyme borreliosis (LB) develops in small fraction of infected individuals; coinfections with other organisms (e.g., *Anaplasma phagocytophilum*) may impact outcome.

GEOGRAPHIC DISTRIBUTION
• Northern hemisphere:
  ◦ North America—most cases reported in the Mid-Atlantic states, New England, Upper Midwest, adjacent Canada. Ecologic conditions supporting LB exist in adjacent states and on West Coast.
  ◦ Europe—central; less frequent in areas bordering Mediterranean basin.

SIGNALMENT
Species
Dog and rarely cat.

Mean Age and Range
Experimentally, puppies are more susceptible than adult dogs.

SIGNS
• LA—acute or recurrent lameness in one or more legs; possible fever, anorexia, depression, local lymphadenopathy. Affected joints may be swollen, warm, painful. Self-limiting or responds well to antibiotic treatment.
• Experimentally—puppies developed acute self-limiting (3–4 days) form of LA in the leg closest to tick bite; may reoccur weeks later in the same or other leg. Older puppies had fewer signs; adult untreated dogs showed no clinical signs but had histologic changes of chronic nonerosive polyarthritis; 10–15% were persistent carriers despite antimicrobial therapy
• LN—protein-losing nephropathy (PLN) due to ICGN; may present for renal failure, thromboembolism, hypertension, or nephrotic syndrome.

CAUSES
• *Bb*—transmitted by three-host *Ixodes* ticks.
• Infection—usually after nymph or adult female tick attachment for 2–4 days.

Ixodes Ticks
• 2- to 3-year life cycle depending on availability of hosts.
• Summer—uninfected eggs laid, hatch in several weeks; become infected by feeding on infected host (small mammal or bird).
• Following spring—larvae molt into nymphs; stay or become infected by feeding on infected host.
• Fall—nymphs molt into adults which stay infected; females mate, feed on larger mammals (e.g., deer); drop off and hide under leaves until laying eggs following summer; males rarely attach or feed.

RISK FACTORS
Canine LB is a peridomestic disease due to expansion of housing into tick habitat; outdoor activities in endemic areas put dogs at risk.

DIAGNOSIS
Diagnosis based on clinicopathologic signs, response to antibiotic therapy, exclusion of other diagnoses, serologic evidence of natural exposure antibodies, and history of exposure to ticks in endemic or emerging area.

DIFFERENTIAL DIAGNOSIS
• LA—infectious (anaplasmosis, ehrlichiosis, Rocky Mountain spotted fever), inflammatory (immune-mediated polyarthropathy, lupus, rheumatoid arthritis), and genetic (Akita, shar-pei) arthritides; degenerative joint disease; neuromuscular, traumatic, or other causes of lameness or weakness.
• LN—leptospirosis, ICGN caused by babesiosis, dirofilariasis, leishmaniasis, lupus, neoplasia; amyloidosis, glomerulosclerosis, genetic, toxic, and other causes of glomerular disease.

CBC/BIOCHEMISTRY/URINALYSIS
• LA—unremarkable.
• LN—proteinuria, hypoalbuminemia, hypercholesterolemia; later azotemia, hyperphosphatemia, thrombocytopenia, isosthenuria, glucosuria.

OTHER LABORATORY TESTS
• Joint tap cytology—hypercellular (up to 75,000 neutrophils/μL).
• Antibodies—VlsE, C_6, and OspF antibodies; OspA and OspC antibodies may be induced by vaccines or natural exposure.
• ELISA to detect a subgroup of antibodies against outer surface protein VlsE of *Bb* using C_6 peptide; C_6 antibodies wane 3–6 months after antibiotic therapy. Low to moderate pretherapy C_6 levels do not drop significantly.

IMAGING
• Thoracic radiographs, abdominal ultrasound—rule out other causes of proteinuria. Usually no ultrasonographic renal changes in LN dogs.
• Orthopedic radiographs—joint effusion, distinguish erosive from nonerosive joint disease; rule out trauma.

DIAGNOSTIC PROCEDURES
• Experimentally, organisms may be demonstrated in skin (tick bite site) or synovium with PCR or culture; these tests are time-consuming, unreliable, and not recommended.
• Blood samples typically test negative via PCR or culture.

PATHOLOGIC FINDINGS
Gross
• Swollen joints with joint effusion.
• Possible local lymphadenopathy.
• PLN: may include peripheral edema, effusions, thromboembolism, hypertensive organ damage (retinal hemorrhage/detachment, left ventricular hypertrophy, cerebrovascular disease).

Histopathology
• LA—acute arthritis, fibrinopurulent synovitis. Mild lymphoplasmacytic synovitis in other joints.
• Lymph nodes—possible cortical hyperplasia, multiple enlarged follicles, expanded parafollicular areas.
• Superficial dermis near tick bite site—perivascular lymphoplasmacytic infiltrate with some mast cells.

LYME BORRELIOSIS (CONTINUED)

• LN—ICGN, diffuse tubular necrosis with regeneration, interstitial inflammation.

TREATMENT

APPROPRIATE HEALTH CARE
LA—outpatient; LN—may require hospitalization, IV fluids, colloids, and PLN therapy, antiemetics, etc.

NURSING CARE
Consider leptospirosis differential (isolation) for LN suspects.

DIET
LA—no change needed; LN—renal diets, omega-3 fatty acid supplement.

CLIENT EDUCATION
• Antibiotics should be administered as prescribed.
• Discuss the risk to humans in same environs.

SURGICAL CONSIDERATIONS
• Aspiration of synovial fluid—may be considered for diagnostic purposes.
• Renal biopsy may be indicated to differentiate ICGN from other causes of renal proteinuria.

MEDICATIONS

DRUG(S) OF CHOICE
• Antibiotics: may not clear infection completely; treatment significantly improves LA clinical signs and pathology:
  ◦ Doxycycline 5–10 mg/kg PO q12h, with food; preferred.
  ◦ Amoxicillin 20 mg/kg PO q8–12h.
  ◦ Azithromycin 25 mg/kg PO q24h.
• Recommended treatment period—4 weeks for LA; LN may be treated until Quant C_6 level wanes.
• Additional therapy for PLN/ICGN may include renin–angiotensin–aldosterone system inhibitors, antithrombotics, antihypertensives, etc. (see consensus statement in Suggested Reading).
• Immunosuppressive drugs (e.g., mycophenolate, corticosteroids) indicated if biopsy-confirmed ICGN or rapid deterioration despite standard treatments.

CONTRAINDICATIONS
Consider potential drug side effects. Renal biopsy contraindicated in dogs with severe thrombocytopenia, unregulated hypertension, or end-stage renal failure.

PRECAUTIONS
Doxycycline can be used during growth without fear of dental harm; may cause esophagitis or gastritis.

ALTERNATIVE DRUG(S)
Nonsteroidal medications—not recommended initially; use caution with renal dysfunction or prior corticosteroid therapy.

FOLLOW-UP

PATIENT MONITORING
• Improvement—in acute LA seen within 1–3 days of antibiotic treatment.
• If no improvement or if signs exacerbate—consider other diagnoses.
• All seropositive dogs should be screened, monitored, and treated if proteinuria present.

PREVENTION/AVOIDANCE
• Mechanical removal of ticks.
• Prevention of tick attachment or fast kill—acaricides and repellents supplied as topicals, collars, or oral medications.
• Vaccines—5 currently available (nonadjuvanted recombinant OspA, 3 adjuvanted bacterins, and an adjuvanted recombinant chimeric OspA with 7 strains of OspC). All induce antibodies against spirochete's OspA to kill the spirochete within the tick while it feeds. Bacterins (produced from inactivated cultured *Bb* organisms) and the recombinant chimeric OspA/OspC also induce OspC antibodies to kill spirochetes within the host.
  ◦ Efficacy is improved by booster immunizations at 6 months after an initial series; at least annual booster is needed thereafter.
  ◦ Tick control still recommended because of inconsistent vaccinal efficacy and duration of immunity.
• Year-round tick population control in environment—restricted to small areas; clear leaf piles, difficult to reduce host mammal population.

POSSIBLE COMPLICATIONS
Renal failure.

EXPECTED COURSE AND PROGNOSIS
• Recovery from acute lameness expected 1–3 days after starting antibiotics.
• Recurrence of LA signs may be due to coinfection or reinfection, not necessarily relapse.
• Prognosis for LN is largely unknown but appears to vary as for other PLN/ICGN cases.

MISCELLANEOUS

ZOONOTIC POTENTIAL
• Infection in humans acquired only from infected ticks.
• Dogs can transport unattached ticks which can later attach to humans—however, ixodid ticks are not intermittent feeders; once feeding starts, they do not change hosts.

PREGNANCY/FERTILITY/BREEDING
• No convincing evidence that *Bb* infection is transmitted *in utero* in dogs.
• Avoid tetracyclines in pregnant animals.
• Maternal C_6 antibodies can be passed to puppies.

SYNONYMS
Lyme arthritis, Lyme nephritis, or Lyme disease.

ABBREVIATIONS
• *Bb* = *Borrelia burgdorferi*.
• ICGN = immune-complex glomerulonephritis.
• LA = Lyme arthritis.
• LB = Lyme borreliosis.
• LN = Lyme nephritis.
• PLN = protein-losing nephropathy.

LYMPHANGIECTASIA

BASICS

DEFINITION
An obstructive disorder of the lymphatic system of the gastrointestinal (GI) tract, resulting in lymphatic hypertension and protein-losing enteropathy (PLE).

PATHOPHYSIOLOGY
- Lymphatic obstruction results in dilation and rupture of intestinal lacteals with subsequent loss of lymphatic contents (plasma proteins, lymphocytes, and chylomicrons) into the intestinal lumen.
- Although some of the proteins may be digested and reabsorbed, excessive enteric loss of plasma proteins will ultimately result in panhypoproteinemia.
- Hypoproteinemia causes a decrease in plasma oncotic pressure, which, if severe, will lead to ascites, pleural effusion, and/or (rarely) edema.
- Loss of antithrombin and other anticoagulants can cause a hypercoaguable state.

SYSTEMS AFFECTED
- GI—diarrhea.
- Respiratory—pleural effusion.
- Skin—subcutaneous edema.
- Systemic—ascites.
- Vascular—thromboembolic disease.

GENETICS
A familial tendency for PLE has been reported for soft-coated wheaten terriers, basenjis, Yorkshire terriers, and Norwegian lundehunds, but the actual genetic cause has not been identified for any of these breeds.

INCIDENCE/PREVALENCE
Uncommon

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Dog

Breed Predilections
Soft-coated wheaten terrier, basenji, Norwegian lundehund, Yorkshire terrier.

Mean Age and Range
Any age; most common in middle-aged dogs.

Predominant Sex
Increased prevalence reported in female soft-coated wheaten terriers; no sex predilection reported for other breeds.

SIGNS
- Clinical signs are variable.
- Diarrhea—chronic; typically small bowel diarrhea; however, not all animals have diarrhea.
- Ascites.
- Subcutaneous edema.
- Dyspnea from pleural effusion.
- Weight loss and sarcopenia.
- Flatulence.
- Vomiting.

CAUSES
Primary or Congenital Lymphangiectasia
- Focal—intestinal only.
- Diffuse lymphatic abnormalities (e.g., chylothorax, lymphedema, chyloabdomen, thoracic duct obstruction).

Secondary Lymphangiectasia
- Right-sided congestive heart failure.
- Constrictive pericarditis.
- Budd–Chiari syndrome.
- Neoplasia (e.g., lymphoma, thymoma, mediastinal masses).
- Fungal disease.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other causes of PLE.
- PLE must be differentiated from other causes of hypoalbuminemia.

CBC/BIOCHEMISTRY/URINALYSIS
- Panhypoproteinemia.
- Hypocholesterolemia.
- Hypocalcemia.
- Hypomagnesemia.
- Lymphopenia.

OTHER LABORATORY TESTS
Differentiate PLE from Other Causes of Hypoalbuminemia
- Serum chemistry and pre- and postprandial serum bile acids to rule out hepatic failure.
- Urine protein:creatinine ratio to rule out protein-losing nephropathy.
- Occult fecal blood test to rule out GI blood loss (*o*-toluidine-based tests are preferable as these tests are less likely to be falsely positive due to meat in the diet than guaiac-based tests).
- Fecal α_1-protease inhibitor to help confirm intestinal protein loss (most useful in dogs that do not yet have any GI signs).

Differentiate Other Causes of Excessive Protein Loss into the GI Tract
- Fecal smear and flotation to rule out intestinal parasites.
- Serum cobalamin and folate concentrations to rule out small intestinal dysbiosis or cobalamin deficiency. Cobalamin deficiency is an indicator of chronic severe distal small intestinal disease, which could be associated with excessive protein loss.
- Fecal culture for diagnosis of specific enteric pathogens (e.g., *Salmonella* spp.); PCR for enteropathogenic *Campylobacter* spp. and other enteropathogens.
- Fluid analysis of cavitary effusions—lymphangiectasia usually results in a transudate, but chyloabdomen and chylothorax may be observed.
- Chronic chylous effusions might be difficult to differentiate from modified transudates. In chylous effusions the triglyceride concentration is higher than in serum.

IMAGING
- Thoracic radiographs—survey to rule out cardiac disease and neoplasia.
- Abdominal radiographs—to rule out mechanical intestinal disease (obstruction or partial obstruction) and other causes of PLE. However, routine abdominal radiographs are less useful for assessment of these patients than abdominal ultrasound.
- Abdominal ultrasound—to rule out mechanical intestinal disease and other causes of PLE. Ultrasound often shows hyperechoic mucosal striations ("tiger stripe" effect), mucosal speckles, and/or a hyperechoic line within the mucosa running parallel to the submucosa. Corn oil 1–2 mL/kg given orally 60–90 minutes before the study may improve the diagnostic yield.
- Echocardiography—to rule out right-sided congestive heart failure.

DIAGNOSTIC PROCEDURES
- Endoscopy—allows intestinal mucosal visualization and biopsy. Ileal biopsies should be procured in hypocobalaminemic animals.
- Laparotomy—allows visualization of dilated intestinal lymphatics and biopsies of intestines (full thickness) and lymph nodes, but may be contraindicated in patients with hypoproteinemia due to increased complications (e.g., dehiscence).
- ECG and/or echocardiography—can aid in evaluating animals suspected of having right-sided congestive heart failure or arrhythmias.

PATHOLOGIC FINDINGS
- Dilated lymphatics may appear as a web-like network throughout the mesentery and serosal surface.
- Lipogranulomas may appear as yellow-white nodules and foamy granular deposits adjacent to lymphatics.
- Lacteal dilatation, villous blunting, and crypt lesions (i.e., dilatation, cysts, abscesses) are the most consistent findings on histopathology with lymphangiectasia and PLE.
- Often associated with mucosal edema or diffuse or multifocal accumulations of lymphocytes and plasma cells in the lamina propria.

LYMPHANGIECTASIA (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE
May need hospitalization if complications due to hypoalbuminemia develop.

NURSING CARE
Consider placement of an esophageal feeding tube in anorectic patients to meet increased caloric demands.

ACTIVITY
Normal

DIET
- Low-fat or ultra-low fat diets are the cornerstone of treatment.
- Commercial low fat diets contain 20 g fat/1000 kcal or less. A lower fat content with a novel protein source (if desired) can be achieved by a home-cooked diet. Protein sources may include chicken breast, tilapia, tuna, and/or fat-free cottage cheese. Possible carbohydrate sources are potato, rice, pasta, and/or egg noodles.
- Initially a simple home-cooked diet can be used, but long-term the diet must be balanced.
- Avoid high-fiber diets.
- Dogs with concurrent lymphangiectasia and inflammatory bowel disease may benefit from a commercial hydrolyzed protein diet that is moderately fat restricted.
- Long-chain triglycerides stimulate intestinal lymph flow and may lead to increased intestinal protein loss.
- Diets fortified with medium-chain triglycerides (MCTs) may be beneficial.
- May feed MCTs (e.g., MCT oil, Enfamil Portagen) to supplement fat and calorie intake.
- Supplement with fat-soluble vitamins—A, D, E, and K.
- Elemental diets can also be used.

CLIENT EDUCATION
Discuss unpredictable disease progression and response to therapy.

SURGICAL CONSIDERATIONS
- Patients that benefit from surgical intervention are rare.
- Consider surgery to relieve an identifiable lymphatic obstruction, if present.
- Pericardiectomy may be indicated with constrictive pericarditis.

MEDICATIONS

DRUG(S) OF CHOICE
- Clopidogrel 1–3 mg/kg PO q24h or ultra-low dose aspirin 0.5 mg/kg PO q24h to reduce the risk of thromboembolic events.
- Try corticosteroids if dietary therapy alone is unsuccessful (however, such therapy is not intended to treat lymphangiectasia but rather concurrent GI inflammation). Prednisone or prednisolone 1–2 mg/kg PO q12h for 5–7 days, followed by 1 mg/kg q12h for at least 6 weeks. In large-breed dogs the starting dose should be more conservative than in small-breed dogs. After remission, dosage can be slowly tapered to the lowest dose effective at controlling the disease. Alternatively, consider the use of a locally effective corticosteroid (e.g., budesonide), or other immunomodulators such as chlorambucil, azathioprine, or cyclosporine.
- In hypocobalaminemic patients, cobalamin must be supplemented parenterally or orally to achieve therapeutic response (see Cobalamin Deficiency for dosing).
- If secondary small intestinal dysbiosis is suspected, the patient should be treated with tylosin at 20 mg/kg q12h for 6 weeks.
- Magnesium sulfate should be supplemented parenterally (IV) at 1 mEq/kg/day in dogs that are hypomagnesemic before oral supplementation with magnesium oxide, magnesium citrate, or magnesium carbonate.
- Diuretics such as furosemide 1 mg/kg q12h or spironolactone 1 mg/kg q12h in animals with severe ascites to improve comfort.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Steroids might increase the risk for thromboembolic events.

POSSIBLE INTERACTIONS
Clopidogrel should not be used with nonsteroidal anti-inflammatory drugs, phenytoin, torsemide, or warfarin.

ALTERNATIVE DRUG(S)
Some patients may respond to treatment with octreotide; dosing for this condition is empirical.

FOLLOW-UP

PATIENT MONITORING
- Body weight, serum total protein, albumin, and globulin concentrations, and clinical signs (pleural effusion, ascites, and/or edema).
- Patients need to be reevaluated depending on the severity of the disease process.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
- Thromboembolic disease.
- Hypocalcemia.
- Dyspnea from pleural effusion or pulmonary thromboembolism.
- Severe protein-calorie depletion.
- Intractable diarrhea.

EXPECTED COURSE AND PROGNOSIS
- Prognosis is guarded. More than 50% of patients die from the disease or from associated thromboembolic disease.
- Remissions of several months to more than 2 years can be achieved in some patients.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Soft-coated wheaten terriers may have concurrent protein-losing nephropathy.

SEE ALSO
- Cobalamin Deficiency.
- Diarrhea, Chronic—Dogs.
- Protein-Losing Enteropathy.

ABBREVIATIONS
- ECG = electrocardiogram.
- GI = gastrointestinal.
- MCT = medium-chain triglycerides.
- PLE = protein-losing enteropathy.

LYMPHADENOPATHY/LYMPHADENITIS

BASICS

DEFINITION
- Lymphadenopathy—lymph node enlargement.
- Generalized lymphadenopathy—enlargement of multiple lymph nodes.
- Lymphoid hyperplasia/reactivity—benign, non-neoplastic, reactive response to immune stimulation; results in proliferation of plasma cells and lymphocytes of all sizes, which results in lymphadenopathy.
- Lymphadenitis—inflammation of the lymph node; can represent primary infection of the lymph node or drainage of regional inflammation.

PATHOPHYSIOLOGY
- Lymphoid hyperplasia/reactivity—can occur secondary to a localized process like dental disease or localized skin allergies (i.e., pododermatitis). Lymphoid hyperplasia can also be seen secondary to systemic inflammation. Lymph node enlargement can be singular or generalized.
- Lymphadenitis—inflammation within a lymph node can represent a primary process (inflammation or necrosis of the lymph node itself) or a secondary process (drainage of an area of inflammation or necrosis).
- Infectious lymphadenitis—the drainage function of lymph nodes increases their exposure to infectious agents within the node.
- Noninfectious lymphadenitis—often occurs secondary to drainage of areas of inflammation.
- Neoplasia—primary lymph node neoplasia (lymphoma) or metastatic disease. Lymph node enlargement can be singular or generalized.

SYSTEMS AFFECTED
- Hemic/lymphatic/immune.
- May be a component of more widespread systemic disease.

GENETICS
No known genetic basis for lymphoid hyperplasia/reactivity or lymphadenitis.

INCIDENCE/PREVALENCE
- Seen with a variety of systemic diseases.
- Overall incidence is unknown.

GEOGRAPHIC DISTRIBUTION
Geographic distribution should be considered in cases of lymphadenitis caused by fungal infection.

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
None for lymphoid hyperplasia or lymphadenitis. Increased incidence of lymphoma can be seen in golden retrievers, basset hounds, St. Bernard, boxer, Scottish terrier, Airedale terrier, Rottweiler, Labrador retriever, bull mastiff, and bouvier des Flandres.

Mean Age and Range
None

Predominant Sex
None

SIGNS

General Comments
- Marked submandibular lymph node enlargement can result in difficulty swallowing.
- Clinical signs are often related to systemic disease.

Historical Findings
- Owners may report finding mass lesions, particularly when lymph node enlargement is marked.
- Systemic signs of inflammatory disease or organ dysfunction may be reported.

Physical Examination Findings
- Hyperplastic lymph nodes vary in size. In early stages, lymph nodes may be firm yet still mobile.
- Inflamed lymph nodes are typically large and firm and may be painful.
- Bacterial infection can result in abscess formation within the node, which may rupture and result in draining tracts. Patients may also have fever and other systemic signs of inflammation.
- Lymph nodes affected by lymphoma are often at least twice normal size and very firm.
- Lymph nodes with metastatic neoplasia can have a variable presentation.

CAUSES

Lymphoid Hyperplasia/Reactivity
- Hyperplastic lymph nodes represent a proliferation of lymphocytes in response to any source of antigenic stimulation.
- Stimulation can be localized where a lymph node drains an area of inflammation.
- Systemic disease can also result in hyperplastic/reactive lymph nodes.
- Chronic hyperplasia can occasionally lead to lymphadenitis.
- A benign condition has been reported in young cats, featuring generalized lymphadenopathy characterized by increased numbers of intermediate to large lymphocytes, which can mimic lymphoma. Care must be taken not to misdiagnose these patients with lymphoma.
- Generalized lymphadenopathy can occur in cats infected with *Bartonella* spp. or feline immunodeficiency virus (FIV).

Neutrophilic Lymphadenitis
- Commonly seen in lymph nodes draining a site of infection.
- Bacterial infection will also result in neutrophilic lymphadenitis, including *Streptococcus* spp., *Brucella* spp., *Francisella tularensis* (tularemia), and *Yersinia pestis* (bubonic plague). The latter two organisms are more likely to cause lymphadenitis in feline patients.

Eosinophilic Lymphadenitis
- Common with dermatitis and parasitic skin diseases.
- Can also be observed with drainage of mast cell tumors, some lymphomas, and with hypereosinophilic syndrome.

Granulomatous/Pyogranulomatous Lymphadenitis
- Indicative of chronic inflammation; can occur concurrently with neutrophilic lymphadenitis.
- Multinucleated giant cells with neutrophils indicate pyogranulomatous inflammation.
- Fungal, protozoal, and bacterial infections.

Neoplasia
- Lymphoma often results in generalized lymphadenopathy with marked lymph node enlargement.
- Metastatic neoplasia may cause a singular or generalized lymphadenopathy of variable size.

RISK FACTORS
- Patients with compromised immune function due to chronic illness or immunosuppressive therapy can be more susceptible to infection and lymphadenitis.
- Feline leukemia virus (FeLV) and FIV infection may also be associated with lymphoid neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- It is essential to determine that a mass effect in the region of a lymph node is not a neoplastic mass or other regional structure (e.g., salivary gland).
- Differentiation between lymphoid hyperplasia, lymphadenitis, lymphoma, or metastatic neoplasia cannot be achieved by evaluating clinical signs alone.
- Fever and painful, enlarged lymph nodes are suggestive of lymphadenitis.
- Lymphoma and lymphoid hyperplasia are more common causes of generalized lymphadenopathy than lymphadenitis.

CBC/BIOCHEMISTRY/URINALYSIS
- Localized lymphoid hyperplasia secondary to local inflammation may not be associated with specific CBC/chemistry abnormalities.
- Patients with infectious causes of lymphadenitis may have marked hyperglobulinemia.

LYMPHADENOPATHY/LYMPHADENITIS (CONTINUED)

• Marked eosinophilia can be seen with hypereosinophilic syndrome or as a paraneoplastic phenomenon.
• Biochemistry results may reflect organ involvement from underlying disease process.
• Hypercalcemia can be seen in dogs with lymphoma, but this finding is uncommon in cats.

OTHER LABORATORY TESTS
Serologic or urine antigen tests for various systemic fungal diseases are available.

IMAGING
• Radiographs—evaluate for enlargement of internal organs or patterns associated with infectious or neoplastic disease.
• Ultrasound—evaluate intra-abdominal lymph nodes and organ architecture.

DIAGNOSTIC PROCEDURES
• Fine-needle aspiration cytology stained with a Romanowsky stain (e.g., Diff-Quik) in most cases is sufficient for diagnosis of the primary cause of lymph node enlargement.
• Culture of aspirated material or a fresh tissue sample obtained via tissue biopsy can be considered if an infectious etiology is suspected.
• Fine-needle aspiration/cytology results:
  ○ Lymphoid hyperplasia—increased numbers of intermediate and large lymphocytes (<50% of the total population); increased numbers of plasma cells.
  ○ Lymphadenitis—increased numbers of neutrophils, eosinophils, macrophages, or a combination of these types.
  ○ Infectious agents—bacterial, fungal, and protozoal organisms can be found free in the background or within the cytoplasm of macrophages and, rarely, neutrophils.
  ○ Lymphoma—over 50% of the lymphocyte population is made up of immature lymphocytes. Immature cells can be intermediate to large in size. Some forms of lymphoma (e.g., indolent lymphoma) cannot be diagnosed with cytology alone and may require advanced diagnostics including flow cytometry or PCR for antigen receptor rearrangement (PARR).
  ○ Metastatic neoplasia—findings include the presence of cells not normally observed in a lymph node and can range from rare nests of neoplastic cells to complete effacement of the lymph node.
• When a definitive diagnosis cannot be made with cytology alone, a lymph node biopsy may be required, particularly if cytology results are consistently inconclusive or if enlargement of a lymph node is persistent, progressive, or unexplained.

TREATMENT

APPROPRIATE HEALTH CARE
Treatments are aimed at the underlying etiology.

MEDICATIONS

DRUG(S) OF CHOICE
• Effective drug therapy involves identification and treatment of the underlying cause.
• Solitary enlarged lymph nodes with neutrophilic lymphadenitis are likely to have a bacterial component either within the node or the primary drainage area.
• Chemotherapeutic agents can be used to treat lymphoma.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Variable

MISCELLANEOUS

AGE-RELATED FACTORS
None

ZOONOTIC POTENTIAL
• Bubonic plague, tularemia, and mycobacterial infections may present risk of human infection.
• Specimens from affected animals should be handled with appropriate caution.

ABBREVIATIONS
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• PARR = PCR for antigen receptor rearrangement.

LYMPHEDEMA

BASICS

OVERVIEW
• Pathologic accumulation of protein-rich lymph into interstitial spaces, especially subcutaneous fat due to primary/secondary failure of lymphatic drainage. • If chronic, causes tissue fibrosis. • May be congenital or acquired.

SIGNALMENT
• Dog (more common) and cat. • Congenital in bulldogs. • Hereditary/congenital in a family of poodles and whippets. • Possible breed predilection in Labrador retrievers and Old English sheepdogs.

SIGNS
Historical Findings
• Primary/congenital—peripheral limb swelling/pitting edema at birth or develops within the first several months. • Progressive, nonpainful swelling starting at distal extremity and slowly advances proximally.

Physical Examination Findings
• Most common in limbs, especially pelvic limbs; unilateral or bilateral. • Less common in ventral thorax, abdomen, ears, and tail. • Nonpainful pitting; affected area is normothermic. • Pitting quality lost with chronicity as fibrosis occurs. • Lameness and pain uncommon unless cellulitis develops.

CAUSES & RISK FACTORS
• Hereditary/congenital malformation of lymphatics—aplasia of thoracic duct, cisterna chyli or peripheral lymphatics, valvular incompetence, and lymph node fibrosis. • Excessive interstitial fluid production due to venous hypertension (e.g., congestive heart failure, venous obstruction) or increased vascular permeability (e.g., infection, trauma, heat, irradiation). • Secondary damage to lymphatic vessels or lymph nodes—associated with trauma, infection (e.g., *Brugia pahangi* lymphatic filarial infection—Southeast Asia), neoplasia (e.g., lymphoma, lymphangiosarcoma [rare]), radiation therapy and thoracic duct ligation (rare).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Edema due to venous stasis (e.g., congestive heart failure, cirrhosis); look for varices, hyperpigmentation, and ulceration. • Arteriovenous fistulae—listen for machinery murmur; feel for pulsatile vessels; confirm with angiogram. • Edema due to hypoproteinemia—protein-losing nephropathy or enteropathy, hepatic failure, serum loss from burns or hemorrhage; check serum protein concentration. • Trauma—review history; look for bruising and lacerations. • Neoplasia—if swelling is firm, obtain aspirate for cytology. • Cellulitis—fever, pain, and warm swelling. • Insect bites.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
Serologic tests for tick-borne infections, including *Bartonella* spp.

IMAGING
• Radiography and ultrasound to rule out obvious masses. • Lymphangiography ± computed tomography allows evaluation of lymphatic abnormalities; best results obtained with direct injection of water-based contrast media into a lymphatic vessel (see Suggested Reading).

DIAGNOSTIC PROCEDURES
• Biopsy of affected tissues to rule out lymphangiosarcoma. • Culture and sensitivity when lymphangitis present.

TREATMENT
• No curative therapy—a number of surgical and medical treatments may be tried. • Rest and massage of the affected limbs do not help. • Conservative care—long-term use of pressure wraps, coupled with skin care and use of antibiotics to treat cellulitis and lymphangitis; may be successful in some patients. • Surgical procedures—attempted when conservative care and medications fail; two main categories: (1) Facilitate lymph drainage (lymphangioplasty, bridging techniques, lymphaticovenous shunts, superficial and deep lymphatic anastomosis). (2) Excisional procedures to remove abnormal tissue; no treatment consistently beneficial; excisional procedures reported in dogs only. • In humans—microwave heating of affected areas appears beneficial and adds to the effect of benzopyrones (see Drugs of Choice). • Diets severely restricted in long-chain triglycerides are being investigated in humans.

MEDICATIONS

DRUG(S) OF CHOICE
• Benzopyrones reduce high-protein edema by stimulating macrophages to release proteases with resulting fragmented proteins reabsorbed into the blood; beneficial effects have been recorded in experimental studies in dogs (e.g., rutin 50 mg/kg PO q8h). A study in humans showed combined usage of oral and topical benzopyrones to be more effective than either alone. • Diuretics, steroids, anticoagulants, and fibrinolytic agents have been used, but no confirmed benefit. • Treat underlying cause where possible (e.g., ivermectin for *Brugia pahangi* infection).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Diuretics—initially reduce swelling but increase protein content of interstitial fluid, resulting in further tissue damage and fibrosis.

FOLLOW-UP
• Puppies with severe lymphedema may die. • Spontaneous resolution may be seen in some puppies with pelvic limb involvement. • Prognosis with lymphangiosarcoma is poor.

LYMPHOMA—CATS

BASICS

DEFINITION
Malignant transformation of lymphocytes.

PATHOPHYSIOLOGY
Viral (feline leukemia virus [FeLV]) or chemical (tobacco smoke) oncogenesis.

SYSTEMS AFFECTED
• Gastrointestinal. • Hemic/lymphatic/immune. • Nervous—most common spinal cord tumor in cats. • Ophthalmic. • Renal (high rate of relapse in CNS). • Respiratory—nasal, thoracic cavities.

GENETICS
N/A

INCIDENCE/PREVALENCE
• About 90% of hematopoietic tumors and 33% of all tumors in cats. • Prevalence—41.6–200 per 100,000 cats.

GEOGRAPHIC DISTRIBUTION
Regional differences may relate to differences in FeLV prevalence.

Breed Predilections
Siamese/Oriental breeds overrepresented in some studies.

Mean Age and Range
• FeLV-positive cats—3 years. • FeLV-negative cats—7 years. • Median age of cats with localized extranodal lymphoma—13 years. • Most cats with Hodgkin's-like lymphoma are older than 6 years.

Predominant Sex
None

SIGNS

General Comments
Depend on anatomic form.

Historical Findings
• Mediastinal form—open-mouthed breathing, coughing, regurgitation, anorexia, weight loss. • Alimentary form—anorexia, weight loss, lethargy, vomiting, constipation, diarrhea, melena, hematochezia. Small cell lymphoma (SCL) typically more chronic signs compared to large cell lymphoma (LCL). • Renal form—consistent with renal failure. • Nasal form—nasal discharge or epistaxis, facial swelling, ocular signs, respiratory noise, sneezing, anorexia. • Multicentric form—possibly none except for swellings in areas of lymph nodes in early stages; anorexia, weight loss, and depression with progression of disease. • Spinal form—quickly progressing posterior paresis may be seen. • Cutaneous form—pruritic, hemorrhagic, or alopecic dermal masses may be seen.

Physical Examination Findings
• Mediastinal form—non-compressible cranial thorax, dyspnea, tachypnea. • Alimentary form—thickened intestines or abdominal masses. • Renal form—large, irregular kidneys. • Nasal form—purulent or mucoid nasal discharge, facial deformity, epiphora, exophthalmos, poor globe retropulsion. • Multicentric form—generalized lymphadenomegaly, possible hepatosplenomegaly. • All forms—fever; dehydration; depression; cachexia in some patients.

CAUSES
FeLV

RISK FACTORS
• FeLV exposure. • Exposure to environmental tobacco smoke (relative risk 2.4, increases linearly with duration and quantity of exposure). • Feline immunodeficiency virus (FIV) infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Mediastinal form—congestive heart failure; cardiomyopathy; chylothorax; pyothorax; hemothorax; pneumothorax; diaphragmatic hernia; allergic lung disease; thymoma; ectopic thyroid carcinoma; pleural carcinomatosis; acetaminophen toxicity. • Alimentary form—foreign body ingestion; intestinal ulceration; intestinal fungal infection; inflammatory bowel disease; intussusception; lymphangiectasia; other gastrointestinal tumor. • Renal form—pyelonephritis; amyloidosis; glomerulonephritis; chronic renal failure; polycystic kidneys; feline infectious peritonitis. • Multicentric form—systemic mycotic infection; immune-mediated disease; toxoplasmosis; lymphoid hyperplasia; hypersensitivity reaction; plague (specifically if prominent cervical lymphadenopathy as with Hodgkin's-like form).

CBC/BIOCHEMISTRY/URINALYSIS
• May see anemia (negative prognostic factor), leukocytosis, and lymphoblastosis. • May find high creatinine, high serum urea nitrogen, high hepatic enzyme activity, hypercalcemia (rare), and monoclonal gammopathy.

OTHER LABORATORY TESTS
FeLV testing—usually negative in older cats and in cats with large granular lymphocyte lymphoma (LGLL), usually positive in younger cats and those with mediastinal (85%) or CNS lymphoma, renal (45% positive), multicentric (20%), intestinal (15%).

IMAGING
• Thoracic radiography—may see mediastinal mass, pleural effusion, abnormal pulmonary parenchymal patterns (rare), perihilar or retrosternal lymphadenomegaly. • Abdominal ultrasonography—may see diffuse echotexture changes in the liver, spleen, and kidneys, focal or diffuse thickening of the intestines and the gastric wall, abdominal lymphadenopathy, intestinal/gastric mass: ○ Hypoechoic subcapsular thickening is associated with renal lymphoma. ○ Despite thickening of intestines, layering may be preserved. • Computed tomography—space-occupying mass effect in affected area, especially used for nasal lymphoma.

DIAGNOSTIC PROCEDURES
• Aspiration or biopsy of a mass or lymph node. • Aspirate often sufficient to diagnose LCL; biopsy often required for SCL. • Can be challenging to distinguish SCL from inflammatory bowel disease (IBD). • Immunohistochemistry (IHC) ± PCR for antigen receptor rearrangement (PARR) testing can be done to distinguish between IBD and SCL; sensitivity of IHC for detecting lymphoma 78% vs. 83% for IHC + PARR; sensitivity of PARR for detecting T-cell and B-cell lymphoma is 78% and 50%, respectively. • Staging—CBC/chemistry profile/urinalysis/FeLV/FIV testing, thoracic radiographs, abdominal ultrasound, regional lymph node aspirates for localized lesions, ± bone marrow aspirate depending on CBC findings; serum cobalamin level in SCL.

PATHOLOGIC FINDINGS
• Gross—usually white to gray in color with areas of hemorrhage and necrosis. • Cytologic—monomorphic population of intermediate to large sized immature lymphocytes (lymphoblasts) in LCL vs monomorphic population of small mature lymphocytes in SCL. • Histopathologic—vary; several morphologic classification schemes in use: ○ Nasal lymphoma is most often immunoblastic B-cell origin. ○ Hodgkin's-like lymphoma is characterized by Reed–Sternberg cells and few neoplastic cells in a background of a reactive T-cell population with histiocytes and granulocytes. ○ LGL lymphoma most commonly affects the intestine and mesenteric lymph nodes. ○ B-cell most common in stomach (100%) and large intestine (88%); T-cell most common in small intestine (52%). ○ In gastrointestinal (GI) lymphoma, LCL more common than SCL when both cytologic and histopathologic samples are evaluated.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient whenever possible, supportive care if needed.

NURSING CARE
Fluid therapy, antiemetics, appetite stimulants, analgesia, thoracocentesis, etc. when indicated.

ACTIVITY
Normal

DIET
No change, can add *n*-3 fatty acids to diet (fish oil origin).

CLIENT EDUCATION
• Emphasize that side effects are treatable and should be addressed promptly. • Inform client that the goal is to induce remission and achieve a good quality of life for as long as possible.

SURGICAL CONSIDERATIONS
• To relieve intestinal obstructions or perforations and remove solitary masses. • To obtain specimens for histopathologic examination.

RADIATION THERAPY
Possible option for localized lesions, such as nasal cavity or mediastinum, as well as rescue treatment for GI LCL.

MEDICATIONS

DRUG(S) OF CHOICE
• Chemotherapy—there are many variations of similar combination protocols, all with similar efficacy. • High-grade lymphoma can respond to CHOP-based protocols (cyclophosphamide, doxorubicin, vincristine, prednisone/prednisolone) such as the University of Wisconsin–Madison protocol (alternating drugs in repeated sequence) or COP-based protocols (cyclophosphamide, vincristine, prednisone/prednisolone).
• Vinblastine has similar efficacy but less GI toxicity compared to vincristine. • SCL can respond to oral chlorambucil (either low dose daily/every other day or high dose pulsed) and prednisone/prednisolone. • Consult a veterinary oncologist for doses, schedules, and to help assess best option(s) for treatment.

CONTRAINDICATIONS
Avoid doxorubicin in cats with preexisting renal failure as high-cumulative dosages have been demonstrated to potentially be nephrotoxic.

PRECAUTIONS
• Myelosuppression secondary to chemotherapy—more in FeLV-positive cats. • Seek advice before initiating treatment if you are unfamiliar with cytotoxic drugs. Some drugs such as vincristine and doxorubicin are vesicants and can cause severe tissue sloughing if leaked outside the vein.

FOLLOW-UP

PATIENT MONITORING
• Physical examination and CBC—before each chemotherapy treatment and 1 week after each new drug is administered, or if there are concerns about low cell counts.
• Diagnostic imaging—as necessary depending on location to assess response to therapy.

PREVENTION/AVOIDANCE
Avoid exposure to or breeding FeLV-positive cats.

POSSIBLE COMPLICATIONS
• Leukopenia/neutropenia. • Sepsis.
• Anorexia, vomiting, weight loss; may need imaging tests to distinguish between chemotherapy side effects and lymphoma progression.

EXPECTED COURSE AND PROGNOSIS
• Depends on initial response to chemotherapy, anatomic type, FeLV status, and tumor burden.
• Median survival according to treatment (overall 50–70% response rate): ○ Prednisone alone—1.5–2 months. ○ COP/CHOP-based chemotherapy—6–9 months. • Doxorubicin-based, lomustine, MOMP (mechlorethamine, vincristine, melphalan, prednisone), and DMAC (dexamethasone, melphalan, actinomycin-D, cytarabine) rescue therapy reported for refractory lymphoma. • Median survival according to FeLV status: ○ Negative—7 months (17.5 months if low tumor burden). ○ Positive—3.5 months (4 months if low tumor burden). • Median survival according to anatomic location: ○ Renal—FeLV-negative, 11.5 months; FeLV-positive, 6.5 months. ○ Nasal—1.5–2.5 years with radiation and chemotherapy. • Chemotherapy may not improve survival over radiation alone. • Higher radiation doses (>32 Gy) result in longer survival. • Mediastinal—about 10% of patients live >2 years. • Alimentary—8 months.
• Peripheral multicentric—23.5 months. • If localized (median remission time)—114 weeks.
• Median survival according to histology (tumor grade or subtype): ○ SCL of GI tract with or without additional visceral involvement—95% overall response to chlorambucil and prednisone for median survival of approximately 2 years (longer in complete vs. partial remission). ○ LGLL—~30% response for median survival 57 days. • Cats with Hodgkin's-like lymphoma can do well for extended periods of time, even without treatment (months to years). • Weight loss during first month of treatment of LCL associated with shorter survival. • Clinical response after 1 cycle of COP chemotherapy associated with longer survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Hypoglycemia (rare). • Monoclonal gammopathy (rare). • Hypercalcemia (10–15%).

AGE-RELATED FACTORS
Young cats with lymphoma are generally FeLV-positive.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Do not use chemotherapy in pregnant animals.

SYNONYMS
• Lymphosarcoma. • Malignant lymphoma.

ABBREVIATIONS
• FeLV = feline leukemia virus.
• GI = gastrointestinal.
• IBD = inflammatory bowel disease.
• IHC = immunohistochemistry.
• LCL = large cell lymphoma.
• LGLL = large granular lymphocyte lymphoma.
• PARR = PCR for antigen receptor rearrangement.
• SCL = small cell lymphoma.

Client Education Handout available online

L

LYMPHOMA—DOGS

BASICS

DEFINITION
• Clonal proliferation of B-, T-, or non-B-/non-T-type (null cell) lymphoblasts found primarily in enlarged peripheral lymph nodes. • Cells can spread systemically to invade bone marrow, peripheral blood, CNS, and visceral organs.

PATHOPHYSIOLOGY
• ~85% of cases are multicentric (involving more than one lymph node). • ~75% are B-cell in origin and ~25% are T-cell in origin. • B-cell lymphoma (LSA) includes mainly multicentric B-cell lymphoma (80% of cases) which is an aggressive disease similar to human diffuse, large B-cell lymphoma (DLBCL), and marginal zone lymphoma (MZL, 20% of cases). Follicular lymphoma (FL) is rare. • Multicentric T-cell LSA includes aggressive (peripheral T-cell LSA—not otherwise specified [PTCL-NOS]) and indolent (T-zone LSA [TZL]) subtypes. T-cell LSAs are most commonly associated with hypercalcemia. • Aggressive lymphomas respond to treatment quickly, but have shorter overall survivals.

SYSTEMS AFFECTED
• Lymphatic (~85%)—generalized peripheral lymphadenopathy with or without splenic, hepatic, peripheral blood, and/or bone marrow involvement. • Gastrointestinal (~5–7%)—focal or diffuse infiltration of intestines, and associated lymph nodes. • Mediastinal (~5%)—proliferation of neoplastic lymphocytes in mediastinal lymph nodes, thymus, or both. • Skin—divided into cutaneous non-epitheliotropic B- and T-cell LSA and mycosis fungoides (epitheleiotropic T-cell LSA). • Hepatosplenic γδ T-cell LSA (rare)—liver/spleen sinusoidal infiltration of T-cells with eventual bone marrow infiltration. Erythrophagia commonly seen. • Intravascular LSA (rare)—typically T- or null cell proliferation in lumen or wall of blood vessel.

GENETICS
• Some chromosome copy number aberrations are shared between human and canine lymphomas. • Gene expression profiling can be used to separate distinct subtypes of human and canine lymphoma. • Canine DLBCL and MZL may be a continuum of the same disease.

INCIDENCE/PREVALENCE
• 20–107 LSA cases per 100,000 dogs. • LSA comprises up to 24% of all canine neoplasms and 83% of all canine hematopoietic malignancies.

SIGNALMENT
Breed Predilections
• Boxer, basset hound, golden retriever, Saint Bernard, Scottish terrier, Airedale terrier, and bulldog—reported high-risk breeds. • Dachshund and Pomeranian—reported low-risk breeds. • Breed determines relative risk for B-cell or T-cell disease: ~85% of boxer LSAs are T-cell in origin (>50% are CD3+CD4+ in origin), while golden retrievers develop both B- and T-cell LSA in an ~50:50 ratio.

Median Age
Historically, 6–9 years.

SIGNS
History
• Multicentric—from no clinical signs to anorexia, lethargy, vomiting, diarrhea, weight loss, fever, polydipsia and polyuria secondary to hypercalcemia. • Gastrointestinal—vomiting, diarrhea, anorexia, weight loss, malabsorption. • Mediastinal—respiratory distress, pleural effusion, coughing, difficulty swallowing, caval syndrome. • Skin: ○ Cutaneous LSA—lesions usually generalized or multifocal: nodules, plaques, ulcers, focal alopecia and hypopigmentation. ○ Mycosis fungoides—initial scaling, alopecia, pruritus progressing to thickened, ulcerated, exudative lesions. Later stages include proliferative plaques and nodules with progressive ulceration. Oral mucosa many times involved. • Extranodal—vary with the anatomic site: ocular—photophobia and conjunctivitis; CNS—neurologic deficits, paresis, paralysis, seizures; hepatosplenic—lethargy, inappetance, weakness, icterus.

Physical Examination Findings
• Multicentric—generalized, painless, enlarged peripheral lymph node(s) with or without hepatosplenomegaly. • Gastrointestinal—unremarkable to palpable thickened gut loops and/or abdominal mass, rectal mucosal irregularities, ascites. • Mediastinal—dyspnea; tachypnea; muffled heart sounds secondary to pleural effusion, pitting edema of head, neck, forelimbs. • Skin—raised plaques that may coalesce, patch lesions, and erythematous, exudative lesions. • Extranodal—ocular—anterior uveitis, retinal hemorrhages, and hyphema; CNS—dementia, seizures, and paralysis.

CAUSES
Suggested causes include heritable breed risks, chromosomal aberrations, increased telomerase activity, germline and somatic genetic mutations, epigenetic changes, retroviral infection, Epstein–Barr virus infection, and environmental factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Multicentric—disseminated infections, metastatic disease, immune-mediated disorders, other hematopoietic tumors. • Gastrointestinal—other GI tumors, foreign body, enteritis, GI ulceration, systemic mycosis. • Mediastinal—other tumors (thymoma, chemodectoma, ectopic thyroid), infectious disease. • Skin—infectious dermatitis, pyoderma, immune-mediated dermatitis, histiocytic or mast cell disease. • Extranodal—depends on affected site.

CBC/BIOCHEMISTRY/URINALYSIS
• Anemia of chronic disease, thrombocytopenia, lymphocytosis, lymphopenia, neutrophilia, monocytosis, circulating blasts, hypoproteinemia (GI). • Hypercalcemia, increased liver enzymes with hepatic involvement, increased creatinine or blood urea nitrogen with renal involvement. • Urinalysis usually normal.

OTHER LABORATORY TESTS
• Immunohistochemistry (lymph node [LN] biopsy/resection)—to determine immunophenotype. • Flow cytometry or PCR for antigen receptor rearrangements (PARR) (LN or affected organ fine-needle aspirates)—to determine immunophenotype.

IMAGING
• Thoracic radiography—sternal or tracheobronchial lymphadenopathy, widened mediastinum, pulmonary densities, and pleural effusion. • Abdominal ultrasonography—abdominal lymphadenopathy, hepatosplenic involvement, thickened bowel loops, other visceral organ involvement, ascites.

DIAGNOSTIC PROCEDURES
• Fine-needle aspirate cytology of enlarged lymph nodes or other affected organs—for cytopathologic confirmation. • LN biopsy or resection—for accurate histopathologic classification. • Bone marrow cytology—for accurate prognosis. • CSF analysis—if patient has neurologic signs. • ECG—identify arrhythmias before doxorubicin administration.

PATHOLOGIC FINDINGS
• Multicentric— effacement of LN parenchyma with large, neoplastic CD79a+ B-cells (high-grade DLBCL) or perifollicular proliferation of CD79a+ cells (MZL) or CD79a+ cell proliferation that maintains follicle architecture (FL). Effacement of LN parenchyma with large, neoplastic CD3+ T-cells (PTCL-NOS) or small, CD3+ cell proliferation between fading follicles (indolent TZL). • Gastrointestinal—infiltration of neoplastic lymphocytes throughout mucosa and submucosa, with occasional transmural infiltration. • Skin—CD79a+ B-cells infiltrating mucosa and submucosa, but sparing the epidermis (non-epitheliotrophic) LSA or CD3+ T-cells invading the epidermis: Pautrier's microabscesses (mycosis fungoides). Hepatosplenic—sinusoidal infiltration of erythrophagocytic CD3+ T-cells.

Staging
• I—one enlarged LN. • II—regionally enlarged LNs. • III—generalized LN involvement. • IV—visceral organ involvement.

• V—blood or bone marrow involvement.
• Substage a—not sick. • Substage b—sick.

TREATMENT

APPROPRIATE HEALTH CARE

• High-grade LSAs are exquisitely sensitive to both chemotherapy and radiation. • Systemic multiagent chemotherapy—therapy of choice. • Radiation therapy—for refractory lymphadenopathy, large mediastinal masses, and solitary cutaneous areas. Half-body irradiation has been included into some chemotherapy protocols. • Surgery—rarely used unless an acutely obstructive GI mass is identified or to remove a refractory lymphadenopathy. • Autologous and allogeneic bone marrow transplantation (BMT)—after total body irradiation can be considered. • Fluid therapy—for advanced disease to treat clinically ill, azotemic, and/or dehydrated patients. Fluid therapy, steroids, ±calcitonin—to treat hypercalcemia. • Consider aggressive fluid therapy—to prevent tumor lysis syndrome when inducing dogs with a high tumor burden or dogs with peripheral blood lymphoblasts.

CLIENT EDUCATION

• Canine LSA is a treatable, but rarely curable disease. • Side effects of chemotherapy drugs include reversible GI tract and bone marrow toxicities. • Most dogs will not experience alopecia, but, dogs who need grooming will.
• The vast majority of dogs receiving chemotherapy enjoy an excellent quality of life.

MEDICATIONS

DRUG(S) OF CHOICE

• Consider combination chemotherapy protocols to treat intermediate and high-grade diseases and single-agent protocols to treat indolent diseases. • Most multiagent protocols have superior remission and survival times when compared to single-agent protocols.
• Corticosteroids alone can induce significant multidrug resistance.

Intermediate and High-Grade Lymphomas

• L-CHOP—L-asparaginase 10,000 IU/m^2, vincristine (Onvcovin) 0.7 mg/m^2 IV, cyclophosphamide (Cytoxan) 250 mg/m^2 IV or PO, doxorubicin (Adriamycin) 30 mg/m^2 IV, prednisone 30, 20, 10 mg/m^2 PO q24h tapering for 3 weeks. Consult a veterinary oncologist concerning the treatment schedule.
• COP—vincristine 0.7 mg/m^2 IV, cyclophosphamide (Cytoxan) 250 mg/m^2 IV or PO, prednisone 30, 20, 10 mg/m^2 PO q24h tapering for 3 weeks. Each drug given weekly.

Single Agent

• Any drug of L-CHOP can be used as a single agent, but expect shorter overall survival than multiagent. • Doxorubicin (Adriamycin) 30 mg/m^2 IV every 3 weeks (1 mg/kg for dog <15 kg) 5–6 treatments.
• CCNU (lomustine) 70 mg/m^2 PO every 3 weeks, prednisone 2 mg/kg PO daily.
• Tanovea (rabacfosadine) 1 mg/kg IV every 3 weeks, prednisone 1 mg/kg PO EOD.

Low-Grade Lymphomas

• Chlorambucil (Leukeran) 6 mg/m^2 PO daily for 7–14 days, prednisone 2 mg/kg PO daily. Consider reducing chlorambucil dose to 3 mg/m^2 for maintenance. • CCNU (lomustine) as above.

PRECAUTIONS

• Doxorubicin—use dexrazoxane (Zinecard) in conjunction with doxorubicin or substitute epirubicin for dogs with cardiac issues. Always use a freshly placed catheter when administering IV doxorubicin.
• L-Asparaginase and doxorubicin—pretreat with diphenhydramine 1–2 mg/kg SC, 15 minutes before administration. • Cytoxan—pretreat with furosemide 2 mg/kg to prevent sterile hemorrhagic cystitis.

POSSIBLE INTERACTIONS

Most chemotherapy drugs have overlapping GI and bone marrow toxicities. Consider antidiarrheals (metronidazole, loperamide) and antiemetics (metoclopramide, maropitant, ondansetron) to abrogate these effects.

ALTERNATIVE DRUG(S)

• Many published rescue protocols have been reported; therefore, always consult with a medical oncologist. • MOPP—mechlorethamine (Mustargen), vincristine, procarbazine, and prednisone. • DMAC—dexamethasone, melphalan, actinomycin-D, and cytosine arabinoside. • CCNU ± L-asparaginase, prednisone, or DTIC (dacarbazine).
• Mitoxantrone alone or doxorubicin/DTIC.

FOLLOW-UP

PATIENT MONITORING

• Weekly physical examination to assess response and CBC to gauge bone marrow toxicities. • If neutropenia (neutrophils <1,500 cells/mm^3) is noted, reduce dosage (20–25%) of drug when given again.

POSSIBLE COMPLICATIONS

• Reversible neutropenia 7–10 days after chemotherapy. • Temporary vomiting, diarrhea, and anorexia 3–5 days after chemotherapy. • Alopecia in certain dog breeds that require grooming (poodle, shih tzu, etc.). • Febrile neutropenia (treated with broad-spectrum antibiotics).

EXPECTED COURSE AND PROGNOSIS

• >80% of dogs will go into clinical remission during the first month of induction chemotherapy. • Stage, substage, and immunophenotype are important prognostic indicators.
• Expect median survivals of ~12–14 months and ~6–9 months in dogs with high-grade multicentric B- and T-cell LSA, respectively, when treated with a multiagent protocol. Dogs with indolent disease can live years. GI, mediastinal (T-cell ± hypercalcemia), and mycosis fungoides are associated with poorer response to treatment and an overall shorter survival time. • Autologous BMT can cure ~33% of dogs with B-cell LSA and ~15% of dogs with T-cell LSA. The cure rate of allogeneic BMT is currently unknown.

L

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Treatment of pregnant dogs is usually contraindicated.

SYNONYMS

• Lymphosarcoma. • Malignant lymphoma.

SEE ALSO

• Hypercalcemia.
• Leukemia, Chronic Lymphocytic.

ABBREVIATIONS

• DLBCL = diffuse, large B-cell lymphoma.
• FL = follicular lymphoma.
• GI = gastrointestinal.
• LN = lymph node.
• LSA = lymphoma.
• MZL = marginal zone lymphoma.
• PTCL-NOS = peripheral T-cell lymphoma—not otherwise specified.
• TZL = T-zone lymphoma.

LYMPHOMA, CUTANEOUS EPITHELIOTROPIC

BASICS

OVERVIEW

- Cutaneous epitheliotropic lymphoma—most common form of cutaneous T-cell lymphoma.
- An uncommon malignant neoplasia of dogs and cats.
- Sézary syndrome—rare; cutaneous lesions, invasion of peripheral lymph nodes by neoplastic lymphocytes, and leukemia occur simultaneously.
- Pagetoid reticulosis—rare; the lymphoid infiltrate is confined to the epidermis and adnexal structures in the early stages of the disease and extends to the dermis in the late stages.
- Systems affected—hemic/lymphatic/immune; skin/exocrine.
- Synonyms—mycosis fungoides, lymphoma epidermotropic.

SIGNALMENT

- Dogs and cats—most common in dogs.
- Age range 6–14 years; mean 8.6 years.
- No apparent breed or sex predilection.

SIGNS

Historical Findings

- Chronic skin disease—months before diagnosis.
- Rarely acute.
- Mimics other inflammatory dermatoses.
- Typically pruritic in dogs and variably pruritic in cats.

Physical Examination Findings

- Four clinical categories of presentation:
  - Exfoliative erythroderma—generalized erythema, scaling, depigmentation, alopecia.
  - Mucocutaneous—depigmentation, erythema, erosion, and ulceration affecting mucocutaneous junctions.
  - Tumoral—solitary or multiple erythematous and scaly plaques, nodules, and masses.
  - Oral mucosal ulceration of gingiva, palate, and/or tongue.
- Lesions—typically throughout the skin; marked tendency for involvement of mucocutaneous junctions or oral cavity; lesions can be limited to the mucocutaneous junctions or oral mucosa.
- Exfoliative erythroderma; progression to the tumor stage is very rapid in dogs compared to humans.
- Mucocutaneous form and oral mucosa form: tend to merge with chronicity.
- Rarely nodules develop without a preexisting patch or plaque stage (d'emblee form).
- Nodular stage may occasionally progress to a disseminated form with lymph node involvement, leukemia, and rarely other organs.

CAUSES & RISK FACTORS

Risk of development from chronic antigenic stimulation (including allergy) theorized.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatophytosis.
- Demodicosis.
- Feline thymoma-associated exfoliative dermatitis.
- Allergic or parasitic dermatitis.
- Discoid lupus erythematosus.
- Erythema multiforme.
- Mucocutaneous pyoderma.
- Non-neoplastic stomatitis.
- Cutaneous neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- Generally unremarkable if only the skin or mucosa is affected.
- Sézary cells—neoplastic lymphocytes (8–20 µm) with convoluted nucleus and cerebriform appearance are present in peripheral blood of Sézary syndrome patients.

DIAGNOSTIC PROCEDURES

Skin biopsy—definitive diagnosis; sample multiple different-appearing lesions, avoid eroded/ulcerated and infected lesions.

PATHOLOGIC FINDINGS

- Infiltrate of neoplastic lymphocytes—into epidermis, hair follicle epithelium, and adnexa; distributed diffusely or as discrete Pautrier microaggregates.
- Dermal infiltrate—polymorphous; malignant lymphocytes may obscure the dermoepidermal junction; patch and plaque stages, limited to the superficial dermis; nodular stage, extends to the deep dermis and subcutis.
- Immunohistochemical tissue staining reveals a predominance of CD8+ cytotoxic T-cells (dogs).

TREATMENT

- Grave prognosis—goal is to maintain a good quality of life.
- Therapy is rarely curative.
- Rarely, solitary nodules can be surgically excised.
- Total skin electron therapy or orthovoltage radiation: well tolerated, may be beneficial in some cases.

MEDICATIONS

DRUG(S) OF CHOICE

- Lomustine (CCNU)—overall response rate of 82% with remission achieved in about 32% of cases (initial dose 60 mg/m^2 PO; range 30–90 mg/m^2 every 3–4 weeks for a mean of 3–5 treatments).
- Dacarbazine 1000 mg/m^2—3 cycles report of remission in one dog with nodal involvement.
- Pegylated liposomal doxorubicin—44% response rate in dogs (average dose, 1 mg/kg IV every 3 weeks).
- Combination protocol (cyclophosphamide, doxorubicin, vincristine, and prednisolone)—partial to complete response in dogs that failed lomustine therapy.
- High-dose linoleic acid (e.g., safflower oil)—3 mL/kg orally twice weekly; good improvement in 7/10 dogs for up to 2 years.
- Topical chemotherapy—mechlorethamine (nitrogen mustard); some success in managing early lesions.
- Corticosteroids—topical and/or systemic may result in some symptomatic relief.
- Retinoids—isotretinoin 3 mg/kg/day or acitretin 2 mg/kg/day may be beneficial.
- Rabacfosadine—45% of dogs (5/11) had either complete remission or partial remission.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Management by veterinary oncologist or dermatologist recommended.

FOLLOW-UP

- Average survival time for dogs depends upon stage of disease at diagnosis, therapeutic choice, and response to therapy; median 6 months (range 1 month–2 years).
- Death is usually the result of euthanasia.

LYSOSOMAL STORAGE DISEASES

BASICS

OVERVIEW

• Inherited disorders caused by partial or complete deficiency of a lysosomal enzyme or an enzyme-activator protein, which leads to intracellular accumulation (storage) of the substrate of that enzyme. • Storage products—proteins, carbohydrates, lipids, or a combination. • Classes of diseases—proteinoses, glycoproteinoses, oligosaccharidoses, sphingolipidoses, mucopolysaccharidoses. • Many different types reported in dogs and cats. • Inheritance is autosomal recessive.

SIGNALMENT

• Dog—German shepherd dog, German shorthaired pointer, English setter, beagle, Cairn terrier, bluetick hound, West Highland white terrier, Sydney silky terrier, English springer spaniel, Portuguese water dog, Japanese spaniel, Labrador retriever, American bulldog, Irish setter, mixed-breed dogs, many others. • Cat—Persian, Siamese, Korat, Balinese, domestic shorthair. • Most affected animals <1 year old; a few adult-onset diseases described, with onset as late as 2 years old, or older.

SIGNS

General Comments

• Vary with severity of the enzyme deficiency. • In certain diseases, carrier animals can be affected with a milder form of the disease. • Many organ systems are affected, but neurologic signs tend to predominate.

Historical Findings

• Affected animals are normal at birth. • Fail to thrive and may manifest skeletal malformations, particularly in the mucopolysaccharidoses. • Neurologic signs within the first few months of life suggest multifocal neurologic disease.

Physical/Neurologic Examination

• Cerebellar dysfunction common—intention tremors, nystagmus, dysmetria. • Peripheral neuropathy occurs in some diseases—weakness, hyporeflexia or areflexia, muscle wasting. • Other neurologic signs—ataxia; exercise intolerance; seizures; behavioral changes; visual deficits, deafness, stereotypical behaviors, proprioceptive deficits, tremors. • Non-neurologic signs—may see organomegaly or skeletal malformations. • Ocular pathology in some diseases—corneal opacification, cataract formation.

CAUSES & RISK FACTORS

• Genetic—deletion or mutation involving a single gene that causes an absolute or partial deficiency of a lysosomal enzyme or activator protein; deficient production of enzymes that do not have normal biologic activity. • Susceptible breed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Metabolic encephalopathy—usually episodic clinical signs; results of CBC, biochemistry, and urinalysis often diagnostic. • Toxicities—acute onset of clinical signs; history of exposure. • Cerebellar hypoplasia—onset at 3–6 weeks of age; nonprogressive. • Cerebellar abiotrophy—deficits limited to the cerebellum; may be difficult to differentiate in the early stages without specific tests. • Prenatal or neonatal infections (especially viral) resulting in meningoencephalomyelitis—differentiated by CSF analysis; may be other signs, such as chorioretinitis. • Metabolic diseases—especially organic and amino acidurias.

CBC/BIOCHEMISTRY/URINALYSIS

• Regular blood smears and CSF analysis—cytoplasmic vacuolation of leukocytes caused by accumulation of storage products is present in some cases. • Urine—may find abnormal accumulation of substances (e.g., oligosaccharide in α-mannosidosis).

IMAGING

• Radiography—bony malformation may be present in diseases in which skeletal pathology is a feature (e.g., mucopolysaccharidoses). • MRI—used in one case to reveal diffuse white matter pathology in the brain of a dog with globoid cell leukodystrophy.

DIAGNOSTIC PROCEDURES

• Molecular genetic testing—available for the diagnosis of many lysosomal storage diseases; may be used to identify potential carriers. • Aspirates or biopsies of parenchymal organs, particularly the liver and spleen—may reveal intracellular storage material. • Biochemical tests—diagnosis may be made by demonstrating low enzyme activity or presence of accumulated substrate or metabolic intermediates in preparations of serum, brain, viscera, leukocytes, or skin fibroblasts. • Electromyography and nerve conduction studies—abnormal in diseases in which peripheral neuropathy or myopathy is a feature. • Biopsy of peripheral nerve or skeletal muscle—may demonstrate specific pathology.

TREATMENT

• Outpatient—unless severe deficits preclude nursing care at home. • Activity—restrict to safe areas; avoid stairs. • Diet and fluids—ensure proper intake in patients often debilitated; parenteral fluid therapy and enteral or parenteral nutritional support may be needed with severe disease. • Bone marrow transplantation—used experimentally with some success. • Gene therapy—area of intense research that may offer hope for specific treatment. • Enzyme replacement therapy—intrathecal enzyme replacement has shown some efficacy in an experimental setting. • Primary treatment—preventive; control of breeding; genetic counseling. • Patients may be at risk of developing secondary infection; initiate appropriate treatment if infection develops.

MEDICATIONS

DRUG(S) OF CHOICE

N/A

FOLLOW-UP

• Progressive; ultimately fatal. • Pedigree analysis—useful in diagnosis; important for identification of potential carrier animals.

MALASSEZIA DERMATITIS

BASICS

OVERVIEW

- *Malassezia pachydermatis* is a lipid-loving commensal of the skin, ears, and mucocutaneous areas; can overgrow causing dermatitis, cheilitis, and otitis externa.
- Transformation from harmless commensal to pathogen related to allergy, seborrheic conditions, and congenital and hormonal factors.
- Systems affected—skin/exocrine.

SIGNALMENT

- Dog—any breed; West Highland white terrier, poodle, basset hound, cocker spaniel, and dachshund predisposed.
- Cat—less common; associated with internal neoplasia in aged cats; affects all breeds; young Rex cats predisposed.

SIGNS

- Pruritus variable; erythema, alopecia, scale, and greasiness of lips, ears, feet, axillae, inguinal area, and ventral neck; malodor.
- Hyperpigmentation and lichenification—chronic cases.
- Concurrent black waxy to seborrheic otitis—frequent.
- Frenzied facial pruritus—uncommon but characteristic.
- Often an allergy history that worsens and develops glucocorticoid tachyphylaxis.
- Concurrent bacterial folliculitis, hypersensitivity, endocrine and seborrheic dermatitis.

CAUSES & RISK FACTORS

- High humidity and temperature—may increase the frequency.
- Concurrent hypersensitivity disease predisposing factor.
- Seborrheic dermatitis (young dogs)—in predisposed breeds.
- Endocrinopathy—suspected predisposing factor.
- Genetic factors—in predisposed dog breeds. In Rex cats: genetic factors of the skin and/or their predisposition to a mast cell abnormality called urticaria pigmentosa are speculative risk factors.
- Concurrent increase of *Staphylococcus pseudintermedius* folliculitis—with overgrowth of both; treatment of one produces partial resolution and unmasks the other.
- Cats have a young and an adult-age disease that can be allergy-associated. Aged cats—*Malassezia* dermatitis associated with thymomas and carcinomas of the pancreas and liver.

DIAGNOSIS

Demonstration of excessive numbers of the organism on diseased skin, and significant improvement following removal of the yeast.

DIFFERENTIAL DIAGNOSIS

- Allergic dermatitis—including flea allergy, atopy, and cutaneous adverse reaction to food.
- Superficial bacterial folliculitis.
- Primary and secondary seborrhea (keratinization defect).
- Acanthosis nigricans—dachshund.

CBC/BIOCHEMISTRY/URINALYSIS

Normal unless affected by underlying cause.

OTHER LABORATORY TESTS

- Fungal culture—press contact plates onto the affected skin surface; incubate for 3–7 days; count the distinctive yellow or buff, round, domed colonies (1–1.5 mm); provides semi-qualitative data.
- Nonquantitative culture methods—no value because *Malassezia* is a normal commensal.

DIAGNOSTIC PROCEDURES

- Skin cytology—touch, cotton swab, or cellophane tape preparation; apply stain as a drop directly onto the slide (yeast may wash off during staining); pass a flame under the slide to improve stain penetration and visualization.
- Greasy and/or scaly areas most likely to produce positive results.

TREATMENT

- Identify and treat predisposing factors or diseases.
- Topical therapy—yeast is principally located in the stratum corneum.
- Shampoo treatment—to remove scale and exudation: miconazole and chlorhexidine shampoo most effective; selenium sulfide shampoo less effective but useful; twice-weekly treatments.
- Other topical antifungal agents (e.g., ketoconazole) also of value if given with suitable systemic medications.
- Alternative combinations—topical keratolytic shampoo treatment with systemic antiyeast and antibacterial drugs.

MEDICATIONS

DRUG(S) OF CHOICE

- Localized cases—may respond to lotions containing imidazole compounds.
- Ketoconazole 10 mg/kg q24h, fluconazole 10 mg/kg q24h, or itraconazole 5 mg/kg q24h for 2–4 weeks in widespread or chronic lichenified cases.
- Other imidazoles also effective.
- Topical antimicrobial antibacterial shampoo—to maintain remission in chronic cases.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Ketoconazole may cause hepatic reaction; masks signs of hyperadrenocorticism and interferes with adrenal function tests due to blocking of cortisol production (via inhibition of P450) in the adrenal gland; may affect metabolism of other medications; contraindicated in cats. Azole-tolerant strains of Malassezia pachydermatis have been described.

FOLLOW-UP

- Physical examination and skin cytology—after 2–4 weeks, to monitor therapy.
- Treat until only rare organisms can be demonstrated or 7 days after a complete response is achieved.
- Pruritus and odor—usually noticeably improved within 1 week.
- Recurrences—common when underlying dermatoses are not well controlled; regular bathing with antifungal antibacterial shampoo combinations helps decrease recurrence.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Ketoconazole contraindicated.

MALIGNANT FIBROUS HISTIOCYTOMA

BASICS

OVERVIEW
- Name based on histologic features of fibroblast- and histiocyte-like cells.
- A group of primitive pleomorphic mesenchymal neoplasms, but definitive cellular origin unknown; likely possibilities include fibroblasts, histiocytes, and undifferentiated mesenchymal cells.
- Several histologic variants.
- Storiform-pleomorphic and giant cell—two major variants; both locally invasive; firm, subcutaneous, or visceral masses on examination.
- Despite previous reports to the contrary, metastatic potential in dogs appears to be moderate to high.
- Have been reported as injection site-related sarcomas of cats.

SIGNALMENT
- More commonly reported in cats than in dogs.
- Similar biologic behavior in both species.
- Mean age—cats: 9 years (range 2–12 years); dogs: 8 years (range <1–10 years).
- No proven breed or sex predilection, although flat-coated retrievers, Rottweilers, and golden retrievers appear overrepresented and may be predisposed.

SIGNS

Historical Findings
- Anorexia, weight loss, and lethargy may occur.
- Depend on site of involvement.

Physical Examination Findings
- Firm, invasive tumor arising in subcutaneous tissue.
- May exhibit deep extension into underlying skeletal muscle.
- May develop adjacent to bone and induce bone destruction and proliferation.
- Most common sites—dorsal thoracic and scapular area, limbs, and pelvic region.
- May also be a primary splenic tumor in dogs; palpable splenomegaly may be found.
- Distant metastasis—common.

CAUSES & RISK FACTORS
- Unknown.
- Can be induced with carcinogens in laboratory animal species.
- Injection sites in cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other forms of soft tissue sarcoma (e.g., fibrosarcoma, leiomyosarcoma).
- Chondrosarcoma.
- Osteosarcoma (extraskeletal).
- Liposarcoma.
- Peripheral nerve sheath tumors.
- Histiocytic diseases, such as histiocytic sarcoma or systemic histiocytosis.
- Mast cell neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC—may vary; may be normal; may see regenerative or nonregenerative anemia.
- Biochemistry—variably abnormal.
- Urinalysis—usually normal.

OTHER LABORATORY TESTS
Cytologic examination of aspirate—may reveal histiocyte- and fibroblast-like cells.

IMAGING
- Radiography—reveals soft tissue dense mass; may note bone proliferation or destruction.
- Three-view thoracic radiography to check for lung metastasis.
- MRI or CT may be superior for delineating extent of tumor invasion into surrounding tissues.
- Ultrasonography may detect abnormalities consistent with abdominal metastasis (most common in lymph nodes and liver).

DIAGNOSTIC PROCEDURES
Histologic examination of biopsy specimen—necessary for definitive diagnosis.

PATHOLOGIC FINDINGS
- Classification—considerable debate exists among pathologists regarding use of the term maligant fibrous histiocytoma, which may account for the apparent differences in behavior reported in the literature.
- Storiform-pleomorphic (may be called inflammatory) and giant cell (also called osteoclast-like) are the two major variants reported. Myxoid variant also described.
- Many are histologically high grade.
- Specialized immunohistologic stains, such as CD18, vimentin, desmin, alpha-smooth muscle actin, extra domain 1 (ED1), and/or azan (for collagen) may aid classification. Definitive staining patterns have not been clearly identified.
- Recent report of considerable overlapping histopathologic characteristics with histiocytic diseases in the splenic form.

TREATMENT
- Surgical excision—difficult owing to local invasive nature; recurrence rate is high.
- Amputation of an affected limb—may be appropriate, however considerable metastatic risk; thoracic and abdominal radiographs and abdominal ultrasound critical for evaluating detectable metastasis before surgical treatment.
- Radiotherapy may be helpful as adjuvant treatment for localized tumor not amenable to complete surgical resection. Expected local tumor control rates may be similar to other high-grade soft tissue sarcomas.

MEDICATIONS

DRUG(S) OF CHOICE
Chemotherapy—may be helpful in residual, high-grade tumor or metastatic disease setting; doxorubicin-based protocols are most popular (dose for canine patients >10 kg, 30 mg/m^2 IV every 3 weeks; patients <10 kg, 1 mg/kg IV every 3 weeks).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Reexamination—metastatic potential would suggest physical examination and possible imaging; monthly for 3 months, then every 3 months thereafter.

POSSIBLE COMPLICATIONS
Temporary acute side effects (e.g., moist dermatitis and alopecia) may be expected with radiation therapy, and consultation with a radiation oncologist is recommended regarding specific, anatomic site-related side effects.

M

MALOCCLUSIONS—SKELETAL AND DENTAL

BASICS

OVERVIEW

• Malocclusion is any deviation from normal occlusion due to abnormal positioning of a tooth (dental malocclusion) or due to asymmetry or deviation of bones that support the dentition (skeletal malocclusion).
• Ideal occlusion:
  ◦ Maxillary incisors positioned rostral to the mandibular incisors.
  ◦ Mandibular canine is inclined labially and bisects the space between the opposing maxillary third incisor and canine.
  ◦ Maxillary premolars do not contact the mandibular premolars; mandibular premolar crowns are positioned lingual to the maxillary premolars; mandibular premolar crown cusps bisect the interdental spaces rostral to the corresponding maxillary premolar.
  ◦ Maxillary fourth premolar mesial cusp is lateral to the space between the mandibular fourth premolar and first molar.

Terms of Malocclusion (American Veterinary Dental College Nomenclature)

• Neutroclusion (Class 1)—a normal rostral–caudal relationship of the maxillary and mandibular dental arches with malposition of one or more individual teeth (dental malocclusion); rostral (anterior) crossbite; mesioversion ("lance tooth"), linguoversion ("base-narrow" mandibular canine), and caudal (posterior) crossbite.
• Mandibular distoclusion (Class 2)—an abnormal rostral–caudal relationship in which the mandibular arch occludes caudal to its normal position relative to the maxillary arch (skeletal malocclusion).
• Mandibular mesioclusion (Class 3)—an abnormal rostral–caudal relationship in which the mandibular arch occludes rostral to its normal position relative to the maxillary (skeletal malocclusion).
• Asymmetrical skeletal malocclusion—maxillary–mandibular asymmetry that can occur in a rostro-caudal direction (unilateral abnormal relationship), in a side-to-side direction (loss of midline alignment), or in a dorso-ventral direction with abnormal vertical space between opposing dental arches (open bite).

SIGNALMENT

Species

Dogs and cats.

Breed Predilections

Breed predilection for certain malocclusions, some within breed standards.

Mean Age and Range

Malocclusion usually apparent after eruption of teeth (permanent or deciduous).

SIGNS

• Vary greatly according to type, extent, and consequent injuries caused by the malocclusion.
• May be associated with open or closed bites or overcrowding of the teeth.
• Periodontal disease—from crowding or misalignment of teeth.
• Soft tissue defects—from traumatic tooth contact; may be seen in the floor of the mouth and palate; palatal trauma may eventually result in oronasal fistula formation.
• Fractures or attrition (wear) of teeth—may result from improper tooth contact.

Class 1 Malocclusions

• Rostral crossbite—palatally displaced maxillary incisor(s) or labially displaced mandibular incisor(s); level bite—maxillary and mandibular cusps contact directly.
• Linguoversion base-narrow canines—tips of mandibular canines touch palate lingual to normal contact point, just labial to the diastema between corner incisor and maxillary canine (linguoversion).
• Lance teeth—mesioversion of maxillary canine(s); the diastema between the corner incisor and this canine is often diminished and may force the mandibular canine into an abnormal position. Dolichocephalic breeds (e.g., shelties and collies).
• Caudal crossbite—one or more mandibular cheek teeth buccal to maxillary teeth; more common in dolichocephalic breeds (e.g., collies, shelties, some sight hounds).

CAUSES & RISK FACTORS

• Congenital or hereditary factors—skeletal malocclusions (Classes 2, 3, and 4) and breed predilection.
• Impediment to tooth eruption—operculum; retention of soft tissue covering.
• Delayed eruption of deciduous or permanent teeth.
• Retention (persistent) or delayed loss of deciduous teeth; permanent mandibular canines (and most other teeth) will erupt lingual to persistent deciduous teeth; the permanent maxillary canine will erupt rostral to the deciduous tooth.
• Traumatic injury affecting the jaws or teeth.

Risk Factors

Hereditary predispositions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Tooth displacement—due to trauma, oral masses, or other causes.
• Mechanical block—due to jaw fractures, luxated or subluxated teeth, or foreign bodies causing open bite.
• Examine breed standards to determine what might be acceptable for the breed.

CBC/BIOCHEMISTRY/URINALYSIS

Generally normal.

IMAGING

• Oral photography—pre-, peri-, and post-therapy.
• Intraoral radiography—to evaluate roots and abnormalities, jaw anatomy, root maturity.

DIAGNOSTIC PROCEDURES

• Complete oral examination to assess other oral abnormalities, including persistent deciduous teeth.
• Impressions and models—for evaluation and appliance production.

TREATMENT

Appropriate Health Care

• The accurate assessment of abnormalities of occlusion will help determine if treatment is warranted and what treatment is appropriate.
• Extraction of affected teeth can many times be an effective alternative to more classic orthodontic treatments.
• If the bite is functional and nontraumatic to the animal, treatment may not be necessary. Extraction (or crown reduction with pulp capping) of offending teeth can often be an effective alternative to more classic orthodontic treatments. Orthodontic treatment is usually based on prevention of improper contact trauma, wear, or injury to hard or soft tissues, and should only be performed by a trained individual.

Diet

Soft diet with appliances.

Client Education

Home Care with Appliance

• Examine the appliance twice daily.
• Flush the mouth with an oral hygiene solution or gel.
• Prevent chewing of items and provide a soft diet until the appliance is removed.

Surgical Considerations

Permanent Tooth Class 1 Malocclusion

• Treatment primarily involves tipping movements of the teeth, although extrusion may be required to provide proper retention.
• Rostral crossbite—correction for esthetics not recommended.
• Linguoversion mandibular canine teeth—prevention of contact trauma, pain and discomfort, and oronasal fistula formation.
  ◦ The maxillary diastema must be sufficient for the mandibular canine to fit; natural retention once corrected.
  ◦ Early intervention with manual manipulation or "ball therapy" for newly

M

erupting teeth may influence a more buccal position.
  - A hard rubber ball is placed in the mouth to help "slide" the canines laterally; two to three times daily, a few minutes at a time.
  - Gingivoplasty in the diastema may release the tooth if there is minimal maxillary mucosal contact.
  - A composite crown extension can help splay the tip buccal to the gingival margin.
  - More severe cases may require an orthodontic appliance (incline plane), to be handled by a specialist.
  - Mandibular canine extraction or crown reduction with vital pulp therapy.
- Maxillary canine mesioversion (Lance tooth): complicated movement; handled by specialist.
- Caudal crossbite—in traumatic situations, extraction of one of the offending teeth; orthodontic correction would be long and tedious.

Permanent Tooth Class 2, 3, and Asymmetrical Malocclusion
- If malocclusion is functional and nontraumatic, treatment may not be necessary.
- May require advanced orthodontic and surgical procedures by a specialist.

Deciduous Tooth Class 1 Malocclusion
Careful and gentle extraction of the malocluded deciduous tooth (interceptive orthodontics) in hopes that the permanent tooth will erupt in the appropriate position; when performed at least 4 weeks prior to permanent tooth eruption, success rate >80% is not uncommon.

Deciduous Tooth Class 2, 3, and 4 Malocclusion
Careful and gentle extraction of the malocluded deciduous tooth in hopes that the short jaws will be released from the bite interlock, allowing it to grow (if the genetic potential is present), performed at least 6 weeks prior to permanent tooth eruption, success rate <20% is common.

FOLLOW-UP

PATIENT MONITORING
- For the corrected occlusion to be stable, it needs to be self-retaining, or it may tend to revert to malocclusion; examine at 2 weeks, 2 months, and 6 months after the treatment is complete to see if desired outcome is stable.
- Radiographs at 6 months post therapy for radiographs to evaluate roots and teeth for any changes.

PREVENTION/AVOIDANCE
- Selective breeding based on preferred breed characteristics.
- Careful monitoring of deciduous and permanent tooth eruption for early detection and treatment, if required.

POSSIBLE COMPLICATIONS
- Deciduous tooth extractions—potential injury to underlying permanent tooth buds; injuries may result in tooth buds dying, teeth becoming nonvital as they erupt, root dysplasia or dilaceration, crown enamel hypoplasia, or hypomineralization.
- Orthodontic movement of permanent teeth—several conditions may result, including movement of anchor teeth, root resorption, root ankylosis, or nonvitality of the tooth; these conditions are uncommon in properly managed orthodontic procedures.

EXPECTED COURSE AND PROGNOSIS
- Course of treatment may vary with the type of malocclusion and the animal's nature and habits (e.g., inappropriate chewing).
- Generally, most cases take 1–7 months for movement and retention phase, depending on severity and if extrusion of tooth/teeth is required for stabilization of the bite. Prognosis is good to excellent in most treated patients.
- Prognosis is fair to good in most untreated malocclusions.
- Complications in untreated cases—periodontal disease; attrition or fractures of teeth; trauma to soft tissues; oronasal fistula formation; drying or desiccation of exposed tooth surfaces, resulting in beige to brown discoloration.
- Some cases do *not* need or require orthodontic intervention; only routine observation for early detection and treatment of any secondary complications (e.g., periodontal disease, worn or chipped teeth) is advised.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Lack of head symmetry.
- Oral soft tissue trauma.
- Chipped teeth.
- Desiccation of exposed tooth surfaces.
- Periodontal disease.

PREGNANCY/FERTILITY/BREEDING
Although animals have the medical right to as functional and correct an occlusion as can be reasonably provided by therapy, animal club rules, professional association principles, and state and national laws may conflict with an animal's right to proper medical therapy. Some kennel club rules disqualify animals with modification to natural appearance (with certain exceptions), and owners should be made aware of this. If hereditary involvement is suspected, inform the owner. If treatment is being considered, the owner or agent should acknowledge his or her responsibility to inform anyone who has the right to know of such alterations. Additionally, the possibility of removing the animal from the genetic pool by appropriate methods should be discussed.

MAMMARY GLAND HYPERPLASIA—CATS

BASICS

OVERVIEW
Benign enlargement of one or more mammary glands.

SIGNALMENT
- Young, intact, cycling, or pregnant queens.
- Cats of either gender after gonadectomy (rare in tom).
- Cats of either gender that are receiving exogenous progestogen (e.g., megestrol acetate).
- Less often in older (9–12 years) pregnant queens.

SIGNS
- Localized or diffuse rapid (2–5 weeks) enlargement of one or more mammary glands.
- Firm and nonpainful masses in uncomplicated cases.
- No concurrent signs of systemic illness.

CAUSES & RISK FACTORS
- Exaggerated proliferation secondary to an endogenous progesterone influence (pregnancy, pseudopregnancy) or exogenous progestogens (megestrol or medroxyprogesterone acetate).
- May develop after gonadectomy; pathogenesis may involve progesterone, growth hormone, prolactin, insulin-like growth factors. Suspect ovarian remnant syndrome.
- Reported in one male with adrenocortical carcinoma producing steroid hormones.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Mastitis—lactating queen; mammary glands erythematous and painful; systemic illness with fever and immature neutrophilia; inflammatory cells and bacteria in fluid expressed from the affected gland(s).
- Mammary neoplasia—old queens (>6 years); gross appearance may be indistinguishable; irregular shape and margins, heterogeneous echogenicity on ultrasound; differentiated by biopsy or fine-needle aspirate of affected tissue.

CBC/BIOCHEMISTRY/URINALYSIS
Normal; leukocytosis possible if secondary mastitis present.

OTHER LABORATORY TESTS
Progesterone analysis—confirm exposure or ovarian remnant syndrome.

IMAGING
- Transabdominal ultrasonography—to rule out pregnancy.
- Ultrasonography of affected gland(s)—homogeneous parenchyma, round or oval with regular margins.

DIAGNOSTIC PROCEDURES
- Cytologic examination of fluid expressed from affected glands—noninflammatory.
- Fine-needle aspirates of affected glands may help to diagnose neoplasia and inflammation.
- Excisional biopsy—benign fibroglandular proliferation with no inflammation or necrosis.

TREATMENT
- Hyperplasia owing to high endogenous progesterone—regresses when progesterone falls at the end of false pregnancy or gestation; consider ovariohysterectomy if preservation of fertility is not desired.
- Hyperplasia owing to exogenous progestagens—regresses when medication is withdrawn.
- Hyperplasia developing after gonadectomy—suspect ovarian remnant; surgical removal of remnants indicated.
- In uncomfortable animals, may attempt progesterone receptor blockers (aglepristone), prolactin inhibitors (bromocriptine, cabergoline), testosterone.
- Mastectomy, systemic antibiotics, or supportive care may be needed with complications.

MEDICATIONS

DRUG(S) OF CHOICE
- Bromocriptine mesylate 0.25 mg (per cat) PO q24h for 5–7 days; not approved for use in cats; may cause nausea. Can divide daily dose q12h to decrease nausea.
- Metoclopramide 0.2 mg/kg PO q6–8h for nausea.
- Cabergoline 5 µg/kg PO q24h for 5–7 days.
- Aglepristone 10–15 mg/kg SC on 2 consecutive days or 20 mg/kg SC once a week until resolution; not approved for use in cats, not readily available in the United States.
- Testosterone cypionate or testosterone enanthate 2 mg/kg IM once; not approved for use in cats.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Aglepristone—pregnant animals will abort. May see dermatitis at the site of injection.
- Dopamine agonists—pregnant animals will abort; may cause vomiting.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Remission within 4 weeks after the end of pseudopregnancy or gestation, withdrawal of progestins, ovariectomy, or aglepristone treatment.
- Unknown likelihood of recurrence in cats left intact.
- Unknown correlation with other abnormal conditions of the reproductive tract.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Fertility not affected after aglepristone treatment.

SEE ALSO
Ovarian Remnant Syndrome.

MAMMARY GLAND TUMORS—CATS

BASICS

DEFINITION
Malignant and benign tumors of the mammary glands in cats.

PATHOPHYSIOLOGY
• The majority of mammary gland tumors are malignant (85–95%) and tend to have an aggressive biologic behavior. Most malignant mammary tumors are adenocarcinomas; sarcomas are rare. • Exposure to ovarian hormones and exogenous progestin increases risk of mammary tumor development. Intact cats have a 7-fold increased risk of developing mammary tumors as compared to spayed cats. Spaying cats prior to 1 year of age greatly reduces risk of mammary tumor development. • While less common at diagnosis, pulmonary metastasis occurs in up to 80% of cats. Regional lymph node metastasis is common at diagnosis and may occur in up to 45% of cats. At necropsy, metastasis is identified in >90% of cats; other sites of metastasis may include liver, spleen, kidney, adrenal gland, pleura, peritoneum, and bone. • Inflammatory mammary carcinomas are rare. These are anaplastic carcinomas with considerable inflammatory cell infiltrates, and are associated with extensive local ulceration, edema, and pain, as well as rapid metastasis.

SYSTEMS AFFECTED
• Reproductive—mammary glands.
• Metastasis can affect any organ system, especially the respiratory and lymphatic systems.

GENETICS
The high incidence of mammary tumors in Siamese cats suggests a genetic component to this disease, but specific genes have not been identified to date.

INCIDENCE/PREVALENCE
• Third most common neoplasia in cats (after lymphoma and skin tumors). • The estimated incidence rate is 12.8–25.4 per 100,000 cats.

SIGNALMENT

Species
Cat

Breed Predilections
• Domestic shorthair and longhair breeds are affected most commonly, but likely reflects the popularity of these breeds rather than a true predilection. • Siamese cats have twice the risk of other breeds for developing mammary tumors.

Mean Age and Range
• Mean—10–12 years. • Range—9 months to 23 years; most are >5 years of age.
• Siamese cats tend to be diagnosed with mammary tumors at a younger age (mean of 9 years). • Male cats tend to be diagnosed with mammary tumors at an older age (mean of 12.8 years).

Predominant Sex
• Females predominate with only 1–5% of mammary carcinomas occurring in male cats.
• While being intact increases the risk of mammary tumors (see Risk Factors), most cats diagnosed with mammary tumors are spayed.

SIGNS

Historical Findings
• Most cats present for evaluation of a palpable ventral abdominal mass. • Cats with advanced metastatic disease may present for general signs of illness (e.g., lethargy or anorexia) or for signs attributable to a specific site of metastasis (e.g., dyspnea due to pulmonary metastasis or pleural effusion).
• The duration of clinical signs can vary from days to several months.

Physical Examination Findings
• Mammary masses can be discrete or infiltrative, soft or firm. Smaller masses often are freely moveable, whereas larger masses can adhere to the underlying abdominal musculature. • The overlying skin is often intact for smaller tumors, but larger tumors may be ulcerated and inflamed. • The associated nipple may be inflamed and exude serous fluid. • Any gland can be affected, although the caudal two glands are affected more commonly. Left and right sides are affected with equal frequency. • Up to 60% of cats will have multiple tumors on the same and/or opposite mammary chain. • Axillary or inguinal lymphadenopathy (reactive or metastatic) may be present. • Cats with inflammatory carcinomas present with severe ulceration, erythema, pain, and edema in the ventral abdomen and pelvic limbs.

CAUSES
Unknown

RISK FACTORS
• Compared to intact cats, those spayed at <6 months of age or 6–12 months had a 91% and 86% risk reduction, respectively, for mammary carcinoma development, suggesting that hormonal influence is significant.
• There is no obvious protective effect when cats are spayed at >12 months of age.
• Exogenous progestins (e.g., medroxyprogesterone acetate) increase the risk of benign and malignant mammary tumor development in female and male cats. In one study, 8 of 22 male cats with mammary carcinomas had a history of exogenous progestin therapy. • Parity has not been shown to affect mammary tumor development.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Fibroepithelial hyperplasia—especially in young (<2 years) intact female cats, and older or spayed cats receiving exogenous progestins. • Mastitis. • Other cutaneous or subcutaneous tumors. • Inguinal or axillary lymphadenopathy (reactive or neoplastic). • Inguinal hernia. • Large/prominent inguinal fat pad.

CBC/BIOCHEMISTRY/URINALYSIS
Usually unremarkable.

OTHER LABORATORY TESTS
Coagulation profile recommended for cats with suspected inflammatory carcinomas due to the high incidence of secondary disseminated intravascular coagulopathy.

IMAGING
• Three-view thoracic radiographs are recommended to screen for pulmonary metastasis, pleural effusion, and/or sternal lymphadenomegaly. Pulmonary metastases commonly appear as ill-defined interstitial nodules or a diffuse pulmonary pattern, although well-defined interstitial nodules are seen occasionally. Malignant pleural effusion is common and can obstruct adequate visualization of pulmonary parenchyma.
• Abdominal ultrasound is recommended to screen the medial iliac lymph nodes and other abdominal viscera for metastases. • Ultrasound also can be used to visualize nonpalpable axillary or inguinal lymph nodes, as well as to look for additional small masses within the mammary glands.

DIAGNOSTIC PROCEDURES
• Cytology can be useful for ruling out other nonmammary malignancies. However, it is not useful for distinguishing between benign and malignant mammary masses.
• Histopathologic evaluation is needed to reach a definitive diagnosis. Since most mammary tumors are malignant, this is usually performed on tissue removed during radical mastectomy (see Treatment). While not contraindicated, incisional biopsies are routinely recommended only for cats with advanced-stage disease that are not candidates for aggressive local surgery. • All tissue removed must be submitted for histopathologic evaluation. This allows for the most accurate diagnosis, and also allows for evaluation of surgical margins for completeness of excision. • The ipsilateral draining lymph nodes (axillary and inguinal) should be removed whenever possible and submitted separately for histopathologic evaluation, even if grossly normal. • Cytology of pleural fluid

MAMMARY GLAND TUMORS—CATS (CONTINUED)

can be useful for confirming intrathoracic metastasis.

PATHOLOGIC FINDINGS

• The most common histologic subtypes are tubulopapillary, cribriform, and solid carcinomas. • Histologic subtype has not consistently been shown to affect prognosis, but there is some evidence that tubulopapillary carcinomas carry a better prognosis. • Tumor grade, based on degree of tubule formation, nuclear and cellular pleomorphism, and mitotic index, is predictive of survival after surgery. • Vascular and lymphatic invasion is associated with more advanced clinical stage and shorter disease-free interval after treatment. • Mammary sarcomas are rare but potentially slow to metastasize. • Benign histologic subtypes are uncommon and may include mammary adenomas, ductal adenomas, fibroadenomas, and intraductal papillary adenomas.

M

TREATMENT

APPROPRIATE HEALTH CARE

• Surgery is recommended for cats with gross disease confined to the mammary glands with or without regional lymph node involvement. • Adjuvant chemotherapy is recommended after the cat has recovered from surgery. • Chemotherapy can be used as a sole treatment modality for cats with nonsurgical local disease and/or distant metastasis, although long-term control would not be expected to be durable. • Radiation therapy has not been evaluated. • Palliative pain therapy is recommended for cats with nonresectable local disease or gross metastasis, or when definitive therapy is declined.

CLIENT EDUCATION

• Stress the benefits of early ovariohysterectomy (<6 months of age) in nonbreeding cats. • Stress the importance of early detection and aggressive treatment as small tumors (<2 cm) have a better prognosis.

SURGICAL CONSIDERATIONS

• Radical mastectomy of the affected mammary chain(s) is recommended. This significantly reduces the risk of local tumor recurrence as well as recurrence in the lymphatic vessels coursing through the mammary tissue. • Bilateral radical mastectomy, regardless of tumor location, has been shown to lead to deceased rates of local tumor recurrence, new mammary tumor development, and metastasis as well as increased survival time as compared unilateral mastectomy. Mastectomies are usually staged 2–4 weeks apart as performing bilateral mastectomies in a single surgical procedure is associated with increased risk of incisional dehiscence and/or infections and, less commonly, respiratory difficulty. • The inguinal and (if possible) axillary lymph nodes should be removed at the same time, regardless if they are normal in size. • In cats with advanced metastatic disease, palliative local mastectomy can be considered to remove an ulcerated or infected tumor.

MEDICATIONS

DRUG(S) OF CHOICE

• Doxorubicin 25 mg/m^2 IV every 3 weeks, alone or in combination with cyclophosphamide 100 mg/m^2 IV or PO divided over 4 days. • Mitoxantrone, carboplatin, and docetaxel might have activity. • Consult with an oncologist for current chemotherapy recommendations. • Palliative analgesics and antibiotics should be considered for cats with tumors that are painful and/or ulcerated.

CONTRAINDICATIONS

Use doxorubicin with caution in cats with renal or hepatic insufficiency.

PRECAUTIONS

If you are unfamiliar with chemotherapy, consult an oncologist before administering.

FOLLOW-UP

PATIENT MONITORING

• Thorough physical examination conducted monthly for the first 3 months, then every 2–3 months thereafter is recommended. Palpation of the previous incision line, the remaining mammary glands (if only unilateral radical mastectomy performed), and regional lymph nodes should be emphasized during examination. • Three-view thoracic radiographs every 2–3 months for detection of metastases. • Consider abdominal ultrasound every 2–3 months to monitor for local lymph node metastasis.

PREVENTION/AVOIDANCE

Ovariohysterectomy prior to 6 months of age is associated with a 91% risk reduction in the development of mammary carcinoma.

POSSIBLE COMPLICATIONS

Malignant pleural effusion may develop rapidly causing life-threatening dyspnea.

EXPECTED COURSE AND PROGNOSIS

• Most cats die from local recurrence and/or metastasis. • Tumor size is strongly predictive of prognosis. For tumors ≤2 cm in diameter median survival is >4.5 years (14 months in males), for tumors 2–3 cm it is 1–2 years (5–6 months in males), for tumors >3 cm it is 4–6 months (1–2 months in males). • Radical mastectomy significantly reduces the risk for local tumor recurrence. The impact on survival is not as consistent because of the high metastatic rate associated with this tumor. • In retrospective studies, adjuvant chemotherapy (doxorubicin with or without cyclophosphamide) has not consistently improved disease-free interval or survival. However, chemotherapy has proven efficacy against nonresectable and metastatic feline mammary tumors (gross disease), and given the high metastatic rate of these tumors adjuvant chemotherapy is still strongly recommended. • For cats with advanced-stage disease treated with chemotherapy alone, response rates are around 50%. Survival times are 6–12 months for cats that do have a positive response to treatment, <6 months for those that do not.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

• Given the possible genetic contribution to this disease, particularly in Siamese cats, breeding affected cats is not recommended. • Chemotherapy is not recommended in pregnant queens, particularly during the early stages of pregnancy.

MAMMARY GLAND TUMORS—DOGS

BASICS

DEFINITION
Benign or malignant tumors of the mammary glands in dogs.

PATHOPHYSIOLOGY
- Estrogen can exert direct genotoxic effects on mammary epithelium leading to mutations and aneuploidy.
- Progesterone may increase growth hormone and growth hormone receptor expression by the mammary gland, leading to increased insulin-like growth factor-1 (IGF-1) which is associated with proliferation and survival.
- Most dogs develop multiple tumors due to entire mammary tissue exposed to sex hormones during puberty, i.e., "field carcinogenesis."
- Mammary gland tumors are a continuum from benign to malignant.
- Obesity decreases sex hormone-binding globulin, leading to increased concentration of free estrogen.

SYSTEMS AFFECTED
- Reproductive.
- Metastasis—lymphatic, respiratory, skeletal, nervous, and other systems.

GENETICS
Germline mutations of *BRCA-1* and *-2* and *CDK5RAP2* genes reported in English springer spaniels.

INCIDENCE/PREVALENCE
Constitute 50–70% of all tumors in female dogs; 71% of all female beagles developed at least one mammary neoplasm.

SIGNALMENT

Breed Predilections
Toy and miniature poodle, English springer spaniel, Brittany spaniel, cocker spaniel, English setter, boxer, English pointer, German shepherd dog, Maltese, Samoyed, schnauzer, Doberman pinscher, shih tzu, and Yorkshire terrier.

Mean Age and Range
Uncommon in dogs <5 years; mean age 9–11 years (malignant) and 7–9 years (benign).

SIGNS
- 70% of patients have multiple tumors.
- Caudal mammary glands more commonly affected.
- Discrete, well-circumscribed mass in systemically healthy patient.
- Inflammatory carcinoma—diffuse edematous, warm, painful mammary chains.
- Inflammatory carcinoma associated with distant metastasis and systemic illness.

CAUSES
Unknown; likely hormonal.

RISK FACTORS
- Age.
- Breed—more common in small breeds than in large breeds.
- Hormone influence (see Prevention/Avoidance).
- Obesity during puberty increases risk. Underweight at 9–12 months of age associated with protective effect.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Lipoma.
- Mast cell tumor.
- Mammary hyperplasia.
- Mastitis.
- Soft tissue sarcoma.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
N/A

IMAGING
- Thoracic radiography may detect metastasis and three views are advised.
- CT is more sensitive for detection of pulmonary metastasis than are plain radiographs.
- CT lymphography could aid in the assessment of sentinel lymph node metastasis.
- Abdominal radiography may detect metastasis to regional lymph nodes or vertebrae.
- Abdominal sonography to evaluate for regional or distant metastasis.

DIAGNOSTIC PROCEDURES
- Fine-needle aspirate cytology—67.5–93% correlation with histopathology; 88% sensitivity and 96% specificity for malignancy.
- Fine-needle aspirate cytology of local lymph node(s).
- Histologic evaluation for definitive diagnosis. Request margin evaluation.

PATHOLOGIC FINDINGS
- There is a wide histologic spectrum of mammary tumors. Dogs may have concurrent benign and malignant tumors. Histologic examination of all excised masses is indicated.
- Histologic grading 1 (well-differentiated) to 3 (poorly differentiated) based on tubule formation, nuclear pleomorphism, and mitotic index valid for epithelial tumors only.
- Stromal invasion, vascular/lymphatic invasion, and lymph node status important.
- Complex carcinoma is more common than simple carcinoma.

TREATMENT

APPROPRIATE HEALTH CARE
- Surgery—primary mode of treatment. Completeness of excision is prognostic.
- Chemotherapy—may be effective and indicated for patients with high risk of metastasis or recurrence: histologic high grade or subtype, lymphatic/vascular invasion, stage III or higher.

CLIENT EDUCATION
- Advise client that a mammary lump should be evaluated by a veterinary health professional.
- Inform client that early surgical intervention is best.
- Advise ovariohysterectomy at time of tumor removal.

SURGICAL CONSIDERATIONS
- Type of surgery determined by therapeutic intent: curative intent with wide excision; preventative with chain mastectomy; palliative intent for advanced disease.
- Consider age, tumor size, number of tumors, history of prior tumors, and clinical stage.
- Most patients with inflammatory carcinoma are poor surgical candidates due to profound diffuse microscopic disease, advanced stage, systemic illness, and local coagulopathies.
- 58% of dogs treated with regional mastectomy will develop a new tumor in the ipsilateral chain; increased risk if initial tumor is malignant (>70%).
- Current recommendations for single tumor of unknown histology: wide excision to achieve complete removal is the adequate surgical "dose," i.e., 2 cm lateral margins and 1 fascial plane deep.
- Extirpation of the draining lymph node is advised. Immunohistochemistry may be indicated to detect occult metastasis.
- Ovariohysterectomy (OHE) concurrent with tumor removal may decrease the risk of relapse in dogs with grade 2, estrogen receptor-positive tumors, or dogs with increased presurgical serum estradiol.
- Remove tumor following abdominal closure if performing concurrent OHE to avoid tumor seeding of abdomen or incision.

MEDICATIONS

DRUG(S) OF CHOICE
- Always consult a veterinary oncologist for updated information.
- Nonsteroidal anti-inflammatory drug (NSAID) as sole adjuvant therapy.
- Doxorubicin 30 mg/m^2 IV (dogs >15 kg)

M

MAMMARY GLAND TUMORS—DOGS (CONTINUED)

every 21 days (maximum 6 treatments).
• NSAID ± chemotherapy for inflammatory carcinoma.

CONTRAINDICATIONS
Doxorubicin—myocardial failure.

PRECAUTIONS
Chemotherapy may be toxic; seek advice before treatment if you are unfamiliar with cytotoxic drugs.

POSSIBLE INTERACTIONS
Doxorubicin—potential side effects include myelotoxicity, vomiting, diarrhea, and cardiac damage.

ALTERNATIVE DRUG(S)
• Carboplatin, mitoxantrone, gemcitabine, fluorouracil (5-FU), cyclophosphamide have been reported with varying impact on clinical outcome.
• Perioperative desmospressin for grade 2–3 carcinoma may improve survival.
• Tamoxifen—helpful in some humans with breast cancer; ineffective in dogs and has serious side effects (e.g., pyometra); do not use in dogs.

FOLLOW-UP

PATIENT MONITORING
Physical examination, abdominal sonography, and thoracic radiographs—1, 3, 6, 9, 12, 15, 18 months after treatment, then every 6 months thereafter.

PREVENTION/AVOIDANCE
• Spayed before first estrous cycle—0.5% lifetime risk of developing tumor.
• Spayed before second estrous cycle—8.0% lifetime risk.
• Spayed after second estrus—26% lifetime risk.
• Spayed after 2.5 years of age—no sparing effect on risk.

POSSIBLE COMPLICATIONS
• Infection or dehiscence with surgery.
• Myelosuppression with chemotherapy.
• Disseminated intravascular coagulation (DIC) with some (especially inflammatory carcinomas) types.

EXPECTED COURSE AND PROGNOSIS
• 50–70% of canine mammary tumors are malignant.
• 50% of malignant tumors metastasize.
• 58–70% of dogs will develop another tumor in the ipsilateral chain.
• Tumor diameter is strong predictor of local recurrence and distant metastasis and is a negative, independent prognosticator of survival.
• Lymph node status, histologic grade, and proposed World Health Organization (WHO) clinical stage (I–V) are most consistent prognostic factors.
  ◦ Stage I: Tumor size <3 cm, no regional or distant metastasis—complete excision has excellent prognosis.
  ◦ Stage II: Tumor 3–5 cm, no regional or distant metastasis—complete excision has excellent prognosis.
  ◦ Stage III: Tumor >5 cm, no regional or distant metastasis—median survival 10 months with surgery alone.
  ◦ Stage IV: Any tumor size, lymph node metastasis, no distant metastasis—median survival time 5–10 months with surgery.
  ◦ Stage V: Any tumor size, any lymph node status, evidence of distant metastasis—median survival time <6 months.
• Clinical stage, presence of lymphatic invasion, ulceration, and incomplete surgical margins are reported as independent negative prognostic factors.
• Complex carcinoma and simple tubular carcinoma associated with prolonged survival
• Simple tubulopapillary carcinoma, intraductal papillary carcinoma, and malignant myoepithelioma carries 10-fold higher risk of tumor-related death
• Adenosquamous carcinoma may have a high recurrence rate (50%).
• Anaplastic carcinoma and carcinosarcoma carry worst prognosis (<3 months) with >90% metastatic rate.
• Inflammatory carcinoma median survival time <3 months.
• WHO clinical stage may be applicable to noninflammatory epithelial tumors.
• Simple carcinoma and grade 1 tumors more commonly associated with stages I, II, or III.
• Lymph node invasion and less cellular differentiation more common in complex carcinoma than simple carcinoma.
• High COX2/CD31 or high COX2/VEGF coexpression have been associated with a decreased survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Paraneoplastic glomerulopathy and proteinuria.
• Hypertrophic osteopathy.
• Metastasis to lymph nodes, lungs, and CNS.

PREGNANCY/FERTILITY/BREEDING
• Treatment with progestin increases the chance of tumor development at a younger age.
• Treatment with progestin increases risk of development of benign tumor.
• Treatment with progestin and estrogen increases risk of malignant tumor development.

ABBREVIATIONS
• 5-FU = fluorouracil.
• DIC = disseminated intravascular coagulation.
• IGF-1 = insulin-like growth factor-1.
• NSAID = nonsteroidal anti-inflammatory drug.
• OHE = ovariohysterectomy.
• WHO = World Health Organization.

MARIJUANA TOXICOSIS

BASICS

OVERVIEW

• Marijuana is a general term that typically refers to *Cannabis sativa* or *C. indica* plants and is synonymous with cannabis. Its legal status in North America has changed substantially in the past decade and varies based on the country and state. • Of the 100+ cannabinoids in marijuana, the primary psychoactive compound (i.e., induces a "high") is δ-9-tetrahydrocannabinol (THC). THC is likely responsible for the clinical signs of poisoning in pets. • THC extracts can be added to foods or sold in a wide variety of products such as tinctures, capsules, oils, sublingual sprays, topical creams, bath bombs, even suppositories, or made into "concentrates"—wax-like formulations which are smoked or vaped. • The minimum lethal dose of marijuana plant material is greater than 3 g/kg for dogs. • THC binds to endocannabinoid receptors CB1 and CB2. • Cannabidiol (CBD), a cannabinoid commonly used in medical cannabis or sold as a "supplement" for pets and people, is not psychoactive although, depending on the quality of the product, some may inadvertently contain THC.
• Commonly affected organ systems are cardiovascular, gastrointestinal, nervous, ophthalmic, respiratory, renal/urologic.

SIGNALMENT

Younger animals may be overrepresented due to an increased tendency to ingest foreign items.

SIGNS

• Often begin 0.5–2 hours after ingestion; may begin in minutes following inhalation. • Lethargy, ataxia, vomiting, glazed eyes, mydriasis, depression, hypothermia, trembling, urinary incontinence. • Higher doses may cause bradycardia, hypotension, and coma. Nystagmus, vocalization, sinus tachycardia, seizures, and hyperthermia may also occur.

CAUSES & RISK FACTORS

• Intoxication occurs via ingestion of foods containing THC, medical cannabis products, marijuana "concentrates," or inhalation of marijuana smoke. Pets in homes of recreational or medical marijuana users are at greater risk for exposure. • Of the cases reported to Pet Poison Helpline, an animal poison control center, about 65% involve food products, the majority of which also contain chocolate. Such foods may contain other toxic ingredients such as raisins, macadamia nuts, xylitol, etc. • Regions with marijuana dispensaries correlate to increased exposures.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other illicit drugs—LSD (lysergic acid diethylamide), PCP (phencyclidine), hallucinogenic mushrooms. • Opioids (greater cardiac/respiratory depression, miosis, reversed with naloxone), benzodiazepines, muscle relaxants, ethanol, ethylene glycol (metabolic acidosis, crystalluria), methanol, diethylene glycol, propylene glycol, tranquilizers, depressants, xylitol (hypoglycemia).

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities but should be used to rule out other causes.

OTHER LABORATORY TESTS

• Human urine drug tests are generally unreliable and may result in false negatives. A positive result can typically be considered a true positive. • Serum, stomach contents and/or urine can be submitted to diagnostic labs for confirmatory testing.

IMAGING

No specific abnormalities but abdominal radiography is useful if an obstruction is suspected (e.g., ingestion of a baggie containing marijuana, packaging of a food product).

TREATMENT

• Mildly affected patients may not require intervention and can be kept in a low-stimulatory, protective environment. • Treatment is focused on decontamination and supportive care. Induce emesis following recent (<2 hours) ingestion in asymptomatic patients if they have not already vomited. If symptomatic, gastric lavage should be considered for large ingestions or if concentrated products were ingested. • Activated charcoal q8h for 2–3 doses if severe signs.
• Warming/cooling measures as needed. • IV fluid support if poor perfusion parameters or dehydration. • Oxygen if respiratory depression. • Provide ocular lubricant and rotation to comatose animals.

MEDICATIONS

DRUG(S) OF CHOICE

• Antiemetics (e.g., maropitant 1 mg/kg SQ, IV q24h dogs or cats) as needed. • Diazepam (0.5–1 mg/kg IV PRN dogs or cats) or butorphanol (0.1–0.4 mg/kg IM or IV dogs or cats) for CNS stimulation, anxiety, agitation.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Use acepromazine cautiously due to risk of hypotension. • Use phenobarbital cautiously due to the risk of severe sedation and respiratory depression.

FOLLOW-UP

PATIENT MONITORING

Monitor temperature, pulse, and respiration q2–3h until normal. Monitor blood pressure in severe cases (hypotension).

PREVENTION/AVOIDANCE

• Educate pet owners about the risks of leaving cannabis products, especially food, accessible to pets. Stress that pets will readily consume such products. • Keep pets confined during parties.

EXPECTED COURSE AND PROGNOSIS

• Clinical signs may last up to 24 hours in mild cases and may be monitored at home.
• Clinical signs may persist for several days in severe cases, especially if a large dose were ingested. • The prognosis is excellent with appropriate care. • Death is rare but has been reported in dogs ingesting foods made with marijuana butter.

MISCELLANEOUS

ABBREVIATIONS

• CBD = cannabidiol.
• THC = δ-9-tetrahydrocannabinol.

Suggested Reading

M

MARKING, ROAMING, AND MOUNTING BEHAVIOR—CATS

BASICS

OVERVIEW

• Urine marking—depositing of urine on vertical (spraying) or horizontal (especially novel) surfaces for communication (territorial, sexual, or agonistic situations).
• Roaming—escape or wandering for the purpose of seeking mates, defining territory, obtaining food, or sensory stimulation/enrichment.
• Urine marking and roaming behavior are normal but undesirable behaviors in companion cats.
• Mounting—mating behavior; mounting of inanimate objects for the purpose of masturbation.

SIGNALMENT

• Common in intact males, especially if estrus females are present.
• Can also occur in intact females or neutered individuals; marking reported in 10% of neutered males and 5% of spayed females.
• Roaming and mounting may be seen in 5–10% of neutered males.
• No age or breed predilection for marking or roaming.
• Mounting may be more common in sexually deprived, intact male cats mounting other males, females, kittens, people, and inanimate objects.

SIGNS

• Urine marking—characterized by the cat backing up to vertical object with an erect and quivering tail and projecting a stream of urine backward; may also occur with the cat assuming a squatting posture and depositing urine on horizontal surfaces, notably personal or novel items in the environment; urine deposited on multiple surface types in conjunction with normal litter box use for toileting of urine and feces.
• Mounting—of other cats, people, or objects.

CAUSES & RISK FACTORS

• Urine marking may function to delineate territory, aggressive intent, or reproductive communication between cats or as a response to anxiety.
• Likelihood of urine marking increases with density of cats in the household; however, urine marking may occur in households with only 1 or 2 cats.
• Marking associated with social conflict between cats in the same household, introduction of new cats, new furniture, or novel objects.
• Roaming is a normal exploratory behavior for enrichment, food, or sexual activity.
• Roaming is more likely in outdoor cats being housed indoors, intact male cats, and cats with a barren indoor environment (resulting in increased motivation to explore outdoors).
• Mounting can be seen in deprived males or isolated males or if males are housed in pairs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Rule out causes of lower urinary tract disease and systemic diseases that might increase irritability including hyperthyroidism.
• Urine marking must be distinguished from inappropriate urination for the purpose of emptying the bladder. The latter problem is characterized by elimination on a consistent surface or location, may involve feces, and is usually associated with a decrease in use or avoidance of the litter box use. Cats that urine mark continue to use the litter box for toileting of urine and feces.
• Roaming behavior may occur due to any disease process that might cause a cat to seek isolation due to illness.
• For marking and mounting also consider neonatal testosterone exposure, treatment with anabolic steroids or testosterone, or retained or residual testicular tissue.

CBC/BIOCHEMISTRY/URINALYSIS

• Rarely do cats with roaming or mounting behaviors display abnormalities in lab work.
• CBC/biochemistry tests and thyroid evaluation can provide helpful information to rule out coexisting conditions and provide baseline data prior to initiating drug therapy.
• Urinalysis required to rule out underlying urinary tract disorders.

OTHER LABORATORY TESTS

• Unless indicated from baseline data, no further lab tests are necessary.
• In neutered and spayed females, rule out potential hormonal effects from retained or residual testicular tissue which might be associated with secondary sexual characteristics such as penile barbs and elevated testosterone in males or estrus-like behaviors in females.

IMAGING

Radiographs and ultrasound if exam, signs, and/or laboratory results indicate a need to further explore the urinary tract.

DIAGNOSTIC PROCEDURES

None indicated.

TREATMENT

Marking

• Neuter and spay intact animals.
• Provide alternate marking options such as scratching posts and facial marking combs (Cat-A-Comb). For some cats the use of a urine marking station (empty litter box placed vertically at location where marking occurs) may be appropriate.
• Multiple resources including feeding stations, water bowls, climbing and perching stations, and litter boxes in multiple locations (one litter box per cat plus one additional).
• Manage litter hygiene so that boxes are scooped daily and completely cleaned weekly (clay litters) or monthly (clumping litters) using hot water only (no cleansers).
• Increase perching and hiding opportunities (especially elevated locations) in each room of the home.
• Prevent access or supervise access to area being marked.
• Make marked areas less appealing by using double-sided tape or bubble wrap, or unpleasant odors (e.g., mothballs).
• Manage stress factors in the household (address relationship issues between cats in the home, provide for each cat's behavioral needs, manage interactions between cats and people in home to increase positive relationships by encouraging play and reinforcement-based training).
• Reduce exposure to outdoor cats by blocking visual access; decrease number of cats in yard (use of fencing, motion-activated sprinkler, remove bird feeders, etc.).
• Consider increasing (or decreasing) time allowed outdoors.
• Use synthetic facial pheromone (F3 fraction) spray or diffuser.
• Consider cat-appeasing pheromone for intraspecific social conflict.
• If necessary, reduce numbers of cats in the household to reduce density if intraspecific conflict due to overcrowding or social incompatibilities are an issue.

Roaming

• Neuter if intact.
• Use double barriers at exits (for example, screen doors) or confine away from doors (e.g., room).
• Alternately, allow controlled access to outdoors using cat fencing or screened areas or outdoor access on a leash and harness.
• Enrich environment with multiple small meals, random treats, and increased play opportunities. Feed the cat as soon as it returns home.

(CONTINUED) # MARKING, ROAMING, AND MOUNTING BEHAVIOR—CATS

• Remove outdoor reinforcements such as outdoor cats through the use of fencing, motion-activated water sprinklers, removing bird feeders, and insuring neighbors not feeding.
• ID cat (tags, tattoo, or microchips).
• Synthetic facial pheromone (F3) diffuser in home.

Mounting
• Neuter if intact.
• Interrupt the behavior and redirect to more desirable behaviors such as play.
• Identify and remove any triggers which initiate the behavior.
• Provide alternative outlets for play/enrichment.

MEDICATIONS

DRUG(S) OF CHOICE

Marking
• Selective serotonin reuptake inhibitors (SSRIs)—fluoxetine or paroxetine 0.25–1.0 mg/kg PO q24h; side effects include sedation, anorexia, irritability, urine retention, constipation.
• Tricyclic antidepressants (TCAs)—clomipramine 0.25–1.0 mg/kg PO q24h; side effects include sedation, anticholinergic effects, arrhythmias, and gastrointestinal disturbances.
• Natural products that might aid in reducing anxiety—pheromones; L-theanine alone or in combination products; alpha-casozepine alone or in stress/calming diets (e.g., with L-tryptophan).

Roaming
No medications are recommended for roaming behavior.

Mounting
• Medications might be a consideration if a stress/anxiety component identified.
• Fluoxetine or clomipramine as in urine marking.
• Lorazepam 0.125–0.5 mg per cat PO q12–24h; side effects include sedation, hyperphagia, and rare hepatic toxicity (as reported with diazepam).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Do not use fluoxetine or clomipramine with monoamine oxidase (MAO) inhibitors such as selegiline.
• Caution in using TCAs when treating cats with diabetes, glaucoma, cardiac disease, or seizures.
• Do not combine a TCA with an SSRI or other drugs that might increase serotonin.

FOLLOW-UP

PATIENT MONITORING
• Telephone follow-up within 2 weeks after consultation, repeat as needed to monitor progress and assess response to treatment.
• ECG if concerns about cardiac status.
• CBC and biochemistry profile 3–4 weeks after initiating medical therapy and then q6–12 months.

EXPECTED COURSE AND PROGNOSIS
• Response to therapy within 4 weeks.
• Continue drug therapy for minimum 8 weeks if response noted; continue 1 month beyond resolution.
• When behavior is stable, wean dose by 25% per week.
• If behavior recurs, reinstitute lowest effective dose.
• Some cats may need to be maintained on medication indefinitely.

MISCELLANEOUS

SEE ALSO
Housesoiling—Cats.

ABBREVIATIONS
• MAO = monoamine oxidase.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

MARKING, ROAMING, AND MOUNTING BEHAVIOR—DOGS

BASICS

DEFINITION

• Marking, roaming, and mounting fall within the normal behavioral repertoire for the dog. However, they are objectionable to owners if shown to excess or in an inappropriate context, particularly in a sexually altered dog. • Normal behaviors with multiple causes—may be maladaptive owing to stimuli in the environment. • Marking—generates a signal for conspecifics with a visual mark, scent (urine, feces, anal sacs, or sebaceous glands) or both on an object or to define territory. • Roaming—wandering from territory for exploration or in search of mates, food, or social contact. • Mounting—primarily a component of mating behavior but also shown in social contexts and play (especially in prepubertal dogs).

GENETICS

None; however, may be more common in familial lines.

INCIDENCE/PREVALENCE

• Mounting—approximately 11%; running away—approximately 11%. • Marking—unknown; estimates up to 8%.

SIGNALMENT

Breed Predilections

Any breed.

Mean Age and Range

• Age at onset—sexual maturity (between 6 and 18 months of age). • Mounting may occur in prepubertal puppies.

Predominant Sex

• Most common in intact males. • May be seen in intact females in estrus, castrated males, and spayed females.

SIGNS

Historical Findings

• Marking—deposition of urine and/or feces in locations unacceptable to owners; occurs inside and outside of the home.
• Roaming—wandering behavior that takes the dog away from its home territory.
• Mounting—a behavior in which a dog places the cranial part of its body onto other dogs, animals, people, or objects while wrapping forelimbs around the target often with pelvic thrusting.

Physical Examination Findings

• Typically unremarkable unless a medical etiology is suspected (especially for marking behavior). • For inappropriate mounting of other dogs, it is advisable to also perform a physical examination on the target animal.

CAUSES

• Normal behaviors. Urine marking occurs most commonly in novel areas. Female dogs rarely mark in the home. • Hormonally regulated; intact males likely to roam, mark, and mount; prenatal testosterone surge leads to the brain's response to testosterone at puberty (i.e., sexual dimorphic behavior).
• Learned components possible; reproductive status not sole variable.

Roaming

• Anxiety. • Curiosity. • Reproduction.
• Social contact and play.

Marking

• Medical. • Communication with conspecifics; communicates social rank, sexual status, territorial boundaries, or general information not related to the need to empty the bladder or bowel. • Anxiety if excessive or in the home.

Mounting

• Sexual (including courtship and masturbation).
• Play. • Social status or cohesion. • Attention-seeking. • Anxiety. • Displacement behavior/compulsive disorder.

RISK FACTORS

• Intact males more likely to roam, mark, and mount. • Marking on walks; learned behavior. • Mounting only in front of owners; attention-seeking. • Intact bitches, or females spayed after first heat.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Normal or a sign of another diagnosis.

Roaming

• Sexually motivated. • Testosterone-producing tumors. • Searching for food.
• Separation anxiety—escape/avoidance.
• Noise phobias—escape/avoidance.
• Territorial behavior. • Social seeking.
• Social conflict in home territory.
• Predatory behavior. • Escaping from enclosure—play/investigative behavior.

Marking

• Sexually motivated. • Testosterone-producing tumors. • Territorial behavior.
• Social status behavior. • Conflict behavior.
• Anxiety. • Cognitive dysfunction syndrome.
• Housesoiling. • Excitement/submissive urination. • Urinary tract disease. • Any medical condition that causes polyuria/polydipsia (PU/PD). • Constipation or diarrhea. • Anal sac disease.

Mounting

• Sexually motivated. • Testosterone-producing tumors. • Social status behavior.
• Endocrine disease. • Urinary tract disease.
• If target is another dog, look at target for:
○ Estrogen-producing tumors. ○ Infections of anal sacs, uterus, vagina, or urinary tract.

OTHER LABORATORY TESTS

• If indicated, based on physical exam, clinical signs, sex, and age. • Thyroid testing if roaming for food. • In neutered males showing intact male behavior, consider baseline testosterone then administer gonadotropin-releasing hormone (GnRH) followed by a post-injection blood sample to rule out retained testicular tissue. • Urine culture and sensitivity. • Vaginal cytology to determine estrus status. • If target of mounting is another dog, exam target for:
○ Blood estrogen levels (reproductive tumors). ○ Urine culture and sensitivity.
○ Vaginal cytology, culture and sensitivity.

DIAGNOSTIC PROCEDURES

• Behavioral history and clinical signs. • Rule out medical differentials.

TREATMENT

ACTIVITY

See Client Education.

DIET

No special dietary considerations.

CLIENT EDUCATION

Roaming

• Secure enclosure to prevent escape. • Leash walk. • Adequate exercise, attention, supervision, stimulation. • Doggie daycare.

Marking

• Restrict access to targeted areas with confinement training or barricades. • Provide indoor supervision when the owner is present.
• Remove stimuli or triggers. • Express anal sacs if necessary. • Use Bellyband (male) or Puppy Pants (female). • Clean marked areas with effective enzymatic cleaners. • Cue/reward-based interaction with dog. • Avoid confrontation or punishment. • Counter-conditioning and desensitization to trigger stimuli or for anxiety conditions.

Mounting

• Obedience training. • Cue/reward-based interaction with dog. • Counter-conditioning or systematic desensitization to trigger stimuli or for anxiety conditions. • Adequate exercise, attention, and stimulation. • Ignore behavior if attention seeking - reorient or redirect into alternative desirable. • Avoid confrontation that adds to anxiety and conflict.

SURGICAL CONSIDERATIONS

• Neuter intact males. • Remove retained testicular tissue if indicated. • Spay marking females.

(CONTINUED) # MARKING, ROAMING, AND MOUNTING BEHAVIOR—DOGS

MEDICATIONS

DRUG(S) OF CHOICE

• Medication is not necessary for roaming unless the primary problem (separation anxiety or noise phobias) warrants its use. Medical etiologies should be treated accordingly. • No drug is approved for the treatment of marking or mounting; medication use is *only* indicated if anxiety is a contributing motivation. • Medication should *only* be used in combination with a sound behavior modification plan.

Tricyclic Antidepressants (TCAs)

• Amitriptyline 2–4 mg/kg PO q12h.
• Clomipramine 1–3 mg/kg PO q12h. • Side effects include sedation, anticholinergic effects, cardiac conduction disturbances, and gastrointestinal (GI) signs.

Selective Serotonin Reuptake Inhibitors (SSRIs)

• Fluoxetine 0.5–2 mg/kg PO q24h.
• Paroxetine 1–2 mg/kg PO q24h.
• Sertraline 1–3 mg/kg PO q24h or divided q12h. • Side effects include inappetence, lethargy, irritability, urine retention and anticholinergic effects with paroxetine.

Azapirone

• Buspirone 0.5–2 mg/kg PO q8–12h.
• Side effects—GI signs.

Benzodiazepines

In dogs with concurrent anxiety diagnoses—alprazolam 0.01–0.1 mg/kg PO q8–12h.

CONTRAINDICATIONS

TCAs are contraindicated in animals with cardiac conduction disturbances or glaucoma.

PRECAUTIONS

• Clients should be advised that occasional cases of increased aggression have been reported with TCAs and SSRIs. • Use caution with all drugs if dog has hepatic or renal compromise. • Use benzodiazepines with caution in aggressive dogs because of potential for disinhibition.

POSSIBLE INTERACTIONS

• TCAs and SSRIs should not be used together. • Do not use TCAs or SSRIs with monoamine oxidase inhibitors, including amitraz products and selegiline.

ALTERNATIVE DRUG(S)

• For anxiety, consider dog-appeasing pheromones and natural supplements containing alpha-casozepine (Zylkene) alone or in a diet in combination with L-tryptophan (Canine Calm diet); L-theanine alone (Anxitane) or in combination products containing whey protein, *Phellodendron amurense* and *Magnolia officinalis* (Solliquin); *Souroubea* and *Plantanus* (Zentrol) or probiotics (Calming Care). • In intact males, when the behavior is suspected to be hormonally modulated, consider the use of medications that decrease blood testosterone levels.

GnRH Agonists

• Do not use in breeding animals during the breeding season. • Effect is reversible when GnRH agonist is discontinued.

Megestrol Acetate

• Outdated treatment. • Side effects include obesity, pyometra, PU/PD, diabetes mellitus, mammary hyperplasia, and carcinoma.

FOLLOW-UP

PATIENT MONITORING

Follow-up is variable depending on the severity of the problem and whether medication is prescribed. Help may be needed implementing changes to the environment and behavior modification. Owners should be encouraged to keep logs or journals detailing episodes of marking, roaming, or mounting to assess treatment success or nonresponse. If medication is prescribed, follow-up and journals are essential to assess response. In urine marking, owners should be encouraged to supervise the dog indoors and to inspect areas daily for urine marks.

PREVENTION/AVOIDANCE

• Neutering males and spaying females reduces likelihood of marking, roaming, and mounting behavior. • Provide client education for prevention and management with proper husbandry and reward-based training.

POSSIBLE COMPLICATIONS

• Roaming—becoming lost or picked up by animal control; possible injury from car accidents or fighting with other animals.
• Marking—property damage when it occurs inside the home. • Mounting—disruption of relationship with familiar dogs; possible fighting with other animals. • Pet relinquishment.

EXPECTED COURSE AND PROGNOSIS

• Prognosis is good if the correct cause is determined and the owner is compliant with the behavior protocols. • Castration will decrease house marking by 90% or better in 40% of male dogs, while 80% of dogs will decrease marking by at least 50%. Castration has little to no effect on urine marking in outdoor areas. • Castration decreases mounting in more than 65% of dogs but relatively few stop completely. Castration has its greatest effect when the target of mounting is human rather than dog.

MISCELLANEOUS

AGE-RELATED FACTORS

Intact animals older than sexual maturity.

ZOONOTIC POTENTIAL

Roaming exposes pet to other animals, including wildlife—rabies exposure possible.

PREGNANCY/FERTILITY/BREEDING

Listed medications should be avoided in pregnant animals.

SEE ALSO

Housesoiling—Dogs.

ABBREVIATIONS

• GI = gastrointestinal.
• GnRH = gonadotropin-releasing hormone.
• PU/PD = polyuria/polydipsia.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

Author Gerrard Flannigan
Consulting Editor Gary M. Landsberg

M

MAST CELL TUMORS

BASICS

DEFINITION
• Malignant round cells derived of hematopoietic origin containing granules packed with many vasoactive substances, including histamine, heparin, serotonin, dopamine, tryptase, and chymase. • Tumors may affect dermis, subcutis, spleen, liver, intestines as well as other connective and mucosal sites.

PATHOPHYSIOLOGY
• Histamine release from mast cell tumors (MCTs) affects a multitude of tissues.
• Histamine (H2) receptors are primarily located within the stomach and histamine is thought to be one of the most significant stimulants of gastric acid secretion in addition to gastrin and acetylcholine. • In extreme cases, perforation of the gastrointestinal (GI) tract may occur, leading to peritonitis.
• Histamine release around a tumor leads to the production of wheals, hives, and erythema (Darier's flare). • Local release of heparin is also common, resulting in bleeding and subsequent bruising, which can be seen around the tumor.

SYSTEMS AFFECTED
• Skin—MCTs are the most common malignant cutaneous tumor of the dog.
• GI—on necropsy evaluation, 35–83% of dogs with MCTs have evidence of GI ulceration. • Hemic/lymph/immune—regional lymph node metastasis is common in high-grade tumors. • Hepatobiliary—liver and spleen are common distant sites of metastasis for high-grade MCTs.

GENETICS
The specific breed predilections indicate that a genetic predisposition exists.

INCIDENCE/PREVALENCE
• Most common malignant skin tumor in the dog, representing approximately 7–21% of all canine skin tumors. • Primary visceral and intestinal MCTs are rare in the dog (small/toy breeds affected). • Second most common malignant skin tumor in the cat, accounting for 20% of cutaneous tumors. • Most common splenic tumors of cats, comprising half of the MCTs diagnosed in cats.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Dogs—brachycephalic breeds, as well as golden retriever, Labrador retriever, Rhodesian ridgeback, beagle, Staffordshire terrier, Weimaraner, shar-pei, and Australian cattle dog. • Cats—Siamese.

Mean Age and Range
• Dogs—middle-aged, range 4 months–18 years. • Cats—middle-aged (8–9 for cutaneous mastocytic types) and older cats (intestinal and splenic); however, the histiocytic form of cutaneous MCTs affects young cats (Siamese) with a mean age of 2.4 years.

Predominant Sex
Dogs—no predilection; cats—male Siamese.

SIGNS

Dogs
• Mass is found in the subcutis or on the skin and may also be present within lipomas.
• Regional edema or a Darier's sign may be seen in the region around a tumor that has degranulated. • Lymphadenopathy of regional lymph nodes may be seen in dogs with metastatic disease. • History of intermittent progression and regression in size. • Systemic illness with advanced local or systemic disease; vomiting, anorexia, weight loss, and melena.

Cats
• Visceral disease manifests as chronic weight loss, anorexia, diarrhea, and lethargy. • Focal mass lesion may be palpated with primary intestinal MCT. • Cutaneous masses tend to be epidermal and on the face or feet.

CAUSES
• Up to 30% of canine MCTs have been shown to contain a mutation in the c-*kit* oncogene, leading to constitutively activated receptor and unchecked cell division. • Up to 56% of feline MCTs have a c-*kit* mutation though these mutations do not appear to have any bearing on prognosis.

RISK FACTORS
See Breed Predilections and Causes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Cutaneous/subcutaneous forms—adenexal tumors, basal cell tumors, histiocytoma, lipoma, and soft tissue sarcoma. • Visceral forms—lymphoma, histiocytic tumors, malignant fibrous histiocytomas, multiple myeloma, hemangiosarcoma, hemangioma, and erythroid myeloid hyperplasia.
• Intestinal forms—lymphoma, adenocarcinoma, leiomyoma, leiomyosarcoma, GI stromal tumors, and fungal infections.

CBC/BIOCHEMISTRY/URINALYSIS
• Anemia (initially regenerative secondary to GI blood loss, but can progress to microcytic, hypochromic, nonregenerative anemia).
• Eosinophilia. • Identification of circulating mast cells is more common in the cat with visceral MCT than the dog. • Increased BUN secondary to GI bleeding.

OTHER LABORATORY TESTS
• Regional lymph node aspiration and cytology. • Liver and splenic aspiration and cytology. • MCT prognostic panel. • c-*kit* PCR and immunohistochemistry staining.

IMAGING
Abdominal ultrasound—viscera assessment with emphasis on liver, spleen, and mesenteric lymph nodes.

DIAGNOSTIC PROCEDURES
• Fine-needle aspirate and cytology for definitive diagnosis. • Biopsy (incisional or excisional) for definitive diagnosis and histologic grading.

PATHOLOGIC FINDINGS

Dogs
• Two tiered grading system for cutaneous MCTs: ◦ Low grade—mitotic index of <7, <3 multinucleated cells per 10 HPFs, <3 bizarre nuclei per 10 HPFs, mild to moderate karyomegaly. ◦ High grade—mitotic index of at least 7, 3 or more multinucleated cells per 10 HPFs, 3 or more bizarre nuclei per 10 HPFs, significant karyomegaly. • No validated grading system for subcutaneous MCTs currently exist. • Intestinal MCTs tend to be high grade in the dog.

Cats
• Histologic forms of cutaneous MCTs: ◦ Mastocytic form—single tumor and is the most common (compact or diffuse). ◦ There are two histologic varieties of mastocytic MCTs in the cat: compact—more benign behavior; diffuse—more undifferentiated and aggressive. • Histiocytic form—multiple lesions on the head and neck with relatively benign behavior.

TREATMENT

ACTIVITY
Limit for animals with heavy tumor burdens (such as cats with visceral MCTs or dogs with large tumors) until the mass has been treated appropriately.

DIET
N/A

CLIENT EDUCATION
Owners of dogs with MCTs should be informed that 14–17% of dogs will develop additional MCTs.

SURGICAL CONSIDERATIONS
• Conventional recommendations (dogs)—2–3 cm margins and one fascial plane deep, may be unnecessary with low-grade MCTs in dogs as many of "dirty" margins fail to locally regrow. • Narrow margins (cats)—majority of tumors will not regrow following narrow

(CONTINUED) MAST CELL TUMORS

surgical margins. • Splenectomy (cats)—recommended in cats with massive visceral tumor burden despite the presence of metastases.

RADIATION THERAPY

• For incompletely excised MCTs in locations that are not amenable to surgical re-excision or in cases where another surgery is not possible (dogs). • Treatment of regional lymph node beds for high-grade tumors • Can be used in a gross disease setting, but severe systemic degranulation reactions (including death) are possible. Pretreatment with ancillary medications is indicated.

MEDICATIONS

DRUG(S) OF CHOICE

Dogs

• Vinblastine 2–3 mg/m^2 IV q7 days for 4 treatments, then q14 days for 4 treatments and prednisone 1 mg/kg PO q24h.
• Vinblastine only 3.5 mg/m^2 IV q14 days.
• Lomustine 50–70 mg/m^2 PO q21 days.
• Toceranib phosphate (Palladia) 2.75 mg/kg PO Monday, Wednesday, Friday.

Cats

• Lomustine 32–60 mg/m^2 PO q4–6 weeks.
• Vinblastine 2 mg/m^2 IV q7 days for 4 treatments, then q14 days for 4 treatments and prednisone 1 mg/kg PO q24h.

CONTRAINDICATIONS AND PRECAUTIONS

• Vinblastine—use with caution in animals with liver disease; drug is also myelosuppressive and possesses vesicant properties. • Lomustine is hepatotoxic and should be avoided in dogs with underlying liver disease; • drug is extremely myelosuppressive and associated with refractory thrombocytopenia. Administer with Denamarin. Unknown time to white blood cell nadir in cats. • Toceranib can cause GI ulcers, myelosuppression, muscle pain, hypertension, proteinuria and GI upset.

POSSIBLE INTERACTIONS

• Toceranib should be used with caution with other drugs that induce gastric ulcers such as prednisone or nonsteroidal anti-inflammatory drugs (NSAIDs), or in patients with gastric ulceration secondary to MCT. • Lomustine should be used with caution with other hepatotoxic drugs such as NSAIDs.

ALTERNATIVE DRUG(S)

Symptomatic treatment—diphenhydramine, prednisone famotidine or other H2 inhibitors, omeprazole, and sucralfate should be considered for any dog or cat with gross mast cell disease and clinical symptoms consistent with GI bleeding.

FOLLOW-UP

PATIENT MONITORING

Dogs

• Low-grade cutaneous—complete surgical resection should be curative in the majority of patients. Median survival time greater than 2 years. Follow-up should include evaluation every 3 months for 1 year with physical examination and lymph node assessment.
• High-grade—complete surgical resection evaluate every 3 months for 1.5 years with physical examination, blood work, abdominal ultrasound, and lymph node assessment then every 6 months for another 1.5 years.

Cats

Visceral or intestinal—abdominal ultrasound and blood work every 3 months for 1 year.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Chemotherapy-related myelotoxicity or hepatotoxicity.

EXPECTED COURSE AND PROGNOSIS

• Complete excision of low-grade MCTs in most locations is curative. • Complete excision of high-grade MCTs even with aggressive treatment is associated with eventual tumor progression/relapse.
• Incomplete excision of a low-grade MCT may require additional local therapy with another surgery (often cured) or radiation therapy (93% disease-free at 3 years).
• Incomplete excision of a high-grade MCT requires additional local therapy in addition to systemic chemotherapy. • Regional metastasis to a lymph node should be treated with surgical excision at the time of the primary tumor removal. Systemic chemotherapy is necessary. • Evidence of distant metastasis is often treated with systemic chemotherapy or ancillary therapies alone with a median survival of 4 months or less.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Progressive and metastatic disease has the potential to cause excessive parietal cell production of hydrochloric acid with associated gastric ulceration, melena, and iron-deficiency anemia and gastric perforation.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

While on chemotherapy dogs should not be bred. There are no long-term studies regarding fertility in dogs or cats previously treated with lomustine, vinblastine, or receptor tyrosine kinase inhibitors (RTKIs).

SYNONYMS

• Mastocytoma. • Systemic mastocytosis.

ABBREVIATIONS

• GI = gastrointestinal.
• MCT = mast cell tumor.
• NSAID = nonsteroidal anti-inflammatory drug.
• RTKI = receptor tyrosine kinase inhibitor.

Consulting Editor Timothy M. Fan

Client Education Handout available online

M

MASTITIS

BASICS

OVERVIEW
- Bacterial infection of one or more lactating mammary glands.
- Result of ascending infection, trauma to the gland, or hematogenous spread.
- *Escherichia coli*, staphylococci, and β-hemolytic streptococci most commonly involved; *Mycobacterium* and blastomycosis reported.
- Potentially life-threatening infection; may lead to sepsis if systemic involvement.

SIGNALMENT
- Postpartum bitch and queen.
- Pseudopregnant lactating bitch or queen (rare).

M

SIGNS
Historical Findings
- Anorexia.
- Lethargy.
- Neglect of puppies or kittens.
- Failure of puppies or kittens to thrive.

Physical Examination Findings
- Firm, swollen, warm, and painful mammary gland(s) from which purulent or hemorrhagic fluid can be expressed.
- Fever, dehydration, and shock—with systemic involvement.
- Abscessation or gangrene of gland(s) can result.

CAUSES & RISK FACTORS
- Ascending infection via teat canals.
- Trauma inflicted by puppy or kitten toenails and teeth.
- Poor hygiene.
- Systemic infection originating elsewhere (e.g., metritis).
- Rarely secondary to fibroadenomatous hyperplasia in queens.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Galactostasis—no systemic illness; cytologic examination and culture of milk aid differentiation.
- Inflammatory mammary adenocarcinoma—affected gland does not produce milk; differentiated by biopsy.

CBC/BIOCHEMISTRY/URINALYSIS
- Leukocytosis with left shift, or leukopenia with sepsis.
- Hemoconcentration (increased packed cell volume, total plasma protein concentration), and azotemia from dehydration or prerenal effects.

N/A

IMAGING
Ultrasonography reveals loss of distinct layering of normal tissue in glands, decreased echogenicity, increased heterogeneity, and altered blood vessel density on color Doppler.

DIAGNOSTIC PROCEDURES
- Cytology—neutrophils, macrophages, and other mononuclear cells can be observed in normal milk; the presence of large numbers of free and phagocytosed bacteria and degenerative neutrophils occurs with mastitis.
- Microbial culture—identification and sensitivity of microorganisms from milk of affected glands; screening for methicillin-resistant *Staphylococcus aureus* recommended.

TREATMENT
- Inpatient until stable.
- Puppies and kittens—neonates may be allowed to continue nursing unless glands are necrotic or dam is systemically ill; affects choice of antibiotics; monitor weight gain in neonates: pups should gain 10% of birth weight per day, kittens should gain a minimum of 7–10 g/day.
- IV isotonic crystalloid fluid to treat dehydration, hypovolemia, shock.
- Correct electrolyte imbalances, hypovolemia, hypoglycemia.
- Apply warm compress and milk out affected gland(s) several times daily.
- Cover friable glands to prevent excoriation if nursing is allowed.
- Application of cabbage leaf wraps to affected glands may speed resolution.
- Abscessed or gangrenous glands—require surgical debridement.
- Open wound management or negative pressure wound therapy may be needed after surgery in some cases; negative pressure therapy may also be used for conservatively managed cases.

MEDICATIONS

DRUG(S) OF CHOICE
- Acidic milk—weak bases; erythromycin 10 mg/kg PO q8h, lincomycin 15 mg/kg PO q8h, or trimethoprim-sulfadiazine 15–30 mg/kg PO q12h for 21 days.
- Alkaline milk—weak acids; amoxicillin or cephalosporin 20 mg/kg PO q8h, dogs and cats; amoxicillin/clavulanic acid 13.75 mg/kg PO q12h (dogs); 62.5 mg/cat PO q12h (cats) for 21 days.
- Either alkaline or acidic milk—chloramphenicol 40–50 mg/kg PO q8h or enrofloxacin 5–20 mg/kg/day PO for 21 days.
- May infuse affected gland(s) with 1% betadine solution by lacrimal cannula.
- Cabergoline 5 μg/kg PO q24h for 5–7 days to suppress lactation in unaffected glands in patients with sepsis; neonates must be hand-reared.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Patient allowed to nurse—avoid tetracycline and chloramphenicol; may use cephalosporins, amoxicillin, and amoxicillin with clavulanic acid. Enrofloxacin may be used in dogs up to 3 weeks of age.

FOLLOW-UP

PATIENT MONITORING
- Physical examination and CBC.
- Repeated ultrasonographic evaluation helps assess healing—normal distinct layering of tissues will appear with recovery.

PREVENTION/AVOIDANCE
- Clean environment.
- Hair shaved from around mammary glands.
- Toenails of puppies and kittens clipped.
- Ensure neonates nurse from all glands.
- Probiotic administration.

POSSIBLE COMPLICATIONS
- Abscessation or gangrene—may cause loss of gland(s).
- Hand-raising puppies and kittens—requires considerable commitment by the owner; may affect behavioral outcome of offspring.

EXPECTED COURSE AND PROGNOSIS
Prognosis—good with treatment.

MATERNAL BEHAVIOR PROBLEMS

BASICS

DEFINITION
Abnormal maternal behavior is either excessive maternal behavior in the absence of neonates or deficient maternal behavior in the presence of the dam's own neonates. The latter is more common in dogs, the former in cats.

PATHOPHYSIOLOGY
The pathophysiology of one type of excessive maternal behavior, pseudocyesis, appears to be elevated progesterone levels following estrus in unbred bitches followed by an abrupt drop in progesterone levels. The pathophysiology of the refusal to accept puppies by females after caesarean section is the waning of factors, including oxytocin, needed during the sensitive period for acceptance of the neonate. The pathophysiology of other types of deficient maternal behavior is unknown. The impairment or absence of mother–infant bonding strongly affects the offspring's sociability or affiliative behavior throughout the animal's lifespan.

SYSTEMS AFFECTED
• Behavioral. • Reproductive.

GENETICS
There is no identified genetic predisposition, but a breed disposition for deficient maternal behavior in Jack Russell terriers indicates there may be a genetic component. There are genetic models in mice. The genes responsible for deficient maternal behavior in mice are paternally imprinted. If this is true in dogs and cats, one would expect that rejecting mothers were normally mothered themselves, but their paternal grandmother may have been deficient.

INCIDENCE/PREVALENCE
The incidence of deficient maternal behavior has not been determined but seems to be low, less than 1% of cases in a behavior practice. Pseudopregnancy is more common. Cannibalism of offspring is more common in cats and may account for approximately 12.5% of all kitten deaths.

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
Poor maternal behavior may be more common in Jack Russell terriers and cocker spaniels, but there has been no quantitative study.

Mean Age and Range
Primiparous females and older bitches seem to be at risk of deficient maternal behavior. Lower ranking females that have not bred successfully have a higher likelihood of entering pseudocyesis, which may allow for them to help raise the offspring.

Predominant Sex
Female generally, but some males may allow suckling behavior.

SIGNS

Deficient Maternal Behavior
Absent maternal behavior; the mother simply abandons her offspring. This is most apt to occur after caesarean section.

Poor Maternal Behavior
• The mother stays with her offspring but will not allow them to nurse. • The mother may show inadequate retrieval of young, insufficient cleaning of the young, or failure to stimulate elimination. • The bitch carries the puppies from place to place without settling down. • In the most extreme form, the mother kills some or all of her litter.

Abnormal Maternal Behavior
• The bitch or queen may allow her offspring to suckle but kills her offspring either at birth or over a period of days. Occasionally the bitch, or more rarely the queen, will abandon or attack her offspring if it has changed in odor or appearance. A female may be disturbed by another animal or by people and can redirect her aggression to her offspring. • Cannibalism of kittens may occur as a result of too large a litter or overcrowding. • A bitch may accidentally disembowel or even consume offspring completely while eating the fetal membranes and umbilical cord. This should be distinguished from normal licking, which can be quite vigorous, even dislodging the pup from a teat.

Maternal Aggression
Cats with kittens may be aggressive to other animals, especially dogs in the same household. Bitches may be aggressive to unfamiliar humans or even to familiar humans, especially if they are hypocalcemic or painful (i.e., mastitis).

Excessive Maternal Behavior
• The pseudopregnant bitch or a bitch spayed during the late luteal phase of the estrous cycle adopts, attempts to nurse, and guards inanimate objects (stuffed animals or even leashes). The pseudopregnant bitch may have mammary development and may lactate. • The newly spayed queen may steal kittens from a lactating queen. Queens post-spaying may also lactate if suckled.

CAUSES
• Genetics—offspring of poor mothers. • Sick/unhealthy offspring. • Environmental (see Risk Factors).

RISK FACTORS
• The presence of kittens in the environment of the recently spayed cat may prompt excessive maternal behavior and kitten stealing. • The risk of excessive carrying of pups, redirected aggression, or even cannibalism is increased if there are other dogs or too many people present in the nest area. • Primiparous females or those subjected to caesarian section are at higher risk than multiparous or naturally delivering females. • A large litter of kittens or sick offspring. • Queens fed low protein diets during late gestation and lactation may show decreased mother–kitten social interactions and retarded attachment formation. • Other risk factors include individual differences, lack of experience, pain, discomfort, and suboptimal conditions. • Inability to perform species-specific behavior before, during, and after parturition increases the possibility of infanticide or ingestion of offspring.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• The most important differential is between primary abnormal maternal behavior and poor maternal behavior secondary to mastitis or metritis. • Lactation tetany can result in aggressive behavior, although this behavior is rarely directed at the puppies and occurs later in lactation, not at parturition.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal unless other medical conditions are present. Blood calcium levels will be low if the bitch is suffering from lactation tetany.

OTHER LABORATORY TESTS
Only as indicated by metabolic conditions of the bitch or queen.

PATHOLOGIC FINDINGS
Presence of milk in the mammary glands of females with excessive maternal behavior.

TREATMENT

APPROPRIATE HEALTH CARE
Normal health care.

DIET
• Adequate diet for nursing bitches and queens to meet protein, energy and calcium demands. • Restricted diets for pseudocyesis to discourage lactation and diminish milk production. • In the case of deficient maternal behavior, the bitch or queen should be fed ad libitum to encourage lactation.

MATERNAL BEHAVIOR PROBLEMS (CONTINUED)

CLIENT EDUCATION

Abnormal or Poor Maternal Behavior

• The bitch that is carrying her pups or exhibiting redirected aggression to them should be isolated in a quiet, dark area. The bitch that bites her pups should be muzzled and mildly sedated. The owner must stimulate elimination of the puppies or kittens because the muzzled female cannot. An Elizabethan collar inhibits cannibalism in queens. • The bitch should be attended at parturition and the pups removed temporarily if she is biting the pups themselves in addition to the umbilical cord. • Bitches and queens with poor maternal behavior may exhibit the same behavior with subsequent litters. • Some mothers reject specific offspring that are cold or inactive, which indicates a problem with the individual offspring and warrants veterinary intervention. • If the mother rejects the entire litter, abnormality is with the dam.

Excessive Maternal Behavior

• Cats that have stolen kittens should be separated from the biologic mother and kittens. • The mothered objects should be removed from the pseudopregnant bitch. However, some bitches will compulsively search for the object or transfer maternal behavior to another. In which case, it is in the bitch's best interest to allow her to remain with the object. • Food intake should be restricted to inhibit lactation.

Maternal Aggression toward Animals or Humans

The best treatment for maternal aggression beyond weaning is to separate the kittens; weaning alone may not suffice because the presence of the kittens alone may sustain or even reinstate maternal aggression in a queen separated from her kittens for several weeks.

SURGICAL CONSIDERATIONS

• Delay spaying for 4 months post estrus to avoid post-spaying maternal behavior and its accompanying aggression. • Spaying avoids future excessive maternal behavior in the absence of young.

MEDICATIONS

DRUG(S) OF CHOICE

Excessive Maternal Behavior

• Mibolerone was the drug of choice for pseudopregnant bitches or those exhibiting maternal behavior and lactation following spaying. The dose is 16 µg/kg PO once daily for 5 days. Mibolerone is a potent anabolic–androgenic steroid which inhibits prolactin and thereby inhibits lactation. The drug is no longer available except through some compounding pharmacies. • Bromocriptine (Parlodel) can be used to inhibit prolactin. The dose is 10 µg/kg for 10 days. Should not be administered to pregnant animals. • Cabergoline is a dopamine agonist shown to be effective for the treatment of pseudopregnancy in dogs by lowering prolactin. Dosage is 5 µg/kg PO q24h for 4–6 days. Some animals may require more than one course of treatment. Not commercially available in North America.

Deficient Maternal Behavior

• Oxytocin may be administered either parenterally 1–5 units or by nasal spray (Syntocinon). • Because prolactin appears to be necessary for maternal behavior in other species, a dopamine blocker, acepromazine (0.55–2.2 mg/kg PO), can be used. Dopamine inhibits prolactin release.

CONTRAINDICATIONS

• Do not use mibolerone in cats because it has a narrow margin of safety in that species. It should not be administered to Bedlington terriers due to their predisposition for chronic hepatitis. • Do not give oxytocin to pregnant animals or in combination with sympathomimetic agents.

PRECAUTIONS

Mibolerone can cause masculinization that may include male sexual behavior, clitoral hypertrophy, vulvovaginitis, and urinary incontinence in females. Bromocriptine can cause gastrointestinal vomiting, sedation, and hypotension as well as abortion.

POSSIBLE INTERACTIONS

• If tranquilizers are administered, care must be taken that the puppies or kittens are not sedated. • Do not use estrogen or progesterones at the same time as mibolerone.

FOLLOW-UP

PATIENT MONITORING

Puppies or kittens of females with deficient or poor maternal behavior should be monitored daily to ensure they are gaining weight.

PREVENTION/AVOIDANCE

• Place a nursing female in quiet, comfortable quarters away from noise and disturbance by other animals or people. • Do not rebreed females with poor maternal behavior. Determine whether any female offspring of the female with abnormal behavior have also exhibited poor maternal behavior. In other species, poor maternal behavior is a paternally imprinted gene; the father must contribute the gene for poor maternal behavior. The daughters of rejecting mothers will not reject, but the daughters of their sons may. • Allow species-specific behavior before, during, and after parturition.

POSSIBLE COMPLICATIONS

• Loss of offspring. • Hand-reared puppies and kittens frequently have abnormal or deficient social behavior. This is due in part to insufficient suckling time and to the consequences of lack of maternal licking, which adversely affects response to stress and reproductive behavior. • Absent maternal environment during the first 8 weeks has been associated with increased anxiety and aggression in puppies.

EXPECTED COURSE AND PROGNOSIS

• Excessive maternal behavior usually wanes around the time of normal weaning (6–8 weeks). • Poor and deficient maternal behavior can occur with each litter. • Maternal aggression by the bitch may begin as early as nest building behavior, reaches its height during the first 2 weeks after parturition and may last for 3 weeks post parturition. • Kittens from queens with poor maternal behavior can be cross-fostered to another lactating queen. Puppies may also be cross-fostered to another lactating bitch, but this is best accomplished within the first week of life. Best success of cross-fostering occurs between related dams.

MISCELLANEOUS

AGE-RELATED FACTORS

Poor maternal behavior is more likely in very young and very old mothers.

PREGNANCY/FERTILITY/BREEDING

• Consider especially drug use and effect of disease on the fetus. • Do not breed dogs with history of poor maternal behavior.

MAXILLARY AND MANDIBULAR FRACTURES

BASICS

DEFINITION
Fractures of the mandibles, maxillae, and associated structures are described according to location, severity (i.e., tooth involvement, soft tissue tears, and type of bone fracture), and effects of the muscles of mastication on reduction.

PATHOPHYSIOLOGY

Effects of the Muscles of Mastication
The muscles that open and close the mouth may help reduce (favorable) or displace (nonfavorable) a fracture.

Classification of Jaw Fracture by Location
• Rostral mandible—including the canines and incisors. • Mandibular horizontal ramus. • Mandibular vertical ramus. • Temporomandibular joint. • Rostral maxillary/incisive bone. • Maxillary/facial fractures. • Maxillary symphysis. • Combination fractures.

SIGNALMENT

Species
Dog and cat.

SIGNS
• Vary greatly according to the location, type, extent, cause, and underlying risk factors resulting in the injury. • Facial deformity, malocclusion, fractured teeth, oral or nasal bleeding, and inability to properly close the jaw are common signs.

CAUSES
Injury, trauma, and predisposing factors.

RISK FACTORS
• High-risk environment or temperament. • Oral infections (e.g., periodontal disease, osteomyelitis), neoplasia, or certain metabolic diseases (e.g., hypoparathyroidism)—may result in weaker jaws that are more prone to injury. • Traumatic injury affecting the jaws or teeth. • Congenital or hereditary factors resulting in weakened or deformed jaw bone.

DIAGNOSIS
A thorough and complete physical examination is very important in traumatic jaw injuries as many unseen or multiple injuries and complications are possible.

DIFFERENTIAL DIAGNOSIS
• Temporomandibular joint (TMJ) conditions—see Temporomandibular Joint Disorders. • Tooth subluxation or luxation (i.e., interference with jaw closure). • Endodontic disease (e.g., tooth abscess). • Foreign body lodged in or near the oral cavity. • Maxillary or mandibular nerve injury or disease. • Masticatory muscle myositis. • Craniomandibular osteopathy. • Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
As required—to assess and treat shock from initial injury; to assess animal prior to surgery.

IMAGING
Radiography—intraoral and extraoral; CT and MRI.

DIAGNOSTIC PROCEDURES
• Oral examination. • Neurologic examination. • Biopsy for histopathology, if indicated. • Bacterial culture and sensitivity, if indicated.

PATHOLOGIC FINDINGS
• Non-unions. • Neoplasia. • Osteomyelitis. • Periodontal and/or endodontic disease.

TREATMENT

APPROPRIATE HEALTH CARE

Typical Types of Treatments for Classes of Fractures
• Interarch stabilization (caudal fractures or severely comminuted combination fractures including the TMJ)—tape muzzle; maxillomandibular fixation (MMF) with dental composites or acrylic materials; cross-arch wiring or buttons (maxilla to mandible). • Intra-arch stabilization (symphyseal and parasymphyseal injuries)—pin and wire combination, dental wiring, acrylic or composite splint. • Intraoral stabilization with splint (mandibular body fractures, useful in edentulous patients)—composite or acrylic splint. • Intraoral stabilization with wire (mandibular body, maxillary fractures)—interdental wiring (Ivy loop, Stout's multiple loop, Essig and Risdon techniques); dental wiring: circumdental for splint anchorage (pig tails, cerclage or twists); osseous wiring (circumferential, transosseous, transcircumferential). • Internal fixation (most types of fractures, used selectively with consideration of teeth and roots): orthopedic wire; mini-plates; screws; intramedullary pins (*not* within the mandibular canal). • External fixation (most types of fractures, used selectively with consideration of teeth and roots)—intramedullary pins with bars (stainless steel or carbon) or tubing (e.g., Penrose) reinforced with composite or acrylic. • Salvage surgery (fractures with large defects, non-unions)—condylectomy (nonrepairable fractures of the TMJ); cheiloplasty (salvage procedure to maintain reasonable mandibular support in certain nonunion conditions); rostral (or other) mandibulectomy (used in certain non-union cases or with massive injury).

Initial Treatment
• Awareness of occlusion, tooth roots, and anatomy during treatment is critical. • Patient should be intubated, pharyngostomy or transmylohyoid placement aids in occlusal checks intraoperatively. • Teeth in the fracture line should be assessed and maintained by appropriate treatment until the fracture heals, if possible, as removal may result in instability. • Bone graft to reestablish structural stability—autograft (harvested from individual); allograft (same species); alloplast (artificial material). • Treatment with composite/acrylic splints in association with wiring (Ivy loop, Stout's multiple loop) is generally very effective. • Assess soft tissue damage; debride and suture where appropriate.

Procedure
• Disinfect with dilute chlorhexidine and clean and polish teeth (flour pumice without fluoride). • Reduce fracture in proper occlusion. • Before applying splint materials, coat adjacent teeth and soft tissue with petroleum jelly. Acid etch the teeth with a 37% phosphoric acid gel; leave on for 30–60 seconds; rinse off thoroughly and air dry the teeth. Spot bonding of the teeth with light-cured unfilled resin if desired to increase adherence of dental materials to teeth.

Materials
Acrylics
• Warning: Use acrylics in well-ventiliated areas. They also generate heat can result in thermal injury to the teeth. • Place the powder and liquid in a salt-and-pepper fashion in small increments (to avoid hyperthermic reaction) until the desired shape and density of splint attained. • Finish and smooth with acrylic bur on high-speed handpiece.

Composites (Protemp Garant, Maxitemp)
• Little exothermal reaction and fumes; more expensive. • After acid-etching, use a dentinal bonding agent and apply a separator agent to opposing arcade to prevent composite from bonding to these teeth during occlusion check. • With a new mixing tip, apply product to splint area, shaping it as it hardens. • Finish and smooth with white stone bur and place a final layer of unfilled resin.

Circumferential Osseous Wiring or Suturing
• Wiring around the bone—used most commonly for symphyseal separations. • 20- or 18-gauge needle—to pass wire. • 24- to 28-gauge wire—in neonates, small dogs or cats, absorbable (long-acting, e.g., PDS) or nonabsorbable 1- to 2-0 suture

MAXILLARY AND MANDIBULAR FRACTURES (CONTINUED)

material can sometimes be substituted for wire. • Run wire from stab incision (ventral intermandibular space) to vestibule; pass behind canines, down through vestibule on opposite side, and back down through the ventral incision. • Tighten wire to reduce fracture, but do not overtighten the wire ends or the teeth may be pulled too far medially (lingually displaced) and hit the palate. If this happens, either loosen the wire ends or place a figure-eight wire looped around the canine teeth and under the jaw.

Homecare

• Orthodontic wax—soft, pliable wax sent with owner to periodically cover irritating wires, or can cover wire twists and ends with dental composite materials. • Oral irrigants—use twice daily for oral hygiene and to reduce bacteria; chlorhexidine solutions help reduce bacteria; zinc and ascorbic acid solutions (Maxi-Guard Gel) help reduce bacteria and stimulate soft tissue healing. • Diet—soft food or gruel may be required during healing.
• Nutritional and fluid maintenance required. • Chewing exercise—avoid hard chew items during healing process.

SURGICAL CONSIDERATIONS

• Based on type of fracture, available equipment, supplies, and the doctor's knowledge, experience, and comfort level.
• Treatment selection is based on four major points: (1) Reduction of fracture and reasonable contact of fracture ends, if possible. (2) Reestablishment of natural occlusion, and avoidance of causing a malocclusion when the fracture is reduced. (3) Stabilization sufficient for proper healing. (4) Salvage condition (nonrepairable or nonstabilizable condition).

MEDICATIONS

DRUG(S) OF CHOICE

Pain Management

• Local anesthesia—intraoral local blocks; regional nerve blocks: mental n., mandibular n., infraorbital n., and maxillary n. • Injectables—hydromorphone, buprenorphine, fentanyl, CRI, certain drug combinations. • Transdermal patches—fentanyl. • Oral—nonsteroidal anti-inflammatory drugs (NSAIDs); gabapentin, tramadol, hydrocodone.

Antibiotics

Limit usage to cases with suspected osteomyelitis; bacterial culture and sensitivity should be performed to prescribe appropriate drug.

FOLLOW-UP

PATIENT MONITORING

• Physical—recheck every 2 weeks postoperatively until appliance is removed.
• Radiographic—recheck 4–6 weeks postoperatively, then every 2 weeks until fracture is healed and/or appliance is removed. • Fracture site may temporarily (1–2 weeks) be more at risk to refracture after the support of the appliance is removed. • Once the fracture line is stable, compromised teeth may need additional endodontic treatment (e.g., root canal) or careful extraction. • If the healing process results in a malocclusion—orthodontics, endodontics, and/or selective exodontia (extraction) may be required. • Other considerations—stability of fracture and appliance; oral hygiene; oral intake of food and water; maintenance of weight; appropriate urination and defecation; indications of pain or swelling.

PREVENTION/AVOIDANCE

Try to minimize risk of trauma.

POSSIBLE COMPLICATIONS

• Malocclusion. • Endodontic disease.
• Osteomyelitis. • Non-union.
• Sequestrum. • Dehiscence. • Neurologic defects. • Facial pain syndrome.
• Impaired mastication. • Temporary weight loss. • Soft tissue trauma due to appliance or wires.

Possible Sequelae

Impaired Mastication

• TMJ arthritis—chronic or intermittent TMJ pain; may require condylectomy.
• Malocclusion—dental attrition; may require extractions. • Non-union—may require partial or complete mandibulectomy or maxillectomy. • Ankylosis or pseudoankylosis of the mandible at the TMJ or zygomatic arch region.

Facial Pain Syndrome

• Acute or chronic. • Due to nerve trauma from injury or as a complication of surgery.

Nerve Damage

Affecting motor function

EXPECTED COURSE AND PROGNOSIS

• Generally good; however, predisposing factors, initiating force, location, type of fracture, quality of homecare, and selection of treatment modality all affect the healing outcome. • 4–12 weeks to bony union.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Malocclusion. • Mastication difficulty.
• Lack of head symmetry. • Soft tissue trauma. • Periodontal disease. • Chipped, broken, luxated, or avulsed teeth.

AGE-RELATED FACTORS

Fracture healing may be faster in younger animals.

SEE ALSO

Temporomandibular Joint Disorders.

ABBREVIATIONS

• MMF = maxillomandibular fixation.
• NSAID = nonsteroidal anti-inflammatory drug.
• TMJ = temporomandibular joint.

MEGACOLON

BASICS

DEFINITION
A disorder characterized by persistent, irreversible dilation of the colon that is often the result of chronic constipation/obstipation.

PATHOPHYSIOLOGY
• Idiopathic dilated megacolon is the most common cause of chronic constipation in cats and occurs due to generalized colonic smooth muscle dysfunction. • The diagnosis of idiopathic dilated megacolon is often preceded by chronic, recurrent constipation so it is unclear whether a primary disorder of colonic smooth muscle occurs first or whether smooth muscle dysfunction results from prolonged colonic distension. • Megacolon can also occur secondary to abnormal neurologic function of the colon, including dysautonomia, spinal cord injury or deformities, pelvic nerve injury, and autonomic ganglioneuritis. • Colonic aganglionosis/hypoganglionosis (Hirschsprung's disease in humans) is a congenital absence of ganglia in the colonic smooth muscle; affected segments are unable to relax, resulting in megacolon. • Hypertrophic megacolon can develop as a consequence of obstructive lesions and will progress to dilated megacolon if the obstruction is not corrected.

SYSTEMS AFFECTED
• Gastrointestinal. • Neuromuscular—concurrent neurologic abnormalities may be seen when megacolon has a neurogenic cause. • Musculoskeletal—megacolon can occur secondary to pelvic fractures. • Endocrine/metabolic—megacolon can result in electrolyte derangements due to prolonged vomiting. Electrolyte and endocrine abnormalities (hypercalcemia, hypokalemia, hypothyroidism) can promote constipation and possibly lead to or exacerbate megacolon.

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Cat > dog.

Breed Predilections
Possible increased risk in Manx cat.

Mean Age and Range
• Idiopathic megacolon—young adult cats most commonly (mean 6 years) although cats of any age can be affected. • Acquired megacolon—none.

Predominant Sex
Male

SIGNS
Historical Findings
• Idiopathic megacolon—typically a chronic/recurrent problem; signs often present for months to years. • Acquired megacolon—signs may be acute or chronic. • Constipation/obstipation. • Tenesmus with small or no fecal volume. • Hard, dry feces. • Infrequent defecation. • Small amount of diarrhea (often mucoid) may occur after prolonged tenesmus. • Occasional vomiting, anorexia, and/or lethargy with chronic fecal impaction. • Weight loss.

Physical Examination Findings
• Abdominal palpation reveals an enlarged colon with hard feces. • Digital rectal examination may indicate an underlying (obstructive) cause and confirms fecal impaction. • Dehydration. • Unkempt hair coat. • Weight loss with chronicity. • Neurologic examination may reveal underlying neurologic disease.

CAUSES
• Mechanical obstruction—pelvic fractures, neoplasia, rectal foreign body, rectal stricture, atresia ani, prostatomegaly. • Neurologic disease—dysautonomia, sacral spinal cord deformities (Manx cat), cauda equina syndrome, pelvic nerve injury or dysfunction. • Endocrine/metabolic—hypercalcemia, hypokalemia, hypothyroidism, severe dehydration. • Drugs—opioids, anticholinergics, phenothiazines.

RISK FACTORS
• Chronic constipation. • Conditions leading to obstruction or difficulty defecating, including prior trauma and spinal cord injury or deformity. • Possible association with low physical activity and obesity as well as consumption of bone meal in dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other causes of palpable colonic masses (e.g., lymphoma, carcinoma, intussusception)—distinguish on the basis of texture, rectal examination, imaging, and mucosal biopsy. • Dysuria/stranguria—exclude by palpation of the bladder and colon, and by urinalysis. • Tenesmus due to inflammation of the colonic mucosa (colitis)—exclude by palpation, rectal examination, and colonoscopy with mucosal biopsy.

CBC/BIOCHEMISTRY/URINALYSIS
• Often normal. • May show evidence of dehydration and stress leukogram. • Electrolyte abnormalities may develop; may be prerenal azotemia with dehydration. • Urinalysis—typically unremarkable.

OTHER LABORATORY TESTS
Total thyroxine (T_4) to assess thyroid function.

IMAGING
• Abdominal/pelvic radiographs to identify underlying causes. • Can easily visualize an enlarged, fecal-filled colon on survey abdominal radiographs. • Abdominal ultrasound may identify mural or obstructive masses.

DIAGNOSTIC PROCEDURES
Rarely need colonoscopy to rule out mural or intraluminal obstructive lesions.

PATHOLOGIC FINDINGS
• Feline idiopathic megacolon has no defining histologic changes. Smooth muscle typically appears normal with evidence of normal innervation. Mucosal and submucosal ulceration, fibrosis, and inflammation can be variably present and are secondary to chronic fecal impaction. • Megacolon resulting from other etiologies may have features such as abnormalities in or reduced numbers of ganglia (ganglioneuritis or hypoganglionosis), or smooth muscle hypertrophy (hypertrophic megacolon).

TREATMENT

APPROPRIATE HEALTH CARE
• If administration of laxatives or enemas fails to resolve fecal impaction, inpatient management and manual evacuation of feces will be necessary. • For manual evacuation of feces, the patient should be placed under general anesthesia and intubated to prevent aspiration should manipulation of the colon trigger vomiting or regurgitation: ○ Warm water combined with a water-based lubricant can be administered during the procedure to help facilitate removal of feces. Feces are then removed manually while providing gentle assistance with abdominal palpation of the colon. ○ Periprocedural administration of an IV antibiotic with a good anaerobic spectrum can be considered in case manipulation of the compromised colon results in bacterial translocation. ○ This procedure may need to be repeated if the impaction is too severe to safely accomplish removal of all feces under one anesthetic event. • Trickle administration of polyethylene glycol 3350 via nasogastric tube for 24–48 hours prior to manual extraction will result in better fecal hydration and may facilitate stool removal.

NURSING CARE
• Most patients require parenteral fluid support to correct dehydration. • IV administration of balanced electrolyte solutions is the preferred route. • Control nausea and vomiting with antiemetic medications.

ACTIVITY
• Encourage activity and exercise. • Restriction indicated postoperatively if surgery is performed.

MEGACOLON (CONTINUED)

DIET
• Many patients require a low-residue producing diet; bulk-forming fiber diets can worsen or lead to recurrence of colonic fecal distension. • A soluble fiber-rich diet may be helpful. • A maintenance-type diet can be supplemented with fiber-enriched foods (pumpkin) or products containing fermentable fiber such as Metamucil.

CLIENT EDUCATION
• Following treatment for constipation, medical therapy, including dietary management, laxatives, and/or colonic prokinetics, may be required long term and has the potential to fail. • Subtotal colectomy is indicated in cases of medical treatment failure.

SURGICAL CONSIDERATIONS
• An underlying obstructive cause should be surgically corrected, if possible. Alternatively, subtotal colectomy has been described in the successful management of megacolon occurring secondary to pelvic fracture malunion. • For patients that do not respond favorably to medical treatment, subtotal colectomy is the treatment of choice. • Subtotal colectomy may be required with obstructive megacolon even if the obstruction is corrected if irreversible changes in colonic motility have already occurred. • Avoid enema administration or attempts at colonic evacuation prior to surgery. These efforts result in increased likelihood of fecal contamination of the abdomen during surgery. • Subtotal colectomy can be performed with either ileorectal or colorectal anastomosis. Preservation of the ileocolic junction is recommended as this results in more formed stool compared to cats in which it is excised.

MEDICATIONS

DRUG(S) OF CHOICE
• Colonic prokinetic agents—cisapride (5-HT receptor agonist) has been shown to stimulate colonic smooth muscle motility in cats and dogs with constipation. The dose is 0.1–0.5 mg/kg PO q8–12h, but may be increased up to 1 mg/kg if well tolerated. Metoclopramide is not effective for constipation. • Hyperosmotic laxatives—polyethylene glycol 3350 powder (Miralax®) 1/8–¼ tsp with food q12h; lactulose 0.5 mL/kg PO q8–12h to effect. In cats with severe constipation, polyethylene glycol electrolyte solution (GoLytely®, Colyte®) can be given via nasogastric or nasoesophageal feeding tube at 6–10 mL/kg/h for 12–48 hours in a 24-hour care hospital setting to facilitate passage of feces, either as an alternative to or in preparation for manual evacuation of feces. • Enemas—5–10 mL/kg warm water or a 50–50 mixture of warm water and water-soluble lubricant administered slowly via a lubricated 10–12 Fr red rubber catheter gently passed into the rectum. Lactulose can also be administered

CONTRAINDICATIONS
• Sodium phosphate retention enemas (e.g., Fleet by C.B. Fleet Co., Inc.)—because of their association with severe hypocalcemia. • Mineral oil and white petrolatum—because of danger of fatal lipoid aspiration pneumonia due to lack of taste.

PRECAUTIONS
Common hairball laxatives (e.g., Laxatone, Cat-a-Lax) are typically ineffective.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• Docusate sodium can be used as a stool softener in place of lactulose. • Psyllium can be added to food at a dose of ¼–1 tsp twice a day. Fiber may be beneficial in early stages but may exacerbate clinical signs in cats with loss of colonic muscle function. • Dioctyl sodium sulfosuccinate (Colace®) is an emollient laxative that can be given as an alternative to lactulose or polyethylene glycol. • Ranitidine, a member of the H_2-receptor antagonist drug class, may stimulate colonic motility and can be given if cisapride is unavailable. The dose is 1–3 mg/kg PO q12h. • One recent pilot study using multistrain probiotic SLAB51™ showed clinical improvement in some cats with chronic constipation and idiopathic megacolon.

FOLLOW-UP

PATIENT MONITORING
• Following colonic resection and anastomosis—for 3–5 days check for signs of dehiscence and peritonitis. • Clinical deterioration warrants abdominocentesis and/or peritoneal lavage to detect anastomotic leakage. • Continue fluid support until the patient is willing to eat and drink.

PREVENTION/AVOIDANCE
• Repair pelvic fractures that narrow the pelvic canal. • Avoid exposure to foreign bodies and feeding bones. • Encourage physical activity.

POSSIBLE COMPLICATIONS
• Recurrence or persistence—most common. • Potential surgical complications include peritonitis, persistent diarrhea, fecal incontinence, stricture formation, and recurrence of obstipation. • Traumatic perforation of the colon is a serious complication of overzealous fecal evacuation.

EXPECTED COURSE AND PROGNOSIS
• Historically, medical management has been unrewarding for the long term. • Cisapride appears to improve the prognosis with medical management in some patients, but may not suffice in severe or long-standing cases. • Postoperative diarrhea—expected; typically resolves within 6 weeks (80% of cats with idiopathic megacolon undergoing subtotal colectomy) but can persist for several months; stools become more formed as the ileum adapts by increasing reservoir capacity and water absorption. • Subtotal colectomy is well tolerated by cats; constipation recurrence rates are typically low.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Perineal hernia.

AGE-RELATED FACTORS
Concurrent medical conditions (e.g., chronic renal insufficiency, hyperthyroidism) may occur with idiopathic megacolon, because many cats are old.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
• The effect of cisapride on the fetus is unknown. • Patients would be at increased risk for dystocia if they carried a pregnancy to term.

SYNONYMS
None

SEE ALSO
• Constipation and Obstipation.
• Dyschezia and Hematochezia.
• Perineal Hernia.

ABBREVIATIONS
• T_4 = thyroxine.

MEGAESOPHAGUS

BASICS

DEFINITION
A focal or generalized, diffuse dilation of the esophagus with decreased to absent peristalsis.

PATHOPHYSIOLOGY
• In the normal esophagus, the presence of a food bolus in the proximal esophagus stimulates afferent sensory neurons. • Signals are transferred centrally, via the vagus and glossopharyngeal nerves to the tractus solitarius and nucleus ambiguus. • Motor impulses travel back via the efferent neurons of the vagus nerve to stimulate striated muscle (canine) and striated and smooth muscle (feline) esophageal contraction. • Lesions anywhere along this pathway may lead to megaesophagus and resultant retention of food and liquids. • Approximately 60% of dogs with megaesophagus have an "achalasia-like" syndrome of the lower esophageal sphincter (LES), that is a well-documented cause of megaesophagus in people.
• Functional obstruction of the LES results in esophageal dilatation, retention of ingesta, loss of esophageal motility, and associated clinical signs of esophageal dysphagia. • Dogs with evidence of esophageal achalasia may respond to targeted therapy with subsequent improvement in esophageal dysphagia.
• Focal megaesophagus is typically caused by esophageal obstruction secondary to strictures or a vascular ring anomaly with dilation of the esophagus proximal to the obstruction.

SYSTEMS AFFECTED
• Gastrointestinal—dysphagia, regurgitation, weight loss. • Musculoskeletal—weakness, weight loss, exercise intolerance, dysphonia.
• Nervous—possible manifestation of systemic neurologic/neuromuscular disorder.
• Respiratory—aspiration pneumonia, coughing.

GENETICS
• Congenital form—megaesophagus can be inherited in smooth fox terriers (autosomal recessive) and miniature schnauzers (autosomal dominant or 60% penetrance autosomal recessive). In addition, Jack Russell terriers, springer spaniels, long-haired miniature dachshunds, golden retrievers, Labrador retrievers, and Samoyeds are predisposed to the congenital form of myasthenia gravis.
• Other breeds in which acquired megaesophagus is more commonly reported include German shepherd dog, Great Dane, Irish setter, Labrador retriever, pug, and Chinese Shar-Pei.
• Acquired form—many diseases, especially neuromuscular diseases, may have an association with megaesophagus. Genetic predispositions for such diseases are listed under each disease separately.

INCIDENCE/PREVALENCE
• Congenital forms—relatively uncommon.
• Acquired disease—increasingly recognized in the dog and rare in the cat.

SIGNALMENT
Species
Dogs are more commonly affected than cats.

Breed Predilections
• Dogs—see Genetics. • Cats—Siamese and Siamese-related cats.

Mean Age and Range
• Congenital cases present soon after birth or at weaning during transition from liquid diets to solid foods. • Acquired cases may be seen at any age, depending on the etiology.

SIGNS
Historical Findings
• Owners often report vomiting; the veterinarian must differentiate vomiting from regurgitation. • Regurgitation (considered the hallmark sign); dysphagia; coughing/nasal discharge with aspiration pneumonia; ravenous appetite or inappetence; weight loss or poor growth; ptyalism, and halitosis. Dysphonia may occur secondary to neuromuscular disease. • Other signs depend upon underlying etiology.

Physical Examination Findings
• Cervical swelling may be noted, representing a distended cervical esophagus; ptyalism; halitosis; increased respiratory noises, nasal discharge, and fever (if concurrent pneumonia); cachexia; weakness; weight loss. • Assess for concurrent neurologic deficits that may indicate generalized disease. Special attention should be paid to cranial nerves IX, X, and XI. Muscle atrophy (if present) may be focal or generalized.

CAUSES
Congenital
Idiopathic megaesophagus; congenital myasthenia gravis (MG) (rare).

Acquired/Adult Onset
• Idiopathic (most common).
• Neuromuscular disease—MG, focal or generalized (25% of cases in dogs); systemic lupus erythematosus (SLE); myositis/myopathic disease; dysautonomia (more common in cats); botulism; vagal dysfunction/damage (bilateral); a possible association between laryngeal paralysis and esophageal dysmotility secondary to polyneuropathy has been identified. • Brainstem disease—disease involving cranial nerves IX, X nuclei or peripheral nerves. • Esophageal obstruction—vascular ring anomaly; esophageal or periesophageal neoplasia (e.g., lymphoma, thymoma, leiomyoma); stricture; foreign body; granuloma. • Toxicity—lead, thallium, anticholinesterase; acrylamide. • Endocrine disease—hypoadrenocorticism, hypothyroidism (controversial). Thymoma is associated with MG and megaesophagus in approximately 25% of cats. • Miscellaneous—gastric dilatation volvulus, hiatal hernia, gastroesophageal intussusception; esophagitis (gastroesophageal reflux, parasitic infection).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Must distinguish regurgitation from vomiting. • Regurgitation—passive; little to no abdominal effort; no prodromal phase; regurgitated material has increased amounts of thick mucus. Regurgitation often occurs many hours after a meal has been consumed due to retention of the food bolus within the esophagus. • Vomiting—active process; prodromal phase; vomited material may have increased bile staining. • The shape of the expelled material, presence of undigested food, and length of time from ingestion to regurgitation or vomiting are less helpful to differentiate.

CBC/BIOCHEMISTRY/URINALYSIS
• May be unremarkable. • Inflammatory leukogram may be seen with pneumonia.
• Other changes may identify underlying etiology—basophilic stippling on red blood cells with lead toxicity; electrolyte disturbances with hypoadrenocorticism, although lack of electrolyte changes does not rule out hypoadrenocorticism; hypercholesterolemia with hypothyroidism; elevated creatine kinase with myopathic disease, particularly during the acute phase.

OTHER LABORATORY TESTS
• Acetylcholine receptor (AchR) antibody titer in all cases of acquired megaesophagus (screen for MG). Approximately 2% of dogs with generalized MG are seronegative; testing should be repeated 2–3 months later, particularly if initial antibody titer is only slightly below the reference interval. Dogs with congenital MG do not have an autoimmune disorder associated with circulating AchR antibodies, but instead have a deficiency of the AchR receptor itself. Serologic testing of antibodies to the AchR in puppies or dogs suspected of the congenital form of MG is thus of no diagnostic value and is a waste of money. • Adrenocorticotropic hormone (ACTH) stimulation test or baseline cortisol level for hypoadrenocorticism. • Thyroid panel for hypothyroidism (may be affected by concurrent disease). • Blood and urine lead

MEGAESOPHAGUS (CONTINUED)

levels. • Antinuclear antibody (ANA) titers for SLE. • Blood cholinesterase levels for organophosphate toxicity.

IMAGING

Survey Thoracic Radiographs

• Dilated esophagus filled with air, fluid, or food. Interpret thoracic radiographs in anesthetized animals and anxious or painful animals with caution in light of aerophagia that can cause distention of the esophagus with air. • Evidence of aspiration pneumonia may be evident. • Ventral displacement of the trachea on lateral radiographs. • Ventrodorsal radiographs may show lateral tracheal displacement. • Evidence of underlying etiology: mediastinal mass (thymoma), hiatal hernia, neoplasia, etc. • Radiographs do not differentiate dogs with megaesophagus due to MG from dogs with megaesophagus due to other etiologies.

Contrast Esophagram and Videofluoroscopy

• Barium liquid and barium meal may demonstrate abnormal pooling, poor motility, or structural lesions. Iohexol may be used if perforation is a concern. • Use with caution in animals with megaesophagus due to risk of aspiration of contrast material. • Exercise extreme caution in animals with radiographic evidence of pneumonia. • Monitor animals closely after radiographs for signs of aspiration. • Videofluoroscopy—may be used to assess primary and secondary esophageal peristalsis. May help determine the best food consistency for long-term management. Videofluoroscopy commonly demonstrates marked retention of the food bolus within the esophagus for hours, despite gravity-assisted feeding in a Bailey chair. A bird-beak effect of the lower esophageal sphincter may be evident due to esophageal achalasia.

DIAGNOSTIC PROCEDURES

• Esophagoscopy—may be used for foreign body retrieval, evaluation of suspected obstructive lesions, neoplasia, or esophagitis. Distal esophageal neoplasia or stricture of the lower esophageal sphincter may mimic idiopathic megaesophagus and may require endoscopy for diagnosis. • Electrophysiology—in cases of suspected neuromuscular disease, may be used in conjunction with muscle and nerve biopsies. • Additional tests—may be indicated in cases of CNS disease: CSF analysis, distemper titers, brain CT or MRI. • Fecal exam—may indicate *Spirocerca lupi* infection.

PATHOLOGIC FINDINGS

Depend upon underlying etiology and presence of complicating factors.

TREATMENT

APPROPRIATE HEALTH CARE

• Treat underlying etiology (when applicable). • Most important aspects are meeting nutritional requirements and treating or preventing aspiration pneumonia.

NURSING CARE

• Aspiration pneumonia may require oxygen therapy, nebulization/coupage, fluid therapy with balanced electrolyte solution. • These animals may be recumbent and require soft bedding and should be maintained in sternal recumbency or turned to alternate down side every 4 hours.

ACTIVITY

Depending on etiology, restricted activity is not necessary.

DIET

• Calculate precise nutritional requirements, including degree of debilitation. • Experimentation with different food consistencies is essential (e.g., liquid gruel, small meatballs, blenderized slurries). • Many cases benefit from gastrostomy tube placement for feeding; however, this does not prevent gastroesophageal reflux and potential aspiration or aspiration of saliva. • Feeding and drinking should be from an elevated position (45–90° from floor) and the upright position should be maintained for 10–15 minutes after eating or drinking. An upright position may be easier to attain with the use of a specific "chair" (e.g., Bailey chair).

CLIENT EDUCATION

• Most cases of megaesophagus require life-long therapy. Even if an underlying etiology is found and treated, prognosis for resolution of idiopathic acquired megaesophagus is unlikely. Client dedication is important for long-term management. • Most animals succumb to or are euthanized because of aspiration pneumonia, malnutrition, or progression of underlying disease.

SURGICAL CONSIDERATIONS

• Surgery is indicated for vascular ring anomalies, bronchoesophageal fistula, some foreign bodies and other obstructive lesions, or thymectomy. • Balloon dilation is indicated for cases of esophageal stricture. • Surgical management of esophageal achalasia (Heller's myotomy followed by fundoplication) has been well documented in people with acquired megaesophagus secondary to esophageal achalasia and in a recent publication evaluating acquired megaesophagus in dogs.

MEDICATIONS

DRUG(S) OF CHOICE

• Antibiotics for aspiration pneumonia (ideally based on culture and sensitivity from transtracheal wash or bronchoalveolar lavage). • Therapy for underlying etiology if indicated—immunosuppressives (use with caution if pneumonia present) for immune-mediated disease; pyridostigmine for MG, prednisone supplementation for hypoadrenocorticism. • Proton pump inhibitors (PPIs) are superior acid suppressants to H_2-receptor antagonists (H2RAs) for the management of moderate to severe esophagitis, and are not susceptible to tolerance (tachyphylaxis) that has been well documented in people, dogs, and cats within 3–5 days following the implementation of H2RA therapy. PPIs such as omeprazole or pantoprazole must always be given twice daily for optimal benefit (1 mg/kg PO or IV q12h). In addition, PPIs should be gradually tapered before discontinuing to avoid acid rebound hypersecretion.

Prokinetics

The use of prokinetics such as cisapride and metoclopramide in dogs and cats with diffuse megaesophagus is contraindicated and should be avoided because they will tighten the LES (which already has increased tone in most dogs with megaesophagus as a consequence of achalasia) and possibly increase the risk of aspiration pneumonia. Prokinetics such as metoclopramide (1.0–2.0 mg/kg/day IV CRI or PO q6–8h) or cisapride (0.5 mg/kg PO q8–12h) are more effective for minimizing gastroesophageal reflux and subsequent esophagitis in dogs that do not have megaesophagus. Cisapride is more potent and effective than metoclopramide for increasing LES tone and enhancing gastric emptying, and can be used in animals with evidence of esophagitis but no evidence of megaesophagus, or in cats with esophageal dysmotility affecting the smooth muscle in the distal 1/3 of the esophagus.

PRECAUTIONS

• Absorption of orally administered drugs may be compromised. • Injectable forms should be used when applicable. • Immunosuppression, if indicated, must be used with caution due to risk of aspiration pneumonia.

(CONTINUED) MEGAESOPHAGUS

FOLLOW-UP

PATIENT MONITORING

• Thoracic radiographs when aspiration pneumonia is suspected (fever, cough, lethargy). • Cases of pneumonia may require CBC, blood gas analysis, and bronchoalveolar lavage. Repeat thoracic radiographs in animals with congenital megaesophagus as spontaneous resolution may occur. • Examine and weigh patients regularly to evaluate disease progression and ensure adequate nutritional intake.

PREVENTION/AVOIDANCE

If an esophageal foreign body is identified, remove as quickly as possible.

POSSIBLE COMPLICATIONS

• Aspiration pneumonia. • Others, depending on etiology.

EXPECTED COURSE AND PROGNOSIS

• Congenital cases have a guarded prognosis (20–46% recovery). • Miniature schnauzers may have better prognosis. • Prognosis may be improved with identification and treatment of specific etiology (e.g., hypoadrenocorticism, vascular ring anomaly). • Roughly 50% cases of MG respond to therapy; however, megaesophagus may persist even if other signs of MG resolve. • Prognosis for idiopathic, adult-onset disease is poor. • Owner dedication is crucial.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Aspiration pneumonia.

AGE-RELATED FACTORS

• Signs of regurgitation in very young animal or at weaning may indicate congenital lesion. • Prognosis may be better in young animals.

ZOONOTIC POTENTIAL

• None for megaesophagus. • Rabies vaccination status should be determined in any animal with possible neurologic disease.

SYNONYMS

• Esophageal aperistalsis. • Esophageal dilatation.

SEE ALSO

• Dysphagia.
• Esophageal Foreign Bodies.
• Myasthenia Gravis.
• Pneumonia, Aspiration.
• Pneumonia, Bacterial.
• Regurgitation.

ABBREVIATIONS

• AchR = acetylcholine receptor.
• ACTH = adrenocorticotropic hormone.
• ANA = antinuclear antibody.
• H2RAs = H_2-receptor antagonists.
• LES = lower esophageal sphincter.
• MG = myasthenia gravis.
• PPI = proton pump inhibitor.
• SLE = systemic lupus erythematosus.

M

MELANOCYTIC TUMORS, ORAL

BASICS

DEFINITION
Tumor of melanocytes arising in the oral cavity (gingiva, palate, tongue), most frequently malignant.

PATHOPHYSIOLOGY
• Locally invasive, may invade into underlying bone. • Metastatic in >75% cases in dogs. • Immunohistochemical evaluation may be required for the diagnosis of amelanotic melanomas.

SYSTEMS AFFECTED
• Oral cavity (gingiva, palate, tongue).
• Metastatic sites—regional lymph nodes and lungs most common; liver, spleen, bones, meninges, other.

M

GENETICS
Unknown

INCIDENCE/PREVALENCE
• Dogs—most common malignant oral tumor, accounting for ~40% of oral malignancies.
• Cats—third most common oral malignancy.

SIGNALMENT

Species
Dog more than cat.

Breed Predilections
• Dogs—cocker spaniel, miniature poodle, retriever breed, dachshunds, chow chow (tongue). • Cats—no predilection reported.

Mean Age and Range
• Dogs—11 years (5–18 years). • Cats—12 years (11–15 years).

Predominant Sex
• Dogs—male predisposed (in some studies).
• Cats—not reported.

SIGNS

Historical Findings
• Excessive salivation. • Halitosis.
• Dysphagia. • Hyporexia. • Bloody oral discharge. • Weight loss.

Physical Examination Findings
• Oral mass (up to a third are poorly pigmented or amelanotic), often friable and ulcerated. • Loose teeth if involvement of mandibular or maxillary bone. • Facial deformity (including exophthalmos).
• Regional lymphadenomegaly. • Pain or discomfort.

RISK FACTORS
Overrepresented breeds of dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other oral malignancy (squamous cell carcinoma, fibrosarcoma). • Acanthomatous ameloblastoma/peripheral odontogenic fibroma. • Gingival hyperplasia. • Tooth root abscess. • Foreign body reaction.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

IMAGING
• High-detail skull radiography or dental radiographs—evaluate for osteolytic changes.
• Advanced imaging (contrast-enhanced CT or MRI) affords better detail and helps with therapeutic planning (surgery or radiation therapy). • Three-view thoracic imaging (radiography or CT)—evaluate lungs for metastasis. • Abdominal imaging (ultrasonography or CT)—to complete clinical staging; occasional distant metastasis in abdominal visceral organs.

DIAGNOSTIC PROCEDURES
• Carefully measure primary tumor—important prognostic information. • Fine-needle aspiration and cytology of ipsilateral and contralateral mandibular lymph nodes recommended to evaluate for regional metastases, regardless of their size and consistency upon palpation—up to 40% of normal-sized regional lymph nodes have metastasis. • Carefully palpate other regional lymph nodes (retropharyngeal, parotid, superficial cervical) and perform fine-needle aspiration and cytology if abnormal. • Large and deep-tissue biopsies may be required to obtain definitive diagnosis (via histopathology) and gather prognostic information.
• Fine-needle aspiration or biopsies of primary tumor should always be taken from inside the mouth, not through the skin (could compromise local control with surgery due to needle or biopsy track seeding).

PATHOLOGIC FINDINGS

Gross
• Masses may be ulcerated and friable; often bleed when large and malignant.
• Amelanotic to dark brown, gray, or black.
• Vary greatly in size; often invasive in surrounding tissues.

Cytologic Findings
• Brown, rod-like intracellular granules (melanin) of various size and shapes.
• Pigment may be absent with amelanotic tumors. • May see melanophages (phagocytic macrophages) with large intracytoplasmic vacuoles containing melanin, especially in lymph nodes. • More cellular atypia observed in malignant tumors.

Histopathologic Findings
• Cells may vary in shape (e.g., epithelioid, fusiform, dendritic, and mixed), degree of pigmentation, and cytoplasmic morphology.
• Malignant—generally high mitotic index; nuclear and nucleolar pleomorphism (more atypia, less differentiation); invasive into surrounding tissues; amelanotic may pose a diagnostic challenge; immunohistochemistry and special stains may be particularly useful; proliferation markers may help predict behavior. • Immunohistochemistry (e.g., Melan-A, S100, PNL2, HMB-45, vimentin)—may help confirm a diagnosis, especially if amelanotic (approximately one-third of cases).
• Histopathology report should include mitotic index (mitoses per 10 HPF), degree of atypia/differentiation, invasiveness, and surgical margins if excisional biopsy.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient if undergoing aggressive oral surgery.

NURSING CARE
Pain management—multimodal analgesia (preemptive, intra- and postoperative) is mandatory with aggressive surgeries.

ACTIVITY
Restrict until sutures are removed and all surgical wounds healed.

DIET
• Soft food recommended to prevent tumor ulceration or following aggressive oral surgery.
• Avoid toys and hard treats until oral tissues are healed completely.

CLIENT EDUCATION
• Discuss importance of clinical staging.
• Discuss need for early aggressive approach with surgical removal • Warn caretaker that malignant melanoma frequently metastasizes early in the course of the disease, resulting in a guarded prognosis. • Adjuvant therapy is recommended to improve survival time and delay metastasis. • Repeat clinical staging recommended after therapy.

SURGICAL CONSIDERATIONS
• Goal should be to remove all macroscopic tumor burden and obtain complete margins in order to improve overall prognosis.
• Radical *en bloc* surgical excision—required (e.g., mandibulectomy or maxillectomy); well

tolerated by most patients; surgical margins of at least 2 cm; improved survival when margins are free of neoplastic cells. • Surgical removal of the draining lymph node(s) is recommended when metastasis confirmed or suspected and no evidence of distant (e.g., lung) metastatic disease.

RADIATION THERAPY

• May be used to improve local disease control following unplanned incomplete resection. • As single modality treatment for macroscopic disease, radiation therapy affords a good response rate (>80%) and may offer long-term control with inoperable tumors; 3–6, weekly to twice weekly, large fractions of megavoltage radiation therapy.

MEDICATIONS

DRUG(S) OF CHOICE

• Carboplatin has been described for oral melanoma in dogs and remains recommended following surgical excision of macroscopic disease (primary tumor, metastatic regional lymph nodes). • Carboplatin may still be advised if surgical excision is not possible, with a response rate approximating 30% on measurable disease, and may be coupled with palliative radiation therapy protocols.
• Contact a veterinary oncologist for any updated treatments that may be available.
• No effective chemotherapy described in cats. • Pain management with multimodal analgesia therapy is mandatory (nonsteroidal anti-inflammatory drugs, opioid, adjuvant analgesia medications, aminobisphosphonates if osteolysis is present).

Immunotherapy

• Many immunotherapies have been attempted with varied success. • A therapeutic vaccine is available (Oncept™) that involves the injection of human cDNA (xenogeneic) coding for a melanocyte-specific protein, tyrosinase, and results in a measurable immune response in some patients. • The tyrosinase vaccine is approved for the postoperative treatment of stage II and III oral malignant melanomas and some reports suggest improved survival times in comparison with historical control studies.

CONTRAINDICATIONS

Avoid the use of cisplatin in cats.

PRECAUTIONS

Seek advice from an oncologist before initiating treatment if you are unfamiliar with cytotoxic drugs (myelosuppression, specific toxicities, etc.).

POSSIBLE INTERACTIONS

Drugs with overlapping toxicities should be avoided.

ALTERNATIVE DRUG(S)

Novel therapeutics or treatment regimens may be available. Contact a veterinary oncologist for any updated treatments that may be available.

FOLLOW-UP

PATIENT MONITORING

• Evaluate for local recurrence and regional metastasis every 2–3 months following surgery or earlier if the owner believes the mass is returning; or if the patient is otherwise not normal. • Recommend three-view thoracic radiography at the time of rechecks (every 3 months).

POSSIBLE COMPLICATIONS

• Poor wound healing, dehiscence, infection possible after aggressive surgery. • Early radiation side effects, such as mucositis or dermatitis, may result from hypofractionated protocols.

EXPECTED COURSE AND PROGNOSIS

• Poor prognosis when untreated (median 2 months). • Depends upon disease stage; better prognosis with stage I. • Complete surgical excision (local and regional lymph node when positive) is essential to improve the prognosis—median survival time with surgery alone varies with stage: ◦ Stage I—over 18 months. ◦ Stage II and III—5–12 months. ◦ Stage IV—less than 3 months. • Adjuvant carboplatin chemotherapy is not consistently reported as beneficial but remains recommended. • Prognosis of stage II and III canine oral melanoma may be improved to over 18 months with the adjuvant use of the recombinant xenogeneic tyrosinase vaccine. • Survival with radiotherapy treatment alone (dogs)—6–10 months. • Cause of death in dogs may be metastatic disease or local tumor recurrence. • Overall prognosis in cats is poor; most tumors are locally invasive and diagnosed late in the course of the disease; cause of death is often due to local disease progression—median survival time of 146 days in 5 cats treated with hypofractionated radiation therapy.

MISCELLANEOUS

AGE-RELATED FACTORS

Older age at diagnosis (>12 years) might predict a poorer prognosis in dogs.

SEE ALSO

Melanocytic Tumors, Skin and Digit.

MELANOCYTIC TUMORS, SKIN AND DIGIT

BASICS

OVERVIEW

• Benign or malignant neoplasm arising from melanocytes within the epidermis or the nail bed. • Anatomic site is highly predictive of invasiveness and metastatic propensity: ○ Digit and mucocutaneous junction melanomas tend to be malignant. ○ Melanomas of haired-skin tend to behave in benign manner. • When malignant—occasionally invades bone (e.g., third phalanx) and metastasizes (lymph node, lungs, and other sites).

SIGNALMENT

• Dogs—around 5% of all skin tumors. • Cats—<5% of all skin tumors. • Dogs, mean age 9 years, certain breeds more common—terriers (Scottish, Boston, and Airedale), schnauzers, cocker and springer spaniels, Irish setter, chow chow, retriever breeds, poodles, Doberman pinschers. • Cats, mean age 10–13 years, no breed predilection.

SIGNS

• Skin mass with variable growth rates, may be ulcerated and friable, usually solitary. • Develops anywhere; in dogs more common on face, trunk, feet, and scrotum; in cats more common on head, digit, pinna, and nose. • Benign—brown to black; varies from macules and plaques to firm, dome-shaped nodules, 0.5–2 cm in diameter, well demarcated. • Malignant—amelanotic to dark brown, gray, or black, often >2 cm in diameter and more invasive in surrounding tissues. • Lameness and pain if digit is involved and associated with infection or bone lysis. • Regional lymphadenomegaly possible.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Distinguish amelanotic melanoma from poorly differentiated discrete cell tumors (mast cell tumor, lymphoma), various sarcomas (e.g., histiocytic, soft tissue sarcoma), carcinomas (especially basal cell), other benign changes (pyogranulomatous inflammation).

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

IMAGING

• Thoracic radiography recommended for evaluation of distant metastasis. • Advanced imaging (CT scan) is more sensitive to detect smaller distant metastases. • With digital melanoma, radiography of the lesion is recommended to determine if underlying bone (P3) is involved; bone lysis is less common with nailbed melanoma (approximately 10%) compared with squamous cell carcinoma (approximately 75%).

DIAGNOSTIC PROCEDURES

• Cytologic examination of fine-needle aspirates (primary mass, draining lymph nodes). • Draining lymph nodes should be evaluated with cytology, regardless of their size and consistency upon palpation. • Tissue biopsies may be required to obtain definitive diagnosis (via histopathology). • Immunohistochemical markers—may help differentiate melanoma (especially amelanotic) from other tumors; may stain positive with Melan-A, S100, PNL2, HMB-45, vimentin; proliferation markers may help predict behavior (e.g., Ki67).

TREATMENT

Surgical Considerations

• Wide surgical excision—treatment of choice. • Amputation of digit (P3 and P2) with nailbed localization. • Lymphadenectomy of the draining lymph node might be indicated when regional metastasis confirmed or suspected and no evidence of detectable distant dissemination.

Radiation Therapy Considerations

• May be used to improve local disease control following unplanned incomplete resection. • Palliative radiation therapy may be considered for inoperable tumors.

MEDICATIONS

DRUG(S) OF CHOICE

• Adjuvant chemotherapy (often carboplatin) recommended following excision of macroscopic malignant melanoma (primary tumor, metastatic regional lymph nodes). • Chemotherapy may still be advised if surgical excision is not possible, with a response rate approximating 30% on measurable disease, and may be coupled with palliative radiation therapy protocols. • Contact a veterinary oncologist for updates on novel therapeutic options or treatment regimens. • Multimodal analgesia recommended to control pain and discomfort.

Immunotherapy

• Many immunotherapies have been attempted with varied success. • Therapeutic vaccination—injection of cDNA coding for a melanocyte-specific protein, tyrosinase, is considered safe and results in a measurable immune response in some patients.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Cisplatin is contraindicated in cats. • Seek advice from an oncologist before initiating treatment if you are unfamiliar with cytotoxic drugs (myelosuppression, specific toxicities, etc.).

FOLLOW-UP

PATIENT MONITORING

• Evaluate for local recurrence and regional metastasis—every 2–3 months following surgery or earlier if the owner believes the mass is returning; or if the patient is otherwise not normal. • 3-view thoracic radiography—at the time of rechecks and periodically thereafter.

EXPECTED COURSE AND PROGNOSIS

Dogs

• Melanomas on the digit, footpad, scrotum, and mucocutaneous junctions are more frequently malignant. • Prognosis with benign cutaneous melanomas is excellent. • Median survival with malignant cutaneous or digit melanoma is 12 months. • Breed differences in prognosis in some studies—majority of cutaneous melanomas in Doberman pinschers and miniature schnauzers behave in a benign fashion, and a majority of cutaneous melanomas in miniature poodles behave in a malignant fashion.

Cats

• 35–50% of melanomas reported to be malignant. • Median survival with melanoma of the skin or digit not well documented and reported to be 4.5 months after surgery. • Cats with auricular melanoma may have a more favorable prognosis compared to melanomas of other cutaneous sites or oral cavity.

MELENA

BASICS

DEFINITION
Black, tarry appearance of feces caused by the presence of digested or oxidized blood.

PATHOPHYSIOLOGY
Usually results from upper gastrointestinal (GI) bleeding (esophagus, stomach, small intestine), but can be associated with ingested blood from the oral cavity or respiratory tract. Rarely can be caused by bleeding in the cecum or colon.

SYSTEMS AFFECTED
- GI.
- Respiratory.
- Coagulation.
- Cardiovascular.

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
- More common in dog than cat.

Breed Predilections
None

Mean Age and Range
Any age.

Predominant Sex
None

SIGNS

Historical Findings
- Patients with clinically significant anemia may demonstrate lethargy, inappetence, weakness, collapse, mucous membrane pallor, and/or dyspnea.
- Patients with primary GI disease may demonstrate hypersalivation, dysphagia, regurgitation, vomiting with or without blood (frank blood or "coffee grounds" appearance), inappetence, weight loss, increased borborygmi, or diarrhea.
- Patients with respiratory tract hemorrhage may demonstrate epistaxis, sneezing, hemoptysis, mucous membrane pallor, weakness, and/or dyspnea.
- Patients with abnormal coagulation may demonstrate petechiae, ecchymoses, mucous membrane pallor, epistaxis, hematuria, hematochezia, hyphema, and/or weakness.

Physical Examination Findings
Depends on the underlying cause.

CAUSES

Primary GI Ulceration/Erosion
- Neoplasia—adenocarcinoma, lymphoma, sarcoma.
- Inflammatory bowel disease (IBD)—lymphoplasmacytic, eosinophilic, granulomatous, and/or histiocytic gastritis/enteritis.
- Benign polyps.
- Infectious—Bacterial (*Salmonella* spp., *Clostridium perfringens*, *C. difficile*); fungal or fungal-like (pythiosis, histoplasmosis), parasitic (*Physaloptera, Ollulanus,* hookworms), viral (parvovirus, circovirus, distemper).
- Mechanical—foreign body.
- Inflammatory—acute and chronic gastritis; acute hemorrhagic diarrhea syndrome.
- Drugs—nonsteroidal anti-inflammatory drugs (NSAIDs), corticosteroids.
- Toxins—ingestion of heavy metals, some plants, cleaners, etc.

Metabolic/Other Diseases That Cause GI Ulceration
- Hypoadrenocorticism.
- Neoplasia—gastrinoma, mast cell tumor.
- Shock, poor perfusion.
- Pancreatitis.
- Acute kidney injury or advanced chronic kidney disease.
- Hepatic disease/failure, intrahepatic portosystemic shunts.

Ingestion of Blood
- Diet (raw foods).
- Esophageal lesion—neoplasia, esophagitis.
- Oral or pharyngeal lesion—neoplasia, abscess.
- Nasal lesion—neoplasia, fungal rhinitis, inflammatory rhinitis, trauma.
- Respiratory lesion—lung lobe torsion, neoplasia, pneumonia, trauma (causing hemoptysis).

Coagulopathy
- Thrombocytopenia.
- Thrombocytopathia—congenital vs. acquired.
- von Willebrand disease.
- Clotting factor abnormalities—anticoagulant rodenticide ingestion, selected clotting factor deficiencies.
- Disseminated intravascular coagulation.

RISK FACTORS
Arthritis, intervertebral disc disease or other conditions requiring use of NSAIDs or corticosteroids.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Medications that cause dark stool—bismuth subsalicylate, oral iron therapy, sucralfate, barium sulfate, activated charcoal.
- Must distinguish primary intestinal from extraintestinal disease.

CBC/BIOCHEMISTRY/URINALYSIS
- Microcytic, hypochromic, poorly regenerative anemia if chronic blood loss.
- Regenerative anemia in early blood loss—may be pre-regenerative if <3–5 days.
- Panhypoproteinemia, hypocholesterolemia if significant blood loss or diffuse GI disease
- Thrombocytopenia—may be mild from consumption with GI bleeding; severe thrombocytopenia may be primary cause of bleeding.
- Neutrophilia in some patients.
- Biochemistry analysis may reveal extraintestinal cause of melena—renal failure, hepatic disease, hypoadrenocorticism. Increased blood urea nitrogen (BUN):creatinine ratio can be seen secondary to GI bleeding.
- Urinalysis may demonstrate hematuria in patients with coagulation defects.

OTHER LABORATORY TESTS
- Prothrobin time/activated partial thromboplastin time (PT/aPTT) may be prolonged with coagulopathy.
- Buccal mucosal bleeding time tests primary hemostasis. Will be prolonged with thrombocytopenia and anemia.
- Fecal centrifugation flotation may reveal parasites.
- Diarrhea PCR panels for bacterial DNA and toxin genes in combination with ELISA testing for *C. perfringens* enterotoxin and *C. difficile* toxins A and B may be helpful but should be interpreted based on history, physical examination findings, environment, and risk factors.
- Parvo antigen testing.
- Serum cobalamin and folate may be useful to screen for diffuse GI disease.
- Rectal scraping may demonstrate fungal organisms (*Histoplasma* spp.).
- Resting cortisol and/or adrenocorticotropic hormone (ACTH) stimulation test abnormally low with hypoadrenocorticism.

IMAGING
- Abdominal radiography may reveal a mass or foreign body, or abnormalities in renal or hepatic size/shape.
- Thoracic radiographs may identify esophageal foreign bodies, pulmonary or tracheobronchial lesions or metastatic disease.
- Nasal CT may demonstrate intranasal lesions.
- Ultrasonography may reveal a GI mass, loss of intestinal layering, evidence of GI ulceration (mucosal defect, intramural gas), alterations in hepatic echotexture and size, pancreatic changes suggestive of pancreatitis, or changes supportive of renal disease or hypoadrenocorticism.
- Upper GI barium series may delineate gastric or proximal small intestinal masses, ulceration, or filling defects; however, upper GI series is insensitive for detection of gastric and intestinal ulceration.

MELENA (CONTINUED)

DIAGNOSTIC PROCEDURES
- Endoscopy allows visualization of masses and/or ulcers (esophageal, gastric, and/or duodenal), retrieval of esophageal or gastric foreign bodies, and procurement of biopsy samples.
- Retroflex and/or anterograde rhinoscopy may allow visualization of nasal lesions.
- Tracheobronchoscopy allows visualization of large airway lesions.
- Capsule endoscopy may be useful for delineating sites of intestinal bleeding that cannot be visualized via flexible endoscopy.

PATHOLOGIC FINDINGS
Vary with underlying disease.

TREATMENT

APPROPRIATE HEALTH CARE
- Inpatient—most patients admitted for work-up and management with exception of animals with melena secondary to intestinal parasites.
- Treat underlying disease—renal failure, hepatic disease, hypoadrenocorticism, respiratory disease, etc.

NURSING CARE
- Fluid replacement with balanced electrolyte solutions and potassium supplementation.
- Whole blood or packed red blood cell transfusions if anemia is severe.
- Whole blood, platelet concentrate or plasma transfusion if the patient has a coagulopathy.

ACTIVITY
Need for restriction varies with underlying disease.

DIET
Temporarily discontinue oral intake if vomiting is intractable.

CLIENT EDUCATION
Depends on underlying disease.

SURGICAL CONSIDERATIONS
Surgery may be required for severe gastroduodenal ulceration, neoplasia, or foreign bodies.

MEDICATIONS

DRUG(S) OF CHOICE
- Varies with underlying disease.
- For known or suspected gastric ulceration:
  - Proton pump inhibitors (PPI; e.g., omeprazole 1 mg/kg PO q12h, pantoprazole 1 mg/kg IV q12h, esomeprazole 0.7 mg/kg IV q12h) are superior to H_2 antagonists for acid suppression. PPIs should be tapered following chronic use >3–4 weeks (50% reduction weekly).
  - Misoprostol (3–5 µg/kg PO q12h) for cases of NSAID-induced gastric ulcers.
  - Sucralfate (0.5–1 g PO q6–8h as a suspension) for esophagitis or gastric ulceration.

CONTRAINDICATIONS
Avoid corticosteroids and NSAIDs in patients with gastroduodenal ulceration/erosion.

PRECAUTIONS
Misoprostol should not be used in pregnant animals.

POSSIBLE INTERACTIONS
- Antacids may cause decreased absorption of medications that require an acid pH for absorption.
- Sucralfate should be separated from meals or other medications by 2 hours.

ALTERNATIVE DRUG(S)
H_2-receptor antagonists (e.g., ranitidine 1–2 mg/kg IV, SC, or PO q12h or famotidine 0.5–1 mg/kg IV, SC, or PO q12h) may be used for acid suppression if PPIs are not available.

FOLLOW-UP

PATIENT MONITORING
- Packed cell volume (PCV) 2–3 times daily until anemia stabilized, then weekly.
- Hydration daily if patient vomiting.

PREVENTION/AVOIDANCE
Use ulcerogenic drugs with caution. Avoid concurrent use of NSAIDs and glucocorticoids.

POSSIBLE COMPLICATIONS
- Gastric or duodenal perforation resulting in peritonitis.
- Hypovolemic shock and death if severe, acute blood loss.

EXPECTED COURSE AND PROGNOSIS
Varies with underlying disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
Bacterial (*Clostridium* spp., *Salmonella* spp.) and parasitic infectious causes are potentially zoonotic.

PREGNANCY/FERTILITY/BREEDING
Misoprostol should not be used in pregnant animals.

MENINGIOMA—CATS AND DOGS

BASICS

DEFINITION
• Tumor of the meninges. Most commonly affects meninges overlying the cerebrum. • Most common tumor of the canine brain and spinal cord. • Most common tumor of the feline brain; second most common tumor of the feline spinal cord (most common being lymphoma).

PATHOPHYSIOLOGY
• Primary tumor arising from the arachnoid cap cells. • Intradural–extramedullary location. • Usually solitary masses; occasionally multiple (cats > dogs). • May occur as plaque-like masses on the floor of the calvaria, paranasally, or retrobulbar space (rare, more common in dogs than in cats). • Causes neurologic deficits secondary to compression of the adjacent tissue. Progresses slowly, causing vasogenic edema and, occasionally, obstructive hydrocephalus or infarction. • Most are *cytologically* benign. In dogs, tend to be more invasive into brain parenchyma or surrounding vasculature, and can be considered *biologically* malignant, unless aggressive surgical resection is possible (e.g., within the olfactory bulb).

SYSTEMS AFFECTED
Nervous—primary effects (e.g., infiltration and compression of adjacent structures) and secondary effects (e.g., edema, increased intracranial pressure [ICP], brain herniation).

INCIDENCE/PREVALENCE
• Reported incidence of brain tumors is 14.5/100,000 dogs and 3.5/100,000 cats. Meningiomas account for approximately 22% of all canine brain tumors, and 59% of all feline brain tumors. • 17% of cats with intracranial meningioma have >1 tumor of the same type. • Incidence of spinal tumors in dogs and cats—unknown; considerably less than that of brain tumors. Spinal meningiomas account for 14% of all canine meningiomas and 4% of all feline meningiomas.

SIGNALMENT
Dog and cat.

Dogs
• Boxers and golden retrievers most commonly affected; dolichocephalic breeds may have an increased risk of intracranial meningioma; mesocephalic breeds may have a higher incidence of paranasal meningioma. • Most >7 years of age; median 9 years, range 11 weeks–14 years; a spinal meningeal sarcoma was diagnosed in an 11-week-old Rottweiler. • Slight predominance for females. • Cystic meningiomas reported.

Cats
• Domestic shorthair cats overrepresented. • Most >9 years of age; mean 12 years, range 1–24 years; slight predominance for males.

SIGNS

General Comments
• Vary with tumor location. • Typically chronic and insidiously progressive over weeks to months. • May be acute if vascular invasion results in focal ischemia or if edema develops rapidly. • Lateralizing deficits predominate. • Elevated ICP, cerebral edema, or brain herniation may cause multifocal deficits, making localization of a focal mass/lesion difficult based on clinical signs.

Historical Findings
May be prolonged history of vague signs until compensatory mechanisms (e.g., decreased cerebrospinal fluid [CSF] and blood volume) are overwhelmed, followed by rapid progression of clinical signs.

Intracranial
• Dogs—late-onset seizures is the most common presenting sign. • Cats—abnormal behavior and mentation are the most common presenting signs. Nonspecific signs include lethargy, inappetence, and anorexia. Seizures less common than in dogs.

Intraspinal
• Neck or back pain. • Progressive incoordination and weakness, which may worsen with exercise.

Physical Examination Findings
Intracranial
• Cerebral disease is most common, causing abnormal behavior and mentation; circling or head-pressing; contralateral hemi-neglect, hemianopsia, facial paresis, facial and thoracic hypesthesia and conscious proprioceptive deficits; seizures. • Brainstem—alterations of consciousness; abnormal gait; ipsilateral proprioceptive and cranial nerve deficits in cranial nerves III to XII; central vestibular abnormalities. • Cerebellum—ataxia and dysmetria; intention tremors; truncal sway; broad-based stance; lack of menace responses with normal vision, and pupillary light and palpebral reflexes. • Orbital—exophthalmos, orbital swelling, prolapsed globe; blindness in the affected eye; fundic abnormalities.

Intraspinal
• Paraspinal or radicular pain referable to the region of spinal column affected. • Ataxia and paresis caudal to the level of the lesion.

CAUSES
• Unknown. • Documentation in young cats with mucopolysaccharidosis type I suggests a causal relationship.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Metabolic or toxic encephalopathy—may also present with seizures or mentation changes and normal neurologic exam; differentiate with brain imaging. • Other primary CNS (e.g., glioma, pituitary, nephroblastoma) or secondary (e.g., lymphoma, extensional, metastatic) tumors—may have more rapid onset and progression of signs; differentiate with brain or spinal imaging. • Granulomatous meningoencephalitis—may cause progressive focal deficits in dogs; differentiate based on age and further diagnostics, such as imaging and CSF analysis. • Nerve sheath tumors, gliomas, lymphoma, focal meningomyelitis, type II intervertebral disc disease, degenerative myelopathy—differentiate by spinal cord imaging. • *Cryptococcus* granuloma—reported to have same appearance on CT as a meningioma in a cat.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

IMAGING
• MRI—preferred imaging modality for intracranial and spinal disease. • MRI—often hyperintense on T2-weighted images (T2WI), isointense on T1-weighted images (T1WI), and uniformly contrast-enhancing mass lesion of the brain or spinal cord; broad-based, with extra-axial attachment. A 'dural tail' is a characteristic feature. If present, 'dural tail' helps to differentiate an intraventricular meningioma from a choroid plexus tumor. Spinal cord swelling may make the distinction between intradural/extramedullary and intramedullary difficult. • CT—often homogeneous contrast enhancement of well-circumscribed mass lesion. • Skull radiography and CT—may reveal hyperostosis of the calvaria adjacent to the meningioma. Calcification of the mass causes increased tissue density. Hyperostosis may be seen in cats. • Spinal radiography—usually normal with intraspinal meningioma; can be helpful to rule out bony lesions. • Myelography—typically reveals an intradural–extramedullary mass and interruption of the normal flow of contrast at the tumor. 'Golf tee' appearance can be present with both nerve sheath tumor and meningioma. Differentiation requires biopsy.

DIAGNOSTIC PROCEDURES
• CSF analysis—infrequently performed because diagnostic imaging is diagnostic. If performed, normal-to-high protein concentration with possible neutrophilic or mixed

MENINGIOMA—CATS AND DOGS (CONTINUED)

pleocytosis. Should not be considered unless CT or MRI have been performed. Contraindicated with increased ICP, as collection of CSF increases risk of brain herniation and consequent neurologic decompensation.• Electroencephalography—reveals slow-wave, medium--to-high-voltage activity, indicating cortical depression. Paroxysmal waveforms characteristic of seizure activity may be evident. • Biopsy—necessary for definitive diagnosis; perform intraoperatively or, for intracranial tumors, using a CT-guided stereotactic system.

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient—necessary if dehydration, anorexia, disequilibrium, and/or frequent or life-threatening seizures. • Surgical excision—for definitive management; usually successful if the tumor is accessible. Incomplete excision is common, particularly for intracranial meningiomas in dogs, intraspinal meningiomas in cats, and in tumors ventral to the spinal cord.
• Fractionated conventional radiation therapy—15–20 treatments over 3–4 weeks, following incomplete excision, if excision not possible, or if a less invasive approach is desired. When combined with surgery, radiation is associated with prolonged survival time in canine intracranial and intraspinal meningiomas compared to surgery alone, and delays or prevents local recurrence of disease. Given the success of complete surgical excision of intracranial meningiomas in cats, radiation is rarely necessary. Feline intracranial meningiomas are likely radiation sensitive, but data are lacking. It should be considered when surgery is not an option • Stereotactic radiosurgery (SRS)—high dose of radiation delivered to tumor with sub-millimeter accuracy. A steep dose-gradient limits exposure of normal tissue and reduces side effects of radiation. Can be conducted on an outpatient basis in 1–5 treatments delivered on consecutive days. The best candidates are those who are stable or able to be stabilized with steroids prior to the procedure. SRS significantly decreases tumor volume, but occurs slowly. SRS should be distinguished from intensity modulated radiation therapy (IMRT) delivered in 3–5 fractions (hypo-fractionated IMRT), the former being more accurate. • Chemotherapy—may be associated with prolonged survival after incomplete excision, post-radiation, or as sole agent. Hydroxyurea inhibits DNA synthesis, leading to cell death during the S phase of the cell cycle. Hydroxyurea shows effectiveness in humans with intracranial meningiomas and is commonly used in veterinary medicine, but controlled studies are lacking. • Medical management—antiepileptic drugs and corticosteroids are palliative, without effect on the primary disease process. Neither radiation or chemotherapy aid directly in control of edema or of neurologic signs such as seizures.

NURSING CARE

• Fluids—avoid overzealous fluid administration, as this may exacerbate cerebral edema and neurologic deficits. • Use caution with jugular compression during venipuncture or when positioning for surgery to avoid increases in ICP.

MEDICATIONS

DRUG(S) OF CHOICE

Cerebral Edema

• Corticosteroids—improve neurologic deficits associated with vasogenic edema.
• Stuporous, severely ataxic, or showing signs of herniation—methylprednisolone sodium succinate 30 mg/kg IV or dexamethasone sodium phosphate 0.1 mg/kg IV. • Continued deterioration or no improvement—20% mannitol solution 0.5–1 g/kg IV over 15–20 minutes. Furosemide 2 mg/kg IV acts synergistically with mannitol and can be added if needed. Hypertonic saline 3–5 mL/kg may be used as an alternative or in addition to mannitol. Dexamethasone 0.05–0.1 mg/kg q24h IV.
• Once patient is stable—dexamethasone 0.05–0.1 mg/kg q24h or in divided daily doses PO or prednisone 0.25–0.5 mg/kg PO q12h; then taper to lowest effective dose.

Seizures

• Antiepileptic drugs—mandatory if isolated seizures >1/month, cluster seizures, or status; recommended if any seizure activity in animal with meningioma, and possibly prophylactically in animals with forebrain meningioma.
• Maintenance treatment—phenobarbital (first choice in dogs and cats) 2–3 mg/kg IV or PO q12h; or zonisamide 5–10 mg/kg q12h PO (dogs or cats); or levetiracetam 20–30 mg/kg q8h IV or PO as starting dose; if extended release levetiracetam q12h PO (dogs or cats). • Cluster seizures or status—diazepam 0.25–5 mg/kg/h CRI; or phenobarbital 4 mg/kg IV q2–6h until 12–16 mg/kg total loading dose; or midazolam 0.2–0.4 mg/kg/h CRI; or levetiracetam 60 mg/kg IV.

Chemotherapy

Hydroxyurea—150 mg/kg/week (dogs) and 75 mg/kg/week (cats).

FOLLOW-UP

PATIENT MONITORING

• Mannitol—monitor serum osmolality and electrolytes, particularly with repeated administration. Maintain osmolality at or below 320 mOsm/L to reduce risk of renal failure due to renal vasoconstriction.
• Corticosteroids—perform serial neurologic examinations; marked neurologic improvement is possible within 24–48 hours after initiation of treatment with corticosteroids. • Antiepileptic drugs—evaluate serum phenobarbital levels 3 weeks after initiation of therapy; evaluate liver enzymes every 6 months while on phenobarbital. • Hydroxyurea—monitor CBC with platelet count before starting, at 2 weeks, 6 weeks then CBC, chemistry profile every 3–4 months. May lead to vomiting or diarrhea, stomatitis, sloughing of nails, alopecia, and dysuria; most serious effects are bone marrow depression and pulmonary fibrosis.

EXPECTED COURSE AND PROGNOSIS

Dogs

Intracranial

• Surgical excision—outcome depends on surgical technique. Reported median survival time is 6.7 months (3 dogs). Survival increased with regional cerebral resection (16.5 months in 6 dogs), or with the use of a surgical aspirator (41.8 months in 17 dogs) or with endoscopy-assisted tumor removal (70.1 months with forebrain and 23.4 months with caudal brain meningioma in 33 dogs). • Surgical excision with postoperative fractionated radiation therapy—reported median survival times of 16.5 months–3 years. • Radiation therapy alone—reported median survival times of 5–12.5 months with conventional radiation.
• Chemotherapy using hydroxyurea—reported mean survival time of 7–8 months. • SRS (e.g., Frameless SRS, Varian Trilogy/TruBeam, Cyberknife)—reported mean survival time of 16.4 months in 38 dogs, and 19.8 months in 20 dogs. • Medical management—reported median survival time of 3–4 months in dogs treated with palliative therapy alone.

Intraspinal

• Surgical excision—reported mean survival time of 19 months in 8 dogs. • Surgical excision with postoperative radiation therapy—reported median survival time of 13.5 months in 6 dogs.

Cats

Intracranial

• Surgical excision—good prognosis. Surgery is curative in 75–80% of patients that undergo surgical excision. Reported mean survival time 22–27 months. Seizure activity may persist despite successful excision. Recurrence, if it occurs, is usually in same location. • Medical management—neurologic deficits become more severe with time. Progression is often slow because meningiomas are slow growing.

Intraspinal

• Surgical excision—survival time is shorter than that of cats with cerebral meningiomas: reported median survival times of 14.2 months in 16 cats and 17.3 months in 26 cats. • Corticosteroids—palliative in the short term. Thoracolumbar disease progresses to paralysis and inability to control urination (urinary retention and possibly bladder atony and cystitis).

MISCELLANEOUS

AGE-RELATED FACTORS

Brain tumor should be suspected in dogs and cats >5 years with recent onset of seizures and unremarkable extracranial diagnostic workup for seizures.

ABBREVIATIONS

- CSF = cerebrospinal fluid.
- GI = gastrointestinal.
- ICP = intracranial pressure.
- IMRT = intensity modulated radiation therapy.
- SRS = stereotactic radiosurgery.
- T1WI = T1-weighted images.
- T2WI = T2-weighted images.

MENINGITIS/MENINGOENCEPHALITIS/MENINGOMYELITIS, BACTERIAL

BASICS

DEFINITION
- Meningitis—inflammation of the meninges.
- Meningoencephalitis—inflammation of the meninges and brain.
- Meningomyelitis—inflammation of the meninges and spinal cord.

PATHOPHYSIOLOGY
- Bacterial infection of the CNS can occur by direct extension from an infected extraneural site or when bacteria are introduced by penetrating trauma or a migrating foreign body.
- Hematogenous spread of bacteria to the CNS from mucous membrane colonization or a distant pyogenic focus can occur. This is the most common cause in septicemic neonates and immunocompromised patients.
- Neurological deficits often develop from secondary inflammation but may be from bacterial invasion of the brain or spinal cord parenchyma.
- Inflammatory debris and adhesions can obstruct cerebrospinal fluid (CSF) flow, leading to secondary hydrocephalus.

SYSTEMS AFFECTED
- Nervous—meninges, brain, or spinal cord.
- Multisystemic signs—may be present when the infection originates in an extraneural site or when the systemic inflammatory response is severe.

INCIDENCE/PREVALENCE
Rare

SIGNALMENT

Species
Dog and cat.

Mean Age and Range
Any age.

Predominant Sex
Males and females affected equally.

SIGNS

General Comments
- Patients are often systemically ill.
- Shock, hypotension, and disseminated intravascular coagulation (DIC) are often found in septicemic patients.
- CNS signs may be profound and rapidly progressive.

Physical Examination Findings
- Pyrexia in approximately 50%.
- Cervical rigidity and hyperesthesia—especially with meningitis.
- Neurologic deficits—reflect the location of the involved spinal cord or brain parenchyma (e.g., altered mentation, cranial nerve deficits, postural reaction deficits, ataxia, paresis, seizures).
- May find an extraneural site of underlying bacterial infection.
- Vomiting.
- Bradycardia with systemic hypertension suggests increased intracranial pressure.

CAUSES
- Meningoencephalitis—can be secondary to local extension from otitis media/interna or infection of the eye, retrobulbar space, sinuses, or nasal passages or due to direct inoculation by traumatic skull fractures or migrating foreign bodies.
- Meningomyelitis—can be secondary to discospondylitis or vertebral osteomyelitis.
- Hematogenous spread of bacterial infection to the CNS can occur in neonates with omphalophlebitis, immunocompromised patients, or in dogs with bacterial endocarditis, prostatitis, discospondylitis, pneumonia, urinary tract infections or severe gastroenteritis.
- The point of origin is not always found.

RISK FACTORS
- Untreated bacterial infection.
- Immunocompromised state.
- Injury involving the CNS or adjacent structures.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infectious Meningitis (Nonbacterial)
- Canine distemper, toxoplasmosis, neosporosis, cryptococcosis, blastomycosis, rickettsial organisms, West Nile virus, and feline infectious peritonitis all cause meningitis/meningoencephalitis that can be difficult to distinguish from bacterial disease.
- CSF—inflammatory with a variable lymphocytic, mixed mononuclear or neutrophilic pleocytosis depending on the specific infectious etiology.
- Antemortem diagnosis suspected based on typical clinical findings and identification of affected extraneural sites.
- Diagnosis is by identifying organisms in the CSF or in extraneural sites (using cytology, culture, or PCR) and by serology.

Steroid-Responsive Meningitis–Arteritis (Aseptic Meningitis)
- Observed mainly in young (6–19 months) adult large-breed dogs.
- Beagles, boxers, Bernese mountain dogs, German shorthaired pointers, Weimaraners, and Nova Scotia duck tolling retrievers are predisposed; any breed can be affected.
- Cervical pain without neurologic deficits is most common.
- Fever occurs in 60–80% of affected dogs. Signs may wax and wane initially.
- Affected dogs are systemically normal.
- CSF—increased nucleated cell count and protein. Neutrophilic pleocytosis in acute cases, mononuclear cells may predominate in chronic cases. Negative bacterial culture.
- Serum and CSF IgA increased.
- Dramatic response to corticosteroid administration.

Meningoencephalitis of Unknown Origin (MUO)
- Idiopathic noninfectious inflammatory diseases of the brain, spinal cord, and meninges in dogs including granulomatous meningoencephalomyelitis (GME), necrotizing meningoencephalitis (NME), and necrotizing leukoencephalitis (NLE). A definitive diagnosis requires histopathology.
- Young adult (3–7 years), female, small-breed dogs are most commonly affected.
- Neurologic abnormalities reflect the location of the lesion(s).
- MRI—usually multifocal parenchymal lesions with variable contrast enhancement.
- CSF— pleocytosis with >50% mononuclear cells and increased protein concentrations.
- CSF culture—negative.

Primary CNS Neoplasia
- History protracted; neurologic signs limited to the CNS; standard laboratory tests normal.
- Diagnosis by CT, MRI, CSF analysis, and biopsy.

CBC/BIOCHEMISTRY/URINALYSIS
- Leukocytosis is common; left-shift or toxicity may be seen. Thrombocytopenia may be present in septicemic patients.
- Biochemical changes are variable and often nonspecific.
- Pyuria and bacteriuria occur in patients with underlying urinary tract or prostatic infection and in some bacteremic animals.

OTHER LABORATORY TESTS
- Serologic tests—may differentiate bacterial from other infectious diseases; in cats, toxoplasma titer may be positive without clinical disease.
- Cytology of infected tissues—skin, eyes, nasal discharge, lymph node, tracheal wash; helps identify nonbacterial causative organisms, especially in patients with fungal disease.
- Blood culture—positive in 30% of dogs with bacterial meningitis.

IMAGING
- Thorax radiography and abdominal ultrasound—to identify underlying infection or other significant disease.
- Vertebral column radiography—discospondylitis may be identified as a focus of infection.
- Head CT—may identify infected sinus, nasal cavity, or middle and inner ear as initiating site. Inflamed regions of brain parenchyma and meninges usually enhance with contrast.

• Echocardiography—performed when valvular endocarditis suspected based on murmur/arrhythmia.
• MRI with contrast—documents brain, spinal cord and meningeal inflammation and can identify extraneural sites of infection (sinus, nasal, ear).

DIAGNOSTIC PROCEDURES

CSF Analysis

• Collection—a concern in animals with altered mentation suggesting high intracranial pressure, because the procedure may precipitate brain herniation. Pretreat with mannitol.
• Analysis—neutrophilic pleocytosis with high protein concentration; neutrophils may appear toxic or degenerated and intracellular bacteria are occasionally seen; often difficult to differentiate aseptic from bacterial meningitis cytologically.
• Culture—aerobic or anaerobic; may be positive (<40%)—inoculation of CSF into broth enrichment media improves diagnostic yield.
• Universal bacterial PCR assay of CSF can be used to identify DNA from causative organisms when bacterial culture is negative.

PATHOLOGIC FINDINGS

• May note subdural empyema, or purulent material on the surface of the brain or spinal cord.
• Asymmetric diffuse or multifocal brain or spinal cord and meningeal suppurative inflammation common.
• Culture of affected neurologic tissue—positive in >75% of patients.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—treat aggressively; intensive care monitoring often necessary.

NURSING CARE

Fluid therapy and supportive care.

CLIENT EDUCATION

Inform client that rapid and aggressive treatment is important and that the prognosis for recovery is guarded.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

• Bactericidal agents that achieve therapeutic concentrations within CSF are most desirable—lipid-soluble drugs with small molecular size, low protein binding, and a low degree of ionization at physiologic pH recommended.
• Cultures—CSF, blood, urine, primary site; determine drug sensitivity; until cultures identify the organism choose a broad-spectrum agent that penetrates the blood–brain barrier (BBB).
• Recommended drugs include third-generation cephalosporins (moxalactam, ceftriaxone, cefotaxime), fluoroquinolones, trimethoprim-sulfonamides, doxycycline and metronidazole.
• Penicillin, ampicillin, amoxicillin-clavulanate, and carbapenems enter the CNS when there is inflammation and are a good choice to use in combination with another antibiotic that will continue to cross the BBB as inflammation resolves, such as trimethoprim-sulfonamides. Ampicillin may achieve high CSF concentrations even without inflammation.
• Metronidazole reaches high levels in CSF, brain parenchyma, and abscesses and demonstrates the best bactericidal activity against anaerobes.
• Clindamycin is lipid soluble but does not readily cross the BBB. Concentrations in brain and spinal cord are adequate for treatment of *Toxoplasma* and *Neospora* infections but insufficient for treating most CNS bacterial infections.
• Administer antibiotics intravenously for 3–5 days to achieve high CSF concentrations rapidly, then maintain on oral therapy.
• Immediate IV therapy can be based on cytology; penicillin for Gram-positive infections, fluoroquinolone or third-generation cephalosporin for Gram-negative infections.

Antiepileptic Drugs

• Indicated for seizures.
• Long-term use may be needed.

Corticosteroids

• Most CNS dysfunction is due to inflammation.
• May administer dexamethasone 0.1 mg/kg q24h for several days but use is somewhat controversial.

CONTRAINDICATIONS

Aminoglycosides and first-generation cephalosporins—do not penetrate the BBB even in the presence of inflamed meninges.

FOLLOW-UP

PATIENT MONITORING

Monitor for nervous system signs, fever, leukocytosis, and systemic signs.

PREVENTION/AVOIDANCE

Treat local infections adjacent to the CNS (e.g., infections of the eyes, ears, sinuses, nose, and vertebral column) early and aggressively to prevent extension to the CNS.

POSSIBLE COMPLICATIONS

Damage to the brain and spinal cord may be irreversible.

EXPECTED COURSE AND PROGNOSIS

• Response to antibiotics—variable; prognosis guarded.
• Many patients die despite treatment
• Residual neurologic deficits are possible.
• Treatment for at least 4 weeks after resolution of all signs is recommended.

MISCELLANEOUS

SEE ALSO

• Encephalitis.
• Meningoencephalomyelitis of Unknown Etiology (MUE).

MENINGOENCEPHALOMYELITIS, EOSINOPHILIC

BASICS

OVERVIEW
Although eosinophilic meningoencephalomyelitis (EME) can be associated with meningitis, encephalitis, and myelitis as a result of CNS infection or parasitic migration, in most cases, no underlying cause can be found. Idiopathic EME occurs in young to middle-aged large-breed dogs and resolves in many cases following steroid treatment.

SIGNALMENT
• Dog and rarely cat. • Idiopathic EME—often larger dogs (>25 kg); Rottweilers and golden retrievers predisposed. • Mean age—4 years (2 months–13 years).

M

SIGNS
• Vary with CNS location and severity. • Neurologic deficits—most frequently associated with cranium, infrequently with spinal cord and rarely with cranial nerve involvement.

CAUSES & RISK FACTORS
• Idiopathic EME (unknown cause)—majority of reported cases. • Infectious—*Dirofilaria immitis* and cuterebra myiasis in cats; *Toxoplasma gondii*, *Neospora* spp., *Prototheca* spp., *Cryptococcus* spp., and nematode migration with *Baylisascaris procyonis* in dogs. • *Angiostrongylus*—dogs in Australia. • Intervertebral disc disease probably as allergic response to disc material.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Cannot be differentiated from other encephalitides solely on clinical signs; CSF analysis must be done. • Idiopathic EME—negative serologic test results; marked CSF eosinophilic pleocytosis (20–95%); usually steroid-responsive. • Infectious diseases—identified on presence of systemic signs, blood work, fecal sample, CSF, serum/CSF serology, and imaging.

CBC/BIOCHEMISTRY/URINALYSIS
• Peripheral eosinophilia—may or may not be present. • Biochemistry and urinalysis—usually normal with idiopathic disease; eosinophilia, liver enzyme activity, and creatine kinase may be elevated in infectious diseases.

OTHER LABORATORY TESTS
• Serology—to rule out suspected infectious diseases. • Fecal flotation and sedimentation—to rule out migratory parasite.

IMAGING
• Thoracic radiography and abdominal ultrasound—to rule out systemic involvement. • MRI—variable; focal mass lesions, diffuse parenchymal abnormalities, postcontrast diffuse meningeal enhancement; abnormalities depend on cause and location of lesion.

DIAGNOSTIC PROCEDURES

CSF Analysis
• Eosinophilic pleocytosis significant when >10%. • Presence of eosinophilic pleocytosis by itself cannot differentiate idiopathic EME from infection causing CSF eosinophilic pleocytosis. • Idiopathic EME—total nucleated cell count 4–3880 cells/µL (median 99 cells/mL; reference <0.003) with 22–95% eosinophils. • Infections—62–4740 cells/mL (median 875 cells/mL) with 30–95% eosinophils.

CSF Serologic Testing
• If CSF eosinophils >10%, look for parasitic and fungal disease. • Test for heartworm, *Neospora caninum*, *Toxoplasma gondii*, and *Cryptococcus neoformans*.

PATHOLOGIC FINDINGS
• CSF eosinophilic pleocytosis does not necessarily correlate with eosinophils observed in CNS parenchyma. • Wide variety of pathologic findings may indicate multiple causes, or the same disease taken at different times.

TREATMENT
• Usually inpatient, because of severity of clinical signs. • Activity—as tolerated. • Regular diet.

MEDICATIONS

DRUG(S) OF CHOICE
• Idiopathic disease—steroid administration; dexamethasone (0.2 mg/kg q24h for 1 day; then 0.15 mg/kg q24h for 6 days); follow with prednisone (0.5 mg/kg q24h for 8 weeks); then slowly wean patient off prednisone over 8 weeks–6 months depending on clinical response. • Protozoal disease—clindamycin, sulfonamides, and pyrimethamine. • Heartworm—microfilarial migration to the CNS is rare; no available treatment other than supportive.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Important to differentiate idiopathic EME from infection as treatment greatly differs—immunosuppressive dose of steroids vs. anti-organism treatment. • Steroid should be used with caution if diagnosis has not been substantiated.

FOLLOW-UP

PATIENT MONITORING
Inpatient—repeat neurologic examination every 6 hours to monitor progress.

PREVENTION/AVOIDANCE
Steroid treatment should not be stopped even if the animal is back to normal within a few days. A minimum of 8 weeks followed by tapering of the medication over as many weeks is mandatory.

POSSIBLE COMPLICATIONS
• Recurrence may occur following cessation of medication. • Ensure treatment dosage is adequate and reinstate for a longer period.

EXPECTED COURSE AND PROGNOSIS
• Idiopathic disease—good prognosis in most cases with early treatment; improvement usually seen in the first 72 hours; full recovery in 2–6 months. Some patients continue to deteriorate despite steroids, and die. • Protozoal and fungal diseases—poor-to-grave prognosis. • Larval migration—prognosis guarded to poor and depends on location of the lesion; signs may resolve, but larvae often continue to migrate and death may ensue. • Degradation of eosinophils is toxic to nervous tissue; patient may have permanent deficits from not only the primary disease but also cell death.

MISCELLANEOUS

AGE-RELATED FACTORS
Idiopathic EME is more frequent in young to middle-aged larger dog breeds (>25 kg).

SEE ALSO
Encephalitis

ABBREVIATIONS
• EME = eosinophilic meningoencephomyelitis.

MENINGOENCEPHALOMYELITIS OF UNKNOWN ETIOLOGY (MUE)

BASICS

DEFINITION
Meningoencephalomyelitis of unknown etiology (MUE) is a broad term used to describe inflammatory disorders that affect the CNS focally, diffusely, or multifocally. In the past, the majority of CNS inflammatory disorders were categorized as granulomatous meningoencephalomyelitis (GME). As a result, multiple less serious viral and idiopathic disorders were frequently erroneously diagnosed as GME. The appropriate clinical term to describe cases in which CNS inflammation is suspected is now considered MUE or meningioencephalitis of unknown etiology (MUO).

PATHOPHYSIOLOGY
• Unknown. Although a specific etiologic agent is not recognized, in the majority of cases, viral and immune causes are strongly suspected. • Three clinicopathologic forms are recognized: ocular, multifocal (brain or brain and spinal cord), and focal (single focus in the brain or spinal cord).

SYSTEMS AFFECTED
• Nervous. • Ophthalmic.

GENETICS
Not proven.

INCIDENCE/PREVALENCE
Unknown. Since brain biopsies are rarely obtained, a presumptive diagnosis is made in most cases.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Breed Predilections
Any breed can develop MUE. Smaller toy breeds may be overrepresented and can be less responsive to therapy. However, the condition also occurs in medium and large-breed dogs.

Mean Age and Range
• Mean—5 years. • Range—6 months–10 years.

Predominant Sex
Slightly higher prevalence in females.

SIGNS
• Depend on the form of the disease and neuroanatomic localization. • Cerebral form—frequently results in seizure activity. • Ocular form—acute onset of blindness with dilated, unresponsive pupils. • Focal form—*cerebral lesion*: disorientation, behavioral changes, seizures, cortical blindness, compulsive circling, head pressing; *brainstem lesion*: somnolence, cranial nerve deficits (most commonly facial and vestibular dysfunction), ipsilateral hemiparesis; *spinal cord*: neck pain, tetraparesis (C1–C5 or C6–T2 lesions) or paraparesis (T3–L3 or L4–S2 lesions) and proprioceptive ataxia. In some patients the clinical signs can be unspecific and vague, delaying a prompt diagnosis and timely therapy.

CAUSES
Unknown

RISK FACTORS
• Unknown. • Some dogs develop clinical signs within 5–15 days of vaccination.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• The combination of history, neurologic examination, CSF analysis, and MRI results usually lead to a presumptive diagnosis of inflammatory disease, but defining the cause of the inflammation can be problematic. • It is possible that some dogs surviving inflammatory CNS disease have lesions compatible with GME, but post-mortem studies are not available to prove it. Alternatively, dogs who survive CNS inflammatory disease could have been suffering from other type of less serious viral or idiopathic inflammatory disease. Therefore the current accepted medical term to group these categories is MUE. • Infectious inflammatory diseases—viral (distemper virus, other viruses); fungal (*Blastomyces dermatitidis*, *Coccidioides* spp., *Cryptococcus neoformans*); rickettsial (*Rickettsia rickettsii*); bacterial (*Ehrlichia* spp., *E. coli*, *Streptococcus*); protozoal (*Neospora caninum*, *Toxoplasma gondii*). • Other inflammatory disease—necrotizing encephalitis of the Yorkshire terrier, Maltese, and pug; immune-mediated steroid-responsive meningitis (beagles, Bernese mountain dogs, Nova Scotia duck tolling retrievers, Weimaraners, boxers). • Sudden acquired retinal degeneration. • Brain tumor—meningioma, glioma, choroids plexus papilloma, lymphoma. • Subatlantoaxial luxation. • Caudo-occipital malformation syndrome (COMS).

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
Serologic testing to rule out infectious CNS diseases.

IMAGING
MRI—method of choice; abnormalities are variable and consist of solitary, multiple, or circumscribed mass lesions. Multiple areas of heterogeneous contrast enhancement are frequent in the multifocal form of the disease. Other findings include mass effect with midline shift, obstructive hydrocephalus, white matter edema, and effacement of the sulci. Usually MRI lesions are characterized as hypointense in T1-weighted and hyperintense in T2-weighted images. Necrotic lesions are recognized by a center of hypointensity with a peripheral ring of enhancement.

DIAGNOSTIC PROCEDURES
CSF Analysis
• Reference range—white cell count (0–3 cells/μL); protein concentration (0–30 mg/dL). • Helps confirm presence of inflammatory disease but rarely demonstrates a definitive cause. The following are only guidelines, as significant overlap exists regarding CSF cytology of different inflammatory disorders. • Inflammatory diseases—white cell count and protein concentration usually increased. Even with a normal cell count, presence of an abnormal cell population (e.g., macrophages) should be taken into consideration as evidence of pathology. • Usually, mononuclear pleocytosis; however, polymorphonuclear pleocytosis, or a normal CSF can be present. • Bacterial (rare in dogs)—marked polymorphonuclear pleocytosis. • Fungal, protozoal infections—mixed pleocytosis (mononuclear and polymorphonuclear); rarely a fungal organism (*Cryptococcus neoformans* or *Blastomyces dermatitidis*) is identified. • Viral infections—mononuclear pleocytosis.

Brain Biopsy
Brain biopsy is the only procedure that can confirm conclusively a diagnosis of MUE. Due to morbidity, mortality, and cost associated with brain biopsy the test is not performed routinely. It is important to note that GME is *not* a clinical diagnosis but a term to describe findings at post-mortem. The term should not be used as clinical diagnosis, to avoid confusion.

PATHOLOGIC FINDINGS
• Hallmark feature—dense perivascular distribution of mononuclear infiltrates (lymphocytes, monocytes, and plasma cells). • Macroscopically, discoloration and softening of affected tissue sometimes evident.

TREATMENT

APPROPRIATE HEALTH CARE
• Stable patients can be discharged with recommended treatment. • Inpatient—for severely affected dogs; monitor patient closely for progression of neurologic deficits. • In severe cases, sequential assessment of pupil size and reaction to light, and mentation are helpful to determine risk of herniation.

NURSING CARE
• IV fluids for the anorexic patient. Take care not to overhydrate to exacerbate cerebral edema. • Provide a padded cage for dogs with vestibular ataxia, severe dementia, or seizure

MENINGOENCEPHALOMYELITIS OF UNKNOWN ETIOLOGY (MUE) (CONTINUED)

activity. • Recumbent patients should be turned frequently (every 4 hours).

ACTIVITY
• Depends on severity of disease and lesion localization. • Ataxic patients should be confined to a padded cage to avoid injury.

DIET
Ensure adequate caloric intake.

CLIENT EDUCATION
• Explain to the client that there is significant overlap of clinical signs among different inflammatory diseases. Insist on the importance of a diagnostic workup.
• Mortality rate is variable but clearly biased by older literature describing the severe cases that went to post-mortem as suffering from GME. Brain biopsies are rarely conducted. Clinical experience suggests that up to 70% of patients can respond to therapy, especially if initiated early in the course of the disease. However, treatment may be prolonged or could be required for life. • Corticosteroid therapy may be necessary indefinitely.

M

MEDICATIONS

DRUG(S) OF CHOICE
• Dexamethasone 0.2 mg/kg IV or PO q24h for 4 days followed by prednisone 0.5–1.0 mg/kg PO q24h for 2 weeks. Dose is adjusted according to response and side effects. The goal is to find dosage that keeps the clinical signs controlled with minimal side effects. If deterioration of clinical signs noted when tapering steroids, immediately go back to previous dose that controlled the signs or consider adding other immunosuppressant listed below. • To prevent gastrointestinal ulceration, combine steroid therapy with omeprazole 0.5 mg/kg PO q24h, famotidine 0.5–1 mg/kg IV or PO q12h. • Azathioprine 2 mg/kg PO q24h can be added if the patient is not tolerating the steroids well, to allow reduction of the prednisone dose. Usually, the dose of azathioprine is reduced to 1 mg/kg PO q 24 after 7 days of initiating the medication.
• Cytosine arabinoside 100 mg/m^2 body surface area as a CRI over 12 hours. Alternatively 6 doses of cytosine arabinoside can be given q12h via SC injection. Repeat treatment every 3 weeks to 8 weeks pending clinical response. • Mycophenolate mofetil has been recently advocated at a dose of 7–20 mg/kg PO q12h for 3–4 weeks, then 10 mg/kg q24h. This medication can cause vomiting and diarrhea. • If there is seizure activity—phenobarbital 2 mg/kg PO q12h, levetiracetam 20–30 mg/kg PO (ideally q8h but may be attempted q12h), or zonisamide 5–10 mg/kg PO q12h. • Gabapentin 2–5 mg/kg PO q8–12h if compulsive circling is present.

CONTRAINDICATIONS
• Fungal, bacterial, and protozoal conditions can be exacerbated by the use of steroids. It is important to rule out these infectious disorders with proper diagnostic workup.
• Steroid should not be used in a patient treated or recently treated with nonsteroidal anti-inflammatory drugs (NSAIDs).

PRECAUTIONS
Reduction in corticosteroid therapy can result in recrudescence of clinical signs that may not be controlled again as initially.

ALTERNATIVE DRUG(S)
• Cyclosporine 3–7 mg/kg PO q12h.
• Leflunomide 4 mg/kg PO q24h.

FOLLOW-UP

PATIENT MONITORING
• Repeat neurologic examination periodically (every 2–4 weeks). • Evaluate CBC and biochemical profile regularly to monitor for leukopenia, thrombocytopenia, and liver and kidney function if alternative drugs are used.
• Monitor urine in patients on long-term steroid treatment—proteinuria or infection are frequent consequences. Patients receiving zonisamide may be at risk for keratoconjunctivitis sicca and immune-mediated conditions—hemolytic anemia, immune thrombocytopenia, and polyarthritis.

POSSIBLE COMPLICATIONS
• Deterioration of clinical signs despite aggressive treatment. • Status epilepticus, dementia, brain herniation, and death.

EXPECTED COURSE AND PROGNOSIS
• Not all patients with CNS inflammatory disease have a poor prognosis. • GME has been stereotyped as fatal without enough evidence. Uncertain if surviving dogs had GME as brain biopsies are rarely done.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Corticosteroid therapy can affect gestation.

SYNONYMS
• Granulomatous encephalitis.
• Granulomatous meningoencephalitis.
• Meningoencephalitis of unknown etiology.
• Meningomyelitis. • Encephalitis. • Myelitis.

Author Carolina Duque

Client Education Handout available online

MESOTHELIOMA

BASICS

OVERVIEW
- Rare tumor in dogs and cats arising from the mesothelial cells of the serosal lining of the pleural, pericardial, or peritoneal cavities.
- Also has been reported in dogs to arise from the tunica vaginalis of the testes.

SIGNALMENT
- Older animals—dog and cat.
- Sclerosing subtype more common in males.
- German shepherd dogs overrepresented.

SIGNS
- Pleural effusion—dyspnea, tachypnea, exercise intolerance, coughing, gagging, cyanosis.
- Pericardial effusion—lethargy, anorexia, weakness, collapse, respiratory distress, exercise intolerance, distended abdomen, vomiting.
- Ascites—distended abdomen, anorexia, vomiting, lethargy, abdominal discomfort.
- Swollen testes.
- Sclerosing subtype signs are secondary to restriction around affected organs—vomiting, urinary issues.

CAUSES & RISK FACTORS
- Increased risk with asbestos exposure.
- Possible increased risk in golden retrievers with idiopathic hemorrhagic pericardial effusion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Other causes of effusions—hypoproteinemia, vasculitis, neoplasia (e.g., lymphoma, chemodectomas, hemangiosarcoma, carcinomatosis), idiopathic, congestive heart failure, liver disease, infectious/inflammatory.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

IMAGING
- Thoracic radiography—identification of pleural effusion, evaluation of cardiac silhouette (i.e., globoid heart consistent with pericardial effusion).
- Echocardiography—identification of pericardial effusion; rule out primary cardiac neoplasia.
- Thoracic and abdominal ultrasonography—evaluation of effusions.
- CT—identification of mass lesions and evaluation of lungs in the face of pleural effusion.

DIAGNOSTIC PROCEDURES
- Cytology of effusions to rule out infectious causes or lymphoma—difficult to diagnose mesothelioma on cytology as mesothelial cells are typically shed into effusions and can be highly reactive.
- Exploratory surgery (open or via thoracoscopic or laparoscopic examination) with biopsies.
- Fibronectin levels in effusions—not specific for mesothelioma but typically elevated in neoplastic effusions.

TREATMENT
- Pericardiectomy or mass removal if possible.
- Symptomatic pericardiocentesis or thoracocentesis.

MEDICATIONS

DRUG(S) OF CHOICE
- Intracavitary chemotherapy:
  - Cisplatin (dog only) 50–70 mg/m^2 every 3 weeks with saline diuresis.
  - Carboplatin (cat) 180–200 mg/m^2 every 3–4 weeks.
  - Carboplatin (dog) 300 mg/m^2 every 3 weeks.
  - Mitoxantrone (dog) 5.0–5.5 mg/m^2 every 3 weeks.
- IV chemotherapy—doxorubicin 30 mg/m^2 (dog >10 kg) or 1 mg/kg (dog <10 kg or cat), or mitoxantrone (4.5–5.5 mg/m^2 dog and cat) once every 3 weeks.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Chemotherapy can cause gastrointestinal, bone marrow, cardiac, and other toxicities—seek advice if unfamiliar with cytotoxic drugs.
- Cisplatin in particular is nephrotoxic. Do not use in cats; causes fatal pulmonary edema.

FOLLOW-UP

PATIENT MONITORING
- Blood tests—especially CBC to monitor for bone marrow suppression secondary to chemotherapy and renal values to monitor for renal toxicity if treating with cisplatin.
- Serial thoracic radiography and/or ultrasounds of heart, thoracic cavity, or abdominal cavity to monitor for recurrence of effusions and to monitor tumor response.

EXPECTED COURSE AND PROGNOSIS
- Prognosis—variable and anecdotal:
  - Intracavitary cisplatin (dogs)—range 8 months to >3 years.
  - Intracavitary carboplatin (cats) with piroxicam—6 months.
  - Surgery and intracavitary cisplatin and IV doxorubicin—>27 months.
  - Reported survival with surgery alone—4–9 months.

MISCELLANEOUS
It is not recommended to breed animals with cancer. Chemotherapy is teratogenic—do not give to pregnant animals.

METABOLIC, NUTRITIONAL, AND ENDOCRINE BONE DISORDERS

BASICS

DEFINITION

• Osteochoendrodysplasia, osteogenesis imperfecta (OI), and growth hormone (GH) anomalies include many metabolic, nutritional, and endocrine bone disorders. • Osteochondrodysplasia (OCDP) is a growth and developmental abnormality resulting in the lack of normal bone growth and bone deformities. • OI is a hereditary disease characterized by extremely fragile bones and teeth caused by defects in the structure of type I collagen. • GH anomalies include, among others: ○ Acromegaly (ACM)—results from excessive pituitary GH production or excessive production of female sex GH. ○ Dwarfism (DW)—results from congenital lack of pituitary GH production.

PATHOPHYSIOLOGY

• OCDP—genetic defect affecting all cartilage in the entire body. • OI—genetic defect of type I collagen formation. Type I collagen is the most abundant structural component of skin, bone, cartilage, tendons, and ligaments. • ACM—endogenous progesterone or exogenous progestins may give rise to GH hypersecretion of mammary origin. Mammary-derived (with or without mammary tumors) GH is biochemically identical to pituitary GH. Pituitary adenoma-related increased progesterone production is also possible. Hypothyroidism can also lead to ACM. • DW—congenital GH deficiency.

SYSTEMS AFFECTED

• Cardiovascular. • Endocrine/metabolic. • Musculoskeletal. • Respiratory. • Skin/exocrine.

GENETICS

• OCDP—autosomal dominant inheritance. • OI—autosomal recessive; collagen type I-encoding genes *COL1A1* and *COL1A2* are affected. • ACM—abnormalities in the anterior pituitary gland; inherited in the Saint Bernard. • DW—autosomal recessive inheritance.

INCIDENCE/PREVALENCE

All conditions discussed are rare.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

• OCDP, ACM—dog and cat. • OI—dog; rare in cat. • DW—dog.

Breed Predilections

• OCPD—Scottish fold cat; great Pyrenees, Alaskan Malamute, Samoyed, Scottish deerhound, Labrador retriever, basset hound, and Norwegian elkhound. • OI—golden retriever, collie, poodle, beagle, Bedlington terrier, wirehaired dachshund, Norwegian elkhound; domestic shorthair cats. • ACM—Saint Bernard, cats. • DW—German shepherd dogs.

Mean Age and Range

• OCDP—immature animals. • OI—3–18 weeks. • ACM—middle-aged to elderly females. • DW—2–5 months.

Predominant Sex

• OCPD—N/A. • OI—N/A. • ACM—dogs: female; cats: male or female.

SIGNS

• OCDP—short, thickened, and hard, movable tail; short, buckled legs. Severity of the clinical signs most likely influenced by level of expression of dominant gene carrier of the mutation (homo- or heterozygous). • OI—signs range from perinatal death to mild bone fragility, severe bone deformity, and innumerable fractures following minor trauma. • ACM—soft tissue swelling of the face and abdomen; severe hypertrophy of soft tissues of the mouth, tongue, and pharynx (latter may cause stridor); polyuria; occasionally polyphagia. • DW—proportionate growth retardation and an abnormally soft and woolly hair coat without guard hair.

General Comments

Signs frequently reported by the owner: • OCDP—difficult and decreased mobility, jumping, climbing, lameness; signs progressing. • OI—sudden onset or progressive lameness. • ACM, DW—similar to physical examination findings.

Physical Examination Findings

• OCDP: ○ Cats—pain of long bones; unwillingness to rise. ○ Dogs—larger than normal head, shorter jaw and resulting malaligned teeth, shortened bones, joint enlargement, lateral deviation of thoracic limbs, spinal deviation to either side. • OI—pain and lameness secondary to fractures. Dentinogenesis imperfecta (secondary to abnormal collagen I) can be noted in addition to or as single entity: severe thinning of the dentine layer, leading to a translucent appearance, pink discoloration, and multiple tooth fractures. Sudden death due to rupture of chordae tendineae (also affected by abnormal cartilage), has been reported. • ACM—inspiratory stridor, thick skin folds (mainly neck), prognathism, wide interdental spaces. Visceromegaly, if generalized, can result in abdominal enlargement. • DW—profound dwarfism, retention of puppy hairs, lack of guard hairs. Hairs can be epilated easily. Gradual progressive truncal alopecia can be noted. Progressive dermal hyperpigmentation, scaly skin, and dermatitis is possible. In males, cryptorchidism is common; in females, persistent estrus is frequent. Continuous heart murmur secondary to a patent ductus arteriosus has been reported.

CAUSES

See Genetics.

RISK FACTORS

N/A for any discussed diseases; except ACM if exogenous progesterone is administered.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• OCDP, OI—metabolic disease, physical abuse, alimentary secondary hyperparathyroidism, hypovitaminosis D, hypothyroidism. • ACM—Pituitary gland tumor; long-term use of progesterone (older dogs, infertile bitches, aggressive dogs). • DW—malnutrition.

CBC/BIOCHEMISTRY/URINALYSIS

• The following should be specifically evaluated for all discussed diseases: serum concentrations of ionized calcium, phosphorus, vitamin D, and parathormone. • OCDP, OI, DW—N/A. • ACM—hyperglycemia, hyperphosphatemia, hypercholesterolemia, hyperproteinemia, increases in liver enzymes (specifically elevated alkaline phosphate), decreased thyroid hormone. • DW—elevated plasma creatinine concentration.

OTHER LABORATORY TESTS

• OCDP, OI—N/A. • ACM—prolactin, cortisol, basal plasma GH levels elevated with disease progression. Elevated plasma insulin-like growth factor I (IGF-I) levels (however, increased GH and IGF can also be seen in healthy animals). Free thyroxine, thyroid-stimulating hormone (TSH), and adrenocorticotropic hormone (ACTH) stimulation tests recommended. GH test recommended to evaluate the pituitary gland function. Follicle-stimulating hormone (FSH) and luteinizing hormone (LH) tests are recommended. Diabetes mellitus has been reported to develop secondary to insulin resistance, thus urinalysis with ACM can reveal glucosuria. • DW—basal plasma concentrations of GH and IGF-I, prolactin, thyrotropin, and LH are low. With combined anterior pituitary function test, often no response of GH, TSH, and prolactin, but minor response of LH and FSH.

IMAGING

• OCDP—radiographic changes more prominent in pelvic limbs (size and shape of the tarsal, carpal, metatarsal, metacarpal bones, phalanges), sacrum (articular spaces decreased), exostoses with diffuse osteopenia, zones of rarefication. Spine may show scoliosis, lordosis, or kyphosis. • OI—radiographs reveal less opaque than normal long bone cortices, frequently pathologic fractures or evidence of chronic healing fractures.

(CONTINUED) METABOLIC, NUTRITIONAL, AND ENDOCRINE BONE DISORDERS

• ACM—radiographs of thorax (in case of mammary tumor metastasis; also 85% cardiomegaly reported in cats); MRI of brain (pituitary); ultrasound of abdomen (assess organomegaly—specifically liver and kidneys). • DW—MRI (brain), echocardiography.

DIAGNOSTIC PROCEDURES

• OCDP—bone histology. • OI—analysis of type I collagen obtained from cultured skin fibroblasts. • ACM/DW—N/A.

PATHOLOGIC FINDINGS

• OCDP, DW—N/A. • OI—bone: absence of secondary spongiosa, irregular woven bone with absence of Haversian canals. • ACM—pituitary or mammary gland changes depend on tumor. • DW—aplasia of the hypophysis/pituitary gland.

TREATMENT

NURSING CARE

N/A

ACTIVITY

• OCDP, OI—decrease activity to reduce discomfort. • ACM—N/A. Rest 3 weeks if surgery (ovariohysterectomy) done. Specific care based on specialist's recommendation following pituitary gland radiation. • DW—N/A.

DIET

OCDP, OI, ACM, DW—healthy diet.

CLIENT EDUCATION

• OCDP, OI—N/A; no cure. • ACM, DW—N/A.

SURGICAL CONSIDERATIONS

• OCDP—N/A; corrective osteotomies are not rewarding. • OI—surgical treatment of fractures. • ACM—withdrawal of exogenous progestagens and/or ovario(hyster)ectomy. If pituitary, consider hypophysectomy. Radiation of the hypophysis can also be considered. • DW—N/A.

MEDICATIONS

DRUG(S) OF CHOICE

• OCDP—dogs: nonsteroidal anti-inflammatory drugs (NSAIDs); cats: robenacoxib 1 mg/kg PO once a day for 3 days. • OI—vitamin C 75 mg/kg PO once a day; bisphosphonate supplementation (alendronate sodium): dogs: 0.5–1 mg/kg PO once a day on empty stomach; cats: 10 mg/cat PO on empty stomach once a week. Note: effectiveness of bisphosphonates to treat OI in dogs and cats has not been evaluated. • ACM: ○ If progestagen-induced—aglepristone (progesterone-receptor blocker) 15 mg/kg SQ on 2 consecutive days, repeat weekly until effect of progestagen ceases; surgery (see Surgical Considerations). ○ If hypothyroidism-induced—levothyroxine sodium 0.02 mg/kg (dog) or 0.01 mg/kg (cat) PO once a day. Adjust dose based on the serum total thyroxine concentrations 4–6 hours post tablet administration, along with clinical response. • DW—porcine GH 0.1–0.3 IU/kg SQ, 3 times a week. Thyroid hormone replacement if evidence of secondary hypothyroidism (see ACM dosing recommendation above).

CONTRAINDICATIONS

N/A

PRECAUTIONS

• OCDP, OI—N/A. If NSAIDs are used, monitor for possible side effects as listed in package inserts. • ACM—N/A.

POSSIBLE INTERACTIONS

• OCDP—must not use other NSAIDs. • OI—none. • ACM—theoretically, the following interactions may occur with aglepristone: efficacy of glucocorticoids and progestins might be reduced. Manufacturer states that despite lack of data, the following medications may interact with aglepristone: ketoconazole, itraconazole, erythromycin. Drug interactions when using levothyroxine sodium can include: amiodarone, antidepressants, antidiabetics, cholestyramine, corticosteroids, digoxin, ferrous sulfate, ketamine, phenobarbital, propylthiouracil, rifampin, sertraline, sucralfate, sympathicomimetic agents, warfarin.

ALTERNATIVE DRUG(S)

• OCDP, OI—N/A. • ACM—aglepristone; may be difficult to obtain in the United States.

FOLLOW-UP

PATIENT MONITORING

• OCDP—2 weeks, then as needed. Note that osteoarthritis can develop long term. • OI—4–8 weeks for bone healing and improvement of bone density. • ACM—initially weekly, then every month to monitor until stable. • DW—weekly.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

• OCDP, DW—N/A. • OI—other fractures. • ACM—if tumorous cause, metastasis and worsening of disease.

EXPECTED COURSE AND PROGNOSIS

• OCDP—recurrence of signs and discomfort from arthritis. • OI—development of other fractures. • ACM—regression of clinical signs over time is expected; if GH did not completely exhaust pancreatic beta cells, diabetes mellitus might resolve. • DW—significant increase in body size often not seen (due to closure of epiphyseal plates); growth of primary hair is expected, while growth of guard hairs is variable.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• OCDP—N/A. • OI—can be accompanied by blue sclera, hearing loss, dwarfism, pulmonary pathology. • ACM—diabetes mellitus, cardiac disease, decreased hepatic and renal function, peripheral neuropathies. • DW—secondary bacterial dermatitis. Due to combined pituitary hormone deficiency, secondary hypothyroidism is frequent. GH administration might result in development of diabetes mellitus.

PREGNANCY/FERTILITY/BREEDING

Affected animals for all discussed topics are not to be used for breeding. To treat ACM, ovario(hyster)ectomy is often needed.

ABBREVIATIONS

• ACM = acromegaly. • ACTH = adrenocorticotropic hormone. • DW = dwarfism. • FSH = follicle-stimulating hormone. • GH = growth hormone. • IGF = insulin-like growth factor. • LH = luteinizing hormone. • OCDP = osteochondrodysplasia. • OI = osteogenesis imperfecta. • TSH = thyroid-stimulating hormone.

M

METALDEHYDE TOXICOSIS

BASICS

OVERVIEW

- Form of acetaldehyde; primarily affects the nervous system.
- Mainly found in slug and snail baits; sometimes in solid fuel for camp stoves.
- Crosses the blood–brain barrier and disrupts GABAergic inhibitory action, facilitating neuronal excitation and increasing potential for convulsions.
- Systems affected include: neuromuscular (seizures and muscle tremors), hepatobiliary (delayed hepatotoxicosis reported in dogs only), and multiple organ failure (secondary to seizures and hyperthermia).
- Incidence/prevalence—depends on presence and accessibility; weather resistant: persists in the environment for >14 days.
- More frequent in coastal, low-lying, temperate and subtropical regions of United States. Snails and slugs are common pests in those locations.

SIGNALMENT

Species

Dogs; much less often in cats.

SIGNS

- Generally, within 3-4 hours but may occur in <30 minutes.
- Anxiety, panting, restlessness.
- Salivation, gastrointestinal upset.
- Tachycardia.
- Tachypnea, dyspnea.
- Hyperthermia up to 108°F (42.2°C).
- Hyperesthesia.
- Ataxia, tremors, seizures (intermittent then continuous).
- Mydriasis, nystagmus (especially in cats).

CAUSES

Ingestion of metaldehyde.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxins capable of neurologic signs—amphetamines, bromethalin, blue-green algae, chocolate, hops, ivermectin, lead, neurotoxic mushrooms, organophosphate and some carbamate insecticides, pyrethroids, salt (ornaments, playdough), strychnine, tremorgenic mycotoxins, xylitol, and zinc phosphide.
- Nontoxic causes.

CBC/BIOCHEMISTRY/URINALYSIS

- No specific diagnostic features.
- Metabolic acidosis.
- Delayed changes in hepatic or renal values from uncontrolled hyperthermia/seizures.

OTHER LABORATORY TESTS

Presence in gastric contents, serum, urine, brain, or liver. Testing capabilities vary by lab; call to see what samples are recommended.

PATHOLOGIC FINDINGS

- Lesions neither consistent nor pathognomonic on necropsy (gross or histopathology).
- Gastric contents may have a formaldehyde odor.

TREATMENT

- Appropriate health care consists of emergency exam, decontamination, intensive care until signs resolve (24–72 hours).
- Full recovery may take several weeks with hepatotoxicosis.
- Nursing care involves controling hyperthermia with cooling measures until reaching 103.5°F (39.7°C). Do not overcool. Monitor to prevent aspiration of vomitus.
- Monitor CNS status.
- Do not feed vomiting, convulsing, or heavily sedated patients.

MEDICATIONS

DRUG(S) OF CHOICE

- No antidote available.
- Emetics if minutes after ingestion or gastric lavage with intubation (preferred with large ingestions or symptomatic patient).
- Activated charcoal with cathartic if no contraindications.
- Crystalloids to prevent/correct dehydration or acidosis.
- Seizures—benzodiazepines (first choice), barbiturates, levetiracetam, propofol, or inhalant anesthetics. Consider CRIs.
- Tremors—methocarbamol 55–220 mg/kg IV; do not exceed 330 mg/kg/day.
- Hepatoprotectants as needed.
- Warm water enemas if toxicant seen in the stool.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Do not induce vomiting or give activated charcoal to a patient that is convulsing or heavily sedated.

Precautions

Use depressant drugs cautiously in an already depressed patient, and only if other options are unavailable or ineffective. Use anticonvulsants at lowest effective doses.

FOLLOW-UP

PATIENT MONITORING

- Periodically allow anticonvulsants to wear off to reevaluate seizure condition.
- Once acute phase has passed, monitor hepatic/renal function. Hepatic damage may develop 48–72 hours later. Rhabdomyolysis-induced acute renal failure rare but possible.

PREVENTION/AVOIDANCE

- Do not apply in areas accessible to pets.
- Manufacturers may add green/blue dye to assist with identification. Can cause confusion with rodenticides.
- Added bittering agents do not reliably discourage ingestion. New products contain iron phosphate instead (less toxic).

POSSIBLE COMPLICATIONS

- Liver or renal dysfunction after initial signs (sequelae to seizures and hyperthermia).
- Aspiration pneumonia secondary to seizures.
- Hyperthermia may lead to disseminated intravascular coagulation (DIC) or multiple organ failure.

EXPECTED COURSE AND PROGNOSIS

- Good to excellent if treated early and aggressively.
- Guarded to poor if large ingestion or if treatment delayed or inadequate.
- Fatalities can be seen secondary to DIC or respiratory failure.
- Survival beyond the first 24 hours is positive prognostic indicator.

MISCELLANEOUS

ABBREVIATIONS

- DIC = disseminated intravascular coagulation.

Client Education Handout available online

METFORMIN TOXICOSIS

BASICS

OVERVIEW
- Metformin (Glucophage) is a biguanide antihyperglycemic prescription medication labeled for the treatment of non-insulin-dependent (type 2) diabetes mellitus in humans.
- Available as single or extended release formulation (Glucophage XR).
- Formulated as a single ingredient and in combination with other antidiabetic medications.
- The agent potentially could be useful in the adjunctive treatment of non-insulin-dependent diabetes mellitus in cats; use is controversial.
- Toxicity causes gastrointestinal signs and lethargy.
- 578 exposures to metformin were reported to the American Society for the Prevention of Cruelty to Animals (ASPCA) Animal Poison Control Center (APCC) during 2015–2018. Of these, 96.1% dogs, 3.7% cats, 0.3% birds. Common findings recorded are vomiting 9.3%, lethargy 3.1%, hypoglycemia 1.9%, trembling 1.5%, diarrhea 1.2%.
- Vomiting developed from doses as low as 15.3 mg/kg with hypoglycemia at 48 mg/kg.

SIGNALMENT
- Dogs and cats.
- No breed, age, or sex predilections.

SIGNS

Dogs
- Common sign—vomiting.
- Possible signs—lethargy, hypoglycemia, trembling and diarrhea.

Cats
- Frequent sign—vomiting.
- Possible signs—lethargy, diarrhea, and vocalization.

CAUSES & RISK FACTORS
Ingestion of metformin in single-ingredient preparations as well as in combination with other antidiabetic agents.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Other gastrointestinal tract irritants.

CBC/BIOCHEMISTRY/URINALYSIS
Azotemia reported in humans due to acute renal failure in cases of biguanide lactic acidosis; not reported in animal toxicities.

OTHER LABORATORY TESTS
- Blood gases—lactic acidosis rare but possible with large ingestions (a shih tzu ingesting 167.2 mg/kg of metformin developed lactic acidosis, vomiting, and hypothermia; no hypoglycemia developed and the dog fully recovered with treatment).
- High-performance liquid chromatography may identify presence of metformin in plasma; drug levels are not clinically useful.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
N/A

TREATMENT
- Induce emesis within the first 2–3 hours of exposure.
- Activated charcoal should only be considered with very large exposure.
- Treat gastrointestinal signs supportively.
- Treat lactic acidosis if present.

MEDICATIONS

DRUG(S) OF CHOICE
- Metoclopramide 0.2–0.5 mg/kg PO, SC, or IM q6h.
- Sucralfate 0.5–1 g PO q8–12h for dogs and 0.25–0.5 g PO q8–12h for cats.
- Famotidine 0.5–1.1 mg/kg orally q12–24h for dogs and cats.
- Ranitidine 1–2 mg/kg PO, SC, or IM q8–12h for dogs and 2.5 mg/kg IV q12h or 3.5 mg/kg PO q12h for cats.
- Omeprazole 0.5–1 mg/kg PO q24h for dogs and cats.
- Bicarbonate—if serum bicarbonate or total CO_2 is unavailable: 2–3 mEq/kg IV over 30 minutes if patient has decreased tissue perfusion or renal failure and does not have diabetic ketoacidosis. Must be used judiciously.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Concurrent administration of cimetidine may reduce the urinary excretion of metformin by competing for renal tubular organic cationic transport systems.
- The manufacturer states that other cationic drugs that undergo substantial tubular secretion (e.g., amiloride, digoxin, morphine, procainamide, quinidine, quinine, ranitidine, triamterene, trimethoprim, and vancomycin) may possibly decrease the urinary excretion of metformin.

FOLLOW-UP

PATIENT MONITORING
N/A

EXPECTED COURSE AND PROGNOSIS
Good prognosis assuming lactic acidosis does not occur.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

PREGNANCY/FERTILITY/BREEDING
- No evidence of harm to the fetus or impaired fertility during reproduction studies in rats and rabbits given metformin hydrochloride dosages of 600 mg/kg daily.
- No adequate and controlled studies to date using metformin hydrochloride in pregnant women.
- Excreted in milk in levels similar to plasma. Caution advised in lactating queens.

METHEMOGLOBINEMIA

BASICS

DEFINITION
• Methemoglobin content in blood >1.5% of total hemoglobin.
• Methemoglobin differs from hemoglobin in that the iron moiety of heme groups has been oxidized from the ferrous (2+) to the ferric (3+) state.

PATHOPHYSIOLOGY
• About 3% of hemoglobin is oxidized to methemoglobin each day in normal animals as a result of autoxidation of hemoglobin or secondary to oxidants produced in normal metabolic reactions.
• Methemoglobin usually accounts for <1% of total hemoglobin, because it is constantly reduced back to hemoglobin by an NADH-dependent cytochrome b_5 reductase (methemoglobin reductase) enzyme reaction within red blood cells (RBCs).
• Caused by either increased production of methemoglobin by oxidants or decreased reduction of methemoglobin associated with a deficiency of the RBC cytochrome b_5 reductase enzyme or defective cytochrome b_5.

SYSTEMS AFFECTED
• Hemic/lymphatic/immune—reduced oxygen-carrying capacity of blood, because methemoglobin cannot bind oxygen; if methemoglobin content reaches high values (e.g., >50% of total hemoglobin), organs may suffer hypoxic injury.
• Hepatobiliary—in addition to hypoxic injury, the liver may be damaged directly by oxidant drugs that it metabolizes.
• Renal/urologic—in addition to hypoxic injury, the kidneys may be damaged if intravascular hemolysis occurs (pigmentary nephropathy).

SIGNALMENT
• Dogs and cats.
• Deficiency in RBC cytochrome b_5 reductase has been recognized in the Chihuahua, borzoi, English setter, mixed-breed dog, coonhound, poodle, corgi, Pomeranian, Staffordshire bull terrier, Parson Russell terrier, Australian shepherd dog, and American Eskimo dog, and in domestic shorthair cats. A defect in cytochrome b_5 has been described in a mixed-breed dog.

SIGNS
Caused Directly
• Possibly none in animals with mild to moderate methemoglobinemia.
• Cyanotic-appearing mucous membranes—may be difficult to recognize in heavily pigmented animals.
• Lethargy, tachycardia, tachypnea, ataxia, and stupor caused by hypoxemia when methemoglobin content exceeds 50%.
• Coma-like state and death when methemoglobin content reaches 80%.

Caused by Associated Diseases
• Vomiting, anorexia, and diarrhea possible in patients with drug toxicity.
• Hemoglobinuria secondary to severe intravascular hemolysis in some patients with Heinz body hemolytic anemia.
• Subcutaneous edema, especially involving the face, and salivation in animals with acetaminophen toxicity.

CAUSES
• Toxicity—acetaminophen, benzocaine, phenazopyridine, and skunk musk cause Heinz body hemolytic anemia; excess nitrite in pet food and hydroxycarbamide toxicity are reported to cause methemoglobinemia without Heinz body hemolytic anemia.
• Deficiency in RBC cytochrome b_5 reductase or a defect in RBC cytochrome b_5.

RISK FACTORS
• Application of benzocaine or prilocaine to traumatized skin or mucous membranes increases the likelihood of systemic absorption and methemoglobinemia.
• Cats are much more likely to develop clinically significant methemoglobinemia than are dogs after acetaminophen administration; this drug is not recommended for use in cats.
• Methemoglobinemia secondary to cytochrome b_5 reductase deficiency and a defect in cytochrome b are inherited disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Both low blood oxygen tension and methemoglobinemia can cause cyanotic-appearing mucous membranes and dark-colored blood samples; hypoxemia is documented by measuring PaO_2 <80 mmHg in an arterial blood sample, or an SpO_2 <95% measured via pulse oximetry.
• Methemoglobinemia is suspected when arterial blood with normal or high PO_2 is dark colored.

LABORATORY FINDINGS
Drugs That Alter Laboratory Results
None

Disorders That May Alter Laboratory Results
Hemolysis in the sample may raise the methemoglobin value, especially if the methemoglobin assay is not conducted soon after sample collection.

Valid If Run in Human Laboratory?
• Valid, as long as the method to lyse RBCs does not cause methemoglobin formation in the animal being tested.
• Saponin should not be used to lyse RBCs, because it raises the methemoglobin value in some species.

CBC/BIOCHEMISTRY/URINALYSIS
• Chronic methemoglobinemia secondary to cytochrome b_5 reductase deficiency can result in an elevated hematocrit (HCT); in contrast, hemolytic anemia may accompany methemoglobinemia caused by oxidant drugs.
• If severe or induced by oxidant drugs, evidence of injury to various organs (e.g., high serum creatinine concentration or alanine aminotransferase [ALT] activity) may be seen.

OTHER LABORATORY TESTS
• Spot test—determine if the patient's methemoglobin content is clinically important: one drop of blood from the patient is placed on a piece of absorbent white paper and a drop of normal control blood is placed next to it. If the methemoglobin content is ≥10%, the patient's blood will be noticeably browner than the bright red of the control blood.
• Co-oximetry is the method of choice for accurate measurement of methemoglobin content in whole blood samples.
• Methemoglobin content in dogs with cytochrome b_5 reductase deficiency reportedly varies from 13 to 51%; the methemoglobin content in six deficient cats ranged from 44 to 52%.
• A definitive diagnosis of cytochrome b_5 reductase deficiency is made by measuring enzyme activity in RBCs; this assay is done in a few research laboratories and requires that arrangements be made before blood samples are submitted. Genetic testing may become available now that mutations have been documented in the cytochrome b_5 reductase gene (*CYB5R3*) in dogs and a cat. Genetic testing is required to diagnose a cytochrome b_5 defect.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Blood smears should be stained with methylene blue for detection of Heinz bodies.
• The presence of Heinz bodies indicates exposure to an oxidant drug that may also cause hemolytic anemia.

TREATMENT
• Mild to moderate—does not require specific treatment to reduce the methemoglobin content.
• Drug-induced—the use of the drug should be discontinued; RBCs can convert much of the methemoglobin back to hemoglobin

within 24 hours after elimination of drug exposure.
• Inherited cytochrome b_5 reductase deficiency—animals have normal life expectancy and generally do not require treatment, although veterinarians may wish to give a single IV injection of methylene blue 1 hour before a deficient animal is anesthetized for surgery to maximize the amount of hemoglobin that is capable of binding oxygen.
• Whole blood or packed RBC transfusions should be given to patients with severe anemia and those with rapidly decreasing HCT and clinical signs suggesting a deteriorating condition.
• Severe intravascular hemolysis—IV fluid administration recommended in addition to blood products.
• Treatment of electrolyte or acid–base imbalances may also be indicated in patients with severe vomiting or diarrhea, concomitant renal injury, or shock.
• Administration of oxygen is of limited value because methemoglobin cannot bind oxygen, and an increase in dissolved oxygen results in only a small increase in blood oxygen content.

MEDICATIONS

DRUG(S) OF CHOICE
• Methylene blue—given slowly over several minutes as a 1% solution (1 mg/kg IV), may be administered in patients with severe methemoglobinemia; a dramatic response should occur during the first 30 minutes of treatment.
• *N*-Acetylcysteine is efficacious in the treatment of acetaminophen toxicity if given within a few hours after exposure; recommended dosage is 140 mg/kg PO, IV followed by 70 mg/kg PO, IV q6h for seven treatments.

CONTRAINDICATIONS
None

PRECAUTIONS
Methylene blue treatment can potentiate the formation of Heinz bodies and cause anemia. In patients that have been given drugs that cause substantial Heinz body formation, it is prudent to measure the HCT for 3 days after methylene blue treatment to ensure that clinically important anemia does not develop.

POSSIBLE INTERACTIONS
Methylene blue treatment will interfere with monitoring of Spo_2 by pulse oximetry.

ALTERNATIVE DRUG(S)
None

FOLLOW-UP

PATIENT MONITORING
• The cyanotic appearance of skin and mucous membranes should disappear after reduction of methemoglobin to an amount that does not produce clinical signs.
• Blood on the spot test should appear bright red after reduction of methemoglobin to values <10% of total hemoglobin.
• HCT should be monitored in patients with Heinz body anemia or following methylene blue administration for at least 3 days after initial exposure.

POSSIBLE COMPLICATIONS
Coma and death can occur if methemoglobin content reaches 80% of total hemoglobin.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Heinz body anemia.

ZOONOTIC POTENTIAL
None

SEE ALSO
• Acetaminophen (APAP) Toxicosis.
• Anemia, Heinz Body.

ABBREVIATIONS
• ALT = alanine aminotransferase.
• HCT = hematocrit.
• RBC = red blood cell.

Consulting Editor Melinda S. Camus

METRITIS

BASICS

OVERVIEW
• Bacterial uterine infection that develops in the immediate postpartum period (usually within the first week); occasionally develops after an abortion or nonsterile artificial insemination—rarely after natural breeding.
• Bacteria—ascend through the open cervix to the uterus; postpartum uterus provides an ideal environment for growth; Gram-negative bacteria (e.g., *Escherichia coli*) commonly isolated.
• Potentially life-threatening infection; may lead to septic shock.
• Can become chronic and lead to infertility.

SIGNALMENT
• Postpartum bitch and queen.
• No age or breed predilection.

SIGNS
Historical Findings
• Malodorous, purulent, sanguinopurulent, or dark green vulvar discharge.
• Depression.
• Anorexia.
• Neglect of puppies and kittens.
• Reduced milk production.
• Polyuria/polydipsia.

Physical Examination Findings
• Fever.
• Large uterus on abdominal palpation.
• Dehydration.
• Injected mucous membranes (septic shock).
• Tachycardia, hypotension, other signs of shock.

CAUSES & RISK FACTORS
• Dystocia.
• Obstetric manipulation.
• Retained fetuses or placentas.
• Prolonged delivery (large litter).
• Post abortion, and post natural or artificial insemination (rare).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Subinvolution of placental sites—no sign of infection on cytologic examination of vagina.
• Eclampsia—differentiated by serum calcium concentration.

CBC/BIOCHEMISTRY/URINALYSIS
• Neutrophilia with left shift, although neutropenia and leukopenia are occasionally seen, especially in patients with septic shock.
• High packed cell volume and total plasma protein concentration; azotemia secondary to dehydration/hypovolemia. Normocytic, normochromic nonregenerative anemia may also occur.
• With endotoxemia or sepsis, hypoalbuminemia, elevation of C-reactive protein concentration, and other acute phase changes may occur. Elevated liver enzyme activities may be seen.
• Urine specific gravity may be elevated (from dehydration) or decreased (isosthenuria).
• Urinalysis (obtain via ultrasound-guided cystocentesis) may reveal bacteriuria.

OTHER LABORATORY TESTS
N/A

IMAGING
• Radiography—reveals a large uterus and possibly retained fetus(es).
• Ultrasonography—intrauterine fluid accumulation and increased horn width, retained placenta(s), and retained fetus(es); abdominal effusion may be present if uterine rupture.

DIAGNOSTIC PROCEDURES
• Vaginal cytologic examination—detect degenerative neutrophils with intracellular bacteria.
• Guarded anterior vaginal or transcervical culture—aerobes and anaerobes; culture and sensitivity recommended.

TREATMENT
• Inpatient until systemic signs resolve.
• Treat shock—IV balanced electrolyte solution.
• Correct electrolyte imbalances and hypoglycemia.
• Ovariohysterectomy—treatment of choice for uterine rupture or severe sepsis, and if future breeding is not desired; the uterus is friable; pack off and handle gently at surgery.

MEDICATIONS

DRUG(S) OF CHOICE
• Antibiotics—start broad-spectrum agents (oral if patient is stable; IV if patient is in shock); choice confirmed by bacterial culture and sensitivity; continued at least 14 days. Give at separate time from prostaglandin F2α (PGF2α) administration due to risk of vomiting.
• Nursing planned—amoxicillin–clavulanic acid 22 mg/kg PO q12h; can administer q8h to treat Gram-negative infections, enrofloxacin 10 mg/kg PO, IV q24h (dogs); 5 mg/kg PO q24h (cats), if puppies <3 weeks of age and susceptibility indicates.
• If ovariohysterectomy not performed and cervix is open—oxytocin 0.5–1 U/kg IM, SC (do not exceed 5 IU total); then repeat in 1–2 hours; may require increased dose to attain similar degree of uterine contraction if >48 hours since parturition.
• PGF2α 10–50 µg/kg SC q3–5h for 3–5 days or 100 µg/kg SC q12h for 3–5 days; to evacuate uterus, ultrasound prior to cessation of treatment to ensure resolution of fluid accumulation in uterine lumen.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Prostaglandin—may induce uterine rupture if the tissue is devitalized.
• Oxytocin—reduced efficacy beyond 48 hours post partum.

FOLLOW-UP

PATIENT MONITORING
• Physical exam, CBC, vaginal cytologic examination.
• Ultrasonography—monitor evacuation of uterine fluid.

POSSIBLE COMPLICATIONS
• Ovariohysterectomy—when medical treatment is ineffective.
• Uterine rupture and peritonitis—may occur with medical treatment.
• Owners may need to foster or hand-raise puppies and kittens.

EXPECTED COURSE AND PROGNOSIS
• Ovariohysterectomy—prognosis for recovery good.
• Medical treatment—prognosis for recovery dependent on early recognition of problem by owner; good if early, but may adversely affect future reproduction.

MISCELLANEOUS

ABBREVIATIONS
• PGF2α = prostaglandin F2α.

MOVEMENT DISORDERS

BASICS

OVERVIEW
• Non-epileptic CNS disorders. • Characterized by the occurrence of continuous or episodic involuntary movements in a conscious, responsive animal. • Unrelated to epileptic activity. • Movements may involve the whole body or be restricted to one body part, e.g., one or two limbs or one side of the body. • Hyperkinetic movement disorders often occur as paroxysmal dyskinesias with long episodes of abnormal movements and increased muscle tone (dystonia) alternating with normal neurologic function. • Hypokinetic movement disorders manifest as bradykinesia or collapse. • Pathophysiology—abnormal CNS neural transmission, unrelated to epilepsy, dysfunction of basal nuclei, altered dopaminergic or serotinergic neurotransmission.

SIGNALMENT
• Dogs; less common in cats. • Breed-related syndromes. • Age of onset variable; often <3 years.

SIGNS
• Physical examination—unremarkable. • Neurologic examination—unremarkable between episodes. • Cardiologic examination—unremarkable between and during episodes. • Signs may include—repeated flexion or kicking, excessive lifting of one or more limbs, episodic muscle rigidity, muscle hypertonicity, difficulty initiating movements, episodic ataxia, kyphosis, scoliosis, backward gait, falling, collapse. • Description of episodes may vary between dog breeds. See specific references for detailed information on breed-specific syndromes. • Frequently long duration—minutes to hours. • Differentiated from epileptic seizures—no autonomic signs: no salivation, urination, normal pupils, no postictal period, responsive during episode. • Triggers are frequent—excitement, stress, excessive exercise, heat. • In some dog breeds there are gastrointestinal signs in association with episodes (Border terriers, paroxysmal gluten-sensitive dyskinesia).

CAUSES & RISK FACTORS
• Frequently breed-specific syndromes—Norwich terrier, chinook (paroxysmal dyskinesia), border collie/Australian shepherd dog (collapse), Scottish terrier (collapse). • Gluten hypersensitivity—border terrier, possibly also other dog breeds. • Gene mutations—cavalier King Charles spaniel (*BCAN*, episodic falling), Irish wolfhound puppies (*SLGA5*; glycine receptor, startle disease), Russell terrier (*KCNJ10*, hereditary cerebellar ataxia associated with myokymia), soft-coated wheaten terrier (*PIGN*); Labrador retriever collapse (*DNM1*); Chinese-crested dog, Kerry blue terrier (multisystem degeneration, *SERAC1*), Sheltie (PCK2).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Epilepsy—autonomous signs: salivation, urination, mydriasis; typically short duration <1–2 minutes; postictal period. • Cardiac disease—bradyarrhythmias, ventricular tachycardia. • Metabolic, electrolyte disorders—hypoglycemia, hypocalcemia, hypokalemia, hyperkalemia, hepatic encephalopathy. • Drugs—phenobarbital, propofol, potassium bromide, dopamine antagonists, metoclopramide. • Toxins—lead, copper, psychoactive drugs, environmental toxins. • Obsessive compulsive behavior—complex behavior, responsive, interruptible. • Episodes of spinal pain. • Vestibular attacks. • Rapid eye movement (REM) sleep disorder. • Myotonic myopathies—inherited, acquired. • Feline hyperesthesia syndrome, feline orofacial pain syndrome—cats, unknown etiology.

CBC/BIOCHEMISTRY/URINALYSIS
• Unremarkable. • Specific consideration—glucose (fasted, during episode), potassium, sodium, ionized calcium, creatine kinase.

OTHER LABORATORY TESTS
• Specific genetic tests—based on availability for the breed. • Ammonia, fasted and postprandial bile acids. • T_4. • Serologic testing for gluten hypersensitivity—border terriers; other breeds if gastrointestinal signs. • Neurometabolic screening—lactate, pyruvate, urinary organic acids, amino acids.

IMAGING
MRI brain, spinal cord—exclude structural disease, frequently unremarkable.

DIAGNOSTIC PROCEDURES
• Video documentation of episodes. • Electrocardiography (ECG)—long-term, ambulatory (Holter); exclude arrhythmias. • Electroencephalography (EEG)—ambulatory video-EEG to exclude epilepsy. • CSF—to exclude CNS inflammation; frequently normal.

PATHOLOGIC FINDINGS
Frequently unremarkable.

TREATMENT
• Avoid triggers—stress, excitement; exercise, heat (Jack Russell terrier). • Treat underlying cause if any identified. • Gluten-free diet in border terriers. • Trial therapy with anti-epileptic drugs, • Dietary trials (gluten-free, hypoallergenic) in other dog breeds.

MEDICATIONS

DRUG(S) OF CHOICE
• Use based on low levels of evidence. 0.5 mg/kg q8–12h; acetazolamide 4–8 mg/kg q8–12h; 4-aminopyridine 0.25–0.5 mg/kg q12h; fluoxetine 1–2 mg/kg q24h. • Trial therapy with antiepileptic drugs—gabapentin 10–20 mg/kg q8h; levetiracetam 10–20 mg/kg q8h; phenobarbital 2.5 mg/kg q12h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
4-aminopyridine - may cause seizures; acetazolamide - metabolic acidosis; fluoxetine - drug interactions, hyperthermia.

FOLLOW-UP

PATIENT MONITORING
Acetazolamide—hypokalemia, acidosis.

PREVENTION/AVOIDANCE
Avoid potential triggers. Avoid heat in Jack Russell terriers.

POSSIBLE COMPLICATIONS
Rarely hyperthermia (death) described in association with collapse.

EXPECTED COURSE AND PROGNOSIS
Unpredictable frequency and clinical course, lifelong or may spontaneously resolve.

MISCELLANEOUS

AGE-RELATED FACTORS
Often appears in dogs <3 years old.

PREGNANCY/FERTILITY/BREEDING
Breeding not recommended. Genetic testing recommended.

SEE ALSO

M

MUCOPOLYSACCHARIDOSES

BASICS

OVERVIEW

• Mucopolysaccharidoses (MPS) are characterized by the accumulation of glycosaminoglycans (GAGs) in cells, and result from the impaired function of 1 of 11 enzymes required for normal GAG degradation.
• Undegraded GAGs are stored in lysosomes, resulting in progressive tissue and organ dysfunction.

Types of MPS Reported in Dogs and Cats

• MPS I—α-L-iduronidase deficiency: dermatan and heparan sulfate stored.
• MPS II—iduronate sulfatase deficiency: dermatan and heparan sulfate stored.
• MPS IIIA—heparan *N*-sulfatase deficiency: heparan sulfate stored.
• MPS VI—arylsulfatase B deficiency: dermatan sulfate stored.
• MPS VII—β-glucuronidase deficiency: dermatan, heparan, and chondroitin sulfate stored.

SIGNALMENT

• Cats—MPS I and VII (domestic shorthair [DSH]); MPS VI (Siamese and DSH).
• Dogs—MPS I, Plott hounds; MPS II, Labrador retrievers; MPS IIIA, wire-haired dachshunds and Huntaways; MPS VI, miniature pinschers, miniature schnauzers, miniature poodles, and Welsh corgis; MPS VII, mixed breeds and Belgian, White Swiss, and German shepherd dogs.
• Both sexes equally affected by MPS I, III, VI, and VII; primarily males affected by MPS II.

SIGNS

• Clinical signs apparent at 2–4 months of age.
• Affected animals may live several years, but locomotor difficulty is progressive.
• Skeletal abnormalities more severe in cats with MPS VI than in those with MPS I; some MPS VI cats develop posterior paresis from spinal cord compression.
• Dwarfism (except cats with MPS I).
• Severe bone disease (dysostosis multiplex), degenerative joint disease, facial dysmorphia.
• Hepatomegaly (except cats with MPS VI).
• Corneal clouding–~8 weeks of age.
• Enlarged tongue (dogs).
• Heart valve thickening, resulting in left- or right-sided heart failure.
• Excess urinary excretion of GAG.
• Manipulation of the head or neck usually painful.

CAUSES & RISK FACTORS

• MPS transmission is autosomal recessive, except MPS II, which is X-linked recessive.
• In-breeding increases risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Metachromatic granules within neutrophils and lymphocytes–suggest MPS; also observed with GM_2 gangliosidosis, which, unlike MPS, is characterized by progressive neurologic disease and early death.
• Corneal clouding—also observed in other storage diseases, including acid lipase deficiency, GM_1 and GM_2 gangliosidosis, and mannosidosis; lysosomal enzyme panels can be performed to definitively diagnose the type of disorder.
• Radiographic appearance of MPS is characteristic; other disorders with similarities include congenital hypothyroidism, epiphyseal dysplasia, and hypervitaminosis A.

CBC/BIOCHEMISTRY/URINALYSIS

• Wright's-stained blood films reveal neutrophils and monocytes containing numerous distinctive metachromatic granules (Alder–Reilly bodies).
• Granules indistinct in animals with MPS I.
• Granules usually inapparent when stained with Diff-Quik.
• Occasional lymphocytes have vacuoles with metachromatic granules, particularly in MPS VII.

OTHER LABORATORY TESTS

• Wright's stained cytologic preparations of lymph node, liver, bone marrow, and joint fluid specimens reveal Alder–Reilly bodies within cells.
• Presence of excess GAG in urine usually indicates MPS.
• Definitive diagnosis made by measuring lysosomal enzyme activity in serum, leukocyte pellets, or frozen liver.

IMAGING

• Radiography—low bone density with thin cortices.
• Epiphyseal abnormalities.
• Degenerative joint disease.
• In some cats, proliferative bone is present around all articular facets of vertebrae, causing fusion of cervical vertebrae.

DIAGNOSTIC PROCEDURES

Specialized laboratories can measure lysosomal enzyme activity in leukocyte pellets and detect specific gene mutations for some disorders.

PATHOLOGIC FINDINGS

Distended lysosomes seen in cells of many tissues examined by light and electron microscopy.

TREATMENT

• Bone marrow transplant (BMT)—after successful engraftment, donor-derived normal leukocytes provide missing enzyme to various tissues; when performed at a very early age, affected animals lead near-normal lives; not as helpful when performed after skeletal maturity; unaffected sibling is needed as a donor.
• Gene therapy has been effective in some animal models.

MEDICATIONS

DRUG(S) OF CHOICE

Affected animals are susceptible to viral and bacterial respiratory infection. Antibiotics may be indicated.

FOLLOW-UP

PREVENTION/AVOIDANCE

• Avoid in-breeding.
• Enzyme assays should be performed to diagnose heterozygotes.

EXPECTED COURSE AND PROGNOSIS

• Prognosis reasonably good in animals treated with BMT.
• Untreated animals usually develop severe skeletal and joint disease and may become nonambulatory at 3–5 years of age or earlier.

MISCELLANEOUS

ABBREVIATIONS

• BMT = bone marrow transplant.
• DSH = domestic shorthair cat.
• GAG = glycosaminoglycan.
• MPS = mucopolysaccharidoses.

MULTIDRUG-RESISTANT INFECTIONS

BASICS

DEFINITION
Antimicrobial resistance (AMR) is the ability of microbes to grow in the presence of antimicrobial agents that would normally kill them or inhibit their growth. Multidrug-resistant (MDR) infections are those that are resistant to more than one class of antimicrobials.

PATHOPHYSIOLOGY
AMR can develop in several ways:
- Use of antimicrobials creates selection pressure, allowing growth of bacteria resistant to a specific drug by decreasing competition with susceptible organisms.
- Antimicrobial-resistant bacteria can share genetic elements, conferring resistance to other bacteria.
- Spontaneous new mutations can develop that allow bacterial survival in the face of antimicrobials.
- MDR infections occur through any of these mechanisms; resistance is often additive with antimicrobial use over time.

SYSTEMS AFFECTED
Any tissue affected by bacterial infections may be affected by antimicrobial-resistant bacterial infections. Some examples are:
- Renal/urologic—recurrent urinary tract infections.
- Skin—abscesses, pyoderma.
- Respiratory—pneumonia.
- Musculoskeletal—surgical site infections.
- Gastrointestinal—gastrointestinal pathogens such as *Campylobacter* spp., *Salmonella* spp., *Escherichia coli*, *Enterococcus* spp.
- Hepatobiliary—ascending cholangitis/cholecystitis.
- Cardiovascular—endocarditis.

GENETICS
N/A

INCIDENCE/PREVALENCE
Due to a lack of robust surveillance, prevalence of MDR infections in dogs and cats is unknown; however, studies suggest between <1 and 50% of bacteria cultured from companion animals are MDR, depending on geographic region.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Dog and cat.

Breed Predilections
N/A

Mean Age and Range
N/A

Predominant Sex
N/A

SIGNS
General Comments
Bacterial infections that do not resolve with first-line empiric antimicrobial therapy should cause suspicion for AMR.

Historical Findings
- No or minimal response to antimicrobial therapy.
- History of previous course(s) of antimicrobial therapy.
- Exposure to humans or animals with MDR infections.
- Recent hospitalization and/or surgery.
- Raw food diet.

Physical Examination Findings
Depends on site of infection.

CAUSES
Any bacteria can become resistant to antimicrobials. Common AMR bacterial pathogens include:
- Methicillin-resistant *Staphylococcus pseudintermedius* (MRSP).
- Methicillin-resistant *Staphylococcus aureus* (MRSA).
- MDR *Enterococcus faecalis* and *Enterococcus faecium*.
- Extended-spectrum beta-lactamase (ESBL) producing Gram-negative bacteria including:
  - *E. coli*.
  - *Salmonella enterica*.
  - *Klebsiella pneumoniae*.
  - *Pseudomonas aeruginosa*.
  - *Proteus mirabilis*.
  - *Enterobacter* spp.

RISK FACTORS
- Antimicrobial use.
- Hospitalization.
- Surgery.
- Co-habitation with health care worker.
- Co-habitation with human colonized with MRSA.
- Co-habitation with animal or human infected or colonized with AMR organism.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Bacterial infections, nonbacterial infections and other inflammatory diseases can mimic AMR bacterial infections, in that clinical response is not achieved with empiric antimicrobial therapy.
- Treating a microbe inherently resistant to empiric drug chosen (e.g., treating anaerobic infection with a drug ineffective against anaerobes) or using drug that does not penetrate site of infection.
- Viral, fungal, or protozoal infections.
- Immune-mediated disease.
- Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
Findings are dependent on location of infection.
- CBC may lack abnormalities or range from leukocytosis and neutrophilia to neutropenia with degenerative left shift.
- Chemistry abnormalities associated with site of infection (e.g., azotemia with pyelonephritis).
- Urinalysis may reveal bacteriuria and pyuria in patients with urinary tract infections.

OTHER LABORATORY TESTS
- Quantitative bacterial culture and susceptibility testing are required for identification of AMR and MDR infections.
- Cytologic examination using a Romanowsky-type stain (e.g., Diff-Quik) and/or Gram stain of samples obtained for culture may help with culture interpretation, especially if more than one organism is cultured or suspected.

IMAGING
Imaging studies should identify source of infection and guide sampling for bacterial culture and susceptibility testing.

DIAGNOSTIC PROCEDURES
Sampling of site of infection is required for diagnosis and for guiding therapy; such procedures may include swabs of skin wounds or lesions, cystocentesis, thoracocentesis, abdominocentesis, pyelocentesis, airway samples (transtracheal, endotracheal wash or bronchoalveolar lavage).

PATHOLOGIC FINDINGS
Findings are dependent on site of infection. In general, active infections would be expected to contain innate immune cells and intracellular bacteria.

TREATMENT

APPROPRIATE HEALTH CARE
- If hospitalization is required, patient should be isolated and proper personal protective equipment (gloves, gowns, eye or face shield, as indicated) utilized to prevent nosocomial infections of other patients and colonization of caregivers.
- Therapy dependent on location and type of infection.
- Treatment of underlying disease and addressing predisposing risk factor(s) is critical to clear infection and prevent recurrence (e.g., removal of urinary cystoliths to resolve bladder infection).
- Surgical debridement of wound infections may be necessary.

MULTIDRUG-RESISTANT INFECTIONS (CONTINUED)

• Topical antiseptic therapy for localized cutaneous infections, such as MRSP and MRSA, is recommended in lieu of systemic antimicrobials, when possible.

NURSING CARE
• For cutaneous wounds, bandaging is recommended to protect wound and prevent spread of AMR organisms.
• For patients with urinary or gastrointestinal infections, patients should eliminate in areas amenable to disinfection.

ACTIVITY
Social activities such as daycare, boarding, grooming, dog parks, should be avoided until infection is resolved.

DIET
Raw food diets are discouraged due to risk of bacterial pathogen contamination.

CLIENT EDUCATION
• Educate clients on potential side effects of antimicrobials.
• Ethical dilemmas regarding using drugs critically important to human medicine should be discussed.
• Educate clients on handwashing and cleaning environment to protect themselves and household from MDR pathogens.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Antimicrobial therapy should be based upon bacterial culture and susceptibility (C&S) testing.
• Use of highest priority drugs of critical importance for human health is controversial in veterinary medicine. If antimicrobial selection choices are limited to drugs of highest priority (e.g., 3rd and 4th generation cephalosporins, carbapenems) at a minimum, the following criteria should be applied: (1) Use is supported by C&S testing. (2) There is no other reasonable alternative or alternatives are contraindicated for the patient (e.g., aminoglycosides for animal with renal disease). (3) Infection is not improving with current management (e.g., topical therapy, wound debridement, bandaging). (4) There is good chance that treatment will be curative; these drugs should not be used in pets likely to have recurrent infections. (5) A specialist in infectious disease, microbiology, and infectious disease pharmacology should be consulted.

CONTRAINDICATIONS
Immunosuppressive drugs.

PRECAUTIONS
Ensure that bacterial C&S-based antimicrobial decisions are appropriate for site of infection (e.g., choose lipophilic drugs with good tissue penetration if treating parenchymal disease such as pyelonephritis). Inadequate drug concentration at site of infection may lead to further AMR.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
For localized and/or mild superficial pyoderma, topical antiseptics are encouraged in lieu of antimicrobials. These may include chlorhexidine or benzoyl peroxide shampoos, lotions and sprays; acetic, lactic and malic acids, benzoyl peroxide and silver sulfadiazine gels, creams and wipes. Mupirocin ointment may be appropriate topical antimicrobial for MRSA infections if supported by bacterial C&S.

FOLLOW-UP

PATIENT MONITORING
• Confirmation of effective antimicrobial treatment via repeated bacterial culture and cytology should be performed during therapy and after cessation of therapy to ensure resolution.
• Consider reevaluation of patient 72 hours after initiation of therapy to evaluate for expected response.

PREVENTION/AVOIDANCE
• Prevention of AMR infections involves judicious use of antimicrobials. In patients likely to have recurrent infections (e.g., aspiration pneumonia in patients with megaesophagus) using the minimal effective duration of therapy is recommended.
• As nosocomial infections are likely to exhibit AMR, appropriate infection control protocols should be used in veterinary hospital settings.

POSSIBLE COMPLICATIONS
In some cases, side effects of antimicrobial therapy required to treat AMR and MDR infections may result in morbidity, precluding clearance of infection.

EXPECTED COURSE AND PROGNOSIS
AMR and MDR infections are not necessarily more virulent than antimicrobial-susceptible infections. With appropriate antimicrobial selection, dose, and duration of therapy, patients without unresolved predisposing factors are expected to have similar prognosis as those with antimicrobial-susceptible infections.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Risk factors that break down immune barrier of urinary bladder (e.g., ectopic ureters, urinary calculi, urachal diverticulum, transitional cell carcinoma) are associated with AMR and MDR urinary tract infections.
• Atopy (chronic or recurrent pyoderma).
• Megaesophagus and chronic bronchitis (chronic or recurrent upper and lower respiratory infections).
• Implants (e.g., bone plates) may be associated with surgical site infections.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
There have been sporadic reports of both zoonotic and reverse-zoonotic transmission of AMR and MDR pathogens between animals and humans.

PREGNANCY/FERTILITY/BREEDING
Female dams or bitches can pass AMR bacteria to their offspring, thus causing colonization or infection with AMR organisms despite a lack of previous antimicrobial exposure.

SYNONYMS
• Antibiotic-resistant infection.
• Antimicrobial-resistant infection.

SEE ALSO
Methicillin-Resistant *Staphylococcus*.

ABBREVIATIONS
• AMR = antimicrobial resistance.
• C&S = culture and susceptibility.
• ESBL = extended-spectrum beta-lactamase.
• MDR = multidrug-resistant.
• MRSA = methicillin-resistant *Staphylococcus aureus*.
• MSRP = methicillin-resistant *Staphylococcus pseudintermedius*.

Author Jennifer L. Granick
Consulting Editor Amie Koenig

MULTIPLE MYELOMA

BASICS

OVERVIEW
• Defined as malignant plasma cells in the bone marrow. • Diagnosis requires documentation of bone marrow plasmacytosis, osteolytic bone lesions, and serum or urine myeloma proteins (M-component).

PATHOPHYSIOLOGY
• Proliferation of malignant plasma cells that produce immunoglobulins or subunits. • Immunoglobulins may polymerize and increase serum viscosity. • Bleeding disorders due to paraprotein coating of platelets, thrombocytopenia, hyperviscosity, or interference with coagulation factors. • Nephrotoxicity due to protein deposition of amyloid or direct effect of the protein on renal tubular epithelial cells. • Hypercalcemia due to osteoclast activation and bone lysis.

Systems Affected
• Musculoskeletal—multiple punctate areas of bone lysis in the absence of bony proliferation. • Nervous, cardiovascular, and respiratory—abnormalities secondary to hyperviscosity. • Soft tissues—neoplastic infiltration.

Incidence/Prevalence
• Dogs—1% of all malignancies; <8% of hematopoietic malignancies; 3.6% of all bone tumors. • Cats—<1% of hematopoietic tumors.

SIGNALMENT
Dogs and cats; 6–13 years.

SIGNS
Due to bone infiltration and lysis, immunoglobulins produced, and infiltration of organ(s).

Dogs
• Lethargy, weakness (62%). • Lameness (47%). • Bleeding diathesis (37%): gingiva and epistaxis. • Funduscopic abnormalities including retinal hemorrhage or detachment and tortuous vessels (35%).

Cats
Anorexia, weight loss, malaise, polydipsia, polyuria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Ehrlichiosis, leishmaniosis. • Metastatic bone lesions. • Rheumatoid arthritis.

CBC/BIOCHEMISTRY/URINALYSIS

Dogs
• Hemogram—nonregenerative anemia (66%); neutropenia (25%); thrombocytopenia (33%). • Chemistry—hyperglobulinemia, hypercalcemia (10–25%), azotemia (33%). • Urinalysis: proteinuria, isosthenuria, cylindruria, pyuria, hematuria, or bacteriuria.

OTHER LABORATORY TESTS
• Serum protein electrophoresis—monoclonal gammopathy in the beta or gamma region, and occasionally a biclonal gammopathy will be present. • Urine protein electrophoresis—Bence-Jones proteins in 25–40%. • Coagulation profile—~50% will have abnormal coagulation values.

IMAGING
• Radiography (dogs)—25–66% have multifocal, lytic lesions or diffuse osteoporosis. • Radiography (cats)—bony lesions rare, more common for visceral organ infiltration (myeloma-related disorder). • Ultrasonography—detect changes in visceral organs.

DIAGNOSTIC PROCEDURES
• Diagnosis depends on identifying at least 3 of 4 pathologies: ○ Monoclonal gammopathy. ○ Lytic bone lesions. ○ Bence Jones proteinuria. ○ Bone marrow cytology: >20% plasma cells or >5% malignant plasma cells. • For cats—bone marrow involvement is rare, and hence diagnosis is based upon the identification of malignant plasma cells within the visceral organs (myeloma-related disorder).

TREATMENT

Appropriate Health Care
• Hospitalization if azotemia, hypercalcemia, bleeding disorder, or bacterial infection. • Plasmapheresis lowers protein burden—for symptomatic patient, withdraw a volume of venous blood, centrifuge, discard plasma, and return red blood cells to patient in IV crystalloid fluids. • Phlebotomy for hyperviscosity; replace with an equal volume of isotonic fluids IV. • Always consult a veterinary oncologist for latest information regarding treatment.

Client Education
• Inform client that chemotherapy is palliative but long remissions are possible. • Warn client that relapse will occur. • Discuss side effects, which depend on the drugs used.

Surgical Considerations
Areas nonresponsive to chemotherapy or solitary lesions can be removed surgically.

Radiation Therapy
Radiation therapy can be palliative and highly effective for managing osteolytic bone cancer pain. Indications include painful bone lesions, spinal cord compression, pathologic fractures (after fracture stabilization), or a large soft tissue mass. Consult with a radiation oncologist.

MEDICATIONS

DRUG(S) OF CHOICE
• Dogs—melphalan and prednisone; cyclophosphamide can be used in addition to or in place of melphalan. • Cats—melphalan and prednisone. • IV aminobisphosphonate drugs for management of hypercalcemia and palliation of bone pain. • Consult a veterinary oncologist or reliable drug resource for dosages.

Precautions
• Melphalan—delayed thrombocytopenia. • Cyclophosphamide—sterile hemorrhagic cystitis.

FOLLOW-UP

PATIENT MONITORING
• CBC and chemistry every 2 weeks for 2 months, then monthly. • Serum electrophoresis and/or Bence Jones proteinuria monthly until at least 50% decrease in baseline values, then once every 2–3 months.

POSSIBLE COMPLICATIONS
Chemotherapy may cause leukopenia or thrombocytopenia, anorexia, alopecia, hemorrhagic cystitis, and/or pancreatitis.

EXPECTED COURSE AND PROGNOSIS
• Improvement in clinical signs and laboratory abnormalities expected within 3–6 weeks. • Radiographic abnormalities could take longer and be partial.

Dogs
• Median survival with alkylating agent and prednisone—18–30 months. • Overall response rate >90%. • Hypercalcemia, extensive bone lysis, or Bence-Jones proteinuria may have shorter survival. • Death typically due to kidney failure, secondary infections, or bone/spinal pain.

Cats
Survival with alkylating agents and prednisone—2–9 months.

MURMURS, HEART

BASICS

DEFINITION
Vibrations caused by disturbed blood flow.

Timing of Murmurs
- Systolic murmurs occur between S1 and S2 (systole).
- Diastolic murmurs occur between S2 and S1 (diastole).
- Continuous and to-and-fro murmurs occur throughout all or most of the cardiac cycle (systole and diastole).
- Continuous murmurs are usually accentuated near S2 and to-and-fro murmurs are usually absent near S2.

Grading Scale for Murmurs
- Grade I—barely audible.
- Grade II—soft, but easily auscultated. Does not radiate far from point of maximal intensity.
- Grade III—intermediate loudness; heard easily some distance from point of maximal intensity (PMI), but not to opposite side of chest; most hemodynamically important murmurs are at least grade III.
- Grade IV—loud murmur radiating widely, often including opposite side of chest.
- Grade V—very loud, audible with stethoscope barely touching the chest; palpable thrill.
- Grade VI—very loud, audible without the stethoscope touching the chest; palpable thrill.

Configuration
- Plateau murmurs have uniform loudness and are typical of atrioventricular (AV) valve regurgitant murmurs such as mitral and tricuspid insufficiency and also ventricular septal defect.
- Crescendo–decrescendo murmurs get louder and then softer and are typical of ejection murmurs such as pulmonic and aortic stenosis and also atrial septal defect.
- Decrescendo murmurs start loud and then get softer and are typical of diastolic murmurs such as aortic or pulmonic insufficiency and mitral or tricuspid stenosis.

Location

Dogs
- Mitral area—left fifth intercostal space at costochondral junction.
- Aortic area—left fourth intercostal space above costochondral junction.
- Pulmonic area—left second to fourth intercostal space at sternal border.
- Tricuspid area—right third to fifth intercostal space near costochondral junction.

Cats
- Mitral area—left fifth to sixth intercostal adjacent to the sterum.
- Aortic area—left second to third intercostal space just above the pulmonic area.
- Pulmonic area—left second to third intercostal space adjacent to the sterum.
- Tricuspid area—right fourth to fifth intercostal space adjacent to the sterum.

PATHOPHYSIOLOGY
- Disturbed blood flow associated with high flow through normal or abnormal valves or with structures vibrating in the blood flow.
- Flow disturbances associated with outflow obstruction or forward flow through stenosed valves or into a dilated great vessel. Intensity of the murmur generally correlates with the severity of the stenosis.
- Flow disturbances associated with regurgitant flow through an incompetent valve, septal defect, or patent ductus arteriosus.

SYSTEMS AFFECTED
Cardiovascular

SIGNALMENT
Dogs and cats.

SIGNS
Relate to cause of the murmur.

CAUSES

Systolic Murmurs
- Myxomatous valve disease (mitral and tricuspid valves).
- Cardiomyopathy and AV valve insufficiency.
- Physiologic flow murmurs.
- Anemia.
- Mitral and tricuspid valve dysplasia.
- Systolic anterior mitral motion.
- Dynamic right ventricular outflow obstruction.
- Dynamic subaortic stenosis.
- Atrial septal defect.
- Ventricular septal defect (VSD).
- Pulmonic stenosis.
- Aortic stenosis.
- Tetralogy of Fallot.
- Mitral and tricuspid valve endocarditis.
- Hyperthyroidism.
- Heartworm disease.

Continuous and To-and-Fro Murmurs
- Patent ductus arteriosus (continuous).
- VSD with aortic regurgitation (to-and-fro).
- Aortic stenosis with aortic regurgitation (to-and-fro).

Diastolic Murmurs
- Mitral and tricuspid valve stenosis.
- Aortic and pulmonic valve endocarditis.

RISK FACTORS
Cardiac disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential Signs
- Must differentiate from other abnormal heart sounds—split sounds, ejection sounds, gallop sounds, and clicks.
- Must differentiate from abnormal lung sounds and pleural rubs; listen to see if timing of abnormal sound is correlated with respiration or heartbeat.

Differential Causes
- Pale mucous membranes support diagnosis of anemic murmur.
- Location and radiation of murmur and timing during cardiac cycle can help determine cause (see Figure 1).

CBC/BIOCHEMISTRY/URINALYSIS
- Anemia in animals with anemic murmurs.
- Polycythemia in animals with right-to-left shunting congenital defects.
- Leukocytosis with left-shift in animals with endocarditis.

OTHER LABORATORY TESTS
N/A

IMAGING
- Thoracic radiography—useful for evaluating heart size and pulmonary vasculature to help determine cause and significance of murmur.
- Echocardiography—allows definitive diagnosis of cause of murmur.
- Doppler studies sometimes required to confirm cause of murmur.

DIAGNOSTIC PROCEDURES
- Electrocardiography may be useful in assessing heart enlargement patterns in animals with murmurs.
- Blood cultures and serology for *Bartonella* if suspect endocarditis.

TREATMENT
- Outpatient unless heart failure is evident.
- Base decisions on the cause of the murmur and associated clinical signs.
- None indicated for murmur alone.

MEDICATIONS

DRUG(S) OF CHOICE
N/A

CONTRAINDICATIONS
N/A

(CONTINUED) MURMURS, HEART

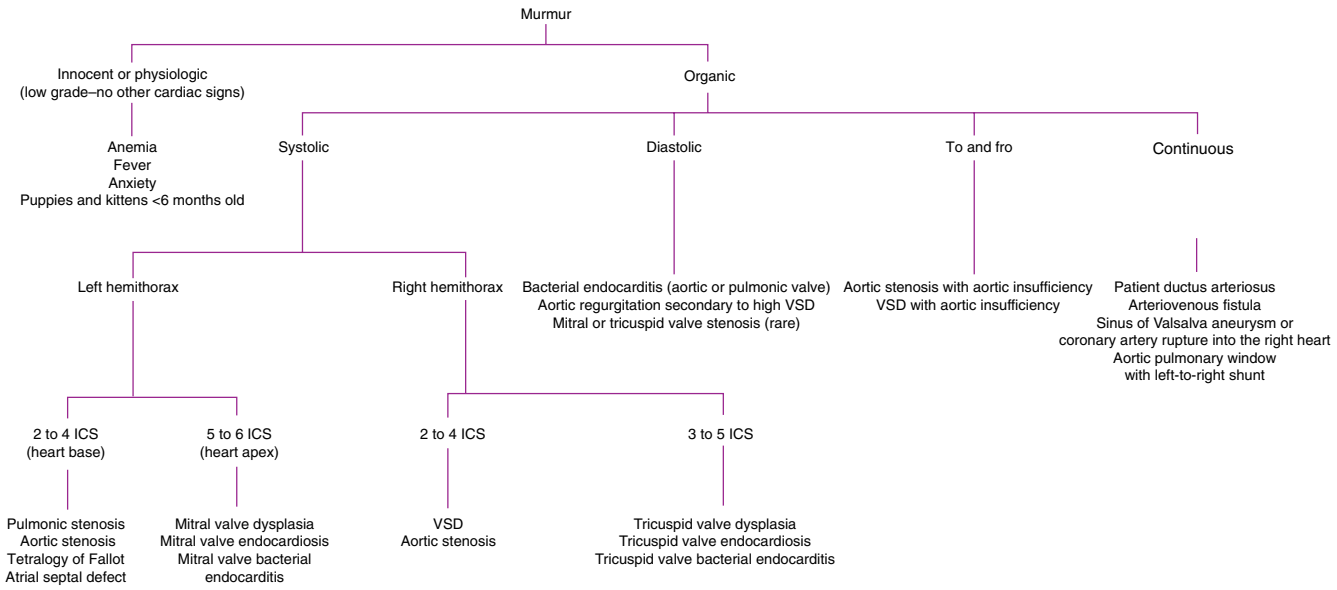

Figure 1.

Algorithm for differential diagnosis of murmurs.

M

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Low-grade systolic ejection murmurs in puppies may be physiologic; most resolve by 6 months of age. If murmur still present after 6 months, include diagnostic imaging.

POSSIBLE COMPLICATIONS
If murmur is associated with structural heart disease, may see signs of congestive heart failure (e.g., coughing, dyspnea, and ascites) or exercise intolerance.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
- Murmurs present since birth generally associated with a congenital defect or physiologic flow murmur.
- Acquired murmurs in geriatric, small-breed dogs usually associated with degenerative valve disease.
- Acquired murmurs in large-breed dogs usually associated with dilated cardiomyopathy.
- Acquired murmurs in geriatric cats can be associated with cardiomyopathy, hyperthyroidism or innocent.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Murmurs in puppies and kittens may reflect a congenital defect and thereby influence decisions on breeding that animal or repeating the mating.

ABBREVIATIONS
- AV = atrioventricular.
- PMI = point of maximal intensity.
- S1 = first heart sound.
- S2 = second heart sound.
- VSD = ventricular septal defect.

MUSCLE RUPTURE (MUSCLE TEAR)

BASICS

OVERVIEW

A normal muscle may be stretched, pinched, or injured directly, resulting in fiber disruption, weakening, and immediate or delayed separation of the uninjured portions. Alternatively, the muscle structure may be compromised by systemic or iatrogenic conditions, and normal activity may cause muscle disruption. The rupture may be complete or incomplete, and it may be mid-substance or at the muscle–tendon junction. The acute stage is characterized by a typical inflammatory reaction that becomes chronic with collagen maturation, cross-linking, fibrosis, and adhesion development over time. Frequently the acute phase is overlooked, as the signs may be temporary and respond well to rest. The chronic effects are often progressive and unresponsive to support therapies.

SIGNALMENT

- Limb and masticatory muscles are the primary structures affected.
- Traumatic injury is indiscriminate, although certain activities may predispose because of exposure.
- The ruptures that are apparently unrelated to trauma seem to affect middle-aged to older working dogs, with no reported sex predilection.
- Cats are affected less frequently than dogs.

SIGNS

Acute Injury

- Immediate lameness that is characterized by the specific muscle affected.
- Localized swelling, heat, and pain.
- Generally present for a few days to a week.
- Animals may experience re-injury.

Chronic Phase (If It Develops)

- Progressive.
- Painless.
- Usually associated with scar tissue that impedes normal function of an extremity.

CAUSES & RISK FACTORS

- Trauma.
- Repeated overuse.
- Overextension.
- Myositis.
- Degenerative (unknown etiology).
- Myopathy secondary to medical conditions such as Cushing disease.
- Apparent risk factor for dogs is involvement in hunting, tracking, or similar activities in the outdoors.

Gait Analysis and Physical Examination Findings

Various disorders will result in characteristic gait abnormalities and pain elicited on specific limb manipulation—a few of which are listed here.

- Psoas muscle injury:
  - Pain on internal rotation with extension or abduction of the pelvic limb.
  - Pain on palpation of the lesser trochanter of the affected femur.
  - Short, choppy gait.
- Gracilis, semimembranosus, and semitendinosus muscle contractures:
  - In late stages, these animals are typically not painful on palpation of the gracilis, semitendinosus or semimembranosus muscles.
  - Palpation of a fibrous band in the area of the affected muscle is also apparent.
  - Shortened stride with medial rotation of the paw, internal rotation of the hock, and external rotation of the calcaneus, with internal rotation of the stifle in late phase of the forward stride.
- Infraspinatus muscle contracture:
  - Significant forelimb lameness with circumduction of the affected limb.
  - Marked elbow adduction/foot abduction; upon flexion of the elbow, the distal antebrachium will deviate laterally.
  - Fibrous band will be apparent on palpation of the infraspinatus muscle.
- Quadriceps contracture:
  - Typically occurs with limb disuse/immobilization after femur fracture fixation in young dogs without appropriate physical therapy.
  - Patient will be unable to flex stifle.
- Achilles mechanism injuries:
  - Non-weight-bearing lameness with soft tissue swelling proximal to the calcaneous for tendinous avulsions (mid-substance tears will present with mid gastroc pain and swelling).
  - Hyperflexion of the tarsus.
  - Hyperflexion of the digits, if superficial digital flexor is unaffected (crab claw).
- Sartorius muscle injury/fibrosis:
  - Scant reports in the veterinary literature.
  - Nonpainful, non-weight-bearing pelvic limb.
  - Palpable fibrous band in the area of the sartorius muscle.
  - Short, choppy gait, characterized by an inability to extend the hip.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Neurologic dysfunction—recognized by neurologic abnormalities.
- Tendon rupture—visible or palpable disruption in the tendon.
- Origin/insertion avulsion fracture—radiographic evidence of bone fragment defect and translocation.
- Luxation/subluxation—palpable or radiographic evidence of joint instability or malalignment.

CBC/BIOCHEMISTRY/URINALYSIS

No injury-specific findings.

OTHER LABORATORY TESTS

- Creatine phosphokinase (CPK) may be elevated in acute cases.
- No known specific tests available.

IMAGING

Radiographic Findings

- Soft tissue swelling may be evident in the early stages.
- Calcification of muscle can occur in the traumatized area in chronic situations.
- Avulsion fractures and calcification of the tendon of insertion or origin may be noted on radiographs.

Ultrasonographic Findings

- Local swelling and disorganization of the normal muscle fiber orientation may be seen at the site of injury in acute cases.
- Scar tissue and contracted areas of fibrous tissue can be seen in the muscle in chronic cases—noted as hyperechoic foci in the muscle belly of concern.
- Measurable differences between normal and abnormal sides may be useful in documenting the affected muscle site.

Cross-Sectional Imaging Studies

- CT findings—produces better tissue contrast than the above but still constrained to an axial plane of view.
- MRI findings—edema and hemorrhage cause a change in the signal that can be differentiated from changes due to fibrous tissue replacement of muscle. This allows localization of the problem and helps to identify the type of problem.

DIAGNOSTIC PROCEDURES

Muscle Biopsy

The presence of fibrous tissue and the loss of muscle cells may be documented. Differentiating disuse atrophy from neurologic atrophy and from injury-induced fibrosis may be impossible without corroborating evidence.

TREATMENT

- There is no documented evidence to support a single "best" way to treat acute muscle injuries, preventing fibrous

contracture and adhesions. It is generally believed that immediate post-injury care should involve rest, local cold application followed within hours (24–48 hours) by heat, and passive physical therapy (movement). Severe, strict immobilization (via cast or cage) is potentially contraindicated as it may encourage muscle contracture and muscle fibrosis, leading to irreversible long-term debilitation. Light or non-weight-bearing activity is appropriate for an extended period of time (4–6 weeks). Analgesics and anti-inflammatory drugs should be recommended for several days to weeks. Surgery may be performed within a few days of the injury to repair obvious, acute muscle rupture that results in a separation of the uninjured muscle segments. An essential part of muscle repair is effective tension relief for the injured muscle so that healing can occur without disruption as function returns. Internal or external orthopedic devices may be necessary to provide effective tension relief (transarticular orthopedic implants or orthotics). Owners should be made aware of the possibility of scar-related problems affecting the patient's gait in the long term.

- Once the muscle injury becomes chronic and associated with contracture or adhesions, treatment is aimed at function salvage. Surgical release of the adhesions or fibrous tissue bands is often accompanied by instantaneous symptomatic relief. The prevention of readhesion and progressive contracture is much less rewarding.
- Specific muscle injuries have widely disparate prognoses. Infraspinatus and psoas muscle contractures respond well to surgical excision of the tendon of insertion. Gracilis, semimembranosus, and semitendinosus contractures have a 100% recurrence rate after surgical resection. Quadriceps contracture has a similarly dismal failure rate after surgery.
- Muscle injuries that have healed in an elongated state have a better prognosis for surgical improvement of function than contracted muscles. The most common elongation injury affects the muscles of the calcaneus (Achilles) group. Hock hyperflexion can be surgically reconstructed to return these animals to relatively normal function. This is usually accomplished by shortening the Achilles tendon rather than the injured muscle or musculotendinous junction.

MEDICATIONS

DRUG(S) OF CHOICE

None are specific. Anti-inflammatory drugs may be indicated in acute situations.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Immobilization of the injured muscle in a position that allows adhesions to develop to nearby bone will often result in "tie down" contractures.

FOLLOW-UP

PATIENT MONITORING

Repetitive range-of-motion monitoring and recheck examination.

PREVENTION/AVOIDANCE

Early inflammation control and non-weight-bearing passive physical therapy accompanied by strict cage rest may be beneficial.

POSSIBLE COMPLICATIONS

Contracture of the muscle and fibrous replacement of muscle tissue.

EXPECTED COURSE AND PROGNOSIS

Specific to the muscle and the type of injury.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Joint hypermobility, angular limb deformities, flexion/extension joint abnormalities.

AGE-RELATED FACTORS

Growth plate fractures in young dogs, particularly distal femoral Salter–Harris fractures, are associated with quadriceps contracture.

ABBREVIATIONS

- CPK = creatine phosphokinase.

MUSHROOM TOXICOSES

BASICS

DEFINITION

Cytotoxic Mushroom Poisoning

• *Amanita verna* (European springtime destroying angel), *A. virosa* (destroying angel), *A. phalloides* (death cap, green death cap), *A. bisporigera* (destroying angel), *A. ocreata*, *A. farinosa* and likely many others in the *Amanita* genus. Other important species include *Galerina autumnalis*, *G. marginata* (white rot fungus), *G. venenata* (deadly lawn galerina), *G. sulciceps*, *G. venenata*, *Lepiota helveola*, *L. brunneoincanata*, *L. castanea*, *L. citrophylla*, and *L. subincarnata*. • A number of *Conocybe* species (notably *C. filaris*), which are very commonly found in urban lawns and other urban environments, have been implicated in many cases of fulminant hepatic failure in dogs.

Primary Acute Nephrotoxic Mushroom Poisoning

Amanita proxima, *A. pseudoporphyria*, *A. smithiana*.

Delayed Nephrotoxic Mushroom Poisoning

Cortinarius gentilis (deadly cort), *C. orellanus* (fool's webcap), *C. speciosissimus*, *C. splendens*.

Hallucinogenic *Mushroom Poisoning*

• *Psilocybe* genus (most species). • *Panaeolus foenisecii* (haymaker mushroom), *P. fimicola*, *P. subbalteatus*. • *Conocybe smithii* (bog conocybe). • *Gymnopilus junonius* (big laughing gym). • *Copelandia* genus. • *Pluteus* genus. • Possibly *Stropharia* genus. • Liquid extracts are commonly sold.

Autonomic Toxicity Mushroom Poisoning

• *Clitocybe* genus (most species). • *Inocybe* genus (most species).

Psychoactive *Isoxazole Mushroom Poisoning*

Amanita cokeri (Coker's amanita), *A. cothurnata*, *A. gemmate*, *A. muscaria* (fly agaric, fly mushroom, fly amanita, Satan's mushroom, sacred mushroom), *A. pantherina*.

Rapid-*Onset Myotoxic Mushroom Poisoning*

Russula subnigricans.

Delayed-Onset Myotoxic Mushroom Poisoning

Tricholoma equestre.

Gamma-Aminobutyric Acid (GABA) *Antagonist Mushroom Poisoning*

Gyrometra genus (many species; false morels).

Gastrointestinal (GI) Irritant Mushroom Poisoning

A wide variety of mushrooms can induce GI

• Paxillus syndrome: *Paxillus involutus* (brown roll-rim, poisonous paxillus, brown chantarelle, roll-rim fungus).

PATHOPHYSIOLOGY

Cytotoxic Mushroom Poisoning

• Major toxins are amatoxins (bicyclic octapeptides with an indole-(*R*)-sulfoxide bridge), phallotoxins (cyclic heptapeptides with an indole/thio-etherbridge), and/or virotoxins (heptapeptides have a monocyclic structure, this includes 2-methylsulfonyltryptophan or 2-methylsulfoxytryptophan and dihydroxyproline). • Critically, amatoxins are heat stable and not inactivated by cooking. • Phallotoxins do not cause poisoning when ingested. • The major mode of action is inhibition of RNA polymerase II, resulting in cell death.

Primary Acute Nephrotoxic Mushroom Poisoning

Major toxin is aminohexadienoic acid, which produces rapid-onset (latent period of 30 minutes to 12 hours), fulminant nephrotoxicity.

Delayed Nephrotoxic Mushroom Poisoning

• Major toxins are orellanine and orelline. • Inhibit DNA and RNA polymerases. • A typical *C. orellanus* mushroom contains 15–20 mg of orellanine.

Hallucinogenic Mushroom Poisoning

• Major toxins are psilocybin and psilocin; psilocybin is a pro-toxin which is metabolized to the active toxin psilocin. • Purchased hallucinogenic mushrooms may be laced with LSD (lysergic acid diethylamide), phencyclidine, and/or ketamine. • Hallucinogenic mushrooms are often incorporated into bars of chocolate to aid ingestion (the mushrooms often have an astringent taste).

Autonomic Toxicity Mushroom Poisoning

• Major toxin is L-(+)-muscarine. • Other muscarine enantiomers are commonly present but are much less potent and less important in cases of poisoning. • L-(+)-Muscarine forms a very stable chlorine salt. • Heating, boiling, and drying does not inactivate the toxin. • Clinical signs reflect muscarinic parasympathetic nervous system stimulation and a muscarinic cholinergic crisis.

Psychoactive Isoxazole Mushroom Poisoning

• Major toxins are ibotenic acid and its decarboxylated derivative muscimol. • Act as GABA antagonists. • Muscarine is present in small amounts. • *A. pantherina* may also contain amatoxins; however, hepatotoxicity with this species appears to be very rare.

Rapid-Onset Myotoxic Mushroom Poisoning

• The major myotoxin is cycloprop-2-ene carboxylic acid. • A number of other cytotoxic toxins (russuphelins) have been identified. • Mushroom also contains a gastrointestinal toxin and cadmium.

Delayed-Onset Myotoxic Mushroom Poisoning

Major toxins are unknown.

GABA Antagonist Mushroom Poisoning

• Major pro-toxin is gyromitrin. • In the digestive tract gyromitrin forms monomethylhydrazine, the ultimate toxin. • Monomethylhydrazine reacts with pyridoxal-5-phosphate forming a hydrazone, which decreases glutamic acid decarboxylase activity and decreases formation of GABA. • Gyromitrin also forms methyl-*N*-formylhydrazine, which is hepatotoxic. • Gyromitrin is a carcinogen. • Uncooked or partially cooked mushrooms have a higher toxicity than fully cooked mushrooms (gyromitrin is volatile).

GI Irritant Mushroom Poisoning

A diverse array of toxins is involved but they produce clinically similar effects.

Paxillus Syndrome

• Major toxins include involutin (a diphenylcyclopenteneone compound). • An antigen of an unknown structure in the fungus stimulates the formation of IgG antibodies in the blood serum. In subsequent meals the antigen–antibody complexes are formed and become attached to the surface of erythrocytes, causing their agglutination and hemolysis.

SYSTEMS AFFECTED

Cytotoxic Mushroom Poisoning

Intestine, liver and kidneys; pancreatitis reported with *A. phalloides*; cellular injury is widespread, but typically the liver is the major target organ.

Primary Acute Nephrotoxic Mushroom Poisoning

Kidneys

Delayed Nephrotoxic Mushroom Poisoning

Kidneys

Hallucinogenic Mushroom Poisoning

• CNS. • Liver, kidneys, and GI systems with mistaken ingestion of other toxic species

Autonomic Toxicity Mushroom Poisoning

Muscarinic parasympathetic nervous system.

Psychoactive Isoxazole Mushroom Poisoning

CNS

Rapid-Onset Myotoxic Mushroom Poisoning

Musculoskeletal system.

Delayed-Onset Myotoxic Mushroom Poisoning

Musculoskeletal system.

(CONTINUED) MUSHROOM TOXICOSES

GABA Antagonist Mushroom Poisoning
CNS

GI Irritant Mushroom Poisoning
GI tract.

Paxillus Syndrome
- GI tract.
- Erythron.

GEOGRAPHIC DISTRIBUTION
Worldwide; classically fruiting occurs during spring to autumn.

SIGNS

Cytotoxic Mushroom Poisoning
Patients commonly presented with fulminant hepatic failure or found dead with fulminant hepatic failure of "unknown origin" identified during necropsy. The classical clinical course occurs over a 7-day period:
• Day 1: Mushroom meal and symptom-free interval (6–12 hours). • Day 2: GI phase with vomiting, abdominal pain, diarrhea. • Day 3: Apparent symptomatic remission, but laboratory evidence of developing liver damage. • Day 4: Coagulopathy develops and GI bleeding commences. • Day 5: Onset of hepatic encephalopathy, onset of hepatic coma. • Day 6: Renal failure. • Day 7: Death.

Primary Acute Nephrotoxic Mushroom Poisoning
• Rapid-onset, acute, fulminant renal failure with a 30-minute to 12-hour post-ingestion latency period. • Clinical presentation resembles nonspecific acute renal failure.

Delayed Nephrotoxic Mushroom Poisoning
Delayed-onset, acute, fulminant renal failure with a 36-hour to 17-day post-ingestion latency period.

Hallucinogenic Mushroom Poisoning
• Latency is typically 10–30 minutes post ingestion. • Clinical signs reflect auditory, visual (e.g., biting at invisible flies) or tactile hallucinations with the degree of clinical signs being dose-dependent. • Most CNS reactions are euphoric or excitatory; however, aggression can be enhanced in some cases. • Clinical signs attributable to anxiety, agitation, and ataxia may occur. • Other effects include pupillary dilation, nausea, abdominal pain, vomiting, yawning, parasthesiae, hyperreflexia, tachycardia, hypertension, cardiac arrhythmias, and myocardial ischemic effects. • Convulsions can occur, but are more likely in young animals. • CNS depression can occur late in the clinical course. • For unadulterated mushrooms the clinical course is typically less than 1 hour; if longer than this ingestion of LSD and/or phencyclidine (effects may last >12 hours) should be considered. • *Beware*—ongoing convulsive episodes, myocardial ischemia, hyperthermia, and rhabdomyolysis are possible, particularly with adulterated mushrooms.

Autonomic Toxicity Mushroom Poisoning
• Onset is typically 15 minutes to 2 hours post ingestion. • The clinical course is dose-dependent: about 2 hours in mild cases and up to 1 day in more severe cases. • *Remember*: DUMBELS—diarrhea, urination, miosis, bradycardia/bronchorrhea/bronchoconstriction, emesis, lacrimation, and salivation. • Impaired sight due to impaired accommodation. • Hypotension, vasodilation, and circulatory shock may occur.

Psychoactive Isoxazole Mushroom Poisoning
• Onset is typically within minutes to 3 hours post ingestion. • The typical clinical course is an initial period of drowsiness followed by a period of manic excitement with visual hallucinations (e.g. biting at invisible flies) and bizarre behavior lasting up to 48 hours. This is then followed by a period of deep CNS depression during which intense dreaming has been reported in humans. • Ataxia, incoordination, dizziness, mydriasis, myoclonus, muscle fasciculation/tremors, hyporeflexia, coma, and convulsions (in severe poisoning) can occur. • Rarely vomiting and/or diarrhea can occur

Rapid-Onset Myotoxic Mushroom Poisoning
• Onset is typically within 2 hours post ingestion. • The initial phase (2–24 hours post ingestion) consists of acute gastroenteritis which may resolve over the next 24 hours. • The later phase, developing around 6–12 hours post ingestion, consists of muscle pain, myalgias, rhabdomyolysis, myoglobinuria, hypertension, dehydration, renal failure, hyperkalemia, arrhythmias, myocarditis, and cardiovascular collapse. • Respiratory failure, acute renal failure, pulmonary edema, ventricular tachycardia, and circulatory shock have been recorded in humans. • In fatal cases, death ensues within 12–24 hours post ingestion.

Delayed-Onset Myotoxic Mushroom Poisoning
Resembles acute myotoxic poisoning except onset is delayed typically for 24 hours with resolution over about 15 days in survivors.

GABA Antagonist Mushroom Poisoning
• Onset is unpredictable.
• Most cases result in mild, self-limiting GI disturbance starting 6–12 hours post ingestion. • Cases of severe poisoning may or may not present with an initial GI upset phase followed by hepatorenal toxicity plus neurological disturbance (seizures, mydriasis, muscle fasciculations progressing to coma). Multiorgan failure is common in severe cases. • Methemoglobinemia and hemoglobinuria occurs in some cases. • Hydrazines also affect the cross-linking of collagen and have been associated with dissecting aortic aneurysms.

GI Irritant Mushroom Poisoning
• Onset is typically 1–3 hours post ingestion.
• Clinical signs include vomiting, abdominal pain and diarrhea. • Fluid and electrolyte disturbances can be severe, particularly in small animals. • Disseminated intravascular coagulation and renal failure can occur.
• GI upset is usually short and self-limiting.

Paxillus Syndrome
• Self-limiting GI upset. • Immune mediate hemolytic anemia. • Sensitivity to the mushroom builds up with repeated ingestion over a period of years.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

Cytotoxic Mushroom Poisoning
• Early stages—resembles per-acute/acute gastroenteritis (fluid loss, hypovolemia, serum ion disturbances). • Later stages—typically reflect fulminant hepatic failure with massive increases in serum liver enzymes, hyperbilirubinemia, and coagulopathy.

Primary Acute Nephrotoxic Mushroom Poisoning
Reflects acute oliguric/anuric renal failure following acute renal tubular necrosis.

Delayed Nephrotoxic Mushroom Poisoning
Reflects acute oliguric/anuric renal failure following acute renal tubular necrosis.

Hallucinogenic Mushroom Poisoning
Nonspecific

Autonomic Toxicity Mushroom Poisoning
Nonspecific

Psychoactive Isoxazole Mushroom Poisoning
Nonspecific

Rapid-Onset Myotoxic Mushroom Poisoning
• Serum chemistry results may reflect acute renal failure with massively elevated serum creatine kinase; other serum chemistry changes may include increased lactate dehydrogenase and increased transaminases. • Hyperkalemia and hypocalcemia are often prominent.
• Urinalysis may indicate myoglobinuria.

Delayed-Onset Myotoxic Mushroom Poisoning
As per rapid-onset myotoxic mushroom poisoning.

GABA Antagonist Mushroom Poisoning
• CBC may indicate oxidative damage to erythrocytes (e.g., Heinz body formation) and hemolysis. • Methemoglobinemia is present in some cases. • Evidence of liver damage (increased serum transaminases) may occur in some cases. • Hyper- and hypoglycemia can occur. • Hypovolemia and serum ion

M

MUSHROOM TOXICOSES (CONTINUED)

abnormalities may occur following GI damage. • Coagulopathies occur in some cases.

GI Irritant Mushroom Poisoning
Reflect fluid loss and serum ion disturbances.

Paxillus Syndrome
Reflect fluid loss and serum ion disturbances and immune-mediated anemia.

OTHER LABORATORY TESTS
Uneaten mushrooms should be placed in a dry paper bag for transport to an expert mycologist.

DIAGNOSTIC PROCEDURES
Identification of uneaten mushrooms or spores in gastric contents by an experienced mycologist

Cytotoxic Mushroom Poisoning
• Meixner test is unreliable. • Serum and urine amatoxins have no clinical value.

Primary Acute Nephrotoxic Mushroom Poisoning
Aminohexadienoic acid determination in body fluids and kidney is possible but rarely performed.

Delayed Nephrotoxic Mushroom Poisoning
In renal biopsy tissue, orellanine is detectable by thin-layer chromatography up to 6 months after poisoning.

Hallucinogenic Mushroom Poisoning
Psilocybin and psilocin can be measured in blood, plasma, serum, and urine; detection period in urine is typically about 3 days.

Autonomic Toxicity Mushroom Poisoning
Response to low-dose treatment with atropine can be considered.

Psychoactive Isoxazole Mushroom Poisoning
Nonspecific

Rapid-Onset Myotoxic Mushroom Poisoning
Nonspecific

Delayed-Onset Myotoxic Mushroom Poisoning
Nonspecific

GABA Antagonist Mushroom Poisoning
Nonspecific

GI Irritant Mushroom Poisoning
Nonspecific

Paxillus Syndrome
Nonspecific.

TREATMENT

APPROPRIATE HEALTH CARE

Cytotoxic Mushroom Poisoning
• Early euthanasia in confirmed cases should be considered. • Cases of suspect ingestion should be hospitalized for observation for at least 3–4 days.

Primary Acute Nephrotoxic Mushroom Poisoning
Cases of suspect ingestion should be hospitalized for observation for at least 3–4 days

Delayed Nephrotoxic Mushroom Poisoning
Cases of suspect ingestion require careful and repeated assessment of renal status for up to 17 days.

Hallucinogenic Mushroom Poisoning
Cases of suspect ingestion should be hospitalized for observation.

Autonomic Toxicity Mushroom Poisoning
Cases of suspect ingestion should be hospitalized for observation.

Psychoactive Isoxazole Mushroom Poisoning
Cases of suspect ingestion should be hospitalized for observation.

Rapid-Onset Myotoxic Mushroom Poisoning
• Early euthanasia in confirmed cases should be considered. • Cases of suspect ingestion should be hospitalized and may require urgent treatment.

Delayed-Onset Myotoxic Mushroom Poisoning
As per rapid-onset myotoxic mushroom poisoning.

GABA Antagonist Mushroom Poisoning
Cases of suspect ingestion should be hospitalized for observation.

GI Irritant Mushroom Poisoning
Cases of suspect ingestion should be hospitalized for observation.

Paxillus Syndrome
Cases of suspect ingestion should be hospitalized for observation.

NURSING CARE

Cytotoxic Mushroom Poisoning
• Observation, fluid resuscitation, and electrolyte replacement as required. • If a confirmed case presents within 1-4 hours post ingestion (very unusual), gastric lavage and oral activated charcoal treatment (for up to the first 36 hours) could be considered. • Hemoperfusion and plasmapheresis are ineffective. • Therapeutic total plasma exchange could be considered.

Primary Acute Nephrotoxic Mushroom Poisoning
• If a confirmed case presents within 1–4 hours post ingestion (very unusual), gastric lavage could be considered. • Treatment as per any form of acute renal failure.

Delayed Nephrotoxic Mushroom Poisoning
• Given the long latency period, patients are unlikely to be presented early enough for GI decontamination to be of any benefit. • Treatment as per any form of acute renal failure.

Hallucinogenic Mushroom Poisoning
• Simple supportive care consisting of placement in a dark, quiet room with the owner is often effective for simple hallucinogenic mushroom poisoning. • *Beware*—risk of self-injury is present.

Autonomic Toxicity Mushroom Poisoning
• If a confirmed case presents within 1–4 hours post ingestion (very unusual), gastric lavage and/or single-dose activated charcoal treatment could be considered. • Careful hemodynamic and electrocardiographic monitoring is recommended. • Fluid resuscitation and careful electrolyte monitoring may be required if diarrhea is severe.

Psychoactive Isoxazole Mushroom Poisoning
• Treatment is primarily supportive. • Placing in a dark, quiet environment in the presence of the owner may be helpful. • *Beware*—risk of self-injury is present.

Rapid-Onset Myotoxic Mushroom Poisoning
• If a confirmed case presents within 1–4 hours post ingestion (very unusual), gastric lavage and/or single-dose activated charcoal treatment could be considered. • Fluid resuscitation and careful electrolyte monitoring and management is required.

Delayed-Onset Myotoxic Mushroom Poisoning
As per rapid-onset myotoxic mushroom poisoning.

GABA Antagonist Mushroom Poisoning
Fluid resuscitation and careful electrolyte monitoring may be required.

GI Irritant Mushroom Poisoning
Fluid resuscitation and careful electrolyte monitoring are the mainstays of treatment.

Paxillus Syndrome
Fluid resuscitation and careful electrolyte monitoring are the mainstays of treatment.

ACTIVITY
As needed and clinically justifiable.

MEDICATIONS

DRUG(S) OF CHOICE

Cytotoxic Mushroom Poisoning
• There are no specific antidotes. • Silibinin (20–40 mg/kg/day in divided doses) may have

limited value. • Penicillin G (300,000–1 million U/kg/day) may have limited value. • IV glucose during hepatic failure phase. • Fresh frozen plasma and vitamin K if coagulopathy is present.

Primary Acute Nephrotoxic Mushroom Poisoning
As per any form of acute renal failure.

Delayed Nephrotoxic Mushroom Poisoning
As per any form of acute renal failure.

Hallucinogenic Mushroom Poisoning
• For severe reactions, longer acting benzodiazepines such as diazepam may be useful. • Convulsions can be managed by the use of barbiturates. • *Beware*—reactions lasting longer than an hour or so may indicate LSD, ketamine, or phencyclidine poisoning.

Autonomic Toxicity Mushroom Poisoning
• Mild cases may not require drug treatment. • In moderate to severe cases the drug of choice (and antidote) is atropine administered slowly and carefully to effect (the key clinical endpoint is the drying of respiratory secretions, not pupil size). • Fluid resuscitation and careful electrolyte monitoring may be required if diarrhea is severe.

Psychoactive Isoxazole Mushroom Poisoning
• Typically monitoring and prevention of self-injury is sufficient. • Benzodiazepines such as diazepam could be considered during the manic phase.

Rapid-Onset Myotoxic Mushroom Poisoning
• Nonspecific symptomatic and supportive care is required. • The major priorities are fluid and electrolyte management. • Dantrolene could be considered.

Delayed-Onset Myotoxic Mushroom Poisoning
As per rapid-onset myotoxic mushroom poisoning.

GABA Antagonist Mushroom Poisoning
• Pyridoxine (vitamin B6) can be used as an "antidote" in treatment of convulsions or coma at about 25 mg/kg IV over 15–20 minutes. • Methylene blue 1 mg/kg IV over 5–30 minutes; if the methemoglobin level remains greater than 30% or if symptoms persist, a repeat dose of 1 mg/kg IV may be given 1 hour after the first dose; if methemoglobinemia does not resolve after 2 doses, consider alternative interventions if methemoglobinemia is clinically significant. • Benzodiazepines and barbiturates may be useful if CNS excitation is present.

GI Irritant Mushroom Poisoning
Mainstay of treatment is fluid resuscitation and electrolyte management.

Paxillus Syndrome
Mainstay of treatment is fluid resuscitation and electrolyte management.

FOLLOW-UP

PATIENT MONITORING

Cytotoxic Mushroom Poisoning
• Survival is unlikely following clinically significant ingestions. • Survivors of fulminant liver failure require ongoing monitoring of liver and kidney functions and monitoring of the coagulation system.

Primary Acute Nephrotoxic Mushroom Poisoning
• Survival is possible. • Ongoing monitoring of renal function is recommended.

Delayed Nephrotoxic Mushroom Poisoning
• Survival is possible. • Ongoing monitoring of renal function is recommended.

Hallucinogenic Mushroom Poisoning
Risk of reexposure if owners are consumers of hallucinogens.

Autonomic Toxicity Mushroom Poisoning
Outcome is typically good when supportive care is provided.

Psychoactive Isoxazole Mushroom Poisoning
Outcome is typically good when supportive care is provided.

Rapid-Onset Myotoxic Mushroom Poisoning
• Survival is rare. • Severe muscle damage is likely in survivors.

Delayed-Onset Myotoxic Mushroom Poisoning
As per rapid-onset myotoxic mushroom poisoning.

GABA Antagonist Mushroom Poisoning
• Poisoning is often severe. • Multiorgan failure (primary, or secondary to hemolysis or hepatorenal failure) occurs in severe cases.

GI Irritant Mushroom Poisoning
GI damage can be severe, but recovery is usual.

Paxillus Syndrome
• GI damage is typically mild and self-limiting. • Require monitoring for immune mediated anemia.

PREVENTION/AVOIDANCE
Prevent dogs roaming, control mushrooms in areas where animals are kept.

EXPECTED COURSE AND PROGNOSIS

Cytotoxic Mushroom Poisoning
Survival following clinically significant ingestion is unlikely; the major determinant of survival is the amount of amatoxins ingested.

Primary Acute Nephrotoxic Mushroom Poisoning
• Poorly documented in veterinary species. • Survival is possible with appropriate treatment.

Delayed Nephrotoxic Mushroom Poisoning
• Poorly documented in veterinary species. • Survival is possible with appropriate treatment.

Hallucinogenic Mushroom Poisoning
Prognosis is typically good provided misadventure is prevented.

Autonomic Toxicity Mushroom Poisoning
Prognosis is typically good with symptomatic and supportive care.

Psychoactive Isoxazole Mushroom Poisoning
Outcome is typically good when supportive care is provided.

Rapid-Onset Myotoxic Mushroom Poisoning
Survival is rare.

Delayed-Onset Myotoxic Mushroom Poisoning
Survival is rare.

GABA Antagonist Mushroom Poisoning
• Many cases are mild. • Evidence of hepatorenal failure indicates a poor prognosis.

GI Irritant Mushroom Poisoning
Prognosis is typically good with symptomatic and supportive care.

Paxillus Syndrome
Prognosis is reasonable provided reexposure to the mushrooms does not reoccur.

MISCELLANEOUS

AGE-RELATED FACTORS
Young animals or animals that are inexperienced with a specific location are possibly more likely to be poisoned.

SYNONYMS
Mushroom poisoning; shroom poisoning.

ABBREVIATIONS
• GABA = γ-aminobutyric acid.
• GI = gastrointestinal.
• LSD = lysergic acid diethylamide.

Consulting Editor Lynn R. Hovda

MYASTHENIA GRAVIS

BASICS

DEFINITION
A disorder of neuromuscular transmission characterized by muscular weakness and excessive fatigability.

PATHOPHYSIOLOGY
Transmission failure at the neuromuscular junction—results from structural or functional abnormalities of the nicotinic acetylcholine receptors (AChRs) or other end-plate proteins and enzymes (congenital form) and from autoantibody-mediated destruction of AChRs and postsynaptic membranes (acquired form).

SYSTEMS AFFECTED
- Neuromuscular—result of abnormalities or destruction of AChRs, choline acetyltransferase or end-plate cholinesterase.
- Respiratory—may find aspiration pneumonia secondary to megaesophagus.

GENETICS
- Congenital familial forms—Jack Russell terrier, springer spaniel, smooth fox terrier; smooth-haired miniature dachshund, Gammel Dansk hønsehund, Labrador retriever; autosomal recessive mode of inheritance.
- Acquired—as with other autoimmune diseases, requires appropriate genetic background for disease to occur; multifactorial, involving environmental, infectious, and hormonal influences.
- Familial forms of acquired myasthenia gravis (MG) occur in the Newfoundland and Great Dane breeds.

INCIDENCE/PREVALENCE
- Congenital—rare.
- Acquired—not uncommon in dogs; uncommon in cats.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
- Congenital—Jack Russell terriers; springer spaniels; smooth fox terriers; smooth-haired miniature dachshunds, Gammel Dansk hønsehund. Labrador retriever.
- Acquired—several breeds: golden retrievers; German shepherd dogs; Labrador retrievers; dachshunds; Scottish terriers; Akitas; and Abyssinian and Somali cats.

Mean Age and Range
- Congenital—6–8 weeks of age.
- Acquired—bimodal age of onset; dogs: 1–4 years of age and 9–13 years of age.

Predominant Sex
- Congenital—none.
- Acquired—may be a slight predilection for females in the young age group; none in the old age group.

SIGNS

General Comments
- Acquired—may have several clinical presentations ranging from focal involvement of the esophageal, pharyngeal, and extraocular muscles to acute generalized collapse.
- Should be on the differential diagnosis of any dog with acquired megaesophagus, lower motor neuron weakness, or a cranial mediastinal mass.

Historical Findings
- Regurgitation—common; important to differentiate between vomiting and regurgitation.
- Voice change.
- Exercise-related weakness.
- Acute collapse.
- Progressive weakness.
- Sleep with eyes open.

Physical Examination Findings
- Patient may look normal at rest.
- Excessive drooling, regurgitation, and repeated attempts at swallowing.
- Muscle atrophy—usually not found.
- Dyspnea—with aspiration pneumonia.
- Fatigue or cramping—with mild exercise.
- Careful neurologic examination—subtle findings: decreased or absent palpebral reflex (may be fatigable); may note a poor or absent gag reflex; spinal reflexes usually normal but fatigable (rarely absent and dog unable to support its weight).
- Ventroflexion of the neck (cats, uncommon in dogs).

CAUSES
- Congenital.
- Immune-mediated.
- Paraneoplastic.

RISK FACTORS
- Appropriate genetic background.
- Neoplasia—particularly thymoma.
- Methimazole treatment (cats)—may result in reversible disease.
- Vaccination can exacerbate active MG.
- Intact female.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other disorders of neuromuscular transmission—tick paralysis; botulism; cholinesterase toxicity.
- Acute or chronic polyneuropathies.
- Polymyopathies—including polymyositis.
- Diagnosis depends upon a careful history, thorough physical and neurologic examinations, and specialized laboratory testing.

CBC/BIOCHEMISTRY/URINALYSIS
- Normal.
- Serum creatine kinase activity—usually normal; may be elevated if MG is associated with polymyositis and concurrent thymoma.

OTHER LABORATORY TESTS
- Serum AChR antibody titer—diagnostic for acquired form.
- Thyroid and adrenal function—may see abnormalities associated with acquired form.

IMAGING
Thoracic radiographs—megaesophagus; cranial mediastinal mass, aspiration pneumonia.

DIAGNOSTIC PROCEDURES
- Ultrasound-guided biopsy of cranial mediastinal mass—may support diagnosis of thymoma.
- Dramatic increase in muscle strength after administration of edrophonium chloride 0.1 mg/kg IV—may see false-negative and false-positive responses.
- Decreased or absent palpebral reflex—may return after edrophonium chloride administration.
- Electrophysiologic evaluation—necessity questionable with increased availability of AChR antibody testing; many patients with acquired form are poor anesthetic risks.
- Electrocardiogram—with bradycardia; third-degree heart block has been documented in some patients with acquired disease.

PATHOLOGIC FINDINGS
Biopsy of a cranial mediastinal mass may reveal thymoma, thymic hyperplasia, or thymic atrophy.

TREATMENT

APPROPRIATE HEALTH CARE
- Inpatient—until adequate dosages of anticholinesterase drugs are achieved.
- Aspiration pneumonia—may require intensive care.
- Gastrostomy tube—may be required if patient is unable to eat or drink without significant regurgitation.

NURSING CARE
- Oxygen therapy, intensive antibiotic therapy, IV fluid therapy, and supportive care—generally required for aspiration pneumonia.
- Nutritional maintenance with a gastrostomy tube—multiple feedings of a high-caloric diet; good hygiene care.
- Elevation of food and water.

ACTIVITY
Self-limited owing to the severity of muscle weakness and extent of aspiration pneumonia.

(CONTINUED)

MYASTHENIA GRAVIS

DIET
May try different consistencies of food—gruel; hard food; soft food; evaluate what is best tolerated.

CLIENT EDUCATION
- Warn client that, although the acquired disease is treatable, most patients require months of special feeding and medication.
- Inform client that a dedicated owner is important to a favorable outcome for acquired myasthenia.
- Prognosis is poor for congenital myasthenic syndrome.

SURGICAL CONSIDERATIONS
- Cranial mediastinal mass—thymoma.
- Before attempting surgical removal, stabilize patient with anticholinesterase drugs and treat aspiration pneumonia.
- Weakness may not be clinically evident initially.
- Suspected thymoma—test all patients for acquired MG before surgery.

MEDICATIONS

DRUG(S) OF CHOICE
- Anticholinesterase drugs—prolong the action of acetylcholine at the neuromuscular junction; pyridostigmine bromide tablets or syrup (Mestinon syrup, diluted half and half in water) at 1–3 mg/kg PO q8–12h.
- Corticosteroids 0.5 mg/kg q24h; initiated if there is a poor response to pyridostigmine or if there is no response to the edrophonium chloride challenge.

CONTRAINDICATIONS
Avoid drugs that may reduce the safety margin of neuromuscular transmission—aminoglycoside antibiotics; antiarrhythmic agents; phenothiazines; anesthetics; narcotics; muscle relaxants; magnesium.

PRECAUTIONS
- Avoid large volumes of barium for evaluating megaesophagus.
- Large air-filled esophagus seen on survey radiographs—barium study not indicated.
- Avoid immunosuppressive dosages of prednisone—may worsen muscle weakness.
- Avoid unnecessary vaccinations.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
- Azathioprine 2 mg/kg PO through gastrostomy tube q24h. Taper to q48h when clinical remission of the disease.
- Mycophenolate 20 mg/kg PO q12h. Reduce dosage by 50% once significant improvement or resolution of clinical signs is noted.

FOLLOW-UP

PATIENT MONITORING
- Return of muscle strength should be evident.
- Thoracic radiographs—evaluated every 4–6 weeks for resolution of megaesophagus.
- AChR antibody titers—evaluated every 8–12 weeks; decrease to the normal range with immune remission.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
- Aspiration pneumonia.
- Respiratory arrest.

EXPECTED COURSE AND PROGNOSIS
- No severe aspiration pneumonia or pharyngeal weakness—good prognosis for complete recovery; resolution usually within 6–8 months.
- Thymoma present—guarded prognosis unless complete surgical removal and control of myasthenic signs are achieved.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Other autoimmune disorders—thyroiditis; skin disorders; hypoadrenocorticism, thrombocytopenia, hemolytic anemia, inflammatory bowel disease.
- Disorders of the thymus—thymoma; thymic hyperplasia.
- Other neoplasias.

AGE-RELATED FACTORS
Bimodal age of onset—1–4 years of age and 9–13 years of age.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
- In humans, weakness may improve during pregnancy but worsens after delivery; some neonates of affected mothers have a temporary MG-like weakness that lasts several days to weeks that is due to *in utero* transfer of autoantibodies from the mother.
- Documented in dogs after whelping.

SEE ALSO
- Chapters covering autoimmune diseases.
- Megaesophagus.

ABBREVIATIONS
- AChR = acetylcholine receptor.
- MG = myasthenia gravis.

MYCOBACTERIAL INFECTIONS

BASICS

OVERVIEW

- Mycobacteria—Gram-positive, acid-fast higher bacteria (genus *Mycobacterium*); obligate or sporadic pathogens in humans and animals.
- Tuberculosis—rare in dogs and cats.
- Leprosy:
  - Cats—two syndromes.
  - Dogs—canine leproid granuloma syndrome.
- Systemic or noncutaneous infection with nontuberculous mycobacteria.
- Cutaneous/subcutaneous infections due to rapidly growing mycobacteria (e.g., mycobacterial panniculitis):
  - Dogs and cats—caused by saprophytic mycobacteria.
- Systems affected—respiratory, skin/exocrine; determined by cause.

SIGNALMENT

Tuberculosis

- Cats and dogs of any age.
- Basset hound and Siamese cat reported as possibly more susceptible.

Feline Leprosy

- Syndome 1—free-roaming kittens and young adult cats.
- Syndrome 2—older cats (average 9 years).

Canine Leproid Granuloma

Shorthaired outdoor-housed large-breed dogs, especially boxers and German shepherd dogs.

Systemic Nontuberculous Mycobacteriosis

Sporadic disease that can affect dogs and cats of any age.

Mycobacterial Panniculitis

Adult dogs and cats.

SIGNS

Tuberculosis

- Organism—*Mycobacterium tuberculosis* (humans), *M. bovis* (cattle, wild mammals), and *M. microti* (voles), and *M. microti*-like.
- Dogs and cats exposed to infected primary hosts sporadically infected.
- Disseminated or multiorgan disease caused by intracellular facultative organism.
- Correlated with the route of exposure.
- Major sites of involvement—oropharyngeal lymph nodes, cutaneous and subcutaneous tissues of the head and extremities; pulmonary system; gastrointestinal system.
- Dogs—respiratory, especially coughing.
- Cats—from contaminated milk: weight loss, chronic diarrhea, and thickened intestines; from predation: cutaneous nodules, ulcers, and draining tracts.
- Most dogs and many cats—pharyngeal and cervical lymphadenopathy; unproductive vomiting, ptyalism, or tonsillar abscess; lymphadenopathy; may ulcerate and drain.
- Pyrexia.
- Depression.
- Anorexia and weight loss.
- Hypertrophic osteopathy or hypercalcemia.
- Disseminated disease—body cavity effusion; visceral masses; bone or joint lesions; dermal and subcutaneous masses and ulcers; lymphadenopathy and/or abscesses; CNS signs; sudden death.

Feline Leprosy

- Organisms—*M. lepraemurium* (from rodents) and two unnamed leprosy organisms (*M. visibilis* [provisional]).
- Syndrome 1—*M. lepraemurium*: young cats with localized nodular disease, affecting limbs with sparse to moderate numbers of acid-fast bacilli present in lesions initially; progress rapidly, may ulcerate; aggressive clinical course; recurrence after surgical excision; widespread lesions develop in several weeks.
- Syndrome 2—unnamed species with affinity to *M. malmoense*: older cats with generalized skin lesions and large numbers of acid-fast bacilli in lesions; initial skin nodules that do not ulcerate, progressive over months to years.
- Feline multisystemic granulomatous mycobacteriosis—diffuse cutaneous thickening and multiple organ involvement.

Canine Leproid Granuloma

- Organism—*Mycobacterium* sp. Murphy identified by DNA sequencing.
- Well-circumscribed painless nodules (2 mm–5 cm) in dermis or subcutis; head or ear, but may be anywhere on the body; only large lesions ulcerate.
- No systemic signs of illness.

Systemic Nontuberculous Mycobacteriosis

- Organisms—*M. chelonae-abscessus* group, *M. avium* complex, *M. fortuitum*, *M. genavense*, *M. kansasii*, *M. massiliense*, *M. simiae*, *M. smegmatis*, *M. thermoresistable*, *M. xenopi*.
- Sporadic infections in dogs and cats; associated in patients with concurrent disease immunosuppression or as a result of traumatic tissue introduction of saprophytic organism; syndromes include pleuritis, granulomas, disseminated disease, neuritis, or bronchopneumonia.
- Pulmonary and systemic infections with atypical mycobacteriosis are rare in dogs, in which case the signs are as for tuberculosis.
- *M. avium* infection—disease most often disseminated.

Mycobacterial Panniculitis

- Organisms—*M. fortuitum* group, *M. chelonae-abscessus* group, *M. smegmati* groups, *M. phlei*, *M. terrae* complex, *M. thermoresistable*, *M. ulcerans*.
- Cutaneous—traumatic lesion that fails to heal with therapy; spreads locally in the subcutaneous tissue (panniculitis); original lesion enlarges, forming a deep ulcer that drains hemorrhagic exudate; surrounding tissue becomes firm; satellite pinpoint ulcerations open and drain.
- Wound dehiscence at surgery sites.

CAUSES & RISK FACTORS

Tuberculosis

- Source of exposure—always an infected typical host.
- Dogs—usually from an infected person in the household (*M. tuberculosis*); route is ingestion of expectorated infectious material; aerosol exposure; patients often found in urban areas with newly arrived immigrants.
- Cats—classically exposed by drinking unpasteurized milk of infected cattle (*M. bovis*); much less common now; may be exposed by predation on infected small mammals (*M. bovis*, undefined tuberculosis species).

Feline Leprosy

- Syndrome 1—cases have been reported from temperate coastal areas and port cities; cool climate may facilitate growth of the organism in extremities.
- Syndrome 2—cases are from rural environments; old age or immune-incompetence may be a risk factor; exact risk factors remain undefined; exposure to rodents postulated.

Canine Leproid Granuloma

- Associated with fly bites and may fluctuate seasonally; short coats may predispose.
- Disease likely to be worldwide; most cases reported from Australia, Asia, and Brazil.
- In the United States, reported in California, Hawaii, and Florida.

Systemic Nontuberculous Mycobacteriosis

- Patients are immunosuppressed or have concurrent systemic disease.
- Routes of exposure in pulmonary and systemic disease are uncertain.

Mycobacterial Panniculitis

- Infections usually have antecedent trauma or surgical wound; most patients are immunecompetent.
- Trauma and accidental inoculation of the subcutaneous fat results in infection; history of bite wound possible (subcutaneous disease).
- Overweight of obese animals are more at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- All manifestations—fungal and other actinomycotic infections.

• Panniculitis: nocardiosis.

OTHER LABORATORY TESTS

Tuberculosis

Tuberculosis (dogs)—intradermal skin testing with PPD (purified protein derivative) or BCG (bacillus Calmette–Guérin) on inner pinna; may produce false-positive.

IMAGING

Radiography

• Thoracic, abdominal, or skeletal lesions—suggest granulomatous infectious disease.
• No specific lesions for the mycobacterioses.
• Pulmonary tuberculosis lesions—may become calcified or cavitated.

DIAGNOSTIC PROCEDURES

• Biopsy material from affected tissue.
• Aspiration of purulent material—used for microbiological identification; ultrasound-guided aspiration techniques may be warranted.
• Biopsy specimens—sterile collection; incorporate center of a granulomatous focus.
• Exudate from infected tissues—detection with acid-fast carbolfuchsin or auramine-rhodamine fluorochromes; on routine staining, organisms are negatively stained, showing "ghosts" of bacilli within macrophages; swabs or aspirations of draining cutaneous lesions or lymph nodes, transtracheal wash; endoscopic brushings; rectal cytology; impressions taken at surgical biopsy; heat-fixed exudate should be submitted with tissue for culture.
• Culture—special media and techniques required; referral to specialized laboratories may be required for nontuberculous organisms.
• PCR methodologies—useful for any of the mycobacterial infections using tissue specimens or fluids; for canine leproid granuloma and the two feline leprosy syndromes, primers are not commercially available, but can be used to identify the suspect organisms.

TREATMENT

TUBERCULOSIS

• Obtain permission of health authorities in cases of *M. tuberculosis* infection; zoonotic potential should be considered.
• Multiple agent chemotherapy with drugs used to treat human tuberculosis have been successful; *M. avium* complex infections are difficult to treat.

Feline Leprosy

• Individual lesions may be excised with aggressive margins.
• Surgical treatment should be preceded by systemic therapy.

Canine Leproid Granuloma

Excision is curative; lesions may self-cure; antimicrobial therapy may assist healing.

Subcutaneous and Systemic Nontuberculous Infections

• Treatment should be based on organism identification and antibiotic sensitivity testing.
• Multiple drug therapy is often warranted.
• Aggressive surgical debulking may aid resolution; antimicrobial therapy pre- and intraoperatively is recommended.

MEDICATIONS

DRUG(S) OF CHOICE

Tuberculosis

• Multidrug oral therapy mandatory.
• Current recommendation—fluoroquinolones, clarithromycin, and doxycycline for 6–9 months.
• Marbofloxacin 5.5 mg/kg PO q24h, pradofloxacin 5–7.5 mg/kg PO q24h.
• Clarithromycin 5–10 mg/kg PO q24h.
• Isoniazid and rifampin—combinations have been used; single report of use in cats.
• Isoniazid 10–20 mg/kg (up to 300 mg total) PO q24h.
• Ethambutol 15 mg/kg PO q24h.
• Pyrazinamide—instead of ethambutol 15–40 mg/kg PO q24h.

Feline Leprosy

• Pradofloxacin 5–7.5 mg/kg PO q24h.
• Clarithromycin 5–10 mg/kg PO q24h.

Subcutaneous and Systemic Nontuberculous Infections

• *In vitro* sensitivity testing may be used to choose chemotherapy.
• Antibiotics reported to be effective: macrolide, trimethoprim-potentiated sulfonamide, tetracycline, aminoglycoside, and fluoroquinolone antibiotics.
• Antituberculosis drugs are not generally effective.
• Single-agent therapy not recommended due to poor long-term response; double-agent therapy recommended.
• Long-term therapy should be based on sensitivity testing.
• Treatment should be continued for 2–6 months.
• Relapses are common.

FOLLOW-UP

PATIENT MONITORING

• Antituberculosis and antileprosy drugs—examine monthly; monitor for anorexia and weight loss.
• Liver profile monthly.
• Instruct owners to report cutaneous lesions immediately.

EXPECTED COURSE AND PROGNOSIS

Tuberculosis

Guarded; but undefined as experience with modern drugs is limited.

Feline Leprosy

• Guarded to poor—syndrome 1.
• Fair—syndrome 2, especially if lesions are amenable to surgical excision.

Canine Leproid Granuloma

Good

Subcutaneous and Systemic Nontuberculous Infections

Relapses are common; aggressive surgical approaches and multiple drug therapy may improve outlook.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Tuberculosis—reverse zoonosis possible.
• Affected domestic pets are potential serious zoonotic threats to owners; do not attempt treatment without agreement of public health authorities.
• *M. tuberculosis*—greatest potential for zoonosis, especially with draining cutaneous lesions.
• Disease transmission from dogs and cats to humans—rarely recorded.

MYCOPLASMOSIS

BASICS

DEFINITION
- Class Mollicutes.
- Divided into hemotropic (formerly Haemobartonella and Eperythrozoon, see: Hemotropic Mycoplasmosis) and nonhemotropic types (discussed here).
- More than 80 genera, three families: Mycoplasmas, Ureaplasmas, and Acholeplasmas.
- Smallest (0.2–0.3 μm) and simplest prokaryotic cells capable of self-replication.
- Fastidious, facultative anaerobic, Gram-negative rods.
- Lack cell wall; thus plastic, highly pleomorphic, fragile and sensitive to lysis by osmotic shock, detergents, alcohols, and specific antibody plus complement. Enclosed by a trilayered cell membrane built of amphipathic lipids and proteins; therefore resistant to lysozyme and cell wall-inhibiting antibacterials; most require sterols for growth.
- Reproduce by binary fission; genome replication not necessarily synchronized with cell division, resulting in budding forms and chains of beads.
- Small genome (0.6–1.6 Mb), believed to be result of reductive evolution from a common Gram-positive ancestor adapting to obligate parasitic life.
- Ubiquitous in nature as parasites, commensals, or saprophytes in animals, plants, and insects; many are pathogens of humans, animals, plants, and insects.

PATHOPHYSIOLOGY
- Often part of the resident flora as commensals on mucous membranes of the upper respiratory, digestive, and genital tracts; pathogenicity and role in disease often controversial.
- Species show considerable host specificity.
- Mechanisms by which disease is caused are poorly understood.
- Some species attach to cells by specific receptors; small size and plastic nature enable them to adapt to the shape and contours of host cell surfaces.
- Intimate contact with host cells—necessary for assimilation of vital nutrients and growth factors which organism cannot synthesize. This, along with the tendency of exogenous proteins to bind to mycoplasmal membrane may allow organism to evade the host's immune response. May incorporate host cell antigen onto mycoplasma membrane (capping) because of lack of cell wall. Conversely, mycoplasmal protein antigen may become incorporated onto surface of host cell, involving host cell in deleterious immunologic reactions intended against the organism.
- Products produced during growth—capsular carbohydrate, hemolysins, proteolytic enzymes, ammonia, and endonucleases; accumulation of *Mycoplasma* metabolites (i.e., H_2O_2, NH_3) may contribute to cytopathic effects and tissue damage; cytotoxic glycoproteins and proteins have been isolated from the membranes of several species.
- Immune response—predominantly humoral; as with bacterial infections, IgM and IgA are first antibodies to appear, followed by IgG.
- Fibrinous exudate accompanying infections—protects organism from antibodies and antimicrobial drugs; contributes to chronicity.
- Secondary bacterial invaders—common (e.g., attachment to respiratory tract cells results in destruction of cilia, which predisposes patient to secondary bacterial infection).
- Sialidase, a virulence factor that promotes colonization, tissue invasion, and damage to host cells—varies in expression among strains of canine mycoplasma species.

SYSTEMS AFFECTED

Dogs
- Gastrointestinal—associated with colitis.
- Musculoskeletal—arthritis; from *Mycoplasma spumans*.
- Renal/urologic—urinary and genital tract infections (e.g., balanoposthitis, urethritis, prostatitis, cystitis, nephritis, vaginitis, endometritis); caused by *M. canis* and *M. spumans*.
- Reproductive—*Mycoplasma* and *Ureaplasma*; associated with infertility, early embryonic death, abortion, stillbirths or weak newborns, and neonatal mortality.
- Respiratory—pneumonia and upper respiratory infections; caused by *M. cynos*; associated with *M. canis*, *M. spumans*, *M. edwardii*, *M. feliminutum*, *M. gateae*, and *M. bovigenitalium*.
- Nervous—meningitis, associated with *M. edwardii*.

Cats
- Musculoskeletal—chronic fibrinopurulent polyarthritis and tenosynovitis; associated with *M. gateae* and unspecified mycoplasmal organisms.
- Ophthalmic—conjunctivitis; associated with *M. felis* (5–25%).
- Renal/urologic—urinary tract infections.
- Reproductive—abortions and fetal deaths; associated with *M. gateae* and ureaplasmas.
- Respiratory—pneumonia, associated with *M. gateae*, *M. feliminutum*, and *M. felis*; upper respiratory infections, associated with *M. felis*.
- Skin/exocrine—chronic cutaneous abscesses.
- Nervous—meningoencephalitis, associated with *M. felis*.

INCIDENCE/PREVALENCE
- Frequent inhabitants of mucosal membranes; *M. gateae* and/or *M. felis* found in oral cavity or urogenital tract of 70–80% of healthy cats.
- Rate of isolation in diseased dogs much higher than in normal dogs.

GEOGRAPHIC DISTRIBUTION
Ubiquitous

SIGNALMENT

Species
Dogs and cats.

Mean Age and Range
All ages.

SIGNS

General Comments
Pathogenic role controversial, can be identified in asymptomatic animals.

Historical Findings
- Polyarthritis—chronic intermittent lameness; reluctance to move; joint pain.
- Fever.
- Malaise.
- Conjunctivitis—unilateral or bilateral.
- Cough.

Physical Examination Findings
- Polyarthritis—diffuse limb edema, joint swelling, pain.
- Conjunctivitis—blepharospasm; chemosis, conjunctival hyperemia, epiphora, and serous or purulent ocular discharge.
- Mild rhinitis—sneezing.

CAUSES
- *Mycoplasma* flora of dogs—*M. canis*, *M. spumans*, *M. maculosum*, *M. edwardii*, *M. cynos*, *M. molare*, *M. opalescens*, *M. felis*, *M. feliminutum*, *M. gateae*, *M. arginini*, *M. bovigenitalium*, *M. mucosicanis*, *Acholeplasma laidlawii*, and ureaplasmas.
- *Mycoplasma* flora of cats—*M. felis*, *M. gateae*, *M. feliminutum*, *M. arginini*, *M. pulmonis*, *M. arthritidis*, *M. gallisepticum*, *Acholeplasma laidlawi*, and ureaplasmas.

RISK FACTORS
- Commensals—occasionally cause systemic infection associated with immunodeficiency, immunosuppression, or cancer.
- Impaired resistance of the host—may allow organism to cross the mucosal barrier and disseminate (e.g., primary ciliary dyskinesia).
- Organism may be opportunistic—one factor in a multifactorial causal complex (e.g., impaired pulmonary clearance from viral infection may allow organism to establish infection in lungs as secondary opportunistic pathogen).
- Predisposing factors—stresses (e.g., reproductive problems associated with overcrowded operations) and other factors (e.g., urinary tumors and urinary calculi).

(CONTINUED) MYCOPLASMOSIS

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Upper respiratory infection (dogs and cats)—viruses (parainfluenza virus, canine distemper, canine influenza virus, herpesvirus, feline calcivirus, reovirus); *Chlamydia psittaci*; bacteria (*Bordetella bronchiseptica*, staphylococci, streptococci, coliforms).
- Urinary tract infection (dogs and cats)—bacteria (staphylococci, streptococci, coliforms); fungus (*Candida*); parasites.
- Infertility, early embryonic death, abortion, stillbirths or weak newborns, and neonatal mortality (dogs)—bacteria (*Brucella*, *Salmonella*, *Campylobacter*, *E. coli*, *Streptococcus*); viruses (canine herpesvirus, canine distemper, canine adenovirus); *Toxoplasma gondii*; endocrinopathies (progesterone deficiency, hypothyroidism).
- Prostatitis (dogs)—bacteria (*E. coli, Brucella canis*); fungi (*Blastomyces, Cryptococcus*).
- Arthritis (dogs and cats)—immune-mediated; bacteria (staphylococci, streptococci, coliforms, anaerobes); L-form bacteria; *Rickettsia* (*Ehrlichia*); *Borrelia burgdorferi*; fungi (*Coccidioides*, *Cryptococcus*, *Blastomyces*); protozoa (*Leishmania*); viruses (feline calicivirus).
- Conjunctivitis (cats)—feline herpesvirus; feline calicivirus; feline reovirus; *Chlamydia psittaci*; bacteria.

CBC/BIOCHEMISTRY/URINALYSIS

With Polyarthritis

- Mild anemia.
- Neutrophilic leukocytosis.
- Hypoalbuminemia.
- Hypoglobulinemia.
- Proteinuria, resulting from immune-complex glomerulonephritis.

OTHER LABORATORY TESTS

- Difficult to demonstrate in and from tissues.
- PCR of 16S rRNA.
  - PCR denaturing gradient gel electrophoresis (PCR-DGGE)—used to identify difficult-to culture or difficult-to-differentiate mycoplasma.
- Fluorescent antibody test—definitive diagnosis; isolate and identify or detect the organism in tissues:
  - Submit cotton swabs placed in Hayflick broth medium or commercially available swabs; organisms fragile; refrigerate specimens and deliver to the laboratory within 48 hours; freeze (–80°C) to preserve longer.
- Extremely pleomorphic—in smears (e.g., conjunctival scrapings) seen as coccobacilli, coccal forms, ring forms, spirals, and filaments.
- Stains—stain poorly (Gram-negative); preferred: Giemsa or other Romanowsky stain.
- Culture—fastidious, require complex growth media; form microcolonies having characteristic "fried egg" appearance.

IMAGING

Polyarthritis—no radiographic changes.

DIAGNOSTIC PROCEDURES

- Arthrocentesis—polyarthritis, high numbers of nondegenerative neutrophils in synovial fluid.
- Prostatic wash/urine —inflammatory cells with negative routine bacterial culture.
- Transtracheal or endotracheal wash—high numbers of nondegenerate neutrophils with no organisms seen.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

MEDICATIONS

DRUG(S) OF CHOICE

- Doxycycline 5 mg/kg PO q12h.
- Tetracyclines 22 mg/kg PO q8h.
- Pradofloxacin 5 mg/kg PO q12h.
- Chloramphenicol 40–50 mg/kg IV, IM, SC, PO q8–12h.
- No standardized procedure for *in vitro* antimicrobial susceptibility tests.
- Topical antibiotic—conjunctivitis.

ALTERNATIVE DRUG(S)

- Gentamicin.
- Kanamycin.
- Spectinomycin.
- Spiramycin.
- Tylosin.
- Erythromycin.
- Nitrofurans.
- Fluoroquinolones.

FOLLOW-UP

PATIENT MONITORING

Treat for an extended period of time.

PREVENTION/AVOIDANCE

- No vaccines are available.
- Organism readily killed by drying, sunshine, and chemical disinfection.

EXPECTED COURSE AND PROGNOSIS

Prognosis good in animals with competent immune systems and given appropriate antibiotic therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

M. pneumoniae—infects respiratory tracts in humans worldwide; causes mycoplasmal pneumonia, bronchitis, or upper respiratory infection; usually self-limited; rarely fatal.

ZOONOTIC POTENTIAL

- Not generally considered zoonotic unless person is immunosuppressed.
- Host specificity of mycoplasmas has been questioned by some, particularly between closely related species of mammals.

SYNONYMS

Pleuropneumonia-like organisms.

ABBREVIATIONS

- PCR-DGGE = polymerase chain reaction denaturing gradient gel electrophoresis.

M

MYCOTOXICOSIS—AFLATOXIN

BASICS

OVERVIEW
Aflatoxins are hepatotoxic mycotoxins (mold toxins) and are the most commonly reported cause of mycotoxicosis associated with pet food. The four major forms of aflatoxin in feedstuffs are aflatoxin B1, B2, G1, and G2. Aflatoxin B1 is the most common and most toxic.

SIGNALMENT
- Rarely reported in dogs but occurs periodically in large outbreaks associated with pet foods.
- Reported experimentally in cats, rarely as field cases.

SIGNS
Acute Onset
- Most common presentation in small animals.
- Refusal of contaminated feeds.
- Rapid onset of signs may develop up to 3 weeks post exposure.
- Vomiting and diarrhea.
- Icterus.
- Coagulopathy and gastrointestinal hemorrhage.

Chronic
- Anorexia or feed refusal.
- Vomiting.
- Diarrhea.
- Liver failure.
- Ascites.

CAUSES & RISK FACTORS
- Common in various cereal grains, peanuts, other nuts, and potatoes.
- Postproduction contamination of improperly stored pet foods; foods with obvious mold spoilage; garbage ingestion.
- Mycotoxin-producing molds grow at temperatures of 24–35°C, moisture of 18–20%.
- Acute signs have been seen in dogs ingesting food containing 60 ppb aflatoxin.
- Activated to toxic epoxide by liver cytochrome P450 enzymes.
- Depletes glutathione.
- Binds with nucleic acids, proteins, and cell and organelle membranes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Leptospirosis:
  - Serology.
- Parvovirus:
  - ELISA.
  - Serology.
  - Viral isolation.
- Anticoagulant rodenticide toxicosis:
  - Anticoagulant rodenticide screen.
- Other causes of subacute to chronic liver disease and associated disseminated intravascular coagulation.

CBC/BIOCHEMISTRY/URINALYSIS
- Decreased serum protein C, antithrombin III, and cholesterol.
- Hyperbilirubinemia.
- Hypoalbuminemia.
- Elevated alanine aminotransferase.
- Variable elevations in γ-glutamyltransferase, aspartate aminotransferase, and alkaline phosphatase.

OTHER LABORATORY TESTS
Prolonged activated partial thromboplastin time (aPTT) and prothrombin time (PT).

DIAGNOSTIC PROCEDURES
- Liver biopsy.
- Histopathology.
- Assay suspect food samples for aflatoxin:
  - Contaminated food is often gone due to delayed clinical signs.

PATHOLOGIC FINDINGS
- Hepatomegaly with fatty change.
- Icterus.
- Ascites.
- Multifocal hemorrhage, especially gastrointestinal.
- Microvesicular fatty change in hepatocytes.
- Centrilobular hepatocellular necrosis.
- Canalicular cholestasis.
- Bridging portal fibrosis, proliferation of bile ducts.

TREATMENT
- Transfusion of whole blood or plasma.
- Correct fluid and electrolyte imbalances.
- Activated charcoal for recent, high-dose exposure.
- B vitamins, vitamin K1, vitamin E, antioxidants, and hepatoprotectants.
- Gastroprotectants.
- Clean, uncontaminated diet:
  - High-quality protein source.

MEDICATIONS

DRUG(S) OF CHOICE
- No specific antidotal therapy.
- Limited success with hepatoprotectants.
- Parenteral *N*-acetylcysteine in severely affected dogs—20% solution diluted 1:4 in sterile saline slow IV at a loading dose of 140 mg/kg, follow with maintenance dose of 70 mg/kg IV q8h × 7 doses.
- Oral *S*-adenosylmethionine—20 mg/kg PO daily as enteric-coated tablets given on empty stomach × 1–2 weeks.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Avoid drugs metabolized by the liver.

FOLLOW-UP

PATIENT MONITORING
- Daily serum enzymes and chemistry, including cholesterol.
- PT and aPTT.
- Protein C.

PREVENTION/AVOIDANCE
- Consider as a cause of food refusal.
- Avoid using moldy feedstuff.
- Store food in cool, clean, dry area.
- Clean food containers and feed bowls regularly.

POSSIBLE COMPLICATIONS
Chronic liver disease possible.

EXPECTED COURSE AND PROGNOSIS
Prognosis—poor, even with treatment. Improved prognosis if treatment initiated before onset of signs.

MISCELLANEOUS

AGE-RELATED FACTORS
Young animals more susceptible to aflatoxin.

PREGNANCY/FERTILITY/BREEDING
- Indirect effects on uterus.
- Potentially teratogenic.
- Pregnant animals may be more susceptible.

ABBREVIATIONS
- aPTT = activated partial thromboplastin time.
- PT = prothrombin time.

MYCOTOXICOSIS—TREMORGENIC TOXINS

BASICS

OVERVIEW
- Penitrem A—produced by the fungus *Penicillium crustosum* (and perhaps other *Penicillium* spp.); poisoning by this toxin has been reported in dogs ingesting moldy bread, cheese, and English walnuts.
- Roquefortine—produced by *Penicillium roquefortii* (and perhaps other *Penicillium* spp.); has been reported to cause poisoning in dogs through ingestion of moldy cheese or decaying organic material (compost).

SIGNALMENT
- Dogs and rarely cats.
- Poisoning by penitrem A and roquefortine has been reported in dogs of various ages and breeds soon after the ingestion of moldy foods or compost.

SIGNS
- Moderate to severe muscle tremors and seizures—begin minutes to hours (0.5–4 hours in case reports) after ingestion of moldy food or compost.
- Affected dogs may be hyperresponsive to external stimuli.
- Early signs—may include panting, hyperactivity, vomiting, ataxia, incoordination, weakness, tachycardia, and/or rigidity.
- Prolonged muscle tremors or seizures—may lead to hyperthermia, hypoglycemia, dehydration, and anorexia.
- Severe cases—may result in death.
- Liver necrosis—has been reported experimentally.

CAUSES & RISK FACTORS
- Dogs (and potentially cats) are exposed to penitrem A and roquefortine when they ingest moldy food or decomposing organic matter (compost).
- Experimentally, doses of 0.125 mg/kg penitrem A produced tremors within 30 minutes. Doses of 0.5 mg/kg of penitrem A resulted in acute onset of tremors, severe liver necrosis, and death.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Toxic causes of seizures—strychnine; insecticides (e.g., organophosphate, carbamate, organochlorine, nicotine, pyrethroid); metaldehyde; zinc phosphide; bromethalin; methylxanthines (theobromine and caffeine); amphetamines; cocaine; sago palm; xylitol.
- Nontoxic causes of seizures—inflammation; congenital abnormal myelin formation; metabolic conditions (e.g., hepatic or uremic encephalopathy).

CBC/BIOCHEMISTRY/URINALYSIS
CBC, biochemistry, and urinalysis to assess the patient's status and to help rule out other causes of tremors and seizures.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- High-pressure liquid chromatography/mass spectroscopy—analysis of vomitus, stomach contents, and gastric lavage washings for penitrem A or roquefortine.
- The presence of roquefortine C in vomitus or stomach contents can serve as a sensitive biomarker for penitrem A intoxication.
- Bile analysis—reported to be of value.

PATHOLOGIC FINDINGS
- There are no pathognomonic lesions associated with penitrem A or roquefortine toxicosis.
- High doses of penitrem A have been reported to cause severe liver damage experimentally.

TREATMENT
- Remove contaminated food or organic material.
- Induce vomiting (if patient is not at risk of aspirating vomitus) or institute gastric lavage followed by administration of activated charcoal.
- Control seizures.
- Thermoregulation as indicated.

MEDICATIONS

DRUG(S) OF CHOICE
- Diazepam 0.25–1 mg/kg IV PRN—to control tremors/seizures.
- Methocarbamol 50–220 mg/kg IV to control tremors/seizures; do not exceed 330 mg/kg/day. Give 1/2 rapidly and administer rest to effect.
- Barbiturates phenobarbital 2–5 mg/kg IV PRN—if tremors and seizures cannot be controlled with diazepam.
- Sodium bicarbonate—may be required if an acid–base imbalance exists.
- Other symptomatic and supportive therapy—as indicated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Patients should be monitored for occurrence of tremors or seizures, hyperthermia, dehydration, acid–base imbalances, liver damage, rhabdomyolysis, and respiratory difficulties.

PREVENTION/AVOIDANCE
Prevent animals from eating moldy food items, garbage, or compost.

POSSIBLE COMPLICATIONS
- Seizures—may not be controlled with diazepam.
- Acid–base imbalances—may develop.
- Hepatic damage and rhabdomyolysis—may occur.
- Aspiration pneumonia has been reported as a sequelae to vomiting and/or gastric lavage.
- Exposure can be fatal if lethal doses are consumed and are absorbed before gastrointestinal decontamination and therapy are instituted.

EXPECTED COURSE AND PROGNOSIS
- Very good if appropriate therapy is promptly instituted, the toxin is removed from the gastrointestinal tract, and the seizures are controlled with diazepam, methocarbamol or barbiturates.
- Recovery in most clinical cases is reported to be complete within 24–48 hours.
- In a few reported cases, signs of weakness, muscle rigidity, and incoordination were persistent and slowly resolved over 1–2 weeks.
- A few severe cases have been reported to be fatal.

MYELODYSPLASTIC SYNDROMES

BASICS

OVERVIEW
- Category of diseases characterized by nonregenerative anemias or cytopenias and dysplastic features in the blood or bone marrow.
- Primary myelodysplastic syndromes (MDS) result from a clonal expansion of a genetically altered pluripotent stem cell resulting in a hypercellular bone marrow with maturation arrest as a consequence of apoptosis.
- Subcategorized as MDS with excessive blasts, which may progress to acute myeloid leukemia, MDS with refractory cytopenia, and MDS with erythroid predominance.
- Secondary MDS in dogs is associated with neoplasia (lymphoma, multiple myeloma), drug or toxin exposure, immune-mediated disease, infections, or ionizing radiation exposure.
- Secondary MDS in cats is typically associated with feline leukemia virus (FeLV) infection.

SIGNALMENT
- Dog and less commonly cat.
- Primary MDS typically older dogs.

SIGNS
- Lethargy.
- Exercise intolerance.
- Depression.
- Anorexia.
- Fever.
- Pale mucous membranes.
- Petechiation.
- Heart murmur due to anemia.

CAUSES & RISK FACTORS
- Viral—FeLV, feline immunodeficiency virus (FIV), parvovirus.
- Neoplasia—lymphoma, multiple myeloma.
- Autoimmune—immune-mediated hemolytic anemia, immune-mediated thrombocytopenia.
- Drugs—chemotherapeutics, estrogen, chloramphenicol, cephalosporins, phenylbutazone, trimethoprim-sulfadiazine, quinidine, thiacetarsamide, griseofulvin, albendazole.
- Iron deficiency, folic acid deficiency.
- Lead toxicity.
- Infectious—ehrlichiosis, bacterial septicemia, and endotoxemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Need to differentiate between primary and secondary MDS.
- Other causes of nonregenerative anemias—anemia of chronic disease, chronic renal failure, myeloproliferative diseases, lymphoproliferative diseases, myelofibrosis.

CBC/BIOCHEMISTRY/URINALYSIS
Nonregenerative anemia, cytopenias.

OTHER LABORATORY TESTS
To diagnose underlying causes of secondary MDS—viral antigen/antibody titers, iron levels, tick titers, Coombs' test.

IMAGING
- As needed to rule out secondary causes of MDS.
- Abdominal radiography—evaluate for lead foreign bodies.
- Abdominal ultrasonography—evaluate for abdominal masses consistent with retained testes and Sertoli cell tumors associated with estrogen secretion.

DIAGNOSTIC PROCEDURES
Bone marrow aspirate or biopsy.

TREATMENT
- Inpatient or outpatient.
- If secondary MDS—treat underlying disease (e.g., discontinue drug, treat underlying infection).
- If neutropenic—limit exposure to other sick animals.
- Blood transfusions for anemic patients.

MEDICATIONS

DRUG(S) OF CHOICE
- For neutropenia—broad-spectrum antibiotics and filgrastim 3–5 µg/kg SC q24h in dogs and cats.
- For anemia—erythropoietin 35–50 U/kg SC 3 times a week or darbepoetin 0.45 µg/kg once a week.
- Chemotherapy for primary MDS has been reported—hydroxyurea, cytosine arabinoside, prednisone, cyclosporine A, vincristine.
- Interferon α (cats with FeLV).

FOLLOW-UP
- Serial monitoring of CBC for resolution of cytopenias.
- Prognosis dependent on primary vs. secondary.
- Increasing blast percentage, multiple cytopenias, marked cellular atypia are poor prognostic factors for patients with primary MDS.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
- Do not use chemotherapy in pregnant or nursing animals.
- It is not recommended to breed animals with cancer.

SEE ALSO
- Feline Immunodeficiency Virus (FIV) Infection.
- Feline Leukemia Virus (FeLV) Infection.
- Myeloproliferative Disorders.

ABBREVIATIONS
- FeLV = feline leukemia virus.
- FIV = feline immunodeficiency virus.
- MDS = myelodysplastic syndromes.

MYELOMALACIA, SPINAL CORD (ASCENDING, DESCENDING, PROGRESSIVE)

BASICS

OVERVIEW
- Acute, progressive, ischemic and hemorrhagic necrosis of the spinal cord after acute spinal cord injury (SCI).
- First appears at the site of injury; then may progress cranially and caudally.
- Overall prevalence: 2% in dogs with acute thoracolumbar intervertebral disc herniation (IVDH), up to about 15% in more severely affected cases with paraplegia and loss of pain perception.
- Death usually caused by respiratory paralysis.

SIGNALMENT
- Any age or breed.
- Because of the close association between acute (type I) IVDH and myelomalacia, chondrodystrophic breeds, particularly dachshunds, are more commonly affected because of their predisposition to the former.
- French bulldogs were at higher risk than dachshunds in one study.

SIGNS
- Not clinically recognizable in acute phase of SCI—suggestive clinical signs usually seen within 48 hours after presentation, but a delayed onset up to 2 weeks after injury has been reported.
- Acute onset of paraplegia—initial clinical sign.
- Pain perception—usually absent caudal to the lesion (i.e., pelvic limbs and tail).
- Thoracolumbar injury—pelvic limbs paralysis with normal to exaggerated spinal reflexes in the pelvic limbs; some dogs might present with absent spinal reflexes (lesion at the lumbosacral intumescence or secondary to spinal shock).
- Involvement of the lumbosacral spinal cord segments within 12–72 hours, causing pelvic limb areflexia and atonia, loss of abdominal and anal tone and flaccid urinary bladder.
- Thoracic and cervical spinal cord segments may be involved within 24 hours to 10 days after initial injury, causing loss of cutaneous trunci muscle reflex, progression to tetraplegia, bilateral Horner syndrome, hypoventilation, and death.
- Extensive subarachnoid hemorrhage may cause hyperthermia and diffuse meningeal pain.

CAUSES & RISK FACTORS
- Acute intervertebral disc herniation — herniation at the lumbosacral intumescence associated with higher risk.
- Acute, severe, spinal cord trauma.
- Fibrocartilaginous embolism or acute noncompressive nucleus pulposus extrusion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- On presentation, cannot be differentiated from spinal shock (acute paralysis with initial areflexia improving after a few hours to days post injury) following acute SCI.
- Diagnosis based on hind limb upper motor neuron paralysis with absent nociception progressing to a lower motor neuron paralysis and rostrally advancing line of analgesia and cutaneous trunci reflex.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Possible degenerative left-shift caused by massive spinal cord necrosis.

OTHER LABORATORY TESTS
Serum glial fibrillary acidic protein (GFAP)—elevated; experimental only.

IMAGING
- Spinal survey radiographs—evidence of calcified, herniated disc, narrowed intervertebral disc space; vertebral fracture or luxation.
- Myelography—cord compression; edema; contrast medium infiltration into the spinal parenchyma.
- MRI—extensive parenchymal T2 hyperintensity and spinal cord swelling; associated with other evidence of SCI.

DIAGNOSTIC PROCEDURES
CSF—unspecific results; hemorrhagic, neutrophilic pleocytosis and high protein concentration.

PATHOLOGIC FINDINGS
Extensive, multifocal, necrosis of the spinal cord parenchyma with ischemic changes and multifocal hemorrhages.

TREATMENT
- None to reverse spinal cord damage and stop disease progression.
- Rapid spinal cord decompression—indicated for IVDH as delayed surgical treatment on dogs with complete sensorimotor loss can alter chances of recovery; if performed less than 12 hours following loss of ambulation the risk of myelomalacia is decreased.
- Surgery does not always prevent its occurrence, especially if delayed: inform the owners of the risk of myelomalacia postoperatively despite rapid intervention.
- Strong suspicion of myelomalacia—poor outcome, consider euthanasia.

MEDICATIONS

DRUG(S) OF CHOICE
For palliative care—gabapentin 10 mg/kg PO q8h, opioids (fentanyl, hydromorphone) to relieve pain associated with SCI.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Gabapentin may cause sedation.
- Opioids side effects include sedation, nausea, constipation, dysphoria.

FOLLOW-UP
In rare cases, condition progresses only caudally; paralysis is permanent, but respiratory compromise does not occur.

MISCELLANEOUS

SEE ALSO
Intervertebral Disc Disease, Thoracolumbar.

ABBREVIATIONS
- GFAP = glial fibrillary acidic protein.
- IVDH = intervertebral disc herniation.
- SCI = spinal cord injury.

M

MYELOPATHY—PARESIS/PARALYSIS—CATS

BASICS

DEFINITION

• Myelopathy—any disease affecting the spinal cord; can cause paralysis (complete loss of voluntary movements) or paresis (weakness) that may affect all limbs (tetraparesis/plegia), the pelvic limbs (para-) only, the ipsilateral thoracic and pelvic limbs (hemi-), or one limb (mono-). • Paresis/paralysis can also be caused by neuromuscular disorders.

PATHOPHYSIOLOGY

• Myelopathy—can affect gray or white matter of the spinal cord or, most often, both. • Lesions of the ascending white matter tracts—affect sensory modalities such as touch, pressure, proprioception, pain, and temperature sensation below the level of the lesion. • Lesions of the descending white matter tracts—affect the motor pathways producing signs of upper motor neuron disorder. The upper motor neuron cell bodies are located in the brain; they control voluntary activity and have inhibitory function on the lower motor neurons. Signs of upper motor neuron disease include paresis/paralysis, normal to increased muscle tone (hypertonia), and normal to exaggerated spinal reflexes (hyperreflexia) below the level of the lesion. • Lesions in the gray matter of the spinal cord—affect sensory and motor functions of the region innervated by the nerves whose cell bodies are located in the gray matter. The motor nerves in the gray matter of the spinal cord are also called lower motor neurons. Signs of lower motor neuron disease include paresis/paralysis, decreased or absent muscle tone (hypo- or atonia), atrophy of the muscles innervated by that segment, and reduced or absent spinal reflexes (hypo- or areflexia).

GENETICS

• Lysosomal storage diseases—gangliosidosis GM1/GM2, sphingomyelinosis (Niemann–Pick disease), mucopolysaccharidosis VI (MPS VI), and glycogenosis type IV cause paresis or paralysis in cats; autosomal recessive pattern of inheritance. • Neuroaxonal dystrophy and spinal muscular atrophy—degenerative diseases of the spinal cord reported as autosomal recessive conditions. • Syringohydromyelia/myelodysplasia may be associated with sacrocaudal (sacrocoggygeal) dysgenesis—autosomal dominant condition in Manx cats.

SIGNALMENT

Breed Predilections

• Gangliosidosis GM1/GM2—Siamese, Burmese, Korat cats, and domestic shorthair (DSH). • Glycogen storage disease type IV—Norwegian forest cats. • Spinal muscular atrophy—Maine coon. • Syringohydromyelia/myelodysplasia—Manx and Manx crosses with sacrocaudal dysgenesis. • Sphyngomyelinosis (Niemann–Pick disease)—Siamese, Balinese, and DSH. • Mucopolysaccharidosis type VI—Siamese and DSH. • Mucopolysaccharidosis type VII—DSH. • Idiopathic complex polysaccharide storage disease—Abyssinians. • Neuroaxonal dystrophy—Siamese and DSH.

SIGNS

• Signs vary with location and severity of lesion. • Cervical lesion (spinal cord segments C1–5)—all limbs or ipsilateral limbs affected with proprioceptive ataxia and tetraparesis/plegia, hemiparesis/plegia; normal to increased reflexes and tone; ± neck pain; ± ipsi-/bilateral Horner's syndrome; ± urinary incontinence with bladder difficult to express; increased urethral sphincter tone and tense bladder. • Cervicothoracic lesion (C6–T2)—all limbs or ipsilateral limbs affected with proprioceptive ataxia and tetraparesis/plegia, hemiparesis/plegia; hypo-/areflexia, hypo-/atonia and muscle atrophy in thoracic limbs with normal to increased reflexes and tone in pelvic limbs; ± neck pain; ± ipsi-/bilateral Horner's syndrome; ipsi-/bilateral decreased/absent cutaneous trunci reflex; ± urinary incontinence with bladder difficult to express; increased urethral sphincter tone and tense bladder. • Thoracolumbar lesion (T3–L3)—normal thoracic limbs; both pelvic limbs or ipsilateral pelvic limb affected with proprioceptive ataxia and paraparesis/plegia; normal to increased reflexes and tone; ± thoracolumbar pain; ± decreased/absent cutaneous trunci reflex below the lesion; ± decreased/absent sensation below lesion; ± Schiff–Sherrington posture; ± urinary incontinence with bladder difficult to express, increased urethral sphincter tone and tense bladder. • Lumbosacral lesion (L4–S3) —normal thoracic limbs; both pelvic limbs or ipsilateral limb affected with proprioceptive ataxia and paraparesis/plegia or monoparesis/plegia; hypo-/areflexia; hypo-/atonia; muscle atrophy; ± regional pain; ± urinary and fecal incontinence, large and flaccid bladder easy to express, decreased urethral sphincter tone; ± decreased or absent tail and anal tone; ± decreased or absent sensation below lesion.

CAUSES

• Degenerative and/or inherited—neuroaxonal or neuronal dystrophy, spinal muscular atrophy, storage diseases (gangliosidosis GM1/GM2, sphingomyelinosis, glycogenosis type IV, idiopathic complex polysaccharide storage disease, and mucopolysaccharidosis type VI) and spinal dural ossification. • Anomalous—syringohydromyelia, myelodysplasia, meningocele or meningomyelocele, and tethered spinal cord often associated with sacrocaudal dysgenesis, spinal arachnoid cyst, spinal intradural epithelial cyst, spinal dermoid cyst/sinus. • Metabolic—hypervitaminosis A, nutritional secondary hyperparathyroidism, cobalamine deficiency-associated myelopathy. • Neoplastic—lymphoma, vertebral column neoplasia (osteosarcoma, fibrosarcoma, plasma cell tumor, and chondrosarcoma), meningiomas, sarcomas, histiocytic tumors, glial tumors (astrocytoma, oligodendroglioma, gliomatosis cerebri), primitive neuroectodermal tumors, peripheral nerve sheath tumors, and metastatic tumors. • Inflammatory or infectious—feline infectious peritonitis (FIP), Borna virus (Europe), bacterial meningomyelitis, fungal meningomyelitis (*Cryptococcus neoformans*, *Coccidioides immitis*, *Histoplasma capsulatum*), *Toxoplasma gondii* meningomyelitis, eosinophilic meningomyelitis, idiopathic poliomyelitis, and feline leukemia virus (FeLV)-associated myelopathy. • Traumatic—vertebral fractures/luxations and penetrating wounds (bite wounds, BB pellets, microchips); intervertebral disc disease. • Vascular—ischemia or infarct of unknown etiology, fibrocartilaginous embolisms, ischemic myelopathy secondary to hyaline arteriopathy, intraosseous vascular malformations, and myelopathy secondary to aortocaval fistula.

RISK FACTORS

• Outdoor cats—at risk for traumatic and infectious myelitis.
• FeLV-positive cats—at risk for lymphoma and FeLV-associated myelopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiate from other disease processes that can cause paresis/paralysis—ischemic neuromyopathy caused by arterial thromboembolism, and peripheral neuromuscular diseases such as diabetic neuropathy, polyradiculoneuritis, hypokalemic myopathy, muscular dystrophy, polymyositis, and myasthenia gravis.

CBC/BIOCHEMISTRY/URINALYSIS

• Often normal. • Various nonspecific abnormalities can be found associated with infectious myelitis and lymphoma.
• Lysosomal storage diseases—abnormal accumulation of products of cell metabolism can be seen within the cytoplasm of peripheral leukocytes.

OTHER LABORATORY TESTS

• Serology—FeLV/FIV, Cryptococcus neoformans, Coccidioides immitis, Histoplasma capsulatum, and Toxoplasma gondii. • Latex agglutination test—

(CONTINUED) MYELOPATHY—PARESIS/PARALYSIS—CATS

Cryptococcus neoformans (serum or CSF). • α-Acid glycoprotein (AGP) can be used as a discriminating marker for FIP when coupled with other high-risk factors. • Urine metabolic screening for lysosomal storage diseases. • Genetic tests for inherited myelopathies—see a frequently updated list of tests available worldwide and genetic testing laboratories in Internet Resources.

IMAGING

• Spinal radiography—may reveal congenital or acquired (MPS VI) vertebral malformations, discospondylitis, vertebral fractures and luxations, bony tumors, and radiographic signs suggestive of intervertebral disc disease. • Myelography—may reveal extradural compression consistent with intervertebral disc disease or tumor, or intradural–extramedullary tumors. • CT—more sensitive than radiography for diagnosis of discospondylitis, vertebral fractures, and bony tumors; may reveal syringomyelia and intramedullary tumors. • MRI—more sensitive than CT for diagnosis of intramedullary tumors, inflammatory/infectious and vascular diseases, and anomalies, such as syringomyelia, myelodysplasia, meningocele or meningomyelocele, tethered spinal cord, spinal arachnoid cyst, spinal intradural epithelial cyst, and spinal dermoid cyst/sinus.

DIAGNOSTIC PROCEDURES

CSF Analysis

• To confirm an inflammatory process affecting meninges and/or spinal cord. • Elevated total nucleated cell count and proteins suggest an inflammatory process affecting meninges and/or spinal cord; should be examined for fungal and bacterial organisms. • Other laboratory tests performed on CSF—latex agglutination test for *Cryptococcus neoformans*; ELISA for *Cryptococcus neoformans* and *Histoplasma capsulatum*; PCR for feline coronavirus and *Toxoplasma gondii*; bacterial and fungal culture.

Electrodiagnostics

Electromyography, nerve conduction velocity, repetitive stimulations—help differentiating paresis/paralysis caused by a myelopathy from peripheral neuromuscular disorders.

TREATMENT

APPROPRIATE HEALTH CARE

• Emergency evaluation and possible surgery—when a traumatic cause of paresis/paralysis is suspected. • Inpatient medical management—for severe neurologic deficits such as paralysis and urinary incontinence.

NURSING CARE

• Non-ambulatory cats should be confined to a soft padded crate or enclosed area, kept dry and clean, and turned every 6 hours if they are not able to assume a sternal position. • If there is urinary incontinence, the bladder should be expressed every 8 hours. • Prevent/treat decubital ulcers and urine scalding. • Treat constipation. • Physical therapy is useful to prevent muscle atrophy and contractures and to keep the joints flexible, especially for postoperative rehabilitation in vertebral trauma or intervertebral disc disease.

CLIENT EDUCATION

If the cat is treated as an outpatient, discuss all aspects of nursing care and possible complications with the client.

SURGICAL CONSIDERATIONS

Surgical management—for vertebral fractures and luxations, intervertebral disc disease, and some neoplasms. The objectives of surgical management should be decompression of the spinal cord, and/or reduction and stabilization of the fracture/luxation.

MEDICATIONS

DRUG(S) OF CHOICE

• Not recommended until a diagnosis has been established. • Spinal trauma—controversial: in experimental studies of acute spinal cord injury (ASCI) in cats, the administration of methylprednisolone sodium succinate (MPSS) within 8 hours from injury (30 mg/kg initial bolus, followed by MPSS CRI of 5.4 mg/kg/h for 24 hours or 15 mg/kg q6h for 2 doses) led to improved neurologic function; however, these studies have not been replicated in a clinical setting. Please note that the use of high-dose glucocorticoids in trauma patients has been associated with hyperglycemia, pneumonia, urinary tract infection, gastrointestinal ulceration, and increased mortality. Dexamethasone was not found to improve neurologic outcome in experimental cat models of ASCI.

CONTRAINDICATIONS

Glucocorticoids—contraindicated when an infectious disease is suspected; may also alter CSF, MRI, or CT results, precluding reaching a diagnosis.

FOLLOW-UP

POSSIBLE COMPLICATIONS

• Urinary infection. • Urine scalding. • Constipation or fecal incontinence. • Muscle atrophy and contractures. • Decubital ulcers.

MISCELLANEOUS

AGE-RELATED FACTORS

• Cats <2 years—myelopathies often caused by anomalous or inherited, inflammatory, or infectious, metabolic, and traumatic diseases. FIP is the most important cause of myelopathy in this age group. • Cats 2–8 years—lymphoma (LSA), FIP, and trauma are important causes of myelopathy. • Cats >8 years—vascular and neoplastic diseases more common, especially LSA and vertebral tumors.

ZOONOTIC POTENTIAL

Toxoplasma gondii infections represent a zoonotic potential.

SEE ALSO

Schiff–Sherrington Phenomenon.

ABBREVIATIONS

• AGP = α-Acid glycoprotein.
• DSH = domestic shorthair.
• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.
• LSA = lymphoma.
• MPS = mucopolysaccharidosis.

M

MYELOPROLIFERATIVE DISORDERS

BASICS

OVERVIEW

- Unregulated neoplastic proliferation of nonlymphoid cells originating in the bone marrow (granulocytic, monocytic, erythrocytic, and megakaryocytic cells) resulting in accumulations of differentiated cells.
- Includes polycythemia vera, chronic myelogenous leukemia, essential thrombocythemia, and possibly primary myelofibrosis.
- Believed to represent a spectrum of disorders in which the stem cell involved is a hematopoietic precursor capable of differentiating into all blood cell types except lymphocytes.

SIGNALMENT

- Cats and dogs—more common in cats.
- May be more common in large-breed dogs than small-breed dogs.

SIGNS

- Pale mucous membranes.
- Petechiation.
- Lethargy.
- Inappetance.
- Weight loss.
- Hepatosplenomegaly.
- Peripheral lymphadenomegaly—occasionally.
- Neurologic signs—disorientation, ataxia, seizure.

CAUSES & RISK FACTORS

- Cats—most commonly associated with feline leukemia virus (FeLV) infection; when recovering from panleukopenia or hemobartonellosis, may be a relatively higher risk of developing a mutant cell line induced by FeLV.
- Dogs—has been experimentally induced with chronic low-dose radiation exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute lymphocytic leukemia—usually differentiated by special staining techniques (immunohistochemistry or immunocytochemistry for lymphoid markers) or PCR for antigen receptor rearrangement (PARR).
- Leukemoid response secondary to inflammation.
- Other causes of eosinophilia—parasitism; allergic disease; eosinophilic gastroenteritis; mast cell neoplasia; differentiate from eosinophilic leukemia.
- Relative and secondary absolute polycythemia.
- Reactive thrombocytosis—secondary to inflammation, hemolytic or iron-deficiency anemia, splenectomy, rebound from immune-mediated thrombocytopenia, and drug-induced (e.g., vincristine).

CBC/BIOCHEMISTRY/URINALYSIS

- Severe, nonregenerative anemia.
- Severe elevated hematocrit in cases of primary polycythemia vera.
- Circulating nucleated red blood cells.
- Megaloblastic erythrocytes.
- Leukocytosis or leukopenia.
- Thrombocytopenia with abnormal platelet morphology.
- Thrombocytosis in cases of essential thrombocythemia.
- Circulation of immature myeloid cells.

OTHER LABORATORY TESTS

- Examination of bone marrow aspirate or core biopsy—reveals hypercellular bone marrow with abnormal morphology in all cell lines; neoplastic proliferation or absence of one cell line.
- Immunohistochemical or other special stains—may be necessary to determine cell lineage.

IMAGING

Abdominal radiography and ultrasonography—hepatomegaly and splenomegaly common.

DIAGNOSTIC PROCEDURES

Examination of bone marrow aspirates or core biopsy.

TREATMENT

- Outpatient or inpatient.
- Supportive care—blood transfusions and fluid administration to correct dehydration.
- Therapeutic phlebotomies.
- Radiophosphorus (^{32}P) has been effective in cases of polycythemia vera and essential thrombocythemia but there are limited facilities that can offer this therapy.
- Seek consultation from a veterinary oncologist regarding treatment.

MEDICATIONS

DRUG(S) OF CHOICE

- Little information available in the literature regarding treatment.
- Cytosine arabinoside—may be used; 100 mg/m^2 SC divided q12h 4 days per week, or as a constant rate infusion over 6–8 hours at a dose of 400 mg/m^2.
- Hydroxyurea 30–45 mg/kg q24h for 7–10 days; then 30–45 mg/kg q48h or 15 mg/kg q24h; initially, titrate dosage to patient response.
- Antibiotics—may be indicated to combat secondary infection.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Chemotherapy can be toxic; seek advice before treatment if unfamiliar with cytotoxic drugs.

FOLLOW-UP

- Complete blood count and examination of bone marrow aspirate—determine response to treatment and progression of disease.
- Prognosis—guarded.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Chemotherapy drugs are contraindicated in pregnant animals.
- It is not recommended to breed animals with neoplasia.

ABBREVIATIONS

- FeLV = feline leukemia virus.
- PARR = polymerase chain reaction for antigen receptor rearrangement.

MYOCARDIAL INFARCTION

BASICS

OVERVIEW

• Rapid development of myocardial necrosis resulting from sustained, complete reduction of blood flow to a portion of the myocardium, caused by thrombus formation.
• Uncommon as a naturally occurring disease in dogs. • Microscopic intramural myocardial infarctions and focal areas of myocardial fibrosis are common in dogs with acquired cardiovascular disease. • Consistent electrocardiogram (ECG) characteristics of spontaneous myocardial infarction are not well characterized in dogs and cats.

SIGNALMENT

Rare in dog and cat

SIGNS

Historical Findings

• Lethargy. • Anorexia. • Weakness.
• Dyspnea. • Collapse. • Vomiting.
• Obesity. • Unexpected death.

Physical Examination Findings

• Lameness. • Tachycardia. • Heart murmur.
• Cardiac rhythm disturbances. • Low-grade fever.

CAUSES & RISK FACTORS

Dogs

• Atherosclerosis and coronary artery disease.
• Nephrotic syndrome. • Vasculitis.
• Hypothyroidism. • Bacterial endocarditis.
• Neoplasia. • Septicemia. • Intramural coronary arteriosclerosis in old dogs.
• Subvalvular aortic stenosis.

Cats

• Cardiomyopathy. • Thromboembolism.

DIAGNOSIS

Generally presumptive, based on acute onset of signs in a patient with predisposing factors, consistent ECG changes (ST segment changes) and elevated circulating biomarkers (cardiac troponin I [cTnI]).

DIFFERENTIAL DIAGNOSIS

Other Causes of ST Segment Changes

• Normal variation. • Myocardial ischemia/hypoxia. • Hyperkalemia or hypokalemia.
• Digitalis toxicity. • Trauma to the heart.
• Pericarditis. • Artifact—wandering baseline.

Other Causes of Weakness and Collapse

• Trauma. • Neurologic disease.
• Thromboembolism. • Pericardial effusion.
• Arrhythmia.

CBC/BIOCHEMISTRY/URINALYSIS

• Mild leukocytosis. • High liver enzymes.
• Hyperlipidemia—if animal is hypothyroid.
• High amylase. • High creatine kinase and cardiac isoenzymes. • High cTnI.

OTHER LABORATORY TESTS

Low triiodothyronine ($T_{3)}$ and thyroxine (T_4).

IMAGING

Echocardiography—2D and M-mode echocardiography useful in evaluating wall motion abnormalities and overall left ventricular function.

DIAGNOSTIC PROCEDURES

Electrocardiographic Findings

• Sudden deviation of the ST segment (Figure 1). • Tall peaked T waves—first few hours. • Sudden development of Q waves or a change in direction of the T wave. • Axis shift of the frontal plane. • Low-voltage QRS complexes. • Sudden development of bundle branch block or heart block. • Sudden onset of ventricular arrhythmias because of myocardial ischemia. • Sloppy "R" wave descent may be associated with intramural myocardial infarction.

TREATMENT

• Treat the underlying disorder; likewise the symptomatic therapy (e.g., congestive heart failure [CHF]). • Must identify and immediately treat life-threatening arrhythmias.

MEDICATIONS

DRUG(S) OF CHOICE

• IV thrombolytic agents—(e.g., streptokinase); cost prohibitive and lack of experience with myocardial infarction in veterinary medicine with dosage and use.
• Lidocaine for ventricular arrhythmias.
• Beta-blockers—use cautiously with dilated cardiomyopathy because of possible development of low-output CHF.
• Antithrombotic agents (e.g., dalteparin; low molecular weight heparin, heparin and aspirin).

FOLLOW-UP

• Determined by clinical status and diagnosis of underlying disorder. • Monitor anticoagulated patient; CBC and bleeding profiles, including fibrinogen.

MISCELLANEOUS

ABBREVIATIONS

• CHF = congestive heart failure. • cTnI = cardiac troponin I. • ECG = electrocardiogram.
• T_3 = triiodothyronine. • T_4 = thyroxine.

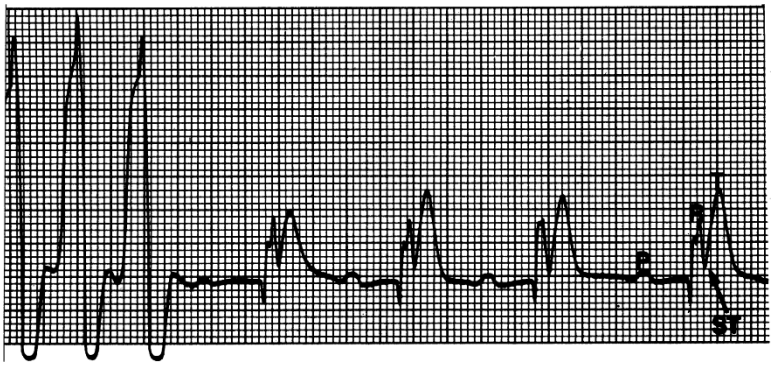

Figure 1.

Transmural infarction of the left ventricle in a dog with arteriosclerosis and hypothyroidism. The first three rapid successive complexes represent ventricular tachycardia.

MYOCARDIAL TUMORS

BASICS

OVERVIEW
- Primary and metastatic myocardial tumors are rare tumors in dogs and cats; incidence 0.19% in dogs and 0.03% in cats.
- Reported primary tumors include hemangiosarcoma, ectopic thyroid carcinoma, lymphoma, with less frequently documented rhabdomyoma, rhabdomyosarcoma, thymoma, mesothelioma, chondrosarcoma, osteosarcoma, fibrosarcoma, myxoma, myxosarcoma, lipoma, peripheral nerve sheath tumor, and granular cell tumor.

SIGNALMENT
- Dogs and cats—but less common in cats.
- In dogs—any age but more common between 7 and 15 years.
- Possible increased incidence in neutered animals.
- Increased incidence in Saluki, French bulldog, Irish water spaniel, flat-coated retriever, golden retriever, boxer, Afghan hound, English Setter, Scottish terrier, Boston terrier, bulldog, German shepherd dog.

SIGNS
- Sudden collapse.
- Abdominal distention.
- Exercise intolerance.
- Dyspnea.
- Anorexia.
- Vomiting.
- Diarrhea.
- Acute death.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Idiopathic pericardial effusion.
- Pericarditis.
- Cardiomyopathy.
- Heart failure.
- Valvular disease.
- Heart base tumors.

CBC/BIOCHEMISTRY/URINALYSIS
Anemia in some patients.

OTHER LABORATORY TESTS
Serum/plasma cardiac troponin I levels are increased in patients with cardiac hemangiosarcoma and might have utility for the detection of other myocardial neoplasms.

IMAGING
- Thoracic radiography—may reveal a globoid heart suggestive of pericardial effusion, masses in the area of the atria, or metastatic lesions in the lungs.
- Echocardiography—helpful in finding primary masses; positive predictive value of 92%, negative predictive values 64%.
- Advanced imaging such as CT, positron emission tomography (PET) scan, and MRI may be helpful in defining mass lesions.

DIAGNOSTIC PROCEDURES
- Pericardiocentesis and fluid evaluation—helpful in diagnosis of lymphoma.
- Cytology of pericardial effusion limited in usefulness in differentiating neoplastic from non-neoplastic effusions.
- ECG—may be normal or display a variety of arrhythmias; may see electrical alternans and small complexes with pericardial effusion.
- Surgical biopsy of mass—if possible.

TREATMENT
- Surgical removal of mass—if possible.
- Pericardectomy—may offer relief of pericardial effusion.
- Address concern for sudden death with owner.

MEDICATIONS

DRUG(S) OF CHOICE
- Management of arrhythmias—lidocaine (dogs) 2–4 mg/kg IV (to a maximum 8 mg/kg over 10-minute period), CRI—25–75 µg/kg/minute IV, mexiletine (dogs) 5–8 mg/kg PO q8–12h, sotalol 1–2 mg/kg PO q12h.
- Chemotherapy dependent on tumor type (see Lymphoma—Cats, Lymphoma—Dogs, and Hemangiosarcoma, Heart).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Chemotherapy can cause gastrointestinal, bone marrow, cardiac, and other toxicities—seek advice if unfamiliar with cytotoxic drugs.

FOLLOW-UP
- Serial echocardiograms—to monitor tumor response to chemotherapy.
- Thoracic radiography and abdominal ultrasonography—to monitor for metastatic disease progression.
- ECG—to monitor response to antiarrhythmogenic medications.
- Blood tests—especially CBC to monitor for bone marrow suppression secondary to chemotherapy.
- Prognosis—guarded to poor.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
- It is not recommended to breed animals with cancer.
- Chemotherapy is teratogenic—do not give to pregnant animals.

SEE ALSO
- Chemodectoma.
- Hemangiosarcoma, Heart.
- Lymphoma—Cats.
- Lymphoma—Dogs.

ABBREVIATIONS
- PET = positron emission tomography.

MYOCARDITIS

BASICS

DEFINITION
• Inflammation of the myocardium, definitive identification of which requires histologic examination. • In humans, the widely accepted Dallas criteria specify that necrosis and/or degeneration of myocytes adjacent to inflammatory infiltrates is a requisite for diagnosis. • Causes are diverse and include infective (viral, bacterial, protozoal, mycotic) pathogens and noninfective (toxic, possibly immune) disease agents. • Traumatic myocarditis is a term applied to the syndrome of arrhythmias that sometimes complicates blunt trauma. The term is a misnomer because myocardial lesions (if present) are more likely to take the form of necrosis than inflammation.

PATHOPHYSIOLOGY
• Numerous mechanisms, determined partly by the nature of the causative agent, are implicated. • Microbial agents and toxins can result in direct cellular damage causing cell death, activation of the immune system, and inflammation. • Though incompletely described in veterinary patients, chronic myocarditis, immune myocarditis and autoreactive myocarditis—the latter occurring in the absence of microbial agents—as well as dilated cardiomyopathy (DCM) are potential sequelae of acute myocarditis. • The cellular character of inflammation is partly determined by the nature of the pathologic insult; protozoal and mycotic agents result in pyogranulomatous infiltrates, while viral myocarditis is generally lymphocytic.
• Myocardial involvement may be focal or diffuse. • Canine parvoviral infection can result in myocarditis in pups, and has been implicated as a cause of DCM. The virus has tropism for dividing cells, and adult myocytes do not replicate. Parvovirus myocarditis is most likely to occur in unvaccinated pups from immunologically naïve dams.
• Protozoal myocarditis resulting from *Trypanosoma cruzi* infection causes Chagas disease. Acute phase illness is characterized primarily by electrocardiogram (ECG) abnormalities. Chronic infection can result in myocardial dysfunction and development of heart failure. • It has been hypothesized that feline endomyocarditis might be a precursor of restrictive cardiomyopathy; recent findings implicate infection by *Bartonella* spp.
• Bacterial myocarditis can be observed in patients with overwhelming sepsis.
• Bacterial, protozoal, and mycotic myocarditis may reflect immunosuppression.
• An apparently rare, as yet idiopathic, atrial myocarditis might be important in the pathogenesis of persistent canine atrial standstill. • The pathogenetic importance of myocardial inflammation in canine arrhythmogenic right ventricular cardiomyopathy is unresolved; however, myocarditis is observed in a substantial proportion of cases. • The pathogenesis of traumatic myocarditis is incompletely defined; direct trauma resulting in necrosis is likely responsible in some cases, but extracardiac factors including electrolyte derangements, hypoxia, acid–base disturbances, and altered function of the autonomic nervous system might contribute.

SYSTEMS AFFECTED
• Systemic involvement depends on the causative agent. • Cardiovascular—myocardial dysfunction and/or arrhythmias.
• Respiratory—if pulmonary edema develops.

INCIDENCE/PREVALENCE
• Histologically confirmed myocarditis is rarely identified in veterinary patients, therefore epidemiology of myocarditis is incompletely described. • Viral myocarditis is seemingly rare. • Chagas disease is uncommon and occurs primarily in the southern United States. • Fungal myocarditis—primarily seen in association with systemic fungal infection—is rare and occurs regionally, where mycoses are endemic.
• Spirochetal myocarditis and atrioventricular (AV) block resulting from *Borrelia burgdorferi* infection has been reported, but seemingly is rare. • Infection by *Bartonella* spp. has been associated with canine and feline myocarditis.

GEOGRAPHIC DISTRIBUTION
Myocarditis can result from infectious agents that have distinct geographic distributions.

SIGNALMENT
Species
Dog and cat.

Mean Age and Range
Largely unknown.

SIGNS
General Comments
• Related to the extent and duration of myocardial involvement. • Signs relating to arrhythmias or heart failure are most common.
• Onset of cardiac dysfunction in association with systemic illness should prompt consideration of myocarditis and, because myocardial disease in veterinary patients is often familial, development of cardiac dysfunction in patients with atypical signalment suggests the possibility of myocarditis.

Historical Findings
• Coughing, exercise intolerance, dyspnea—associated with congestive heart failure (CHF).
• Syncope and weakness—associated with arrhythmias. • Concurrent manifestations of systemic disease reflective of the etiologic agent. • Road traffic or other accidents often precede the development of traumatic myocarditis.

Physical Examination Findings
• Gallop sounds or murmurs may be heard.
• Arrhythmias—may be auscultated.
• Fever—potentially observed in patients with infective myocarditis. • Evidence of injury in those with traumatic myocarditis.

CAUSES
• Virus (e.g., parvovirus, distemper virus, herpesvirus, West Nile virus). • Protozoa (e.g., *T. cruzi*, *Toxoplasma gondii*, *Neospora caninum*, *Hepatozoon canis*, *Babesia* spp., and *Leishmania* spp.). • Bacteria (e.g., *Bartonella vinsonii* subsp. *berkhoffii*). • Fungi (e.g., *Cryptococcus neoformans, Coccidioides immitis, Blastomyces dermatitidis,* and *Aspergillus terreus*). • Algae (e.g., *Prototheca* spp.).
• Blunt trauma can result in the syndrome of traumatic myocarditis.

RISK FACTORS
• Exposure to infectious agents.
• Immunosuppression. • Debilitating diseases. • Trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Consider the possibility that preexisting heart disease such as congenital defects, cardiomyopathy, and acquired valvular disease are responsible for clinical findings. • History of a heart murmur or the presence of arrhythmias before onset of systemic illness helps differentiate from other diseases.
• Extracardiac organ involvement and identification of infectious agents may aid in the diagnosis. • History of road traffic accident generally makes the diagnosis of traumatic myocarditis obvious.

CBC/BIOCHEMISTRY/URINALYSIS
Abnormalities—vary, depending on organ involvement.

OTHER LABORATORY TESTS
• Serologic tests can be used to detect exposure to infectious agents. • Cytologic examination of pericardial, pleural, and peritoneal effusions to identify the infectious organism. • Blood culture to identify bacteremia. • Troponin—concentrations might be high and reflect myocyte necrosis.

IMAGING
Thoracic Radiography
• Cardiac silhouette may be enlarged if myocarditis has resulted in cardiac dysfunction; potential consequences of cardiac dysfunction include: pulmonary edema and/or pleural effusion. • Pulmonary granuloma may be found in animals with granulomatous myocardial infection.
• Evidence of trauma potentially including pulmonary contusions or pneumothorax.

MYOCARDITIS (CONTINUED)

Echocardiography
• Reflects the extent of myocardial damage; may be normal if lesions are small or primarily affect the conduction system. • Evaluation of systolic myocardial function might reveal minor segmental abnormalities, or global dysfunction associated with chamber enlargement. • In humans and experimental models, an increase in wall thickness has been associated with inflammatory infiltrates/edema; this observation might be relevant to the syndrome of "transient wall thickening" observed in cats. • Pericardial effusion in patients with pancarditis. • In exceptional cases granulomas result in echocardiographically evident masses.

DIAGNOSTIC PROCEDURES

ECG
• Arrhythmias of all types—supraventricular tachyarrhythmias, ventricular tachyarrhythmias, and bradyarrhythmias, perhaps particularly AV block—can be observed in association with inflammatory myocardial disease. • Arrhythmias associated with trauma—ventricular tachyarrhythmias occur in most affected patients; supraventricular arrhythmias and bradyarrhythmias are rare. Ventricular rhythms that complicate blunt trauma often have relatively slow rates detected only during pauses in the sinus rhythm; they are most appropriately referred to as accelerated idioventricular rhythms (AIVRs). The QRS complexes are wide and bizarre; the rate is >100 bpm but <160 bpm. Usually, these rhythms are electrically and hemodynamically benign. However, dangerous ventricular tachycardias can complicate blunt trauma and evolve from seemingly benign AIVRs, compromising perfusion and placing the patient at risk for sudden death.

Endomyocardial Biopsy
A minimally invasive technique that is required for definitive ante-mortem diagnosis but rarely performed in veterinary patients.

Pericardiocentesis
• Alleviates tamponade caused by pericardial effusion. • Submit fluid for cytologic examination and, possibly, bacterial culture.

Holter Monitoring
• To define the burden of arrhythmia in terms of frequency and character over a 24-48 hour period. • To monitor antiarrhythmic therapy.

PATHOLOGIC FINDINGS
• Dilated cardiac chambers with patchy areas of hyperemia, necrosis, or fibrosis. • Granulomas seen grossly in some patients. • Histologic examination of the myocardium or pericardium may reveal inflammatory cells (e.g., lymphocytes, plasma cells, and macrophages), patchy fibrosis, or the infectious agents themselves.

TREATMENT

APPROPRIATE HEALTH CARE
• Hospitalize patients with decompensated heart failure for initial medical management. • Hospitalize patients with hemodynamically consequential ventricular arrhythmias for initial, parenteral antiarrhythmic therapy. • Hospitalize patients with severe systemic manifestations for appropriate medical therapy.

ACTIVITY
Restricted

DIET
Sodium restriction if CHF.

CLIENT EDUCATION
• Cardiac manifestations may persist even after resolution of systemic illness. • Certain arrhythmias (e.g., ventricular tachycardia, third-degree AV block) may predispose to sudden death. • Antemortem diagnosis may be difficult. • Some infectious agents may pose a public health risk.

SURGICAL CONSIDERATIONS
Complete AV block may require pacemaker implantation.

MEDICATIONS

DRUG(S) OF CHOICE
• If a specific pathogenetic agent is identified, appropriate, etiologically targeted therapy. • Tailor antiarrhythmic therapy based on ECG findings.

CONTRAINDICATIONS
N/A.

PRECAUTIONS
• All antiarrhythmic drugs potentially have proarrhythmic properties and their effects should be closely monitored. • Systemic organ involvement (e.g., renal involvement) may necessitate modifying drug dosages. • Some agents that result in canine or feline myocarditis can also affect humans, so potentially there are public health considerations.

FOLLOW-UP

PATIENT MONITORING
• Antiarrhythmic therapy—frequent auscultation and ECG. • Serologic titers when appropriate. • Auscultation and follow-up radiographs—treatment of heart failure. • Hemograms and serum biochemical analysis—systemic effects.

PREVENTION/AVOIDANCE
• Avoid breeding animals that have not been immunized. • Avoid endemic areas if possible.

EXPECTED COURSE AND PROGNOSIS
• Depend on the extent and severity of myocardial involvement. • Many systemic fungal and protozoal diseases do not respond well to medical management. • Patients with extensive myocardial inflammation, degeneration, and signs of heart failure have a very poor prognosis. • Good prognosis if the underlying cause can be treated successfully.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Often accompanies systemic illness.

AGE-RELATED FACTORS
Viral myocarditis—most often seen in animals <1 year old.

ZOONOTIC POTENTIAL
• Varies with infectious agent involved. • May be high with protozoal and mycotic infections.

PREGNANCY/FERTILITY/BREEDING
Some viral diseases (e.g., canine herpesvirus and parvovirus) have been passed to the fetus during pregnancy.

SEE ALSO
• Aspergillosis, Disseminated Invasive. • Babesiosis. • Bartonellosis. • Blastomycosis. • Canine Distemper. • Canine Parvovirus. • Chagas Disease (American Trypanosomiasis). • Coccidioidomycosis. • Cryptococcosis. • Hepatozoonosis. • Idioventricular Rhythm. • Leishmaniosis. • Neosporosis. • Prototheocosis. • Toxoplasmosis. • Ventricular Premature Complexes. • Ventricular Tachycardia.

ABBREVIATIONS
• AIVR = accelerated idioventricular rhythm. • AV = atrioventricular. • CHF = congestive heart failure. • DCM = dilated cardiomyopathy. • ECG = electrocardiogram

MYOCLONUS

BASICS

OVERVIEW

• Involuntary, rhythmic, or irregular muscle jerks. Can involve only a few adjacent muscles (focal), many or most muscles of the body (generalized), or many muscles in different jerks (multifocal) synchronously or asynchronously. • The myoclonic movements are spontaneous or activated by sensory stimulation (reflex myoclonus). • May persist during sleep. • CNS dysfunction involving segmental lower motor neurons and interneurons of the spinal cord or the brainstem. • Canine distemper virus infection—most frequent cause of myoclonus in dogs; thought to be secondary to some pacemaker activity in neurons damaged by the virus. May be caused by other encephalitides and degenerative processes affecting motor neurons.

SIGNALMENT

Acquired

• Dog and rarely cat. • No breed, sex, or age predispositions.

Congenital

• Familial reflex myoclonus—Labrador retriever and Dalmatian; develops in the first 3 weeks of life. • Spongy degeneration of either gray and/or white matter—dogs: myoclonus of the paravertebral muscles in neonate silky terrier; Samoyed at 2 weeks; Saluki at 3 months; Labrador retriever at 4–6 months. Cats—Egyptian mau at 7 weeks. Rare syndromes.

SIGNS

Historical Findings

• Canine distemper—after a bout of gastrointestinal signs, cough, and/or ocular or nasal purulent discharge; persists at rest and even during sleep or light anesthesia; consistent frequency in a given patient; distemper diagnosis may precede the myoclonus by months to years; occurs more frequently in chronic phase of distemper. • Familial reflex myoclonus—observed when the patient starts walking; intermittent muscle contractions induced by auditory or tactile stimulus and by exercise; involves all limbs, neck, and head (e.g., the facial and masticatory muscles); patient unable to rise without assistance. • With spongy degeneration—variety of signs observed such as tremor, spasticity, opisthotonos, and myoclonus. • Chlorambucil-induced myoclonus reported in a cat with lymphoma.

Physical Examination Findings

• The patient may be otherwise healthy. • Masticatory and appendicular muscles—most frequent affected muscles in distemper virus-induced myoclonus; may be paresis of the affected limb. • May see other signs suggesting distemper (e.g., hard pads, ocular and nasal purulent discharge, and chorioretinitis). • Neurologic deficits suggest multifocal lesions in some patients.

CAUSES & RISK FACTORS

Congenital

• Familial in Labrador retrievers. • Spongy degeneration of unknown cause but likely inherited.

Acquired

• Canine distemper virus—the only CNS disease repeatedly associated with myoclonus in dogs; unvaccinated dogs at risk. • Encephalitis of any cause—dogs and cats. • Degenerative disease—especially spongy degeneration. • Described in a dog with lead poisoning. • Total IV anesthesia with propofol. • Intrathecal administration of morphine. • Treatment with chlorambucil in cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• The quickness of the jerks and the absence of voluntary influence help differentiating myoclonus from other movement disorders. • Congenital myoclonus—in neonates or during the first months of life in otherwise healthy dogs. Excitement, voluntary activity, and tactile/auditory stimuli often increase the myoclonus. • Canine distemper virus—unvaccinated dog; observed before, during, or after the acute CNS disease; more frequently observed later when the animal is otherwise healthy. Myoclonus involves one limb, more than one limb, the facial or the masticatory muscles. • Lafora disease (progressive myoclonic epilepsy)—neurodegenerative disease that can cause myoclonic jerks. Differentiated on presence of other seizure types (generalized tonic–clonic seizures) and altered mentation. • Myoclonic epilepsy—jerks usually generalized, proximal more than distal, and flexor more than extensor; exacerbated by sensory stimulus (light, noise) and voluntary movements. Other types of seizures may be present concomitantly.

CBC/BIOCHEMISTRY/URINALYSIS

• Congenital or post canine distemper virus infection—normal. • Other acquired forms—may suggest a specific cause if the patient has infectious encephalomyelitis; otherwise, normal.

IMAGING

MRI—may help determine diagnosis in acute acquired disease.

DIAGNOSTIC PROCEDURES

Acute onset—CSF analysis, serologic testing, imaging to determine the cause if other physical or neurologic signs present. Electroencephalography and electromyography—may help differentiate myoclonic epilepsy and peripheral nervous system disease from myoclonus.

TREATMENT

• Active encephalomyelitis—inpatient; establish a diagnosis and initiate treatment. • Exercise—as tolerated. • Diet—ensure proper nutrition with active CNS disease; modify, if necessary, with vomiting or diarrhea. • Familial reflex myoclonus—clinical signs in Labrador retriever and Dalmatian are severe and usually not compatible with quality of life.

MEDICATIONS

DRUG(S) OF CHOICE

• With chronic, inactive canine distemper—treatment often unnecessary; alleviation may be obtained with procainamide 125–250 mg/dog PO q6–12h. • Gabapentin 10–20 mg/kg q8h reported beneficial in tremor syndrome. • Clorazepate 0.6–2 mg/kg PO q8h—familial reflex myoclonus; may see improvement. • Active encephalomyelitis—treat accordingly.

FOLLOW-UP

• Monitor CNS disease. • Myoclonus usually persists indefinitely; spontaneous remission may occur. • Active distemper virus infection—poor-to-grave prognosis. • Chronic distemper—myoclonus persists but patient otherwise healthy.

MYOPATHY—HEREDITARY X-LINKED MUSCULAR DYSTROPHY

BASICS

OVERVIEW

• Muscular dystrophy is an inherited, progressive and degenerative, generalized myopathy. Most muscular dystrophies are due to mutations in genes that code for muscle membrane associated proteins in the dystrophin–glycoprotein (DAG) complex. • Most common form in dogs occurs as a result of a deficiency of the protein dystrophin. • Muscular dystrophy due to dystrophin deficiency has an X-linked mode of inheritance and affected animals are predominantly male. • Dystrophin deficiency—identified first in golden retrievers. Subsequently, cases have been reported in many other dog breeds. Sporadic cases in other breeds are likely. • The dystrophin gene is large and new mutations are likely to occur. • Hypertrophic muscular dystrophy associated with dystrophin deficiency also occurs in domestic shorthair cats. • Deficiency of other muscle-associated proteins, e.g., alpha2 laminin (merosin) and sarcoglycan, has been identified more recently in dogs and cats and is not necessarily X-linked (females affected). • A myopathy associated with loss of alpha-dystroglycan with an autosomal recessive mode of inheritance occurs in young Devon Rex and Sphynx cats. Alpha-dystroglycan expression, which is associated with *COLQ* anchorage at the motor end-plate, has been shown to be deficient in affected cats, resulting in a congenital myasthenic syndrome. • Unclassified muscular dystrophies have also been reported in other dogs (males and females).

SIGNALMENT

• Seen primarily in neonate and young dogs (<1 year). • Described in cats. • Muscular dystrophy due to dystrophin deficiency primarily affects males. • Several dog breeds known to be affected. Best described in golden retrievers. • Females—usually carriers of dystrophin gene defect, but dystrophin-deficient females may exhibit muscle weakness, tremors, limb deformities, and exercise intolerance. • Muscular dystrophy due to other muscle protein or unclassified defects may be seen in young male or female dogs and cats of any breed.

SIGNS

Dogs

• Golden retrievers—exercise intolerance; stilted gait; bunny-hopping pelvic limb gait; plantigrade stance; partial trismus; muscle atrophy (especially the truncal and temporalis muscles); hypertrophy of some muscles (especially the tongue); kyphosis; lordosis; drooling; dysphagia; aspiration pneumonia (due to pharyngeal and/or esophageal involvement). • Other breeds—similar; include vomiting and megaesophagus. • Abnormalities vary in severity, onset, and progression; may be seen as early as 6 weeks; tend to stabilize by 6 months. • Stunting and ineffective suckling—may be evident in younger pups. • Cardiac failure—may occur owing to cardiomyopathy. • Severe muscle contractures may develop. • Spinal reflexes—normal initially; may become hypoactive.

Cats

• Dystrophin deficient—muscle hypertrophy; stiff gait; cervical rigidity; exercise intolerance; vomiting; may see calcified nodules on the tongue. • Usually young animals but not apparent in one cat until 21 months of age. • Other hereditary myopathies in cats may cause muscle atrophy; weakness; ventroflexion of the head and neck; dorsal protrusion of the scapulae with triceps brachii and dorsal cervical muscles most severely affected.

CAUSES & RISK FACTORS

• Dystrophin deficiency—inherited defect of the X chromosome. • Other muscular dystrophies may not be X-linked. • Devon Rex/Sphynx myopathy—autosomal recessive.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other inherited myopathies such as centronuclear X-linked myotubular myopathies, infectious (especially protozoal), immune-mediated, or metabolic myopathies. Distinguished by muscle histology and demonstration of dystrophin deficiency or other muscle membrane protein associated deficiency.

CBC/BIOCHEMISTRY/URINALYSIS

• Dystrophin deficiency—normal except for marked elevation in serum creatine kinase (may be >10,000 U/L; further increased after exercise). Aspartate aminotransferase also likely to be elevated. • Other muscular dystrophies—creatine kinase may be normal.

OTHER LABORATORY TESTS

• Muscle biopsy—dystrophin deficiency demonstrated by immunohistochemical evaluation of fresh frozen muscle; diagnostic. • Immunohistochemistry and immunoblotting analysis of muscle biopsy specimens can also assess abnormalities of other muscle proteins including dystrophin-associated proteins, laminin, sarcoglycan. • DNA tests available for specific genetic abnormalities in some breeds. • Serologic testing—may be warranted to rule out infectious and immune-mediated causes.

DIAGNOSTIC PROCEDURES

Electromyography—shows complex repetitive discharges.

PATHOLOGIC FINDINGS

Histologic examination of muscle—muscle fiber necrosis and regeneration; myofiber mineralization (may be dramatic); myofiber hypertrophy (may be variation in myofiber size); fibrosis.

TREATMENT

None proven effective.

MEDICATIONS

DRUG(S) OF CHOICE

Glucocorticosteriods—may provide some improvement; reason unknown. However, myofiber calcification increases, which may be deleterious.

FOLLOW-UP

PATIENT MONITORING

Monitor periodically for aspiration pneumonia or cardiomyopathy.

PREVENTION/AVOIDANCE

• Discourage breeding of affected animals. • Do not repeat dam–sire matings that result in affected offspring. • Consider DNA testing of breeding animals where tests are available.

EXPECTED COURSE AND PROGNOSIS

• Overall prognosis—guarded to poor as no effective palliative treatment. • Golden retrievers—signs tend to stabilize at 6 months. • Other dog breeds and cats—progression variable.

MYOPATHY—MASTICATORY AND EXTRAOCULAR MYOSITIS

BASICS

DEFINITION
• Masticatory—focal inflammatory myopathy affecting the muscles of mastication (temporalis, masseter, and pterygoid muscles) and sparing the limb muscles.
• Extraocular—selectively affects the extraocular muscles, sparing limb and masticatory muscles.

PATHOPHYSIOLOGY
• Masticatory—suspected immune-mediated cause owing to autoantibodies against type 2M fibers and a positive clinical response to immunosuppressive doses of corticosteroids.
• Extraocular—suspected immune-mediated cause owing to positive clinical response to corticosteroids.

SYSTEMS AFFECTED
Neuromuscular—muscles of mastication; extraocular muscles.

GENETICS
• Unknown.
• As with autoimmune diseases in general, the appropriate genetic background must exist.
• Masticatory—cavalier King Charles spaniels have a familial form and may be affected at less than 6 months of age.
• Extraocular—golden retrievers may have a genetic predisposition.

INCIDENCE/PREVALENCE
• Unknown.
• Masticatory—relatively common.

GEOGRAPHIC DISTRIBUTION
Probably worldwide.

SIGNALMENT

Species
• Dog (common).
• Cat (rare).

Breed Predilections
• Various.
• Masticatory—Rottweiler, Doberman, Samoyed, and cavalier King Charles spaniel develop severe forms.
• Extraocular—golden retriever.

Mean Age and Range
No obvious age predisposition.

Predominant Sex
None obvious.

SIGNS

General Comments
Masticatory—usually related to abnormalities of jaw movement, jaw pain, and masticatory muscle atrophy; not a "tabletop" diagnosis; usually requires laboratory testing to confirm diagnosis.

Historical Findings
• Masticatory—acute or chronic pain when opening the jaw; inability to pick up a ball or get food into the mouth; acutely swollen muscles; progressive muscle atrophy.
• Extraocular—bilateral exophthalmos.

Physical Examination Findings
• Masticatory—marked jaw pain with manipulation and/or trismus; acute muscle swelling with exophthalmos; muscle atrophy with enophthalmos; inability to open the jaw under anesthesia.
• Extraocular—bilateral exophthalmos; impaired vision.

CAUSES
Immune-mediated.

RISK FACTORS
• Appropriate genetic background.
• Possible previous bacterial or viral infection.
• Vaccination may exacerbate active disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Retro-orbital abscess—probe behind last upper molar.
• Temporomandibular joint disease—radiographically abnormal joint.
• Polymyositis—high serum creatine kinase activity; generalized electromyogram (EMG) abnormalities; diagnostic muscle biopsies.
• Neurogenic atrophy of temporalis muscles—determined by EMG and muscle biopsy.
• Atrophy of masticatory muscles from corticosteroids—history of corticosteroid use; characteristic changes on muscle biopsy.
• Atrophy of masticatory muscles from endocrine disorders—test for thyroid and adrenal disorders.

CBC/BIOCHEMISTRY/URINALYSIS
Serum creatine kinase activity—normal or mildly elevated.

OTHER LABORATORY TESTS
• Muscle biopsy—diagnostic test of choice for masticatory muscle disease.
• Immunohistochemical assay—demonstrate autoantibodies against masticatory muscle type 2M fibers in frozen muscle biopsy sections; negative in polymyositis and extraocular disease.
• ELISA—demonstrate autoantibodies against masticatory muscle type 2M fiber proteins.

IMAGING
• Radiography of the temporomandibular joints.
• Orbital sonogram—for extraorbital disease; demonstrate swollen extraocular muscles.
• MRI—for demonstration of inflammation/myonecrosis in muscles.

DIAGNOSTIC PROCEDURES
EMG—differentiate between extraocular disease and polymyositis; abnormal masticatory muscles in masticatory myositis only; generalized abnormalities including masticatory muscles in polymyositis.

PATHOLOGIC FINDINGS

Masticatory
• Swelling or atrophy of the masticatory muscles.
• Biopsy specimen—may see myofiber necrosis, phagocytosis, mononuclear cell infiltration with a multifocal and perivascular distribution; may see myofiber atrophy and fibrosis with chronic condition; eosinophils rare.

Extraocular
Mononuclear cell infiltration—restricted to extraocular muscles

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient

NURSING CARE
Gastrostomy tube—may be required with severe restrictions in jaw mobility; requires good hygiene and supportive care.

ACTIVITY
N/A

DIET
Masticatory—may require liquid food or gruel until jaw mobility is regained; may need a gastric feeding tube to facilitate fluid and caloric intake.

CLIENT EDUCATION
• Warn client that long-term corticosteroid therapy may be required.
• Inform client that residual muscle atrophy and restricted jaw movement may occur with chronic masticatory muscle disease.

SURGICAL CONSIDERATIONS
Not indicated.

MEDICATIONS

DRUG(S) OF CHOICE
Corticosteroids—immunosuppressive dosages, tapered as jaw mobility, swelling, and serum creatine kinase activity return to normal; maintained at lowest alternate-day dosage that prevents restricted jaw mobility; treated for a minimum of 6 months.

CONTRAINDICATIONS
N/A

PRECAUTIONS
• Corticosteroids—watch for infection and undesirable side effects.
• Clinical signs may recur if treatment is stopped too soon.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Intolerable side effects of corticosteroids—institute a lower dose of corticosteroids and combine with another drug (e.g., azathioprine).

MYOPATHY—MASTICATORY AND EXTRAOCULAR MYOSITIS (CONTINUED)

FOLLOW-UP

PATIENT MONITORING
• Masticatory—return of jaw mobility and decreased serum creatine kinase activity.
• Extraocular—decreased swelling of extraocular muscles.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• Corticosteroids—undesirable side effects.
• Recurrence of clinical signs—treatment stopped too early.
• Poor clinical response—inadequate dosages of corticosteroids.
• Restrictive strabismus (extraocular myositis).
• Note position of tongue—venous congestion and tongue protrusion may occur under anesthesia.

EXPECTED COURSE AND PROGNOSIS
• Masticatory—jaw mobility should return to normal unless the condition is chronic and severe fibrosis develops; good prognosis if treated early with adequate dosages of corticosteroids.
• Extraocular—good response to corticosteroids; good prognosis unless chronic with restrictive strabismus.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Other concurrent autoimmune disorders.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Unknown

SYNONYMS
• Atrophic myositis.
• Eosinophilic myositis.

MYOPATHY, NONINFLAMMATORY—ENDOCRINE

BASICS

DEFINITION
Myopathies associated with various endocrinopathies (including hypothyroidism, hyperthyroidism, hypoadrenocorticism, hyperadrenocorticism) and associated with exogenous corticosteroid use (steroid myopathy).

PATHOPHYSIOLOGY

With Adrenal Dysfunction
- Glucocorticoid excess—impaired muscle protein metabolism; may accelerate degradation of myofibrillar and soluble protein in skeletal muscle; impairment of carbohydrate metabolism owing to induction of an insulin-resistant state; may note elevated adrenocorticotropic hormone (ACTH) levels.
- Adrenal insufficiency—circulatory insufficiency; fluid and electrolyte imbalance; impaired carbohydrate metabolism.

With Thyroid Disease
- Hyperthyroidism—increased mitochondrial respiration; accelerated protein degradation and lipid oxidation; glycogen depletion; impaired glucose uptake.
- Hypothyroidism—impaired muscle energy metabolism by reduced glycogen breakdown, gluconeogenesis, and oxidative and glycolytic capacity; impaired insulin-stimulated carbohydrate metabolism.

SYSTEMS AFFECTED
- Neuromuscular—impaired energy metabolism.
- Cardiovascular—impaired energy metabolism; circulatory disorders.

GENETICS
N/A

INCIDENCE/PREVALENCE
- Exact incidence unknown.
- Myopathies related to exogenous corticosteroids—common.
- Myopathies associated with Cushing syndrome and hypothyroidism—not uncommon.

GEOGRAPHIC DISTRIBUTION
Probably worldwide.

SIGNALMENT

Species
- Dog—steroid myopathy; weakness associated with hyperadrenocorticism and hypoadrenocorticism; hypothyroidism.
- Cat—weakness associated with hyperthyroidism.

Breed Predilections
Affects several breeds.

Mean Age and Range
- Steroid myopathy—dogs of any age.
- Other disorders—see specific disease.

Predominant Sex
None found.

SIGNS

General Comments
Corticosteroid use in dogs—muscles very susceptible; muscle atrophy (particularly the masticatory muscles) is not uncommon with prolonged corticosteroid use.

Historical Findings
- Muscle weakness, atrophy, and stiffness.
- Regurgitation.
- Dysphagia.
- Dysphonia.

Physical Examination Findings
- Muscle weakness, stiffness, cramping, and myalgia.
- Muscle hypertrophy or atrophy.
- May not note other clinical signs of an endocrine disorder.

CAUSES
- Endocrine dysfunction.
- Autoimmune.
- Neoplastic.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Inflammatory myopathies—distinguished by muscle biopsy.
- Noninflammatory myopathies—distinguished by muscle biopsy.

CBC/BIOCHEMISTRY/URINALYSIS
- Baseline testing—abnormalities consistent with endocrine disorder.
- Serum creatine kinase activity—usually normal, but may be mildly elevated if necrotic muscle fibers.

OTHER LABORATORY TESTS
Thyroid and adrenal function tests—should be diagnostic.

IMAGING
- Dynamic studies—evaluate pharyngeal and esophageal function; with regurgitation and dysphagia.
- Cardiac evaluation—for cats with hyperthyroidism.

DIAGNOSTIC PROCEDURES
- Muscle biopsy—fiber typing in fresh frozen muscle biopsy sections important, paraffin sections will not be diagnostic.
- Electromyography.

PATHOLOGIC FINDINGS
- Hyperadrenocorticism and steroid myopathies—selective atrophy of type 2 muscle fibers; may see lobulated or ragged-red fibers with associated myotonia.
- Hypoadrenocorticism—muscle biopsies normal.
- Hyperthyroidism (cats)—muscle biopsies normal.
- Hypothyroidism—atrophy of type 2 fibers; may see an increase in type 1 fibers; may see periodic acid–Schiff (PAS)-positive deposits and nemaline rod bodies.

TREATMENT

APPROPRIATE HEALTH CARE
Depends on specific endocrine disorder.

NURSING CARE
Physical therapy—with musculoskeletal manifestations.

ACTIVITY
- Clinical corticosteroid myopathy (humans)—inactivity worsens condition; increased muscle activity may partially prevent atrophy.
- Physical therapy—may help prevent and treat muscle weakness and wasting in dogs receiving glucocorticoids.

DIET
- Regurgitation and megaesophagus—feed from an elevation.
- Dysphagia and esophageal dilation—give food with the best-tolerated consistency.
- Gastric feeding tube—if oral feeding is not tolerated.

CLIENT EDUCATION
Depends on specific endocrine disorder.

SURGICAL CONSIDERATIONS
Removal of neoplasia.

MEDICATIONS

DRUG(S) OF CHOICE
- Depends on specific endocrine disorder.
- Corticosteroid myopathy—decrease corticosteroid dosage to the lowest possible level; use a nonfluorinated corticosteroid and alternate-day dosing.
- Intramyofiber lipid storage with steroid myopathy—L-carnitine 50 mg/kg PO q12h may improve muscle strength.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Depend on specific endocrine disorder.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Fluorinated corticosteroids, triamcinolone, betamethasone, and dexamethasone—most likely to produce muscle weakness; use an equivalent dose of another corticosteroid.

MYOPATHY, NONINFLAMMATORY—ENDOCRINE (CONTINUED)

FOLLOW-UP

PATIENT MONITORING
- Depends on specific endocrine disorder.
- Steroid myopathy—should note return of muscle strength and mass with decreased steroid use.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Depend on specific endocrine disorders.

EXPECTED COURSE AND PROGNOSIS
- Myotonia associated with hyperadrenocorticism—poor prognosis for resolution.
- Steroid myopathy—good prognosis for return of muscle strength and mass; recovery may take weeks.
- Hypothyroid myopathy—improvement in muscle pain and stiffness common.
- Hyperthyroidism (cats)—good prognosis for return of muscle strength following reversion to euthyroid state.
- Hypoadrenocorticism—good prognosis for return of muscle strength.
- Dysphagia and regurgitation—may resolve with adequate treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- May note multiple endocrinopathies.
- Hypothyroidism (dogs)—concurrent myasthenia gravis.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Unknown

ABBREVIATIONS
- ACTH = adrenocorticotropic hormone.
- PAS = periodic acid–Schiff.

MYOPATHY, NONINFLAMMATORY—HEREDITARY LABRADOR RETRIEVER

BASICS

OVERVIEW
• An inherited myopathy of Labrador retrievers. • Recognized worldwide. • Autosomal recessive mode of inheritance; severity of clinical signs varies. • More recently classified as a centronuclear myopathy (CNM). • The causative genetic mutation has been identified—called protein tyrosine phosphatase-like A gene (*PTPLA*). CNM-causing genes, including *PTPLA*, interact to build a functional muscle and to maintain its homeostasis. • Loss of tendon reflexes and muscle histology—may be more suggestive clinically of a neurogenic than a myopathic cause without further testing. No histologic abnormalities found in CNS or peripheral nervous system (PNS). • Studies suggest *PTPLA* mutation may have arisen spontaneously in one popular sire and is now disseminated widely in the Labrador population.

SIGNALMENT
• Occurs in black and yellow Labrador retrievers. • Age of onset—variable (6 weeks–7 months); most commonly recognized at 3–4 months. • Affects males and females. • A similar inherited CNM has been identified in young male and female Great Danes.

SIGNS
• Severity ranges from stilted gait and exercise intolerance to severe muscle weakness, bunny-hopping pelvic limb gait, ventro-flexion of the head and neck, arched back, and abnormal joint posture (cow-hocked stance, hyperextended carpi). • Worsen with exercise, excitement, and cold weather. • Patient may collapse with forced exercise. • Some improvement with rest. • Generalized muscle atrophy—mild to severe. • Atrophy of proximal limb and masticatory muscles often most prominent. • Tendon reflexes—normal, hypoactive, or absent. • Occasionally, patients become recumbent or develop megaesophagus.

CAUSES & RISK FACTORS
Autosomal recessive mode of inheritance.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• With little muscle atrophy—exercise intolerance may mimic signs of myasthenia gravis, cardiac or orthopedic disease. • Exercise-induced collapse syndrome also recognized in this breed; however, not associated with muscle atrophy and collapse seen only after strenuous exercise. • With marked muscle atrophy—consider other myopathies (infectious, immune-mediated, metabolic, congenital) and generalized lower motor neuron disorders. • Infectious myopathy due to congenital neospora caninum infection has a higher incidence in Labrador retrievers. • Congenital muscular dystrophy in a male due to dystrophin deficiency and in a female due to sarcolemmal collagen deficiency myopathy have also been reported in Labrador retrievers. • An X-linked myotubular myopathy (XLMTM), which is an unrelated CNM, due to a mutation in *MTM1* gene, has also been identified in young male Labrador retrievers. Affected dogs show progressive and severe weakness and muscle atrophy in the first 2 months of life resulting in euthanasia before 6 months of age.

CBC/BIOCHEMISTRY/URINALYSIS
Creatine kinase—normal or mildly or moderately elevated.

OTHER LABORATORY TESTS
A DNA test is available for the causative genetic mutation.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Electromyogram (EMG)—spontaneous activity, including complex repetitive discharges, especially in proximal limb and masticatory muscles; may reveal no abnormalities with mild disease. • Muscle histology—reveals variation in fiber size, angular atrophy of both type 1 and 2 myofibers, grouped atrophy, increase in central nuclei, muscle degeneration and regeneration, and fibrosis; may note deficiency in type 2 myofibers or predominance of type 1 myofibers. • DNA test for causative genetic mutation.

TREATMENT
• None specific. • Avoid cold, because it exacerbates clinical signs. • DNA testing of breeding animals recommended. • Discourage breeding of affected animals and parents and littermates of affected dogs. • Do not repeat dam–sire matings that result in affected offspring.

MEDICATIONS

DRUG(S) OF CHOICE
Supplementation with L-carnitine 50 mg/kg PO q12h may be of benefit in improving muscle strength.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
None known.

FOLLOW-UP
• Clinical signs generally stabilize at approximately 1 year of age. • Mild disease—may be an acceptable pet; may show some improvement in exercise tolerance. • Aspiration pneumonia—a risk in dogs with megaesophagus.

M

MYOPATHY, NONINFLAMMATORY—HEREDITARY MYOTONIA

BASICS

OVERVIEW

- Myotonia characterized by persistent contraction or delayed relaxation of muscle fibers on initiation of movement or when stimulated to contract.
- May affect all skeletal muscles.
- Myotonia may be congenital or acquired.
- A genetic basis has been determined in some breeds.
- Acquired myotonia may be associated with noninflammatory or inflammatory myopathy.
- Neuromyotonia and myokymia, characterized by continuous muscle fiber activity, are believed to be due to hyperexcitability of terminal nerve branches (neuromyotonia) or hyperexcitability of the motor nerve axon at any level (myokymia) rather than a primary muscle disorder.
- Neuromyotonia is characterized by muscle stiffness and delayed relaxation.
- Myokymia describes rhythmic undulating muscle movements that produce a rippling movement of the skin.
- The cause of neuromyotonia and myokymia (continuous muscle fiber activity [CMFA]) in all reported cases remains unclear.
- CMFA and spinocerebellar ataxia may occur concurrently in Jack Russell terriers (JRTs) (and related breeds) and both are associated with a genetic mutation causing neuronal ion channel dysfunction.

SIGNALMENT

- Congenital myotonia—chow chows, miniature schnauzers and Australian cattledogs; rarely seen in other dog breeds.
- Clinical signs seen when affected puppies begin to walk.
- Acquired myotonia—all breeds of any age potentially susceptible.
- Myotonia reported in young domestic cats.
- Neuromyotonia and myokymia (CMFA)—described in predominantly young JRTs worldwide, rarely in other breeds, and a cat.

SIGNS

- Difficulty rising.
- Stiffness after rest or initiation of activity.
- May note dyspnea, voice change, dysphagia, and/or regurgitation, especially after eating.
- May improve with exercise.
- May be exacerbated by cold.
- Muscle stiffness and myokymia observed in young JRTs may result in life-threatening hyperthermia. In this breed clinical signs are episodic but dogs may have continuous ataxia.

Physical Examination Findings

- Hypertrophy of proximal limb muscles, neck muscles, and tongue.
- Tongue may protrude from the mouth.
- Abduction of thoracic limbs.
- Stiff, stilted, pelvic limb gait.
- Patient may fall and remain rigid in lateral recumbency for short periods. May become cyanotic.
- Affected miniature schnauzers may have craniofacial abnormalities such as mandibular shortening.

CAUSES & RISK FACTORS

- Chow chows—suspected autosomal recessive mode of inheritance.
- Miniature schnauzers, Australian cattledogs—autosomal recessive mode of inheritance (*CLCN1* gene).
- JRT group CMFA and spinocerebellar ataxia—autosomal recessive mode of inheritance (*KCNJ10* gene).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other myopathies—distinguished by signalment and clinical, electromyographic, and histologic findings.
- Hypertonicity disorders or other movement disorders—recognized breed association.

CBC/BIOCHEMISTRY/URINALYSIS

Creatine kinase—may be normal or slightly elevated.

OTHER LABORATORY TESTS

DNA testing for known genetic mutations.

DIAGNOSTIC PROCEDURES

- Percussion of muscles and tongue—causes sustained dimpling.
- Electromyography—myotonia characterized by multifocal or generalized high-frequency discharges that wax and wane in amplitude and frequency (dive bomber sounding potentials) and are increased after muscle percussion. Myokymic discharges—rhythmic high-frequency bursts of single motor unit potentials are characteristic findings in myokymia.

PATHOLOGIC FINDINGS

- Muscle histology—congenital myotonia: normal or mild changes.
- Degenerative and/or inflammatory changes on muscle histology may be seen in cases of acquired myotonia.
- No abnormalities found on muscle biopsy in JRTs with neuromyotonia and myokymia (CMFA).

TREATMENT

- None specific.
- Discourage activities that result in hyperventilation.
- Avoid strenuous exercise and excitement.
- Avoid cold.
- Anesthesia (induction and recovery)—possible risk of respiratory obstruction owing to adduction of vocal cords or regurgitation.

MEDICATIONS

DRUG(S) OF CHOICE

- Membrane-stabilizing drugs—procainamide, quinidine, phenytoin, and mexiletine; may decrease severity of clinical signs.
- Procainamide reported to be most effective in chow chows. Treatment may decrease stiffness, stridor, and regurgitation, but gait remains abnormal.
- Extended-release procainamide 40–50 mg/kg q8–12h or mexiletine 8.3 mg/kg q8h reported to be effective in miniature schnauzers.
- Procainamide 10 mg/kg q8h or mexiletine 4 mg/kg q12h or sustained-release phenytoin at an increasing dose 50–100 mg/kg for 6 weeks then on serum concentration monitoring 2–8 mg/L reported to reduce frequency of episodes of CMFA in approximately half of affected JRTs, but response is generally temporary.
- Anesthesia and cooling to treat hyperthermia may be required to treat episodes of CMFA in JRTs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Myotonia in humans is worsened with treatment with dantrolene, beta-adrenergic blocking agents, diuretics, and neuromuscular blocking agents. Bromide-containing agents such as potassium bromide may be contraindicated.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Chow chows, miniature schnauzers, Australian cattledogs—inherited condition; advise owner regarding breeding.
- DNA testing for carrier dogs prior to breeding.
- Discourage breeding of affected animals.
- Do not repeat dam–sire matings that resulted in affected offspring.

POSSIBLE COMPLICATIONS

- Respiratory obstruction and/or aspiration of regurgitated food—may be life-threatening; advise owners of the clinical symptoms and treatment.
- Hyperthermia associated with CMFA in JRTs is life-threatening.

EXPECTED COURSE AND PROGNOSIS

Prognosis guarded.

ABBREVIATIONS

- CMFA = continuous muscle fiber activity.
- JRT = Jack Russell terrier.

MYOPATHY, NONINFLAMMATORY—HEREDITARY SCOTTIE CRAMP

BASICS

OVERVIEW
- Inherited disorder in Scottish terriers characterized by episodic muscle hypertonicity or cramping.
- Not associated with any morphologic changes in muscle, peripheral nerve, or the CNS.
- Is better characterized as a hypertonicity disorder than a myopathy.
- Thought to be the result of a disorder in serotonin metabolism within the CNS.
- Similar condition (reflex myoclonus) reported in young Dalmatians and Labrador retrievers—may be result of low numbers of neurotransmitter glycine receptors in the CNS.
- Episodic muscle hypertonicity syndromes also occur in cavalier King Charles spaniels (episodic falling syndrome), Norwich terriers, bichon frises, border terriers (Spike's disease or canine epileptoid cramping syndrome), Wheaten terriers, springer spaniels, and sporadically in other breeds.

SIGNALMENT
- Young Scottish terriers, typically <1 year of age. Clinical signs may be seen in puppies as early as 6–8 weeks of age.
- No known sex predilection. Females may be overrepresented.

SIGNS
- Normal at rest and on initial exercise.
- Further exercise or excitement—abduction of the thoracic limbs; arching (kyphosis) of the thoracolumbar vertebral column; stiffening or overflexion of the pelvic limbs (goose-stepping gait).
- Patient may fall, with tail and pelvic limbs flexed tightly against the body.
- Respiration—may cease for a short time.
- Facial muscles—may be contracted.
- No loss of consciousness.
- Severity varies. Generalized spasticity may be seen during episodes or only hind limb spasticity and skipping.
- Episodes—may last up to 30 minutes.

CAUSES & RISK FACTORS
Inherited condition with probable autosomal recessive mode of transmission. Presence of dogs with cerebellar degeneration in the same pedigrees may suggest a more complex mode of inheritance than previously reported.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Seizure disorder—distinguished on basis of family history, typical clinical signs with no loss of consciousness, and induction of signs with serotonin antagonists.
- Cerebellar cortical degeneration described in Scottish terriers—clinical signs are not episodic and neurologic abnormalities are slowly progressive.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
DNA test available for episodic falling syndrome in cavalier King Charles spaniels. Genetic abnormality associated with other hypertonicity disorders not yet determined.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
Diagnosis usually made on clinical presentation. Clinical signs may be induced by giving the serotonin antagonist methysergide (0.3 mg/kg PO). Cramping is evident in 2 hours and may last for 8 hours.

TREATMENT
Behavioral modification and/or environmental changes—eliminate triggering situations (excitement, stress); may be adequate in controlling episodes.

MEDICATIONS

DRUG(S) OF CHOICE
- Acepromazine maleate 0.1–0.75 mg/kg IM or PO, diazepam 0.5–1.5 mg/kg PO q8h, or vitamin E >125 U/kg q24h—may reduce the incidence and severity of Scottie cramp.
- Fluoxetine, a selective serotonin-reuptake inhibitor, may result in reduction in clinical signs. Recommended dose 1.2 mg/kg q12h initially followed by 0.8 mg/kg q12h. Clinical improvement has been maintained for >1 year in some dogs.
- Clonazepam 0.5 mg/kg q8h may result in improvement in cavalier King Charles spaniels with hypertonicity syndrome (episodic falling syndrome).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Serotonin antagonists—increase severity of clinical signs.
- Aspirin, indomethacin, phenylbutazone, flunixin meglumine (Banamine), and penicillin—may exacerbate clinical signs.

FOLLOW-UP

PATIENT MONITORING
Nonprogressive

PREVENTION/AVOIDANCE
- Discourage breeding of affected and related animals.
- Do not repeat dam–sire matings that result in affected offspring.

EXPECTED COURSE AND PROGNOSIS
- Mild to moderate—fair to good long-term prognosis; usually manageable disability by owners; nonprogressive.
- Severe—guarded prognosis.

MYOPATHY, NONINFLAMMATORY—METABOLIC

BASICS

DEFINITION
• Myopathy associated with disorders of glycogen metabolism, lipid metabolism, or oxidative phosphorylation and mitochondrial metabolism.
• Currently poorly characterized in veterinary medicine.

PATHOPHYSIOLOGY
• Usually associated with inherited or acquired enzyme defects involving major metabolic pathways.
• May result in storage of the abnormal metabolic byproduct or morphologic abnormalities of mitochondria.

SYSTEMS AFFECTED
• Cardiovascular—dependent on oxidative metabolism for energy.
• Hemic/lymphatic/immune—red blood cells (RBCs) depend on glycolytic metabolism.
• Nervous—dependent on glycolytic and oxidative metabolism for energy.
• Neuromuscular—dependent on oxidative metabolism for energy.
• Storage products in other organs—liver, spleen.

GENETICS
Undetermined

INCIDENCE/PREVALENCE
Rare, except lipid-storage myopathies.

GEOGRAPHIC DISTRIBUTION
Unknown; probably worldwide.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Muscle phosphofructokinase deficiency—English springer spaniel, American cocker spaniel, whippet.
• Acid maltase deficiency—Lapland dog.
• Branching enzyme deficiency—Norwegian forest cat.
• Debranching enzyme deficiency—German shepherd dog, Akita, curly-coated retrievers.
• Pyrvuate dehydrogenase phosphatase 1 deficiency—Clumber spaniel, Sussex spaniel.
• Mitochondrial myopathy—Old English sheepdog, Yorkshire terrier, possibly Jack Russell terrier.

Mean Age and Range
• Inherited metabolic defects—2–3 months.
• Acquired metabolic defects—adults.

Predominant Sex
None found.

SIGNS

General Comments
Very few of these conditions have been adequately described.

Historical Findings
• Muscular weakness.
• Exercise intolerance.
• Cramping.
• Collapse.
• Regurgitation and/or dysphagia.
• Esophageal and/or pharyngeal abnormalities.
• Dark urine; myoglobinuria, hemoglobinuria.
• Encephalopathy.
• Vomiting.

Physical Examination Findings
• Exercise-related weakness, stiffness, and/or cramping.
• Abnormal neurologic examination—disorientation; stupor; coma.
• Abdominal distention—storage product accumulation in liver.
• May appear normal, with fluctuating clinical signs.

CAUSES
• Inborn error of metabolism.
• Acquired metabolic defect.
• Viral infections.
• Drug-induced.
• Environmental factors.

RISK FACTORS
• Inherited disorders.
• Appropriate genetic background.
• Others unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Inflammatory myopathies—differentiated by muscle biopsy.
• Other noninflammatory myopathies—differentiated by muscle biopsy.
• Other metabolic encephalopathies—differentiated by laboratory evaluation.

CBC/BIOCHEMISTRY/URINALYSIS
• Plasma lactate and pyruvate levels—elevated resting or post exercise with disorders of fatty acid oxidation or oxidative phosphorylation; no elevation with glycolytic disorders.
• Serum creatine kinase activity—may be elevated with exercise and normal at rest; may be persistently elevated.
• Hypoglycemia—may occur with some glycolytic and oxidative disorders.
• Hyperammonemia—may occur with urea cycle defects.

OTHER LABORATORY TESTS
• Quantitation of plasma amino acids—abnormal accumulations.
• Quantitation of urine organic acids—demonstrate abnormal organic acid production.
• Quantitation of plasma, urine, and muscle carnitine—may be low with primary or secondary disorders of carnitine; low with primary organic acidurias.
• Specific enzyme assays—depend on suspected metabolic defect.
• Fibroblast cultures—study metabolic defect.
• DNA-based tests to identify affected dogs and carriers when available.

IMAGING
MRI—evaluate the CNS; reveals abnormalities in humans.

DIAGNOSTIC PROCEDURES
• Light microscopy—fresh frozen muscle sections; demonstrates storage products (glycogen, lipid) or abnormal mitochondria.
• Electron microscopy of muscle reveals abnormal mitochondria, paracrystalline inclusions, and glycogen or lipid accumulation.
• Cardiovascular system evaluation—may have concurrent cardiomyopathy.
• Other organ biopsies—with organomegaly.

PATHOLOGIC FINDINGS
• Triglyceride droplets in muscle—lipid storage myopathy.
• Ragged-red fibers in muscle—mitochondrial myopathy.
• Glycogen deposition in muscle—glycogen storage disorder.

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient—may require intensive care for severe encephalopathy, seizures, lactic acidemia, hypoglycemia, or hyperammonemia.
• Outpatient—clinical signs related only to neuromuscular system.

NURSING CARE
Depends on type and severity of disorder.

ACTIVITY
Exercise restriction—with muscle weakness, stiffness, or exercise-induced collapse.

DIET
• Avoid prolonged periods of fasting.
• Restrictions—depend on underlying defect.
• Vitamin and co-factor therapy—determined by underlying defect.

CLIENT EDUCATION
• Warn client that most inherited metabolic defects cannot be cured, although some can be treated.
• Advise against breeding affected individuals.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Depend on the abnormality and clinical signs.

(CONTINUED) MYOPATHY, NONINFLAMMATORY—METABOLIC

• Lipid storage myopathies—L-carnitine 50 mg/kg PO q12h; riboflavin 50–100 mg PO q24h; coenzyme Q10 1 mg/kg PO q24h.
• Mitochondrial myopathies—may benefit from therapy similar to that listed for lipid storage myopathies.

CONTRAINDICATIONS
None known.

PRECAUTIONS
Avoid fasting and strenuous exercise if they precipitate clinical signs.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Lipid storage myopathies—return of muscle strength; elimination of muscle pain.
• Elevated serum creatine kinase—should return to normal.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Severe neurologic impairment.

EXPECTED COURSE AND PROGNOSIS
• Untreatable disorder—poor prognosis.
• Lipid storage myopathies—good prognosis if no underlying organic academia.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Iatrogenic and naturally occurring Cushing syndrome.
• Lipid storage myopathies—found in some dogs.
• Hemolytic anemia—due to underlying metabolic defect.

AGE-RELATED FACTORS
• Inborn errors—usually found in young dogs.
• Acquired defects—found in adult dogs.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Unknown

SYNONYMS
• Acid maltase deficiency—glycogenosis type II.
• Cori disease—glycogenosis type III.
• Glycogen storage disorders.
• Lipid storage myopathies.
• Mitochondrial myopathies.
• Phosphofructokinase deficiency—glycogenosis type VII.

ABBREVIATIONS
• RBC = red blood cell.

MYOPATHY—POLYMYOSITIS AND DERMATOMOSITIS

BASICS

DEFINITION
- Polymyositis—a condition in which skeletal muscles are damaged by a nonsuppurative inflammatory process dominated by lymphocytic infiltration. Terminology restricted to the immune-mediated form.
- Dermatomyositis—polymyositis is associated with characteristic skin lesions.

PATHOPHYSIOLOGY
- Inflammation of skeletal muscles—results in muscle weakness, stiffness, myalgia, and atrophy.
- Muscle inflammation—may be a result of immune-mediated, infectious, or paraneoplastic disorders; may be a sequela to certain drug therapies.

SYSTEMS AFFECTED
- Gastrointestinal—particularly the pharyngeal and esophageal muscles, because they are composed predominantly of skeletal muscle in dogs.
- Neuromuscular—generalized muscle involvement including masticatory and limb muscles.
- Skin/exocrine—particularly if related to a generalized immune-mediated connective tissue disorder. Skin lesions predominate over neuromuscular signs in canine dermatomyositis.

GENETICS
- Unknown.
- As for autoimmune diseases in general, the appropriate genetic background must exist.
- Familial form of autoimmune polymyositis in Newfoundland and vizsla.
- Dermatomyositis—reported to have an autosomal dominant inheritance pattern in rough-coated collie and Shetland sheepdog.

INCIDENCE/PREVALENCE
- Unknown.
- Generalized inflammatory myopathies—not common but recognition may be increasing.

GEOGRAPHIC DISTRIBUTION
Probably worldwide.

SIGNALMENT

Species
Dog and rarely cat.

Breed Predilections
- Polymyositis—various breeds of dogs and cats may be affected; breed-associated in Newfoundland, boxer, and vizsla.
- Dermatomyositis—reported in rough-coated collie, Shetland sheepdog, and Australian cattle dog.

Mean Age and Range
- Polymyositis—none obvious.
- Dermatomyositis—3–5 months of age.

Predominant Sex
None obvious.

SIGNS

General Comments
- Polymyositis—usually associated with a stiff-stilted gait, variable myalgia, and/or muscle weakness. May see regurgitation and megaesophagus.
- Elevated serum creatine kinase activity—supports but does not make the diagnosis of myositis. Do not rule out polymyositis if creatine kinase activity normal.
- Muscle biopsy—needed to confirm the diagnosis.

Historical Findings
- Stiff-stilted gait—acute or chronic.
- Muscle swelling and/or atrophy.
- Variable muscle pain.
- Generalized muscle weakness and exercise intolerance.
- Regurgitation of food or difficulty swallowing.

Physical Examination Findings
- Variable pain upon palpation of muscle groups.
- Generalized muscle atrophy, including the muscles of mastication.
- Gait abnormalities, including a stiff-stilted gait.
- Neurologic examination—not abnormal; may be a decreased gag reflex if the pharyngeal muscles are affected.
- Dermatomyositis (dogs)—typical skin lesions.

CAUSES
- Immune-mediated.
- Infections—*Toxoplasma gondii*; *Neospora canis*; *Sarcocystis* spp.; tick-related diseases, bacterial infection uncommon.
- Drug-induced.
- Paraneoplastic or pre-neoplastic syndrome.

RISK FACTORS
- Appropriate genetic background.
- Possibly previous bacterial or viral infection.
- Neoplasia, possibly occult.
- Exposure to ticks.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Polyarthritis—differentiated by physical examination and evaluation of joint fluid.
- Noninflammatory muscle disorders—differentiated by muscle biopsy.
- Polyneuropathy—differentiated by neurologic examination, electrophysiology, and muscle and peripheral nerve biopsies.
- Chronic intervertebral disc disease—differentiated by neurologic examination and serum creatine kinase activity.
- Myasthenia gravis—differentiated by positive acetylcholine receptor (AChR) antibody titer.

CBC/BIOCHEMISTRY/URINALYSIS
Serum creatine kinase activity—variably elevated.

OTHER LABORATORY TESTS
- Serum antinuclear antibody titer—may be positive in connective tissue disorders.
- May see concurrent hypothyroidism.
- Cardiac troponin I—may have concurrent myocarditis.

IMAGING
- Regurgitation—evaluate thoracic radiography for esophageal dilatation, neoplasia.
- Cardiac silhouette—evaluate myocardial size and shape.
- Pharyngeal weakness—perform a dynamic study for the evaluation of the swallowing process.

DIAGNOSTIC PROCEDURES
- Muscle biopsy—single most important test for diagnosing polymyositis; sample multiple muscles, because condition may be missed if distribution is patchy.
- Echocardiograph—evaluate myocardial function.
- Electrodiagnostic evaluation (electromyogram [EMG], measurement of nerve conduction velocity)—performed to determine the distribution of muscle involvement and the muscles to be biopsied; should help differentiate myopathic from neuropathic causes of muscle weakness.

PATHOLOGIC FINDINGS
- Muscle swelling or atrophy.
- Biopsy specimens—usually contain mononuclear cell infiltrates.
- Rare neutrophils or eosinophils—may be noted.
- Regenerating myofibers—may be observed.
- Intramyofiber parasite cyst—rare.
- Chronic condition—may see extensive myofiber atrophy and fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient

NURSING CARE
Supportive care—may be required to prevent skin wounds and decubital ulcers in nonambulatory, severely affected patients.

ACTIVITY
Should increase, along with muscle strength, as muscle inflammation decreases.

(CONTINUED) # MYOPATHY—POLYMYOSITIS AND DERMATOMOSITIS

DIET
• Megaesophagus—may require feeding from an elevation; try foods of different consistencies.
• Severe regurgitation—may need to place a gastric feeding tube to maintain hydration and nutrition.

CLIENT EDUCATION
• Warn client that long-term immunosuppressive therapy may be required for an immune-mediated condition.
• Inform client that residual muscle atrophy and contractures may occur with chronic disease and extensive fibrosis.
• Suggest genetic counseling for familial disorders.

SURGICAL CONSIDERATIONS
Only for concurrent neoplasia.

MEDICATIONS

DRUG(S) OF CHOICE
• Corticosteroids—immunosuppressive dosages usually result in clinical improvement of immune-mediated condition; decrease to the lowest alternate-day dosage that maintains normal creatine kinase activity and improved muscle strength and mobility; may require long-term therapy.
• Identified infectious agent—initiate specific therapy.
• Identified myocardial failure—initiate specific therapy.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Corticosteroids—observe for infection and undesirable side effects; remember that chronic therapy may lead to muscle atrophy (steroid myopathy).

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Intolerable side effects of corticosteroids—institute a lower dose of corticosteroids combined with another drug (e.g., azathioprine, cyclosporine).

FOLLOW-UP

PATIENT MONITORING
• Serum creatine kinase activity—periodic evaluation; if elevated, should decrease into the normal range.
• Corticosteroids—side effects.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• Corticosteroids—undesirable side effects.
• Recurrence of clinical signs—treatment stopped too early.
• Poor clinical response—inadequate dosages of corticosteroids. May need additional or alternative immunosuppressant.

EXPECTED COURSE AND PROGNOSIS
• Immune-mediated condition—good to fair prognosis.
• Paraneoplastic disorder associated with occult neoplasia—guarded prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Other concurrent autoimmune disorders.
• Neoplasia.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Unknown

SEE ALSO
Myopathy, Noninflammatory—Endocrine.

ABBREVIATIONS
• AChR = acetylcholine receptor.
• EMG = electromyogram.

M

MYXEDEMA AND MYXEDEMA COMA

BASICS

OVERVIEW

• Myxedema coma is a rare, life-threatening manifestation of severe hypothyroidism and an endocrine emergency.
• The development of myxedema coma requires a precipitating event (often infection) that overwhelms normal homeostatic mechanisms.
• The greatest challenge with myxedema coma is recognition. Once recognized, immediate and intensive supportive care is necessary. Successful treatment requires treatment of the underlying cause, if present. Mortality rates can be high.

M

SIGNALMENT

• Dogs.
• Median age—6 years.
• Female dogs predisposed.
• Not reported in cats.

SIGNS

Historical Findings

• The most common findings are changes in mental status, altered thermoregulation, and nonpitting skin edema.
• Mentation changes are due to brain edema, ranging from altered alertness to obtundation. Mental depression is the most common mental status. Coma is rarely reported.
• Other signs consistent with hypothyroidism.
• Prior diagnosis of hypothyroidism.

Physical Examination Findings

• Hypothermia, nonpitting edema, tachypnea, alopecia, dehydration, dermatitis, otitis.
• Mental dullness is common and decreased postural reactions may be present.
• In humans, classic signs of myxedema coma include mental dullness, bradycardia, hypothermia, hypoventilation, and hypotension. These signs have been reported in dogs, but most do not present with all of them.

CAUSES & RISK FACTORS

• Myxedema coma results from chronic untreated severe primary hypothyroidism.
• Both forms of primary hypothyroidism (lymphocytic thyroiditis and idiopathic thyroid atrophy) have been associated with the development of myxedema coma.
• A secondary precipitating event is usually associated with the onset of a myxedema crisis.
• Precipitating events can include infections, respiratory disease, heart failure, and hypovolemia.
• Exposure to cold temperatures may be a precipitating event.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Weakness may be associated with cardiovascular disease, neurologic disease, and other endocrinopathies.

CBC/BIOCHEMISTRY/URINALYSIS

• Mild nonregenerative anemia.
• Hypercholesterolemia.
• Hypertriglyceridemia.
• Hypoglycemia.
• Hyponatremia.
• Urinalysis is normal.

OTHER LABORATORY TESTS

• Thyroid function tests—severe hypothyroidism with low total thyroxine (T_4), low free T_4, and elevated thyroid-stimulating hormone (TSH) levels.
• Blood gas analysis may note hypoxemia or hypercarbia.
• Diagnostics are aimed at identifying an underlying cause.

IMAGING

Thoracic radiographs/ultrasound—pulmonary alveolar pattern, pleural effusion (modified transudate).

PATHOLOGIC FINDINGS

Skin biopsies show dermal thickening, myxedema, and vacuolation of arrector pili muscles.

TREATMENT

• Myxedema coma is a medical emergency.
• Once a presumptive diagnosis is made, immediate inpatient treatment is necessary.
• Due to the critical nature of myxedema coma, treatment must be initiated before thyroid function test results confirm diagnosis.
• Immediate provision of a patent airway and resuscitation of hypotension are necessary.
• Mechanical ventilation may be necessary.
• IV fluid therapy to support blood pressure and to address hyponatremia. Patients with myxedema have a decreased ability to excrete free water.
• Replacement isotonic crystalloids (Normosol-R or lactated Ringer's solution, 20–30 mL/kg, IV initial bolus) are first-line therapy. Reassess and continue IV fluids (2.5–7 mL/kg/h) as necessary to maintain blood pressure and heart rate.
• IV administration of synthetic thyroid hormone.
• Rapid rewarming may cause peripheral vasodilatation, hypotension, and potential cardiovascular collapse; correction of hypothermia should be passive and occur over a number of hours.

MEDICATIONS

DRUG(S) OF CHOICE

• Definitive immediate treatment—levothyroxine 5 µg/kg (0.005 mg/kg) IV q12h.
• A more conservative dose should be used when there is concern about cardiac function, and the heart's ability to deal with a rapid increase in metabolic rate. Decrease levothyroxine dose by 50–75% in these cases.
• Once the patient's condition has stabilized and the patient is able to swallow, oral levothyroxine therapy should be initiated at 0.02 mg/kg PO q12h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Lower IV levothyroxine dose in patients with cardiac disease.
• Avoid rapid rewarming.

FOLLOW-UP

• Prognosis is guarded to grave.
• If patient survives initial treatment, treat and monitor as recommended for hypothyroidism.

MISCELLANEOUS

SEE ALSO

Hypothyroidism.

ABBREVIATIONS

• T_4 = thyroxine, tetraiodothyronine.
• TSH = thyroid-stimulating hormone.

MYXOMATOUS MITRAL VALVE DISEASE

BASICS

DEFINITION
Myxomatous mitral valve disease (MMVD) is characterized by progressive myxomatous degeneration, which refers to a characteristic pathologic weakening and disorganization of valvular connective tissue. Although myxomatous degeneration most commonly affects the mitral valve, any of the four intracardiac valves can be affected, and the most commonly used descriptor "mitral" does not exclude involvement of other valves.

PATHOPHYSIOLOGY
• Pathologic weakened and disorganized valvular connective tissue, in which the spongiosa component is unusually prominent with accumulation of mucopolysaccarides and glycosaminoglycans. • Valve leaflets become thickened and elongated with disease progression. • Degenerative changes in chordae tendineae lead to thickening and elongation of these structures, thus contributing to valve flattening and prolapse.
• With progression, valve lesions cause insufficient systolic coaptation of the leaflets, leading to backward regurgitation of blood from the ventricle into the atrium. • Severity of mitral regurgitation depends on severity of valve lesions (leaflets and/or chordae tendineae).
• Compensatory mechanisms include cardiac dilation and eccentric hypertrophy, increased force of contraction, increased heart rate, increased pulmonary lymphatic drainage, fluid retention, and neurohormonal modulation of cardiovascular function.
• With progression, valvular regurgitation eventually may not be compensated, leading to reduced cardiac output and increased venous pressures, leading to pulmonary edema if left-sided congestive heart failure (CHF) and ascites if right-sided CHF.
• Acute cardiac tamponade may result from atrial tear.

SYSTEMS AFFECTED
• Cardiovascular—myxomatous degeneration most commonly affects the mitral valve but any intracardiac valve can be affected.
• Hepatobiliary—passive congestion at advanced stages. • Renal/urologic—prerenal azotemia at advanced stages. • Respiratory—if edema and/or pulmonary hypertension (PH) develops.

GENETICS
Etiology currently unknown, but the current leading scientific hypothesis is that a genetically determined dystrophic process initiates valve degeneration. Age of onset is inherited as a polygenetic threshold trait (i.e., multiple genes influence the trait and a certain threshold has to be reached before the disease develops). This mode of inheritance means that a combination of a sire and a dam that both have an early onset of MMVD will give offspring that have, on average, an early onset of the disease. A combination of dogs with late onset will give offspring that manifest the disease at old age or never.

INCIDENCE/PREVALENCE
The most common cardiac disease in dogs. Prevalence is strongly influenced by age: it is uncommon in young dogs but common in old dogs. MMVD is encountered in all breeds, but the highest prevalence is seen in small to medium-sized dog breeds. The prevalence reaches >90% in some affected dog breeds >10 years.

SIGNALMENT
Species
Dogs; extremely rare in cats.

Breed Predilections
Typically small breeds (<20 kg, but may be encountered in larger dogs), such as cavalier King Charles spaniel (CKCS), Chihuahua, miniature schnauzer, Maltese terrier, Pomeranian, cocker spaniel, Pekingese, poodle, and others.

Mean Age and Range
Murmur may be detected from 2 years of age with a peak incidence for detection at 6–8 years in widely affected breeds such as the CKCS. Onset of CHF from 8–12 years.

Predominant Sex
Males develop the disease at a younger age than females, which means higher prevalence at a given age in males,

SIGNS
Signs depend on the stage of disease. The descriptions here align with the grading system described in the American College of Veterinary Internal Medicine (ACVIM) consensus statement on MMVD.

Clinically Healthy Patients but at a Higher Risk of Developing the Disease (ACVIM Stage A)
No abnormal findings.

Dogs Diagnosed with the Disease but with No Overt Clinical Signs (ACVIM Stage B)
• Systolic click (early stage). • Systolic murmur best heard over the mitral or tricuspid areas. • Murmurs may range from soft low-intensity to loud holosystolic.
• With progression, murmurs typically get louder and radiate more widely. • Initially, patients have no obvious radiographic or echocardiographic changes in cardiac chamber size or have mild cardiomegaly and do not meet the so called "EPIC trial criteria" (see ACVIM stage B1). Stage B2 is defined as dogs with cardiac enlargement meeting EPIC trial criteria, i.e., presenting a moderate or loud intensity murmur (≥3/6), VHS >10.5, bodyweight normalized left ventricular end-diastolic diameter (LVIDDn) ≥1,7, and a left atrial to aortic root ratio (LA/Ao) ≥1.6.

Dogs with Overt Clinical Signs of CHF or with Clinical Signs Stabilized by CHF Therapy (ACVIM stages C and D)
• Usually a loud holosystolic heart murmur.
• Tachypnea/dyspnea/orthopnea if decompensated CHF. • Tachycardia and loss of respiratory sinus arrhythmia if decompensated CHF. • Arrhythmia, such as supraventricular premature beats, ventricular premature beats, or atrial fibrillation, may be present.
• Respiratory crackles if decompensated CHF.
• Weak femoral pulse, prolonged capillary refill time and pale mucous membranes in low output failure. • Pink froth, i.e., pulmonary edema, may be evident in the nares and oropharynx in severe decompensated CHF.
• Ascites if right-sided CHF (caused by myxomatous tricuspid lesions and/or pulmonary hypertension [PH]).

CAUSES
Primary (inciting) factor unknown but the disease is influenced by genetic factors in affected breeds.

RISK FACTORS
• Breed. • Sex (males have earlier onset).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Bacterial endocarditis. • Congenital heart disease. • Dilated cardiomyopathy.
• Chronic airway or interstitial lung disease.
• Pneumonia. • Pulmonary embolism.
• Pulmonary neoplasia. • Heartworm disease.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC/biochemistry usually unremarkable unless severe disease and ongoing CHF therapy. • Prerenal azotemia secondary to impaired renal perfusion; high urine specific gravity unless complicated by underlying kidney disease or recent/ongoing diuretics.
• High liver enzyme activity in many patients with right-sided CHF.

OTHER LABORATORY TESTS
• Natriuretic peptides—often unremarkable unless moderate to severe disease. • Serum troponin I—unremarkable unless severe disease.

IMAGING
Radiography
• Heart size ranges from normal to left-sided or generalized cardiomegaly. • LA enlargement is usually the earliest finding. • LV may be enlarged. • Left-sided CHF—pulmonary congestion; increased interstitial pattern ± alveolar pattern with air bronchograms.

MYXOMATOUS MITRAL VALVE DISEASE (CONTINUED)

Initially, congestion and edema are perihilar, but all lungfields may eventually show changes.

Echocardiography

• Thickened and distorted mitral valve leaflets. • Elongated and ruptured chordae tendineae, causing mitral valve prolapse. • Normal to severely dilated atrium (uni- or bilateral). • LV may be dilated and is hyperdynamic if regurgitant flow is significant and myocardial function intact; as LV becomes more grossly distended, it may become normo- or, uncommonly, hypodynamic because of myocardial failure. • Pericardial effusion (usually mild) may be present in severe disease. • Doppler studies show a jet of regurgitation into the atrium. • Doppler evaluation for the presence of PH should be routinely performed.

DIAGNOSTIC PROCEDURES

• Arterial/venous blood gases can be used to quantify hypoxemia and monitor treatment response. • Systemic blood pressure should be monitored; especially patients receiving diuretics and other cardiovascular drugs to check for hypotension; hypertension is not associated with the disease, but if concurrent can exacerbate the disease.

Electrocardiographic Findings

• Sinus tachycardia common in patients with CHF. • May show evidence of LA enlargement (P mitrale) or LV enlargement (tall and wide R waves). • Supraventricular, or ventricular arrhythmias may develop in severe disease.

PATHOLOGIC FINDINGS

• Gross valvular changes range from only a few discrete nodules at the line of closure to gross distortion by gray-white nodules and plaques causing contraction of the cusps and rolling of the free edge; the chordae are irregularly thickened, with regions of tapering and rupture. • Mild disease—normal cardiac size. More progressed cases—LA and LV dilation. Degree of right-sided dilatation variable. • Degree of LV hypertrophy may be apparent only when weighing the heart. • Jet lesions—irregular thickening and opacity of the atrial endocardium. • LA splits or tears in some cases.

TREATMENT

APPROPRIATE HEALTH CARE

Dogs with preclinical MMVD can be managed at home with scheduled rechecks to identify dogs that meet EPIC trial criteria for initiation of pimobendan. Some dogs with mild to moderate signs of CHF may be managed at home, whereas dogs with more severe signs should be hospitalized initially for intensive CHF therapy.

NURSING CARE

Oxygen therapy as needed for hypoxemic dogs with moderate to severe CHF. Dogs receiving diuretics must be given the opportunity to urinate. Dyspnea-associated anxiety should be treated. Carefully monitor blood pressure and respiratory response to narcotics and tranquilizers in the setting of acute decompensated CHF. Butorphanol 0.2–0.25 mg/kg IM or IV is commonly used for sedation, but combinations of buprenorphine 0.0075–0.01 mg/kg and acepromazine 0.01–0.03 mg/kg IV, IM, or SQ can also be used.

ACTIVITY

• Exercise restriction for symptomatic patients in acute decompensated CHF. • Exercise recommended for stable CHF patients on medical therapy, but avoid strenuous exercise.

DIET

• Prevent cardiac cachexia by ensuring adequate calorie intake. • Avoid high sodium diets.

CLIENT EDUCATION

• Discuss the progressive nature of the disease. • Mild disease severity is suggestive of a long period without clinical signs; moderate to severe disease indicates a shorter period until signs of CHF may develop. • If a breeder, inform about the disease genetics and impact for future breeding. • Pimobendan therapy prolongs preclinical period and survival times in dogs meeting the EPIC criteria. • Appropriate level of exercise, but at the same time maintain quality of life. • Common signs of CHF listed earlier. • How to medicate (if indicated)—information about consistent dosing and that diuretic doses should be adjusted in consultation with the veterinarian. • Possible adverse side reactions of medications. • How to monitor resting and/or sleeping respiratory rates at home, and at which rate new contact with the clinician should be initiated. • Diet (if indicated)—emphasize importance of avoiding cardiac cachexia by paying close attention to appetite and using an appropriate diet. Salt loads should be avoided.

SURGICAL CONSIDERATIONS

Surgical valve repair can be performed at a few sites in the world.

MEDICATIONS

DRUG(S) OF CHOICE

Recommended treatment depends on disease stage; these recommendations follow the guidelines set by the consensus statement developed by the ACVIM.

Patients without Overt Clinical Signs (ACVIM Stage B)

• If no cardiomegaly, no treatment currently recommended. • Pimobendan 0.25–0.3 mg/kg q12h PO prolongs preclinical period (by a median of approximately 15 months) and survival in Stage B2 dogs. • Administering angiotensin-converting enzyme inhibitors (ACEIs) to Stage B patients has been shown to be ineffective in two clinical trials.

Patients Showing Overt Clinical Signs (ACVIM Stages C and D)

Acute Decompensated CHF

• Furosemide IV, SC, IM, or PO; dose is dependent on severity of CHF: ◦ Mild to moderate CHF: 2–4 mg/kg q8–24h. ◦ Severe or fulminant CHF: 4–8 mg/kg q2–6h, preferably IV, IM, or SC. ◦ Monitor outcome of treatment by respiratory rate and general clinical status. ◦ Dose can often be reduced once the patient is stabilized. • Oxygen supplementation and cage rest to patients with significant dyspnea: 40% in O_2 cage (can intermittently go as high as 100%) up to 24 hours; nasal O_2 may be used in large-breed dogs, 50–100 mL/kg/min through humidifier. • Pimobendan 0.25–0.3 mg/kg q12h PO. In many countries outside of the United States, IV pimobendan is available and used as an initial single-dose treatment before oral medication. • Additional options in severe fulminant CHF: ◦ Nitroglycerin: ointment (one-fourth inch/5 kg up to 2 inches percutaneously), sublingual spray (one puff/10 kg) or injectable (1–5 µg/kg/min CRI). ◦ Arterial vasodilator to decrease afterload rapidly, e.g., hydralazine 0.5 mg/kg q12h (titrate up to 2 mg/kg if necessary) or sodium nitroprusside 1–10 µg/kg/min (expensive drug and difficult to obtain). Both drugs require blood pressure monitoring and should be considered only in hospitalized dogs under care of a specialist. ◦ Dobutamine—dogs: 1–10 µg/kg/min; cats: 1–5 µg/kg/min. • Antiarrhythmics—as needed. • Severe ascites may require abdominocentesis.

Chronic CHF (Typically Treated as an Outpatient)

• Exact composition of medical therapy depends on disease severity and clinical signs. All dogs with CHF require life-long treatment with a diuretic, such as furosemide: ◦ Mild to moderate CHF: 1 mg/kg q12h to 2 mg/kg q8h PO. ◦ Moderate to severe CHF: 2–3 mg/kg q12h or higher. • Pimobendan at 0.25–0.3 mg/kg q12h PO. • ACEI (e.g., enalapril, benazepril, ramipril)—dose and frequency depend on ACEI used, e.g., enalapril 0.5 mg/kg q12–24h; benazepril 0.25–0.5 mg/kg q24h. • Spironolactone 2 mg/kg q12–24h PO and/or hydrochlorothiazide at 2–4 mg/kg q12h PO. • Digoxin 0.22 mg/m^2 q12h PO, or lower. • Antiarrhythmics—as needed. • Sildenafil 1–2 mg/kg q8–12h if PH present.

(CONTINUED) MYXOMATOUS MITRAL VALVE DISEASE

PRECAUTIONS

• Use digoxin, diuretics, and ACEIs cautiously in patients with renal disease. • Beta blockers are negative inotropes and may have an acute adverse effect on myocardial function and clinical status.

POSSIBLE INTERACTIONS

• Furosemide potentiates the effects of ACEIs, spironolactone, or thiazides. • Use nonsteroidal anti-inflammatory drugs cautiously in patients receiving furosemide or ACEIs.

ALTERNATIVE DRUG(S)

• Diuretics—add thiazide and/or spironolactone in refractory animals. • Torsemide—administered at approximately 1/10th of the furosemide dose, or 0.1–0.6 mg/kg once to twice daily is an alternative to furosemide. • Vasodilators—isosorbide dinitrate can be used in place of nitroglycerin ointment in patients requiring long-term nitrate administration.

FOLLOW-UP

PATIENT MONITORING

• Frequency of rechecks depends on stage of MMVD and severity of CHF (if present). • Dogs without signs of CHF: ○ Mild to moderate disease—perform echocardiography when a murmur is first detected and every 6–12 months (interval depends on findings of previous echocardiogram) thereafter to document progressive cardiomegaly. Baseline radiographs may be useful. ○ Owners are instructed to regulary measure respiratory rates at home during rest or sleep and contact the veterinarian should rates be consistently higher than 30 breaths/minute. • Dogs with signs of CHF: ○ Once acute CHF has been successfully treated, dogs can be treated at home. ○ Follow-up with owner, by phone or email, should be conducted after 1–3 days at home, to monitor for maintained treatment effect. A change in the furosemide dose (partly based on respiratory rates during sleep or deep rest and amount of side effects of the treatment initiated) may be performed. ○ Reexamine after 1–2 weeks (check for signs of decompensated CHF, dehydration, electrolyte imbalance, renal dysfunction, and presence of complications) or sooner if treatment response is unsatisfactory. ○ Thereafter once every 3–6 months if the patient is stable on the medications. More severe cases may require more frequent monitoring. • Monitor BUN and creatinine especially when high doses of diuretics and ACEIs are used. • Monitor potassium, especially if combinations of spironolactone, ACEIs, and digoxin are used.

POSSIBLE COMPLICATIONS

• Preclinical patients may develop acute CHF. • Recurrent decompensated CHF in patients stabilized by medical therapy. • PH. • Biventricular CHF in dogs with initial left-sided CHF. • Mild pleural and/or pericardial effusion. • Arrhythmia. • Rupture of major chordae tendineae, leading to a flail valve leaflet and acute decompensation. • Atrial tear leading to acquired atrial septal defect or cardiac tamponade.

EXPECTED COURSE AND PROGNOSIS

Valve lesions are progressive in nature and myocardial function may worsen, requiring increased drug dosages. Long-term prognosis depends on response to therapy and stage of heart disease.

MISCELLANEOUS

SYNONYMS

• Chronic valvular disease (CVD). • Chronic mitral valve disease. • Degenerative valvular disease. • Degenerative mitral valve disease (DMVD). • Degenerative valve disease.

SEE ALSO

• Atrial Wall Tear. • Congestive Heart Failure, Left-Sided. • Congestive Heart Failure, Right-Sided.

ABBREVIATIONS

• ACEI = angiotensin-converting enzyme inhibitor. • ACVIM = American College of Veterinary Internal Medicine. • CHF = congestive heart failure. • LA = left atrium. • LV = left ventricle. • MMVD = myxomatous mitral valve disease. • PH = pulmonary hypertension.

NARCOLEPSY AND CATAPLEXY

BASICS

OVERVIEW

Narcolepsy/cataplexy refer to the same disorder, cataplexy being the clinical sign easiest to recognize in domestic animals.

Narcolepsy

• Sleep disorders. • Syndrome characterized by excessive sleepiness, cataplexy sleep paralysis, and hypnagogic hallucinations (humans). Sudden episodes of paradoxical sleep without a preceding period of slow-wave sleep.

Cataplexy

• Sudden, episodic, and spontaneous collapse secondary to complete atonia of skeletal muscles (flaccid paralysis) caused by inhibition of spinal cord lower motor neurons. • Patient stays alert and will follow with its eyes.• Most common clinical sign of narcolepsy in small animals.

SIGNALMENT

• Dog and rarely cat. • Proven hereditary—Labrador retriever, dachshund, and Doberman pinscher. • Autosomal recessive gene mutation—*canarc-1* gene found on chromosome 12, which codes for a hypocretin (orexin) receptor. Mutations of *OxR2* (type II orexin receptor gene). Increased microglial expression of MHC II in Doberman pinscher. • Assumed genetic basis for miniature poodle—mode of inheritance unknown. • For inherited disease, clinical signs appear between 2 and 4 months of age with escalation of signs around 1 year of age. Possible disappearance of clinical signs later in life. • Acquired form may develop in older animals (possible depletion of hypocretin production by hypothalamus) and can occur in any dog breed or mixed breed, at any age. • Clinical signs in acquired form will usually remain for life.

SIGNS

• Physical and neurologic examinations—normal except during an episode. • Onset—peracute. • Excessive daytime sleepiness and fragmented sleep patterns reported in domestic animals, but cataplexy is usually the clinical sign recognized by owners. • Cataplexy episodes—acute onset of flaccid paralysis without loss of consciousness lasting a few seconds to minutes (up to 20 minutes) with sudden return to normal; multiple episodes in 1 day. • Narcolepsy—eye movements, muscular twitching, and whining (as in REM sleep) frequently observed during episodes. • Patients are usually aroused by loud noises, petting, or other external stimuli.

CAUSES & RISK FACTORS

• Hereditary in some breeds. • Possible immune system involvement in acquired disease. • Neurotransmitter abnormalities—serotonin, dopamine, norepinephrine, neuropeptide hypocretin (orexin). • Rarely reported with pontomedullary (brainstem) lesions. • Excitement, emotions, feeding, and general anesthesia may induce narcoleptic episodes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Syncope. • Seizure activity—urinary or fecal incontinence, excessive salivation and muscle rigidity are not characteristic of narcolepsy in which atonia predominates. Recovery after a narcoleptic event is immediate. • Nonconvulsive seizure (drop attack). • Neuromuscular disorders—onset of clinical signs usually not as sudden and recovery not immediate as in narcolepsy.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

• DNA test for specific breeds (Labrador retriever, dachshund, and Doberman pinscher). • CSF—normal. Low levels of orexin A in CSF. • Standardized food-elicited cataplexy test; play-elicited cataplexy.

IMAGING

Brain MRI—normal.

DIAGNOSTIC PROCEDURES

• Observe an episode—if a consistent activity (feeding, excitement, etc.) elicits attacks, attempt to simulate the activity. • Food-elicited cataplexy test—place 10 pieces of food in a row 12–24 inches apart; record the time required for the patient to eat all the pieces and the number, type, and duration of any attacks that occur; normal dogs eat all food in <45 seconds and have no attacks; affected dogs take >2 minutes to eat the food and can have 2–20 attacks. • Play-elicited cataplexy—2 dogs are left in a room and allowed to interact together and with toys. • Physostigmine (cholinesterase inhibitor) challenge to induce cataplexy in an affected dog—administer 0.025–0.1 mg/kg IV; repeat the food-elicited test 5–15 minutes after the injection; increase dosage if necessary (0.05 mg/kg, 0.075 mg/kg, 0.10 mg/kg); effects of each dose last 15–45 minutes.

TREATMENT

• Primary goal—reduce the severity and frequency of cataplectic episodes. • Inform client that cataplexy is not a fatal disease, choking on food and airway obstruction do not occur, and the pet is not suffering. • Inform client that activities such as hunting, swimming, and unleashed exercise put the patient at risk. • If episodes are infrequent and quality of life is preserved, treatment should be postponed and environment adapted to avoid specific stimulations.

MEDICATIONS

DRUG(S) OF CHOICE

• Imipramine 0.5 mg/kg PO q8h. • Methylphenidate 0.25 mg/kg PO q12–24h. • Selegiline 2 mg/kg PO q24h. • Yohimbine 50–100 µg/kg SC or PO q8–12h. • Combination also possible—imipramine and methylphenidate.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Many patients develop drug tolerance; change of drug may become necessary. • Increased heart and respiratory rates, anorexia, tremors, exercise-induced hyperthermia.

FOLLOW-UP

• Avoiding inciting activities may reduce episodes so that medication is not needed. • Patients with the inherited form may improve with age. • Prognosis varies even with treatment; some patients remain symptomatic.

NASAL AND NASOPHARYNGEAL POLYPS

BASICS

OVERVIEW
- Non-neoplastic, inflammatory growths arising from epithelium, usually originate from a stalk.
- Nasal—uncommon; originate from the mucosa of the nasal turbinates and are inflammatory in dogs and cats.
- Nasopharyngeal—relatively common; originate from the base of the epithelial lining of the tympanic bulla or eustachian tube; when polyps extend into the nasopharynx they are referred to as nasopharyngeal polyps; when extending into the ear, they are known as middle ear polyps, aural or auricular polyps, or benign, inflammatory polyps.

SIGNALMENT
- Nasal polyps—middle-aged to older dogs and cats.
- Nasopharyngeal polyps—typically kittens and young adult cats, but can be seen in older cats (months—15 years), rarely seen in dogs.

SIGNS

Nasal Polyps
- Chronic mucopurulent nasal discharge.
- Noisy breathing—stertor.
- Nasal congestion and/or discharge.
- Sneezing or epistaxis.
- Decreased nasal airflow, generally unilateral.
- Generally nonresponsive to antibiotics.

Nasopharyngeal or Aural Polyps
- Inspiratory stridor.
- Gagging.
- Cyanosis.
- Voice change.
- Dysphagia.
- Chronic otitis externa/otitis media.
- Head tilt.
- Nystagmus.
- Ataxia.
- Horner's syndrome.

CAUSES & RISK FACTORS
Unknown—suspect congenital or response to chronic inflammatory processes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Feline upper respiratory disease complex.
- Nasopharyngeal stenosis.
- Chronic otitis externa or media.
- Nasal or nasopharyngeal foreign body.
- Laryngeal paralysis.
- Nasal neoplasia—lymphoma, nasal adenocarcinoma.
- Laryngeal neoplasia—squamous cell carcinoma, lymphoma, adenocarcinoma.
- Aural neoplasia—ceruminous adenocarcinoma.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
Feline leukemia virus/feline immunodeficiency virus (FeLV/FIV)—general retroviral screening.

IMAGING
- Skull radiographs—soft tissue density within nasal cavity, nasopharynx, tympanic bulla, external ear canal; 25% false-negative rate.
- CT and MRI—better sensitivity for nasal, nasopharyngeal, and aural masses.

DIAGNOSTIC PROCEDURES
- Digital palpation of soft palate, visual examination of the nasopharynx and larynx under general anesthesia utilizing spay hook, dental mirror, and laryngoscope.
- Flexible fiber-optic caudal rhinoscopy to examine the dorsal nasopharynx, choanae, and caudal nasal cavity.
- Rigid rostral rhinoscopy to examine the nasal cavity.
- Deep otoscopic examination.
- Fine-needle aspirate and/or biopsy.
- Cytology and histopathology.

TREATMENT
- Excisional biopsy for nasal polyps.
- Traction removal of nasopharyngeal polyps via oral cavity.
- Ventral bulla osteotomy for nasopharyngeal polyps to release stalk and remove epithelial lining; may decrease rate of recurrence of polyps. Recommended if bullous involvement (clinical evidence of otitis media) is apparent.

MEDICATIONS

DRUG(S) OF CHOICE
- Consider anti-inflammatory course of corticosteroids following traction removal of nasopharyngeal polyps; decreased recurrence rate reported.
- Appropriate antimicrobial medications if secondary nasal or otic infection present.

FOLLOW-UP
- Incomplete removal of polyp and stalk may result in recurrence.
- Horner's syndrome can occur following removal by traction or ventral bulla osteotomy; usually transient but can be permanent.
- Facial paresis or paralysis or vestibular syndrome may develop after bulla osteotomy but is generally transient.
- Prognosis excellent with complete removal.

MISCELLANEOUS

ABBREVIATIONS
- FeLV = feline leukemia.
- FIV = feline immunodeficiency virus.

NASAL DERMATOSES—CANINE

BASICS

DEFINITION
Pathologic condition of the nasal skin involving either the haired portion (bridge of the nose/dorsal muzzle) or non-haired portion (nasal planum).

PATHOPHYSIOLOGY
Dependent on cause.

SYSTEMS AFFECTED
Skin/exocrine.

SIGNALMENT
• Dogs <1 year of age—dermatophytosis, zinc-responsive dermatosis, dermatomyositis, demodicosis, eosinophilic folliculitis and furunculosis (often insect trigger; also seen in adult patients). • Zinc-responsive dermatosis—Siberian husky, Alaskan Malamute. • Dermatomyositis—collie, Shetland sheepdog. • Uveodermatologic syndrome—Akita, Samoyed, Siberian husky. • Systemic lupus erythematosus (SLE) and discoid lupus erythematosus (DLE)—collie, Shetland sheepdog, German shepherd dog. • DLE may occur more often in females. • Epitheliotropic lymphoma—older dogs. • Dermal arteritis of the nasal philtrum—Saint Bernard and other large breeds. • Nasal solar dermatosis—lightly pigmented breeds. • Nasal parakeratosis—Labrador retriever. • Senile idiopathic nasal hyperkeratosis—cocker spaniel, Boston terrier, bulldogs. • Seasonal nasal hypopigmentation—Labrador retriever, golden retriever, Siberian husky, Bernese mountain dog. • Idiopathic leukoderma/leukotrichia (vitiligo)—Doberman pinscher, Rottweiler, dachshund. • Reactive histiocytosis ("clown nose")—Bernese mountain dog, golden retriever. • Mucocutaneous pyoderma – German shepherd dog.

SIGNS
• Depigmentation. • Erythema. • Erosion/ulceration. • Vesicles/pustules. • Crusts. • Scarring. • Alopecia. • Nodules/plaques. • Hyperkeratosis.

CAUSES
• Nasal pyoderma/furunculosis; mucocutaneous pyoderma. • Demodicosis. • Dermatophytosis, cryptococcosis, sporotrichosis, aspergillosis. • DLE and SLE. • Eosinophilic folliculitis and furunculosis. • Mosquito-bite hypersensitivity. • Pemphigus foliaceus (PF) and erythematosus (PE). • Pemphigus vulgaris (PV). • Nasal philtrum arteritis. • Nasal solar dermatitis. • Dermatomyositis. • Zinc-responsive dermatosis. • Uveodermatologic syndrome. • Superficial necrolytic dermatitis. • Vitiligo. • Idiopathic nasal depigmentation. • Contact dermatitis— irritant or hypersensitivity; plastic dish dermatitis, topical drug hypersensitivity (neomycin). • Neoplasia—squamous cell carcinoma, basal cell carcinoma, epitheliotropic lymphoma, cutaneous histiocytosis. • Trauma. • Idiopathic sterile granuloma. • Idiopathic nasal hyperkeratosis. • Distemper virus dermatitis. • Xeromycteria – otitis media compromising sympathetic nerve supply/parasympathetic function or lacrimal gland damaged, cause drying of nasal tissues.

RISK FACTORS
• Adult cats—may be inapparent carriers of dermatophytes. • Rooting behavior—pyoderma, dermatophytosis. • Sun exposure—nasal solar dermatitis, DLE, SLE, PE. • Poorly pigmented nose—nasal solar dermatitis, squamous cell carcinoma. • Large, rapidly growing breeds—zinc-responsive dermatosis. • Immunosuppression—demodicosis, pyoderma, dermatophytosis. • Insect exposure—mosquito-bite dermatitis, eosinophilic folliculitis and furunculosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Nasal Solar Dermatitis
• Lesions—confined to nose; precipitated by heavy sunlight exposure. • Begins in poorly pigmented skin at junction of nasal planum and dorsal muzzle. • Lightly pigmented eyelid margins may also be affected.

DLE
• Primarily affects nasal area. • May affect mucocutaneous margins of the lips and eyelids. • Exacerbated by sunlight. • Dermatitis often preceded by depigmentation. • Biopsy—interface dermatitis with pigmentary incontinence.

SLE
• Multisystemic disease. • Skin lesions—often involve nose, face, mucocutaneous junctions; multifocal or generalized.

Pemphigus Foliaceus
• Lesions—usually start on face and ears; commonly involve footpads and pinnae; eventually generalize. • Biopsy—subcorneal pustules with acantholysis.

Pemphigus Erythematosus
• Lesions—primarily confined to face and ears; features of both PF and DLE; typically more severe than lesions of DLE. • Dermatitis often preceded by depigmentation. • Biopsy—intraepidermal pustules with acantholysis and pigmentary incontinence.

Demodicosis
• Often starts on face or forelimbs; affects only haired skin of the dorsal muzzle. • Juvenile-onset frequently facial at first. • May generalize.

Contact Dermatitis: Plastic (or Rubber) Dish Dermatitis
• Depigmentation and erythema of anterior nasal planum and lips. • No ulceration or crusting. • Uncommon; overly suspected—lesions more often due to trauma from roughened bowl edges. Similar symptoms seen with trauma from rubber toys.

Dermatomyositis
• Breeds at increased risk. • Young age of onset. • Nasal, facial, and extremity lesions—erosion, alopecia, scarring, and hyperpigmentation. • Lesions especially noted at points of trauma or pressure. • Polymyositis and megaesophagus may be seen. • Biopsy—interface dermatitis with follicular atrophy.

Uveodermatologic Syndrome
• Breeds at increased risk. • Dermatitis often preceded by ocular symptoms (uveitis). • Striking leukotrichia and leukoderma on nose, lips and eyelids. • Biopsy of early lesions—interface dermatitis, pigmentary incontinence.

Zinc-Responsive Dermatosis
• Breeds at increased risk. • Typical signalment or diet (i.e., high-fiber or calcium supplementation). • Crusted lesions—face, mucocutaneous junctions, pressure points, footpads. • Biopsy—parakeratotic hyperkeratosis.

Eosinophilic Folliculitis and Furunculosis
• Rapid progression from popular papular/nodular pattern to ulcers and plaques. • Highly pruritic. • Acute reaction to insect or arthropod bite and stings.

Mucocutaneous Pyoderma
• Crusting and fissures on mucocutaneous junctions of lateral aspects of the nares, lips and perioral skin.

Mosquito Bite Hypersensitivity
• Seasonal pruritic dermatitis. • Erythema, papules, crusts affecting face and nasal planum, occasionally lesions on pinnae and feet. • Biopsy—eosinophilic inflammation, collagen necrosis around the hair follicles.

Other
• Dermatophytosis—haired portion of the nose; diagnosed by culture or biopsy. • Vitiligo—cutaneous macular depigmentation without inflammation on nose, lips, eyelids, footpads, and claws; leukotrichia with leukoderma may be seen; diagnosed by biopsy. • Nasal hypopigmentation—normal black coloration of nasal planum fades to light brown or whitish light pink color; loss of pigment is usually symmetrical and often becomes complete; in some individuals may be seasonal or wax and wane; considered cosmetic and not pathologic. • Idiopathic

(CONTINUED) NASAL DERMATOSES—CANINE

nasal hyperkeratosis—dry, horny growths of keratin localized to nasal planum; may or may not be associated with digital hyperkeratosis, possibly associated with senility. • Other diseases—differentiate by history or biopsy (i.e., neoplastic cell infiltrate).

CBC/BIOCHEMISTRY/URINALYSIS

• Usually normal. • SLE—may see hemolytic anemia, thrombocytopenia, evidence of glomerulonephritis (high BUN, proteinuria), joint disease, or other symptoms based on body system(s) affected.

DIAGNOSTIC PROCEDURES

• Skin scrapings—*Demodex*. • Cytology—fungal organisms, bacteria, eosinophils (eosinophilic folliculitis and furunculosis), or acantholytic keratinocytes (pemphigus). • Dermatophyte test medium (fungal culture)—dermatophytosis. • Culture on Sabouraud agar—other fungal infections. • Bacterial culture and sensitivity or cytologic evaluation—pyoderma. • Joint tap—evidence of polyarthritis in SLE. • Antinuclear antibody (ANA)—positive in cases of SLE. • Ocular examination—uveitis in uveodermatologic syndrome. • Electrocardiogram (ECG)—evidence of myocarditis in SLE. • Electromyography (EMG)—evidence of polymyositis in SLE and dermatomyositis. • Direct immunofluorescence—deposition of immunoglobulin at the basement membrane zone in DLE, SLE, and PE, and intercellular spaces of epidermis in PF, PE, and PV. • Neoplasia—cytology or biopsy.

PATHOLOGIC FINDINGS

Histopathology

• Folliculitis/furunculosis (± mites, bacteria, fungal elements)—demodicosis, dermatophytosis, nasal pyoderma/furunculosis. • Eosinophilic predominance—mosquito-bite dermatitis, eosinophilic folliculitis and furunculosis. • Follicular atrophy and perifollicular fibrosis—dermatomyositis. • Interface dermatitis—DLE, SLE, dermatomyositis, uveodermatologic syndrome. • Intraepidermal pustules with acantholysis—PF and PE. • Suprabasilar acantholysis—PV. • Parakeratotic hyperkeratosis—zinc-responsive dermatosis. • Hypomelanosis—vitiligo, uveodermatologic syndrome. • Granulomatous/pyogranulomatous dermatitis—pyoderma, fungal, foreign body, idiopathic sterile granuloma. • Neoplastic cell infiltrate—cutaneous histiocytosis, other neoplasia.

TREATMENT

• Outpatient, except SLE with multiorgan dysfunction or tumors requiring surgical excision or radiation therapy. • Reduce exposure to sunlight—DLE, SLE, PE, nasal solar dermatitis, squamous cell carcinoma. • Discourage rooting behavior—pyoderma, dermatophytosis. • Protection from insects (mosquito-bite dermatitis; eosinophilic folliculitis furunculosis). • Warm soaks—aid removal of exudate and crusts. • Replace plastic or rubber dish and avoid contact with topical drug or other agent causing hypersensitivity reaction.

MEDICATIONS

DRUG(S) OF CHOICE

• Fungal infections—systemic antifungals: ketoconazole, itraconazole; surgical excision of early discrete lesions (deep fungal infections). • Nasal solar dermatitis—topical corticosteroids; antibiotics for secondary infection; sunscreens; firocoxib. • DLE and PE—topical corticosteroids or tacrolimus 0.1% (Protopic); cyclosporine (Atopica); tetracycline and niacinamide; oral therapy (as for PF) if temporarily needed in severe cases. • PF, PV, SLE—immunosuppressive therapy with prednisolone ± azathioprine (dogs), chlorambucil. • Vitiligo/nasal depigmentation—no treatment. • Neoplasia—surgical excision; chemotherapy; radiation therapy. • Idiopathic nasal hyperkeratosis—topical antibiotic-corticosteroid cream, topical keratolytic and humectant; topical tacrolimus. • Other diseases—see specific cause.

PRECAUTIONS

Ketoconazole—caution in animals with liver disease or thrombocytopenia; avoid use in cats.

FOLLOW-UP

PATIENT MONITORING

Varies with specific disease and treatment prescribed.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Dermatophytosis

PREGNANCY/FERTILITY/BREEDING

Ketoconazole may cause infertility in male dogs.

SYNONYMS

• Superficial necrolytic dermatitis = superficial necrolytic migratory erythema and hepatocutaneous syndrome. • Uveodermatologic syndrome = Vogt–Koyanagi–Harada-like syndrome.

ABBREVIATIONS

• ANA = antinuclear antibody.
• DLE = discoid lupus erythematosus.
• ECG = electrocardiogram.
• EMG = electromyography.
• PE = pemphigus erythematosus.
• PF = pemphigus foliaceus.
• PV = pemphigus vulgaris.
• SLE = systemic lupus erythematosus.

NASAL DISCHARGE

BASICS

DEFINITION
May be serous, mucoid, mucopurulent, purulent, blood tinged, or frank blood (epistaxis); may contain food debris, from one or both nasal cavitiy(ies), may be permanent or in variable amount or consistency over time.

PATHOPHYSIOLOGY
• Secretions—produced by mucous cells of the epithelium and submucosal glands; increased production from glandular hypertrophy and hyperplasia owing to irritation of the nasal mucosa by infectious, mechanical, chemical, or inflammatory stimuli. • Blood from vascular leakage related to infectious, mechanical, chemical, inflammatory, or tumoral stimuli.
• Xeromycteria—"dry nose"; facial nerve damage secondary to middle ear disease may decrease serous secretions from the lateral nasal glands leading to compensatory mucoid secretion; usually unilateral with unilateral nasal planum hyperkeratosis, ± keratoconjunctivitis sicca (KCS).

SYSTEMS AFFECTED
• Respiratory—mucosa of the upper tract, including the nasal cavities, sinuses, and nasopharynx; lower tract disease can also result in secretions from the upper airways.
• Gastrointestinal—signs may be observed with swallowing disorders or esophageal or gastrointestinal diseases when secretions are forced into the nasopharynx. • Hemic/lymphatic/immune—blood-tinged discharge or epistaxis owing to platelet or hemostatic defects. • Ophthalmic—may have KCS ipsilaterally if there is nerve damage due to middle ear disease.

SIGNALMENT
• Dogs and cats. • Young animals—cleft palate; nasal polyp, ciliary dyskinesia; immunoglobulin deficiency. • Older animals—nasal tumors; primary dental disease (tooth root abscess). • Hunting dogs—foreign body. • Dolichocephalic dogs—aspergillosis, nasal neoplasia.

SIGNS

Historical Findings
• Sneezing—often found concurrently.
• Reverse sneezing—can be found concurrently, if nasopharyngeal involvement or passage of nasal secretions through the choanae towards the nasopharynx.
• Important to know both the initial and current character of the discharge as well as whether it originally started unilaterally or bilaterally. • Stertor—owners frequently report noisy breathing, especially when animal is sleeping. • Response to previous antibiotic therapy common due to secondary bacterial infection.

Physical Examination Findings
• Secretions or dried discharge on the hair of the muzzle or forelimbs. • May note reduction in nasal air flow, particularly with nasal neoplasia. • Concurrent dental, nasopharyngeal, or lower airway disease.
• Bony involvement—with a tumor or fourth premolar abscess; may be detected as facial or hard palate swelling or as pain secondary to fungal or bacterial osteomyelitis or neoplasia. • Mucosal depigmentation of the nasal alar cartilage—observed with canine nasal aspergillosis. • Mandibular lymphadenomegaly—neoplasia, fungal infection, dental disease. • Polyp—may be visible on otoscopic exam, or pushing the soft palate down on oral exam. • Chorioretinitis—may be seen with canine distemper or cryptococcosis. • Eyeball deviation (abscess, sino-orbital aspergillosis in cats, tumors).

CAUSES
• Unilateral—often associated with non-systemic processes; foreign body; dental-related disease; fungal infections; nasal tumor; facial nerve damage leading to xeromycteria, nasopharyngeal stenosis, or atresia.
• Bilateral—infectious agents (e.g., feline viral rhinotracheitis or calicivirus, canine herpesvirus, canine distemper, secondary bacterial infection); IgA deficiency; airborne irritant; allergy; ciliary dyskinesia; lymphoplasmacytic or hyperplastic rhinitis.
• Unilateral progressing to bilateral—*Aspergillus*; nasal tumor. • Either unilateral or bilateral—epistaxis; foreign body; extranasal disease; nasal parasites, inflammatory rhinitis.
• Extranasal diseases—chronic pneumonia, chronic vomiting, nasopharyngeal diseases.

RISK FACTORS
• Dental disease. • Foreign bodies.
• Infectious—poorly vaccinated animal; kennel situations, exposure to other animals.
• Nasal aspergillosis. • Thrombocyte disorder—thrombocytopenia or thrombocytopathy: primary immune or secondary to infectious (i.e., rickettsial) disease or neoplasia.
• Coagulation defect due to rodenticide intoxication. • Nasal mites—kennel-raised dogs. • Immunosuppression, chronic corticosteroid use; feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV) infection. • Chronic, low-grade pneumonia. • Chronic vomiting. • Chronic otitis (facial nerve damage).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Important to differentiate nasal discharge, secretions, or crusting from diseases that occur at mucocutaneous junctions, such as pemphigus, vasculitis, or leishmaniosis.

Differential Diagnosis Causes
• Serous—mild irritation; viral and parasitic (e.g., nasal mites) disorders. • Mucoid—allergy; nonspecific airborne irritants; early neoplasia. • Purulent (or mucopurulent)—secondary bacterial or fungal infection, neoplasia. • Serosanguinous to epistaxis—nasal tumor and aspergillosis; after violent or paroxysmal sneezing episodes; coagulopathy, platelet disorder, angiostrongylosis and systemic hypertension.

CBC/BIOCHEMISTRY/URINALYSIS
Results not specific for any particular cause but can detect concurrent problems; part of a thorough evaluation before general anesthesia for diagnostic procedures.

OTHER LABORATORY TESTS
• Serologic tests—help to diagnose fungal or rickettsial disease. • Coagulation studies—determine platelet numbers and function, coagulation panel.

IMAGING

Skull Imaging
• Anesthetize and carefully position patient.
• Perform before rhinoscopy and periodontal probing, which may cause nasal bleeding and alter imaging findings. • Radiography (not performed when CT is available):
○ Lateral view—detect any periosteal reaction; note gross changes in the maxillary teeth, nasal cavity, and frontal sinuses; evaluate air column outlining the nasopharynx for filling defects. ○ Open-mouth ventrodorsal and intraoral views (using sheet film)—excellent for evaluating nasal cavities and turbinates. ○ Rostrocaudal view—evaluate each frontal sinus (periosteal reaction and filling). • CT and MRI—CT superior to radiography in making diagnosis; CT and MRI help detect the extent of bony changes or CNS involvement associated with nasal tumors, fungal rhinitis, or chronic otitis.

Thoracic Radiography
May reveal areas of alveolar infiltrates in patient with chronic pneumonia, or situs inversus in some dogs with primary ciliary dyskinesia.

DIAGNOSTIC PROCEDURES
• Rhinoscopy—indicated with chronic or recurrent nasal discharge; acute epistaxis; evaluate both anterior and posterior; may be contraindicated with bleeding disorders.
• Nasal cytologic examination—nonspecific inflammation most commonly found.
• Fungal culture—difficult to interpret; false positives and negatives common. • Bacterial culture may be useful when resistant organisms are suspected, but requires deep nasal sampling under anesthesia. • Biopsy of

(CONTINUED) NASAL DISCHARGE

the nasal cavity—indicated with chronic nasal discharge or visualized abnormalities; multiple samples required to ensure adequate representation; may perform electron microscopy for suspected ciliary dyskinesia. • Bronchoscopy—indicated if there has been a history of coughing with nasal discharge. • Periodontal probing of all upper teeth—perform after rhinoscopy; the normal gingival sulcus: dogs, ≤4 mm; cats, ≤1 mm. • Blood pressure, platelets, and coagulation profile for epistaxis. • Angiostrongylosis rapid detection test or PCR. • Schirmer tear test, otoscopic exam, or CT—to evaluate for possible facial nerve damage from chronic otitis. • Tracheal/bronchial scintigraphy and electron transmission microscopy—to confirm primary ciliary dyskinesia.

TREATMENT

• Outpatient—adequate hydration, nutrition, warmth, and hygiene (keeping nares clean)—important with chronic sneezing and nasal discharge. Prioritize local therapy (nasal drops, nasal nebulization). • Inpatient—any surgical treatment, topical therapy for aspergillosis.

MEDICATIONS

DRUG(S) OF CHOICE

• Secondary bacterial infection—antibiotics; choose a good Gram-positive spectrum of activity (e.g., amoxicillin, clavamox, clindamycin, azithromycin, cephalosporins). • Attempt to dry up serous nasal secretions—decongestants (dogs: ephedrine at 10–50 mg total PO q8–12h, to a maximum of 4 mg/kg; cats: 2–4 mg/kg q8–12h); topical vasoconstrictors (neosynephrine at 0.25–0.5% q8–24h or oxymetazoline at 0.25% q24h) but for a limited period of time—less than 1 week—since they do not treat any cause and could induce damage to the nasal mucosa. • Dental-associated rhinitis—antibiotics; dental surgery as indicated. • Foreign body—removal, antibiotics. • Nasal parasites—ivermectin 300 µg/kg PO or SC weekly for 3 weeks or milbemycin 1 mg/kg PO weekly for 3 weeks (in collie and similar breeds) to treat *Pneumonyssoides*; fenbendazole 50 mg/kg PO q24h for 10 days to treat *Eucoleus* (nasal nematode). • Nonspecific inflammation—prednisolone 1–2 mg/kg PO q12–24h or piroxicam 0.3 mg/kg PO q24–48h. • Canine nasal aspergillosis—topical treatment with enilconazole or clotrimazole. • Feline cryptococcosis or sporothricosis—itraconazole 5–10 mg/kg PO q24h or fluconazole 50 mg/cat q12h. • Feline aspergillosis—topical therapy, itraconazole. • Canine angiostrongylosis—antiparasitic (e.g., fenbendazole 50 mg/kg PO q24h for 3 weeks), • Neoplasia—radiotherapy and chemotherapy. • Xeromycteria—oral administration of ophthalmic pilocarpine in attempt to stimulate nasal secretions.

CONTRAINDICATIONS

• Ephedrine—in cardiac patients. • Ivermectin—in collies and similar breeds.

PRECAUTIONS

• Itraconazole—anorexia, nausea, vomiting, and high liver enzymes. • Rebound phenomenon—reported with overuse of topical nasal vasoconstrictors.

FOLLOW-UP

PATIENT MONITORING

• Nasal discharge and sneezing—note changes in frequency, volume, and character. • Repeat rhinoscopy—indicated to ensure adequate response to treatment of fungal rhinitis. • Recheck thoracic radiographs or bronchoscopy—monitor response to treatment for chronic pneumonia.

POSSIBLE COMPLICATIONS

• Loss of appetite—especially in cats. • Extension of primary disease (e.g., fungal infection, tumor) into the mouth, eye, or brain. • Respiratory distress—with nasal obstruction. • Involvement of the cribriform plate in dogs with aspergillosis—CNS damage during topical drug therapy is a risk.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Sinusitis. • Dental disease. • Secondary causes—coagulopathy, pneumonia, cricopharyngeal disease, megaesophagus.

AGE-RELATED FACTORS

Middle-aged to old patients—often associated with dental or neoplastic conditions.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

The safety of most recommended drugs has not been established in pregnant animals.

N

NASOPHARYNGEAL STENOSIS

BASICS

OVERVIEW

• Formation of a thin soft tissue membrane or a fibrous band of tissue at the choanae or anywhere above the soft palate, resulting in the occlusion of the caudal nasopharyngeal openings or narrowing of the orifice from a 1+ cm oval opening to a 1- to 2-mm opening or less.
• Inflammation secondary to chronic rhinitis, or from regurgitation or vomiting of material into the nasopharynx, particularly after anesthesia, should be considered as possible causes. Might also occur secondary to lodging of a foreign body in the choana.
• Congenital narrowing or dysgenesis of the region can also be encountered; thickened palatopharyngeal muscles have been reported as a cause of nasopharyngeal stenosis in the dachshund.

SIGNALMENT

• Cats of any breed or sex.
• Less commonly seen in dogs.
• Age—any age as long as ample time has passed since exposure to the inciting cause; congenital cases may present early or late in life.

SIGNS

• Evidence of upper respiratory obstruction.
• Whistling, stridorous, or snoring sounds during respiration.
• Open-mouth breathing.
• Minimal nasal discharge in many cases.
• Duration of signs for at least several months.
• Aggravation of obstruction during eating or drinking.
• Failure to respond to antibiotics or corticosteroids.
• Absence of nasal airflow from one or both nares.

CAUSES & RISK FACTORS

• Chronic upper respiratory disease.
• Foreign body or irritant contacting the affected area (perianesthetic regurgitation, reflux of gastric contents secondary to esophageal or gastric disease).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Nasopharyngeal polyps—seen during oral examination or by radiography or endoscopy.
• Chronic rhinitis or sinusitis—moderate to severe nasal discharge and sneezing; obvious radiographic changes in the rostral nasal cavity commonly seen.
• Foreign body—unilateral mucopurulent nasal discharge; radiographic abnormalities.
• Intranasal neoplasia—unilateral obstruction; nasal discharge often bloody; radiographic changes.
• Mycotic rhinitis—moderate-to-severe nasal discharge, often hemorrhagic; radiographic changes.
• Laryngeal disease—no improvement with open-mouth breathing; lack of snoring or nasal discharge; abnormalities on laryngeal examination.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

• Near-normal radiographic findings rostrally.
• Lateral neck radiograph will occasionally show a tissue obstruction.
• Nasopharyngeal stenosis sometimes can be visualized on CT. Sagittal reconstruction of the images can be required.

DIAGNOSTIC PROCEDURES

• Inability to pass a 3.5 French catheter through the ventral nasal meatus into the pharynx in a cat.
• Visualization of the stenosis by use of a retroflexed pediatric bronchoscope into the nasopharynx or use of an illuminated dental mirror.

TREATMENT

• Balloon dilatation—noninvasive; fluoroscopy simplifies procedure; repeat episodes can be required (more often needed in the dog than cat).
• Stent placement can be required for cases with recurrent stenosis. Temporary red rubber stents have shown promise in reestablishing airway openings.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics and steroids sometimes used post balloon dilation.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

Have owners evaluate nasal airflow at home and warn that recurrence is possible.

Consulting Editor Elizabeth Rozanski

NECK AND BACK PAIN

BASICS

DEFINITION
Discomfort along the vertebral column.

PATHOPHYSIOLOGY
Caused by multiple neurologic or non-neurologic diseases (e.g., polyarthritis). Secondary to stimulation of nociceptors located in meninges, nerve roots, spinal nerves, vertebrae and associated structures (e.g., periosteum, joint capsules), and epaxial musculature. An intracranial disease can develop referred neck pain when intracranial pressure is elevated.

SYSTEMS AFFECTED
• Nervous. • Musculoskeletal. • Neuromuscular.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Intervertebral disc herniation (IVDH)—dogs; extrusion chondrodystrophic breeds, protrusion large breeds. Less common in cats. • Cervical spondylomyelopathy (CSM)—Doberman, Great Dane, Bernese mountain dog, Rottweiler, Dalmatian. • Atlantoaxial (AA) instability—small and miniature canine breeds (e.g., Yorkshire terrier, Chihuahua). • Steroid-responsive meningitis-arteritis (SRMA)—Bernese mountain dog, Boxer, Beagle. • Caudal occipital malformation syndrome and syringomyelia—cavalier King Charles spaniel. • Immune-mediated polymyositis—Newfoundland, boxer.

Mean Age and Range
• IVDH extrusion—unusual <2 years, peak 3–8 years. • IVDH protrusion—>5 years. • CSM—middle-aged to older Dobermans (mean: 6 years), young Great Danes (<3 years). • AA instability—young to middle-aged. • SRMA—<2 years (6–18 months). • Lumbosacral syndrome—middle-aged large dogs; German shepherd dogs.

SIGNS

Historical Findings
Primary complaint—relates to perceived discomfort; e.g., vocalization, decreased activity, reluctance to get up or lie down, reluctance to go up or down stairs, inability to drink or eat from bowls on the floor (neck), neck muscle spasms. Neck pain may be intermittent.

Physical Examination Findings
• Abnormal neck carriage, reluctance to move the head, stiff neck posture. • Arched back (kyphosis). • Pain on spinal palpation and/or neck manipulation. • Abdominal rigidity (referred from back pain). • Increased epaxial muscle tone. • Intermittent neck muscle spasms. • Reluctance to walk, stilted gait, limb stiffness, guarded short stride. • Non-weight-bearing lameness (nerve root signature). • Autonomic signs (e.g., tachycardia, pupillary dilation).

CAUSES

Degenerative
• IVDH—most common cause of spinal pain in dogs. • CSM. • Spinal synovial cysts. • Vertebral facet hypertrophy. • Calcinosis circumscripta.

Anomalous/Developmental
• AA instability. • Caudal occipital malformation syndrome (COMS) and syringomyelia. • Vertebral malformations: e.g., hemivertebra (usually asymptomatic). • Osteochondromatosis. • Dermoid sinus.

Neoplastic
• Spinal (primary or secondary), nerve root–peripheral nerve (e.g., peripheral nerve sheath tumor), muscle. • Intracranial tumors with secondary increased intracranial pressure (ICP) (referred neck pain).

Nutritional
Feline hypervitaminosis A.

Inflammatory
• Discospondylitis, vertebral osteomyelitis, vertebral physitis. • Infectious meningitis/meningomyelitis—viral (e.g., feline infectious peritonitis [FIP]), bacterial, rickettsial, fungal, protozoal, parasitic, algae. • Noninfectious meningitis/meningomyelitis—SRMA, meningoencephalomyelitis of unknown origin (MUO). • Spinal epidural empyema. • Paraspinal abscess. • Polyarthritis—immune-mediated, infectious. • Polymyositis—immune-mediated polymyositis, infectious, exertional rhabdomyolysis.

Idiopathic
Subarachnoid diverticulum (rarely painful).

Traumatic
• Spinal fracture, luxation. • Traumatic intervertebral disc herniation.

Vascular
Spinal hemorrhage.

RISK FACTORS
• Breed—chondrodystrophic (IVDH), miniature dog (AA instability). • Trauma. • Previous surgical procedure (discospondylitis, subluxation). • Malignant neoplasm. • Bite wound, foreign body, urinary tract infection (UTI), endocarditis. • Coagulopathy. • Liver diet (hypervitaminosis A). • Feline leukemia virus (FeLV) infection (spinal lymphoma).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Orthopedic disease. • Abdominal pain (back). • Behavioral or abnormal mentation (delirium). • Increased ICP (referred neck pain). • Nonpainful myelopathy—e.g., degenerative myelopathy, fibrocartilaginous embolic myelopathy. • Paroxysmal disorders. • Feline hyperesthesia syndrome.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC usually normal. May see neutrophilia (SRMA, dyscospondylitis), thrombocytopenia (rickettsial disease, malignant neoplasm). • Elevated creatine kinase (CK), aspartate aminotransferase (AST)—myositis, recumbence, trauma, anorexia (cat). • Hyperproteinemia—neoplastic, infectious. • UTI— primary focus for discospondylitis, with urinary retention. • Myoglobinuria—myositis.

OTHER LABORATORY TESTS
• Serologic titers, PCRs (blood, CSF) for infectious diseases. • Blood/urine cultures—discospondylitis. • IgA and acute phase proteins levels (blood, CSF) in SRMA. • Serum protein electrophoresis. • Coagulation panel.

IMAGING

Survey Spinal Radiography
• Not able to identify spinal cord compression. • IVDH—may detect narrowed and/or mineralized intervertebral disc space. • Detects discospondylitis but potentially normal first 3 weeks. • Spinal neoplasms—osteolysis, bony proliferation, wider vertebral canal. • Detects fractures, luxations, AA instability, vertebral facet hypertrophy, malformations, calcinosis circumscripta, osteochondromatosis.

Thoracic Radiography and Ultrasonography
Detect neoplasms (primary or metastatic), disseminated infections, endocarditis, trauma-related lesions.

Myelography
Detects and delineates spinal cord lesions as extradural, intradural–extramedullary and intramedullary. Low sensitivity in detecting parenchymal lesions.

CT
• More sensitive than radiographs for discospondylitis, vertebral fractures, bone tumors. Clearly defines bony lesions but less soft tissue contrast than MRI. Can be useful to diagnose IVDH extrusion if mineralized material. • CT-myelogram—more sensitive to assess spinal cord compressive lesions.

MRI
More sensitive than CT for soft tissue. Most rewarding imaging technique for identifying location and extent of spinal cord parenchymal lesion, nerve roots, nerves, and muscle.

DIAGNOSTIC PROCEDURES

CSF
• Useful in meningitis/meningomyelitis, but normal or nonspecific in many other situations. Rarely, neoplastic cells can be detected (spinal lymphoma). • Consider measuring IgA levels, acute phase proteins, serologic titers, PCRs, bacterial culture.

Arthrocentesis and Synovial Fluid Analysis

N

NECK AND BACK PAIN (CONTINUED)

Electrodiagnostics
EMG, nerve conduction studies—detect and localize neuromuscular disease (e.g., polymyositis).

Fluoroscopy or CT-Guided Percutaneous Fine-Needle Aspiration (FNA)
Discospondylitis, neoplasms.

Biopsy
Bone (e.g., neoplasia, osteomyelitis), muscle (e.g., polymyositis).

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient—when severe clinical signs; emergency intensive care due to severe pain or neurologic deficit. • Outpatient—when medical treatment is pursued (restricted exercise can be done). • Emergency surgery—if traumatic spinal instability or severe neurologic deficit (nonambulatory paraparesis, tetraplegia) due to an acute spinal cord compression.

NURSING CARE
• Nonambulatory patients—soft bedding, alternate recumbence site, urinary bladder voiding. • Vertebral instability—extreme care on manipulation to avoid exacerbating injury.

ACTIVITY
Restrict exercise at least 3–4 weeks in medically treated patients.

DIET
Change diet in case of hypervitaminosis A.

CLIENT EDUCATION
• Monitor pain, response to treatment and possible gait abnormalities. Relapses common in many diseases. • Most common cause of spinal pain in dogs is IVDH. Inform that restricted activity and cage confinement for 3–4 weeks are necessary when medical treatment is pursued; recurrence frequent. If pain persists or neurologic status deteriorates, surgical treatment is recommended, even as an emergency procedure.

SURGICAL CONSIDERATIONS
Vary according to disease. Generally, deep pain perception is considered the most important prognostic indicator for functional recovery in neurologic disease. AA instability correction is associated with high perioperative morbidity and mortality.

MEDICATIONS

DRUG(S) OF CHOICE
• Opioids—morphine 0.1–1.0 mg/kg q4h (dog), hydromorphone 0.05–0.2 mg/kg q4h (dog), buprenorphine 0.005–0.02 mg/kg q8h (dog); SR 0.03–0.06 mg/kg q72h (dog), fentanyl(transdermalpatch).• Glucocorticoids—Use of glucocorticoids in acute spinal cord trauma is controversial as no benefits in outcome are proven. Medical management of acute IVDH should focus on cage confinement. Prednisone 0.5–1 mg/kg q24h (dog) in decreasing dosage could be used in many noninfectious chronic and compressive conditions (IVDH protrusion, CSM, etc.) but never in combination with nonsteroidal anti-inflammatory drugs (NSAIDs). Higher doses required in immune-mediated disease (2–4 mg/kg q24h). • NSAIDs—potentially more effective in acute cervical IVDH. Meloxicam 0.1 mg/kg q24h (dog), carprofen 2.2 mg/kg q12h (dog). • Gabapentin 10–15 mg/kg q8h PO (dog); chronic neuropathic pain (syringomyelia, nerve root disease). • According to disease—antimicrobials (e.g., discospondylitis), immunosuppressive drugs, chemotherapy (neoplasms).

CONTRAINDICATIONS
• Glucocorticoids, immunosuppressive agents—infections. • Opioids—diarrhea caused by a toxic ingestion, constipation.

PRECAUTIONS
• Concurrent administration of NSAIDs and glucocorticoids is strongly contraindicated. • Glucocorticoids, NSAIDs—may cause gastrointestinal ulceration/hemorrhage. • Glucocorticoids—may cause UTI. • Vertebral instability or IVDH—strict cage rest mandatory while on anti-inflammatory and analgesic drugs; increased activity can exacerbate the problem. • Opioids—caution if respiratory dysfunction, increased ICP, CNS depression, bradyarrhythmias. • Gabapentin—caution if renal insufficiency.

POSSIBLE INTERACTIONS
• Opioids—increased CNS and respiratory depression when combined with other CNS depressants. • Gabapentin—oral antacids may decrease oral bioavailability 20%.

ALTERNATIVE DRUG(S)
• NMDA antagonists (e.g., ketamine)—analgesics. • Pregabalin—chronic neuropathic pain. • Furosemide, omeprazol—COMS/syringomyelia. • Azathioprine, cyclosporine, cytosine arabinoside—immune-mediated diseases.

FOLLOW-UP

PATIENT MONITORING
• Primarily based on clinical signs and response to treatment. Initially, monitor at least once a week. If acute severe pain and/or neurologic deficit present, inpatient or daily monitoring recommended. Make adjustments or consider surgery when medical treatment is not effective. • CSF analysis (e.g., SRMA), spinal radiographs (e.g., discospondylitis), acute phase proteins levels, bloodwork/thoracic radiographs/ultrasound (e.g., neoplasms, infectious diseases).

PREVENTION/AVOIDANCE
Avoid excessive activity, jumping, going up-/downstairs, and excess weight. Avoid neck collars (harness preferred).

POSSIBLE COMPLICATIONS
• Recurrences or deterioration. Surgical treatment can be recommended on an emergency basis according to disease. • Chronic unresponsive pain. • Permanent neurologic dysfunction. • Spread to other locations, pathological vertebral fracture/luxation (discospondylitis, neoplasms). • Degenerative joint disease (polyarthritis).

EXPECTED COURSE AND PROGNOSIS
• Varies with disease, severity of clinical signs, and neurologic deficit. • IVDH extrusion—success with medical treatment in dogs with only pain or mild deficits is about 50%.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Immune-mediated non-erosive polyarthritis and SRMA. • Discospondylitis and UTI. • FeLV and feline spinal lymphoma. • Polymyositis and lymphoma. • Polymyopathies/myositis—megaesophagus/dysphagia and aspiration pneumonia.

ABBREVIATIONS
• AA = atlantoaxial. • AST = aspartate aminotransferase. • CK = creatine kinase. • COMS = caudal occipital malformation syndrome. • CSM = cervical spondylomyelopathy (wobbler). • EMG = electromyography. • FeLV = feline leukemia virus. • FIP = feline infectious peritonitis. • FNA = fine-needle aspiration. • GME = granulomatous meningoencephalomyelitis. • ICP = intracranial pressure. • IVDH = intervertebral disc herniation. • MUO = meningoencephalomyelitis of unknown origin. • NSAID = nonsteroidal anti-inflammatory drug. • SR = slow release (drug formulation). • SRMA = steroid-responsive meningitis-arteritis. • UTI = urinary tract infection.

Author Luis Gaitero

NECROTIZING ENCEPHALITIS

BASICS

OVERVIEW
• Historically restricted to a few breeds such as the pug, Yorkshire terrier, and Maltese dog. Described nowadays also in other breeds such as the Chihuahua, the shih tzu, and others. Even described in large-breed dogs. The disease includes necrotizing meningoencephalitis (NME) and necrotizing leukoencephalitis (NLE), since an overlap of clinical signs and histopathologic findings occurs.
• Systems affected—nervous.
• Genetics—a genetic basis (genetic risk loci) detected in pug dogs, Maltese dogs, and toy dog breeds; multifactorial disorder suspected.
• Incidence/prevalence—not determined but disease occurring regularly.
• Geographic distribution—occurs worldwide, mostly seen in toy breeds.

SIGNALMENT
Breed Predilections
Maltese, pugs, Yorkshire terriers, French bulldogs, Chihuahuas, shih tzus, Pekingese, and other toy breeds.

Mean Age and Range
Mostly young adult dogs (range 4 months–10 years).

Predominant Sex
No sex predilection.

SIGNS
Progressive signs related to a forebrain lesion (abnormal behavior, seizures, circling, blindness), brainstem lesions with central vestibular signs, or a multifocal lesion.

CAUSES & RISK FACTORS
• Genetic risk factors.
• An infectious agent might be suspected, but was never confirmed; multifactorial disorder, autoimmune disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other CNS inflammatory/infectious diseases—differentiated on serology, CSF, MRI, and brain biopsy results.
• Neoplasia—differentiated on MRI findings and brain biopsy results.

CBC/BIOCHEMISTRY/URINALYSIS
Results are usually normal.

OTHER LABORATORY TESTS
Genetic test for predisposition.

IMAGING
MRI—results help support the clinical diagnosis considering breed, age, clinical signs, and course of the disease. Lesions may be asymmetric, multifocal prosencephalic with varying contrast enhancement, and can include multiple cystic areas of necrosis.

DIAGNOSTIC PROCEDURES
• CSF—pleocytosis with predominantly mononuclear cells; mild to marked protein elevation.
• Brain biopsy—to confirm diagnosis.

PATHOLOGIC FINDINGS
• Necrosis and nonsuppurative inflammation of the cerebral gray and white matter; multifocal lesions; active lesions consist of a large malacic gliotic center surrounded by a wall of severe mononuclear inflammation.
• Old lesions consist of rarefied or cystic areas surrounded by intense astroglial sclerosis.

TREATMENT
• Inpatient or outpatient based on the neurologic status.
• Symptomatic treatment recommended.

Client Education
• Disease cannot be treated specifically; improvement with anti-inflammatory or immunosuppressive drugs.
• Seizures may be the only sign at onset of the disease in pug dogs; diagnostic workup including MRI in pug dogs presented with seizures is recommended.

MEDICATIONS

DRUG(S) OF CHOICE
• Symptomatic treatment.
• To control seizures, phenobarbital 2–6 mg/kg PO q12h.
• Corticosteroids can reduce the inflammatory response and improve clinical signs (e.g., prednisolone or prednisone 1–2 mg/kg PO q24h for the first 1–2 weeks; then the dosage can be tapered slowly); frequently used medication: cytosine arabinoside 50 mg/m^2 SQ q12h for 2-4 days, repeat about every 4 weeks (other dosage regimens possible); other immunosuppressive drugs are used successfully.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

Alternative Drug(s)
Procarbazine, azathioprine, cyclosporine, leflunomide, lomustine, mycophenolate mofetil.

FOLLOW-UP

PATIENT MONITORING
• Regular clinical and neurologic examinations to monitor response to symptomatic treatment.
• Monitoring of seizures and phenobarbital serum levels.

PREVENTION/AVOIDANCE
N/A

EXPECTED COURSE AND PROGNOSIS
• The course of the disease is chronic for months or even years; in every confirmed case, the neurologic signs have been progressive.
• Prognosis is guarded, survival with good quality of life in part of the cases.

MISCELLANEOUS

ASSOCIATED CONDITIONS
In one pug dog, myocardial necrosis was seen in addition to the encephalitic lesions.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Three pugs described in Japan had a history of pregnancy before onset of clinical signs.

ABBREVIATIONS
• NLE = necrotizing leukoencephalitis.
• NME = necrotizing meningoencephalitis.

Suggested Reading
Flegel T. Breed-specific magnetic resonance imaging characteristics of necrotizing encephalitis in dogs. Front Vet Sci 2017, 864:203.

Author Andrea Tipold

N

NEONATAL MORTALITY AND CANINE HERPESVIRUS

BASICS

DEFINITION
• Death occurring between birth and 2–3 weeks of age. • Fading syndrome describes a clinical presentation rather than a specific etiology.

PATHOPHYSIOLOGY
• Four major factors lead to vulnerability of neonates—poorly developed thermoregulatory mechanisms; increased risk of dehydration (immature kidney function); increased risk of hypoglycemia (small reserve of glycogen); and immunologic immaturity (95% of antibodies from derived from colostrum). • Highly susceptible to environmental, infectious, nutritional, and metabolic factors.

SYSTEMS AFFECTED
All systems.

SIGNALMENT
• Puppies and kittens. • Pedigree puppies, kittens—more prone to congenital and hereditary defects, higher overall incidence of stillbirth and neonatal mortality.

SIGNS

General Comments
• Preweaning mortality —typically 10–30%; about 65% occur during first week; greater losses in a cattery or kennel should be considered abnormal. • Thorough history vital to identify potential causes; attention should be given to signalment, breeding history, vaccination, deworming history, exposure to toxins, problems during parturition, size of litter, feeding regimen, whelping environment, mothering abilities.

Historical Findings
• Low birth weight, loss of weight, failure to gain weight. • Decreased activity, appetite. • Weakness. • Poor suckling response. • Constantly vocal or restless early, quiet and inactive later. • Separation from dam and rest of litter. • Low Apgar scores at birth (see Neonatal Resuscitation and Early Neonatal Care).

Physical Examination Findings
• Nonspecific. • Dark red or bluish ventral abdominal skin indicates sepsis or cyanosis. • Red to purple toes, swollen red and/or purulent umbilical stump may indicate sepsis. • Gross anatomic defects—e.g., cleft palate, imperforate anus, pectus excavatum, asymmetry of limbs; abnormal haircoat over dorsum may indicate spina bifida. • Weakness, hypothermia (newborn temperature is 34.7–37.2°C [94.5–99°F], rising to 36.1–37.8°C [99–100°F] during first week of life); hypoglycemia and dehydration are common interrelated findings. • Respiratory distress, diarrhea, hemoglobinuria.

CAUSES
Infection, poor maternal management, low birthweight and congenital abnormalities most common.

Noninfectious
• Dam-related—dystocia or prolonged labor, cannibalism, lactation failure, trauma, inattention or overattention, inadequate nutrition (e.g., taurine deficiency in kittens). • Signalment—breed, older dam, larger litters associated with mortality rate. • Environmental—factors that discourage nursing and allow hypothermia including temperature or humidity extremes, inadequate sanitation, overcrowding, stress. • Nutritional—inadequate, ineffective nursing, hypoglycemia, hypothermia-induced digestive dysfunction. • Neonatal isoerythrolysis—queen with blood type B, kitten with blood type A.

Birth Defects
• Gross anatomic defects—more frequent in kittens than puppies. • Alimentary—cleft palate, segmental intestinal agenesis/atresia, imperforate anus, congenital megaesophagus, portosystemic shunt, mucopolysaccharide storage disease. • Cardiac defects—valvular dysplasia, ventricular septal defect, atrioventricular fistula, tetralogy of Fallot, patent ductus arteriosis, congenital rhythm disorders. • Respiratory defects—thoracic wall abnormalities, pectus excavatum, ciliary dyskinesia, surfactant deficiency. • Renal defects—agenesis, dysplasia, fanconi syndrome, polycystic kidney disease, ureteral abnormalities. • Endocrine—diabetes mellitus, hypothyroidism, hyposomatrotropism, central diabetes insipidus. • CNS—cerebellar hypoplasia and abiotrophy, hydrocephalus, spinal dysraphism, neuronopathies, lysosomal storage disease. • Hematologic—coagulopathies, von Willebrand disease, pyruvate kinase deficiency, hemolytic anemia, phosphofructokinase deficiency. • Immune system—thymus dysfunction, atrophy. • Miscellaneous—anasarca, skin or ocular defects.

Infectious
• Viral: ◦ Kittens—feline calicivirus; feline leukemia virus (FeLV); feline immunodeficiency virus (FIV); feline herpesvirus type 1, feline panleukopenia virus. ◦ Puppies—canine adenovirus type 1; canine distemper virus; canine herpesvirus-1 (CHV-1); canine parvovirus type 1 (minute virus) and type 2; canine influenza virus, canine coronavirus. • Bacterial—acquired mainly across placenta or via umbilicus but also through gastrointestinal tract, respiratory tract, urinary tract, skin wounds: ◦ *E. coli*, β-hemolytic *Streptococcus*, coagulase-positive *Staphylococcus*, *Salmonella* spp., *Campylobacter* spp., *Bordetella bronchiseptica*, *Pasteurella multocida*, *Brucella canis*, *Leptospirosis*. • Parasitic: ◦ Helminths—*Toxocara* spp., *Ancylostoma* spp. ◦ Protozoal—*Toxoplasma*, *Neospora*, *Cryptosporidium*, *Giardia*. ◦ Coccidia—*Isospora*.

RISK FACTORS
• Low birth weight, failure to gain weight; gain of 5–10% body weight per day acceptable: ◦ Kittens: minimum daily gain of 7–10 g. ◦ Puppies: should double in weight by 10–12 days. • Dystocia or prolonged labor. • Inbreeding—higher incidence of homozygous recessive genotype. • Blood type mismatch (cats). • Increased litter size, older dam, certain breeds. • CHV-1 is temperature sensitive; cold puppies more susceptible.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Excessive losses often due to combination of environmental, immunologic, nutritional, infectious, and metabolic factors; detection and correction of all necessary to prevent ongoing losses.

CBC/BIOCHEMISTRY/URINALYSIS

CBC
• Hydration status and age influence results. • Mild normocytic, normochromic anemia (normal packed cell volume at 1 week 33–52%, at 2 weeks 29–34%). • White blood cell concentration variable; thrombocytopenia and neutrophilia (with left shift) if septic.

Biochemistry
• Hypoglycemia. • Hypocholestrolemia, hypertriglyceridemia. • Low alkaline phosphatase activity, hypophosphatemia. • Low gamma-glutamyltransferase activity—indicates failure to receive colostrum. • Other changes depend on organ system.

Urinalysis
• Hemoglobinuria—with neonatal isoerythrolysis. • Bacteria—with infection. • Urine specific gravity >1.017 suggests inadequate hydration.

OTHER LABORATORY TESTS
• FeLV/FIV tests. • Serology—*Brucella canis*; CHV-1; canine influenza virus; *Toxoplasma*; *Neospora*; *Leptospirosis*.

IMAGING
• Abdominal ultrasound. • Thoracic and abdominal radiographs can show aspiration pneumonia, gastrointestinal obstruction, but difficult to obtain diagnostic films (low contrast).

(CONTINUED) # NEONATAL MORTALITY AND CANINE HERPESVIRUS

DIAGNOSTIC PROCEDURES

• Histopathologic—tissues collected at necropsy. • Metabolic urine screening—rule out inborn errors of metabolism. • Virus isolation. • Bacterial culture. • PCR of placenta or fetal tissues—*Brucella canis*; CHV-1; *Toxoplasma*; *Neospora*; *Leptospirosis*. • Blood typing in cats (dam and kitten). • Fecal examination.

PATHOLOGIC FINDINGS

• Post-mortem—important; examine as soon after death as possible to minimize autolysis: ◦ Stomach—empty: lack of nursing; consider dam-related causes or neonatal problems; filled with milk: suggests sudden death or digestive dysfunction. ◦ Thymus small—not necessarily thymic dysfunction; atrophy can be a result of multiple causes (e.g., viral infection, stress, toxins, nutrition, defective immune system). ◦ Petechiation—common; suggests coagulopathy or septicemia. ◦ Urine in urinary bladder—implies renal dysfunction or inadequate care by dam. ◦ Lungs—homogeneous dark red color typical of a stillborn animal that has not taken a breath; hemorrhage, edema, congestion, mottled color abnormal but nonspecific. ◦ CHV-1—renal hemorrhage, multifocal areas of necrosis in lungs and liver are pathognomonic findings. • Note malformations. • Multiple tissue samples—submit to diagnostic laboratory; virus isolation, bacterial culture and sensitivity, PCR, histopathology; check with laboratory for proper submission.

TREATMENT

• Correct deficiencies in husbandry or breeding selection. • Warmth—slowly warm neonate to 36–37.2°C (97–99°F) by 1°C per hour, if necessary; provide ambient temperature of 29–35°C (85–95°F) and relative humidity of 55%–65%. • Oxygen—supplement at 30–40%, if necessary. (Difficult to detect hypoxia as puppies and kittens do not always hyperventilate; clinical signs can include increased respiratory effort, bradycardia, hypotension, distended abdomen due to aerophagia.) • Fluid therapy—IV via jugular or cephalic vein; intraosseous in femur or humerus. • Fluid requirements: 80–100 mL/kg/day, or 3-6 mL/kg/h using balanced isotonic replacement crystalloid; volume overload can occur due to immature kidney function • Dextrose supplementation—0.5–1.0 g/kg IV/IO, given as a bolus, diluted to 5% dextrose in isotonic replacement crystalloid; then administered as CRI (2.5–5% dextrose in crystalloids) as needed. • Do not attempt to feed if body temperature <35°C (95°F) and no sucking reflex; once warmed, encourage nursing. • Neonatal isoerythrolysis—prevent nursing for first 24 hours after birth; provide alternative colostrum, strip dam's colostrum before allowing kittens to nurse. • CHV-1—prevention is key; antiviral medication has not proven effective; CHV-1 vaccine available in Europe.

MEDICATIONS

DRUG(S) OF CHOICE

• Antibiotics—penicillins (penicillin G, ampicillin, amoxicillin, amoxicillin with clavulanic acid) and first-generation cephalosporins preferred; reduce adult dose by one-half and use same dosage interval. • Supplement—milk replacer; serum or plasma can be provided (10–20 mL/kg PO, split in 2–4 feedings in first 24 hours of life) as colostrum supplement. • Vitamin K1 0.01–0.1 mg SC or IM, once.

CONTRAINDICATIONS

Aminoglycosides, tetracyclines, fluoroquinolones, trimethoprim/sulfonamide, chloramphenicol—avoid during neonatal period.

PRECAUTIONS

Drug absorption, distribution, metabolism, and excretion during first 5 weeks of life differs from adults.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

• Hydration—monitor regularly (mucous membranes, urine specific gravity, nursing and urination). • Body weight—monitor daily or every other day. • Dam—monitor mothering abilities and milk production; supplement nutrition to neonates if required.

POSSIBLE COMPLICATIONS

N/A

MISCELLANEOUS

ZOONOTIC POTENTIAL

Some infectious agents have zoonotic potential (e.g., *Toxoplasma*, *Leptospira*, *Brucella*).

PREGNANCY/FERTILITY/BREEDING

Do not breed individuals with congenital defects.

SYNONYMS

• Fading puppy or kitten syndrome. • Wasting syndrome.

ABBREVIATIONS

• CHV-1 = canine herpesvirus-1. • FeLV = feline leukemia virus. • FIV = feline immunodeficiency virus.

N

NEONATAL RESUSCITATION AND EARLY NEONATAL CARE

BASICS

DEFINITION
The neonatal period is defined as the first 3 weeks of extrauterine life. It is a delicate period where neonates are particularly susceptible to disease as well as congenital pathology. Neonatal organ systems including renal and hepatic function, gastrointestinal disease, and basic reflexes such as gagging, shivering, and thermoregulation are undeveloped or absent. Efforts to assist the neonate with cardiopulmonary function and consciousness during the immediate period following birth is referred to as neonatal resuscitation.

SIGNALMENT
Young puppies and kittens less than 3 weeks of age.

SIGNS
- Poor weight gain (<5–10% of body weight per day) is the earliest sign of failure to thrive.
- Hypothermia (normal body temperature for 1st week of life is 35–36°C [95–97°F]).
- Hypoglycemia.
- Hypovolemia (concentrated urine, dry or tacky mucous membranes).
- Bradycardia (normal 200–250 bpm at birth, 180–200 bpm until 2 weeks).
- Excessive crying.
- Weak or absent suckle reflex.

RISK FACTORS
- Dystocia.
- Prolonged stage 2 labor >5 hours.
- Decreased Apgar score within 8 hours of life (6 or lower on a 10-point scale; see Table 1).
- Low birth weight (less than 50% of average litter weight).
- Agalactia.
- Failure of passive transfer.
- Improper hygiene.
- Bacterial or viral infections.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Congenital defects.
- Bacterial sepsis.
- Failure of passive transfer.
- Viral infections.

CBC/BIOCHEMISTRY/URINALYSIS
- Alkaline phosphatase and gamma-glutamyltransferase enzyme activities—markedly elevated in neonates that have ingested colostrum.
- Urine—color is best indication of hydration status; should be nearly colorless in healthy neonate; brown color may indicate hemoglobinuria in kittens with neonatal isoerythrolysis.

OTHER LABORATORY TESTS
N/A

IMAGING
Thoracic radiography—helpful in diagnosis of aspiration pneumonia, a common cause of neonatal mortality.

PATHOLOGIC FINDINGS
- Congenital abnormalities such as cleft palate, atresia ani, omphalocele, anasarca, etc. may be noted at the time of birth. Many breeders will opt for euthanasia in these instances.
- Renal petechiation may indicate herpesvirus infection.
- On necropsy, clotted milk in the stomach often indicates intestinal ileus secondary to hypothermia. Only saliva in the stomach may indicate death secondary to starvation and failure of the bitch to produce milk.
- If possible, submit both deceased neonate and placenta for necropsy.

TREATMENT
- Vigorous external rubbing with a warm dry towel is sufficient for neonatal resuscitation at birth. Suction may be warranted to clear secretions from airway. "Swinging" neonates to clear airways is contraindicated and may result in cerebral hemorrhage.
- Cyanotic or pale mucous membranes at birth necessitate oxygen administration or mouth-to-mouth resuscitation.
- Bradycardia during the first 4 days is not vagally mediated and is indicative of hypoxemia.
- Warm slowly if body temperature is below 34.5°C (94°F). External heat sources are best, or warmed interosseous or IV fluids may be used.
- Do not feed unless body temperature is greater than 34.5°C (94°F) due to presence of intestinal ileus.
- Milk should be given in the form of commercially available milk replacer. Homemade formula and goat's milk are deficient in arginine and may result in cataract formation.
- Only feed neonates via a bottle if they are warm and have a strong suckle reflex. As neonates cannot gag during the first week of life, it is the author's preference that all neonates be fed via orogastric intubation until strong enough to nurse due to the risk of aspiration pneumonia. Droppers, cosmetic sponges, and syringe feeding are not recommended feeding methods due to excessive swallowing of air and high risk of aspiration.
- IV or intraosseous fluids are treatment of choice for hypovolemia. Neonates poorly absorb SQ fluids due to lack of fat. All fluids should be warmed before administration to avoid hypothermia.

MEDICATIONS

DRUG(S) OF CHOICE

Neonatal Resuscitation Drugs
- Epinephrine 0.2 mg/kg IV, in umbilical vein or intraosseous route if cardiac arrest.
- Naloxone 0.1 mg/kg IM, only if opioids used during anesthesia of bitch.
- Doxapram—unlikely to be beneficial due to lack of efficacy in stimulating hypoxic neonates.

Antibiotics for Neonatal Sepsis
- Ceftiofur sodium (Naxcel) 2.5 mg/kg SQ q12h.
- Amoxicillin/clavulanic Acid (Clavamox) 13.75 mg/kg PO q12h.

Plasma or Serum for Failure of Passive Transfer
- Live donor can be used or commercially-available fresh frozen plasma at body temperature.
- For puppies: 22 mL/kg divided and administered SQ. Half dose can be administered PO if neonate is less than 12 hours old.
- For kittens: 15 mL per kitten, SQ, in 5 mL boluses given at birth, at 12 hours, and 24 hours of age.

Pain Control
- Opioids (fentanyl, buprenorphine) may be used with careful monitoring.

CONTRAINDICATIONS
- Fluoroquinolones may be used safely in neonates until 3 weeks of age. Afterwards there is a risk of cartilage defects with use.
- Tetracyclines (doxycycline), aminoglycocides (amikacin), and chloramphenicol should not be used unless absolutely necessary due to systemic effects.
- Metronidazole is contraindicated in patients younger than 2 weeks of age.
- Atropine is contraindicated during neonatal resuscitation due to exacerbation of myocardial hypoxemia.
- Nonsteroidal anti-inflammatory drugs should not be used in neonates due to potential for renal injury.

FOLLOW-UP

PATIENT MONITORING
Weight gain should be monitored daily at home using a scale capable of measuring

(CONTINUED) NEONATAL RESUSCITATION AND EARLY NEONATAL CARE

Table 1

Apgar scoring: each row is scored based on newborn activity and scores added together to obtain full Apgar score. A score of 7–10 indicates no distress, 4–6 indicates moderate distress, and 0–3 severe distress. Scoring should be performed at 5 minutes, 30 minutes, and 2 hours after birth.

	0	*1*	*2*	*Score:*
Mucous membrane color	Cyanotic	Pale	Pink	
Heart rate	<180 bpm	180–220 bpm	>220 bpm	
Respiratory effort/rate	No crying/<6 rpm	Mild crying/6–15 rpm	Crying/>15 rpm	
Reflex irritability	Absent	Feeble reaction (grimace)	Vigorous reaction (grimace/vocalization)	
Mobility, muscle tone	Flaccid	Some tone in extremities	Active movements	
Suckling (scored as –, +, ++)				
Rooting (scored as –, +, ++)				

Source: From Wilborn (2018). Reprinted with permission of Elsevier.

grams or ounces (kitchen scale). Failure to gain weight is the first clinical sign of a problem and should not be ignored.

PREVENTION/AVOIDANCE

- Neonates should be kept separate from other animals for the first 3 weeks postpartum to avoid disease transmission.
- Good environmental hygiene is imperative.
- Environmental temperatures should be kept warm yet comfortable (19.5–24°/67–75°F) and free of drafts in order to prevent the dam from leaving the whelping box. Increased temperatures of 27–32°C (80–90°F) are only required if puppies are orphaned.
- Ensure colostrum ingestion during the first 12 hours of life. If dam is not producing milk, or neonate is orphaned, serum or plasma should be given to provide immunoglobulins, but colostrum should be the first line of defense.
- Ensure the umbilicus is clamped and cleaned with a tincture of iodine solution immediately following birth to prevent ascending umbilical infections.
- Dam's mammary glands should be inspected daily for cleanliness and early signs of mastitis. Neonatal septicemia has been reported to occur secondary to bacterial exposure via the dam's milk.
- Probiotics can be given to minimize diarrhea associated with antibiotic use. Pastes and powders can be mixed into milk replacer or dabbed under the tongue to provide dosage without a risk of aspiration.

POSSIBLE COMPLICATIONS

Highest mortality rate occurs within the first 7 days of life (17–30% in dogs).

EXPECTED COURSE AND PROGNOSIS

- Depends on underlying cause—many "fading puppies/kittens" can be saved with early recognition and intervention.
- Bacterial sepsis and herpesvirus infections in puppies have fair to poor prognosis.

NEONICOTINOID TOXICOSIS

BASICS

OVERVIEW

- Neonicotinoids are a class of insecticides referred to as nitroguanidines, neonicotinyl, chloronicotines, and most recently as chloronicotinyls. Neonicotinoids are chemically similar to nicotine.
- Like nicotine, neonicotinoid insecticides act as agonists to nicotinic acetylcholine receptors.
- They act on insects at three different postsynaptic nicotinic receptors found in CNS.
- Wide safety margin in mammals due to high selectivity for specific subtypes of nicotinic receptors in insects.
- Compounds used in veterinary products include imidacloprid, nitenpyram and dinotefuran. Other common neonicotinoid products on the parket include acetamiprid, clothianidin, nithiazine, sulfoxaflor, and thiamethoxam.
- Widespread use in veterinary medicine for flea control. Used as oral tablets and in collars and topical spot on products.
- Used in termite and grub control and crop production against sucking and chewing pests in a variety of formulationsas well as ant and roach baits.

SIGNALMENT

- Primarily dogs—chewing up ant bait containers, collars, boxes of tablets, bags, liquid products.
- Rarely reported in cats.

SIGNS

- Imidacloprid has low toxicity in mammals. Results of a chronic feeding study revealed no adverse effects in dogs given imidacloprid at a dose of 15 mg/kg/day for a year. Topical application in dogs and cats at a dose of 50 mg/kg also caused no adverse effects.
- Most common adverse effects observed were decreased activity, tremors, mydriasis or miosis and uncoordinated gait; hypothermia was observed at higher doses.
- Alopecia and erythema have been reported following dermal application.
- Due to the large safety margin of safety margin in mammals, CNS signs are rarely seen.
- Oral toxicity is possible if the concentration or dose is excessively high.

CAUSES & RISK FACTORS

- Dietary indiscretion in dogs increases risk of exposure.
- Wide availability and frequent access to products.

DIAGNOSIS

History of exposure and clinical signs.

TREATMENT

- Dermal exposure—bathe with liquid dishwashing detergent.
- Oral exposure—dilute with cool water, emesis, gastric lavage, activated charcoal, depending on amount ingested, time of ingestion, and clinical signs.
- Baseline CBC, chemistry profile, and urinalysis to rule out any preexisting organ dysfunction, which could increase the risk for toxicosis.
- Antihistamines and/or dexamethasone SP for signs of dermal hypersensitivity.
- Methocarbamol for tremors.
- IV or SC fluids (crystalloid) as needed for dehydration.

MEDICATIONS

- Dog emesis—apomorphine 0.04 mg/kg IV.
- Cat emesis—dexmedetomidine 7 mcg/kg IM or IV; or xylazine 0.44 mg/kg IM or SC. Avoid hydrogen peroxide due to risk for hemorrhagic gastroenteritis.
- Activated charcoal with a cathartic (sorbitol), 1 g/kg × one dose.
- Methocarbamol 50–220 mg/kg IV. Max daily dose 330 mg/kg/day (cats and dogs). Give 1/2 dose rapidly, wait until animal relaxes, and give remainder of dose to effect.
- Diphenhydramine (dog and cat): 2–4 mg/kg IM, PO q8–12 hours; 0.5–2 mg/kg IM, IV, SC.
- Dexamethasone sodium phosphate: 0.5 mg/kg IV (dog); 0.125–0.5 mg per cat IM or IV.

FOLLOW-UP

Patients usually recover with symptomatic and supportive care; no long-term organ damage is expected.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Puppies/young dogs are less discriminating and more likely to chew up product containers.
- Young and geriatric animals may have lower detoxification capabilities.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Studies confirmed that imidacloprid is not mutagenic, non-embryotoxic, and nonteratogenic.

NEOSPOROSIS

BASICS

OVERVIEW
- *Neospora caninum*—obligate, intracellular, coccidial, protozoan.
- Domestic and wild canids excrete infective oocysts in feces; numerous ruminant intermediate hosts.
- Transmission—vertical (transplacental or transmammary), ingestion of sporulated oocysts in dog feces, or ingestion of infected tissues from intermediate hosts.
- Disease caused by necrosis and inflammation from cyst rupture and tachyzoite invasion.
- Neurologic disease in dogs; other organ systems less commonly affected.

SIGNALMENT
- Dogs—puppies and adults.
- Cats—experimentally infected; antibodies in domestic and wild cats without known disease; *N. caninum* myocarditis reported in adult lion.

SIGNS
- Young dogs (4 weeks to 6 months of age)—ascending lower motor neuron paralysis, myositis, muscle atrophy, fibrous muscle contracture, and arthrogryposis; may progress to tetraparesis/plegia, trismus, dysphagia, hypoventilation; subclinical disease of other organ systems possible; less common: meningoencephalomyelitis, hepatitis, myocarditis, pneumonia, acute dyspnea, sudden death.
- Adult dogs—meningoencephalomyelitis and/or polymyositis; lesions can be found anywhere in CNS but have predilection for the cerebellum, resulting in slowly progressive cerebellar ataxia ± other cerebellovestibular signs; uncommonly affects other organs.
- Nodular dermatitis, particularly in immunosuppressed dogs.

CAUSES & RISK FACTORS
Raw meat may be a risk factor; should be avoided.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Other infectious disease (toxoplasmosis, sarcocystosis, hepatozoonosis, mycoses, rabies, canine distemper), neuronal storage diseases, noninfectious meningoencephalomyelitis or polymyositis, or immune-mediated neuromuscular disease, neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
- Dependent on the organ system involved.
- Muscle involvement—creatine phosphokinase and aspartate aminotransferase activities increased.

OTHER LABORATORY TESTS
- CSF analysis—normal to markedly increased total nucleated cell count; mononuclear pleocytosis more common than neutrophilic or eosinophilic; elevated total protein.
- Serologic testing (IFA, ELISA, and immunoprecipitation)—CSF or serum.
- Antibodies do not crossreact with *Toxoplasma gondii*, but do with *Neospora hughesi*, an equine protozoan.
- Organism detection—oocysts in feces; must distinguish from *Hammondia* spp.
- Tachyzoites in aspirates, smears, or biopsies need to be differentiated from those of *Toxoplasma* (immunohistochemistry).
- PCR—diagnostic tool, distinguishes between other parasites.

IMAGING
MRI of adult dogs—moderate to marked cerebellar atrophy with or without meningeal contrast enhancement; single or multifocal T2-weighted hyperintensities that contrast enhance within the CNS or muscles.

DIAGNOSTIC PROCEDURES
Muscle biopsy in dogs with myositis can identify organism by microscopy or PCR.

PATHOLOGIC FINDINGS
- Nonsuppurative encephalomyelitis.
- Severe nonsuppurative inflammation of cerebellar leptomeninges and cortex (more severe than that caused by *T. gondii*); cerebellar atrophy.
- Myositis, myofibrosis.
- Polyradiculoneuritis.
- Pneumonia, cerebellar atrophy, multifocal necrotizing myocarditis, and nodular dermatitis possible.
- Ulcerative and pyogranulomatous dermatitis.
- Histology—differentiate by location in host cell cytoplasm (*T. gondii* within a parasitophorous vacuole).
- Tissue cysts—those of *N. caninum* have thicker walls; differentiated from *T. gondii* by immunohistochemistry.
- Electron microscopy—rhoptries of *N. caninum* tachyzoites electron dense; those of *T. gondii* honeycomb.

TREATMENT
- Long treatment period (min. 8 weeks); continue treatment 2 weeks beyond plateau of clinical improvement.
- Consider treatment of all puppies with infected littermates.
- Avoid immunosuppression if possible.

MEDICATIONS

DRUG(S) OF CHOICE
- Ideal treatment unknown; clindamycin most commonly used but bradyzoites persist despite treatment.
- Clindamycin 10–20 mg/kg PO q12h.
- Trimethoprim-sulfadiazine (TMS) 15 mg/kg PO q12h.
- Combination therapy—clindamycin and TMS, clindamycin and pyrimethamine (1 mg/kg PO q24h), or TMS and pyrimethamine.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
- Progression of clinical disease might cease with treatment.
- Once muscle contracture or ascending paralysis has occurred, prognosis for clinical improvement is poor.
- Serologically test dam or other in-contact dogs and cattle.

MISCELLANEOUS

ZOONOTIC POTENTIAL
N/A

SEE ALSO
Toxoplasmosis

ABBREVIATIONS
- TMS = trimethoprim-sulfadiazine.

NEPHROLITHIASIS

BASICS

DEFINITION
• Nephroliths—uroliths located in the renal pelvis or collecting diverticula of the kidney.
• Nephroliths or nephrolith fragments may pass into the ureters (ureteroliths).
• Nephroliths that are not infected, causing obstruction or clinical signs, or progressively enlarging are termed *incidental* nephroliths.

PATHOPHYSIOLOGY
Nephroliths can obstruct the renal pelvis or ureter, predispose to pyelonephritis, and lead to compressive injury of the renal parenchyma and chronic kidney disease (CKD); see urolithiasis chapters for pathophysiology.

SYSTEMS AFFECTED
• Renal/urologic—affects the urinary tract, with potential for obstruction, recurrent urinary tract infection (UTI), or progressive CKD.
• Obstruction of the renal pelvis or ureter with pyelonephritis may result in septicemia and affect any body system.

GENETICS
See specific chapter on type of stone.

INCIDENCE/PREVALENCE
• Nephroliths comprise 1–1.5% of uroliths submitted to the Minnesota Urolith Center for analysis. The true incidence of nephroliths is likely higher. Many animals with nephroliths are asymptomatic, or are not treated by methods that allow retrieval of uroliths for analysis.
• Composition of canine nephroliths submitted for analysis, in descending frequency: calcium oxalate, struvite, compound, purines, calcium phosphate, cystine, and silica. Composition of nephroliths in cats (descending frequency): calcium oxalate, dried solidified blood calculi, compound, struvite, calcium phosphate, and purine.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Dogs
• Calcium oxalate—shih tzu, Yorkshire terrier, bichon frise, miniature schnauzer, and Maltese.
• Struvite—miniature schnauzer, shih tzu, pug, and miniature poodle.
• Purine—English bulldog, Dalmatian, Yorkshire terrier, and shih tzu.
• Cystine—Newfoundland, English bulldog, and French bulldog.

Cats
Domestic shorthair, European and American shorthair, domestic longhair, Persian, Siamese and Scottish fold.

Mean Age and Range
• Dogs—mean age 10 years (range 2 months–21.5 years).
• Cats—mean age 7.7 years (range 5 months–19.5 years).

Predominant Sex
• Dogs—nephroliths slightly more common in females than males; struvite nephroliths, females > males; however, calcium oxalate, cystine, and urate nephroliths males > females.
• Cat— nephroliths slightly more common in females than males; for calcium oxalate females > males; however, noncrystalline matrix (includes dried blood), and urate nephroliths males > females.

SIGNS

General Comments
Many patients are asymptomatic, and the nephroliths are diagnosed during evaluation of other problems.

Historical Findings
• None or hematuria, vomiting, and recurrent UTI; dysuria and pollakiuria in animals with UTI or concomitant urocystoliths.
• Uremia in animals with bilateral obstruction or nonfunctional contralateral kidney.
• Signs referable to lower urinary tract urolithiasis if uroliths are present in the upper and lower urinary tract.
• Renal colic with acute abdominal/lumbar pain and vomiting is possible.

Physical Examination Findings
Abdominal or lumbar pain upon palpation of kidneys or no significant findings.

CAUSES
See chapters on each urolithiasis.
Oversaturation of the urine with calculogenic minerals is a risk factor for urolithiasis.

RISK FACTORS
• Alkaluria—struvite and calcium phosphate uroliths.
• Aciduria—calcium oxalate, cystine, urate, and xanthine uroliths.
• Urine retention and formation of highly concentrated urine.
• Lower UTI—ascending infection and pyelonephritis.
• Conditions that predispose to UTI.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Consider nephroliths in any patient with CKD, recurrent UTI, acute vomiting (pancreatitis, gastroenteritis, intestinal or gastric obstruction, etc.), or abdominal or lumbar pain (e.g., intervertebral disc protrusion, peritonitis).
• Nephroliths are usually confirmed by radiographs or ultrasonography; differentiate mineralization of the renal pelvis or collecting diverticula from true nephrolithiasis.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—usually normal; patients with pyelonephritis may have leukocytosis, immature neutrophilia, and thrombocytopenia.
• Serum biochemistry—usually normal unless bilateral obstruction, pyelonephritis, or compressive renal injury leads to acute kidney injury (AKI) or CKD; hypercalcemia may contribute to formation of calcium oxalate or calcium phosphate nephroliths.
• Urinalysis—may reveal hematuria and crystalluria; crystal type may suggest mineral composition; pyuria, proteinuria, and bacteriuria may also be seen with UTI.

OTHER LABORATORY TESTS
• Submit nephroliths or nephrolith fragments for quantitative analysis.
• Urine culture may confirm UTI or concurrent pyelonephritis.

IMAGING
• Can detect radiopaque nephroliths (e.g., calcium phosphate, calcium oxalate, struvite) by survey radiography; cystine and silica are slightly radiopaque.
• Purines (urate or xanthine) are often radiolucent or faintly radiopaque when large unless they contain other radiodense minerals.
• Use ultrasonography or contrast CT to confirm, size and number of nephroliths or ureteroliths.

DIAGNOSTIC PROCEDURES
After extracorporeal shock wave lithotripsy (ESWL), fragments can be retrieved for quantitative analysis by voiding, cystoscopic basket retrieval, or voiding urohydropropulsion.

TREATMENT

APPROPRIATE HEALTH CARE
Manage patients with incidental nephroliths as outpatients. When appropriate, medical dissolution protocols can be administered to outpatients. Removal of nephroliths by surgery or ESWL requires hospitalization.

DIET
Medical dissolution of nephroliths requires a diet appropriate for the specific nephrolith type. See Medications.

(CONTINUED) NEPHROLITHIASIS

CLIENT EDUCATION

• Incidental nephroliths—may not require removal but should be monitored periodically by urinalysis, urine culture, and radiography. Nephroliths may cause obstruction at any time, which can result in hydronephrosis without clinical signs. Conservative management and monitoring carries a risk of undetected and potentially irreversible renal damage, which must be weighed against the potential renal damage from nephrotomy.
• Nephroliths often recur after removal; monitor the patient every 3–6 months.

SURGICAL CONSIDERATIONS

• Indications for removal of canine nephroliths—obstruction, recurrent infection, progressive nephrolith enlargement, and a nonfunctional contralateral kidney. In cats, only obstructive uroliths in the renal pelvis or ureters are treated (see Ureterolithiasis).
• Treatment options for nephroliths—medical dissolution, surgery, and ESWL. Calcium oxalate is the most common nephrolith in dogs and cats, and is not amenable to medical dissolution. Medical dissolution of nephroliths causing outflow obstruction requires endoscopic or surgical placement of a ureteral stent.
• Surgical options—nephrotomy, percutaneous endoscopic nephrolithotomy, or surgically assisted endoscopic nephrolithotomy. Endoscopic nephrolithotomy may be preferred over ESWL for nephroliths >1.5 cm in diameter.
• ESWL—safe and effective method of treating canine nephroliths and ureteroliths; nephrolith fragments pass down the ureter into the bladder and are voided with urine or removed by voiding urohydropropulsion. Large (1–1.5 cm) nephroliths may be managed by endoscopic placement of ureteral stent to induce ureteral dilatation followed by ESWL 2–4 weeks later.
• ESWL is not effective for treatment of nephroureteroliths in cats.

MEDICATIONS

DRUG(S) OF CHOICE

• Antibiotics selected on the basis of urine culture and sensitivity testing as needed; periprocedural antibiotics are recommended when infected nephroliths are treated by ESWL or surgical removal.
• Medical dissolution protocols are limited to struvite, purine, and cystine uroliths.
• When feasible, consumption of water in high moisture (canned) foods should be incorporated into dissolution protocol. Target urine specific gravity <1.020 (dogs), <1.025 (cats).
• Medical dissolution protocols for canine struvite nephroliths include struvite-preventative or -dissolution diets and culture-guided antibiotic therapy for the duration of dissolution.
• Medical dissolution of canine purine nephroliths can be attempted by a purine-restricted diet, allopurinol 15 mg/kg PO q12h, and supplemental potassium citrate as needed to maintain urine pH ~7.0.
• Medical dissolution of canine cystine nephrolithiasis can be attempted using a therapeutic diet, 2-mercaptopropionylglycine (2-MPG, tiopronin) 15 mg/kg PO q12h, and supplemental potassium citrate as needed to maintain urine pH ~7.5.

CONTRAINDICATIONS

• Do not use allopurinol without dietary purine restriction; this combination may cause xanthine nephrolithiasis in dogs predisposed to urate urolithiasis.
• Do not give acidifying diets to azotemic patients unless blood pH and total CO_2 are monitored for development of metabolic acidosis.

FOLLOW-UP

PATIENT MONITORING

Abdominal radiographs or ultrasonography, urinalysis, and urine culture every 3–6 months to detect nephrolith recurrence. Dogs treated with ESWL—check every 2–4 weeks by radiographs and ultrasonography until nephrolith fragments have passed.

PREVENTION/AVOIDANCE

Eliminate factors predisposing to individual urolith type, augment urine volume, and correct factors contributing to urine retention. Dietary therapy is indicated for prevention of calcium oxalate, urate and cystine nephroliths. Castration of male dogs with cystine uroliths aids in prevention.

POSSIBLE COMPLICATIONS

Hydronephrosis, AKI, CKD, recurrent UTI, and pyelonephritis.

EXPECTED COURSE AND PROGNOSIS

• Highly variable; depends on nephrolith type, location, and size, secondary complications (e.g., obstruction, infection, CKD), and owner compliance with treatment and prevention protocol.
• Incidental nephroliths may remain inactive for years, resulting in an excellent prognosis.
• Return to normal health and good prognosis have been observed with ESWL for treatment of dogs with nephroliths.
• The prognosis for patients with CKD caused by nephrolithiasis depends on the severity and rate of progression of CKD.
• Nephroliths causing outflow obstruction should not be dissolved medically without placement of a ureteral stent.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hyperadrenocorticism and glucocorticoid administration are associated with calcium oxalate uroliths, and UTI resulting in struvite urolithiasis.

PREGNANCY/FERTILITY/BREEDING

ESWL is contraindicated in pregnant animals.

SYNONYMS

• Kidney stones.
• Nephroureteroliths
• Renal calculi.
• Renoliths.
• Kidney calculi.

SEE ALSO

• Chronic Kidney Disease.

N

NEPHROTIC SYNDROME

BASICS

DEFINITION
Concurrent proteinuria, hypoalbuminemia, hypercholesterolemia, and third-space fluid accumulation (i.e., ascites, subcutaneous edema, etc.). Partial nephrotic syndrome refers to proteinuria, hypoalbuminemia, hypercholesterolemia without fluid accumulation.

PATHOPHYSIOLOGY
• Magnitude of hypoalbuminemia and proteinuria causing nephrotic syndrome in dogs and cats is unknown; although affected patients usually have very low serum albumin concentrations, not all hypoalbuminemic patients will develop nephrotic syndrome. • Reduced plasma oncotic pressure may result in hyperaldosteronism, which induces sodium and water retention, leading to edema and ascites. • Hypercholesterolemia is a consequence of decreased catabolism and increased hepatic synthesis of lipoproteins. • Complications include hypertension, hypercoagulability, muscle wasting, and weight loss. • Thromboembolism is a consequence of a generalized procoagulative state, due to increased platelet number and sensitivity, urinary loss of antithrombin, and increased concentrations of clotting factors.

SYSTEMS AFFECTED
• Renal/urologic—persistent proteinuria. With progressive disease and nephron loss, azotemia chronic kidney disease and uremia may occur. • Cardiovascular—edema, ascites, hypercholesterolemia/hyperlipidemia, hypertension, hypercoagulability, and thromboembolic disease.

GENETICS
Familial glomerular diseases have been reported (see Glomerulonephritis and Amyloidosis), but may be less likely to result in nephrotic syndrome than nonfamilial disease.

INCIDENCE/PREVALENCE
• Nephrotic syndrome is an uncommon complication of glomerular disease, with a median of 0.5 new cases per year diagnosed at 8 veterinary teaching hospitals. • Nephrotic syndrome has not been associated with histologic subtype of glomerular disease. Amyloidosis and immune-complex mediated glomerulonephritis have the highest magnitude of proteinuria and might be expected to have a higher prevalence of nephrotic syndrome.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
Dogs with nephrotic syndrome are typically younger than those with non-nephrotic glomerular disease (mean, 6.2 years vs. 8.4 years).

Predominant Sex
None

SIGNS
Historical Findings
• Pitting subcutaneous edema and/or ascites. • Clinical signs associated with an underlying infectious, inflammatory, or neoplastic disease may be the primary reason for seeking veterinary care. • Rarely, acute dyspnea, severe panting, weakness, or collapse due to pleural or pericardial effusion, pulmonary edema, or pulmonary thromboembolism.

Physical Examination Findings
• Dependent pitting, subcutaneous edema, or ascites. • Complications of hypertension: retinal hemorrhage or detachment, papilledema, arrhythmia and/or murmur secondary to left ventricular hypertrophy. • Dyspnea and/or cyanosis with pleural effusion or pulmonary thromboembolism.

CAUSES
• Glomerular disease may be a consequence of chronic inflammatory conditions (e.g., infection, neoplasia, or immune-mediated diseases). • Nephrotic syndrome is unlikely to be solely a consequence of severe proteinuria; additional unidentified factors appear to be necessary.

RISK FACTORS
See Causes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Proteinuria
• Rule out inflammatory or hemorrhagic postglomerular urinary tract disease (e.g., bacterial cystitis/pyelonephritis, urolithiasis, tubular renal failure, or lower urinary tract neoplasia). Inflammation of the urinary tract is usually associated with active urine sediment. • Protein-losing nephropathies typically associated with inactive urine sediment (although hyaline casts may be present); renal biopsy is the only accurate way to distinguish the various types of glomerular disease.

Hypoalbuminemia
Rule out decreased albumin production (severe liver disease) and gastrointestinal albumin loss (protein-losing enteropathy).

CBC/BIOCHEMISTRY/URINALYSIS
• Persistent, significant proteinuria with inactive urine sediment. • Hypoalbuminemia and hypercholesterolemia. • Renal failure may occur with advanced disease. Azotemia may precede loss of urine concentrating ability.

OTHER LABORATORY TESTS
Urine protein:creatinine ratio (UPC)—confirms and quantifies the severity of proteinuria and can be used to assess response to therapy or progression of disease.

IMAGING
• Radiography—loss of abdominal detail due to ascites, pleural effusion (uncommon), pulmonary edema, or pericardial effusion (very uncommon) may be present. • Abdominal ultrasonography—confirms peritoneal and retroperitoneal fluid. Mild renomegaly may be observed with glomerular diseases.

DIAGNOSTIC PROCEDURES
Renal biopsy is indicated if significant and persistent proteinuria with inactive urine sediment exists. Microscopic evaluation of renal tissue will establish subtype of glomerular disease and help in formulating a prognosis. Consider renal biopsy after CBC, serum biochemistry profile, urinalysis, UPC, and coagulation testing are completed.

PATHOLOGIC FINDINGS
Renal biopsy specimens should be evaluated by light, fluorescent, and electron microscopy by a pathologist with expertise in nephropathology. Some of the more common glomerular diseases include glomerulonephritis (e.g., immune-complex mediated, membranous, membranoproliferative, proliferative), minimal change disease, hereditary nephritis, amyloidosis, podocyopathy, focal segmental glomerulosclerosis, glomerulosclerosis.

TREATMENT

APPROPRIATE HEALTH CARE
• Most can be treated as outpatient. • Severely azotemic or hypertensive patients, or those with thromboembolic disease may require hospitalization.

NURSING CARE
• Abdominocentesis—reserve for patients with respiratory distress or abdominal discomfort caused by ascites. Excessive fluid removal will promote fluid accumulation and electrolyte abnormalities. • Plasma transfusion is not indicated for treatment of hypoalbuminemia. Very large volumes of plasma are required to significantly increase serum albumin concentration, and transfused proteins have short half-lives. • IV albumin can be used in patients with life-threatening complications due to fluid accumulation (e.g., pulmonary edema; pleural effusion). • Hypotonic "maintenance"-type fluids (e.g., 0.45%

(CONTINUED) NEPHROTIC SYNDROME

NaCl) as IV fluid therapy may minimize extravascular fluid accumulation. • Synthetic colloids may exacerbate fluid extravasation in patients with nephrotic syndrome. These fluids should therefore be limited to patients with immediate, life-threatening needs for oncotic pressure support.

ACTIVITY
Activity restriction may increase likelihood of thromboembolic disease; activity promotes fluid mobilization and lymphatic uptake.

DIET
• Sodium-reduced, high-quality, low-quantity protein diets are recommended, such as prescription "renal diets." • Normal or high dietary protein may contribute to renal disease progression by exacerbating glomerular hyperfiltration, proteinuria, and glomerulosclerosis. However, dogs that have persistent and severe hypoalbuminemia may benefit from amino acid supplementation.

CLIENT EDUCATION
• Identifying and correcting underlying disease may slow or stop the progression of kidney disease. • Renal biopsy is required to differentiate between the various subtypes of glomerular disease and to optimize treatment protocols. • Nephrotic syndrome is associated with shortened survival time. In one canine study, median survival time of nephrotic syndrome was 12.5 (range 0–2,783 days), vs. 104.5 (range 0–3,124 days) with non-nephrotic glomerular disease. Azotemia and uremia are associated with shorter survival.

SURGICAL CONSIDERATIONS
Animals with severe hypoalbuminemia (i.e., <2 g/dL) present unique challenges to anesthesia. Consideration should be given to referral of these patients to a secondary or tertiary care facility if anesthesia and/or surgery are indicated.

MEDICATIONS

DRUG(S) OF CHOICE
See Glomerulonephritis.

Edema and Ascites
• Dietary sodium reduction. • Reserve abdominocentesis and diuretics for patients with respiratory distress or abdominal discomfort. Overzealous diuretic use may result in dehydration and acute renal decompensation. • Severe, persistent extravascular fluid accumulation should be treated with an aldosterone antagonist (spironolactone 1–2 mg/kg PO q12h), and low doses of loop diuretics (i.e., furosemide 0.5–2 mg/kg PO q8–12h). • Plasma or albumin transfusions provide only temporary benefit.

Proteinuria
• Angiotensin receptor blocker (ARB) (e.g., telmisartan 1 mg/kg PO q24h) or an angiotensin-converting enzyme (ACE) inhibitor (e.g., enalapril 0.5 mg/kg PO q12h) decrease severity of proteinuria. Because proteinuria is toxic to renal tubules, therapy should be initiated at the time of diagnosis, unless severe azotemia is present. • Aspirin (1–5 mg/kg PO q24h) or clopidogrel (1.1 mg/kg PO q24h) decreases thromboembolism risk.

CONTRAINDICATIONS
Highly protein bound drugs may be contraindicated if their margin of safety is small.

PRECAUTIONS
• Dose adjustment may be needed for highly protein-bound drugs that have a wider margin of safety. • Use ACE inhibitors or ARBs cautiously in patients with serum creatinine >5.0 mg/dL. • Diuretics should be used cautiously in nephrotic syndrome because of the risk of causing or worsening azotemia.

POSSIBLE INTERACTIONS
See Precautions.

FOLLOW-UP

PATIENT MONITORING
UPC; serum urea nitrogen, creatinine, albumin, and electrolyte concentrations; blood pressure; and body weight. Nephrotic syndrome is a dynamic condition and affected animals may require frequent reevaluation to address new symptoms or evaluate changes in medications.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• See Glomerulonephritis for complications unassociated with nephrotic syndrome. • Complications more likely to develop include: thrombosis (e.g., pulmonary thromboembolism), electrolyte disturbances, particularly with repeated abdominocenteses or high doses of diuretics.

EXPECTED COURSE AND PROGNOSIS
Nephrotic syndrome is associated with a faster progression to azotemia and uremia, and decreased median survival time when compared to dogs that have glomerular disease without nephrotic syndrome.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Amyloidosis. • Glomerulonephritis. • Glomerulopathy. • Hypercoagulability. • Hypertension.

AGE-RELATED FACTORS
Familial glomerular diseases should be considered in young animals with nephrotic syndrome.

ZOONOTIC POTENTIAL
Glomerular diseases can occur with some zoonotic infectious diseases.

PREGNANCY/FERTILITY/BREEDING
Likely high risk in those patients with severe hypoalbuminemia and/or hypertension.

SYNONYMS
N/A

SEE ALSO
• Amyloidosis.
• Glomerulonephritis.
• Proteinuria.

ABBREVIATIONS
• ACE = angiotensin-converting enzyme.
• ARB = angiotensin receptor blocker.
• UPC = urine protein:creatinine ratio.

N

NEPHROTOXICITY, DRUG-INDUCED

BASICS

DEFINITION
Renal injury caused by a pharmacologic agent used to diagnose or treat a medical disorder.

PATHOPHYSIOLOGY
- Drugs can cause nephrotoxicosis by interfering with renal blood flow, glomerular function, tubular function, or inducing interstitial inflammation.
- Many drugs are nephrotoxic because they are excreted primarily by the kidneys.
- Most nephrotoxic drugs cause proximal renal tubular necrosis.
- If renal injury is severe, acute kidney injury develops.

SYSTEMS AFFECTED
- Renal/urologic.
- Gastrointestinal—inappetence, vomiting, diarrhea, or melena due to gastrointestinal irritation or uremic ulceration.
- Endocrine/metabolic—metabolic acidosis due to decreased elimination of acid by kidneys and inability to reclaim bicarbonate filtered into tubules by glomeruli.
- Hemic/lymphatic/immune—anemia due to blood loss or decreased red blood cell survival in patients with uremia; increased susceptibility to infections because of immune dysfunction in patients with uremia.
- Nervous—depression, lethargy associated with effect of uremic toxins on the CNS.
- Neuromuscular—weakness due to systemic effects of uremia.
- Respiratory—tachypnea or respiratory distress due to uremic pneumonitis or compensatory response for metabolic acidosis.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
N/A

Mean Age and Range
Any age; older patients are more susceptible.

Predominant Sex
N/A

SIGNS

Historical Findings
- Polyuria and polydipsia; sometimes oliguria.
- Inappetence.
- Depression.
- Vomiting.
- Diarrhea.

Physical Examination Findings
- Dehydration.
- Oral ulcers.
- Uremic halitosis.

CAUSES

Antimicrobial Drugs
- Aminoglycosides—all drugs in this class are potentially nephrotoxic, including neomycin, gentamicin, amikacin, kanamycin, and streptomycin. Due to frequent use in the past, nephrotoxicosis associated with aminoglycoside treatment was most often associated with gentamicin.
- Tetracyclines—outdated products can cause acquired Fanconi-like syndrome characterized by glucosuria, proteinuria, and renal tubular acidosis; IV administration to dogs at high dosages (>30 mg/kg) can cause acute kidney injury.
- Administration of sulfa drugs (e.g., trimethoprim–sulfadiazine) has been associated with acute kidney injury in dogs, but no causal relationship has been proven.

Antifungal Drugs
Amphotericin B.

Antineoplastic Drugs
- Cisplatin—clinically important cause of nephrotoxicosis in dogs.
- Doxorubicin—possible cause of nephrotoxicosis in cats but not well documented.

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)
- Aspirin, ibuprofen, naproxen, carprofen, piroxicam, meloxicam, flunixin meglumine, and others may cause nephrotoxicosis.
- Most likely to cause renal injury in patients with preexisting kidney disease or patients with concomitant dehydration or other causes of hypovolemia.

Angiotensin-Converting Enzyme (ACE) Inhibitors
- Enalapril, benazepril, and others.
- Most likely to cause acute kidney injury in patients with hyponatremia, dehydration, or congestive heart failure.

Radiographic Contrast Agents
IV administration of ionic radiographic contrast agents can cause acute kidney injury, especially in patients with dehydration, hypovolemia, or hypotension associated with inhalational anesthesia.

RISK FACTORS
- Dehydration.
- Advanced age, probably because older patients have preexisting kidney disease.
- Kidney disease, inactive or active.
- Renal hypoperfusion; potential causes include any disorder associated with hypovolemia (e.g., vomiting, hemorrhage, hypoadrenocorticism), low cardiac output (e.g., congestive heart failure, pericardial disease, cardiac arrhythmias, inhalational anesthesia), or renal vasoconstriction (e.g., NSAID administration).
- Electrolyte and acid–base abnormalities including hypokalemia, hyponatremia, hypocalcemia, hypomagnesemia, and metabolic acidosis.
- Concurrent drug therapy—administration of furosemide increases nephrotoxicosis of aminoglycosides; treatment with cytotoxic drugs (e.g., cyclophosphamide) may increase nephrotoxic potential of drugs.
- Fever.
- Sepsis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Must differentiate from other causes of acute kidney injury (e.g., ethylene glycol toxicosis, raisin/grape ingestion [dogs], lily toxicosis [cats], renal ischemia, leptospirosis).
- Most patients have a history of recent treatment (i.e., within the previous 2 weeks) with a potentially nephrotoxic drug; acute kidney injury may occur several days after discontinuation of an aminoglycoside.
- Accidental ingestion of large doses of medications may occur, especially with palatable chewable formulations (prescribed for this patient or other animals).
- Determine all drugs that have been administered to the patient, including over-the-counter preparations (e.g., aspirin, ibuprofen, and naproxen) and medications prescribed for human use (e.g., NSAID or ACE inhibitor).

CBC/BIOCHEMISTRY/URINALYSIS
- Hemogram—usually normal unless concomitant problems exist (e.g., gastrointestinal hemorrhage associated with administration of NSAIDs).
- Biochemistry—normal in early stages of drug-induced nephrotoxicosis or reveals signs consistent with acute kidney injury including azotemia, hyperphosphatemia, and metabolic acidosis.
- Urinalysis—may reveal inadequately concentrated urinary specific gravity (often <1.025), proteinuria, glucosuria, or cylindruria. Casts may be one of the earliest indicators of acute kidney injury.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
Renal biopsy may be indicated to determine cause of acute kidney injury and potential for reversibility, especially in patients that do not favorably respond to treatment as expected. The magnitude of renal morphologic changes may appear mild compared to the magnitude of azotemia.

PATHOLOGIC FINDINGS
Most nephrotoxic drugs cause proximal renal tubular necrosis.

(CONTINUED) # NEPHROTOXICITY, DRUG-INDUCED

TREATMENT

APPROPRIATE HEALTH CARE
• Manage patients with acute kidney injury as inpatients.
• Manage patients without azotemia that can eat, and drink enough to maintain hydration, as outpatients.

NURSING CARE
• Administer balanced polyionic fluid (e.g., lactated Ringer's solution).
• Correct hydration deficits rapidly (i.e., over 6–8 hours) to minimize further renal injury. Calculate volume of fluid to administer as follows: volume (mL) = body weight (kg) ×% dehydration × 1,000 mL.
• In addition to correcting hydration deficits, administer maintenance requirements (~66 mL/kg/day) unless the patient is oliguric or anuric, and replace any ongoing losses caused by vomiting and diarrhea or polyuria.
• Extracorporeal therapies such as hemodialysis, charcoal hemoperfusion, or therapeutic plasma exchange may be indicated for certain drugs before toxicity has manifest.

ACTIVITY
Reduce

DIET
• Outpatients can be fed their regular food.
• Avoid oral feeding until vomiting is controlled, but initiate nutritional support as early as possible with acute kidney injury.
• If oral feeding is not possible initially, consider total or partial parenteral nutrition.
• The appropriate nutritional composition for patients with severe acute kidney injury has not been determined.
• Patients that recover from drug-induced nephrotoxicosis may develop chronic kidney disease, which should be managed by feeding a therapeutic renal diet indefinitely.

CLIENT EDUCATION
• Provide unlimited access to clean, fresh water at all times.
• If any signs of illness such as inappetence, vomiting, or diarrhea develop, return the patient immediately for veterinary care to minimize worsening of renal function.

SURGICAL CONSIDERATIONS
• Avoid elective surgery until kidney disease is resolved.
• If surgery is necessary, administer fluids (5–20 mL/kg/h) during anesthesia to maintain adequate mean arterial blood pressure (>60 mmHg) and renal perfusion. Monitor urine output and adjust rate of fluid administration to maintain urine production of 1–2 mL/kg/h.

MEDICATIONS

DRUG(S) OF CHOICE
None

CONTRAINDICATIONS
Do not use furosemide to promote diuresis in patients with aminoglycoside nephrotoxicosis.

PRECAUTIONS
• Avoid drugs that may worsen renal injury in patients with nephrotoxicosis, including NSAIDs, vasodilators, and ACE inhibitors.
• Use less toxic drugs when possible (e.g., carboplatin instead of cisplatin, other effective antimicrobials instead of aminoglycosides).

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
• Weigh hospitalized patients several times daily to detect changes in fluid balance and adjust fluid therapy accordingly.
• Perform biochemical analysis, including electrolytes, every 1–2 days to evaluate severity of azotemia and to detect electrolyte and acid/base abnormalities.
• Patients receiving aminoglycosides—perform urinalysis every 1–2 days to detect early signs of nephrotoxicosis such as glucosuria, increased proteinuria, and cylindruria; discontinue aminoglycoside if any of these signs are observed.
• Measure urine output to determine if patient is polyuric or oliguric; adjust fluid therapy on the basis of these findings and determine need for additional treatment to stimulate urine production. Do not overhydrate patient with parenteral fluids.

PREVENTION/AVOIDANCE
• Avoid or correct risk factors that predispose to development of drug-induced nephrotoxicosis.
• Initiate saline diuresis to all dogs receiving cisplatin.
• Avoid using nephrotoxic drugs unless they are necessary (e.g., use aminoglycosides only if patient has overwhelming sepsis and culture results indicate aminoglycosides are the only effective antimicrobial).
• Monitor serum aminoglycoside concentration and perform frequent urinalyses while administering an aminoglycoside; cylindruria may precede changes to urine concentration.
• Do not administer furosemide with an aminoglycoside as this combination is likely to enhance nephrotoxicity of the aminoglycoside.

POSSIBLE COMPLICATIONS
• Acute kidney injury.
• Chronic kidney disease.

EXPECTED COURSE AND PROGNOSIS
• Patients without azotemia may develop acute kidney injury after several days of exposure, especially to aminoglycosides.
• Renal injury caused by nephrotoxic drugs may lead to development of chronic kidney disease months to years after recovery from drug-induced renal injury.

MISCELLANEOUS

NERVE SHEATH TUMORS

BASICS

OVERVIEW

• Tumors of the peripheral nerves, spinal nerves, or nerve roots. • Malignant peripheral nerve sheath tumor is the recommended denomination for these tumors, instead of schwannoma, neurilemmoma, or neurofibroma, since determination of the cell of origin is often impossible. • Most tumors (80%) occur in the thoracic limb of dogs. • Approximately 50% of the tumors are located in the plexus or peripheral nerve region and 50% in the nerve root region.

SIGNALMENT

• Dogs—no breed or gender predisposition. • Mean age in dogs—7.9 years; uncommon in dogs younger than 3 years. • Rare in cats.

SIGNS

• Chronic progressive thoracic limb lameness. • Muscle atrophy (neurogenic atrophy) often present, more severe than that observed with orthopedic disorders. • Decreased muscle tone and decreased flexor reflex can be observed. • Axillary palpation detects a mass in less than 30% of cases. • Axillary pain upon palpation occasionally. • Horner's syndrome can be seen in tumors involving the T1–T3 nerve roots. • Ataxia, paresis, and asymmetric proprioceptive deficits can be seen if the tumor compresses the spinal cord. • Cutaneous trunci reflex may be poor to absent on the affected side. • In lumbosacral tumors, rectal palpation can be useful for mass detection. • Self-mutilation is occasionally observed.

CAUSES & RISK FACTORS

Mutation of the *neu* oncogene was identified in some cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Orthopedic conditions causing thoracic or pelvic limb lameness. Differentiate by orthopedic examination, radiographs, scintigraphy, CT, or MRI and response to rest and anti-inflammatory drugs. The severity of muscle atrophy also useful. • Lateralized nerve root compression by intervertebral disc disease, lumbosacral disease (cauda equina syndrome), or spinal neoplasia. Intervertebral disc disease and lumbosacral disease are usually associated with spinal pain. Advanced imaging (CT or MRI) is required to distinguish these diseases. • Secondary nerve neoplasia—lymphoma, histiocytic sarcoma, chondrosarcoma. Fine-needle or core biopsy needed to differentiate these conditions.

OTHER LABORATORY TESTS

• CSF analysis—nonspecific findings. • Cytology—ultrasound (US)-guided fine-needle biopsy can provide diagnostic sample. Cytologic features of malignant peripheral nerve sheath tumor (MPNST) are characteristics of a soft tissue sarcoma.

IMAGING

• Survey radiographs—well-positioned survey radiographs may allow visualization of an enlarged intervertebral foramen; most often unrewarding. • US—can identify a mass in cases where axillary palpation is unrewarding in distally located tumors. Patient sedation allows better positioning and US-guided fine-needle aspiration biopsy. Tumor echogenicity is variable. • Myelography—if the neoplasm has invaded the vertebral canal, an intradural extramedullary pattern can be seen. Due to the location of neoplasms, myelography is diagnostic in approximately 50% of dogs. • CT and MRI—to visualize proximal or distal limb tumors. Hyperintensity on T2-weighted images is the most common MRI pattern. MPNSTs usually show contrast enhancement on both CT and MRI. Due to the high soft tissue characterization, MRI is the diagnostic modality of choice.

DIAGNOSTIC PROCEDURES

• Electromyography (EMG)—to differentiate neurogenic from disuse muscle atrophy. Fibrillation potentials and positive sharp waves are suggestive of neurogenic muscle atrophy. EMG changes found in 96% of dogs with confirmed or suspected nerve sheath tumors. Epaxial muscle EMG changes predictive of vertebral canal invasion in cases of proximal tumors. • Nerve conduction velocity—conduction velocities may be prolonged with amplitude reduced. • F-wave, H-wave, cord dorsum potentials—evaluate the root portion of the nerve and can be useful to differentiate a lesion affecting predominantly the sensory or motor root.

TREATMENT

• Surgical resection following the principles of oncologic surgery is the recommended treatment. • Local resection with clean margins was recently shown to yield very long survival times. • Amputation is also an option for large size tumors. • Hemilaminectomy or dorsal laminectomy may be required to allow resection of the nerve root region. • Oral corticosteroids may allow clinical improvement by reduction of peritumoral edema. • Radiation therapy—can be used for nonresectable tumors or in cases where surgery is contraindicated. It can also be used postoperatively to decrease the chance of local recurrence.

MEDICATIONS

DRUG(S) OF CHOICE

• Chemotherapy—metronomic therapy (cyclophosphamide 10 mg/m^2 and piroxicam 0.3 mg/kg) can be used for incompletely resected nerve sheath tumors in dogs. • Dexamethasone 0.1–0.25 mg/kg q24h or prednisone 0.5–1 mg/kg q12–24h can be used to provide short-term improvement. • Gabapentin 5–20 mg/kg q8–12h can be used for analgesia in cases of neuropathic pain. • Pregabalin 2–4 mg/kg q12h can be used in cases refractory to gabapentin.

FOLLOW-UP

• Nerve sheath tumors are locally invasive and rarely metastasize. • Postoperative local recurrence is common (up to 72% of cases).

MISCELLANEOUS

ABBREVIATIONS

• EMG = electromyography. • MPNST = malignant peripheral nerve sheath tumor. • US = ultrasonography.

NEUROAXONAL DYSTROPHY

BASICS

OVERVIEW
- Inherited degenerative diseases of neurons in diverse regions of the CNS, particularly the cerebellum and associated pathways.
- Primary neuroaxonal dystrophy disorders are sometimes classified as abiotrophies.
- Inheritance—autosomal recessive in breeds where heritability is proven.
- The main pathologic feature of neuroaxonal dystrophy, axonal spheroids, also occurs in normal aging, as well as secondary to a number of other diseases, such as acquired or inherited metabolic diseases, and toxicities.

SIGNALMENT
- Dog and cat.
- Breeds predisposed—domestic and Siamese cats, Rottweilers, collies, papillons, Chihuahuas, German shepherd dogs, Jack Russell terriers, and boxers.
- Age at onset—breed-specific, ranging from under 2 months of age in cats, Chihuahuas, and papillons, to 1–2 years in Rottweilers.

SIGNS
- Cerebellar ataxia—progressive dysmetria and hypermetria of the limbs (rarely hypometria) with patellar hyperreflexia.
- Strength and proprioception normal in most cases. Rottweilers may have extensive involvement of the dorsal columns of the cervical spinal cord and may exhibit proprioceptive deficits.
- Loss of menace responses despite normal vision and facial nerves.
- Progressive signs of brainstem involvement may be a feature, especially in papillons, including loss of swallowing reflex and abnormal tongue movement; tetraplegia may develop in the final stages.
- Mild intention tremors or head and neck dysmetria in some patients.
- Primarily cerebellar signs in Rottweilers, collies, Chihuahuas, and domestic cats; predominantly spinal cord lesions in German shepherd dogs and boxers; tremors and cerebellar ataxia present in all affected animals.

CAUSES & RISK FACTORS
- Unknown.
- Usually classified as neuronal abiotrophy.
- Autosomal recessive inheritance proven in some breeds.
- Breed predisposition.

DIAGNOSIS
- Suspicion is based on clinical signs in a predisposed breed, usually in juvenile animals.
- Definitive diagnosis requires histopathologic examination of CNS tissue, usually post-mortem.

DIFFERENTIAL DIAGNOSIS
- Other congenital cerebellar anomalies, abiotrophies, and degenerative disorders. Reported occasionally in cats, and in a number of breeds of dog including border collie, Brittany, coton de Tulear, Gordon setter, Jack Russell (Parson Russell) terrier, Labrador retriever, Old English sheepdog, and many others.
- Other structural anomalies of the caudal brainstem, including caudal occipital malformation syndrome and Dandy–Walker syndrome. Differentiated by imaging studies, particularly MRI. Certain breeds are predisposed, e.g., caudal occipital malformation syndrome in the cavalier King Charles spaniel.
- Cerebellar hypoplasia caused by *in utero* infection of kittens with feline panleukopenia virus—apparent by 3–6 weeks of age; nonprogressive.
- Distemper encephalitis—differentiated on the basis of systemic signs preceding or accompanying the neurologic deficits and on results of CSF analysis (normal with neuroaxonal dystrophy).
- Other infectious encephalitides—fungal, rickettsial, and protozoal; differentiated on the basis of multisystemic signs in some patients, serologic testing, and CSF analysis.
- Noninfectious inflammatory encephalitides, particularly granulomatous meningoencephalomyelitis. Breed-specific encephalitides (pug, Maltese terrier, Yorkshire terrier) usually cause forebrain signs (seizures), but cerebellar involvement may occur. Differentiated by the presence of inflammatory changes in CSF and, in some cases, by contrast-enhancing lesions in the brain apparent with MRI.
- Neoplasia affecting the cerebellum—primary, metastatic, or locally invasive. Occurs in older dogs and cats, usually over 5 years of age. Differentiated on the basis of imaging studies (particularly MRI), CSF analysis in some cases, and systemic involvement in the case of metastatic neoplasia.
- Cervical spinal cord disease—proprioceptive deficits and tetraparesis.
- Diagnosis of neuraxonal dystrophy is by exclusion; it may not be possible to reach an antemortem diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

IMAGING
Atrophy of the cerebellum may be appreciable on MRI in certain patients (e.g., papillons).

PATHOLOGIC FINDINGS
- Axonal spheroids—present throughout the CNS gray or white matter, depending on the breed affected. Spheroids contain abnormal accumulations of intracellular proteins, particularly several associated with axonal transport and synaptic function.
- Myelin degeneration may occur secondary to axonal pathology.

TREATMENT
- None available that alters the course of the disease.
- Activity—restrict activity to areas where a fall can be avoided (avoid stairs, swimming pools, etc.).

MEDICATIONS

DRUG(S) OF CHOICE
N/A

FOLLOW-UP
- Rottweilers—worsen over 1–5 years; develop clonic patellar and crossed extensor reflexes.
- Not fatal, but severely incapacitating.

NEUTROPENIA

BASICS

DEFINITION
- Neutrophil count below the reference interval.
- Can occur alone or as a component of bi- or pancytopenia.
- Often accompanied by a left shift and toxic change (e.g., cytoplasmic basophilia, Döhle bodies, foamy cytoplasmic vacuolation, and/or toxic granulation).
- Certain breeds (e.g., greyhound, Belgian Tervuren) can have a neutrophil count below the reference interval for other breeds.

PATHOPHYSIOLOGY
Results from one of four mechanisms: (1) decreased production or release of neutrophils from the bone marrow, (2) a shift from the circulating pool within the large vessels to the marginating pool, (3) increased migration from blood into the tissues due to severe inflammation/tissue consumption, and (4) immune-mediated destruction.

SYSTEMS AFFECTED
Predisposes to infections, affecting many body systems in any combination, depending on the site(s) of infection.

GENETICS
- Cyclic hematopoiesis can result in intermittent neutropenia.
- A genetic trait with delayed penetrance results in age-related neutropenia in Belgian Tervuren dogs.
- Selective cobalamin malabsorption is an autosomal recessive trait in many breeds that results in neutropenia, including Imerslund–Gräsbeck syndrome in border collies.
- An autosomal recessive neutropenia (trapped neutrophil syndrome) in border collies from Australia and New Zealand is characterized by a deficiency of circulating segmented neutrophils and myeloid cell hyperplasia in the bone marrow.

SIGNALMENT
- Not specific for secondary infections.
- Schnauzers, beagles, Australian shepherd dogs, shar-peis, Komondorok, and border collies can have heritable cobalamin malabsorption.
- Grey collies and possibly border collies and Basset hounds may exhibit cyclic hematopoiesis.
- Aged Belgian Tervurens.
- Related border collies in Australia and New Zealand can have chronic neutropenia.
- Rottweiler dogs overrepresented for granulocyte colony-stimulating factor (G-CSF) deficiency.

SIGNS
- Septic animals usually have nonspecific signs. Fever is common, but normothermia does not exclude infection. Septic shock may be present.
- Grey collies with cyclic hematopoiesis exhibit severe neutropenia every 12–14 days. Episodes of fever, diarrhea, gingivitis, respiratory infection, lymphadenitis, and arthritis occur in association with the neutropenia.
- No clinical signs in Belgian Tervurens.

CAUSES

Deficient Neutrophil Production, Stem Cell Death, or Inhibition
- Infectious agents—parvovirus, bacteria-induced myelonecrosis, systemic mycosis (dogs and cats); feline leukemia virus (FeLV) and feline immunodeficiency virus (FIV) (cats); monocytic and granulocytic ehrlichiosis, babesiosis (dogs).
- Drugs, chemicals, and toxins—chemotherapy agents and cephalosporins (dogs and cats); T-2 mycotoxin ingestion, chloramphenicol and benzene-ring compounds, methimazole, and griseofulvin (cats); estrogen, phenylbutazone, trimethoprim–sulfadiazine, phenobarbital (dogs).
- Lack of trophic factors—inherited malabsorption of cobalamin/vitamin B12.
- Ionizing radiation.

Reduced Hematopoietic Space (Myelophthisis)
- Myelonecrosis.
- Myelofibrosis.
- Disseminated neoplasia, leukemia, or myelodysplastic syndrome.
- Disseminated infectious disease (e.g., histoplasmosis, cryptococcosis, leishmaniasis).

Cyclic Stem Cell Proliferation
- Inherited cyclic hematopoiesis.
- Cyclophosphamide treatment.
- Idiopathic disease.
- Immune-mediated suppression of granulopoiesis.

Neutrophil Migration
A shift in neutrophils from the circulating pool to the marginating pool can occur in patients with endotoxemia or anaphylaxis.

Reduced Survival
- Severe bacterial infection—sepsis, pneumonia, peritonitis, pyothorax, pyometra.
- Immune-mediated destruction.
- Drug-induced destruction.
- Hypersplenism (sequestration).
- Heat stroke.

RISK FACTORS
- Inherited disease—cyclic hematopoiesis, cobalamin malabsorption as noted earlier.
- Drug or toxin exposure.
- Infectious agents exposure (e.g., in kennels or catteries): *Ehrlichia canis*, parvovirus, *Bordetella bronchiseptica* (causing secondary pneumonia) (dogs); panleukopenia, FIV, and FeLV infection (cats).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Most neutropenias are due to nonbacterial infectious diseases (e.g., FeLV, FIV, systemic mycoses, parvoviruses).
- Acute bacterial infection with marked inflammation and/or endotoxemia.
- Direct cytotoxic effects of drugs or toxins on myeloid stem cells.
- Primary bone marrow disease.
- Immune-mediated destruction (diagnosis of exclusion).
- Inherited disease (more likely in younger animals unless adult-onset).

CBC/BIOCHEMISTRY/URINALYSIS
- Diagnosis is verified by CBC with blood smear evaluation.
- Serial CBCs may be necessary to confirm neutropenia or detect cyclic hematopoiesis.
- Urinalysis to identify urinary tract infection.

Factors That May Erroneously Alter Laboratory Results
- Inadequately mixed blood sample.
- Partial clotting of the specimen.
- Leukergy/leukocyte agglutination caused by antibody-related factors, leading to incorrect counting by automated machines. May rarely occur as a temperature-dependent phenomenon, resolved by warming the sample to 37°C (98.5°F).

OTHER LABORATORY TESTS
- Infectious disease screening—serologic or molecular testing for infectious organisms.
- Detection of antineutrophil antibodies by flow cytometry and observation of leuko-agglutination identifies immune-mediated neutropenia (IMN).
- Aerobic or anaerobic microbial culture of blood or areas of bacterial infection when indicated.

IMAGING
Survey radiography or ultrasonography may identify sites of infection or inflammation.

DIAGNOSTIC PROCEDURES/ PATHOLOGIC FINDINGS
- Bone marrow aspirate and core biopsy—to evaluate neutrophil precursors; a higher percentage of myeloblasts may be seen in animals rebounding from neutropenia, and should not be misdiagnosed as acute leukemia. Patients with IMN have myeloid hyperplasia with a left-shift, but hypoplasia can be seen if antibodies are precursor-directed.
- Cytologic examination of tissues—to verify neutrophil presence in body cavity effusions or tissues, confirm bacterial infections.

• Genetic testing or identification of abnormal urine metabolites may identify dogs with cobalamin malabsorption.

TREATMENT

APPROPRIATE HEALTH CARE

• Primary concern is the presence or development of infection.
• Nonfebrile patients—prophylactic broad-spectrum oral antibiotics that spare normal gastrointestinal flora are indicated.
• Febrile patients—suggests infection; inpatient treatment recommended for further diagnostic testing and therapy with IV broad-spectrum antibiotics and other therapies (e.g., IV fluids, surgery) as indicated.

MEDICATIONS

DRUG(S) OF CHOICE

• Nonfebrile patients—cephalexin 30 mg/kg PO q12h or enrofloxacin 10 mg/kg PO q24h; cephalosporins or other classes of antimicrobials are contraindicated if thought to be the trigger for neutropenia.
• Febrile patients—ampicillin 22 mg/kg IV q6–8h or ampicillin + sulbactam 22–30 mg/kg IV q8h and enrofloxacin 10 mg/kg IV q24h (caution in cats) or cefotaxime 50 mg/kg IV q6–8h (dogs), 20–60 mg/kg IV q6–8h (cats).
• If clinically warranted, metronidazole 10 mg/kg IV q12h provides anerobic bacterial coverage.
• Recombinant human G-CSF (rhG-CSF) 5–10 µg/kg/day SC for 3–6 doses may stimulate short-term neutrophil production, but can result in production of neutralizing antibodies in 14–21 days, which may crossreact with endogenous G-CSF; ineffective in canine parvovirus.
• IMN—prednis(ol)one 1 mg/kg PO q12h, additional immunosuppression from either azathioprine 1–2 mg/kg PO q24h (dogs), 0.3 mg/kg PO q24h (cats), cyclosporine 3.3–6.7 mg/kg PO q24h, or mycophenolate 7–20 mg/kg PO q12h (dogs), 7–10 mg/kg PO (cats) may be necessary.

FOLLOW-UP

PATIENT MONITORING

• Neutropenia is likely to occur 7–10 days after administration of most chemotherapeutic drugs but may develop as late as 2–3 weeks following lomustine (CCNU) or carboplatin administration.
• Improvement is generally denoted by a rising leukocyte or neutrophil count, resolution of left shift, and disappearance of toxic changes on CBC analysis.
• Rebound neutrophilic leukocytosis is expected during recovery from neutropenia.
• The accelerated neutrophil production following rhG-CSF therapy can result in toxic-appearing and left-shifted neutrophils in circulation.

POSSIBLE COMPLICATIONS

Secondary infections.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Viral or bacterial infection, sepsis, chemotherapy.

AGE-RELATED FACTORS

Middle-aged and older animals are less effective at repopulating the bone marrow with hematopoietic cells after an insult, due to age-related reduction in stem cell numbers.

PREGNANCY/FERTILITY/BREEDING

Pregnant Animals

• Drugs listed should be used only if the benefits supersede the inherent risks.
• Adequately controlled safety studies of rhG-CSF have not been performed in dogs and cats (including pregnant animals).

SEE ALSO

• Canine Parvovirus.
• Cobalamin deficiency.
• Cyclic Hematopoiesis.
• Ehrlichiosis and Anaplasmosis.
• Feline Immunodeficiency Virus (FIV) Infection.
• Feline Leukemia Virus (FeLV) Infection.
• Feline Panleukopenia.
• Sepsis and Bacteremia.

ABBREVIATIONS

• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• G-CSF = granulocyte colony-stimulating factor.
• IMN = immune-mediated neutropenia.
• rhG-CSF = recombinant human granulocyte colony-stimulating factor.

NOCARDIOSIS/ACTINOMYCOSIS—CUTANEOUS

BASICS

OVERVIEW
Nocardiosis and actinomycosis are deep suppurative or pyogranulomatous cutaneous infections caused by bacteria of the genera *Nocardia* or *Actinomyces* and *Arcanobacteria* (respectively). Infection arises from direct inoculation of the organisms into the skin. *Nocardia* spp are ubiquitous soil and water saprophytes: Infection is usually a consequence of inoculation via scratch, bite or foreign body penetrating wound. *Actinomyces* and *Arcanobacteria* are normal inhabitants of the oropharynx and infection frequently follows a bite wound. Infection typically remains restricted to the skin, but dissemination to internal organs (lungs) can occur in both diseases.

SIGNALMENT
Dogs and cats with access to the outdoors are predisposed.

SIGNS
Cutaneous lesions in both infections consist of nodules, subcutaneous swellings or abscesses that often develop draining sinuses. Diffuse cellulitis with numerous draining tracts may occur. In actinomycosis, draining tracts discharge a thick yellow-gray or hemorrhagic exudate that may contain sulfur granules. In nocardiosis the discharge is less abundant. Lesions are typically located on areas of wounds as limbs, feet, thorax, or abdomen. Regional lymphadenopathy is common.

CAUSES & RISK FACTORS
Nocardia (most commonly *N. cyriacigeorgica*, *N. nova*, *N. abscessus*, *N. farcinica*, and *N. otitisdiscaviarum*) are Gram-positive, partially acid-fast, branching filamentous aerobic bacteria with worldwide distribution. *Actinomyces* (most commonly *A. bowdenii*, *A. canis*, *A. viscosus, A. odontolyticus,* A. *meyeri*, and *Arcanobacterium pyogenes*) are Gram-positive, non-acid fast, filamentous anaerobic rods that are opportunistic commensals of the oral cavity and bowel. Most *Actinomyces* infections are complicated by mixed infections with other bacteria.

DIAGNOSIS
Diagnosis is by skin biopsy obtained for culture and histopathology. *Nocardia* is easily cultured under aerobic conditions. *Actinomyces* has fastidious growth requirements and may be slow-growing and/or difficult to grow. Species identification may require a specialized laboratory. Fine-needle aspiration for cytology and culture may also be useful.

DIFFERENTIAL DIAGNOSIS
Other systemic fungal infections, subcutaneous mycosis, panniculitis (sterile or due to mycobacterial infection), bacterial pseudomycetoma, and foreign body reactions.

CBC/BIOCHEMISTRY/URINALYSIS
Usually subtle. May vary according to the extent and duration of disease. Extensive, chronic, or disseminated disease may cause a mild to moderate nonregenerative anemia, leukocytosis, neutrophilia, and monocytosis. Hypercalcemia due to granulomatous disease can be present.

IMAGING
Thoracic radiography and abdominal ultrasound are recommended to assess for dissemination of infection.

PATHOLOGIC FINDINGS
Histopathologic lesions consist of granulomatous to pyogranulomatous dermatitis and panniculitis accompanied by extensive fibrosis. Special stains are used to identify microorganisms in tissues. Granules of actinomycosis are basophilic with an eosinophilic periphery (Splendore–Hoepli phenomenon).

TREATMENT
Surgical drainage of abscesses or surgical debridement followed by long-term antibiotic administration is recommended. Treatment must be continued at least 1 month after clinical cure.

MEDICATIONS

Nocardiosis
Sulfonamides (trimethoprim-sulfonamide 30 mg/kg q12h). Clinical improvement should be observed within 2 weeks. Susceptibility testing is strongly recommended in cases that fail to respond to empirical treatment or in cases of relapse. Treatment success with alternative antibiotics, including amikacin, cephalosporins, clarithromycin, and doxycycline, has been reported.

Actinomycosis
High-dose penicillin (penicillin G 40 mg/kg q8h). Strains of *Actimomyces* spp. have not shown resistance to penicillin. For animals not tolerating penicillin, alternative antibiotics include clindamycin, erythromycin, and doxycycline.

CONTRAINDICATIONS
Caution advised with use of sulfonamides in Doberman pinschers.

FOLLOW-UP
Prolonged treatment with monitoring is required. Prognosis is guarded, although most immunocompetent animals with only cutaneous infection and properly treated are usually cured.

MISCELLANEOUS

ZOONOTIC POTENTIAL
No cases of human of actinomycosis or nocardiosis acquired from direct contact with a dog or cat with clinical disease have been reported. Rare cases of cutaneous actinomycosis or nocardiosis in humans as a consequence of a scratch or bite from a cat or dog have been reported. Pet owners, veterinarians, and nurses should wear protective gloves when handling infected dogs and cats to avoid inadvertent infection through damaged skin.

Author Lluís Ferrer
Consulting Editor Alexander H. Werner Resnick

NONSTEROIDAL ANTI-INFLAMMATORY DRUG TOXICOSIS

BASICS

DEFINITION
• Toxicosis secondary to the acute or chronic ingestion of a nonsteroidal anti-inflammatory drug (NSAID). • NSAIDs—classed as carboxylic acids (aspirin, indomethacin, sulindac, ibuprofen, naproxen, carprofen, meclofenamic acid, etodolac, flunixin meglumine) or enolic acids (phenylbutazone, dipyrone, meloxicam, tepoxalin, and piroxicam); selective cyclooxygenase-2 (COX-2) inhibitors (deracoxib, firocoxib, mavacoxib (Europe), and robenacoxib).
• Newer selective COX-2 inhibitors and NSAIDs with preferential activity against COX-2 may have fewer adverse reactions than older COX-1 inhibitors, though both pathways may be inhibited following overdose.

PATHOPHYSIOLOGY
• Action—analgesic, antipyretic, and anti-inflammatory due to the inhibition of cyclooxygenase; decreases production of prostaglandins that act as mediators of inflammation. • Well absorbed orally.
• Clearance—varies greatly among species; eliminated slowly in dogs and cats; half-life varies significantly among NSAIDs.
• Metabolized in the liver to active or inactive metabolites. • Excreted in the kidney via glomerular filtration and tubular secretion, and/or biliary excretion.

SYSTEMS AFFECTED
• Gastrointestinal (GI)—irritation, erosions, and ulcerations. • Renal/urologic—acute kidney injury; acute interstitial nephritis.
• Hepatobiliary—idiosyncratic hepatocellular damage. • Hemic/lymphatic/immune—bleeding disorders from decreased platelet aggregation.
• Nervous – ataxia, seizures, CNS depression, and coma may occur with very large doses.

GENETICS
• Very large species differences in absorption, excretion, and metabolism of different agents; avoid extrapolation of data from other species or dosages. • Off-label use of NSAIDs can result in significant, potentially life-threatening adverse effects in all species, especially cats. • Over-the-counter NSAIDs (especially ibuprofen and naproxen) are common causes of NSAID toxicosis in dogs and cats. Naproxen has an extremely long half-life in domestic animals and exposures carry a high risk of significant adverse effects.

INCIDENCE/PREVALENCE
Among the 10 most common toxicoses reported to both the Pet Poison Helpline (PPH) and the American Society for the Prevention of Cruelty to Animals (ASPCA) Animal Poison Control Center (APCC).

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
• Dogs and cats. • Cats are more sensitive.
• No breed or gender predilections.

SIGNS
General Comments
• GI irritation—within a few hours. • Renal involvement or GI ulceration—may be delayed several days.

Historical Findings
• Evidence of accidental consumption of medication or reported administration of an NSAID (either prescribed or unprescribed).
• Lethargy. • Anorexia. • Vomiting—with or without blood. • Diarrhea. • Icterus.
• Melena. • Polyuria, polydipsia, and oliguria.
• Ataxia, seizures, coma—may occur with large ingestions. • Collapse and sudden death—may occur from a perforated gastric ulcer.

Physical Examination Findings
• Depression. • Pale mucous membranes.
• Painful abdomen. • Dehydration. • Fever.
• Tachycardia. • Icterus.

CAUSES
Accidental exposure or inappropriate administration.

Toxic Doses for Common NSAIDs
• Carprofen: ○ Dogs: 20 mg/kg—GI ulceration; 40 mg/kg—renal injury. ○ Cats: 4 mg/kg—GI ulceration; 8 mg/kg—renal injury. • Ibuprofen: ○ Dogs: 50 mg/kg—GI ulceration; 100–175 mg/kg—renal injury; 400 mg/kg—CNS signs. ○ Cats: considered about twice as sensitive as dogs. • Naproxen: ○ Dogs: 5 mg/kg—GI ulceration; 25 mg/kg—severe renal injury (may occur at lower doses); 50 mg/kg—CNS signs. ○ Cats: considered at least twice as sensitive as dogs.

RISK FACTORS
• Age—neonatal or geriatric. • Previous history of GI disease, ulcer, or bleeding. • Preexisting renal, hepatic, or cardiovascular disease.
• Hypotension; dehydration or hypovolemia.
• Other concurrent illness and/or medications (especially other NSAIDs or corticosteroids).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Other conditions that cause GI and/or renal effects:
• Inflammatory bowel disease, hemorrhagic gastroenteritis, hypoadrenocorticism, GI foreign body, neoplasia, ethylene glycol toxicosis, lily ingestion (cats), grape/raisin ingestion (dogs), renal failure (acute or chronic), urinary tract obstruction, pyelonephritis. • Diagnosis based on history of exposure and compatible clinical signs.

CBC/BIOCHEMISTRY/URINALYSIS
• Anemia—regenerative or nonregenerative, depending on duration of bleeding.
• Leukocytosis with left shift—associated with perforated gastric ulcer and accompanying peritonitis. • BUN and creatinine—may be elevated secondary to prerenal azotemia or primary renal insult.
• Panhypoproteinemia – secondary to GI bleeding. • Liver enzymes—occasionally elevated. • Monitor urine output for evidence of oliguria; monitor for isosthenuria, glucosuria, proteinuria, and casts.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
Endoscopy—verify GI ulceration.

PATHOLOGIC FINDINGS
• GI irritation, ulceration, or hemorrhage with possible perforation and peritonitis.
• Renal tubular or papillary necrosis or interstitial nephritis.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient—mild clinical signs (with low ingested dose); managed at home with appropriate medication and dietary and symptomatic measures. • Inpatient—high ingested dose; potential for renal toxicosis; more serious clinical signs (frequent vomiting, bloody vomitus, melena, anemia, or evidence of renal involvement); aggressive treatment to avoid life-threatening complications.

Recent Ingestion
• Ingestion within 2 hours and no vomiting—induce emesis (apomorphine or hydrogen peroxide), only if patient not at-risk for aspiration. • After emesis—activated charcoal (1–2 g/kg PO) with a cathartic ×1 dose.
• Repeat activated charcoal without a cathartic q6–8h ×2 doses for NSAIDs that undergo enterohepatic recirculation.

NURSING CARE
• Fluid therapy—restore hydration when moderate to severe vomiting; twice maintenance rates with known or potential renal involvement. Titrate fluids as needed based on clinical signs and blood work results. Use caution in patients with underlying cardiac disease to avoid fluid overload. • If severely anemic, a blood transfusion may be indicated.

NONSTEROIDAL ANTI-INFLAMMATORY DRUG TOXICOSIS (CONTINUED)

ACTIVITY
N/A

DIET
• Vomiting—NPO. • Vomiting resolved—begin with a bland, low-protein diet.

CLIENT EDUCATION
• Stress the importance of contacting a veterinarian or animal poison control center (PPH or ASPCA APCC) whenever an animal is exposed to a nonprescribed NSAID or an overdose of a prescribed NSAID. • Inform client that dogs and particularly cats have a low tolerance to NSAIDs. • With a prescribed NSAID, instruct client to look for adverse or idiosyncratic effects and to stop the drug and contact the clinic if they occur.

SURGICAL CONSIDERATIONS
Surgical intervention may be required for a perforated GI ulcer.

N

MEDICATIONS

DRUG(S) OF CHOICE

H_2-Receptor Antagonists
• For GI upset or ulceration.
• Primarily effective for treating ulcers from acute overdose or from chronic administration after the drug withdrawn.
• Famotidine or ranitidine may be best choices as cimetidine may inhibit microsomal enzymes that metabolize some NSAIDs.
• Famotidine—dogs: 0.5–1.0 mg/kg PO, SC, IV, or IM q12–24h; cats: 0.5 mg/kg PO, SC, IV, or IM q12–24h. • Ranitidine—dogs: 2 mg/kg PO, IV q8h; cats: 2.5 mg/kg IV q12h or 3.5 mg/kg PO q12h.

Proton Pump Inhibitors
• Omeprazole 0.5–1 mg/kg PO q24h.
• Pantoprazole 0.7–1 mg/kg IV over 15 minutes q24h.

Other
• Sucralfate—dogs: 0.5–1 g PO q8–12h; cats: 0.25 g PO q8h; binds to proteins in the ulcer base; stimulates mucus and bicarbonate secretion. • Misoprostol 1–3 µg/kg PO q8h; prostaglandin E2 analogue; prevents GI bleeding and ulceration; promotes healing during chronic use in humans and dogs treated with aspirin.• Dopamine—may be indicated for acute renal failure. • Standard anticonvulsant therapy—diazepam, phenobarbital, levetiracetam, etc. if needed. • Naloxone may be useful in comatose patients.

Duration of Treatment
Depends on the dose and half-life of the NSAID ingested.

CONTRAINDICATIONS
Avoid concomitant use of corticosteroids or multiple NSAIDs; contraindicated in pregnancy (abortifacient effect).

PRECAUTIONS
Patients using other nephrotoxic drugs (e.g., aminoglycosides and angiotensin-converting enzyme [ACE] inhibitors)—at higher risk for developing NSAID nephropathy.

POSSIBLE INTERACTIONS
NSAIDs are highly protein-bound; may be affected by concurrent use of other highly protein-bound drugs.

FOLLOW-UP

PATIENT MONITORING
• Urine output—monitor for oliguria; examine for casts, protein, and glucose.
• Stool and vomitus—check for GI bleeding (may not develop for several days). • BUN and creatinine—daily for several days (full extent of renal damage may not be immediately evident); recheck 2–3 days after discharge if hospitalized. • Packed cell volume/total solids—check q12–24h while hospitalized, then 2–3 days after discharge to monitor for GI bleeding.

PREVENTION/AVOIDANCE
• Store medications out of the reach of pets.
• Discourage owners from medicating pet without veterinary supervision. • Appropriate laboratory tests for high-risk patients before beginning NSAID therapy.

POSSIBLE COMPLICATIONS
• Perforation of a GI ulcer and peritonitis.
• Irreversible acute and chronic renal failure.

EXPECTED COURSE AND PROGNOSIS
• GI upset or ulceration—usually complete recovery with appropriate treatment. • Renal effects—generally reversible with early and aggressive treatment. • Acute hepatopathies—generally resolve with early symptomatic treatment and discontinuation of the drug.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
• Exposure during pregnancy—risk for fetal cardiopulmonary and renal effects. • May prolong pregnancy, especially if administered during the third trimester and before the onset of labor.

SEE ALSO
• Acute Kidney Injury.
• Aspirin Toxicosis.
• Poisoning (Intoxication) Therapy.

ABBREVIATIONS
• ACE = angiotensin-converting enzyme.
• APCC = Animal Poison Control Center.

NOTOEDRIC MANGE

BASICS

OVERVIEW
- A nonseasonal, intensely pruritic, highly contagious parasitic skin disease of cats caused by *Notoedres cati*.
- Mites burrow through the superficial skin between follicles causing intense pruritus.
- Can cause transient pruritus in humans.

SIGNALMENT
- Domestic cats of all ages and both sexes.
- Fairly host-specific, but can also produce symptoms in dogs, cheetahs, raccoons, rabbits, coatis, palm civets, bobcats, ocelots, foxes, and humans.
- All in-contact cats usually develop clinical signs.
- Epizootic in localized areas.
- Endemic in large feral cat populations.
- Transmission by direct contact: mite is very short-lived when off the host.

SIGNS
- Nonseasonal intense pruritus.
- Following exposure, initial pruritus may be mild, but progresses to severe.
- Change from mild pruritus to onset of severe pruritus (incubation period) of 3–6 weeks may indicate eventual seroconversion and the development of hypersensitivity (IgG as well as humoral response).
- Rare individuals do not seroconvert, and therefore may not develop severe pruritus.
- Papules and crusts develop on pinnae and spread to eyelids, face, and neck (also known as "head mange").
- Progresses to the legs, feet and perineum.
- Severe self-trauma leads to secondary lesions.
- Skin becomes thickened, lichenified, and covered with gray-yellow crust.
- Large patches of lesions and alopecia develop over the entire body if untreated.
- Unlike canine scabies, large numbers of mites are present on the skin.
- Peripheral lymphadenopathy often develops.
- Causes significant debilitation in severe cases.

CAUSES & RISK FACTORS
Close contact with other cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Atopy.
- Cutaneous adverse reaction to food.
- Bacterial folliculitis.
- Dermatophytosis.
- Demodicosis.
- *Malassezia* dermatitis.
- *Cheyletiellosis*.
- Trombiculosis (chiggers).
- Otodectic dermatitis.
- Pemphigus foliaceus.
- Pemphigus erythematosus.
- Systemic lupus erythematosus.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

DIAGNOSTIC PROCEDURES
- Superficial skin scraping—relatively easy to find mites.
- Mite smaller than *S. scabiei*, with dorsal anus, typical dorsal concentric "finger print" striae, and only two pairs of forelegs protruding from the body line.
- Serum testing (ELISA) for mite antibody not available.
- Acetate tape impression—as sensitive as skin scraping.

TREATMENT
- When scabicidal dips are used, the entire cat must be treated.
- Treatment failures occur if product is not applied to the face and ears.
- All in-contact cats should be treated.
- Response is usually quick if all in-contact animals are treated.
- Thorough cleaning of the cat's environment may be helpful if severely contaminated.
- Systemic antibiotics—may be needed to resolve secondary bacterial folliculitis.

MEDICATIONS

DRUG(S) OF CHOICE
- Lime sulfur rinses 2–3%; apply to entire body weekly for 6–8 applications; clipping might be necessary to permit adequate contact with the skin.
- Ivermectin—effective; 0.2–0.3 mg/kg SC every 2 weeks for 2–3 treatments.
- Doramectin 0.2–0.3 mg/kg SC once.
- Selamectin—off-label; applied every 2 weeks for three applications.
- Imidacloprid/moxidectin spot-on applied once or twice as directed on the label.
- Isoxazoline parasiticides—not FDA approved: single administration.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Amitraz rinse may cause sedation.
- Lime sulfur has unpleasant odor and is staining.

FOLLOW-UP

PREVENTION/AVOIDANCE
Reinfestation may occur if contact with infested animals continues; the source of infestation must be determined (if possible) as well as all in-contact cats must be treated.

POSSIBLE COMPLICATIONS
- Topical scabicidal treatments are more prone to failure because of incomplete application of the treatment solution.
- Persistent infection if not all in-contact animals are treated.

EXPECTED COURSE AND PROGNOSIS
- Response to therapy is rapid providing all in-contact animals are treated; symptoms should significantly reduce within 2 weeks of treatment.
- There is no immunity from repeat infestation; clinical signs following a reinfestation are likely to be more rapid due to previous exposure and sensitization.

MISCELLANEOUS

ZOONOTIC POTENTIAL
- Humans in close contact with an affected cat may develop a pruritic, papular rash (often on arms, chest, or abdomen).
- Human lesions are usually transient and resolve spontaneously following treatment of affected animals.

NYSTAGMUS

BASICS

DEFINITION
• Involuntary, rhythmic oscillation of the eyeballs.
• Jerk nystagmus—most common; slow eye movements in one direction with a rapid recovery phase in the opposite direction.
• Pendular nystagmus—seen less frequently; characterized by slow oscillations of the eyes in a trajectory that resembles that of a pendulum, with no fast phase.

PATHOPHYSIOLOGY
• Neural projections traverse in the brainstem from the vestibular nuclei to cranial nerve (CN) III, IV, and VI nuclei, which innervate the extraocular muscles. This pathway is part of the vestibular system, and provides coordinated conjugate eye movements in association with changes in head position.
• Physiologic nystagmus (ocular–vestibular reflex)—normal finding, induced by rotating the head from side to side; characterized by a jerk nystagmus with a slow drifting of the eye in the opposite direction of the head rotation followed by a fast compensatory phase in the same direction as the head movement. Decreased to absent physiologic nystagmus is indicative of vestibular disease.
• Pathologic nystagmus—a sign of vestibular dysfunction; characterized by a jerk nystagmus that develops independent of head movement. The nystagmus is described according to the axis of movement of the globe (horizontal, rotary, or vertical), and the direction of the fast phase of movement.
• Spontaneous or resting nystagmus—pathologic nystagmus that occurs when the head is in a normal position and not moving; frequently resolves after several days.
• Positional nystagmus—pathologic nystagmus, elicited only when the head is placed in unusual position; can often be seen in more chronic conditions.
• Jerk nystagmus must be differentiated from pendular nystagmus and from opsoclonus.
• Pendular nystagmus—congenital abnormality in which a larger-than-usual portion of the optic nerve fibers crosses in the chiasm; most often observed as an incidental finding in Siamese, Birman, and Himalayan cats but can also be seen with cerebellar disease and with visual deficits.
• Opsoclonus—involuntary, rapid, random eye movements in multiple directions that can be seen with cerebellar disease; can be differentiated from jerk nystagmus by the lack of a slow phase and its chaotic nature.

SYSTEMS AFFECTED
Nervous

GENETICS
N/A

INCIDENCE/PREVALENCE
Nystagmus, as a sign of vestibular disease, is a relatively common clinical presentation in dogs and cats.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
Varies, depending on underlying cause; neoplastic and vascular conditions and canine geriatric vestibular disease more common in older animals.

Predominant Sex
None

CAUSES

Peripheral Vestibular Disease
• Metabolic—hypothyroidism.
• Neoplastic—nerve sheath tumor or tumor involving surrounding bone or soft tissues.
• Inflammatory—otitis media-interna; nasopharyngeal polyps (cats).
• Idiopathic—canine geriatric vestibular disease; feline idiopathic vestibular disease.
• Toxic—e.g., aminoglycosides, topical iodophors, topical chlorhexidine.
• Trauma.

Central Vestibular Disease
• Degenerative—storage disorders; neuronal degeneration; demyelinating disease.
• Neoplastic—primary or metastatic tumors.
• Nutritional—thiamine deficiency.
• Inflammatory/infectious—viral (canine distemper, feline infectious peritonitis); bacterial; protozoal (toxoplasmosis, neosporosis); fungal (cryptococcosis, blastomycosis, histoplasmosis, coccidioidomycosis, aspergillosis); rickettsial (ehrlichiosis, Rocky Mountain spotted fever); inflammatory, noninfectious (meningoencephalitis of unknown etiology; includes granulomatous meningoencephalomyelitis and the necrotizing meningoencephalitides).
• Toxic—lead; hexachlorophene; metronidazole.
• Trauma.
• Vascular—cerebrovascular disease (hemorrhage, infarction).

RISK FACTORS
Systemic administration of certain antibiotics (metronidazole, aminoglycoside), otic administration of iodophors and chlorhexidine solutions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Peripheral Vestibular Disease
• Nystagmus—either rotary or horizontal in character, with the fast phase directed away from the side of the lesion; does not change direction with different head positions.
• Other signs of vestibular disease—head tilt, ataxia, circling, falling or rolling, and vestibular strabismus often present and occur ipsilateral to the lesion.
• Ipsilateral facial nerve deficits and/or Horner's syndrome—can be seen due to the close association of CN VII and sympathetic nerve to CN VIII as they course through the petrous temporal bone.

Central Vestibular Disease
• Nystagmus—horizontal, rotary, or vertical; can change direction with different head positions.
• Other signs of vestibular disease—head tilt, ataxia, circling, falling or rolling, and vestibular strabismus often present.
• Involvement of other brainstem structures—alterations in level of consciousness, paresis, postural reaction deficits, and other CN deficits (V and VII most common); deficits are typically ipsilateral to the lesion.
• Paradoxical vestibular disease—with certain lesions of the cerebellum; in these cases, postural reaction deficits occur ipsilateral to the lesion whereas the head tilt and other vestibular signs are contralateral to the lesion.

CBC/BIOCHEMISTRY/URINALYSIS
Results usually normal

OTHER LABORATORY TESTS
• Thyroid profile—if hypothyroidism is suspected.
• Bacterial culture of sample obtained via myringotomy—if otitis media-interna is likely.
• Serologic testing—for potential infectious agents.

IMAGING
• Imaging of the tympanic bullae to assess for otitis media-interna—survey radiographs of limited value; CT and MRI are more sensitive.
• Brain imaging (CT or MRI)—indicated in animals with central vestibular disease to evaluate for structural brain abnormalities. MRI is superior to CT for imaging the brain.

DIAGNOSTIC PROCEDURES
CSF—if central disease, to evaluate for inflammation.

PATHOLOGIC FINDINGS
Variable, depending of the underlying cause

TREATMENT

APPROPRIATE HEALTH CARE

- The cause of the disease and the severity of signs determine whether the animal is best treated on an inpatient or an outpatient basis.
- In general, animals with central disease require more intensive care than those with peripheral disease.

NURSING CARE

- Fluid therapy is indicated in the acute stages of disease for animals that experience anorexia and vomiting.
- Animals with severe vestibular dysfunction should be confined to a well-padded area in the acute stage of the disease to minimize self-trauma secondary to disorientation.

ACTIVITY

- Animals should be housed on nonslippery surfaces; stairs should be avoided.
- Exercise should be supervised, with assistance provided until signs of imbalance resolve.

DIET

N/A

CLIENT EDUCATION

- Many animals show improvement over the first several days; the nervous system is able to compensate for vestibular disturbances that remain static or are slowly progressive regardless of cause.
- Compensation involves visual and somatosensory (tactile) cues and is dependent on feedback from vestibular pathways; return to normal activity should be encouraged to enhance compensatory mechanisms.

SURGICAL CONSIDERATIONS

Signs of vestibular dysfunction can transiently worsen after an anesthetic episode; most likely reflects a loss of compensation.

MEDICATIONS

DRUG(S) OF CHOICE

- Meclizine (dogs: 4 mg/kg PO q24h) or maropitant (dogs: 1 mg/kg SC or 2 mg/kg PO q24h; cats: 1 mg/kg SC q24h)—used to treat motion sickness; can alleviate nausea and vomiting associated with acute disease.
- Diazepam (dogs: 0.5 mg/kg PO q8h)—recommended in cases of metronidazole toxicity; can help decrease acute vestibular signs from other causes by decreasing the resting activity of vestibular neurons and alleviating the imbalance in vestibular input to the brain.
- Specific medical therapy is directed at the underlying cause, if one can be identified.

CONTRAINDICATIONS

- Avoid potential ototoxic drugs, such as aminoglycosides. Toxicity is more likely in animals with renal impairment.
- Avoid instilling topical medications into the ear of an animal with suspected otitis media-interna, especially if the tympanic membrane cannot be visualized or is not intact. Such agents can exacerbate vestibular signs and cause deafness.

PRECAUTIONS

- Avoid the use of metronidazole at daily doses greater than 60 mg/kg, as this has been associated with vestibular dysfunction in dogs.
- Vestibular dysfunction can develop after administration of metronidazole at lower dosages but is less likely.

FOLLOW-UP

PATIENT MONITORING

Repeat neurologic examination—perform 2 weeks after initial diagnosis to monitor for improvement or progression of disease.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

- Dehydration and electrolyte imbalance associated with anorexia and vomiting.
- Rare extension of otitis media-interna into the adjacent brainstem.

EXPECTED COURSE AND PROGNOSIS

- Prognosis varies, depending on the cause of the vestibular disturbance.
- In general, animals with peripheral vestibular disease have a better prognosis than those with central involvement.
- Residual deficits can remain after resolution of the underlying disease process due to irreversible damage to the neural structures.
- Recurrence is possible with some of the conditions (otitis media-interna, canine geriatric vestibular disease, feline idiopathic vestibular disease).

OBESITY

BASICS

DEFINITION
Obesity is the unhealthy accumulation of body fat. Precise definitions are debated but it is widely accepted that dogs or cats with body condition score (BCS) 6 or 7 on a 9-point scale are overweight, and those with BCS 8 or 9 are obese.

PATHOPHYSIOLOGY
• Animals gain weight when energy intake from food chronically exceeds energy expended to maintain basic homeostatic processes and during exercise. • Homeostatic neuroendocrine responses ensure food intake meets energy requirements and establish modest energy reserves in case of a period of fasting. • Energy homeostasis may be disrupted by: ready availability of highly palatable energy-dense food (which elicits hedonic responses that override homeostatic satiation); genetic variation in appetite; neutering; and limits to a pet's ability to exercise.

SYSTEMS AFFECTED
• Endocrine—insulin resistance develops secondary to obesity and can lead to diabetes mellitus in cats. • Immune—adipose tissue dysfunction in obesity causes a proinflammatory state. • Other organ systems may be affected by the mechanical effect of increased body fat and/or endocrine and metabolic disruption.

GENETICS
• Breed variation in obesity predisposition suggests obesity susceptibility is in part heritable with a polygenic mode of inheritance. • Mutations in the genes *POMC* (Labrador and flatcoat retrievers) and *MC4R* (beagles) are associated with obesity and/or food motivation.

INCIDENCE/PREVALENCE
Common. As many as 65% of dogs and 25% cats are overweight or obese.

GEOGRAPHIC DISTRIBUTION
Widespread

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Domestic shorthair cats. • Labrador retriever, Cairn terrier, cavalier King Charles spaniel, Scottish terrier, cocker spaniel.

Mean Age and Range
Obesity prevalence is highest in middle age but can occur throughout life.

Predominant Sex
Neutered pets of either sex are predisposed.

SIGNS

Historical Findings
• Weight gain. • Change in BCS. • A full diet and exercise history and understanding of concurrent medical problems is essential to

Physical Examination Findings
Excess body fat and BCS (see Diagnostic Procedures).

CAUSES
Energy intake chronically exceeding energy output.

RISK FACTORS
• Neutering. • Middle age. • Feeding highly palatable, energy-dense foods without adequate restriction. • Restricted exercise (e.g., following injury, indoor cats, or leash-only exercise). • High drive for food, driven by genetic variation (e.g. Labrador retriever *POMC* mutation). • Uncommonly, endocrinopathies can cause obesity (hypothyroidism, insulinoma), or mimic obesity (as with the abdominal enlargement of hyperadrenocorticism).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Abdominal distention from pregnancy, ascites, hyperadrenocorticism, or neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
Normal or may reflect endocrine disruption (hyperglycemia, dyslipidemia) or concurrent disease.

OTHER LABORATORY TESTS
N/A

IMAGING
Ultrasound, MRI, or dual-energy x-ray absorptiometry can measure body fat more accurately.

DIAGNOSTIC PROCEDURES
• BCS is a semi-quantitative, ordinal measure of body composition. Observation and palpation are used to assign a score based on how findings best match a series of descriptors. The best validated 9-point scale assigns BCS 4–5 as ideal, 6–7 as overweight, and 8–9 as obese. • Serial measurement of body weight is more sensitive for monitoring.

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient. • Calorie restriction is the mainstay of successful weight loss. • Changes in owner management behavior are critical to success. • Energy requirements for maintenance are lower after weight loss so long-term vigilance and food restriction are required to prevent recurrence.

NURSING CARE
N/A

ACTIVITY
• Increasing exercise is ineffective to induce weight loss alone so if owners are reluctant to make management changes, focus should be on food restriction. • However, exercise is encouraged because it promotes retention of lean mass (muscle) during weight loss.

DIET
• Reducing daily energy intake in food to below maintenance requirements is essential. • Target weight is estimated from current weight and BCS—every 1 unit increase over BCS 5/9 equates to 10% excess body mass; e.g., to calculate the target weight of a dog in BCS 7, divide current weight by 1.2. • The amount of food required to promote weight loss can be estimated from calculated maintenance energy requirements (MER) or by reducing current food intake by 10–20%. • To calculate MER, use estimated target weight (MER (kJ) = 440 × body weight $[BW]_{kg}^{0.75}$) and feed 50–65% of MER as a starting point. • Feeding recommendations should be altered from baseline to maintain weight loss at 0.5–1% per week until target weight is reached. • For weight loss of <20% (i.e., starting BCS ≤6), food restriction is moderate and a conventional diet is adequate, although specialized diets may be advantageous. Where energy restriction is greater (starting BCS ≥7), the density of essential nutrients in maintenance diets may be inadequate so a specialized diet is recommended. • Specialized diets improve the success of weight loss programs and improve satiety, which itself may improve compliance because owners are subjected to less begging behavior. • Specialized diets are commonly formulated to provide: high essential nutrient density; low energy density (added water in canned food or air in kibble); high protein (improves satiety and promotes lean mass retention); and high fiber (promotes satiety). Canned (compared to dry) food may improve weight loss in cats. • Accurate feeding using weighed portions is important. Treats are ideally excluded but if owners feel they are essential, factor them into the diet plan.

CLIENT EDUCATION
• Owners of obese pets often do not follow advice to reduce their pets' weight because they do not recognize obesity, do not see it as a problem, or struggle to follow the advice. By definition, they have already failed to make the small adjustments needed to keep their dog slim; it follows that they are likely to find making the major changes required to reduce their dog's weight difficult. • Although it might sound simple to "feed less and exercise more," the reality is that owners are being asked to change established habits, spend more time caring for their pets, and perhaps work to motivate other family members. • Promoting those behavior changes requires us to motivate owners, to understand their barriers to change,

how to overcome those barriers. Information does not automatically lead to motivation; it is more likely if the actions required are consistent with their existing values and beliefs. • Owners may not recognize obesity. Being overweight is regarded as the norm for some breeds. Regular recording of body weight and BCS can objectively identify a problem early ("I see she's gained a pound—it would be good to cut the food down before that becomes a problem"). • Owners may not appreciate that obesity causes health problems. Positive motivation ("slimming him down could really improve his mobility") is more effective than negative ("if he doesn't lose weight he'll never walk properly again"). • Lack of motivation may be difficult to modify ("his breeder says his weight is fine") or challenge ("everyone in our family carries a little extra weight—it's cuddly"). • Owners often find food restriction difficult. Reducing intake in highly food-motivated animals may require constant vigilance to reduce scavenging, stealing, or hunting. Ignoring begging requires a strong will because of the importance of food-giving in maintaining the human–animal bond. Owners may not feel confident in how or what to feed. Practical problems may limit the exercise they offer their pet. • Practical advice to overcome those barriers should ideally be tailored to each owner. If owners complain their pets are always hungry, a satiety-promoting diet or trickle feeding using toys or frequent small meals may help. If owners insist on treat feeding, suggest low-calorie treats or factor planned treats into the daily ration. If owner mobility restricts dog walks, suggest ball play or longer time in the yard to increase activity. • Human behavior change is also improved by goal-setting, action planning, and monitoring. For instance, the aim for a weight loss consultation could be that owners leave with written plans formulated in the session: "my goal is to slim her down to 18 kg"; "I have chosen to make these 3 management changes from the list of suggestions…"; and "I will bring her back once a month to be weighed." • Fostering a nonjudgmental and supportive veterinary practice culture regarding pet obesity should encourage owners to seek support and act early.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
No approved medications for use in United States or Europe.

CONTRAINDICATIONS
N/A

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUGS
N/A

FOLLOW-UP

PATIENT MONITORING
• Monitoring progress is important. After initiating a diet change, check progress after 2 weeks and alter food ration to aim for 0.5–1% body weight loss per week. Regular monthly visits promote owner compliance and allow ration changes to maintain progress. • Once target weight is achieved, ongoing monitoring is essential to minimize rebound weight gain. Weighing at veterinary visits is ideally supplemented by owners becoming more adept at noticing weight gain and acting to reverse it.

PREVENTION/AVOIDANCE
• Prevention should be a central aim of routine vet visits. Veterinary teams should work to empower owners to recognize a healthy weight and to intervene effectively when obesity occurs. • Weight and BCS should be recorded at every practice visit. • Incorporating weight management advice into waiting room displays will establish the importance of maintaining a healthy weight to the client population.

POSSIBLE COMPLICATIONS
See Associated Conditions.

EXPECTED COURSE AND PROGNOSIS
• Food restriction leads to weight loss in research settings but in client-owned dogs has lower success rates. Compliance is frequently poor and total weight loss often falls short of the target. Rebound weight gain is common. • Encouragingly, however, even modest weight loss (of approximately 10%) can produce clinically significant improvement.

ODONTOGENIC TUMORS

BASICS

OVERVIEW

• Odontogenic tumors are defined by the World Health Organization (WHO) as "lesions derived from epithelial, ectomesenchymal and/or mesenchymal elements that still are, or have been, part of the tooth-forming apparatus".
• *Epulis* (Greek *epi-oulon* meaning "on the gum") is a nonspecific, clinical term used to describe tumors and tumor-like masses of the gingiva.
• Odontogenic tumors are categorized into three broad groups with specific tumor types in each category:
  ◦ Tumors of odontogenic epithelium: conventional ameloblastoma; canine acanthomatous ameloblastoma; amyloid-producing odontogenic tumor.
  ◦ Tumors of odontogenic epithelium with odontogenic ectomesenchyme: ameloblastic fibroma, ameloblastic fibro-dentinoma, and ameloblastic fibro-odontoma; feline inductive odontogenic tumor; odontoma.
  ◦ Tumors of mesenchyme and/or odontogenic ectomesenchyme: peripheral odontogenic fibroma; feline "epulides"; odontogenic myxoma/myxofibroma.

We focus here on the most common odontogenic tumors:
• Conventional ameloblastoma (CA):
  ◦ Benign but expansile, locular to multilocular tumor of the jaws in dogs and cats.
  ◦ Differs in biological behavior from the more common CAA.
• Canine acanthomatous ameloblastoma (CAA):
  ◦ Benign but invasive tumor of the jaws.
  ◦ Typically more invasive than expansile.
  ◦ No apparent human analogue.
• Amyloid-producing odontogenic tumor (APOT):
  ◦ Benign but expansile tumor of the jaws affecting primarily dogs.
  ◦ Similar biological behavior to the CA with a propensity to produce amyloid.
• Feline inductive odontogenic tumor (FIOT):
  ◦ Benign odontogenic tumor unique to cats.
  ◦ Generally expansile and locular with epicenter at an impacted and/or malformed maxillary canine tooth.
• Peripheral odontogenic fibroma (POF):
  ◦ Benign tumor primarily composed of periodontal ligament-like stroma arising from tissue near the alveolar margin.
  ◦ Current debate as to whether this is a tumor or a reactive lesion.
• Feline "epulides":
  ◦ Clinically presents as a typical epulis.
  ◦ Not clear whether this lesion is analogous to POF of dogs.
  ◦ Most cats are presented with multifocal lesions distributed throughout the entire oral cavity.

SIGNALMENT

• Dog—odontogenic tumors are generally considered uncommon but CAA has been reported to be the fourth most common oral tumor in dogs. POF may be even more common.
• Cat—odontogenic tumors are rare in cats.
• CAA is more common in golden retrievers and possibly cocker spaniels.
• Boxers may have higher incidence of POF.

SIGNS

Historical Findings

• Often minimal—incidental finding detected on routine physical examination.
• If severe—excessive salivation, halitosis, dysphagia, bloody oral discharge, weight loss.

Physical Examination Findings

• Oral mass—in early cases, may appear as small, pedunculated masses.
• Displacement of tooth structures due to the expansile nature of the mass.
• Possible facial deformity due to asymmetry of the maxilla or mandible.
• Occasionally cervical lymphadenopathy.
• CA—generally an intraosseous cystic lesion with osseous expansion.
• CAA—generally an extraosseous lesion with an irregular surface that arises within the gingiva; more common in rostral mandible.
• APOT—generally an expansile mass, similar to the CA; when the amyloid deposits become mineralized a mixed radiolucent–radiopaque appearance may be seen.
• FIOT—a central tumor typically presenting as a large swelling of the rostral maxilla in young cats.
• POF—typically a firm, sessile to pedunculated, nonulcerated lesion that is most often associated with the free gingiva. Infrequently seen primarily as a broad-based mass in the attached gingiva.
• Feline "epulides"—most cats present with multifocal lesions distributed throughout the entire oral cavity.

CAUSES & RISK FACTORS

None identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Benign oral tumor.
• Malignant oral tumor.
• Focal fibrous hyperplasia.
• Pyogenic granuloma.
• Gingival hyperplasia/enlargement.
• Differentiated from other types of masses by incisional biopsy coupled with radiographic appearance.

CBC/BIOCHEMISTRY/URINALYSIS

Results usually normal.

OTHER LABORATORY TESTS

Cytologic preparations are rarely diagnostic.

IMAGING

• Determine tumor borders by CT or intraoral radiographs.
• Radiographs of CA, APOT and FIOT typically demonstrate significant expansion with loculated appearance; APOT may exhibit mixed radiopacity due to mineralization of amyloid; CAA is typically infiltrative into bone; POF and feline "epulides" generally do not invade bone but can displace tooth structures and may have ossified component.
• CT scan is best modality for surgical planning.

DIAGNOSTIC PROCEDURES

A large, deep tissue biopsy (down to and including bone) is required to definitively diagnose.

TREATMENT

Surgical Considerations

• Ameloblastomas and APOT—complete surgical excision is realistic and prognosis with clean margins is good to excellent, making wide surgical excision the treatment of choice. Radiation therapy has been utilized in dogs and cats with variable results. CA is located primarily within bone and is, as such, more radioresistant.
• POF—POFs arise from periodontal-like stroma in the gingiva or underlying periosteum at or near the cementoenamel junction. Local conservative excision of the tumor with particular attention paid to removing the entire lesion, excising down to and including the affected periosteum, should be anticipated to be curative. Such an approach may, however, require reconstruction of the gingiva surrounding the remaining tooth. Recurrence is likely if the entire lesion is not excised. More aggressive treatments may be reserved for recurrent lesions or those that have a more regional, broad-based presentation.
• FIOT—similar to most odontogenic tumors, no case-controlled studies have been performed to evaluate the appropriate treatment for FIOTs. However, similar to most odontogenic tumors, it appears that if the tumor is surgically resected in its entirety (0.5–1 cm intended surgical margins), the tumor is unlikely to recur.
• Feline "epulides"—it is clear that surgical management of feline epulides, while recommended, is not as straightforward as is the case with canine POF. This is because most cats are presented with multifocal lesions, making local surgical excision alone

challenging. Recurrence with such a conservative approach is likely and some cases require multiple extractions and gingivectomy to achieve complete resolution.

MEDICATIONS

DRUG(S) OF CHOICE

- Efficacy of outpatient chemotherapy is unreported; most tumors of mesenchymal origin respond poorly.
- Intralesional bleomycin has been reported for CAA.

FOLLOW-UP

PATIENT MONITORING

- Thorough oral, head, and neck examination regularly after treatment.
- Medical surveillance with CT or intraoral radiographs every 3–6 months.

EXPECTED COURSE AND PROGNOSIS

- CA, CAA, APOT, and FIOT are highly invasive/expansile in bone.
- No known metastasis.
- Good to excellent prognosis/surgical cure can be expected when excisional margins are free of neoplastic cells.
- Mean survival after radiotherapy in dogs with CAA ranges from 1 to 102 months (median, 37 months); 1-year survival rate 85%; 2-year survival rate 67%.

MISCELLANEOUS

ABBREVIATIONS

- APOT = amyloid-producing odontogenic tumor.
- CA = conventional ameloblastoma.
- CAA = canine acanthomatous ameloblastoma.
- FIOT = feline inductive odontogenic tumor.
- POF = peripheral odontogenic fibroma.
- WHO = World Health Organization.

ODONTOMA

BASICS

OVERVIEW

- Odontoma—oral mass that arises from odontogenic epithelial and mesenchymal origin:
  - Ameloblastic fibro-odontoma (AFO) (formerly ameloblastic odontoma)—radiolucent, mass with osteolysis and varying amounts of intralesional mineralization.
  - Complex odontoma—radiodense mass with fully differentiated dental components (more organized than AFO), but unorganized at the cellular level with no tooth-like structures.
  - Compound odontoma—mass with fully differentiated dental components resulting in the presence of denticles (tooth-like structures).
- Hamartoma—proliferation of normal cellular components with an abnormal organization; not a true neoplasm (applicable to complex and compound odontoma types).
  - A definition to help delineate the three types of odontoma, not a type in itself.

SIGNALMENT

Typically found in young animals.

SIGNS

- Oral swelling or mass.
- Delayed deciduous tooth exfoliation or delayed or abnormal tooth eruption at site.
- AFO:
  - Most lesions are radiolucent with single or multiple (multilocular) expansile lesions of irregular configurations of dental components.
  - Some lesions are associated with impacted teeth.
  - Neoplastic mechanism, may recur (World Health Organization [WHO]—benign neoplasm).
- Complex:
  - Disorganized tissues within a thin, fibrous capsule.
  - Radiographically, often a radial structure of hard tissue particles inside a radiolucent zone, embedded in the maxilla or mandible.
  - Erupted teeth in that area may allow for communication between the odontoma and oral cavity, with a potential for bacterial contamination and infection.
- Compound:
  - The presence of denticles is pathognomonic.
  - Small, rudimentary teeth with crown formed, but the roots are often misshapen (dilacerated).
  - Denticles often associated with radiolucency.
  - May be embedded or have some extent of eruption.

CAUSES & RISK FACTORS

AFO

- Mixed odontogenic tumor with differentiation of odontoblasts, ameloblasts and cementoblasts embedded in cellular mesenchymal tissue.
- Reciprocal inductive interaction of epithelial and mesenchymal tissues.
- WHO classification as a benign neoplasm with possible reoccurrence.

Complex Odontoma

Inductive processes resulting in dental components but not fully organized.

Compound Odontoma

Differentiation of dental components into varying levels of organization—denticles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection.
- Foreign body.
- Dentigerous cyst.
- Other oral masses:
  - Ameloblastic fibroma—similar to AFO but would contain no hard tissue.
  - Calcifying epithelial odontogenic tumor (CEOT)—osteolysis but no mineralization or dental (mesenchymal) aspect; slow, not inductive, noninvasive.
  - Amyloid producing odontogenic tumor (APOT)—similar to CEOT, but amyloid producing; shares biologic features with ameloblastoma.
  - Peripheral odontoma (4 human cases diagnosed)—develops in gingiva or alveolar mucosa with no attachment to bone; associated with impacted or retained teeth; similar to erupted odontoma.

CBC/BIOCHEMISTRY/URINALYSIS

Typically not affected.

IMAGING

- Intraoral radiography.
- Advanced imaging typically not warranted.

DIAGNOSTIC PROCEDURES

- Histopathology.
- Complete oral examination.

TREATMENT

Surgical Considerations

- Appropriate antimicrobial and pain management therapy when indicated.
- Appropriate patient monitoring and support during anesthetic procedures.
- AFO:
  - More aggressive excision may be necessary due to neoplastic classification; consider obtaining a 1 cm surgical margin.
  - Monitor for local recurrence.
- Complex and compound odontoma:
  - Enucleation and intracapsular excision with aggressive debridement of cyst; more aggressive surgical excision can decrease the chance of recurrence.
  - No chemotherapeutic regimens recommended.
  - Rarely radiotherapy may be beneficial by treating microscopically recurring disease.

MEDICATIONS

None indicated.

FOLLOW-UP

PATIENT MONITORING

Typical postoperative—pain management, nutrition.

POSSIBLE COMPLICATIONS

Recurrence, local infection, fragile jaw structure.

EXPECTED COURSE AND PROGNOSIS

- AFO—fair to guarded prognosis, as there is a chance of recurrence.
- Complex and compound odontoma—short- and long-term prognosis good with adequate therapy.

MISCELLANEOUS

ABBREVIATIONS

- AFO = ameloblastic fibro-odontoma.
- APOT = amyloid-producing odontogenic tumor.
- CEOT = calcifying epithelial odontogenic tumor.
- WHO = World Health Organization.

OLIGURIA AND ANURIA

BASICS

DEFINITION
• Oliguria—production of an abnormally small amount of urine. Several proposed definitions; in hydrated patients with good perfusion, urine output (UOP) <1.0 mL/kg/h = absolute oliguria. Acute kidney injury (AKI) is typically polyuric, where UOP >2 mL/kg/h is expected.
• Anuria—limited/no urine formation (UOP <0.08 mL/kg/h).

PATHOPHYSIOLOGY
• Physiologic (prerenal) oliguria—kidneys limit water loss during state of reduced renal perfusion to preserve fluid and electrolyte balance. High plasma osmolality or low circulating fluid volume stimulate antidiuretic hormone (ADH) synthesis and release, which induces formation of small quantity of concentrated urine.
• Pathologic (renal) oliguria—severe renal parenchymal impairment. Factors include: high resistance in afferent glomerular vessels, low glomerular permeability, back leak of filtrate from damaged renal tubules, renal intratubular obstruction, and extensive loss of nephrons resulting in marked reduction of glomerular filtrate produced.
• Anuria—may be renal or postrenal origin. Severe renal disease occasionally causes anuria. Mechanisms are the same as for pathologic oliguria (e.g., urinary tract obstruction (UTO) or excretory pathway rupture).

SYSTEMS AFFECTED
• Renal—inability to adequately eliminate wastes and water; hyperkalemia.
• Urologic—obstruction-induced distension of the collecting system. Increased risk of urinary tract infection (UTI) due to failure to empty bladder.

SIGNALMENT
• Dog and cat.
• Young adult cats—higher incidence of anuria associated with UTO.

SIGNS
• Reduction in quantity of urine voided.
• Enlarged urinary bladder, stranguria, pollakiuria with urethral obstruction.
• Systemic signs of uremia if oliguria/anuria persists.

CAUSES
• Physiologic oliguria—renal hypoperfusion or serum hyperosmolality.
• Pathologic oliguria—AKI or advanced chronic kidney disease (CKD).
• Anuria—complete UTO, urinary tract rupture, or severe primary kidney disease.

RISK FACTORS
• Physiologic oliguria—dehydration, decreased cardiac output, hypotension.
• Pathologic oliguria and anuria—primary kidney disease, nephrotoxin exposure, dehydration, low cardiac output, hypotension, electrolyte imbalance, acidosis, fever, sepsis, liver disease, multiple organ failure, trauma, hypoalbuminemia, hyperviscosity syndrome.
• Anuria—caused by urolithiasis, urinary tract neoplasia, idiopathic feline lower urinary tract disease, functional micturition disorder, trauma, gross hematuria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Physiologic oliguria—poor tissue perfusion, history of recent fluid loss, signs of uremia are typically absent. Oliguria resolves rapidly when renal hypoperfusion is corrected.
• Pathologic oliguria—caused by CKD have a history of progressive kidney disease (polyuria, polydipsia, poor appetite, weight loss). Patients with CKD are at risk for AKI. Signs of uremia are commonly observed; fluid therapy and other measures to restore adequate renal perfusion often fail to increase urine flow.
• Suspect anuria due to UTO or rupture of the excretory pathway with repeated stranguria and inability to produce urine. Patients may have a history of pollakiuria, dysuria, hematuria, urolithiasis, trauma, instrumentation of the urinary tract. Physical exam may reveal enlarged urinary bladder, painful posterior abdomen, masses or uroliths in the urethra or bladder. Patients with rupture of the urinary tract may have ascites, fluid infiltration in tissues, painful caudal abdomen, masses or uroliths in the bladder or urethra, or evidence of trauma. UTO caused by functional urinary obstruction: suspect in patients with urinary bladder enlargement, increased resistance to manual bladder expression, and neurologic signs affecting the hind limbs and/or tail. Signs of uremia may develop. Restoring urinary flow/correcting rents in the excretory pathway rapidly restores adequate urine flow.

CBC/BIOCHEMISTRY/URINALYSIS
• Serum urea nitrogen, creatinine concentration—elevated unless onset of oliguria or anuria is very recent.
• Hyperkalemia—common with pathologic oliguria and anuria, less common/less severe in animals with physiologic oliguria (except with hypoadrenocorticism).
• Physiologic oliguria—characterized by high urine specific gravity (USG) (dogs >1.030, cats >1.035). Oliguria associated with lower USG suggests renal parenchymal disease or UTO. Patients with urine concentrating defects due to other diseases or drugs are the exception to this rule.
• Renal parenchymal anuria is typically characterized by USG <1.030 (dogs) or <1.035 (cats). USG varies in patients with post-renal anuria. Adequate urine-concentrating ability often lost after UTO.

IMAGING
• Abdominal radiographs and ultrasound are useful to rule out UTO/excretory pathway rupture.
• Excretory urography, retrograde urethrocystography, pyelography, or vaginourethrocystography may provide definitive proof of UTO/excretory pathway rupture.
• Distension of the excretory pathway or detection of uroliths in the ureters, bladder neck, urethra suggest UTO.
• Detection of fluid within the peritoneum supports a diagnosis of excretory pathway rupture. Contrast media leakage confirms a rupture.

DIAGNOSTIC PROCEDURES
• Electrocardiography—to identify significant arrhythmia (see Hyperkalemia).
• Urethrocystoscopy—may provide evidence for UTO/urinary tract rupture.
• Urinary catheterization—may provide information about the integrity of the lower urinary tract. Not recommended as a diagnostic procedure because it may be misleading and may cause additional trauma; iatrogenic UTI.

TREATMENT
• Oliguria and anuria are emergencies. Untreated, may lead to death within hours to days from uremia, hyperkalemia, acidosis, sepsis.
• Persistent hypovolemia may lead to ischemic renal injury.
• Correct renal hypoperfusion rapidly by intravenous administration of balanced isotonic crystalloid.
• Therapy for primary renal oliguria/anuria is limited to symptomatic, supportive care while awaiting spontaneous renal function recovery. Elimination of causative factors may slow or stop further renal injury (e.g., terminating aminoglycoside therapy, correcting hypercalcemia, or restoring adequate renal perfusion); however, once pathologic oliguria/anuria has developed, few kidney diseases will be amenable to specific treatment (exception = leptospirosis).
• Correct postrenal causes for anuria by nonsurgical/surgical methods including retrogradeurohydropropulsion of uroliths/urethral plugs; placement of transurethral catheters to restore low-pressure urinary flow; removal of uroliths, polyps, neoplastic tissue; or surgical repair of rents, strictures, malposition of kidneys, ureters, bladder, urethra.

OLIGURIA AND ANURIA (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

• Diuretics—indicated after establishing euvolemia in patients with renal oliguria. Diuretic-induced UOP facilitates fluid and electrolyte therapy and may imply less severe kidney injury.
• Administration of diuretics before restoring adequate renal perfusion is counterproductive and may promote renal injury.
• Avoid diuretic-induced dehydration.
• Furosemide 2–4 mg/kg IV—often used first in patients with renal oliguria. Urinary flow should increase within 1 hour; if not, repeat at the same or double dosage. If diuresis ensues, administer to sustain diuresis (0.25–1 mg/kg/h or 2–4 mg/kg IV q8h). Reduction in glomerular filtration rate (GFR) may be seen with therapy.
• Mannitol 0.25–1 g/kg IV can be given as a 10% or 20% solution over 15–20 minutes. Urinary flow should increase within 1 hour. Do not repeat if diuresis does not ensue; may cause excessive volume expansion. If diuresis ensues, mannitol may be continued as continuous infusion (1–2 mg/kg/h) or intermittent IV doses (0.25–0.5 g/kg every 4–6 hours) to sustain diuresis. Avoid mannitol when overhydration, pulmonary edema, or congestive heart failure present.
• Fenoldopam 0.1–0.8 µg/kg/min, a selective dopamine A1 receptor antagonist, promotes diuresis in healthy animals and increases GFR in dogs. Evidence of efficacy in animals with renal disease is lacking.

CONTRAINDICATIONS

Nephrotoxic drugs.

PRECAUTIONS

• Administer fluids carefully to patients that are persistently oligoanuric to avoid overhydration. Do not continue to administer fluids to oligoanuric patients after their fluid volume deficit has been restored in the absence of a plan to prevent development of overhydration. In patients with unresponsive renal oliguria, peritoneal dialysis/hemodialysis may be required to correct iatrogenic fluid-induced volume overexpansion.
• Failure to correct fluid deficits before initiating diuretic administration may cause further renal hypoperfusion and ischemic renal injury.
• Use drugs requiring renal excretion with caution.
• Avoid electrolyte solutions containing >4 mEq of potassium/L. Some hypokalemic patients may require cautious administration of higher doses of potassium.
• Dopamine can cause arrhythmias, particularly in animals with hyperkalemia. Its use is no longer recommended.

POSSIBLE INTERACTIONS

Furosemide may promote the nephrotoxicity associated with aminoglycoside antibiotics.

FOLLOW-UP

PATIENT MONITORING

• UOP—determine early during the course of management. When unclear, consider transurethral catheterization to accurately determine UOP. Place catheters using aseptic technique. Short indwelling time lowers the risk of UTI. Properly placed/managed indwelling catheters are usually safe for at least 48 hours. Use a closed, sterile drainage system.
• Creatinine, serum urea nitrogen, and potassium concentrations should be reevaluated q12–24 hours; patients with severe hyperkalemia need more frequent monitoring.
• ECG should be performed at appropriate intervals to assess cardiac effects of drugs and hyperkalemia and to monitor response to therapy.

PREVENTION/AVOIDANCE

• Avoid nephrotoxic drugs.
• Avoid dehydration and hypoperfusion.

POSSIBLE COMPLICATIONS

• Hyperkalemia and arrhythmia.
• Uremia.
• Dehydration.
• Overhydration.

EXPECTED COURSE AND PROGNOSIS

• Oliguria and anuria are poor prognostic signs in AKI or CKD; unless urine outflow can be corrected, survival is not expected.
• Anuria associated with UTO is often reversible if urethral patency is restored.

MISCELLANEOUS

SEE ALSO

• Acute Kidney Injury.
• Azotemia and Uremia.
• Chronic Kidney Disease.
• Hyperkalemia.
• Nephrotoxicity, Drug-Induced.
• Urinary Tract Obstruction.

ABBREVIATIONS

• ADH = antidiuretic hormone.
• AKI = acute kidney injury.
• CKD = chronic kidney disease.
• GFR = glomerular filtration rate.
• UOP = urine output.
• USG = urine specific gravity.
• UTI = urinary tract infection.
• UTO = urinary tract obstruction.

OLLULANUS INFECTION

BASICS

OVERVIEW
- *Ollulanus* adult worms are found in stomach of cats.
- Infection causes chronic gastritis resulting in anorexia, vomiting, weight loss.
- No intermediate hosts required to complete lifecycle; transmission is mainly by contact with vomitus of infected cats.
- Eggs develop into larvae within female worm; released larvae may mature to adults without leaving stomach.

SIGNALMENT
- Colony cats—predisposed, probably because of access to other cats' vomitus.
- Stray cats living in urban areas heavily populated with cats—high incidence of infection.
- Captive cheetahs, lions, tigers, cougars—susceptible.

SIGNS
- Chronic vomiting, anorexia, weight loss.
- Death from chronic gastritis.

CAUSES & RISK FACTORS
- *Ollulanus tricuspis*—adults (only up to 1 mm in length) coil into gastric mucosa, causing superficial erosions.
- Over time, gastric erosions can become severe with marked inflammation, accumulation of lymphoid aggregates, and fibrous changes in mucosa and submucosa.
- Eggs—hatch within female worms; larvae develop to infective L3 larvae within stomach.
- L3 larvae and adults—vomited and infective to other cats; internal autoinfection also occurs.
- No fecal transmission known.
- Distributed throughout North America, Australia, New Zealand, Europe, Argentina, Chile.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Other causes of vomiting including:
- Dietary.
- Intoxications.
- Metabolic—diabetes mellitus, renal disease, liver disease, acidosis, heat stroke, hypoadrenocorticism, hyperthyroidism.
- Gastric abnormalities—inflammatory bowel disease, neoplasia, obstruction, atrophic gastritis, ulcers, dilatation/volvulus, parasitic such as *Physaloptera*.
- Gastroesophageal junction disorders—hiatal hernia.
- Small intestinal disorders—inflammatory bowel disease, neoplasia, fungal, viral, obstruction, paralytic ileus.
- Large intestinal disorders—colitis, obstipation, inflammatory bowel disease.
- Abdominal disorders—pancreatitis, gastrinoma, peritonitis, steatitis, pyometra, diaphragmatic hernia, other neoplasia.
- Neurologic disorders—psychogenic, motion sickness, vestibular lesions, head trauma, neoplasia.
- Miscellaneous—heartworm disease and heart disease.

CBC/BIOCHEMISTRY/URINALYSIS
Reflects vomiting—dehydration, hypovolemia.

OTHER LABORATORY TESTS
- Baermann—examine vomitus for L3 larvae.
- Fecal examination, direct or flotation—larvae or eggs seldom found in feces as they are digested within the gastrointestinal tract.

IMAGING
Abdominal ultrasound—may show gastric thickening; rarely see parasites.

DIAGNOSTIC PROCEDURES
- View worms through an endoscope—difficult due to size of worms.
- Gastric lavage—using saline collection followed by centrifugation to precipitate L3 larvae, or use Baermann technique.
- Histopathology—gastric biopsy occasionally shows parasites.

TREATMENT

Anthelmintic use is extra-label and anecdotal.

MEDICATIONS

DRUG(S) OF CHOICE
- Fenbendazole 50 mg/kg PO q24h for 5 days, oxfendazole 10 mg/kg q24h for 5 days, and pyrantel pamoate 10 mg/kg PO q24h for 3 days are recommended but there is little information available regarding treatment success.
- Tetramisole—give as a 2.5% formulation at 5 mg/kg PO once; effective but not available in the United States.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Tetramisole—at this dose should not cause any side effects in cats.

FOLLOW-UP

Warn owner to watch for further vomiting—retreatment may be required.

MISCELLANEOUS

Ollulanus infection has been identified in a cat with concurrent gastric adenocarcinoma.

Consulting Editor Amie Koenig

OPHTHALMIA NEONATORUM

BASICS

OVERVIEW
- Infection of the conjunctiva and/or cornea before or just after the separation of the eyelids in the neonate.
- Occurs in puppies and kittens.
- Associated with *Staphylococcus* spp. or *Streptococcus* spp. in dogs and cats, and with herpesvirus in cats.
- Potentially vision threatening.
- Source of infection—believed to be from an intrauterine infection, a vaginal infection of the dam at the time of birth, or from a nonhygienic environment.

SIGNALMENT
- Affects all breeds of cats and dogs.
- Neonates before the time that the eyelids open (10–14 days postpartum).

SIGNS
- Upper and lower eyelid margins are fused (physiologic ankyloblepharon) and lids bulge outward because of the accumulation of debris and discharge within the conjunctival sac (Figure 1).
- Mucous to mucopurulent discharge may extrude through a patent opening at the medial canthus.
- Cornea and conjunctiva may be ulcerated.
- May note adhesions (symblepharon) of the conjunctiva to the cornea or to other areas of the conjunctiva (including that of the nictitans).
- Perforation of the cornea with iris prolapse and collapse of the globe is occasionally seen.

CAUSES & RISK FACTORS
- Intrauterine or vaginal infections in the dam near the time of birth.
- Unclean environment for the neonates.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Neonates with entropion in which the eyelids have already separated—mucus to mucopurulent discharge may be present; view of the cornea may be obscured; may have appearance of ankyloblepharon; differentiated by age (patients older than 10–14 days) and ability to separate the eyelids.

CBC/BIOCHEMISTRY/URINALYSIS
Normal unless there is a concurrent systemic infection.

OTHER LABORATORY TESTS
- Cultures of neonate's ocular discharge and/or dam's vaginal discharge—may help diagnose bacterial infection and guide antibacterial therapy.
- Cytology of the affected tissues—may help diagnose bacterial infection and guide antibacterial therapy.
- Immunofluorescent antibody or PCR tests (cats)—feline herpesvirus.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Full physical examination of the dam and neonate.
- Fluorescein staining—corneal or conjunctival ulceration.

TREATMENT
- Separation of the eyelids—cornerstone of treatment; can be accomplished by careful massage and manual traction beginning at the medial canthus or introduction of a closed hemostat, small blunt scissor blade or the blunt, butt end of a scalpel blade into the patent opening or groove of the future lid fissure at the medial canthus and gently separating (not cutting) the eyelids.
- Lavage of conjunctival sac and cornea with warm saline or a 1:50 diluted povidone–iodine aqueous solution to remove the discharge.
- Warm compresses may aid in separating the eyelids and preventing readherence.
- Systemic support as needed.

MEDICATIONS

DRUG(S) OF CHOICE
- Broad-spectrum, topical antibiotics—e.g., neomycin/bacitracin/polymyxin B; applied 4 times daily for at least 1 week; antibiotic chosen on basis of bacterial culture and sensitivity, if available.
- Antiviral therapy in the case of herpesvirus infection in cats.

Figure 1.

Ophthalmia neonatorum. Typical outward-bulging lids due to accumulation of debris and discharge within the conjunctival sac. Source: Ophthalmology Section, Vetsuisse Faculty, University of Zurich.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Tetracyclines—do not use in neonates because of the risk of affecting bone or teeth; topical ofloxacin or ciprofloxacin is drug of choice for *Chlamydophila*.
- Topical corticosteroids—contraindicated.

FOLLOW-UP

PATIENT MONITORING

- Warm compresses—may be necessary for a few days to keep the eyelids from readhering.
- Topical antibiotics—continued for a minimum of 7 days.
- Observe littermates that are not initially affected.
- Treat vaginal infections in the dam with appropriate medications.

PREVENTION/AVOIDANCE

- Keep the external environment and the dam's nipples clean.
- Treat vaginal infection in the dam before delivery, if possible.

POSSIBLE COMPLICATIONS

- Severe keratitis with scarring and symblepharon.
- Rupture of the cornea with secondary phthisis; blindness may be irreversible.

EXPECTED COURSE AND PROGNOSIS

Favorable with correct and timely diagnosis and treatment and if no major complications occur.

OPIATES/OPIOIDS TOXICOSIS

BASICS

DEFINITION
- Opiates are derived from opium; opioids are synthetic.
- Opium was initially obtained from unripe seed capsules of the *Papaver somniferum* (poppy plant). Raw opium powder contains 24 alkaloids including ~10% morphine, 0.5% codeine, and thebaine (codeine methyl enol ether).
- Opioids have been used for millennia, but human use and abuse of opioids has drastically increased the last several years and has been increasing overall for the prior 20 years. This corresponds to an increase in accidental canine oral exposures.
- In dogs, opioids generally act as CNS, respiratory, and cardiovascular depressants, however thebaine has stimulatory properties.
- In cats, CNS stimulation often occurs following opioid toxicosis.
- Range of opioids and opiates includes:
  - Agonists—morphine, codeine, hydromorphone, oxycodone, fentanyl, heroin, desomorphine, alfentanil, tramadol (also a serotonin reuptake inhibitor), loperamide (relatively low concentrations achieved in the CNS).
  - Partial agonists or agonists/antagonists—butorphanol, buprenorphine.
- Toxic dose is highly variable depending on specific opioid. Cats have an increased susceptibility to morphine due to the lack of glucuronyl transferase and therefore glucuronidation.

PATHOPHYSIOLOGY
- Opioids are weakly acidic and well absorbed by oral and transmucosal route.
- Significant hepatic metabolism and first pass effect.
- Oral exposure to cut or chewed transdermal patches can result in increased and rapid absorption compared to that of the intended transdermal route. The amount of fentanyl remaining in used patches is highly variable and can be between 28 and 84%.
- Opioid receptors are found in the CNS, autonomic nervous system (ANS), gastrointestinal (GI) tract, heart, kidney, adipocytes, lymphocytes, vas deferens, and adrenal gland. The receptor types present and the clinical significance in toxicosis varies widely between tissue type.
- Major opioid receptors include:
  - mu—2 specific types. Agonist stimulation of mu_1 results in supraspinal analgesia while mu_2 results in spinal analgesia, respiratory suppression and decreased GI motility.
  - delta—equivocal role; possibly potentiates mu receptor agonists or has increased selectivity for enkephalins compared to mu receptors. Results in spinal analgesia and possibly decreased GI motility, decreased cardiovascular function, and altered behavior.
  - kappa—agonist stimulation results in analgesia, sedation, and dysphoria.
  - sigma—does not mediate analgesia significantly; no longer classified as an opioid receptor.
- Minor receptors include: epsilon and zeta.

SYSTEMS AFFECTED
- Respiratory—respiratory depression, hypoxia, apnea.
- Cardiovascular—bradycardia, hypotension, cardiovascular collapse, vasodilation, hypertension.
- Nervous—dog: CNS depression, ataxia, seizures, coma; cat: CNS stimulation, aggression, vocalization, ataxia.
- Gastrointestinal—vomiting, hypersalivation, ileus, constipation.
- Behavioral—aggression.
- Ophthalmic—miosis initially; mydriasis more commonly in cats and in dogs if hypoxia occurs.
- Hemic/lymphatic/immune—immune suppression reported in humans and potential in canines/felines with chronic exposures.
- Other—hypothermia, hyperthermia.

GENETICS
Dogs with the *MDR1*/*ABCB1* genetic mutation have an increased sensitivity to loperamide. Clinical signs may occur at approximately 0.06 mg/kg, compared to 0.65 mg/kg in dogs with no mutation.

INCIDENCE/PREVALENCE
- Opioid exposures are underreported by animal owners due to stigma and fear of law enforcement.
- Increased incidence of exposure among police or narcotic working dogs.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Collies, and other breeds prone to the *MDR1*/*ABCB1* gene mutation have a greater sensitivity to loperamide.

Mean Age and Range
Increased risk of exposure with puppies and younger adult dogs due to general increased incidence of dietary indiscretions.

SIGNS
- Dogs—analgesia, lethargy, ataxia, hypotension, bradycardia, arrhythmia, bradypnea, vomiting, ileus, early excitation and tachypnea, hypothermia, miosis, hypersalivation, defecation, cyanosis, coma.
- Cats—analgesia, CNS excitation, aggression, depression, hypotension, arrhythmia, seizures, mydriasis, ileus, bradypnea (tachypnea possible early), hypothermia, miosis, hyperthermia.

CAUSES
- Primarily dietary indiscretion of prescription medications or illicit opioids.
- Other possible exposures include iatrogenic exposure, malicious intent, and severe exposures in dogs that have been used to transport drugs illicitly ("pack dogs" or "mule dogs") where the packages have ruptured while inside the dog.

RISK FACTORS
- Access to opioids/opiates.
- Police or narcotic working dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Depressants—other possible intoxicants including benzodiazepines, barbiturates, marijuana/tetrahydrocannabinol (THC), rodenticide (bromethalin), ivermectin, alcohol, ethylene glycol, xylitol; trauma; infection (encephalitis); other causes of encephalopathy or hypoglycemia.
- Stimulants—amphetamines and amphetamine-like medications/drugs, cocaine, caffeine, metaldehyde, strychnine.

CBC/CHEMISTRY/URINALYSIS
No alterations expected directly from opioid exposure, though secondary alterations may occur depending on presence and degree of clinical signs.

OTHER LABORATORY TESTS
- Over-the-counter urine drug tests may have positive results following an exposure to opioids/opiates depending on the specific drug, dose ingested, and time frame. Possible false positives include rifampin, quinolone antibiotics, and poppy seeds.
- Serum or urine gas chromatography–mass spectrometry (GC/MS) or liquid chromatography tandem mass spectrometry (LC/MS-MS) may be performed, but results are unlikely to be available in a timely fashion to help guide treatment.

IMAGING
None

DIAGNOSTIC PROCEDURES
None

PATHOLOGIC FINDINGS
No specific findings.

TREATMENT

APPROPRIATE HEALTH CARE
- Inpatient vs. outpatient medical management depends largely on the dose ingested, time

(CONTINUED) OPIATES/OPIOIDS TOXICOSIS

frame, and clinical signs. Typically, inpatient medical management is recommended with a recent ingestion significantly above therapeutic doses (if available).
• For inpatient care, monitor for development or worsening of clinical signs and treat as needed. If there is severe respiratory depression, intubation and ventilation may be required and may necessitate transfer to a referral center depending on locally available facilities.

NURSING CARE
Monitor neurological status, temperature, respiratory rate, heart rate/electrocardiogram, blood pressure, hydration, and evidence of normal GI motility. Correct abnormalities as needed.

ACTIVITY
Prevent self-trauma while the patient has CNS depression or agitation.

DIET
Feed normally if the patient can protect their airway.

CLIENT EDUCATION
• Minimize potential future exposures.
• Keep medications/drugs out of reach of pets and pets away from gatherings where exposure is possible.

SURGICAL CONSIDERATIONS
If packets containing drugs have been surgically placed in a "pack dog" or ingested whole by a police or narcotic working dog, surgical removal of the intact packets is prudent.

MEDICATIONS

DRUG(S) OF CHOICE
• Decontamination:
  ◦ If asymptomatic, induce emesis in dogs within 1–2 hours post ingestion with apomorphine (0.03 mg/kg IV) or H_2O_2 (1 mL/kg PO first dose, 2 mL/kg (up to 50 mL) PO second dose if the dog does not vomit within 10–15 minutes). Do not induce emesis if there is risk of aspiration.
  ◦ Gastric lavage may be performed within 1–2 hours of an ingestion if unable to induce emesis due to clinical signs or large dose was ingested.
• Activated charcoal with a cathartic (sorbitol) ×1 dose. Administer activated charcoal without a cathartic q6–8h × 2 additional doses for medications/drugs that undergo enterohepatic recirculation (e.g., morphine) or extended release products.
• IV fluids to maintain hydration and perfusion; adjust rate as needed based on cardiovascular and hydration status.
• Naloxone (reversal agent with a high affinity for the mu receptor) 0.01–0.04 mg/kg IV, IM, or SQ. Depending on response, may need to increase dose (0.1–0.2 mg/kg) to reach an effective dose in cats or with opioids such as buprenorphine that have a strong mu bonds and/or also bind the delta or kappa receptors. The duration of action is short (<2–3 hours in dogs; <1 hour in cats); redose as needed based on recurrence of clinical signs.
• Ileus—metoclopramide 0.1–0.5 mg/kg IM, SQ, PO q6h or 1–2 mg/kg/day IV CRI.
• Seizures—diazepam 0.5–1 mg/kg IV or phenobarbital 3–10 mg/kg IV to effect.

CONTRAINDICATIONS
None

PRECAUTIONS
Naloxone is not effective for reversing seizures resulting from meperidine, tramadol, or propoxyphene toxicosis.

POSSIBLE INTERACTIONS
None

ALTERNATIVE DRUG(S)
Butorphanol 0.05–0.1 mg/kg IV, IM PRN to partially reverse pure mu agonists.

FOLLOW-UP

PATIENT MONITORING
• Discharge when asymptomatic. No further monitoring is expected to be required if severe clinical signs such as persistent poor perfusion, hyperthermia, seizures did not occur.
• If severe signs occurred, secondary renal or hepatic elevations are possible (though unlikely), and ongoing monitoring is recommended as needed based on the clinical signs. Acute kidney injury may occur if there is prolonged hypotension present; hepatic and creatine kinase elevations with persistent seizures/hyperthermia.

PREVENTION/AVOIDANCE
• Minimize access for ingestion of opioids/opiates. Additional training, supervision, and use of basket muzzles for working police or narcotic dogs.
• Verify dose and concentration prior to administration of opioids therapeutically.

POSSIBLE COMPLICATIONS
• None routinely expected.
• Possibility for secondary complications in rare cases with severe clinical signs.

EXPECTED COURSE AND PROGNOSIS
Prognosis is dose dependent, though generally good if clinical signs are controlled.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Potential for co-ingestion of other medications/drugs (illicit or prescription).

AGE-RELATED FACTORS
Neonatal patients may have an increased risk of CNS signs due to incomplete blood–brain barrier formation.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Potential for exposure to fetus, embryos, and nursing young.

SYNONYMS
• Codeine—schoolboy, T-3.
• Desomorphine—krokodil.
• Fentanyl—cash, China white, tango, TNT.
• Heroin—brown sugar, H, hell dust, junk, smack, [black] tar.
• Morphine—M, Miss Emma, dreamer.

ABBREVIATIONS
• ANS = autonomic nervous system.
• GC/MS = gas chromatography–mass spectrometry.
• GI = gastrointestinal.
• LC/MS-MS = liquid chromatography tandem mass spectrometry.

O

OPTIC NEURITIS AND PAPILLEDEMA

BASICS

DEFINITION
• Optic neuritis—inflammation of one or both optic nerves, resulting in reduction of visual function.
• Papilledema is edema of the optic nerve head that does not obviously affect the function of the optic nerve.

PATHOPHYSIOLOGY
• Optic neuritis may be a primary disease or secondary to CNS disease because the optic nerve communicates with the subarachnoid space.
• Papilledema occurs when intracranial pressure (ICP) is elevated.
• Papilledema may occur separately from optic neuritis.
• Optic neuritis may also feature papilledema.

SYSTEMS AFFECTED
• Nervous.
• Ophthalmic.

GENETICS
No genetic basis.

INCIDENCE/PREVALENCE
Occasional cause of blindness in dogs; rare in cats.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
Middle-aged.

Predominant Sex
None

SIGNS

Historical Findings
• Optic neuritis—acute blindness, may report other neurologic abnormalities such as ataxia, seizures, or behavior changes.
• Papilledema—no clinically detectable visual abnormalities but may report other neurologic abnormalities attributable to increased ICP.

Physical Examination Findings
• Optic neuritis—may be unilateral or bilateral; absent menace response, absent dazzle, mydriatic and nonresponsive pupil; may have anisocoria if unilaterally affected. Usually, the anterior segment appears normal, but hyperemia, congestion, and hemorrhages of the optic nerve head are seen. The retina surrounding the optic nerve may be detached; chorioretinitis can occur concurrently.
• Papilledema—usually bilateral, menace response is present, dazzle is present, normal pupillary light reflexes. The anterior segment appears normal, but there is swelling and elevation of optic nerve head with loss of the physiologic cup in the center of the optic nerve head. The retina usually appears normal.

CAUSES

Optic Neuritis
• Idiopathic (dogs).
• Systemic mycoses.
• Canine distemper (dogs).
• Feline infectious peritonitis (FIP) (cats).
• Neoplasia—primary or metastatic.
• Toxoplasmosis.
• *Neosporum caninum*.
• Granulomatous meningoencephalomyelitis.
• Ehrlichiosis.
• Orbital cellulitis.
• Hepatozoonosis.
• Toxicity—lead.
• Tick-borne encephalitis virus.

Papilledema
• CNS neoplasia (primary or metastatic).
• Hepatic encephalopathy.
• Hydrocephalus.
• Distemper (dogs).
• FIP (cats).
• Systemic mycoses.
• Toxoplasmosis.
• Granulomatous mengingoencephalitis.
• Trauma.

RISK FACTORS
None

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Papilledema is differentiated from optic neuritis by the presence of normal pupillary light reflexes and no obvious visual deficits.
• Cortical blindness—normal pupillary light reflex; normal fundus examination; possibly other neurologic deficits; normal electroretinogram.
• Sudden acquired retinal degeneration syndrome (SARDS, dogs)—normal to absent pupillary light reflex; normal fundus (early in course); flat electroretinogram.

CBC/BIOCHEMISTRY/URINALYSIS
No specific abnormalities.

OTHER LABORATORY TESTS
Specific viral, protozoal, or fungal serologic tests as indicated.

IMAGING
Neuroimaging—MRI and/or CT may demonstrate intracranial disease.

DIAGNOSTIC PROCEDURES
• CSF analysis.
• Electroretinogram—investigate retinal function; normal in patients with optic neuritis and papilledema, flat in those with SARDS.
• Measure ICP.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient—most cases will need to be hospitalized for workup and medical therapy depending on the primary disease process.

NURSING CARE
Depending on degree of neurologic impairment, special attention to patient cleanliness.

ACTIVITY
Activity may need to be restricted if visual deficits are present and depending on degree of neurologic impairment.

DIET
May need to be altered depending on degree of neurologic impairment.

CLIENT EDUCATION
Optic neuritis—important to emphasize that vision may not return, particularly in idiopathic cases, and treatment may be life-long (immunosuppressive therapy).

SURGICAL CONSIDERATIONS
Surgery infrequently indicated.

MEDICATIONS

DRUG(S) OF CHOICE

Optic Neuritis
• Depends on primary disease process when identifiable, treat any infectious process identified.
• Idiopathic—prednisone 2 mg/kg PO q12h for 14 days; then 1 mg/kg PO q12h for 14 days; then gradual reduction to maintenance dosage.

Papilledema
• Mannitol 1 g/kg IV over 20 minutes; repeated as necessary to treat elevated ICP.
• Hypertonic saline 3 mL/kg IV over 10 minutes as alternative therapy for elevated ICP.
• Corticosteroids—prednisone 0.5 mg/kg PO q12h or dexamethasone SP 0.025 mg/kg IV q12h; not indicated for head trauma.

CONTRAINDICATIONS
Immunosuppressive drugs may be contraindicated in patients where etiology is unknown.

PRECAUTIONS
Ensure patients receiving mannitol can urinate; immunosuppressive agents should be used cautiously in patients with infectious disease.

(CONTINUED) OPTIC NEURITIS AND PAPILLEDEMA

POSSIBLE INTERACTIONS
None

FOLLOW-UP

PATIENT MONITORING
Serial ophthalmic examinations should be performed, including fundic exam. Careful attention should be paid to visual deficits; resolution of deficits indicates improvement in disease, but may also reflect the patient's adaptation to vision loss, making client's reports of vision unreliable.

PREVENTION/AVOIDANCE
None

POSSIBLE COMPLICATIONS
- Optic neuritis—vision loss may be permanent.
- Papilledema—increased ICP may result in brain herniation if not treated emergently.

EXPECTED COURSE AND PROGNOSIS
- Optic neuritis—guarded to poor prognosis for return of vision, but idiopathic cases have good prognosis for life.
- Papilledema—guarded to poor prognosis for life.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Optic neuritis—chorioretinitis, CNS disease.
- Papilledema—CNS disease.

AGE-RELATED FACTORS
None

ZOONOTIC POTENTIAL
Zoonotic infectious CNS disease is rare.

PREGNANCY/FERTILITY/BREEDING
Infectious diseases such as canine distemper may be associated with fetal disease and congenital abnormalities.

ABBREVIATIONS
- FIP = feline infectious peritonitis.
- ICP = intracranial pressure.
- SARDS = sudden acquired retinal degeneration syndrome.

Suggested Reading

ORAL CAVITY TUMORS, UNDIFFERENTIATED MALIGNANT TUMORS

BASICS

OVERVIEW
- Uncommon, highly aggressive, rapidly growing tumor typically affecting the caudal maxilla and orbit of young dogs.
- Most are highly bone-invasive and are non-encapsulated with a smooth to slightly nodular surface (mistaken as benign); may become ulcerated.
- Biopsy—reveals undifferentiated malignancy of undetermined histogenesis.
- Highly metastatic—regional lymphatic spread and distant sites.
- Local disease often represents life-limiting issue despite the high metastatic propensity.

SIGNALMENT
- Dog.
- Primarily a disease of large breeds.
- All dogs <2 years old; range 6–22 months.
- No sex predilection reported.

O

SIGNS

Historical Findings
- Excessive salivation.
- Halitosis.
- Dysphagia.
- Hyporexia.
- Bloody oral discharge.
- Weight loss.

Physical Examination Findings
- Oral mass.
- Loose teeth.
- Facial deformity, exophthalmia.
- Regional lymphadenopathy.
- Pain upon palpating or opening the mouth.

CAUSES & RISK FACTORS
None identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other aggressive oral malignancy such as oral melanoma, squamous cell carcinoma, or fibrosarcoma.
- Acanthomatous ameloblastoma/peripheral odontogenic fibroma.
- Foreign body reaction.
- Tooth root abscess.

CBC/BIOCHEMISTRY/URINALYSIS
Often normal.

OTHER LABORATORY TESTS
N/A

IMAGING
- High detail skull/dental radiography—evaluate for osteolytic changes.
- 3-view thoracic radiography—detect lung metastasis.
- Advanced sectional imaging (CT or MRI)—define local and regional/distant extent of disease, and facilitate therapeutic planning.

DIAGNOSTIC PROCEDURES
- Carefully palpate regional lymph nodes (mandibular, retropharyngeal, superficial cervical).
- Cytologic evaluation of primary tumor and regional lymph nodes may provide tentative diagnosis of malignancy.
- Large, deep-tissue biopsy required to differentiate from other oral malignancies.
- Fine-needle aspiration or biopsies of primary tumor should always be taken from inside the mouth, not through the overlying skin (could compromise local control with surgery).
- Histopathology consistent with an undifferentiated tumor without characteristic morphologic features of mesenchymal or epithelial origin.
- Immunocytochemistry (various markers) required to rule out other tumors, including rhabdomyosarcoma (aggressive tumor also seen in young dogs).

TREATMENT

Diet
Soft food recommended to prevent tumor ulceration or following radical oral excision.

Surgical Considerations
- Radical surgical excision—often ineffective because of extensive local disease or regional metastasis at diagnosis.
- If attempted, must have margins of at least 2 cm into normal bone and soft tissues and ideally be planned with the help of contrast-enhanced advanced sectional imaging.

Radiation Therapy
- Efficacy unreported.
- Undifferentiated tumors often poorly responsive to megavoltage radiation therapy.
- Considered for palliation (hypofractionated protocol).

MEDICATIONS

DRUG(S) OF CHOICE
- Chemotherapy—efficacy unreported; undifferentiated tumors often poorly responsive to systemic chemotherapy.
- Pain management with multimodal analgesic therapy is mandatory (nonsteroidal anti-inflammatory drug, opioid, adjuvant analgesic medications, aminobisphosphonate if osteolysis is present).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Chemotherapy can be toxic; seek advice of a medical oncologist before initiating treatment if you are unfamiliar with cytotoxic drugs.

FOLLOW-UP
- Most dogs have detectable metastatic dissemination at diagnosis.
- Patients often euthanized within 30 days of diagnosis because tumor growth is progressive and uncontrolled, resulting in decreased quality of life and condition.

ORBITAL DISEASES (EXOPHTHALMOS, ENOPHTHALMOS, STRABISMUS)

BASICS

DEFINITION
- Abnormal position of the globe.
- Exophthalmos—anterior displacement of the globe.
- Enophthalmos—posterior displacement of the globe.
- Strabismus—deviation of the globe from the correct position of fixation, which the patient cannot correct.

PATHOPHYSIOLOGY
- Orbit cannot be examined directly; orbital disease manifested by signs that alter the position, appearance, or function of the globe and adnexa.
- Malpositioned globe—caused by changes in volume (loss or gain) of the orbital contents or abnormal extraocular muscle function.
- Exophthalmos—caused by space-occupying lesions posterior to the equator of the globe.
- Enophthalmos—caused by loss of orbital volume, Horner's syndrome, or space-occupying lesions anterior to the equator of the globe.
- Strabismus—usually caused by an imbalance of extraocular muscle tone or lesions that restrict extraocular muscle mobility.

SYSTEMS AFFECTED
- Ophthalmic.
- Respiratory—because of proximity, the nasal cavity and frontal and maxillary sinuses may be involved.

SIGNALMENT
- Dog and cat.
- Orbital abscess or cellulitis and myositis—more common in young adult dogs.
- Myositis—predisposed breeds: German shepherd dog, golden retriever, Weimaraner.
- Orbital neoplasia—more common in middle-aged to old dogs.

SIGNS

Exophthalmos
- Secondary signs of space-occupying orbital disease.
- Difficulty in retropulsing the globe.
- Serous to mucopurulent ocular discharge.
- Chemosis.
- Eyelid swelling.
- Lagophthalmos—inability to close the eyelids over the cornea during blinking.
- Exposure keratitis—with or without ulceration.
- Pain on opening the mouth.
- Third eyelid protrusion due to extraconal mass or advanced intraconal mass.
- Visual impairment due to optic neuropathy.
- Fundic abnormalities, including retinal detachment, retinal vascular congestion, optic disc swelling.
- Focal inward deviation of the posterior globe.
- Neurotropic keratitis after damage to the ophthalmic branch of cranial nerve V.
- Fever and malaise—with orbital abscess or cellulitis.
- Intraocular pressure (IOP)—rarely high.

Enophthalmos
- Ptosis.
- Third eyelid protrusion.
- Extraocular muscle atrophy.
- Entropion—with severe disease.

Strabismus
- Deviation of one or both eyes from the normal position.
- May note exophthalmos or enophthalmos.

CAUSES

Exophthalmos
- Neoplasm—primary or secondary.
- Abscess or cellulitis—bacterial or fungal; fungal more likely in cats; look for foreign bodies:
  - Bacterial infections may be mixed; *Pasteurella multocida* and *Enterobacteriaceae* common.
- Zygomatic mucocele—not described in cats.
- Myositis—muscles of mastication or extraocular muscles (eosinophilic or extraocular polymyositis).
- Orbital hemorrhage secondary to trauma.
- Arteriovenous fistula or varix—rare.

Enophthalmos
- Ocular pain.
- Microphthalmia.
- Phthisis bulbi.
- Collapsed globe.
- Horner's syndrome.
- Dehydration.
- Loss of orbital fat or muscle.
- Conformational enophthalmos in dolichocephalic breeds.
- Neoplasia—especially if originating from rostral orbit.

Strabismus
- Abnormal innervation of extraocular muscle.
- Restriction of extraocular muscle mobility by scar tissue from previous trauma or inflammation.
- Destruction of extraocular muscle attachments after proptosis.
- Convergent strabismus—congenital; results from abnormal crossing of visual fibers in the CNS (Siamese cats).
- Shar-pei strabismus.

RISK FACTORS
Proptosis—more common in brachycephalic dogs with shallow orbits.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Similar Signs
- Buphthalmic globe—may simulate a space-occupying mass causing anterior displacement of the eye owing to its size in relationship to the orbital volume; IOP usually high; corneal diameter greater than normal, corneal edema, mydriatic pupil, optic nerve cupping (i.e., signs of glaucoma), blindness.
- Episcleritis—may cause severe diffuse or focal thickening of the fibrous tunic, imitating a buphthalmic globe; corneal edema; normal or low IOP; aqueous flare.

Causes
- Acute onset of exophthalmos—often with inflammatory orbital disease. Pain, especially on opening the mouth, is more likely inflammatory orbital disease than orbital neoplasia.
- Salivary mucoceles—more variable in speed of onset and degree of patient discomfort.
- Extraocular or eosinophilic myositis—bilateral diseases; *Neospora caninum* caused extraocular polymyositis in a litter of dogs.
- Neoplasia—usually slowly progressive, nonpainful, unilateral exophthalmos.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Leukogram—may show inflammation (abscess, cellulitis, or myositis).
- Peripheral eosinophilia—occasionally seen in dogs with eosinophilic (masticatory muscle) myositis.

IMAGING
- Orbital ultrasonography, CT and MRI—define the extent of the lesion(s) and distinguish between types of myositis.
- Skull radiographs (especially of the frontal sinuses and nasal cavity).
- Thoracic radiographs—to identify metastatic disease.

DIAGNOSTIC PROCEDURES
- Lack of globe retropulsion—confirms space-occupying mass.
- Oral examination, ocular ultrasound, and fine-needle aspiration (FNA) of the orbit—may require anesthesia.
- FNA (18- to 20-gauge)—submit samples for aerobic and anaerobic bacterial cultures, Gram staining, and cytologic examination.
- Cytology—often diagnostic for abscess or cellulitis, zygomatic salivary gland mucocele, and neoplasia.
- Biopsy—indicated if FNA is nondiagnostic. Biopsy of masseter, temporal, or extraocular muscle if myositis suspected; assays for type 2M fibers may be helpful.
- Forced duction of the globe (strabismus)—grasp the conjunctiva with a fine pair of forceps following topical anesthesia; differentiates neurologic disease (globe moves freely) from restrictive condition (globe cannot be moved manually).

O

ORBITAL DISEASES (EXOPHTHALMOS, ENOPHTHALMOS, STRABISMUS) (CONTINUED)

TREATMENT

Proptosis
See Proptosis.

Orbital Abscess or Cellulitis
- Drainage is seen in less than half of patients, usually because the lesion is just cellulitis and a true abscess has not yet formed.
- If an obvious swelling of the oral mucosa behind the last molar is not present and ultrasound does not show an abscess, it is best to avoid incising the oral mucosa and treat with systemic antibiotics and anti-inflammatory medications; the affected globe should also be kept moist with topical lubricants q6h.
- Severe cases may require IV fluids to restore and maintain hydration until patient is able to eat.
- If a swelling of the oral mucosa behind the last molar is evident, establish ventral orbital drainage:
  - Incise the surgically prepared mucosa approximately 1 cm behind the last molar.
  - Push blunt-tipped forceps (e.g., Kelly or Carmalt) into the orbital space and open; in general, advance the forceps until the abscess drains, to the level of the box lock, or until movement of the eye occurs with forceps opening.
  - Minimize retrobulbar trauma and optic nerve damage; use only blunt dissection; never cut or crush tissue.
  - Complications from aggressive dissection include damage to the optic and ciliary nerves.
  - Collect samples for bacterial culture and cytologic examination through this port.
- Feed soft food until globe is back in normal position and pain resolved.
- Hot packing—q6h; helps decrease swelling and cleans discharge.

Orbital Neoplasms
- Usually primary and malignant.
- Early exenteration or orbital exploratory surgery and mass debulking via a lateral approach to the orbit to save the globe are rational therapeutic choices.
- Adjunctive chemotherapy or radiotherapy—depending on neoplasm and extent of the lesion.
- Without adjunct therapy—survival is weeks to months if malignant (patients are usually presented late in the course of disease).
- Consultation with an oncologist is recommended once the diagnosis is made.

Zygomatic Mucocele
May resolve with antibiotic and corticosteroid administration; if not, surgical excision of the cyst and associated salivary gland is usually curative.

Strabismus
- Neurologic—Identify and treat the underlying cause, if possible.
- Restrictive or post-traumatic—may be treated surgically by repositioning or excising the attachments of extraocular muscles to relieve excessive tension on those muscles; usually a very difficult procedure.

MEDICATIONS

DRUG(S) OF CHOICE
- Exophthalmos (all patients)—lubricate cornea with artificial tear ointment or gel, q6h, to prevent desiccation and ulceration.
- Corneal ulceration—topical antibiotic (e.g., bacitracin, neomycin, polymyxin, q8h) and cycloplegic (e.g., 1% atropine, q12–24h), to prevent infection and reduce ciliary spasm, respectively.

Orbital Abscess or Cellulitis
- Oral or IV antibiotics—ampicillin 20 mg/kg q8h ×2–3 weeks or drugs with an anaerobic spectrum (amoxicillin with clavulanic acid or clindamycin) should be considered while awaiting results of bacterial culture and cytologic examination, or if client declines diagnostic testing.
- Fluconazole 2.5 mg/kg PO q12h or 5 mg/kg PO q24h or posaconazole 5 mg/kg PO q12h for orbital aspergillosis.
- Prednisone 1 mg/kg SC, IM q24h, once, to minimize optic neuritis and reduce orbital swelling and globe exposure (severe cases).
- Nonsteroidal anti-inflammatory drugs can be used in place of prednisone and administered for a longer period.

Acute Myositis
- Difficult prehension—systemic corticosteroids (prednisone 2 mg/kg SC, IM), then oral (prednisone 2 mg/kg q24h) for 4–6 weeks until swelling subsides; then taper.
- Azathioprine 1–2 mg/kg PO q24h for 3–7 days then q48h and taper, with or without corticosteroids. May be used chronically to manage recurrent disease.

PRECAUTIONS
- Systemic corticosteroids—extreme caution with deep fungal orbital disease.
- Azathioprine—may be hepatotoxic and cause myelosuppression. Follow CBC and liver enzyme activities every 1–2 weeks for 8 weeks, then periodically.

FOLLOW-UP

PATIENT MONITORING
- Inflammatory orbital disease—examine at least weekly until clinical signs abate.
- Advise client to watch for recurrence of signs, especially if an orbital foreign body likely.
- Treat fungal infections for 60 days after signs resolve.

POSSIBLE COMPLICATIONS
- Vision loss.
- Loss of the eye.
- Permanent malposition of the globe.
- Death.

MISCELLANEOUS

AGE-RELATED FACTORS
Give a course of antibiotic therapy first prior to attempting ventral orbital drainage.

PREGNANCY/FERTILITY/BREEDING
Avoid systemic corticosteroids, antifungals, and azathioprine in pregnant animals.

SEE ALSO
- Proptosis.
- Red Eye.

ABBREVIATIONS
- FNA = fine-needle aspiration.
- IOP = intraocular pressure.

ORGANOPHOSPHORUS AND CARBAMATE TOXICOSIS

BASICS

DEFINITION
• Results from exposure to organophosphorus compounds or carbamates.
• Calls to the American Society for the Prevention of Cruelty to Animals (ASPCA) Animal Poison Control Center (APCC) regarding exposure to organophosphorus compounds continue to decrease. In 2017, organophosphate and carbamate exposures represented only 2.2% of insecticide-related exposure calls..
• The decrease is likely related to EPA cancellations of various registrations and approval of new, less hazardous compounds and delivery formulations. Canceled products, however, often remain in homes and businesses for years. In 2017 the most commonly reported exposures from most to least were to products containing propoxur, acephate, carbaryl, and tetrachlorvinphos.
• Animal products—organophosphate: chlorpyrifos, coumaphos, cythioate, diazinon, famphur, fenthion, phosmet, and tetrachlorvinphos; carbamate: carbaryl and propoxur. (Many animal products containing phosmet, tetrachlorvinphos, carbaryl, chlorpyrifos, diazinon [all] have been discontinued.)
• Agricultural, lawn, and garden products—organophosphate: acephate, chlorpyrifos, diazinon, disulfoton, fonofos, malathion, parathion, terbufos, and others; carbamate: carbofuran and methomyl. (Same comment as above for environmental products.)

PATHOPHYSIOLOGY
• Cause nervous system effects by inhibiting cholinesterase, which includes acetylcholinesterase, pseudocholinesterase, other esterases.
• Acetylcholinesterase—normally hydrolyzes the neurotransmitter acetylcholine in nervous tissue, red blood cells, and muscle, resulting in termination of nervous transmission.
• Pseudocholinesterase—found in plasma, liver, pancreas, nervous tissue; mainly in cats.
• Cholinesterase inhibition—allows acetylcholine accumulation at the postsynaptic receptor; causes stimulation of effector organs; spontaneous reactivation after organophosphorus compound binding is very slow and once aging occurs is virtually nonexistent; reversible after carbamate binding.

SYSTEMS AFFECTED
Nervous—results from overriding stimulation of parasympathetic pathways; may also result from sympathetic stimulation; acetylcholine stimulates nicotinic receptors of the somatic nervous system (skeletal muscle), parasympathetic preganglionic nicotinic and postganglionic muscarinic receptors (cardiac muscle, pupil, blood vessels, smooth muscles in lung and gastrointestinal tract, exocrine glands), and sympathetic preganglionic nicotinic receptors (adrenal and indirectly cardiac muscle, pupil, blood vessels, smooth muscles in lung and gastrointestinal tract, exocrine glands).

GENETICS
• Animals with inherently low cholinesterase activity—more susceptible to cholinesterase depression.
• Cholinesterase activity—more easily inhibited in cats than in dogs.

INCIDENCE/PREVALENCE
Uncommon in small animals.

GEOGRAPHIC DISTRIBUTION
Historically more common in areas of high flea prevalence and intense agricultural activity.

SIGNALMENT
Species
• Dog and cat.
• Cats most susceptible.

Breed Predilections
Lean dogs (e.g., sight hounds and racing breeds) and lean longhaired cats—more susceptible to cholinesterase inhibition because of lack of fat; many organophosphorus compounds and metabolites are stored in fat and slowly released into circulation.

Mean Age and Range
Young animals—more likely intoxicated due to lower detoxification capability.

Predominant Sex
Intact males more susceptible to some organophosphates.

SIGNS
General Comments
• Parasympathetic stimulation—usually predominates.
• Sympathetic stimulation—may result in lack of specific expected signs; may note signs opposite from expected.

Historical Findings
• Medical history—often discloses heavy or repeated applications of flea and tick insecticides; evidence of exposure to an agricultural or home and garden product.
• Carbamate insecticides (methomyl and carbofuran)—may cause rapid onset of seizures, respiratory failure, and death; treat aggressively without delay.
• Organophosphate insecticides (cats, especially chlorpyrifos)—chronic anorexia, muscle weakness and twitching, with or without episodes of acute toxicosis; may last days to weeks.

Physical Examination Findings
• Hypersalivation.
• Vomiting.
• Diarrhea.
• Miosis.
• Bradycardia.
• Depression.
• Ataxia.
• Muscle tremors.
• Seizures.
• Hyperthermia.
• Dyspnea.
• Respiratory failure.
• Death.
• Patient may not exhibit all signs.
• Sympathetic stimulation—signs reversed.

CAUSES
• Overuse, misuse, or use of multiple cholinesterase-inhibiting insecticides.
• Misuse of organophosphate insecticides in cats (e.g., organophosphate-containing dips labeled for dogs only, inappropriately applied to cats).
• Intentional dermal application of house or yard insecticides.

RISK FACTORS
• Concurrent exposure to multiple products containing organophosphate and/or carbamate.
• Exposure to floors that are damp with organophosphorus premise products.
• Incorrect dilution of insecticides.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Exposure to other insecticidal products—pyrethrin/pyrethroids (flea and tick); d-limonene (citrus flea and tick); fipronil (flea and tick); imidacloprid (flea).
• Other pesticides—strychnine; fluoroacetate (1080); 4-aminopyridine (avicide); metaldehyde (snail bait); zinc/aluminum phosphide (rodenticide); bromethalin (rodenticide).
• Other toxicants—chocolate; caffeine; cocaine; amphetamine; tremorgenic mycotoxins.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
Cholinesterase Activity
• Reduced to <25% of normal in whole blood, retina, or brain—suggests exposure to a cholinesterase-inhibiting compound; must compare to normal reference values in that species generated by the same laboratory.
• Test results—must be interpreted in context of the amount of exposure and the clinical signs and the time of their onset.
• Use laboratories experienced in handling animal samples.
• Chlorpyrifos—experimentally exposed animals may remain clinically normal with no detectable cholinesterase activity.

O

ORGANOPHOSPHORUS AND CARBAMATE TOXICOSIS (CONTINUED)

• Carbamate inhibition—reactivation can occur during sample transport, storage, and testing, giving false-negative results.

DIAGNOSTIC PROCEDURES

• Atropine response test—administer atropine at pre-anesthetic dose (0.02 mg/kg IV). Antimuscarinic response (tachycardia, mydriasis) suggests lack of anticholinesterase exposure.
• Detection of insecticides—tissue (e.g., brain, liver, kidney, and fat); stomach contents; gastrointestinal tract; fur or hair; negative results do not rule out toxicosis.
• May find pieces of chewed containers in the gastrointestinal tract.

PATHOLOGIC FINDINGS

• Histopathologic lesions—rare, no characteristic lesions likely in acute toxicosis.
• Delayed neuropathy—not usually associated with commercially available organophosphorus compounds.

O

TREATMENT

APPROPRIATE HEALTH CARE

• Outpatient—mild signs from exposure to flea and tick collars and powders; treat by removing the collar or brushing excess powder from the coat.
• Inpatient—continued salivation, tremors, or dyspnea.

NURSING CARE

• Basics—stabilization; decontamination; antidotal treatment with atropine (and pralidoxime chloride for organophosphate toxicosis); supportive care.
• Control seizure activity, tremors.
• Oxygen—if necessary, until respiration returns to normal.
• Fluid therapy—may be needed in anorexic cats and dehydrated animals.
• Bathing (dermal exposure)—use hand dish-washing detergent; rinse with copious amounts of water.

DIET

Chronically anorexic cats—maintain nutritional and fluid requirements.

CLIENT EDUCATION

• Stress the importance of following insecticide label directions.
• Caution client that cats with chronic anorexia and weakness may need days to weeks of supportive care for full recovery.

MEDICATIONS

DRUG(S) OF CHOICE

• Emesis:
  ◦ Ingestion of liquid insecticidal solution—avoid inducing emesis; risk of aspiration because many solutions contain hydrocarbon solvents.
  ◦ Liquid solvent *not* ingested, no clinical signs, and very recent ingestion—induce emesis with 3% hydrogen peroxide (2.2 mL/kg PO to a maximum of 45 mL) after feeding a moist meal.
• Activated charcoal:
  ◦ Evacuation of the stomach for patient with clinical signs—gastric lavage with the patient intubated, under anesthesia, with a large-bore stomach tube; then administration of activated charcoal (2 g/kg PO) containing sorbitol as a cathartic in a water slurry.
  ◦ Diarrhea—do not administer sorbitol-containing products.
• Diazepam (0.5–1 mg/kg IV to effect) used initially for seizures. Pentobarbital (5–15 mg/kg IV to effect) added for persistent seizure activity. Phenobarbital (3–30 mg/kg IV to effect, low dosage in cats), propofol (3–6 mg/kg IV or 0.1 mg/kg/min CRI) or levetiracetam (30–60 mg/kg slow IV bolus in dogs; 20 mg/kg IV in cats) can be used for refractory seizures.
• Atropine sulfate—0.2 mg/kg one-quarter IV, remaining SC, as needed; administered immediately; repeated only as needed to control life-threatening clinical signs from muscarinic stimulation.
• Pralidoxime chloride (Protopam) 10–15 mg/kg IM, SC q8–12h until recovery; discontinue after 3 doses if no response; reduces muscle fasciculations; most beneficial against organophosphorus insecticides when started within 24 hours of exposure; even several days after dermal exposure may stimulate anorexic cats (with or without tremors) to resume eating; if refrigerated and wrapped in foil, reconstituted bottles may be successfully used for up to 2 weeks.

CONTRAINDICATIONS

Phenothiazine tranquilizers may potentiate organophosphate toxicosis.

PRECAUTIONS

Atropine—avoid overuse; may cause tachycardia, CNS stimulation, seizures, disorientation, drowsiness, and respiratory depression.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

Monitor heart rate, respiration, and fluid and caloric intake.

PREVENTION/AVOIDANCE

• Follow directions on insecticide labels closely.
• Avoid use on sick or debilitated animals.
• Avoid simultaneous use of organophosphate and carbamate products.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

• Chronic organophosphate insecticide-induced weakness and anorexia (cats, chlorpyrifos exposure)—may last 2–4 weeks; most patients fully recover with aggressive nursing care.
• Acute toxicosis treated promptly—good prognosis.

MISCELLANEOUS

Client Education Handout available online

ORONASAL FISTULA

BASICS

OVERVIEW
- An oronasal fistula is an abnormal connection between the oral and nasal cavities.
- which can occur from pathology of any of the tissues surrounding the maxillary teeth or hard palate.
- The maxillary canines are most commonly involved.
- The palatal root of the maxillary fourth premolar is the next most common area involved.

SIGNALMENT
- Dogs—dolichocephalic head types are affected most often, especially dachshunds.
- Cats—rare

SIGNS
- Chronic rhinitis—with or without blood.
- Sneezing—common, especially when the maxillary canines are digitally palpated.

CAUSES & RISK FACTORS
- Usually associated with advanced-periodontitis (PD4) of the maxillary canine tooth, leading to destruction of the bone separating the nasal and oral cavities.
- Other causes include trauma, penetration of a foreign body, bite wounds, traumatic tooth extraction, electrical shock, or oral cancer.
- Fistula width can be related to the size of the tooth affected; fistula depth to the chronicity of the periodontal infection.
- Dogs with lingually displaced (mesioverted) mandibular canines, mandibular distoclusion (overbite) resulting in penetration of the hard palate are predisposed to oronasal fistulas.
- Dachshunds predisposed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Periodontal disease.
- Oral neoplasia.
- Trauma.
- Foreign body penetration.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
- Skull radiographs rarely helpful in diagnosing oronasal fistula because the lesions are generally isolated to the palatal surface.
- Intraoral radiographs are highly recommended to evaluate the periodontal status of the patient's teeth.
- Radiographs may show foreign body entrapment or lysis consistent with neoplasia.

DIAGNOSTIC PROCEDURES
Periodontal probing-—results in direct extension into the nasal cavity or epistaxis in cases of oronasal fistula. Periodontal probing will also identify areas where significant palatal defects are present which can be treated to help prevent the occurrence of oronasal fistulas.

TREATMENT
- Extract the tooth and close the defect; after extraction, the goal of surgical closure is to place an epithelial layer in both the oral and nasal cavities.
- Full-thickness flap—after tooth extraction, a mucoperiosteal pedicle flap may be elevated from the dorsal aspect of the fistula, released, advanced to cover the defect, and sutured in place; a successful full-thickness flap requires at least 2 mm attached gingiva above the defect, with sutures at the edge of the defect (not over the void), without tension on the suture line.
- Double reposition flap—used for large fistulas or repair failures where no attached gingiva remains or where periosteal tissue cannot be included; after extraction, the first flap is harvested from the hard palate and inverted so that the oral epithelium is toward the nasal passage; the second flap is muco-buccal and harvested from the alveolar mucosa and underside of the lip rostral to the fistula; it is sutured over the first flap and donor site.
- Guided tissue regeneration of the maxillary canine—may be used for repair of a deep palatal pocket if not yet fistulated; a palatal flap is elevated to approach the infrabony defect; soft tissue and calculus are removed from the defect with a curette.
- In deep, infrabony pockets before fistulation, bone grafts such as PerioGlas, Consil, synthetic and natural hydroxyapatite, autogenous and heterologous bone, polylactic acid, and Osteoallograft (freeze-dried canine cadaver bone) have been used to exclude regrowth of gingival connective tissue and epithelium, promoting regeneration of bone and periodontal ligament. Implant materials should not be used if an oronasal fistula is present.
- Ear cartilage has been used as a membrane to cover the defect before closure.
- Oroantral fistulas located in the central portion of the hard palate may be surgically repaired with a transposition flap of the hard palate mucoperiosteum from tissue adjacent to the defect.

MEDICATIONS

DRUG(S) OF CHOICE
N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Normal postoperative monitoring.

EXPECTED COURSE AND PROGNOSIS
Even with adequate tissue, excellent release of tension on the flap, and good technique, a persistent opening may occur due to constant tension on the site during each breath. With inadequate tissue or technique, the prognosis decreases, and additional surgeries with advanced flaps may be required.

OSTEOCHONDRODYSPLASIA

BASICS

OVERVIEW

• A developmental abnormality of cartilage and bone; encompasses many disorders involving bone growth. • Results from abnormal endochondral ossification.
• Skeletal defects—usually involve the appendicular skeleton; specifically the metaphyseal growth plates.
• Achondroplasia—failure of cartilage growth; characterized by a proportionate short-limbed dysplasia; evident soon after birth.
• Hypochondrodysplasia—less severe form of achondrodysplasia. • Characteristic breeds—result of selection of certain desirable traits. • Affects musculoskeletal and possibly ophthalmic systems.

SIGNALMENT

• Achondroplastic breeds—bulldog; Boston terrier; pug; Pekingese; Japanese spaniel; shih tzu.
• Hypochondroplastic breeds—dachshund; basset hound; beagle; Welsh corgi; Dandie Dinmont terrier; Scottish terrier; Skye terrier.
• Reported nonselected chondrodysplastic abnormalities—Alaskan Malamute; Samoyed; Labrador retriever; English pointer; Norwegian elkhound; Great Pyrenees; cocker spaniel; Scottish terrier; Scottish deerhound; beagle; miniature poodle; French bulldog; Scottish fold cat.
• Oculoskeletal dysplasia—diagnosed in Labrador retriever and Samoyed.

SIGNS

Historical Findings

Phenotypically normal at birth, retardation of growth recognized in first few months of life.

Physical Examination Findings

• Usually affects the appendicular skeleton; may affect axial skeleton. • Long bones—appear shorter than normal; often bowed.
• Major joints (elbow, stifle, carpus, tarsus)—appear enlarged. • Radius and ulna—often severely affected owing to asynchronous growth. • Lateral bowing of the forelimbs.
• Enlarged carpal joints. • Valgus deformity of the paws. • Shortened maxilla—relative mandibular prognathism. • Spinal deviations—due to vertebral abnormalities (hemi, wedge, block, transitional, etc.). • Retina—dysplasia; partial to complete detachment.

CAUSES & RISK FACTORS

• Achondrodysplastic and hypochondrodysplastic breeds—autosomal dominant trait.
• Nonselected chondrodysplastic breeds—autosomal recessive or polygenic trait.
• Littermates often affected. • Congenital hypothyroidism. • Autosomal incomplete dominant trait in Scottish folds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Premature closure of the ulnar or radial physes—history of trauma; no other bones affected; unilateral or bilateral abnormalities.
• Pituitary dwarfism.

IMAGING

• Radiography of affected limbs—irregular flattening of the metaphysis; stippled appearance of epiphyses; widening of the physeal line; retained endochondral cores; irregularities in ossification of the affected long bone; degenerative joint disease and joint laxity owing to abnormal stress and weightbearing on the limbs. • Radiography of the spine—hemivertebrae; wedge-shaped vertebrae. Tail/caudal vertebrae—bony proliferation, shortened and malformed, reduced intervertebral spaces.

DIAGNOSTIC PROCEDURES

Bone biopsy of growth plate—definitive diagnosis.

PATHOLOGIC FINDINGS

Histologic findings—disorganization of the proliferative zone, abnormalities within the hypertrophic zone, abnormal formation of the primary and secondary spongiosa.

TREATMENT

• Achondrodysplasia—considered a normal abnormality in some (chondrodystrophic) breeds.
• Surgery—usually of little benefit for nonselected chondrodysplasia. • Corrective osteotomy to realign limb(s) or joint(s)—may have limited benefit. • Radiation therapy—pain relief for long periods in Scottish folds.

MEDICATIONS

DRUG(S) OF CHOICE

• Analgesics and anti-inflammatory agents—palliative use warranted. ◦ Carprofen 2.2 mg/kg PO q12h or q24h. ◦ Deracoxib 1–2 mg/kg PO q24h. ◦ Firocoxib 5 mg/kg PO q24h. ◦ Gabapentin 10–20 mg/kg PO q8h. ◦ Gapiprant 2 mg/kg/day PO. ◦ Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid). ◦ Tramadol 4–10 mg/kg PO q8–12h. • Chondroprotective agents—polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate; may have limited benefit in preventing articular cartilage changes.

FOLLOW-UP

PREVENTION/AVOIDANCE

• Do not repeat dam–sire breedings that resulted in affected offspring. • Discourage breeding affected animals.

POSSIBLE COMPLICATIONS

Intra-articular and periarticular joint structures—degenerate owing to abnormal conformation of the appendicular skeleton; leads to altered biomechanics; results in poor quality of life.

MISCELLANEOUS

SYNONYMS

• Cherubism, • Dwarfism.

ABBREVIATIONS

• NSAID = nonsteroidal anti-inflammatory drug.

Consulting Editor Mathieu M. Glassman

OSTEOCHONDROSIS

BASICS

DEFINITION
A pathologic process in growing cartilage, primarily characterized by a disturbance of endochondral ossification that leads to excessive retention of cartilage.

PATHOPHYSIOLOGY
- Cells of the immature articular joint cartilage and growth plates do not differentiate normally.
- For articular cartilage, the process of endochondral ossification is retarded, presumably due to localized, focal disruption of blood supply. If blood supply is reestablished, healing occurs. Alternatively, if blood supply is not reestablished, cartilage remains thick and there is separation between the cartilage and subchondral bone. Eventually a fissure occurs through the articular cartilage that allows communication with the joint cavity. The result is creation of a cartilage flap that is separated from the underlying subchondral bone; this condition is known as osteochondritis dissecans (OCD).
- Bilateral disease common.
- Most commonly affected joints—shoulder (caudocentral humeral head); elbow (medial aspect of the humeral condyle); stifle (femoral condyle, lateral more often than medial); hock (ridge of the talus, medial more common than lateral).
- Other reported locations—femoral head; dorsal rim of the acetabulum; glenoid cavity (scapula); patella; distal radius; medial malleolus; cranial end plate of the sacrum; vertebral articular facets; cervical vertebrae.

Immature Joint Cartilage
- Thickened cartilage results in impaired metabolism, leading to degeneration and necrosis of the poorly supplied cells.
- Fissure within the thickened cartilage—may result from mechanical stress; eventually leads to the formation of a cartilage flap or OCD; may cause lameness.
- Lameness (pain)—usually becomes evident once OCD develops; osteochondrosis is often asymptomatic.

Retention of Cartilage in Growth Plates
- Usually does not lead to necrosis, probably owing to nutrition provided by vessels within the cartilage.
- Failure of endochondral ossification can lead to decreased longitudinal bone growth. When this is severe and occurs in the distal ulnar physis, angular limb deformity may result.

SYSTEMS AFFECTED
Musculoskeletal

GENETICS
- Polygenetic transmission—expression determined by an interaction of genetic and environmental factors.
- Heritability index—depends on breed; 0.25–0.45.

INCIDENCE/PREVALENCE
Frequent and serious problem in many dog breeds.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog

Breed Predilections
Large and giant breeds—Great Dane, Labrador retriever, Newfoundland, Rottweiler, Bernese mountain dog, English setter, Old English sheepdog.

Mean Age and Range
- Onset of clinical signs—typically 4–8 months.
- Diagnosis—generally 4–18 months.
- Symptoms of osteoarthritis—any age.

Predominant Sex
- Shoulder—males (2:1).
- Elbow, stifle, and hock—none.

SIGNS

General Comments
Depend on the affected joint(s) and concurrent osteoarthritis.

Historical Findings
Lameness—most common; sudden or insidious in onset; one or more limbs; becomes worse after exercise; duration of several weeks to months; slight, moderate, or severe.

Physical Examination Findings
- Pain—usually elicited on palpation by flexing, extending, or rotating the involved joint.
- Generally a weight-bearing lameness.
- Joint effusion with capsular distention—common with OCD of elbow, stifle, and hock.
- Muscle atrophy—consistent finding with chronic lameness.
- Hock OCD—hyperextension of the tarsocrural joint.

CAUSES
- Developmental.
- Nutritional.

RISK FACTORS
- Diet containing 3 times the recommended calcium levels.
- Rapid growth and weight gain.
- Overfeeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Soft tissue trauma.
- Intra-articular (osteochondral) fractures.
- Elbow dysplasia.
- Panosteitis.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING

Radiography
- Standard craniocaudal and mediolateral views—necessary for all involved joints.
- Failure of normal endochondral ossification results in radiolucency. Thus the normal bone contour is lost, which radiographically appears as flattening of the subchondral bone or as a subchondral lucency.
- Cannot be differentiated from OCD on plain radiographs unless the cartilage flap is mineralized.
- Sclerosis of the underlying bone—common in chronic OCD lesions.
- Calcified bodies within the joint (joint mice)—indicate dislodged cartilage flap.
- Contralateral joint—comparison; check for involvement.
- Oblique views—may improve visualization, especially for hock, elbow, and shoulder lesions.
- Skyline views of the talar ridges of the hock joint—help identify medial and lateral lesions.

CT and MRI
Useful for visualizing extent of subchondral lesions. MRI is the most accurate method of detecting osteochondrosis/OCD lesions, flaps, and fragments.

Ultrasonography
Can be used to detect lesions, but is very operator dependent and is the least accurate diagnostic imaging method.

Positive Contrast Arthrography
Useful for differentiating OCD of the shoulder from other conditions.

DIAGNOSTIC PROCEDURES
- Diagnosis most frequently made based on physical examination and diagnostic imaging.
- Arthrocentesis and analysis of synovial fluid—confirms involvement; should note straw-colored fluid with normal to decreased viscosity; from cytology, should note >90% mononuclear cells. Not specific for osteochondrosis.
- Arthroscopy—minimally invasive; excellent method for differentiating from OCD and for therapeutic treatment.

OSTEOCHONDROSIS (CONTINUED)

PATHOLOGIC FINDINGS
• Articular cartilage—initially may appear yellowish.
• Retention of articular cartilage extending into subchondral bone surrounded by increased amount of trabecular bone.
• Clefts between the underlying subchondral bone and the degenerated and necrotic deep layer of the overlying thickened (retained) cartilage.

TREATMENT

APPROPRIATE HEALTH CARE
N/A

NURSING CARE
• Cryotherapy (ice packing) of affected joint—immediately post-surgery; 5–10 minutes q8h for 3–5 days.
• Range-of-motion exercises—initiated as soon as patient can tolerate.

ACTIVITY
• Restricted.
• Avoid hard concussive activities (e.g., running on concrete).

DIET
Weight control—important for decreasing load and, therefore, the stress on the affected joint(s).

CLIENT EDUCATION
• Discuss the heritability of the disease.
• Warn client that osteoarthritis is likely to develop.
• Discuss the influence of excessive intake of nutrients that promote rapid growth.

SURGICAL CONSIDERATIONS
• Osteochondrosis of articular cartilage is generally a nonsurgical condition..
• May progress to OCD as the patient grows. If OCD develops, surgery is generally recommended.
• Surgery is performed by arthrotomy or arthroscopy, and is indicated for most patients with OCD.
• Surgical treatment usually involves removal of the cartilage flap and subchondral bone debridement.
• Osteochondral autografts have been described for treatment of OCD of the caudal humeral head, medial aspect of the humeral condyle, and femoral condyles. Benefit beyond surgical debridement by flap removal requires further investigation.
• Synthetic osteochondral implants are available for resurfacing and have been described for use in the stifle joint of dogs.
• Shoulder—indicated for all OCD lesions; exploratory procedure indicated for pain and lameness with radiographic evidence of osteochondrosis.
• Elbow—indicated for all OCD lesions; indicated to assess for other conditions (see Elbow Dysplasia).
• Stifle—controversial; patients develop osteoarthritis even with procedure; arthroscopy may improve the recovery rate and long-term function.
• Hock—remove osteochondral flap; controversial; all patients develop severe osteoarthritis even with procedure. Arthrodesis is considered an option for patients with severe disease.
• Sacrum—remove fragment if impinging on the cauda equina.

MEDICATIONS

DRUG(S) OF CHOICE
Nonsteroidal anti-inflammatory drugs (NSAIDs) and analgesics—may be used to symptomatically treat osteoarthritis associated with OCD; does not promote healing of the cartilage flap (thus surgery is still indicated).

CONTRAINDICATIONS
Avoid corticosteroids owing to potential side effects and articular cartilage damage associated with long-term use.

PRECAUTIONS
NSAIDs—gastrointestinal irritation or renal/hepatic toxicity may preclude use in some patients.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, green-lipped mussel extract, and glucosamine/chondroitin sulfate)—may help limit cartilage damage and degeneration; may help alleviate pain and inflammation.

FOLLOW-UP

PATIENT MONITORING
• Periodic monitoring until patient is skeletally mature—recommended to assess progression to an OCD lesion.
• Post-surgery for OCD—limit activity for 4–6 weeks; encourage early, active movement of the affected joint(s).
• Yearly examinations—recommended to assess progression of osteoarthritis.

PREVENTION/AVOIDANCE
• Discourage breeding of patients.
• Do not repeat dam–sire breedings that resulted in affected offspring.
• Restricted weight gain and growth in young dogs—may decrease incidence.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
• Shoulder—good to excellent prognosis for return to full function; minimal osteoarthritis development with osteochondrosis and after OCD surgery.
• Elbow, stifle, and hock—fair prognosis for osteochondrosis, guarded for OCD; depends on size of lesion (most important), osteoarthritis, and age at diagnosis and treatment; progressive osteoarthritis development, even after surgery.
• Sacrum—good after cartilage fragment removal.

OSTEOMYELITIS

BASICS

DEFINITION
Acute or chronic inflammation of bone, usually caused by bacteria. Less common causes include fungi, parasites, viruses, foreign bodies, and corrosion of metallic implants.

PATHOPHYSIOLOGY
• Direct inoculation of bone with pathogenic bacteria—most common route of infection. May not initiate infection unless local tissue environment is affected (e.g., poor vascularity, necrotic bone or soft tissue, sequestration, altered tissue defenses or systemic immune response, foreign material, or surgical implants). • Hematogenously disseminated microorganisms from a distant site in the body localize in the metaphyseal region of long bones in young animals and vertebrae of adults. Inflammation and thrombus formation produce an ischemic environment that promotes bacterial proliferation. Mycotic infections are often due to hematogenous dissemination of inhaled spores. • Extension of soft tissue infections to bone—uncommon in small animals. • Biofilm formation protects bacteria from phagocytes, antibacterials and antibodies.

SYSTEMS AFFECTED
Musculoskeletal

GENETICS
Breeds with heritable immunodeficiency or hematogenous diseases.

INCIDENCE/PREVALENCE
• Hematogenous disease—rare. • Prevalence of fracture-associated osteomyelitis—radius/ulna 41.5%; femur 28.5%. • Discospondylitis in adult dogs and cats and fungal disease—not uncommon.

GEOGRAPHIC DISTRIBUTION
• Actinomycosis—migrating grass awns can cause soft tissue infections, which may extend to bone. • Blastomycosis—central and eastern regions of the United States, Canadian provinces of Quebec, Manitoba, and Ontario. • Coccidioidomycosis—southwestern United States, Mexico, and Central and South America. • Histoplasmosis—Ohio, Missouri, and Mississippi river valleys.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
Breeds with immunodeficiency and hematogenous diseases.

Mean Age and Range
Hematogenous metaphyseal infection—immature dogs.

Predominant Sex
Male dogs—for post-traumatic infection; blastomycosis.

SIGNS
General Comments
• Acute postoperative wound infections after orthopedic surgery—may be indistinguishable from acute condition; may progress to chronic disease. • Most patients have chronic disease at time of examination and diagnosis.

Historical Findings
• Lameness. • Draining tracts. • Previous trauma. • Fracture or surgery. • Hind limb weakness and difficulty in rising—discospondylitis or vertebral osteomyelitis. • Travel to regions endemic for mycotic infections.

Physical Examination Findings
• Acute hematogenous disease (dogs)—sudden onset of systemic illness; soft tissue swelling over affected site; lameness; pyrexia; lethargy; limb pain. • Chronic condition—localized disease, usually no systemic component; chronic draining tracts, pain, muscle atrophy, muscle contracture.
• Infected non-union fracture—instability, crepitus, limb deformity. • Bone infections of the spine—pain and neurologic deficits.

CAUSES
• Trauma or orthopedic surgery. • Penetrating foreign body. • Extension to bone of soft tissue infection—periodontitis; rhinitis; otitis media; paronychia. • Hematogenous infection.
• *Staphylococcus pseudintermedius* common—almost 50% are methicillin-resistant strains; often monomicrobial infection. Polymicrobial infections are common—may include Gram-negative organisms: *E. coli*, *Pasteurella*, *Serratia*, *Pseudomonas*, *Proteus*, and *Klebsiella* spp. • Anaerobic bacteria—*Actinomyces*, *Clostridium*, *Peptostreptococcus*, *Bacteroides*, *Nocardia* and *Fusobacterium*. • Fungal infection—*Coccidioides*, *Blastomyces*, *Histoplasma*, *Candida*, *Cryptococcus*, *and Aspergillus* species.

RISK FACTORS
• Open fracture. • Soft tissue trauma.
• Penetrating wounds. • Migrating foreign body. • Orthopedic surgery/implants.
• Cortical bone allograft. • Immunodeficiency.
• Nosocomial infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Panosteitis. • Neoplasia. • Bone cysts.
• Delayed fracture union due to instability.
• Hypertrophic osteodystrophy.
• Hypertrophic osteopathy. • Medullary bone infarction.

CBC/BIOCHEMISTRY/URINALYSIS
• Hemogram—neutrophilia ± left shift with acute disease. • Fungal hyphae may be present in the urine of systemically ill patients with aspergillosis.

OTHER LABORATORY TESTS
• Serology—confirms some fungal infections.
• Blood cultures if hematogenous infection suspected. • Urine excretion of antigen for blastomycosis.

IMAGING
Radiographic Findings
• Acute disease—bone architecture normal; soft tissue swelling; gas may be evident if anaerobic infection. • Chronic disease—sequestrum (avascular segment of bone); periosteal new bone formation; involucrum formation (reactive bone surrounding sequestrum); bone resorption—widening of fracture gaps; cortical thinning; generalized osteopenia; implant loosening.
• Fistulogram—can help identify sequestra or radiolucent foreign bodies.

Other
• Ultrasonography—localize large fluid accumulations for needle aspiration or foreign bodies. • Contrast CT or MRI identification of sequestra, foreign material.
• Scintigraphy—uncommonly available and performed.

DIAGNOSTIC PROCEDURES
• Fluid aspirates of fluctuant areas or Jamshidi needle tissue biopsies for aerobic and anaerobic culture and *in vitro* antimicrobial drug susceptibility—collect by sterile techniques.
• Open surgical biopsy—indicated when needle aspirates are negative or when debridement is necessary for treatment; culture samples of necrotic tissue, sequestra, implants, and foreign material; histopathologic examination for suspected fungal infection and to rule out neoplasia. Request special fungal stains on pathology samples. • Samples for anaerobic culture—immediately place into appropriate transport medium. Avoid culturing purulent fluid from draining tracts—results misleading as often get contaminants from skin. • Blood cultures—indicated in acute hematogenous osteomyelitis or chronic disease with septicemia. • Urine culture to rule out urinary tract infection as a source for hematogenous disease.

PATHOLOGIC FINDINGS
• Bone sequestration—virtually diagnostic.
• Inflammation and necrosis of bone and the adjacent tissues. • Cytologic or histopathologic examination of smears or sections—can be helpful for identification of pathogenic organisms (especially fungal hyphae).

OSTEOMYELITIS (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient—surgical debridement, drainage, culturing, irrigation, and wound management until infection begins to resolve; infected fractures (surgical stabilization).
• Outpatient—long-term oral antimicrobial drug therapy.

NURSING CARE
• Depends on severity, location, and degree of associated soft tissue injury. • Avoid pathogen contamination to other patients.
• Physical rehabilitation therapy.

ACTIVITY
Restricted—to prevent pathologic fracture; with an unhealed fracture.

DIET
No restriction.

CLIENT EDUCATION
• Warn the client about cost of treatment, likelihood of recurrence, possibility of repeated surgical intervention, and long duration of therapy. • Discuss prognosis.

SURGICAL CONSIDERATIONS
• Chronic disease—surgical debridement; sequestrectomy; establish drainage. • Infected stable fracture—leave preexisting implants in place during healing. • Infected unstable fracture—remove implants; stabilize with external or internal skeletal fixation. • Bone deficits—graft with autologous cancellous bone either acutely or after infection has abated and granulation tissue is present.
• Large segmental deficits in long bones—bone regeneration by bone transport utilizing the Ilizarov technique or other bone segment transport mechanism. • Localized chronic infection—consider amputation or *en bloc* resection and primary wound closure.
• Remove all implants after the fracture has healed to eliminate biofilm. • Muscle flap coverage of exposed bone early in the course of treatment greatly reduces contamination of bone and promotes fracture healing.

MEDICATIONS

DRUG(S) OF CHOICE
• Administer a broad-spectrum bactericidal antimicrobial intravenously for 3–5 days while awaiting culture and susceptibility results, then switch to appropriate antimicrobial which must be given for 4–8 weeks; continue for at least 2 weeks beyond radiographic and clinical resolution of infection. • *S. pseudintermedius*—amoxicillin–clavulanate, cefazolin, oxacillin are reasonable empirical choices. • Antibiotics effective against anaerobes that are also available for parenteral administration—ampicillin sodium, metronidazole, clindamycin.
• Aminoglycosides and quinolones—effective against Gram-negative aerobic bacteria.
• Quinolones—may give orally; not nephrotoxic; to protect against resistance, use only for infections caused by Gram-negative organisms that are resistant to other oral antimicrobial drugs. • Chronic disease—continuous local delivery of antimicrobial drugs by antibiotic-impregnated bone cement (beads) or biodegradable material (gels).
• Fungal osteomyelitis—long-term therapy (months); treat at least a month beyond resolution of clinical signs; e.g., itraconazole 5–10 mg/kg PO q24h; given continuously may control disseminated aspergillosis long-term. • Analgesics— important to encourage limb use.

CONTRAINDICATIONS
Quinolones— potential for cartilage injury in immature dogs.

PRECAUTIONS
Aminoglycosides—may cause nephrotoxicity.

ALTERNATIVE DRUG(S)
Identify other antimicrobial drugs by repeating cultures and susceptibility determination if the infection becomes unresponsive to the initial agent.

FOLLOW-UP

PATIENT MONITORING
• Radiography—2–3 weeks after intervention and then every 4–6 weeks to monitor bone healing. • Reculture bone—suspected persistent infection.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• Recurrence. • Progression to chronic disease. • Malignant neoplasia—rare sequela to chronic infection of fractures repaired by internal fixation.

EXPECTED COURSE AND PROGNOSIS
• Acute infection—may be cured by 4–8 weeks of antimicrobial drug therapy if there is limited bone necrosis and no fracture.
• Chronic disease—resolution with antimicrobial drug therapy alone unlikely; provide appropriate surgical treatment.
• Recurrence of chronic infection may require repeated sequestrectomy. • Consider amputation in severe chronic cases with irreversible loss of limb function.

OSTEOSARCOMA

BASICS

DEFINITION
Osteosarcoma (OS) is a cancer derived from a malignant osteoblast cell lineage within the endosteum, and is the most common primary bone tumor in dogs. Large- to giant-breed dogs most commonly develop appendicular OS, while axial OS tends to affect smaller breeds (<15 kg). The biologic behavior of OS is aggressive locally and distantly, with presumed microscopic lung metastases present in ≥85% of dogs at diagnosis. OS is rare in cats, and the biologic behavior is less malignant than in dogs.

PATHOPHYSIOLOGY
Genetic predisposition is likely a major contributor for the development of OS. Other factors contributing include chronic inflammation associated with metallic implants, history of prior radiation therapy to the site of tumorigenesis, and rapid bone turnover, all associated with the development of OS in dogs.

SYSTEMS AFFECTED
- Musculoskeletal—the appendicular skeleton (metaphyseal region of long bones) is most commonly affected in dogs. OS may also occur in the axial skeleton.
- Respiratory—the most common metastatic site is the lung parenchyma; however, other sites include bones, regional lymph node, skin, and visceral organs (liver, kidney).

GENETICS
There is a strong breed predilection, with some degree of heritability being identified in giant breeds such as Scottish deerhound, Rottweiler, greyhound, and Irish wolfhound.

INCIDENCE/PREVALENCE
- Dogs—OS accounts for up to 85% of primary bone tumors in dogs, representing ~5% of all reported malignancies in dogs.
- Cats—OS is the most common primary bone tumor in cats, accounting for <7% of all reported cancers in this species.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
- Dogs—large to giant breed (>40 kg).
- Cats—domestic shorthair cats.

Mean Age and Range
- Dogs—bimodal peak at 2 years and 7 years, reported to occur as young as 6 months.
- Cats—average age 8.5 years (range 4–18 years).

Predominant Sex
Dogs and cats—no strong sex predilection.

SIGNS
General Comments
- Because OS occurs most commonly in the appendicular skeleton of dogs and cats, lameness and pain are common clinical findings.
- Clinical symptoms associated with OS affecting the axial skeleton can be variable depending upon the anatomic site involved.

Historical Findings
- Lameness (acute or chronic) is the most common presenting clinical sign.
- Signs of axial skeletal OS vary, depending on the site of the lesion.

Physical Examination Findings
- A firm, painful swelling of the affected site is common with either appendicular or axial skeletal OS.
- Degree of lameness varies from mild to non-weight-bearing.
- Soft tissue swelling secondary to tumor infiltration.

CAUSES
Unknown in both species.

RISK FACTORS
- Dogs—large- to giant-breed dogs at greater risk.
- Metallic implants at fracture repair sites.
- Exposure to ionizing radiation.
- Cats—unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other primary bone tumor (i.e., fibrosarcoma, chondrosarcoma).
- Metastatic bone tumor (i.e., prostatic, mammary, other carcinoma).
- Infectious (i.e., fungal or bacterial osteomyelitis).

CBC/BIOCHEMISTRY/URINALYSIS
Elevated alkaline phosphatase is a poor prognostic factor.

IMAGING
Radiography of Primary Site
- At least two views of the primary lesion should be acquired.
- Radiographic findings include mixed osteolytic/osteoproductive effects involving the affected skeletal site.
- Soft tissue swelling overlying diseased bone.

Thoracic Radiography
- Three-view thoracic radiographs should be performed; although visible macroscopic metastatic disease is present in <10% of cases at the time of presentation.
- Pulmonary metastases at initial diagnosis is associated with an extremely poor prognosis.
- Metastatic lesions typically appear as discrete, round, soft tissue density nodules.

OTHER DIAGNOSTIC PROCEDURES
Bone Aspirate
- A relatively noninvasive, high-yield procedure using an 18-gauge needle to collect OS cells from the diseased skeletal site.
- Cytology can provide a diagnosis of malignant mesenchymal neoplasia.
- Concurrent alkaline phosphatase positivity on cytology is sensitive and specific for OS diagnosis.

Bone Biopsy
- Performed with the patient under light general anesthesia or moderate sedation.
- Samples should be taken through the center of the lesion; peripheral biopsies are often nondiagnostic and contain reactive osteoblasts.
- Biopsy may be performed using a Michele trephine, Jamshidi bone biopsy needle, or open biopsy technique.

PATHOLOGIC FINDINGS
- Gross—moderate to severe destruction of cortical bone with new bone proliferation.
- Histologic—malignant population of mesenchymal cells that are plump, polygonal to spindyloid in shape. The finding of osteoid production is necessary and diagnostic for OS.

TREATMENT

DIET
No specific dietary management is required, although weight loss may benefit amputees in general.

CLIENT EDUCATION
- Long-term prognosis is poor; however, a subpopulation (15%) of patients achieve long-term survival (>2 years).
- Clients must understand that treatment goals are to relieve discomfort and prolong life; a cure is unlikely.

SURGICAL CONSIDERATIONS
Dogs—Appendicular Sites
- Surgical management involves amputation of the affected limb.
- Limb salvage therapy is available at a limited number of referral hospitals. This technique is appropriate only for locally confined and small distal radial lesions. The primary tumor is surgically removed, replaced by a commercially available metal endoprosthesis with modified bone plate.

Dogs—Axial Sites
- Depending on location, aggressive surgical excision or radiation therapy, in conjunction with adjuvant chemotherapy are recommended.

OSTEOSARCOMA (CONTINUED)

• If surgical resection is not possible, palliative radiation is effective for the alleviation of osteolytic bone pain.

Cats—Appendicular Sites

• Amputation alone is considered appropriate.
• Adjuvant chemotherapy not necessary.

Cats—Axial Sites

• Depending on site of lesion, aggressive surgical excision or radiation therapy should be instituted.
• Local recurrence appears to be the main reason for treatment failure.

Metastatectomy

• Pulmonary metastatectomy has been described for dogs with OS; however, is not routinely practiced.
• Selection criteria for dogs to undergo this procedure include a long disease-free interval (>300 days) and only 1–2 pulmonary nodules based on thoracic radiographs.

Inoperable Neoplasms

• Palliative (coarse fractionation) radiotherapy or stereotactic radiosurgery combined with systemic chemotherapy and aminobisphosphonate therapy can provide prolonged survival times with acceptable pain control (10–12 months).
• Pain management with nonsteroidal anti-inflammatory drugs, opioids, and/or bisphosphonates may improve quality of life and thus prolong survival.

MEDICATIONS

DRUG(S) OF CHOICE

Definitive Therapy

• Chemotherapy with either platinum-based drugs (cisplatin or carboplatin) or doxorubicin is the current standard of care; a minimum of four doses is recommended.
• Cisplatin 70 mg/m^2 IV q3 weeks. Must be given with a saline-induced diuresis to prevent nephrotoxocity: 18.3 mL/kg/h for 4 hours, administer chemotherapy over 20 minutes, then continue diuresis for another 2 hours. Antiemetics must be given before cisplatin, and the patient may need to be sent home with antiemetic therapy.
• Carboplatin 300 mg/m^2 IV q3 weeks.
• Doxorubicin 30 mg/m^2 IV q3 weeks for 5 doses.
• Chemotherapy or toceranib phosphate (Palladia) is not effective against gross disease; less than 5% expected response rate.
• Chemotherapy typically initiated within 2 weeks of surgery.

CONTRAINDICATIONS

• Patients with preexisting renal dysfunction should not be treated with platinum-based chemotherapy drugs.
• Do not give cisplatin to cats.

ALTERNATIVE DRUG(S)

Palliative Therapy

• Pain management must be addressed in patients whose owners decline definitive therapy.
• Manage pain with nonsteroidal anti-inflammatory drugs, ± tramadol (2–5 mg/kg q8–12h), ± acetaminophen with codeine (0.5–2 mg/kg q8–12h), ± transdermal fentanyl (as per package instructions) ± gabapentin (3–10 mg/kg q8–24h).
• Euthanasia when quality of life declines.

FOLLOW-UP

PATIENT MONITORING

• Monitor CBC for evidence of myelosuppression 7–14 days following chemotherapy.
• Doxorubicin—periodic echocardiography and ECGs as cumulative cardiotoxicity may occur at >180 mg/m^2.
• Three-view thoracic radiographs every 2–3 months after surgery to assess for metastasis.

POSSIBLE COMPLICATIONS

• Metastatic disease is very likely; sites of spread include lungs, other bones, soft tissue.
• Animals that undergo limb salvage may develop recurrent infections, local recurrence, or implant failure.
• Animals treated with systemic chemotherapy can develop adverse side effects, including bone marrow suppression and gastrointestinal upset. Symptomatic management is typically effective, however, life-threatening complications can occur infrequently.

EXPECTED COURSE AND PROGNOSIS

Dogs

• Without treatment, with amputation alone, or with palliative radiotherapy alone, median survival is approximately 4 months. When conventional palliative radiotherapy is combined with IV aminobisphosphonates and oral analgesics, acceptable quality of life can be extended up to 6–9 months. The use of stereotactic radiosurgery in combination with chemotherapy and aminobisphosphonates can extend survival times to 10–12 months.
• With surgery and chemotherapy, median survival is extended to a median of 10 months.

Cats

• Appendicular OS, with surgery, median survival of >2 years.
• Axial OS, with surgery, median survival of 5.5 months.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Do not breed animals that are undergoing chemotherapy.

SYNONYMS

Osteogenic sarcoma.

SEE ALSO

• Chondrosarcoma, Bone.
• Fibrosarcoma, Bone.
• Hemangiosarcoma, Bone.

ABBREVIATIONS

• ECG = electrocardiogram.
• OS = osteosarcoma.

OTITIS EXTERNA AND MEDIA

BASICS

DEFINITION
• Otitis externa—inflammation of the external ear canal; includes anatomic structures of the pinna, horizontal and vertical canals, and the external layer of the tympanic membrane.
• Otitis media—inflammation of the middle ear; includes anatomic structures of the tympanic membrane, bulla (tympanic cavity), auditory ossicles, and auditory tube.

PATHOPHYSIOLOGY
• Otitis externa—chronic inflammation results in alterations in the environment of the canal; with inflammation, cerumen glands enlarge and produce excessive wax; the epidermis and dermis thicken and become fibrotic; thickened canal folds reduce canal width; calcification/ossification of auricular cartilage is the end-stage result.
• Otitis media—often an extension of otitis externa through the tympanic membrane (dogs); a result of infection ascending through the auditory tube to the middle ear (cats). Chronic viral upper respiratory infection early in life may change the ability of the auditory tube to protect the bulla from infection. Otitis media can occur from polyps or neoplasia within the middle ear or auditory tube.

SYSTEMS AFFECTED
• Skin/exocrine.
• Nervous.

GEOGRAPHIC DISTRIBUTION
Environmental humidity may predispose to infection.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
• Pendulous-eared dogs—especially spaniel and retriever.
• Dogs with hirsute external canals—terrier and poodle.
• Stenosis of the external ear canal—pug and bulldog; stenosis of the external orifice of ear canal—shar pei.
• Primary secretory otitis media—cavalier King Charles spaniel.

SIGNS
Historical Findings
• Pain—shying from touching of the head, refusing to open the mouth, dropping food.
• Head shaking.
• Scratching at the pinnae.
• Malodor from canals.
• Peripheral vestibular deficits or facial paralysis or paresis.

Physical Examination Findings
Otitis Externa
• Inflammation, pain, pruritus, and erythema of the pinnae and external canals.
• Stenosis of external orifices and/or ear canals.
• Deafness from obstruction.
• Purulent and malodorous exudates.
• Aural hematoma.
• Palpable scarring and calcification of the auricular cartilage.
• Holding of the pinna down and/or head tilt toward the affected side (if unilateral).

Otitis Media
• Vestibular signs—ipsilateral facial nerve paralysis and/or Horner's syndrome; uncommon in the cat, more common in the dog.
• Intact tympanic membrane—bulging pars flaccida.
• Evidence of fluid and/or gas behind the pars tensa; membrane may be opaque; fluid may be purulent or hemorrhagic.
• Ruptured tympanic membrane—discharge into canal or bullae filled with debris.
• Deafness (otitis media progressing to otitis interna).
• Pain on palpation or opening of the mouth.
• Xeromycteria (uni- or bilateral nasal planum hyperkeratosis—lack of nasal secretion due to parasympathetic nerve dysfunction).

CAUSES
• Predisposing factors—present prior to the development of ear disease:
  ◦ Conformation (see Breeds).
  ◦ Excessive moisture (high humidity, swimming).
  ◦ Obstructive ear disease (neoplasia, polyp).
  ◦ Primary otitis media.
• Perpetuating factors—changes in anatomy or physiology in response to otitis externa:
  ◦ Altered wax migration, excessive production of debris.
  ◦ Proliferative changes, stenosis.
  ◦ Calcification.
• Primary causes—directly initiate or cause inflammation within the ear canal:
  ◦ Parasites—*Otodectes cynotis*, *Demodex* spp., *Otobius megnini*, chiggers.
  ◦ Hypersensitivities—atopy, food, contact; recurrent otitis externa may be the only clinical sign of hypersensitivity.
  ◦ Foreign bodies—plant awns.
  ◦ Keratinization disorders and increased cerumen production.
  ◦ Endocrinopathy—immune-mediated; drug reaction (topical or systemic).
• Secondary causes—create disease in an abnormal ear:
  ◦ Bacterial or yeast infection.
  ◦ Excessive moisture and maceration (overcleaning, trauma).
  ◦ Topical irritants.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
• Strict diet trial to diagnosis cutaneous adverse reaction to food.

IMAGING
• Bullae radiographs—may be normal; bullae may appear cloudy if filled with exudate; thickening of bulla and petrous temporal bone with chronic disease; presence of bone lysis with osteomyelitis or neoplastic disease.
• CT or MRI—detailed evidence of fluid or tissue density in the bulla, adjacent tissues, or auditory tube.

DIAGNOSTIC PROCEDURES
• Otoscopy or video-otoscopy—visualization of the external canal, tympanic membrane, and portions of the bulla (if tympanum ruptured).
• Cytologic examination of exudate—most important diagnostic tool after complete examination of the ear canal; otic discharge sample should be taken before cleaning or treatment are initiated; examine exudates from each ear canal:
  ◦ Morphologically describe and quantitate bacteria, yeast, inflammatory cells (0 to 4+ scale) for treatment monitoring.
  ◦ Type(s) of bacteria or yeast—assist in the choice of therapy .
• Infections within the canal can change with prolonged or recurrent therapy; repeat cytology is required in chronic cases.
• Myringotomy—spinal needle or sterile catheter is inserted through the tympanic membrane to sample fluid within the bulla for cytologic examination and culture.
• Culture of otic exudate—recommended in cases of otitis media and/or persistent infection.
• Parasites—*Otodectes*, *Otobius*, and chiggers are visualized on otoscopy; *Demodex* can be diagnosed on ear cytology.

TREATMENT

CLIENT EDUCATION
Demonstrate proper method for cleaning and medicating ears (e.g., volume of medication to instill).

SURGICAL CONSIDERATIONS
• Lateral ear resection—disease affects primarily the vertical canal.
• Total ear ablation—entire canal is severely stenotic and oral glucocorticoids have failed to decrease stenosis or proliferative changes; tympanic bulla is diseased; or neoplasia affects the canal.

O

OTITIS EXTERNA AND MEDIA (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

Cleansing Solutions

- Tympanum integrity should be assessed prior to introduction of solutions and/or medications into the external ear canal.
- At home cleaning:
  - Cleanser/dryer 2–3 times a week for mild to moderate amounts of wax. Combination cleanser/drying products—contain ceruminolytics (e.g., docusate sodium or dioctyl sodium sulfocuccinate, propylene glycol), drying agents (e.g., dimethicone), germicidals (e.g., acetic acid, boric acid)—contraindicated in cases of perforated tympanic membrane.
  - Acetic acid 5% (white vinegar) diluted 1:2 in water—good activity against bacteria including *Pseudomonas*, and yeast. Safe in middle/inner ear.
  - Tris-EDTA—antibacterial activity; enhances susceptibility of bacteria to various antibiotics. Low ototoxic potential; safe in middle ear.
  - Chlorhexidine—antiseptic, concentrations of less than 0.2% are safe within the middle ear.
  - *N*-Acetylcysteine—antimicrobial and mucolytic properties, and ability to disrupt bacterial biofilm.
- "In clinic" cleaning on awake animals:
  - Bulb syringe or trimmed French red rubber catheter used to flush in solution and remove debris.
  - Deep ear cleaning with general anesthesia when needed.

Systemic Antibiotics (Indications)

- Severe otitis and neutrophils are seen on cytology suggesting a deeper infection.
- Otitis media.
- Best chosen by culture and sensitivity test—empiric choices include cephalexin 30 mg/kg q12h, amoxicilin+clavulanic acid 13.75 mg/kg q12h, clindamycin 11 mg/kg q12h when cocci are seen cytologically; marbofloxacin 2.75 mg/kg q24h if rods are seen cytologically.

Systemic Antifungals (Indications)

- Refractory *Malassezia* infection or when owners are unable to apply topical treatment.
- Otitis media caused by *Malassezia* or other fungal organism.
- Dogs—ketoconazole 5–10 mg/kg q24h, terbinafine 20–30 mg/kg q24h.
- Cats—itraconazole 5 mg/kg q24h.

Systemic Glucocorticoids (Indications)

- Reduce inflammation and cerumen production associated with otitis externa.
- Reduce proliferative changes secondary to inflammation in ear canals.
- Starting dosages—prednisolone 1 mg/kg/day, dexamethasone 0.1 mg/kg/day, triamcinolone 0.1 mg/kg/day; higher dosages can be used for more severe inflammatory changes.
- Antiparasitic therapy against mites—avermectins, isoxazolines.
- *Otobius* (ear tick) should be removed from inside the ear canal.

Topical

- Continue cleanings until symptoms resolve and then routinely to maintain control.
- Apply appropriate topical medications in sufficient quantity to completely treat the entire canal: Amount used is determined by the size of ear—instilled once or twice daily.
- Antibiotic—based on cytologic evaluation and/or empiric choice. Gentamicin, neomycin—cocci infection; enrofloxacin and silver sulfadiazine—rods; amikacin—resistant *Pseudomonas*.
- Antifungal (anti-*Malassezia*)—clotrimazole, ketoconazole, miconazole, thiabendazole, nystatin, terbinafine; posaconazole—refractory *Malassezia* cases.
- Anti-inflammatory (glucocorticoid)—dexamethasone, fluocinolone, betamethasone, triamcinolone, hydrocortisone aceponate, and mometasone.
- Antiparasitic—ivermectin and thiabendazole.

CONTRAINDICATIONS

- Ruptured tympanum—use caution with topical cleansers other than sterile saline or dilute acetic acid; potential for ototoxicity; controversial.
- Ivermectin—non-FDA approved for use systemically; herding (dog) breeds have increased sensitivity (*MDR1*/*ABCB1* gene mutation).

PRECAUTIONS

- Use caution when cleaning the external ear canals of all animals with severe and chronic otitis externa; the tympanum can easily rupture.
- Post-flushing vestibular complications are more common in cats, although usually temporary; warn clients of possible complications and residual effects.

POSSIBLE INTERACTIONS

Topical medications infrequently induce contact irritation or allergic response; reevaluate all worsening cases.

FOLLOW-UP

PATIENT MONITORING

Cytology of ear canals should be repeated at each clinic visit.

PREVENTION/AVOIDANCE

- Routine ear cleaning at home.
- Control of underlying diseases.

POSSIBLE COMPLICATIONS

Deafness, vestibular disease, cellulitis, facial nerve paralysis, progression to otitis interna, and rarely meningoencephalitis.

EXPECTED COURSE AND PROGNOSIS

- Otitis externa—with proper therapy, most mild initial cases resolve in 3–4 weeks; failure to correct underlying primary cause results in recurrence.
- Otitis media—requires at least 6 weeks of systemic antibiotics until all signs resolve.
- Osteomyelitis of petrous temporal bone and bulla—may require 6–8 weeks of antibiotics.
- Vestibular signs may improve within 2–6 weeks; some animals may have residual symptoms.

OTITIS MEDIA AND INTERNA

BASICS

DEFINITION
Inflammation of the middle (otitis media) and inner (otitis interna) ears, commonly caused by bacterial infection.

PATHOPHYSIOLOGY
• Media—from extension of infection of the external ear through the tympanic membrane; may extend from the oral and nasopharyngeal cavities via the eustachian tube. • Interna—may also result from hematogenous spread of a systemic infection.

SYSTEMS AFFECTED

Nervous
• Impaired balance due to damage to the vestibular apparatus in the inner ear or to the vestibular portion of vestibulocochlear nerve. • Nausea from dizziness due to impaired balance. • Hearing loss due to damage to hair cells in the cochlea or to the cochlear portion of vestibulocochlear nerve. • CNS signs when spread of infection intracranially (otogenic intracranial infection).

Ophthalmic
• Keratoconjunctivitis sicca (KCS; dry eye)—from damage to parasympathetic branch of the facial nerve supplying the lacrimal gland. • Corneal ulcer—as a consequence of inability to blink due to damage to facial nerve or from KCS. • Horner's syndrome—from damage to sympathetic nerve as they course through the middle ear.

SIGNALMENT

Breed Predilections
• Dogs more often affected than cats. • Cocker spaniels and other long-ear breeds. • Poodles with chronic otitis or pharyngitis from dental disease. • Primary secretory otitis media in cavalier King Charles spaniels.

SIGNS

Historical Findings
• Pain when opening the mouth; reluctance to chew; shaking the head; pawing at the affected ear. • Vestibular deficits, which may be persistent, transient, or episodic. • Unilateral involvement causes head tilt, leaning, veering, or rolling. • Bilateral involvement causes wide head excursions, truncal ataxia; ± deafness. • Vomiting and nausea may occur during the acute phase. • Saliva and food dropping from corner of the mouth; inability to blink; ocular discharge. • Anisocoria (smaller pupil on affected side), protrusion of the third eyelid, enophthalmos and ptosis (Horner's syndrome) may be noted.

Physical Examination Findings
• The presence of aural erythema, discharge, and thickened and stenotic external canals support otitis externa. • Pain upon opening of the mouth or on bulla palpation. • Gray, dull, opaque, and bulging tympanic membrane on otoscopic examination indicates middle ear exudate. • Dental tartar, gingivitis, tonsillitis, or pharyngitis may be present and have a role in the pathogenesis. • With severe infections, the ipsilateral mandibular lymph nodes may be enlarged. • Corneal ulcer from inability to blink or KCS.

Neurologic Examination Findings
• Unilateral damage to vestibular portion of cranial nerve VIII—ipsilateral head tilt, leaning, veering, falling, or rolling. • Nystagmus—resting or positional; rotary or horizontal; fast phase characteristically opposite the affected side, and does not change in direction with a change in head position. • Vestibular strabismus—ipsilateral ventral deviation of eyeball with neck extension. • Bilateral damage of vestibular portion of cranial nerve VIII—patient reluctant to move, may stay in a crouched posture, wide head excursions; physiologic nystagmus poor to absent. • Facial nerve damage—ipsilateral paresis/paralysis of the ear, eyelids, lips, and nares; reduced tear production (indicated by Schirmer tear test). • Chronic facial paralysis—contracture of the affected face caused by fibrosis of denervated muscles. • Sympathetic nerve damage—ipsilateral Horner's syndrome; always miosis; may also note protrusion of third eyelid, ptosis, and enophthalmos.

CAUSES
• Bacteria—*Staphylococcus* spp., *Streptococcus* spp., *Proteus* spp., *Pseudomonas* spp., *Pasteurella* spp., and *E. coli* and obligate anaerobes. • Fungi—yeast (*Malassezia* spp., *Candida* spp.) and *Aspergillus*. • Ear mites predispose to secondary bacterial infections. • Foreign bodies (e.g., grass awns, foxtail awns, or spear grass in endemic areas), trauma, polyps, tumors (e.g., fibromas, squamous cell carcinoma, ceruminous gland carcinoma, primary bone tumors). • Iatrogenic damage during cleaning or flushing or in investigation of otitis externa.

RISK FACTORS
• Recurrent otitis externa. • Nasopharyngeal polyps and inner, middle, or outer ear neoplasia may predispose to bacterial infection. • Ear-cleaning solutions (e.g., chlorhexidine) may be irritating to middle/inner ear or be ototoxic. These should be avoided if tympanum is ruptured.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Congenital vestibular anomalies—signs present from birth. • Hypothyroidism may be associated with cranial nerve VII and VIII deficits. Abnormal thyroid profile supports diagnosis. • Neoplasia and nasopharyngeal polyps are common causes of refractory and relapsing otitis media and interna. Diagnosed by oral and otic exam and imaging of the head. • Idiopathic vestibular disease (old dogs and young to middle-aged cats), idiopathic facial paralysis, and idiopathic Horner's syndrome are diagnoses made by exclusion. • *Cryptococcus* is reported to be associated with peripheral vestibular disease in cats. • Traumatic causes may have physical external evidence of injury, and history supporting occurrence of a traumatic event. • Thiamine deficiency occurs in cats with a history of an all-fish diet or persistent anorexia; causes bilateral central vestibular signs. • Metronidazole used for an extended duration and/or at a high dose damages the vestibular portion of the cerebellum. Signs of bilateral cerebellar disease and history of metronidazole use. • Central vestibular disease may cause lethargy, somnolence, vertical nystagmus, and other brainstem signs.

CBC/BIOCHEMISTRY/URINALYSIS
• Leukocytosis with left-shift may be noted. • Globulins may be high if chronic infection.

OTHER LABORATORY TESTS
• Blood, urine cultures may show growth if hematogenous source of infection. • Low thyroxine (T_4), free T_4 with normal or high thyroid-stimulating hormone (TSH) level with hypothyroidism.

IMAGING
• Video-otoscopy—enables detailed examination of external ear canal and tympanic membrane. With middle ear exudate, the membrane may appear cloudy. Helpful in evaluating the integrity of the tympanic membrane, obtaining samples for cytology and culture/sensitivity, and performing therapeutic lavages of the ear canal and middle ear cavity. • Bullae radiographs—not sensitive. May show thickening of the bullae and petrous temporal bone with chronic disease, boney lysis with severe cases of osteomyelitis, evidence of neoplasia, or may be normal. • CT or MRI—necessary to demonstrate fluid and soft tissue density within the middle ear and extent of involvement of adjacent structures. CT is better at revealing associated bony changes, MRI for evaluating soft tissue structures including brainstem and cerebellum.

OTITIS MEDIA AND INTERNA (CONTINUED)

DIAGNOSTIC PROCEDURES

• Myringotomy—insert a spinal needle (20-gauge; 2.5- to 3.5-inches) through the otoscope and tympanic membrane to aspirate middle ear fluid for cytologic examination and culture and sensitivity. Examine for bacterial and fungal causes of infection.
• Brainstem auditory evoked response (BAER)—tests the peripheral and central auditory pathways, detects hearing loss.
• CSF analysis—if evidence of intracranial extension, perform culture and sensitivity.

PATHOLOGIC FINDINGS

Purulent exudate within the middle ear cavity surrounded by a thickened bullae and microscopic evidence of degenerate neutrophils with intracellular bacteria or other microorganisms; other causes such as polyps or neoplasia.

O

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient care is recommended with severe debilitating infection or if significantly compromising neurologic signs are present.
• Outpatient care is appropriate if the patient is stable, pending further diagnostics, if indicated.

DIET

• If vomiting, withhold food and water for 12–24 hours. • If unable to stand or severely disoriented, hand-feed and water small amounts frequently. Ensure that the patient is sternal during feeding to decrease risk of aspiration pneumonia.

CLIENT EDUCATION

• Inform client that most bacterial infections resolve without recurrence when treated early with an aggressive course of long-term, broad-spectrum antibiotics. • Warn client that relapsing signs may occur, that the patient may improve but may never be neurologically normal. • Warn client that the condition may require surgical intervention.

SURGICAL CONSIDERATIONS

• Severity of neurologic signs is not directly related to degree of pathology, and should not be used to make decisions regarding need for surgical intervention. • Surgical treatment is indicated for patients with evidence of middle ear exudate, osteomyelitis refractory to medical management, nasopharyngeal polyps, or neoplasia. • Bullae osteotomy allows drainage of the middle ear cavity. • Total ablation of ear canal is indicated when otitis media is associated with recurrent otitis externa or neoplasia. • Perform cytologic examination and culture of middle ear effusion and histopathology of abnormal tissue sampled at the time of surgery.

MEDICATIONS

DRUG(S) OF CHOICE

• Topical sterile water, saline, or TrizEDTA-based otic antimicrobial preparations if tympanum is ruptured. • Treat mites if present. • Long-term (6–8 weeks) topical and systemic antibiotics selected on basis of culture and sensitivity, if available.
• Amoxicillin/clavulanic acid (12.5–22 mg/kg q12h PO) is a good first-choice antibiotic.
• Fluoroquinolone or third-generation cephalosporins are good second alternatives or can be used in combination, if culture and sensitivity unavailable; enrofloxacin (Baytril) 5–10 mg/kg q24h (dogs), 5 mg/kg q24h (cats), or marbofloxacin (Zeniquin 5 mg/kg q24h), or cefpodoxime (Simplicef 10 mg/kg q12h); clindamycin (Cleocin 5–30 mg/kg q12h), if anaerobes are suspected. • In cats, where oral dosing is too challenging, consider using cefovecin (Convenia) 8 mg/kg SC every 2 weeks. This can also be used in combination with a fluoroquinolone. • Antiemetics to treat or prevent nausea, vomiting, and dizziness. Meclizine (Antivert, Antrizine, Bonine, Dramamine Less Drowsy Formula) 12.5 mg PO q24h (dogs <10 kg and cats), 25 mg PO q24h (dogs >10 kg); or maropitant citrate (Cerenia) 1 mg/kg SC or 2 mg/kg PO q24h (dogs), 1 mg/kg SC or 1 mg/kg PO q24h (cats); or dolasetron mesylate (Anzemet) 0.6 mg/kg IV q24h (dogs, cats).

CONTRAINDICATIONS

• If ruptured tympanum or associated neurologic deficits, avoid oil-based or irritating external ear preparations (e.g., chlorhexidine) and aminoglycosides, which are toxic to inner ear structures. • Use topical and systemic corticosteroids judiciously in treatment of otitis media or interna. May exacerbate infection. Reserve for cases in which flushing of the ear canal is prevented by inflammation, or to treat edema associated with intracranial spread of infection.

PRECAUTIONS

Avoid vigorous external ear flush.

FOLLOW-UP

PATIENT MONITORING

Evaluate for resolution of signs after 10–14 days or sooner if the patient is deteriorating.

POSSIBLE COMPLICATIONS

• Signs associated with vestibular (head tilt) and facial nerve damage or Horner's syndrome may not resolve. • Severe middle/inner ear infections may spread to brainstem or sometimes forebrain. Clinical signs indicate central vestibular lesion, typically preceded by peripheral vestibular or middle/inner ear signs. Aggressive surgical debridement and antibiotic therapy are required. • Osteomyelitis of the petrous temporal bone and middle ear effusion are common sequelae to severe, chronic otitis externa. • Complications following bulla osteotomy include Horner's syndrome, facial paralysis, onset or exacerbation of vestibular dysfunction, and deafness.

EXPECTED COURSE AND PROGNOSIS

• Otitis media-interna is usually responsive to medical management. To decrease likelihood of relapse, a 2- to 4-month course of antibiotic is recommended. • When medical management of otitis externa is ineffective, consider lateral ear resection. • Vestibular signs typically improve in 2–6 weeks.

MISCELLANEOUS

AGE-RELATED FACTORS

Ear mites more common in kittens and puppies.

SEE ALSO

• Facial Nerve Paresis and Paralysis.
• Head Tilt.
• Horner's Syndrome.
• Otitis Externa and Media.

ABBREVIATIONS

• BAER = brainstem auditory evoked response.
• KCS = keratoconjunctivitis sicca.
• T_4 = thyroxine.
• TSH = thyroid-stimulating hormone.

OVARIAN REMNANT SYNDROME

BASICS

OVERVIEW

- Ovarian remnant syndrome is the presence of behavioral and/or physical signs of estrus in a female dog or cat reported as having previously undergone ovariohysterectomy or ovariectomy (OVH/OE).
- It is caused by the presence of functional residual ovarian tissue.
- It is responsible for 17% of all post-OVH/OE complications.

SIGNALMENT

- Female dog and cat; more common in the cat.
- No breed predisposition or geographic distribution.
- Signs of an estrous cycle usually occur months to years after OVH/OE; can begin within days after surgery.

SIGNS

Bitches

Estrogen Influence

- Attraction of male dogs.
- Swelling of the vulva.
- Mucoid to sanguineous vaginal discharge.
- Flagging.
- May allow copulation.
- Signs of pro-estrus last an average of 9 days; signs of estrus last an average of 9 days; average interval between signs of estrous cycles is 7 months.
- Signs are typically cyclical (i.e., q6 months), unlike estrogen toxicity.

Progesterone Influence

- Prominent vulva compared to patients with complete OVH/OE.
- Enlargement of the uterine stump ultrasonographically.
- Uterine stump pyometra can develop due to progesterone effect.

Queens

Estrogen Influence

- Vocalization.
- Lordosis.
- Restlessness.
- Head rubbing.
- Rolling.
- Tail deviation and treading the hind limbs.
- May allow copulation.
- Demonstrate typical behavioral signs of estrus in a cyclical (seasonally polyestrous) fashion.
- Estrus lasts 2–19 days, followed by an interestrous interval that lasts for 8–10 days unless ovulation and luteinization occurred, in which case the interestrous interval is at least 45 days.

Progesterone Influence

- Enlargement of the uterine stump ultrasonographically.
- Uterine stump pyometra can develop due to progesterone effect.

CAUSES & RISK FACTORS

- Failure to remove both ovaries completely.
- No correlation with age at OVH/OE, difficulty of surgery, obesity of patient, or experience of surgeon.
- Presence of anatomically abnormal ovarian tissue (fragmentation into the broad ligament) is possible; more common in queens.
- Supernumerary ovary (rare).
- Experimentally, functionality returns to ovarian tissue removed from its vascular supply and replaced into or onto the lateral abdominal wall, mesentery, or serosal surface.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammation or infection of the genitourinary tract.
- Vaginal hemorrhage due to trauma, foreign body, or coagulopathy.
- Uterine stump granuloma secondary to local pathology (foreign body reaction to suture material or grass awn).
- Neoplasia of a remnant portion of the tubular tract (uterine stump leiomyoma or leiomyosarcoma).
- Neoplasia of an ovarian remnant (granulosa cell tumor, carcinoma, luteoma, functional teratoma), typically not cyclical.
- Neoplasia of the urinary tract (transitional cell carcinoma).
- Vascular anomalies of the genitourinary tract.
- Exogenous estrogen administration, typically not cyclical.
- Exposure to human transdermal hormone replacement therapy, typically not cyclical.
- Endogenous extra-ovarian source of estrogen—adrenal pathology (rare), typically not cyclical.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Chronic blood loss anemia if vaginal hemorrhage is profound.
- Pancytopenia from estrogen toxicity is uncommon.
- An inflammatory leukogram and isosthenuria can occur subsequent to uterine stump pyometra.

OTHER LABORATORY TESTS

- Observation of behavioral and physical signs of estrus together with vaginal cytology and/or measurement of serum progesterone concentration confirming the presence of functional ovarian tissue.
- Vaginal cytology—vaginal mucosal cornification is an excellent bioassay for elevated plasma estradiol concentrations (see Breeding, Timing).
  - Bitch—epithelial cell cornification is generally >90% during estrus (superficial and pyknotic or anuclear cells).
  - Queen—epithelial cell cornification ranges from 10% to 40% (usually retain nucleus); clearing (absence of debris and clumping of cells) occurs in 90% of smears during estrus.
- Serum progesterone:
  - Bitch—a serum progesterone concentration >2 ng/mL (measured 1–3 weeks after behavioral estrus) is consistent with functional luteal tissue. Gonadotropin-releasing hormone (GnRH, 50 µg, IM), human chorionic gonadotropin (hCG; 400 IU, IV, or 500 IU, IV and 500 IU, IM) can be used to attempt to induce ovulation/luteinization for diagnostic purposes; serum progesterone concentration is measured 2–3 weeks later. Note: both normal and pathologic ovarian tissue may fail to respond to either hormone.
  - Queen—ovulation and luteinization is stimulated most commonly by coital stimulation during behavioral estrus, and serum progesterone concentration is measured 2–3 weeks later; post-stimulation serum progesterone concentrations >2 ng/mL are consistent with adequate coital stimulation and functional luteal tissue. Feline ovulation can occur spontaneously. GnRH (25 µg, IM) can be used to attempt to induce ovulation or luteinization for diagnostic purposes; serum progesterone concentration is measured 2–3 weeks later. Both normal and pathologic ovarian tissue may fail to respond.
- Luteinizing hormone (LH) assay (Witness LH, Zoetis)—should be positive (>1 ng/mL) in a completely gonadectomized bitch due to lack of pituitary feedback. When an unexpected positive result is obtained in a bitch suspected to have a remnant, consider repeating in >24 hours to rule out inadvertent detection of the LH surge in the estrual bitch (should also have representative vaginal cytology with superficial cells predominating). If both are positive, then the bitch has been spayed. A negative test (<1 ng/mL) is found in intact dogs unless performed at the moment of the natural LH surge. The assay is licensed for use in the bitch, but likely is applicable in male dogs, toms and queens, provided that the queen is exposed to >14 hours of light/day. Note: exogenous estrogen exposure in a gonadectomized dog can cause the LH to become misleadingly negative.
- Anti-Müllerian hormone (AMH) testing: A positive test in a bitch or queen >6 months of age supports the presence of ovarian tissue (UC Davis Clinical Endocrinology Laboratory, Animal Health Diagnostic Center, Cornell University). In cases with a negative AMH but convincing clinical evidence supporting remnant syndrome, investigators advise obtaining a progesterone to identify persistent

OVARIAN REMNANT SYNDROME (CONTINUED)

luteal structures lacking AMH. AMH differentiates exogenous estrogen exposure (negative) from the ovarian remnant (positive).
• Cytology of vulvar discharge can be suppurative if a uterine stump granuloma or pyometra exists.
• Provocative adrenal testing (pre- and post-adrenocorticotropin [ACTH] administration).

IMAGING

Ultrasonography

• Can be used to support a diagnosis of ovarian remnant syndrome that is based on cytology and hormonal profiles; guides the surgical approach.
• Remnant ovarian tissue is most visible during the follicular phase (anechoic, cystic structures) or the luteal phase (hypo- or isoechoic cystic structures).
• Ultrasonographic imaging of ectopic ovarian tissue requires technical expertise and is best accomplished with a higher frequency, linear transducer (8–10 mHz). Ovarian remnants containing follicular or luteal structures often cause distal enhancement due to their fluid content; this can be used to locate them caudolateral to the ipsilateral kidney (see Web Figure 1).
• Evaluate the region dorsal to the bladder for a uterine remnant, which can enlarge under hormonal influence or with pathology (see Web Figure 2a,b).
• Evaluate the adrenal glands for normal size and shape. Normal canine adrenal glands are <0.51–0.74 cm in sagittal (see Web Figures 3 and 4).

DIAGNOSTIC PROCEDURES

• Exploratory laparotomy/laparoscopy—removal of residual ovarian tissue confirms and resolves the problem.
• Identification of residual ovarian tissue is facilitated by the presence of follicles or corpora lutea; schedule procedure during times of elevated progesterone or during behavioral estrus.
• Histopathology—always submit visible ovarian tissue; if no visible ovarian tissue is identified, submit all residual tissue at the ovarian pedicles. This helps confirm the diagnosis and screens for malignancy. Submit revised abnormal uterine stump tissue for aerobic and anaerobic cultures and histopathology (hormone influence, inflammatory response, malignancy).

TREATMENT

• Surgical removal of residual ovarian tissue.
• Surgical removal of diseased uterine stump if present.
• Although not curative, restricting light exposure to <8 hours per day can suppress signs of estrus in some, but not all, cats with residual ovarian tissue.

MEDICATIONS

DRUG(S) OF CHOICE

• Progestational or androgenic compounds to suppress follicular ovarian activity—not recommended because of undesirable side effects (mammary neoplasia, diabetes, undesirable behavior, hepatopathy, dermatopathy).
• GnRH agonist (Suprelorin) administration will offer a viable alternative or adjunctive therapy to laparotomy when perfected and commercially available in the United States.

FOLLOW-UP

POSSIBLE COMPLICATIONS

• Removal of functional luteal tissue may induce transient signs of pseudopregnancy in dogs and cats postoperatively (see False Pregnancy).
• The use of oral antiprolactin agents (cabergoline) can be considered for pseudopregnancy.

EXPECTED COURSE AND PROGNOSIS

• Successful removal of remnant ovarian tissue should result in cessation of clinical signs of estrus/diestrus.
• Adjunctive therapy for stump pyometra (systemic antibiotics, supportive care) as indicated.
• Adjunctive therapy for functional ovarian neoplasia as indicated.

MISCELLANEOUS

SEE ALSO

• Breeding, Timing.
• False Pregnancy.
• Hyperestrogenism (Estrogen Toxicity).

ABBREVIATIONS

• ACTH = adrenocorticotropic hormone.
• AMH = anti-Müllerian hormone.
• GnRH = gonadotropin-releasing hormone.
• hCG = human chorionic gonadotropin.
• LH = luteinizing hormone.
• OE = ovariectomy.
• OVH = ovariohysterectomy.

OVARIAN TUMORS

BASICS

OVERVIEW
- Epithelial (carcinoma), germ cell (dysgerminoma and teratoma), and sex cord stromal (granulosa cell tumor, Sertoli–Leydig cell tumor, thecoma, and luteoma) tumors.
- Dogs—rare (0.5–1.2% of tumors); 40% carcinomas, 10% germ cell, and 50% sex cord.
- Cats—rare (0.7–3.6% of tumors); 15% germ cell, and 85% sex cord.
- Metastasis common for malignant epithelial and germ cell tumors in the dog and all tumors in cats.
- Some tumors produce hormones resulting in paraneoplastic syndromes.

SIGNALMENT
- Dog and cat.
- Middle-aged to older animals.
- Teratoma may develop in young patients.

SIGNS
- Bilaterally symmetrical alopecia; pancytopenia; masculinization (hormone-secreting tumors with associated paraneoplastic manifestation).
- Malignant ascites or pleural.
- Effusion (carcinomatosis)—occasionally.
- Other signs associated with mass effects of the tumor (abdominal discomfort, compression of adjacent organs).

CAUSES & RISK FACTORS
- Intact sexual status.
- Dogs—pointer, English bulldog, boxer, German shepherd dog, and Yorkshire terrier at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other causes of abdominal effusion including vasculitis and pancreatitis.
- Other mid-abdominal masses or gossypiboma (foreign body granuloma).
- Ovarian cysts, paraovarian cysts, cystic rete tubules, vascular hematomas, metastatic neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
- No consistent abnormalities.
- Pancytopenia in dogs with functional estrogen-secreting tumors.

OTHER LABORATORY TESTS
Serum progesterone—levels >2 mg/mL with functional tumors.

IMAGING
- Abdominal radiography—may reveal unilateral or bilateral mid-abdominal mass at the caudal pole of the kidney or effusion, mineralization of tumor may be seen.
- Abdominal ultrasonography—confirm abdominal radiographic findings and provide greater certainty for the origin of mass effect.
- Advanced imaging—CT or MRI can provide detailed assessment for origin and associated tissues that might be involved in disease process.
- Thoracic radiography—may reveal distant metastasis (rare).

DIAGNOSTIC PROCEDURES
- Cytologic evaluation of pleural or abdominal fluid—may be diagnostic for malignant effusion (carcinomatosis).
- Cytologic evaluation of tumor—tumor cells may readily implant on the body wall via fine-needle aspirate. Therefore, excisional biopsy is often recommended over fine-needle aspirate of the mass.
- Histopathologic examination—necessary for definitive diagnosis.

TREATMENT
- Ovariohysterectomy—treatment of choice for a solitary mass.
- Peritoneal transplantation during surgical removal is possible; change gloves and surgical instruments during procedure.
- Laparoscopic-assisted ovariohysterectomy may be possible for smaller tumors.

MEDICATIONS

DRUG(S) OF CHOICE
- Chemotherapy—little information for dogs and cats, no standard therapy.
- Cisplatin—successful treatment reported in three dogs and treatment of choice for comparative tumors in human beings.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Cisplatin—do not use in dogs with renal disease; do not use without appropriate and concurrent diuresis; do not use in cats (fatal).
- Chemotherapy may be toxic; seek advice if unfamiliar with these agents.

FOLLOW-UP
- Abdominal ultrasonography and thoracic radiography—every 3 months; monitor for recurrence and metastasis.
- Ovariohysterectomy—prevention.
- Prognosis—guarded.
- Chemotherapy—has potential to lengthen survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Pyometra.
- Ovarian cysts.
- Cystic endometrial hyperplasia.
- Ovarian remnant syndrome.

Acknowledgment The author and editors acknowledge the prior contribution of Terrance A. Hamilton.

OVULATORY FAILURE

BASICS

OVERVIEW
• Breakdown in the process of ovulation, without normal corpus luteum formation and progesterone production.
• Clinical signs of prolonged estrogen production; may develop estrogen toxicity.

SIGNALMENT
• Intact bitch or queen of any age—greater predisposition in older females.
• Reported in 1.2% of bitches presented for breeding management.
• No breed predisposition for anovulation; follicular cysts reported more commonly in German shepherd dog, Malamute, golden retriever, bouvier des Flandres, and Labrador retriever.
• Heritability unknown.

O

SIGNS
• Prolonged proestrus or estrus.
• Edematous vulva.
• Sanguineous vulvar discharge (bitch).
• Anestrus.
• Decreased interestrous interval.
• Bilaterally symmetric alopecia (progressive, nonpruritic).
• If neoplasia—abdominal mass ± ascites.
• If chromosome abnormality—genitalia ranges from infantile or ambiguous to normal to enlarged clitoris or os clitoris; small stature; anestrus.

CAUSES & RISK FACTORS
• Failure of release of gonadotropin-releasing hormone (GnRH) or luteinizing hormone (LH).
• Failure of receptors on the follicular wall to respond to LH.
• Failure of the follicles to produce adequate estrogen to elicit GnRH surge.
• Functional follicular cysts—may mimic normal estrous cycle initially, but estrus persists and ovulation does not occur.
• Immune-mediated oophoritis.
• Cachexia or obesity.
• Stress (performance, travel, kennel).
• Adrenal disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Prolonged proestrus (up to 30 days) or estrus (up to 30 days).
• Split heat—anovulatory cycle will be followed by a normal, fertile, ovulatory cycle in 1–8 weeks.
• Hypoluteoidism.
• Granulosa cell tumor or serous cystadenoma—abdominal mass; enlarged ovary on ultrasound; ± ascites; ± bilaterally-symmetric alopecia.
• Ovarian senescence.
• Immune-mediated oophoritis.
• Chromosomal abnormality—may develop follicles that either ovulate or regress.
• Exogenous estrogen administration or exposure.

CBC/BIOCHEMISTRY/URINALYSIS
If estrogen toxicity—normocytic, normochromic anemia, thrombocytopenia, leukocytosis followed by leukopenia.

OTHER LABORATORY TESTS
• Serum progesterone concentration <4–10 ng/mL over multiple samplings once vaginal cytology exceeds 70% anucleated superficial cells. Often remains 3–5 ng/mL for prolonged period, never exceeding 10 ng/mL. Vaginal cytology eventually returns to proestrus/anestrus characteristics, confirming ovulatory failure.
• Karyotyping—diagnose chromosomal abnormality.

IMAGING
• Radiography—ovarian mass.
• Ultrasonography—multiple anechoic structures on the ovary may be considered follicles, anechoic structures >1 cm considered cystic; enlarged ovaries may be neoplastic; anechoic structures with thickened walls may indicate luteinization (partial or complete) of follicular structures. Daily ultrasonography to document ovulation; color Doppler can assess ovarian follicular blood flow (increased with follicles, minimal with luteal structures).

DIAGNOSTIC PROCEDURES
Exploratory laparotomy to examine the ovaries or to obtain ovarian biopsies—the ovarian bursa must be opened to visualize the ovary.

TREATMENT

N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Ovulation induction may be attempted once cytology reaches >70% anucleated cells and follicles are >4–5 mm (toy to small-breed canine), 5–7 mm (medium to large-breed canine), 7–10 mm (giant-breed canine), or 2–3 mm (feline).
• Ovulation-inducing agents:
  ◦ GnRH: 1.1–2.2 µg/kg IM or IV; 25 µg/cat IM; may repeat daily for 1–3 days in bitches, single dose for queens.
  ◦ Human chorionic gonadotropin (hCG): 500–1,000 IU/dog IM; 500 IU/queen IM; may repeat in 2–3 days if ovulation does not occur.
  ◦ GnRH and hCG may be given concurrently or alternating days.
  ◦ Deslorelin implant (2.1 mg implant—Ovuplant® or 4.7 mg implant—Suprelorin®) placed subcutaneously. If breeding and ovulation is confirmed (progesterone >10 ng/mL), implant should be removed. If not breeding, leave implant in place.
  ◦ In queens, cervical stimulation may be performed from initial induction several times daily for 24–48 hours.

FOLLOW-UP

• Monitor progesterone concentrations during pregnancy—luteal failure or hypoluteoidism more common with induced ovulation.
• Monitor progesterone after induction to confirm normal rise.
• Serial ultrasound exams (using color Doppler) may be useful to document ovulation.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Bilaterally symmetric nonpruritic alopecia (with prolonged estrus).

PREGNANCY/FERTILITY/BREEDING
• Anovulation may be hereditary; discuss with owner prior to breeding.
• Subsequent cycles may be normal, necessitating no treatment, or abnormal again.

SEE ALSO
• Infertility, Female—Dogs.
• Sexual Development Disorders.

ABBREVIATIONS
• GnRH = gonadotropin-releasing hormone.
• hCG = human chorionic gonadotropin.
• LH = luteinizing hormone.

PAIN (ACUTE, CHRONIC, AND POSTOPERATIVE)

BASICS

DEFINITION

• Unpleasant sensory or emotional experience associated with actual or potential tissue damage (adaptive pain) or altered sensory neurobiology (chronic pain).
• The inability for the animal to communicate does not negate presence of pain and the need for appropriate pain-relieving treatment.

PATHOPHYSIOLOGY

• With physiologic pain, an application of a noxious stimulus activates specialized nerve endings called nociceptors; nociceptors transduce noxious chemical, mechanical, or thermal stimuli into electrochemical potentials that are transmitted via sensory nerves from the affected tissue to the spinal cord.
• In the dorsal horn of the spinal cord, the incoming first-order peripheral nerve synapses with ascending spinal neurons, which terminate in the brainstem. Incoming noxious information can be modulated in the dorsal horn by other incoming information, descending inhibitory nerve impulses, or pharmacologic inhibition by several classes of drugs. The ascending neurons synapse in the brainstem to form ascending tracts that end in the cortex, where sensation occurs. Neuroendocrine and physiologic responses (e.g., tachycardia, elevated cortisol) to noxious stimuli may originate from the brainstem and do not necessarily correlate with the perceived intensity of pain.
• Nociceptive processes (i.e., transduction, transmission, and modulation) appear to be similar anatomically and physiologically in most mammalian and many non-mammalian species. The perception of pain may vary between species and individuals of the same species since anatomic differences in cortical development exist and integration of past experiences and learned behaviors varies.
• Prolonged activity in nociceptive pathways (e.g., days, weeks, or months) from chronic injury or disease, or injury to nervous system tissues, may cause altered neuroprocessing resulting in sensitization of these pathways and hyperresponsiveness. This may cause an increased response to a stimulus not normally considered noxious (allodynia).

SYSTEMS AFFECTED

• Pain may originate from any tissue, including the nervous system itself. In humans, certain pain syndromes may be associated with fear, anxiety, or depression in the absence of any observable injury.
• The physiologic response to pain can include decreased immune function, increased catabolism, and elevated neuroendocrine markers of stress. Pain can result in a loss of function of affected tissues.

GENETICS

Age, sex, breeding strain, and species can influence responses to noxious stimuli. Genes have been described that modify individual behavioral responses to noxious stimuli in several species. Genes may also be variably expressed depending on stimulus intensity and duration, which can lead to altered neuroprocessing and maladaptive or chronic pain.

INCIDENCE/PREVALENCE

• Evolutionarily, aversion to noxious stimuli was protective to organisms, keeping them away from harm.
• While acute pain is beneficial to warn or teach an animal about potential harmful objects in its environment, persistent acute pain associated with surgery or injury does not benefit the patient and should be treated appropriately.
• Any form of chronic pain syndrome does not serve a protective function and should be treated.

SIGNS

• Behavioral signs of pain and distress vary considerably among individuals.
• Experience, environment, age, species, and other factors can modify the intensity of the reaction to noxious stimuli or to an altered neurobiology associated with maladaptive or chronic pain.
• The most obvious clinical signs of distress in the dog and cat can include vocalization, agitation, abnormal posture or gait, thrashing, hyperesthesia, or hyperalgesia.
• More subtle signs shared by many conditions include trembling, lethargy, reduced appetite, stupor, and biting.
• Tachypnea, tachycardia, mydriasis, and hypertension are signs observed with the stress response that may also accompany pain; these are nonspecific and present in many nonpainful conditions. The stress response is often not associated with chronic pain due to adaptation.
• Clinical signs associated with chronically painful conditions may be very subtle or difficult to evaluate since homeostatic mechanisms tend to help the animal compensate. Chronically painful conditions are often associated with decreased activity, lameness, and/or depression.

CAUSES

• Physiologic or adaptive pain can be caused by perceived or actual tissue disruption associated with trauma or surgery and also by chronic degenerative changes and inflammation associated with conditions such as osteoarthritis.
• Pain that extends beyond the initial tissue damage and healing processes is pathologic (maladaptive) and may indicate that the initiation of altered nervous system processing has occurred.

RISK FACTORS

• All animals that experience surgical or traumatic tissue damage or have recently altered behavior should be evaluated for the presence of pain.
• Due to the increasing prevalence of degenerative diseases in older patients, routine examination should include evaluation for pain.
• Pain intensity may not always correlate with the degree of tissue damage. However, more invasive soft tissue and orthopedic procedures or inflammatory disease progression in older patients are likely associated with greater pain.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Identifying pain in veterinary patients is a diagnosis, and the medical record should reflect the veterinarian's clinical diagnostic and treatment plan.
• Acute pain is almost always accompanied by tissue damage or disease, and diagnosis and treatment of the primary disorder should be done before or concomitantly with treatment of pain. The presence or absence of pain is sometimes used as a way of monitoring and diagnosing some conditions, and treatment should be in accordance with good medical practice. Pain should be differentiated from distress associated with other factors, such as restraint, restrictive bandaging, and separation from owners. Drugs used to treat pain, particularly opioids and dissociative anesthetics, may cause dysphoria, which often resembles and can be confused with signs of pain and distress.

CBC/BIOCHEMISTRY/URINALYSIS

• Cortisol release associated with acute pain may appear as a stress leukogram.
• Hyperglycemia may also be observed in some patients, but can also be seen with anesthesia in the absence of tissue trauma.
• Normal laboratory test values do not rule out the presence of pain.

OTHER LABORATORY TESTS

N/A

IMAGING

• Many painful patients have underlying changes in anatomic structures observable on ultrasound, radiography, CT or MRI.
• Chronic pathologic tissue changes such as the degree of osteophyte formation with osteoarthritis do not necessarily always correlate with the degree of pain and dysfunction experienced by the patient. Some patients can be painful without observable tissue or structural changes.

PAIN (ACUTE, CHRONIC, AND POSTOPERATIVE) (CONTINUED)

DIAGNOSTIC PROCEDURES

• Review patient signalment, obtain a thorough history, and include pain assessment as part of every physical examination. The pain score should be recorded in the patient's record along with temperature, pulse, and respiration.
• Thoroughly evaluate underlying conditions that may be contributing to pain and treat appropriately.
• Use a species-specific scoring tool for pain assessment to decrease subjectivity and observer bias. This will result in more effective pain management. Such tools are referred to as multifactorial clinical measurement instruments (CMIs) and are available for acute postoperative or chronic pain.
• CMIs for acute postoperative pain involve observing the patient without interaction; observing the patient while interacting with a caregiver; observing the patient's response to palpation of the surgical site; and assigning a numerical score using a dynamic interactive visual analogue scale. The reevaluation interval will depend on the procedure, duration of intervention chosen, and previous pain score.
• CMIs for chronic pain primarily involve owner observations of their pets regarding exercise tolerance and general activity; ability to stand, walk, do stairs, jump, or rise; grooming behavior; and urination or defecation habits.
• Complete abolishment of pain may not be possible or desirable if analgesic administration results in excessive adverse effects. Therapy should aim to make pain tolerable.

TREATMENT

APPROPRIATE HEALTH CARE

• Analgesic drug selection depends on species, pain intensity, and underlying cause.
• Treat the underlying cause at the same time if possible.
• Acupuncture, prescribed activity (e.g., physical therapy), mesenchymal stromal cell or platelet-rich plasma injection, and physical manipulation (massage, trigger point manipulation, chiropractic) may be useful adjunctive treatment modalities for certain types of painful musculoskeletal conditions.
• If the patient's quality of life is not acceptable after all reasonable therapeutic options have been explored, euthanasia may be the most humane option.

NURSING CARE

• General good nursing practices.
• Nonpharmacologic, including bandaging and hydrotherapy, may be appropriate.

ACTIVITY

• Rehabilitation medicine and weight loss is a useful adjunct for some musculoskeletal conditions.
• Cage rest or limited activity may be useful for certain types of pain.

DIET

• Dietary changes to help treat the underlying condition (e.g., weight reduction for hip dysplasia) may be beneficial.
• Many supplements have been marketed that may have beneficial effects on articular cartilage or modify inflammatory disease progression.
• Commercial veterinary diets are marketed specifically for animals with mobility issues.

CLIENT EDUCATION

• When pain medication is dispensed, educate clients on what to look for with effective treatment, as well as adverse effects. Use caution when dispensing opioids to clients for at-home administration and ensure they understand requirements for safe storage and disposal.
• Inform the client that analgesic effectiveness varies and several drugs may need to be tried before an effective treatment is found. Pain management must be individualized because of the neurobiologic complexity of pain perception.
• Clients should be asked to participate in evaluation of their pet's pain, especially chronic pain. Species-specific CMIs are available and can help document treatment effectiveness.

SURGICAL CONSIDERATIONS

• Surgical treatment of the underlying condition causing pain may be the best treatment in some circumstances.
• Ablative procedures (neurectomy) to halt pain transmission is not always associated with positive results and may result in worsening of the painful condition. These procedures are rarely performed in veterinary patients.

MEDICATIONS

DRUG(S) OF CHOICE (SEE ALSO APPENDIX VII)

• Opioids, alone or in combination with other classes of drugs, such as sedative/tranquilizers or nonsteroidal anti-inflammatory drugs (NSAIDs), are widely used for the management of acute postoperative pain.
• Full μ-opioid receptor agonists, such as morphine, hydromorphone, and fentanyl, are usually effective for moderate to severe pain. Partial agonist or agonist–antagonist drugs, such as buprenorphine and butorphanol, are usually reserved for mild to moderate pain.
• Opioids generally have poor oral bioavailability, and oral doses should be adjusted accordingly.
• Full μ-opioid receptor agonists can be used safely in cats; however, doses are usually reduced relative to dog doses.
• An SC injectable formulation of buprenorphine has been approved for 24-hour postoperative pain control in cats.
• Should dysphoria develop after opioid administration, tranquilization with an α_2-agonist or acepromazine may be beneficial.
• NSAIDs are used most commonly for the chronic treatment of painful conditions in dogs. They can be safe when administered chronically, but gastrointestinal (GI), hepatic, and renal adverse effects are possible. The best strategy appears to be reducing the dose to the lowest effective dose in an individual. If chronic administration is anticipated serum chemistries should be considered to monitor for hepatic and renal adverse effects.
• Veterinary-approved NSAIDs for dogs and cats have demonstrated acceptable safety profiles; however, there is no strong indication that any particular veterinary-approved NSAID is associated with a greater or lesser incidence or prevalence of adverse events.
• Long-term use of low-dose meloxicam is approved in cats in many countries other than the United States.
• Grapiprant is a non-cyclooxygenase (COX)-inhibiting NSAID that targets prostaglandin E2 (EP4 receptors) approved for osteoarthritic pain and inflammation in dogs.
• Liposome-encapsulated bupivacaine is approved for peri-incisional infiltration in dogs undergoing cranial cruciate ligament surgery and for peripheral nerve block in cats. Gradually released local anesthetic can provide analgesia for up to 72 hours. Extralabel use is also encountered frequently for other types of procedures.
• Additional information is available for many drugs and should be referred to when considering extralabel use. Owners should be informed of the risks of analgesic drug therapy in their pet before consenting to treatment.

Neuropathic Pain

Treatment of neuropathic pain is a subcategory of pathologic pain. It may originate from brain or spinal masses, injury (such as with intervertebral disc disease), inflammation, or the repetitive stimulation of the pain transmission system by a chronic injury outside the CNS. Classic signs that accompany neuropathic pain are allodynia and hyperalgesia. Neuropathic pain does not always respond well to traditional analgesics, such as NSAIDs and opioids, although these drugs are usually tried initially (except for NSAIDs when neurosurgery is imminent). Tricyclic antidepressants, antiepileptic drugs (e.g., gabapentin), *N*-methyl-D-aspartate (NMDA) receptor antagonists, and other alternative (complementary) therapies may be effective. Most of these treatments consist of extra- or off-label use of human medications and require careful client communication and approval.

(CONTINUED) # PAIN (ACUTE, CHRONIC, AND POSTOPERATIVE)

CONTRAINDICATIONS

• Opioids may be associated with severe respiratory depression in human patients, but in most dogs and cats cause only minimal respiratory depression. In patients with severe respiratory compromise or intracranial hypertension, opioids may be contraindicated. Most μ-opioid receptor agonists can also alter GI and urinary tract motility, resulting in constipation, urinary retention, and vomiting.
• NSAIDs can cause GI ulceration, hepatopathies, and impaired renal function. Preexisting GI, hepatic, or renal disease may be a contraindication to their use. Concomitant glucocorticoid therapy, severe stress, or anorexia may predispose many animals to adverse effects. NSAIDs that significantly inhibit COX-1 may also alter platelet function and may result in increased surgical blood loss. Acetaminophen or acetaminophen-containing analgesics should not be used in cats.

PRECAUTIONS

• Carefully monitor patients for adverse effects and clinical effectiveness following administration of analgesic drugs.
• Opioid-induced hyperthermia has been reported in feline patients, most commonly after fentanyl patch application or hydromorphone administration.
• Opioid administration may result in altered GI motility (constipation), inappetence, and urine retention. These signs usually appear soon after initiation of opioid therapy and should resolve within 12–36 hours of stopping opioid administration. In the interim supportive care such as passing a urinary catheter may be necessary.
• In consultation with the pet owner, the veterinarian may feel the need to prescribe NSAIDs to a particular patient even if the risk for adverse events is deemed increased due to disease or preexisting conditions. The veterinarian should strive to ethically balance the long-term therapeutic risk of drugs such as NSAIDs against the benefit of improved quality of life.
• Opioid abuse has affected all health professions including veterinary medicine and veterinarians must play active roles in combating abuse and misuse of opioids. With new opioid prescribing guidelines now published in many jurisdictions, veterinarians must remain up to date on all relevant regulations.

POSSIBLE INTERACTIONS

• Opioids can reduce the anesthetic requirements for most species, especially when combined with α_2-agonists or acepromazine as a premedication before anesthesia. In humans the combination of certain opioids such as meperidine with serotonin-altering drugs may result in toxicity (e.g., L-deprenyl, amitriptyline, tramadol, trazadone) and are occasionally prescribed to veterinary patients.
• Concurrent glucocorticoid therapy may enhance NSAID toxicity.
• Other drugs that predispose animals to GI or renal impairment, such as aminoglycoside antimicrobials, should be used with caution when NSAIDs are also being administered.

ALTERNATIVE DRUG(S)

• Adjunctive analgesic drugs (e.g., gabapentin, amantadine, amitriptyline, tramadol) may be beneficial for patients that have altered neuroprocessing associated with chronic disease changes or nervous system injury. To select and administer an adjuvant analgesic properly, the veterinarian should be aware of the drug's clinical pharmacology. The following information about the drug is necessary: (1) approved indication, (2) unapproved indication (e.g., as an analgesic) widely accepted in veterinary medical practice, (3) common side effects and potentially serious adverse effects, (4) pharmacokinetic features, and (5) specific dosing guidelines for pain (see Appendix VII).
• Nontraditional medical treatments are common, but should be evaluated for safety and effectiveness before recommendation.
• A number of alternative treatments for chronic pain in dogs and/or cats are in various stages of development and marketing including mesenchymal stem cell therapy and anti-nerve growth factor (anti-NGF) monoclonal drugs.
• Potential novel approaches to chronic pain currently being investigated include cannabidiol (CBD) which is available commercially and from marijuana dispensaries in jurisdictions where allowed. The FDA has decided to regulate CBD as a food additive and the legality of recommending and producing CBD for veterinary patients is unclear at this time. More research is needed before such therapies can be routinely recommended.
• Low-level laser therapy has gained popularity as an adjunctive technique to manage postoperative pain and facilitate earlier return to function following cruciate surgery in dogs. While this therapy may prove beneficial in individual cases, controlled studies using force plate analysis have not documented efficacy to date.

FOLLOW-UP

PATIENT MONITORING

• Frequent evaluation of analgesic drug effectiveness should be performed.
• Patients receiving chronic analgesic medication, especially NSAIDs, should be evaluated periodically to monitor GI, liver, and renal function.
• It is the responsibility of the veterinarian to ensure that information about the effects of prescribed drugs is disseminated to clients.

PREVENTION/AVOIDANCE

Although some degree of pain is usually an unavoidable consequence of surgery or trauma, when possible, the preemptive administration of analgesic drugs may provide better pain control and reduce the potential for CNS wind-up. Use of proper anesthetic techniques incorporating analgesic premedications and local and regional analgesic techniques where appropriate, are effective ways of practicing preemptive analgesia.

EXPECTED COURSE AND PROGNOSIS

Acute pain associated with surgery or trauma usually resolves with tissue healing. Opioids may be most effective for the 12–24 hours following surgery, whereas NSAIDs may be better after that period. Some NSAIDs are effective analgesics immediately after surgery. When pain signs persist beyond the normal course of a few days to weeks, suspect persistent disease, injury, or CNS changes and consult an anesthesiologist or a board-certified specialist trained in pain management for suggestions about appropriate therapy.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

• Opioids may cause fetal respiratory depression following delivery. NSAIDs may alter maternal or fetal prostaglandin production, resulting in pregnancy complications.
• The effects on the fetus of many of the analgesic drugs approved for use in dogs and cats are not widely reported.

ABBREVIATIONS

• CBD = cannabidiol.
• CMI = multifactorial clinical measurement instrument.
• COX = cyclooxygenase.
• GI = gastrointestinal.
• NGF = nerve growth factor.
• NMDA = *N*-methyl-D-aspartate.
• NSAID = nonsteroidal anti-inflammatory drug.

Client Education Handout available online

PALATAL DEFECTS

BASICS

DEFINITION
Communication between the nasal and oral cavities.

PATHOPHYSIOLOGY
- Secondary to congenital cleft of the secondary palate to include the hard and/or soft palate.
- Secondary to a traumatic injury causing disruption of the lateral maxilla and/or hard palate.
- Secondary to resective surgery for neoplasms of the lateral maxilla and/or hard palate.
- Secondary to extraction of maxillary canine and rostral premolar teeth (see Oronasal Fistula).

SYSTEMS AFFECTED
- Gastrointestinal (oral cavity).
- Respiratory.

GENETICS
May be inherited or secondary to intrauterine abnormality.

INCIDENCE/PREVALENCE
- Primary cleft palate is an abnormality of the lip and premaxilla and is rarely associated with a palatal defect communicating with the nasal cavity.
- Brachycephalic breeds are predisposed to primary cleft palate.
- Breed predilection for congenital cleft of the secondary palate.

SIGNALMENT

Species
Dogs more common than cats.

Breed Predilections
Brachycephalic breeds, miniature schnauzer, beagle, cocker spaniel, dachshund, and Siamese cats.

Mean Age and Range
At birth in dogs with primary or secondary cleft palate.

Predominant Sex
N/A

SIGNS
- Difficulty nursing.
- Regurgitation.
- Nasal discharge; often mucopurulent.
- Sneezing.
- Gagging when drinking water or eating.
- Poor growth.
- Lethargy and depression in chronic cases with severe secondary rhinitis.
- Cough in cases of secondary aspiration pneumonia.

General Comments
Dogs with primary or secondary cleft palate should be neutered since the condition is considered to be inherited.

Historical Findings
Signs reported by the owner as above; or following trauma or oncologic surgery.

Physical Examination Findings
- Hard and/or soft plate defect communicating with the nasal cavity.
- Nasal discharge.
- Thoracic auscultation for aspiration pneumonia.
- Patient is "poor doer."
- Check for other congenital abnormalities.

CAUSES
- Failure of the palatine shelves to fuse during development at 25–28 days of gestation.
- Foreign body, vehicular, or bite trauma.
- Oncologic surgery for neoplasms of the hard palate and/or lateral maxilla.
- Wound dehiscence following maxillofacial reconstructive surgery.

RISK FACTORS
- Inherited (recessive or irregular dominant, polygenic).
- Nutritional.
- Hormonal (steroids).
- *In utero* abnormality.
- Viral.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Fungal or bacterial rhinitis.

CBC/BIOCHEMISTRY/URINALYSIS
- Recommended as preoperative database.
- CBC may reflect secondary chronic rhinitis and/or secondary aspiration pneumonia.

OTHER LABORATORY TESTS
Consider aerobic bacterial culture and sensitivity of nasal tissue in cases of chronic rhinitis.

IMAGING
- Thoracic radiographs are recommended to rule out aspiration pneumonia.
- MRI or CT imaging is recommended prior to oncologic surgery for imaging of the maxillary/palatal lesion.
- Three-view thoracic radiographs are recommended to check for distant metastasis before operating patients with neoplasms.

DIAGNOSTIC PROCEDURES
Sedated oral examination.

PATHOLOGIC FINDINGS
- Secondary rhinitis is usually self-limiting and resolves following surgical repair.
- Long-term (4–6 weeks) antimicrobial therapy based on culture and sensitivity may be necessary to treat the chronic rhinitis.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient

NURSING CARE
Supportive preoperative care.

ACTIVITY
N/A

DIET
- Preoperative diet should be small-dog food "meatballs" fed by hand or a diet with a consistency that does not cause potential aspiration pneumonia.
- Postoperative diet should be a thick liquid consistency for the first 2 weeks.

CLIENT EDUCATION
- A palatal defect requires surgery for repair.
- Multiple surgeries may be required to repair the palatal defect.
- Medical management is ineffective and is only indicated when multiple surgical attempts to repair the palatal defect have failed.
- There is a higher surgical success rate in older puppies.
- Tube feeding may be required for the neonate patient until surgery, or until the patient can eat a diet of appropriate consistency.
- Secondary rhinitis is expected and self-limiting with clinical signs more of a nuisance than pathologic.

SURGICAL CONSIDERATIONS
- The surgical goal is to provide a soft tissue barrier or layer to reestablish and segregate the oral and nasal cavities.
- Congenital secondary cleft palate—recommend using a sliding bipedicle flap repair technique or an overlapping flap repair technique.
- Traumatic palatal defect—recommend either a buccal mucosal flap repair technique or hard palate mucoperiosteal flap repair technique.
- Palatal defect following oncologic surgery—recommend either a buccal mucosal flap repair technique and/or hard palate mucoperiosteal flap repair technique.
- Palatal defect following maxillofacial reconstruction dehiscence—recommend either a buccal mucosal flap repair technique and/or hard palate mucoperiosteal flap repair technique.
- Lavage the nasal cavity before surgery to remove any foreign material or debris that may have accumulated in the nose.
- A permanent silastic obturator may used to occlude small palatal defects in refractory cases where surgery has failed multiple times.

PALATAL DEFECTS (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE
N/A unless treating preoperative rhinitis.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUGS
N/A

FOLLOW-UP

PATIENT MONITORING
Recommend 2- and 4-week postoperative examinations to determine success of the surgical procedure.

PREVENTION/AVOIDANCE
- Diet should be a thick liquid consistency for 2 weeks postoperatively.
- Chew toys and other objects are prohibited for the first 8 weeks postoperatively.

POSSIBLE COMPLICATIONS
- Wound dehiscence and failure to repair the palatal defect.
- Chronic, preexisting rhinitis may require extended postoperative antimicrobial therapy.

EXPECTED COURSE AND PROGNOSIS
- Surgery is usually successful, however multiple surgical procedures may be required.
- The overall prognosis is "good."

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Rhinitis.
- Aspiration pneumonia.

AGE-RELATED FACTORS
- There is a higher surgical success rate in older puppies.
- Tube feeding may be required for the neonate patient until surgery, or until the patient can eat a diet of appropriate consistency.
- Initial dietary management and feeding by the owner is labor intensive.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Congenital cleft palate defects are considered inherited and affected dogs should be neutered.

SYNONYMS
N/A

PANCREATITIS—CATS

BASICS

DEFINITION
• Inflammation of the pancreas most often of unknown cause(s). • Acute pancreatitis—inflammation of the pancreas that occurs abruptly with little or no permanent pathologic change. • Chronic pancreatitis—continuing inflammatory disease that is accompanied by irreversible morphologic change such as fibrosis.

PATHOPHYSIOLOGY
• Host defense mechanisms normally prevent pancreatic autodigestion by pancreatic enzymes, but under select circumstances these natural defenses fail; autodigestion occurs when these digestive enzymes are activated within acinar cells. • Local and systemic tissue injury is due to the activity of released pancreatic enzymes and a variety of inflammatory mediators such as kinins, free radicals, and complement factors that are released by infiltrating neutrophils and macrophages. The most common pathologies involving the feline pancreas include acute necrotizing pancreatitis (ANP), acute suppurative pancreatitis, and chronic nonsuppurative pancreatitis.

SYSTEMS AFFECTED
• Gastrointestinal (GI)—altered GI motility (ileus) due to regional chemical peritonitis; local or generalized peritonitis due to enhanced vascular permeability; concurrent inflammatory bowel disease (IBD) may be seen in some cats. • Hepatobiliary—lesions due to shock, pancreatic enzyme injury, inflammatory cellular infiltrates, hepatic lipidosis, and intra/extrahepatic cholestasis. Feline GI inflammatory disease (concurrent cholangitis ± IBD) may be seen in some cats. • Respiratory—pulmonary edema or pleural effusion. • Cardiovascular—cardiac arrhythmias may result from release of myocardial depressant factor. • Hematologic—activation of the coagulation cascade and systemic consumptive coagulopathy (disseminated intravascular coagulation [DIC]) may occur.

GENETICS
No genetic basis for disease pathogenesis in cats has been identified.

INCIDENCE/PREVALENCE
• True prevalence is unknown but this is a relatively common clinical disorder in cats. • Necropsy surveys suggest an increased prevalence in cats with cholangitis, and IBD. The unique feline pancreaticobiliary anatomy and intestinal microbiota likely contribute to multiorgan inflammatory disease in this species.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Cat

Breed Predilections
Siamese cats.

Mean Age and Range
Mean age for acute pancreatitis is 7.3 years; any age may be affected.

Predominant Sex
None

SIGNS

Historical Findings
• Vague, nonspecific, and nonlocalizing signs. • Anorexia, lethargy, and vomiting are reported most frequently. • Weakness. • Abdominal pain. • Diarrhea—small bowel and large bowel diarrhea and fever are less common in cats than in dogs.

Physical Examination Findings
• Severe lethargy. • Inappetance. • Dehydration—common; due to GI losses. • Abdominal pain—recognized much less frequently in cats than dogs. • Mass lesions may be palpable. • Fever—observed in 25% of cats.

CAUSES
Etiology is most often unknown; possibilities include: • Hepatobiliary disease—both inflammatory and degenerative (hepatic lipidosis). • Pancreatic trauma/ischemia. • Duodenal reflux. • Drugs/toxins (organophosphates). • Pancreatic duct obstruction. • Hypercalcemia. • Inflammatory GI disease. • Nutrition—excessively lean body mass is associated with ANP.

RISK FACTORS
• Breed? • Obesity? • Organophosphate poisoning. • Concurrent hepatic/intestinal inflammatory disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• GI disease (obstruction, foreign body, perforation, infectious gastroenteritis, ulcer disease)—exclude with CBC/biochemistry/urinalysis, diagnostic imaging, and paracentesis. • GI or hepatic neoplasia—exclude with tissue biopsy. • Urogenital disease (pyelonephritis, prostatitis or abscessation, pyometra, urinary tract rupture or obstruction, acute renal failure)—exclude with CBC/biochemistry/urinalysis, urine culture/sensitivity, and imaging. • Hepatobiliary disease (cholangitis and extrahepatic biliary obstruction [EHBO])—exclude with CBC/biochemistry/urinalysis, bile acids, imaging, and liver biopsy. • Abdominal neoplasia—exclude with imaging and cytology or biopsy.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—often reveals nonregenerative anemia (40%), leukocytosis (38%), and/or leukopenia (15%). • Serum biochemistries—often show prerenal azotemia; liver enzyme activities (alanine aminotransferase, alkaline phosphatase) are often elevated because of hepatic ischemia or exposure to pancreatic enzymes; hyperbilirubinemia with intra/extrahepatic biliary obstruction; hyperglycemia with necrotizing pancreatitis due to hyperglucagonemia; hypoalbuminemia, hypercholesterolemia, and hypertriglyceridemia are common. Hypocalcemia is more common in cats than dogs, and a low ionized calcium concentration is a negative prognostic indicator in cats. • Urinalysis—increased urine specific gravity associated with dehydration or can be unremarkable.

OTHER LABORATORY TESTS
• Serum amylase and lipase activities are unreliable serologic markers—may be elevated, but are nonspecific; can also increase with hepatic, renal, or neoplastic disease in the absence of pancreatitis. • Serum pancreatic lipase immunoreactivity (fPL) is a highly sensitive and specific serologic marker of acute pancreatic inflammation. A cage-side fPL assay (SNAP fPL) has been developed as a useful screening tool. Elevation in SNAP fPL should be followed up by laboratory measurement of serum Spec fPL to quantitate the degree of elevation.

IMAGING
• Abdominal radiographs—may include increased soft tissue opacity in the right cranial abdominal compartment; loss of visceral detail ("ground glass appearance") due to abdominal effusion; static gas pattern in the proximal duodenum. • Abdominal ultrasound—nonhomogeneous solid or cystic mass lesions suggest pancreatic abscess; may be a pancreatic mass or altered echogenicity (hypoechoic) in the area of the pancreas; pancreas is usually enlarged with irregular borders, surrounding mesentery may be hyperechoic due to focal peritonitis, may see peritoneal effusion and extrahepatic biliary obstruction. • fPL assay and pancreatic ultrasound in combination have the highest specificity for an antemortem diagnosis of acute pancreatitis.

DIAGNOSTIC PROCEDURES
• Ultrasound-guided needle aspiration may confirm inflammation (cytology), abscess, or cyst. • Laparoscopy with pancreatic forceps biopsy for histologic diagnosis. • Histopathologic evaluation may miss focal or segmental pancreatic inflammation and results should be interpreted with caution.

PATHOLOGIC FINDINGS
• Gross findings (acute pancreatitis)—mild swelling with edematous pancreatitis. • Gross findings (chronic pancreatitis)—pancreas is reduced in size, firm, gray, and irregular; may contain extensive adhesions to surrounding

PANCREATITIS—CATS (CONTINUED)

viscera. • Microscopic changes (acute pancreatitis)—include edema, parenchymal necrosis, hemorrhage, and neutrophilic cellular infiltrate with acute lesions. • Microscopic changes (chronic pancreatitis)—pancreatic fibrosis around ducts, ductal epithelial hyperplasia, atrophy, and mononuclear cellular infiltrate.

TREATMENT

APPROPRIATE HEALTH CARE

• Eliminate the inciting cause (if possible). • Supportive care is most important.

NURSING CARE

• Aggressive IV fluid therapy. Fluid therapy goals—correct hypovolemia and maintain pancreatic microcirculation. • An isotonic crystalloid such as lactated Ringer's solution or Normosol-R® is the first-choice rehydration fluid. • Correct initial dehydration (mL = % dehydration × weight in kg × 1000) and give over 4–6 hours. • May need colloids to improve pancreatic circulatory needs and prevent ischemia. • Following replacement of deficits, give additional fluids to match maintenance requirements (2.5 × weight in kg = mL/kg/h) and ongoing losses (estimated). • Potassium chloride (KCl) supplementation usually needed because of potassium loss in the vomitus; base potassium supplementation on measured serum levels (use 20 mEq of KCl/L of IV fluid if serum potassium levels are not known; do not administer faster than 0.5 mEq/kg/h).

ACTIVITY

Restrict

DIET

• Continue to feed orally unless vomiting is intractable; feeding maintains intestinal epithelial integrity and minimizes bacterial translocation. • Initiate enteral feeding via esophagostomy, gastrostomy enteral feeding device, or nasoesophageal tube placement. • NPO in animals with persistent vomiting for the shortest time possible; when there has been no vomiting for 12 hours, offer small volumes of water; if tolerated, begin small, frequent feedings of a diet that does not contain excessive amounts of dietary fat. Most nutritionists agree that excessive dietary fat restriction is not necessary in cats with pancreatitis.

CLIENT EDUCATION

• Discuss the need for extended hospitalization. • Discuss the expense of diagnosis and treatment. • Discuss possible short-term and long-term complications (see Associated Conditions).

SURGICAL CONSIDERATIONS

• May need surgery to remove pseudocysts, abscesses, or devitalized tissue seen with necrotizing pancreatitis. • May need laparotomy and pancreatic biopsy to confirm pancreatitis and/or rule out other, nonpancreatic diseases such as cholangitis, lipidosis, and/or IBD. • EHBO from pancreatitis may require ductal decompression with surgical correction.

MEDICATIONS

DRUG(S) OF CHOICE

• Animals with intermittent vomiting should be treated with antiemetics. Maropitant 1 mg/kg SQ or PO q24h or ondansetron 0.1–0.5 mg/kg slow IV q8–12h are good first-choice options. • Analgesics to relieve abdominal pain, e.g., butorphanol 0.1–0.4 mg/kg SQ q6h, buprenorphine 0.005–0.015 mg/kg IM or IV q6–12h or fentanyl CRI 2–4 µg/kg/h as needed. • Antibiotics only if evidence of sepsis from bacterial translocation and to prevent pancreatic infection.

CONTRAINDICATIONS

Drugs reported to cause or exacerbate pancreatitis: • Anticholinergics (e.g., atropine). • Azathioprine. • Chlorothiazide. • Estrogens. • Furosemide. • Tetracycline. • L-Asparaginase.

PRECAUTIONS

Only use antibiotics if a clear clinical condition exists, such as infection.

FOLLOW-UP

PATIENT MONITORING

• Evaluate hydration status closely during first 24 hours of therapy; twice daily check physical examination, body weight, hematocrit, total plasma protein, BUN, and urine output. Evaluate the effectiveness of fluid therapy after 24 hours and adjust flow rates and fluid composition accordingly; repeat biochemistries to assess electrolyte/acid–base status. • Watch closely for systemic complications involving a variety of organ systems; perform appropriate diagnostic tests as needed (see Associated Conditions). • Gradually taper fluids down to maintenance requirements if possible. Maintain oral alimentation or enteral nutrition as described above, being careful to feed diets that do not contain excessive amounts of dietary fat. • Monitor for clinical evidence of IBD and treat accordingly. • Monitor for progression to diabetes mellitus, exocrine pancreatic insufficiency (EPI), and/or hepatic lipidosis in cats with ANP.

PREVENTION/AVOIDANCE

• Weight reduction if obese. • Avoid high-fat diets.

POSSIBLE COMPLICATIONS

• Failed response to supportive therapy. • Associated conditions such as EPI, diabetes mellitus, and hepatic lipidosis. • Progression of acute pancreatitis to chronic pancreatitis.

EXPECTED COURSE AND PROGNOSIS

• Guarded for most patients with ANP; cats with multiorgan inflammation may be less responsive to treatment. • More guarded to poor for patients with severe necrotizing pancreatitis, decreased ionized calcium fraction, hyperkalemia, fPL >20 µg/L, and systemic conditions.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Life-Threatening

• Pulmonary edema (e.g., adult respiratory distress syndrome). • Cardiac arrhythmias. • Peritonitis. • DIC.

Non-Life-Threatening

• Diabetes mellitus. • EPI. • Chronic pancreatitis. • Cholangitis and hepatic lipidosis. • IBD.

SEE ALSO

• Acute Abdomen. • Cholangitis/Cholangiohepatitis Syndrome. • Exocrine Pancreatic Insufficiency. • Inflammatory Bowel Disease.

ABBREVIATIONS

• ANP = acute necrotizing pancreatitis. • DIC = disseminated intravascular coagulation. • EHBO = extrahepatic biliary obstruction. • EPI = exocrine pancreatic insufficiency. • fPL = feline pancreatic lipase immunoreactivity. • GI = gastrointestinal. • IBD = inflammatory bowel disease.

PANCREATITIS—DOGS

BASICS

DEFINITION
Inflammation of the pancreas, which may occur abruptly with little or no permanent pathologic change (acute pancreatitis) or occur continuously or intermittently with irreversible morphologic change such as fibrosis and atrophy (chronic pancreatitis).

PATHOPHYSIOLOGY
• Premature intrapancreatic activation of zymogens results in local inflammation, edema, and necrosis of the pancreas and peripancreatic fat. • Pancreatic enzymes and inflammatory cytokines result in local (abdominal pain, vomiting) and possibly systemic effects (pyrexia, systemic inflammatory response syndrome [SIRS], multiple organ dysfunction syndrome [MODS], and acute kidney injury [AKI]). • An autoimmune mechanism is suspected in English cocker spaniels, but remains unproven.

SYSTEMS AFFECTED
• Gastrointestinal (GI)—altered GI motility (ileus) due to regional chemical peritonitis; local or generalized peritonitis due to enhanced vascular permeability.
• Cardiovascular—cardiac arrhythmias may result from release of myocardial depressant factor. • Hemic/lymphatic/immune—circulating proinflammatory cytokines and altered endothelial cell function can result in complications such as SIRS and/or disseminated intravascular coagulation (DIC).
• Hepatobiliary—hepatocellular damage can occur secondary to regional inflammation. Inflammation of the pancreas can also result in extrahepatic bile duct obstruction. • Renal/urologic—AKI can occur as a consequence of MODS. • Respiratory—regional vasculitis can cause pulmonary edema and/or pleural effusion. In severe cases, life-threatening acute respiratory distress syndrome can develop.

GENETICS
A possible genetic basis has been reported in miniature schnauzers where mutations in the *SPINK1* gene may confer increased susceptibility.

INCIDENCE/PREVALENCE
• Unknown, but it is a relatively common clinical disorder. • Up to 1% of normal dogs may have histologic evidence of pancreatitis.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Dog

Breed Predilections
• Acute—miniature schnauzer, Yorkshire terrier, other terriers. • Chronic—cocker spaniel and cavalier King Charles spaniel.

Mean Age and Range
Acute pancreatitis is most common in middle-aged and older (>7 years) dogs.

Predominant Sex
Females overrepresented in some reports.

SIGNS
Historical Findings
• Duration and severity of clinical signs can be variable, depending on the form of disease (acute vs. chronic). • Lethargy/anorexia.
• Vomiting. • Weakness. • Abdominal pain (may be absent in chronic disease).
• Diarrhea—small or large bowel type.

Physical Examination Findings
• Lethargy. • Dehydration—common; due to GI losses. • Abdominal pain—may adopt a "prayer position." • Mass lesions may be palpable. • Fever—common with more severe acute pancreatitis. • Less common—respiratory distress, bleeding, and cardiac arrhythmias.

CAUSES
Etiology is most often unknown; possibilities include: • Nutritional factors (e.g., dietary indiscretion, hyperlipoproteinemia).
• Pancreatic trauma/ischemia. • Duodenal reflux. • Drugs/toxins. • Pancreatic duct obstruction. • Hypercalcemia. • Infectious agents—babesiosis.

RISK FACTORS
• Breed—miniature schnauzers, terriers.
• Obesity. • Prior GI disease. • Endocrine disease. • Dietary indiscretion—access to garbage or fatty foods. • Hypertriglyceridemia—while an association exists between hypertriglyceridemia and pancreatitis, a causative link remains unclear. • Infectious—vector-borne diseases (babesiosis, ehrlichiosis, and leishmaniasis) have been identified in some cases of acute pancreatitis. • Drugs/toxins—idiosyncratic reactions to certain drugs (L-asparaginase, azathioprine, chlorpromazine, clomipramine, potassium bromide) have been described. Zinc toxicosis, mainly from ingestion of pennies minted after 1982, may cause pancreatitis.
• Hypercalcemia—not specifically documented in dogs, but shown in multiple species. • Surgery—possible; secondary to hypoperfusion or traumatic manipulation of the pancreas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• GI (obstruction, septic peritonitis, ulcer, neoplasia)—differentiate via abdominal imaging. • Hepatobiliary (cholangiohepatitis, copper hepatopathy, mucocele, neoplasia, toxicity)—abdominal imaging showing significant gallbladder pathology, liver histopathology, hepatic copper quantification.
• Genitourinary (AKI, pyelonephritis, leptospirosis, uroabdomen, pyometra, prostatitis)—azotemia, hyperphosphatemia, hyperkalemia, isosthenuric urine, active urinary sediment; positive urine culture; leptospiral microscopic agglutination titers. Abdominal imaging showing uterine, prostatic or urinary bladder pathology. • Other:
○ Hypoadrenocorticism—concurrent hyponatremia and hyperkalemia, lack of a stress leukogram, post adrenocorticotropic hormone stimulation cortisol of <1 µg/dL. ○ Splenic torsion—splenomegaly with abnormal splenic positioning on abdominal imaging.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—hemoconcentration; inflammatory leukogram; thrombocytopenia.
• Biochemistry—azotemia; increased liver enzyme activities; hyperbilirubinemia; electrolyte abnormalities associated with vomiting; hyperglycemia; hypoalbuminemia; hypercholesterolemia and hypertriglyceridemia.
• Urinalysis—may show evidence of proteinuria or may be unremarkable.

OTHER LABORATORY TESTS
• Serum amylase and lipase activities are unreliable serologic markers. • Serum pancreatic lipase immunoreactivity (cPL) is a sensitive and specific marker of acute pancreatic inflammation, although is less sensitive for detecting chronic pancreatic inflammation. A cage-side cPL assay (SNAP cPL) is a useful screening tool. Elevation in SNAP cPL should be followed up by measurement of serum Spec cPL to obtain a quantitative value.

IMAGING
• Abdominal radiographs—increased soft tissue opacity in the right cranial abdomen; loss of visceral detail ("ground glass appearance") due to abdominal effusion; static gas pattern in the proximal duodenum; widened pyloroduodenal angle. • Abdominal radiographs are insensitive for pancreatitis and are of greater value for ruling out other causes of vomiting such as gastric or intestinal foreign bodies. • Thoracic radiographs—may be normal, reveal pleural effusion or pulmonary edema. • Abdominal ultrasound—imaging modality of choice; nonhomogeneous mass lesions suggest pancreatic abscess; pancreas is usually enlarged and irregular; may be a pancreatic mass or hypoechogenicity in the area of the pancreas due to edema; surrounding mesentery is typically hyperechoic due to peritonitis; may see peritoneal effusion and extrahepatic biliary obstruction. • cPL assay and ultrasound in combination have the highest sensitivity for an antemortem diagnosis of acute pancreatitis.

DIAGNOSTIC PROCEDURES
• Ultrasound-guided needle-aspiration cytology may confirm inflammation, abscess, or cyst. • Laparoscopy with pancreatic biopsy for histologic diagnosis. • Histopathologic

PANCREATITIS—DOGS (CONTINUED)

evaluation may miss focal or segmental pancreatic inflammation and must be interpreted with caution.

PATHOLOGIC FINDINGS

• Gross findings (acute)—mild swelling with edema; gray-yellow areas of necrosis with varying amounts of hemorrhage with necrotizing pancreatitis. • Gross findings (chronic)—pancreas is reduced in size, firm, gray, and irregular; may contain extensive adhesions to surrounding viscera. • Microscopic changes (acute)—edema, parenchymal necrosis, hemorrhage, and neutrophilic cellular infiltrate. • Microscopic changes (chronic)— fibrosis around ducts, ductal epithelial hyperplasia, atrophy, and mononuclear cellular infiltrate.

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient management typically required. • Identify and remove any predisposing causes.

NURSING CARE

• Patients are at increased risk of aspiration pneumonia because of the concurrent presence of vomiting and lethargy. Therefore, aggressive nursing care (maintain in sternal recumbency with elevated head) and management of vomiting (antiemetics and promotility drugs, suction of gastric contents with nasogastric tube) should be instituted. • Aggressive IV fluid resuscitation with isotonic crystalloids should be administered to correct dehydration and encourage perfusion of the pancreas. • In cases where hypoalbuminemia is present, colloid support with synthetic colloids may be needed (10–20 mL/kg/day). • Hypokalemia is common, so IV potassium supplementation (not to exceed 0.5 mEq/kg/h) is often required.

ACTIVITY

Clinical status will determine.

DIET

• Food should be withheld if patient has uncontrolled vomiting. • Enteral feeding should be encouraged as it supports enterocyte health, decreases bacterial translocation, and decreases incidence of vomiting episodes. • Feeding cranial to the duodenum (prepyloric) is safe. Therefore, if the patient is not eating voluntarily, nasoesophageal, nasogastric, or esophageal feeding tubes should be used to deliver low-fat diets.

CLIENT EDUCATION

Discuss possible complications, variable clinical severity, and risk of recurrence associated with pancreatitis.

SURGICAL CONSIDERATIONS

• Surgery should be avoided if possible; minimally invasive techniques (laparoscopy) or alternatives to surgery (ultrasound-guided percutaneous drainage) should be used. • Surgical intervention may be indicated if there is suspicion of an infected necrotic area of the pancreas, pancreatic abscess, or pancreatic enlargement causing extrahepatic biliary obstruction.

MEDICATIONS

DRUG(S) OF CHOICE (EMPHASIS ON ACUTE PANCREATITIS)

• Analgesic—fentanyl 2–5 µg/kg/h IV CRI; buprenorphine 0.01–0.02 mg/kg q6–8h IV or IM. • Antiemetics—maropitant 1 mg/kg SQ q24h; ondansetron 0.5–1.0 mg/kg IV or SQ q8h; metoclopramide 2 mg/kg/day IV CRI. • Antibiotics—usually not indicated. If bacterial translocation from the GI tract is suspected, broad-spectrum antibiotic therapy is recommended (e.g., ampicillin/sulbactam 30 mg/kg IV q8h). • Fresh frozen plasma—no clinical benefit has been shown. • Glucocorticoids—limited evidence to support benefit. Dogs with chronic autoimmune pancreatitis (English cocker spaniels are predisposed) may be treated with prednisone 2 mg/kg PO as induction therapy and then tapered as based on cPL levels and clinical signs.

CONTRAINDICATIONS

• Anticholinergics. • Azathioprine. • Chlorothiazide. • L-Asparaginase. • Meglumine antimonite. • Potassium bromide.

PRECAUTIONS

Use antimicrobials only if indicated.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

• The patient's hydration status as well as electrolyte levels should be monitored frequently. Special attention should be paid to development of systemic signs suggestive of SIRS or MODS (increased respiratory rate, decreased urine production, bleeding). • The patient's need for more or less aggressive pain control should be frequently reassessed. • Since ultrasound findings can lag behind clinical improvement and circulating cPL levels can remain increased for extended periods, the decision of when a patient is ready to be discharged from veterinary care should be based on the overall clinical disease activity.

PREVENTION/AVOIDANCE

Patients with a history of pancreatitis should be fed a low-fat diet and medications known to be triggers for pancreatitis should be avoided.

POSSIBLE COMPLICATIONS

• Acute complications—extrahepatic biliary tract obstruction, aspiration pneumonia, SIRS, MODS. • Chronic complications—exocrine pancreatic insufficiency, diabetes mellitus.

EXPECTED COURSE AND PROGNOSIS

Prognosis is generally good for mild cases. Severe cases with development of SIRS/MODS have a more guarded prognosis. Negative prognostic factors—increases in blood urea/creatinine, thrombocytopenia, and marked increases in Spec cPL have been associated with increased mortality. Increased alanine aminotransferase has been associated with extended hospitalization in dogs with acute pancreatitis.

PANCYTOPENIA

BASICS

DEFINITION
Simultaneous leukopenia, nonregenerative anemia, and thrombocytopenia; not a disease itself—rather, a group of laboratory findings that can result from multiple causes.

PATHOPHYSIOLOGY
- Mechanisms may include decreased production of cells in the bone marrow or increased peripheral use, destruction, or sequestration; one or more of these mechanisms may occur together.
- Decreased production occurs when pluripotent, multipotent, or committed stem cells are destroyed, their proliferation or differentiation is suppressed, or the maturation of differentiated cells is delayed or arrested.
- If pluripotent stem cells are affected, pancytopenia develops; if committed stem cells are involved, cytopenia of the specific cell type develops.
- Increased use and destruction of cells typically results in increased production in the bone marrow. At least 2–3 days are required before increased production begins to have an effect on peripheral blood cell counts, and peak output usually takes about a week; thus, the rate of use or destruction necessary to cause cytopenia is not as great during the first few days of disease as it is later.
- Sequestration of cells in the microcirculation, especially that of the spleen, intestine, and lungs, can cause cytopenia of the cell type involved.

SYSTEMS AFFECTED
Hemic/lymphatic/immune—bone marrow, spleen, lymph nodes, and other lymphocytic tissues; depending on the cause, these organs can be affected by cellular depletion, degeneration, necrosis, hyperplasia, dysplasia, or dyscrasia; changes may occur alone or in combination.

INCIDENCE/PREVALENCE
Pancytopenia is an uncommon occurrence and does not always occur with the causes listed (see Causes). The incidence is reported as 2.4% in dogs and 2.8% in cats.

GEOGRAPHIC DISTRIBUTION
Unless the cause of pancytopenia is an infectious agent that is localized to a certain region (e.g., leishmaniasis, histoplasmosis), no specific geographic distribution exists.

SIGNALMENT
- Dogs and cats.
- No age, sex, or breed predilection.

SIGNS
Historical Findings
- History reflects the underlying cause.
- Lethargy, weakness, or pallor from anemia.
- Petechial hemorrhage or mucosal bleeding from thrombocytopenia.
- Repeated febrile episodes or frequent or persistent infections from leukopenia.

Physical Examination Findings
- Lethargy, weakness.
- Pale mucous membranes.
- Petechial hemorrhages.
- Mucosal hemorrhage (e.g., hematuria, epistaxis, hemoptysis, melena).
- Fever.

CAUSES
Infectious Diseases/Agents
- Feline leukemia virus (FeLV).
- Feline immunodeficiency virus (FIV).
- Feline infectious peritonitis (FIP).
- Infectious canine hepatitis (ICH).
- Canine and feline parvovirus.
- Anaplasmosis.
- Histoplasmosis.
- Ehrlichiosis.
- Cytauxzoonosis.
- Leishmaniasis.
- Endotoxemia or septicemia.

Drugs, Chemicals, and Toxins
- Chloramphenicol.
- Second-generation cephalosporins.
- Trimethoprim–sulfadiazine.
- Albendazole.
- Fenbendazole.
- Griseofulvin.
- Angiotensin-converting enzyme inhibitors (e.g., enalapril).
- Methimazole.
- Phenobarbital.
- Phenylbutazone.
- Estrogen (exogenous administration, Sertoli cell tumor, interstitial cell tumor).
- Chemotherapeutic drugs (azathioprine, carboplatin, cyclophosphamide, cytosine arabinoside, doxorubicin, hydroxyurea, vinblastine).
- *Fusarium* T-2 toxin.
- Thallium.
- Ionizing radiation.

Proliferative and Infiltrative Diseases
- Hematopoietic neoplasia (e.g., leukemias, lymphoma, histiocytic tumors, myelodysplastic syndrome).
- Myelofibrosis.
- Osteosclerosis.

Immune-Mediated Diseases
- Aplastic anemia (also known as aplastic pancytopenia).
- Immune-mediated hemolytic anemia and thrombocytopenia (when precursor cells are targeted by the immune system).

RISK FACTORS
Vary with individual cause.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Acute onset with severe clinical signs—more consistent with conditions that cause necrosis, destruction, or sequestration of cells.
- Slow, insidious onset—more consistent with conditions that cause bone marrow suppression.

LABORATORY FINDINGS
Drugs That May Alter Laboratory Results
Glucocorticoids often mildly to moderately increase the segmented neutrophil count, which may then obscure the presence of neutropenia.

Disorders That May Alter Laboratory Results
Phlebotomy technique may result in platelet clumping and hemolysis, leading to spuriously low platelet count and packed cell volume, respectively.

CBC/BIOCHEMISTRY/URINALYSIS
- Leukopenia—characterized by neutropenia with or without lymphopenia.
- Nonregenerative anemia—severity depends on duration and underlying cause.
- Thrombocytopenia.
- Blood smear evaluation—may reveal infectious agents (e.g., *Ehrlichia* spp., *Histoplasma capsulatum*); may reveal abnormal cells of any lineage, suggesting myeloproliferative or lymphoproliferative diseases.
- Toxic changes in leukocytes—may suggest bone marrow injury or early release.
- Biochemical alterations—depends on organ and degree of involvement (e.g., increased liver enzymes may be seen with certain infectious diseases, toxins, and infiltrative diseases).

OTHER LABORATORY TESTS
- Reticulocyte count—a regenerative response to anemia suggests destruction, use, or sequestration of red blood cells; a nonregenerative response suggests bone marrow suppression and merits bone marrow examination
- Immunologic tests for infectious diseases (e.g., FeLV, FIV, *Ehrlichia* spp.); FeLV may be detected on immunofluorescence assay of bone marrow aspirate, even with negative serology.
- PCR for infectious agents.

DIAGNOSTIC PROCEDURES
- Bone marrow examination (aspirate smear or biopsy)—indicated when cause of pancytopenia cannot be determined with other tests.
- Hypercellular bone marrow associated with myelodysplastic syndrome, leukemias, myelophthisis, or recovery from prior neutropenia.

PANCYTOPENIA (CONTINUED)

• Hypocellular bone marrow associated with necrosis, myelofibrosis, and suppression (e.g., drugs, estrogen).
• If a bone marrow aspirate cannot be obtained, myelofibrosis, necrosis, or marked hypocellularity should be suspected and a core biopsy should be evaluated.

PATHOLOGIC FINDINGS
Bone marrow core biopsy—may see replacement of normal hematopoietic tissue with necrotic, neoplastic, fibrous, or adipose tissue, depending on the specific underlying cause.

TREATMENT
• Supportive treatment depends on the clinical situation and includes aggressive antibiotic therapy and blood component transfusions.
• Treatment of the underlying condition is paramount.

MEDICATIONS
DRUG(S) OF CHOICE
Treatment should be appropriate for the clinical situation (i.e., the degree to which each cell population is decreased, presence of fever or infection, and established or suspected specific diagnoses); see specific causes.

CONTRAINDICATIONS
• Drugs that may suppress hematopoiesis or trigger immune-mediated destruction (see Causes).
• Nonsteroidal anti-inflammatory drugs, clopidogrel, or other drugs that may interfere with platelet function if thrombocytopenia present.

PRECAUTIONS
Because of the patient's potentially compromised immune status, glucocorticoids and other immunosuppressive drugs should be used only when necessary (e.g., when an immune component is suspected) and with extreme care and frequent monitoring.

ALTERNATIVE DRUG(S)
Recombinant Hematopoietic Growth Factors
• Recombinant human granulocyte colony-stimulating factor (rhG-CSF) 1–5 µg/kg/day SC; stimulates neutrophil production, may result in development of antibodies against endogenous G-CSF.
• Recombinant human erythropoietin (rhEPO)—initial dosage 100 U/kg SC, 3 times/week; stimulates erythropoiesis, may result in development of antibodies against endogenous EPO, darbepoetin may also be considered.

FOLLOW-UP
PATIENT MONITORING
• Daily physical examination, including frequent monitoring of body temperature.
• Periodic CBC—frequency depends on severity of cytopenia, age, general physical condition of the patient, and underlying cause.

PREVENTION/AVOIDANCE
• Castration of cryptorchid males (to prevent development of a Sertoli or interstitial cell tumor).
• Vaccination for infectious diseases.
• Frequent monitoring of CBC in cancer patients receiving chemotherapy or radiation therapy.

POSSIBLE COMPLICATIONS
• Hemorrhage.
• Sepsis.

EXPECTED COURSE AND PROGNOSIS
• Depends on the underlying cause.
• Often a guarded prognosis is warranted.

MISCELLANEOUS
ASSOCIATED CONDITIONS
Secondary infections—in patients with neutropenia.

ZOONOTIC POTENTIAL
• Tularemia, if this is the underlying cause.
• An owner can contract histoplasmosis from the same source as the patient.

PREGNANCY/FERTILITY/BREEDING
Stress of underlying disease may cause abortion; see respective topics for the effects of different causes on pregnancy.

SEE ALSO
• Anemia, Aplastic.
• Anemia, Immune-Mediated.
• Anemia, Nonregenerative.
• Anemia, Regenerative.
• Neutropenia.
• Thrombocytopenia.
• Thrombocytopenia, Primary Immune-Mediated.

ABBREVIATIONS
• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.
• ICH = infectious canine hepatitis.
• rhEPO = recombinant human erythropoietin.
• rhG-CSF = recombinant human granulocyte colony-stimulating factor.

PANNICULITIS/STEATITIS

BASICS

OVERVIEW
Inflammation of the subcutaneous fat tissue.

SYSTEMS AFFECTED
Skin/exocrine.

SIGNALMENT
Species
Steatitis—predominantly cats, but can occur in dogs with concurrent diseases.

Mean Age and Range
• Panniculitis—any age. • Steatitis—young to middle-aged cats; older dogs.

SIGNS
• Uncommon in dogs and cats. • Single or multiple subcutaneous nodules or draining tracts. • May be painful and fluctuant to firm. • Nodules—few millimeters to several centimeters in diameter. • Involved fat may necrose. • Exudate—usually a small amount of oily discharge; yellow-brown to bloody. • Multiple lesions (dogs and cats)—systemic signs common (e.g., anorexia, pyrexia, lethargy, and depression).

CAUSES & RISK FACTORS
• Infectious—bacterial, fungal (deep mycosis or dermatophyte), opportunistic mycobacteria, *Nocardia*, viral. • Immune-mediated—lupus panniculitis, erythema nodosum, vasculitis, or drug reaction. • Idiopathic—sterile nodular panniculitis, thromboembolism, sterile pyogranulomatous dermatitis and panniculitis. • Trauma. • Neoplastic—multicentric mast cell tumors, cutaneous lymphoma, pancreatic carcinoma. • Foreign bodies. • Post-injection—corticosteroids, vaccines, other subcutaneous injections. • Nutritional—vitamin E deficiency in cats, oily fish-based diet (steatitis).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Infectious
• More common than sterile/immune-mediated panniculitis. • Deep pyoderma. • Feline infectious peritonitis.

Cutaneous Cyst
• Usually nonpainful, noninflamed. • Well demarcated.

Lipoma
• Soft; usually well demarcated. • No inflammation or draining tracts. • Usually solitary.

Mast Cell Tumors/Epitheliotropic Lymphoma
• Multifocal. • Often erythematous. • Variable presentations.

Sterile Nodular Panniculitis
Diagnosis made by ruling out other causes of panniculitis.

CBC/BIOCHEMISTRY/URINALYSIS
• Panniculitis—no abnormalities. • Steatitis and panniculitis (occasional)—moderate to severe neutrophilia with mild eosinophilia; mild to moderate leukocytosis; mild nonregenerative anemia; hypoalbuminemia and proteinuria, possible hypocalcemia.

OTHER LABORATORY TESTS
• Antinuclear antibody—lupus panniculitis. • Serum protein electrophoresis. • Serum lipase/amylase levels. • Feline leukemia virus/feline immunodeficiency virus.

IMAGING
• Abdominal ultrasound: ◦ Panniculitis—pancreatitis may be a contributing factor. ◦ Steatitis—may see mottled subcutaneous, inguinal, or falciform fat; loss of contrast in abdominal cavity.

DIAGNOSTIC PROCEDURES
• Aspirates and impression smears: ◦ Pyoderma—numerous neutrophils and variable numbers of mononuclear cells and bacteria. ◦ Fungal infections—fungal organisms and variable numbers of mononuclear cells may be noted. • Blastomycosis—urine antigen testing. • Bacterial culture and susceptibility testing (tissue)—identify primary or secondary bacterial infection. • Fungal and opportunistic mycobacteria culture (tissue). • Biopsy with negative cultures for diagnosis of sterile nodular panniculitis. • Special stains of histopathologic samples—may help identify causative agent.

PATHOLOGIC FINDINGS
• Surgical excisional biopsies—more accurate than punch biopsy specimens in most cases. • Panniculitis—lobular or diffuse infiltrate (granulomatous, pyogranulomatous, suppurative, eosinophilic, necrotizing, or fibrosing) of panniculus; may identify if vasculitis present. • Steatitis—lumpy, granular fat, normal to yellowish-orange coloration of body fat.

TREATMENT
Diet
Steatitis—remove fish products from diet; feed nutritionally complete, balanced, commercially prepared food; may require parenteral feeding (e.g., PEG tube, esophagostomy feeding tube).

MEDICATIONS

DRUG(S) OF CHOICE
Positive culture results require appropriate antibacterial, antifungal, or antimycobacterial treatment.

Sterile Nodular Panniculitis
• Systemic treatment with corticosteroids; prednisolone 2.2 mg/kg daily in dogs or 4.4 mg/kg daily in cats: taper based on response: may require low dose to maintain remission. • Azathioprine (dogs: 1 mg/kg PO daily initially)—used with corticosteroids if insufficient response. • Oral vitamin E 200 IU q12h <10 kg, 400 IU q12h >10 kg. • Cyclosporine beneficial in some dogs (initially 5 mg/kg q24h for 4–8 weeks, then tapered).

Steatitis
Oral vitamin E 200 IU q12h <10 kg, 400 IU q12h >10 kg; corticosteroids at an anti-inflammatory dosage; *S*-adenosylmethionine PO on an empty stomach.

FOLLOW-UP
• Depends on underlying etiology type and duration of treatment. • Monitor CBC, platelet count, chemistry profile, and urinalysis/urine bacterial culture and sensitivity if immunosuppressive agents or long-term corticosteroids prescribed.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Pancreatic carcinoma. • Chylous ascites. • Peritonitis.

ABBREVIATIONS
• PEG tube = percutaneous endoscopically placed gastrostomy tube.

PANOSTEITIS

BASICS

DEFINITION
A self-limiting, painful condition of uncertain etiology that typically affects juvenile dogs of large to giant breeds. It is characterized clinically by lameness and pain on palpation of one or more long bones, and radiographically by increased density of the marrow cavity of affected long bones.

PATHOPHYSIOLOGY
- Cause unknown.
- Attempts to isolate microorganisms have failed.
- Suggested metabolic, allergic, or endocrine aberrations are without support.
- Pain may be associated with the disturbance of endosteal and periosteal elements, vascular congestion, or high intramedullary pressure.

SYSTEMS AFFECTED
Musculoskeletal—causes lameness of variable intensity; may affect a single limb or progress to a shifting leg lameness.

GENETICS
- No proven transmission.
- Predominance of German shepherd dogs in the affected population strongly suggests an inheritable basis.

INCIDENCE/PREVALENCE
Estimated at 2.6 per 1000 patients.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog

Breed Predilections
- Large- to giant-breed dogs are more commonly affected.
- German shepherd dogs and German shepherd dog mixes are more commonly affected.

Mean Age and Range
- Usually 5–12 months of age.
- As young as 2 months and as old as 5 years.

Predominant Sex
Males affected more than females by a ratio of 4:1.

SIGNS

General Comments
Lameness evaluation—if no distinct abnormalities noted on physical examination or radiographs, repeat examination and radiographs 4–6 weeks later.

Historical Findings
- No associated trauma.
- Lameness of varying intensity; often involves the forelimbs initially; may affect the hind limbs; may see shifting leg lameness; may be non-weight-bearing.
- Mild depression, inappetence, fever, and weight loss may be seen with severe disease.

Physical Examination Findings
- Pain on deep palpation of the long bones (diaphysis) in an affected limb; distinguishing characteristic; palpate firmly along the entire shaft of each bone while carefully avoiding any pinching of nearby muscle.
- Bones—ulna most commonly affected; may affect radius, humerus, femur, and tibia (in decreasing order of frequency) either concurrently or subsequently.
- May note low-grade fever or lethargy with severe disease.
- May see muscle atrophy.

CAUSES
Unknown

RISK FACTORS
Purebred German shepherd dog or German shepherd dog mix.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Always consider the diagnosis with lameness in a young large- and giant-breed dogs; especially in German shepherd dog or German shepherd dog mix.
- May occur alone or with other juvenile orthopedic diseases.
- Hypertrophic osteodystrophy.
- Osteochondritis dissecans.
- Fragmented medial coronoid process.
- Un-united anconeal process.
- Hip dysplasia.
- Fractures and ligamentous injuries from unobserved trauma.
- Shifting leg lameness—immune-mediated arthropathy; Lyme disease; bacterial endocarditis.
- Coccidioidomycosis.
- Bacterial osteomyelitis.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- May note eosinophilia early in disease.

OTHER LABORATORY TESTS
N/A

IMAGING
- Radiographic densities within the medulla of long bones are characteristic finding.
- Early, middle, and late radiographic lesions.
- Early—trabecular pattern of the ends of the diaphysis becomes more prominent; may appear blurred; may see granular opacities.
- Middle—patchy sclerotic opacities first around the nutrient foramen and later throughout the diaphysis; widened cortex; thickened periosteum with increased opacity.
- Late—during resolution, diminished overall opacity of the medullary canal (toward normal); a coarse trabecular pattern and some granular opacity may remain; may be a period in which the medullary canal becomes more lucent than normal.
- Bone scintigraphy may reveal subtle lesions that later become more apparent on follow-up radiographs.

DIAGNOSTIC PROCEDURES
Bone biopsy is occasionally indicated to rule out neoplasia and bacterial or fungal osteomyelitis that have similar radiographic appearances.

PATHOLOGIC FINDINGS
- Biopsy or necropsy are rarely performed because of excellent prognosis for recovery.
- No gross pathologic lesions.
- Degeneration of the marrow adipocytes surrounding the nutrient foramen followed by proliferation of vascular stromal cells within the marrow sinusoids.
- Osteoid formation and endosteal new bone formation—progress proximally and distally.
- Vascular congestion—may accompany the proliferation of new bone, secondarily stimulating endosteal and periosteal reaction.
- Remodeling of the endosteum—occurs during resolution; reestablishes normal endosteal and marrow architecture.

TREATMENT

APPROPRIATE HEALTH CARE
Typically treat as an outpatient.

NURSING CARE
Maintenance and replacement fluid therapy is occasionally needed if prolonged periods of inappetence and pyrexia.

ACTIVITY
- Limit activity to lessen pain; not shown to hasten recovery.
- Moderate to severe disease can cause pain that limits movement, leading to muscle atrophy.

CLIENT EDUCATION
- Warn client that patient may develop other juvenile orthopedic diseases.
- Inform client that signs of pain and lameness may last for several weeks.
- Warn client that recurrence of clinical signs is common up to 2 years of age.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
- Nonsteroidal anti-inflammatory drugs (NSAIDs):
  - Minimize pain; decrease inflammation.
  - Symptomatic therapy has no bearing on the duration of the disease.

- Carprofen 2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h.
- Deracoxib 1–2 mg/kg PO q24h, chewable.
- Etodolac 10–15 mg/kg PO q24h.
- Firocoxib 5 mg/kg PO q24h.
- Grapiprant 2 mg/kg PO q24h, to animals >3.6 kg.
- Meloxicam—load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid.
- Tepoxalin—load 20 mg/kg, then 10 mg/kg PO q24h.

• Glucocorticoids:
- May give anti-inflammatory dosage—prednisone 0.5–1 mg/kg PO.
- Potential side effects well documented.
- Goal for chronic use—low-dose and alternate-day therapy.

PRECAUTIONS
NSAIDs—can cause gastrointestinal tract ulceration, hepatotoxicity, or nephrotoxicity.

POSSIBLE INTERACTIONS
NSAIDs—do not use in conjunction with glucocorticoids; risk of gastrointestinal tract ulceration; consider appropriate washout times when switching from one NSAID to another.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Recheck lameness every 2–4 weeks to detect more serious concurrent orthopedic problems.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
• Self-limiting disease.
• Treatment is symptomatic and appears to have no influence on duration of clinical signs.
• Multiple limb involvement is common.
• Lameness typically lasts from a few days to several weeks; may persist for months; may recur.
• Occasional case has unrelenting pain and lameness that is unresponsive to therapy. Euthanasia has been recommended in these dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Typically affects immature and young dogs

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Females reported to be more susceptible to panosteitis during estrus; no proven relationship to reproductive hormones or pregnancy.

SYNONYMS
• Enostosis.
• Eosinophilic panosteitis.
• Fibrous osteodystrophy.
• Juvenile osteomyelitis.

ABBREVIATIONS
• NSAID = nonsteroidal anti-inflammatory drug.

PANTING AND TACHYPNEA

BASICS

DEFINITION
- Tachypnea—increased respiratory rate.
- Panting—rapid, shallow, open-mouth breathing that is usually not associated with gas exchange issues.

PATHOPHYSIOLOGY
- Respiratory rate, rhythm, and effort are controlled by the respiratory center in the brainstem in response to numerous afferent pathways, both central and peripheral in origin. These include the cerebral cortex, central chemoreceptors, peripheral chemoreceptors, stimulation of mechanoreceptors in the airways that sense lung inflation and deflation, stimulation of irritant receptors of the airways, stimulation of C-fibers in the alveoli and pulmonary blood vessels that sense interstitial congestion, and baroreceptors that sense changes in blood pressure.
- Tachypnea and panting can occur in response to stimulation of any of the above receptor pathways.

SYSTEMS AFFECTED
Respiratory

SIGNALMENT
- Dog and cat; no age, or sex predilection.
- Older, large-breed dogs predisposed to panting associated with laryngeal paralysis.
- Brachycephalic dogs prone to panting due to upper airway obstruction.

SIGNS

Historical Findings
- Patients with primary respiratory or cardiac disease usually have associated coughing or exercise intolerance.
- Nonrespiratory causes—clinical complaints associated with the primary disease, e.g., polyuria, polydipsia, polyphagia (PU/PD/PP) with hyperadrenocorticism, intermittent signs of systemic hypertension with pheochromocytoma.

Physical Examination Findings
- Brachycephalic syndrome (stenotic nares, stertorous respirations associated with soft palate elongation or saccular eversion) may be observed.
- Stridor can be evident with upper airway diseases.
- Lower airway disease—cough, expiratory wheezes on auscultation, abdominal effort.
- Pulmonary parenchymal disease—may have crackles on auscultation; harsh or moist lung sounds common, may be normal.
- Cardiogenic pulmonary edema—heart murmur or arrhythmia, tachycardia, gallop sound, hypothermia, pale mucous membranes, poor capillary refill time.
- Pleural space disease—diminished breath sounds: ventrally—fluid; dorsally—air; unilaterally—space-occupying lesions, pyothorax, chylothorax.
- Thoracic wall disease—can have paradoxical respiratory pattern, visible and/or palpable trauma.
- Nonrespiratory diseases—findings will depend on the other diseases, e.g., pale mucous membranes if anemic, hepatomegaly with hyperadrenocorticism.
- Other signs could indicate trauma.

CAUSES

Panting
- Pain, anxiety, hyperthermia, fever.
- Brachycephalic airway syndrome.
- Laryngeal disease.
- CNS disease causing abnormal ventilatory control.
- Cardiovascular compromise (shock), hypertension, arrhythmia.
- Drug therapy (opioids)
- Metabolic acidosis.
- Hyperadrenocorticism, corticosteroid therapy.
- Pheochromocytoma.
- Hyperthyroidism.
- Hypocalcemia.
- Can be a normal behavioral pattern in some dogs.

Tachypnea
- Hypoxemia, hypercapnia, hypotension, hyperthermia/fever, anemia, acidosis, systemic inflammatory response syndrome (SIRS)/sepsis, brainstem disease.
- Upper airway/larynx—elongated soft palate, laryngeal paralysis, edema, collapse, foreign body, neoplasia, granuloma, stenosis, inflammation, trauma, webbing.
- Trachea—collapse, stenosis, trauma, foreign body, neoplasia, parasites, extraluminal compression (lymphadenopathy, enlarged left atrium, heart-base tumors).
- Lower airway disease—allergic disease, inflammation, infection (*Mycoplasma*), parasites, neoplasia.
- Pulmonary parenchymal disease—edema (cardiogenic or noncardiogenic), pneumonia or pneumonitis, neoplasia (primary or metastatic), hemorrhage, fibrosis, lung lobe torsion, atelectasis.
- Pulmonary thromboembolism associated with—immune-mediated hemolytic anemia (IMHA), hyperadrenocorticism, pulmonary thromboembolism (PLE), protein-losing nephropathy (PLN), cardiac disease, neoplasia, heartworm disease.
- Pleural space disease—pleural effusion or pneumothorax, neoplasia, diaphragmatic hernia.
- Abdominal distention—organomegaly; neoplasia, pregnancy; obesity; ascites; gastric dilatation, torsion.
- CNS disease—compression or infarct near the respiratory center.
- Metabolic acidosis—diabetic ketoacidosis, lactic acidosis, uremia, renal tubular acidosis, diarrhea.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Tachypnea without respiratory distress—may be a nonrespiratory problem.
- Stertor and stridor are features of upper airway disease—auscultation over the trachea can help delineate upper airway noises from lower airway noises.
- Thoracic auscultation and percussion—most useful for distinguishing pleural disease (dampened lung sounds, dull percussion) from parenchymal disease (normal, harsh or moist lung sounds, crackles on auscultation).
- Wheezes on auscultation are suggestive of narrowed lower airway (bronchi, bronchioles).
- Crackles on auscultation are features of pulmonary parenchymal diseases.
- Congestive heart failure—murmur, tachycardia, poor pulse quality, jugular pulses, hypothermia.

CBC/BIOCHEMISTRY/URINALYSIS
- Anemia—can cause nonrespiratory tachypnea.
- Polycythemia—chronic hypoxia.
- Inflammatory leukogram—pneumonia, pneumonitis, pyothorax, or nonrespiratory causes (SIRS, sepsis).
- Eosinophilia—hypersensitivity or parasitic airway disease.
- Thrombocytosis—hyperadrenocorticism predisposes to pulmonary thromboembolism (PTE); alternatively, could indicate iron-deficiency anemia.
- Sodium:potassium ratio <27—can be seen with pleural or abdominal effusions.
- High alkaline phosphatase—hyperadrenocorticism predisposes to panting and PTE.
- Hypoproteinemia—may suggest protein-losing disease that can predispose to PTE.
- Proteinuria—can predispose to PTE.
- Azotemia—if severe can lead to uremic pneumonitis.
- Hyperglycemia, glucosuria, and ketonuria—could indicate ketoacidosis as cause of tachypnea.

OTHER LABORATORY TESTS
- Fecal examinations for parasites if indicated.
- Low-dose dexamethasone suppression test or adrenocorticotropic hormone stimulation test to assess adrenal cortical function, if indicated.
- Pleural fluid analysis.
- Serum antigen or antibody titers—heartworm, toxoplasmosis, distemper, feline leukemia virus, feline immunodeficiency virus.
- Pulse oximetry or arterial blood gas—can help differentiate pulmonary from nonrespiratory causes.

(CONTINUED) PANTING AND TACHYPNEA

- Hemoglobin saturation with oxygen <95% supportive of hypoxemia.
- Pao_2—partial pressure of oxygen dissolved in arterial blood; normoxemia: Pao_2 80–120 mmHg (room air, sea level), hypoxemia: Pao_2 <80 mmHg; F_1o_2—fraction of inspired oxygen ranges from 0.21 (room air) to 1.0; Pao_2/F_1o_2 ratio—measure of lung efficiency during oxygen therapy; Pao_2/F_1o_2 ≥400—normal lung efficiency; 300–400—mild insufficiency; 200–300—moderate insufficiency; <200—severe insufficiency. Reduction in lung efficiency can be due to venous admixture, hypoventilation, low inspired oxygen.
- $Paco_2$ or $Pvco_2$—partial pressure of CO_2 dissolved in arterial or venous blood; measure of ventilation; normal 30 mmHg <Pco_2 <40 mmHg. Hypercapnia = hypoventilation = decreased alveolar minute ventilation. Hypocapnia = hyperventilation = increased alveolar minute ventilation. Hypoventilation can be due to airway obstruction, pleural space disease, thoracic wall disease and abdominal distention; respiratory muscle fatigue from a prolonged period of tachypnea can lead to hypoventilation.
- Blood gas may reveal metabolic acidosis as a cause.
- Coagulation testing—if suspect hemothorax and/or pulmonary hemorrhage.

IMAGING

Cervical and Thoracic Radiography

- Increased density could suggest edema or soft tissue mass lesion. Also can see soft palate elongation, large airway narrowing, lymphadenopathy, intraluminal abnormalities.
- Lower airway disease—bronchial thickening, middle lung lobe consolidation (cats), atelectasis, hyperinflation and diaphragmatic flattening (primarily cats).
- Pneumonia—alveolar infiltrates; aspiration pneumonia usually cranioventral distribution or middle lobe affected.
- Cardiogenic pulmonary edema—enlarged cardiac silhouette, pulmonary venous distention, enlarged left atrium with perihilar pulmonary infiltrates in dogs; infiltrates can be of any distribution in cats.
- Noncardiogenic pulmonary edema—usually caudodorsal distribution. Acute respiratory distress syndrome (ARDS)—diffuse, symmetrical alveolar infiltrates.
- Pulmonary vascular abnormalities—PTE, heartworm disease.
- Pleural space disease—pneumothorax, pleural effusion, mass lesions, diaphragmatic hernias.
- Thoracic wall disease—rib fractures, neoplasia.

Thoracic Ultrasonography

- Evaluation of distribution of pleural effusion (excellent as guide for thoracocentesis), pneumothorax (absence of "glide sign"), and parenchymal disease (presence of "comet tail" artifact).
- Pulmonary mass identification—guide fine-needle aspiration; mediastinal evaluation.

Echocardiography

Evaluate cardiac function and chamber size if cardiogenic pulmonary edema or pleural effusion suspected; elevated pulmonary artery pressure and right ventricular overload with ventricular septal flattening can support diagnosis of PTE; visualize heart-based masses, rule out pericardial effusion.

Abdominal Ultrasound

Evaluation of abdominal distension; assess adrenal gland size.

Fluoroscopy

Evaluate tracheal and bronchial collapse; evaluate diaphragmatic function.

CT

Airway, pulmonary parenchymal, and pleural space disease can be evaluated; can detect lesions not clearly defined on radiographs.

Pulmonary Vascular Angiography

Gold standard for diagnosis of PTE.

Ventilation Perfusion Scintigraphy

Abnormal perfusion scan is considered supportive of PTE.

Other

May need CNS imaging.

DIAGNOSTIC PROCEDURES

- Pulse oximetry—Spo_2; peripheral capillary hemoglobin oxygen saturation. The relationship between Pao_2 and Spo_2 is defined by the oxygen hemoglobin dissociation curve; Pao_2 of 60 mmHg = Spo_2 of 90%; Pao_2 of 80 mmHg = Spo_2 of 95%; Pao_2 of >100 mmHg = Spo_2 of 100%. Below 95%, small changes in Spo_2 signify large changes in Pao_2. Spo_2 measurements in animals on high inspired oxygen lack sensitivity.
- Thoracentesis—fluid analysis and culture.
- Laryngoscopy/nasopharyngoscopy/tracheoscopy—to evaluate laryngeal function and visualize foreign bodies and masses; visualize caudal nasopharyngeal region with flexible endoscope or spay hook and dental mirror.
- Bronchoscopy—evaluate upper and lower airways; take biopsies; perform bronchoalveolar lavage for cytology and culture.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient care if life-threatening; therapy depends on underlying cause.
- Administer oxygen and see if tachypnea resolves—this would be supportive of a primary respiratory problem.
- Upper airway disease—use sedation to reduce respiratory effort. Check body temperature frequently and actively cool patients as needed. Severe upper airway disease requires intubation to stabilize; if the problem cannot be immediately cured, placement of a temporary tracheostomy tube is indicated. Remove foreign bodies; perform surgical excision/biopsy of masses, surgical correction for laryngeal paralysis and brachycephalic syndrome; give anti-inflammatory medications for laryngeal edema.
- Lower airway disease—bronchodilators; systemic corticosteroids may be required to stabilize cats with acute bronchoconstriction.
- Pulmonary parenchymal disease—antibiotics if pneumonia; treat coagulation disorders; cardiogenic edema requires furosemide ± vasodilators. Noncardiogenic edema requires oxygen therapy, may require positive-pressure ventilation if oxygen therapy alone is not adequate to stabilize the patient.
- Pleural space disease—thoracentesis for air and fluid. Place a chest tube if repeated chest taps are needed to keep patient stable.
- Abdominal distention—drain ascites only as needed to keep the patient comfortable; relieve gastric distention.
- Nonrespiratory diseases—treat primary problem.

NURSING CARE

- Oxygen therapy via cage, nasal cannula, E-collar covered in plastic wrap, mask, or flow-by. Humidify oxygen source if giving oxygen therapy for more than a few hours.
- Monitor temperature regularly, as hyperthermia will worsen respiratory difficulty.

DIET

Weight-reducing diet if obesity is a contributing cause.

SURGICAL CONSIDERATIONS

- Anesthesia must be carefully tailored to the patient. Securing an airway is essential and rapid IV induction is important. Have multiple sizes of endotracheal tubes available if upper airway obstruction is suspected.
- If laryngeal paralysis or brachycephalic syndrome is suspected, prepare for surgical correction at the time of diagnosis. Warn owners of increased likelihood of aspiration pneumonia in dogs with laryngeal disease.

MEDICATIONS

DRUG(S) OF CHOICE

Varies with underlying cause (see Appropriate Health Care).

PAPILLOMATOSIS

BASICS

OVERVIEW
Cutaneous mucous membrane lesions of dogs and cats caused by various papillomaviruses.

SIGNALMENT

Dogs
• Puppies and young adult dogs—oral papillomatosis, venereal papillomatosis, multiple papillomas of the footpad, cutaneous inverted papillomas, canine pigmented viral plaques (breed predisposition). • Older dogs—exophytic cutaneous papillomas, cutaneous inverted papillomas. • Miniature schnauzers and pugs—pigmented viral plaques; associated with immunosuppression in other breeds.

Cats
• More common in older cats; associated with immunocompromise (e.g., feline immunodeficiency virus [FIV]). • Feline sarcoids—younger cats, especially with outdoor exposure.

SIGNS

Dogs
• Cutaneous papillomas—pedunculated, fronds of epithelium, up to 1 cm in diameter. • Canine oral papillomatosis/papillomavirus (COPV)—oral mucosa, hard palate, epiglottis; may interfere with prehension, swallowing; trauma results in halitosis and ptyalism; may be confined to genital or eyelid regions. • Cutaneous inverted papillomas—less common, multiple lesions found with a central pore; on ventral abdomen; caused by distinctly different papillomavirus from COPV. • Multiple papillomas affecting footpads in younger dogs—firm, hyperkeratotic lesions causing discomfort, lameness. • Canine pigmented viral plaques—miniature schnauzers, pugs; Boston terriers, French bulldogs; rarely transform to squamous cell carcinoma (SCC); ventral abdomen, inner thigh region.

Cats
• Feline cutaneous papillomas—rare. • Feline viral plaques—more common; may progress to bowenoid *in situ* carcinoma (BISC) or invasive carcinoma. • Feline sarcoid lesions—uncommon. • Cats 10 years or older; other systemic disease causing immunosuppression (e.g., FIV).

CAUSES & RISK FACTORS
• Oral papillomas affecting naive dogs and recovered animals develop lifelong immunity. • Dogs—cutaneous papillomas may involve cell-mediated immunologic defects. • Older and/or immunosuppressed cats develop plaques and BISC. • Canine pigmented viral plaques—strong breed predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs
• Oral cavity, oropharynx—fibromatous epulis, transmissible venereal tumor, SCC. • Cutaneous—sebaceous hyperplasia, acrochordon. • Pigmented plaque—melanocytoma. • Inverted—infundibular keratinizing acanthoma.

Cats
• Eosinophilic granuloma. • Actinic keratoses • Cutaneous feline leukemia virus (FeLV) lesions. • Multicentric SCC *in situ*. • SCC.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
Cats—FeLV, FIV.

DIAGNOSTIC PROCEDURES
• Gross lesions have a typical appearance. • Biopsy for histopathology; immunohistochemistry demonstrates viral antigens within lesions; PCR not definitive.

PATHOLOGIC FINDINGS
• Dependent upon syndrome; all lesions share cytopathic effects of papillomavirus infection: hyperkeratosis, acanthosis, koilocytes in stratum spinosum, abnormal, large keratohyalin granules in stratum granulosum. • Viral pigmented plaques may lack koilocytes and viral inclusion bodies.

TREATMENT
• Usually regress spontaneously (especially oral forms). • Surgery if needed (excision, cryosurgery, or electrosurgery). • Persistent disease (dogs)—COPV vaccine reported to induce epithelial tumors and SCC at vaccination sites; latency period 11–34 months; autogenous vaccination: treatment controversial. • Cats—diagnosis for visceral diseases, causes of immunosuppression.

MEDICATIONS

DRUG(S) OF CHOICE
• α-Interferon—20,000iu PO q24h; various reports of efficacy for the treatment of persistent COPV but studies are lacking regarding dosage and protocol for administration. • Imiquimod—applied to lesions 3 times/week for 4 weeks. • Azithromycin 10 mg/kg PO q24h × 14 days.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Imiquimod—human exposure potential; causes severe localized reaction; use with caution at mucocutaneous junctions.

FOLLOW-UP

PATIENT MONITORING
Monitor for signs of malignant transformation to SCC.

PREVENTION/AVOIDANCE
• Separate dogs with oral papillomas from susceptible animals. • Commercial kennels—may consider autogenous vaccination.

EXPECTED COURSE AND PROGNOSIS
• Dogs—prognosis good; incubation period 1–8 weeks; regression usually 1–5 months; lesions persist 24 months or more. • Cats—long-term prognosis for plaques and BISC depends on concurrent diseases.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Viral strain dependent.

ZOONOTIC POTENTIAL
Papillomaviruses—species specific.

PREGNANCY/FERTILITY/BREEDING
• Venereal lesions may preclude breeding. • Transmission of viral infection likely; especially if active lesions present.

SYNONYMS
Bowen's disease = BISC.

SEE ALSO
Dermatoses, Viral (Nonpapillomatosis).

ABBREVIATIONS
• BISC = bowenoid *in situ* carcinoma. • COPV = canine oral papillomatosis/papillomavirus. • FeLV = feline leukemia virus. • FIV = feline immunodeficiency virus. • SCC = squamous cell carcinoma.

Suggested Reading

Consulting Editor Alexander H. Werner Resnick

PARALYSIS

BASICS

DEFINITION

• Paresis—weakness of voluntary movement. • Paralysis—lack of voluntary movement. • Quadriparesis (tetraparesis)—weakness of voluntary movements in all limbs. • Quadriplegia (tetraplegia)—absence of all voluntary limb movement. • Paraparesis—weakness of voluntary movements in pelvic limbs. • Paraplegia—absence of all voluntary pelvic limb movement. • Schiff–Sherrington syndrome—may occur with severe spinal cord trauma below T2. Patient presents paraplegic, in lateral recumbency with extension of front limbs and neck. However front limb function is normal on neurologic examination. Prognosis based on presence or absence of pain perception in pelvic limbs. • Spinal shock—may occur with severe spinal cord trauma, usually near the thoracolumbar spine. Initially the paralyzed pelvic limbs are areflexic but become hyperreflexic (and more indicative of a T3–L3 lesion localization) within minutes to a few hours after the trauma.

PATHOPHYSIOLOGY

• Weakness—caused by lesions in the upper motor neuron (UMN) or lower motor neuron (LMN) systems. • UMN system—cell bodies or nuclei located within the brain are responsible for initiating voluntary movement; axons from these cell bodies form tracts (rubrospinal, corticospinal, vestibulospinal, reticulospinal) that descend from the brain to synapse on the interneurons in the spinal cord. Interneuronal axons synapse on large alpha motor neurons in the ventral gray matter of the spinal cord; these are cell bodies of origin for the LMN system, which is responsible for spinal reflexes. • LMN system—collections of lower motor neurons in the cervical and lumbar intumescences give rise to axons that form the ventral nerve roots, spinal nerves, and (ultimately) the peripheral nerves that innervate limb muscles. • Evaluation of limb reflexes—determines which system (UMN or LMN) is involved. • UMN and their axons—have inhibitory influence on the large alpha motor neurons of the LMN system; maintain normal muscle tone and normal spinal reflexes. • If UMN is injured, spinal reflexes are no longer inhibited or controlled and spinal reflexes become exaggerated or hyperreflexic. • If LMN system is injured, spinal reflexes cannot be elicited (areflexic) or are reduced (hyporeflexic). Large alpha motor neurons or their processes (peripheral nerves) also maintain normal muscle tone. With LMN injury, muscle wasting is usually severe and within 5–7 days of injury.

SYSTEMS AFFECTED

Nervous

SIGNALMENT

Dog and cat.

SIGNS

General Comments

Limb weakness—acute or gradual onset.

Historical Findings

• Owner may describe the patient as being "down," unable to move, walk, or get up. • Many focal compressive spinal cord diseases begin with ataxia and progress to weakness, then to paralysis.

Physical Examination Findings

• Usually normal, unless the disease is systemic. • If in pain, patient may resent handling and manipulation. • Aortic emboli (ischemic neuromyopathy)—patient may be paraplegic and areflexic or hyporeflexic; femoral pulses absent; limbs often cold; nail beds often blue.

Neurologic Examination Findings

• Confirm that the problem is weakness or paralysis. • If limbs are paralyzed—likely bladder is also paralyzed, negating voluntary urination. • Localize problem to either LMN or UMN system. • Tetraparesis with exaggerated spinal reflexes in all limbs—lesion located at C1–C5 spinal segments or in the brain. • Tetraparesis with normal or depressed front limb spinal reflexes and exaggerated pelvic limb spinal reflexes—lesion located at C6–T2 spinal segments. • Tetraparesis with depressed spinal reflexes and decreased muscle tone in all limbs—lesion is diffuse involving muscles or peripheral nerves, or both intumescences (cervical C6–T2 spinal cord segments and lumbar L4–S2 spinal segments). • Normal front limbs but paraparesis/paraplegia with exaggerated pelvic limb spinal reflexes—lesion located at T3–L3 spinal segments. • Normal front limbs but paraparesis/paraplegia with depressed to absent pelvic limb spinal reflexes—lesion located at L4 spinal segment and caudally. • Normal front limb and pelvic limb motor activity but flaccid tail/anus and urinary and/or fecal incontinence—lesion located at S2 spinal segment and caudally. • Normal front limbs but paraparesis/paraplegia and depressed patellar reflexes—lesion involves spinal segments L4–6, located in vertebral bodies L3–4. • Normal front limbs but paraparesis/paraplegia, exaggerated patellar reflexes, and weak flexor and sciatic reflexes—if only the spinal cord is affected (no root involvement), lesion involves spinal segments L6–S2, located in vertebral bodies L4–L6.

CAUSES

Quadriplegia

• If LMN system—acute onset: acute idiopathic polyradiculoneuritis (coonhound paralysis), botulism, tick paralysis, fulminating form of myasthenia gravis, protozoal myoneuritis. • If LMN system—more gradual onset: polyneuropathies and polymyopathies from toxicity, infection, inflammation, endocrinopathy, metabolic disease, or congenital/inherited disease. • If UMN system—acute onset: disc herniation; fibrocartilaginous embolism; trauma; neoplasia; myelitis of many causes. • If UMN system—gradual onset: disc herniation; discospondylitis; neoplasia; myelitis of many causes; malformations of the spine or spinal cord.

Paraplegia

• If UMN or LMN system—acute onset: disc herniation; fibrocartilaginous embolism; neoplasia; trauma. • If UMN or LMN system—gradual onset: disc herniation; congenital malformations of spine or spinal cord; degenerative myelopathy; lumbosacral instability; discospondylitis; neoplasia.

Quadriplegia with Cranial Nerve Deficits, Seizures, or Stupor

• UMN system—diseases of the brainstem: encephalitis; neoplasia; trauma; vascular accidents; congenital or inherited disorders.

RISK FACTORS

• Degenerative disc disease—dachshunds, poodles, cocker spaniels, beagles, others. • Hunting dogs—acute idiopathic polyradiculoneuritis (coonhound paralysis). • Roaming animals—spinal cord and vertebral trauma, tick paralysis, botulism. • Atlantoaxial luxation—toy and small breeds. • Lumbosacral instability—large breeds, working breeds, German shepherd dogs. • Cervical spondylomyelopathy (wobbler syndrome)—large breeds, Doberman pinschers, Great Danes. • Syringomyelia—cavalier King Charles spaniels, brachycephalic toy breeds and others. • Spinal arachnoid diverticulum: Rottweilers, pugs, small breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Weak or paralyzed pelvic limbs—ensure femoral pulses are present and normal; aortic or femoral artery emboli may lead to LMN paraparesis or paraplegia. • Spinal reflexes—localize weakness to the cervical, thoracolumbar, or lower lumbar cord segments. • Acute onset—be careful when moving patient if possibility of trauma.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal, unless inflammatory diseases involved.

OTHER LABORATORY TESTS

• Urinary tract inflammation—urine culture may be positive in discospondylitis or in any dog that has had chronic bladder paralysis or repeated urinary catheterizations.

• Discospondylitis—diagnose by spinal radiography (intervertebral disc space lysis); perform *Brucella* titer; consider blood and urine bacterial cultures. • Exercise-induced weakness—determine acetylcholine receptor antibody titers (test for myasthenia gravis); check serum creatine kinase concentration (polymyositis or polymyopathy), red blood cell count (anemia or polycythemia), and blood glucose concentration (hypoglycemia); check for cardiac arrhythmia/hypoxia via electrocardiogram, thoracic radiography, Holter monitoring, echocardiography; muscle biopsy. • LMN weakness or muscle pain, muscle atrophy, or hypertrophy—determine creatine kinase concentration (polymyositis or polymyopathy); evaluate *Neospora caninum* and *Toxoplasma gondii* serum titers; perform electromyography, nerve conduction, muscle and nerve biopsies. • Myelitis or meningitis—Dog: perform titers for *N. caninum*, *T. gondii*, canine distemper virus and/or fungal diseases; perform PCR for Rocky Mountain spotted fever, *Ehrlichia* spp., and canine distemper virus; evaluate spinal fluid for infectious diseases. Cat: evaluate for feline leukemia virus and feline immunodeficiency virus; perform serum titers for *T. gondii* and *Cryptococcus* spp.; evaluate spinal fluid for signs of feline infectious peritonitis virus and *Cryptococcus* spp.

IMAGING

• Spinal radiography—may reveal disc herniation, discospondylitis, bony tumor, congenital vertebral malformation, and fracture or luxation. • Myelography—required if survey radiography not diagnostic and if CT or MRI unavailable. • CT or MRI—has replaced myelography where technology is available.

DIAGNOSTIC PROCEDURES

• CSF—before myelography to detect myelitis and meningitis; if high protein value or inflammatory cells, consider infectious disease diagnostics (titers, PCR). • Needle electromyography and motor nerve conduction velocity—may help with diagnosis and characterization of generalized LMN. • Muscle and nerve biopsy—generalized LMN weakness. • Aspiration of intervertebral disc space under fluoroscopy if discospondylitis observed on imaging studies—perform cytology and culture to isolate an infectious agent.

TREATMENT

• Inpatient—with severe weakness or paralysis until bladder function can be ascertained. • Hand feeding if necesssary—with diffuse LMN, swallowing can be affected. • Feeding from an elevated platform or installation of a feeding tube if necessary—recommended for animals with megaesophagus. • Activity—restrict until spinal trauma and disc herniation can be ruled out. • Physical therapy—important for paralyzed patients; tone muscles and keep joints flexible. • Bedding—check and clean frequently to prevent urine scalding and superficial pyoderma; use padded bedding or waterbed to help prevent decubital ulcer formation. • Turn quadriplegic patients from side to side 4–8 times daily to prevent hypostatic lung congestion and decubital ulcer formation. • Surgery—for disc herniation, fracture, and some neoplasias and congenital conditions; often the quickest and most effective method to improve neurologic status.

MEDICATIONS

DRUG(S) OF CHOICE

• Medications depend on underlying cause of weakness. • NSAIDs for spinal diseases associated with bone discomfort or pain. • Corticosteroid use, even in known diseases like spinal trauma or disc herniation, is controversial. May help to allay pain associated with some causes of paralysis, but does not expedite spinal cord recovery. • Dexamethasone 0.1–0.2 mg/kg q48h for pain relief for 2–3 doses. Prednisolone 0.5–1 mg/kg q12–24h for pain relief for 3–5 days. • Antibiotics or antifungals—used for discospondylitis, protozoal myelitis/meningitis. • Pyridostigmine bromide 0.5–3 mg/kg PO q8–12h for suspected myasthenia gravis; administer cautiously at low dose while waiting for titer results. • If acute generalized LMN signs—check for ticks; use appropriate insecticides.

CONTRAINDICATIONS

Corticosteroids—do not use with discospondylitis or fungal or protozoal myelitis/meningitis; do not use with myasthenia gravis if aspiration pneumonia is present.

PRECAUTIONS

Corticosteroids—associated with GI ulceration and hemorrhage, delayed wound healing, and heightened susceptibility to infection.

ALTERNATIVE DRUG(S)

• Tramadol 2 mg/kg q12h PO (dogs or cats), up to 4–5 mg/kg q12h (dogs only) for pain relief. Avoid using with antidepressants. • Gabapentin 3–10 mg/kg q12h PO for neuropathic pain. • Butorphanol 0.2–0.6 mg/kg q2–4h for pain control.

FOLLOW-UP

PATIENT MONITORING

• Neurologic examinations—daily to monitor status. • Bladder—evacuate (via manual expression or catheterization) 3–4 times a day to prevent overdistension and subsequent bladder atony; once bladder function has returned, patient can be managed at home.

POSSIBLE COMPLICATIONS

• Urinary tract infection, bladder atony, urine scalding and pyoderma, constipation, decubital ulcer formation. • Aspiration pneumonia—with generalized LMN disease or in any quadriplegic patient. • Myelomalacia—with severe spinal cord trauma or disc herniations. • Respiratory compromise or paralysis—with myelomalacia or generalized LMN disease.

PARANEOPLASTIC SYNDROMES

BASICS

DEFINITION
Paraneoplastic syndromes (PNS) are a diverse group of systemic disorders resulting from the metabolic or physiologic effects of cancer on tissues remote from the tumor. These disorders are usually caused by production and release of substances not normally released by the cancerous cell of origin or in amounts not normally produced by those cells. Other etiologies of PNS aside from production of metabolically active substances include autoimmune disease stimulation, immune complex formation, immunosuppression, and ectopic receptor production/competitive blockade of normal signaling molecules.

PATHOPHYSIOLOGY
The pathophysiology depends on the specific PNS (see Table 1). Many PNS in veterinary medicine have an unknown pathophysiologic etiology.

SYSTEMS AFFECTED
Any body system can be affected by a PNS. Some of the more common systems include:
- Endocrine/metabolic—hypercalcemia.
- Hemic/lymphatic/immune—anemia, thrombocytopenia.

GENETICS
One known genetic cause of a PNS is the mutation H255R of the encoding folliculin gene (*FLCN*) leading to renal cystadenocarcinoma and nodular dermatofibrosis, predominantly seen in German shepherd dogs but rarely noted in non-shepherds.

SIGNALMENT
Any dog or cat with a histologically malignant (most common) or benign cancer (rare).

SIGNS
Vary with tumor type and organ systems affected but include:
- Alopecia (feline paraneoplastic syndrome).
- Anemia.
- Cutaneous flushing.
- Diencephalic syndrome.
- Disseminated intravascular coagulation.
- Eosinophilia.
- Gastroduodenal ulceration.
- Hypercalcemia.
- Hypertrophic osteopathy.
- Hypoglycemia.
- Myelofibrosis.
- Neutrophilic leukocytosis.
- Nodular dermatofibrosis.
- Polycythemia.
- Superficial necrolytic dermatitis.
- Thrombocytopathy.
- Thrombocytopenia.
- Thrombocytosis.

CAUSES
By definition, PNS are caused by an underlying neoplasia, and occur due to a wide range of tumor-related factors including substances secreted from the tumor or cells within the local microenvironment. Many PNS do not have a recognized etiology.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Varies with syndrome.

CBC/BIOCHEMISTRY/URINALYSIS
Helpful in identifying and monitoring several of the reported syndromes.

OTHER LABORATORY TESTS
Ionized calcium and parathormone levels—assess patients with hypercalcemia; hypercalcemia of malignancy usually characterized by high ionized calcium and inappropriate parathormone (PTH) levels; may have elevated parathyroid hormone-related protein (PTH-rP).

IMAGING
Imaging is crucial for the detection of many of the tumors that underlie the PNS:
- Radiography—assess thorax for masses, assess bones for lytic lesions, and detect hypertrophic osteopathy.
- Abdominal ultrasound—assess liver/spleen/kidneys/pancreas/GI tract for masses
- Ventral neck ultrasound—assess for parathyroid or thyroid masses.
- Advanced imaging (CT or MRI)—more sensitive detection of occult tumors within body cavities.

DIAGNOSTIC PROCEDURES
- Fine-needle aspirate and cytology—can provide diagnosis for several tumor types commonly associated with PNS, including lymphoma, multiple myeloma, and apocrine gland adenocarcinoma of the anal sac.
- Biopsy—may be needed for some tumor types; also use to diagnose paraneoplastic skin lesions.

TREATMENT
- Varies based on the underlying tumor and the clinical manifestations of the paraneoplastic syndrome.
- The only definitive treatment is to address the underlying neoplasia rather than to try to control the clinical signs of the paraneoplastic syndrome. If the primary tumor cannot be treated, then management of clinical signs is indicated for palliation.

MEDICATIONS

DRUG(S) OF CHOICE
Depends on underlying tumor type.

FOLLOW-UP

PATIENT MONITORING
As for underlying tumor type.

MISCELLANEOUS

ABBREVIATIONS
- AGASACA = apocrine gland adenocarcinoma of the anal sac.
- PNS = paraneoplastic syndromes.
- PTH = parathormone.
- PTH-rP = parathyroid hormone-related protein.

(CONTINUED) PARANEOPLASTIC SYNDROMES

Table 1

Syndrome	*Primary Tumor Association (Dog)*	*Primary Tumor Association (Cat)*	*Primary Mechanism*
Alopecia	Adrenal carcinoma		Dogs: due to an excess of cortisol production; most often associated with hyperadrenocorticism
Alopecia (feline paraneoplastic alopecia)		Pancreatic carcinoma and carcinoma of the biliary tree	Cats: mechanism unknown. See Adenocarcinoma, Pancreas; Feline Paraneoplastic Alopecia; Hyperadrenocorticism (Cushing's Syndrome—Cats)
Cutaneous flushing syndrome	Pheochromocytoma; mast cell tumor	Not reported	Inappropriate release of vasoactive substances, such as histamine, causes paroxysmal flushing of the skin
Diencephalic syndrome	Astrocytoma, anaplastic ependymoma	Not reported	Tumor is present in the diencephalon region of the brain; excess of growth hormone results in dramatic weight loss (without acromegaly) despite adequate caloric intake
Disseminated intravascular coagulation	Hemangiosarcoma; many others	Myeloproliferative disease	See Disseminated Intravascular Coagulation
Eosinophilia	Assorted, including lymphoma and mast cell tumors	Assorted, including lymphoma and mast cell tumors	May be due to stimulation of eosinophil precursors by products such as interleukin-2, -3, and -5 and granulocyte–macrophage colony-stimulating factor
Exfoliative dermatitis (feline thymoma-associated exfoliative dermatitis)	Not reported	Thymoma	Not completely elucidated, likely due to the induction of autoreacting T-lymphocytes
Feminization syndrome	Testicular tumors—especially functional Sertoli cell and seminoma tumors	Not reported	Due to hyperestrogenism or a relative testosterone:estrotgen imbalance that is uncomplicated by myelosuppression
Gastroduodenal ulceration	Non-islet cell pancreatic neoplasia; mast cell tumor	Rare	Inappropriate gastrin secretion (non-islet cell tumor) or excess histamine secretion (mast cell tumor)
Hypercalcemia	Lymphoma; apocrine gland adenocarcinoma of the anal sac (AGASACA); multiple myeloma; others	Relatively rare; lymphoma; squamous cell carcinoma; others	Dogs: multiple secreted factors involved; AGASACA is the most likely tumor to lead to parathyroid hormone-related protein (PTHrP) production Cats: mechanisms unexplored. See Hypercalcemia
Hypertrophic osteopathy	Metastatic and primary tumors of the lung, also seen with intra-abdominal tumors	Metastatic and primary tumors of the lung, also seen with intra-abdominal tumors	Characterized by severe lameness and distal limb soft tissue swelling followed by periosteal new bone growth. The etiology is unknown. Several mechanisms likely play a role, including vagally mediated changes in limb perfusion, cytokine and growth factor secretion, immune mechanisms, vascular thrombi caused by platelets and antiphospholipid antibodies, and interaction between activated platelets and the endothelium
Hyperviscosity syndrome	Immunoglobulin-secreting tumor (e.g., multiple myeloma, lymphoma, and rarely plasma cell tumor)	Immunoglobulin-secreting tumor	Accumulation of large immunoglobulin proteins or polymerized small immunoglobulin proteins in the blood that result in decreased blood flow from increased viscosity. See Multiple Myeloma and Paraproteinemia

P

PARANEOPLASTIC SYNDROMES (CONTINUED)

Table 1

(*Continued*)

Syndrome	*Primary Tumor Association (Dog)*	*Primary Tumor Association (Cat)*	*Primary Mechanism*
Hypoglycemia	Insulinoma; benign and malignant smooth muscle tumors; large mesenchymal tumors; others	Rare; insulinoma	Involves the excess production of insulin or insulin-like factors or excessive glucose utilization. See Insulinoma
Immune complex disorders	Lymphocytic leukemia; primary erythrocytosis	Lymphoma	Secondary to antigen-antibody–immune complex activation; glomerulonephritis is most recognized problem
Myasthenia gravis	Thymoma; others	Very rare; thymoma	Exact mechanism is unknown, likely immune-mediated, may be due to effects of follicular helper T-cells. See Myasthenia Gravis
Myelofibrosis	Assorted	Assorted	See Myelodysplastic Syndromes
Neutrophilic leukocytosis	Hemangiosarcoma; lymphoma; others	Assorted; lymphoma, carcinomas and sarcomas	Production of a granulocyte–monocyte-stimulating cytokine is likely cause
Nodular dermatofibrosis	Renal cystadenoma or cystadenocarcinoma primarily in German shepherd dogs and shepherd crosses	Not reported	Mechanism is unknown but involves proliferation of fibroblasts. Propensity to develop is inherited in an autosomal dominant pattern. May be linked to chromosome 5. Loss of heterozygosity/function of the *FLCN* gene may contribute to neoplastic transformation of renal epithelial cells. Renal tumors are usually slowly progressive and almost always bilateral
Pemphigus	Rare; reported in one case of mediastinal lymphoma and one splenic sarcoma	Not reported	Autoimmunity to target antigens (periplakin and envoplakin) in the skin
Peripheral nerve syndromes	Various	Not reported	Unknown, but usually subclinical and secondary to changes in myelination
Polycythemia	Renal sarcoma and carcinoma; others	Renal carcinoma	Inappropriate secretion of erythropoietin or erythropoietin-like peptides. See Polycythemia Vera
Superficial necrolytic dermatitis (metabolic epidermal necrosis, hepatocutaneous syndrome, necrolytic migratory erythema)	Hepatic neoplasia; pancreatic neoplasia (glucagonoma)	Pancreatic neoplasia (glucagonoma)	Many names used to describe similar clinical entities; usually observed in patients with hepatic disease and less commonly with glucagon-secreting pancreatic tumors; sometimes referred to as glucagonoma syndrome; exact mechanism is unclear; may see associated glucose intolerance or diabetes mellitus
Thrombocytopathy	Immunoglobulin-secreting tumors	Immunoglobulin-secreting tumors	Immunoglobulin molecules inhibit normal platelet aggregation. See Thrombocytopathies
Thrombocytopenia	Lymphoma, multiple myeloma, hemangiosarcoma, others	Lymphoma, others	Thrombocytopenia, primary immune-mediated or secondary to myelophthisis. See Thrombocytopenia and Thrombocytopenia, Primary Immune-Mediated
Thrombocytosis	Myeloproliferative disorders	Myeloproliferative disorders	Overproduction of cytokines that stimulate thrombopoietin production (e.g., interleukin-1, -3, -6, -11)

P

PARAPHIMOSIS, PHIMOSIS, AND PRIAPISM

BASICS

OVERVIEW

- Phimosis—inability to protrude the penis beyond the preputial orifice.
- Paraphimosis—inability for exteriorized penis to retract into the sheath.
- Priapism—prolonged extrusion of an erect penis not associated with sexual arousal.

SIGNALMENT

- Dog and cat.
- German shepherd dog, Golden retriever (phimosis)—observed congenital preputial stenosis; possibly hereditary.
- Siamese cat—overrepresented.

SIGNS

- Phimosis—can go undetected until unsuccessful copulation attempts as an adult; severe cases in the neonate resulting in preputial urine pooling may lead to balanoposthitis and septicemia.
- Paraphimosis—initially: licking of an exteriorized penis; after hours of exposure: ischemic necrosis and urethral obstruction; edema and swelling may make differentiation from priapism difficult.
- Priapism—persistent penile erection lasting >4 hours; bulbus glandis firm and swollen.

CAUSES & RISK FACTORS

- Phimosis—abnormally small preputial orifice; congenital or acquired (e.g., caused by injury or disease); may be associated with persistent penile or preputial frenulum (thin band of connective tissue joining the penis and prepuce along the ventral glans).
- Paraphimosis—preputial hair rings; stenotic preputial orifice; injury; os penis fractures; neurologic disease (encephalomyelitis, intervertebral disc disease); penile swelling (neoplasia, balanoposthitis, strangulation with foreign body); incompetent preputial muscles.
- Priapism—ischemic (most common and serious in nature, veno-occlusive/low flow): cause often unknown, trauma during mating, chronic distemper encephalomyelitis, penile thromboembolism, amphetamine use, penile neoplasia, perineal abscess; nonischemic (arterial/high flow): trauma, vasoactive drugs, neurologic conditions, canine distemper; less likely to cause necrosis due to lack of venous obstruction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Phimosis (cats)—inability for penis to exteriorize in prepubertal tom cats is normal as penile adhesion breakdown is androgen-dependent and occurs about 7–12 months of age; early neutered cats may continue to maintain penile adhesion.
- Paraphimosis—abnormality of the retractor penis muscles or prepuce muscles, large preputial opening, short prepuce, or priapism.
- Priapism—urethral obstruction.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Phimosis in neonates—septicemia may result from preputial urine pooling.

OTHER LABORATORY TESTS

Penile blood-gas analysis differentiates forms of priapism:

- Ischemic (i.e., veno-occlusive)—pH <7.25, Po_2 <30 mmHg, Pco_2 >60 mmHg; may respond to phenylephrine therapy (see Medications).
- Nonischemic (i.e., arterial)—pH of 7.4, Po_2 >90 mmHg, Pco_2 <40 mmHg.

DIAGNOSTIC PROCEDURES

- Ultrasonography—visualization of engorged penile vessels.
- Neurologic exam, radiographs, magnetic resonance imaging—to evaluate spinal cord.

TREATMENT

Phimosis

- Surgical enlargement of the preputial orifice, if required, due to presenting clinical signs.
- Persistent penile frenulum (dogs)—remove band of tissue holding the glans penis to the parietal lamina of prepuce.

Paraphimosis and Priapism

- Main goal—detumesce (priapism) and replace the penis within the prepuce.
- Castration not effective; not testosterone-dependent.
- At times only lubrication required (paraphimosis).
- Penile amputation and urethrostomy required if excessive damage present.
- If urethral patency is in question place an indwelling urinary catheter.
- Under sedation, apply firm pressure wrap soaked with hypertonic glucose solution (decrease edema), firmly replace within prepuce once able; temporary preputial stay sutures may be required for continued reduction (preputial orifice patency for urine flow required if urinary catheter not maintained); surgically enlarge preputial orifice, if necessary.
- Recurrent paraphimosis may require phallopexy.
- Aspiration of penile blood may provide analgesia and prove diagnostic (blood gas analysis).
- Intrapenile phenylephrine may enhance venous outflow if veno-occlusive priapism.
- Penile amputation and perineal urethrostomy—indicated for cats with difficulty urinating.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotic ointments—prevent penile adhesions with prepuce.
- Phenylephrine (priapism)—intracavernosal infusion of 100–500 µg diluted in 1 mL of 0.9% saline.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Phimosis—fair to good if identified prior to development of septicemia.
- Paraphimosis and priapism—depending on cause, may be guarded to poor for return to breeding activity; fair to good for life with successful medical and/or surgical management.

PARAPROTEINEMIA

BASICS

OVERVIEW

• The presence of excessive serum paraproteins. Paraproteins are produced by a single clone of cells and may be whole immunoglobulins, subunits, light chains, or heavy chains. Commonly seen with plasma cell neoplasms (multiple myeloma), chronic lymphocytic leukemia, or B-cell lymphoma. • Primary signs are related to the underlying neoplasm and could be related to bone or bone marrow invasion with neoplastic cells. • Markedly elevated paraprotein concentration can result in hyperviscosity syndrome (HVS).

SYSTEMS AFFECTED

• Musculoskeletal—bone lysis by neoplasia can cause pain, lameness and pathologic fractures. More common in dogs. • Nervous—vertebral lysis and HVS can cause neurologic abnormalities including seizures, acute blindness, paraparesis. • Hemic/lymphatic/immune—myelophthisis and secondary immune-mediated destruction may cause cytopenias. Paraproteins may interfere with platelet and coagulation factor function; decreased production of normal immunoglobulins may increase susceptibility to infection. • Ophthalmic—dilated, tortuous retinal vessels, retinal detachment, or retinal hemorrhage from HVS. • Cardiovascular—HVS can cause hypervolemia and tachycardia, gallop rhythm, and cardiac failure (cats more than dogs). • Renal—failure due to antibody deposition in tubules.

SIGNALMENT

• Dogs—middle to old aged. • Cats (rare)—middle to old aged. • No sex predilection.

SIGNS

• Lethargy and weakness. • Lameness, paresis. • Bleeding. • Blindness or retinal hemorrhage. • Polyuria and polydipsia. • Seizures.

CAUSES & RISK FACTORS

• Multiple myeloma—genetic predisposition, viral infections, chronic immune stimulation, and carcinogen exposure. • Lymphoma or leukemia linked to retroviral infections in cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Monoclonal gammopathy—extramedullary plasmacytoma, lymphoma, lymphocytic leukemia, ehrlichiosis, leishmaniasis, bartonellosis, dirofilariasis, plasmacytic gastroenteritis, feline stomatitis, feline infectious peritonitis (FIP). • Polyclonal gammopathy—chronic infectious/inflammatory disorders, stomatitis, chronic autoimmune disease, and neoplasia. • Bleeding— thrombocytopenia, thrombocytopathy, other coagulopathy. • Neurologic or ophthalmologic signs of HVS—intracranial or spinal disease (neoplasia, meningitis, immune-mediated), hypertension.

CBC/BIOCHEMISTRY/URINALYSIS

• Anemia/leukopenia/thrombocytopenia—secondary to myelophthisis or autoimmune mechanisms; marked lymphocytosis associated with chronic lymphocytic leukemia or lymphoma. • Serum total protein and globulin concentrations—elevated. • Serum albumin concentration—may be low. • Serum total or ionized calcium concentration—elevated secondary to malignancy, renal failure, or bone lysis. • Proteinuria—caused by light chains (i.e., Bence Jones protein) not detected on routine urinalysis; urine protein electrophoresis to identify.

OTHER LABORATORY TESTS

• Serum/urine protein electrophoresis—to further characterize immunoglobulins. • Immunoelectrophoresis—helps define the type of gammopathy. • Infectious disease testing (serology or PCR as indicated). • Flow cytometry—characterization of leukemia, lymphoma.

IMAGING

• Skeletal survey radiographs or bone scan—identify lytic lesions and sites to aspirate or biopsy. Common locations for multiple myeloma lesions include vertebral bodies, ribs, pelvis, skull, and proximal long bones. • Thoracic and abdominal radiographs or ultrasound.

OTHER DIAGNOSTIC PROCEDURES

• Bone marrow aspiration/biopsy—plasmacytosis is often marked (>20%) in dogs with multiple myeloma (<5% is normal); in cats, presence of plasma cell atypia is more important than number. • Biopsy of lytic bony lesions. • Organ or lymph node aspiration—to identify neoplastic populations of cells, *Leishmania* amastigotes, or amyloid. Relatively contraindicated with coagulopathy.

TREATMENT

• Supportive care—analgesia, anticonvulsant therapy, other therapy as indicated. • Automated or manual plasmapheresis may rapidly decrease paraproteins. • Chemotherapy for neoplasia.

MEDICATIONS

DRUG(S) OF CHOICE

See specific diseases.

FOLLOW-UP

• See specific diseases. • Electrophoresis may be monitored to assess response to therapy.

PATELLAR LUXATION

BASICS

DEFINITION
Medial or lateral displacement of the patella from its normal anatomic position in the femoral trochlea.

PATHOPHYSIOLOGY
• Clinical signs may be mild to severe; different degrees of clinical and pathologic changes; classified into grades I–IV (see Physical Examination Findings). • Common musculoskeletal changes occur secondary to abnormal forces on the femur and tibia and lack of normal patellar position during growth—tibial rotation on its long axis; bowing of the distal femur and proximal tibia; shallow to absent femoral trochlea; dysplasia of the femoral and tibial epiphysis; displacement of the quadriceps muscle group.

SYSTEMS AFFECTED
Musculoskeletal

GENETICS
• Recessive, polygenic, and multifocal inheritances proposed. Genetic markers are not yet identified to facilitate the choice of selective elimination of patella luxation from specific breeds. • Hereditary factor in Devon Rex cats.

INCIDENCE/PREVALENCE
• One of the most common stifle joint abnormalities in dogs. • Medial—>75% of cases (large and small dogs and cats).
• Bilateral involvement—50% of cases.
• Uncommon in cats, but may be more common than suspected because most affected cats are not lame.

SIGNALMENT

Species
• Predominantly dog.
• Rarely cat.

Breed Predilections
• Most common in toy and miniature dog breeds. • Dogs—miniature and toy poodles; Yorkshire terriers; Pomeranians; Pekingese; Chihuahuas; Boston terriers. In large-breed dogs, Great Pyrenees and Labrador retrievers are most commonly affected.

Mean Age and Range
Clinical signs—may develop soon after birth with severe luxation or secondary bone deformities; generally after 4 months of age. Mild clinical signs that are not interpreted by clients as lameness are often undetected until secondary osteoarthritis advances.

Predominant Sex
Risk for females 1.5 times that for males.

SIGNS

General Comments
Clinical expression depends on grade (severity), amount of degenerative arthritis, chronicity of disease, and occurrence of other stifle joint abnormalities (e.g., cruciate ligament rupture).

Historical Findings
• Persistent abnormal hind limb carriage and function in neonates and puppies. Clients may complain of "bowed legs" (genu varum) or crouched gait in small-breed dogs.
• Occasional skipping or intermittent hind limb lameness—worsens in young to mature dogs. • Sudden signs of lameness—owing to minor trauma or worsening degenerative joint disease in mature animals.

Physical Examination Findings
• Grade I—patella can be manually displaced from the trochlea, but immediately resumes a normal position when pressure is released. Usually an incidental finding on physical examination and is not normally associated with clinical lameness. • Grade II—patella can be manually displaced or can spontaneously do so with flexion of the stifle joint; patella remains malpositioned until it is manually reduced or the patient extends the stifle joint. Patient intermittently carries the affected limb with the stifle joint flexed, but ambulates normally at other times. • Grade III—patella remains luxated most of the time but can be manually reduced with the stifle joint in extension; movement of the stifle joint results in reluxation of the patella. • Grade IV—patella is permanently luxated and cannot be manually repositioned; may be up to 90° of rotation of the proximal tibial plateau; shallow or missing femoral trochlea. • Grades III and IV—crouching, bowlegged (genu varum) or knock-kneed (genu valgum) stance for medial or lateral luxations, respectively; more of the body weight is transferred to the front limbs.
• Pain—occurs as the patella relocates or if abrasion creates contact with exposed bone.

CAUSES
• Congenital due to polygenetic influences.
• Rarely, traumatic; clinical history will determine traumatic etiology and secondary bone malformations are not present in acute traumatic patella luxation.

RISK FACTORS
Coxa vara—lateral displacement of the proximal femur; vastus medialis and rectus femoris muscles pull the patella medially.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Cranial cruciate ligament rupture—positive cranial drawer; concurrent in 15–20% of cases. • Avulsion of the tibial tubercle—patellar alta. • Rupture of the patellar tendon—patella alta. • Excessive tibial plateau angle—patella baja. • Malunion and malalignment of fractures of the femur or tibia—may result in displacement of the quadriceps muscle group.

LABORATORY FINDINGS
Not useful in the diagnosis of patella luxation in the dog.

IMAGING
Patella luxation is diagnosed based on clinical signs and physical examination. CT or orthogonal radiography of the femur and tibia may be indicated in grade III and IV luxations to assess bowing and torsion of the femur and tibia and evaluate the need for femoral or tibial osteotomy as an adjunct to correction.

DIAGNOSTIC PROCEDURES
• Palpation of patellar position and movement during flexion and extension of the stifle. Medial and lateral force exerted on patella to relocate the patella into the trochlear groove (if luxated) or luxate the patella (in grade I or II luxations).
• Calculation of the "Q-angle," or the angle of the direction of the quadriceps femoris muscle, under MRI may help to differentiate patella luxation from dogs with partial cranial cruciate ligament rupture. Q-angle (10.5° in normal dogs) increases with increasing grade of patella luxation, but should be only slightly increased in dogs with cranial cruciate rupture.

PATHOLOGIC FINDINGS
• Gross—cartilage wear lesions of the patella and femoral trochlea; joint capsule redundancy on the side opposite to luxation; fibrosis and contracture on the side of luxation. • Microscopic—cartilage fibrillation and loss of glycosaminoglycan content; synovitis.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient—all grade I and some grade II luxations. • Inpatient (surgery)—most grade II and all grade III and IV luxations.

NURSING CARE
• Cryotherapy (ice packing)—immediately after surgery; 5–10 minutes q8h for 3–5 days, followed by warm-packing, 5–10 minutes q8h for 3–5 additional days. • Passive stifle range-of-motion exercises—as soon as tolerated.

ACTIVITY
Normal to restricted, depending on severity and if surgical correction was performed.

PATELLAR LUXATION (CONTINUED)

DIET
Weight control—decreases the load and stress on the patella support mechanism.

CLIENT EDUCATION
• Discuss the heritability of the condition.
• Warn about relapse potential after surgery. Retrospective studies indicate that 8–19.8% of patellas reluxate after surgery. Revision surgery is necessary in 13% of cases. • Inform about increased risk of cranial cruciate ligament disease. • Warn that the condition could worsen over time (e.g., from grade I to grade II).

SURGICAL CONSIDERATIONS
• Malalignment is the underlying cause—tibial crest transposition is the definitive realignment procedure, but often needs to be combined with other techniques such as sulcoplasty. • Retinacular and joint capsule tension on the side of luxation prevents realignment—medial capsulotomy (release) is essential. • Shallowness of the trochlea sulcus is assessed and managed with one of the following: ○ Trochleoplasty—rasp or burr to deepen the sulcus. Not recommended as a primary means of deepening the sulcus because of the poor quality of the fibrocartilage upon healing; often leads to increased secondary osteoarthritis of the stifle. ○ Trochlea chondroplasty—only indicated in very young dogs because of easy separation of the cartilage and subchondral bone in these dogs; lift the surface hyaline cartilage and curette out cancellous bone to deepen the sulcus; lay the cartilage back over exposed bone. ○ Recession sulcoplasty—remove a pie-shaped wedge; deepen the defect, replace the wedge; preferred technique for most patients since the surface cartilage is mostly intact. ○ Block recession sulcoplasty—remove a block instead of a wedge; increases surface area of cartilage in contact with patella. More difficult surgical procedure than simple recession sulcoplasty. ○ Transposition of the tibial tubercle—realign the longitudinal axis of the quadriceps mechanism so that it is centered over the femoral trochlea, in effect, deepening the Q-angle; osteotomize the tibia tubercle leaving it attached distally, transpose it opposite the direction of luxation, and stabilize it with K-wires and, in larger dogs, a tension band wire. ○ Imbricate the joint capsule and supporting soft tissues on the side opposite the luxation—to help keep the patella in the sulcus. Imbrication can occur by removal of a longitudinal full-thickness portion of the excess capsule and edge-to-edge tissue apposition during closure (strongest method), or by overlapping the joint capsule incision with a "vest-over-pants" surgical technique. Imbrication as a sole procedure is not sufficient to permanently correct the position. ○ Corrective osteotomies of the distal femur and proximal tibia—realigns the longitudinal axis of the hind limb; generally indicated most commonly for grade IV luxations with significant femoral or tibial bowing and torsion.

MEDICATIONS

DRUG(S) OF CHOICE
• Nonsteroidal anti-inflammatory drugs (NSAIDs)—minimize pain; decrease inflammation; meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg q24h PO—liquid), carprofen (2.2 mg/kg PO q12h), etodolac (10–15 mg/kg PO q24h), deracoxib (3–4 mg/kg PO q24h—chewable) for 7 days (for postoperative pain). • Food supplementation with omega-3 fatty acids to decrease inflammation and progression of secondary osteoarthritis. Commercial diets containing 1.7–3.4% omega-3 fatty acids or precursors are beneficial.

CONTRAINDICATIONS
Avoid corticosteroids because of potential side effects and articular cartilage damage associated with long-term use.

PRECAUTIONS
NSAIDs—gastrointestinal irritation may preclude their use.

ALTERNATIVE DRUG(S)
Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—may help limit cartilage damage and degeneration, but recent evidence suggests they are not or are only minimally efficacious.

FOLLOW-UP

PATIENT MONITORING
• Post-trochleoplasty—encourage early, active use of the limb. Small-breed dogs are commonly reluctant to bear weight on the operated limb at an early period and are prime candidates for joint range of motion and other exercises to encourage early limb use. • Leash walk exercise for 4–8 weeks; prevent jumping. The duration of exercise restriction is variable depending on the surgical procedure with 4 weeks for only soft tissue corrections and 8 weeks for osteotomy procedures recommended. When corrected with tibial crest transposition, cage rest is indicated until follow-up radiographs indicate the crest is healed in its new position. • Yearly examinations—to assess progression of uncorrected patella luxation or to monitor progression of secondary osteoarthritis.

PREVENTION/AVOIDANCE
• Discourage breeding of affected animals.
• Do not repeat dam–sire breedings that result in affected offspring.

POSSIBLE COMPLICATIONS
Infection, recurrence, tibial crest avulsion, pin migration.

EXPECTED COURSE AND PROGNOSIS
• With surgical treatment—>90% of patients are free from lameness and clinical dysfunction.
• Osteoarthritis—radiographic evidence in almost all affected stifle joints after surgery. Clinical impact appears minimal in small dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Cranial cruciate ligament rupture.

SEE ALSO
Arthritis (Osteoarthritis).

ABBREVIATIONS
• NSAID = nonsteroidal anti-inflammatory drug.

PATENT DUCTUS ARTERIOSUS

BASICS

DEFINITION
Persistent patency of this normal fetal structure.

PATHOPHYSIOLOGY
Due to insufficient vascular smooth muscle the ductus arteriosus fails to close after birth, maintaining a persistent communication between the low-pressure pulmonary artery (PA) and high-pressure aorta (see Web Figures 1 and 2). Blood typically shunts left to right, with hemodynamic consequences depending on the magnitude of the shunt, pulmonary vascular resistance, and concurrent heart defects. Moderate-to-large shunts cause left-sided congestive heart failure (CHF) from volume overload of the left ventricle (LV). Less often a large-diameter patent ductus arteriosus (PDA) induces severe pulmonary vascular injury, high pulmonary vascular resistance, and pulmonary hypertension (PH), causing shunt reversal from Eisenmenger's pathophysiology. This is termed a "reversed" PDA (rPDA), and leads to bidirectional shunting, arterial desaturation, and secondary erythrocytosis.

SYSTEMS AFFECTED
• Cardiovascular—volume overload or pulmonary vascular disease. • Hemic/lymph/immune—potential for erythrocytosis and hyperviscosity. • Respiratory—cough or labored breathing from pulmonary edema or PH.

GENETICS
"Polygenic" model defect in many canine breeds.

INCIDENCE/PREVALENCE
Estimated prevalence up to 2.5 cases/1,000 live canine births; less common in cats.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Bichon frise, cavalier King Charles spaniel, Chihuahua, cocker spaniel, collie, English springer spaniel, German shepherd dog, Labrador retriever, Maltese, miniature (and toy) poodle, Pomeranian, Shetland sheepdog, and others.

Mean Age and Range
• Vast majority identified during initial vaccination sequence. • Onset of signs—weeks to years.

Predominant Sex
Dogs—females predisposed in some breeds.

SIGNS

General Comments
• Signs vary by major hemodynamic effect at time of presentation—no signs vs. volume overload vs. increased pulmonary vascular resistance. • Onset of rPDA may be sudden in dogs (usually before 4–6 months of age); can develop gradually in cats but often before 1 year of age. • Signs related to rPDA can be overlooked for years.

Historical Findings
• Most have no clinical signs at initial evaluation. • Dyspnea, coughing, exercise intolerance with development of CHF. • Stunted growth in some. • Exertional rear limb weakness and complications of hyperviscosity (seizures or sudden death) with rPDA. • Signs usually precipitated by or worsened with exercise.

Physical Examination Findings
• Continuous, loud, machinery-type murmur loudest over PA at the left craniodorsal cardiac base; often a systolic mitral regurgitant murmur at the left apex. The murmur in puppies <6 weeks of age or cats of any age might resemble a long systolic and abbreviated diastolic murmur. • Precordial thrill. • Arterial pulses—hyperkinetic ("waterhammer"). • Caudoventral displacement of palpable LV apex. • Tachypnea, dyspnea, and inspiratory crackles—can indicate left-sided CHF or concurrent respiratory disease such as pneumonia. • Rapid, irregular cardiac rhythm with variable-intensity arterial pulses if atrial fibrillation develops—more common in large-breed dogs. • In rPDA findings differ— systolic ejection murmur with tympanic or split second heart sound; normal arterial pulses, prominent right ventricular impulse, and prominent jugular pulse. Differential cyanosis—blue discoloration limited to the caudal mucous membranes.

CAUSES
Genetic in most cases.

RISK FACTORS
Breed and sex in dogs; unknown for cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Congenital aortic stenosis with aortic insufficiency (to-and-fro systolic/diastolic murmurs) and ventricular septal defect (VSD) with aortic valve prolapse (systolic murmur of VSD and diastolic murmur of aortic insufficiency). • Rare causes of continuous thoracic murmurs—pulmonary arteriovenous malformations, aortopulmonary communication, rupture of the aorta into the right atrium or ventricle, and coronary artery fistula. • Systemic arterial to PA vascular malformations can result in similar imaging findings to those of PDA but murmurs are often soft or absent. • Exertional rear limb weakness of rPDA often misdiagnosed as myasthenia gravis.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal unless rPDA (erythrocytosis with packed cell volume [PCV] 55–80%).

OTHER LABORATORY TESTS
Low femoral arterial PO_2 compared to brachial artery in rPDA (rarely necessary).

IMAGING

Thoracic Radiography
• Lateral projection—left cardiomegaly; pulmonary overcirculation; frequently the lobar pulmonary veins are slightly larger than attendant arteries (see Web Figure 3). • Dorsoventral projection—cardiac elongation (LV enlargement), left auricular enlargement, dilation of the descending aorta ("ductus bump") and the main PA. • Left-sided CHF—distended pulmonary veins; increased interstitial/alveolar densities. • With rPDA—heart normal sized but contour of the right ventricle (RV) is more prominent, the pulmonary circulation appears normal to reduced, and main PA and proximal lobar branches are dilated (see Web Figure 4); a ductus bump may be evident; lung fields are clear.

Echocardiography
• The left atrium (LA), LV, ascending aorta, and main PA are dilated and LV systolic dysfunction might be observed. The RV is normal, except in rPDA or in some animals with progressive PH. • Ductal ampulla and the entry to PA can be imaged; optimally with transesophageal echo (see Web Figure 5). • Doppler studies demonstrate continuous flow into the main PA (see Web Figure 6), usually with concurrent pulmonary insufficiency from dilation of that vessel, along with mitral regurgitation from LV and LA dilation. Transmitral flow velocity is increased from increased flow volume and LA pressure. Aortic outflow velocities are augmented substantially (often around 3 m/s), mimicking mild aortic stenosis. Trace aortic regurgitation is common from aortic dilation. • With rPDA—small left heart chambers, right atrial dilation, RV hypertrophy, and dilation of the main PA and branches. Saline contrast injected in peripheral vein is identified in the abdominal aorta. Color and spectral Doppler studies identify low velocity and bidirectional or right-to-left shunting across ductus (see Web Figure 7). High-velocity pulmonary and tricuspid regurgitation indicate PH.

PATENT DUCTUS ARTERIOSUS (CONTINUED)

Angiography

Fluoroscopic angiography or CT angiography can be useful for the differential diagnosis of rare aortic or coronary arterial malformations, abnormal aortic arch (with right-sided PDA), systemic to pulmonary arterial malformations, and during interventional catheterization procedures to demonstrate ductal morphology and guide catheter-based ductal occlusion.

DIAGNOSTIC PROCEDURES

Electrocardiogram

• Typical abnormalities are wide P-waves and tall R-waves in the caudal leads (II, aVF, III) and left precordial leads. • Atrial fibrillation—observed infrequently; related to marked dilatation of the LA; more common in large-breed dogs. • With rPDA—findings of RV hypertrophy with S-waves in leads I, II, III, and right axis deviation are more typical.

PATHOLOGIC FINDINGS

• Persistent patency of the ductus arteriosus between descending aorta and origin of the left PA. • Left-to-right shunting PDA—pulmonary edema, cardiomegaly (left-sided), and dilation of the aorta and PA. • rPDA—RV hypertrophy, PA dilation, and prominent bronchial arteries; ductal diameter is invariably very wide, similar to descending aorta. Histologic changes of pulmonary vascular disease (medial hypertrophy, plexiform lesions or necrotizing arteritis).

TREATMENT

APPROPRIATE HEALTH CARE

• Manage pulmonary edema with furosemide, pimobendan, and, if necessary, oxygen, nitrates, and cage rest; following stabilization, promptly occlude the PDA. If medical stabilization is ineffective, surgery can often relieve CHF.
• Ductal closure by surgical ligation or various catheter-based occlusion techniques (See Web Figure 8). These are referral procedures.
• Schedule stable animals for elective surgery or device closure without delay; dogs as young as 7–8 weeks of age show no higher operative mortality. • Treat dogs with erythrocytosis from rPDA with rehydration and salting of food to encourage water intake. If needed, consider periodic phlebotomy to maintain target PCV of 62–65%.

ACTIVITY

• Restrict activity until the ductus is closed and in all dogs with CHF. • After suture removal and first follow-up examination, resume normal activity.

DIET

Normal; restrict sodium intake if CHF.

CLIENT EDUCATION

• Do not delay treatment as mortality is higher and LV function impaired if clinical signs or atrial fibrillation develop.
• Following successful PDA closure and a 2 week convalescence, most dogs can be treated normally.

SURGICAL CONSIDERATIONS

• Smaller patient sizes (<2.5 kg) are a limiting factor with current intravascular PDA occlusion devices. • Surgery can generally proceed within 24–48 hours of medical stabilization. • Surgical therapy involves ductal ligation via left thoracotomy; surgical and perioperative mortality is <3% at the most experienced centers. • Mortality with devices is even lower, but complications including failure to achieve closure and device embolization infrequently occur. • Never close a true rPDA as the RV cannot eject against the pulmonary vascular resistance. PDA with moderate PH and predominately left-to-right shunting can often be closed, especially in cats, provided pulmonary vascular resistance is not fixed. Medication trial with sildenafil may be performed cautiously to determine degree of vascular reactivity in PDA with PH; monitor in-hospital for first 24 hours if pursued.

MEDICATIONS

DRUG(S) OF CHOICE

• Treat pulmonary edema with furosemide 2–4 mg/kg q6–12h PO, SC, IM, or IV as required; and pimobendan 0.2–0.3 mg/kg q12h PO. These are usually discontinued once the PDA is closed. • When closure is not an option—if CHF, prescribe furosemide, ACE inhibitor such as enalapril 0.5 mg/kg q12–24h PO, and pimobendan. • If atrial fibrillation develops add digoxin and diltiazem (see Atrial Fibrillation and Atrial Flutter). An alternative is electrical cardioversion—this is a reasonable therapy provided the ductus can be closed. Refer to a cardiologist. • To control severe, life-threatening CHF—can use direct vasodilators such as hydralazine 1–2 mg/kg q12h PO or sodium nitroprusside 1–5 µg/kg/min IV to reduce left-to-right shunting. Maintain systolic blood pressure at 85–90 mmHg. Artificial ventilation might be needed.
• Consider sildenafil at 1–2 mg/kg q8h PO if moderate to severe PH is present.

CONTRAINDICATIONS

• Left-to-right PDA—drugs that increase systemic vascular resistance and arterial blood pressure, except as needed for anesthesia and surgery. • rPDA—drugs that cause systemic arterial vasodilation and reduce systemic arterial blood pressure, including drugs with arterial vasodilating effects.

PRECAUTIONS

• Measure digoxin levels if prescribed.
• Monitor arterial blood pressure, renal function, and serum electrolytes to identify problems related to diuretic and vasodilator therapies.

POSSIBLE INTERACTIONS

Aggressive diuresis leading to dehydration or hypokalemia exacerbates the risk for digoxin toxicity. Sildenafil in a balanced PDA can increase pulmonary overcirculation and result in left-sided CHF.

ALTERNATIVE DRUG(S)

• Prostaglandin inhibitors (e.g., indomethacin) do *not* close PDAs effectively in dogs.
• Hydroxyurea—infrequently considered for treatment of severe erythrocytosis unresponsive to phlebotomy. Consult with internist or oncologist before using.

FOLLOW-UP

PATIENT MONITORING

• Intra- and postoperative pain management with opiates and regional blocks as appropriate for the procedure. Analgesic therapy following catheter-based closure is less aggressive but also continued for 24–48 hours. • Postoperative—vital signs and respiratory rate. • Cardiac auscultation postoperatively and at suture removal; if heart sounds are normal, no further follow-up or diagnostic studies are required unless preoperative echocardiography showed moderate to severe LV dysfunction. There is no basis for recommending annual cardiac reevaluation of uncomplicated cases.
• Persistent, continuous murmur indicates either incomplete closure of the ductus, recanalization (infection or device migration), or a concurrent cardiac or vascular defect.
• Systolic murmurs are variably heard postoperatively; these typically abate by the time of suture removal. Reinvestigate unexpected murmurs by Doppler echocardiography. When only partial surgical ligation is achieved, consider referral for device occlusion.

PREVENTION/AVOIDANCE

Do not breed.

POSSIBLE COMPLICATIONS

• Sudden illness, fever, or acute respiratory signs postoperatively—consider bacterial infection of the closure site with hematogenous pneumonia; aggressive

antibiotic therapy needed. • An unusual complication is acquired stenosis of the main or branch PA following surgery to correct PDA.

EXPECTED COURSE AND PROGNOSIS

• Infrequently dogs remain asymptomatic for life. PDA closure adds an estimated 10 years to median lifespan in dogs (12 years with closure, 2 years without). In older reports, ~50–60% of dogs died from CHF within 1 year of diagnosis if the PDA was not closed. • Closure prior to onset of moderate-to-severe CHF—excellent prognosis. • Moderate-to-severe CHF is related to myocardial failure of LV or atrial fibrillation—guarded prognosis; referral to a cardiologist is advised. • Dogs with rPDA can live for several years but often die suddenly; occasionally, dogs live beyond 5 years of age (especially cocker spaniels). • Cats—varies from rapidly progressive left-sided CHF to gradual development of pulmonary vascular disease; even right-sided CHF can develop with PDA and PH.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Typically an isolated defect, but is recognized with other congenital heart lesions—more likely in larger breeds. Occasionally a vascular ring anomaly is evident, such as persistent right fourth aortic arch.

AGE-RELATED FACTORS

Presentation is typically young animals; median age of presentation reported as 5 months in dogs.

PREGNANCY/FERTILITY/BREEDING

Greater risk for CHF in pregnant bitches; offspring have greater risk for large PDA or rPDA; do not breed affected dogs.

SYNONYMS

Duct of Botallo, ductus Botalli, patent arterial duct.

PECTUS EXCAVATUM

BASICS

OVERVIEW

- Deformity of the sternum and costal cartilages that results in a dorsal-to-ventral narrowing of the chest, primarily in the caudal aspect.
- Can have secondary abnormalities of respiratory and cardiovascular function from restriction of ventilation and cardiac compression.
- Considered congenital in origin although an acquired case has been reported.
- Upper respiratory obstruction at a young age could cause abnormal respiratory gradients and subsequent pectus excavatum.
- Uncommon defect.
- Concurrent cardiac defects common.
- Some patients demonstrate swimmer syndrome—neonatal dogs lack the ability to posture properly and remain in sternal recumbency, which can lead to invagination of the sternum.

Systems Affected

- Respiratory.
- Cardiovascular.

SIGNALMENT

- Dogs and cats.
- Brachycephalic breeds and Bengal cats are overrepresented.
- Most common age of presentation—4 weeks–3 months.
- Male cats more often reported than females, no sex predisposition noted in dogs.

SIGNS

- Thoracic defect, easily palpated or seen.
- Varying degrees of respiratory distress.
- Exercise intolerance.
- Weight loss.
- Recurrent respiratory infections.
- Cough.
- Vomiting.
- Cyanosis.
- Poor appetite.
- Cardiac murmurs associated with concurrent cardiac defects or compression of the heart.
- Muffled heart sounds.
- No correlation between severity of signs and severity of anatomic or physiologic abnormalities.
- Vertebral deformities.
- Swimmer syndrome—limbs not adducted properly; ambulation impaired.

CAUSES & RISK FACTORS

- Genetic predisposition—may exist.
- Unknown etiology—suspected causes include intrauterine pressure abnormalities, shortening of central tendon of the diaphragm, cranial abdominal muscle deficiency, and abnormal osteogenesis or chondrogenesis.
- Dogs predisposed to respiratory obstructive processes have a higher risk than others.
- Single report in a geriatric golden retriever with laryngeal paralysis.
- Puppies raised on surfaces causing poor footing may be predisposed to swimmer syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital diaphragmatic hernia (pleuroperitoneal or pericardioperitoneal).
- Tracheal malformations or collapse.
- Congenital heart defects.
- Pulmonary edema.
- Pleural effusion.
- Pneumonia.
- Tracheobronchitis/bronchitis.
- Brachycephalic obstructive airway syndrome.

IMAGING

Thoracic Radiography (see Web Figure 1)

- Confirm sternal and costal skeletal abnormalities.
- Decreased thoracic volume.
- Cardiac malpositioning—left and cranial displacement of cardiac silhouette.
- Concurrent secondary pulmonary disease.
- Measure frontosagittal and vertebral indices to characterize degree of deformity as mild, moderate, or severe and help predict response to treatment.
- The frontosagittal index is the ratio between the width of the chest at the 10th thoracic vertebra and the distance between the center of the ventral surface of the 10th thoracic vertebral body and the nearest point on the sternum.
- The vertebral index is the ratio between the distance from the center of the dorsal surface of the 10th vertebral body to the nearest point on the sternum and the dorsoventral diameter of the vertebral body at the same level.

Echocardiography

Rule out concurrent congenital cardiac defects or other cardiac disease.

TREATMENT

- Decision to repair deformities is made on the basis of clinical signs. If it is an incidental finding with minimal to no clinical signs, then intervention may not be indicated.
- Treatment options include external coaptation, partial sternectomy, or both. Decision is based on age of the animal and degree of deformity.
- Surgery benefits patients with concurrent respiratory distress; benefits are unknown in patients with no respiratory distress but with moderate or severe deformity.
- Nonclinical patients can develop signs at a later date; patients with clinical signs of disease may show progression.
- For puppies with swimmer syndrome, place on surfaces with excellent footing; careful toggling of front and rear legs may improve adduction.
- Brachycephalic breeds with concurrent upper airway obstruction may benefit from surgery directed at these problems.
- Anesthesia—patients require constant monitoring; ventilatory support should be available.

MEDICATIONS

N/A

FOLLOW-UP

- Examinations—dictated by clinical signs or when surgical intervention has been precluded.
- No specific actions for avoiding disease; genetic factors may sometimes be involved.
- Progression of respiratory signs—can develop in nonclinical or mildly clinical patients.
- Prognosis—guarded to good depending on properly timed and expertly administered intervention.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Cardiac defects.
- Swimmer syndrome.

Author Catriona M. MacPhail
Consulting Editor Elizabeth Rozanski

PELGER–HUËT ANOMALY

BASICS

OVERVIEW
- Congenital hereditary disorder that has been seen in several breeds of dogs and domestic shorthair cats.
- Results in nuclear hyposegmentation of many to all granulocytes (neutrophils, eosinophils, and basophils).
- Hypolobulation of monocytes and megakaryocytes has also been reported.
- Chromatin patterns of leukocytes are normochromatic, or occasionally hyperchromatic, rather than the open, immature chromatin of immature leukocytes.
- Cytoplasm of cells is unremarkable (i.e., no toxic changes are observed).
- Cell function is unaffected in heterozygotes; homozygotes are usually stillborn or die *in utero*.
- Care should be taken not to misinterpret as a severe left shift.

SIGNALMENT
- Dogs—Pelger–Huët anomaly (PHA) has been reported in mixed-breed dogs as well as numerous pure-breed animals. Overall the incidence is low; however, Australian shepherd dogs have been shown to have a 9.8% incidence rate.
- Cats—PHA has only been reported in domestic shorthair cats. The overall incidence in cats is unknown; however, it is likely rare when compared to dogs.
- An autosomal dominant mode of inheritance is likely; however, incomplete penetrance has been seen in Australian shepherd dogs.

SIGNS
No clinical signs are associated with heterozygous animals, as the leukocytes are fully functional.

CAUSES & RISK FACTORS
- In humans, caused by an inherited defect of the lamin B receptor.
- Australian shepherd dogs are overrepresented in reported canine cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
- The primary differential diagnosis to rule out is a severe left shift, indicating severe inflammation or infection.
- An inflammatory leukogram may show a leukocytosis or leukopenia. Immature leukocytes exhibit an open, pale chromatin pattern.
- Toxic changes (Döhle bodies, blue foamy cytoplasm, toxic granulation, etc.) are frequently seen with severe inflammation, but not PHA.
- Pelger–Huët cells have a nucleus that shows a mature, condensed chromatin pattern and exhibit no toxic changes.
- Animals with PHA are clinically healthy, whereas animals with severe left shifts tend to be systemically ill.
- Pseudo- or acquired PHA is an acquired condition that results in granulocyte hyposegmentation, secondary to myelodysplastic conditions or drug therapy.

CBC/SERUM BIOCHEMISTRY/URINALYSIS
- The blood smear reveals a persistent varying hyposegmentation of all granulocytes and often monocytes.
- Granulocyte nuclei have mature, condensed chromatin and may be round, oval, peanut, dumbbell, horseshoe, and bilobed in shape.
- The serum biochemistry profile and urinalysis are unremarkable.

OTHER LABORATORY TESTS
Examination of a peripheral blood smear which exhibits hyposegmentation of all granulatocytes is all that is needed to diagnose PHA.

IMAGING
Imaging is not useful in diagnosing PHA.

DIAGNOSTIC PROCEDURES
- Establishment of a hereditary pattern typically an academic exercise, but potentially useful.
- No additional diagnostic procedures are indicated to diagnose PHA.
- Additional diagnostics are warranted if an underlying disease is suspected to cause a severe left shift.

TREATMENT
No treatment is indicated for PHA.

MEDICATIONS
N/A

FOLLOW-UP
No follow-up is necessary.

MISCELLANEOUS
Affected animals should not be bred, as it is lethal *in utero*.

ABBREVIATIONS
- PHA = Pelger–Huët anomaly.

PELVIC BLADDER

BASICS

OVERVIEW
Pelvic bladder or "intrapelvic bladder" is characterized by abnormal position of the urinary bladder neck caudal to the pubic bone, causing the proximal urethra and a variable portion of the trigone or the body of the bladder to remain within the pelvic canal. It is commonly associated with a short urethral length and urethral sphincter mechanism incompetence (USMI).

SIGNALMENT
- Dogs and rarely cats.
- Primarily young female dogs (<1 year of age).

SIGNS
- May be asymptomatic.
- Incontinence can be continuous or intermittent.
- Conscious voiding patterns often present.
- Perineum stained/soaked with urine, urine scalding, wet vulva/prepuce.
- Urgency with small volume elimination may be seen.

CAUSES & RISK FACTORS
The position of the bladder in incontinent female dogs has been shown to be more intrapelvic and associated with a shorter urethral length, suggesting that an intrapelvic bladder neck and a short urethra together encourage urinary incontinence. It is hypothesized that this could result from an unbalanced distribution of the pressure exerted by the abdominal organs between the bladder and urethra.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Urinary incontinence—ectopic ureter, USMI, inappropriate urination, urge incontinence, urinary tract infection (UTI), neurogenic incontinence, overflow incontinence.
- Often associated with ectopic ureters.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC and biochemistry typically unremarkable.
- Urinalysis may reveal evidence of a UTI (including pyuria, bacteriuria, and hematuria) or polyuria (urine specific gravity [USG] <1.035).
- Urine culture and sensitivity via a cystocentesis should be performed.

IMAGING
- Abdominal radiographs may reveal a caudally displaced bladder, but this should be interpreted carefully without bladder distension.
- Excretory urography may allow visualization of the kidneys, ureteral terminations, urinary bladder, and urethra but does not provide bladder distension. Without bladder distension, interpretation of bladder neck location should be made with caution.
- Retrograde vaginourethography or urethrocystography allows visualization of the vaginal vault, urethra, urethral length, prostate, urinary bladder shape, and bladder neck location.
- If the urinary bladder and urethra are inside the bony pelvis, double contrast cystourethrography may be required for full visualization.
- Ultrasonography of the kidneys, ureters, and urinary bladder can aid in documentation of concurrent urologic anomalies, hydronephrosis, pyelonephritis, or ectopic ureters.
- The diagnostic combination of choice is cystourethroscopy with contrast cystourethrography, allowing investigation of urethral, ureteral, urinary bladder, vaginal, and vestibular defects. It also allows measurement of urethral length and width and aids in formulating therapy.

DIAGNOSTIC PROCEDURES
- Neurologic exam should be normal.
- Urodynamic procedures—consider cystometrography and urethral pressure profilometry to evaluate urinary bladder and urethral function, as well as urethral length.

TREATMENT
- Identify UTI and treat appropriately.
- Goal is to increase urethral resistance (intraurethral injections of bulking agents, urethral hydraulic occluder, etc.), and/or relocate the bladder neck to an intra-abdominal position (colposuspension, urethropexy, prostatopexy, or vas deferensopexy).
- Detrusor relaxation may treat refractory incontinent dogs with an overactive bladder contributing to incontinence or urgency.
- Medical management for traditional USMI is typically successful in 75–90% of female dogs.

Surgical Considerations
- Colposuspension has a reported cure rate of 53%.
- Placement of a urethral hydraulic occluder, also termed "artificial urethral sphincter" has been successful and is currently the surgical treatment of choice if other minimally invasive or medical interventions fail. Experience with this procedure has been limited and the risk of urethral strictures can be up to 20%. Cystopexy can also be considered.

Minimally Invasive Treatment
Transurethral submucosal bulking agent (e.g., collagen) therapy has been described for patients refractory to medical management and is associated with good, but temporary success. While this may improve incontinence, it does not alter the location of the urinary bladder.

MEDICATIONS

DRUG(S) OF CHOICE
- All should be reduced to lowest effective dosage. Combination therapy may be more effective.
- Phenylpropanolamine (PPA)—an α-agonist (1–2 mg/kg PO q8–12h) will improve continence in a majority of USMI cases.
- Diethylstilbestrol (DES)—an estrogen (0.1–1 mg PO q24h for 3–5 days, then 0.1–1 mg per week thereafter). DES can be toxic to the bone marrow in dogs and cats and can cause blood dyscrasias. This can progress, in rare cases, to fatal aplastic anemia. Estrogenic effects may also be seen.
- Estriol—an estrogen (2 mg once daily per dog (regardless of body weight) for 14 days, then taper every 7 days). Estriol can be toxic to the bone marrow in dogs and cats and can cause blood dyscrasias, but is considered safer than DES. Estrogenic effects may also be seen.

FOLLOW-UP

PATIENT MONITORING
- Monitor for the development of lower urinary tract signs which could indicate UTI.
- Patients receiving an α-agonist should have serial blood pressure evaluations, as this is contraindicated in hypertensive patients or those with renal or heart disease.
- Patients receiving estrogen therapy (DES or estriol) should have serial CBC evaluations to monitor for bone marrow dyscrasia.
- Use all medications at the lowest effective dose.

MISCELLANEOUS

ABBREVIATIONS
- DES = diethylstilbestrol.
- PPA = phenylpropanolamine.
- USG = urine specific gravity.
- USMI = urethral sphincter mechanism incompetence.
- UTI = urinary tract infection.

PEMPHIGUS

BASICS

DEFINITION
• A group of autoimmune dermatoses characterized by varying degrees of erosion, ulceration, crusting, pustule and vesicle formation. • Affects the skin and sometimes mucous membranes. • Forms identified in animals—pemphigus foliaceus (PF), pemphigus erythematosus (PE), pemphigus vulgaris (PV), paraneoplastic pemphigus (PP), and panepidermal pustular pemphigus (PEP)/pemphigus vegetans (PVeg).

PATHOPHYSIOLOGY
• Tissue-bound autoantibody directed at intraepidermal cell antigens (desmoglein and desmocollin) and acetylcholine receptors is deposited within the intercellular spaces, causing epidermal cell separation and cell rounding (acantholysis). • Severity of ulceration and disease—related to depth of autoantibody deposition within the skin. • PF—autoantibody deposition in the superficial layers of the epidermis. • PV—lesions more severe; auto-antibody deposition just above the basement membrane zone; rapidly leads to ulcer formation. • The disease is typically considered to be idiopathic. Possible drug association has been proposed in dogs and cats with PF. Sunlight exposure is suspected to induce flares of PF and PE. Thymoma has been associated with pemphigus variants in dogs and cats.

SYSTEMS AFFECTED
Skin/exocrine

INCIDENCE/PREVALENCE
• PF—most common autoimmune skin disease in dogs and cats. • PE—relatively common. • PV/PP—more severe forms, much rarer than PF/PE. • PEP/PVeg—rarest form; may represent a more severe variant of PF.

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
PF— Dogs: Akita, chow chow, dachshund, cocker spaniel, Labrador retriever, and English bulldog. Cats: possibly short-haired and Siamese.

Mean Age and Range
Usually middle-aged to old animals.

Predominant Sex
None reported.

SIGNS

PF
• Scales, crust, pustules, epidermal collarettes, erosions, erythema, alopecia, and footpad hyperkeratosis with fissuring. • Common involvement—head, face, ears, and footpads. • Most cases develop extensive disease within one month. • Nasal depigmentation may develop, but this is a late event. • Head and facial distribution is an important distinction from a staphylococcal pyoderma. • Cats—nipple and ungual fold involvement common. • Lymphadenopathy, edema, depression, fever, and lameness (if footpads involved) when severe or generalized. • Variable pain and pruritus. • Secondary bacterial infection possible.

PE
• May be a variant of PF or a crossover between PF and discoid lupus erythematosus (DLE). • Dogs and cats—pustules, erosions and crusts on face and pinnae. Along with depigmentation, erythema and erosion/ulceration of the nasal planum and dorsal muzzle. Rare patients exhibit nonfacial lesions. • Depigmentation more common than with other pemphigus forms, often precedes crusting.

PV/PP
• Oral cavity lesions frequent and may precede skin lesions. • Initially vesiculobullous lesions rapidly progressing to ulcerations and erosions. • More severe than PF and PE. • Affects mucous membranes, mucocutaneous junctions, and skin; may become generalized. • Footpads and ungual folds may be involved, with resultant onychomadesis. • Positive Nikolsky sign (new or extended erosive lesion created when lateral pressure is applied to the skin near an existing lesion). • Variable pruritus and pain. • Anorexia, depression, and fever. • Secondary bacterial infections common.

PEP/PVeg
• Pustule groups become eruptive papillomatous lesions with exudation. • No oral involvement. • No systemic illness.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

PF
• Superficial pyoderma. • Dermatophytosis. • Demodicosis. • Candidiasis. • Keratinization disorders. • Cutaneous lupus erythematosus or DLE. • PE. • Subcorneal pustular dermatosis. • Drug eruption. • Zinc-responsive dermatitis. • Dermatomyositis. • Tyrosinemia. • Mycosis fungoides. • Metabolic epidermal necrosis. • Linear IgA dermatosis.

PE
• PF. • DLE. • Mucocutaneous pyoderma. • Demodicosis. • Dermatophytosis. • Epidermolysis bullosa simplex. • Uveodermatologic syndrome.

PV/PP
• Subepidermal blistering diseases. • Systemic lupus erythematosus. • Toxic epidermal necrolysis. • Drug eruption. • Mycosis fungoides. • Ulcerative stomatitis causes. • Erythema multiforme.

PEP/PVeg
• PF. • PV. • Superficial pyoderma. • Lichenoid dermatoses.

CBC/BIOCHEMISTRY/URINALYSIS
• Abnormalities uncommon. • Leukocytosis and hyperglobulinemia with chronicity and/or secondary infection.

OTHER LABORATORY TESTS
Antinuclear antibody—may be weakly positive in PE only.

DIAGNOSTIC PROCEDURES
• Cytology of pustules—aspirates or impression smears from pustules or under crusts: acantholytic keratinocytes (rounded and deeply staining isolated keratinocytes) and neutrophils; occasionally with eosinophils. • Biopsy of pustules or crusted lesions (submit crusts with the biopsy samples of the skin).

PATHOLOGIC FINDINGS
• Histopathology: ◦ PF—subcorneal pustules with acantholytic cells and neutrophils; eosinophils often present; follicles may be involved. ◦ PE—intragranular and subcorneal pustules, eosinophils, neutrophils, lichenoid interface dermatitis. ◦ PV—suprabasilar intraepidermal cleft with the remaining basal cells exhibiting a tombstone appearance. ◦ PP—suprabasilar clefting with interface dermatitis and apoptotic keratinocytes. ◦ PEP/PVeg—pustules present throughout the epidermal layers and includes follicular epithelium. • Immunopathology of biopsied skin via immunofluorescent antibody assays or immunohistochemical testing—may demonstrate positive staining in the intercellular spaces in 50–90% of cases; results can be affected by concurrent or previous corticosteroid (or other immunosuppressive drug) administration; indirect immunofluorescence usually negative; PE may demonstrate staining of basement membranes and intercellular spaces.

TREATMENT

APPROPRIATE HEALTH CARE
• Initial inpatient supportive therapy for severely affected patients. • Outpatient treatment with initial frequent hospital visits (every 1–3 weeks); taper to every 1–3 months when remission is achieved and the patient is on a maintenance medical regimen.

NURSING CARE
Severely affected patients may require antibiotics and hydrotherapy/soaks.

CLIENT EDUCATION
Sun avoidance/use of sunblock—ultraviolet light may exacerbate lesions (PF and PE).

PEMPHIGUS (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

PF

Corticosteroids—Dogs

• Prednisone or prednisolone 2 mg/kg/day PO divided q12h to initiate control. An attempt to reduce this dose should be made when the disease undergoes remission. • Minimum maintenance—0.5 mg/kg PO q48h to twice weekly. • High pulse therapy—10 mg/kg once daily for 3 consecutive days, followed by standard dosage (<2 mg/kg/day). Pulses can be repeated if new lesions continue to appear in spite of the lower doses. Pulse should not be repeated more than once weekly.

Corticosteroids—Cats

• Prednisolone—2 mg/kg/day until clinical resolution. Majority of cats achieve disease control with corticosteroids monotherapy.

Cytotoxic Agents

• Most patients require additional immunomodulating drugs. • Work synergistically with corticosteroids to allow reduction in dose and side effects. • Azathioprine 1.5–2.5 mg/kg PO q24h, then q48h. Recommended for canine cases that fail to achieve adequate control with glucocorticoids alone (dogs only; potential for marked bone marrow suppression in cats). • Chlorambucil 0.1–0.2 mg/kg every other day; best option for cats with disease control that is not achieved with corticosteroid monotherapy. • Cyclosporine 5–10 mg/kg PO q24h; variable efficacy in dogs and cats. • Mycophenolate mofetil 10–20 mg/kg twice daily.

PE

• Oral prednisone or prednisolone 1.1 mg/kg PO q24h; then q48h; then to the lowest maintenance dose possible; may be stopped when in remission. • Topical steroids may be sufficient in mild cases. • Topical tacrolimus.

PV

• Aggressive therapy with corticosteroids and azathioprine or chlorambucil + systemic antibiotic therapy.

PP

• Aggressive therapy with corticosteroids and azathioprine or chlorambucil + systemic antibiotic therapy. • Identification and treatment or removal of underlying neoplasia.

PEP/PVeg

• Treatment similar to PF. • Response more variable; some patients may achieve remission with conservative treatment.

PRECAUTIONS

• Corticosteroids—polyuria, polydipsia, polyphagia, temperament changes, diabetes mellitus, pancreatitis, and hepatotoxicity. • Azathioprine—pancreatitis, bone marrow suppression. • Cytotoxic drugs—leukopenia, thrombocytopenia, nephrotoxicity, hepatotoxicity, and gastrointestinal upset. • Immunosuppression—can predispose animal to demodicosis, cutaneous and systemic bacterial and fungal infection.

ALTERNATIVE DRUG(S)

Alternative Corticosteroids

• Use instead of prednisone if undesirable side effects or poor response noted. • Methylprednisolone 0.8–1.5 mg/kg PO q12h; for patients that tolerate prednisone poorly. • Triamcinolone or dexamethasone 0.2–0.3 mg/kg PO q12h; then 0.05–0.1 mg/kg q48–72h.

Topical Steroids

• Hydrocortisone cream. • Potent topical corticosteroids—0.1% betamethasone valerate, fluocinolone acetonide, or 0.1% triamcinolone; q12h; then q24–48h.

Miscellaneous

• PE cases—doxycycline 5 mg/kg twice daily and niacinamide 500 mg twice daily for dogs >10 kg; 250 mg for dogs <10 kg.

FOLLOW-UP

PATIENT MONITORING

• Monitor response to therapy. • Monitor for medication side effects—routine hematology and serum biochemistry, especially patients on high doses of corticosteroids and cytotoxic drugs; check every 1–3 weeks, then every 1–3 months when in remission.

EXPECTED COURSE AND PROGNOSIS

PV and PF

• Dogs—poor (PV/PP) to fair (PF/PEP): life-long or long-term therapy with corticosteroids and cytotoxic drugs usually needed; good (PE): relatively benign and self-limiting. • Cats—good (PF), but long-term treatment required, tendency to relapse spontaneously or with treatment changes. • Regular monitoring necessary. • Side effects of medications may affect quality of life. • May be fatal if untreated (especially PV). • Secondary infections cause morbidity and possible mortality (especially PV).

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Avoid steroids and cytotoxic drugs during pregnancy.

ABBREVIATIONS

• DLE = discoid lupus erythematosus.
• PE = pemphigus erythematosus.
• PEP/PVeg = panepidermal pustular pemphigus/pemphigus vegetans.
• PF = pemphigus foliaceus.
• PP = paraneoplastic pemphigus.
• PV = pemphigus vulgaris.

PERIANAL FISTULA

BASICS

OVERVIEW
Chronic inflammatory condition characterized by multiple, painful, progressive, ulcerating sinuses or, less frequently, true fistulous tracts involving the perianal region.

SIGNALMENT
• Dog. • German shepherd dogs primarily; Irish setters. • Mean age 5–7 years; range 7 months–14 years. • Males more commonly affected.

SIGNS
• Dyschezia. • Tenesmus. • Hematochezia. • Constipation. • Diarrhea. • Malodorous mucopurulent anal discharge. • Ulceration of the perianal skin with sinus tract formation. • Licking and self-mutilation. • Reluctance to sit; posturing difficulties; personality changes. • Pain on manipulation of tail and examination of perianal area. • Fecal incontinence. • Anorexia. • Weight loss.

CAUSES & RISK FACTORS
• Multifactorial immune-mediated mechanism is suspected. • Appears to be an inappropriate T-cell mediated response. • An association with colitis has also been proposed, particularly in German shepherd dogs. • A genetic predisposition has been proposed but not proven. • Low tail carriage and a broad-based tail may contribute in German shepherd dogs. • High density of apocrine sweat glands in the cutaneous zone of the anal canal of German shepherd dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other inflammatory processes—e.g., anusitis, hydradenitis suppurativa. • Chronic anal sac abscess. • Perianal adenoma or adenocarcinoma with ulceration and drainage. • Squamous cell carcinoma. • Atypical bacterial infection. • Oomycosis. • Rectal fistula.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually unremarkable. • May have an inflammatory leukogram.

DIAGNOSTIC PROCEDURES
• Presumptive diagnosis—clinical signs and physical examination. • Definitive diagnosis—biopsy of the affected area. • Colonoscopy with biopsy—may reveal associated colitis.

TREATMENT
• Outpatient medical therapy recommended initially in all cases. • Clipping and cleaning the perianal area facilitates local therapy. • Bathing with an antimicrobial shampoo may be helpful. • Dietary modification—strictly enforced hydrolyzed or novel protein elimination diet. • Stool softeners—with pain or tenesmus. • Surgery is considered for patients with incomplete resolution following appropriate medical therapy. • Anal sacculectomy—if anal sac involvement. • Surgical options—resection of inflammatory tissue and/or ablation of remaining sinuses with carbon dioxide laser is preferred. • Surgical debridement (deroofing) with fulguration by chemical cautery or electrocautery; surgical resection followed by primary closure or second intention healing are other options. • Radical excision of the rectal ring with modified rectal pull-through is rarely necessary and is associated with a higher risk of fecal incontinence.

MEDICATIONS

DRUG(S) OF CHOICE
• Cyclosporine (CsA) ± ketoconazole is treatment of choice but is expensive. Ketaconazole reduces dose of cyclosporine required by inhibiting CsA-metabolizing enzymes: ○ Give CsA orally at 1–5 mg/kg/day PO and ketoconazole at 5–10 mg/kg/day PO and then taper CsA as clinical signs resolve. ○ Continue treatment at least 4 weeks after complete resolution of fistula(e). Many patients require chronic treatment at reduced frequency to prevent recurrence. • Tacrolimus (0.1% ointment) topically as maintenance therapy may be sufficient to control lesions; begin application as dose of oral medications is reduced: ○ Apply q12h with gloved hand, then taper to q24–72h. • Oral prednisone and topical tacrolimus appears to be efficacious and economical in less severe cases: ○ Prednisone 2 mg/kg PO q24h for 2 weeks, decrease to 1 mg/kg q24h for 4 weeks and then 1 mg/kg q48h for 10 weeks. ○ Tacrolimus 0.1% ointment as above. ○ Chronic maintenance therapy with tacrolimus and possibly prednisone likely necessary for long-term control. • Azathioprine alone or combined with prednisone is another treatment option.

ALTERNATIVE DRUG(S)
• Analgesics may be necessary. • Metronidazole 10 mg/kg q12h for 2 weeks at initiation of therapy to control secondary infection.

FOLLOW-UP

PATIENT MONITORING
• Assess CsA trough levels if improvement is not seen or if toxicity is suspected. • Reexamine to assess healing, signs of recurrence, and associated complications.

POSSIBLE COMPLICATIONS
• Reversible alopecia. • Vomiting, diarrhea, anorexia. • Weight loss. • Recurrence. • Failure to heal. • Surgical dehiscence. • Tenesmus. • Fecal incontinence. • Anal stricture. • Flatulence. • Iatrogenic Cushing's disease from corticosteroids. • Gingival hyperplasia from CsA.

EXPECTED COURSE AND PROGNOSIS
• Guarded for complete resolution except in mildly affected patients. • Chronic treatment may be necessary.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Colitis. • Constipation and/or obstipation may develop.

ABBREVIATIONS
• CsA = cyclosporine.

PERICARDIAL DISEASE

BASICS

DEFINITION
Pericardial diseases include pericardial effusion (PE), constrictive pericardial disease, and space-occupying entities in the pericardial space. PE can be defined as an abnormally high volume of fluid within the pericardial sac; cardiac tamponade refers to the clinical syndrome that results from reduced cardiac output due to mechanical compression of the heart. Constrictive pericardial disease results when a markedly thickened and fibrotic pericardium limits the diastolic filling of the heart. Examples of space-occupying pericardial disease can include large masses in the pericardial space and peritoneopericardial diaphragmatic hernia (PPDH).

PATHOPHYSIOLOGY
- All pericardial diseases cause diastolic dysfunction, resulting in elevation and equalization of ventricular and venous pressures and reduced cardiac output.
- Accumulation of effusion exceeds the elastic capabilities of the pericardial sac, resulting in elevated intrapericardial pressure. Cardiac tamponade occurs when intrapericardial pressure exceeds cardiac diastolic filling pressures. The compliant right atrium and right ventricle normally have the lowest filling pressures and are thus predominantly affected. Cardiac tamponade is present when intrapericardial pressures exceed the central venous pressure. The resultant reduction in cardiac venous return diminishes cardiac output. Animals with acute effusions typically exhibit signs of weakness or collapse. If intrapericardial pressure exceeds central venous pressure continuously for more than a few minutes, death occurs.
- Constrictive pericardial disease directly restricts diastolic filling, causes dissociation of intracardiac and intrathoracic pressures and increases interventricular interdependence.
- In animals with chronic pericardial disease, low cardiac output activates compensatory mechanisms that lead to fluid accumulation, typically manifested as right-sided congestive heart failure (CHF).

SYSTEMS AFFECTED
- Cardiovascular—signs of low cardiac output and CHF.
- Hepatobiliary—chronic passive congestion with mildly to moderately high liver enzymes.
- Renal/urologic—prerenal azotemia.
- Respiratory—tachypnea or pleural effusion.
- Gastrointestinal—vomiting seen in some cases.

GENETICS
N/A

INCIDENCE/PREVALENCE
Pericardial disorders comprise approximately 4–8% of the canine cardiology caseload at referral institutions.

GEOGRAPHIC DISTRIBUTION
Worldwide distribution; increased incidence of coccidioidomycosis-induced effusive constrictive pericarditis in the southwestern United States, Mexico, and Central and South America.

SIGNALMENT
Species
Dog; PE in cat is often secondary to CHF.

Breed Predilections
- Golden retrievers and German shepherd dogs are predisposed to both right atrial hemangiosarcoma (HSA) and idiopathic effusion.
- Brachycephalic breeds are predisposed to aortic body tumors (chemodectoma common in Boston terrier, boxer and bulldogs).
- Idiopathic hemorrhagic pericarditis is more common in young to middle-aged, large-breed dogs (e.g., Great Pyrenees, Great Dane, Saint Bernard, golden retriever).

Mean Age and Range
Middle-aged to older dogs.

Predominant Sex
Male dogs may be predisposed to idiopathic effusion.

SIGNS
General Comments
Chronic PE often causes jugular distension and ascites without a murmur. Acute cardiac tamponade often results in collapse and signs of low cardiac output.

Historical Findings
- Lethargy.
- Anorexia.
- Weakness.
- Exercise intolerance.
- Abdominal distension.
- Respiratory distress; occasionally cough.
- Syncope or collapse.
- Vomiting.

Physical Examination Findings
- Jugular vein distension.
- Ascites (especially with chronic effusion).
- Muffled heart sounds.
- Weak arterial pulses.
- Pulsus paradoxus.
- Pallor or slow capillary refill time.
- Tachypnea and/or tachycardia.

CAUSES
- Neoplasia—HSA, heart base tumor, thyroid adenoma/carcinoma, mesothelioma, metastatic neoplasia, and lymphosarcoma (LSA) (especially cats).
- Idiopathic—pericarditis (benign hemorrhagic effusion vs. effusive constrictive pericarditis with pericardial fibrosis).
- Coagulopathy—anticoagulant rodenticide toxicity, other coagulopathies.
- CHF (especially cats).
- Infection—feline infectious peritonitis (FIP), coccidioidomycosis, bacterial pericarditis.
- Congenital disorders—PPDH, intrapericardial cysts.
- Left atrial tear or cardiac trauma.
- Pericardial foreign body.

RISK FACTORS
- Cardiac neoplasia.
- Advanced myxomatous mitral valve disease.
- Coagulopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- CHF secondary to other causes (e.g., valvular disease, cardiomyopathy, congenital heart disease such as tricuspid valve dysplasia, myocarditis), hepatic failure, abdominal neoplasia with hemorrhage, protein-losing nephropathy or enteropathy, Budd–Chiari-like syndrome.
- Other causes of ascites (e.g., hepatic failure, hypoproteinemia, intraabdominal neoplasia, and hemorrhage)—characteristically result in remarkable abnormalities on CBC and biochemistry profile, with a lack of jugular venous distension.
- Other causes of collapse and shock with low cardiac output signs such as sepsis, trauma, cardiac arrhythmias, blood loss and tension pneumothorax.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC—usually normal; anemia possible with HSA, LSA, or coagulopathy; red cell morphology may be abnormal; may see thrombocytopenia with neoplasia or disseminated intravascular coagulation (DIC).
- Biochemistry profile—often normal; may see mild to moderately elevated liver enzymes (hepatic congestion), mild azotemia (typically prerenal), hypoproteinemia, and mild electrolyte abnormalities (e.g., hyponatremia, hypochloremia, and hyperkalemia).
- Urinalysis—usually normal unless diuretics administered.

OTHER LABORATORY TESTS
- Elevated serum cardiac troponin I demonstrated in dogs with PE, especially with HSA.
- Clotting times (e.g., activated partial thromboplastin time and one-stage prothrombin time)—prolonged with anticoagulant rodenticide toxicity or DIC.

• Pericardial fluid analysis, although limited in diagnostic sensitivity and specificity, may be helpful in identifying certain neoplastic etiologies (e.g., LSA) or infectious causes.
• FIP testing or feline leukemia virus testing may be useful in cats.

IMAGING

Thoracic Radiography

• Mild-to-severe cardiomegaly; cardiac silhouette often globoid with very sharp edges most evident on the dorsoventral view due to lack of cardiac motion artifact. Cardiac size sometimes normal.
• Pleural effusion in some patients.
• Ascites in many patients.
• Large caudal vena cava in some patients.
• May see nodular pulmonary infiltrates with metastatic neoplasia.

Echocardiography

• Ideally prior to pericardiocentesis in stable patients to facilitate detection of intrapericardial masses.
• Superior diagnostic test to diagnose PE and evaluate for a cardiac mass (depends on operator skill); only moderate accuracy in predicting histopathologic diagnosis of masses.
• Echo-free space between the parietal pericardium and the epicardium.
• Often demonstrates the cause of PE in patients with neoplasia (e.g. right atrial HSA or heart base tumor) or PPDH.
• Left atrial rupture suspected based on concurrent findings of PE and advanced chronic valvular disease, especially if an intra-atrial or intra-pericardial thrombus is visualized.
• Diastolic collapse of the right atrium or ventricle indicates cardiac tamponade.

Advanced Imaging

Cardiac MRI has not been found to be superior to echocardiography in detecting cardiac neoplasia to date; CT may be helpful in detecting pulmonary, hepatic, or splenic metastases.

DIAGNOSTIC PROCEDURES

ECG

• Often sinus tachycardia; occasionally ventricular or supraventricular arrhythmias.
• May see low-voltage QRS complexes (<0.9 mV in leads I, II, III, aVR, aVL, and aVF).
• May see ST segment elevation in leads II, aVF, V3.
• May see electrical alternans, a regular (1:1 or 2:1) variation in QRS-T wave height or morphology, due to swinging of the heart within the pericardial sac.

Pericardial Fluid Analysis

Cytology of PE cannot reliably differentiate the common neoplastic (e.g., HSA, chemodectoma, mesothelioma) and idiopathic causes of effusion. Cytology can identify or rule out some potential causes of effusion (e.g., LSA, FIP, sepsis). If an infectious agent is suspected, aerobic and anaerobic cultures of the effusion are indicated.

PATHOLOGIC FINDINGS

• Vary based on the underlying cause of pericardial disease.
• Small masses may be identified that were not visible on antemortem testing.
• Dogs with left atrial tears will have advanced mitral degeneration with thickened and irregular mitral and/or tricuspid valve leaflets, left atrial enlargement and endocardial jet lesions, and possible ruptured chordae tendineae.
• Mesothelioma can be difficult to differentiate from idiopathic pericardial disease in some dogs, even with histopathology.

TREATMENT

APPROPRIATE HEALTH CARE

Cardiac tamponade warrants immediate pericardiocentesis. Repeated pericardiocentesis may be needed; surgery may be indicated in selected dogs. Pericardiocentesis is rarely required in the cat.

Pericardiocentesis

• Sedation with low-dose narcotic may be appropriate, except if moribund. Patient may be placed in sternal or lateral recumbency. Clip haircoat on the right or left thorax between the 3rd and 8th intercostal spaces from above the costochondral junction ventrally to the sternum. Simultaneous ECG and/or echocardiographic monitoring is ideal to confirm the presence of the catheter tip in the pericardium and detect arrhythmias caused by the catheter contacting the heart. If echocardiography is not available, perform pericardiocentesis at the 5th intercostal space (at the palpable apex beat) below the costochondral junction. Following aseptic skin preparation and local anesthetic block of the skin, subcutaneous tissues and pleura with lidocaine, advance a long, large-bore (~14–18 gauge), preferably fenestrated, over-the-needle catheter into the pericardial sac. In dogs, PE is usually hemorrhagic, but some patients have a serous, serosanguinous, or purulent effusion. If echocardiography is available, removal and reinjection of approximately 1 mL of pericardial fluid causes visible spontaneous echo contrast to appear in the pericardial space, confirming catheter placement. Remove as much effusion as possible (unless active bleeding is suspected). If ventricular arrhythmias develop, reposition the catheter and be prepared to administer IV lidocaine.
• Unless the patient has active hemorrhage into the pericardial sac, the effusion obtained by pericardiocentesis should not clot, and should have a packed cell volume that differs from that of peripheral blood. The supernatant of chronic effusions is often xanthochromic.

NURSING CARE

Unless there is marked dehydration, fluids are generally not required or recommended for chronic PE. Mild volume expansion may be useful in some animals with acute PE and signs of cardiovascular collapse. Administer oxygen if tachypneic or signs of hemodynamic instability.

ACTIVITY

Cage rest for animals with cardiac tamponade, followed by exercise restriction after pericardiocentesis.

DIET

N/A

CLIENT EDUCATION

Inform that PE is typically recurrent in nature, though prognosis may vary greatly depending on the underlying cause. Educate about the importance for close monitoring for recurrent effusion and warn of the potential for sudden death.

SURGICAL CONSIDERATIONS

• Pericardiectomy may be useful in the treatment of recurrent cardiac tamponade for PE accompanying heart base tumors and prolongs survival; this may also be considered for palliation of right atrial HSA but whether it has any impact on survival is unknown.
• Idiopathic PE may respond to pericardiocentesis; pericardiectomy is indicated for recurrent effusion.
• Infectious pericarditis due to bacterial cause, and pericardial foreign bodies, is usually best treated surgically to avoid subsequent constrictive pericardial disease.
• Right auricular appendage masses may be treated surgically but resection alone without adjuvant chemotherapy is unlikely to significantly prolong survival.
• Thoracoscopy allows for partial pericardiectomy with reduced risk and reduced postoperative pain. However some surgeons believe that extensive pericardiectomy is preferred in cases of benign PE to avoid the possibility of recurrent pleural effusion.
• Constrictive pericardial disease is usually best treated surgically.
• PPDH is treated surgically when clinical signs referable to the defect are clearly present; the diagnosis is sometimes established incidentally and the need for surgery is uncertain.
• Radiation therapy may also play a role in management of pericardial disease due to certain neoplastic causes, although concerns exist about the development of radiation-induced cardiac injury or cardiac arrhythmias.

PERICARDIAL DISEASE (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE
- Drugs should not be used in place of pericardiocentesis.
- Vitamin K—indicated for patients with anticoagulant rodenticide intoxication.
- Appropriate antibiotics or antifungals are indicated with infectious pericarditis.
- Chemotherapy—may be useful to treat effusion caused by LSA; partially effective in the treatment of atrial HSA and generally ineffective for heart-base tumor; adjuvant doxorubicin-based chemotherapy following right atrial mass resection has been shown to increase survival times but dogs rarely survive more than 6 months postoperatively.
- In a double blind, randomized study in dogs with splenic HSA, a mushroom extract delayed the progression of metastases and afforded the longest survival times reported in canine HSA.
- Some clinicians use antifibrinolytic drug (aminocaproic or tranexamic acid) or other possible clot-stabilizing drugs (Yunnan Baiyao) in an attempt to reduce recurrent bleeding, although the efficacy of these compounds is uncertain.

CONTRAINDICATIONS
Diuretics may worsen tamponade by reducing circulating blood volume, and hence intracardiac pressures, and can lead to progressive azotemia, patient weakness and collapse. Digitalis, vasodilators, and angiotensin-converting enzyme inhibitors are reported to be relatively or absolutely contraindicated. Corticosteroids or other immunosuppressive drugs may exacerbate infection, if present.

PRECAUTIONS
N/A

ALTERNATIVE DRUG(S)
- Intracavitary chemotherapy may be attempted to treat mesothelioma, especially in cases with recurrent pleural effusion after pericardiectomy.
- Anti-inflammatory, immunosuppressive, or antifibrotic strategies have been tried in dogs with idiopathic PE (e.g., corticosteroids, nonsteroidal anti-inflammatory drugs, azothiaprine, or colchicine); efficacy of these strategies for preventing recurrent effusion is unknown.

FOLLOW-UP

PATIENT MONITORING
PE may recur at any stage; examination and echocardiography at 10–14 days and every 2–4 months recommended to detect recurrent idiopathic PE.

POSSIBLE COMPLICATIONS
- Hypotension or shock.
- Pneumothorax, arrhythmias, and myocardial perforation or coronary laceration secondary to pericardiocentesis.

EXPECTED COURSE AND PROGNOSIS
- Right atrial HSA—poor; tumor is highly malignant, usually not resectable at the time of diagnosis; may respond transiently to doxorubicin-based chemotherapy; the benefit of palliative pericardiectomy is unproven.
- Chemodectoma—fair; slow-growing tumor, late to metastasize; pericardiectomy often resolves clinical signs; may respond to chemotherapy or radiation therapy; survival of up to 3 years has been reported following pericardiectomy alone. Large masses sometimes cause compression of cardiovascular structures that might be resolved with IV stent placement.
- Prognosis is good with idiopathic PE; approximately 50% of cases resolve after one or two pericardiocenteses; pericardiectomy is often curative in persistent cases, although recurrent pleural effusion is seen in some dogs after surgery.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Splenic HSA.

AGE-RELATED FACTORS
- Idiopathic PE may be more common in middle-aged to elderly dogs.
- HSA and heart-base tumors more common in elderly dogs.

ZOONOTIC POTENTIAL
Coccidioidomycosis

SYNONYMS
- Cardiac tamponade.
- Pericardial tamponade.

PERINEAL HERNIA

BASICS

OVERVIEW
• Perineal hernia (PH) refers to a spectrum of disorders in which the pelvic diaphragm is weakened, with rupture or atrophy of the muscles. Rectal sacculation and dilation often occur. This results in abnormal function during defecation and, if left untreated, leads to herniation of pelvic and abdominal viscera.
• Weakening of the pelvic diaphragm in male dogs is postulated to result from hormonal influences and by increased pressure secondary to enlargement of the prostate.
• Separation of the perineal muscles (levator ani and coccygeus) from the external anal sphincter (EAS) and rectum allows lateral and ventral bulging and sacculation of the rectum when caudal abdominal pressure increases during defecation. Feces become entrapped within the sacculated rectum, contributing to the uncoordinated defecation often presented in patients with PH. Separation and weakening of the muscles also allows pelvic and abdominal viscera to migrate caudally, enter the hernia sac, and eventually become incarcerated or strangulated.

SIGNALMENT
Intact male dogs are at highest risk. The disease occurs rarely in castrated male dogs, female dogs, and cats.

SIGNS
• Constipation is the main feature, although some patients present with diarrhea as looser stool escapes around the firmer stool.
• Unilateral or bilateral perineal bulge due to fecal impaction and/or herniation:
  ◦ May be dynamic or static.
  ◦ May become more obvious during events of increased intra-abdominal pressure—barking, coughing, defecation, and urination.
  ◦ Often the only presenting sign in cats.
• Straining to urinate if bladder incarceration occurs.

CAUSES & RISK FACTORS
• Intact status in older male dogs and male dogs with unilateral or bilateral cryptorchidism.
• Underlying pathology leading to excessive straining:
  ◦ Prostatomegaly in male dogs.
  ◦ Megacolon and malunion of pelvic fractures in cats.
• Caudal neuropathy, malformation or injury such as tail traction or avulsion.
• Trauma (rare).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other causes of straining during defecation or urination include perineal or intrapelvic mass:
  ◦ Neoplasia (adenoma, lipoma, adenocarcinoma, sarcoma).
  ◦ Sublumbar lymphadenomegaly secondary to anal sac adenocarcinoma.
  ◦ Rectal tumor.
  ◦ Paraprostatic cyst or abscess.
  ◦ Perineal abscess (e.g., anal sac).

CBC/BIOCHEMISTRY/URINALYSIS
No specific abnormalities. Azotemia if urinary obstruction occurs.

OTHER LABORATORY TESTS
N/A

IMAGING
• Abdominal radiography—evaluate constipation or obstipation, prostatomegaly, sublumbar lymphadenomegaly, location of urinary bladder and prostate, and megacolon in cats.
• Pelvic radiography—evaluate pelvic fracture malunion, intrapelvic mass, caudal displacement of the prostate and bladder, entrapment of bladder or bowel in hernia.
• Abdominal ultrasonography—evaluate the size and consistency of the prostate, location of urinary bladder and prostate, intrapelvic or caudal abdominal masses, sublumbar lymphadenomegaly, presence of abdominal cryptorchid testicle.
• Perineal ultrasonography—evaluate presence of abdominal viscera or masses.

DIAGNOSTIC PROCEDURES
• Visual perianal examination:
  ◦ Normally the anus and EAS are held in position dorsal and slightly cranial to the caudal extent of the tuber ischii.
  ◦ When the perineal diaphragm is weakened, the anus migrates caudally. May be severe in bilateral PH.
  ◦ Eliciting a cough reflex by gentle tracheal palpation will increase intra-abdominal pressure and aid evaluation of the position and movement of the anus.
• Rectal examination:
  ◦ Confirm accumulation of feces in the dilated and sacculated rectum and perineal laxity.
  ◦ If the integrity of the pelvic diaphragm has been compromised, it will be possible to pinch the rectal mucosa and skin together between the tip of the forefinger and thumb without palpating a muscle shelf in between.
  ◦ Evaluate both sides; bilateral PH is common especially in intact male dogs.
• Endoscopy or percutaneous fine-needle aspiration biopsy may be indicated if a mass lesion is present extra- or intraluminally.

TREATMENT
• Surgical management required for definitive treatment:
  ◦ Emergency if bladder retroflexion and entrapment, or intestinal entrapment have occurred.
• Conservative treatment may temporarily ameliorate clinical signs:
  ◦ Low residue diet.
  ◦ Stool softeners.

Nursing Care
• IV fluid therapy in the pre- and post-operative period.
• Incisional icing postoperatively.
• Elizabethan collar postoperatively.

Activity
Restrict for at least 3–4 weeks following surgical repair.

Diet
• Low-residue canned diet:
  ◦ Part of conservative medical management.
  ◦ Postoperatively.

Client Education
N/A

Surgical Considerations
• Castration of male dogs should always be performed simultaneously with herniorrhaphy, due to the high rate of recurrence in intact dogs regardless of surgical technique used.
• In patients with bladder retroflexion and entrapment, the urethra should be catheterized, and the bladder decompressed if possible:
  ◦ Percutaneous perineal cystocentesis may be required to decompress and reposition the bladder before a urethral catheter can be passed.
  ◦ If the bladder is able to be decompressed, correction of biochemical abnormalities is preferred prior to anesthesia and surgery in the urinary obstruction patient with PH.
• Prior to surgical correction, the author prefers the use of an epidural with local anesthetic and/or morphine.
• Impacted feces should be gently removed from the rectum prior to surgery:
  ◦ Enemas are not recommended as liquid feces may not be completely evacuated, leading to excessive contamination during surgery and postoperatively.
• Primary repair of the weakened muscles alone often leads to recurrence and is not recommended as the only form of repair.
• The internal obturator muscle flap is the preferred local method of repair combined with primary bolstering of the perineal musculature. The author prefers to repair both sides of the pelvic diaphragm regardless of the unilateral nature of the hernia.
• It may be helpful in large dogs with large bilateral hernias, especially if bladder

PERINEAL HERNIA (CONTINUED)

retroflexion or visceral entrapment, to perform exploratory laparotomy, reposition the bladder and rectum, and perform incisional colopexy and cystopexy:
  - Herniorrhaphy can be performed at a later time (2–7 days), when the patient's condition has stabilized and the perineal edema has resolved.
  - In patients with poor perineal muscle development and in patients with large defects, the repair is often bolstered with the use of secondary local muscle flaps.
  - Absorbable and nonabsorbable mesh implants are needed in some severe cases.
  - A superficial gluteal muscle flap is recommended in cats and very small dogs to bolster the internal obturator muscle flap and primary repair techniques.

MEDICATIONS

DRUG(S) OF CHOICE

- Stool softeners may be considered as a component of conservative medical management or prior to surgery:
  - Lactulose 0.5–1 mL/kg PO q8–12h, adjusted to effect.
  - PEG 3350 (MiraLax®) ¼–1 tsp on food q12h, adjusted to effect.
  - Goal is 2–3 soft-formed stools per day.
- Intraoperative antibiotics may be given, but there is no indication to continue antibiotic treatment postoperatively unless significant contamination occurs during surgery.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid stool softeners postoperatively, as they may lead to diarrhea and fecal soiling in the first days after surgery, especially if a bilateral repair has been performed.

FOLLOW-UP

PATIENT MONITORING

- The patient should be evaluated frequently for the first 48 hours following surgery, with particular attention paid to urination and defecation regardless if bladder entrapment was present preoperatively.
- A rectal examination should be performed at the time of suture removal (10–14 days) if feasible.

PREVENTION/AVOIDANCE

- Castration.
- Address conditions causing straining during defecation and urination, if present.

POSSIBLE COMPLICATIONS

- Constipation, obstipation, and bladder retroflexion/obstruction, visceral entrapment, and strangulation.
- Postoperative complications include recurrence (greatly reduced by castration and use of internal obturator flap), and temporary or permanent dysfunction of the anal sphincter due to stretching following bilateral herniorrhaphy:
  - Fecal and urinary incontinence can occur if excessive dissection around the pudendal nerve, caudal rectal nerve, or peritoneal reflections are performed.

EXPECTED COURSE AND PROGNOSIS

- Excellent with surgery.
- There is a 10–50% risk of recurrence depending on presence of underlying conditions, surgical technique, and reproductive status of the dog.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Primary conditions causing excessive straining (e.g., megacolon in cats).

ABBREVIATIONS

- EAS = external anal sphincter.
- PH = perineal hernia.

PERIODONTAL DISEASE

BASICS

DEFINITION
Inflammation and destruction of the periodontium (i.e., gingiva, cementum, periodontal ligament, and alveolar bone) secondary to the subgingival biofilm of bacteria.

PATHOPHYSIOLOGY
A pellicle of salivary glycoproteins adheres to the clean tooth and first colonizing Gram-positive aerobic bacteria attach; the plaque biofilm is created. The supragingival plaque biofilm matures and influences the development of the subgingival biofilm. The constituents of the biofilm progress to Gram-negative anaerobic, motile, and spirochete bacteria. Bacterial byproducts and proteolytic enzymes with the host inflammatory response cause destruction of the periodontium, resulting in the loss of attachment for the tooth. The biofilm forms within days. Calculus is the mineralization of plaque. It is rough, acts a surface area for more plaque development, and can be mechanically irritating to the tissues.

SYSTEMS AFFECTED
Gastrointestinal—oral cavity/dentition (primary); systemic inflammation/distant organ changes.

GENETICS
N/A

INCIDENCE/PREVALENCE
Common—estimated to be around 85%.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Toy, brachycephalic, sighthounds, long-facial haired, and purebred cats.

Mean Age and Range
Begins as juvenile and progresses through life.

Predominant Sex
None

SIGNS

Historical Findings
Hidden/no clinical signs to halitosis, head shyness, oral bleeding, dropping food, reluctance to chew, pawing at the mouth, exaggerated jaw movements, face rubbing, maxillofacial swellings, ptyalism, sneezing, and nasal discharge.

Physical Examination Findings
• Conscious examination—inflammation of the gingiva, plaque and/or calculus, root exposure, furcation exposure, mobile teeth, parulides, disproportionate plaque and calculus distribution, oral discharge, maxillofacial swellings, and mandibular lymphadenopathy. The conscious examination significantly underestimates the presence and severity of PD and therefore an anesthetized examination with periodontal probing and intraoral radiographs is required for complete assessment. • Anesthetized examination—the degree of severity of periodontal disease relates to a single tooth. • American Veterinary Dental College (AVDC) nomenclature: ◦ Normal (PD 0)—clinically normal; no gingival inflammation or periodontitis clinically evident. ◦ Stage 1 (PD 1)—gingivitis only without attachment loss. The height and architecture of the alveolar margin are normal. ◦ Stage 2 (PD 2)—early periodontitis; less than 25% of attachment loss,* or at most, there is a Stage 1 furcation involvement in multirooted teeth. ◦ Stage 3 (PD 3)—moderate periodontitis; 25–50% of attachment loss*, and/or there is a Stage 2 furcation involvement in multirooted teeth. ◦ Stage 4 (PD 4)—advanced periodontitis; more than 50% of attachment loss* or there is a Stage 3 furcation involvement in multirooted teeth. Furcation indices subjectively measure when the periodontal probe extends less than half way between the roots (F1), extends greater than half way (F2), or through and through from one side of the furcation and out the other under the crown (F3).

*Periodontal attachment loss is measured by probing of the clinical attachment level and radiographic determination of the distance of the alveolar margin from the tooth's cementoenamel junction relative to the length of the root.

CAUSES
Bacterial plaque biofilm and associated host inflammatory response.

RISK FACTORS
Lack of daily preventive home care and professional veterinary dental care, signalment, systemic health (e.g., immunosuppression from pharmaceuticals or metabolic disease), inappropriate chewing behavior, malocclusions, crowding of dentition, oral foreign bodies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Oral neoplasia, drug-associated gingival enlargement (e.g., cyclosporine, amlodipine), oral autoimmune inflammatory conditions, viral ulcerative gingivitis/mucositis (e.g., calicivirus), oral trauma and foreign bodies, rare fungal. Clinical history, imaging (i.e., intraoral radiographs and/or advanced imaging), and histopathology for differentiation.

CBC/BIOCHEMISTRY/URINALYSIS
Overall systemic/metabolic health status and for preparation for anesthesia.

OTHER LABORATORY TESTS
N/A

IMAGING
• Intraoral radiography—required diagnostic instrument to assess attachment loss, to include marginal bone loss, loss of the lamina dura, widening of the periodontal ligament space, horizontal and vertical bone loss, inflammatory resorption of the tooth root surface, furcation bone loss, combined patterns of bone loss. Horizontal bone loss is a pattern where the cortical and alveolar bone surrounding the tooth and adjacent teeth are lost at a similar rate; the periodontal pocket is above the bone (i.e., suprabony pocket). Vertical bone loss is a pattern where there is bone loss around a tooth root where the adjacent supporting bone remains more coronal; the periodontal pocket is within the bone (i.e., infra(intra) bony pocket).
• Osteopermeative patterns mimicking neoplasia can be present in severe cases. Osteitis secondary to the inflammation may result in paradoxical proliferation of bone.
• Cone-beam CT has been reported to be of additional valuable in assessing periodontal attachment loss in brachycephalic breeds.

DIAGNOSTIC PROCEDURES
• Periodontal probing—the distance between free gingival margin and apical extent of the sulcus or pocket; probing depths <3 mm in dogs and <1 mm in cats are considered normal gingival sulcus; variations based on the range of breed sizes in dogs. • Measurement of root exposure, furcation exposures and tooth mobility are recorded. • Clinical probing information and intraoral radiographic assessment are used to assign periodontal score to each tooth (PD0–PD4).

PATHOLOGIC FINDINGS
Tissues may be edematous, exhibit gingival hyperplasia/enlargement, exocytosis of inflammatory cells such as lymphocytes, plasma cells, and polymorphonuclear leukocytes, abundant colonies of bacterial microorganisms, areas of fibrosis, edema, and hemorrhage; bone may demonstrate infiltration of inflammatory cells, and resorption with both osteoclastic and osteoblastic activity. Osteomyelitis/osteitis can result.

TREATMENT

APPROPRIATE HEALTH CARE
• Prevention of PD with daily home care and annual preventive cleaning, starting in first 1–2 years of life; oral examinations and

PERIODONTAL DISEASE (CONTINUED)

periodontal treatments before excessive attachment loss. • Daily home care prevention should begin the first year of life. Daily tooth brushing is the best daily home care prevention. • Annual or semi-annual evaluations and periodontal cleanings/"prophylaxis" and treatment based on the patient signalment and progressive PD stage status. • Client communication and education throughout all patient life stages.

NURSING CARE
Acute-on-chronic periodontal abscessation—nonsteroidal anti-inflammatory medications, if not contraindicated; analgesia and appropriate antibiotic selection pending scheduling for anesthesia, assessment, and treatment.

ACTIVITY
No restrictions.

DIET
Dental diets with fiber arrangements and/or added dental products added for patients without other dietary restrictions, or needs, and who have teeth remaining to chew.

CLIENT EDUCATION
Daily home care, the necessity of general anesthesia, and the lifelong prevention, management, and treatment of PD.

SURGICAL CONSIDERATIONS
• Remove the plaque biofilm and calculus, eliminate periodontal pocket(s), prevent further attachment loss, extract hopelessly compromised teeth, address contributing dental factors, and treat oral/dental pain. Individualized general anesthetic management. • Periodontal surgery including, but not limited to, gingivectomy/gingivoplasty, periceutical treatment, closed root planing, open root planing, periodontal flaps, osseous resective surgery, osseous additive surgery including bone augmentation and guided tissue regeneration. Plans are based on PD stage, tooth/teeth involved, overall systemic health of the patient, ability for home care, ability to have further follow-up treatments and anesthetic procedures, and overall financial aspects for the client with the goal to have a pain- and infection-free oral cavity.

MEDICATIONS

DRUG(S) OF CHOICE
Systemic use of antimicrobials is *not* indicated in the treatment of PD without surgical attention to the underlying cause. Clindamycin, amoxicillin/clavulanic acid, and doxycycline may be chosen to augment periodontal surgical treatment. Metronidazole may be selected based on clinical findings and patient history.

CONTRAINDICATIONS
• Immunosuppressive drugs in untreated PD can cause acute-on-chronic exacerbations.
• Chronic use of bisphosphonates should be avoided unless the oral cavity and dentition have all active infection and inflammation treated.

PRECAUTIONS
Prolonged/increased dosages of immunosuppressive medications may contribute to acute on chronic exacerbations.

POSSIBLE INTERACTIONS
Oral chlorhexidine and oral fluoride inactivate with simultaneous use.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
The diagnosed PD stage guides the recheck interval; evaluation every 3–12 months.

PREVENTION/AVOIDANCE
Daily tooth brushing with pet toothpaste mechanically removes the supragingival plaque biofilm. Oral 0.1–0.12% chlorhexidine products target oral bacteria involved in the plaque biofilm. Dental diets, dental chews, barriers sealants, dental wipes, dental enzyme systems, dental gels, and water additives can be a part of a dental home care program based on individual patient and client needs. The Veterinary Oral Health Council can help guide selection of pet dental products.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
Due to the multifactorial aspect of PD and individual patient response, the expected course and prognosis can be variable, but predicable with appropriate treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Progresses with age; Adult-onset periodontitis is most common; juvenile and aggressive forms of periodontitis occur.

ZOONOTIC POTENTIAL
Capnocytophaga spp. may cause serious opportunistic infections in immunosuppressed humans; *Pasteurella multocida* may cause severe infections in humans following cat bites. Scientific developments in the study of oral microbiomes suggest transmission/sharing of oral bacteria can occur between species.

PREGNANCY/FERTILITY/BREEDING

PERIPHERAL EDEMA

BASICS

DEFINITION
Edema is focal or diffuse excessive accumulation of tissue fluid within the interstitium; often at gravitative surfaces, whether localized or generalized.

PATHOPHYSIOLOGY
• High capillary hydrostatic pressure. • Increased capillary permeability. • Lymphatic drainage abnormality. • Low plasma colloid osmotic pressure.

SYSTEMS AFFECTED
• Musculoskeletal. • Skin/exocrine.

GENETICS
• Dominantly inherited primary lymphedema has been described in poodles. • Lethal congenital edema has been documented in bulldogs.

INCIDENCE/PREVALENCE
Variable

GEOGRAPHIC DISTRIBUTION
Pertinent when considering infectious disease mechanisms.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Primary or congenital lymphedema has been reported in bulldogs, poodles, Old English sheepdogs, Labradors, and myriad other canine breeds as well as cats.

SIGNS

Historical Findings
• Allergic or other immune, cardiac, hepatic, or other organic disease. • Trauma. • Exposure to infectious or toxic (venomous) agents such as ticks or other arachnids.

Physical Examination Findings
• Unexplained weight gain may be noted initially; otherwise, early detection is unlikely. • Noninflammatory subcutaneous edema is often first recognized at the dependent thorax, abdomen, or distal limbs. • Inflammatory edema may be noted in nondependent foci of the interstitium.

CAUSES

Localized or Single-Limb Edema
• High capillary hydrostatic pressure. • Venous or arterial obstruction (e.g., thrombosis or postcaval syndrome). • Arteriovenous fistula. • Increased capillary permeability. • Focal or multifocal immune, infectious, or toxic (chemical or biologic) insults (e.g., snake bite or bee sting). • Trauma. • Burns. • Lymphatic obstruction. • Sterile (juvenile pyoderma) or infectious lymphangitis. • Primary or metastatic neoplastic invasion of lymphatic tissue. • Congenital aplasia or dysgenesis of the lymphatic system.

Regional or Generalized Edema
• High capillary hydrostatic pressure. • Congestive heart failure (CHF). • Cardiac tamponade. • Cranial or caudal vena caval thrombosis. • Renal failure and hypernatremia (salt retention). • Paralysis or prolonged recumbency with subsequent failure of the venous pump. • Tourniquet effect of a bandage. • Increased capillary permeability. • Systemic immune, infectious, or toxic insults (e.g., sepsis or vasculitis). • Lymphatic abnormalities. • Acquired regional traumatic, immune, infectious, or neoplastic process. • Congenital aplasia or other lymphatic dysgenesis. • Low plasma colloid osmotic pressure. • Protein-losing disease (e.g., nephrotic syndrome or intestinal lymphangiectasia). • Failure to produce protein (e.g., cirrhosis). • Exudative protein loss (e.g., severe burn).

RISK FACTORS
Variable

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Peripheral edema secondary to myxedema or inflammation is typically non-pitting. • Bilateral forelimb edema with jugular venous distention implies cranial vena caval syndrome. • Bilateral rear limb edema with or without ascites implies either hypoalbuminemia or caudal vena caval obstruction. • Fore and/or rear limb edema with jugular venous distension, hydrothorax, and/or ascites implies cardiac disease. • Focal edema with bruit and fremitus implies an arteriovenous fistula. • Focal edema with erythema may be secondary to an insect or other bite. • Multifocal or diffuse edema with petechiation and/or ecchymosis may be associated with a coagulopathy or vasculitis.

CBC/BIOCHEMISTRY/URINALYSIS
• Leukocytosis suggests inflammatory or infectious disease. • Thrombocytopenia may be secondary to vasculitis (e.g., Rocky Mountain spotted fever [RMSF]), systemic lupus erythematosus, or a coagulopathy (e.g., disseminated intravascular coagulation [DIC]). • Panhypoproteinemia is consistent with gastrointestinal disease, but diarrhea is not an obligatory clinical sign. • Panhypoproteinemia and hypocholesterolemia are seen with intestinal lymphangiectasia. • Hypoalbuminemia may occur with hepatic failure. • Hypoalbuminemia with proteinuria suggests glomerular disease. • Hypoalbuminemia with proteinuria and hypercholesterolemia in an edematous patient defines nephrotic syndrome.

OTHER LABORATORY TESTS
• Antithrombin III assay indicated in conditions with albumin loss. • Further delineate thrombocytopenia with a bone marrow biopsy, antinuclear antibody, screen for *Ehrlichia* and RMSF, and a coagulation profile. • Panhypoproteinemia may dictate a need for intestinal biopsy. • Hypoalbuminemia may warrant liver function testing (e.g., bile acid test, hepatic biopsy). • Confirm proteinuria with a urine protein:creatinine ratio. • Bacterial and fungal cultures of blind fistulae may prove useful. • Fungal or other assays of infectious disease may be warranted; patient's primary residence and patient's travel history need to be considered. • Pleural or peritoneal fluid analysis is suggested, if effusion is present. • Low resting thyroid hormone (T_4) should be elaborated with a thyrotropin-releasing hormone stimulation test, free T_4 by equilibrium dialysis, or thyroid-stimulating hormone (TSH) concentration.

IMAGING
• Suspected heart disease necessitates thoracic radiographs and/or echocardiogram. • Angiography (e.g., venacavagram) may help to define a vascular obstruction. • Diagnostic ultrasound may help to delineate a vascular occlusion. • Thermography and perfusion scans (e.g., scintigraphy) are esoteric but have been used to diagnose occlusive vascular disease.

DIAGNOSTIC PROCEDURES
• Fine-needle aspiration of an affected area for cytology and culture may be helpful. • Biopsy and deep culture may help define an underlying cause for edema.

PATHOLOGIC FINDINGS
Depend on cause of the edema.

TREATMENT

APPROPRIATE HEALTH CARE
Depends on the cause of the edema and stability of the patient.

NURSING CARE
• Application of warm compresses is recommended for patients with edema secondary to infection. • Good nursing care required to prevent decubital ulceration in recumbent patients.

ACTIVITY
Depends on cause of edema—e.g., exercise restriction is recommended in patients with congestive heart failure.

PERIPHERAL EDEMA (CONTINUED)

DIET
Depends on the cause of edema—e.g., patients with protein-losing nephropathy require a restricted protein diet.

CLIENT EDUCATION
Depends on the cause of edema.

SURGICAL CONSIDERATIONS
• Surgery such as lymphangioplasty, thrombectomy, or lymphaticovenous shunt may be palliative. • Amputation of the edematous limb is sometimes indicated. • Arteriovenous fistulae may be treated by various surgical methods.

MEDICATIONS

DRUG(S) OF CHOICE
• Anaphylaxis—epinephrine (1 mg/mL) at 0.01 mL/kg IM or SC to a maximum of 0.02–0.05 mL; prednisone sodium succinate 10–30 mg/kg IV; antihistamines are of equivocal benefit once anaphylaxis ensues. • Lymphedema—benzopyrone use yields variable results in veterinary medicine; rutin 50 mg/kg PO q8h has been mixed with food for cats with chylothorax. • Cardiogenic edema—combinations of positive inotropes, vasodilators, and diuretics commonly used in patients with CHF. • Immune-mediated edema requires immunosuppressive therapy (e.g., prednisone). • Vasculitis and edema secondary to rickettsial disease typically responds to tetracycline 22 mg/kg PO q8h or doxycycline 5 mg/kg PO q12h. • Edema in association with other infectious agents requires antifungal therapy or antibiotic therapy. • Myxedema secondary to hypothyroidism should respond gradually to T_4 supplementation. • Edema associated with toxic insults may be slowed with antidotes (e.g., antivenom). • Anticoagulant therapy may benefit patients with DIC or antithrombin III deficiency. • Vascular volume expanders such as hydroxyethyl starch or plasma often benefit patients with low plasma oncotic pressure; very-low-dose furosemide in a constant-rate infusion of 0.1 mg/kg/h has been effective in conjunction with a volume expander.

CONTRAINDICATIONS
• Diuretics generally aggravate edema of noncardiogenic origin. • Steroids may worsen edema secondary to infectious disease. • Epinephrine—generally contraindicated in shock except in anaphylaxis. • Propranolol (beta-blocker)—contraindicated in patients predisposed to bronchospasm.

PRECAUTIONS
• Avoid intramuscular injections in patients with thrombocytopenia. • Taper patients on long-term steroid therapy so that endogenous steroid production resumes. • Use epinephrine cautiously in patients predisposed to ventricular fibrillation. • Use enalapril and other ACE inhibitors cautiously in patients with renal disease. • Long-term antibiotic therapy may facilitate a superinfection by a fungus (e.g., *Candida*) or resistant bacteria. • Monitor anticoagulants closely to avoid fatal hemorrhage.

FOLLOW-UP

PATIENT MONITORING
• Repeat complete blood counts, chemistries, and urine protein:creatinine ratios for blood dyscrasias and serum and urine protein concentrations. • Weekly assessment of prothrombin or partial thromboplastin time for patients on warfarin or heparin. • Serial biopsies of affected tissue such as kidney with glomerulonephritis may help to prognosticate. • Repeat cultures or acute and convalescing titers for patients suffering from an infectious disease. • Periodic T_4/TSH assay (4–6 hours post pill) for patients receiving thyroid supplementation.

PREVENTION/AVOIDANCE
Depends on the cause of the edema.

POSSIBLE COMPLICATIONS
• Decubital ulceration. • Fatal hemorrhage. • Fatal thrombosis. • Refractory cardiac, gastrointestinal, hepatic, or renal failure. • Malnutrition. • Cerebral edema and herniation. • Resistant infection and sepsis.

EXPECTED COURSE AND PROGNOSIS
Depends on cause of the edema.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Pericardial, pleural, or peritoneal effusion.

AGE-RELATED FACTORS
Vascular anomalies or primary lymphedema are generally documented in juvenile patients (e.g., anasarca).

ZOONOTIC POTENTIAL
• Tick exposure is common in pets and their owners; both may suffer simultaneously from rickettsial disease. • Certain protozoal (*Leishmania*), fungal (*Sporothrix*), and bacterial (*Brucella*) organisms may transfer to people via direct contact.

PREGNANCY/FERTILITY/BREEDING
Brucellosis has been associated with vulvar edema, necrotizing vasculitis, and embryonic death or fetal abortion.

SYNONYMS
Anasarca

PERIRENAL PSEUDOCYSTS

BASICS

OVERVIEW
• Capsulogenic renal cyst, capsular cyst, pararenal pseudocyst, capsular hydronephrosis, perirenal cyst, and perirenal pseudocyst are terms used to describe renomegaly caused by accumulation of fluid between the kidney and its surrounding capsule. One or both kidneys are affected. • The tissue sac in which the fluid accumulates is not lined with secretory epithelium; and thus the name "pseudo"-cyst is appropriate.

SIGNALMENT
• Primarily older male cats (>8 years). • When detected in young cats, the disease is usually unilateral. • Rare in dogs; the difference in prevalence between species may be related to the prominent network of subcapsular veins that characterize feline kidneys.

SIGNS
• May be asymptomatic. • Nonpainful, enlarged abdomen is common. • Signs of concomitant renal failure in some patients.

CAUSES & RISK FACTORS
• Cause of perirenal accumulation of fluid is often not understood. • Accumulation of pseudocyst fluid is a dynamic, not a static, process. • Cytologic and biochemical evaluation of pseudocyst fluid may aid understanding of pathophysiologic mechanisms. • Fluid with characteristics of a transudate may accumulate because of high capillary hydrostatic pressure or lymphatic obstruction. Some cats have light microscopic evidence of renal fibrosis. However, it is not known whether progressive renal parenchymal contraction occludes lymphatics and blood vessels, promoting transudation of fluid. • Perirenal accumulation of transudate can also result from rupture of renal cysts. • Accumulation of perirenal urine may indicate disruption of the renal pelvis or the proximal ureter. • Accumulation of blood in pseudocysts can result from external trauma, surgery, neoplastic erosion of blood vessels, rupture of aneurysms, coagulopathies, or paracentesis of the urinary tract.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Causes of renomegaly include renal neoplasia, hydronephrosis, polycystic kidney disease (common), feline infectious peritonitis, and mycotic or bacterial nephritis (less common). • Ascites and enlargement of other abdominal organs can cause nonpainful distension of the abdomen.

CBC/BIOCHEMISTRY/URINALYSIS
• Results unremarkable until patient develops renal insufficiency. • Azotemia and inappropriately low urinary specific gravity (<1.035) indicate concomitant chronic kidney disease (CKD).

OTHER LABORATORY TESTS
N/A

IMAGING
• Renomegaly is commonly detected by abdominal radiography. • Excretory urography and ultrasonography can be used to determine whether the underlying renal parenchyma is normal or abnormal. Small kidneys beneath an abnormally wide fluid-filled intracapsular space is a common finding.

DIAGNOSTIC PROCEDURES
Cytologic examination of pseudocyst fluid may provide evidence of the underlying disease process resulting in fluid accumulation (e.g., transudation, hemorrhage, lymphatic obstruction, inflammation, urine, etc.) or secondary complications (e.g., infection). Creatinine concentrations that are higher in pseudocyst fluid compared to serum are consistent with urinary tract rupture.

TREATMENT
• Perirenal pseudocysts are not immediately life-threatening. • Some patients need no treatment. • Many patients require further diagnostic evaluation and treatment of concomitant CKD. • Capsulectomy or pseudocyst fenestration (remove greater than 1 cm × 1 cm section of capsule to minimize spontaneous closure of the fenestration) is generally associated with amelioration of abdominal distention and abdominal organ displacement. Early stages of CKD may resolve; however, progression of CKD commonly occurs. • Long-term response is unknown. • Avoid nephrectomy to maximize remaining kidney function. • Decompression by paracentesis with a needle and syringe provides temporary relief. • If pseudocysts refill with fluid (often in 1–2 weeks), paracentesis can then be repeated.

MEDICATIONS

DRUG(S) OF CHOICE
Consider appropriate antimicrobic (i.e., lipid-soluble antibiotic chosen on the basis of antimicrobial susceptibility) if pseudocysts become infected.

FOLLOW-UP
• Monitor patients periodically (every 2–6 months) for development and progression of CKD. • Short-term prognosis appears favorable with or without pseudocyst decompression in patients with no evidence of CKD. • Long-term prognosis is unknown because it has not been determined whether perirenal pseudocysts are associated with underlying lesions in the renal parenchyma that may be progressive. It is also unknown whether perirenal pseudocysts are associated with hypertension. • Survival is related to the severity and progression of CKD.

MISCELLANEOUS

ABBREVIATIONS
• CKD = chronic kidney disease.

PERITONEOPERICARDIAL DIAPHRAGMATIC HERNIA

BASICS

OVERVIEW
- Embryologic malformation of the ventral midline allowing communication between the pericardial and peritoneal cavities.
- May be associated with other congenital malformations including sternal deformities (especially in cats), cranial abdominal hernia, and ventricular septal defects.
- Signs may be due to large amounts of abdominal viscera compressing the heart or lungs and incarceration of abdominal organs (e.g., liver and small bowel). However, many affected animals remain asymptomatic.

SIGNALMENT
- Dog and cat.
- Age when clinical signs first occur varies; more than one-third of patients are 4 years of age or older.
- Weimaraners and Persians may be predisposed.
- No evidence that lesions are hereditary, but they have been reported in littermates.

SIGNS

General Comments
Depend on the nature and amount of abdominal contents that are herniated.

Historical Findings
- Vomiting.
- Diarrhea.
- Weight loss.
- Abdominal pain.
- Coughing.
- Dyspnea.

Physical Examination Findings
- Muffled heart sounds.
- Displaced or attenuated apical cardiac impulse.
- Palpable sternal deformity or cranial abdominal hernia.
- Cardiac tamponade and signs of right-sided congestive heart failure (rare).

CAUSES & RISK FACTORS
- Embryologic malformation.
- Prenatal injury of the septum transversum and pleuroperitoneal folds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Never an acquired traumatic defect because no natural direct communication exists between the peritoneal and pericardial cavities after birth.
- Pericardial effusion.

CBC/BIOCHEMISTRY/URINALYSIS
No associated hematologic or biochemical alterations.

OTHER LABORATORY TESTS
N/A

IMAGING
- Radiographic findings depend on size of defect and amount of herniated abdominal contents; caudal heart border and diaphragm usually overlap; thoracic radiographs may show an "empty" abdomen and possible multiple radiographic densities within the cardiac silhouette.
- Positive and negative contrast peritoneography have been used to evaluate the diaphragm. Injection of 1–2 mL/kg body weight of water-soluble positive contrast into the peritoneal cavity followed by right and left lateral, sternal, and dorsal recumbent radiographs allows complete evaluation of the diaphragm. Identification of contrast within the pleural space confirms the diagnosis of diaphragmatic rupture. Air, carbon dioxide, or nitrous oxide may also be used.
- Barium series may demonstrate bowel loops crossing the diaphragm and within the pericardial sac.
- Nonselective angiography outlines the cardiac chambers within the large cardiac silhouette.
- Echocardiography gives a definitive diagnosis.

DIAGNOSTIC PROCEDURES
Electrocardiogram may show small complexes if abdominal contents have herniated or if marked effusion is present.

TREATMENT
Surgical closure of the hernia after returning viable organs to their normal location is usually curative. In asymptomatic adult patients, treatment may not be indicated.

MEDICATIONS

DRUG(S) OF CHOICE
- Myocardial contractility is unaffected in most patients; drugs for improving cardiac output are not indicated.
- Can give symptomatic treatment based on nature and amount of abdominal contents that are herniated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Drugs that reduce ventricular afterload (e.g., arteriolar vasodilators) or preload (e.g., venous dilators and diuretics) are not useful and can cause reduction of ventricular filling, hypotension, and low cardiac output.

FOLLOW-UP
Prognosis after surgery is excellent in animals with no other significant congenital anomalies or complicating factors. Some affected animals remain asymptomatic throughout life.

PERITONITIS

BASICS

DEFINITION
Inflammatory process involving the serous membrane of the abdominal cavity.

PATHOPHYSIOLOGY
• Insult to the peritoneal cavity (localized or generalized) leads to inflammation characterized by vasodilation, cellular infiltration, pain, and development of adhesions. Fluid production is eventually favored over absorption, and progresses from transudate to exudate. • Extent and severity depend on type and severity of insult.
• Response to bacterial peritonitis associated with lipopolysaccharide (LPS; Gram-negative bacteria) or peptidoglycans (Gram-positive bacteria), causing inflammatory cytokine and nitric oxide (NO) production. NO causes vasodilation, can lead to hypotension.
• Inflammation causes vasodilation and increased vascular permeability. Cytokine release from leukocytes results in chemotaxis and activation of complement. Activation of complement results in coagulation, fibrin production and decreased fibrinolysis, resulting in adhesion formation. • Result of significant abdominal inflammation can be systemic inflammatory response syndrome (SIRS) and sepsis. SIRS can progress to multiple organ dysfunction (MODS) and affect respiratory system (acute respiratory distress syndrome or pulmonary thromboembolism), or cause renal dysfunction, reduced cardiac function, and neurologic dysfunction.

SYSTEMS AFFECTED
• Cardiovascular. • Gastrointestinal (GI). • Hemic/lymphatic/immune. • Renal/urologic hepatobiliary.

GENETICS

SIGNALMENT
Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
None

Predominant Sex
None

SIGNS
General Comments
Signs may be vague and nonspecific and depend on timeline of evaluation in relation to inflammation and systemic response.

Historical Findings
Lethargy, depression, anorexia, vomiting (common), diarrhea, collapse.

Physical Examination Findings
• Abdominal discomfort or pain—localized or generalized. • Shock: ○ Compensatory—tachycardia, tachypnea, injected mucus membranes, rapid capillary refill time (CRT). ○ Early decompensatory—tachycardia, poor pulse quality, depressed mentation, pallor, prolonged CRT. Cats may show a normal to decreased heart rate (<140/min). ○ Decompensatory—bradycardia, weak or absent pulses, severely depressed mentation, pallor or cyanosis, prolonged CRT.
• Arrhythmias/pulse deficits may be detected. • Fever. • Weight loss—reported in 1/3 of dogs and cats with secondary peritonitis. • SIRS—tachycardia (dog >140/min, cat >240/min) or bradycardia (cat <130/min); tachypnea (dog >30/min, cat >40/min), hyperthermia (dog >102.5°F [39.1°C], cat >104.5°F [40.3°C]) or hypothermia (dog or cat <100°F [37.7°C]), leukocytosis (dog >19,000/µL, cat >18,000/µL), or leukopenia (dog <6000/µL, cat <5000/µL).

CAUSES
Primary Peritonitis
• Uncommon, no identifiable intraperitoneal source. More common in cats (14%). • May be monomicrobial, Gram-positive in 80% of dogs, 60% of cats. • Results from hematogenous or lymphatic spread or translocation from GI tract; may spread from oviduct. • Feline infectious peritonitis (FIP) in cats.

Secondary Peritonitis
• Most common. • Contamination of peritoneal cavity from abdominal organ: ○ GI source (up to 75%) from perforation (ulcerations, neoplasia, ischemia), leakage following GI surgery, penetrating trauma, biliary tract rupture (obstruction, trauma, mucocele), or pancreatitis. ○ Abscessation (liver, pancreas, kidney, prostate, lymph nodes, spleen). ○ Urogenital source (pyometra, urine leakage). ○ Uroabdomen and bile peritonitis may or may not be septic; regardless, chemical peritonitis is present.

RISK FACTORS
• Trauma. • Foreign body ingestion. • Biliary mucocele. • GI surgery. • Nonsteroidal anti-inflammatory drug (NSAID) use associated with GI perforation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Other causes of abdominal pain or distention, sepsis, and shock.

CBC/BIOCHEMISTRY/URINALYSIS
• Neutrophilic leukocytosis common; possible left shift; degenerative left shift, or development of neutropenia may portend worsening prognosis. • Hemoconcentration or anemia. • Hypoproteinemia. • Hypo- or hyperkalemia; hyponatremia (fluid loss into peritoneum). • Azotemia—prerenal, renal, or post renal. • Metabolic acidosis. • Hypoglycemia—may indicate sepsis; hyperglycemia may be present in cats. • Liver enzyme activity elevations—hepatic causes of peritonitis or MODS. • Hyperlactatemia—poor tissue oxygen delivery.

OTHER LABORATORY TESTS
Coagulation testing—disseminated intravascular coagulation (DIC): prolonged activated partial thromboplastin time (aPTT) and thrombocytopenia initially, progress to prolonged prothrombin time (PT), aPTT, elevated D-dimers (>1,000 ng/mL).

IMAGING
Radiography
• Findings depend on cause; make right and left lateral projections of abdomen. • Loss of serosal detail (ground-glass appearance suggests fluid in abdominal cavity)—rule out lack of intra-abdominal fat (cachexia, neonates). • Generalized ileus. • Pneumoperitoneum—gas in abdomen may be slight, closely evaluate region near diaphragm; consider making lateral beam images with patient in a sternal or lateral recumbency.
• Can be diagnostic for gastric dilatation/volvulus, GI foreign bodies, mass lesions, organs enlargement (neoplasia, abscess).
• Contrast procedures—rarely warranted; may complicate management if contrast material enters abdominal cavity; avoid barium if GI perforation suspected.

Ultrasound
Identify (and aspirate) small volumes of peritoneal effusion, abscesses, gallbladder rupture or mucocele, tumors, obstructions, or mass lesions.

DIAGNOSTIC PROCEDURES
• Abdominocentesis and diagnostic peritoneal lavage—perform as soon as possible: (1) Cytology—collect aliquot of sample into EDTA tube; note color and clarity and presence of fibrin. (2) Place second aliquot into red-top tube for biochemical testing if needed, based on suspected etiology. Chemical

PERITONITIS (CONTINUED)

peritonitis—analyze abdominal fluid for creatinine (for uroabdomen), specific pancreatic lipase (for pancreatitis), and bilirubin (for bile leakage). (3) Culture and sensitivity—next, aseptically place an aliquot of sample in a sterile-white top (no additive) tube. • Suspect FIP—submit abdominal fluid for protein electrophoresis and globulin determination.

PATHOLOGIC FINDINGS

• Intracellular bacteria, degenerative neutrophils, and plant material are diagnostic of septic peritonitis. • Normal peritoneal fluid contains <2,500 cells/µL. • Glucose concentration in abdominal fluid more than 20 mg/dL less than peripheral blood glucose concentration suggests septic peritonitis. • Peritoneal lactate >4.2 mmol/L suggests peritonitis in dogs. • Recent surgery results in <10,000 cells/mL; primary peritonitis usually results in 7,000 cells/µL in dogs and 3,000 cells/µL in cats. • Fluid bilirubin or creatinine levels at least two times higher than that of peripheral blood indicate bile peritonitis or uroabdomen, respectively. Acellular homogenous, laminated, basophilic material on cytology may be mucoid material associated with bile peritonitis.

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient—intensive monitoring and supportive care are required. • Goals—blood pressure >90 mmHg (measured by Doppler), heart rate 80–140/min (dogs) and 160–225/min (cats), CRT 1.5–2 seconds, urine output >1–2 mL/kg/h, blood lactate <2.5 mmol/L. Blood lactate concentration should improve with resuscitation; inability to do so suggests poorer prognosis.

IV Fluid Therapy

• Critical for correction of hemodynamic disturbances, electrolyte and acid–base abnormalities prior to surgery. • Balanced isotonic replacement crystalloid solution—evaluate response to therapy frequently:
◦ Rate—may initially require multiple boluses of 10–30 mL/kg (depending on other patient parameters); reevaluate patient frequently, adjust fluid rate or repeat boluses as patient status changes. • Potassium and glucose supplementation as necessary: ◦ Rate of potassium supplementation should not exceed 0.5 mEq/kg/h of potassium.
• Synthetic colloids sometimes utilized (up to 20 mL/kg/d); concerns for acute kidney injury have decreased usage, especially in patients with sepsis. • Canine albumin transfusion indicated for severe hypoalbuminemia (<1.2 mg/dL). • Whole blood or packed red blood cells—as required for anemia. • Inadequate response to therapy may prompt vasopressor administration (norepinephrine, vasopressin, dopamine). Norepinephrine is recommended for animals with sepsis. • DIC—remove inciting cause, support coagulation with fresh frozen plasma transfusion.

NURSING CARE

• Significant; dependent upon severity of systemic signs.
• IV fluid therapy and maintenance of tissue oxygen delivery.

ACTIVITY

Decreased; depends on inciting cause and clinical signs.

DIET

• Dictated by cause and concurrent conditions (e.g., heart disease). • Feeding tube placement should be considered and placed at time of surgery for early nutritional support (e.g., esophagostomy, gastrostomy, jejunostomy). Nasogastric tube for feeding and gastric decompression if necessary.
• Adequate nutrition—essential to optimize outcome, attenuate hypermetabolic state, preserve hepatic antioxidant defenses, prevent protein-calorie malnutrition, maintain GI barrier function.

CLIENT EDUCATION

• Advise client of high rate of morbidity and (especially septic peritonitis) mortality.
• Extensive monitoring and intensive care may be costly, with prolonged hospitalization.

SURGICAL CONSIDERATIONS

• Decision to treat medically or surgically—dictated by etiology, patient's response to initial treatment, and owner's financial constraints. • Known bacterial contamination or suspected chemical peritonitis—surgical intervention necessary. • Perform surgery as soon as patient is stable. Prompt source control allows deescalation of antibosis, which may only be required for 4–8 days.
• Exploratory laparotomy—prepare for incision extending from xiphoid to pubis; goals of surgery are to remove source of contamination, debride and lavage abdomen, collect fluid or tissue for Gram stain and aerobic and anaerobic culture, and provide access for nutritional support; use monofilament absorbable or nonabsorbable suture within abdomen; before closing, thoroughly lavage abdomen with 200–300 mL/kg warm sterile saline. Do not add antimicrobials or other products to lavage solution; remove all lavage solution from abdomen. • Surgeon must assess organ viability and perform resections if necessary. Anastomosis of GI tract should utilize healthy tissue; consider serosal patching, perform omental patching if serosal patching not done. Stapled anastomoses may have a decreased risk of dehiscence in septic peritonitis. • Consider omentalization of pancreatic abscesses, perform omentalization for prostatic abscessation. Remove affected organ or part in other cases of abscessation (liver lobectomy, nephrectomy). • Consider abdominal drainage—based on degree of contamination, ability to debride abdomen, severity of illness, and anticipation of septic complications: ◦ Allows continued removal of fluid, bacteria, and toxins. ◦ Forms include closed suction drains, vacuum-assisted peritoneal drainage (VAPD), and closure of caudal abdomen with partial closure of cranial abdomen. Sterile bandaging is required in each form; less external materials for VAPD, but regulate suction and specialized foam and connections to suction required. ◦ Requires anesthesia for abdominal closure unless closed suction drains are used. Severe peritonitis may require repeated exploration, debridement, and lavage prior to closure.

MEDICATIONS

DRUG(S) OF CHOICE

• Antimicrobials—early and aggressive broad-spectrum therapy for suspected septic peritonitis; final therapy based on culture and susceptibility testing. • Initial therapy—Gram-negative (enrofloxacin, cefotaxime, amikacin); Gram-positive (ampicillin, clindamycin); anaerobes (metronidazole):
◦ Ampicillin 22 mg/kg IV q6–8h.
◦ Ampicillin/sulbactam 25–30 mg/kg IV q6–8h. ◦ Clindamycin 12 mg/kg IV q12h.
◦ Cefotaxime 20–80 mg/kg IV q8h.
◦ Enrofloxacin 10–20 mg/kg IV q24h (dogs); 5 mg/kg IV q24h (cats). ◦ Amikacin 15 mg/kg IV q24h. ◦ Metronidazole 10 mg/kg IV q12h. ◦ Analgesia—depends on pain severity; may be intermittent or via CRI; opioids recommended: ◦ Multimodal IV combinations for pain; dogs, morphine 0.05–0.2 mg/kg/h or fentanyl 2–5 µg/kg/h, ketamine 0.2–0.5 mg/kg/h, lidocaine 2–4 mg/kg/h; cats, fentanyl 2–5 µg/kg/h, ketamine 0.05–0.2 mg/kg/h. Lidocaine may improve outcome following surgery in dogs.
• GI protectants— if GI ulceration:
◦ Famotidine 0.5–1.0 mg/kg IV q12h.
◦ Pantoprazole 1 mg/kg IV q12–24h (more effective acid reduction). ◦ Sucralfate: dogs, 0.5–1.0 mg PO q8h; cats, 0.25–0.5 mg PO q8h.

CONTRAINDICATIONS

• Glucocorticoids—physiologic dose (0.5 mg/kg prednisone equivalent) may be indicated for hypotension unresponsive to fluids and pressors. • NSAIDs are not recommended due to risk of acute kidney injury and GI ulceration in poorly perfused patients.

PRECAUTIONS
• Aminoglycosides—use with caution if hypotensive, dehydrated, impaired renal function. • Adequate hydration—essential to enhance safety of these drugs.

POSSIBLE INTERACTIONS
Sucralfate works best at low pH; administration should be staggered with GI acid reducers, if both used. Avoid giving oral medications at same time as sucralfate.

ALTERNATIVE DRUG(S)
Fluoroquinolone—enrofloxacin or orbifloxacin; substitute for an aminoglycoside, especially with impaired renal function.

FOLLOW-UP

PATIENT MONITORING
• Fluid balance, electrolyte balance, acid–base status, blood lactate—as necessary depending on severity of condition. • Frequency of monitoring—varies with condition and response to treatment; generally q2h. • Urine output—target 1–2 mL/kg/h. • Quantify and replace fluid losses (vomiting, diarrhea). • Change recumbency q4–6h. • Enteral nutrition as soon as possible via oral or tube feeding: promotes enterocyte health and decreases bacterial translocation. Does not increase risk of complications. • Repeat ultrasound and abdominal fluid cytologic evaluation depending on index of suspicion for leakage of intestinal surgery sites. • CBC, chemistry profile, urinalysis—every 1–2 days during periods of intensive monitoring, even in patients that are responding. • Coagulation testing q24–48h.

PREVENTION/AVOIDANCE
Prevention—difficult except with specific risk factors (e.g., pyometra, prostatic abscess can be avoided with sterilization).

POSSIBLE COMPLICATIONS
• If underlying cause is not identified and managed, patient is at risk for complications. • Open peritoneal drainage—increased cost and required intensive care, repeated sedation or anesthesia for aseptic bandage changes, nosocomial infection, hypoproteinemia, electrolyte imbalances, enterocutaneous fistulation, and abdominal hernia formation. • Adhesions, granuloma formation with barium peritonitis.

EXPECTED COURSE AND PROGNOSIS
• Prognosis—depends on rapid identification and successful management of underlying cause and appropriate follow-up care. • Septic peritonitis—mortality of 30–68%. Prognosis worse in animals with preexisting septic peritonitis, uncorrectable hypotension, low serum albumin and total protein concentrations, respiratory dysfunction, DIC, low concentrations of protein C, or antithrombin, MODS; better survival in patients with lower preoperative alanine aminotransferase, gamma-glutamyltransferase, packed cell volume, total solids, and albumin concentration. Open peritoneal drainage may improve survival. • Septic bile peritonitis—27% survival compared to 100% with nonseptic bile peritonitis. • Antibiotic treatment within first hour in cases of suspected septic peritonitis may significantly reduce mortality. • Blood lactate >2.5 mmol/L or inability to normalize plasma lactate—poorer survival. • Feeding tube complications depend on site of placement—esophagostomy (localized infection or abscessation); gastrostomy and jejunostomy (leakage or premature dislodgement associated peritonitis): nasoesophageal or nasogastric (sneezing, epistaxis). Refeeding syndrome—decreased magnesium, phosphorus, potassium; relatively rare but warrants close monitoring. • Bradycardia and hypothermia in cats with primary septic peritonitis associated with mortality.

BASICS

DEFINITION
Pinpoint (petechia) or larger (ecchymosis) hemorrhage in the skin or mucous membranes most often secondary to abnormal primary hemostasis (platelet or vessel wall-mediated); may appear spontaneously or following trauma. Spontaneous development often occurs at sites of increased capillary trauma.

PATHOPHYSIOLOGY
- Thrombocytopenia results in impaired primary hemostasis and decreased production of platelet-derived trophic factors that maintain endothelial cell junction integrity.
- Platelet numbers below $50 \times 10^3/\mu L$ and more often below $25 \times 10^3/\mu L$ are associated with an increased risk of spontaneous hemorrhage.
- Thrombocytopathies are not generally associated with the development of petechiae. Some animals with von Willebrand disease (VWD) may develop petechiae.
- Vascular hemostatic defects—generally caused by systemic disease causing increased capillary permeability, vasculitis, or altered dermal vascular support (e.g., collagen alterations).

SYSTEMS AFFECTED
- Gastrointestinal—melena/hematochezia/hematemesis.
- Hemic/lymphatic/immune—anemia from bleeding.
- Neurologic—variable depending on location of bleeding.
- Ophthalmic—scleral/retinal hemorrhage, hyphema, secondary glaucoma, and uveitis.
- Renal/urologic—hematuria.
- Respiratory—epistaxis/hemoptysis.
- Skin/exocrine—petechia/ecchymosis/bruising.

GENETICS
Most etiologies are acquired; immune-mediated thrombocytopenia (ITP) has a possible genetic predisposition in cocker spaniels, poodles, Maltese, and Old English sheepdogs. Genetic associations exist for many thrombocytopathies. VWD is seen in Doberman pinschers, German shorthaired pointers, Shetland sheepdogs, Scottish terriers, and Chesapeake Bay retrievers.

INCIDENCE/PREVELENCE
Common in dogs. Uncommon in cats.

GEOGRAPHIC DISTRIBUTION
Applicable if associated with a vector-borne disease.

SIGNALMENT
- Middle-aged female dogs are at increased risk.
- Cats—primary ITP is rare.

CAUSES
- Thrombocytopenia—due to platelet consumption, destruction, or sequestration
- Vasculitis—secondary to inflammation, infection (e.g., *Rickettsia rickettsia*, sepsis), immune-mediated causes.

RISK FACTORS
- Nonsteroidal anti-inflammatory drug (NSAID) use.
- Geography/travel history (susceptibility to tick-borne disease).
- Certain drug exposures (e.g., sulfa-containing antimicrobials).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Some inflammatory skin lesions may look like petechiae. Vasculitis lesions may have associated edema. Trauma may cause ecchymoses/bruising.

CBC/BIOCHEMISTRY/URINALYSIS
- Thrombocytopenia.
- Red blood cell fragmentation (schistocytosis) is associated with disseminated intravascular coagulation or microangiopathies.
- *Ehrlichia* morulae or other hemoparasites may be seen on a peripheral blood smear.
- Patients with myeloproliferative or lymphoproliferative disease, myelofibrosis, or a history of chemotherapy or administration of drugs such as estrogens may be concurrently leukopenic or have other cytopenias. Excessive blood loss will result in anemia.
- Urinalysis (free catch or catheter sample instead of cystocentesis if animal may be coagulopathic)—may identify hematuria.

OTHER LABORATORY TESTS
- Coagulation studies (activated partial thromboplastin time [aPTT], prothrombin time [PT], D-dimer, antithrombin activity).
- von Willebrand's factor antigen assay.
- Platelet function tests (e.g., buccal mucosal bleeding time [BMBT], PFA-100) are inaccurate with thrombocytopenia, but may be necessary to rule out platelet function disorders, especially if platelet count is normal in animals with petechiae.
- Feline leukemia virus (FeLV)/feline immunodeficiency virus (FIV) testing—underlying cause of thrombocytopenia.
- Serology—to diagnose ehrlichiosis, *Anaplasma platys*, *Bartonella vinsonii*, or RMSF.
- PCR—for possible infections such as *Ehrlichia* spp., *Anaplasma platys* or *Babesia* spp., *Mycoplasma* spp.

IMAGING
Thoracic and abdominal radiography or abdominal ultrasonography may help to identify neoplasia, pulmonary or other hemorrhage, abnormal splenic or lymph node architecture.

DIAGNOSTIC PROCEDURES
- Animals with pancytopenia may benefit from bone marrow aspirate or biopsy.
- Invasive diagnostic or therapeutic procedures may be performed with less risk if platelet concentrate or fresh whole blood can be administered before or during the procedure.

TREATMENT
- Minimize activity to reduce the risk of trauma.
- Discontinue any medications that may alter platelet function (e.g., NSAIDs).
- Discontinue medications that might be associated with ITP.
- Avoid jugular venipuncture.
- Fresh whole blood, platelet-rich plasma, or platelet concentrate transfusions may be necessary before a definitive diagnosis is made. Blood samples for diagnostic testing should be collected prior to transfusion if possible.
- Desmopressin acetate (DDAVP) may be an effective therapy to control bleeding in patients with VWD or NSAID-associated thrombocytopathia.
- Acquired thrombopathias and vascular disorders should have the underlying disease corrected.

MEDICATIONS

DRUG(S) OF CHOICE
Depends on the underlying diagnosis; see specific chapters.

CONTRAINDICATIONS
Avoid IM injectable medications whenever possible.

PRECAUTIONS
Avoid NSAIDs and other drugs that inhibit platelet function.

FOLLOW-UP
Serial platelet count for patients with thrombocytopenia until an adequate response to therapy is seen.

POSSIBLE COMPLICATIONS
- Death or morbidity caused by hemorrhage into critical organs.
- Shock caused by hemorrhagic shock.
- Blindness secondary to sequelae of hyphema.

PETROLEUM HYDROCARBON TOXICOSIS

BASICS

DEFINITION

• Petroleum hydrocarbons are a diverse group of products derived or synthesized from crude oil.
• Certain nonpetroleum-origin hydrocarbons, such as turpentine and linseed oil, are toxicologically similar enough to be considered with petroleum-origin products of similar molecular weight. Halogenated hydrocarbons, such as carbon tetrachloride or methylene chloride, are sufficiently unique to warrant separate consideration.
• Small animal poisoning most commonly results from exposure to refined commercial products including such disparate mixtures as fuels, solvents, lubricants, and waxes.
• Petroleum-based solvents are often used as "inert" carriers for other potential toxicants (e.g., pesticides, paints, medications).
• Most petroleum hydrocarbons can be "lumped" into a relatively few broad categories based on volatility, viscosity, and surface tension. Mixtures with high boiling points (low volatility), such as asphalt, mineral oil, and waxes, are relatively nontoxic. Products with relatively low boiling points and low viscosities, such as benzene or turpentine, are more readily aspirated, penetrate further into airways, and are more likely to cause chemical pneumonitis. In general, products that are more volatile also tend to be more lipophilic and more readily absorbed systemically. Products with high aromatic content are also predisposed to cause systemic toxicity.

PATHOPHYSIOLOGY

• In general, the most *acutely* life-threatening effects of hydrocarbon ingestion result from aspiration-induced pneumonitis.
• Viscosity and surface tension are reliable determinants of pneumotoxic potential. Low viscosity permits hydrocarbons to penetrate further into smaller airways. Low surface tension increases their tendency to "wet" pulmonary surfaces. For example, aspiration of as little as 0.1 mL of a low-viscosity hydrocarbon (e.g., hexane) may produce severe pneumonitis, whereas a high-viscosity product (e.g., motor oil) would not penetrate past the major airways.
• Inhalation of hydrocarbon vapors (as opposed to aspirating liquid) may compromise pulmonary immune function and displace oxygen.
• Topical exposure to hydrocarbon-based solvents (e.g., petroleum distillates, turpentine) may result in irritation and necrosis of skin and cornea.
• Systemic toxicity is possible after oral or topical exposure. Although there are no quantitative data readily applicable to small animals, systemic toxicity should be considered when evaluating pets that have received a heavy topical exposure if the hydrocarbon is aromatic (e.g., benzene) or a low molecular weight (e.g., hexane). Topical exposure is especially important in very small animals (e.g., puppies, kittens, rodents), which have a relatively high body surface area to mass ratio. Systemic uptake and thus toxicity are also enhanced by factors such as a long hair coat, which traps the product against the skin.

SYSTEMS AFFECTED

• Cardiac.
• Gastrointestinal.
• Nervous.
• Respiratory.
• Skin.
• Hematopoietic.

INCIDENCE/PREVALENCE

In the author's experience, the incidence of small animal poisonings has decreased in recent years.

SIGNALMENT

Species

Dogs and cats.

SIGNS

General Comments

• Pneumonitis is the most serious complication associated with ingestion of more volatile (e.g., gasoline) hydrocarbons. Respiratory signs usually occur within a few minutes to 1–2 hours post ingestion. The central nervous and gastrointestinal systems may also be affected; death usually results from respiratory failure.
• If aspiration occurs simultaneously with ingestion, choking, coughing, gagging, and varying degrees of dyspnea will occur. Direct damage of airway components and bronchospasm may result in hypoxia. Cyanosis may develop immediately as alveolar oxygen is displaced by hydrocarbon vapor.
• There is some evidence that *some* hydrocarbons sensitize the myocardium to both endogenous and exogenous catecholamines, precipitating arrhythmias; hemolytic anemia has been occasionally reported in children.

Historical Findings

• A history of (possible) exposure is essential to the diagnosis of hydrocarbon intoxication. Signs of hydrocarbon poisoning are seldom sufficiently characteristic to permit diagnosis.
• Respiratory involvement, when present, is usually progressive over the first 24–48 hours, then gradually resolves 3–10 days following exposure. Animals that remain completely asymptomatic for 6–12 hours after ingestion are unlikely to develop respiratory illness.

Physical Examination Findings

• Characteristic hydrocarbon odor on the animal's breath or coat.
• Animals appear to experience a burning sensation in the mouth and pharynx after ingesting hydrocarbons, evidenced by slobbering, champing the jaws, shaking the head, and pawing at the muzzle.
• Fever in 3–4 hours following aspiration; may occur in less than an hour or as much as 24 hours.
• Vomiting, colic, and diarrhea after oral exposure. The severity and presence of such signs are a function of the dose and the individual hydrocarbon. Heavy aliphatic hydrocarbons (e.g., mineral oil) may produce mild diarrhea but little else. Lighter hydrocarbons (e.g., gasoline) are more likely to produce colic and vomiting.
• Intoxicated animals may exhibit vertigo, ataxia, and mental confusion. Hydrocarbons produce depression and narcosis in most cases, but tremors and convulsions have also been reported in a few cases. If the dose is very high, the animal may become comatose and die prior to exhibiting signs of pneumonitis, although this is very rare.
• Arrhythmias and syncope may occur as a result of myocardial sensitization to endogenous catecholamines. Myocardial sensitization may persist for 24–48 hours after apparent recovery from the neurologic effects of intoxication.

CAUSES

• Storage in inappropriate containers and failure to clean up spills.
• Folk remedies using gasoline, kerosene, and other solvents as tonics or vermifuges.
• Use of gasoline or other solvents to remove sticky material from an animal's coat. Cats may ingest significant amounts of gasoline or other hydrocarbons by grooming themselves after topical contamination.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Infectious diseases, toxins, and/or injuries may result in respiratory signs like hydrocarbon aspiration, but only very acute processes (e.g., trauma, chylothorax) exhibit a similar rapid onset.
• Acute ethylene glycol, ethanol, or drug intoxication.

CBC/BIOCHEMISTRY/URINALYSIS

• Urine and serum will be negative for ethylene glycol; serum osmolality will be normal.
• CBC may indicate stress, but this usually does not occur early in the process.

OTHER LABORATORY TESTS

• A simple spot test involves mixing vomitus or gastric contents vigorously with warm water. Gasoline or other petroleum distillates will float to the surface. Care must be taken to distinguish between petroleum products and dietary lipids. The former usually have a characteristic odor.

(CONTINUED) PETROLEUM HYDROCARBON TOXICOSIS

• Most petroleum products lighter than kerosene, if isolated and absorbed onto a paper towel, evaporate relatively quickly with little residue and have a characteristic odor.
• Chemical analysis of ingesta or post-mortem tissues is useful forensically but is not practical for clinical evaluation. If chemical analysis is conducted, samples must be taken quickly and frozen in airtight containers to prevent loss due to volatilization.

IMAGING
Radiographic findings are typical of aspiration pneumonia and consist of fine, perihilar densities and extensive infiltrates in ventral portions of the lungs. These are worst at 3–4 days, then gradually improve. Not all animals with radiographic signs of hydrocarbon aspiration develop respiratory signs, and radiographic changes usually persist past the resolution of clinical signs.

PATHOLOGIC FINDINGS
• If aspiration has occurred, the principle lesions will be in the respiratory tract. Pulmonary lesions are bilateral and typically involve caudoventral portions of the lung. The earliest lesions include hyperemia, edema, and hemorrhage into the airways. Foreign matter may be grossly visible in the smaller airways. Later, there is bronchospasm, emphysema, and atelectasis. Pneumatoceles, pneumothorax, and subcutaneous emphysema result from airway collapse. There may be ulcerations in the mucosa of the trachea and larger airways.
• Bacterial pneumonia occasionally supervenes and may result in abscesses.
• Systemic toxicity very occasionally results in hepatic, myocardial, and/or renal tubular necrosis if the animal survives >24 hours.

TREATMENT

APPROPRIATE HEALTH CARE
• In all cases of uncomplicated (i.e., not contaminated with some other, more toxic, substance) petroleum hydrocarbon ingestion, the primary goal is to minimize the risk of aspiration.
• If the amount ingested was small and the hydrocarbon ingested was one of the less volatile, more viscous products (e.g., motor oil, grease), cage rest and observation may be all that is required.
• Emetics and activated charcoal are not normally recommended due to potential vomiting and aspiration.
• If the volume ingested was substantial and the product involved known to cause systemic toxicity (e.g., gasoline) or if the product contains other, highly toxic substances (e.g., pesticides), gastric decontamination may be indicated, despite the risk of aspiration. It is essential that precautions (e.g., tracheal intubation) be taken to prevent possible aspiration of stomach contents. Emetics are contraindicated unless an absolute last resort.
• Respiratory effects should be treated symptomatically. Supplemental oxygen and mechanical ventilation should be used as needed. Pneumomediastinum, pneumatoceles, and pneumothorax are common complications so positive pressure systems must be used with caution. High-frequency jet ventilation reportedly results in fewer adverse sequelae than conventional mechanical ventilation. Since the lungs are the major route of systemic elimination for volatile hydrocarbons, closed or semi-closed systems should be purged frequently.
• Topical exposure may be treated by gently bathing with warm water and a mild detergent shampoo. If the hair coat is heavy or matted, it may be necessary to clip the contaminated areas.
• Symptomatic treatment of petroleum burns may involve topical antibacterials or other agents.
• Very viscous hydrocarbons (e.g., tar, waxes) may also be removed with mild detergents. They are not readily absorbed, pose only a cosmetic and skin irritation problem, and removal is not critical. Lipophilic materials (e.g., butter, lard, mechanic's hand cleaner) may also be useful, but the use of solvents is not recommended.

NURSING CARE
Cage rest is indicated, both for promotion of healing and to minimize the effects of excitement-induced catecholamines on a potentially sensitized myocardium.

CLIENT EDUCATION
Pet owners should be educated about proper storage and use of petroleum products.

MEDICATIONS

DRUG(S) OF CHOICE
• Historically, oral mineral or vegetable oil was recommended to increase the viscosity of petroleum hydrocarbons and decrease the risk of aspiration. Retrospective studies suggest that such treatment increases the likelihood of aspiration pneumonia, and the use of such oils is no longer recommended.
• The routine use of antibiotics is questionable. Hydrocarbon pneumonitis is largely nonbacterial in origin; however, given the potentially severe consequences and the relatively small downside to antibiotic use, it may be prudent to use antimicrobial prophylaxis if vomiting has occurred.
• Corticosteroids have been associated with increased numbers of positive lung cultures and are contraindicated.
• Bronchospasm may be treated with a beta-adrenergic agonist such as albuterol.

PRECAUTIONS
Emesis should only be used when there is a high degree of certainty that leaving the foreign material in the gut poses a greater hazard than aspiration.

FOLLOW-UP

PATIENT MONITORING
Monitor patients for 3–4 days to ensure that ingested hydrocarbons have cleared the gastrointestinal tract and no pulmonary sequelae will occur.

EXPECTED COURSE AND PROGNOSIS
The diversity of this class of products precludes absolute prediction, but most hydrocarbon exposures respond well to conservative, supportive therapy.

PHEOCHROMOCYTOMA

BASICS

DEFINITION
A tumor arising from catecholamine-producing chromaffin cells that originate from neural crest cells within the adrenal medulla.

PATHOPHYSIOLOGY
Clinical signs develop as a result of the space-occupying nature of the tumor and its metastases or from excessive secretion of catecholamines (e.g., causing hypertension or tachycardia). Signs of catecholamine release may be constant or intermittent. Paragangliomas are catecholamine-secreting tumors that arise from cells in the sympathetic ganglia.

SYSTEMS AFFECTED
- Cardiovascular.
- Neurologic.
- Renal.
- Respiratory.

INCIDENCE/PREVALENCE
Uncommon disease in dogs; rare in cats.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
- Median age in dogs is 11 years; range is 1–16 years.
- Older cats.

SIGNS

General Comments
- The predominant clinical signs result from alpha-mediated vasoconstriction and beta-mediated cardiac effects that cause systemic hypertension or tachyarrhythmias.
- Signs of hypertension may be constant or paroxysmal. Signs may be present for more than a year or develop suddenly, resulting in death.
- 30% of cases are asymptomatic and only identified at necropsy.

Historical Findings
- Clinical signs are often episodic or acute.
- Generalized weakness and lethargy are common.
- Collapse.
- Anorexia.
- Vomiting.
- Weight loss.
- Panting, dyspnea.
- Diarrhea.
- Whining, pacing.
- Ascites, edema.
- Polyuria and polydipsia.
- Shaking/shivering.
- Epistaxis.

Physical Examination Findings
- May be normal.
- Panting, tachypnea, dyspnea.
- Pale or hyperemic mucous membranes.
- Dehydration and/or hypovolemic shock.
- Thin, muscle wasting.
- Abdominal pain.
- Weakness.
- Blindness/retinal detachment.
- Cardiac arrhythmias.
- Peripheral edema.
- Ascites.
- Abdominal mass.

CAUSES
Chromaffin cell tumor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hyperadrenocorticism.
- Hyperaldosteronism.
- Essential hypertension (cats).
- Renal disease with secondary hypertension.
- Other abdominal neoplasia, especially adrenocortical tumor (adenoma vs. adenocarcinoma).
- Paraganglioma (rare).

CBC/BIOCHEMISTRY/URINALYSIS
- Nonregenerative anemia.
- Hemoconcentration.
- Leukocytosis.
- Mild hyperglycemia.
- Mild azotemia.
- Increased liver enzyme activities.
- Hypoalbuminemia.
- Proteinuria.

OTHER LABORATORY TESTS

Arterial Blood Pressure
Systolic >160 mmHg or diastolic >100 mmHg represents significant hypertension. Only 50% of animals with pheochromocytoma are hypertensive when blood pressure is measured because of the episodic nature of secretion of catecholamines from the tumor.

Electrocardiography
Sinus tachycardia is the most common arrhythmia; ventricular premature contractions or ventricular tachycardia less common.

IMAGING

Abdominal Radiography
- Abdominal mass.
- Mineralization of the adrenal mass (rare).
- Hepatomegaly.
- Renal displacement.
- Abnormal renal contour.
- Ascites.
- Enlargement of the caudal venal cava.

Thoracic Radiography
- Generalized cardiomegaly.
- Pulmonary congestion or edema.

Abdominal Ultrasonography
- Adrenal mass.
- Tumor invasion of the caudal vena cava and other adjacent structures (does not differentiate pheochromocytoma from other adrenocortical tumor).
- Intra-abdominal and liver metastasis.

Other Imaging Modalities
- CT scan and MRI to evaluate invasion of nearby structures; superior to ultrasound for surgical planning.
- Scintigraphy using ^{123}I-meta-iodobenzyl-guanidine scan.

DIAGNOSTIC PROCEDURES
- The plasma half-life of catecholamines is short (1–3 minutes), and release from pheochomocytomas is episodic. However, catecholamine metabolites (metanephrines—normetanephrine and metanephrine) constantly leak into peripheral circulation. Thus, measurement of metanephrines is preferred over measurement of catecholamines. Urinary normetanephrine:creatinine ratio is superior to the metanephrine:creatinine ratio for differentiating pheochromocytoma from hyperadrenocorticism (HAC). Additionally, using plasma normetanephrine concentrations is better than metanephrine concentrations.
- Urinary metanephrine:creatinine and normetanephrine:creatinine ratios:
  - Urine must be acidified soon after collection, and shipped cold. Follow the specific instructions of the laboratory used; laboratory may provide a special tube with acid for shipping.
  - In the United States, Marshfield Labs will run these ratios and provides canine reference ranges.
  - No vanilla ingestion, drugs (including phenoxybenzamine), or radiographic contrast agents prior to obtaining the urine sample.
  - Urine normetanephine:creatinine ratio greater than 4 times the upper limit of the reference range is consistent with a diagnosis of pheochromocytoma. Some cases may have ratios between (or below) 2 and 4 times the upper limit, but so do some cases of HAC.
- Inhibin concentration:
  - In one study, inhibin concentrations were found to be very low in neutered patients with and without pheochromocytoma, whereas the concentrations were higher in patients with adrenocortical tumors. Thus, it could be used to differentiate between pheochromocytoma and HAC in neutered dogs.
  - No longer commercially available.

PATHOLOGIC FINDINGS
Immunohistochemical staining of tumor tissues with chromogranin A or synaptophysin allows differentiation of pheochromocytomas from other tumor types.

TREATMENT

APPROPRIATE HEALTH CARE

- Surgical removal of the tumor is the treatment of choice.
- Medical therapy is most commonly used to stabilize patients prior to surgery, but may be elected as the sole therapy if the patient is not a surgical candidate due to vascular invasion or other factors. If the patient is not a surgical candidate, phenoxybenzamine, with or without atenolol, is used, as described under Drug(s) of Choice.

CLIENT EDUCATION

Survival times may be as long as 3 years following successful resection of tumor. Perioperative mortality is 20–30%, and decreased survival is associated with larger tumors (>5 cm) and invasion of nearby structures (such as the vena cava). In cats, removal of tumor is often curative; these are often benign, in contrast to the malignant tumors seen in dogs.

SURGICAL CONSIDERATIONS

Preoperative Care

Medications as described under Drug(s) of Choice.

Complications and Patient Monitoring

Common complications—hypertension, severe tachycardia, other cardiac arrhythmias, and hypovolemia/hypotension. Postoperative thromboembolism has been reported.

Anesthesia

- A balanced anesthetic protocol should be used, with close monitoring of arterial blood pressure, urine output, patient volume status, and analgesia. Patients should have a blood type performed prior to surgery, and adequate blood products available in the event of perioperative hemorrhage.
- Anticipate cardiac arrhythmias (brady and tachyarrhythmias); ECG monitoring should be initiated prior to and during anesthetic induction.

Surgery

Unilateral adrenalectomy and often thrombectomy. Manipulation of the tumor may cause severe hypertension if patient is not properly premedicated.

MEDICATIONS

DRUG(S) OF CHOICE

- Phenoxybenzamine 0.2–1.5 mg/kg PO q12h, should be given for 2 weeks prior to surgery. Start at 0.25 mg/kg twice daily and increase every 2–3 days to a final dose of 1 mg/kg twice daily. Monitor blood pressure and decrease dose if hypotension occurs.
- Atenolol, a β_1-selective antagonist 0.2–1 mg/kg PO q12–24h to control clinically significant supraventricular tachycardia. Do not use a beta-blocker prior to using an alpha-blocker for at least 2 days, as hypertension may become more severe.
- In the anesthetized patient or emergent patient with critical unresponsive supraventricular tachycardia—esmolol 0.05–0.5 mg/kg IV followed by 0.01–0.2 mg/kg/min IV may be used.
- In the anesthetized patient or emergent patient with critical unresponsive hypertension—nitroprusside 0.0005–0.005 mg/kg/min IV may be used.

CONTRAINDICATIONS

Severe hypertension can develop if a nonselective beta-blocker (e.g., propranolol) is used without prior alpha-adrenergic blockade (e.g., phentolamine, phenoxybenzamine).

PRECAUTIONS

Nonselective beta-blockade without alpha-blockade can lead to fatal hypertension.

ALTERNATIVE DRUG(S)

Prazosin 0.5–2.5 mg/dog PO q12h is an alpha-blocking drug that can be used if phenoxybenzamine is not available.

FOLLOW-UP

PATIENT MONITORING

Blood pressure, urine output, and ECG should be closely monitored in the immediate postoperative period (24–72 hours).

POSSIBLE COMPLICATIONS

Perioperative—intra-abdominal hemorrhage, hypotension, peritonitis, sepsis.

EXPECTED COURSE AND PROGNOSIS

Prognosis is guarded to fair. Dogs that survive the perioperative period may survive for 2–3 years or longer. Patients that are medically managed can live more than a year.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Multiple endocrine neoplasia types II and III.

PHOSPHOFRUCTOKINASE DEFICIENCY

BASICS

OVERVIEW
- Phosphofructokinase is the most important rate-controlling enzyme in glycolysis, and red blood cells (RBCs) and intensely exercising skeletal muscles depend heavily on anaerobic glycolysis for energy.
- Affected dogs have compensated hemolytic anemia and mild myopathy caused by markedly reduced total phosphofructokinase activity in both tissues.
- Anemia develops because of insufficient generation of ATP to maintain normal RBC shape, ionic composition, and deformability and because RBCs from affected dogs are alkaline fragile and lyse when blood pH is slightly high.

SIGNALMENT
- English springer spaniel, American cocker spaniel, mixed-breed, whippet, and wachtelhund dogs are overrepresented.
- Transmitted as an autosomal recessive trait.
- Affected homozygous animals generally not recognized as abnormal before age 1.

SIGNS
- Some animals exhibit mild clinical signs that go unrecognized for years; others regularly exhibit episodes of severe illness.
- Depression or weakness concomitant with episodes of pigmenturia.
- Mild lethargy with slight fever during mild hemolytic episodes.
- Marked lethargy, weakness, pale or icteric mucous membranes, mild hepatosplenomegaly, and fever as high as 106°F (41°C) during severe hemolytic crises.
- Intravascular hemolysis can be caused by hyperventilation-induced alkalemia associated with exercise or excitement.
- Signs of muscle dysfunction—usually limited to exercise intolerance and slightly diminished muscle mass, but muscle cramping and severe progressive myopathy can occur.
- Two affected whippets had progressive cardiac disease in addition to muscle cramping after exercise.
- Heterozygous carrier animals appear clinically normal.

CAUSES & RISK FACTORS
Deficiency of the muscle-type subunit of phosphofructokinase—markedly reduced total activity in RBCs and skeletal muscle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other causes of hemolytic anemia—immune-mediated hemolytic anemia, hemotropic mycoplasmosis, babesiosis, Heinz body anemia, microangiopathic hemolytic anemia, and pyruvate kinase deficiency.
- Affected dogs—negative Coombs' test, no parasites or Heinz bodies in stained blood films, seronegative for *Babesia* spp., and no evidence of disseminated intravascular coagulation or heartworm disease.
- Differentiated from pyruvate kinase deficiency by specific enzyme assays or DNA test.

CBC/BIOCHEMISTRY/URINALYSIS
- Persistent compensated hemolytic anemia.
- Mean cell volume usually 80–90 fL.
- Reticulocyte counts generally 10–30% of the total RBC number.
- Hematocrit values generally 30–40%; during hemolytic crises may decrease to ≤15%.
- Bilirubinuria—often markedly high in male dogs.
- Hemoglobinuria in association with episodes of intravascular hemolysis.
- Serum biochemical analysis—slight elevations of serum potassium, magnesium, calcium, urea, total protein, and globulin concentrations and aspartate aminotransferase activity; slight to moderate elevation of serum iron and bilirubin concentrations and lactate dehydrogenase and alkaline phosphatase activities; marked hyperbilirubinemia during hemolytic crisis; marked azotemia if renal failure develops secondary to pigmentary nephropathy or shock.

OTHER LABORATORY TESTS
- RBC phosphofructokinase activity—identifiable in affected animals older than 3 months; heterozygous carriers have approximately one-half normal activity.
- DNA testing to differentiate normal and carrier animals of any age. Wachtelhund dogs have a genetic mutation different from other dog breeds (http://research.vet.upenn.edu/penngen).

TREATMENT
- Bone marrow transplantation is the only cure.
- In patients with severe intravascular hemolysis, IV fluid therapy minimizes the chance of acute renal failure.
- Blood transfusions, if anemia becomes life-threatening.

MEDICATIONS
N/A

FOLLOW-UP
- Infrequently, affected dogs may die during a hemolytic crisis because of anemia or renal failure.
- Affected animals can have a normal lifespan if properly managed.
- Owners should avoid placing affected dogs in stressful situations or subjecting them to strenuous exercise, excitement, or high environmental temperatures.

MISCELLANEOUS

ABBREVIATIONS
- RBC = red blood cell.

PHYSALOPTEROSIS

BASICS

OVERVIEW
- *Physaloptera* spp. are parasitic nematodes that occur in dogs and cats; adults attach to stomach mucosa; no larval migration occurs outside the gastrointestinal tract.
- Infection can be asymptomatic or cause gastritis and vomiting.
- Typically, few worms are present; single-worm or all-female infections are common.
- Transmitted by ingestion of infective larvae in intermediate hosts (e.g., coprophagous grubs, beetles, cockroaches, crickets) or in paratenic hosts (e.g., birds, rodents, frogs, snakes, lizards).

SIGNALMENT
Dogs and cats; any breed, age, or sex. Infected animals often undergo extensive workups for suspected inflammatory bowel disease/ulcers, only for the nematodes to be discovered via endoscopy.

SIGNS
- Vomiting, often chronic and intermittent; occasionally find worms in vomitus.
- Weight loss can occur, especially with chronic infection.
- Signs can occur without egg production during prepatent period, single-worm, or female-only infections.
- Possible melena, especially in cats.

CAUSES & RISK FACTORS
- Outdoor exposure—access to insect intermediate hosts or small vertebrate transport hosts.
- Access to habitat occupied by wildlife species (raccoon, fox, coyote, bobcat, cougar, badger, skunk) infected with *Physaloptera*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other infectious causes of vomiting including parasite, viral, or bacterial infections.
- *Spirocerca*, the esophageal worm—produces similar but smaller eggs (11–15 × 30–37 µm).
- *Ollulanus*, a trichostrongylid nematode, can cause chronic vomiting; seen mainly in colony and feral cats; larvae and adults (<1 mm long) but no eggs present in vomitus or feces.
- Roundworms (ascarids) in puppies and kittens—worms can be present in feces and vomitus; larger than *Physaloptera*; characterized by three lips and cervical alae.
- Other noninfectious causes of vomiting including dietary indiscretion, foreign objects in the stomach, noxious substances accidentally ingested, gastrointestinal neoplasia, metabolic diseases.

CBC/BIOCHEMISTRY/URINALYSIS
Mild anemia and eosinophilia can occur.

OTHER LABORATORY TESTS
N/A

IMAGING
Abdominal radiography and ultrasonography, to eliminate other causes of vomiting.

DIAGNOSTIC PROCEDURES
- Endoscopy (gastroscopy) to visualize and remove worms, usually attached to stomach or duodenal mucosa; careful, thorough exam necessary to detect all worms; typically few are present and they can be hidden by mucus, ingesta, stomach rugae; pinpoint hemorrhages from prior attachment sites can be seen:
  - *Physaloptera* spp. are small (2.5–5 cm long), stout, white or pink, with an anterior cuticular collar; male and female *P. praeputialis* have a posterior prepuce-like cuticular sheath.
- Direct smear, wet mount, or fecal flotation to detect eggs in vomitus or feces; prepatent period is 2–5 months; eggs are dense and can be difficult to detect by fecal flotation using low specific gravity solutions; use flotation solution with specific gravity >1.25:
  - Eggs are small (42–58 × 29–42 µm), thick-shelled, larvated, ovoid to ellipsoidal, often clear and colorless.

TREATMENT
- Outpatient treatment; anthelmintic with or without endoscopic removal of worms.
- Anthelmintic use is extra-label and anecdotal.

MEDICATIONS

DRUG(S) OF CHOICE
- Pyrantel pamoate (dogs/cats) 20 mg/kg PO every 2 weeks for at least 3 treatments; repeat if signs persist; treatment of choice.
- Fenbendazole (dogs) 50 mg/kg PO q24h for 3–5 days; repeat if signs persist.
- Ivermectin (cats) 0.2 mg/kg PO, SC, once.
- Medication to reduce gastritis—histamine H_2-antagonists (e.g., famotidine 0.5 mg/kg PO q12h); sucralfate 0.25–1 g PO q8–12h.

FOLLOW-UP

PATIENT MONITORING
Recheck 1–2 weeks post treatment and re-treat with anthelmintic if eggs still present on fecal exam and/or if vomiting persists.

PREVENTION/AVOIDANCE
- Prompt removal and disposal of feces to prevent infection of arthropod intermediate hosts.
- Prevent exposure to arthropod intermediate hosts.
- No products approved specifically for *Physaloptera* spp. prevention or control; monthly intestinal parasite control likely effective to limit infections.

EXPECTED COURSE AND PROGNOSIS
Clinical signs and/or shedding of eggs in feces should resolve within 2 weeks of treatment.

PLAGUE

BASICS

OVERVIEW

• *Yersinia pestis*—Gram-negative, bipolar staining rod; reservoir: wild rodents (sylvatic), ground squirrels, prairie dogs, rabbits, bobcats, coyotes. • Occurs worldwide; movement of animals results in occurrence in non-endemic areas. • United States—Western states/Hawaii. • Common May–October. • Bacterium transmitted by infected fleas, also by ingestion of infected rodents; incubation period 2–7 days after infection. • Bacteria migrate from skin lymphatics to regional lymph nodes (LN), survive phagocytosis and multiply in LN; phagocytic cells rupture. • Fever and painful lymphadenopathy (bubo); intense local inflammation results in bubonic plague; intermittent bacteremia; LN rupture; may become septicemic with or without LN involvement. • Cats—severe fatal disease. • Dogs—naturally resistant. • Potential bioterrorist agent (beware of clusters of cases).

SIGNALMENT

Cat and rarely dog.

SIGNS

• Dogs—exhibit mild fever/depression. • Cats—exhibit bubonic/pneumonic/septicemic forms. • Bubonic (cats): ○ Most common form. ○ Buboes—head and neck; marked lymphadenopathy; if patient survives long enough, LN abscess, rupture, form fistulae to skin. ○ Fever: 103–105°F (39.5–40.5°C). ○ Lethargy, ataxia, coma. ○ Enlarged tonsils, oral ulcers. ○ Vomiting, diarrhea, anorexia. ○ Dehydration. ○ Ocular discharge. ○ Weight loss. • Septicemic (cats): ○ Rare. ○ Septicemia without lymphadenopathy or abscess formation. ○ Other signs same as bubonic. • Pneumonic (cats): ○ Severe disease; greatest risk for spread to humans (euthanasia strongly recommended to prevent zoonotic spread).

CAUSES & RISK FACTORS

• Outdoor, hunting cats. • Travel to endemic areas. • Environment—heavy flea infestation, large nearby rodent populations. • More common as homes encroach on wildlife habitats in plague-endemic areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infection (feline calicivirus, feline coronavirus, feline immunodeficiency virus, feline leukemia virus, cryptococcosis, histoplasmosis, toxoplasmosis, tularemia, leishmaniasis), neoplasia, drug eruption/skin hypersensitivity, epidermolysis bullosa, pemphigus, systemic lupus erythematosus, oropharyngeal foreign body, trauma, gingivitis, stomatitis, osteomyelitis, sequestrum.

CBC/BIOCHEMISTRY/URINALYSIS

• Leukocytosis: left shift/marked toxic change. • Thrombocytopenia. • High liver enzyme activity and hyperbilirubinemia.

OTHER LABORATORY TESTS

• Serology—Communicable Disease Center/state health department. • Fluorescent antibody test—presumptive identification. • Molecular testing—PCR of blood/tissues. • Coagulation profile—prolonged with consumptive coagulopathy.

DIAGNOSTIC PROCEDURES

• Culture is definitive; sample abscess, LN, peripheral blood before treatment is given or culture from post-mortem tissue (LN, abscess, liver, spleen). • Impression smears of tissue—large numbers of Gram-negative coccobacilli with bipolar staining. • Thoracic radiographs may show nodular lesions with pneumonic plague.

PATHOLOGIC FINDINGS

• Acutely ill cats—few lesions; enlarged head and neck LN; enlarged liver and spleen. • LN—destruction of normal architecture, hemorrhagic necrosis, extracellular bacteria.

TREATMENT

• Inpatient. • High mortality if not treated early. • Treat sepsis aggressively (see Sepsis and Bacteremia). • Treat for fleas.

MEDICATIONS

DRUG(S) OF CHOICE

• Treat all suspect cases empirically pending confirmation. • Systemic antimicrobials: ○ Tetracycline 20 mg/kg PO q8h for 21–42 days. ○ Doxycycline 5–10 mg/kg PO q12h; likely effective (not definitively established). ○ Chloramphenicol 30–50 mg/kg PO q8h. ○ Aminoglycosides, trimethoprim-sulfamethoxazole—also likely effective. • Coordinate with public health officials; bioengineered strains may be drug resistant.

FOLLOW-UP

PATIENT MONITORING

Consumptive coagulopathy common later in infection.

PREVENTION/AVOIDANCE

• Avoid travel to endemic areas. • Endemic areas—keep pet on leash; use flea control on pet and home. • Limit cat hunting behavior/rodent exposure. • Eliminate rodents/habitats near houses/outbuildings; store food in rodent-proof containers.

EXPECTED COURSE AND PROGNOSIS

• Duration of illness variable. • Prognosis—poor if not treated early. • Pneumonic plague has greatest risk of death.

MISCELLANEOUS

ZOONOTIC POTENTIAL

High

CDC Recommendations

• Notify public health officials. • Avoid contact with infectious materials from patient, fleas. • Disinfect/autoclave/incinerate any material used in examination of patients. • Isolate patients and wear mask/gloves when handling. • Assess pulmonary involvement. • Use respirator/protective eye equipment during necropsies. • Monitor staff for 2 weeks post exposure; discuss postexposure prophylaxis/fever watch with health care provider.

ABBREVIATIONS

• LN = lymph node.

PLASMACYTOMA, MUCOCUTANEOUS

BASICS

OVERVIEW
- Tumor of plasma cell origin.
- Typically benign and local therapy can be curative.
- Rarely (<1%) part of multiple myeloma process.
- Gastrointestinal extramedullary plasmacytoma (GI EMP) may be more aggressive.

SIGNALMENT
- Dog, rarely cat.
- Cocker spaniel, West Highland white terrier, boxer, German shepherd dog, Airedale.
- Median age 9–10 years.

SIGNS
- 86% are cutaneous, 9% affect mucous membranes, 4% colorectal, 1% noncutaneous/non-oral.
- Solitary, smooth, raised pink nodules, typically 1–2 cm in diameter.
- Bleeding, hematochezia, tenesmus, rectal prolapse if colorectal form.
- Vague, nonspecific signs if GI EMP.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other round cell tumor types including lymphoma, mast cell tumor, histiocytoma, transmissible venereal tumor.
- Poorly differentiated carcinoma.
- Amelanotic melanoma.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal for EMP

OTHER LABORATORY TESTS
Bone marrow aspirate cytology and serum electrophoresis may be indicated for GI EMP.

IMAGING
- Colonoscopy recommended for colorectal EMP.
- Thoracic radiographs and abdominal ultrasound may be indicated for GI EMP.

DIAGNOSTIC PROCEDURES
- Cytologic examination of fine-needle aspirate reveals moderate to marked cellularity with round to polyhedral individual tumor cells with discrete margins, abundant royal blue cytoplasm, paranuclear clear zone, eccentric round nucleus, and clumped chromatin. Multinuclearity is common.
- Histologic evaluation—classified into mature, hyaline, cleaved, asynchronous, monomorphous blastic, and polymorphous blastic cell types. However, no prognostic significance has been associated with this classification.
- Immunohistochemistry may be necessary to distinguish from other neoplasms.

TREATMENT
- Conservative surgery.
- Radiation therapy if nonresectable.

MEDICATIONS

DRUG(S) OF CHOICE
Melphalan and prednisone or single-agent lomustine may be indicated in GI EMP or multiple tumors.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Reevaluation every 3 months to monitor for local tumor control and metastases.

EXPECTED COURSE AND PROGNOSIS
- Excellent in most patients.
- Long-term survival expected for GI EMP treated with surgery ± chemotherapy.
- Reported 15-month median survival time for colorectal form with surgery alone.
- 5% local recurrence rate with conservative surgery for the majority of EMP.
- Metastasis reported in 2% of patients with EMP.
- 2% of patients will develop *de novo* EMP.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Multiple myeloma.
- Lymphoma—dogs.
- Cats—may note systemic amyloidosis.

SEE ALSO
- Amyloidosis.
- Lymphoma—Dogs.
- Multiple Myeloma.

ABBREVIATIONS
- EMP = extramedullary plasmacytoma.
- GI = gastrointestinal.

PLEURAL EFFUSION

BASICS

DEFINITION
Abnormal accumulation of fluid within the pleural cavity.

PATHOPHYSIOLOGY
• More than normal production or less than normal resorption of fluid. • Alterations in hydrostatic and oncotic pressures or vascular permeability and lymphatic function may contribute to fluid accumulation.

SYSTEMS AFFECTED
• Cardiovascular. • Respiratory.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
Varies with underlying cause.

Mean Age and Range
• Young animals—more commonly infection. • Old animals—more commonly cardiac or neoplastic.

Predominant Sex
Varies with underlying cause.

SIGNS
General Comments
Depend on the fluid volume, rapidity of fluid accumulation, and the underlying cause.

Historical Findings
• Dyspnea. • Tachypnea. • Orthopnea. • Open-mouth breathing. • Cyanosis. • Exercise intolerance. • Lethargy. • Inappetence. • Cough.

Physical Examination Findings
• Dyspnea—respirations often shallow and rapid. • Muffled or inaudible heart and lung sounds ventrally. • Preservation of breath sounds dorsally. • Dullness ventrally on thoracic percussion.

CAUSES
High Hydrostatic Pressure
• Congestive heart failure (CHF). • Overhydration. • Intrathoracic neoplasia.

Low Oncotic Pressure
Hypoalbuminemia—occurs in protein-losing enteropathy, protein-losing nephropathy, and liver disease.

Vascular or Lymphatic Abnormality
• Infectious—bacterial, viral, or fungal. • Neoplasia (e.g., mediastinal lymphoma, thymoma, mesothelioma, primary lung tumor, and metastatic disease). • Chylothorax (e.g., from lymphangiectasia, CHF, cranial vena caval obstruction [sometimes associated with transvenous pacemaker implantation], neoplasia, fungal infections, heartworms, diaphragmatic hernia, lung lobe torsion, trauma). • Diaphragmatic hernia. • Hemothorax (e.g., from trauma, neoplasia, coagulopathy, *Angiostrongylus vasorum*). • Lung lobe torsion. • Pulmonary thromboembolism. • Pancreatitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Historical or physical evidence of external trauma—consider hemothorax or diaphragmatic hernia. • Fever suggests an inflammatory, infectious, or neoplastic cause. • Murmurs, gallops, or arrhythmias combined with jugular venous distension or pulsation suggest an underlying cardiac cause. • Concurrent ascites suggests feline infectious peritonitis (FIP), CHF (mainly dogs), severe hypoalbuminemia, diaphragmatic hernia, disseminated neoplasia, or pancreatitis. • In cats, decreased compressibility of the cranial thorax suggests a cranial mediastinal mass. • Concurrent ocular changes (e.g., chorioretinitis and uveitis) suggest FIP or fungal disease. • Hypothermia often associated with cardiac cause.

CBC/BIOCHEMISTRY/URINALYSIS
• Hemogram results may be abnormal in patients with pyothorax, FIP, neoplasia, or lung lobe torsion. • Severe hypoalbuminemia (generally <1 g/dL to cause effusion) suggests protein-losing enteropathy, protein-losing nephropathy, or liver disease. • Hyperglobulinemia (polyclonal) suggests FIP.

OTHER LABORATORY TESTS
• Fluid analysis should include physical characteristics (i.e., color, clarity, odor, clots), pH, glucose, total protein, total nucleated cell count, and cytologic examination; Table 1 provides characteristics of various pleural fluid types and their disease associations. • In cats the lactate dehydrogenase concentration in transudates is <200 IU/L and in exudates it is >200 IU/L. • Pleural fluid pH <6.9 suggests pyothorax in cats. • Glucose concentration in pleural fluid usually parallels levels in serum. In cats, pyothorax and malignancy lower pleural fluid glucose concentration relative to serum glucose concentration; thus, pleural fluid with a normal pH and low glucose concentration suggests malignancy in cats. • Serologic tests for feline leukemia virus (if patient has mediastinal lymphoma), feline immunodeficiency virus (if patient has pyothorax), and coronavirus (if FIP is suspected) are available. • Cardiac disease suspected—consider a heartworm test in dogs and cats; NT-proBNP and thyroid evaluation in cats. • Infection suspected—obtain aerobic and anaerobic bacterial culture and sensitivity tests and consider special stains (e.g., Gram and acid-fast stains) of the fluid. • FIP suspected—consider protein electrophoresis of the fluid; gamma-globulin level >32% of total protein strongly suggests a diagnosis of FIP. • Chyle suspected—do an ether clearance test or Sudan stain of the pleural fluid, and triglyceride and cholesterol evaluations of the fluid and serum.

IMAGING
Radiographic Findings
• Used to confirm pleural effusion; should not be performed until after thoracocentesis in dyspneic patients with evidence of pleural effusion on physical examination. • Evidence of pleural effusion includes separation of lung borders away from the thoracic wall and sternum by fluid density in the pleural space, fluid-filled interlobar fissure lines, loss or blurring of the cardiac and diaphragmatic borders, blunting of the lung margins at the costophrenic angles (ventrodorsal view), and widening of the mediastinum (ventrodorsal view). • Rounding of the caudal lung lobe borders (lateral view)—most common in patients with fibrosing pleuritis caused by chylothorax, pyothorax, or FIP. • Unilateral effusion—most common in patients with chylothorax and pyothorax; hemothorax, pulmonary neoplasia, diaphragmatic hernia, and lung lobe torsion. • Evaluate post-thoracocentesis radiographs carefully for cardiomegaly, intrapulmonary lesions, mediastinal masses, diaphragmatic hernia, lung lobe torsion, and evidence of trauma (e.g., rib fractures). • Can diagnose a diaphragmatic hernia with positive-contrast peritoneography. • Can evaluate the thoracic duct by positive-contrast lymphangiography. • CT imaging may help differentiate malignant from inflammatory effusions.

Echocardiographic Findings
• Ultrasonographic evaluation of the thorax is recommended whenever cardiac disease, diaphragmatic hernia, or cranial mediastinal mass is suspected. • Echocardiography is easiest to perform before thoracocentesis, provided the patient is stable.

DIAGNOSTIC PROCEDURES
• Thoracocentesis—allows characterization of the fluid type and determination of potential underlying cause. • Exploratory thoracotomy or thoracoscopy—to obtain biopsy specimens of lung, lymph nodes, or pleura, if indicated.

TREATMENT
• First, thoracocentesis to relieve respiratory distress; if the patient is stable after thoracocentesis, outpatient treatment may be possible for some diseases. Most patients are

(CONTINUED) PLEURAL EFFUSION

Table 1

Characterization of pleural fluid.

	Transudate	*Modified Transudate*	*Nonseptic Exudate*	*Septic Exudate*	*Chyle*	*Hemorrhage*
Color	Colorless to pale yellow	Yellow or pink	Yellow or pink	Yellow to red-brown	Milky white	Red
Turbidity	Clear	Clear to cloudy	Clear to cloudy; fibrin	Cloudy to opaque; fibrin	Opaque	Opaque
Protein (g/dL)	<1.5	2.5–5.0	3.0–8.0	3.0–7.0	2.5–6.0	3.0
Nucleated cells/μL	<1,000	1,000–7,000 (LSA up to 100,000)	5,000–20,000 (LSA up to 100,000)	5,000–300,000	1,000–20,000	Similar to peripheral blood
Cytology	Mostly mesothelial cells and macrophages	Mostly macrophages and mesothelial cells; few nondegenerate PMNs; neoplastic cells in some cases	Mostly nondegenerate PMNs and macrophages; neoplastic cells in some cases	Mostly degenerate PMNs; also macrophages; bacteria	Small lymphocytes, PMNs, and macrophages	Mostly RBCs;with erythrophagocytosis
Disease associations	Hypoalbuminemia (protein-losing nephropathy, protein-losing enteropathy, or liver disease); early CHF	CHF; neoplasia; diaphragmatic hernia; pancreatitis	FIP; neoplasia; diaphragmatic hernia; lung lobe torsion	Pyothorax	Lymphangiectasia, CHF, cranial vena cava obstruction, neoplasia, fungal, dirofilariasis, diaphragmatic hernia, lung lobe torsion, trauma	Trauma, coagulopathy, neoplasia, lung lobe torsion

Source: Modified from Sherding RG. Diseases of the pleural cavity. In: Sherding RG, ed., The Cat: Diseases and Clinical Management, 2nd ed. New York: Churchill Livingstone, 1994, p. 1061.

P

hospitalized because they require intensive management such as indwelling chest tubes (e.g., patients with pyothorax) or thoracic surgery. • Preventing fluid reaccumulation requires treatment based on a definitive diagnosis. • Surgery is indicated for management of some neoplasias, diaphragmatic hernia repair, lymphangiectasia (i.e., thoracic duct ligation), foreign body removal, and lung lobe torsion (i.e., lung lobectomy). • Pleuroperitoneal shunts may relieve clinical signs in animals with intractable pleural effusion. • Vascular access ports attached to intrathoracic Jackson–Pratt drains can be tried for chronic effusions that are not responsive to the therapy of the underlying disorder.

MEDICATIONS

DRUG(S) OF CHOICE

• Treatment varies with specific disease. • Diuretics generally reserved for patients with diseases causing fluid retention and volume overload (e.g., CHF).

PRECAUTIONS

• Avoid drugs that depress respiration or decrease blood pressure. • Inappropriate use of diuretics predisposes the patient to dehydration and electrolyte disturbances without eliminating the effusion.

FOLLOW-UP

PATIENT MONITORING

Radiographic evaluation is key to assessment of treatment in most patients.

POSSIBLE COMPLICATIONS

• Death due to respiratory compromise. • Reexpansion pulmonary edema may develop after pleural effusion is manually removed.

EXPECTED COURSE AND PROGNOSIS

Varies with underlying cause, but usually guarded to poor. In a study of 81 cases of pleural effusion in dogs, 25% recovered completely and 33% died during or were euthanized immediately after completing diagnostic evaluation.

MISCELLANEOUS

SYNONYMS

• Hydrothorax = transudates and modified transudates. • Pyothorax = empyema, septic pleuritis.

ABBREVIATIONS

• CHF = congestive heart failure. • FIP = feline infectious peritonitis. • LSA = lymphoma. • PMN = polymorphonuclear cell. • RBC = red blood cell.

Consulting Editor Michael Aherne

Client Education Handout available online

PNEUMOCYSTOSIS

BASICS

OVERVIEW

• *Pneumocystis* spp.—saprophyte/commensal of low virulence; infect virtually all mammals worldwide. ○ *Pneumocystis carinii* f. sp. *canis*: organism infecting dogs (hereafter "*Pneumocystis canis*"). • Primary habitat is lung. • Atypical fungal organism, based on nucleic acid sequencing; exhibits behavior more typical of protozoa. • Subclinical infections in cats and dogs; clinical infections in dogs linked with immunodeficiency; clinical infection not reported in cats even with immunosuppression.

SIGNALMENT

• Young dogs (<1 year of age). • Miniature dachshunds and cavalier King Charles spaniels (CKCS, worldwide), Pomeranians (in Japan) predisposed (congenital immunodeficiencies).

SIGNS

• Progressive respiratory difficulty (weeks to months). • Dyspnea and tachypnea, cyanosis. • Exercise intolerance. • Cough. • Fever uncommon. • Inappetence, weight loss, and thin body condition. • Some dogs have concurrent generalized demodicosis.

CAUSES & RISK FACTORS

• Spread by airborne droplets. Neonates may be infected at birth. • Congenital or acquired immunodeficiency predisposes to development of clinical disease: ○ Severe immunosuppression—deficiency of IgA, IgG, IgM in dachshunds; immunoglobulin deficiency and decreased lymphocyte function in CKCS.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Inflammatory (chronic pulmonary fibrosis, eosinophilic bronchopneumopathy, inhalational irritants). • Infection (viral, bacterial, fungal, protozoal or parasitic pneumonia). • Pulmonary edema (cardiogenic or noncardiogenic). • Thromboembolism. • Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

• Usually nonspecific. • Leukocytosis with neutrophilia and a left shift. • Eosinophilia and monocytosis. • Erythrocytosis—secondary to chronic hypoxia. • Thrombocytopenia (CKCS) or thrombocytosis (dachshunds). • Variable hypoglobulinemia.

OTHER LABORATORY TESTS

• Arterial blood gas—hypoxemia; hypocapnia. • Immunoglobulin fraction quantification—hypogammaglobulinemia. • Indirect or direct fluorescent antibody test—detect organism in sputum, washes, and pulmonary tissues. • PCR of bronchoalveolar fluid and tissues.

IMAGING

Thoracic Radiography

• Diffuse miliary—interstitial to alveolar pattern with peribronchial opacification. • Middle lung lobes may be more severely affected. • Rarely cavitary lesions and pneumothorax.

CT

Diffuse to multifocal "ground-glass" appearance with variable bronchial bands; signs consistent with pulmonary hypertension.

DIAGNOSTIC PROCEDURES

• Transtracheal aspiration, bronchoalveolar lavage, transbronchoscopic and endobronchial brushing: ○ Direct visualization of *P. canis*. • Biopsy for histopathology (cytology not as sensitive or specific): ○ Invasive, potential complications of hemorrhage, pneumothorax. • PCR assays for *P. canis*—interpreted in light of consistent clinical signs and other diagnostic findings because of subclinical infection in dogs; assays designed to detect *P. jirovecii* may not detect *P. canis*.

PATHOLOGIC FINDINGS

• Lungs—firm, consolidated, pale brown or gray; fluid not expressed from cut surfaces; do not collapse when chest cavity opened; alveoli may be filled with amorphous, foamy, eosinophilic material with honeycomb appearance; trophozoites and cyst stages may be identified. • Pulmonary and mediastinal lymphadenopathy. • Right-sided cardiomegaly. • H&E only weakly stains internal structures of organism; methenamine silver, toluidine blue, Gram and periodic acid–Schiff will stain cyst walls.

TREATMENT

• Inpatient—supportive care for pneumonia: oxygen, nebulization, bronchodilators, IV fluids as required. • Discontinue immunosuppressant agents. • Cage rest.

MEDICATIONS

DRUG(S) OF CHOICE

• Trimethoprim-sulfonamide 15–20 mg/kg PO q8h or 30 mg/kg PO q12h for 3 weeks—preferred therapy (IV may be more effective than PO in humans). • Alternative treatments—pentamidine isethionate 4 mg/kg IM q24h for 3 weeks; atovaquone 15 mg/kg PO q24h for 3 weeks (not as effective but less toxic); combination of clindamycin and primaquine or dapsone and trimethoprim. • Potential new drug options—caspofungin (no veterinary cases reported) and trimetrexate. • Short-term treatment with anti-inflammatory doses of glucocorticoids may be beneficial.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Pentamidine isethionate—renal and hepatic dysfunction (check renal parameters daily during therapy), hypoglycemia, hypotension, hypocalcemia, urticaria, and hematologic disorders. • Trimethoprim-sulfonamides—keratoconjunctivitis sicca, thrombocytopenia.

FOLLOW-UP

PATIENT MONITORING

• Monitor clinical signs, radiographs; may need months-long treatment. • For side effects of medications.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Ubiquitous in environment; humans and animals are exposed to same sources.

ABBREVIATIONS

• CKCS = cavalier King Charles spaniel.

PNEUMONIA, ASPIRATION

BASICS

OVERVIEW
• Inflammation of the lungs caused by inhalation of oral ingesta, regurgitated material, and vomitus with subsequent pulmonary dysfunction; develops when laryngeal reflexes function improperly or are overwhelmed. • Pulmonary dysfunction—caused by (1) direct obstruction of small airways and indirect obstruction from bronchospasm and production of mucus and exudate; (2) aspiration of gastric acid—damages respiratory epithelium; can cause bronchospasm and acute lung injury/acute respiratory distress syndrome (ALI/ARDS); (3) bacterial pneumonia—bacteria in aspirated material can initiate an immediate infection; or later infections occur secondary to lung damage.

SIGNALMENT
Dogs; less commonly cats.

SIGNS
• Peracute, acute, or chronic. • Cough, tachypnea, nasal discharge, or exercise intolerance. • Respiratory distress or cyanosis when severe. • Depending on underlying cause—regurgitation; vomiting; dysphagia; altered consciousness; stertor or stridor.

CAUSES & RISK FACTORS
• Pharyngeal abnormalities—local paralysis; generalized neuromuscular disease; cricopharyngeal motor dysfunction; anatomic malformations. • Esophageal abnormalities—megaesophagus; reflux esophagitis; esophageal dysmotility; esophageal obstruction; broncho-esophageal fistula. • Laryngeal paralysis, webbing, or obstruction; post-laryngeal surgery. •Altered consciousness—sedation, anesthesia; post-ictus; forebrain disease; metabolic disturbance. • Iatrogenic—force feeding; tube feeding, mineral oil administration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Bacterial pneumonia. • Lung abscess.

CBC/BIOCHEMISTRY/URINALYSIS
Neutrophilic leukocytosis, left shift, although white blood cells may be normal.

OTHER LABORATORY TESTS
• Arterial blood gas analysis—hypoxemia; $Paco_2$ generally low. • Consider tests for predisposing problems—acetylcholine receptor antibodies, resting cortisol or adrenocorticotropic hormone stimulation, creatine kinase.

IMAGING
• Thoracic radiography—bronchoalveolar pattern usually most severe in the gravity-dependent lobes (right cranial and middle, left cranial); can take up to 24 hours for pattern to develop after aspiration; scrutinize for evidence of esophageal or mediastinal disease. • Videofluoroscopic swallowing study—provides evidence of swallowing or esophageal dysfunction that can predispose to aspiration. Caution: could result in aspiration of contrast medium.

DIAGNOSTIC PROCEDURES
• Tracheal wash—for bacterial culture and sensitivity testing before administering antibiotics; infection often caused by multiple organisms with unpredictable susceptibility.
• Bronchoscopy—rarely indicated.
• Laryngeal function examination—always perform if patient anesthetized for other purposes; otherwise, after resolution of pneumonia if supportive clinical signs.

TREATMENT
• Oxygen and cage rest—respiratory distress.
• Ventilatory support—if not oxygen responsive. • IV fluids—avoid overhydration, which can exacerbate secondary edema.
• Oral intake—withhold until primary problem identified and managed. • Do not allow patient to remain laterally recumbent on one side for more than 2 hours. • Mild exercise and saline nebulization with coupage can facilitate airway clearance. • Airway suction—only if performed immediately following aspiration (such as during recovery from anesthesia). • Airway lavage—contraindicated.

MEDICATIONS

DRUG(S) OF CHOICE
• Antibiotic therapy—if signs of sepsis or severe compromise, ampicillin with sulbactam (20 mg/kg IV q8h) plus a fluoroquinolone IV. Adjust antibiotic selection based on results of airway cytology, culture and sensitivity, and clinical response; continue for 10 days after resolution of clinical and radiographic signs; if no signs of sepsis, ampicillin with sulbactam pending results of culture.
• Beta-agonist bronchodilators—sometimes cause dramatic improvement but have the potential to worsen ventilation:perfusion mismatch; most often helpful in acute aspiration or with auscultable wheezes.
• Short-acting corticosteroids—consider for up to 48 hours to combat inflammation associated with life-threatening aspiration.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Diuretics—generally contraindicated; drying of airways reduces mucociliary clearance.
• Corticosteroids—contraindicated beyond initial stabilization; predispose patient to infection.
• Fluoroquinolones and chloramphenicol—can prolong clearance of theophylline-derivative bronchodilators; decrease theophylline dosage by 30–50% or prolong dosing interval.

FOLLOW-UP

PATIENT MONITORING
• Radiographs—evaluate every 2–7 days initially to determine appropriateness of treatment; then every 1–2 weeks. • If signs do not resolve or suddenly worsen—possible recurrence of aspiration or a secondary infection; repeat diagnostic evaluation, including tracheal wash or bronchoscopy.

PREVENTION/AVOIDANCE
• Predisposed patients undergoing anesthesia—cisapride (slow infusion, 1 mL/kg over 30 minutes) 1–2 hours pre-induction may decrease esophageal reflux. • Suction esophagus prior to extubation. • Antacids could decrease acid-related lung injury in predisposed patients; may also increase risk of infection.

POSSIBLE COMPLICATIONS
• Secondary infection common. • ALI/ARDS.
• Abscessation or granuloma formation rare.

EXPECTED COURSE AND PROGNOSIS
• Prognosis—depends on severity of signs and ability to correct underlying disease.
• Severe aspiration—can be fatal.
• Recurrence—likely if underlying cause not addressed.

MISCELLANEOUS

SEE ALSO
• Acute Respiratory Distress Syndrome.
• Megaesophagus. • Pneumonia, Bacterial.

ABBREVIATIONS
• ALI/ARDS = acute lung injury/acute respiratory distress syndrome.

PNEUMONIA, BACTERIAL

BASICS

DEFINITION
Acquired inflammatory response to bacteria in lung parenchyma characterized by exudation of cells and fluid into conducting airways and alveolar spaces.

PATHOPHYSIOLOGY
• Bacteria—enter the lower respiratory tract primarily by inhalation or aspiration; less commonly by the hematogenous route. Infection incites an inflammatory reaction. • Tracheobronchial tree and carina—normally not sterile. • Oropharyngeal bacteria—frequently aspirated; may be present for an unknown time period in the normal tracheobronchial tree and lung; can cause or complicate respiratory infection; presence complicates interpretation of airway and lung cultures. • Respiratory infection—development depends on the complex interplay of many factors: inoculation site, number of organisms and their virulence, and age and resistance of the host. • Bacteria produce extracellular proteins called invasins that impair host defenses and assist in the spread of bacteria. • Viral infections—alter bacterial colonization patterns; increase bacterial adherence to respiratory epithelium; reduce mucociliary clearance and phagocytosis; allow resident bacteria to invade the lower respiratory tract. • Foreign body—inoculates bacteria into a focal lung region and leads to obstructive pneumonia. • Exudative phase—inflammatory hyperemia; extravasation of high-protein fluid into interstitial and alveolar spaces. • Leukocytic migration phase—leukocytes infiltrate the airways and alveoli; consolidation, ischemia, tissue necrosis, and atelectasis owing to bronchial occlusion, obstructive bronchiolitis, and impaired collateral ventilation.

SYSTEMS AFFECTED
Respiratory—primary or secondary infection.

GENETICS
Heritable rhinitis/bronchopneumonia syndrome of Irish wolfhounds, unknown pathogenesis.

INCIDENCE/PREVALENCE
Common in both young and old dogs, less common in cats.

GEOGRAPHIC DISTRIBUTION
Widespread

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Dogs—sporting breeds, hounds, working breeds, and mixed breeds >12 kg.

Mean Age and Range
Dogs—range, 1 month–15 years.

Predominant Sex
Dogs—60% males.

SIGNS

Historical Findings
• Cough. • Labored breathing. • Recent vomiting/regurgitation (aspiration). • Anorexia. • Lethargy. • Nasal discharge.

Physical Examination Findings
• Cough. • Fever. • Difficult or rapid breathing. • Abnormal breath sounds on auscultation—increased intensity, crackles, and wheezes. • Nasal discharge. • Lethargy. • Dehydration.

CAUSES

Dogs
• Most common primary pathogens—*Bordetella bronchiseptica* and *Mycoplasma* spp. • Most common Gram-positive bacteria—*Staphylococcus*, *Streptococcus*, and *Enterococcus* spp. • Most common Gram-negative bacteria—*Escherichia coli*, *Klebsiella* spp., *Pseudomonas* spp., *Pasteurella* spp. • Anaerobic bacteria—found in pulmonary abscesses and various types of pneumonia (particularly with aspiration or foreign bodies); reported in ~20% of cases.

Cats
• Bacterial pathogens—poorly documented; *B. bronchiseptica*, *Pasteurella* spp., and *Moraxella* spp. most frequently reported. *Mycoplasma* spp. may be a primary pathogen in the lower respiratory tract. • Carrier state—may exist; periods of shedding *B. bronchiseptica* after stress; infected queens may not shed organism prepartum but begin shedding post partum, serving as a source of infection for kittens.

RISK FACTORS
• Prior viral infection. • Regurgitation, dysphagia, or vomiting. • Functional or anatomic defects—laryngeal paralysis, brachycephalic breed, megaesophagus, cleft palate, primary ciliary dyskinesia. • Reduced level of consciousness—stupor, coma, and anesthesia. • Bronchial foreign body. • Bronchiectasis. • Immunosuppressive therapy—chemotherapy, glucocorticoids. • Severe metabolic disorders—uremia, diabetes mellitus, hyperadrenocorticism. • Sepsis. • Age—very young more susceptible to fatal infections. • Immunization status. • Environment—housing, sanitation, ventilation. • Phagocyte dysfunction—feline leukemia virus and diabetes mellitus. • Complement deficiency—rare. • Selective IgA deficiency—rare. • Combined T-cell and B-cell dysfunction—rare.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Viral pneumonia (canine distemper virus, adenovirus, influenza virus, herpesvirus). • Protozoal pneumonia (*Toxoplasma*). • Parasitic pneumonia (capillariasis, filaroidiasis, lungworm). • Fungal pneumonia (*Histoplasma*, *Blastomyces, Coccidioides*, *Cryptococcus*). • Eosinophilic pneumonia. • Feline bronchial disease (asthma). • Pulmonary abscess. • Pleural infection (pyothorax). • Bronchial foreign body.

CBC/BIOCHEMISTRY/URINALYSIS
Inflammatory leukogram—neutrophilic leukocytosis with or without a left shift; absence does not rule out the diagnosis.

OTHER LABORATORY TESTS
• Arterial blood gas analysis—values correlate well with the degree of physiologic disruption; sensitive monitor of progress during treatment; Pa_{O_2} <80 mmHg on room air = mild or moderate hypoxemia; Pa_{O_2} <60mmHg on room air = severe hypoxemia. • Consider viral serology. • Molecular diagnostics also available for viral and bacterial presence.

IMAGING

Thoracic Radiography
• Variable—diffuse, bronchointerstitial pattern, partial or complete alveolar infiltrates, consolidation. • Most common—alveolar pattern characterized by increased pulmonary densities (margins indistinct; air bronchograms or lobar consolidation). • More variable lung patterns in cats such as multifocal, patchy interstitial and alveolar changes and/or a diffuse nodular pattern.

DIAGNOSTIC PROCEDURES
• Microbiologic (aerobic, anaerobic, and *Mycoplasma* culture) and cytology for definitive diagnosis. • Samples—transtracheal or endotracheal washing, bronchoscopy, bronchoalveolar lavage (with or without bronchoscope), or fine-needle lung aspiration. • Degenerate neutrophils with septic inflammation (intracellular bacteria) predominating. • Recent antibiotic administration—nonseptic inflammation likely. • Bacteria—not always obvious microscopically; always culture specimens even if no bacteria are seen on cytology.

PATHOLOGIC FINDINGS
• Irregular consolidation in cranioventral regions. • Consolidated lung—varies from dark red to gray-pink to more gray, depending on age of patient and nature of the process. • Palpable firmness of the tissue. • Nidus of inflammation—bronchiolar-alveolar junction. • Early—bronchioles and adjacent alveoli filled with neutrophils and an admixture of cell debris, fibrin, and macrophages; necrotic to hyperplastic epithelium. • Later—neutrophilic, fibrinous, hemorrhagic, or necrotizing inflammation depending on virulence of bacteria and host response.

(CONTINUED) PNEUMONIA, BACTERIAL

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient—recommended with multisystemic signs (e.g., anorexia, fever) or in patients with respiratory compromise in the absence of multisystemic signs.

NURSING CARE
• Maintain normal systemic hydration—important to aid mucociliary clearance and secretion mobilization; use a balanced electrolyte solution. • Saline nebulization—results in more rapid resolution if used with physical therapy and systemic antimicrobials. • Physical therapy—chest wall coupage, tracheal manipulation to stimulate mild cough and postural drainage; may enhance clearance of secretions; always do immediately after nebulization; avoid allowing the patient to lie in one position for a prolonged time. • Oxygen therapy—as warranted for patients with hypoxemia, signs of respiratory distress.

ACTIVITY
Restrict during treatment (inpatient or outpatient), except as part of physical therapy after aerosolization.

DIET
• Ensure normal intake with food high in protein and energy density. • Enteral or parenteral nutritional support—indicated in severely ill patients. • Use caution in feeding animals with megaesophagus, laryngeal dysfunction or surgery, pharyngeal disease, or recumbent patients.

CLIENT EDUCATION
Warn client that high morbidity and mortality are associated with severe hypoxemia and sepsis.

SURGICAL CONSIDERATIONS
Lung lobectomy may be required with pulmonary abscessation or bronchopulmonary foreign body with secondary pneumonia; may be indicated if patient is unresponsive to conventional treatment and disease is limited to one or two lobes.

MEDICATIONS

DRUG(S) OF CHOICE

Antimicrobials
• Antimicrobials are best selected based on results of culture and susceptibility testing from tracheal wash or other pulmonary specimens. • Empiric antimicrobial therapy is justified when there is significant risk in obtaining adequate samples or if the time required to culture causes a life-threatening delay in treatment. • Recently administered antimicrobials should be avoided. • Reasonable initial antimicrobial choices pending culture results include amoxicillin-clavulanic acid 15 mg/kg PO q12h or cephalexin 22–30 mg/kg PO q12h with enrofloxacin (dogs, 10–20 mg/kg q24h; cats, maximum 5 mg/kg q24h), or trimethoprim-sulfonamide 15 mg/kg PO q12h. • Gram-positive cocci—ampicillin 20–40 mg/kg IV q6–8h, ampicillin-sulbactam 22–30 mg/kg IV q6–8h; amoxicillin 22 mg/kg PO q12h; amoxicillin-clavulanic acid; azithromycin; chloramphenicol, erythromycin; trimethoprim-sulfonamide; first-generation cephalosporins. • Gram-negative rods—enrofloxacin or marbofloxacin; cefpodoxime; chloramphenicol; trimethoprim-sulfonamide; amikacin. • *Bordetella*—doxycycline 5 mg/kg PO q12h; chloramphenicol; enrofloxacin; azithromycin. • *Mycoplasma*—doxycycline, enrofloxacin, marbofloxacin, chloramphenicol. • Anaerobes—amoxicillin–clavulanic acid; chloramphenicol; metronidazole; clindamycin; ticarcillin-clavulanic acid. • Antimicrobial nebulization for *Bordetella*—gentamicin nebulization 5 mg/kg q24h for 5–7 days, typically adjunctive with systemic antimicrobials.

Duration of Treatment
• Authors have traditionally recommended continued treatment for at least 10 days beyond clinical resolution and/or 1–2 weeks following radiographic resolution. • Total of ≤14 days of therapy is not associated with worse outcomes when compared to >14 days of therapy in dogs.

CONTRAINDICATIONS
• Anticholinergics and antihistamines—may thicken secretions and inhibit mucokinesis and exudate removal from airways. • Antitussives—potent, centrally acting agents inhibit mucokinesis and exudate removal from airways; can potentiate pulmonary infection and inflammation.

POSSIBLE INTERACTIONS
Avoid use of theophylline and fluoroquinolones concurrently.

ALTERNATIVE DRUG(S)
• Expectorants—recommended by some clinicians; no objective evidence that they increase mucokinesis or mobilization of secretions. • Bronchodilators—recommended by some clinicians to alleviate bronchospasm.

FOLLOW-UP

PATIENT MONITORING
• Monitor respiratory rate and effort. • Complete blood count will normalize. • Arterial blood gases—sensitive monitor of progress, pulse oximetry can be helpful. • Frequent thoracic auscultation. • Thoracic radiographs—improve more slowly than the clinical appearance.

PREVENTION/AVOIDANCE
• Vaccination—against upper respiratory viruses and *Bordetella* if a dog is boarded or exposed to large numbers of other animals. • Catteries—environmental strategies to lower population density and improve hygiene help control outbreaks of bordetellosis.

POSSIBLE COMPLICATIONS
• Sepsis can develop. • Severe respiratory compromise may require intubation/mechanical ventilation.

EXPECTED COURSE AND PROGNOSIS
• Prognosis—good with aggressive antibacterial and supportive therapy; more guarded in young animals, patients with immunodeficiency, and patients that are debilitated or have severe underlying disease. • Prolonged infection—potential for chronic bronchitis or bronchiectasis in any patient. • Mortality—associated with severe hypoxemia and sepsis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Frequently develops secondary to underlying functional or anatomic abnormalities—cleft palate; tracheal hypoplasia; primary ciliary dyskinesia; laryngeal paralysis; megaesophagus or other esophageal dysmotility disorder. • Bronchiectasis—both predisposing factor and potential complication.

AGE-RELATED FACTORS
• Young puppies and kittens—may have a poorer prognosis. • Underlying functional and anatomic problems and immunodeficiencies—suspect in young patients.

PREGNANCY/FERTILITY/BREEDING
Bitches or queens infected with *B. bronchiseptica*—may transmit infection to neonates.

P

PNEUMONIA, EOSINOPHILIC

BASICS

DEFINITION
The fully developed inflammatory response to antigens in lung parenchyma characterized by exudation of eosinophils and fluid into lung interstitium, conducting airways, and alveolar spaces.

PATHOPHYSIOLOGY
• Immunologic basis—supporting evidence generally accepted; mechanisms involved not yet clarified. • Eosinophilic infiltration and a predominance of CD4+ T-cells in broncho-alveolar lavage fluid support the role of a dominant Th2 immune response in the lower airways. • Evolution of disease—likely determined by characteristics of antigens, host response, and regulation of that response. • Antigens enter the lower respiratory tract by inhalation or hematogenous routes. • Chronic exposure to antigens—elicits a humoral and cellular immune response. • Allergic or hypersensitivity pulmonary disorders—associated with an abnormal humoral antibody response and a cell-mediated immunoregulatory defect. • Immunoglobulin classes involved—IgE, IgG, and others. • High numbers of activated macrophages and T-lymphocytes and depressed suppressor T-cell activity—alter cell-mediated immunity. • Collagenolytic enzyme activity—increased. • Generally referred to as eosinophilic broncho-pneumopathy although at least three disease patterns appear to exist: eosinophilic pneumonitis, eosinophilic bronchitis, and pulmonary eosinophilic granulomatosis. • Severely affected dogs appear to develop marked granulomatous disease. • Heartworm disease with pneumonitis—microfilaria may become entrapped in the pulmonary circulation and trigger an immune response. • Mortality—associated with severe hypoxemia (e.g., low arterial oxygen concentration) and (rarely) severe hemoptysis.

SYSTEMS AFFECTED
• Respiratory—lower respiratory tract primarily but nasal cavity can also be involved. • Cardiovascular—can develop cor pulmonale.

GENETICS
N/A

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Widespread

SIGNALMENT
Species
Dog

Breed Predilections
Siberian husky, possibly.

Mean Age and Range
All ages but more often young adults (4–6 years of age).

Predominant Sex
None

SIGNS
General Comments
Extremely variable, depending on the severity.

Historical Findings
• Cough—unresponsive to antibacterial therapy. • Labored breathing. • Exercise intolerance. • Anorexia. • Lethargy. • Weight loss. • Nasal discharge. • Fever (uncommon).

Physical Examination Findings
• Harsh, moist cough. • Tachypnea or respiratory distress. • Abnormal breath sounds on auscultation—increased-intensity breath sounds; crackles; wheezes; decreased sounds can occur. • Weight loss. • Yellow-green or mucopurulent nasal discharge. • Fever (uncommon).

CAUSES
• Purported aeroallergens—spores or hyphae from fungi and actinomycetes; pollen; insect antigens; dust or storage mites; unidentified triggers of the immune response. • Parasitic antigens—heartworm microfilaria, respiratory parasites.

RISK FACTORS
• Living in a heartworm-endemic area without receiving preventive medication. • Dusty or moldy environment. • Air pollution.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Parasitic pneumonia—capillariasis; paragonimiasis; dirofilariasis. • Fungal pneumonia—histoplasmosis; blastomycosis; coccidioidomycosis; cryptococcosis. • For eosinophilic pneumonitis—bacterial pneumonia; viral pneumonia (e.g., canine distemper virus and canine adenovirus); rickettsial pneumonia (e.g., ehrlichiosis and Rocky Mountain spotted fever); protozoal pneumonia (e.g., toxoplasmosis); congestive heart failure; bartonellosis. • For eosinophilic bronchitis—infectious tracheobronchitis; chronic bronchitis. • For pulmonary eosinophilic granulomatosis—neoplasia (including lymphomatoid granulomatosis); pulmonary abscess; bronchial foreign body.

CBC/BIOCHEMISTRY/URINALYSIS
• Inflammatory leukogram—neutrophilic leukocytosis with or without a left shift, eosinophilia, basophilia, or monocytosis. • Absence of eosinophilia does not exclude diagnosis. • Hyperglobulinemia—suggests chronic antigenic stimulus; rule out occult dirofilariasis.

OTHER LABORATORY TESTS
Arterial Blood Gas Analysis
• Values correlate well with the degree of physiologic disruption; sensitive monitor of patient's progress during treatment. • Hypoxemia—mild or moderate, PaO_2 <80 mmHg on room air; severe, PaO_2 <60 mmHg on room air.

Other
• Heartworm microfilaria and antigen tests—positive results suggest dirofilariasis or eosinophilic pneumonitis associated with microfilaria trapped in the lung. Multiple tests can be required to rule out disease. • Fecal flotation and Baermann sedimentation. • Protein electrophoresis—β-globulin spike (hyperbetaglobulinemia) often found with occult dirofilariasis.

IMAGING
• Radiographic findings depend on extent and severity of disease. • Thoracic radiographs—help document the severity of pulmonary artery disease; reveal interstitial pneumonitis in dogs with dirofilariasis. • Eosinophilic pneumonitis—linear or miliary interstitial pattern that resembles changes seen with early pulmonary edema or fungal pneumonia; alveolar pattern characterized by increased pulmonary densities with indistinct margins in severely affected patients; tortuous, large pulmonary arteries and right-sided cardiomegaly in patients with dirofilariasis. • Eosinophilic bronchitis—bronchial pattern with thickened bronchi extending into the periphery of the lung (tram/railroad track and donut signs); bronchiectasis in chronic cases. • Eosinophilic granuloma—multiple nodular lesions of variable sizes in different lung lobes; patchy, focal alveolar densities; tracheo-bronchial lymphadenopathy possible.

DIAGNOSTIC PROCEDURES
• Transtracheal or endotracheal wash appropriate for sample collection. • Bronchoscopy; yellow-green mucus, polypoid mucosal proliferation, partial airway collapse. Occlusive eosinophilic plaques or granulomas sometimes visible within airways. • Bronchoalveolar lavage—with or without bronchoscope. • Bacterial and mycoplasmal culture of bronchoalveolar lavage fluid is recommended to rule-out bacterial infection. Occasionally, concurrent bacterial infection can be identified in dogs with eosinophilic lung disease. • Fine-needle lung aspiration and examination. • Cytologic examination of aspirates, washings, or brushings—definitive diagnosis: eosinophilic inflammation predominates; may note other types of inflammatory cells; carefully examine specimens for antigenic sources (e.g., parasites, fungi, or neoplasia). • Consider intradermal skin or serologic allergen testing—rarely may identify allergens. • Fecal

examinations—routine flotation, direct smear, sediment examination, and Baermann technique to rule out parasitic pneumonia; negative test can occur due to intermittent shedding and empirical therapy warranted in some cases.

PATHOLOGIC FINDINGS
• Gross—diffuse, patchy, or nodular firm lesions; usually pale or mottled.
• Histopathologic—eosinophilic, lymphocytic, and macrophagic infiltration of alveolar walls and alveolar spaces; as disease progresses, interstitial infiltrative process becomes fibrotic with obliteration of alveolar spaces, and granulomas can be dispersed within the interstitial fibrosis. Upper respiratory tract epithelium can also be involved with eosinophilic infiltration.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient—recommended with multisystemic signs (e.g., anorexia, weight loss, or lethargy).

NURSING CARE
• Dehydration—hinders mucociliary clearance and secretion mobilization; maintain normal systemic hydration with a balanced multielectrolyte solution.
• Supplemental oxygen—for respiratory distress.

ACTIVITY
Restricted during treatment (inpatient or outpatient).

DIET
Ensure normal intake.

CLIENT EDUCATION
Warn client that morbidity and mortality are associated with severe hypoxemia.

SURGICAL CONSIDERATIONS
Lung lobectomy can be required with large granulomas.

MEDICATIONS

DRUG(S) OF CHOICE
• Corticosteroids—prednisolone or prednisone at 2 mg/kg/day until clinical signs begin to resolve (typically 2–3 weeks); then taper slowly (over months). Maintenance dosages of prednisone are often required long term (0.125–0.5 mg/kg q48h or every 3 or 4 days for 4–6 months or longer). • Following adequate control of disease and/or due to side effects of systemic glucocorticoids, inhaled corticosteroids (e.g., fluticasone propionate) can be used in conjunction with a spacing chamber and facemask. • Antibiotic therapy indicated only if active infection documented on airway culture. Prophylactic therapy could lead to development of antimicrobial resistance. • Heartworm adulticidal therapy—for heartworm-positive patient; initiate after the patient has been stabilized with corticosteroids and rest. • Itraconazole or ketoconazole—use antifungal drugs only if the fungal infection is confirmed by cytologic examination or culture. • Hyposensitization—allergy shots based on results of intradermal skin or serologic testing can be attempted but is not the treatment of choice in most patients. Most dogs will still require steroid therapy.

CONTRAINDICATIONS
N/A

PRECAUTIONS
N/A

ALTERNATIVE DRUG(S)
Other immunosuppressive drugs (e.g., cyclosporine)—can use when corticosteroids are contraindicated or have been ineffective, although inhaled steroids are preferred. No trial results are available to date.

FOLLOW-UP

PATIENT MONITORING
• Complete blood count will show resolution of peripheral eosinophilia or neutrophilia.
• Arterial blood gases—most sensitive monitor of progress. Can remain abnormal even with successful management of disease.
• Auscultate patient thoroughly several times daily. • Thoracic radiographs—improve more slowly than the clinical appearance.

PREVENTION/AVOIDANCE
• Routine heartworm-prevention medication.
• Consider changing patient's environment if an aeroallergen is suspected.

POSSIBLE COMPLICATIONS
Pulmonary embolization—dogs treated with adulticidal therapy for dirofilariasis.

EXPECTED COURSE AND PROGNOSIS
• Prognosis good for mild-to-moderate cases; many patients require long-term treatment with steroids. • If allergen can be identified and eliminated—suspect improved prognosis. • Heartworm infection—prognosis depends on severity of pulmonary hypertension, cor pulmonale, and embolization.
• Eosinophilic granulomatosis—prognosis guarded; often disease is progressive.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Dirofilariasis. • Bronchopulmonary fungal infection.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Corticosteroids and other immunosuppressive drugs are relatively contraindicated in pregnant animals.

SYNONYMS
• Allergic alveolitis. • Allergic bronchitis.
• Bronchitic pulmonary eosinophilia.
• Eosinophilic bronchitis or bronchopneumopathy. • Eosinophilic pneumonia/pneumonitis. • Eosinophilic pulmonary granulomatosis. • Extrinsic allergic alveolitis. • Hypersensitivity pneumonitis. • Occult heartworm pneumonia. • Parasitic pulmonary eosinophilia. • Pulmonary infiltrates with eosinophilia.

SEE ALSO
• Cough.
• Dyspnea and Respiratory Distress.
• Heartworm Disease—Dogs.
• Panting and Tachypnea.

PNEUMONIA, FUNGAL

BASICS

DEFINITION
Inflammation of the pulmonary interstitial, lymphatic, and peribronchial tissues caused by deep mycotic infection.

PATHOPHYSIOLOGY
• Mycelial fungal elements—inhaled from contaminated soil or plant debris; organisms then colonize the lungs. • Dimorphic fungi such as *Blastomyces dermatitidis*, *Histoplasma capsulatum*, *Coccidioides immitis*—yeast phase at body temperature. Invasive fungal infections with *Aspergillus* spp. follow inhalation of airborne spores with growth as mycelia within tissue. • Systemic dissemination of yeast from the lungs common in dogs and cats.
• Pulmonary interstitial and alveolar involvement—can cause hypoxia. • Airway involvement—causes cough. • Cell-mediated immune response leads to pyogranulomatous inflammation. • Pulmonary complications include interstitial and/or bronchial pneumonia, pleural effusion, mediastinal granuloma formation, acute respiratory distress syndrome, and pulmonary thromboembolism.

SYSTEMS AFFECTED
• Depend on the specific fungal disease.
• Blastomycosis—respiratory involvement in ~85% of cases; diffuse interstitial, alveolar, or bronchial pneumonia most common; solitary mass lesions can be seen, especially in cats; tracheobronchial lymphadenopathy can contribute to cough; nasal infection rare. Multisystemic involvement of skin, lymph nodes, eyes, bone, reproductive tract, and CNS often seen. • Histoplasmosis—respiratory disease alone is only seen in 10% of cases; but multisystemic involvement with diffuse interstitial pneumonia is common, especially in cats; perihilar or mediastinal lymphadenopathy contributes to cough. Multisystemic involvement of gastrointestinal tract, liver, lymph nodes, spleen, bone marrow, eyes, bone, and CNS often seen. • Coccidioidomycosis—diffuse interstitial or bronchial pneumonia common in dogs but less common in cats; perihilar or mediastinal lymphadenopathy common. Multisystemic involvement of bone, skin, eyes, lymph nodes, heart, and CNS often seen. • Cryptococcosis—nasal cavity involvement most common in cats, neurologic system in dogs. Skin and other organs also affected. • Systemic aspergillosis—*Aspergillus terreus*: pneumonia less common, renal and bone (especially vertebral) involvement common.

GENETICS
Breed susceptibilities may be related to defects in cell-mediated immunity.

INCIDENCE/PREVALENCE
Depends on geographic distribution.

GEOGRAPHIC DISTRIBUTION
• Blastomycosis—endemic in US Southeast and Midwest along the Mississippi, Ohio, Missouri, and Tennessee rivers and southern Great Lakes; also in southern Mid-Atlantic States, Pacific Northwest, and southern Canada from east coast to prairie regions of southern Saskatchewan and Manitoba.
• Histoplasmosis—similar to but more widely distributed than blastomycosis; pockets of disease in Texas, Oklahoma, and California.
• Coccidioidomycosis—US Southwest from Texas to California. Northern Mexico and parts of South America. • Cryptococcosis and aspergillosis—worldwide.

SIGNALMENT

Species
Dog and less commonly cat (except cryptococcosis and histoplasmosis where the cat is affected more often than dogs).

Breed Predilections
• Systemic mycosis—large-breed, sporting, working, hunting or field trial dogs; Doberman pinschers and Rottweilers appear predisposed to disseminated disease. • Systemic aspergillosis—German shepherd dogs overrepresented. • Cryptococcosis—cocker spaniels overrepresented.

Mean Age and Range
• Young animals (<5 years) predisposed.
• Any age can be affected.

Predominant Sex
Males affected 2–4 times more often than females.

SIGNS

General Comments
Multisystemic illness depends on organ systems involved.

Historical Findings
• Chronic weight loss and inappetence.
• Oculonasal discharge. • Coughing—can be prominent but seen inconsistently even with marked pulmonary disease. • Tachypnea or exercise intolerance common. • Labored breathing—more common in cats; sign of severe disease in both dogs and cats. • Acute blindness or blepharospasm—if eyes are affected. • Papules and cutaneous nodules—common but often missed until draining tracts appear. • Lameness—if bones affected or if osteomyelitis develops. • Seizures, ataxia, behavior change—if CNS affected.

Physical Examination Findings
• Emaciation—in chronically affected patients. • Fever—about 50% of patients.
• Harsh, loud breath sounds, crackles in cats, cough on tracheal palpation.
• Dyspnea—at rest with severe disease.
• Lymphadenopathy—common in dogs with dimorphic fungal infections.
• Blastomycosis (dogs)—cutaneous and subcutaneous nodules with draining tracts; chorioretinitis; granulomatous retinal detachment common. • Coccidioidomycosis (dogs)—lameness and pain from osteomyelitis, pericardial disease; cats—skin lesions.
• Histoplasmosis (dogs)—emaciation and bloody diarrhea; cats—skin lesions.
• Cryptococcosis—nasal cavity and soft tissue infection common in cats; chorioretinitis in dogs and cats.

CAUSES
• Primary route of infection—*Blastomyces dermatitidis*: lungs, *Histoplasma capsulatum*: lungs and possibly gastrointestinal tract, *Coccidioides immitis*: lungs. • *Cryptococcus neoformans* and *C. gattii*—nasal cavity, with direct extension into the eyes or CNS, lungs (especially in dogs, less often in cats).
• *Aspergillus* spp.—nasal cavity and lungs.

RISK FACTORS
• Blastomycosis, histoplasmosis, and cryptococcosis—environmental exposure to soils rich in organic matter; blastomycosis and cryptococcosis—exposure to bird droppings or other fecal matter; blastomycosis—living near water. • Coccidioidomycosis—environmental exposure to sandy, alkaline soil after periods of rainfall; outdoor activities (hunting and field trials). • Feline leukemia virus does not appear to be a risk factor and feline immunodeficiency virus may be minor risk factor. • Prednisone—may worsen the disease. • Antineoplastic chemotherapy.
• Lymphoreticular neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Metastatic neoplasia. • Eosinophilic lung disease. • Lymphomatoid granulomatosis.
• Lymphoreticular and histiocytic neoplasia.
• Idiopathic pyogranulomatous disease.
• Feline infectious peritonitis or other vasculitic disease. • Parasitic pneumonia.
• Bacterial pneumonia. • Viral pneumonia.
• Chronic bronchial disease. • Pulmonary edema. • Pulmonary thromboembolism.

CBC/BIOCHEMISTRY/URINALYSIS
• Moderate leukocytosis with or without a left shift. • Lymphopenia common.
• Leukopenia, thrombocytopenia, nonregenerative anemia—with histoplasmosis.
• Hyperglobulinemia and hypoalbuminemia common. • Hypercalcemia—occasionally (most often in dogs with blastomycosis).
• Liver enzyme activities—more likely to be increased with histoplasmosis. • Urinalysis usually normal; proteinuria—occasionally seen. • Organisms—rarely can be seen in urine (common with *Aspergillus*) if kidneys or lower urinary tract are affected.

OTHER LABORATORY TESTS

• Antigen can be detected in serum or urine by enzyme immunoassay for diagnosis of *Blastomyces* or *Histoplasma*—sensitivity and specificity high, especially in urine. Cross-reaction occurs between *Blastomyces* and *Histoplasma*. Antigen testing for *Coccidioides* is insensitive. • Serologic (antibody) testing for blastomycosis and histoplasmosis—false-positive and false-negative results common. Positive titer for *Coccidioides* using heat-precipitated agar gel immunodiffusion consistent with infection with relevant clinical history and signs. • Latex agglutination test—for capsular antigen; highly reliable for cryptococcosis. • Cytologic or histologic identification of the organism—definitive diagnosis. • Culture—not usually necessary; can be difficult to isolate and risky due to zoonosis.

IMAGING

• Thoracic radiography—diffuse interstitial (histoplasmosis and coccidioidomycosis) to nodular interstitial and peribronchial infiltrates (blastomycosis); nodular densities can coalesce to granulomatous masses with indistinct edges; tracheobronchial lymphadenopathy common; large focal granulomas more likely in cats. • Appendicular or axial skeleton radiography—osteolysis with periosteal proliferation; soft tissue swelling. • Abdominal ultrasonography—granulomas or large lymph nodes. • Ocular ultrasonography—retrobulbar mass, posterior uveitis.

DIAGNOSTIC PROCEDURES

• Impression smear or aspirate of a skin nodule—most likely to yield organisms. • Fine-needle lung aspirate—possibly more diagnostic than tracheal aspirate or bronchoalveolar lavage specimen. • Lymph node aspirate or biopsy. • CSF tap—with cryptococcosis. • Bone marrow or liver/splenic aspirate—with histoplasmosis. • Biopsy—may be needed.

PATHOLOGIC FINDINGS

• Pyogranulomatous inflammation. • Organisms—usually seen with blastomycosis, histoplasmosis, cryptococcosis, and aspergillosis; difficult to find with coccidioidomycosis.

TREATMENT

APPROPRIATE HEALTH CARE

• Outpatient—if patient is stable. • Inpatient evaluation and treatment—dehydration, anorexia, and severe hypoxia.

NURSING CARE

Administration of fluids, oxygen, and antifungals as needed.

DIET

• Feed high-quality protein, calorically dense food. • Histoplasmosis accompanied by marked gastrointestinal involvement—feed highly digestible food.

CLIENT EDUCATION

• Complete response to treatment in <70% of dogs and a smaller percentage of cats. • Relapse is common. • Treatment is expensive and will be long term (>2 months). • Clean environmental areas of highly organic matter or feces.

SURGICAL CONSIDERATIONS

Focal granulomas or glaucomatous painful eyes can require removal.

MEDICATIONS

DRUG(S) OF CHOICE

• Itraconazole 5–10 mg/kg PO daily; must be given with food. Liquid suspension more bioavailable in cats (dose 1–1.5 mg/kg/day PO). • Fluconazole 10 mg/kg PO q12h; drug of choice for cryptococcosis and patients with CNS or urinary tract involvement. Usually requires longer treatment. • Lipid-complex amphotericin B 1–2 mg/kg IV q48h for 12 treatments; nephrotoxicity low; diuresis not required. • Posaconazole 5 mg/kg PO q24h with food may be more effective for aspergillosis.

CONTRAINDICATIONS

Corticosteroids are relatively contraindicated but may be required to reduce inflammation during initial treatment in severely dyspneic patients or patients with CNS disease.

PRECAUTIONS

• Azole drugs—do not use with severe liver disease. • Amphotericin B—do not use in azotemic or dehydrated patients; stop use if BUN >50 mg/dL or creatinine >3 mg/dL. • Itraconazole and the other azole drugs—anorexia; increase in liver enzymes; cutaneous vasculitis.

POSSIBLE INTERACTIONS

Antacids and anticonvulsants—can lower blood concentration of itraconazole.

ALTERNATIVE DRUG(S)

• Ketoconazole 10–30 mg/kg PO q12h; can be effective; higher incidence of side effects; longer treatment is necessary; relapse common. • Amphotericin B 0.5 mg/kg (dogs) or 0.25 mg/kg (cats) IV three times/week to a total dose of 8 mg/kg if used alone or 4 mg/kg if used with an azole drug; administer in 200–500 mL of D_5W after saline diuresis; best used with itraconazole or ketoconazole for severely affected patients. • Amphotericin B—alternative: 0.5–0.8 mg/kg 2–3 times per week; to reduce nephrotoxicity, can give subcutaneously diluted in 0.45% saline/2.5% dextrose solution (400 mL for cats, 500 mL for dogs <20 kg, 1,000 mL for dogs >20 kg). • Voriconazole 3–4 mg/kg PO q12h for invasive aspergillosis; causes CNS signs in cats. • Terbinafine 30–40 mg/kg PO q12h can be added to azole treatment regimes in resistant infections. • Nikkomycin Z 250 mg PO q12h for dogs 5–15 kg; 500 mg PO q12h for dogs >15 kg for treatment of coccidioidomycosis.

FOLLOW-UP

PATIENT MONITORING

• Liver enzymes—evaluated monthly during azole therapy. • BUN and creatinine—measure before each dose of amphotericin B. • Thoracic radiographs—reevaluate before discontinuing treatment. • Urine antigen testing for *Blastomyces*/*Histoplasma*—use to monitor therapy.

PREVENTION/AVOIDANCE

Reduce possible exposure.

POSSIBLE COMPLICATIONS

• Blindness is usually permanent. • Renal failure from amphotericin B.

EXPECTED COURSE AND PROGNOSIS

• Blastomycosis—requires a minimum of 2 months of treatment; 60–70% of dogs cured by itraconazole. Dogs with dyspnea or hypoxemia have poorer prognosis. • Histoplasmosis, coccidioidomycosis—continue at least 1 month past remission (usually 6 months or more). • Systemic aspergillosis—poor prognosis. • Relapse—can occur up to 1 year after treatment.

MISCELLANEOUS

AGE-RELATED FACTORS

Young animals predisposed.

ZOONOTIC POTENTIAL

Infections in people—primarily from a common environmental source; no direct transmission from animals to humans, except by penetrating wounds contaminated by the organism; needle stick injury.

PREGNANCY/FERTILITY/BREEDING

• Fungal abortion possible. • Azole antifungals—teratogenic; do not use in pregnant animals.

SEE ALSO

• Aspergillosis, Disseminated Invasive. • Aspergillosis, Nasal. • Blastomycosis. • Coccidioidomycosis. • Cryptococcosis. • Histoplasmosis.

PNEUMONIA, INTERSTITIAL

BASICS

DEFINITION
A form of pneumonia in which the inflammatory process occurs in alveolar walls and interstitial space.

PATHOPHYSIOLOGY
• Results from either aerogenous injury to the alveolar epithelium (type I or II pneumocytes) or hematogenous injury to the alveolar capillaries; may be triggered by infectious agents. • Alveolar wall damage often occurs secondary to inflammation and antigen–antibody complex deposition. • Progression from acute to chronic interstitial pneumonia can occur leading to alveolar fibrosis ± interstitial mononuclear cell accumulation and persistent type II pneumocyte hyperplasia.

SYSTEMS AFFECTED
• Respiratory. • Cardiovascular (if cor pulmonale develops).

GENETICS
Idiopathic pulmonary fibrosis (IPF) is breed-associated (West Highland white terriers/terrier breeds); a definitive genetic defect is not known.

INCIDENCE/PREVALENCE
Incompletely understood.

GEOGRAPHIC DISTRIBUTION
• Infectious organisms: *Aelurostrongylus abstrusus*—Europe, United States, Australia. • *Angiostrongylus vasorum*—Europe, Africa, South America, North America. • *Leishmania chagasi*—South and Central America. • H3N2/H3N8—China, USA. Pneumocystis and toxoplasmosis—worldwide.

SIGNALMENT
• Canine distemper virus—dogs 3–6 months of age. Greyhounds, Siberian huskies, Weimaraners, Samoyeds, and Alaskan Malamutes overrepresented. • Endogenous lipid pneumonia (EnLP)—older cats of either sex. • Pulmonary interstitial lung disease—middle- to old-aged West Highland white terrier, ± Cairn terriers and bull terriers. • Feline IPF-like disease—middle-aged to older cats. • *Pneumocystis jirovecii*—miniature dachshunds <1 year of age at risk, cavalier King Charles spaniels, any immunocompromised dog. • Toxoplasmosis—middle-aged male cats.

SIGNS

General Comments
Depends on severity of disease.

Historical Findings
Tachypnea, coughing, respiratory difficulty, exercise intolerance.

Physical Examination Findings
• Open-mouth breathing, end-inspiratory and early expiratory crackles, orthopnea, cyanosis, ± hemoptysis. • Animals with paraquat toxicity often display vomiting, oliguria, diarrhea, and oropharyngeal ulcers (± hyperexcitability and neurologic signs in the early phase). • Retinitis, uveitis, neurologic signs, and/or gastrointestinal signs can be seen with toxoplasmosis.

CAUSES
• Congenital—bronchiolitis obliterans with organizing pneumonia (BOOP) secondary to primary ciliary dyskinesia. • Metabolic—uremic pneumonitis ± BOOP, hepatic disease, or pancreatitis in cats. • Neoplastic—bronchiectasis or BOOP, pulmonary carcinoma associated with pulmonary fibrosis in cats. • Idiopathic—pulmonary interstitial fibrosis and desquamative interstitial pneumonitis (DIP), some cases of EnLP, BOOP, primary pulmonary alveolar proteinosis (PAP). • Inflammatory—EnLP most common in cats with bronchitis, bronchiectasis or necrotizing bronchiolitis. • Infectious—Dogs: canine distemper virus, canine adenovirus-2, H3N2 or H3N8 influenza virus, *Leishmania chagasi*, *Pneumocystis jirovecii*, *Angiostrongylus vasorum*, *Mycoplasma* sp, Toxoplasma, Leptospirosis, *Babesia* sp, *Ehrlichia canis*. Cats: *Aelurostrongylus abstrusus*, *Toxoplasma*, feline immunodeficiency virus, influenza virus (anthroponotic transmission described). • Toxic—inhalation of dusts, gases, or vapors, thiacetarsamide, aspiration of petroleum-based products in cats, secondary PAP, paraquat toxicity, silicosis, asbestosis. • Vascular—thromboembolism, circulating larval migrans.

RISK FACTORS
• Immunosuppression, inadequate vaccination or preventative, and exposure to other animals can predispose to viral or parasitic pulmonary disease. • Inhalation of toxic material or gases may predispose to pulmonary fibrosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Airway disease. • Bronchopneumonia. • Heartworm disease. • Embolic pneumonia. • Granulomatous pneumonia. • Neoplasia. • Cardiac disease.

CBC/BIOCHEMISTRY/URINALYSIS
• Neutrophilia, eosinophilia, lymphocytosis, hyperglobulinemia possible; polycythemia if chronically hypoxemic. • Thrombocytopenia with *Angiostrongylus vasorum*. • Neutropenia or high liver enzymes and hyperbilirubinemia possible with *Toxoplasma*. • High liver enzymes and hyperbilirubinemia (dogs only) possible with hepatotoxicity due to thiacetarsemide therapy ± paraquat toxicity. • Severe azotemia and isosthenuria with uremic pneumonitis.

OTHER LABORATORY TESTS
• Arterial blood gas measurement and calculation of alveolar–arterial (A-a) gradient to assess degree of respiratory impairment; Pao_2 <80 mmHg indicates hypoxemia, A-a gradient >15 is abnormal. • Serologic and other tests for infectious causes. • Fecal Baermann examination for *Aelurostrongylus abstrusus* or *Angiostrongylus vasorum*. • Toxicologic analysis of the urine or serum to diagnose paraquat toxicity in live animals. • Coagulation testing with *Angiostrongylus*. • Immunodiagnostic testing for exposure to *Leishmania*.

IMAGING

Thoracic Radiographic Findings
• A focal or diffuse, mild to severe interstitial to bronchial to alveolar pattern can be present, dilated bronchi with bronchiectasis or BOOP. • Right heart ± PA enlargement and hepatosplenomegaly if secondary pulmonary hypertension. • Pleural effusion occasionally seen.

CT
CT characteristics include ground-glass opacification, peribronchovascular thickening, and parenchymal banding.

DIAGNOSTIC PROCEDURES
• Electrocardiography—arrhythmias can occur with severe hypoxia or systemic disease. • Open lung biopsy required for definitive diagnostic test. • Endotracheal or transtracheal wash, bronchoscopy with bronchoalveolar lavage, and/or fine-needle aspirate of lungs might be useful (e.g., may visualize trophozoite or cysts of *Pneumocystis jirovecii* or *Toxoplasma* or see L1 larvae with *Aelurostrongylus abstrusus or Angiostrongylus vasorum*); cultures can reveal secondary bacterial infections. Viral testing (serology or swab). With PAP, an opaque white material is retrieved from airway wash. • Echocardiogram can document pulmonary hypertension.

PATHOLOGIC FINDINGS
• *Aelurostrongylus abstrusus*—greenish nodules in lungs, eggs and larvae in the alveolar spaces with foreign body type reaction (surrounded by mononuclear cells and giant cells), submucosal gland hypertrophy, and smooth muscle hypertrophy in airway and vessel walls. • *Angiostrongylus vasorum*—thrombosing arteritis and fibrotic peribronchitis, parasites in arterioles. • BOOP—polypoid plugs of loose, fibrous tissue fill bronchioles and alveoli, foamy macrophages within alveoli, variable inflammatory infiltrate with type II pneumocyte reactivity. • Interstitial lung disease in the West Highland white terrier—diffuse, mature pulmonary fibrosis (most common in caudal lung lobes),

multifocal areas of accentuated subpleural and peribronchiolar fibrosis, thickening of the alveolar septum due to excess collagen in the extracellular matrix. • IPF-like disease in the cat lacks inflammation and may be associated with pulmonary carcinoma. Typical changes include multifocal distribution of interstitial fibrosis with foci of fibroblast/myofibroblasts, alveolar epithelial metaplasia, and interstitial smooth muscle metaplasia/hyperplasia. • *Leishmania chagasi* is characterized by chronic and diffuse interstitial pneumonitis and thickened interalveolar septae in some cases. • Lipid pneumonias—macroscopic lesions can include subpleural, parenchymal, or perivascular white, firm nodules. Mixed pattern of inflammation with accumulation of lipid-laden macrophages, cholesterol clefts, and multinucleated giant cells. • Paraquat toxicity—lungs are heavy, edematous, and hemorrhagic. Emphysematous bullae and pneumomediastinum are commonly present. • PAP—alveolar spaces are distended with a periodic acid–Schiff staining eosinophilic proteinaceous material. Intra-alveolar cholesterol clefts and mucus-laden macrophages with mild mixed inflammatory infiltrates are common. • Uremic pneumonitis—pulmonary edema and calcification of smooth muscle and/or alveolar walls.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient care and monitoring for animals with evidence of respiratory distress.

NURSING CARE
• Oxygen therapy. • Minimize exposure to house dust, vapors, chemical fumes, or tobacco smoke. • Humidification of inspired air. • PAP—therapeutic bronchoalveolar lavage. • Antimicrobial therapy—as indicated by results of culture and susceptibility.

ACTIVITY
• Exercise restriction as needed. • Harness preferred to collar.

DIET
Weight loss if obese.

CLIENT EDUCATION
Palliative care employed.

SURGICAL CONSIDERATIONS
Definitive diagnosis of interstitial lung disease requires histopathology; it is best preceded by CT to determine an appropriate site for biopsy.

MEDICATIONS

DRUG(S) OF CHOICE
• Inhaled corticosteroids (e.g., fluticasone, 1 puff q12h) using a spacing chamber and facemask. • Bronchodilators can be helpful in reducing respiratory effort: extended-release theophylline (dog, 10 mg/kg PO q12h; cat, 15–19 mg/kg q24h in the evening), terbutaline sulfate (dog or cat, 0.01 mg/kg SC, IM, or IV q8–12h). Inhaled bronchodilators can also be used. • *Aelurostrongylus abstrusus*—fenbendazole 50 mg/kg PO q24h for 14 days (off-label), ivermectin (400 µg/kg SC twice at a 3-week interval), or spot-on selamectin 45 mg (once). • *Angiostrongylus vasorum*—levamisole 20–40 mg/kg PO q48h for 5 treatments ± aspirin ± corticosteroids. Alternative therapies include fenbendazole, mebendazole, and ivermectin. • BOOP—corticosteroid use has been reported. • IPF—no effective therapy. Anti-inflammatory steroid therapy with prednisolone (0.5–1 mg/kg PO q24–48h often used) and bronchodilators, antitussives, or antibiotics if indicated. Pirfenidone not yet investigated. • *Leishmania chagasi*—meglumine antimonate 100 mg/kg IV or SC q24h for 3–4 weeks or sodium stibogluconate 30–50 mg/kg IV or SC q24h for 3–4 weeks. • Paraquat toxicity—vomition and activated charcoal therapy is indicated if recent ingestion is known. Supportive care, diuresis using furosemide (most effective in the first 3 days following ingestion), ± immunosuppressive dexamethasone, cyclophosphamide, nicotinamide, superoxide dismutase, and vitamin A.

CONTRAINDICATIONS/PRECAUTIONS
Immunosuppressive therapy can exacerbate secondary infections.

FOLLOW-UP

PATIENT MONITORING
• Have owners observe clinical response to therapy, monitor respiratory rate and effort. • Repeat physical examination/chest auscultation, chest radiographs, lab test, and arterial blood gas analysis as indicated.

PREVENTION/AVOIDANCE
• Avoid proximity to toxic fumes or paraquat. • Vaccinate and deworm animals. • Appropriate insect and rodent control. Avoid ingestion by pets of frogs, lizards, rodents, and birds.

POSSIBLE COMPLICATIONS
• Secondary pulmonary infections possible. • Pulmonary hypertension can develop.

EXPECTED COURSE AND PROGNOSIS
• Guarded to poor with interstitial pneumonia caused by infectious agents or uremic pneumonitis. • Poor long-term prognosis with IPF (mean survival time is 17 months in dogs and 5.5 months in cats). • Paraquat toxicity—commonly fatal in dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Pulmonary carcinoma—associated with IPF in cats.

AGE-RELATED FACTORS
Young, free-roaming animals are more likely to succumb to infectious diseases.

ZOONOTIC POTENTIAL
Toxoplasmosis, if animal is shedding oocysts.

PREGNANCY/FERTILITY/BREEDING
Transplacental infection with *Toxoplasma* and canine distemper virus is possible.

SEE ALSO
• Bronchiectasis. • Canine Distemper. • Canine Infectious Respiratory Disease. • Feline Immunodeficiency Virus (FIV) Infection. • Leishmaniosis. • Toxoplasmosis.

ABBREVIATIONS
• BOOP = bronchiolitis obliterans with organizing pneumonia. • DIP = desquamative interstitial pneumonitis. • EnLP = endogenous lipid pneumonia. • IPF = idiopathic pulmonary fibrosis. • PAP = pulmonary alveolar proteinosis.

P

PNEUMOTHORAX

BASICS

DEFINITION
- Air accumulation in the pleural space (traumatic or spontaneous).
- Closed pneumothorax—no defects in the thoracic wall.
- Open pneumothorax—defect in the thoracic wall
- Tension pneumothorax—pleural pressure in a closed pneumothorax exceeds atmospheric pressure created by unidirectional transfer of air into the pleural space.

PATHOPHYSIOLOGY
- The pleural space is a potential space between the visceral and parietal pleura containing a thin layer of fluid that contributes to "tethering" of the lungs to the thoracic wall.
- Closed pneumothorax—air leakage from the pulmonary parenchyma, large airway, or esophagus.
- Tension pneumothorax—typically due to a pleural or pulmonary flap-like defect that opens on inspiration to allow leakage of air into the pleural space and closes during expiration. Development of high intrathoracic pressure can cause cardiovascular collapse.
- Open pneumothorax—pleural pressure equals atmospheric pressure, leading to lung collapse.
- Spontaneous pneumothorax—associated with underlying pulmonary disease that ruptures, allowing air leakage.
- Pneumothorax is usually bilateral disease due to mediastinal fenestrations.

SYSTEMS AFFECTED
- Respiratory.
- Cardiovascular.

INCIDENCE/PREVALENCE
Traumatic pneumothorax occurs in >40% of cases with chest trauma and 11–18% of dogs and cats presented for vehicular trauma. Pneumothorax has been reported in 25% of cases with intrathoracic grass awns and 70% of dogs with thoracic bite wounds.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Spontaneous pneumothorax—more common in large, deep-chested dogs. Siberian huskies may be overrepresented.

SIGNS

Historical Findings
- Traumatic—recent trauma, thoracocentesis, jugular venipuncture, lung aspirate, thoracotomy, mechanical ventilation, neck surgery, recent endotracheal intubation.
- Spontaneous—possible history of pulmonary disease; usually acute.

Physical Examination Findings
- Respiratory distress (tachypnea, increased respiratory effort, ± orthopnea).
- Shallow, rapid abdominal breathing.
- Decreased to absent breath sounds dorsally.
- Cyanosis.
- Tachycardia.

Traumatic Pneumothorax
- Signs of trauma (blunt or penetrating thoracic wall injury) or hypovolemic shock (pale mucous membranes, prolonged capillary refill time, altered mentation, poor pulse quality, tachycardia, decreased extremity compared to core temperature).
- Subcutaneous emphysema in some cases with pneumomediastinum and/or tracheal trauma.

CAUSES
- Traumatic—blunt trauma, penetrating thoracic or cervical injuries, post-thoracocentesis or thoracotomy, esophageal perforation, endotracheal tube-associated tracheal trauma, mechanical ventilation, pulmonary aspirate.
- Spontaneous—bullous emphysema (most common in dogs), pulmonary bullae or bleb.
- Migrating pulmonary foreign body, pulmonary neoplasia, pulmonary abscess, feline asthma, bronchopneumonia, mycotic pulmonary granuloma, parasitic pulmonary disease (*Paragonimus*), congenital pulmonary cyst, congenital lobar emphysema, secondary to lung lobe torsion.
- Extension of pneumomediastinum.

RISK FACTORS
- Trauma.
- Thoracocentesis.
- Thoracotomy.
- Overinflation of endotracheal cuff.
- Excessive airway pressure during ventilation.
- Pulmonary disease/pathology.
- Migrating grass awns.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Pleural effusion.
- Diaphragmatic hernia.
- Pulmonary parenchymal disease.

CBC/BIOCHEMISTRY/URINALYSIS
Neutrophilia with a left shift if infection or inflammation.

OTHER LABORATORY TESTS
- Arterial blood gases—hypoxemia; hypocapnia or hypercapnia.
- Fecal sedimentation or zinc sulfate flotation for *Paragonimus kellicotti*.

IMAGING

Thoracic Radiography
- Delay until patient is stable.
- Air in pleural space, pulmonary vascular pattern does not extend to the chest wall, cardiac silhouette elevated off the sternum.
- Pulmonary pathology can be obscured by lung lobe collapse.
- Traumatic pneumothorax—pulmonary contusions, rib fractures, diaphragmatic hernia, hemothorax, foreign bodies.
- Spontaneous pneumothorax—evaluate for any sign of parenchymal pathology.
- Right lateral horizontal beam results in the highest rate of detection and severity gradation while ventrodorsal/dorsoventral views have the lowest rate.

Thoracic Ultrasound
- Pneumothorax evidenced by loss of the "glide sign."
- Reverse sliding sign has a 100% specificity for detecting mild pneumothorax.
- Sensitivity of 78% and specificity of 93% compared to thoracic radiographs in identification of traumatic pneumothorax in dogs with higher sensitivity in penetrating trauma (93%) compared to blunt trauma (65%).
- CT has a higher diagnostic yield for detecting pneumothorax than thoracic-focused assessment with sonography for trauma.

Thoracic CT
- Used preoperatively to improve localization of pulmonary pathology in cases with spontaneous pneumothorax.
- CT can fail to detect pulmonary bullae prior to surgical exploration.

DIAGNOSTIC PROCEDURES
- Thoracocentesis.
- Bronchoscopy—consider if evidence of tracheal or large airway trauma.

PATHOLOGIC FINDINGS
- Varies depending on underlying disease.
- Gross evaluation—pulmonary blebs, pulmonary or airway tears, pulmonary parenchymal disease or masses.
- Histopathology—blebs are most commonly found at the apex and are contained entirely within the pleura; bullae are lined by pleura, fibrous pulmonary tissue, and emphysematous lung.

TREATMENT

APPROPRIATE HEALTH CARE
- Inpatient care until air accumulation has stopped or has stabilized.
- Thoracocentesis in patients with respiratory distress—can be performed with an IV catheter attached to an extension set and stopcock or via a butterfly needle.
- *Always* provide oxygen therapy until patient is stabilized.
- If large open chest wound—chest tube placement, cover with sterile airtight bandage; surgical closure once animal is stable.

(CONTINUED) PNEUMOTHORAX

• Tube thoracostomy—use if unable to stabilize with thoracocentesis or repeated thoracocentesis required for continued pneumothorax. A Seldinger technique allows chest tube placement under light sedation and may be preferable over other thoracostomy tube placement techniques.
• If pneumothorax is rapidly accumulating—use continuous chest tube suction via one-, two- or three-bottle drainage system with an underwater seal. If pneumothorax is not severe—use intermittent tube aspiration.
• Emergency thoracotomy in life-threatening pneumothorax.
• Open traumatic pneumothorax—surgery as soon as patient is stable.
• Closed traumatic pneumothorax—rarely requires surgical intervention.
• Spontaneous pneumothorax—early surgical intervention recommended in dogs (consider median sternotomy), ± pleural access port placed for medical management.
• Blood pleurodesis may be of benefit in refractory cases—blood is collected from the jugular vein and injected into the pleural cavity via a thoracostomy tube.

NURSING CARE
• Appropriate pain control.
• Chest tube maintenance—ensure all connections are airtight (cable ties for securing connections); ensure the tube is attached at two points. Clean tube site and change dressing once daily.

ACTIVITY
Strict rest for at least a week following resolution.

CLIENT EDUCATION
• Traumatic pneumothorax—discuss possibility of a chest tube, hospitalization; ± surgery.
• Spontaneous pneumothorax—early surgical intervention. Discuss possibility of underlying pulmonary disease that can make resolution challenging and recurrence possible. Warn owner that even with thoracotomy, the source of the pneumothorax may not be found and recurrent disease is possible.

SURGICAL CONSIDERATIONS
• Do not use positive-pressure ventilation for closed pneumothorax. Place chest tube prior to ventilation or await thoracotomy prior to ventilation.
• Thoracoscopy—may allow visualization of local lesion; allows instillation of substances for pleurodesis.
• Thoracotomy—if lesion is not evident, can fill thorax with saline and look for bubbles as sign of a leak. Partial or full lung lobectomy for localized lesions. Place thoracostomy tube.
• Pleurodesis with mechanical abrasion of the pleura or instillation of an inflammatory substance, such as talc, into the pleural space (success rate poor).
• Autologous blood-patch for persistent pneumothorax (simple and relatively safe procedure) in patients that have failed conservative or surgical management.

MEDICATIONS

DRUG(S) OF CHOICE
Judicious use of pain control.

PRECAUTIONS
Beware excess respiratory depression with opiates.

FOLLOW-UP

PATIENT MONITORING
• Respiratory rate—increased rate suggests recurrence.
• Serial thoracic radiographs to quantitate accumulation of air.
• Pulse oximetry and arterial blood gases may be considered.
• Central venous (jugular) blood gases to evaluate ventilation status ($PvCO_2$).
• Rate of air production from chest tube.

PREVENTION/AVOIDANCE
Keep pets confined—less likely to be injured.

POSSIBLE COMPLICATIONS
• Death from hypoxemia and cardiovascular compromise.
• Incorrect placement of chest tube or trauma associated with thoracocentesis—lung lobe laceration, cardiac puncture, diaphragmatic laceration, liver trauma.
• Pleural infection from thoracocentesis or thoracostomy tube. The risk of pyothorax associated with thoracostomy tube is higher between 4 and 6 days after placement.

EXPECTED COURSE AND PROGNOSIS
• Traumatic pneumothorax—good prognosis with mild trauma ± chest drain placement. Guarded prognosis with severe trauma usually because of severe pulmonary contusions.
• Spontaneous pneumothorax—prognosis depends on underlying cause. Good prognosis with focal lesion amenable to surgical resection. Poor prognosis with multiple lesions or neoplasia.

MISCELLANEOUS

SYNONYMS
Punctured lung.

SEE ALSO
• Dyspnea and Respiratory Distress.
• Panting and Tachypnea.
