Blackwell's Five-Minute Veterinary Consult: Canine and Feline

Seventh Edition

Blackwell's Five-Minute Veterinary Consult

Canine and Feline

Seventh Edition

Edited by

Larry P. Tilley, DVM
Diplomate, American College of Veterinary Internal Medicine
(Small Animal Internal Medicine)
President, VetMed Consultants, Inc.
Santa Fe, New Mexico
USA

Francis W.K. Smith, Jr., DVM
Diplomate, American College of Veterinary Internal Medicine
(Small Animal Internal Medicine and Cardiology)
Vice-President, VetMed Consultant, Inc.
Lexington, Massachusetts
USA

Meg M. Sleeper, VMD
Diplomate, American College of Veterinary Internal Medicine
(Cardiology)
Professor of Clinical Cardiology
College of Veterinary Medicine
University of Florida, Florida
USA

Benjamin M. Brainard, VMD
Diplomate, American College of Veterinary
Anesthesia and Analgesia and
American College of Veterinary Emergency and
Critical Care
Edward H. Gunst
Professor of Small Animal Critical Care
College of Veterinary Medicine
University of Georgia
Athens, Georgia

10 9 8 7 6 5 4 3 2 1

To my love and joy in life, Ellen Lefkowitz, my son Kyle, and grandson Tucker.
To my late mother Dorothy, who instilled values that have helped me throughout life.
To family and animals who represent the purity of life.

Larry P. Tilley

To my wife, May, my son, Ben, and my daughter, Jade, who are a constant source of inspiration, love, and joy. To my late father, Frank, who was my perfect role model. To Kaylee (dog) and Centie (cat) who remind me each day to make time for play.

Francis W.K. Smith, Jr.

To my parents and sister for their stalwart support and to the many animals who have touched my life and made me a better person.

Meg M. Sleeper

To my family, my mentors, my colleagues; to colleagues and friends who are no longer with us. “Keep cool, but care”—Thomas Pynchon.

Benjamin M. Brainard

Contents

Topic	
5-Fluorouracil (5-FU) Toxicosis	1
Abortion, Spontaneous (Early Pregnancy Loss)—Cats	2
Abortion, Spontaneous (Early Pregnancy Loss)—Dogs	4
Abortion, Termination of Pregnancy	6
Abscessation	8
Acetaminophen (APAP) Toxicosis	10
Acidosis, Metabolic	12
Acne—Cats	14
Acne—Dogs	15
Acral Lick Dermatitis	16
Actinomycosis and Nocardia	17
Acute Abdomen	18
Acute Diarrhea	21
Acute Kidney Injury	23
Acute Respiratory Distress Syndrome	25
Acute Vomiting	27
Adenocarcinoma, Anal Sac	29
Adenocarcinoma, Lung	31
Adenocarcinoma, Nasal	32
Adenocarcinoma, Pancreas	34
Adenocarcinoma, Prostate	35
Adenocarcinoma, Renal	36
Adenocarcinoma, Salivary Gland	37
Adenocarcinoma, Skin (Sweat Gland, Sebaceous)	38
Adenocarcinoma, Stomach, Small and Large Intestine, Rectal	39
Adenocarcinoma, Thyroid—Dogs	40
Aggression—Between Dogs in the Household	42
Aggression to Unfamiliar People and Unfamiliar Dogs—Dogs	44
Aggression Toward Children—Dogs	46
Aggression Toward Familiar People—Dogs	47
Aggression Toward Humans—Cats	49
Aggression, Food and Resource Guarding—Dogs	51
Aggression, Intercat Aggression	53
Aggression, Overview—Cats	56
Aggression, Overview—Dogs	58
Alkaline Hyperphosphatasemia in Dogs	61

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Alkalosis, Metabolic 63
Alopecia—Cats 65
Alopecia—Dogs 67
Alopecia, Noninflammatory—Dogs 69
Ameloblastoma 71
Amphetamine and ADD/ADHD Medication Toxicosis 72
Amyloidosis 74
Anaerobic Infections 76
Anal Sac Disorders 77
Anaphylaxis 78
Anemia of Chronic Kidney Disease 80
Anemia, Aplastic 82
Anemia, Heinz Body 83
Anemia, Immune-Mediated 84
Anemia, Iron-Deficiency 86
Anemia, Nonregenerative 87
Anemia, Nuclear Maturation Defects (Anemia, Megaloblastic) 89
Anemia, Regenerative 90
Anisocoria 92
Anorexia 94
Antebrachial Growth Deformities 96
Anterior Uveitis—Cats 98
Anterior Uveitis—Dogs 100
Antidepressant Toxicosis—SSRIs and SNRIs 102
Antidepressant Toxicosis—Tricyclic 104
Aortic Stenosis 106
Aortic Thromboembolism 108
Apudoma 111
Arteriovenous Fistula and Arteriovenous Malformation 112
Arteriovenous Malformation of the Liver 113
Arthritis (Osteoarthritis) 115
Arthritis, Septic 118
Ascites 120
Aspergillosis, Disseminated Invasive 122
Aspergillosis, Nasal 124
Aspirin Toxicosis 126
Asthma, Bronchitis—Cats 127
Astrocytoma 129
Ataxia 130
Atlantoaxial Instability 132
Atopic Dermatitis 134
Atrial Fibrillation and Atrial Flutter 136
Atrial Premature Complexes 139
Atrial Septal Defect 141
Atrial Standstill 142
Atrial Wall Tear 144

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Atrioventricular Block, Complete (Third Degree) 146
Atrioventricular Block, First Degree 148
Atrioventricular Block, Second Degree—Mobitz Type I 150
Atrioventricular Block, Second Degree—Mobitz Type II 152
Atrioventricular Valve Dysplasia 154
Atrioventricular Valvular Stenosis 156
Azotemia and Uremia 159
Babesiosis 161
Baclofen Toxicosis 163
Bartonellosis 164
Basal Cell Tumor 165
Battery Toxicosis 166
Baylisascariasis 167
Benign Prostatic Hyperplasia 168
Benzodiazepine and Other Sleep Aids Toxicosis 169
Beta Receptor Antagonist (Beta Blockers) Toxicosis 171
Beta-2 Agonist Inhaler Toxicosis 172
Bile Duct Carcinoma 173
Bile Duct Obstruction (Extrahepatic) 174
Bile Peritonitis 177
Bilious Vomiting Syndrome 179
Blastomycosis 180
Blepharitis 182
Blind Quiet Eye 184
Blood Transfusion Reactions 186
Blue-Green Algae Toxicosis 187
Botulism 188
Brachial Plexus Avulsion 189
Brachycephalic Airway Syndrome 190
Brain Injury 192
Brain Tumors 194
Breeding, Timing 196
Bronchiectasis 198
Bronchitis, Chronic 200
Brucellosis 202
Calcipotriene/Calcipotriol Toxicosis 204
Calcium Channel Blocker Toxicosis 205
Campylobacteriosis 206
Candidiasis 207
Canine Coronavirus Infections 208
Canine Degenerative Myelopathy 209
Canine Distemper 211
Canine Infectious Diarrhea 213
Canine Infectious Respiratory Disease 215
Canine Parvovirus 217
Canine Schistosomiasis (Heterobilharziasis) 219

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Car Ride Anxiety—Dogs and Cats 220
Carbon Monoxide Toxicosis 223
Carcinoid and Carcinoid Syndrome 224
Cardiac Glycoside Plant Toxicosis 225
Cardiomyopathy, Arrhythmogenic Right Ventricular—Cats 226
Cardiomyopathy, Arrhythmogenic Right Ventricular—Dogs 227
Cardiomyopathy, Dilated—Cats 229
Cardiomyopathy, Dilated—Dogs 232
Cardiomyopathy, Hypertrophic—Cats 235
Cardiomyopathy, Hypertrophic—Dogs 238
Cardiomyopathy, Nutritional 239
Cardiomyopathy, Restrictive—Cats 241
Cardiopulmonary Arrest 243
Cataracts 245
Cerebellar Degeneration 247
Cerebellar Hypoplasia 248
Cerebrovascular Accidents 249
Ceruminous Gland Adenocarcinoma, Ear 251
Cervical Spondylomyelopathy (Wobbler Syndrome) 252
Chagas Disease (American Trypanosomiasis) 254
Chediak-Higashi Syndrome 255
Chemodectoma 256
Cheyletiellosis 257
Chlamydiosis—Cats 258
Chocolate Toxicosis 260
Cholangitis/Cholangiohepatitis Syndrome 262
Cholecystitis and Choledochitis 265
Cholelithiasis 267
Chondrosarcoma, Bone 269
Chondrosarcoma, Nasal and Paranasal Sinus 270
Chondrosarcoma, Oral 271
Chorioretinitis 272
Chronic Kidney Disease 274
Chylothorax 277
Cirrhosis and Fibrosis of the Liver 279
Claw and Clawfold Disorders 282
Clostridial Enterotoxicosis 284
Coagulation Factor Deficiency 286
Coagulopathy of Liver Disease 288
Cobalamin Deficiency 290
Coccidioidomycosis 292
Coccidiosis 294
Cognitive Dysfunction Syndrome 295
Cold Agglutinin Disease 297
Colibacillosis 298
Colitis and Proctitis 300

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Colitis, Histiocytic Ulcerative 303
Compulsive Disorders—Cats 304
Compulsive Disorders—Dogs 306
Congenital and Developmental Renal Diseases 308
Congenital Ocular Anomalies 310
Congenital Spinal and Vertebral Malformations 313
Congestive Heart Failure, Left-Sided 315
Congestive Heart Failure, Right-Sided 317
Conjunctivitis—Cats 319
Conjunctivitis—Dogs 321
Constipation and Obstipation 323
Contact Dermatitis 325
Coonhound Paralysis (Acute Polyradiculoneuritis) 326
Copper Associated Hepatopathy 328
Coprophagia and Pica 332
Corneal and Scleral Lacerations 334
Corneal Opacities—Degenerations and Infiltrates 336
Corneal Opacities—Dystrophies 337
Corneal Sequestrum—Cats 338
Cough 339
Craniomandibular Osteopathy 341
Cruciate Ligament Disease, Cranial 342
Cryptococcosis 344
Cryptorchidism 346
Cryptosporidiosis 347
Crystalluria 348
Cutaneous Drug Eruptions 350
Cuterebriasis 351
Cyanosis 352
Cyclic Hematopoiesis 354
Cylindruria 355
Cytauxzoonosis 356
Deafness 357
Deciduous Teeth, Persistent (Retained) 359
Deep Cutaneous Mycoses 360
Demodicosis 362
Dental Caries 364
Dentigerous Cyst 366
Dermatomyositis 367
Dermatophilosis 369
Dermatophytosis 370
Dermatoses, Depigmenting Disorders 372
Dermatoses, Erosive or Ulcerative 374
Dermatoses, Exfoliative 376
Dermatoses, Neoplastic 378
Dermatoses, Papulonodular 380

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Dermatoses, Sterile Nodular/Granulomatous 382
Dermatoses, Sun-Induced 384
Dermatoses, Vesiculopustular 385
Dermatoses, Viral (Non-Papillomatosis) 387
Destructive and Scratching Behavior—Cats 388
Destructive Behavior—Dogs 389
Diabetes Insipidus 391
Diabetes Mellitus With Hyperosmolar Hyperglycemic State 393
Diabetes Mellitus With Ketoacidosis 395
Diabetes Mellitus Without Complication—Cats 397
Diabetes Mellitus Without Complication—Dogs 399
Diaphragmatic Hernia 401
Diarrhea, Antibiotic Responsive 402
Diarrhea, Chronic—Cats 403
Diarrhea, Chronic—Dogs 405
Digoxin Toxicity 407
Diisocyanate Glues 408
Discolored Tooth/Teeth 409
Discospondylitis 411
Disseminated Intravascular Coagulation 413
Drowning (Near Drowning) 415
Ductal Plate Malformation (Congenital Hepatic Fibrosis) 416
Dysautonomia (Key-Gaskell Syndrome) 419
Dyschezia and Hematochezia 420
Dysphagia 422
Dyspnea and Respiratory Distress 425
Dystocia 428
Dysuria, Pollakiuria, and Stranguria 430
Ear Mites 432
Eclampsia 433
Ectopic Ureter 434
Ectropion 435
Ehrlichiosis and Anaplasmosis 436
Elbow Dysplasia 438
Electric Cord Injury 440
Enamel Hypoplasia/Hypocalcification 441
Encephalitis 442
Encephalitis Secondary to Parasitic Migration 444
Endocarditis, Infective 445
Endomyocardial Diseases—Cats 447
Entropion 449
Eosinophilia 450
Eosinophilic Granuloma Complex 451
Epididymitis/Orchitis 453
Epilepsy, Genetic (Idiopathic)—Dogs 454
Epiphora 456

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Episcleritis 458
Epistaxis 459
Erythrocytosis 462
Esophageal Diverticula 464
Esophageal Foreign Bodies 465
Esophageal Stricture 467
Esophagitis 469
Essential Oils Toxicosis 472
Ethanol Toxicosis 473
Ethylene Glycol Toxicosis 474
Excessive Vocalization and Waking at Night—Dogs and Cats 476
Exercise-Induced Weakness/Collapse in Labrador Retrievers 478
Exocrine Pancreatic Insufficiency 480
Eyelash Disorders (Trichiasis/Distichiasis/Ectopic Cilia) 482
Facial Nerve Paresis and Paralysis 483
False Pregnancy 485
Familial Shar-Pei Fever 487
Fanconi Syndrome 489
Fear and Aggression in Veterinary Visits—Cats 490
Fear and Aggression in Veterinary Visits—Dogs 492
Fears, Phobias, and Anxieties—Cats 494
Fears, Phobias, and Anxieties—Dogs 496
Feline Alveolar Osteitis 498
Feline Calicivirus Infection 499
Feline Herpesvirus Infection 501
Feline Hyperesthesia Syndrome 503
Feline Idiopathic Lower Urinary Tract Disease 504
Feline Immunodeficiency Virus (FIV) Infection 506
Feline Infectious Diarrhea 508
Feline Infectious Peritonitis (FIP) 510
Feline Ischemic Encephalopathy 512
Feline Leukemia Virus (FeLV) Infection 514
Feline Panleukopenia 516
Feline Paraneoplastic Alopecia 518
Feline Stomatitis—Feline Chronic Gingivostomatitis (FCGS) 519
Feline Symmetrical Alopecia 521
Feline Tooth Resorption (Odontoclastic Resorption) 522
Feline (Upper) Respiratory Infections 524
Fever 526
Fiber-Responsive Large Bowel Diarrhea 528
Fibrocartilaginous Embolic Myelopathy 530
Fibrosarcoma, Bone 532
Fibrosarcoma, Gingiva 533
Fibrosarcoma, Nasal and Paranasal Sinus 534
Fipronil Toxicosis 535
Flatulence 536

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Flea Bite Hypersensitivity and Flea Control 538
Food Reactions, Dermatologic 540
Food Reactions (Gastrointestinal), Adverse 542
Gallbladder Mucocele 544
Gastric Dilation and Volvulus Syndrome 546
Gastric Motility Disorders 548
Gastritis, Chronic 550
Gastroduodenal Ulceration/Erosion 552
Gastroenteritis, Acute Hemorrhagic Diarrhea Syndrome 554
Gastroenteritis, Eosinophilic 556
Gastroesophageal Reflux 558
Gastrointestinal Obstruction 559
Gestational Diabetes Mellitus 561
Giardiasis 562
Gingival Enlargement/Hyperplasia 563
Glaucoma 564
Glomerulonephritis 566
Glucagonoma 568
Glucosuria 570
Gluten Enteropathy in Irish Setters 572
Glycogen Storage Disease 573
Glycogen-Type Vacuolar Hepatopathy 574
Grape and Raisin Toxicosis 577
Hair Follicle Tumors 578
Halitosis 579
Head Pressing 581
Head Tilt 583
Head Tremors (Bobbing), Idiopathic—Dogs 585
Heartworm Disease—Cats 586
Heartworm Disease—Dogs 587
Heat Stroke and Hyperthermia 589
Helicobacter spp. 591
Hemangiopericytoma 593
Hemangiosarcoma, Bone 594
Hemangiosarcoma, Heart 595
Hemangiosarcoma, Skin 596
Hemangiosarcoma, Spleen and Liver 598
Hematemesis 600
Hematuria 602
Hemoglobinuria and Myoglobinuria 604
Hemothorax 606
Hemotropic Mycoplasmosis 607
Hepatic Amyloid 609
Hepatic Encephalopathy 611
Hepatic Failure, Acute 614
Hepatic Lipidosis 617

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Hepatic Nodular Hyperplasia and Dysplastic Hyperplasia 620
Hepatitis, Chronic 622
Hepatitis, Granulomatous 626
Hepatitis, Infectious (Viral) Canine 628
Hepatitis, Suppurative and Hepatic Abscess 630
Hepatocellular Adenoma 632
Hepatocellular Carcinoma 633
Hepatocutaneous Syndrome 634
Hepatomegaly 636
Hepatoportal Microvascular Dysplasia 639
Hepatosupportive Therapies 642
Hepatotoxins 643
Hepatozoonosis 645
Hiatal Hernia 646
Hip Dysplasia 647
Histiocytic Diseases—Dogs and Cats 650
Histiocytosis, Cutaneous 652
Histoplasmosis 653
Hookworms (Ancylostomiasis) 655
Horner's Syndrome 656
Housesoiling—Cats 657
Housesoiling—Dogs 661
Hydrocephalus 663
Hydronephrosis 665
Hyperadrenocorticism (Cushing's Syndrome)—Cats 667
Hyperadrenocorticism (Cushing's Syndrome)—Dogs 668
Hypercalcemia 672
Hypercapnia 674
Hyperchloremia 676
Hypercoagulability 677
Hypereosinophilic Syndrome (HES) 678
Hyperestrogenism (Estrogen Toxicity) 679
Hyperglycemia 681
Hyperkalemia 683
Hyperlipidemia 685
Hypermagnesemia 687
Hypermetria and Dysmetria 689
Hypernatremia 691
Hyperosmolarity 692
Hyperparathyroidism 694
Hyperparathyroidism, Renal Secondary 696
Hyperphosphatemia 698
Hypersomatotropism/Acromegaly in Cats 700
Hypertension, Portal 701
Hypertension, Pulmonary 704
Hypertension, Systemic Arterial 706

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Hyperthyroidism 709
Hypertrophic Osteodystrophy 711
Hypertrophic Osteopathy 713
Hypertrophic Pyloric Gastropathy, Chronic 714
Hyperviscosity Syndrome 716
Hyphema 717
Hypoadrenocorticism (Addison's Disease) 719
Hypoalbuminemia 722
Hypocalcemia 724
Hypochloremia 726
Hypoglycemia 727
Hypokalemia 729
Hypomagnesemia 731
Hypomyelination 733
Hyponatremia 734
Hypoparathyroidism 736
Hypophosphatemia 739
Hypopituitarism 741
Hypopyon and Lipid Flare 742
Hyporexia 743
Hyposthenuria 744
Hypothermia 745
Hypothyroidism 747
Hypoxemia 750
Icterus 752
Idioventricular Rhythm 754
Ileus 756
Illicit/Club Drug Toxicosis 758
Imidazoline Toxicosis 759
Immunodeficiency Disorders, Primary 760
Immunoproliferative Enteropathy of Basenjis 762
Incontinence, Fecal 763
Incontinence, Urinary 765
Infertility, Female—Dogs 767
Infertility, Male—Dogs 769
Inflammatory Bowel Disease 771
Influenza 773
Insoluble Oxalate Plant Toxicosis 775
Insulinoma 776
Interstitial Cell Tumor, Testicle 779
Intervertebral Disc Disease—Cats 780
Intervertebral Disc Disease, Cervical 781
Intervertebral Disc Disease, Thoracolumbar 784
Intussusception 788
Iris Atrophy 790
Iron Toxicosis 791

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Ivermectin and Other Macrocyclic Lactones Toxicosis 792
Joint Luxations 793
Keratitis, Eosinophilic—Cats 795
Keratitis, Nonulcerative 796
Keratitis, Ulcerative 798
Keratoconjunctivitis Sicca 800
Kitten Behavior Problems 801
Kitten Socialization and Kitten Classes 803
Lactic Acidosis (Hyperlactatemia) 805
Lameness 808
Laryngeal and Tracheal Perforation 810
Laryngeal Diseases 812
Lead Toxicosis 814
Left Anterior Fascicular Block 816
Left Bundle Branch Block 818
Legg–Calvé–Perthes Disease 820
Leiomyoma, Stomach, Small and Large Intestine 822
Leiomyosarcoma, Stomach, Small and Large Intestine 823
Leishmaniosis 824
Leishmaniosis, Cutaneous 825
Lens Luxation 827
Leptospirosis 828
Leukemia, Chronic Lymphocytic 830
Leukocytosis 831
Leukoencephalomyelopathy in Rottweilers 833
Lily Toxicosis 834
Lipoma, Infiltrative 835
Liver Fluke Infestation 836
Lower Urinary Tract Infection, Bacterial 838
Lower Urinary Tract Infection, Fungal 840
Lumbosacral Stenosis and Cauda Equina Syndrome 841
Lung Lobe Torsion 843
Lupus Erythematosus, Cutaneous (Discoid) 844
Lupus Erythematosus, Systemic (SLE) 845
Lyme Borreliosis 847
Lymphangiectasia 849
Lymphadenopathy/Lymphadenitis 851
Lymphedema 853
Lymphoma—Cats 854
Lymphoma—Dogs 856
Lymphoma, Cutaneous Epitheliotropic 858
Lysosomal Storage Diseases 859
Malassezia Dermatitis 860
Malignant Fibrous Histiocytoma 861
Malocclusions—Skeletal and Dental 862

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Mammary Gland Hyperplasia—Cats 864
Mammary Gland Tumors—Cats 865
Mammary Gland Tumors—Dogs 867
Marijuana Toxicosis 869
Marking, Roaming, and Mounting Behavior—Cats 870
Marking, Roaming, and Mounting Behavior—Dogs 872
Mast Cell Tumors 874
Mastitis 876
Maternal Behavior Problems 877
Maxillary and Mandibular Fractures 879
Megacolon 881
Megaesophagus 883
Melanocytic Tumors, Oral 886
Melanocytic Tumors, Skin and Digit 888
Melena 889
Meningioma—Cats and Dogs 891
Meningitis/Meningoencephalitis/Meningomyelitis, Bacterial 894
Meningoencephalomyelitis, Eosinophilic 896
Meningoencephalomyelitis of Unknown Etiology (MUE) 897
Mesothelioma 899
Metabolic, Nutritional, and Endocrine Bone Disorders 900
Metaldehyde Toxicosis 902
Metformin Toxicosis 903
Methemoglobinemia 904
Metritis 906
Movement Disorders 907
Mucopolysaccharidoses 908
Multidrug-Resistant Infections 909
Multiple Myeloma 911
Murmurs, Heart 912
Muscle Rupture (Muscle Tear) 914
Mushroom Toxicoses 916
Myasthenia Gravis 920
Mycobacterial Infections 922
Mycoplasmosis 924
Mycotoxicosis—Aflatoxin 926
Mycotoxicosis—Tremorgenic Toxins 927
Myelodysplastic Syndromes 928
Myelomalacia, Spinal Cord (Ascending, Descending, Progressive) 929
Myelopathy—Paresis/Paralysis—Cats 930
Myeloproliferative Disorders 932
Myocardial Infarction 933
Myocardial Tumors 934
Myocarditis 935

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Myoclonus 937
Myopathy—Hereditary X-linked Muscular Dystrophy 938
Myopathy—Masticatory and Extraocular Myositis 939
Myopathy, Noninflammatory—Endocrine 941
Myopathy, Noninflammatory—Hereditary Labrador Retriever 943
Myopathy, Noninflammatory—Hereditary Myotonia 944
Myopathy, Noninflammatory—Hereditary Scottie Cramp 945
Myopathy, Noninflammatory—Metabolic 946
Myopathy—Polymyositis and Dermatomositis 948
Myxedema and Myxedema Coma 950
Myxomatous Mitral Valve Disease 951
Narcolepsy and Cataplexy 954
Nasal and Nasopharyngeal Polyps 955
Nasal Dermatoses—Canine 956
Nasal Discharge 958
Nasopharyngeal Stenosis 960
Neck and Back Pain 961
Necrotizing Encephalitis 963
Neonatal Mortality and Canine Herpesvirus 964
Neonatal Resuscitation and Early Neonatal Care 966
Neonicotinoid Toxicosis 968
Neosporosis 969
Nephrolithiasis 970
Nephrotic Syndrome 972
Nephrotoxicity, Drug-Induced 974
Nerve Sheath Tumors 976
Neuroaxonal Dystrophy 977
Neutropenia 978
Nocardiosis/Actinomycosis—Cutaneous 980
Nonsteroidal Anti-Inflammatory Drug Toxicosis 981
Notoedric Mange 983
Nystagmus 984
Obesity 986
Odontogenic Tumors 988
Odontoma 990
Oliguria and Anuria 991
Ollulanus Infection 993
Ophthalmia Neonatorum 994
Opiates/Opioids Toxicosis 996
Optic Neuritis and Papilledema 998
Oral Cavity Tumors, Undifferentiated Malignant Tumors 1000
Orbital Diseases (Exophthalmos, Enophthalmos, Strabismus) 1001
Organophosphorus and Carbamate Toxicosis 1003
Oronasal Fistula 1005
Osteochondrodysplasia 1006

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Osteochondrosis 1007
Osteomyelitis 1009
Osteosarcoma 1011
Otitis Externa and Media 1013
Otitis Media and Interna 1015
Ovarian Remnant Syndrome 1017
Ovarian Tumors 1019
Ovulatory Failure 1020
Pain (Acute, Chronic, and Postoperative) 1021
Palatal Defects 1025
Pancreatitis—Cats 1027
Pancreatitis—Dogs 1029
Pancytopenia 1031
Panniculitis/Steatitis 1033
Panosteitis 1034
Panting and Tachypnea 1036
Papillomatosis 1039
Paralysis 1040
Paraneoplastic Syndromes 1042
Paraphimosis, Phimosis, and Priapism 1045
Paraproteinemia 1046
Patellar Luxation 1047
Patent Ductus Arteriosus 1049
Pectus Excavatum 1052
Pelger–Huët Anomaly 1053
Pelvic Bladder 1054
Pemphigus 1055
Perianal Fistula 1057
Pericardial Disease 1058
Perineal Hernia 1061
Periodontal Disease 1063
Peripheral Edema 1065
Perirenal Pseudocysts 1067
Peritoneopericardial Diaphragmatic Hernia 1068
Peritonitis 1069
Petechiae, Ecchymosis, Bruising 1072
Petroleum Hydrocarbon Toxicosis 1074
Pheochromocytoma 1076
Phosphofructokinase Deficiency 1078
Physalopterosis 1079
Plague 1080
Plasmacytoma, Mucocutaneous 1081
Pleural Effusion 1082
Pneumocystosis 1084
Pneumonia, Aspiration 1085
Pneumonia, Bacterial 1086

Pneumonia, Eosinophilic 1088
Pneumonia, Fungal 1090
Pneumonia, Interstitial 1092
Pneumothorax 1094
Pododermatitis 1096
Poisoning (Intoxication) Therapy 1098
Polioencephalomyelitis—Cats 1100
Polyarthritis, Erosive, Immune-Mediated 1101
Polyarthritis, Nonerosive, Immune-Mediated, Dogs 1103
Polycystic Kidney Disease 1105
Polycythemia Vera 1106
Polyneuropathies (Peripheral Neuropathies) 1107
Polyphagia 1109
Polypoid Cystitis 1111
Polyuria and Polydipsia 1113
Portosystemic Shunting, Acquired 1115
Portosystemic Vascular Anomaly, Congenital 1118
Poxvirus Infection—Cats 1122
Pregnancy Edema in the Bitch 1123
Pregnancy Toxemia 1125
Premature Labor 1126
Prolapsed Gland of the Third Eyelid (Cherry Eye) 1127
Proptosis 1128
Prostate Disease in the Breeding Male Dog 1129
Prostatic Cysts 1131
Prostatitis and Prostatic Abscess 1132
Prostatomegaly 1134
Protein-Losing Enteropathy 1136
Proteinuria 1138
Protothecosis 1141
Pruritus 1142
Pseudoephedrine/Phenylephrine Toxicosis 1144
Pseudomacrothrombocytopenia (Inherited Macrothrombocytopenia) 1145
Ptyalism 1146
Pulmonary Contusions 1148
Pulmonary Edema, Noncardiogenic 1149
Pulmonary Thromboembolism 1151
Pulmonic Stenosis 1153
Puppy Behavior Problems 1155
Puppy Socialization and Puppy Classes 1157
Puppy Strangles (Juvenile Cellulitis) 1159
Pyelonephritis 1160
Pyoderma 1162
Pyoderma—Methicillin-Resistant 1164
Pyometra 1165
Pyothorax 1168

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Pyrethrin and Pyrethroid Toxicosis 1170
Pyruvate Kinase Deficiency 1171
Pythiosis 1172
Pyuria 1174
Q Fever 1176
Quadrigeminal Cyst 1177
Rabies 1178
Rectal and Anal Prolapse 1180
Rectal Stricture 1181
Rectoanal Polyps 1182
Red Eye 1183
Regurgitation 1185
Renal Tubular Acidosis 1187
Renomegaly 1188
Respiratory Parasites 1190
Retained Placenta 1192
Retinal Degeneration 1193
Retinal Detachment 1195
Retinal Hemorrhage 1197
Rhinitis and Sinusitis 1199
Right Bundle Branch Block 1202
Rocky Mountain Spotted Fever 1204
Rodenticide Toxicosis—Anticoagulants 1206
Rodenticide Toxicosis—Bromethalin 1208
Rodenticide Toxicosis—Cholecalciferol 1209
Rodenticide Toxicosis—Phosphides 1211
Roundworms (Ascariasis) 1212
Sago Palm Toxicosis 1213
Salivary Mucocele 1214
Salmon Poisoning Disease 1216
Salmonellosis 1217
Salt Toxicosis 1219
Sarcoptic Mange 1221
Schiff–Sherrington Phenomenon 1222
Schwannoma 1223
Sebaceous Adenitis, Granulomatous 1224
Seizures (Convulsions, Status Epilepticus)—Cats 1225
Seizures (Convulsions, Status Epilepticus)—Dogs 1227
Seminoma 1230
Separation Anxiety Syndrome 1231
Sepsis and Bacteremia 1235
Sertoli Cell Tumor 1237
Sexual Development Disorders 1238
Shaker/Tremor Syndrome, Corticosteroid Responsive 1240
Shock, Cardiogenic 1241
Shock, Hypovolemic 1243

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Shock, Septic 1245
Shoulder Joint, Ligament, and Tendon Conditions 1247
Sick Sinus Syndrome 1250
Sinus Arrest and Sinoatrial Block 1252
Sinus Arrhythmia 1254
Sinus Bradycardia 1256
Sinus Tachycardia 1258
Sjögren-Like Syndrome 1260
Skin Fragility Syndrome, Feline 1261
Small Intestinal Dysbiosis 1262
Smoke Inhalation 1264
Snake Venom Toxicosis—Coral Snakes 1265
Snake Venom Toxicosis—Pit Vipers 1266
Sneezing, Reverse Sneezing, Gagging 1268
Soft Tissue Sarcoma 1270
Spermatocele/Sperm Granuloma 1272
Spermatozoal Abnormalities 1273
Spider Venom Toxicosis—Black Widow 1274
Spider Venom Toxicosis—Brown Recluse 1275
Spinal Dysraphism 1276
Splenic Torsion 1278
Splenomegaly 1279
Spondylosis Deformans 1281
Sporotrichosis 1282
Squamous Cell Carcinoma, Digit 1283
Squamous Cell Carcinoma, Ear 1284
Squamous Cell Carcinoma, Gingiva 1285
Squamous Cell Carcinoma, Lung 1286
Squamous Cell Carcinoma, Nasal and Paranasal Sinuses 1287
Squamous Cell Carcinoma, Nasal Planum 1288
Squamous Cell Carcinoma, Skin 1289
Squamous Cell Carcinoma, Tongue 1290
Squamous Cell Carcinoma, Tonsil 1291
Staphylococcal Infections 1292
Steroid-Responsive Meningitis-Arteritis—Dogs 1294
Stertor and Stridor 1295
Stomatitis and Oral Ulceration 1297
Streptococcal Infections 1299
Stupor and Coma 1300
Subarachnoid Cysts (Arachnoid Diverticulum) 1302
Subinvolution of Placental Sites 1304
Submissive and Excitement Urination—Dogs 1305
Superficial Necrolytic Dermatitis 1306
Supraventricular Tachycardia 1307
Syncope 1309
Synovial Cell Sarcoma 1311

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Syringomyelia and Chiari-Like Malformation 1312
Systolic Anterior Motion 1315
Tapeworms (Cestodiasis) 1317
Temporomandibular Joint Disorders 1318
Testicular Degeneration and Hypoplasia 1319
Tetanus 1320
Tetralogy of Fallot 1322
Third Eyelid Protrusion 1323
Thrombocytopathies 1325
Thrombocytopenia 1327
Thrombocytopenia, Primary Immune-Mediated 1329
Thrombocytosis 1331
Thunderstorm and Noise Phobias 1333
Thymoma 1335
Tick Bite Paralysis 1336
Ticks and Tick Control 1338
Toad Venom Toxicosis 1340
Tooth—Missing 1341
Tooth Formation/Structure, Abnormal 1342
Tooth Root Abscess (Apical Abscess) 1343
Torsion of the Spermatic Cord 1345
Toxoplasmosis 1346
Tracheal Collapse 1348
Transitional Cell Carcinoma 1350
Transmissible Venereal Tumor 1352
Traumatic Dentoalveolar Injuries (TDI) 1353
Tremors 1355
Trichomoniasis 1357
Trigeminal Neuritis, Idiopathic 1358
Tularemia 1359
Unruly Behaviors: Jumping, Pulling, Chasing, Stealing—Dogs 1361
Ureterolithiasis 1363
Urethral Prolapse 1365
Urinary Retention, Functional 1366
Urinary Tract Obstruction 1368
Urinary Tract Parasites 1370
Urolithiasis, Calcium Oxalate 1372
Urolithiasis, Calcium Phosphate 1375
Urolithiasis, Cystine 1376
Urolithiasis, Pseudo (Dried Blood, Ossified Material) 1378
Urolithiasis, Struvite—Cats 1379
Urolithiasis, Struvite—Dogs 1381
Urolithiasis, Urate 1383
Urolithiasis, Xanthine 1385
Uterine Inertia 1386
Uterine Tumors 1387

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Uveal Melanoma—Cats 1388
Uveal Melanoma—Dogs 1389
Uveodermatologic Syndrome (VKH) 1390
Vaginal Discharge 1391
Vaginal Hyperplasia and Prolapse 1393
Vaginal Malformations and Acquired Lesions 1394
Vaginal Tumors 1396
Vaginitis 1397
Vascular Ring Anomalies 1399
Vasculitis, Cutaneous 1400
Vasculitis, Systemic (Including Phlebitis) 1401
Ventricular Arrhythmias and Sudden Death in German Shepherds 1404
Ventricular Fibrillation 1405
Ventricular Pre-Excitation and Wolff–Parkinson–White Syndrome 1407
Ventricular Premature Complexes 1409
Ventricular Septal Defect 1411
Ventricular Standstill (Asystole) 1413
Ventricular Tachycardia 1415
Vertebral Column Trauma 1419
Vesicourachal Diverticula 1421
Vestibular Disease, Geriatric—Dogs 1422
Vestibular Disease, Idiopathic—Cats 1424
Vomiting, Chronic 1426
Von Willebrand Disease 1429
Weight Loss and Cachexia 1431
West Nile Virus Infection 1434
Whipworms (Trichuriasis) 1435
Xylitol Toxicosis 1436
Zinc Toxicosis 1437

Appendix I Normal Reference Ranges for Laboratory Tests 1441
Table I-A Normal hematologic values 1441
Table I-B Normal biochemical values 1441
Table I-C Conversion table for hematologic units 1442
Table I-D Conversion table for clinical biochemical units 1443
Appendix II Endocrine Testing 1444
Table II-A Endocrine function testing protocols 1444
Table II-B Tests of the endocrine system 1445
Table II-C Conversion table for hormone assay units 1446
Appendix III Approximate Normal Ranges for Common Measurements in Dogs and Cats 1447
Appendix IV Normal Values for the Canine and Feline Electrocardiogram 1448
Appendix V Antidotes and Useful Drugs: Methods of Treatment 1449
Appendix VI Toxic Home and Garden Hazards for Pets 1452
Table VI-A Toxic plants and their clinical signs—antidotes and treatment 1452
Table VI-B Herbal toxicities 1457

Behavior

Aggression—Between Dogs in the Household 42
Aggression to Unfamiliar People and Unfamiliar Dogs—Dogs 44
Aggression Toward Children—Dogs 46
Aggression Toward Familiar People—Dogs 47

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Aggression Toward Humans—Cats 49
Aggression, Food and Resource Guarding—Dogs 51
Aggression, Intercat Aggression 53
Aggression, Overview—Cats 56
Aggression, Overview—Dogs 58
Car Ride Anxiety—Dogs and Cats 220
Cognitive Dysfunction Syndrome 295
Compulsive Disorders—Cats 304
Compulsive Disorders—Dogs 306
Coprophagia and Pica 332
Destructive and Scratching Behavior—Cats 388
Destructive Behavior—Dogs 389
Excessive Vocalization and Waking at Night—Dogs and Cats 476
Fear and Aggression in Veterinary Visits—Cats 490
Fear and Aggression in Veterinary Visits—Dogs 492
Fears, Phobias and Anxieties—Cats 494
Fears, Phobias and Anxieties—Dogs 496
Housesoiling—Cats 657
Housesoiling—Dogs 661
Kitten Behavior Problems 801
Kitten Socialization and Kitten Classes 803
Marking, Roaming, and Mounting Behavior—Cats 870
Marking, Roaming, and Mounting Behavior—Dogs 872
Maternal Behavior Problems 877
Polyphagia 1109
Puppy Behavior Problems 1155
Puppy Socialization and Puppy Classes 1157
Separation Anxiety Syndrome 1231
Submissive and Excitement Urination—Dogs 1305
Thunderstorm and Noise Phobias 1333
Unruly Behaviors: Jumping, Pulling, Chasing, Stealing—Dogs 1361

Cardiology

Aortic Stenosis 106
Aortic Thromboembolism 108
Arteriovenous Fistula and Arteriovenous Malformation 112
Ascites 120
Atrial Fibrillation and Atrial Flutter 136
Atrial Premature Complexes 139
Atrial Septal Defect 141
Atrial Standstill 142
Atrial Wall Tear 144
Atrioventricular Block, Complete (Third Degree) 146
Atrioventricular Block, First Degree 148
Atrioventricular Block, Second Degree—Mobitz Type I 150

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Atrioventricular Block, Second Degree—Mobitz Type II 152
Atrioventricular Valve Dysplasia 154
Atrioventricular Valvular Stenosis 156
Cardiomyopathy, Arrhythmogenic Right Ventricular—Cats 226
Cardiomyopathy, Arrhythmogenic Right Ventricular—Dogs 227
Cardiomyopathy, Dilated—Cats 229
Cardiomyopathy, Dilated—Dogs 232
Cardiomyopathy, Hypertrophic—Cats 235
Cardiomyopathy, Hypertrophic—Dogs 238
Cardiomyopathy, Nutritional 239
Cardiomyopathy, Restrictive—Cats 241
Cardiopulmonary Arrest 243
Congestive Heart Failure, Left-Sided 315
Congestive Heart Failure, Right-Sided 317
Digoxin Toxicity 407
Electric Cord Injury 440
Endocarditis, Infective 445
Endomyocardial Diseases—Cats 447
Fever 526
Heartworm Disease—Cats 586
Heartworm Disease—Dogs 587
Heat Stroke and Hyperthermia 589
Hypertension, Pulmonary 704
Hypertension, Systemic Arterial 706
Hypothermia 745
Idioventricular Rhythm 754
Left Anterior Fascicular Block 816
Left Bundle Branch Block 818
Lymphedema 853
Murmurs, Heart 912
Myocardial Infarction 933
Myocarditis 935
Myxomatous Mitral Valve Disease 951
Patent Ductus Arteriosus 1049
Pericardial Disease 1058
Peripheral Edema 1065
Peritoneopericardial Diaphragmatic Hernia 1068
Pleural Effusion 1082
Pulmonary Thromboembolism 1151
Pulmonic Stenosis 1153
Right Bundle Branch Block 1202
Shock, Cardiogenic 1241
Shock, Hypovolemic 1243
Shock, Septic 1245
Sick Sinus Syndrome 1250

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Sinus Arrest and Sinoatrial Block 1252
Sinus Arrhythmia 1254
Sinus Bradycardia 1256
Sinus Tachycardia 1258
Supraventricular Tachycardia 1307
Syncope 1309
Systolic Anterior Motion 1315
Tetralogy of Fallot 1322
Vascular Ring Anomalies 1399
Vasculitis, Systemic (Including Phlebitis) 1401
Ventricular Arrhythmias and Sudden Death in German Shepherds 1404
Ventricular Fibrillation 1405
Ventricular Pre-Excitation and Wolff–Parkinson–White Syndrome 1407
Ventricular Premature Complexes 1409
Ventricular Septal Defect 1411
Ventricular Standstill (Asystole) 1413
Ventricular Tachycardia 1415

Dentistry

Deciduous Teeth, Persistent (Retained) 359
Dental Caries 364
Dentigerous Cyst 366
Discolored Tooth/Teeth 409
Enamel Hypoplasia/Hypocalcification 441
Feline Alveolar Osteitis 498
Feline Stomatitis—Feline Chronic Gingivostomatitis (FCGS) 519
Feline Tooth Resorption (Odontoclastic Resorption) 522
Gingival Enlargement/Hyperplasia 563
Halitosis 579
Malocclusions—Skeletal and Dental 862
Maxillary and Mandibular Fractures 879
Odontogenic Tumors 988
Odontoma 990
Oronasal Fistula 1005
Palatal Defects 1025
Periodontal Disease 1063
Stomatitis and Oral Ulceration 1297
Temporomandibular Joint Disorder 1318
Tooth—Missing 1341
Tooth Formation/Structure, Abnormal 1342
Tooth Root Abscess (Apical Abscess) 1343
Traumatic Dentoalveolar Injuries (TDI) 1353

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Dermatology

Acne—Cats	14
Acne—Dogs	15
Acral Lick Dermatitis	16
Alopecia—Cats	65
Alopecia—Dogs	67
Alopecia, Noninflammatory—Dogs	69
Anal Sac Disorders	77
Atopic Dermatitis	134
Cheyletiellosis	257
Claw and Clawfold Disorders	282
Contact Dermatitis	325
Cutaneous Drug Eruptions	350
Deep Cutaneous Mycoses	360
Demodicosis	362
Dermatomyositis	367
Dermatophilosis	369
Dermatophytosis	370
Dermatoses, Depigmenting Disorders	372
Dermatoses, Erosive or Ulcerative	374
Dermatoses, Exfoliative	376
Dermatoses, Neoplastic	378
Dermatoses, Papulonodular	380
Dermatoses, Sterile Nodular/Granulomatous	382
Dermatoses, Sun-Induced	384
Dermatoses, Vesiculopustular	385
Dermatoses, Viral (Non-Papillomatosis)	387
Ear Mites	432
Eosinophilic Granuloma Complex	451
Feline Paraneoplastic Alopecia	518
Feline Symmetrical Alopecia	521
Flea Bite Hypersensitivity and Flea Control	538
Food Reactions, Dermatologic	540
Histiocytosis, Cutaneous	652
Leishmaniosis, Cutaneous	825
Lupus Erythematosus, Cutaneous (Discoid)	844
Lymphoma, Cutaneous Epitheliotropic	858
Malassezia Dermatitis	860
Mycobacterial Infections	922
Nasal Dermatoses—Canine	956
Nocardiosis/Actinomycosis—Cutaneous	980
Notoedric Mange	983
Otitis Externa and Media	1013
Panniculitis/Steatitis	1033
Papillomatosis	1039
Pemphigus	1055

Hypomagnesemia 731
Hyponatremia 734
Hypoparathyroidism 736
Hypophosphatemia 739
Hypopituitarism 741
Hyporexia 743
Hyposthenuria 744
Hypothyroidism 747
Insulinoma 776
Lactic Acidosis (Hyperlactatemia) 805
Myxedema and Myxedema Coma 950
Pheochromocytoma 1076

Gastroenterology

Acute Abdomen 18
Acute Diarrhea 21
Acute Vomiting 27
Anorexia 94
Bilious Vomiting Syndrome 179
Cobalamin Deficiency 290
Colitis and Proctitis 300
Colitis, Histiocytic Ulcerative 303
Constipation and Obstipation 323
Diarrhea, Antibiotic Responsive 402
Diarrhea, Chronic—Cats 403
Diarrhea, Chronic—Dogs 405
Dyschezia and Hematochezia 420
Dysphagia 422
Esophageal Diverticula 464
Esophageal Foreign Bodies 465
Esophageal Stricture 467
Esophagitis 469
Exocrine Pancreatic Insufficiency 480
Fiber-Responsive Large Bowel Diarrhea 528
Flatulence 536
Food Reactions (Gastrointestinal), Adverse 542
Gastric Dilation and Volvulus Syndrome 546
Gastric Motility Disorders 548
Gastritis, Chronic 550
Gastroduodenal Ulceration/Erosion 552
Gastroenteritis, Acute Hemorrhagic Diarrhea Syndrome 554
Gastroenteritis, Eosinophilic 556
Gastroesophageal Reflux 558
Gastrointestinal Obstruction 559
Gluten Enteropathy in Irish Setters 572

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Hematemesis 600
Hiatal Hernia 646
Hypertrophic Pyloric Gastropathy, Chronic 714
Ileus 756
Immunoproliferative Enteropathy of Basenjis 762
Incontinence, Fecal 763
Inflammatory Bowel Disease 771
Intussusception 788
Lymphangiectasia 849
Megacolon 881
Megaesophagus 883
Melena 889
Obesity 986
Pancreatitis—Cats 1027
Pancreatitis—Dogs 1029
Perianal Fistula 1057
Perineal Hernia 1061
Protein-Losing Enteropathy 1136
Ptyalism 1146
Rectal and Anal Prolapse 1180
Rectal Stricture 1181
Rectoanal Polyps 1182
Regurgitation 1185
Salivary Mucocele 1214
Small Intestinal Dysbiosis 1262
Vomiting, Chronic 1426
Weight Loss and Cachexia 1431

Hematology/ Immunology

Anaphylaxis 78
Anemia, Aplastic 82
Anemia, Heinz Body 83
Anemia, Immune-Mediated 84
Anemia, Iron-Deficiency 86
Anemia, Nonregenerative 87
Anemia, Nuclear Maturation Defects (Anemia, Megaloblastic) 89
Anemia, Regenerative 90
Blood Transfusion Reactions 186
Chediak-Higashi Syndrome 255
Coagulation Factor Deficiency 286
Cold Agglutinin Disease 297
Cyclic Hematopoiesis 354
Disseminated Intravascular Coagulation 413
Eosinophilia 450

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Erythrocytosis 462
Familial Shar-Pei Fever 487
Hemotropic Mycoplasmosis 607
Hypercoagulability 677
Hypereosinophilic Syndrome (HES) 678
Hyperviscosity Syndrome 716
Immunodeficiency Disorders, Primary 760
Leukocytosis 831
Lupus Erythematosus, Systemic (SLE) 845
Lymphadenopathy/Lymphadenitis 851
Methemoglobinemia 904
Mucopolysaccharidoses 908
Neutropenia 978
Pancytopenia 1031
Paraproteinemia 1046
Pelger–Huët Anomaly 1053
Petechiae, Ecchymosis, Bruising 1072
Phosphofructokinase Deficiency 1078
Pseudomacrothrombocytopenia (Inherited Macrothrombocytopenia) 1145
Pyruvate Kinase Deficiency 1171
Sjögren-Like Syndrome 1260
Splenic Torsion 1278
Thrombocytopathies 1325
Thrombocytopenia 1327
Thrombocytopenia, Primary Immune-Mediated 1329
Thrombocytosis 1331
Von Willebrand Disease 1429

Hepatology

Alkaline Hyperphosphatasemia in Dogs 61
Arteriovenous Malformation of the Liver 113
Bile Duct Obstruction (Extrahepatic) 174
Bile Peritonitis 177
Cholangitis/Cholangiohepatitis Syndrome 262
Cholecystitis and Choledochitis 265
Cholelithiasis 267
Cirrhosis and Fibrosis of the Liver 279
Coagulopathy of Liver Disease 288
Copper Associated Hepatopathy 328
Ductal Plate Malformation (Congenital Hepatic Fibrosis) 416
Gallbladder Mucocele 544
Glycogen Storage Disease 573
Glycogen-Type Vacuolar Hepatopathy 574
Hepatic Amyloid 609
Hepatic Encephalopathy 611

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Hepatic Failure, Acute 614
Hepatic Lipidosis 617
Hepatic Nodular Hyperplasia and Dysplastic Hyperplasia 620
Hepatitis, Chronic 622
Hepatitis, Granulomatous 626
Hepatitis, Infectious (Viral) Canine 628
Hepatitis, Suppurative and Hepatic Abscess 630
Hepatocutaneous Syndrome 634
Hepatomegaly 636
Hepatoportal Microvascular Dysplasia 639
Hepatosupportive Therapies 642
Hepatotoxins 643
Hypertension, Portal 701
Hypoalbuminemia 722
Icterus 752
Liver Fluke Infestation 836
Portosystemic Shunting, Acquired 1115
Portosystemic Vascular Anomaly, Congenital 1118
Splenomegaly 1279

Infectious Diseases

Abscessation 8
Actinomycosis and Nocardia 17
Anaerobic Infections 76
Aspergillosis, Disseminated Invasive 122
Babesiosis 161
Bartonellosis 164
Baylisascariasis 167
Blastomycosis 180
Brucellosis 202
Campylobacteriosis 206
Candidiasis 207
Canine Coronavirus Infections 208
Canine Distemper 211
Canine Infectious Diarrhea 213
Canine Parvovirus 217
Canine Schistosomiasis (Heterobilharziasis) 219
Chagas Disease (American Trypanosomiasis) 254
Chlamydiosis—Cats 258
Clostridial Enterotoxicosis 284
Coccidioidomycosis 292
Coccidiosis 294
Colibacillosis 298
Cryptococcosis 344

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Cryptosporidiosis 347
Cuterebriasis 351
Cytauxzoonosis 356
Ehrlichiosis and Anaplasmosis 436
Feline Calicivirus Infection 499
Feline Herpesvirus Infection 501
Feline Immunodeficiency Virus (FIV) Infection 506
Feline Infectious Diarrhea 508
Feline Infectious Peritonitis (FIP) 510
Feline Leukemia Virus (FeLV) Infection 514
Feline Panleukopenia 516
Feline (Upper) Respiratory Infections 524
Giardiasis 562
Helicobacter spp. 591
Hepatozoonosis 645
Histoplasmosis 653
Hookworms (Ancylostomiasis) 655
Influenza 773
Leishmaniosis 824
Leptospirosis 828
Lyme Borreliosis 847
Multidrug-Resistant Infections 909
Mycoplasmosis 924
Neonatal Mortality and Canine Herpesvirus 964
Neosporosis 969
Ollulanus Infection 993
Peritonitis 1069
Physalopterosis 1079
Plague 1080
Pneumocystosis 1084
Poxvirus Infection—Cats 1122
Pythiosis 1172
Q Fever 1176
Rabies 1178
Rocky Mountain Spotted Fever 1204
Roundworms (Ascariasis) 1212
Salmon Poisoning Disease 1216
Salmonellosis 1217
Sepsis and Bacteremia 1235
Staphylococcal Infections 1292
Streptococcal Infections 1299
Tapeworms (Cestodiasis) 1317
Tetanus 1320
Toxoplasmosis 1346
Trichomoniasis 1357
Tularemia 1359

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

West Nile Virus Infection 1434
Whipworms (Trichuriasis) 1435

Musculoskeletal

Antebrachial Growth Deformities 96
Arthritis (Osteoarthritis) 115
Arthritis, Septic 118
Atlantoaxial Instability 132
Craniomandibular Osteopathy 341
Cruciate Ligament Disease, Cranial 342
Discospondylitis 411
Elbow Dysplasia 438
Hip Dysplasia 647
Hypertrophic Osteodystrophy 711
Hypertrophic Osteopathy 713
Intervertebral Disc Disease, Cervical 781
Intervertebral Disc Disease, Thoracolumbar 784
Joint Luxations 793
Lameness 808
Legg–Calvé–Perthes Disease 820
Metabolic, Nutritional, and Endocrine Bone Disorders 900
Muscle Rupture (Muscle Tear) 914
Myasthenia Gravis 920
Myopathy—Hereditary X-linked Muscular Dystrophy 938
Myopathy—Masticatory and Extraocular Myositis 939
Myopathy, Noninflammatory—Endocrine 941
Myopathy, Noninflammatory—Hereditary Labrador Retriever 943
Myopathy, Noninflammatory—Hereditary Myotonia 944
Myopathy, Noninflammatory—Hereditary Scottie Cramp 945
Myopathy, Noninflammatory—Metabolic 946
Myopathy—Polymyositis and Dermatomositis 948
Osteochondrodysplasia 1006
Osteochondrosis 1007
Osteomyelitis 1009
Panosteitis 1034
Patellar Luxation 1047
Polyarthritis, Erosive, Immune-Mediated 1101
Polyarthritis, Nonerosive, Immune-Mediated, Dogs 1103
Shoulder Joint, Ligament, and Tendon Conditions 1247

Nephrology/ Urology

Acidosis, Metabolic 12
Acute Kidney Injury 23

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Alkalosis, Metabolic	63
Amyloidosis	74
Anemia of Chronic Kidney Disease	80
Azotemia and Uremia	159
Benign Prostatic Hyperplasia	168
Chronic Kidney Disease	274
Congenital and Developmental Renal Diseases	308
Crystalluria	348
Cylindruria	355
Dysuria, Pollakiuria, and Stranguria	430
Ectopic Ureter	434
Fanconi Syndrome	489
Feline Idiopathic Lower Urinary Tract Disease	504
Glomerulonephritis	566
Glucosuria	570
Hematuria	602
Hemoglobinuria and Myoglobinuria	604
Hydronephrosis	665
Hyperparathyroidism, Renal Secondary	696
Incontinence, Urinary	765
Lower Urinary Tract Infection, Bacterial	838
Lower Urinary Tract Infection, Fungal	840
Nephrolithiasis	970
Nephrotic Syndrome	972
Nephrotoxicity, Drug-Induced	974
Oliguria and Anuria	991
Pelvic Bladder	1054
Perirenal Pseudocysts	1067
Polycystic Kidney Disease	1105
Polypoid Cystitis	1111
Polyuria and Polydipsia	1113
Prostatic Cysts	1131
Prostatitis and Prostatic Abscess	1132
Prostatomegaly	1134
Proteinuria	1138
Pyelonephritis	1160
Pyuria	1174
Renal Tubular Acidosis	1187
Renomegaly	1188
Ureterolithiasis	1363
Urethral Prolapse	1365
Urinary Retention, Functional	1366
Urinary Tract Obstruction	1368
Urinary Tract Parasites	1370
Urolithiasis, Calcium Oxalate	1372
Urolithiasis, Calcium Phosphate	1375

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Urolithiasis, Cystine 1376
Urolithiasis, Pseudo (Dried Blood, Ossified Material) 1378
Urolithiasis, Struvite—Cats 1379
Urolithiasis, Struvite—Dogs 1381
Urolithiasis, Urate 1383
Urolithiasis, Xanthine 1385
Vesicourachal Diverticula 1421

Neurology

Ataxia 130
Botulism 188
Brachial Plexus Avulsion 189
Brain Injury 192
Brain Tumors 194
Canine Degenerative Myelopathy 209
Cerebellar Degeneration 247
Cerebellar Hypoplasia 248
Cerebrovascular Accidents 249
Cervical Spondylomyelopathy (Wobbler Syndrome) 252
Congenital Spinal and Vertebral Malformations 313
Coonhound Paralysis (Acute Polyradiculoneuritis) 326
Deafness 357
Dysautonomia (Key-Gaskell Syndrome) 419
Encephalitis 442
Encephalitis Secondary to Parasitic Migration 444
Epilepsy, Genetic (Idiopathic)—Dogs 454
Exercise-Induced Weakness/Collapse in Labrador Retrievers 478
Facial Nerve Paresis and Paralysis 483
Feline Hyperesthesia Syndrome 503
Feline Ischemic Encephalopathy 512
Fibrocartilaginous Embolic Myelopathy 530
Head Pressing 581
Head Tilt 583
Head Tremors (Bobbing), Idiopathic—Dogs 585
Hydrocephalus 663
Hypermetria and Dysmetria 689
Hypomyelination 733
Intervertebral Disc Disease—Cats 780
Leukoencephalomyelopathy in Rottweilers 833
Lumbosacral Stenosis and Cauda Equina Syndrome 841
Lysosomal Storage Diseases 859
Meningioma—Cats and Dogs 891
Meningitis/Meningoencephalitis/Meningomyelitis, Bacterial 894
Meningoencephalomyelitis, Eosinophilic 896
Meningoencephalomyelitis of Unknown Etiology (MUE) 897

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Movement Disorders 907
Myelomalacia, Spinal Cord (Ascending, Descending, Progressive) 929
Myelopathy—Paresis/Paralysis—Cats 930
Myoclonus 937
Narcolepsy and Cataplexy 954
Neck and Back Pain 961
Necrotizing Encephalitis 963
Nerve Sheath Tumors 976
Neuroaxonal Dystrophy 977
Nystagmus 984
Otitis Media and Interna 1015
Pain (Acute, Chronic, and Postoperative) 1021
Paralysis 1040
Polioencephalomyelitis—Cats 1100
Polyneuropathies (Peripheral Neuropathies) 1107
Quadrigeminal Cyst 1177
Schiff–Sherrington Phenomenon 1222
Seizures (Convulsions, Status Epilepticus)—Cats 1225
Seizures (Convulsions, Status Epilepticus)—Dogs 1227
Shaker/Tremor Syndrome, Corticosteroid Responsive 1240
Spinal Dysraphism 1276
Spondylosis Deformans 1281
Steroid-Responsive Meningitis-Arteritis—Dogs 1294
Stupor and Coma 1300
Subarachnoid Cysts (Arachnoid Diverticulum) 1302
Syringomyelia and Chiari-Like Malformation 1312
Tick Bite Paralysis 1336
Tremors 1355
Trigeminal Neuritis, Idiopathic 1358
Vertebral Column Trauma 1419
Vestibular Disease, Geriatric—Dogs 1422
Vestibular Disease, Idiopathic—Cats 1424

Oncology

Adenocarcinoma, Anal Sac 29
Adenocarcinoma, Lung 31
Adenocarcinoma, Nasal 32
Adenocarcinoma, Pancreas 34
Adenocarcinoma, Prostate 35
Adenocarcinoma, Renal 36
Adenocarcinoma, Salivary Gland 37
Adenocarcinoma, Skin (Sweat Gland, Sebaceous) 38
Adenocarcinoma, Stomach, Small and Large Intestine, Rectal 39
Adenocarcinoma, Thyroid—Dogs 40
Ameloblastoma 71

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Astrocytoma	129
Basal Cell Tumor	165
Bile Duct Carcinoma	173
Ceruminous Gland Adenocarcinoma, Ear	251
Chemodectoma	256
Chondrosarcoma, Bone	269
Chondrosarcoma, Nasal and Paranasal Sinus	270
Chondrosarcoma, Oral	271
Fibrosarcoma, Bone	532
Fibrosarcoma, Gingiva	533
Fibrosarcoma, Nasal and Paranasal Sinus	534
Hair Follicle Tumors	578
Hemangiopericytoma	593
Hemangiosarcoma, Bone	594
Hemangiosarcoma, Heart	595
Hemangiosarcoma, Skin	596
Hemangiosarcoma, Spleen and Liver	598
Hepatocellular Adenoma	632
Hepatocellular Carcinoma	633
Histiocytic Diseases—Dogs and Cats	650
Interstitial Cell Tumor, Testicle	779
Leiomyoma, Stomach, Small and Large Intestine	822
Leiomyosarcoma, Stomach, Small and Large Intestine	823
Leukemia, Chronic Lymphocytic	830
Lipoma, Infiltrative	835
Lymphoma—Cats	854
Lymphoma—Dogs	856
Malignant Fibrous Histiocytoma	861
Mammary Gland Tumors—Cats	865
Mammary Gland Tumors—Dogs	867
Mast Cell Tumors	874
Melanocytic Tumors, Oral	886
Melanocytic Tumors, Skin and Digit	888
Mesothelioma	899
Multiple Myeloma	911
Myelodysplastic Syndromes	928
Myeloproliferative Disorders	932
Myocardial Tumors	934
Oral Cavity Tumors, Undifferentiated Malignant Tumors	1000

Sertoli Cell Tumor 1237
Soft Tissue Sarcoma 1270
Squamous Cell Carcinoma, Digit 1283
Squamous Cell Carcinoma, Ear 1284
Squamous Cell Carcinoma, Gingiva 1285
Squamous Cell Carcinoma, Lung 1286
Squamous Cell Carcinoma, Nasal and Paranasal Sinuses 1287
Squamous Cell Carcinoma, Nasal Planum 1288
Squamous Cell Carcinoma, Skin 1289
Squamous Cell Carcinoma, Tongue 1290
Squamous Cell Carcinoma, Tonsil 1291
Synovial Cell Sarcoma 1311
Thymoma 1335
Transitional Cell Carcinoma 1350
Transmissible Venereal Tumor 1352
Uterine Tumors 1387
Vaginal Tumors 1396

Ophthalmology

Anisocoria 92
Anterior Uveitis—Cats 98
Anterior Uveitis—Dogs 100
Blepharitis 182
Blind Quiet Eye 184
Cataracts 245
Chorioretinitis 272
Congenital Ocular Anomalies 310
Conjunctivitis—Cats 319
Conjunctivitis—Dogs 321
Corneal and Scleral Lacerations 334
Corneal Opacities—Degenerations and Infiltrates 336
Corneal Opacities—Dystrophies 337
Corneal Sequestrum—Cats 338
Ectropion 435
Entropion 449
Epiphora 456
Episcleritis 458
Eyelash Disorders (Trichiasis/Distichiasis/Ectopic Cilia) 482
Glaucoma 564
Horner's Syndrome 656
Hyphema 717
Hypopyon and Lipid Flare 742
Iris Atrophy 790
Keratitis, Eosinophilic—Cats 795
Keratitis, Nonulcerative 796

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Keratitis, Ulcerative 798
Keratoconjunctivitis Sicca 800
Lens Luxation 827
Ophthalmia Neonatorum 994
Optic Neuritis and Papilledema 998
Orbital Diseases (Exophthalmos, Enophthalmos, Strabismus) 1001
Prolapsed Gland of the Third Eyelid (Cherry Eye) 1127
Proptosis 1128
Red Eye 1183
Retinal Degeneration 1193
Retinal Detachment 1195
Retinal Hemorrhage 1197
Third Eyelid Protrusion 1323
Uveal Melanoma—Cats 1388
Uveal Melanoma—Dogs 1389

Respiratory

Acute Respiratory Distress Syndrome 25
Aspergillosis, Nasal 124
Asthma, Bronchitis—Cats 127
Brachycephalic Airway Syndrome 190
Bronchiectasis 198
Bronchitis, Chronic 200
Canine Infectious Respiratory Disease 215
Chylothorax 277
Cough 339
Cyanosis 352
Diaphragmatic Hernia 401
Drowning (Near Drowning) 415
Dyspnea and Respiratory Distress 425
Epistaxis 459
Hemothorax 606
Hypercapnia 674
Hypoxemia 750
Laryngeal and Tracheal Perforation 810
Laryngeal Diseases 812
Lung Lobe Torsion 843
Nasal and Nasopharyngeal Polyps 955
Nasal Discharge 958
Nasopharyngeal Stenosis 960
Panting and Tachypnea 1036
Pectus Excavatum 1052
Pneumonia, Aspiration 1085
Pneumonia, Bacterial 1086
Pneumonia, Eosinophilic 1088

331 client education handouts are available at www.fiveminutevet.com/canineandfeline7th for you to download and use in practice

Pneumonia, Fungal	1090
Pneumonia, Interstitial	1092
Pneumothorax	1094
Pulmonary Contusions	1148
Pulmonary Edema, Noncardiogenic	1149
Pyothorax	1168
Respiratory Parasites	1190
Rhinitis and Sinusitis	1199
Smoke Inhalation	1264
Sneezing, Reverse Sneezing, Gagging	1268
Stertor and Stridor	1295
Tracheal Collapse	1348

Theriogenology

Abortion, Spontaneous (Early Pregnancy Loss)—Cats	2
Abortion, Spontaneous (Early Pregnancy Loss)—Dogs	4
Abortion, Termination of Pregnancy	6
Breeding, Timing	196

PREFACE

Keeping abreast of advances in veterinary internal medicine is extremely difficult, especially for the busy general practitioner. To keep current with all the veterinary journals while practicing medicine is impossible. The veterinarian in practice can be overwhelmed by all of the findings and conclusions of thousands of studies conducted by veterinary specialists. *Blackwell's Five-Minute Veterinary Consult* is designed to provide the busy veterinary practitioner and student of veterinary medicine with concise practical reviews of almost all the diseases and clinical problems in dogs and cats. Our goal in creating this textbook was also to provide up-to-date information in an easy-to-use format. Emphasis is placed on diagnosis and treatment of problems and diseases likely to be seen by veterinarians.

Our fondest dream was realized when the first six editions of this book were chosen as a comprehensive reference source for canine and feline medicine by veterinary students, practicing veterinarians, and board-certified specialists. The format has proven easy to use and very popular with busy practitioners. The scope of the book and the number of Consulting Editors and authors have been expanded. We have also increased the number of authors from outside North America, to provide the best advice in the world. The number of topics has been increased, and every topic has been updated to provide you with the most current information possible in a textbook. The appendixes have also been expanded to include more useful tables.

Several good veterinary internal medicine textbooks are available. The uniqueness and value of *Blackwell's Five-Minute Veterinary Consult* as a quick reference is the consistency of presentation, the breadth of coverage, the contribution of large numbers of experts, and the timely preparation of the manuscript. The format of every topic is identical, making it easy to find information. An extensive list of topic headings ensures complete coverage of each topic.

As the title implies, one objective of this book is to make information quickly available. To this end, we have organized topics alphabetically from A to Z. Most topics can be found without using the index. A table of contents broken out by organ system and a detailed index are provided. Large volumes of useful information are summarized in charts in the appendixes. Included in the appendixes are normal laboratory values, endocrine testing protocols, common procedures and testing protocols, toxicology tables, pain management tables, Rx for Osteoarthritis, disease-modifying drugs table, an epilepsy classification table, conversion tables, and other information pages with important resources for veterinarians. For this new edition, an appendix has been added to include common procedures and testing protocols used in veterinary medicine.

We are delighted and privileged to have had the assistance of numerous experts in veterinary internal medicine from around the world. More than 450 veterinary specialists contributed to this text, allowing each chapter to be written by an expert on the subject. In addition to providing outstanding information, this large pool of experts allowed us to publish this major text in a timely manner.

Many large textbooks take several years to write, making some of the information outdated by the time the book is published. We are indebted to the many contributors and Consulting Editors whose hard work allowed us to write, edit, and publish this work in 3 years, with most chapters completed within a year of publication. Our goal is to revise the text every 3–4 years, so that the contents will always be current.

Blackwell's Five-Minute Veterinary Consult: Canine and Feline, Seventh Edition is available in a variety of digital formats. Visit www.wiley.com/go/5MVC for more information. This edition also includes Client Education Handouts based on the content of *Blackwell's Five-Minute Veterinary Consult*. The complimentary Client Education Handouts are available on a companion website at www.fiveminutevet.com/canineandfeline featuring 331 Client Education Handouts for you to customize and use in practice. These Handouts can be edited to reflect your practice preferences and then printed on your letterhead to distribute to your clients.

The book will also be published as an e-book, in downloadable ePub/ePDF formats. Now veterinarians can quickly access information about necessary clinical skills and new developments in diagnosis and treatment on their computers or mobile versions. The electronic versions offer fast, affordable access to much of the accumulated wisdom in veterinary medicine. This technology brings to the clinic examination room and doctor's office an easy-to-use resource that will markedly improve the quality of continuing education and clinical practice, and a companion website offers client education handouts to be downloaded and used in practice.

The seventh edition of this textbook constitutes an important, up-to-date medical reference source for your practice and clinical education. We strived to make it complete yet practical and easy to use. Our dreams are realized if this text helps you to quickly locate and use the "momentarily important" information that is essential to the practice of high-quality veterinary medicine. We would appreciate your input so that we can make future editions even more useful. If you would like to see any changes in content or format, additions, or deletions, please let us know. Send comments to the following:

Acknowledgments

The completion of this textbook provides a welcome opportunity to recognize in writing the many individuals who have helped along the way. The Editors gratefully acknowledge the Consulting Editors and the contributors who, by their expertise, have so unmistakably enhanced the quality of this textbook.

We would also like to acknowledge and thank our families for their support of this project and the sacrifices they made to allow us the time to complete the book.

In addition to thanking veterinarians who have referred patients to us, we would like to express our gratitude to all the veterinary students, interns, and residents who we have had the privilege to teach. Their curiosity and intellectual stimulation have enabled us to grow and have prompted us to undertake the task of writing this book.

Finally, a special acknowledgment goes to everyone at Wiley Blackwell. The marketing and sales departments also must be acknowledged for generating such an interest in this book. They are all meticulous workers and kind people who have made the final stages of preparing this book both inspiring and fun. We would also like to thank copy-editors Sally Osborn and Harriet Stewart-Jones, and Erica Judisch, Executive Editor. A special thank you goes to Mirjana Misina, Editorial Project Manager, who spent hours and days keeping track of all the contributors and the deadline dates for manuscripts. This edition would not have taken place without her. An important life goal of ours has been fulfilled: to provide expertise in small animal internal medicine worldwide and to teach the principles contained in this textbook to veterinarians and students everywhere.

Larry P. Tilley, Francis W.K. Smith, Jr.,
Meg M. Sleeper and Benjamin M. Brainard

Diplomate ACVIM (Small Animal Internal Medicine)
Diplomate ECVIM-CA
Diplomate ABVP (Feline Practice)
Professor, Small Animal Internal Medicine
Department of Small Animal Clinical Sciences
College of Veterinary Medicine and Biomedical Sciences
Texas A&M University
College Station, Texas
USA

LESLIE LARSON COOPER, DVM
Diplomate ACVB
Animal Behavior Counseling and Therapy
Davis, California
USA

EDWARD S. COOPER, VMD, MS
Diplomate ACVECC
Professor—Clinical
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
Ohio State University
Columbus, Ohio
USA

RHIAN COPE, BVSc, BSc(Hon1), PhD, FACTRA
Diplomate ABT
Diplomate ABVT
Principal Toxicologist
Australian Pesticides and Veterinary Medicines Authority
Symonston
Australia

JOHN M. CRANDELL, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Veterinary Internist
MedVet Akron
Akron, Ohio
USA

SIGNE E. CREMER, DVM, PhD
Associate Professor, Clinical Pathology
Department of Veterinary Clinical Sciences
Faculty of Health and Medical Sciences
University of Copenhagen
Frederiksberg
Denmark

SUZANNE M. CUNNINGHAM, DVM
Diplomate ACVIM (Cardiology)
Associate Professor
Department of Clinical Sciences
Cummings School of Veterinary Medicine
Tufts University
North Grafton, Massachusetts
USA

ELIZABETH A. CURRY-GALVIN, DVM
Barrington Hills, Illinois
USA

TERRY MARIE CURTIS, DVM, MS
Diplomate ACVB
Veterinary Behaviorist
St. Augustine, Florida
USA

SARAH L. CZERWINSKI, BSc, DVM
Diplomate ACVO
Clinical Assistant Professor
Department of Small Animal Medicine and Surgery
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

RONALDO CASIMIRO DA COSTA, DMV, MSc, PhD
Diplomate ACVIM (Neurology)
Professor and Service Head, Neurology and Neurosurgery
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
The Ohio State University
Columbus, Ohio
USA

AUTUMN P. DAVIDSON, DVM, MS
Diplomate ACVIM (Small Animal Internal Medicine)
Clinical Professor
VMTH
School of Veterinary Medicine
University of California
Davis, California
USA

THOMAS K. DAY, DVM, MS
Diplomate ACVAA
Diplomate ACVECC
Emergency and Critical Care Specialist
Anesthesiology and Pain Management Specialist
VCA Veterinary Emergency Service and Specialty Center
Middleton, Wisconsin
USA

ALEXANDER DE LAHUNTA, DVM, PhD
Retired Professor of Veterinary Anatomy
at Cornell University
Ithaca, New York
USA

HELIO S. AUTRAN DE MORAIS, DVM, PhD
Diplomate ACVIM (Internal Medicine and Cardiology)
Director
Lois Bates Acheson Veterinary Teaching Hospital
College of Veterinary Medicine
Oregon State University
Corvallis, Oregon
USA

JONATHAN D. DEAR, DVM, MAS
Diplomate ACVIM (Small Animal Internal Medicine)
Assistant Professor of Clinical Internal Medicine
Department of Medicine and Epidemiology
School of Veterinary Medicine
University of California, Davis
Davis, California
USA

TERESA C. DEFRANCESCO, DVM
Diplomate ACVIM (Cardiology), ACVECC
Department of Clinical Sciences
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

VICTORIA A. DEMELLO, DVM
Nashville Veterinary Specialists
Nashville, Tennessee
USA

SAGI DENENBERG, DVM, MRCVS
Veterinary Psychiatrist
Diplomate ACVB
Diplomate ECAWBM
RCVS Recognized Specialist in Veterinary Behavioural Medicine
North Toronto Veterinary Behaviour Specialty Clinic
Thornhill, Ontario
Canada

THERESA L. DEPORTER, BSc, DVM, MRCVS
Diplomate DECAWBM
Diplomate ACVB (Behavior)
Veterinary Behaviorist
Behavioral Medicine Department
Oakland Veterinary Referral Services
Bloomfield Hills, Michigan
USA

NICK DERVISIS, DVM, PhD
DACVIM (Oncology)
Medical Oncology
Associate Professor
Department of Small Animal Clinical Sciences;
Associate Professor
Faculty of Health Sciences
VA-MD College of Veterinary Medicine
DSACS, Phase II
Blacksburg, Virginia
USA

IAN DESTEFANO, DVM
Resident, Emergency & Critical Care
Foster Hospital for Small Animals
Tufts University
North Grafton, Massachusetts
USA

SHARON M. DIAL, DVM, PhD
Diplomate ACVP (Clinical and Anatomic Pathology)
Research Scientist
College of Veterinary Medicine
University of Arizona
Tucson, Arizona
USA

STEPHEN P. DIBARTOLA, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Professor Emeritus of Internal Medicine
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
Ohio State University
Columbus, Ohio
USA

DAVID C. DORMAN, DVM, PhD
Diplomate ABVT
Diplomate ABT
Professor of Toxicology
Department of Molecular Biomedical Sciences
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

ELIZABETH R. DRAKE, DVM
Diplomate ACVD
Associate Professor
Department of Small Animal Clinical Sciences
College of Veterinary Medicine
University of Tennessee
Knoxville, Tennessee
USA

EDWARD J. DUBOVI, PhD
Professor of Virology
Department of Population Medicine and Diagnostic Sciences
Animal Health Diagnostic Center
College of Veterinary Medicine
Cornell University
Ithaca, New York
USA

DAVID D. DUCLOS, DVM
Diplomate ACVD
Clinical Dermatologist—Animal Skin & Allergy Clinic
Lynnwood, Washington
USA

CEDRIC P. DUFAYET, DVM
Associate Veterinarian
Advanced Urinary Disease and Extracorporeal Therapies Service
University of California Veterinary Medicine Center
San Diego, California
USA

STÉPHANIE DUGAS, DVM, MSc
Diplomate ACVIM (Neurology)
Medical Neurologist
BluePearl Specialty & Emergency Hospital
Irvine, California
USA

ERIC K. DUNAYER, MS, VMD
Diplomate ABT
Diplomate ABVT
Senior Toxicologist
ASPCA Animal Poison Control Center
Urbana, Illinois
USA

CAROLINA DUQUE, DVM, MSc, DVSc
Diplomate ACVIM (Neurology)
Mississauga Oakville Emergency Hospital and Referral Group
Oakville, Ontario
Canada

DAVID DYCUS, DVM, MS, CCRP
Diplomate ACVS (Small Animal)
Chief of Orthopedics
Nexus Veterinary Bone & Joint Center
Medical Director
Nexus Veterinary Specialists
Baltimore, Maryland
USA

HEATHER D. EDGINTON, DVM
Diplomate ACVD
Animal Medical Center of Seattle
Shoreline, Washington
USA

MELISSA N.C. EISENSCHENK, DVM, MS
Diplomate ACVD
Owner, Veterinary Dermatologist
Pet Dermatology Clinic
Maple Grove, Minnesota
USA

MARC ELIE, DVM
Diplomate ACVIM (Internal Medicine)
Staff Internist
Small Animal Internal Medicine
BluePearl Veterinary Partners
Southfield, Michigan
USA

ROBYN ELLERBROCK, DVM, PhD
Diplomate ACT
Assistant Professor
Department of Large Animal Medicine
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

NAHVID M. ETEDALI, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Staff Internist
Head of Hemodialysis and Extracorporeal Therapies
Animal Medical Center
New York, New York
USA

TIMOTHY M. FAN, DVM, PhD
Diplomate ACVIM (Small Animal Internal Medicine, Oncology)
Professor
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois at Urbana-Champaign
Urbana, Illinois
USA

JUSTIN FARRIS, DVM
Clinical Pathology Resident
Department of Pathology
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

RICHARD A. FAYRER-HOSKEN, BVSc, PhD
Diplomate ACT (Theriogenology)
Diplomate ECAR
Research Scientist
Institute for Conservation Research
San Diego Zoo Global
Escondido, California
USA

LEAH FERGUSON, DVM, MS
Diplomate ACVIM (Internal Medicine)
Veterinary Internist
VCA Great Lakes Veterinary Specialists
Warrensville Heights, Ohio
USA

LLUÍS FERRER, BVSc, PhD
Diplomate ECVD
Professor
Department of Animal Medicine and Surgery
Veterinary School
Universitat Autònoma de Barcelona,
Bellaterra, Barcelona
Spain

MARIA SOLEDAD FERRER, DVM, MS
Diplomate DACT (Theriogenology)
Associate Professor
Department of Large Animal Medicine
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

TESSA FIAMENGO, DVM, MS
Diplomate ACT
Slade Veterinary Hospital
Framingham, Massachusetts
USA

ANDREA M. FINNEN, DVM, DES, MSc
Diplomate ACVIM (Neurology)
Mississauga Oakville Veterinary
Emergency Hospital
Neurology Service
Oakville, Ontario
Canada

ANDREA FISCHER, DVM, Dr.med.vet., Dr. habil.
Diplomate ACVIM (Neurology)
Diplomate ECVN
Professor
Centre for Clinical Veterinary Medicine
LMU University of Munich
Munich
Germany

GERRARD FLANNIGAN, DVM, MSc
Diplomate ACVB
Kernersville, North Carolina
USA

LINDA M. FLEEMAN, BVSc, PhD, MANZCVS
Animal Diabetes Australia
Melbourne, Victoria
Australia

CHARLOTTE FLINT, DVM, DABT
Senior Consulting Veterinarian, Clinical Toxicology
Pet Poison Helpline & SafetyCall International
Bloomington, Minnesota
USA

J.D. FOSTER, VMD
Diplomate ACVIM (Small Animal Internal Medicine)
Nephrology/Urology & Internal Medicine
Friendship Hospital for Animals
Washington, DC
USA

DANIEL S. FOY, MS, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Diplomate ACVECC
Clinical Assistant Professor
College of Veterinary Medicine
Midwestern University
Glendale, Arizona
USA

LINDA A. FRANK, MS, DVM
Diplomate ACVD
Professor
Department of Small Animal Clinical Sciences
College of Veterinary Medicine
University of Tennessee
Knoxville, Tennessee
USA

JONI L. FRESHMAN, DVM MS CVA
Diplomate ACVIM (Internal Medicine)
Owner
Canine Consultations
Peyton, Colorado
USA

CANNY FUNG, DVM
Surgery Intern
Southwest Veterinary Surgical Service
Phoenix Arizona
USA

EVA FURROW, VMD, PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Associate Professor
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
University of Minnesota
St. Paul, Minnesota
USA

LUIS GAITERO, DVM
Diplomate ECVN
Associate Professor and Head Neurology and Neurosurgery Service
HSC Chief Medical Officer
Department of Clinical Studies
Ontario Veterinary College
University of Guelph
Guelph, Ontario
Canada

JOAO FELIPE DE BRITO GALVAO, MV, MS
Diplomate ACVIM (Small Animal Internal Medicine)
Internal Medicine Specialist
VCA Arboretum View Animal Hospital
Downers Grove, Illinois;
Adjunct Assistant Professor
The Ohio State University
Columbus, Ohio
USA

BRIDGET C. GARNER, DVM, PhD
Diplomate ACVP (Clinical Pathology)
Associate Professor
Department of Pathology
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

LAURENT GAROSI, DVM, FRCVS
Diplomate ECVN
RCVS and EBVS®
European Specialist in Veterinary Neurology
Clinical Director Vet Oracle Teleneurology
Bedford
United Kingdom

LAURA D. GARRETT, DVM
Diplomate ACVIM (Oncology)
Clinical Professor
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois
Urbana, Illinois
USA

CATHY J. GARTLEY, DVM, DVSc
Diplomate ACT
Assistant Professor
Department of Population Medicine
Ontario Veterinary College
University of Guelph
Guelph, Ontario
Canada

ANNA R.M. GELZER, Dr.med.vet., PhD
Diplomate ACVIM
Diplomate ECVIM-CA-Cardiology
Professor of Cardiology
Department of Clinical Sciences & Advanced Medicine
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

ANNE J. GEMENSKY METZLER, DVM, MS
Diplomate ACVO
Professor—Clinical
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
The Ohio State University
Columbus, Ohio
USA

KATHERINE GERKEN, DVM, MS
Diplomate ACVECC
Assistant Clinical Professor
Small Animal Emergency and Critical Care
Department of Clinical Sciences
Bailey Small Animal Teaching Hospital
College of Veterinary Medicine
Auburn University
Auburn, Alabama
USA

VIRGINIA L. GILL, DVM
Diplomate DACVIM (Oncology)
Medical Director
Maine Veterinary Medical Center
Scarborough, Maine
USA

MARGI A. GILMOUR, DVM
Diplomate ACVO
Professor
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
Oklahoma State University
Stillwater, Oklahoma
USA

ERIC N. GLASS, MS, DVM
Diplomate ACVIM (Neurology)
Section Head, Neurology and Neurosurgery
Red Bank Veterinary Hospital
Tinton Falls, New Jersey;
Chief of Neurology and Neurosurgery
Compassion First Pet Hospital
Tinton Falls, New Jersey
USA

MATHIEU M. GLASSMAN, VMD
Diplomate ACVS
Chief of Surgery
Friendship Surgical Specialists
Friendship Hospital for Animals
Washington, DC
USA

RITA GONÇALVES, DVM, MVM, FHEA, MRCVS
Diplomate ECVN
European and RCVS Recognized Specialist in Veterinary Neurology
Senior Lecturer in Veterinary Neurology
Small Animal Clinical Science
University of Liverpool
Neston, Cheshire
United Kingdom

SARA E. GONZALEZ, DVM, MS
Clinical Assistant Professor of Community Practice
Department of Small Animal Medicine and Surgery
University of Georgia College of Veterinary Medicine
Athens, Georgia
USA

JENNIFER GOOD, DVM
Diplomate ACVECC (Emergency and Critical Care)
Assistant Clinical Professor
Department of Emergency and Critical Care
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

SHARON FOOSHEE GRACE, M Agric, MS, DVM
Diplomate ACVIM (Small Animal)
Diplomate ABVP (Canine/Feline)
Clinical Professor
Department of Clinical Sciences
College of Veterinary Medicine
Mississippi State University
Mississippi State, Mississippi
USA

W. DUNBAR GRAM, DVM, MRCVS
Diplomate ACVD
Clinical Associate Professor and Dermatology Service Chief
Small Animal Clinical Sciences, University of Florida
Gainesville, Florida
USA

JENNIFER L. GRANICK, DVM, PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Associate Professor
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
University of Minnesota
St. Paul, Minnesota
USA

GREGORY F. GRAUER, DVM, MS
Diplomate ACVIM (Small Animal Internal Medicine)
Professor Emeritus
Department of Clinical Sciences
College of Veterinary Medicine
Kansas State University
Manhattan, Kansas
USA

SARAH L. GRAY, DVM
Diplomate ACVECC (Emergency and Critical Care)
Horizon Veterinary Specialist
Ventura, California
USA

KURT A. GRIMM, DVM, MS, PhD
Diplomate ACVCP
Diplomate ACVAA
Owner
Veterinary Specialist Services, PC
Conifer, Colorado
USA

AMY M. GROOTERS, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Professor, Companion Animal Medicine
Veterinary Clinical Sciences
Louisiana State University
Baton Rouge, Louisiana
USA

MARGARET E. GRUEN, DVM, PhD
Diplomate ACVB
Assistant Professor, Behavioral Medicine
Department of Clinical Sciences
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

SOPHIE A. GRUNDY, BVSc (Hons), MANZCVS (Small Animal Internal Medicine)
Diplomate ACVIM (Small Animal Internal Medicine)
Internal Medicine Consultant
IDEXX Laboratories, Inc.
Westbrook, Maine
USA

REBEKAH G. GUNN-CHRISTIE, DVM
Diplomate ACVP (Clinical Pathology)
Veterinary Clinical Pathologist
Antech Diagnostics
Cary, North Carolina
USA

TALIA GUTTIN, VMD
Diplomate ACVIM (Small Animal Internal Medicine)
Assistant Professor
Small Animal Medicine and Surgery Department
School of Veterinary Medicine
St. George's University
True Blue Campus
St. George, Grenada
West Indies

SHARON GWALTNEY-BRANT, DVM, PhD
Diplomate ABVT
Diplomate ABT
Consultant
Veterinary Information Network
Mahomet, Illinois
USA

TIMOTHY B. HACKETT, DVM, MS
Diplomate ACVECC
Professor
Department of Clinical Sciences
College of Veterinary Medicine and Biomedical Sciences
Colorado State University
Fort Collins, Colorado
USA

DEBORAH J. HADLOCK, VMD
Diplomate ABVP (Canine and Feline)
Certified Veterinary Acupuncturist—CVA (IVAS)
Certified Veterinary Spinal Manipulative Therapist—CVSMT (HOWC)
Owner
Hadlock Integrative Veterinary Consulting
Salt Lake City, Utah
USA

JENS HÄGGSTRÖM, DVM, PhD
Diplomate ECVIM-CA (Cardiology)
Professor
Department of Clinical Sciences
Faculty of Veterinary Medicine and Animal Science
Swedish University of Agricultural Sciences
Uppsala
Sweden

FRASER A. HALE, DVM, FAVD
Diplomate AVC
Hale Veterinary Clinic
Guelph, Ontario
Canada

EDWARD J. HALL, MA, VetMB, PhD, FRCVS
Diplomate ECVIM-CA
Emeritus Professor of Small Animal Internal Medicine
Langford Vets
Bristol Veterinary School
University of Bristol
Langford
United Kingdom

STEVEN R. HANSEN, DVM, MS, MBA
Diplomate ACAW
Diplomate ABVT
President and CEO
Arizona Humane Society
Phoenix, Arizona
USA

Diplomate ACVB
Texas Veterinary Behavior Services
Sugar Land, Texas
USA

ELEANOR C. HAWKINS, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Professor
Department of Clinical Sciences
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

CRISTINE L. HAYES, DVM
Diplomate ABVT
Diplomate ABT
Medical Director
ASPCA Animal Poison Control Center
Urbana, Illinois
USA

IAN P. HERRING, DVM, MS
Diplomate ACVO (Ophthalmology)
Associate Professor
VA-MD Regional College of Veterinary Medicine
Virginia Tech
Blacksburg, Virginia
USA

MEGHAN E. HERRON, DVM
Diplomate ACVB
Senior Director Behavioral Medicine, Education, and Outreach
Gigi's (Shelter for Dogs)
Canal Winchester, Ohio
USA

MILAN HESS, DVM, MS
Diplomate ACT (Theriogenology)
Colorado Veterinary Specialty Group
Littleton, Colorado
USA

STEVE HILL, DVM, MS
Diplomate ACVIM (Small Animal Internal Medicine)
Small Animal Internal Medicine Consultant
Flagstaff Veterinary Internal Medicine Consulting
Flagstaff, Arizona
USA

TRACY HILL, DVM PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Assistant Professor
Department of Small Animal Medicine and Sur gery
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

LORA S. HITCHCOCK, DVM
Diplomate ACVIM (Cardiology)
Clinical Cardiologist
Ohio Veterinary Cardiology, Ltd
Metropolitan Veterinary Hospital
Akron, Ohio
USA

KATE HOLAN, BS, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Assistant Professor and Head
Small Animal Internal Medicine
Department of Small Animal Clinical Sciences
Michigan State University
East Lansing, Michigan
USA

MASON HOLLAND, VMD
Diplomate ACVR
Staff Radiologist
Port City Veterinary Referral Hospital
Portsmouth, New Hampshire
USA

SUSAN HOLLAND, DVM
Associate Veterinarian, Clinical Toxicology
Pet Poison Helpline
Bloomington, Minnesota
USA

Diplomate ACT (Theriogenology)
Registered Specialist in Small Animal Reproduction
Glenbred, Matamata Veterinary Services Ltd
Matamata
New Zealand

STEPHEN B. HOOSER, DVM, PhD
Diplomate ABVT
Professor of Veterinary Toxicology & Head Toxicology Section
Department of Comparative Pathobiology & ADDL
College of Veterinary Medicine
Purdue University
West Lafayette, Indiana
USA

KATE HOPPER, BVSc, PhD
Diplomate ACVECC
Associated Professor, Small Animal Emergency & Critical Care
Department of Veterinary Surgical & Radiological Sciences
School of Veterinary Medicine
University of California, Davis
Davis, California
USA

DEBRA F. HORWITZ, DVM
Diplomate ACVB
Veterinary Behavior Consultations
St. Louis, Missouri
USA

LYNN R. HOVDA, RPH, DVM, MS
Diplomate ACVIM (Large Animal Internal Medicine)
Director of Veterinary Medicine
SafetyCall International & Pet Poison Helpline
Bloomington, Minnesota;
Assistant Adjunct Professor
Department of Veterinary and Biomedical Sciences
College of Veterinary Medicine
University of Minnesota
St. Paul, Minnesota
USA

TYNE HOVDA, DVM
Anesthesia Intern
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

JUNE C. HUANG, DVM, PhD
Diplomate ACVP (Clinical Pathology)
Veterinary Clinical Pathologist
ANTECH Diagnostics
Atlanta, Georgia
USA

WAYNE HUNTHAUSEN, DVM
Director
Animal Behavior Consultations
Westwood, Kansas
USA

CASSANDRA O. JANSON, DVM
Diplomate ACVECC
Staff Criticalist
Mount Laurel Animal Hospital
Mount Laurel, New Jersey
USA

NICK D. JEFFERY, BVSc, PhD, MSc, FRCVS
Diplomate ECVS
Diplomate ECVN
Professor, Neurology & Neurosurgery
Department of Small Animal Clinical Sciences
College of Veterinary Medicine
Texas A&M University
College Station, Texas
USA

ALBERT E. JERGENS, DVM, PhD, AGAF
Diplomate ACVIM (Small Animal Internal Medicine)
Professor, Associate Chair for Research and Graduate Studies and Donn E. and Beth M. Bacon Professor in Small Animal Medicine and Surgery
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
Iowa State University
Ames, Iowa
USA

JEBA R.J. JESUDOSS CHELLADURAI, BVSc, MS, PhD
Diplomate ACVM (Parasitology)
Postdoctoral Associate
Department of Veterinary Pathology
College of Veterinary Medicine
Iowa State University
Ames, Iowa
USA

AIME K. JOHNSON, DVM
Diplomate American College of Theriogenology
Associate Professor
Department of Clinical Sciences
Auburn University College of Veterinary Medicine
Auburn, Alabama
USA

JESSICA JOHNSON, DVM
Senior Dental & Oral Surgery Resident
Elevate Your Small Animal Dental Team, LLC
Main Street Veterinary Hospital & Dental Clinic
Dallas, Texas
USA

LYNELLE R. JOHNSON, DVM, MS, PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Professor
Department of Medicine and Epidemiology
University of California, Davis
Davis, California
USA

SPENCER A. JOHNSTON, VMD
Diplomate ACVS
James and Marjorie Waggoner Professor
Head
Department of Small Animal Medicine and Surgery
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

RICHARD J. JOSEPH, DVM
Diplomate ACVIM (Neurology)
Founder, CEO
AnimalMR.com
VetsOnCall.org
Katonah, New York
USA

RONNIE KAUFMANN, BSc, DVM
Diplomate ECVD (Dermatology)
Head of Dermatology Service
The Veterinary Teaching Hospital
Koret School of Veterinary Medicine
The Hebrew University of Jerusalem
Israel

BRUCE W. KEENE, DVM, MSc
Diplomate ACVIM (Cardiology)
Jane Lewis Seaks Distinguished Professor of Companion Animal Medicine
Department of Clinical Sciences
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

LISA S. KELLY, DVM, PhD
Diplomate ACVP (Clinical Pathology)
Veterinary Clinical Pathologist
Antech Diagnostics
Atlanta, Georgia
USA

DANIEL E. KEYLER, BS, PharmD, FAACT
Senior Clinical Toxicologist
SafetyCall International
Bloomington, Minnesota;
Adjunct Professor
Experimental & Clinical Pharmacology
University of Minnesota
Minneapolis, Minnesota
USA

YUNJEONG KIM, DVM, PhD
Diplomate ACVM (Immunology)
Associate Professor
Department of Diagnostic Medicine and Pathobiology
College of Veterinary Medicine
Kansas State University
Manhattan, Kansas
USA

SHAWNA L. KLAHN, DVM
Diplomate ACVIM (Oncology)
Associate Professor
Department of Small Animal Clinical Sciences
Virginia-Maryland College of Veterinary Medicine
Virginia Tech
Blacksburg, Virginia
USA

MARY P. KLINCK, DVM, PhD
Diplomate ACVB
Veterinary Behavioural Medicine Consultant
Sainte-Anne-de-Bellevue, Quebec
Canada

MARGUERITE F. KNIPE, DVM
Diplomate ACVIM (Neurology)
Health Sciences Associate Clinical Professor, Neurology/Neurosurgery
Department of Surgical and Radiological Sciences
UC Davis School of Veterinary Medicine
Davis, California
USA

JOYCE S. KNOLL, VMD, PhD
Diplomate ACVP (Clinical Pathology)
Associate Professor and Interim Chair
Department of Biomedical Sciences
Cummings School of Veterinary Medicine
Tufts University
North Grafton, Massachusetts
USA

AMIE KOENIG, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Diplomate ACVECC
Professor of Emergency and Critical Care
Department of Small Animal Medicine and Surgery
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

CASEY J. KOHEN, DVM
Diplomate ACVECC
Emergency and Critical Care Specialist
MarQueen Veterinary Emergency and Specialty
Roseville, California
USA

BARBARA KOHN, Prof. Dr. med. vet
Diplomate ECVIM-CA
Clinic for Small Animals
Faculty of Veterinary Medicine
Freie Universität Berlin
Germany

MARC S. KRAUS, DVM
Professor of Clinical Cardiology
Diplomate ACVIM (Cardiology, Internal Medicine)
Diplomate ECVIM-CA (Cardiology)
University of Pennsylvania
Department of Clinical Sciences and Advanced Medicine
Philadelphia, Pennsylvania
USA

NATALI KREKELER, Dr. med. vet., PhD
Diplomate ACT
Senior Lecturer in Veterinary Reproduction
Melbourne Veterinary School
The University of Melbourne
Werribee, Victoria
Australia

ERIKA L. KRICK, VMD
Diplomate ACVIM (Oncology)
Medical Oncologist and Oncology Department Head
Mount Laurel Animal Hospital
Mount Laurel, New Jersey
USA

PAULA M. KRIMER, DVM, DVSc
Diplomate ACVP (Clinical Pathology)
Professor & Outreach Services Chief
Athens Veterinary Diagnostic Laboratory and Department of Pathology
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

ANNEMARIE T. KRISTENSEN, DVM, PhD
Diplomate ACVIM (Small Animal)
Diplomate ECVIM-CA & Oncology
Professor, Companion Animal Clinical Oncology
Department of Veterinary Clinical Sciences
Faculty of Health and Medical Sciences
University of Copenhagen
Frederiksberg
Denmark

JOHN M. KRUGER, DVM, PhD
Diplomate ACVIM- SAIM
Professor and Carrigan Chair in Feline Health
Department of Small Animal Clinical Sciences
College of Veterinary Medicine
Michigan State University
East Lansing, Michigan
USA

STEPHANIE KUBE, DVM, CCRT, CVPP
Diplomate ACVIM (Neurology)
Veterinary Neurology and Pain Management Center of New England
Walpole, Massachusetts
USA

Diplomate ACVD
Midwest Veterinary Dermatology Center
Veterinary Specialty Center
Buffalo Grove, Illinois
USA

LEIGH A. LAMONT, DVM, MS
Diplomate ACVAA
Associate Dean of Academic and Student Affairs
Atlantic Veterinary College
University of Prince Edward Island
Charlottetown, Prince Edward Island
Canada

GARY M. LANDSBERG, BSc, DVM
Diplomate ACVB, ECAWBM
Veterinary Behaviorist
Vice-President
CanCog Incorporated
Fergus, Ontario;
Head
Fear Free Research
Canada

SELENA LANE, DVM
Diplomate ACVECC
Clinical Assistant Professor of Small Animal Emergency and Critical Care
Small Animal Medicine and Surgery
University of Georgia College of Veterinary Medicine
Athens, Georgia
USA

CATHY E. LANGSTON, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Professor - Clinical
Veterinary Medical Center
College of Veterinary Medicine
The Ohio State University
Columbus, Ohio
USA

PATTY A. LATHAN, VMD, MS
Diplomate ACVIM (Small Animal Internal Medicine)
Associate Professor
Department of Clinical Sciences
Mississippi State University
Mississippi State, Mississippi
USA

KENNETH S. LATIMER, DVM, PhD
Diplomate ACVP (Clinical Pathology)
Lanexa Veterinary & Consulting Services, LLC
Toano, Virginia
USA

ROBIN LAZARO, RVT, VTS(ECC)
ICU Supervisor
North Carolina State Veterinary Hospital
College of Veterinary Medicine
Raleigh, North Carolina
USA

AMY LEARN, VMD
Resident in Clinical Behavior Medicine
Animal Behavior Wellness Center
Richmond, Virginia
USA

MYLÈNE-KIM LECLERC, DMV
Diplomate ACVIM (Neurology)
Head of the Neurology Service
Centre Veterinaire Rive Sud
Brossard, Quebec
Canada

RICHARD A. LECOUTEUR, BVSc, PhD
Diplomate ACVIM (Neurology)
Diplomate ECVN
Professor Emeritus
Department of Surgical & Radiological Sciences
School of Veterinary Medicine
University of California, Davis
Davis, California
USA

MICHAEL S. LEIB, DVM, MS
Diplomate ACVIM (Small Animal Internal Medicine)
Emeritus Professor of Internal Medicine
Department of Small Animal Clinical Sciences
Virginia-Maryland College of Veterinary Medicine
Virginia Tech
Blacksburg, Virginia
USA

MATTHEW S. LEMMONS, DVM
Diplomate AVDC
Dentistry and Oral Surgery
MedVet
Carmel, Indiana
USA

JOSE A. LEN, DVM, MS, PhD
Diplomate ACT
Assistant Professor, Theriogenology
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

SOPHIE LE PODER, DVM, MS, PhD
Professor in Virology
Unity of Bacteriology, Immunology and Virology
Ecole Nationale Vétérinaire d'Alfort
Maisons-Alfort
France

JOHN R. LEWIS, VMD, FAVD
Diplomate AVDC
Veterinary Dentistry Specialists
Silo Academy Education Center
Chadds Ford, Pennsylvania
USA

ELLEN M. LINDELL, VMD
Diplomate ACVB
Veterinary Behaviorist
Central Hospital for Veterinary Medicine
North Haven, Connecticut
USA

MERYL P. LITTMAN, VMD
Diplomate ACVIM (Small Animal Internal Medicine)
Professor Emerita of Medicine
Department of Clinical Sciences & Advanced Medicine
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

INGRID LJUNGVALL, DVM, PhD
Diplomate ECVIM-CA (Cardiology)
Associate Professor
Department of Clinical Sciences
Faculty of Veterinary Medicine
Swedish University of Agricultural Sciences
Uppsala
Sweden

HEIDI B. LOBPRISE, DVM
Diplomate AVDC (Dentistry)
Main Street Veterinary Dental Clinic
Flower Mound, Texas
USA

JOHN P. LOFTUS, PhD, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Assistant Professor
Department of Clinical Sciences
College of Veterinary Medicine
Cornell University
Ithaca, New York
USA

DAWN E. LOGAS, DVM
Diplomate ACVD
Owner/Staff Dermatologist
Veterinary Dermatology Center
Maitland, Florida
USA

JAYME S. LOOPER, DVM
Diplomate ACVR (Radiation Oncology)
Associate Professor
Department of Veterinary Clinical Sciences
School of Veterinary Medicine
Louisiana State University
Baton Rouge, Louisiana
USA

CHERYL LOPATE, MS, DVM
Diplomate ACT
Veterinarian and Owner
Reproductive Revolutions and Wilsonville Veterinary Clinic
Wilsonville, Oregon
USA

BIANCA N. LOURENÇO, DVM, MSc, PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Assistant Professor
Department of Small Animal and Surgery
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

VIRGINIA LUIS FUENTES, MA, VetMB, PhD, CertVR, DVC, MRCVS
Diplomate ACVIM (Cardiology)
Diplomate ECVIM-CA (Cardiology)
Professor
Department of Veterinary Clinical Science and Services
Royal Veterinary College
North Mymms
United Kingdom

JODY P. LULICH, DVM, PhD
Diplomate ACVIM (Internal Medicine)
Professor
Department of Veterinary Clinical Sciences
Director of the Minnesota Urolith Center
College of Veterinary Medicine
University of Minnesota
St. Paul, Minnesota
USA

ALYCEN P. LUNDBERG, DVM
Diplomate ACVIM (Oncology)
Assistant Professor
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois at Urbana-Champaign
Urbana, Illinois
USA

CANDACE C. LYMAN, DVM
Diplomate DACT (Theriogenology)
Associate Professor
Department of Clinical Sciences
College of Veterinary Medicine
Auburn University
Auburn, Alabama
USA

KASEY E. MABRY, DVM
Resident, Small Animal Internal Medicine
Department of Small Animal Medicine and Surgery
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

CATRIONA M. MACPHAIL, DVM, PhD
Diplomate ACVS
ACVS Founding Fellow, Surgical Oncology
Professor, Small Animal Surgery
Department of Clinical Sciences
Colorado State University
Fort Collins, Colorado
USA

ORLA MAHONY, MVB
Diplomate ACVIM (Internal Medicine)
Diplomate ECVIM
Clinical Assistant Professor
Department of Clinical Sciences
Cummings School of Veterinary Medicine at Tufts University
North Grafton, Massachusetts
USA

SEAN B. MAJOY, DVM, MS
Diplomate ACVECC
Clinical Assistant Professor
Department of Clinical Sciences
Cummings School of Veterinary Medicine at Tufts University
North Grafton, Massachusetts
USA

GUILLERMINA MANIGOT, DMV UBA
Diplomate CPMV (Dermatology)
Dermlink Buenos Aires
Buenos Aires
Argentina

KATIA MARIONI-HENRY, DMV, PhD, MRCVS
Diplomate ACVIM (Neurology) and ECVN
EBVS® European Veterinary Specialist in Small Animal Neurology
RCVS Specialist in Veterinary Neurology; Senior Lecturer
Neurology/Neurosurgery Service
Hospital for Small Animals
Royal (Dick) School of Veterinary Studies
University of Edinburgh
Roslin, Midlothian
United Kingdom

STANLEY L. MARKS, BVSc, PhD
Diplomate ACVIM (Internal Medicine, Oncology)
Diplomate ACVN
Professor
Department of Medicine & Epidemiology
University of California, Davis
School of Veterinary Medicine
Davis, California
USA

STEVEN L. MARKS, BVSc, MS, MRCVS
Diplomate ACVIM (Small Animal Internal Medicine)
Associate Dean, Director of Veterinary Medical Services
College of Veterinary Medicine
NC State University
Raleigh, North Carolina
USA

SINA MARSILIO, Dr.med.vet., PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Diplomate ECVIM-CA
Assistant Professor
University of California, Davis School of Veterinary Medicine
Department of Veterinary Medicine and Epidemiology
Davis, California
USA

DEBBIE MARTIN, LVT, VTS (Behavior)
Veterinary Technician Specialist (Behavior)
TEAM Education in Animal Behavior, LLC
Veterinary Behavior Consultations, LLC
Spicewood, Texas
USA

KATY A. MARTIN, DVM, MPH
USDA Resident in Veterinary Parasitology
Graduate Research Assistant
Department of Veterinary Pathology
College of Veterinary Medicine
Iowa State University
Ames, Iowa
USA

KENNETH M. MARTIN, DVM
Diplomate ACVB (Veterinary Behaviorists)
TEAM Education in Animal Behavior, LLC
Veterinary Behavior Consultations, LLC
Spicewood, Texas
USA

PAULA MARTÍN VAQUERO, DVM, PhD
Diplomate ACVIM (Neurology)
FCB Health Europe
FCB Health Madrid
Madrid
Spain

KENNETH V. MASON, BSc, MVSc, FACVSc
Veterinary Dermatologist
Managing Director
Dermcare-Vet Pty Ltd
Springwood, Queensland
Australia

PHILIPP D. MAYHEW, BVM&S, MRCVS
Diplomate ACVS
Professor, Small Animal Surgery
Department of Surgical and Radiological Sciences
University of California, Davis
Davis, California
USA

TERRI L. MCCALLA, DVM, MS
Diplomate ACVO
Animal HealthQuest Solutions LLC
Bellingham, Washington
USA

MEGAN MCCLOSKY, DVM
Clinical Assistant Professor
Small Animal Internal Medicine
Department of Clinical Sciences and Advanced Medicine
University of Pennsylvania School of Veterinary Medicine
Philadelphia, Pennsylvania
USA

PATRICK L. MCDONOUGH, MS, PhD
Atkinson Center for a Sustainable Future Faculty Fellow
Professor Emeritus of Veterinary Microbiology
Animal Health Diagnostic Center
Department of Population Medicine and Diagnostic Sciences
College of Veterinary Medicine
Cornell University
Ithaca, New York
USA

KATHRYN M. MCGONIGLE, MPH DVM
Diplomate ACVIM (Internal Medicine)
Assistant Professor
Clinical Small Animal Internal Medicine
Department of Clinical Sciences and Advanced Medicine
University of Pennsylvania School of Veterinary Medicine
Philadelphia, Pennsylvania
USA

ANNA K. MCMANAMEY, DVM
Cardiology Resident
North Carolina State University Veterinary Hospital
Raleigh, North Carolina
USA

STEPHEN MEHLER, DVM
Diplomate ACVS
Chief Medical Officer
Veterinarian Recommended Solutions
Blue Bell, Pennsylvania
USA

KRISTINA MEICHNER, DVM
Diplomate ECVIM-CA (Oncology)
Diplomate ACVP (Clinical Pathology)
Assistant Professor
Department of Pathology
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

KATHRYN M. MEURS, DVM, PhD
Diplomate ACVIM (Cardiology)
Professor
Department of Clinical Sciences
North Carolina State University College of Veterinary Medicine
Raleigh, North Carolina
USA

LYNDA M.J. MILLER, DVM, PhD
Diplomate ACT
Director of Large Animal Clinical Skills
Associate Professor of Theriogenology
Lincoln Memorial University
College of Veterinary Medicine
Harrogate, Tennessee
USA

MATTHEW W. MILLER, DVM, MS
Diplomate ACVIM (Cardiology)
Staff Cardiologist and Cardiology Section Head
VetMed Emergency and Specialty Care
Phoenix, Arizona
USA

PAUL E. MILLER, DVM
Diplomate ACVO
Clinical Professor of Comparative Ophthalmology
Department of Surgical Sciences
School of Veterinary Medicine
University of Wisconsin-Madison
Madison, Wisconsin
USA

MELISSA L. MILLIGAN, VMD
Resident in Internal Medicine
The Animal Medical Center
New York, New York
USA

KELLY MOFFAT, DVM
Diplomate ACVB (Behavior)
Medical Director
VCA Mesa Animal Hospital
Mesa, Arizona
USA

SARAH A. MOORE, DVM
Diplomate ACVIM (Neurology)
Professor
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
The Ohio State University
Columbus, Ohio
USA

ANDREW R. MOORHEAD, DVM, MS, PhD
Diplomate ACVM (Parasitology)
Assistant Professor
Department of Infectious Diseases
University of Georgia
College of Veterinary Medicine
Athens, Georgia
USA

DANIEL O. MORRIS, DVM, MPH
Diplomate ACVD
Professor of Dermatology & Allergy
Department of Clinical Studies
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

BRADLEY L. MOSES, DVM
Diplomate ACVIM (Cardiology)
Staff Clinician
VCA Roberts Animal Hospital and
VCA South Shore Animal Hospital
South Weymouth, Massachusetts
USA

JOCELYN MOTT, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
VCA TLC Pasadena Veterinary Specialty and Emergency
South Pasadena, California
USA

CHRISTINE MULLIN, VMD
Diplomate ACVIM (Oncology)
Medical Oncologist
Hope Veterinary Specialists
Malvern, Pennsylvania
USA

JENNIFER M. MULZ, DVM
Diplomate ACVIM (Cardiology)
BluePearl Veterinary Partners
Sarasota, Florida
USA

KAREN R. MUÑANA, DVM, MS
Diplomate ACVIM (Neurology)
Professor, Neurology
Department of Clinical Sciences
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

LISA A. MURPHY, VMD
Diplomate ABT
Associate Professor of Toxicology
Department of Pathobiology
University of Pennsylvania
School of Veterinary Medicine
PADLS New Bolton Center Toxicology Laboratory
Kennett Square, Pennsylvania
USA

ANTHONY J. MUTSAERS, DVM, PhD
Diplomate ACVIM (Oncology)
Associate Professor
Department of Clinical Studies
Department of Biomedical Sciences
Ontario Veterinary College
University of Guelph
Guelph, Ontario
Canada

KATHERN E. MYRNA, DVM, MS
Diplomate ACVO
Associate Professor of Ophthalmology
Department of Small Animal Medicine and Surgery
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

GEORGINA M. NEWBOLD, DVM
Diplomate ACVO
Assistant Professor- Ophthalmology
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
The Ohio State University
Columbus, Ohio
USA

REBECCA G. NEWMAN, DVM, MS
Diplomate ACVIM (Oncology)
Medical Oncologist
Pittsburgh Veterinary Medical Specialist and Emergency Center
Pittsburgh, Pennsylvania
USA

DENNIS P. O'BRIEN, DVM, PhD
Diplomate ACVIM (Neurology)
Professor Emeritus
Department of Veterinary Medicine and Surgery
College of Veterinary Medicine
University of Missouri
Columbia, Missouri
USA

LINDA K. OKONKOWSKI, DVM
Internal Medicine Resident, ACVIM (Small Animal Internal Medicine)
Small Animal Clinical Sciences
Michigan State University
College of Veterinary Medicine
East Lansing, Michigan
USA

NATASHA J. OLBY, Vet MB, PhD, MRCVS
Diplomate ACVIM (Neurology)
Professor of Neurology/Neurosurgery
Dr. Kady M. Gjessing and Rahna M. Davidson Distinguished Chair in Gerontology
Department of Clinical Sciences
Member of the Comparative Medicine Institute
North Carolina State CVM
Raleigh, North Carolina
USA

GAVIN L. OLSEN, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Staff Internist
Carolina Veterinary Specialists
Greensboro, North Carolina
USA

JENNIFER L. OWEN, DVM, PhD
Diplomate ACVP (Clinical Pathology)
Assistant Professor
Department of Physiological Sciences
College of Veterinary Medicine
University of Florida
Gainesville, Florida
USA

JOANE M. PARENT, DVM, MVetSc
ACVIM Neurology
Professor
Centre Hospitalier Universitaire Vétérinaire
Faculté de Médecine Vétérinaire
Université de Montréal
Montréal
Canada

VALERIE J. PARKER, DVM
Diplomate ACVIM
Diplomate ACVN
Associate Professor, Clinical
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
The Ohio State University
Columbus, Ohio
USA

THOMAS PARMENTIER, DVM
Diplomate ACVIM (Neurology)
PhD Candidate
Department of Biomedical Sciences
Ontario Veterinary College
University of Guelph
Guelph, Ontario
Canada

R. MICHAEL PEAK, DVM
Diplomate AVCD
The Pet Dentist at Tampa Bay
Largo, Florida
USA

KATHERINE L. PETERSON, DVM
Diplomate ACVECC
Diplomate ABT
Emergency and Critical Care Specialist
Pet Poison Helpline & SafetyCall International
Bloomington, Minnesota
USA

MICHAEL E. PETERSON, DVM, MS
Gem Veterinary Clinic
Emmett, Idaho
USA

JASON PIEPER, DVM, MS
Diplomate ACVD
Assistant Professor
Department of Veterinary Clinical Medicine
University of Illinois at Urbana-Champaign
Urbana, Illinois
USA

SARAH B. PIERARD, BVSc, PgCertVS, MVS
Animal Diabetes Australia
Melbourne, Victoria
Australia

AMY L. PIKE, DVM
Diplomate ACVB
Owner, Animal Behavior Wellness Center
Fairfax, Virginia
USA

KATHRYN A. PITT, DVM, MS
Diplomate ACVS-SA
Assistant Professor of Small Animal Soft Tissue Surgery
Small Animal Clinical Sciences
Michigan State University
East Lansing, Michigan
Bloomington, Minnesota
USA

AMANDA L. POLDOSKI, DVM
Senior Consulting Veterinarian, Clinical Toxicology
Associate Manager of Veterinary & Regulatory Affairs
Pet Poison Helpline & SafetyCall International
Bloomington, Minnesota
USA

DAVID J. POLZIN, DVM, PhD
Diplomate ACVIM (Internal Medicine)
Professor and Chief of Small Animal Internal Medicine
University of Minnesota
College of Veterinary Medicine
Department of Veterinary Clinical Sciences
St. Paul, Minnesota
USA

JILL S. POMRANTZ, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Small Animal Internal Medicine Consultant
IDEXX Laboratories, Inc.
Westbrook, Maine
USA

ERIC R. POPE, DVM, MS
Diplomate ACVS
Professor of Surgery
Department of Clinical Sciences
Ross University School of Veterinary Medicine
Basseterre
St Kitts

ROBERT H. POPPENGA, DVM, PhD
Diplomate ABVT
Head, Toxicology Section
California Animal Health and Food Safety Laboratory
School of Veterinary Medicine
University of California
Davis, California
USA

SIMON A. POT, DVM
Diplomate ACVO
Diplomate ECVO
Associate Professor of Ophthalmology
Equine Department
Vetsuisse Faculty
University of Zurich
Zurich
Switzerland

SILVIA G. PRYOR, DVM
Diplomate ACVO
Ophthalmology Service
BluePearl Emergency and Specialty Hospital-Irvine
Irvine, California
USA

DAVID A. PUERTO, DVM
Diplomate ACVS
Chief of Surgery
Center for Animal Referral and Emergency Services
Langhorne, Pennsylvania
USA

BIRGIT PUSCHNER, DVM, PhD
Diplomate ABVT
Dean and Professor
College of Veterinary Medicine
Michigan State University
East Lansing, Michigan
USA

ANDHIKA PUTRA, DVM, MS
Dermatology Specialty Intern
Department of Small Animal Medicine and Surgery
University of Georgia
Athens, Georgia
USA

BARBARA QUROLLO, MS, DVM
Associate Research Professor
Department of Clinical Sciences-CVM
North Carolina State University
Raleigh, North Carolina
USA

MARYANN G. RADLINSKY, DVM, MS
Diplomate ACVS
Founding Fellow
Minimally Invasive Surgery, Small Animal Soft Tissue Surgeon
Salt River Veterinary Specialists
Scottsdale, Arizona
USA

LISA RADOSTA, DVM
Diplomate ACVB
Florida Veterinary Behavior Service
West Palm Beach, Florida
USA

ELEANOR RAFFAN, BVM&S, PhD, CertSAM, MRCVS
Diplomate ECVIM-CA
University Lecturer in Systems Physiology
Department of Physiology, Development and Neuroscience
University of Cambridge
Cambridge
United Kingdom

MERL F. RAISBECK, DVM, MS, PhD
Diplomate ABVT
Emeritus Professor
Department Veterinary Sciences
University of Wyoming
Laramie, Wyoming
USA

LAURA RAYHEL, DVM
Assistant Professor
Department of Medicine
College of Veterinary Medicine
Midwestern University
Glendale, Arizona
USA

JONJO REECE, DVM, ECFVG, BSc
Small Animal Internal Medicine Resident
Department of Clinical Sciences
Cummings School of Veterinary Medicine
Tufts University
North Grafton, Massachusetts
USA

TABATHA J. REGEHR, DVM
Consulting Veterinarian, Clinical Toxicology
SafetyCall International & Pet Poison Helpline
Bloomington, Minnesota
USA

MARSHA R. REICH, DVM
Diplomate ACVB
Veterinary Behaviorist
Maryland-Virginia Veterinary Behavioral Consulting
Silver Spring, Maryland
USA

JENNIFER M. REINHART, DVM, PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Diplomate ACVCP
Assistant Professor
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois Urbana-Champaign
Urbana, Illinois
USA

ILANA R. REISNER, DVM, PhD
Diplomate ACVB (Behavior)
Reisner Veterinary Behavior Services, LLC
Wallingford, Pennsylvania
USA

ALEXANDER M. REITER, Dipl.Tzt., Dr.med.vet
Diplomate AVDC, Diplomate EVDC
Professor of Dentistry and Oral Surgery
Department of Clinical Sciences and Advanced Medicine
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

LISA RESTINE, DVM
Associate Veterinarian
Alamo Feline Health Center
San Antonio, Texas
USA

AUSTIN RICHMAN, DVM
Diplomate ACVD
Los Angeles, California
USA

SHARON L. RIPPEL, DVM
Diplomate ABVT
Diplomate ABT
Clinical Toxicologist
Pet Poison Helpline
Bloomington, Minnesota
USA

WESLEY J. ROACH, DVM
Diplomate ACVS
Head of Surgery Department
Nashville Veterinary Specialists
Nashville, Tennessee
USA

Diplomate ACVP (Clinical Pathology)
Staff Clinical Pathologist
Friendship Hospital for Animals
Washington, DC
USA

KATHRYN A. ROOK, VMD
Diplomate ACVD
Assistant Professor of Clinical Dermatology
Department of Clinical Sciences and Advanced Medicine
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

SHERI ROSS, BSc, DVM, PhD
Diplomate ACVIM (Internal Medicine)
Coordinator
Advanced Urinary Disease and Extracorporeal Therapies Service
University of California Veterinary Medical Center - San Diego
San Diego, California
USA

JAMES K. ROUSH, DVM, MS
Diplomate ACVS
Doughman Chair Professor
Department of Clinical Sciences
College of Veterinary Medicine
Kansas State University
Manhattan, Kansas
USA

ELIZABETH ROZANSKI, DVM
Diplomate ACVECC
Diplomate DACVIM (Small Animal Internal Medicine)
Associate Professor
Department of Clinical Science
Cummings School of Veterinary Medicine
Tufts University
North Grafton, Massachusetts
USA

RENEE RUCINSKY, DVM
Diplomate ABVP (Feline Practice)
Medical Director
Mid Atlantic Cat Hospital
Mid Atlantic Feline Thyroid Center
Queenstown, Maryland
USA

ELKE RUDLOFF, DVM, CVMA
Diplomate ACVECC
Clinical Specialist
Emergency and Critical Care
Lakeshore Veterinary Specialists
Glendale, Wisconsin
USA

HÉLÈNE L.M. RUEL, DVM, DES, MSc
Diplomate ACVIM (Neurology)
PhD Candidate
Department of Clinical Sciences
Faculty of Veterinary Medicine
Université de Montréal
Saint-Hyacinthe, Québec
Canada

WILSON K. RUMBEIHA, BVM, PhD, ATS
Diplomate ABT
Diplomate ABVT
Professor of One Environmental Health Toxicology
Department of Molecular Biosciences
School of Veterinary Medicine
University of California, Davis
Davis, California
USA

ERIN E. RUNCAN, DVM
Diplomate ACT
Associate Professor, Clinical Theriogenology and Reproductive Medicine
Department of Veterinary Clinical Sciences
The Ohio State University
College of Veterinary Medicine
Columbus, Ohio
USA

CLARE RUSBRIDGE, BVMS, PhD, FRCVS
Diplomate ECVN
Professor in Veterinary Neurology
University of Surrey
School of Veterinary Medicine
Faculty of Health & Medical Sciences
Guildford, Surrey
United Kingdom

JOHN E. RUSH, DVM, MS
Diplomate ACVIM (Cardiology)
Diplomate ACVECC
Professor
Department of Clinical Sciences
Tufts University
Cummings School of Veterinary Medicine
North Grafton, Massachusetts
USA

KAREN E. RUSSELL, DVM, PhD
Diplomate ACVP (Clinical Pathology)
Professor and Associate Department Head for Clinical Services and Residency Programs
Department of Veterinary Pathobiology
College of Veterinary Medicine & Biomedical Sciences
Texas A&M University
College Station, Texas
USA

SHERISSE A. SAKALS, DVM
Diplomate ACVS-SA
VCA Vancouver Animal Emergency & Referral Center
Vancouver, WA
Canada

CARL D. SAMMARCO, BVSc MRCVS
Diplomate ACVIM (Cardiology)
Head of Cardiology
Red Bank Veterinary Hospital
Tinton Falls, New Jersey
USA

SHERRY LYNN SANDERSON, BS, DVM, PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Diplomate ACVN
Associate Professor
Department of Veterinary Biosciences and Diagnostic Imaging
College of Veterinary Medicine
The University of Georgia
Athens, Georgia
USA

DOMENICO SANTORO, DVM, MS, DrSc, PhD
Diplomate ACVD
Diplomate ECVD
Diplomate ACVM (Bacteriology/Mycology/Immunology)
Assistant Professor
Department of Small Animal Clinical Sciences
College of Veterinary Medicine
University of Florida
Gainesville, Florida
USA

ASHLEY B. SAUNDERS, DVM
Diplomate ACVIM (Cardiology)
Professor of Cardiology
Department of Veterinary Small Animal Clinical Sciences
College of Veterinary Medicine & Biomedical Sciences
Texas A&M University
College Station, Texas
USA

BRIAN A. SCANSEN, DVM, MS
Diplomate ACVIM (Cardiology)
Associate Professor and Service Head, Cardiology & Cardiac Surgery
Department of Clinical Sciences
Colorado State University
Fort Collins, Colorado
USA

MICHAEL SCHAER, DVM
Diplomate ACVIM (Small Animal Internal Medicine)
Diplomate ACVECC
Emeritus Professor
Adjunct Professor, Emergency and Critical Care Medicine
University of Florida
College of Veterinary Medicine
Gainesville, Florida
USA

THOMAS SCHERMERHORN, VMD
Diplomate ACVIM (Small Animal Internal Medicine)
Professor and Jarvis Chair
Department of Clinical Sciences
College of Veterinary Medicine
Kansas State University
Manhattan, Kansas
USA

PHILIP SCHISSLER, DVM
Diplomate ACVIM (Neurology)
Staff Neurologist/Neurosurgeon
Veterinary Neurology Center
Tustin, California
USA

RENEE D. SCHMID, DVM
Diplomate ABVT
Diplomate ABT
Senior Consulting Veterinarian, Clinical Toxicology
Pet Poison Helpline & SafetyCall International
Bloomington, Minnesota
USA

KARSTEN E. SCHOBER, DVM, MS, PhD
Diplomate ECVIM-CA (Cardiology)
Professor
Head, Cardiology and Interventional Medicine
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
The Ohio State University
Columbus, Ohio
USA

GRETCHEN L. SCHOEFFLER, DVM
Diplomate ACVECC
Chief, Emergency and Critical Care
Department of Clinical Sciences
College of Veterinary Medicine
Cornell University
Ithaca, New York
USA

JOHAN P. SCHOEMAN, BVSc, MMedVet(Med)(Pretoria), PhD(Cantab), DSAM(RCVS-UK)
Diplomate ECVIM-CA
EBVS® European Veterinary Specialist in Internal Medicine
RCVS Recognized Specialist in Small Animal Medicine;
Professor
Department of Companion Animal Clinical Studies
Chair, Pathobiology Research
Faculty of Veterinary Science
University of Pretoria
Onderstepoort
South Africa

DONALD P. SCHROPE, DVM
Diplomate ACVIM (Cardiology)
Department of Cardiology
Oradell Animal Hospital
Paramus, New Jersey
USA

ERIN M. SCOTT, VMD
Diplomate ACVO
Department of Small Animal Clinical Sciences
College of Veterinary Medicine
Texas A&M University
College Station, Texas
USA

CHRISTOPHER J. SCUDDER, BVSc, MVetMed, PhD, MRCVS
Diplomate ACVIM-SAIM
Diplomate ECVIM-CA
Head of Internal Medicine
Southfields Veterinary Specialists
Essex
United Kingdom

LYNNE M. SEIBERT, DVM, MS, PhD
Diplomate ACVB
Veterinary Behavior Consultants LLC
Lawrenceville, Georgia
USA

ASHLEIGH SEIGNEUR, DVM, MVSc
Diplomate ACVIM
Associate Veterinarian
Internal Medicine Department
South Carolina Veterinary Specialists and Emergency Care
Columbia, South Carolina
USA

KIM A. SELTING, DVM, MS
Diplomate ACVIM (Oncology)
Diplomate ACVR (Radiation Oncology)
Associate Professor
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois at Urbana-Champaign
Urbana, Illinois
USA

LINDA G. SHELL, DVM
Diplomate ACVIM (Neurology)
Veterinary Neurology Education and Consulting
Pilot, Virginia
USA

BARBARA L. SHERMAN, MS, PhD, DVM
Diplomate ACVB (Behavior) & ACAW (Animal Welfare)
Clinical Professor Emerita
Department of Clinical Sciences
College of Veterinary Medicine
North Carolina State University
Raleigh, North Carolina
USA

TRACI A. SHREYER, MA
Applied Animal Behaviorist
Consultant
Department of Comparative Pathobiology
Purdue University
West Lafayette, Indiana
USA

DEBORAH C. SILVERSTEIN, DVM
Diplomate ACVECC
Professor of Critical Care
Department of Clinical Sciences and Advanced Medicine
University of Pennsylvania
School of Veterinary Medicine
Philadelphia, Pennsylvania
USA

LESLIE SINN, DVM
Diplomate ACVB
Specialist in Behavior
Behavior Solutions
Hamilton, Virginia
USA

KIM SLENSKY, DVM
Diplomate ACVECC
Assistant Professor of Clinical Emergency and Critical Care
Department of Clinical Sciences and Advanced Medicine
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

FRANCIS W.K. SMITH, JR., DVM
Diplomate, ACVIM (Small Animal Internal Medicine and Cardiology)
Vice-President
VetMed Consultants, Inc.
Lexington, Massachusetts
USA

MARK M. SMITH, VMD
Diplomate ACVS
Diplomate AVDC
Founding Fellow, ACVS Oral & Maxillofacial Surgery
Founding Fellow, AVDC Oral & Maxillofacial Surgery
Center for Veterinary Dentistry and Oral Surgery
Gaithersburg, Maryland
USA

PATRICIA J. SMITH, MS, DVM, PhD
Diplomate ACVO
PJSmith Animal Eye Consulting
Adjunct Ophthalmologist Animal Eye Care
Milpitas, California
USA

CHRISTOPHER J. SNYDER, DVM
Diplomate AVDC
Clinical Associate Professor
Dentistry and Oral Surgery, Department of Surgical Sciences
University of Wisconsin-Madison
School of Veterinary Medicine
Madison, Wisconsin
USA

PAUL W. SNYDER, DVM, PhD
Diplomate ACVP (Anatomical Pathology)
Fellow, International Academy Toxicologic Pathologists
Senior Pathologist
Experimental Pathology Laboratories, Inc.
Bonita Springs, Florida
USA

LAIA SOLANO-GALLEGO, DVM, PhD
Diplomate ECVCP
Professora Agregada (Associate Professor)
Departament de Medicina i Cirurgia Animals
Facultat de Veterinària
Universitat Autònoma de Barcelona
Barcelona
Spain

MITCHELL D. SONG, DVM
Diplomate ACVD
Animal Dermatology, PC
Phoenix, Arizona;
Adjunct Assistant Clinical Professor
Midwestern University
College of Veterinary Medicine
Glendale, Arizona
USA

JASON W. SOUKUP, DVM
Diplomate AVDC
Founding Fellow, AVDC Oral & Maxillofacial Surgery
Clinical Associate Professor
Dentistry and Oromaxillofacial Surgery
Department of Surgical Sciences
School of Veterinary Medicine
University of Wisconsin-Madison
Madison, Wisconsin
USA

SAMANTHA B. SOUTHER, DVM
Diplomate ACT
Associate Veterinarian, Theriogenology
Mohnacky Animal Hospitals
Carlsbad, California
USA

CLARISSA P. SOUZA, DVM, MS, PhD
Diplomate ACVD
Assistant Professor of Dermatology and Otology
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois
Urbana-Champaign, Illinois
USA

JÖRG M. STEINER, MedVet, DrVetMed, PhD, AGAF
Diplomate ACVIM
Diplomate ECVIM-CA
University Distinguished Professor
Dr. Mark Morris Chair in Small Animal Gastroenterology and Nutrition
Director, Gastrointestinal Laboratory
Department of Small Animal Clinical Sciences
College of Veterinary Medicine and Biomedical Sciences
Texas A&M University
College Station, Texas
USA

KEVIN S. STEPANIUK, DVM, FAVD
Diplomate AVDC
Veterinary Dentistry Education and Consulting Services
Ridgefield, Washington
USA

JOSHUA A. STERN, DVM, PhD
Diplomate ACVIM (Cardiology)
Associate Professor
Department of Medicine & Epidemiology
School of Veterinary Medicine
University of California, Davis
Davis, California
USA

VICTOR J. STORA, DVM
Postdoctoral Fellow Transgenesis & Large Animal Model Creation
Vite Lab, Referral Center for Animal Models
Department of Clinical Sciences and Advanced Medicine
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

JAN S. SUCHODOLSKI, MedVet, DrVetMed, PhD, AGAF
Diplomate ACVM (Immunology)
Associate Professor
Small Animal Medicine
Associate Director for Research
Head of Microbiome Sciences
Gastrointestinal Laboratory
Texas A&M University
College of Veterinary Medicine
Department of Small Animal Clinical Sciences
College Station, Texas
USA

ALYSSA M. SULLIVANT, DVM, MS
Diplomate ACVIM (Small Animal Internal Medicine)
Assistant Professor
Department of Clinical Sciences
College of Veterinary Medicine
Mississippi State University
Mississippi State, Mississipi
USA

ANNIKA SUNDBY, DVM
Rotating Intern
Nashville Veterinary Specialists
Nashville, Tennessee
USA

WAILANI SUNG, MS, PhD, DVM
Diplomate ACVB
Veterinary Behaviorist
Behavior Service
The San Francisco Society for the Prevention of Cruelty to Animals (SPCA)
San Francisco, California
USA

STEVEN E. SUTER, VMD, MS, PhD
Diplomate ACVIM (Oncology)
Professor
Department of Clinical Sciences
North Carolina State University College of Veterinary Medicine
Raleigh, North Carolina
USA

JANE E. SYKES, BVSc(Hons), PhD
Diplomate ACVIM (Small Animal Internal Medicine)
Professor of Small Animal Internal Medicine
Department of Medicine & Epidemiology
University of California, Davis
Davis, California
USA

JOSEPH TABOADA, DVM
Diplomate ACVIM
Professor and Associate Dean
Department of Veterinary Clinical Sciences
School of Veterinary Medicine
Louisiana State University
Baton Rouge, Louisiana
USA

LAUREN TALARICO, BS, DVM
Diplomate ACVIM (Neurology)
Section Head Neurology/Neurosurgery
VCA Southpaws Veterinary Specialty & Emergency Center
Fairfax, Virginia
USA

PATRICIA A. TALCOTT, MS, DVM, PhD
Diplomate ABVT
Professor
Department of Integrative Physiology and Neuroscience
College of Veterinary Medicine
Washington State University
Pullman, Washington
USA

KENDALL TANEY, DVM
Diplomate AVDC
Center for Veterinary Dentistry and Oral Surgery
Gaithersburg, Maryland
USA

JAIME L. TARIGO, DVM, PhD
Diplomate ACVP (Clinical Pathology)
Associate Professor
Department of Pathology
College of Veterinary Medicine
University of Georgia
Athens, Georgia
USA

DOMINIC A. TAUER, DVM
Diplomate ABT
Consulting Veterinarian in Clinical Toxicology
Pet Poison Helpline and SafetyCall International, PLLC
Bloomington, Minnesota
USA

SUSAN M. TAYLOR, DVM
Diplomate ACVIM
Professor Emeritus
Department of Small Animal Clinical Sciences
Western College of Veterinary Medicine
University of Saskatchewan
Saskatoon, Saskatchewan
Canada

MICHELLE C. TENSLEY, DVM, MS
Diplomate ACVIM (Neurology)
Associate Neurologist
The Animal Neurology and Imaging Center
Algodones, New Mexico
USA

VINCENT J. THAWLEY, VMD
Diplomate ACVECC
Clinical Assistant Professor
Emergency and Critical Care Medicine
Department of Clinical Sciences and Advanced Medicine
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania
USA

JUSTIN D. THOMASON, DVM
Diplomate ACVIM (Cardiology; SAIM)
Clinical Associate Professor
Department of Clinical Sciences
College of Veterinary Medicine
Kansas State University
Manhattan, Kansas
USA

CRAIG A. THOMPSON, DVM
Diplomate ACVP
Clinical Associate Professor - Clinical Pathology
Department of Comparative Pathobiology
Purdue University- College of Veterinary Medicine
West Lafayette, Indiana
USA

JERRY A. THORNHILL, DVM
Diplomate ACVIM
Director, Nephrology & Dialysis
Division of Internal Medicine
Veterinary Specialty Center

5-FLUOROURACIL (5-FU) TOXICOSIS

BASICS

OVERVIEW

- Antimetabolite, antineoplastic agent; it is metabolized to thymidine, which blocks the methylation reaction of deoxyuridylic and thymidylic acids, resulting in thymine deficiency; thymine is critical for DNA and to a lesser extent RNA replication; the result is cell death due to interruption of normal DNA and RNA synthesis; this mechanism targets rapidly growing cells like bone marrow and intestinal crypts; 5-FU has various active metabolites resulting in delayed clearance from bone marrow and γ-aminobutyric acid (GABA) depletion in the brain.
- Labeled for human use only.
- Topical preparation for actinic and solar keratoses: Efudex® (5% cream, 2% and 5% solution), Carac® (0.5% cream), Fluoroplex® (1% cream), Tolak® (4% cream).
- IV preparation used for a variety of neoplastic conditions: Adrucil® (50 mg/m: IV solution).
- Causes acute and severe gastroenteritis and seizures; seizures can develop within 30 minutes to 6 hours post exposure; bone marrow suppression occurs 7–21 days after acute presentation.
- Patients may survive acute toxicity to succumb to bone marrow suppression later.
- Any suspected exposure in animals warrants immediate veterinary evaluation.

SIGNALMENT

- No species or breed predilection.

SIGNS

- Cardiovascular—hypotension, myocardial ischemia, arrhythmias.
- Immune—bone marrow suppression of all cell lines.
- Gastrointestinal (GI)—nausea, salivation, profuse vomiting, hematemesis, diarrhea, hematochezia, abdominal pain, stomatitis.
- Nervous—lethargy, ataxia, depression, disorientation, tremors, seizures (often refractory to treatment), death.
- Ophthalmic—blindness (cats).
- Reproductive—teratogenic, embryotoxic.
- Respiratory—noncardiogenic pulmonary edema, dyspnea, cyanosis, tachypnea.

CAUSES & RISK FACTORS

- Access to topical preparations in the home.
- Cats and small dogs may be exposed by licking pet owner.
- Pets in geographic locations of high human UV exposure due to increased human use.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other toxins—bromethalin, castor bean, cycad palms (*Cycas* and *Zamia* spp.), disulfoton, iron, metaldehyde, mushrooms (*Amanita*, *Galerina*, and *Lepiota* spp.), sodium fluoroacetate (Compound 1080), strychnine.
- Metabolic—hepatic failure, hepatic encephalopathy.
- Nervous—idiopathic epilepsy, meningitis, neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—baseline, then continue to monitor q3–4 days post exposure for 21 days; monitor for echinocytes; leukopenia develops by day 7 and continues to day 13; thrombocytopenia develops by day 7 and can continue for 21 days; acute anemia due to blood loss can be secondary to bone marrow suppression by day 9, persisting until day 21.
- Chemistry—baseline; hepatic values may increase.
- Electrolytes—baseline; recheck PRN based on GI losses.

OTHER LABORATORY TESTS

- Blood gases—metabolic acidosis can occur; monitor PRN.
- Packed cell volume (PCV)/total protein (TP) q6–24h.
- Blood glucose q2–4h.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Emesis—not typically indicated due to rapid onset of seizures.
- Single dose activated charcoal with sorbitol in asymptomatic patients; seizures may develop before opportunity to administer charcoal.
- Gastric lavage can be performed in patients with recent exposure; a single dose of activated charcoal with a cathartic (AC/C) can be administered, recovering patient with endotracheal tube in place.
- Balanced crystalloid IVF to maintain hydration, aid in elimination, and maintain perfusion.
- Monitor blood pressure q4–6h.

MEDICATIONS

DRUG(S) OF CHOICE

- Anticonvulsant—levetiracetam 60 mg/kg IV loading dose, 20 mg/kg IV q8h; propofol 4–6 mg/kg IV bolus followed by 0.6 mg/kg/minute CRI; inhalant anesthesia; valium is typically ineffective; phenobarbital and pentobarbital have unpredictable efficacy, but can be attempted, phenobarbital 5–8 mg/kg IV slowly to effect.
- Antiemetic—maropitant 1 mg/kg IV, SC q24h; ondansetron 0.1–0.2 mg/kg IV q6–12h; metoclopramide 0.1–0.5 mg/kg IV, SC q6–8h.
- GI protection—proton pump inhibitors, H2 blockers, sucralfate.
- Analgesia—buprenorphine 0.005–0.03 mg/kg IM or IV q6–12h, butorphanol 0.1–0.5 mg/kg SC, IV, or IM.
- Antibiotic—broad-spectrum antibiotic therapy if total white blood cell count is below 2000.
- Bone marrow stimulation—filgrastim (Neupogen®) 4–6 µg/kg SQ q24h.
- Transfusion therapy may be indicated if PCV <20%.
- 20% intravenous fat emulsion (IFE) unlikely to be effective.
- Antidote—uridine triacetate has not been used in veterinary medicine; must be instituted prior to development of CNS signs; cost prohibitive.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Avoid nonsteroidal anti-inflammatory drugs (NSAIDs) and CNS depressants.

FOLLOW-UP

- CBC q3–4 days for 21 days or more.

MISCELLANEOUS

ABBREVIATIONS

- 5-FU = 5-fluorouracil.
- AC/C = activated charcoal with a cathartic.
- GABA = γ-aminobutyric acid.
- GI = gastrointestinal.
- IFE = intravenous fat emulsion.
- NSAID = nonsteroidal anti-inflammatory drug.
- PCV = packed cell volume.
- TP = total protein.

A

ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—CATS

BASICS

DEFINITION
• Abortion: loss of a pregnancy at any time prior to the fetus's ability to survive outside the uterus. • Early pregnancy loss: loss of a pregnancy and death of conceptus within the first half of gestation

PATHOPHYSIOLOGY
• Noninfectious causes—more common. • Infectious causes—direct infection of embryo, uterus, placenta, or fetuses, or indirectly by systemic infection.

SYSTEMS AFFECTED
• Reproductive. • Endocrine. • Other systems resulting in debilitating illness.

GENETICS
Higher incidence in purebred or closed research catteries with closely related individuals; heritability of susceptibility to feline infectious peritonitis virus (FIPV) suspected to be high.

INCIDENCE/PREVALENCE
Difficult to determine, as pregnancy may not be diagnosed early. Loss or resorption of one or two conceptus within a litter is not uncommon.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Increased incidence in queens >5 years old; increased risk in purebred cats with high inbreeding.

SIGNS

General Comments
Frequently no clinical symptoms other than lack of pregnancy or reduced litter size.

Historical Findings
Failure to deliver kittens at expected due date, return to estrus sooner than expected (approximately 45 days), discovery of fetal tissues or placenta, behavior change, systemic illness.

Physical Examination Findings
Signs range from normal to dehydration, fever, abdominal straining, and discomfort to presence of purulent, mucoid, watery, or sanguineous vaginal discharge.

CAUSES

Infectious
• Bacterial—organisms implicated in causing abortion via ascending infection through the vaginal vault and cervix include *E. coli*, *Staphylococcus* spp., *Streptococcus* spp., *Chlamydia* spp., *Pasteurella* spp., *Klebsiella* spp., *Pseudomonas* spp., *Salmonella* spp., *Mycoplasma* spp., and *Ureaplasma* spp. • Protozoal—*Toxoplasma gondii*. • Viral— feline leukemia virus (FeLV), feline herpesvirus 1 (FHV-1), FIP, feline immunodeficiency virus (FIV), feline panleukopenia virus (FPLV).

Noninfectious
• Uterine—cystic endometrial hyperplasia, endometritis, pyometra, anatomic abnormalities of uterus (e.g., adhesions or strictures), uterine trauma. • Ovarian—primary hypoluteoidism is rare in cats, but secondary hypoluteoidism may result from prostaglandin exposure, prolonged stress, and uterine inflammation. • Fetal—chromosomal abnormalities resulting in abnormal or arrested development and embryonic or fetal death. • Systemic—malnutrition or nutritional disorders (e.g., taurine deficiency, vitamin A deficiency or toxicity), severe nonreproductive illness, exposure to exogenous estrogens, glucocorticoids, chemotherapeutic agents, antifungal agents, some antibiotics (trimethoprim–sulfonamides, tetracyclines, gentamicin), modified live vaccines.

RISK FACTORS
• Cats with high coefficient of inbreeding (COI). • Previous pregnancy loss. • Previous history of reduced litter size. • Evidence of cystic endometrial hyperplasia (CEH) on ultrasound. • Concurrent systemic disease or recent trauma. • Older queens (over 6 years). • Malnourishment. • Unsanitary housing conditions. • Raw diets.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Early pregnancy loss—failure to ovulate, failure to conceive, chromosomal disorder, or disorder of sexual development. • Vaginal discharge—pyometra, uterine stump pyometra, mucometra, vaginitis, neoplasia, cystitis, active labor or impending abortion, trauma to urogenital tract. • Mass or tissue from vaginal vault—dystocia, neoplasia, hemorrhage/blood clot, uterine prolapse.

CBC/BIOCHEMISTRY/URINALYSIS
• Generally normal. • Inflammatory leukogram with infection or systemic disease. • Anemia of pregnancy; hemoconcentration and azotemia may be seen with dehydration or hypovolemia.

OTHER LABORATORY TESTS

Infectious Causes
• Cytology and bacterial culture of vaginal discharge, fetus, fetal membranes, or uterine contents (aerobic and mycoplasma). • FeLV—test for antigens in queens using ELISA or indirect fluorescent antibody (IFA). • FHV-1—IFA or PCR from corneal or conjunctival swabs, viral isolation from conjunctival, nasal, or pharyngeal swabs. • FIP—submit fetal tissue for histopathology and immunohistochemistry. • FIV—ELISA: confirm positive results with Western blot. • FPLV—viral isolation from fetuses submitted for necropsy; document seroconversion in queen.

Noninfectious Causes
• To rule out anovulatory cycle, confirm progesterone >2 ng/mL one week following mating. • Hypoluteoidism—serum progesterone level <1.0 ng/mL prior to abortion indicates luteal failure. • Disorder of sexual development—evaluate external genitalia, karyotype, and histopathology of reproductive tract and gonads.

IMAGING
• Abdominal ultrasound—most specific; pregnancy confirmed after 25 days. Re-ultrasound every 1–2 weeks for high-risk queens. Confirm fetal heart rates and assess fetal fluids and placenta in late gestation (normal fetal heart rates >200 bpm). Visualization of fetal kidney and intestinal peristalsis indicates fetal maturity. • Abdominal radiographs—after 45 days, can evaluate fetal number, relative size, and position; also assess fetal death (gas pockets) or fetal malformation.

DIAGNOSTIC PROCEDURES
• Submit aborted, stillborn, mummified fetuses and fetal membranes (fresh or refrigerated on ice) for gross necropsy, histopathology, cultures, and viral isolation. Submit culture of reproductive tract or entire tract if removed (uterus, ovaries, oviducts). Submit samples from aborted and stillborn fetus for karyotyping. • Pedigree analysis—evaluate COI. • Evaluate cattery management for vaccination protocols, feeding regime, sanitation procedures, and quarantine procedures. • Nutrition—nutritional analysis of diet: of particular importance when queen is fed homemade and/or raw diet.

PATHOLOGIC FINDINGS
Variable with etiology.

TREATMENT

APPROPRIATE HEALTH CARE
None, for noninfectious, stable queens; primary hypoluteoidism—managed on outpatient basis.

NURSING CARE
Inpatient management if systemically ill, debilitated, severely dehydrated, or for medical management of ongoing fetal loss or pyometra.

ACTIVITY
• Isolation for queens with infectious disease. • No activity restrictions for most; restrict activity as indicated if due to trauma.

(CONTINUED) ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—CATS

DIET
• Feed commercially available diet labeled for use in pregnancy. • Correct diets with inappropriate taurine or vitamin A concentrations. • Avoid feeding raw meats or allowing queens to hunt during pregnancy to reduce risk for ingestion of pathogenic bacteria and *T. gondii*.

CLIENT EDUCATION
• Infectious diseases—verify vaccination status (vaccinate prior to pregnancy) and disease surveillance measures; ensure use of quarantine facilities for pregnant queens and new arrivals. • Breeding management—keep detailed records of reproductive performance, pedigree analysis, and social behavior of queens (including when not receptive to male). • Nutrition—advise feeding commercial cat food during pregnancy. • Genetic disease—discuss COI and value of introducing new genetics. • Discuss risk of zoonotic disease from *T. gondii*.

SURGICAL CONSIDERATIONS
Ovariohysterectomy (OHE) may be considered if queen is systemically ill from uterine infection or deceased fetuses. If valuable breeding animal, Cesarean section can be performed to remove deceased fetuses.

MEDICATIONS

DRUG(S) OF CHOICE
• Depends on etiology. • Amoxicillin–clavulanic acid 13.75 mg/kg PO q12h—safe for pregnancy. • Enrofloxacin 5 mg/kg/day PO—excellent penetration to uterus; contraindicated if live fetuses present. • Prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$; dinoprost/Lutalyse®) 80–100 µg/kg IM q8–12h—promotes uterine contractions, loss of corpus luteum, and cervical opening to expulse aborted materials. • Tocolytics—prevent uterine contractions: terbutaline 0.03–1.0 mg PO as needed based on tocodynamometry (www.whelpwise.com); 0.03 mg/kg PO q8h if tocodynamometry not available. • Hypoluteoidism—oral progestogene (altrenogest) 0.088 mg/kg PO q24h to maintain pregnancy; can monitor queen's progesterone, as altrenogest will not interfere with progesterone assay.

CONTRAINDICATIONS
• Terbutaline—cardiac disease, pyometra, infectious disease, hypertension. • Altrenogest—contaminated uterus with systemically ill queen. • Prostaglandin-cats with previously diagnosed respiratory disease.

PRECAUTIONS
• Use of tocolytics requires accurate breeding dates to know when to stop treatment; most successful in combination with tocodynamometry. • Terbutaline can cause hypertension leading to hemorrhage from placental sites during parturition or at time of Cesarean section. • Altrenogest can cause agalactia and failure of parturition, leading to death of litter; discontinue use 2 days before due date. • Caution with use of altrenogest with infectious processes or necrotic fetuses in uterus; may keep infection within uterus, causing metritis and systemic illness; monitor pregnancy often with ultrasound. • $PGF_{2\alpha}$—side effects vomiting, hypersalivation, defecation, urination, and tachypnea; dose dependent and self-limiting.

POSSIBLE INTERACTIONS
• Progesterone administration during pregnancy associated with masculinization of female fetuses; do not administer in first half of pregnancy and use with informed consent thereafter. • Tocolytics associated with increased risk of dystocia, failure of placental separation, lack of milk production, and poor maternal behavior for first days postpartum.

ALTERNATIVE DRUG(S)
Dopamine agonists (e.g., cabergoline 5 µg/kg PO q24h) can be used to lower progesterone and facilitate uterine emptying. Use in conjunction with low dose of $PGF_{2\alpha}$.

FOLLOW-UP

PATIENT MONITORING
• Serial ultrasound—follow pregnancy loss, uterine emptying, or viability of remaining fetuses; initially daily; decrease frequency when stable, continue until birth (with partial loss) or uterus is free of fluid (complete abortion). • Monitor health and attitude of queen. • If live fetuses are present—delayed parturition my occur with progesterone or terbutaline treatment; Cesarean section may be necessary.

PREVENTION/AVOIDANCE
• Institute infectious disease prevention, control, and surveillance. • Replace subfertile queens with more reproductively fit individuals. • Avoid exposure to abortifacient, teratogenic, or fetotoxic drugs. • Serial progesterone assays and fetal ultrasound during next pregnancy.

POSSIBLE COMPLICATIONS
• Loss of entire litter. • Metritis, chronic endometritis, uterine rupture, sepsis, shock. • Uterine pathology. • Masculinization of female fetuses with progesterone therapy.

EXPECTED COURSE AND PROGNOSIS
• Poor prognosis for live kittens for current litter, even with aggressive monitoring and treatment. • May recur in future pregnancies depending on cause and treatment. • Poor prognosis for normal pregnancy with severe CEH. • Fair prognosis for successful pregnancy with treatment for primary hypoluteoidism; significant monitoring required for good outcome. • Pregnancy loss due to genetic abnormalities likely to recur if queen is bred to tom with similar pedigree.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Severe systemic disease otf any kind, malnutrition.

AGE-RELATED FACTORS
Queens >6 years old—higher incidence of lower litter size and infertility.

ZOONOTIC POTENTIAL
T. gondii.

PREGNANCY/FERTILITY/BREEDING
Queens with previous pregnancy loss are at higher risk of subsequent pregnancy loss or infertility and should be monitored intensively.

SYNONYMS
• Pregnancy loss. • Abortion. • Fetal mummification. • Early embryonic loss.

SEE ALSO
• Breeding, Timing.
• Sexual Development Disorders.

ABBREVIATIONS
• CEH = cystic endometrial hyperplasia.
• COI = coefficient of inbreeding.
• FeLV = feline leukemia virus.
• FHV-1 = feline herpesvirus 1.
• FIPV = feline infectious peritonitis virus.
• FIV = feline immunodeficiency virus.
• FPLV = feline panleukopenia virus.
• IFA = indirect fluorescent antibody.
• OHE = ovariohysterectomy.
• $PGF_{2\alpha}$ = prostaglandin $F_{2\alpha}$.

A

ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—DOGS

BASICS

DEFINITION
Loss of a fetus because of resorption in early stages or expulsion in later stages of pregnancy.

PATHOPHYSIOLOGY
• Direct—congenital abnormality, infectious disease, trauma.
• Indirect—infectious placentitis, abnormal ovarian function, abnormal uterine environment.

SYSTEMS AFFECTED
• Reproductive.
• Any major body system dysfunction can adversely affect pregnancy.

GENETICS
• No genetic basis for most causes.
• Lymphocytic hypothyroidism—single-gene recessive trait in Borzois.

INCIDENCE/PREVALENCE
• True incidence unknown.
• Resorption estimated between 11% and 13%, up to 30% (at least one resorption).
• Incidence of stillbirth 2.2–4.4%; with dystocia up to 22.3%.

SIGNALMENT

Species
Dog

Breed Predilections
• Familial lymphocytic hypothyroidism (Borzoi)—prolonged interestrus interval, poor conception rate, mid-gestation abortion, stillbirths.
• Many breeds at risk for hypothyroidism, although evidence of role in abortion unclear.

Mean Age and Range
• Infectious causes, pharmacologic agents causing abortion, fetal defects—all ages.
• Cystic endometrial hyperplasia—usually >6 years old.

Predominant Sex
Intact bitches.

SIGNS

Historical Findings
• Failure to whelp on time.
• Expulsion of recognizable fetuses or placental tissues.
• Decrease in abdominal size; weight loss.
• Anorexia, vomiting, diarrhea.
• Behavioral changes.

Physical Examination Findings
• Sanguineous or purulent vulvar discharge.
• Disappearance of previously documented vesicles or fetuses.
• Abdominal straining, discomfort.
• Depression.
• Dehydration.
• Fever.

CAUSES

Infectious
• *Brucella canis*.
• Canine herpesvirus.
• *Toxoplasma gondii*, *Neospora caninum*.
• *Mycoplasma* and *Ureaplasma*.
• Bacteria—*Escherichia coli*, *Streptococcus*, *Campylobacter*, *Salmonella*.
• Viruses—distemper, parvovirus, adenovirus.

Uterine
• Cystic endometrial hyperplasia and pyometra.
• Trauma—acute and chronic.
• Neoplasia.

Ovarian
• Hypoluteoidism—abnormal luteal function in absence of fetal, uterine, or placental disease: progesterone concentrations <1–2 ng/mL, most commonly 40–45 days' gestation.

Exogenous Administration
• Embryotoxic drugs.
• Chemotherapeutic agents.
• Estrogens.
• Glucocorticoids.
• Prostaglandins—lysis of corpora lutea.
• Dopamine agonists—lysis of corpora lutea via suppression of prolactin; bromocriptine, cabergoline.

Hormonal Dysfunction
• Hypothyroidism (less common).
• Hyperadrenocorticism.
• Endocrine-disrupting contaminants documented in human and wildlife fetal loss.

Fetal Defects
• Lethal chromosomal abnormality or organ defects.

RISK FACTORS
• Exposure of brood bitch to carrier animals.
• Old age.
• Hereditary factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Differentiate infectious from noninfectious causes—*B. canis* immediate and zoonotic concern.
• Differentiate resorption from infertility—helped by early diagnosis of pregnancy.
• History of drug use during pregnancy—particularly during first trimester, or use of drugs (e.g., dexamethasone, prostaglandins, ketoconazole, griseofulvin, doxycycline, tetracycline, dantrolene) known to cause fetal death.
• Vulvar discharge during diestrus—may mimic abortion; evaluate discharge and origin to differentiate uterine from distal reproductive tract disease.
• Necropsy of aborted fetus, stillborn puppies, and placenta(s)—enhance chances of definitive diagnosis.
• Systemic or endocrine disease—problems with maternal environment.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually normal.
• Systemic disease, uterine infection, viral infection, or endocrine abnormalities—may produce changes in CBC, biochemistries, or urinalysis.

OTHER LABORATORY TESTS
• Serologic testing—*B. canis*, canine herpesvirus, *Toxoplasma*, *Neospora*; collect serum as soon as possible after abortion; repeat testing for paired titers for canine herpesvirus, *Toxoplasma*, *Neospora*.
• *B. canis*—
  ◦ Slide test (D-Tec CB®, Zoetis) very sensitive; negative results reliable; prevalence of false positives as high as 60%.
  ◦ PCR best to use on abortive discharge (Kansas State Veterinary Diagnostic Laboratory).
  ◦ Definitive diagnosis made via culture of abortive discharge or dam serum.
  ◦ Tube agglutination—titers >1 : 200 considered positive; titers 1 : 50–1 : 200 suspicious.
  ◦ Agar gel immunodiffusion—differentiates between false positives and true positives in agglutination tests; detects cytoplasmic and cell surface antigens.
• Baseline T_4 serum concentration—hypothyroidism possible cause for fetal wastage; role in pregnancy loss unclear.
• Serum progesterone concentration (hypoluteoidism; if no infectious cause); dogs depend on ovarian progesterone production throughout gestation (minimum of 2 ng/mL required to maintain pregnancy); determine as soon as possible after abortion; in subsequent pregnancies, start weekly monitoring at week 3 (may be before pregnancy documented with ultrasound); start biweekly sampling around gestational age of prior loss. Pregnancy loss typically occurs during seventh week of gestation (see Premature Labor).
• Vaginal culture—*B. canis* with positive serologic test; *Mycoplasma*, *Ureaplasma*, other bacterial agents; all except *B. canis* can be normal flora, so diagnosis difficult from vaginal culture alone; limited benefit unless heavy growth of single organism; *Salmonella* associated with systemic illness.

IMAGING
• Radiography—identifies fetal structures after 45 days of gestation; earlier determines uterine enlargement but not uterine contents.
• Ultrasonography—identify uterine size and contents; assess fluid and its consistency; assess fetal viability (heartbeats: normal, >200 bpm; stress, <150 or >280 bpm).

(CONTINUED) ABORTION, SPONTANEOUS (EARLY PREGNANCY LOSS)—DOGS

DIAGNOSTIC PROCEDURES
• Vaginoscopy—identify source of vulvar discharge and vaginal lesions; use scope of sufficient length (16–20 cm) to examine entire length of vagina.
• Cytologic examination, bacterial culture—may reveal inflammatory process (e.g., uterine infection): use guarded swab to ensure anterior sample (distal reproductive tract is heavily contaminated with bacteria), or collect secretions by transcervical catheterization.

PATHOLOGIC FINDINGS
Histopathologic examination and culture of fetal and placental tissue—may reveal infectious organisms; tissue culture, particularly of stomach contents, may identify infectious bacteria.

TREATMENT

APPROPRIATE HEALTH CARE
• Most bitches should be isolated pending diagnosis.
• Hospitalization of infectious patients preferred.
• *B. canis*—highly infective; shed in high numbers during abortion; suspected dogs should be isolated.
• Outpatient—medically stable patients with noninfectious pregnancy loss.
• Partial abortion—attempt to salvage live fetuses; antibiotics indicated if bacterial component.

NURSING CARE
Dehydration—isotonic crystalloid fluids, electrolyte supplementation as indicated.

ACTIVITY
Partial abortion—cage rest, but effect on reducing further abortion unknown.

DIET
No special considerations; abortions have been associated with raw diets.

CLIENT EDUCATION
• Critical for *B. canis*—if confirmed, euthanasia recommended due to lack of successful treatment and to prevent spread; may try ovariohysterectomy (OHE) and long-term antibiotics with surveillance program for kennel situations (monthly serology, culling any positive animals until three consecutive negative tests are obtained); discuss zoonotic potential.
• Primary uterine disease—OHE is indicated in nonbreeding patients; cystic endometrial hyperplasia (CEH) is irreversible.
• Infertility or pregnancy loss—may recur in subsequent estrous cycles despite successful immediate treatment; pedigree analysis may be beneficial in highly linebred animals if pregnancy loss and small litter size due to inbreeding depression.
• Prostaglandin treatment—discuss side effects (e.g., abortion).
• Infectious disease—establish surveillance and control measures.

SURGICAL CONSIDERATIONS
OHE preferred for stable nonbreeding patients.

MEDICATIONS

DRUG(S) OF CHOICE
• Prostaglandin F2α ($PGF_{2\alpha}$; Lutalyse®, dinoprost tromethamine)—uterine evacuation after abortion; 0.05–0.1 mg/kg SC q8–24h; cloprostenol (Estrumate®, cloprostenol)—1–5 µg/kg SC q24h; not approved for use in dogs, but adequate documentation for use; use only if all living fetuses expelled.
• Antibiotics—broad-spectrum agent appropriate pending culture and sensitivity of vaginal tissue or fetus.
• Progesterone (altrenogest) at 0.088 mg/kg (1 mL/25 kg PO q24h); progesterone in oil at 2 mg/kg IM q48–72h; progesterone (Prometrium®; 10 mg/kg PO q24h, adjust daily dosage based on serum progesterone)—for documented hypoluteoidism only to maintain pregnancy; must have accurate due date to know when to discontinue therapy; inadvertently prolonging gestation results in fetal death.

CONTRAINDICATIONS
Progestogen supplementation contraindicated with endometrial or mammary gland disease.

PRECAUTIONS
• $PGF_{2\alpha}$—dose-related side effects related to smooth muscle contraction, diminish with each injection; panting, salivation, vomiting, and defecation common; caution in brachycephalics; dosing critical (LD_{50} for dinoprost—5 mg/kg).
• Progesterone supplementation will prevent whelping—administration needs to be discontinued before 2–3 days prior to due date; risk of masculinization of female fetuses if used before day 45 of gestation.

ALTERNATIVE DRUG(S)
Oxytocin—1 U/5 kg SC q6–24h for uterine evacuation; consider only where uterine evacuation solely through uterine contraction desired.

FOLLOW-UP

PATIENT MONITORING
• Partial abortion—monitor viability of remaining fetuses with ultrasonography; monitor systemic health of dam for rest of pregnancy.
• Vulvar discharges—daily; for decreasing amount, odor, and inflammatory component; for consistency (increasing mucoid content prognostically good).
• $PGF_{2\alpha}$—continued for 5 days or until most of discharge ceases (range 3–15 days).
• *B. canis*—monitor after neutering and antibiotic therapy; yearly serologic testing (identify recrudescence).
• Hypothyroidism—see Hypothyroidism.

PREVENTION/AVOIDANCE
• Brucellosis, other infectious agents—surveillance programs to prevent spread to kennel.
• OHE—for nonbreeding bitches.
• Use of modified-live vaccines (e.g., some distemper, parvovirus), currently unavailable in United States.

POSSIBLE COMPLICATIONS
• Untreated pyometra—septicemia, death.
• Brucellosis—discospondylitis, endophthalmitis, uveitis, zoonotic.

EXPECTED COURSE AND PROGNOSIS
• Pyometra—recurrence during subsequent cycle likely (up to 70%) unless pregnant.
• CEH—recovery of fertility unlikely; pyometra common complication.
• Hormonal dysfunction—manageable; heritability should be considered.
• Brucellosis—guarded; extremely difficult to eliminate infection even with neutering.

MISCELLANEOUS

AGE-RELATED FACTORS
Older bitches more likely to have CEH.

ZOONOTIC POTENTIAL
B. canis—can be transmitted to humans (especially if immunosuppressed), particularly when handling bitch and expelled tissues. Notify pathologists if *B. canis* is suspected.

SEE ALSO
• Brucellosis.
• Hypothyroidism.
• Infertility, Female—Dogs.
• Premature Labor.
• Pyometra.

ABBREVIATIONS
• CEH = cystic endometrial hyperplasia.
• OHE = ovariohysterectomy.
• $PGF_{2\alpha}$ = prostaglandin $F_{2\alpha}$.

A

ABORTION, TERMINATION OF PREGNANCY

BASICS

DEFINITION
Termination of an unwanted pregnancy. May be accomplished by drugs that alter embryo transport in the oviduct, impeding establishment of a pregnancy, and/or cause luteal regression, terminating an established pregnancy. Due to their possible side effects (cystic endometrial hyperplasia, aplastic anemia, and bone marrow suppression), drugs that impair embryonic transit through the oviduct (estrogens) are not commonly used or recommended.

PATHOPHYSIOLOGY
After fertilization the embryo travels the oviduct in a timely manner before entering the uterus. Impaired embryo transport through the oviduct leads to embryonic degeneration and implantation abnormalities. In the dog and cat, pregnancy maintenance is dependent on progesterone production from the corpora lutea. In dogs and cats, maintenance of the corpora lutea during the second half of gestation is also supported by prolactin (PRL). Drugs that cause luteal regression, antagonize PRL, and/or compete with progesterone receptors will terminate pregnancy.

SYSTEMS AFFECTED
- Cardiovascular.
- Digestive.
- Neurologic (caused by drugs used for treatment).
- Reproductive.
- Respiratory.

GENETICS
N/A

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
N/A

Mean Age and Range
Postpubertal bitch and queen.

Predominant Sex
Female

SIGNS
- Depends on stage of gestation:
  - None.
  - Vaginal discharge.
  - Fetal expulsion.

CAUSES
- Impaired oviductal transport.
- Luteal regression.
- Progesterone receptor antagonism.

RISK FACTORS
N/A

DIAGNOSIS
- Confirm pregnancy first, ~60% of mismated bitches do not become pregnant:
  - Abdominal palpation—bitch: 31–33 days after luteinizing hormone (LH) surge; queen: 21–25 days after breeding.
  - Transabdominal ultrasound—bitch: >25 days after LH surge; queen: >16 days after breeding.
  - Abdominal radiographs—bitch: >45 days after LH surge; queen: >38 days after breeding.
  - Serum relaxin concentration in the bitch (>28 days after LH surge; Witness® Relaxin, Synbiotics/Zoetis).

DIFFERENTIAL DIAGNOSIS
- Hydrometra.
- Mucometra.
- Hematometra.
- Pyometra.
- Pseudopregnancy.

CBC/BIOCHEMISTRY/URINALYSIS
- Within normal limits during first half of pregnancy in healthy patients.
- Decrease in hematocrit during second half of pregnancy in bitches and queens is normal.
- Recommended as screening tests prior to treatment in patients with suspected underlying disease.

OTHER LABORATORY TESTS
- Vaginal cytology—determines stage of estrous cycle and presence of sperm (absence does not rule out previous breeding).
- Serum progesterone concentration determines if female in diestrus and monitors luteal regression during treatment.

IMAGING
- Transabdominal ultrasound (method of choice)—diagnose pregnancy and monitor uterine evacuation during treatment.
- Abdominal radiographs.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
- Physical examination before initiation of treatment.
- Monitor 30–60 minutes after treatment for side effects (vomiting, defecation, hypersalivation, hyperpnea, micturition, tachycardia).
- Pregnancy status in early diestrus is unknown; ultrasound confirmation of pregnancy not possible until ~4 weeks after breeding.
- Treatment on day 6–10 of diestrus—may have reduced efficacy compared to mid-gestation, but can be less distasteful to client (less discharge and recognizable fetuses are not passed).
- Multimodal treatment improves efficacy of drugs given alone.

NURSING CARE
N/A

ACTIVITY
Normal

DIET
Avoid feeding prior to each treatment and for 1–2 hours after treatments (reduces nausea and vomiting).

CLIENT EDUCATION
- Discuss patient's reproductive future with owner. If no litters are desired, then ovariohysterectomy (OHE) is the best option.
- Discuss with client potential side effects of treatment options; reach mutual agreement on treatment plan.

SURGICAL CONSIDERATIONS
OHE recommended for patients with no reproductive value or when owners do not desire future litters.

MEDICATIONS

DRUG(S) OF CHOICE
- Confirmation of pregnancy before initiating any of treatment protocols suggested below is recommended. Duration of suggested treatment may vary; treatments should be continued until abortion is complete.
- Prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$)—causes luteal regression with subsequent decline in progesterone concentration, cervical relaxation, and uterine contractions. Higher doses necessary prior to day 28 of gestation.
  - Bitch low dose protocol—10 µg/kg SC q6h for 7–10 days or until pregnancy termination.
  - Bitch standard dose protocol—100 µg/kg SC q8h for 2 days, then 200 µg/kg SC q8h until pregnancy termination.
  - Queen low dose protocol—25 µg/kg SC q6h for 1–2 days, then 50 µg/kg SC q6h for 3–4 days (queen more resistant to luteolytic effects of $PGF_{2\alpha}$ than bitches; often higher doses for longer periods are required).
  - Queen standard protocol—0.5–1 mg/kg SC q12h every other day (>day 40), or 2 mg/cat SC q24h for 5 days (>day 33).
- Cloprostenol (prostaglandin analogue):
  - Bitch—2.5 µg/kg SC q8–12h every 48 hours until pregnancy termination (~6 days after start of treatment).
- Dexamethasone—mode of action unknown:
  - Bitch—0.2 mg/kg PO q8–12h for 5 days, then decreasing incrementally from

0.16 to 0.02 mg/kg over last 5 days; treatment failures not uncommon.
- Cabergoline (PRL antagonist)—causes luteal regression:
  - Bitch—1.65 µg/kg SC q24h for 5 days or 5 µg/kg PO q24h for 5 days (>day 40).
  - Queen—1.65 µg/kg SC for 5 days (>day 30) or 5 µg/kg PO q24h for 5 days (>day 35).
- Bromocriptine (PRL antagonist)—causes luteal regression:
  - Bitch—50–100 µg/kg IM/PO q12h for 4–7 days >day 35 (50% effective); common side effect vomiting; reduce dose and give with meal.
- Cloprostenol and cabergoline combination:
  - Bitch—cabergoline 5 µg/kg PO q24h for 10 days plus cloprostenol 2.5 µg/kg SC at start of treatment or 1 µg/kg SC at start of treatment and at day 5 of treatment; treatment should be initiated >28 days post-LH surge.
  - Queen—cabergoline 5 µg/kg PO q24h plus cloprostenol 5 µg/kg SC q48h (>30 days after breeding) until abortion complete (~9 days).
- Cloprostenol and bromocriptine combination:
  - Bitch—bromocriptine 30 µg/kg PO q8h for 10 days plus cloprostenol 2.5 µg/kg SC or 1 µg/kg SC at start of treatment and at day 5 of treatment; treatment should be initiated >28 days post-LH surge.

CONTRAINDICATIONS
- $PGF_{2\alpha}$ and analogues—animals with respiratory disease (bronchoconstriction); do not administer intravenously. Use with caution in brachycephalic breeds.
- Cabergoline and bromocriptine—avoid administration in animals hypersensitive to ergot alkaloids; use with caution in patients with impaired liver function.
- Estrogens may cause cystic endometrial hyperplasia (CEH), pyometra, and bone marrow suppression leading to pancytopenia.

PRECAUTIONS
- $PGF_{2\alpha}$ and analogues—side effects dose dependent and include vomiting, defecation, dyspnea, tachycardia, salivation, restlessness, and anxiety; side effects subside within 60 minutes; use extreme caution in dogs and cats with preexisting cardiopulmonary, liver, and renal diseases.
- Dexamethasone—polydipsia, polyuria, and polyphagia are reported side effects; long-term administration can result in signs of hyperadrenocorticism.
- Cabergoline and bromocriptine—should be administered with caution in patients with impaired liver function; side effects may include vomiting and anorexia; prolonged use (>2 weeks) may cause coat color changes.

POSSIBLE INTERACTIONS
- $PGF_{2\alpha}$ and analogues—effect may be reduced by concomitant administration of progestins; use may enhance effects of oxytocin.
- Cabergoline and bromocriptine—cabergoline effects may be reduced with concomitant treatment with dopamine (D_2) antagonists; avoid concomitant treatment with drugs causing hypotension.

ALTERNATIVE DRUG(S)
- The following drugs are recommended for use in bitches but are not readily available in the United States:
  - Aglepristone (progestin and glucocorticoid receptors antagonist)—10 mg/kg SC q24h for 2 days >14 days post-LH surge; highly effective in preventing pregnancy (>95% treatment efficacy); abdominal ultrasound at 28–30 days essential to insure treatment success; if pregnancy still present, repeat injection protocol. Mild reactions at injection site have been reported; mild vaginal discharge may be observed; slight risk (3.4%) of development of pyometra in field studies.
  - Aglepristone and cloprostenol combination—aglepristone (10 mg/kg SC) combined with cloprostenol (1 µg/kg SC) q24h for 2 days >25 days' pregnancy; pregnancy terminated within 6 days. Side effects after treatment include vomiting and diarrhea; vaginal discharge may be observed.
  - Aglepristone (10 mg/kg SC q24h for 2 days) with intravaginal misoprostol (200–400 µg depending on body size) daily until abortion complete; abortion complete within 7 days. Vomiting, diarrhea, polydipsia, anorexia not observed with this regimen.

FOLLOW-UP

PATIENT MONITORING
In animals treated with luteolytic drugs (prostaglandins and PRL antagonists), progesterone assays and transabdominal ultrasound examinations should be performed to monitor decrease of serum progesterone concentration and complete evacuation of uterine contents. In patients treated with progesterone receptor antagonist drugs, transabdominal ultrasound examinations are recommended to monitor complete evacuation of the uterus.

PREVENTION/AVOIDANCE
- OHE for bitches and queens not intended for breeding.
- Estrus suppression or confinement of bitches and queens intended for breeding during a later cycle to avoid mismating.

POSSIBLE COMPLICATIONS
Pregnancy termination may not be achieved after one treatment protocol and continuation or change in treatment protocol may be necessary.

EXPECTED COURSE AND PROGNOSIS
- Interestrous interval in bitches treated with prostaglandins and PRL inhibitors may be shortened (~1 month). Queens may resume estrous behavior 7–10 days after pregnancy termination.
- Subsequent estrus fertility not affected.

A

ABSCESSATION

BASICS

DEFINITION
An abscess is a focal collection of purulent exudate within a confined tissue space or cavity.

PATHOPHYSIOLOGY
- Bacterial organisms may enter tissue by penetrating trauma, spread from another source of infection (hematogenous or adjacent infected tissues), or migration of a contaminated object (e.g., plant awn).
- Most often, bacteria are inoculated under the skin via puncture or bite wounds.
- When bacteria or foreign objects persist in tissue, purulent exudate accumulates.
- If exudate not quickly resorbed or drained, fibrous capsule forms to "wall off" infection; abscess may eventually rupture.
- With fibrous capsule—to heal, the cavity must fill with granulation tissue from which causative agent may not be totally eliminated; may lead to chronic or intermittent discharge of exudate from a draining tract.
- Sterile abscesses can occur when irritants (injectable medications, venom) or inflammatory processes (pancreatitis, immune mediated, decreased blood supply) lead to local collection of purulent exudate.

SYSTEMS AFFECTED
- Skin/exocrine—percutaneous (cats > dogs); anal sac (dogs > cats).
- Reproductive—prostate gland (dogs > cats); mammary gland.
- Ophthalmic—periorbital tissues.
- Hepatobiliary—liver parenchyma.
- Gastrointestinal—pancreas (dogs > cats).
- Respiratory—pulmonary parenchyma.

GENETICS

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Cat and dog.

Breed Predilections
N/A

Mean Age and Range
N/A

Predominant Sex
Mammary glands (female); prostate gland (male).

SIGNS

General Comments
- Determined by organ system and/or tissue affected.
- Associated with combination of inflammation (pain, swelling, redness, heat, and loss of function), tissue destruction, and/or organ system dysfunction caused by accumulation of exudates.

Historical Findings
- Often nonspecific signs (e.g., lethargy, anorexia).
- History of trauma or prior infection.
- Rapidly appearing painful swelling with or without discharge, if affected area is visible.

Physical Examination Findings
- Determined by organ system or tissue affected.
- Classic signs of inflammation (heat, pain, swelling, and loss of function) associated with specific anatomic location of abscess.
- Inflammation and discharge from fistulous tract may be visible if abscess has ruptured to an external surface.
- Variably sized, painful mass of fluctuant to firm consistency attached to surrounding tissues.
- Fever common, but may be absent if abscess has ruptured.
- Sepsis or infection of body cavity (e.g., pyothorax) may be seen if abscess ruptures internally.

CAUSES
- Foreign objects.
- Pyogenic bacteria—*Staphylococcus* spp., *Escherichia coli*, β-hemolytic *Streptococcus* spp., *Pseudomonas*, *Mycoplasma* and *Mycoplasma*-like organisms (l-forms), *Pasteurella multocida*, *Corynebacterium*, *Actinomyces* spp., *Nocardia*, *Bartonella*.
- Obligate anaerobes—*Bacteroides* spp., *Clostridium* spp., *Peptostreptococcus*, *Fusobacterium*.
- Noninfectious—pancreatitis, suture reaction, vaccination, other injectable drug administration, stinging insects, snake envenomation, immune-mediated panniculitis, dermatitis, neoplasia (especially when blood supply outgrown).

RISK FACTORS
- Anal sac—impaction, anal sacculitis.
- Brain—otitis interna, sinusitis, oral infection.
- Liver—omphalophlebitis, sepsis.
- Lung—foreign object aspiration or migration, bacterial pneumonia.
- Mammary gland—mastitis.
- Periorbital—dental disease, chewing of wood or other plant material.
- Percutaneous—fighting, trauma, or surgery.
- Prostate gland—bacterial prostatitis.
- Immunosuppression—feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV) infection, immunosuppressive chemotherapy, acquired or inherited immune system dysfunctions, underlying predisposing disease (e.g., diabetes mellitus, chronic renal failure, hyperadrenocorticism).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Mass Lesions
- Cyst—transiently painful, slower growing, no overt signs of inflammation.
- Fibrous scar tissue—firm, nonpainful.
- Granuloma—less painful, slower growing, firmer without fluctuant center.
- Hematoma/seroma—variable pain, nonencapsulated, rapid initial growth but slows once full size attained, fluctuant initially, may become more firm over time.
- Neoplasia—variable growth, variable pain.

Draining Tracts
- Fungal infection—blastomycosis, coccidioidomycosis, cryptococcosis, histoplasmosis, sporotrichosis.
- Mycobacterial disease.
- Mycetoma—botryomycosis, actinomycotic mycetoma, eumycotic mycetoma.
- Neoplasia.
- Phaeohyphomycosis.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC—normal, neutrophilia with or without left shift, neutropenia and degenerative left shift (severe infection).
- Serum chemistry profile—depends on severity, system affected. Signs of cholestasis if pancreatic abscess causes obstruction, hyperglycemia if diabetes mellitus, etc.
- Urinalysis—pyuria (prostatic abscess).

OTHER LABORATORY TESTS
- FeLV, FIV testing—recurrent or slow-healing abscesses (cats).
- Cerebrospinal fluid evaluation—increased cellularity and protein with brain abscess.
- Adrenal function—hyperadrenocorticism.

IMAGING
- Radiography—soft-tissue density mass in affected area, may reveal foreign material.
- Ultrasonography—determine if mass is fluid filled; may reveal foreign object; echogenic fluid suggests purulent exudate.
- Echocardiography—pericardial abscess, endocarditis.
- CT or MRI—pulmonary or brain abscess.

DIAGNOSTIC PROCEDURES

Fine-Needle Aspiration
- Red, white, yellow, or greenish liquid.
- Protein content >2.5–3.0 g/dL.
- Nucleated cell count—3,000–100,000 (or more) cells/μL; primarily degenerate neutrophils, fewer macrophages, lymphocytes.
- Bacteria—intra- and extracellular:
  - Gram stain to classify organism for empiric therapy.
  - If causative agent not readily identified with a Romanowsky-type stain, acid-fast

stain to detect mycobacteria or *Nocardia* and periodic acid-Schiff stain to detect fungus.

Biopsy

- Sample should contain both normal and abnormal tissue.
- Impression smears.
- Tissue—for histopathologic examination and culture.
- Necessary to confirm nodular panniculitis.

Culture and Susceptibility Testing

- Affected tissue and/or exudate—aerobic and anaerobic bacterial and fungal.
- Blood and/or urine if systemic disease.

PATHOLOGIC FINDINGS

- Exudate-containing mass lesion accompanied by inflammation.
- Causative agent may be detectable.

TREATMENT

APPROPRIATE HEALTH CARE

- Establish and maintain adequate drainage.
- Surgical removal of nidus of infection or foreign object(s) if necessary.
- Initiate appropriate antimicrobial therapy.
- Outpatient—minor abscesses, localized infection, nodular panniculitis.
- Inpatient—sepsis or systemic inflammation, extensive surgical procedures, treatment requiring hospitalization.

NURSING CARE

- Depends on location of abscess.
- Apply hot packs to inflamed area as needed.
- Use protective bandaging, Elizabethan collar as needed.
- Accumulated exudate—surgical drainage, debridement of necrotic tissue.
- Sepsis, peritonitis, pyothorax—fluid therapy, antimicrobial therapy, intensive care.

ACTIVITY

Restrict until abscess has resolved and adequate healing occurs.

DIET

N/A

CLIENT EDUCATION

- Correct or prevent risk factors.
- Maintain adequate drainage and continue antimicrobial therapy for adequate period of time.

SURGICAL CONSIDERATIONS

- Appropriate debridement and drainage—may need to leave wound open to external surface; may need drain placement.
  - Penrose drains must exit ventrally to encourage drainage; may be bandaged, if bandage is changed regularly.
  - If no ventral drainage, use active drains (e.g., Jackson-Pratt drain).
- Early drainage—to prevent further tissue damage and abscess wall formation.
- Remove foreign objects(s), necrotic tissue, nidus of infection.
- Complications to discuss include progressive tissue damage, necrosis, dehiscence of wound, prolonged healing times in high-motion areas (axillary, inguinal).

MEDICATIONS

DRUG(S) OF CHOICE

- Antimicrobial drugs that are effective against infectious agent and penetrate site of infection.
- Broad-spectrum agent—bactericidal with both aerobic and anaerobic activity until results of culture and sensitivity are known; Gram stain of exudate may guide therapy.
  - Dogs and cats—amoxicillin (22 mg/kg PO q12h); amoxicillin–clavulanic acid (22 mg/kg PO q12h); clindamycin (5–10 mg/kg PO q12h); trimethoprim–sulfadiazine (15 mg/kg PO q12h).
  - Cats only—pradofloxacin (7.5 mg/kg PO q24 for 7 days).
  - Cats with *Mycoplasma* and L-forms—doxycycline (5 mg/kg PO q12h).
- Aggressive IV antimicrobial therapy—sepsis, peritonitis, pyothorax.
- Antimicrobials not required for confirmed sterile abscesses.

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Sterile nodular panniculitis—corticosteroids.

FOLLOW-UP

PATIENT MONITORING

Monitor for progressive decrease in drainage, resolution of inflammation, and improvement of clinical signs.

PREVENTION/AVOIDANCE

- Percutaneous abscesses—prevent fighting; consider castration to reduce roaming or aggressive behavior.
- Anal sac abscesses—prevent impaction; consider anal saculectomy for recurrent cases.
- Prostatic abscesses—consider castration.
- Mastitis—prevent lactation (spay).
- Periorbital abscesses—do not allow chewing on foreign objects.

POSSIBLE COMPLICATIONS

- Sepsis.
- Peritonitis/pleuritis if intra-abdominal or intrathoracic abscess ruptures.
- Compromise of organ function.
- Delayed evacuation may lead to chronic, draining fistulous tracts.

EXPECTED COURSE AND PROGNOSIS

Depends on cause, organ system involved, and amount of tissue destruction.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- FeLV or FIV infection.
- Immunosuppression.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

- Mycobacteria and systemic fungal infections carry some potential.
- If prostatitis secondary to *Brucella canis*.

PREGNANCY/FERTILITY/BREEDING

N/A

A

ACETAMINOPHEN (APAP) TOXICOSIS

BASICS

DEFINITION
Results from accidental animal ingestion or owner administration of over-the-counter acetaminophen-containing analgesic and antipyretic medications.

PATHOPHYSIOLOGY
When the normal biotransformation mechanisms for detoxification (glucuronidation and sulfation) are saturated, cytochrome P450–mediated oxidation produces a toxic metabolite (*N*-acetyl-p-benzoquinone imine) that is electrophilic, conjugates with glutathione, and binds to sulfhydryl groups, leading to hepatic necrosis.

Dogs
- Liver is most susceptible to toxicity.
- Signs commonly observed at exposures >75–100 mg/kg.
- Methemoglobinemia may develop at doses >200 mg/kg.

Cats
- Cannot effectively glucuronidate; more limited capacity for acetaminophen elimination than dogs.
- Saturate glucuronidation and sulfation biotransformation routes.
- Red blood cells (RBCs) are most susceptible to oxidative injury following glutathione depletion.
- Develop toxic cytochrome P450 metabolite at much lower doses than dogs.
- Poisoned by as little as 50–60 mg/kg (often as little as one half tablet); deacetylation of acetaminophen to p-aminophenol (PAP) causes oxidative damage to RBCs, rapidly producing methemoglobinemia by binding to sulfhydryl groups on hemoglobin.
- Slower-developing hepatotoxicosis may not be fully expressed before development of fatal methemoglobinemia.

SYSTEMS AFFECTED
- Hemic/lymph/immune—RBCs damaged by glutathione depletion, allowing oxidation of hemoglobin to methemoglobin.
- Hepatobiliary—liver necrosis (more common in dogs).
- Cardiovascular (primarily cats)—edema of face, paws, and (to lesser degree) forelimbs through undefined mechanism.

GENETICS
Cats—genetic deficiency in the glucuronide conjugation pathway makes them vulnerable.

INCIDENCE/PREVALENCE
Common drug toxicity in cats; less frequent in dogs.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Cats more often than dogs.

SIGNS

General Comments
Relatively common—owing to widespread human use.

Historical Findings
- Depression.
- Hyperventilation.
- Darkened mucous membranes.
- Signs may develop 1–4 hours after dosing.

Physical Examination Findings
- Progressive depression.
- Salivation.
- Vomiting.
- Abdominal pain.
- Tachypnea and cyanosis or muddy mucous membranes—reflect methemoglobinemia.
- Edema—face, paws, and possibly forelimbs; after several hours.
- Chocolate-colored urine—hematuria and methemoglobinuria; especially in cats.
- Icterus.
- Hypothermia.
- Shock.
- Death.

CAUSES
Acetaminophen toxicosis.

RISK FACTORS
- Nutritional deficiencies of glucose and/or sulfate.
- Simultaneous administration of other glutathione-depressing drugs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other Causes of Liver Injury
- Hepatotoxic mushrooms.
- Blue-green algae.
- Aflatoxins.
- Iron, copper, zinc.
- Xylitol.
- Cycad palms.
- Nonsteroidal anti-inflammatory drugs (NSAIDs).

Other Causes of Methemoglobinemia
- Onions/garlic.
- Naphthalene.
- Chlorates.
- Nitrites.
- Sulfites.
- Phenol.
- Benzocaine.
- Propylene glycol (cats).

CBC/BIOCHEMISTRY/URINALYSIS
- Methemoglobinemia and progressively rising serum concentrations of liver enzymes (alanine aminotransferase [ALT], aspartate transaminase [AST])—characteristic.
- As hepatic function becomes impaired—decreased blood urea nitrogen (BUN), cholesterol, and albumin, and increased serum bilirubin.
- Heinz bodies (cats)—prominent in RBCs within 72 hours.
- Anemia, hemoglobinemia, and hemoglobinuria or hematuria.

OTHER LABORATORY TESTS
Acetaminophen plasma, serum, or urine concentrations.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
- Methemoglobinemia.
- Pulmonary edema.
- Centrilobular necrosis and congestion of the liver.
- Renal tubular edema and degeneration with proteinaceous tubular casts.

TREATMENT

APPROPRIATE HEALTH CARE
- With methemoglobinemia—must evaluate promptly.
- With dark or bloody colored urine or icterus—inpatient.

NURSING CARE
- Gentle handling—imperative for clinically affected patients.
- Induced emesis and gastric lavage—useful within 4–6 hours of ingestion.
- Anemia, hematuria, or hemoglobinuria—may require whole blood transfusion.
- Fluid therapy—maintain hydration and electrolyte balance.
- Oxygen therapy may be needed.
- Drinking water—available at all times.
- Food—offered 24 hours after initiation of treatment.

ACTIVITY
Restricted

DIET
N/A

CLIENT EDUCATION
- Warn client that treatment in clinically affected patients may be prolonged and expensive.
- Inform client that patients with liver injury may require prolonged and costly management.

SURGICAL CONSIDERATIONS
N/A

(CONTINUED) # ACETAMINOPHEN (APAP) TOXICOSIS

MEDICATIONS

DRUG(S) OF CHOICE

- Activated charcoal 1–2 g/kg PO with a cathartic; immediately after completion of emesis or gastric lavage.
- *N*-acetylcysteine (Mucomyst®) 140 mg/kg diluted in 5% dextrose injection (D5W) as loading dose PO/IV; then 70 mg/kg diluted in D5W PO/IV q6h for 7 additional treatments. Large overdoses may require up to 17 treatments.
- S-adenosylmethionine (SAMe) as a glutathione donor; 40 mg/kg PO × 1 dose, then 20 mg/kg q24h PO × 7 days.
- Added benefit of using methylene blue, cimetidine, and/or ascorbic acid is controversial.

CONTRAINDICATIONS

Drugs that contribute to methemoglobinemia or hepatotoxicity.

PRECAUTIONS

Drugs requiring extensive liver metabolism or biotransformation—use with caution; expect their half-lives to be extended.

POSSIBLE INTERACTIONS

Drugs requiring activation or metabolism by the liver have reduced effectiveness.

FOLLOW-UP

PATIENT MONITORING

- Continual clinical monitoring of methemoglobinemia—vital for effective management; laboratory determination of methemoglobin percentage every 2–3 hours.
- Serum liver enzyme activities (ALT, ALP) every 12 hours; monitor liver damage.

PREVENTION/AVOIDANCE

- Never give acetaminophen to cats.
- Give careful attention to acetaminophen dose in dogs.

POSSIBLE COMPLICATIONS

Liver necrosis and resulting fibrosis—may compromise long-term liver function in recovered patients.

EXPECTED COURSE AND PROGNOSIS

- Rapidly progressive methemoglobinemia—serious sign.
- Methemoglobin concentrations ≥50%—grave prognosis.
- Progressively rising serum liver enzymes 12–24 hours after ingestion—serious concern.
- Expect clinical signs to persist 12–48 hours; death owing to methemoglobinemia possible at any time.
- Dogs and cats receiving prompt treatment that reverses methemoglobinemia and prevents excessive liver necrosis—may recover fully.
- Dogs—death as a result of liver necrosis may occur within 72 hours.
- Cats—death as a result of methemoglobinemia occurs 18–36 hours after ingestion.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Keratoconjunctivitis sicca may develop in small-breed dogs as a sequela.

AGE-RELATED FACTORS

Young and small dogs and cats—greater risk from owner-given single-dose acetaminophen medications.

PREGNANCY/FERTILITY/BREEDING

Imposes additional stress and higher risk on exposed animals.

SYNONYMS

- Paracetamol.
- Tylenol®.

SEE ALSO

Poisoning (Intoxication) Therapy.

ABBREVIATIONS

- ALT = alanine aminotransferase.
- AST = aspartate transaminase.
- BUN = blood urea nitrogen.
- D5W = 5% dextrose injection.
- NSAID = nonsteroidal anti-inflammatory drug.
- PAP = p-aminophenol.
- RBC = red blood cell.
- SAMe = S-adenosylmethionine.

A

ACIDOSIS, METABOLIC

BASICS

DEFINITION

A process in the body that leads to a decrease in pH below the reference interval. A decline in blood pH is specifically termed acidemia. Associated with a decrease in plasma bicarbonate concentration (HCO_3^- ; dogs, <18 mEq/L; cats, <16 mEq/L) and base excess (BE; –4 mmol/L) with a compensatory decrease in carbon dioxide tension (PCO_2).

PATHOPHYSIOLOGY

- Metabolic acidosis may develop either from a *loss of* HCO_3^- (hyperchloremic acidosis) or a *gain in acid* (high anion gap [AG] acidosis). It is usually secondary to an accumulation of metabolically produced strong anions (strong ion gap or high anion gap acidosis), accumulation of weak acids (hyperphosphatemia), corrected hyperchloremia (hyperchloremic acidosis), or as a compensatory mechanism for respiratory alkalosis.
- *High anion gap* acidosis—increase in the concentration of other strong anions through addition (e.g., ethylene glycol toxicity), excessive production (e.g., lactate produced by prolonged anaerobic metabolism), or renal retention (e.g., renal failure) of strong anions other than Cl^- causes metabolic acidosis without increasing Cl^- concentration (so-called normochloremic or high AG metabolic acidosis).
- *Hyperphosphatemic* acidosis—increase in plasma weak acids (e.g., inorganic phosphate) is associated with metabolic acidosis and increased AG. At a pH of 7.4, a 1 mg/dL increase in phosphate concentration is associated with a 0.58 mEq/L decrease in HCO_3^- and a 0.58 mEq/L increase in AG. Hyperphosphatemia commonly develops with decreased renal phosphorus excretion (e.g., renal failure, hypoparathyroidism), cellular lysis (e.g., tumor lysis syndrome, trauma, rhabdomyolysis), bone neoplasms (increased bone resorption), and hypervitaminosis D.
- *Hyperchloremic* acidosis—may be caused by Cl^- retention (e.g., renal failure, renal tubular acidosis) that typically occurs in response to HCO_3^- loss. Cl^- and HCO_3^- are reciprocally related; loss of HCO_3^- generally results in retention of Cl^-. Other mechanisms for hyperchloremic acidosis include excessive loss of Na^+ relative to Cl^- (e.g., diarrhea, Addison's) and administration of substances containing more Cl^- than Na^+ compared with normal extracellular fluid composition (e.g., administration of KCl, 0.9% NaCl). Acidemia is usually not severe in patients with hyperchloremic acidosis.

SYSTEMS AFFECTED

- Cardiovascular—fall in pH results in increase in sympathetic discharge, but simultaneously causes decrease in responsiveness of cardiac myocytes and vascular smooth muscle to effects of catecholamines. In mildly acidemic conditions (pH >7.2), effects of increased sympathetic stimulation predominate and result in mild increase in heart rate and cardiac output. More severe acidemia (pH <7.1), especially if acute, may decrease cardiac contractility and predispose heart to ventricular arrhythmias and ventricular fibrillation.
- Respiratory—increased hydrogen ion [H^+] stimulates peripheral and central chemoreceptors to increase alveolar ventilation; hyperventilation decreases PCO_2, which counters effects of low plasma HCO_3^- on pH. In dogs, a decrease of approximately 1 mmHg in PCO_2 is expected for each 1 mEq/L decrease in plasma HCO_3^-. Little known about compensation in cats, but appears to be almost nonexistent.
- Renal/urologic—kidneys increase net acid excretion, primarily by increasing excretion of NH_4^+ and Cl^-. This compensatory mechanism not very effective in cats.

SIGNALMENT

Any breed, age, or sex of dog and cat.

SIGNS

Historical Findings

Chronic disease processes that lead to metabolic acidosis (e.g., renal failure, diabetes mellitus, and hypoadrenocorticism), acute circulatory shock (hemorrhagic), exposure to toxins (e.g., ethylene glycol, salicylate, and paraldehyde), diarrhea, administration of carbonic anhydrase inhibitors (e.g., acetazolamide and dichlorphenamide).

PHYSICAL EXAMINATION FINDINGS

- Generally relate to underlying disease.
- Depression, stupor, seizures, and/or generalized muscle weakness in severely acidotic patients.
- Tachypnea in some patients results from compensatory increase in ventilation.
- Kussmaul's respiration, typically seen in human beings with metabolic acidosis, not commonly observed in dogs and cats.
- Vomiting and/or diarrhea.

CAUSES

Associated with Hyperchloremia (Hyperchloremic Metabolic Acidosis)

- Renal—renal tubular acidosis; carbonic anhydrase inhibitors.
- Gastrointestinal—diarrhea.
- Other: Cl^--rich fluids (e.g., 0.9% NaCl, KCl supplementation); total parenteral nutrition with cationic amino acids: lysine, arginine, and histidine; rapid correction of hypocapnia (chronic respiratory alkalosis); NH_4Cl or HCl.

Associated with Normochloremia (High Anion Gap Metabolic Acidosis)

- Renal—uremic acidosis, acute renal failure.
- Ketoacidosis—diabetic ketoacidosis, starvation, liver disease.
- Lactic acidosis—impaired perfusion, impaired carbohydrate metabolism.
- Toxins—ethylene glycol, salicylate, paraldehyde, methanol intoxication.
- Hyperphosphatemia (see Hyperphosphatemia)—raises AG. At a pH of 7.4, each 1 mg/dL increase in phosphate concentration is associated with a 0.58 mEq/L increase in AG.

RISK FACTORS

- Chronic renal failure, diabetes mellitus, and hypoadrenocorticism.
- Poor tissue perfusion or hypoxia—lactic acidosis.
- Tumor lysis syndrome or osteosarcoma—hyperphosphatemia.
- Trauma, snake envenomation, or malignant hyperthermia—rhabdomyolysis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Low plasma HCO_3^- and hyperchloremia may also be compensatory in animals with chronic respiratory alkalosis, in which PCO_2 is low and pH is high or near normal, despite decreased HCO_3^- and increase in Cl^- concentration. Blood gas determination is required to differentiate.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

Potassium bromide measured as Cl^- in most analyzers; administration artificially decreases AG.

Disorders That May Alter Laboratory Results

- Too much heparin (>10% of sample) decreases HCO_3^-.
- Blood samples stored at room temperature for >15 minutes have low pH because of increased PCO_2.
- Hypoalbuminemia lowers AG; negative charges of albumin are main component of AG.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Low total CO_2—total CO_2 in serum samples handled aerobically closely approximates serum HCO_3^- concentration; unfortunately, patients with chronic respiratory alkalosis also have low total CO_2, and distinction cannot be made without blood gas analysis.
- Metabolic acidoses traditionally divided into hyperchloremic and high AG by means of AG. Anion gap, the difference between the measured cations and the measured anions, is calculated as AG = $[Na^+] - (HCO_3^- + [Cl^-])$ or AG = $([Na^+] + [K^+]) - (HCO_3^- + [Cl^-])$, depending on preference of clinician or laboratory. Normal values with potassium included in calculation usually 12–24 mEq/L

in dogs and 13–27 mEq/L in cats. Negative charges of albumin are major contributors to normal AG; this should be taken into account when evaluating AG in patients with hypoalbuminemia. At pH 7.4 in dogs, decrease of 1 g/dL in albumin associated with decrease of 4.1 mEq/L in AG.
- Normal AG (i.e., hyperchloremic metabolic acidosis).
- High AG (i.e., normochloremic metabolic acidosis).
- Hyperglycemia.
- Azotemia.
- Hyperphosphatemia.
- High lactate concentration.
- Hyperkalemia (*formulas to adjust potassium concentration based on pH changes should not be used*).

OTHER LABORATORY TESTS
Blood gas analysis reveals low HCO_3^-, low PCO_2, and low pH.

DIAGNOSTIC PROCEDURES
None

TREATMENT
- Acid-base disturbances are secondary phenomena; successful resolution depends on diagnosis and treatment of underlying disease process.
- Restore blood volume and perfusion deficits before considering sodium bicarbonate ($NaHCO_3$).
- Treat patients with blood pH ≤7.1 aggressively while pursuing definitive diagnosis.
- Discontinue drugs that may cause metabolic acidosis.
- Nursing care—isotonic, *buffered* electrolyte solution is fluid of choice for patients with mild metabolic acidosis and normal liver function.

MEDICATIONS

DRUG(S) OF CHOICE
- $NaHCO_3$ may help patients with hyperchloremic, hyperhosphatemic, or uremic acidosis, but not patients with lactic acidosis or diabetic ketoacidosis.
- $NaHCO_3$ may be considered for alkaline diuresis in salicylate toxicity. ° Estimation of HCO_3^- dose—dogs, 0.3 × body weight (kg) × (21 – patient HCO_3^-); cats, 0.3 × body weight (kg) × (19 – patient HCO_3^-). Give half of this dose slowly IV and reevaluate blood gases before deciding on need for additional administration. Empirical dose of 1–2 mEq/kg followed by reevaluation of blood gas status is safe in most patients. ° Potential complications of $NaHCO_3$ administration—volume overload resulting from administered Na^+, tetany from low ionized calcium concentration, increased affinity of hemoglobin for oxygen, paradoxical CNS acidosis, overshoot metabolic alkalosis, hypokalemia.
- Hyperchloremic acidosis—$NaHCO_3$ may be effective and considered whenever pH <7.1.
- Uremic acidosis—efficacy of $NaHCO_3$ in acute therapy of uremic acidosis is related to shift of phosphate inside cells and consequent amelioration of hyperphosphatemic acidosis.
- Lactic acidosis—$NaHCO_3$ increases lactate production and is of little to no value in lactic acidosis. Therapy should be directed at augmenting oxygen delivery to tissues and reestablishing cardiac output. Small titrated doses of $NaHCO_3$ can be used as temporizing measure to maintain HCO_3^- above 5 mEq/L, if needed.
- Diabetic ketoacidosis—$NaHCO_3$ adversely affects outcome in humans with diabetic ketoacidosis even when pH is <7.0. Administration of $NaHCO_3$ to ketoacidotic patients cannot be recommended at any pH. Therapy should be direct at insulin and fluid administration. Reestablishing plasma volume and renal perfusion will allow kidneys to excrete ketoanions, replacing them with Cl^-.

CONTRAINDICATIONS
- Avoid $NaHCO_3$ in patients with respiratory acidosis because it generates CO_2.
- Patients with respiratory acidosis cannot adequately excrete CO_2, and increased PCO_2 will further decrease pH.
- Avoid diuretics that act in distal nephron (e.g., spironolactone).
- Avoid carbonic anhydrase inhibitors (e.g., acetazolamide, dichlorphenamide).
- Avoid $NaHCO_3$ in acute (<10 mins) cardiac arrest as it may impair tissue oxygen unloading.

PRECAUTIONS
Use $NaHCO_3$ cautiously in patients with congestive heart failure because Na^+ load may cause decompensation of heart failure.

POSSIBLE INTERACTIONS
None

ALTERNATIVE DRUG(S)
None

FOLLOW-UP

PATIENT MONITORING
Recheck acid-base status; frequency dictated by underlying disease and patient response to treatment.

POSSIBLE COMPLICATIONS
- Hyperkalemia in acute hyperchloremic acidosis.
- Myocardial depression and ventricular arrhythmias.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Hyperkalemia.
- Hyperchloremia.

AGE-RELATED FACTORS
None

PREGNANCY/FERTILITY/BREEDING
N/A

SYNONYMS
- Dilutional acidosis—metabolic acidosis resulting from increased free water in plasma.
- Hyperchloremic acidosis—normal anion gap acidosis.
- Hyperphosphatemic acidosis—metabolic acidosis resulting from high phosphate concentration.
- Nonrespiratory acidosis.
- Normochloremic acidosis—high anion gap acidosis.
- Organic acidosis—metabolic acidosis resulting from accumulation of organic anions (e.g., ketoacidosis, uremic acidosis, and lactic acidosis).

SEE ALSO
- Azotemia and Uremia.
- Diabetes Mellitus With Ketoacidosis.
- Hyperchloremia.
- Hyperkalemia.
- Hyperphosphatemia.
- Lactic Acidosis (Hyperlactatemia).

ABBREVIATIONS
- AG= anion gap.
- BE = base excess.
- H^+ = hydrogen ion.
- HCO_3^- = bicarbonate.
- $NaHCO_3$ = sodium bicarbonate.
- PCO_2 = carbon dioxide tension.

A

ACNE—CATS

BASICS

OVERVIEW
• Inflammatory dermatitis affecting the chin and lips.
• Symptoms may be recurrent or persistent.

SIGNALMENT
• Cats.
• Prevalence for sex, age, or breed not reported.

SIGNS
• Cats may have a single episode, a life-long recurrent problem, or a continual disease.
• Frequency and severity of each occurrence vary with the individual.
• Comedones, mild erythematous papules, serous crusts, and dark keratin debris develop on the chin and less commonly on the lips.
• Swelling of the chin.
• Severe cases—nodules, hemorrhagic crusts, pustules, cysts, fistulae, severe erythema, alopecia, and pain.
• Pain often associated with bacterial furunculosis.

CAUSES & RISK FACTORS
Precise etiology unknown; often is associated with allergic skin diseases; may be a disorder of keratinization, poor grooming, abnormal sebum production, immunosuppression, viral infection, or stress.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Hypersensitivity (atopy, flea bite, food, contact).
• Bacterial folliculitis.
• Demodicosis.
• *Malassezia* infection.
• Dermatophytosis.
• Neoplasia of sebaceous or apocrine glands.
• Eosinophilic granuloma.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Skin scrapings—demodicosis.
• Bacterial culture—resistant infection.
• Fungal culture—dermatophytosis.
• Cytology—bacteria, *Malassezia*.
• Biopsy—rarely needed; necessary in selected cases to characterize changes such as cystic follicles, to differentiate acne from other diseases such as demodicosis, infections (bacterial, yeast, or dermatophytes), or to diagnose neoplasia.

PATHOLOGIC FINDINGS
• Mild disease—follicular distention with keratin (comedo), hyperkeratosis, and follicular plugging, most often associated with allergic dermatitis.
• Severe disease—mild to severe folliculitis and perifolliculitis with follicular pustule formation leading to furunculosis and pyogranulomatous dermatitis.
• Bacteria and *Malassezia* in these lesions are considered secondary invaders and not causative agents.
• *Demodex* mites can be primary agents of this disease.

TREATMENT
• Initial treatment—gentle clipping and soakings to soften crusts.
• Food elimination diet.
• Intradermal allergy testing.
• Continue one or a combination of the therapies listed below until all lesions have resolved.
• Discontinue treatment by tapering medication over a 2- to 3-week period.
• Recurrent episodes—once the recurrence rate is determined, an appropriate maintenance protocol can be designed for each individual.
• Continual episodes—life-long maintenance treatment necessary.

MEDICATIONS

DRUG(S) OF CHOICE

Topical
• Shampoo—once or twice weekly with antiseborrheic (sulfur-salicylic acid, benzoyl peroxide, or ethyl lactate).
• Cleansing agents—benzoyl peroxide, salicylic acid, chlorhexidinephytosphingosine.
• Medicated wipes.
• Antibiotic ointment—mupirocin 2%.
• Other topicals—clindamycin or erythromycin solution or ointment.
• Combination topicals—benzoyl peroxide-antibiotic gels (e.g., Benzamycin).
• Topical retinoids—tretinoin (e.g., Retin-A® 0.01%): gel more effective because of better penetration.
• In severe inflammatory periods 10–14 days of oral prednisolone (1–2 mg/kg q24h) may help to reduce scar tissue formation.

Systemic
• Antibiotics—amoxicillin with clavulanate, cephalosporin, or fluoroquinolone.
• Severe cases may warrant treatment with isotretinoin (Accutane) or cyclosporine, modified (Atopica®).
• Demodicosis—isoxazoline parasiticides.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Benzoyl peroxide and salicylic acids—can be irritating.
• Some wipes contain alcohols that can be irritating.
• Systemic isotretinoin—use with caution, if animal will not allow application of topical medications; potential deleterious side effects in human beings (drug interactions and teratogenicity); container should be labeled for animal use only and kept separate from human medications to avoid accidental use; currently difficult to obtain for animal patients.

FOLLOW-UP
• Monitor for relapses.
• Maintenance cleansing programs can be used to reduce relapses; affected cats are likely to have variable numbers of comedones life-long, which often are just cosmetic, and treatment is not necessary.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Systemic isotretinoin should not be used on breeding animals.

Author David D. Duclos
Consulting Editor Alexander H. Werner Resnick

BASICS

OVERVIEW
• Also (more correctly) muzzle folliculitis and furunculosis.
• Chronic inflammatory disorder of the chin and lips of mostly young animals.
• Characterized by folliculitis and furunculosis; almost never comedogenic as seen in "true acneiform" lesions of human beings.
• Recognized almost exclusively in short-coated breeds.
• Genetic predisposition, local trauma, and allergic disease often play a role.

SIGNALMENT
• Dogs, often younger, sometimes puppies.
• Predisposed short-coated breeds—boxer, Doberman pinscher, English bulldog, Great Dane, Weimaraner, mastiff, Rottweiler, German shorthaired pointer, pit bull terrier.

SIGNS
• Ventral chin and lip margins may have few to numerous erythematous papules and sometimes bullae. These may coalesce to form plaques.
• Initial lesions are inflammatory and sterile; bacteria may not be isolated and lesions may not respond to antibiotics.
• Advanced lesions may contain pus or blood, indicating secondary deep bacterial folliculitis and furunculosis.
• Lesions may be pruritic, some are painful on palpation, but most are nonpainful and nonpruritic.
• Chronic and pruritic lesions may become hyperpigmented, lichenified, scarred, and alopecic.

CAUSES & RISK FACTORS
Several short-coated breeds appear to be genetically predisposed to acne. Lesions may be worse in allergic individuals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Dermatophytosis.
• Demodicosis.
• Juvenile cellulitis.
• Contact dermatitis.
• With other symptoms, consider allergic/atopic disease as playing a role.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Impression cytology will help determine if bacteria or yeast are present.
• Skin scrape—demodicosis.
• Dermatophyte culture—dermatophytosis.
• Bacterial culture and sensitivity testing—in patients with suppurative folliculitis and furunculosis that are nonresponsive to initial antibiotic selection.
• Biopsy—histologic confirmation for cases in which diagnosis is in question.

PATHOLOGIC FINDINGS
• Clinical signs and histopathologic findings are diagnostic.
• Characterized histopathologically by folliculitis and furunculosis.
• Bacteria—not always isolated from lesions in early stages.
• As disease progresses, papules enlarge and rupture, promoting a suppurative folliculitis and furunculosis.

TREATMENT
• Reduce behavioral trauma to the chin (e.g., rubbing on the carpet, chewing bones that increase salivation).
• Frequent cleaning with chlorhexidine-containing pads, shampoos, or solutions can be helpful, but instruct owners not to scrub at the area.
• Gentamicin/steroid-containing ointments for the ears work well on the chin when applied twice daily.
• If topicals are not helpful by themselves, add oral antibiotics based on positive cytology and culture and sensitivity testing.
• Severe cases may necessitate short courses of oral steroids.
• Evaluate for underlying allergic/atopic disease and institute proper therapy for diagnosis and control of these diseases; control of allergic disease may permit resolution of muzzle folliculitis and furunculosis.
• Instruct owners to avoid squeezing the lesions; trauma may make inflammation worse.

MEDICATIONS

DRUG(S)

Topical
• Daily cleaning with chlorhexidine-containing pads, shampoos, or solutions can be helpful; instruct owners not to scrub at the areas.
• Gentamicin/steroid-containing ointments for the ears can be applied to localized lesions twice daily; most useful for lesions on the chin, as the pet cannot lick this area. Constant long-term use over months may cause alopecia and cutaneous atrophy: limit frequency and duration of application.

Systemic
• Antibiotics based on culture and sensitivity—when indicated (e.g., cephalexin, 22–30 mg/kg PO q12h for 2–4 weeks).
• Oral corticosteroids: tapering dosages of prednisolone (initial 0.5 mg/kg/day) to reduce significant inflammation; not for continued use.
• Evaluate for and manage concurrent allergic/atopic skin disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Topical steroids—may cause adrenal suppression and thinning of skin with frequent or constant use.

FOLLOW-UP

PATIENT MONITORING
• Continue antibiotics until lesions have healed.
• Repeat bacterial culture/sensitivity if lesions worsen.
• Discontinue topical corticosteroids when possible.

EXPECTED COURSE AND PROGNOSIS
• Long-term topical treatment may be required.
• Chronic scarring may be prevented by early and aggressive therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Allergic/atopic disease may cause and exacerbate this condition.

Suggested Reading

A

ACRAL LICK DERMATITIS

BASICS

OVERVIEW
- Compulsion to lick limb/s resulting in plaque formation.
- Skin/exocrine affected.

SIGNALMENT
- Dogs.
- Most common in large breeds—Labrador retrievers, Doberman pinschers, Great Danes, Irish setters, golden retrievers, German shepherd dogs, boxers, and Weimaraners.
- Median age 4 yrs, range 1–12 yrs; no sex predilection.

SIGNS
- Excessive licking of affected area.
- Alopecic, eroded/ulcerated, thickened, and raised firm plaques with scabs and exudation, usually located on dorsal aspect of carpus, metacarpus, tarsus, or metatarsus.
- Single or multiple lesions.

CAUSES & RISK FACTORS
- Anything causing local irritation or lesion may initiate lick–itch cycle.
- Associated diseases: staphylococcal furunculosis, hypersensitivity, endocrinopathy, demodicosis, dermatophytosis, foreign body reaction, neoplasia, underlying joint disease or arthritis, trauma, neuropathy, psychogenic, or sensory nerve dysfunction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Neoplasia.
- Bacterial furunculosis.
- Focal demodicosis.
- Focal dermatophytosis.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
Endocrinopathy—total T_4/free T_4/thyroid-stimulating hormone (TSH); adrenocorticotropin hormone (ACTH) stimulation test or low-dose dexamethasone suppression test (LDDST).

IMAGING
Radiology (entire limb +/– neck/lumbar region)—neoplasia; local trauma; radiopaque foreign bodies; bony proliferation may be seen secondary to chronic irritation; evidence of underlying arthritis if over a joint.

DIAGNOSTIC PROCEDURES
- Skin scrapings—demodicosis.
- Dermatophyte PCR and/or culture—fungal infection.
- Epidermal cytology—bacterial infection.
- Bacterial culture and sensitivity—tissue cultures may differ from surface culture.
- Food elimination diet—determine food allergy.
- Intradermal allergy testing—atopy.
- Biopsy—to rule out neoplasia, other infections.
- Behavioral history (additional behavioral signs typical).
- Neurologic and orthopedic evaluation.

PATHOLOGIC FINDINGS
Histopathology—epidermal hyperplasia, plasmacytic dermal inflammation, folliculitis, furunculosis, perihidradenitis, hidradenitis, epitrichial gland dilation/rupture, vertical streaking fibrosis.

TREATMENT
- Rule in/out bacterial, fungal, ectoparasitic, endocrine causes and treat accordingly along with pruritus control.
- If infection resolves and pruritus and/or lesions persist, consider biopsy, allergy workup, neurologic/orthopedic exam, radiographs, behavioral modification.
- Physical restraints—to permit healing.
- Limited research to support effectiveness: radiation, acupuncture, CO_2 laser, cryosurgery, standard surgery.
- Difficult to treat, especially if no underlying cause found; warn owner that patience and time are necessary.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics
Based on bacterial culture/susceptibility. Administer until resolution of infection plus 2 weeks.

Systemic
- Pruritus—antihistamines (2 weeks for response typically), e.g., hydroxyzine (2.2 mg/kg PO q8h); chlorpheniramine (4–8 mg/dog PO q8–12h; maximum of 0.5 mg/kg q12h); amitriptyline (1–2 mg/kg PO q12h), also tricyclic antidepressant (TCA); corticosteroids, e.g., prednisolone 1 mg/kg PO q24h and taper based on response (or other steroid equivalent).
- Behavioral—selective serotonin reuptake inhibitors (SSRIs), e.g., fluoxetine (1 mg/kg PO q24h); TCAs, e.g., amitriptyline (1–2 mg/kg PO q12h, also antihistamine); doxepin (3–5 mg/kg PO q12h; maximum 150 mg q12h); clomipramine (2–4 mg/kg PO q24h); dopamine antagonists, e.g., naltrexone (2.2 mg/kg PO q24h).
- Combine/withdraw administration of these medications carefully.

Topical
Pruritus—flunixin meglumine and fluocinolone in dimethyl sulfoxide (combined), topical capsaicin products; intralesional corticosteroids rarely helpful; wear gloves when applying; prevent licking of area for 10–15 minutes.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Doxepin—caution using with monoamine oxidase inhibitors, clonidine, anticonvulsants, oral anticoagulants, steroid hormones, antihistamines, or aspirin.
- Antihistamines—may cause sedation.
- Psychotropic medications should be combined and/or withdrawn carefully.
- Cardiotoxicity and hepatoxicity—rare cases in animals on TCAs. Routine monitoring recommended.

FOLLOW-UP
- Monitor level of licking and chewing closely.
- Treat underlying disease to prevent recurrence.
- If no underlying disease detected, psychogenic causes possible (compulsive or self-mutilation disorder); prognosis is guarded.

MISCELLANEOUS

AGE-RELATED FACTORS
Dogs <5 years old—strongly consider allergy.

ZOONOTIC POTENTIAL
Dermatophytosis (rare) and methicillin-resistant *Staphylococcus aureus* may have zoonotic implications.

ABBREVIATIONS
- ACTH = adrenocorticotropin hormone.
- LDDST = low-dose dexamethasone suppression test.
- SSRI = selective serotonin reuptake inhibitor.
- TCA = tricyclic antidepressant.
- TSH = thyroid-stimulating hormone.

ACTINOMYCOSIS AND NOCARDIA

BASICS

OVERVIEW

- Opportunistic bacterial infections caused by branching Gram-positive bacteria that cause clinically similar suppurative-to-granulomatous inflammation:
  - *Actinomyces* spp. (anaerobic-to-microaerophilic, normal flora of mucous membranes, gastrointestinal and urogenital tracts).
  - *Nocardia* spp. (aerobic soil saprophytes).
- Organ systems affected may include:
  - Skin and subcutaneous.
  - Respiratory.
  - Cardiovascular.
  - Musculoskeletal.
  - Nervous.
  - Disseminated (*Nocardia*).

SIGNALMENT

- Dogs and cats (uncommon).
- Dogs with outdoor access (*Actinomyces*); young dogs (*Nocardia*); male cats (both).

SIGNS

- Depends on whether infection is localized or disseminated (*Nocardia*) and on organ systems involved.
- Cutaneous and subcutaneous swellings (cervicofacial—*Actinomyces*), abscesses, or nonhealing wounds with draining tracts; localized draining cutaneous lesions are common in cats.
- Poor body condition, pain, fever, weight loss.
- Exudative pleural or peritoneal effusions.
- Cough, dyspnea, decreased ventral lung sounds (empyema).
- Lameness due to osteomyelitis.
- Motor and sensory deficits.
- Retroperitonitis (*Actinomyces*)—lumbar pain, rear limb paresis or paralysis.

CAUSES & RISK FACTORS

Scratches and bite wounds, traumatic inoculation, foreign body migration (e.g., grass awn), immunosuppression (*Nocardia*).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- *Actinomyces* and *Nocardia* appear similar and are not reliably distinguished by Gram staining, cytology, or clinical signs. *Actinomyces* is usually accompanied by multiple other coinfective bacteria.
- Other causes of similar clinical signs must be considered, including other bacterial or fungal infections, neoplasia, and other diseases that cause effusions.

CBC/BIOCHEMISTRY/URINALYSIS

- Nonregenerative anemia.
- Leukocytosis with a left shift and monocytosis.
- Hyperglobulinemia.
- Ionized hypercalcemia (nocardiosis).

OTHER LABORATORY TESTS

N/A

IMAGING

- Dependent on systems affected.
- Thoracic radiographs—alveolar and interstitial lung pattern with possible alveolar disease, pleural effusion (pyothorax), pericardial effusion, subcutaneous masses.
- Abdominal radiographs—peritoneal effusion, abdominal mass effect.
- Radiographs of infected bone—periosteal new bone, reactive osteosclerosis, osteolysis.

DIAGNOSTIC PROCEDURES

- Gram staining, cytology, and acid-fast staining are helpful, but do not preclude the need for culture; acid-fast stain—*Actinomyces* negative, *Nocardia* variable; sulfur granules suggest *Actinomyces*.
- Exudates or osteolytic bone fragments submitted in aerobic and anaerobic specimen containers for culture can provide a definitive diagnosis (see Anaerobic Infections).
- Nocardia may require speciation if not responding to empiric therapy.

PATHOLOGIC FINDINGS

Histopathologic examination—pyogranulomatous or granulomatous cellulitis with colonies of filamentous bacteria; special stains may enhance visualization. Sulfur granules are a useful diagnostic tool, but can be difficult to find.

TREATMENT

- Prolonged antimicrobial therapy is required.
- Surgical debridement or excision of infected tissue (e.g., lung lobe, body wall mass) may improve outcome.
- Exudative fluid (thorax, abdomen, subcutaneous tissue) should be drained and the infected cavity lavaged.
- A thoracostomy tube with intermittent or continuous drainage is usually needed for cats with pyothorax; dogs may benefit from surgical exploration of thorax prior to thoracostomy tube placement to attempt foreign body removal.

MEDICATIONS

DRUG(S) OF CHOICE

- Important to distinguish between *Actinomyces* and *Nocardia* for appropriate antimicrobial selection.
- Antibiotics—protracted course of therapy (weeks to months) usually required; continue for several weeks after resolution of all signs.
- Actinomycosis—penicillins considered drug of choice; amoxicillin: 20–40 mg/kg PO q8h.
- Nocardiosis—potentiated sulfonamides at 15–30 mg/kg PO q12h are usually first choice.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Dogs can develop toxic or hypersensitivity adverse reactions to sulfonamides.
- Metronidazole and aminoglycosides are ineffective against *Actinomyces* spp.

FOLLOW-UP

PATIENT MONITORING

Monitor closely for recurrence after therapy discontinued.

PREVENTION/AVOIDANCE

Avoid areas with grass awns; prevent bites and scratches.

POSSIBLE COMPLICATIONS

Difficult to fully clear infection.

EXPECTED COURSE AND PROGNOSIS

- Redevelopment of infection after discontinuation of antibiotics is possible.
- *Actinomyces*—up to 90% cure reported in dogs after appropriate therapy.
- *Nocardia*—up to 50% mortality reported.

MISCELLANEOUS

AGE-RELATED FACTORS

Young outdoor dogs.

ZOONOTIC POTENTIAL

No reports of humans being infected by either organism through direct contact. Bite and scratch wounds can cause human disease.

A

ACUTE ABDOMEN

BASICS

DEFINITION
An emergency condition characterized by historical and physical examination findings of a tense, painful abdomen. May represent a life-threatening condition.

PATHOPHYSIOLOGY
- An affected patient has pain associated with either distention of an organ, inflammation, traction on the mesentery or peritoneum, or ischemia.
- Abdominal viscera are sparsely innervated, and diffuse involvement is often necessary to elicit pain; nerve endings also exist in the submucosa-muscularis of the intestinal wall.
- Inflammation produces abdominal pain by releasing vasoactive substances that directly stimulate nerve endings.

SYSTEMS AFFECTED
- Behavioral—trembling, inappetence, vocalizing, lethargy, and abnormal postural changes such as the praying position to achieve comfort.
- Cardiovascular—ischemia, severe inflammation, systemic inflammatory response syndrome and sepsis may lead to shock. Tachycardia or other arrhythmia may affect capillary refill time and mucous membrane color. Pain may cause arrhythmias.
- Gastrointestinal (GI)—vomiting, diarrhea, inappetence, generalized functional ileus; pancreatic inflammation, necrosis, and abscesses may lead to cranial abdominal pain, vomiting, and ileus.
- Hepatobiliary—jaundice associated with cholestasis from biliary obstruction (including pancreatitis) or bile peritonitis. Hyperbilirubinemia may occur secondary to sepsis.
- Renal/urologic—azotemia due to prerenal (dehydration, hypovolemia, and shock), renal (acute pyelonephritis and acute kidney injury), and postrenal causes (ureteral obstruction, urethral obstruction, and uroperitoneum from bladder rupture).
- Respiratory—increased respiratory rate due to pain or metabolic/acid-base disturbances.

SIGNALMENT

Species
- Dogs and cats.
- Dogs more commonly; often challenging to identify abdominal pain in feline patients.

Breed Predilections
- Male Dalmatians have a higher risk of urethral obstruction because of the high incidence of urate urolithiasis.
- German shepherds with pancreatic atrophy have a higher risk of mesenteric volvulus.

Mean Age and Range
Any

Predominant Sex
Male cats and dogs are at higher risk for urethral obstruction.

SIGNS

General Comments
Clinical signs vary greatly, depending on type and severity of underlying disease.

Historical Findings
- Trembling, reluctance to move, inappetence, vomiting, diarrhea, vocalizing, and abnormal postures (tucked up or praying position).
- Question owner carefully to ascertain what system is affected; for example, melena with a history of nonsteroidal anti-inflammatory drug (NSAID) treatment may suggest GI mucosal ulceration.

Physical Examination Findings
- Abdominal pain, splinting of abdominal musculature, gas- or fluid-filled abdominal organs, abdominal mass, ascites, pyrexia or hypothermia, tachycardia, and tachypnea.
- Pain may be localizable to cranial, middle, or caudal abdomen.
- Perform rectal examination to evaluate colon, pelvic bones, urethra, and prostate, as well as for presence of melena.
- Rule out extra-abdominal causes of pain by careful palpation of kidneys and thoracolumbar vertebrae.
- Pain associated with intervertebral disc disease often causes referred abdominal guarding and may be mistaken for true abdominal pain. Renal pain can be associated with pyelonephritis.

CAUSES

GI
- Stomach—gastritis, ulceration, perforation, foreign body, gastric dilatation-volvulus.
- Intestine—obstruction (foreign body, intussusception, mass, etc.), enteritis, ulceration, perforation.
- Rupture after obstruction, ulceration, or blunt or penetrating trauma, or due to tumor growth.
- Vascular compromise from infarction, mesenteric volvulus, or torsion.

Pancreas
- Inflammation, abscess, ischemia.
- Mass or inflammation obstructing common bile duct may cause jaundice.

Hepatic and Biliary System
- Acute hepatitis—rapid distention of the liver and its capsule can cause pain.
- Biliary obstruction, rupture, or necrosis may lead to bile leakage and peritonitis.
- Gallbladder mucocele.
- Hepatic abscess.

Spleen
Torsion, mass, thrombus, abscess.

Urinary Tract
- Distention is main cause of pain in urinary tract.
- Obstruction due to tumors of trigone area of bladder or urethra, urinary calculi, or granulomatous urethritis.
- Traumatic rupture of ureters or bladder.
- Urethral tear associated with pelvic fractures from acute trauma.
- Uroabdomen leads to chemical peritonitis.
- Acute pyelonephritis, acute kidney injury, nephroliths, and ureteroliths are uncommon causes of acute abdomen.

Genital Tract
- Prostatitis and prostatic abscess, pyometra; a ruptured pyometra or prostatic abscess can cause endotoxemia, sepsis, and cardiovascular collapse.
- Uncommon—rupture of gravid uterus after blunt abdominal trauma, uterine torsion, ovarian tumor or torsion, and intra-abdominal testicular torsion (cryptorchid).

Abdominal Wall/Diaphragm
- Umbilical, inguinal, scrotal, abdominal, or peritoneal hernia with strangulated viscera.
- Organ displacement or entrapment in hernia will lead to abdominal pain if vascular supply of organ(s) involved becomes impaired or ischemic.

RISK FACTORS
- Exposure to NSAIDs or corticosteroid treatment (increased risk when used concurrently)—gastric, duodenal, or colonic ulcers.
- Garbage or fatty food ingestion—pancreatitis.
- Foreign body ingestion—intestinal obstruction.
- Abdominal trauma—hollow viscus rupture.
- Hernia—intestinal obstruction/strangulation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Renal-associated pain, retroperitoneal pain, spinal or paraspinal pain, and disorders causing diffuse muscle pain may mimic abdominal pain; careful history and physical examination are essential in pursuing the appropriate problem.
- Parvoviral enteritis can present similarly to intestinal obstructive disease; fecal parvoviral antigen assay and CBC (leukopenia) are helpful differentiating diagnostic tests.

CBC/BIOCHEMISTRY/URINALYSIS
- Inflammation or infection may be associated with leukocytosis or leukopenia.
- Active inflammation may be characterized by a neutrophilic left shift.
- Anemia may be seen with blood loss associated with GI ulceration.

• Azotemia is associated with prerenal, renal, and postrenal causes.
• Electrolyte abnormalities can help to evaluate GI disease (i.e., hypochloremic metabolic alkalosis with gastric outflow obstruction) and renal disease (i.e., hyperkalemia with acute kidney injury or postrenal obstruction).
• Hyperbilirubinemia and increased hepatic enzyme activity help localize a problem to liver or biliary system.
• Urine specific gravity (before fluid therapy) is needed to help differentiate prerenal, renal, and postrenal azotemia.
• Urine sediment may be helpful in acute kidney injury, ethylene glycol intoxication, and pyelonephritis.

OTHER LABORATORY TESTS
• Venous blood gas analysis including lactate concentration may indicate acid-base abnormalities, and increased lactate may be associated with hypoperfusion.
• Canine and feline pancreatic lipase immunoreactivity can be useful in evaluating pancreatitis.

IMAGING
Abdominal Radiography
• May see abdominal mass or changes in shape or shifting of abdominal organs.
• Loss of abdominal detail suggests abdominal fluid accumulation.
• Free abdominal gas suggests ruptured GI viscus or infection with gas-producing bacteria and is indication for emergency surgery.
• Use caution when interpreting radiographs following abdominocentesis with an open needle. Free gas may be introduced with this technique.
• Use caution when evaluating postoperative radiographs; free gas is a normal postoperative finding.
• Diffuse GI distension is a consistent finding with peritonitis.
• Foreign bodies may be radiopaque.
• Upper GI barium contrast radiographs are useful in evaluating the GI tract, particularly for determination of GI obstruction.
• Loss of contrast or radiographic detail in the area of the pancreas can be observed with pancreatic inflammation.

Abdominal Ultrasound
• A sensitive diagnostic tool for detection of GI obstruction, pancreatitis, abdominal masses, abdominal fluid, abscesses, cysts, lymphadenopathy, and biliary or urinary calculi.
• Focused Assessment with Sonography in Trauma (FAST) may be used for rapid assessment.

Abdominal CT
May provide superior information to ultrasound in large patients; useful when surgeon requires additional information.

DIAGNOSTIC PROCEDURES
Abdominocentesis/Abdominal Fluid Analysis
• Perform abdominocentesis on all patients presenting with acute abdomen. Four-quadrant approach may improve yield. Fluid can often be obtained for diagnostic evaluation, even when only a small amount of free abdominal fluid exists, well before detectable radiographically. Ultrasound is much more sensitive than radiography for detection of fluid and can be used to direct abdominocentesis. Blind abdominocentesis can be performed safely without ultrasound guidance. Abdominal fluid analysis with elevated white blood cell (WBC) count, degenerate neutrophils, and intracellular bacteria is consistent with septic peritonitis and is an indication for immediate surgery.
• Diagnostic peritoneal lavage can be performed by introducing sterile saline (10–20 mL/kg) and performing abdominocentesis, with or without ultrasound guidance.
• Measurement of glucose concentration in abdominal effusion in comparison with peripheral blood may aid in diagnosis of septic abdomen. A blood-to-abdominal fluid glucose difference of >20 mg/dL is consistent with septic effusion.
• Pancreatitis patients may have abdominal effusion characterized as nonseptic (sterile) peritonitis.
• Creatinine concentration higher in abdominal fluid than in serum indicates urinary tract leakage.
• Similarly, higher bilirubin concentration in abdominal fluid than in serum indicates bile peritonitis.

Sedation and Abdominal Palpation
Because of abdominal splinting associated with pain, thorough abdominal palpation is often not possible without sedation; this is particularly useful for detecting intestinal foreign bodies that do not appear on survey radiographs.

Exploratory Laparotomy
Surgery may be useful diagnostically (as well as therapeutically) when ultrasonography (or other advanced imaging) is not available, or when no definitive cause of acute abdomen has been established with appropriate diagnostics.

PATHOLOGIC FINDINGS
Varies with underlying disease.

TREATMENT
APPROPRIATE HEALTH CARE
• Inpatient management with supportive care until decision about whether problem to be treated medically or surgically. Early intervention with surgery is important when indicated.
• Aggressive therapy and prompt identification of underlying cause are very important.
• Many causes of acute abdominal pain require emergency surgical intervention.

NURSING CARE
• Keep patient NPO if vomiting, until a definitive cause is determined and addressed.
• Intravenous fluid therapy usually required because of large fluid loss associated with acute abdomen; goal is to restore normal circulating blood volume.
• If shock exists, supplement initially with isotonic crystalloid fluids (up to 90 mL/kg, dogs; 70 mL/kg, cats) to restore volume; hypertonic fluids or colloids may also be beneficial if refractory to isotonic crystalloids or hypoproteinemic.
• Evaluate hydration and electrolytes (with appropriate treatment adjustments) frequently after commencement of treatment.

ACTIVITY
N/A

DIET
Early nutritional support is important. Nutritional support can be enteral (oral, nasoesophageal, esophageal tube, gastrostomy tube, enterostomy tube) or parenteral.

CLIENT EDUCATION
Acute abdomen may represent a life-threatening condition. Prompt diagnosis and appropriate treatment essential to a favorable outcome.

SURGICAL CONSIDERATIONS
• Many different causes of acute abdomen exist; make definitive diagnosis whenever possible prior to surgical intervention.
• Definitive diagnosis prior to surgery can prevent both potentially unnecessary and expensive surgical procedures and associated morbidity and mortality.
• Also allows surgeon to prepare for task and educate owner on prognosis and financial investment.

MEDICATIONS
DRUG(S) OF CHOICE
Analgesics
• Pain medication may be indicated for control of abdominal discomfort.
• Opioids are good choices.
  ◦ Fentanyl—2–5 µg/kg as initial IV bolus, 2–10 µg/kg/h as CRI.
  ◦ Hydromorphone—0.05–0.2 mg/kg SC/IM/IV q4–6h.
  ◦ Morphine—0.5–2 mg/kg SC/IM, q4–6h.
  ◦ Buprenorphine—0.01–0.02 mg/kg SC/IM/IV q4–6h.
  ◦ Methadone—0.1–0.4 mg/kg SC/IM/IV q6h.

A

ACUTE ABDOMEN (CONTINUED)

Histamine H2 Antagonists
- Reduce gastric acid production.
- Famotidine 0.5–1 mg/kg IV/SC/IM q12h.
- Ranitidine 2 mg/kg IV q12h.

Proton Pump Inhibitor
Pantoprazole 0.5 mg/kg IV q12h or 0.05–0.1 mg/kg/hr as CRI.

Protectants
Sucralfate 0.25–1 g PO q8h.

Antiemetics
- Metoclopramide 0.2–0.4 mg/kg IV q6–8h (or 24-hour CRI at 1–2 mg/kg/24h).
- Maropitant: dogs 2–4 months of age, 1 mg/kg SC q 24h; dogs >4 months of age and cats, 1 mg/kg SC/IV q24h.
- Ondansetron 0.2–0.5 mg/kg IV slowly q6–12h.

Antibiotics
- Antibiotics may be indicated if signs of infection are seen or hemorrhagic diarrhea is present.
- Broad-spectrum coverage pending culture results.
- Obtain cultures prior to treatment if possible, but do not delay intervention if indicated.

CONTRAINDICATIONS
- Do not use metoclopramide if GI obstruction is suspected.
- Do not use barium if GI perforation is suspected; use iodinated contrast agent instead.

PRECAUTIONS
- Gentamicin and NSAIDs can be nephrotoxic and should be avoided in hypovolemic patients and those with renal impairment.
- NSAIDs may also cause GI complications.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUGS
N/A

FOLLOW-UP

PATIENT MONITORING
Patients usually require intensive medical care and frequent evaluation of vital signs and laboratory parameters.

PREVENTION/AVOIDANCE
Avoidance of indiscriminate eating may prevent GI foreign body obstruction and decrease incidence of pancreatitis.

POSSIBLE COMPLICATIONS
Varies with underlying cause.

EXPECTED COURSE AND PROGNOSIS
Varies with underlying cause; guarded until this is determined.

MISCELLANEOUS

AGE-RELATED FACTORS
Younger animals have higher incidence of trauma-related problems, intussusceptions, and acquired diet- and infection-related diseases; older animals have higher incidence of malignancies.

SYNONYMS
Colic

Author Steven L. Marks
Consulting Editor Mark P. Rondeau

BASICS

DEFINITION
Nonepisodic diarrhea of fewer than 7 days' duration.

PATHOPHYSIOLOGY
Excess water and/or solid content of feces is caused by five main mechanisms:
• Osmotic—from maldigestion, ingestion of poorly absorbable compounds, toxins.
• Decreased absorption—mucosal damage causing loss of absorptive cells from infection, inflammation, or toxins. • Increased secretion (secretory)—mediated by toxins, inflammation, parasympathetic stimulation.
• Increased permeability/exudative—severe mucosal, lacteal, and vessel damage, due to inflammation, ulceration, or direct damage.
• Dysmotility—increased or decreased motility alters digestion, absorption, secretion, and therefore water regulation.

SYSTEMS AFFECTED
• Cardiovascular—fluid losses can be significant, with progressive dehydration to hypovolemia.
• Gastrointestinal (GI)—colitis can develop secondary to orad causes of diarrhea.
• Immune—with enterocyte loss, the mucosal barrier can be compromised, leading to translocation of GI bacteria and sepsis. • Metabolic—electrolyte losses, especially bicarbonate and potassium. Hypokalemia is common with concurrent hyporexia. • Vascular—albumin and globulin losses via increased permeability can be significant and lead to hypoalbuminemia, decreased vascular oncotic pressure, and edema or cavitary effusion.

GENETICS
N/A

INCIDENCE/PREVALENCE
Increased incidence due to dietary indiscretion or infectious etiologies in young patients.

GEOGRAPHIC DISTRIBUTION
Some infectious etiologies have specific geographic distributions.

SIGNALMENT
• Species—dog and cat. • Breed predilections—none. • Mean age and range—common in puppies and kittens due to dietary indiscretion and infectious etiologies.
• Predominant sex—N/A.

SIGNS

General Comments
• Acute diarrhea common, and usually self-limiting. Most animals stable, and require minimal diagnostics/treatment. • In patients that are unstable, with cardiovascular or metabolic compromise, more aggressive diagnostic and treatment approach is warranted.

Historical Findings
• Dietary history, dietary indiscretion, medication/toxin history, and general husbandry should be investigated. ○ Special care should be taken to identify potentially contagious causes of diarrhea, and isolate these patients early. ○ Patients that should be isolated for further diagnostics include unvaccinated, raw diet consumption, housing with many other cats/dogs, or multiple cats/dogs from same household affected.
• Varying activity levels can be seen, from normal to lethargic. • Character of diarrhea can help localize etiology: ○ Small intestinal diarrhea characteristics: large volume, normal frequency, concurrent weight loss and/or vomiting. ○ Melena, if present, points to gastric or upper small intestinal bleed. ○ Steatorrhea, if present, points to maldigestive disorder like exocrine pancreatic insufficiency (EPI). ○ Large intestinal diarrhea characteristics—small volume, increased frequency, tenesmus, mucus, hematochezia.

Physical Examination Findings
• Patients can vary from stable to unstable.
• Common findings—dehydration, hypovolemia, abdominal pain, nausea, fluid–gas interface on intestinal palpation, increased borborygmi. • Rectal examination may reveal melena, hematochezia, steatorrhea.

CAUSES
• Extra-GI causes: ○ Common—hepatobiliary disease, pancreatitis, neoplasia (non-GI). ○ Uncommon—endocrine (hypoadrenocorticism, hyperthyroidism), peritonitis, sepsis.
• Intra-GI causes: ○ Infectious—bacterial: *Campylobacter* spp., *E. coli*, *Salmonella* spp., Clostridial enterotoxins; parasitic: many species of ascarids, cestodes, hookworms, whipworms; protozoal: giardiasis, tritrichomoniasis, coccidiosis; viral: parvovirus, canine distemper virus, corona virus; rickettsial: salmon poisoning (*Neorickettsia*); fungal: histoplasmosis, mycotoxins. ○ Inflammatory (most common cause)—acute enteritis/enterocolitis due to dietary indiscretion or sudden diet change, acute hemorrhagic diarrhea syndrome. ○ Medications/toxins—antibiotics, chemotherapeutic agents, methimazole, nonsteroidal anti-inflammatory drugs (NSAIDS), toxins (corrosive, heavy metals). ○ Motility—obstructive or nonobstructive foreign bodies, intussusception, mesenteric torsion. ○ Neoplasia—primary neoplasia including adenocarcinoma, lymphoma (small cell and large cell) leiomyoma/leiomyosarcoma, mast cell tumor (cats), metastatic.

RISK FACTORS
• Dietary—abrupt diet change or dietary indiscretion. • Medications—many medications can cause acute diarrhea (see Causes).
• Infectious—geographic distribution effect.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Unlikely to be confused with other conditions; however, rarely intestinal bleeding or expulsion of liquid in constipated patient can mimic acute diarrhea.

CBC/BIOCHEMISTRY/URINALYSIS
• Extra-GI etiologies—may reflect etiology: ○ Increased hepatic enzyme activity in hepatobiliary diseases. ○ Increased hepatic enzyme activity, hypoalbuminemia, inflammatory leukogram in pancreatitis. ○ Hypoalbuminemia, decreased Na : K ratio in hypoadrenocorticism. • Intra-GI causes of diarrhea—often normal. • Parvoviral enteritis causes significant neutropenia.
• As result of diarrhea, following may be present: ○ Hemoconcentration. ○ Prerenal azotemia. ○ Hypokalemia. ○ Hypoalbuminemia, hypocholesterolemia. ○ Hypoglycemia—toy breed puppies with GI signs predisposed.

OTHER LABORATORY TESTS
• Extra-GI interrogation: ○ Baseline cortisol or adrenocorticotropic hormone (ACTH) stimulation test in dogs. ○ T_4 in cats. ○ Quantitative pancreatic lipase immunoreactivity. ○ Trypsin-like immunoreactivity if EPI suspected. • Intra-GI interrogation: ○ Parvovirus ELISA should be immediately performed in any suspect so isolation protocols may be initiated as soon as possible. ○ Fecal flotation, fecal direct smear cytology, *Giardia* ELISA. ○ Diarrhea PCR panel may be useful for specific pathogens (i.e., *Salmonella*), but note there is controversy about some bacteria on this panel causing clinical signs.

IMAGING

Abdominal Radiography
• Survey abdominal radiographs interrogate mainly extra-GI causes of diarrhea. • Acute enteritis/enterocolitis—mild gas and/or fluid dilation of stomach/intestine. • Pancreatitis—widened gastroduodenal angle, focal decreased serosal detail at proximal duodenal flexure.

Abdominal Ultrasonography
• Abdominal ultrasonography may be useful in interrogation of intra- and extra-GI causes of diarrhea, such as pancreatitis. • Emergency cage-side focused ultrasonographic examination of abdomen is indicated in patients with acute abdominal pain, to evaluate for etiologies that are surgical emergencies, such as septic or bile peritonitis. • If peritoneal effusion is seen, abdominocentesis and immediate in-house cytology are indicated (+/– culture).

DIAGNOSTIC PROCEDURES
Endoscopy rarely indicated in acute diarrhea, except for patients with melena where gastroduodenal ulceration is suspected.

A

ACUTE DIARRHEA (CONTINUED)

PATHOLOGIC FINDINGS
Dependent on underlying etiology.

TREATMENT

APPROPRIATE HEALTH CARE
• Stable patients, mild diarrhea—outpatient medical care. Careful assessment of young patients should be made, as they can become unstable with mild signs. • Unstable patients, hypovolemic or acute abdominal pain—inpatient medical care.

NURSING CARE
• Isolation protocols should be instituted immediately for any patient that may have a contagious etiology of diarrhea, i.e., patients that are unvaccinated, fed raw diets, come from housing situations with many other animals, or if multiple animals in same household are exhibiting same clinical signs. • Fluid therapy as mandated by hydration/perfusion status and ongoing losses. • Most hyporexic patients with dehydration/hypovolemia need isotonic crystalloids to replenish losses and provide maintenance. • Potassium supplementation may be needed.

ACTIVITY
Activity restriction only required in postoperative care of surgical patients.

DIET
Feeding bland, highly digestible diet is indicated for 3–5 days, then gradual reintroduction of patient's routine diet.

CLIENT EDUCATION
Client education on dietary indiscretion, gradual diet changes, routine deworming, and vaccination may be appropriate.

SURGICAL CONSIDERATIONS
Surgery rarely may be indicated to treat etiology, such as mechanical obstruction.

MEDICATIONS

DRUG(S) OF CHOICE
• In acute diarrhea caused by stress or antibiotics, veterinary-grade probiotics may be useful. • Antibiotics not indicated in acute diarrhea patients, and should be avoided in accordance with antibiotic stewardship, unless specifically indicated with known bacterial etiology, or in cases where bacterial translocation and sepsis are of concern (e.g., parvoviral enteritis with neutropenia). Gastric antacids not indicated unless concurrent vomiting and/or regurgitation. • Anti-diarrheal medications like loperamide not indicated in acute diarrhea, as usually self-limiting; if diarrhea persists beyond 5–7 days, further etiologic investigation and appropriate treatment are warranted. • Anthelmintics (e.g., fenbendazole 50 mg/kg PO q24h for 5 days) are recommended for empiric treatment of parasitic enteritis. • Antiprotozoal or coccidiostatic medication should be used if fecal analysis warrants.

CONTRAINDICATIONS
• Prokinetic medications should not be given to patients with diarrhea. • Anti-diarrheal medications like loperamide should not be given to breeds with possible ABCB-1/MDR-1 mutation.

PRECAUTIONS
• For puppies and kittens, see manufacturer's instructions regarding age and safety labeling. • Many drugs such as antibiotics and anti-diarrheal medications can perpetuate diarrhea. • Metronidazole can cause neurologic toxic effects with high dose and/or chronic use.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Continuation of diarrhea for 3–5 days is to be expected, but should be continual improvement in signs. • If diarrhea not improving, or getting more severe, further diagnostics are warranted. • If diarrhea persists beyond 7 days or recurs despite appropriate therapy, consider chronic diarrhea etiologies.

PREVENTION/AVOIDANCE
Avoid rapid diet changes and dietary indiscretion, and institute prophylactic deworming and vaccinations.

POSSIBLE COMPLICATIONS
• Dehydration and hypovolemia.
• Hypoalbuminemia and subsequent cavitary effusion.

EXPECTED COURSE AND PROGNOSIS
• Mild acute diarrhea usually self-limiting.
• Other prognoses etiology dependent.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Acute vomiting. • Hyporexia.

AGE-RELATED FACTORS
Younger patients more likely to have infectious etiologies.

ZOONOTIC POTENTIAL
Parasitic, protozoal, and bacterial etiologies (e.g., *Ancylostoma*, *Campylobacter*, *Giardia*, *Salmonella*).

PREGNANCY/FERTILITY/BREEDING
Varies with treatment.

SYNONYMS
N/A

SEE ALSO
• Acute Vomiting. • Diarrhea, Chronic—Cats. • Diarrhea, Chronic—Dogs. • Gastroenteritis, Acute Hemorrhagic Diarrhea Syndrome. • Pancreatitis—Cats. • Pancreatitis—Dogs.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone. • EPI = exocrine pancreatic insufficiency. • GI = gastrointestinal. • NSAID = nonsteroidal anti-inflammatory.

BASICS

DEFINITION
• Acute kidney injury (AKI) represents a continuum of renal injury, from mild, clinically inapparent, nephron loss to severe acute renal failure.
• AKI is likely underrecognized. Any increase in serum creatinine >0.3 mg/dL from hydrated baseline is considered an AKI.
• The spectrum of injury is highly variable and may range from mild subclinical to severe damage, requiring renal replacement therapy.
• Patients with AKI have the potential for recovery of renal function.

PATHOPHYSIOLOGY
• AKI may be categorized as prerenal, intrinsic renal, or postrenal based on underlying etiology. Pre- and postrenal causes may progress to intrinsic renal damage.
• Patients with preexisting chronic kidney disease (CKD) are very predisposed to development of clinical AKI due to decreased renal reserve. Special care must be taken in patients with existing CKD to minimize predisposing factors: volume depletion, nephrotoxic medications, etc.

SYSTEMS AFFECTED
• Renal/urologic.
• Uremia may affect all body systems.

INCIDENCE/PREVALENCE
• Prevalence is lower than for CKD.
• Prevalence may increase in environments that support *Leptospira*.
• Ureteral obstruction is most common cause of severe acute uremia in cats.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
• 6–8 years peak prevalence.
• Older animals at greater risk due to decreased renal reserve (AKI on CKD).

SIGNS
Historical Findings
Sudden onset of anorexia, listlessness, depression, vomiting or diarrhea (± blood), halitosis, ataxia, seizures, known toxin or drug exposure, recent medical or surgical procedure.

Physical Examination Findings
Normal body condition and hair coat, depression, dehydration (or iatrogenic overhydration), scleral injection, oral ulceration, necrosis of tongue, uremic breath, hypothermia, fever, tachypnea, bradycardia, nonpalpable urinary bladder, and asymmetric,

CAUSES
Hemodynamic/Hypoperfusion
Shock, trauma, thromboembolism (e.g., disseminated intravascular coagulation [DIC]), vasculitis, transfusion reaction), heatstroke, excessive vasoconstriction (e.g., administration of nonsteroidal anti-inflammatory drugs [NSAIDs]), adrenal insufficiency, excessive vasodilation (e.g., angiotensin-converting enzyme inhibitors [ACEIs] or antihypertensive drugs), prolonged anesthesia, significant hypertension, heart failure.

Nephrotoxic
Grape or raisin ingestion (dogs), lily ingestion (cats), ethylene glycol, aminoglycoside, amphotericin B, chemotherapeutic agents, NSAIDs, radiographic contrast agents, heavy metals, insect or snake venom, heme pigment, and many others. Patients with ethylene glycol toxicity may be exposed from other sources than antifreeze, such as some paints, freezer packs, catering heat sources, etc.

Intrinsic and Systemic Disease
Leptospirosis, immune-mediated glomerulonephritis, pancreatitis, septicemia, DIC, hepatic failure, heat stroke, transfusion reaction, bacterial endocarditis, pyelonephritis, lymphoma, and ureteral obstruction.

RISK FACTORS
• Endogenous—preexisting CKD, pancreatitis, dehydration, sepsis, hypovolemia, hypotension, advanced age, concurrent disease.
• Exogenous—drugs, prolonged anesthesia, trauma, multiple organ disease, high environmental temperature.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Prerenal azotemia—oliguria correctable with fluid repletion. Typically hypersthenuric, but consider ability to concentrate urine: preexisting kidney disease, endocrine disorders, medications, and diet may all affect concentrating ability.
• Postrenal azotemia—anuria, dysuria, stranguria, painful or asymmetric kidneys, ureteral/urethral obstruction, enlarged prostate, urethral tear, uroperitoneum.
• CKD—polyuria, polydipsia, history of chronic illness, loss of body condition, anemia.
• Hypoadrenocorticism—hyponatremia, hyperkalemia, low serum cortisol.
• Pancreatitis—cranial abdominal pain, hyperbilirubinemia, increase in liver enzyme activity.

CBC/BIOCHEMISTRY/URINALYSIS
• Variable packed cell volume (PCV), leukocytosis, or lymphopenia.
• Variable increases in blood urea nitrogen (BUN), creatinine, phosphorus, potassium, and glucose; and variably low bicarbonate and
• Urine specific gravity (USG) ≤1.020, mild to moderate proteinuria, glucosuria, casts, pyuria, hematuria, and tubular epithelial cells; variable bacteriuria and crystalluria.

OTHER LABORATORY TESTS
• Metabolic acidosis—mixed disorders may occur.
• Leptospirosis testing.
• Ethylene glycol testing.
• Canine pancreatic lipase immunoreactivity (cPLI) for pancreatitis.

IMAGING
• Survey and contrast radiography—kidneys normal to large with smooth contours; asymmetric in cats ("big kidney–little kidney" syndrome) with ureteral obstruction, uroliths may be seen.
• Antegrade nephropyelography for ureteral obstruction.
• Ultrasonography—evidence of pancreatitis, marked cortical hyperechogenicity may suggest ethylene glycol toxicity. Moderate cortical hyperechogenicity suggests glomerulonephritis or nephrosis. Pelvic and/or ureteral dilation may suggest outflow obstruction.

DIAGNOSTIC PROCEDURES
• Monitor urine output (UOP): anuria (≤0.25 mL/kg/h), oliguria, polyuria (≥2 mL/kg/h). Avoid urinary catheterization due to infection risk. Assess UOP with serial body weights, ultrasound bladder assessment, weigh bedding, etc.
• Fine-needle aspiration may diagnose lymphoma.
• Renal biopsy may help identify underlying cause and prognosticate recovery.

PATHOLOGIC FINDINGS
Nephrosis or nephritis, glomerulonephritis, calcium oxalate crystals, interstitial edema, and lack of interstitial fibrosis, variable tubular regeneration.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient management—eliminate inciting causes; discontinue nephrotoxic drugs; maintain hemodynamic stability; ameliorate life-threatening fluid imbalances, biochemical abnormalities, and uremic complications.

NURSING CARE
• Hypovolemia—correct estimated fluid deficits with balanced isotonic solution within 2–4 hours if patient condition permits; once hydrated, ongoing fluid requirements are provided by 5% dextrose for insensible losses (~20–25 mL/kg/day) and balanced electrolyte solution equal to sensible losses; avoid overhydration.
• Hypervolemia—stop fluid administration and eliminate excess fluid by diuretics or dialysis.

A

ACUTE KIDNEY INJURY (CONTINUED)

• Monitor body weight and blood pressure several times daily and adjust fluids to maintain stable weight once rehydrated.

DIET

• Nutritional support should be provided within 3 days using moderately protein-restricted diets.
• Caloric and protein requirements supplied by blended renal diets, liquid enteral solutions, or formulated diets delivered by enteral feeding tube. Parenteral nutrition may be needed in some cases.

CLIENT EDUCATION

• Depending on inciting cause, prognosis for recovery of renal function is variable. Average recovery for all causes of AKI is 50%. Likelihood of some degree of persistent kidney damage.
• Potential for complications of treatment (e.g., fluid overload, pancreatitis, sepsis, and multiple organ failure); expense of prolonged hospitalization; options for continued care if conventional medical management fails (hemodialysis, peritoneal dialysis); zoonotic potential of leptospirosis.

SURGICAL CONSIDERATIONS

• See Ureterolithiasis.
• Renal transplantation may provide long-term survival for cats with severe, nonrecovered AKI.

Peritoneal or Hemodialysis

• Dialysis can stabilize the patient to allow time for renal recovery. Without, most oliguric patients die before sufficient renal repair occurs.
• Indications—oliguria or anuria, life-threatening fluid overload or acid-base/electrolyte disturbances, BUN ≥100 mg/dL, serum creatinine ≥5 mg/dL, clinical course refractory to conservative treatment, perioperative stabilization, and poisoning/overdosage with dialyzable toxin/drug.

MEDICATIONS

DRUG(S) OF CHOICE

Inadequate Urine Production

• Avoid overhydration. Once fluid replete, administer diuretics.
• Hypertonic mannitol (20%)—0.5 g/kg IV over 15–30 minutes; if effective, continue IV bolus q6h.
• Furosemide—1–4 mg/kg IV; if effective, continue at 0.5 mg/kg/h or 2 mg/kg q6h.
• Dopamine—potential side effects and lack of efficacy contraindicate its use except for pressor control. Fenoldopam may be more efficacious.
• Dialysis for refractory cases.

Metabolic Disorders, Acid-Base Disorders

Administer bicarbonate if serum bicarbonate <16 mEq/L; bicarbonate replacement: mEq = 0.3 × kg body weight × (desired bicarbonate − measured bicarbonate); give half IV over 30 minutes and remainder over 2–4 hours, then reassess.

Hyperkalemia

• Correct dehydration with potassium-free fluids.
• Minimize potassium intake.
• Discontinue medications that promote hyperkalemia.
• Loop diuretics—furosemide 1–2 mg/kg IV.
• Sodium bicarbonate—correct bicarbonate deficit, if bicarbonate status unknown 1–2 mEq/kg IV.
• Dextrose ± insulin—1–2 mL/kg of 50% dextrose diluted to 25% IV or regular insulin 0.1–0.2 U/kg IV bolus followed by 1–2 g dextrose/unit insulin.
• Calcium gluconate 10%—0.5–1.0 mL/kg IV over 10–15 minutes (cardioprotective, does not alter serum potassium).
• Refractory hyperkalemia—dialysis.

Vomiting

• Reduce gastric acid production—pantoprazole (1 mg/kg IV q12h), famotidine CRI.
• Mucosal protectant for gastrointestinal (GI) ulceration—sucralfate (0.25–1 g PO q6–8h).
• Antiemetics—maropitant (1 mg/kg SC/IV q24h); ondansetron (0.2–1 mg/kg IV q8–12h).

PRECAUTIONS

Modify dosages of drugs requiring renal metabolism or elimination.

FOLLOW-UP

PATIENT MONITORING

Fluid, electrolyte, and acid-base balances; body weight; blood pressure; UOP; and clinical status.

PREVENTION/AVOIDANCE

• Anticipate AKI in aged patients or those with systemic disease, sepsis, trauma, hemodynamic instability, receiving nephrotoxic drugs, multiple organ failure, or undergoing prolonged anesthesia.
• Monitor urine production, BUN, and creatinine in high-risk patients.

POSSIBLE COMPLICATIONS

Seizures, coma, cardiac arrhythmias, hypo- or hypertension, congestive heart failure, pulmonary edema, uremic pneumonitis, GI bleeding, sepsis, cardiopulmonary arrest, and death.

EXPECTED COURSE AND PROGNOSIS

• Prognosis depends on underlying cause, extent of renal injury, concomitant disease or organ failure, and response to therapy.
• Survival rate ~50%, but depends on cause: <20% for advanced ethylene glycol toxicosis, >80% for acute leptospirosis.
• Polyuric AKI—typically milder than oliguric; recovery may occur over 2–6 weeks, but prognosis remains guarded.
• Oliguric AKI—extensive kidney injury, difficult to manage, and has poor prognosis signaled by sudden (and often excessive) polyuria and sluggish and possibly incomplete return of renal function over 4–12 weeks; dialysis extends potential for renal regeneration and repair.
• Anuric AKI—poor prognosis without dialysis. Anuria is not prognostic and does not impact ability for renal recovery, if hemodialysis is available to maintain patient during recovery period.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Leptospirosis

PREGNANCY/FERTILITY/BREEDING

A rare complication of pregnancy; promoted by acute metritis, pyometra, and postpartum sepsis or hemorrhage.

SYNONYMS

• Acute renal failure.
• Acute tubular necrosis.
• Acute uremia.

SEE ALSO

• Azotemia and Uremia.
• Hyperkalemia.
• Hypertension, Systemic Arterial.
• Leptospirosis.
• Ureterolithiasis.

ABBREVIATIONS

• ACEI = angiotensin-converting enzyme inhibitors.
• AKI = acute kidney injury.
• BUN = blood urea nitrogen.
• CKD = chronic kidney disease.
• cPLI = canine pancreatic lipase immunoreactivity.
• DIC = disseminated intravascular coagulation.
• GI = gastrointestinal.
• NSAID = nonsteroidal anti-inflammatory drug.
• PCV = packed cell volume.
• UOP = urine output.
• USG = urine specific gravity.

ACUTE RESPIRATORY DISTRESS SYNDROME

BASICS

DEFINITION

• Acute respiratory distress syndrome (ARDS) is a syndrome of acute onset of respiratory failure typified by diffuse bilateral pulmonary infiltrates on a dorsoventral thoracic radiograph, with no clinical evidence of left atrial hypertension or volume overload. ARDS results from an overwhelming inflammatory reaction in the alveolocapillary membrane in response to a systemic or pulmonary inflammatory insult. The end result is increased vascular permeability leading to edema. • The 2012 Berlin Definition of ARDS defines three categories of severity based on PaO_2/FiO_2 (PF) ratio and level of positive end-expiratory pressure (PEEP) employed during ventilation, with mild ARDS defined by a PF ratio of 200–300 mmHg with PEEP ≥5 mmHg, moderate ARDS as a PF ratio of 100–200 mmHg with PEEP ≥5 mmHg, and severe ARDS as a PF ratio <100 mmHg with PEEP ≥5 mmHg.

PATHOPHYSIOLOGY

• ARDS is due to a diffuse inflammatory insult that causes widespread damage to alveolar endothelial and epithelial cells, resulting in thickening of the membrane and impaired gas exchange. This inflammatory insult can be triggered by primary pulmonary disease or it can be of nonpulmonary origin, and leads to exudative, proliferative, and fibrotic changes within the lung. • First, excessive accumulation and activation of neutrophils, monocytes, and platelets in the pulmonary microvasculature lead to increased alveolar endothelial permeability. This causes protein-rich edema fluid and inflammatory cells to leak into the interstitial and alveolar spaces. • Alveolar epithelial injury results from release of cytokines and other inflammatory mediators from leukocytes and platelets. • Epithelial injury involves both type I and type II alveolar epithelial cells, and results in alveolar flooding and surfactant dysfunction. This causes collapse and consolidation of alveoli with development of severe hypoxemia, and hyaline membrane formation in the alveolar spaces.
• Microthrombi in the pulmonary vasculature, hypoxic pulmonary vasoconstriction, and release of endogenous vasoconstrictors lead to pulmonary arterial hypertension, which can lead to right-sided heart failure. • Proliferation of type 2 alveolar epithelial cells and pulmonary fibrosis occurs in the late stages of ARDS.

SYSTEMS AFFECTED

• Respiratory. • Cardiovascular—right-sided heart failure secondary to pulmonary hypertension; hemodynamic compromise may be associated with aggressive mechanical ventilator settings.

GENETICS

Certain humans are more prone to developing ARDS than others due to specific gene polymorphisms. This has not been investigated in the veterinary population.

INCIDENCE/PREVALENCE

Unknown

SIGNALMENT

Species

Dog and cat.

Breed Predilections

A familial form of ARDS has been reported in a group of related Dalmatian dogs; it is clinically indistinguishable from ARDS.

Mean Age and Range

Unknown

SIGNS

Historical Findings

• Acute onset of respiratory distress in patient with significant underlying disease or exposure to known risk factors. • Patient often hospitalized for primary disease when develops ARDS.

Physical Examination Findings

• Severe respiratory distress. • Crackles (if present) heard bilaterally on auscultation.
• Fever—depends on underlying disease.
• Cyanosis in more severe cases. • Signs relevant to primary disease process.

CAUSES

Primary Pulmonary Causes

• Aspiration pneumonia. • Pneumonia.
• Pulmonary contusion. • Near drowning.
• Chemical or smoke inhalation. • Idiopathic form of ARDS associated with acute interstitial pneumonia or idiopathic pulmonary fibrosis has been reported in humans and dogs.

Nonpulmonary Causes

• Systemic inflammatory response syndrome (SIRS). • Sepsis. • Neoplasia. • Pancreatitis.
• Severe trauma and shock. • Severe bee sting envenomation.

RISK FACTORS

• SIRS. • Sepsis. • Severity of illness. • Multiple transfusions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Left-sided congestive heart failure. • Fluid overload. • Diffuse pneumonia. • Pulmonary hemorrhage.

CBC/BIOCHEMISTRY/URINALYSIS

• Leukocytosis or leukopenia. • Other changes dependent on underlying disease process.

OTHER LABORATORY TESTS

• Arterial blood gases—low PF ratio (where PaO_2 is measured in mmHg and FiO_2 is 0.21–1.0). Normal PF ratio = 500; comparison of this ratio allows evaluation of severity of lung disease and direct comparison of blood gases taken at different FiO_2. $PaCO_2$ is often low; hypercapnia tends to be late (preterminal) development. • Total protein of airway edema fluid compared with serum total protein—ratio of edema fluid to serum total protein <0.5 supportive of low-protein hydrostatic pressure pulmonary edema (e.g., heart failure, fluid overload); edema fluid/serum total protein ratio >0.7 suggests high-protein, increased permeability pulmonary edema such as ARDS and pneumonia. • Coagulation panel may reveal hypocoagulable state supportive of disseminated intravascular coagulation (DIC) or cause of pulmonary hemorrhage.

IMAGING

Thoracic Radiographs

• Bilateral/diffuse pulmonary infiltrates.
• Severity of radiographic signs can lag behind clinical disease by 12–24 hours. • Can be difficult to distinguish from cardiogenic edema; cardiac silhouette and pulmonary vascular size usually normal in ARDS.

Echocardiography

• Attempt to rule out cardiogenic cause for pulmonary edema. • May be able to estimate degree of pulmonary hypertension.

DIAGNOSTIC PROCEDURES

Pulmonary artery catheter to measure pulmonary artery occlusion pressure can be used to rule out cardiogenic cause for edema; by definition, ARDS is associated with pulmonary artery occlusion pressure (PAOP) ≤18 mmHg.

PATHOLOGIC FINDINGS

Gross Pathology

Lungs are dark, heavy, and ooze fluid when cut.

Histopathology

• Acute phase—pulmonary vascular congestion with edema fluid and inflammatory cell accumulation in interstitium and alveoli; epithelial cell damage, hyaline membrane formation, microthrombi, microatelectasis.
• Proliferative phase—hyperplasia of type 2 pneumocytes, interstitial mononuclear infiltration, organization of hyaline membranes, and fibroproliferation.

TREATMENT

APPROPRIATE HEALTH CARE

• No specific therapy; general aims to maintain tissue oxygenation and minimize iatrogenic lung injury while treating underlying disease.
• Oxygen therapy—no more than required to maintain PaO_2 >60–80 mmHg to minimize oxygen toxicity. • Positive-pressure ventilation (PPV) essential in management of ARDS patients; indicated in patients that are hypoxemic despite

A

ACUTE RESPIRATORY DISTRESS SYNDROME (CONTINUED)

oxygen therapy, patients requiring high levels of inspired oxygen for prolonged periods, or patients working so hard to breathe that at risk of exhaustion. • ARDS thought to be exacerbated by ventilator-induced lung injury associated with alveolar overdistension compounded by cyclic opening and collapse of atelectatic alveoli; therefore, lung-protective strategies of PPV with moderate to high PEEP, low tidal volumes, and permissive hypercapnia recommended to minimize ventilator-induced lung injury; tidal volumes of 6 mL/kg have been found to increase survival significantly in human ARDS patients compared to tidal volumes of 12 mL/kg. • Recruitment maneuvers and high levels of PEEP can both cause significant hemodynamic compromise and patients should have constant direct arterial blood pressure monitoring. • Intensive supportive care of cardiovascular system and other organ systems is vital, as these patients at high risk for development of multiple organ dysfunction.

NURSING CARE

• Monitor temperature closely, especially if using an oxygen cage, as animals with excessive work of breathing can easily become hyperthermic. • Ventilator patients require frequent position changes and physical therapy; regular oral care with dilute chlorhexidine solution is important to reduce oral colonization with bacteria as source of sepsis, and frequent endotracheal tube suctioning needed to prevent occlusion; inflate cuff carefully and change endotracheal cuff position regularly to prevent tracheal damage. • Blood pressure monitoring, as septic patients prone to hypotension. • Fluid therapy important to support cardiovascular system and maintain normovolemia while avoiding fluid overload, as this will negatively affect lung function.

ACTIVITY

If not anesthetized for ventilation, strict cage confinement.

DIET

Nutritional support important but challenging. Enteral feeding desired over parenteral nutrition, but must consider high risk of regurgitation and aspiration in recumbent patient.

CLIENT EDUCATION

Clients need to be aware of the guarded prognosis and high costs of therapy.

SURGICAL CONSIDERATIONS

Underlying disease may require surgery.

MEDICATIONS

DRUG(S) OF CHOICE

• No specific drug therapy. • Antibiotics for underlying disease where indicated. • Vasoactive drugs to maintain blood pressure. • Anesthetic drugs to allow PPV. • Analgesia as appropriate. • Low-dose corticosteroid—use remains controversial, with conflicting reports of efficacy for low-dose steroids in early or late ARDS.

ALTERNATIVE DRUG(S)

Furosemide may produce pulmonary venous dilation and improve lung function, as intermittent bolus of 1 mg/kg IV q6–12h or as CRI of 0.2 mg/kg/h IV. Beware dehydration and effects on organ function.

FOLLOW-UP

PATIENT MONITORING

Arterial blood gases, pulse oximetry, end-tidal carbon dioxide, thoracic radiographs, arterial blood pressure, ECG, temperature, urine output, CBC, coagulation profiles, serum chemistry, blood cultures, monitoring for other organ dysfunction.

PREVENTION/AVOIDANCE

• Appropriate therapy of primary disease processes to reduce inflammatory insult to lung. • Intensive cardiovascular monitoring and support of critically ill animals to ensure adequate tissue perfusion. • Careful management of recumbent animals to reduce chance of aspiration, especially if patient has neurologic disease or upper airway disorders that reduce ability to protect airway. • Judicious use of blood products in patients with inflammatory or severe systemic disease.

POSSIBLE COMPLICATIONS

• Multiorgan dysfunction syndrome—acute kidney injury, DIC, and gastrointestinal disease are more common forms of organ dysfunction seen. • Barotrauma—can result in pneumothorax; incidence thought to be less with lower tidal volume ventilation strategies. • Ventilator-associated pneumonia—patients on PPV have increased risk of pneumonia that may be difficult to differentiate from worsening of initial lung injury; airway cultures should be considered in deteriorating patients. • Oxygen toxicity may be unavoidable due to severity of hypoxemia in spite of PPV; oxygen toxicity indistinguishable from ARDS on histopathology, making incidence of this problem impossible to determine.

EXPECTED COURSE AND PROGNOSIS

• Mortality in human patients remains at 40–60%. • Mortality in veterinary patients is likely greater than 90%.

MISCELLANEOUS

ASSOCIATED CONDITIONS

SIRS, multiple organ dysfunction syndrome, sepsis.

SYNONYMS

• Acute hypoxemic respiratory failure. • Acute interstitial pneumonia. • Adult respiratory distress syndrome. • High-protein pulmonary edema. • Shock lung.

SEE ALSO

• Dyspnea and Respiratory Distress. • Panting and Tachypnea. • Pulmonary Edema, Noncardiogenic. • Sepsis and Bacteremia.

ABBREVIATIONS

• ARDS = acute respiratory distress syndrome. • DIC = disseminated intravascular coagulation. • PAOP = pulmonary artery occlusion pressure (formerly pulmonary capillary wedge pressure). • PEEP = positive end-expiratory pressure. • PF ratio = PaO_2/FiO_2 ratio. • PPV = positive-pressure ventilation. • SIRS = systemic inflammatory response syndrome.

Author Casey J. Kohen
Consulting Editor Elizabeth Rozanski

BASICS

DEFINITION
Vomiting of fewer than 7 days' duration.

PATHOPHYSIOLOGY
• Vomiting is a reflex initiated by the vomiting center in the medulla, triggered by three major mechanisms—gastric/duodenal mucosal irritation, gastric/duodenal distention, or the chemoreceptor trigger zone (CRTZ). • Mucosal irritation or gastric/duodenal distention signal the vomiting center via sympathetic and vagal afferent innervation. Anti-peristaltic waves force intestinal contents back to the duodenum, then distention becomes the main trigger for the vomiting reflex. • The CRTZ can directly trigger the vomiting center via receptor activation or vestibular input; known receptors are α_2, D_2, H1, M1, NK_1, $5HT_3$. • Cerebral cortex and vestibular apparatus can also directly stimulate the vomiting center. • The vomiting center initiates an autonomic motor reaction via spinal nerves to diaphragmatic and abdominal muscles, and cranial nerves 5, 7, 9, 10, and 12 to the upper gastrointestinal (GI) tract. • The reflex involves a deep breath, opening the upper esophageal sphincter, closing the glottis, strong diaphragmatic and abdominal muscle contractions, and lower esophageal sphincter relaxation, leading to expulsion of contents.

SYSTEMS AFFECTED
• Cardiovascular—fluid losses can be significant, with progressive dehydration to hypovolemia; vagal stimulation can lead to bradycardia, and rarely syncope. • GI—esophagitis. • Metabolic—vomiting of mixed small intestinal and gastric contents results in isotonic electrolyte losses; pyloric obstruction results in metabolic alkalosis; hypokalemia is common with concurrent hyporexia. • Respiratory—aspiration pneumonitis/pneumonia.

GENETICS
N/A

INCIDENCE/PREVALENCE
Increased incidence of infectious causes and dietary indiscretion in young patients.

GEOGRAPHIC DISTRIBUTION
Some infectious etiologies have specific geographic distributions.

SIGNALMENT
• Species—dog and cat. • No breed, age, or sex predilections.

SIGNS
Historical Findings
• Care should be taken to differentiate vomiting from regurgitation. • Dietary indiscretion, foreign body, and medication/toxin history should be investigated. • Nausea and hypersalivation. • Varying amounts, frequency, and severity of vomiting. • Varying activity levels can be seen, from normal to lethargic. • Hematemesis may be seen.

Physical Examination Findings
• Dehydration/hypovolemia, cranial abdominal pain, nausea, fluid–gas interface on intestinal palpation, increased borborygmi. • Careful sublingual examination for anchored linear foreign bodies. • Careful abdominal palpation for mechanical obstruction. • Rectal examination for melena or concurrent diarrhea.

CAUSES
• Extra-GI causes: ○ Common—hepatobiliary disease, kidney disease, pancreatitis, neoplasia (non-GI). ○ Uncommon—CNS, cardiac, endocrine (hypoadrenocorticism, hyperthyroidism, diabetic ketoacidosis), respiratory disease, peritonitis, sepsis. ○ Intra-GI causes: ○ Congenital/genetic—hiatal hernia. ○ Infectious—parasitic, protozoal, viral (parvovirus, canine distemper virus, corona virus), fungal, bacterial (*Campylobacter*, *Salmonella*). ○ Inflammatory (most common cause)—acute gastritis/gastroenteritis due to dietary indiscretion or sudden diet change, acute hemorrhagic diarrhea syndrome. ○ Mechanical obstruction—foreign body, intussusception, obstructive mass (granuloma, neoplasia, pyloric hypertrophy, trichobezoar), torsion/volvulus (gastric, mesenteric). ○ Medications/toxins—α_2 agonists, antibiotics, apomorphine, chemotherapeutic agents, methimazole, nonsteroidal anti-inflammatory drugs (NSAIDS), opioids, toxins (corrosive, heavy metals). ○ Neoplasia—primary such as adenocarcinoma, lymphoma, leiomyoma/leiomyosarcoma, gastrointestinal stromal tumor, mast cell tumor (cats), metastatic. ○ Ulcers—gastric and/or duodenal ulceration is usually secondary: NSAIDS, neoplasia (primary GI, mast cell tumor, gastrinoma), hypoadrenocorticism, uremia, infectious (controversial—*Helicobacter*), stress.

RISK FACTORS
• Dietary—abrupt diet change or dietary indiscretion. • Medications—many medications can cause acute vomiting. • Infectious—geographic distribution effect.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Vomiting can be mistaken for regurgitation. ○ Vomiting—prodromal nausea (hypersalivation), retching, abdominal contractions. ○ Regurgitation—no prodromal nausea, passive expulsion of fluid/food. ○ Vomiting can lead to regurgitation via esophagitis, so if both signs are present, it is important to establish chronology. • In cats, vomiting can be mistaken for coughing. ○ Coughing involves extension of neck and elbows. ○ Physical exam findings may differentiate. ○ Videos can be helpful to differentiate.

CBC/BIOCHEMISTRY/URINALYSIS
• Extra-GI causes: ○ Increased hepatic enzyme activity in hepatobiliary diseases. ○ Renal azotemia in kidney disease. ○ Increased hepatic enzyme activity, hypoalbuminemia, inflammatory leukogram in pancreatitis. ○ Hypoalbuminemia, decreased Na : K ratio in hypoadrenocorticism. • Intra-GI causes—often normal. • As result of vomiting, following may be present: ○ Hemoconcentration. ○ Prerenal azotemia. ○ Hypokalemia, hypochloremia. ○ Hypoalbuminemia, hypocholesterolemia. ○ Hypoglycemia—toy-breed puppies predisposed.

OTHER LABORATORY TESTS
• Extra-GI interrogation—baseline cortisol or adrenocorticotropic hormone (ACTH) stimulation test in dogs, T_4 in cats, quantitative pancreatic lipase immunoreactivity. • Intra-GI interrogation—fecal flotation, fecal direct smear cytology.

IMAGING
Abdominal Radiography
• Survey abdominal radiographs indicated in most acutely vomiting patients to evaluate potential surgical emergencies, like mechanical obstructions and sepsis. Survey abdominal radiographs also interrogate many extra-GI causes of vomiting. • Acute gastritis/gastroenteritis—mild gas and/or fluid dilation of stomach/intestine. • Mechanical obstruction—foreign body may be radiopaque, or two populations of bowel may be seen, one distended orad to the obstruction, and one normal aborad to the obstruction. • If foreign body is suspected, but no radiographic evidence, serial radiographs every 6 hours or contrast radiography may be considered. • Gastric dilatation and volvulus—malpositioned pylorus on right lateral radiograph. • Pancreatitis—widened gastroduodenal angle, focal decreased serosal detail at proximal duodenal flexure.

Abdominal Ultrasonography
• Abdominal ultrasonography may be useful in interrogation of intra- and extra-GI causes of vomiting, such as pancreatitis and intussusception. • Emergency cage-side focused ultrasonographic examination of abdomen is indicated in patients with acute abdominal pain, to evaluate for etiologies that are surgical emergencies, such as septic or bile peritonitis. • If peritoneal effusion seen, abdominocentesis and immediate in-house cytology are indicated (+/- culture).

A

ACUTE VOMITING (CONTINUED)

DIAGNOSTIC PROCEDURES
• Endoscopy rarely indicated in acute vomiting, except for gastric foreign bodies or gastric ulceration. • Exploratory celiotomy may be considered with high suspicion for mechanical obstruction, even when not confirmed with imaging.

PATHOLOGIC FINDINGS
Dependent on underlying etiology.

TREATMENT

APPROPRIATE HEALTH CARE
• Stable patients, mild vomiting—outpatient medical care. Careful assessment of young patients should be made, as they can become unstable with mild signs. • Unstable patients, hypovolemic or acute abdominal pain—inpatient medical care. • Emergency surgery may be indicated—mechanical obstruction, septic or bile peritonitis, volvulus.

NURSING CARE
• Fluid therapy as mandated by hydration/perfusion status. • Most patients with dehydration/hypovolemia need isotonic crystalloids to replenish losses and provide maintenance. • Nothing PO—only indicated in patients with mechanical obstruction, severe intractable vomiting, or patients with high risk of aspiration.

ACTIVITY
Activity restriction only required in postoperative care of surgical patients.

DIET
Once vomiting resolves, gradual reintroduction of small amounts of water, then small, frequent meals of bland, highly digestible diet is indicated for 3–5 days, then gradual reintroduction of patient's routine diet and feeding schedule.

CLIENT EDUCATION
Client education on dietary indiscretion, gradual diet changes, and foreign body avoidance may be appropriate.

SURGICAL CONSIDERATIONS
Surgery may be indicated to treat etiology, such as mechanical obstruction.

MEDICATIONS

DRUG(S) OF CHOICE
• Anti-emetics not usually needed for mild acute vomiting, but may be needed in more severe cases—$5HT_3$ antagonists such as ondansetron (0.2–1 mg/kg SC/IV q8h), NK_1 antagonist maropitant (1 mg/kg SC q24h or 2 mg/kg PO q24h), dopamine antagonist and prokinetic metoclopramide (0.2–0.5 mg/kg SC/PO q6–8h, or 1–2 mg/kg/day as CRI), phenothiazine derivative chlorpromazine (0.5 mg/kg SC q8h). • Refractory vomiting patients (i.e., pancreatitis) may need multimodal anti-emetics that act on different receptors. • Gastric/duodenal ulcers—proton pump inhibitor such as pantoprazole IV or omeprazole PO (1 mg/kg IV/PO q12h) is preferred treatment. Sucralfate, while used conventionally in ulcers, has only been shown to help cats with esophagitis, and due to impaired absorption of concurrently given medications, and q8 dosing, is of questionable efficacy. • NSAID-induced ulceration—consider misoprostol. • Vestibular mediated—H_1 antagonist like diphenhydramine (2–4 mg/kg PO/IM q6–8h).

CONTRAINDICATIONS
• Prokinetic medications should not be given to patients with mechanical obstruction.
• Phenothiazine derivatives—caution in patients with seizures or hypovolemia/hypotension.
• Anticholinergics should not be given, as exacerbation of signs from ileus can result.

PRECAUTIONS
Anti-emetic medications should not be given to patient receiving outpatient care, unless mechanical obstruction has been ruled out.

POSSIBLE INTERACTIONS
Ondansetron IV can react with other medications and precipitate.

ALTERNATIVE DRUGS
Dolasetron, famotidine.

FOLLOW-UP

PATIENT MONITORING
• If patient receives anti-emetic with outpatient medical care, and continues to vomit—hospitalize for further diagnostics and inpatient medical care. • If vomiting not improving, or getting more severe, further diagnostics are warranted. • If vomiting persists beyond 7 days or recurs despite appropriate therapy, consider chronic vomiting etiologies.

PREVENTION/AVOIDANCE
Avoid rapid diet changes and dietary indiscretion, and institute prophylactic deworming and vaccinations.

POSSIBLE COMPLICATIONS
• Aspiration pneumonia. • Esophagitis.
• Dehydration and hypovolemia.

EXPECTED COURSE AND PROGNOSIS
• Mild acute vomiting from acute gastritis/gastroenteritis usually self-limiting.
• Mechanical obstruction from foreign bodies has good prognosis with rapid recognition and treatment. • Other prognoses etiology dependent.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Acute diarrhea, hyporexia.

AGE-RELATED FACTORS
Younger patients more likely to have ingested foreign body or have infectious etiologies.

ZOONOTIC POTENTIAL
Parasitic, protozoal, and bacterial etiologies (*Ancylostoma*, *Campylobacter*, *Giardia*, *Salmonella*).

PREGNANCY/FERTILITY/BREEDING
Misoprostol for treatment of NSAID-induced ulcers is contraindicated in pregnant animals and humans.

SYNONYMS
Emesis

ADENOCARCINOMA, ANAL SAC

BASICS

DEFINITION
Malignant neoplasm derived from the apocrine glands of the anal sac.

PATHOPHYSIOLOGY
- Locally invasive.
- High metastatic rate (~50–80% at diagnosis), often to locoregional lymph nodes including medial iliac (MILN), internal iliac, sacral, less frequently to distant sites including liver, spleen, or lungs.
- Frequently associated with hypercalcemia, secondary to parathyroid hormone–related peptide (PTH-rP) secretion.
- Prognosis good to guarded with appropriate treatment intervention.

SYSTEMS AFFECTED
- Gastrointestinal.
- Endocrine/metabolic.
- Hemic/lymphatic/immune.

GENETICS
English cocker spaniels significantly overrepresented, springer and Cavalier King Charles spaniels also overrepresented.

INCIDENCE/PREVALENCE
Relatively uncommon—17% of perianal tumors, 2% of all skin/subcutaneous tumors.

SIGNALMENT
- Older dogs; extremely rare in cats.
- Females overrepresented in some studies.
- Breed predilection as stated above.

SIGNS

Historical Findings
Signs may be due to physical presence of primary tumor (visible mass near anus, tenesmus, scooting behaviors) or lymph nodes enlarged due to metastasis (tenesmus, obstipation, stranguria), or systemic manifestations due to hypercalcemia (polyuria/polydipsia, anorexia).

Physical Examination Findings
- Mass associated with anal sac; may be quite small relative to significant metastatic disease burdens.
- Caudal abdominal lymphadenopathy—on rectal or abdominal palpation.

CAUSES & RISK FACTORS
None definitively identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Anal sac abscess.
- Perianal adenoma/adenocarcinoma.
- Mast cell tumor.
- Melanoma.
- Lymphoma.
- Squamous cell carcinoma.
- Perineal hernias.

CBC/BIOCHEMISTRY/URINALYSIS
- Hypercalcemia—15–30% of cases; associated hyposthenuria.
- Secondary renal failure may develop with longstanding and severe hypercalcemia. Beware of interpreting urine specific gravity to differentiate prerenal versus renal azotemia in hypercalcemic patients. Hypercalcemia inhibits concentrating abilities of kidneys, thus azotemia with dilute urine may be seen with both prerenal and renal azotemia. Treatment of disease to resolve hypercalcemia and fluid therapy is needed to determine if underlying renal pathology is present.

OTHER LABORATORY TESTS
If hypercalcemia is present, and tumor cannot be identified, parathyroid hormone and PTHrP levels can be assessed—high PTHrP supports neoplasia as cause of hypercalcemia. This ancillary screening test is not commonly required, as anal gland tumors are easily palpable.

IMAGING
- Abdominal radiography—to evaluate medial iliac lymph nodes and lumbar and pelvic bones.
- Thoracic radiography—to evaluate for pulmonary metastasis.
- Abdominal ultrasonography—may identify enlarged locoregional lymph nodes not visible radiographically, and also metastatic lesions involving visceral organs (liver/spleen).
- CT scan—identifies lymphadenopathy with greater sensitivity than ultrasound. In one study ultrasound found all affected lymph nodes in only 30.8% of cases where CT identified multiple nodes involved.

DIAGNOSTIC PROCEDURES
- Fine-needle aspiration and cytology of anal sac mass to rule out conditions other than adenocarcinoma; while differentiation of benign versus malignant neoplasm of perianal masses is difficult, apocrine gland adenocarcinoma of anal sac will have neuroendocrine appearance and can be differentiated from perianal gland tumors.
- Fine-needle aspiration and cytology of enlarged lymph nodes, liver, or splenic nodules to confirm metastasis.
- Histopathology required for definitive diagnosis. Incisional biopsy can be considered, but excisional biopsy appropriate if location of mass and cytology supportive of anal sac neoplasia.

TREATMENT
- Surgical resection is treatment of choice.
- Resection of primary tumor and enlarged lymph nodes prolongs survival—both at initial diagnosis and upon relapse.
- If mass is large and locally invasive at diagnosis, surgery will be palliative, not curative.
- Debulking all disease present may control hypercalcemia until tumor recurrence.
- Surgery may not be possible if primary mass is very large.
- Adjuvant radiation for microscopic disease may help delay local recurrence and evidence of lymph node metastases.
- Hypofractionated radiation can provide benefit in cases of advanced or inoperable disease, with about one-third of dogs showing partial response to radiation, and about two-thirds of dogs having improvement or resolution of their clinical signs.

MEDICATIONS

DRUG(S) OF CHOICE
- Saline diuresis (200–300 mL/kg/day) preoperatively if hypercalcemia is severe. Also can consider bisphosphonate (zoledronate, pamidronate) or low-dose (0.25 mg/kg BID) prednisone to increase calciuresis, if corticosteroids not contraindicated.
- Low-dose prednisone can also be used to manage hypercalcemia palliatively in dogs that are not receiving any other therapy.
- No controlled studies showing improved outcomes with adjuvant chemotherapy postoperatively; however, such studies fraught with challenges, including range of stages of presenting dogs and retrospective nature of most publications. Theoretically, systemic therapy needed to address the highly metastatic biologic behavior of this tumor.
- Limited reports of partial responses to platinum compounds in dogs—cisplatin (70 mg/m^2 IV with 6h saline diuresis—18.3 mL/kg/h), carboplatin (300 mg/m^2 IV as slow bolus) every 3 weeks.
- Mitoxantrone (5 mg/m^2 IV every 3 weeks for five treatments) in combination with radiation therapy used in one small case series.
- Possible role for melphalan after debulking surgery (7 mg/m^2 PO q24h for 5 days every 3 weeks).
- Toceranib phosphate reported to have some benefit (partial response or stable disease) in 28 dogs with measurable tumor. In 15 dogs with stage 4 (distant metastasis) disease,

A

ADENOCARCINOMA, ANAL SAC (CONTINUED)

toceranib phosphate led to stable disease and modest improvement in clinical signs in 13 dogs, with median progression-free interval and survival time of 1 year.
• Phase 1 trial combining carboplatin and toceranib phosphate in 11 dogs, 4 of which had apocrine adenocarcinoma of anal sac, identified combination of carboplatin (200 mg/m^2 IV every 3 weeks) and toceranib phosphate (~2.75 mg/kg PO every other day) to be well tolerated. Neutropenia was dose-limiting toxicity. All dogs with anal sac tumors responded, with 1 partial response and 3 stable disease. Further studies are warranted.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Use caution with platinum chemotherapeutic agents in dogs with renal insufficiency.
• Do not use cisplatin in cats.

FOLLOW-UP

PATIENT MONITORING

• If complete resection was achieved—physical examination, thoracic radiography, abdominal ultrasonography, or abdominal +/– thoracic CT and serum biochemistry at 3, 6, 9, and 12 months postoperatively, then every 6 months thereafter.
• Incomplete resection—frequency of and modalities for monitoring dependent on ancillary treatments selected. If further therapies declined, at minimum monitor tumor size, blood calcium, and renal values. If using adjuvant therapy, monitor based on specifics of therapy.

EXPECTED COURSE AND PROGNOSIS

• Wide ranges of survivals reported. Many dogs do well with multiple surgeries with or without adjuvant therapies (chemotherapy, radiation therapy). Long-term prognosis is fair, with both local progression and metastasis occurring.
• Cures may occur if tumor is found early and treated aggressively—median survival time for nonmetastatic tumors <3.2 cm in largest diameter was 1,237 days.
• Growth of tumor may be slow and debulking lymph node metastatic disease burdens may significantly prolong survival.
• Hypercalcemia variably associated with poor prognosis, with some studies showing it as negative factor.
• Four papers (involving 200 dogs) showed median survival times of 6–20 months, depending on stage and treatment.
• Dogs with lymph node metastasis lived significantly longer if nodes were extirpated.
• Ultimately, dogs that cannot have their tumors excised completely succumb to hypercalcemia-related complications or mass effect from primary tumor or regional nodal metastases.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hypercalcemia as paraneoplastic syndrome.

ABBREVIATIONS

• MILN = medial iliac.
• PTHrP = parathyroid hormone-related peptide.

Consulting Editor Timothy M. Fan

Client Education Handout available online

ADENOCARCINOMA, LUNG

BASICS

OVERVIEW

• Comprises >75% of primary pulmonary tumors in dogs and cats. • Strongest predictors of outcome: tumor grade, node involvement, clinical signs. • May metastasize. • May be associated with hypertrophic osteopathy.

SIGNALMENT

Dogs

• 1% of all tumors. • Mean age of affected animals 10 yrs. • No sex predilection, though more females in some reports. • Medium to large breeds overrepresented.

Cats

• Rarer than in dogs. • Mean age of affected animals 11 yrs. • No breed predilection.

SIGNS

Historical Findings

• Related to presence of lung mass: ○ Nonproductive cough (>50% dogs, ~40% cats). ○ Dyspnea (may be related to pneumothorax or pleural effusion). ○ Tachypnea. ○ Hemoptysis. • Paraneoplastic signs: ○ Lameness—bone metastasis or hypertrophic osteopathy (dogs or cats), weight-bearing lytic digit metastasis (cats). ○ Polyuria or polydipsia—hypercalcemia or hyperadrenocorticism from ectopic production of adrenocorticotrophic hormone (ACTH). ○ Fever.

Physical Examination Findings

• May be asymptomatic or lack respiratory signs (~25% dogs, 9% cats). • Tachypnea, dyspnea. • Fever. • Limb swelling. • Ascites, pleural effusion.

CAUSES & RISK FACTORS

Some (controversial) evidence correlates risk to urban environment; secondhand environmental tobacco smoke not definitively linked to primary lung cancer in dogs, though weak association seen in dogs with short and medium-length noses.

DIAGNOSIS

• Cytology of mass aspirate. • Tissue biopsy/definitive resection.

DIFFERENTIAL DIAGNOSIS

• Granulomatous lesion (fungal, foreign body, parasitic). • Pulmonary abscess. • Other primary lung tumor: ○ Squamous cell carcinoma. ○ Sarcomas (osteo-, chondro-, lipo-). • Metastatic lung tumor. • Pneumonia. • Asthma. • Pulmonary thromboembolism. • Congenital cyst. • Lung torsion/hematoma.

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities.

OTHER LABORATORY TESTS

N/A

IMAGING

• Thoracic radiography—usually demonstrates focal, solitary, well-circumscribed mass in dogs, often in caudal lung lobes; caudal lobes most common in cats, though radiographic patterns vary more and can include diffuse interstitial disease; radiographs must be performed in cats presenting with multiple digit tumors to screen for primary lung tumor (lung-digit syndrome). • Ultrasonography—to obtain aspirate or biopsy specimen if mass in contact with chest wall, or evaluate abdomen for primary tumor. • CT—to assess surgical feasibility, lymphadenopathy (93% accuracy), metastatic disease; can see cavitated areas, irregular margins, bronchial invasion.

DIAGNOSTIC PROCEDURES

• Thoracocentesis with cytologic examination (for pleural effusion). • Cytology—transthoracic fine-needle aspiration (83% agreement with histopathology). • Percutaneous tissue biopsy—use Tru-Cut instrument, not commonly performed. • Open lung biopsy—via thoracotomy, or minimally invasive thoracoscopy.

PATHOLOGIC FINDINGS

• Adenocarcinoma—classified by location (bronchial, bronchiolar, bronchiolar-alveolar, or alveolar) and degree of differentiation. • Immunohistochemistry on biopsy for thyroid transcription factor-1 (TTF-1), surfactant protein A, and napsin A to confirm pulmonary carcinoma, especially adenocarcinoma. TTF-1 and napsin A can also be seen in thyroid tumors. • Cats tend to have less differentiated tumors, corresponding to more aggressive behavior.

TREATMENT

• Surgery—mainstay of treatment: partial or complete lobectomy with tracheobronchial lymph node biopsy or removal; thoracoscopic removal possible at limited centers and offers less postoperative morbidity. • Radiotherapy—reports anecdotal, but certain patients may benefit. • Chemotherapy should be considered following surgery for tumors that are high grade, undifferentiated, and/or have nodal involvement, though no benefit confirmed. Intracavitary chemotherapy can be used to treat malignant pleural effusion.

MEDICATIONS

DRUG(S) OF CHOICE

• Chemotherapy—vinorelbine concentrates in lungs and responses have been seen. ○ Doxorubicin, cisplatin, carboplatin, mitoxantrone, vinorelbine, and/or vindesine: rational choices for primary or adjuvant therapy. ○ Platinum-based or gemcitabine chemotherapy may be superior. ○ Toceranib phosphate (Palladia) has shown some anecdotal success. • Chemotherapy can be toxic; seek advice if unfamiliar with cytotoxic drugs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Doxorubicin—cardiotoxic, avoid in dogs with myocardial disease (arrhythmias); nephrotoxic in cats. • Cisplatin—do not give to cats (fatal); do not use in dogs with preexisting renal disease; never use without appropriate and concurrent diuresis.

FOLLOW-UP

PATIENT MONITORING

• Serial thoracic radiographs—every 3 mths; administer minimum two cycles of chemotherapy before evaluating response. • Perform CBC (with any chemotherapy), biochemical analysis (cisplatin), and urinalysis (cisplatin) before each chemotherapy.

POSSIBLE COMPLICATIONS

• Following diagnostic procedures or thoracotomy—pneumo- or hemothorax. • Resulting from chemotherapy—myelosuppression, fever, sepsis, nausea.

EXPECTED COURSE AND PROGNOSIS

• Metastasis to tracheobronchial lymph nodes—single best prognostic indicator; median survival without metastasis approaches 1 yr and with metastasis, 60 days. More common (75%) in cats. • Postoperative survival around 2 yrs in both cats and dogs if positive prognostic factors present, and ~1 yr overall in dogs, 4 mths overall in cats. • Other patient, tumor, and treatment factors positively influencing prognosis—complete surgical excision; size of primary tumor (<5 cm); lack of metastasis; well-differentiated cellular morphology on histopathology, lack of clinical signs prior to surgery. • Poor prognosis for cats with lung-digit syndrome poor (~1 mth).

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Chemotherapy not advised in pregnant animals.

ABBREVIATIONS

• ACTH = adrenocorticotrophic hormone. • TTF-1 = thyroid transcription factor-1.

A

ADENOCARCINOMA, NASAL

BASICS

DEFINITION
Malignant neoplasm involving the nasal cavity and paranasal sinuses.

PATHOPHYSIOLOGY
Progressive local and regional invasion of the nasal cavity, paranasal sinuses, and surrounding tissues by neoplastic epithelial and glandular epithelial cells.

SYSTEMS AFFECTED
- Respiratory—congestion, epistaxis, mucopurulent nasal discharge, obstruction, dyspnea.
- Ophthalmic—exophthalmos, epiphora.
- Musculoskeletal—facial deformity.
- Nervous—seizures, altered mentation.

INCIDENCE/PREVALENCE
- In dogs, less than 2% of all tumors are nasal tumors.
- In dogs, adenocarcinoma more common than squamous cell carcinoma, chondrosarcoma, and other histologies, comprising 31.5% of all nasal tumors.
- In cats, nasal tumors comprise <1% of all tumors. In cats, adenocarcinoma and lymphoma are most common.

GEOGRAPHIC DISTRIBUTION
Nasal adenocarcinomas are more commonly reported in urban areas.

SIGNALMENT
- Dog and cat.
- Median age in dogs is 10 years and in cats is 13 years.
- In dogs, medium to large breeds affected more commonly, with possible overrepresentation of mesocephalic and dolichocephalic breeds.

SIGNS

Historical Findings
- Intermittent and progressive history of unilateral to bilateral epistaxis and/or mucopurulent discharge that initially responds to antibiotic therapy (median duration 3 months).
- Sneezing and increased upper respiratory noises, including reverse sneezing.
- Open-mouth breathing.
- Halitosis.
- Anorexia (more frequent in cats).
- Seizures (rare—secondary to invasion of cranial vault).

Physical Examination Findings
- Nasal discharge (blood, mucopurulent).
- Decreased or absent airflow in nasal passages (unilateral or bilateral).
- Facial deformity, exophthalmos, epiphora.
- Pain upon nasal or paranasal sinus palpation or upon opening mouth.
- Regional lymphadenomegaly (rare).
- Abnormal mentation or other neurologic findings (rare).

CAUSES
Dolichocephalic morphology, p53 mutations, and cyclooxygenase-2 (COX-2) overexpression may all play a role.

RISK FACTORS
Urban environment and secondhand smoke may be risk factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other sinonasal tumors (e.g., squamous cell carcinoma, lymphoma, sarcomas, olfactory neuroblastoma).
- Intracranial neoplasia (in dogs or cats with neurologic signs).
- Viral infection—cats.
- Fungal infections, including aspergillosis (dogs) and cryptococcosis (cats).
- Bacterial sinusitis.
- Parasites (e.g., nasal mites).
- Foreign body.
- Trauma.
- Tooth root abscess and oronasal fistula.
- Coagulopathies (nasal tumors most often tend to be unilateral epistaxis; coagulopathy tends to be bilateral epistaxis).
- Systemic hypertension (nasal tumors most often tend to be unilateral epistaxis; hypertension tends to be bilateral epistaxis).

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Occasional blood loss anemia.

OTHER LABORATORY TESTS
- Cytologic examination—occasionally helpful (e.g., aspirates of subcutaneous mass if facial deformity).
- Coagulation profile to rule out coagulopathy.
- Blood pressure to rule out systemic hypertension.

IMAGING
- Survey skull radiography—not sensitive; may show asymmetric destruction of turbinates accompanied by soft tissue mass effect; may see fluid density in frontal sinuses secondary to outflow obstruction.
- Thoracic radiography—evaluate for lung metastasis (uncommon).
- CT or MRI best imaging method for local staging and observing integrity of cribriform plate or orbital invasion; also used for therapeutic planning.

DIAGNOSTIC PROCEDURES
- Oral examination under anesthesia.
- Rhinoscopy may permit visual observation of mass and aid biopsy.
- Tissue biopsy necessary for definitive diagnosis—biopsies may be performed blind, following advanced imaging, using pinch biopsy instrument including retroflex rhinoscopic biopsy of nasopharynx, cannula (closed suction), or hydropulsion techniques.
- Cytologic evaluation of regional lymph nodes to detect regional metastatic disease.

PATHOLOGIC FINDINGS
- Bilateral involvement and osteolysis common.
- Regional lymph node metastasis <10% at time of diagnosis, but up to 45% at necropsy.

TREATMENT

APPROPRIATE HEALTH CARE
- Radiation therapy is standard of care.
- Radiation therapy can be administered with curative intent (conventional definitive or stereotactic radiotherapy) or for palliation of clinical signs.
- Conventional definitive radiation involves multiple fractions for high total dose; usually 10–20 fractions to allow normal tissue recovery with goal of minimizing risk of late permanent radiation side effects.
- Stereotactic radiation therapy is newer technique that allows more conformal treatment than conventional techniques to avoid toxicity to normal tissue without sacrificing tumor control; comparable dose delivered over much shorter time than with conventional techniques; stereotactic radiotherapy involves 1–5 consecutive daily fractions.
- Palliative radiation involves much lower total dose than definitive to minimize toxicity while improving quality of life through reduction of tumor size; usually 4–6 fractions.
- Combining radiation therapy with novel drug therapy (toceranib phosphate—Palladia®, and others) appears safe and well tolerated.
- Radiation therapy followed by surgery to debulk residual mass may improve local control time, but results in higher rate of complications.
- Surgery alone considered ineffective, with most tumors relapsing within 6 months.

NURSING CARE
- During radiation therapy, supportive care for radiation-related mucositis may involve softening food; rinsing mouth with "magic mouthwash" (topical anesthetic), saline, or dilute black tea; and administration of medications to control discomfort.
- These side effects temporary, but may cause discomfort for 10–14 days.

ACTIVITY
- Limit activity to minimize risk of epistaxis and dyspnea.
- Using harness instead of collar during walks may help minimize epistaxis.

DIET
- Soften food if needed during radiation therapy.

• Avoid extremes of temperatures and salty foods with radiation therapy–related mucositis.

CLIENT EDUCATION
• Nasal adenocarcinoma may be painful even though pet not showing visible signs of pain.
• Consider use of medications for discomfort, epistaxis, and congestion.
• Radiation therapy most effective option and well tolerated using modern radiotherapy techniques, with fewer side effects than previously reported.
• Radiation side effects may impact patient's quality of life during treatment, but most pets enjoy relatively normal quality of life following treatment.
• Intermittent congestion, nasal discharge, and sneezing may occur post therapy due to increased sensitivity from tumor's destruction of nasal turbinates.

SURGICAL CONSIDERATIONS
Anesthetic recovery—ensure airway is maintained until animal is sternal and alert, to prevent apnea in patients with bilateral nasal obstruction.

MEDICATIONS

DRUG(S) OF CHOICE
• Chemotherapy is considered ineffective for durable tumor control, but may benefit some patients if radiation therapy is not viable option. Various drugs have been described, including cisplatin (dogs only), carboplatin, doxorubicin, and piroxicam. Toceranib phosphate (Palladia) exerts therapeutic activity against nasal carcinoma.
• Consult with oncologist for more details.
• Adequate analgesic therapy should be employed as needed in patients suffering from invasive disease with bone destruction, signs of pain, or radiation therapy side effects.

CONTRAINDICATIONS
Cisplatin—never use in cats.

PRECAUTIONS
• Most chemotherapeutics have risk of gastrointestinal, hematologic, and other potential side effects, and should be administered and monitored by an oncologist.
• Piroxicam can cause gastric ulceration, so careful monitoring of appetite, vomiting, and stool color (melena) is recommended.

POSSIBLE INTERACTIONS
Concurrent radiation therapy and chemotherapy will increase risk of side effects, but have not shown to significantly improve tumor control.

ALTERNATIVE DRUG(S)
• Palladia, a tyrosine kinase inhibitor, may have anticancer activity in some carcinomas, including nasal adenocarcinomas. It is currently being investigated alone and in combination with radiation therapy.
• Objective responses have been documented with use of Palladia alone.
• Yunnan Baiyao, a Chinese herbal medication, is often prescribed for epistaxis.

FOLLOW-UP

PATIENT MONITORING
• Clinical response is usually observed within 2–3 weeks from start of radiation therapy. Reductions in epistaxis, nasal discharge, congestion, and sneezing are expected.
• CT or MRI is needed to assess objective tumor response to therapy and is recommended 2–3 months post radiation treatment.
• Other staging tests, including thoracic imaging (radiography or CT) and lymph node evaluation, are generally recommended at 3-month intervals during/following therapy.
• Routine staging with CT/MRI and monitoring of recurrent clinical signs can detect early recurrence.

POSSIBLE COMPLICATIONS
• Pain.
• Dyspnea.
• Epistaxis.
• Secondary infections.
• Weight loss.
• Anorexia.
• Chemotherapy or radiation toxicity.

EXPECTED COURSE AND PROGNOSIS
• Untreated—median survival around 2–6 months.
• Definitive conventional and stereotactic radiation therapy—median survival times reported at 12–18 months in dogs and 12–20 months in cats; 1-year survival rate 20–57% (dogs and cats); 2-year survival rate 20–48% (dogs and cats).
• Presence of cribriform lysis, brain involvement, or metastatic disease (advanced stage) are poor prognostic indicators.
• Ophthalmic complications of radiation therapy—more likely in dogs than cats.
• Incidence and severity of ophthalmic toxicity have dramatically decreased with advanced radiation therapy techniques now commonly used.
• Chronic rhinitis is possible following radiation therapy for sinonasal tumors and may require periodic symptomatic therapy.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Chemotherapeutic drugs and general anesthesia are a risk to the fetus and would not be recommended in pregnant animals.

SYNONYMS
• Nasal carcinoma.
• Nasal tumor.

Author Jayme S. Looper
Consulting Editor Timothy M. Fan

A

ADENOCARCINOMA, PANCREAS

BASICS

OVERVIEW
- Malignant tumor of ductal or acinar origin arising from the exocrine pancreas.
- Usually metastatic by the time of diagnosis, affecting regional lymph nodes and visceral abdominal organs (liver) and associated peritoneal cavity.

SIGNALMENT
- Rare in dogs—0.5–1.8% of all tumors.
- Rare in cats—2.8% of all tumors.
- Older female dogs and Airedale terriers at higher risk than others.
- Median age (dogs)—9.2 years.
- Mean age (cats)—11.6 years.

SIGNS
- Nonspecific—fever; vomiting; weakness; anorexia; icterus; malabsorption syndrome; weight loss.
- Abdominal pain—variable.
- Abdominal effusion—malignant.
- Metastasis to bone and soft tissue common.
- Pathologic fractures secondary to metastasis reported.
- Palpable abdominal mass (cats).
- Paraneoplastic syndromes of epidermal necrosis, hyperinsulinemia, and hyperglucagonemia may be present.
- Average duration of clinical signs (cats): 41 days, range 2–180 days.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Primary pancreatitis; may be concurrent and complicate or delay early diagnosis.
- Pancreatic pseudocyst.
- Pancreatic nodular hyperplasia.
- Hepatic neoplasia.
- Other causes of vomiting and icterus.
- Peritoneal carcinomatosis.
- Other causes of abdominal effusion in cats.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually nonspecific changes (e.g., mild anemia and neutrophilia).
- Hyperamylasemia less reliable than hyperlipasemia.
- Lipase concentrations are often markedly elevated and may serve as a noninvasive biochemical marker of neoplasia in dogs.

OTHER LABORATORY TESTS
Rarely there may be significant metabolic alterations that affect glucagon, insulin, and amino acid concentrations.

IMAGING
- Abdominal radiographs may reveal a mass or loss of serosal detail associated with concurrent pancreatitis or peritoneal effusion.
- Ultrasonography may reveal one or more masses or concurrent pancreatitis (mixed echogenicity, large pancreas, hyperechoic peripancreatic fat). Pancreatic thickening, abdominal effusion, and single to multiple nodules of varying size may be identified. Sonographic findings may be impossible to distinguish from pancreatic nodular hyperplasia. Rarely the ultrasound of the pancreas may appear normal except for dilation of the pancreatic duct.
- Abdominal CT will allow for therapeutic decisions regarding surgical resectability and approach, which can affect the owner's willingness to treat.

DIAGNOSTIC PROCEDURES
- Surgical biopsy—definitive.
- Fine-needle aspirate cytology—supportive.

In many cases, where the tumor is not resectable, the fine-needle aspirates may provide strong enough evidence to start medical treatment.

TREATMENT
- None reported curative.
- Palliation of pain with aggressive analgesic combinations is necessary.
- Surgical intervention to alleviate intestinal and biliary obstruction, if necessary.
- Surgery is typically not a good option in many cases, due to the extent of the disease at the time of diagnosis.
- If surgery is an option, partial or total pancreatectomy may prolong survival. A Whipple procedure (pancreaticoduodenectomy) and/or partial colon resection may be required for tumor resection. This can influence the perisurgical morbidity and mortality risk.
- Treat concurrent pancreatitis.
- Antiemetics and supportive care (hydration and caloric requirements).

MEDICATIONS

DRUG(S) OF CHOICE
- Gemcitabine is used in humans for the treatment of pancreatic carcinoma, and while used in dogs with cancer, it has not been established as the standard of care for dogs with pancreatic adenocarcinoma.
- Always consult a veterinary oncologist for updates in treating this rare neoplasm.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

POSSIBLE COMPLICATIONS
- Intestinal obstruction
- Biliary obstruction
- Pancreatic abscess
- Peritonitis
- Metastasis

EXPECTED COURSE AND PROGNOSIS
Progression to death is often rapid given that there is no successful curative treatment available. Despite the grave prognosis, individual patients treated with complete resection of their tumor and chemotherapy, in the absence of systemic metastasis, may have prolonged survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Gastrin-secreting pancreatic carcinoma (gastrinoma) has been reported in dogs and cats. Clinical signs are associated with hypergastrinemia, which results in inappropriate hydrochloric acid secretion by the stomach, leading to gastroduodenitis.

ADENOCARCINOMA, PROSTATE

BASICS

OVERVIEW
- Prostatic adenocarcinoma (PAC) is a malignant tumor that occurs in both neutered and intact male dogs.
- Although this neoplasm represents <1% of all canine malignancies, it is the most common prostatic disorder in neutered male dogs.
- Metastases to regional lymph nodes, lungs, and the lumbosacral skeleton are common.

SIGNALMENT
- Dogs and rarely cats.
- Medium- to large-breed intact or neutered male dogs.
- Median age of 9–10 years.

SIGNS

Historical Findings
- Tenesmus (with the production of ribbon-like stool).
- Weight loss.
- Stranguria and dysuria.
- Rear limb lameness.
- Lethargy.
- Exercise intolerance.

Physical Examination Findings
- A firm, asymmetric, and immobile prostate gland.
- Prostatomegaly is common, but is not always present.
- Pain may be elicited in response to abdominal or rectal palpation.
- Caudal abdominal mass, cachexia, pyrexia, and dyspnea may also be identified.

CAUSES & RISK FACTORS
Neutered males are at increased risk for prostatic neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other primary neoplasia (i.e., squamous cell carcinoma, transitional cell carcinoma).
- Metastatic or locally invasive neoplasia (i.e., transitional cell carcinoma).
- Acute or chronic prostatitis, benign prostatic hypertrophy, and prostatic cysts are possible differentials in intact male dogs, but are highly unlikely in neutered dogs.

CBC/BIOCHEMISTRY/URINALYSIS
- Inflammatory leukogram possible.
- Alkaline phosphatase may be high.
- Postrenal azotemia may be present if urethral obstruction exists.
- It is prudent to evaluate urine samples via cystocentesis and free-catch techniques, as hematuria, pyuria, and malignant epithelial cells may be observed in free-catch samples, but are unusual in samples obtained by cystocentesis.

OTHER LABORATORY TESTS
Serum and seminal plasma markers such as acid phosphatase, prostate-specific antigen, and canine prostate-specific esterase are not elevated in dogs with PAC.

IMAGING
- Thoracic radiography—metastases may appear as pulmonary nodules or increased interstitial markings.
- Abdominal radiography—sublumbar lymphadenomegaly, mineralization of the prostate, and lytic lesions to the lumbar vertebrae or pelvis may be seen.
- Abdominal ultrasonography—focal to multifocal hyperechogenicity with asymmetry and irregular prostatic outline, ± prostatic mineralization.
- Contrast cystography may help differentiate prostatic from urinary bladder disease.

DIAGNOSTIC PROCEDURES
- Prostatic aspirate (percutaneous or transrectal).
- Prostatic wash.
- Prostatic biopsy performed percutaneously or surgically.
- Percutaneous biopsy has been associated with tumor seeding along the biopsy tract.

TREATMENT
- Prostatectomy if local disease (success of this procedure depends on skill of surgeon and extent of disease).
- Radiation therapy may palliate signs and prolong survival.
- Neutering—however, most tumors are not androgen responsive.
- Stenting of the prostatic urethra will resolve urinary outflow obstruction and thereby prolong survival.

MEDICATIONS

DRUG(S) OF CHOICE
- Chemotherapy—carboplatin, cisplatin, or doxorubicin; may offer short-term benefit.
- Pain relief with nonsteroidal anti-inflammatory drugs (NSAIDs), morphine-derived drugs.
- Stool softeners to relieve tenesmus.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Ability to urinate and defecate, pain secondary to skeletal metastases, quality of life.

PREVENTION/AVOIDANCE
Keeping dogs sexually intact may decrease risk.

POSSIBLE COMPLICATIONS
- Urethral obstruction.
- Metastasis to regional lymph nodes, skeleton, and lungs.

EXPECTED COURSE AND PROGNOSIS
Guarded to poor, survival of 2–6 months depending upon presenting clinical symptoms.

MISCELLANEOUS

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
N/A

ABBREVIATIONS
- NSAID = nonsteroidal anti-inflammatory drug.
- PAC = prostatic adenocarcinoma.

A

ADENOCARCINOMA, RENAL

BASICS

OVERVIEW
- Accounts for <1% of all reported neoplasms in dogs.
- Renal tumors tend to be highly metastatic, locally invasive, and often bilateral.
- Renal cystadenocarcinoma, a rare heritable syndrome with a less aggressive behavior and better long-term prognosis than renal adenocarcinoma, has been described in German shepherd dogs.

SIGNALMENT
- Adenocarcinoma—older (8–9 years) dogs, 1.6 : 1 male-to-female ratio, no breed predilection.
- Cystadenocarcinoma—German shepherd dogs, often female.

SIGNS
- Adenocarcinoma—insidious, nonspecific signs such as weight loss, inappetance, lethargy, hematuria, and pale mucous membranes.
- Cystadenocarcinoma—may present for nodular dermatofibrosis, a syndrome of painless, firm, fibrous lesions of the skin and subcutaneous tissues.

CAUSES & RISK FACTORS
- Adenocarcinoma—unknown.
- Cystadenocarcinoma—heritable in German shepherd dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other primary neoplasia (i.e., lymphoma, nephroblastoma).
- Metastatic neoplasia (i.e., hemangiosarcoma).
- Renal adenoma or cyst.
- Pyelonephritis.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC may show paraneoplastic polycythemia or leukocytosis, or anemia.
- Biochemistry may be normal, or may reveal azotemia. Marked gamma-glutamyltransferase (GGT) elevation may be prognostic.
- Urinalysis may show hematuria, proteinuria, bacteriuria, or casts.

OTHER LABORATORY TESTS
Urine culture and sensitivity.

IMAGING
- Thoracic radiographs—metastatic disease reported in up to 16% of patients.
- Abdominal radiographs—mass visualized in 81% of patients.
- Abdominal ultrasonography, CT, or contrast radiography—useful in identifying and staging the disease.

DIAGNOSTIC PROCEDURES
- Renal biopsy (ultrasound guided or surgical) for definitive diagnosis.
- Mitotic index found to be prognostic in 70 dogs treated with nephrectomy.

TREATMENT
- Aggressive surgical excision is the treatment of choice for unilateral disease.
- Successful chemotherapeutic management of either disease has not been described.
- Supportive management for patients in renal failure may be necessary.

MEDICATIONS

DRUG(S) OF CHOICE
None

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
- Renal failure—measure serum urea nitrogen and creatinine; urinalysis.
- Quality of life if bilateral or otherwise nonsurgical disease.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
- Renal failure.
- Metastatic disease.
- Invasion of local vital structures (vena cava, aorta).

EXPECTED COURSE AND PROGNOSIS
- Adenocarcinoma—median reported survival of 49 dogs was 16 months (range 0–59).
- Cystadenocarcinoma—few large studies of this rare disease, reported median survival of 12+ months with no definitive therapy.
- Based on mitotic index: >30 mitotic figures/10 high-power fields (hpf; median survival of 187 days) vs. 10–30/10 hpf (median survival of 452 days) vs. <10/hpf (median survival of 1184 days).

MISCELLANEOUS

ASSOCIATED CONDITIONS
- The paraneoplastic syndromes of hypertrophic osteopathy, polycythemia, and a neutrophilic leukocytosis have been reported in isolated cases.
- Renal failure.
- Nodular dermatofibrosis and uterine leiomyomas are commonly associated with cystadenocarcinoma.

ABBREVIATIONS
- GGT = gamma-glutamyltransferase.
- hpf = high-power field.

ADENOCARCINOMA, SALIVARY GLAND

BASICS

OVERVIEW

- Tumor arising from major (e.g., parotid, mandibular, sublingual, or zygomatic) or minor salivary glands.
- Mandibular or parotid glands constitute 80% of cases.
- Mandibular gland most frequently affected in dogs.
- Parotid gland most frequently affected in cats.
- Locally invasive.
- Cats typically have more advanced disease than dogs at time of diagnosis.
- Metastasis—regional lymph node in 39% of cats and 17% of dogs at diagnosis; distant metastasis reported in 16% of cats and 8% of dogs at diagnosis, but may be slow to develop.
- Epithelial malignancies—constitute roughly 85% of salivary gland tumors.
- Adenomas comprise only 5% of salivary tumors.

SIGNALMENT

- Dogs and cats.
- Mean age, 10–12 years.
- Siamese cats may be at relatively higher risk.
- Male cats affected twice as often as female cats.
- No other breed or sex predilection has been determined.

SIGNS

- Unilateral, firm, painless swelling of the upper neck (mandibular and sublingual), ear base (parotid), upper lip or maxilla (zygomatic), or mucous membrane of lip (accessory or minor salivary tissue).
- Other signs may include halitosis, weight loss, anorexia, dysphagia, exophthalmus, Horner's syndrome, sneezing, and dysphonia.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Squamous cell carcinoma.
- Mucocele.
- Abscess.
- Soft tissue sarcoma, e.g., fibrosarcoma.
- Lymphoma.

CBC/BIOCHEMISTRY/URINALYSIS

Results often normal.

OTHER LABORATORY TESTS

N/A

IMAGING

- Regional radiographs usually are normal; may see periosteal reaction on adjacent bones or displacement of surrounding structures.
- MRI or CT imaging allows superior discrimination of tumor for surgery and/or radiation treatment planning.
- Thoracic radiographs indicated to check for lung metastases.

DIAGNOSTIC PROCEDURES

- Cytologic examination of aspirate may differentiate salivary adenocarcinoma from mucocele and abscess.
- Biopsy for histopathology is required for definitive diagnosis.

TREATMENT

- Aggressive surgical resection—when possible; most are invasive and difficult to excise completely.
- Radiotherapy—good local control and prolonged survival may be possible.
- Aggressive local resection (usually histologically incomplete) followed by adjuvant radiation can achieve local control and long-term survival in some cases, but further studies are needed to determine the most effective treatment, including the possible role for chemotherapy.

MEDICATIONS

DRUG(S) OF CHOICE

Chemotherapy efficacy is largely unreported; however, it may be indicated for treatment/palliation of metastatic disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Evaluations—physical examination and thoracic radiographs every 3 months reasonable if aggressive surgery and/or radiation therapy employed.

POSSIBLE COMPLICATIONS

Temporary acute side effects (e.g., moist dermatitis and alopecia) expected with radiation therapy. Consultation with a radiation oncologist is recommended regarding specific, anatomic site–related side effects associated with planned dose and field size.

EXPECTED COURSE AND PROGNOSIS

- Improved survival time in dogs without evidence of nodal or distant metastasis at diagnosis; clinical stage not prognostic for cats.
- Median survival 550 days for dogs and 516 days for cats in retrospective study.
- Local control obtained through radiation and/or surgery is critical to outcome.

A

ADENOCARCINOMA, SKIN (SWEAT GLAND, SEBACEOUS)

BASICS

OVERVIEW
• Malignant growth originating from sebaceous or apocrine sweat glands of the skin.
• Approximately 2% of all skin tumors in dogs.

SIGNALMENT
• Apocrine sweat gland—rare in dogs, uncommon in cats.
• Sebaceous gland—rare in both dogs and cats.
• Middle-aged to older pets.
• Male intact dogs overrepresented for sebaceous gland adenocarcinomas.
• Female dogs overrepresented for apocrine adenocarcinoma in one study.

SIGNS
• May appear as solid, firm, raised, superficial skin lesions.
• May be ulcerated and bleeding and accompanied by inflammation of the surrounding tissue.
• Apocrine sweat gland—often poorly circumscribed, ulcerated and potentially purple in color; very invasive into underlying tissue; may occur anywhere on the body, frequently affecting the limbs and trunk in dogs and head, limbs, and abdomen in cats.
• Sebaceous gland—often nodular, ulcerated and inflamed, moderate risk of lymph node involvement; frequently found on head and neck in dogs and on the head, thorax, and perineum in cats.
• Dermal and lymphatic tracking can be observed early in disease course.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other more frequent skin tumors.
• Cutaneous histiocytic diseases.
• Immune-mediated skin diseases.
• Deep bacterial/fungal infections.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
N/A

IMAGING
Thoracic radiographs recommended at time of diagnosis to assess for distant metastases.

DIAGNOSTIC PROCEDURES
• Biopsy for histopathology and definitive diagnosis.
• Cytologic examination or biopsy of draining lymph nodes.

PATHOLOGIC FINDINGS
• Apocrine gland adenocarcinomas are divided into multiple subtypes based on the anatomic location they arise in. They typically are invasive into the underlying stroma and blood vessels, and often show poorly demarcated borders and a high mitotic index.
• Sebaceous gland adenocarcinomas often reveal lymphatic vessel invasion.

TREATMENT
• Aggressive *en bloc* surgical excision, including resection of draining lymph node, recommended for both types. Histopathologic analysis of lymph nodes assists with determining prognosis and establishing adjuvant treatment plan.
• Margins of entire tissue specimen must be evaluated histologically to assess completeness of resection.
• Radiation therapy may be recommended for treatment of draining lymph nodes after resection to prevent recurrence and development of regional metastasis; radiation therapy of primary tumor site recommended when wide and complete resection not possible.

MEDICATIONS

DRUG(S) OF CHOICE
• Chemotherapy has been used anecdotally for the treatment of both tumor types, in both species.
• Contact a veterinary oncologist for any updated treatments that may be available.
• Nonsteroidal anti-inflammatory drugs and other analgesics are recommended, as indicated, for pain control.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
None

FOLLOW-UP
• Sebaceous gland adenocarcinoma—little is known about the metastatic potential of this malignancy, but it may be rapidly metastatic to regional lymph nodes in some patients; long-term prognosis is anecdotally good with multimodal therapy combining aggressive surgery, chemotherapy, and radiation therapy.
• Apocrine gland adenocarcinoma—fair to good long-term prognosis; the histologic finding of vascular invasion is a negative prognostic factor predicting systemic metastases; aggressive surgical resection (local and regional tumor control) followed by adjuvant chemotherapy is recommended to improve survival. A study reported a postexcisional median survival time of 30 months in dogs.

ADENOCARCINOMA, STOMACH, SMALL AND LARGE INTESTINE, RECTAL

BASICS

OVERVIEW
- Uncommon tumor arising from the epithelial lining of the gastrointestinal tract.
- Prognosis guarded to poor.

SIGNALMENT
- Dog more commonly affected than cat.
- Middle-aged to older (>6 years) animals; age range 3–13 years.
- No breed predisposition.
- Possible male predisposition.

SIGNS

Historical Findings
- Stomach—vomiting, anorexia, weight loss, hematemesis, and melena.
- Small intestine—vomiting, weight loss, borborygmus, flatulence, and melena.
- Large intestine and rectum—mucus, blood-tinged feces, and tenesmus.

Physical Examination Findings
- Stomach—nonspecific, melena on rectal exam.
- Small intestine—may feel mid-abdominal mass; distended, painful loops of small bowel.
- Large intestine and rectum—palpable mass per rectum, may form annular ring, may have multiple nodular lesions protruding into the colon; bright red blood on rectal exam.

CAUSES & RISK FACTORS
- Unknown.
- Possible genetic cause—gastric adenocarcinomas in related Belgian shepherds and Dutch Tervuren shepherds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Foreign body.
- Inflammatory bowel disease.
- Lymphoma.
- Parasites.
- Leiomyoma.
- Leiomyosarcoma.
- Pancreatitis.

CBC/BIOCHEMISTRY/URINALYSIS
- Stomach and small intestine—may see microcytic, hypochromic, nonregenerative anemia (iron-deficiency anemia). Mild and persistent elevations in blood urea nitrogen in the face of normal creatinine can support GI protein or blood loss.
- Large intestine and rectum—no characteristic changes.

OTHER LABORATORY TESTS
Fecal occult blood may be positive; diet affects results—can recheck to confirm after 3 days of non-meat diet.

IMAGING
- Ultrasound—may reveal a thickened stomach or bowel wall; may see mass in the gastrointestinal tract, enlarged lymph nodes.
- Positive contrast radiography—filling defect (stomach); intraluminal space-occupying or annular constriction (small bowel); gastric neoplasm most often found in distal two-thirds of stomach.
- Double contrast radiography—large intestine and rectum; polypoid or annular space-occupying masses.
- Advanced imaging with contrast CT can provide highest-quality images of gastrointestinal tract and assessment for presence and extent of lymphadenopathy.

DIAGNOSTIC PROCEDURES
- Ultrasound-guided fine-needle aspirate of bowel mass or enlarged lymph node may provide definitive cytologic diagnosis.
- Endoscopic biopsy may be nondiagnostic because tumors are frequently deep to the mucosal surface; thus surgical biopsy often required.
- Presence of signet ring cells and/or cytoplasmic microvacuolation on cytologic evaluation of gastric biopsy squash prep samples correlated well with diagnosis of gastric adenocarcinoma in one study.

TREATMENT
- Surgical resection—treatment of choice; seldom curative.
- Gastric—usually nonresectable.
- Small intestine—remove by resection and anastomosis; metastasis to regional lymph nodes and liver common.
- Large intestine and rectal—may occasionally be resected via pull-through surgical procedure; metastasis common; transcolonic debulking may provide palliation of obstruction.

MEDICATIONS

DRUG(S) OF CHOICE
- Chemotherapy—only anecdotal reports, usually unsuccessful.
- Piroxicam 0.3 mg/kg PO q24h can provide palliation for large intestinal and rectal tumors.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Seek advice before initiating treatment with cytotoxic drugs.

FOLLOW-UP
Physical examination, thoracic radiographs, and abdominal ultrasound—at 1, 3, 6, 9, and 12 months post surgery.

EXPECTED COURSE AND PROGNOSIS

Dogs
- Overall poor; pedunculated rectal tumors do best; most cases recur locally, develop metastasis, or do both rapidly.
- Median survival gastric—2 months.
- Median survival small intestinal—10 months.
- Mean survival large intestinal—annular 1.6 months vs. pedunculated 32 months.

Cats
- Guarded.
- Few reported cases, but may have prolonged survival (>1 year).

Consulting Editor Timothy M. Fan

A

ADENOCARCINOMA, THYROID—DOGS

BASICS

DEFINITION
A malignant tumor arising from the follicular or parafollicular cells (medullary/C-cells) of the thyroid gland.

PATHOPHYSIOLOGY
• About 60% of patients are euthyroid, 30% hypothyroid, and 10% hyperthyroid. • Typically very invasive tumors with high rate of metastasis (lungs, retropharyngeal lymph nodes, liver), with up to 35–40% of dogs having metastasis at time of diagnosis. • Animals with bilateral tumors have a 16 times greater risk of developing metastatic disease than animal with unilateral tumors.

SYSTEMS AFFECTED
• Cardiovascular—hyperthyroid dogs are usually tachycardic and may have systemic hypertension. • Endocrine/metabolic—affected dogs may be hypothyroid, euthyroid, or hyperthyroid; hypercalcemia may be seen as a paraneoplastic syndrome or secondary to concurrent parathyroid hyperplasia or parathyroid adenocarcinoma. • Respiratory—dogs may be dyspneic owing to a space-occupying mass adjacent to the trachea; metastasis to the lungs common. Large compressive masses can result in caval syndrome manifested as facial edema. Compression and/or deviation of the trachea can lead to nonproductive cough.

GENETICS
Unknown

INCIDENCE/PREVALENCE
Accounts for 1.2–3.8% of all canine tumors and represents 10–15% of all primary head and neck tumors.

GEOGRAPHIC DISTRIBUTION
May be more common in iodine-deficient areas.

SIGNALMENT

Species
Dog

Breed Predilections
Boxers, golden retrievers, Siberian huskies, and beagles at increased risk, but seen in any breed.

Mean Age and Range
Older dogs (median 9–15 years; range 4–18 years).

Predominant Sex
No sex predilection.

SIGNS

General Comments
• Usually not diagnosed until a large mass is palpable. • Approximately 65% are unilateral, 35% are bilateral.

Historical Findings
• Palpable mass/swelling in cervical neck, coughing, dyspnea, dysphagia, dysphonia, facial edema, neck pain. • If functional thyroid tumor—may see polyuria, polydipsia, polyphagia, weight loss, restless behavior, diarrhea (symptoms associated with hyperthyroidism). • If hypothyroid—may see poor hair coat, weight gain, lethargy.

Physical Examination Findings
• Freely movable or fixed cervical mass, unilateral or bilateral. • Rarely may see Horner's syndrome, or cranial vena cava syndrome. • If hyperthyroid—cardiac arrhythmias or murmurs.

CAUSES
Unknown

RISK FACTORS
• Breed predilection.
• Iodine deficiency.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other primary neoplasms—lymphoma; soft tissue sarcoma; salivary gland adenocarcinoma; parathyroid carcinoma; carotid body tumor. • Secondary tumors—metastatic oral/tonsillar squamous cell carcinoma; oral melanoma. • Inflammatory—abscess or granuloma. • Salivary mucocele.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually normal. • May see nonregenerative normocytic normochromic anemia of chronic disease, leukocytosis. • Rare—hypercalcemia; isosthenuria.

OTHER LABORATORY TESTS
Thyroid hormone (T_4 and/or free T_4 levels) and endogenous thyroid-stimulating hormone (TSH) levels.

IMAGING
• Thoracic radiography (three-view)—evaluation of lungs and other thoracic structures for metastasis. • Cervical ultrasonography, CT, and MRI—evaluation of tissue of origin, vascularity, invasion, and cervical lymph nodes. • Technetium-99m scintigraphy to evaluate for ectopic and functional thyroid tissue or metastatic lesions. • Radioiodine studies—may provide information about the tumor's ability to produce thyroid hormone.

DIAGNOSTIC PROCEDURES

Biopsy
Tru-Cut® not recommended owing to high risk of severe hemorrhage; open biopsy usually required and allows for controlled hemostasis in the event of bleeding.

Cytology
• Examination of fine-needle aspirates from tumor and palpable regional lymph nodes. • Specimen almost always heavily contaminated with blood owing to highly vascular nature of tumor. • Homogeneous population of epithelial cells, sometimes with colloid and/or tyrosine-containing granules. Often, cell fragility leads to cell rupture and free nuclei. • Unable to differentiate malignant from benign thyroid cells; but almost all thyroid neoplasms in dogs are malignant.

PATHOLOGIC FINDINGS

Gross
• Characterized by high vascularity with areas of hemorrhage and necrosis. • Usually poorly encapsulated; often invade adjacent tissues (e.g., trachea and esophagus, and surrounding vasculature); may adhere to jugular vein, carotid artery, and vagosympathetic trunk.

Histopathology
• Thyroid follicular carcinomas are subclassified as well differentiated (follicular, compact, follicular–compact, or papillary), poorly differentiated, or undifferentiated—with follicular–compact and compact tumors most common in dogs. • C-cell (e.g., parafollicular, medullary) carcinomas less common. May need special stains to differentiate between C-cell and follicular carcinomas.

TREATMENT

APPROPRIATE HEALTH CARE
• Definitive treatment dependent on tumor stage (tumor size, mobility, and evidence of metastatic disease). • Complete surgical excision recommended for freely movable thyroid tumors. • Full course external beam radiation therapy recommended preoperatively for large tumors, as sole therapy for nonresectable tumors, or postoperatively for incompletely surgically removed tumors. • Palliative radiation and/or chemotherapy recommended for tumors that are metastatic at presentation. • Functional thyroid carcinomas can be treated with iodine-131, but doses are very large (60–100 mCi) and therefore there are limited facilities that offer this therapy. • Toceranib phosphate (Palladia®) can exert cytoreductive activity. • Isotretinoin 9-cis postoperatively may improve median survival time (MST) in follicular–compact and compact thyroid carcinoma.

NURSING CARE
Varies with signs on examination.

ACTIVITY
Restrict activity if dyspneic.

CLIENT EDUCATION
• Warn owners of importance of controlling heart rate and rhythm in hyperthyroid patients and of possibility of episodes of collapse. • Warn owners of possible postoperative laryngeal paralysis and intraoperative hemorrhage. • Warn owners of acute radiation therapy toxicities—moist desquamation, laryngitis, tracheitis, esophagitis.

SURGICAL CONSIDERATIONS
See Appropriate Health Care.

Risks
• Marked hemorrhage—tumors highly vascular and invasive into surrounding structures, including vasculature; may need blood transfusion and intensive postoperative care. • Laryngeal paralysis—owing to trauma to recurrent laryngeal nerve. • Damaged parathyroid glands—may occur during surgery.

MEDICATIONS

DRUG(S) OF CHOICE
• Chemotherapeutic agents: ○ Chemotherapy recommended as sole therapy, or possibly in combination with surgery and/or radiation therapy. ○ Cisplatin (60 mg/m^2 every 3 weeks), carboplatin (300 mg/m^2 every 3 weeks), or doxorubicin (30 mg/m^2 every 3 weeks)—reported to effect partial remission in approximately 50% of cases. ○ Toceranib (2.5–3 mg/kg 3 times a week)—had biologic activity in 80% of cases (26% partial remission, 53% stable disease). ○ Isotretinoin 9-cis (2 mg/kg/day)—potentially difficult to obtain in United States due to prescribing restrictions. • Thyroid management: ○ Thyroxine—maintenance doses to decrease TSH production have been recommended; some tumors contain TSH receptors; value of hormone replacement therapy in affected dogs not determined. ○ Methimazole 5 mg PO q8h for medium to large dogs; may be beneficial for hyperthyroid patients. ○ Beta blockers—may be indicated for tachycardia or hypertension in hyperthyroid patients.

CONTRAINDICATIONS
• Doxorubicin is cumulatively toxic to cardiac myocytes, causing decreased myocardial function; do not give to animals with poor cardiac function or dilated cardiomyopathy. • Cisplatin is nephrotoxic; do not give to animals with renal disease.

PRECAUTIONS
Chemotherapy can cause gastrointestinal, bone marrow, cardiac, and other toxicities—seek advice from medical oncologist if unfamiliar with cytotoxic drugs.

POSSIBLE INTERACTIONS
Verapamil—may potentiate doxorubicin-induced cardiotoxicity.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Serum calcium concentration—if bilateral thyroidectomy was performed; signs of hypocalcemia (agitation, panting, muscle tremors, tetany, and seizures) may be observed. ○ Treat with 10% calcium gluconate (1–1.5 mL/kg IV over 10–20 minutes). ○ Maintain serum calcium with dihydrotachysterol (vitamin D) orally and/or oral calcium supplementation if necessary. • Thyroid hormone—supplementation with thyroxine may be necessary after bilateral thyroidectomy. • TSH concentration—a goal of thyroxin supplementation is to down-regulate the body's secretion of TSH. • Site of primary tumor—physical examination and cervical ultrasound; thoracic radiographs every 3 months to detect pulmonary metastasis.

PREVENTION/AVOIDANCE
Unknown

POSSIBLE COMPLICATIONS
• Tumor—anemia; thrombocytopenia; hypercalcemia; respiratory distress. • Chemotherapy—dilated cardiomyopathy; renal failure; pancreatitis; sepsis; gastrointestinal upset. • Surgery—hemorrhage; hypothyroidism; hypoparathyroidism leading to hypocalcemia; laryngeal paralysis. • Radiotherapy—acute side effects: moist desquamation, pharyngeal mucositis, esophagitis, tracheitis; late side effects: hypothyroidism, alopecia, and skin or coat color change (at radiation site).

EXPECTED COURSE AND PROGNOSIS
• Prognosis—related to grade and stage of disease (tumor size, mobility, and evidence of metastatic disease) with small, low-grade, nonattached unilateral, nonmetastatic tumors having best prognosis. • MST after surgical removal of unilateral thyroid tumors is 1,462 days vs. 365 days for patients undergoing bilateral thyroidectomy. • For animals treated with full course external beam radiation therapy—progression-free survival at 1 year 80% and 72% at 3 years in one study, and in another study MST 24.5 months. • Palliative radiation therapy in 13 dogs—MST 24 months vs. 170 days in dogs with advanced disease. • ^{131}I therapy in combination with surgery—MST 34 months, or ^{131}I alone MST 30 months. • Animals treated with cisplatin alone (13 dogs)—overall response rate 53%, median progression-free interval for responders 202 days, and overall MST 98 days.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Nonthyroidal malignancies common.
• Multiple endocrine neoplasia reported.

AGE-RELATED FACTORS
None

PREGNANCY/FERTILITY/BREEDING
It is not recommended to breed animals with cancer. Chemotherapy is teratogenic—do not give to pregnant animals.

SYNONYMS
Thyroid carcinoma.

ABBREVIATIONS
• MST = median survival time.
• TSH = thyroid stimulating hormone.

A

AGGRESSION—BETWEEN DOGS IN THE HOUSEHOLD

BASICS

OVERVIEW

• Aggression toward other dog(s) within a household or with dogs that are familiar and spend time together regularly. • Dogs can form stable social relationships quickly, sometimes within minutes of being introduced. Aggression usually revolves around resources (e.g., food, toys, owner attention, resting places), but may be fear related or can occur at times of excitement/arousal (e.g., visitors or other dogs on the property). • Usually within the range of normal behavior, but may be excessive, abnormal, or related to underlying medical conditions.

SYSTEMS AFFECTED

Behavioral

INCIDENCE/PREVALENCE

Approximately 11%.

SIGNALMENT

Breed Predilections

• No breed or sex predilection. • Although genetic factors contribute, environment may play a stronger role in degree of aggression exhibited.

Mean Age and Range

Signs usually develop at social maturity (approximately 18–36 months of age).

Predominant Sex

May be more common/intense between intact males and females.

SIGNS

• Barking, growling, lip-lifting, snarling, snapping, lunging, biting, directed toward other dogs in the home. • Subtle communication signals between dogs may include blocking access to rooms or other resources, hard stare, taller stance, tail elevated, ears perked forward, and approaching/direct contact with other dog. • May be accompanied by fearful/submissive body postures/facial expressions (e.g., crouching, backing away, ears back, tail tucked, looking away, lip-licking). • Dogs fighting in a household may get along well except in specific trigger situations, especially resources, access to passageways/doorways, and at times of arousal. • Predictors of aggression—presence of owner; access to resources such as food, toys, spaces, and beds; periods of high arousal such as people entering the house.

CAUSES & RISK FACTORS

• Underlying medical conditions including pain, endocrinopathies, neurologic, and sensory decline. • May be normal canine behavior; can be strongly influenced by previous experience (e.g., early socialization, previous aggressive encounters with other dogs, inappropriate punishment) and other behavioral disorders such as anxiety; in some cases, one dog may not read or respond appropriately to other dog's body language. • Aggression likely to be more severe between dogs of equal size, age, and sex. • Owner's inability to read early signs of conflict between household dogs. • Owner's failure to create or maintain social stability and predictability in dogs' interactions and relationship with each other.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Status-related aggression. • Conflict-related aggression. • Play behavior/nonaggressive arousal. • Possessive aggression. • Protective aggression. • Fear aggression. • Pain-related aggression. • Irritable aggression. • Generalized anxiety disorder.

CBC/BIOCHEMISTRY/URINALYSIS

To rule out underlying medical conditions and as baseline prior to drug use.

OTHER LABORATORY TESTS

As needed to rule out underlying medical conditions; thyroid screening.

IMAGING

As needed to rule out underlying medical conditions, (e.g., pain); MRI if CNS disease suspected.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

CLIENT EDUCATION

General Comments

• Treatment requires a multifaceted approach, including immediate management to ensure safety and prevent recurrence, behavior modification, and medication (if indicated). • Successful treatment requires owner understanding of canine social behavior and communication, identification of all aggression-eliciting stimuli, risks involved in living with an aggressive dog(s), willingness and ability to follow safety and management recommendations, and effective implementation of reward-based behavior modification. • Realistic expectation is for managing triggers, most often for rest of dog's life and gradually improving, not resolving. • Owners must be aware that the only way to entirely prevent future injuries may be to continually separate dogs when no one is home, remove one of the dogs from the home, or use of safety equipment and constant supervision to safely manage when dogs are in same space. • Positive punishment and dominance-based training can lead to increased aggression, fear, and injuries, and must be avoided.

Safety Recommendations

• *Never* allow dogs to "fight it out," as serious injuries may occur. • Owners must ensure safety by identifying and avoiding all situations that may trigger aggressive interactions, such as when dogs are walking past each other in a confined space or being given attention or high-valued treats; the dogs may at least initially need to be kept physically separated to prevent agonistic encounters. • Owners must be instructed in methods of safely breaking up fights by never reaching toward the dogs' heads or necks to physically pull them apart; preferred methods include physical barrier deterrent (e.g., noise distractor, water, or deterrent spray) or leashes left constantly attached when dogs are together. • Owners should be advised of their liability for bites. • For treatment to be effective, aggression-provoking stimuli should be prevented prior to behavior modification. • At any time or place an aggression-evoking situation could arise (e.g., around food/valued resources), dogs must be confined away from each other or under direct physical control of a responsible adult; dogs can be separated by placing in separate rooms, with pet gates, exercise pens, or crates, or securely tethered short term to hooks installed in walls. • Tools for safety and management include head halters, basket muzzles, or harnesses with leashes attached for prevention, and to safely remove dogs from situations that may elicit aggression. • If safety cannot be ensured, it may be necessary to rehome dog to a single-dog household, where all triggers can be avoided.

Behavior Therapy

• Structured interaction programs (such as "Learn to earn" or "Say please by sitting"), where dog is taught to consistently perform a desired behavior (e.g., sit) before receiving anything it values (e.g., attention, food), give the dog control of its resources by being calm, provide structure and predictability in all interactions, teach impulse control, and train dog using positive interactions (e.g., good things happen by sitting calmly). • Separately, teach each dog behaviors that will serve as a foundation for management and control when together including sit and relax, down-settle, go to mat or crate, focus on owner (e.g., watch/look), and leave it; private sessions with force-free trainer can be the best option for achieving success. • Once each dog can reliably perform foundation and relaxation exercises, then owners can work with dogs together, separated by distance to ensure both dogs can remain focused or engaged in desirable behaviors (e.g., mat) that can be reinforced. • During times together, close supervision is needed; owners must be able to recognize body language and be vigilant for stimuli that might incite aggression; verbal cues should be used to prevent or interrupt undesirable behaviors and teach what is desirable; use of a leash attached to each dog with head halter or while wearing

basket muzzle will increase safety when dogs are in close proximity. • Use positive reinforcement (e.g., treats, toys, petting) to teach behaviors incompatible with those that lead to aggression (e.g., response substitution, differential reinforcement of alternative behavior). • Systematic desensitization and counter-conditioning to triggers—desensitization is a process by which dogs will be exposed to their triggers under their threshold; food, toys, verbal praise, or physical attention (e.g., petting) can be used to reward calm behavior. Counter-conditioning is a process in which positive associations are paired with each stimulus exposure, (e.g., most-valued treats); dogs should be exposed to each other under control of handlers and at distance at which they can remain calm and focused on their handlers while performing cued behaviors for rewards; gradually dogs can be moved closer in proximity to each other and in varied situations while focusing on handlers.

SURGICAL CONSIDERATIONS
Castration reduced intermale aggression in 62% of dogs.

MEDICATIONS

DRUG(S) OF CHOICE
• No medications licensed for treatment of canine aggression; owners must have informed consent of potential side effects and risks, and that use is off-label. • Owners need to understand that medication will not ensure safety and to follow all safety procedures. • Medications may be indicated for moderate to intense fear and anxiety, impulsivity, and reactivity. • Proper diagnosis with behavioral modification plan, including appropriate selection of behavioral drugs, leads to most successful outcomes.

Selective Serotonin Reuptake Inhibitors (SSRIs)
• Fluoxetine 0.5–2 mg/kg PO q24h.
• Paroxetine 0.5–1 mg/kg PO q24h.
• Sertraline 1–3 mg/kg PO q24h. • Side effects—sedation, irritability, gastrointestinal tract (GIT) effects, agitation; decreased appetite common and usually transient.

Tricyclic Antidepressants (TCAs)
• Clomipramine 1–3 mg/kg q12h (label-restricted for aggression). • Side effects—sedation, GIT effects, anticholinergic effects, cardiac conduction disturbances if predisposed, agitation.

For Situational or Adjunctive Use
Alpha-2 Agonists
• Clonidine 0.01–0.05 mg/kg PO PRN 1.5–2 hours before eliciting trigger, up to q8–12h. • Side effects—transient hyperglycemia, anticholinergic, hypotension, collapse, bradycardia, and agitation.

Serotonin 2a Antagonist/Reuptake Inhibitors
• Trazodone 2–5 mg/kg PO PRN prior to eliciting trigger, up to q8h—may titrate up to 8–10 mg/kg if no adverse effects; use cautiously at higher doses and when combining with other drugs that increase serotonin due to risk of serotonin syndrome. • Side effects—sedation, anorexia, ataxia, GIT effects, cardiac conduction disturbances, agitation.

Benzodiazepines
• Might be used to reduce anxiety prior to eliciting trigger. • Side effects—sedation, lethargy, ataxia, paradoxical excitement; may disinhibit aggression.

CONTRAINDICATIONS
Corticosteroids may cause or contribute to polyphagia, increased food guarding, and irritability.

PRECAUTIONS
Use caution, as any psychotropic medication may cause undesirable changes in behavior, including increased irritability and aggression.

POSSIBLE INTERACTIONS
Do not combine SSRIs, TCAs, or monoamine oxidase (MAO) inhibitors (e.g., amitraz, selegiline) and use cautiously or avoid with opioids, tramadol, or other medications that increase serotonin—can result in serotonin syndrome.

ALTERNATIVE DRUG(S)
Natural products—dog-appeasing pheromones, supplements containing alpha-casozepine or l-theanine, or a calming probiotic might be considered for mild to moderate anxiety or used adjunctively.

FOLLOW-UP

PATIENT MONITORING
• Clients will need ongoing assistance and should receive at least one follow-up within first 1–3 weeks after consultation. Provisions for further follow-up should be made at that time. • Drugs should only be prescribed under direct supervision and monitoring of veterinarian.

PREVENTION/AVOIDANCE
Safety and management recommendations are lifelong.

POSSIBLE COMPLICATIONS
Injuries to dogs and humans.

EXPECTED COURSE AND PROGNOSIS
• Lifelong management likely necessary.
• Prognosis for improvement depends on severity of aggression; motivation; whether triggers can be identified, avoided, and safely managed; and owner compliance; prognosis more favorable if triggers are predictable and preventable, and aggression occurs at low intensity. • Aggression may recur with change in routine, housing, or health, and increasing age.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Other fear- or anxiety-related conditions; possessive, redirected, and territorial aggression.

ZOONOTIC POTENTIAL
Human injury/bite wounds.

PREGNANCY/FERTILITY/BREEDING
Do not breed dogs that exhibit aggressive behavior.

SEE ALSO
• Aggression, Food and Resource Guarding—Dogs.
• Aggression, Overview—Dogs.
• Fears, Phobias, and Anxieties—Dogs.

ABBREVIATIONS
• GIT = gastrointestinal tract.
• MAO = monoamine oxidase.

A

AGGRESSION TO UNFAMILIAR PEOPLE AND UNFAMILIAR DOGS—DOGS

BASICS

OVERVIEW

• Aggression directed toward person or dog that does not live in the household. • Variety of motivations including fear, territoriality, conflict, and possessiveness. • Usually within range of normal behavior, but may be excessive or abnormal due to learning, early experiences, genetics, or underlying medical conditions.

SYSTEMS AFFECTED

Behavioral

INCIDENCE/PREVALENCE

Stranger-directed aggression represents 32.5% of canine behavioral referral caseload. May be skewed as many cases may go unreported.

SIGNALMENT

Breed Predilections

None

Mean Age and Range

• Any age. • Signs may begin to emerge as primary socialization wanes (12–16 weeks of age) or may arise or intensify at social maturity (18–36 months). • Genetic concerns and more guarded prognosis when signs arise before 12 weeks.

Predominant Sex

• May be overrepresented in males.
• Territorial aggression more common in intact males—initial signs usually present by 1 year.

SIGNS

• Barking, growling, lip-lifting, snarling, snapping, lunging, biting, directed toward other dogs or people. • Subtle communication signals may include blocking access to resources, hard stare, taller stance, tail elevated, ears perked forward, and approaching or direct contact. • May be accompanied by fearful/submissive body postures/facial expressions (e.g., crouching, backing away, ears back, tail tucked, looking away, lip-licking).
• Territorial aggression arises in familiar locations or spaces (e.g., home, yard, car) with confident body language. • Fear aggression more likely when dog is cornered or cannot escape. • May be more frequent or severe on-than off-leash, on own property, or when behind barrier (e.g., fence, pet gate, crate).

CAUSES & RISK FACTORS

• Underlying medical conditions, including pain, endocrinopathies, neurologic, sensory decline. • May be normal canine behavior. Strongly influenced by previous experience, (e.g., socialization, unpleasant outcomes/associations) such as previous fear-evoking or aggressive encounters with dogs or people, punishment, and other behavior disorders including fear, anxiety, and reactivity. • May begin as unruly or exuberant behavior or during leash (walk) training. Owner responses including leash corrections, verbal and/or physical punishment may increase fear, anxiety, and arousal, and condition further negative associations. • Owner's inability to read early signs of fear or conflict. • Owner's failure to create or maintain predictable pattern of positive interactions with unfamiliar people and dogs. • Fear of strangers.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Fear aggression. • Territorial aggression.
• Possessive aggression. • Protective aggression. • Conflict-related aggression.
• Generalized anxiety disorder. • Pain-related aggression. • Irritable aggression.

CBC/BIOCHEMISTRY/URINALYSIS

To rule out underlying medical conditions and as baseline prior to any drug use.

OTHER LABORATORY TESTS

As needed to rule out underlying medical conditions, including thyroid screening.

IMAGING

As needed to rule out underlying medical conditions, (e.g., pain); MRI if CNS disease suspected.

TREATMENT

CLIENT EDUCATION

General Comments

• Treatment requires a multifaceted approach including management to ensure safety and prevent recurrence, behavior modification, and medication. • Treatment must focus on managing the problem and gradually modifying behavior to reduce fear, anxiety, and aggression, not cure/full resolution. • Successful treatment requires owner understanding of canine social behavior and communication, risks, identification of all aggression-eliciting stimuli, how to implement safe management, and effective implementation of reward-based behavior modification. • Owners must be aware that the only certain way to prevent future injuries is avoidance of stimuli.
• Educate owners that use of physical or verbal punishment, confrontation, or establishing dominance (such as alpha rolls), and corrections with choke chains or prong collars, can lead to human injury, further negative associations with stimuli, increased fear, anxiety, and aggression, and disruption of human–animal bond.

Safety Recommendations

• Preventing or avoiding stimuli/triggers that evoke fear, anxiety, or aggression is essential to ensure safety, prevent further repetition and potential intensification of the problem, address pet welfare, and provide an environment in which pet can learn and desired outcomes can be achieved, prior to implementing behavior modification.
• Decrease or avoid visitors and unfamiliar dogs to the home. • Avoid walks at times or in locations where stimulus exposure might occur. On walks, maintain a 15 ft distance from other people and dogs. • Confine dog away from potential targets; stay below threshold, (e.g., distance, location); and ensure direct physical control of adult together with safety products if any possible exposure. • Confine territorial dogs to where they cannot see/hear visitors approaching territory before they become alerted or aggressive. Confine dogs for duration of visitor's stay inside house. • Safety measures include training dogs to wear a basket muzzle, use of head collars or harnesses with leashes attached, and confinement training (e.g., safe haven, closed doors, barricades) away from potential triggers. • Owners should be advised of their liability for bites. • Ensure that dog cannot escape through fencing or unlatched gates or doors. • If safety cannot be ensured, dog should be removed from household.

Behavior Therapy

• Structured interaction programs (such as "Learn to earn" or "Say please by sitting"), where dog is taught to consistently perform desired behavior (e.g., to sit) before receiving anything it values (e.g., attention, petting, feeding, going for a walk), give dog control of its resources for being calm, provide structure and predictability in all interactions, teach impulse control, and train dog using positive interactions (e.g., good things happen by sitting calmly). • Use positive reinforcement to train alternative desirable behaviors (e.g., response substitution) that can be used during stimulus exposure. • Train each behavior in neutral situations with most motivating rewards (e.g., treats, food, toys, petting) to achieve outcomes immediately and successfully in absence of stimuli, including a calm sit; go to bed or crate to settle; walk on loose leash; focus on owner for guidance using eye contact (e.g., watch, look); find it (e.g., move away for a reward); and hand target (e.g., touch nose to owner's hand). • Private sessions with force-free trainer are often recommended to achieve foundation basics before any exposure. • Behavior modification—desensitization (DS) is process by which dogs will be exposed to their triggers under their threshold and rewarded if remain calm. Counter-conditioning (CC) is process in which trigger or stimulus is paired with positive outcomes with each exposure.
• When owner can effectively keep dog calm and under control, and get desirable outcomes on cue in absence of stimuli, begin exposure by determining limit (e.g., distance, location,

person, dog) at which dog will orient but not yet react. Pair highest-value rewards with each exposure. • Gradually (baby steps) increase stimulus intensity, staying below threshold that will result in fear and/or aggression by decreasing distance, increasing distractions, or moving to more challenging environments. • Progress is slow (typically weeks to months). Carefully monitor body language to avoid setbacks. • Owners must always be vigilant for approach of stimuli that might incite fear or aggression. • Discuss whether referral to veterinary behavior specialist is recommended for counseling on risk assessment, prognosis, behavioral management, behavior modification, and medication use.

SURGICAL CONSIDERATIONS

Castration reduced aggression by at least 50% toward unfamiliar dogs in <20% of dogs and toward human territorial intruders in <10% of dogs. Castration reduced intermale aggression in 62% of dogs.

MEDICATIONS

DRUG(S) OF CHOICE

• No medications licensed for treatment of canine aggression. Owners must have informed consent of risks, potential side effects, and that medication use is off-label. • Medications may be indicated for moderate to intense fear, anxiety, impulsivity, and reactivity. • Ensure that owners understand risks of owning aggressive dog, that medication will not ensure safety, and that they follow safety procedures. • Proper diagnosis with behavioral modification plan, including appropriate selection of behavioral drugs, leads to most successful outcome.

For Ongoing Use

Selective Serotonin Reuptake Inhibitors

• Fluoxetine 0.5–2 mg/kg PO q24h.
• Paroxetine 0.5–1 mg/kg PO q24h.
• Sertraline 1–3 mg/kg PO q24h. • Side effects—sedation, irritability, gastrointestinal tract (GIT) effects, agitation; decreased appetite common and usually transient.

Tricyclic Antidepressants

• Clomipramine 1–3 mg/kg q12h (label-restricted for aggression). • Side effects—sedation, GIT effects, anticholinergic effects, cardiac conduction disturbances if predisposed, and increased agitation.

For Situational or Adjunctive Use

Alpha-2 Agonists

• Clonidine 0.01–0.05 mg/kg PO PRN 1.5–2 hours before eliciting trigger, up to q8–12h. • Side effects—transient hyperglycemia, anticholinergic, hypotension, bradycardia, and agitation.

Serotonin 2a Antagonist/Reuptake Inhibitors

• Trazodone 2–5 mg/kg PO PRN prior to eliciting trigger, up to q8h—may titrate up to 8–10 mg/kg if no adverse effects. Use cautiously at higher doses and when combining with other drugs that increase serotonin due to risk of serotonin syndrome. • Side effects—sedation, anorexia, ataxia, GIT effects, cardiac conduction disturbances, agitation.

Benzodiazepines

• May be used to reduce anxiety prior to eliciting trigger. • Side effects—sedation, lethargy, ataxia, paradoxical excitement, may disinhibit aggression.

CONTRAINDICATIONS

Corticosteroids can be contraindicated in food-aggressive dogs; could cause or contribute to polyphagia, resource guarding, and irritability.

PRECAUTIONS

Use caution—any psychotropic medication may cause undesirable changes in behavior, including increased irritability or aggression.

POSSIBLE INTERACTIONS

Do not combine selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants (TCAs), and monoamine oxidase (MAO) inhibitors (e.g., amitraz, selegiline) and use cautiously or avoid with opioids, tramadol, and other medications that increase serotonin—can result in serotonin syndrome.

ALTERNATIVE DRUG(S)

Natural products—dog-appeasing pheromones, supplements containing alpha-casozepine or l-theanine, or a calming probiotic might be considered for mild to moderate anxiety or used adjunctively.

FOLLOW-UP

PATIENT MONITORING

• Clients will need ongoing assistance with at least one follow-up within the first 1–3 weeks after consultation. Provisions for further follow-up should be made at that time.
• Drugs should only be prescribed under the supervision and monitoring of a veterinarian.

PREVENTION/AVOIDANCE

Safety and management recommendations are lifelong.

POSSIBLE COMPLICATIONS

Injuries to dogs and humans.

EXPECTED COURSE AND PROGNOSIS

• Resolution may not be achievable and lifelong management may be necessary.
• Prognosis based on whether triggers can be avoided to ensure safety and prevent recurrence, and whether improvement can be achieved with behavior modification and medication.
• Prognosis more favorable if aggression occurs at low intensity and in predictable situations.
• Prognosis dependent on owner compliance.
• Approximately 75% of dogs aggressive toward unfamiliar dogs could be around other dogs on leash after treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other fear- or anxiety-related conditions; possessive, redirected, and territorial aggression.

ZOONOTIC POTENTIAL

Human/dog injury and bite wounds.

PREGNANCY/FERTILITY/BREEDING

Do not breed dogs that exhibit aggressive behavior.

SEE ALSO

• Aggression, Food and Resource Guarding—Dogs.

A

AGGRESSION TOWARD CHILDREN—DOGS

BASICS

OVERVIEW
Children are the most frequently reported victims of dog bites and tend to be injured more severely than adults.

SIGNALMENT
Dogs of any breed, age, sex, and neuter status.

Breed
• Breeds vary with demographics. Breed identification may be unreliable. • Breeds most commonly presenting to a behavior referral service that had bitten a child include English springer spaniel, German shepherd, Labrador retriever, Golden retriever, and American cocker spaniel. • Most fatal attacks (rare) are attributed to Rottweilers, pit bulls, and their mixes. • Larger dogs may be more likely to inflict severe injury. • Smaller breeds can also be dangerous and may invite inappropriate handling by children.

Sex
• More frequent in males than females. • Unneutered males are overrepresented in severe bites. • Neutering will not significantly reduce the risk.

Age
• Any age, but more frequent at or beyond social maturity (2+ years). • Risk may increase in geriatric dogs because of pain, sensory impairment, or cognitive decline.

SIGNS
Aggression

CAUSES & RISK FACTORS

Clinical Categories/Motivation
• Fear related. • Pain related. • Play related. • Conflict related. • Predatory behavior. • Territorial. • Resource guarding.

Dog-Associated Risk Factors
• Disease and associated irritability. • Pain-related aggression and resource guarding are the most common reasons for bites to familiar children <6 years old. • Anxiety. • Fear. • Dog lying down, particularly under or on furniture. • Parent/littermate aggression. • History of growling, snapping, biting.

Environmental/Social Risk Factors
• Younger children most likely bitten by the family pet or other familiar dogs. • Presence of infants (risk of predatory attacks). • Presence of young children. • Presence of food, edible toys. • Punishment-based training triggering defensiveness. • Inadequate supervision by parents/caregivers. • Hugging, kissing, or bending over anxious, fearful, conflict-aggressive, or resource-guarding dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
See Causes & Risk Factors.

CBC/BIOCHEMISTRY/URINALYSIS
To rule out medical contributing factors.

OTHER LABORATORY TESTS
Anecdotal evidence correlates hypothyroidism with increased aggression; however, no data-based evidence exists.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Detailed history of the bite event and the behavior of both dog and child to determine motivation or trigger. • Pain assessment.

TREATMENT

SAFETY WITH FAMILIAR DOGS
• Never leave infants or young children unsupervised with dogs. Securely separate infants from dogs when alone, even if both asleep. • If one adult is present, separate dog from young children. • If more than one adult is present, assign responsibility for one adult to dog, and one to child. • Educate owners to read and recognize canine communication signals and triggers. • Do not allow child to approach or interact with dog when dog is lying down or in possession of resources. • Separate dog when eating or chewing valued items. • Do not allow child to hug, kiss, bend over, or lie down beside dog.

SAFETY WITH UNFAMILIAR DOGS
• Do not tether unsupervised. • Do not allow young children to interact with unfamiliar dogs. • Securely lock gates in yards. • Avoid underground electric fences that do not prevent entry of children into yard or escape of dogs.

BEHAVIOR MODIFICATION
• Establish secure, separate "safe haven" for dog. • Restrict fearful or reactive dog on lead and offer food at safe distance from children, to turn a negative situation into a positive one. • Do not rely on training alone; safety requires prevention. • Redirect dog's attention: teach "look" or "touch" cues. • Consider positive conditioning to basket muzzle; however, supervised interactions are still essential, as muzzles do not insure safety. • Avoid punishment, which may increase anxiety and aggression.

MEDICATIONS

DRUG(S) OF CHOICE
May be indicated for dogs with generalized or situational anxiety or fearful behavior.

Selective Serotonin Reuptake Inhibitors (SSRIs)
• Fluoxetine 0.5–2.0 mg/kg q24h. • Sertraline 0.5–4 mg/kg q24h or divided q12h. • Paroxetine 0.5–1.5 mg/kg q24h.

Tricyclic Antidepressants (TCAs)
• Clomipramine 1–3 mg/kg q12h.
Natural products containing alpha-casozepine, l-theanine, calming probiotic, or a dog-appeasing pheromone may aid in reducing anxiety.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Psychotropic medication can increase agitation and anxiety or disinhibit aggression. Use with safety recommendations to prevent bites. • Avoid SSRI or TCA in combination. ◦ Use cautiously or avoid with any drugs that increase serotonin. ◦ Avoid use of SSRI or TCA + monoamine oxidase inhibitor (MAOI), including amitraz.

FOLLOW-UP

PREVENTION/AVOIDANCE
• Do not rely on training alone to eliminate aggression. • Preventive measures are most important in management of aggression to children. • Even well-trained, socialized dogs may bite.

POSSIBLE COMPLICATIONS
• Family may not recognize or acknowledge risks. • Disease may aggravate aggression. • Family may not be compliant. • Psychotropic drug may be unrealistically relied upon or ineffective. • Access of young children to dog may be difficult to control.

EXPECTED COURSE AND PROGNOSIS
• Aggressive behavior can often be reduced and controlled, but not "cured." Lifetime compliance is needed. • Prognosis is poor if social/physical environment cannot be controlled. • In some cases it may be necessary to rehome or euthanize dog, while in some dogs behavior may improve as child grows older.

MISCELLANEOUS

ABBREVIATIONS
• MAOI = monoamine oxidase inhibitor. • SSRI = selective serotonin reuptake inhibitor. • TCA = tricyclic antidepressant.

Suggested Reading

AGGRESSION TOWARD FAMILIAR PEOPLE—DOGS

BASICS

OVERVIEW

• Aggression directed toward household members or people with an established relationship with the dog, often in situations when they are handling or attempting to interact with the dog, or involving access to certain resources. • Variety of motivations including fear, protective, conflict, and possessiveness. • Usually within range of normal behavior, but may be excessive, abnormal, or related to underlying medical conditions.

SYSTEMS AFFECTED

Behavioral

INCIDENCE/PREVALENCE

• Approximately 7%. • Represents 20–44% of behavioral referral caseloads may be skewed as many cases unreported. • Bites from larger dogs may require medical attention, therefore more likely documented.

SIGNALMENT

Breed Predilections

• Behavior is a result of interplay between ontogeny and phylogeny. • Environmental stimuli may play a more critical role in aggression. • May be increased occurrence in related dogs. • May be genetic factors associated with impulse dyscontrol in English springer spaniel and English cocker spaniel; more common in conformation lineage than field lineage in English springer spaniels. • In other breeds, dogs bred for show may be associated with less aggression.

Mean Age and Range

• Usually manifested by social maturity (12–36 months of age). • Genetic concerns and poorer prognosis if signs arise before 12 weeks.

Predominant Sex

May be overrepresented in males (castrated and intact).

SIGNS

• Barking, growling, lip-lifting, snarling, snapping, lunging, biting, directed toward familiar people. • Subtle communication signals may include blocking access to resources, hard stare, taller stance, tail elevated, ears perked forward, and approaching or direct contact. • May be accompanied by fearful/submissive body postures/facial expressions (e.g., crouching, backing away, ears back, tail tucked, looking away, lip-licking). • May be more frequent when handled or approached when resting, avoiding, or hiding (e.g., under furniture) or grabbing (e.g., collar). • Protective or possessive aggression arises in vicinity of highly valued objects/space or people. • Fear aggression can be defensive or offensive and more likely to occur when cornered or cannot escape.

CAUSES & RISK FACTORS

• Underlying medical conditions including pain, endocrinopathies, neurologic, and sensory decline. • May be normal canine behavior; can be strongly influenced by previous experience (e.g., socialization, early development, unpleasant outcomes including previous aggressive encounters, punishment), and other behavioral disorders such as fear, anxiety, and impulsivity. • Owner's inability to read early signs of fear or conflict. • Owner's failure to create or maintain predictable pattern of positive interactions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Fear/defensive aggression. • Territorial aggression. • Possessive aggression. • Protective aggression. • Conflict-related aggression. • Generalized anxiety disorder. • Pain-related aggression. • Irritable aggression.

CBC/BIOCHEMISTRY/URINALYSIS

To rule out underlying medical conditions and as baseline prior to drug use.

OTHER LABORATORY TESTS

As needed to rule out underlying medical conditions; thyroid screening.

IMAGING

As needed to rule out underlying medical conditions (e.g., pain); MRI if CNS disease suspected.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

CLIENT EDUCATION

General Comments

• Treatment requires multifaceted approach, including immediate management to ensure safety and prevent recurrence, behavior modification, and medication (where indicated). • Realistic expectation is for managing triggers, most often for rest of dog's life, and gradually improving, not resolving, the problem. • Successful treatment requires owner understanding of canine social behavior and communication, identification of all aggression-eliciting stimuli, willingness and ability to follow safety and management recommendations, and effective implementation of reward-based behavior modification. • Educate owners that use of physical or verbal punishment, confrontation, or establishing dominance such as with alpha rolls, and corrections with choke chains or prong collars, can lead to human injury, further negative associations with the stimuli, increased fear, anxiety and aggression, and disruption of human–animal bond.

Safety Recommendations

• Owners must ensure safety by identifying and avoiding situations that may evoke fearful or aggressive response; identification and avoidance of triggers is essential to ensure safety, for pet welfare, and to provide environment in which pet can learn and desired outcomes be achieved, prior to implementing behavior modification. • Safety measures include training to wear a basket muzzle, use of head collars or harnesses with leashes attached, and use of confinement training and barriers (e.g., safe haven, gates, closed doors) to keep dog from triggers and triggers from dog. • Owners should be advised of their liability for bites. • Treatment more likely to be successful if aggression-provoking stimuli can be effectively prevented prior to behavior modification. • Common triggers include handling or moving dog when on furniture or resting, use of physical punishment, touching painful areas, and removing valued items; this can be managed by keeping dog away from areas/furniture, when using physical punishment, using pain control and taking dog to veterinarian for uncomfortable procedures, and not to give (or confine when giving) valued items. • If safety cannot be ensured, dogs should be removed from household and euthanasia considered if prognosis poor for safe rehoming.

Behavior Therapy

• Structured interaction programs (such as "Learn to earn" or "Say please by sitting") where dog is consistently taught to perform a desired behavior (e.g., sit) before receiving anything it values (e.g., attention, petting, feeding, toys) give dog control of its resources for being calm, provide structure and predictability in all interactions, teach impulse control, and train dog using positive interactions (e.g., good things happen by sitting calmly). • Use positive reinforcement to teach alternative desirable behaviors that are incompatible (e.g., response substitution) with those that have resulted in aggression. • Teach each behavior in neutral situations using most motivating rewards (e.g., food, toys, play, attention), including sit and relax on verbal cue; down-settle; go to bed or crate; focus on owner (e.g., watch/look), and hand targeting (e.g., touch nose to owner's hand). Private sessions with force-free trainer often recommended to achieve foundation basics before any exposure. • Behavior modification—desensitization is process by which dogs are exposed to triggers under their threshold; rewards should be given when calm (e.g., food, toys, verbal praise, or physical attention); counter-conditioning is process in which positive associations paired with exposure to stimulus, (e.g., most valued

A

AGGRESSION TOWARD FAMILIAR PEOPLE—DOGS (CONTINUED)

treats); operant counter-conditioning or response substitution is process in which acceptable alternative behaviors that are incompatible with undesirable behavior are reinforced. • Reinforce your dog for being calm as family members approach or beyond threshold distance when in a location or in possession of an item that might trigger aggression; always use nonconfrontational techniques; start handling in nonpainful/sensitive areas. • Start by staying below threshold that would result in fear and/or aggression, then gradually (baby steps) increase stimulus intensity by decreasing distance, increasing distractions, or moving to more challenging environments. • Progress is slow (typically months); however, immediate safety and welfare can be achieved if triggers can be identified and prevented or avoided; owners should be counselled on reading and monitoring body language to identify thresholds and avoid setbacks. • Owners must always be vigilant for stimuli that might incite fear or aggression. • Discuss whether referral to veterinary behavior specialist is recommended for counseling on risk assessment, prognosis, behavioral management, behavior modification, and medication.

SURGICAL CONSIDERATIONS

Aggression may be lower in neutered animals, but opposite has also been reported.

MEDICATIONS

DRUG(S) OF CHOICE

• No medications licensed for treatment of canine aggression; owners must give informed consent that use is off-label and be advised of potential side effects and risks. • Medications are likely indicated for moderately intense fear and anxiety, impulsivity, and reactivity. • Ensure that owners understand risks in owning an aggressive dog, that medication will not ensure safety, and that they must follow safety procedures. • Proper diagnosis with behavioral modification plan, together with appropriate selection of behavioral drugs, leads to most successful outcome.

Selective Serotonin Reuptake Inhibitors

• Fluoxetine 0.5–2 mg/kg PO q24h.
• Paroxetine 0.5–1 mg/kg PO q24h.
• Sertraline 1–3 mg/kg PO q24h. • Side effects—sedation, irritability, gastrointestinal tract (GIT) effects, agitation; decreased appetite is common and usually transient.

Tricyclic Antidepressants

• Clomipramine 1–3 mg/kg q12h (label-restricted for aggression). • Side effects—sedation, GIT effects, anticholinergic effects, cardiac conduction disturbances if predisposed, agitation.

For Situational or Adjunctive Use

Alpha-2 Agonists

• Clonidine 0.01–0.05 mg/kg PO PRN 1.5–2 hours before eliciting trigger, up to q8–12h. • Side effects—transient hyperglycemia, anticholinergic, hypotension, collapse, bradycardia, agitation.

Serotonin 2a Antagonist/Reuptake Inhibitors

• Trazodone 2–5 mg/kg PO PRN prior to eliciting trigger, up to q8h—may titrate up to 8–10 mg/kg if no adverse effects. Use cautiously at higher doses and when combining with other drugs that increase serotonin due to risk of serotonin syndrome. • Side effects—sedation, anorexia, ataxia, GIT effects, cardiac conduction disturbances, agitation.

Benzodiazepines

• Might be used to reduce anxiety prior to eliciting triggers. • Side effects—sedation, lethargy, ataxia, paradoxical excitement, may disinhibit aggression.

CONTRAINDICATIONS

Corticosteroids may contribute to polyphagia, increased food guarding, and irritability.

PRECAUTIONS

Use caution, as any psychotropic medication may cause undesirable changes in behavior, including increased irritability or aggression.

POSSIBLE INTERACTIONS

Do not combine selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants (TCAs), or monoamine oxidase (MAO) inhibitors (e.g., amitraz, selegiline), and use cautiously or avoid with opioids, tramadol, or other medications that increase serotonin—can result in serotonin syndrome.

ALTERNATIVE DRUGS

Natural products—dog-appeasing pheromones, supplements containing alpha-casozepine or l-theanine, or a calming probiotic might be considered for mild to moderate anxiety or used adjunctively.

FOLLOW-UP

PATIENT MONITORING

• Clients will need ongoing assistance and should receive at least one follow-up within first 1–3 weeks after the consultation. Provisions for further follow-up should be made at that time. • Drugs should only be prescribed under supervision and monitoring of veterinarian.

PREVENTION/AVOIDANCE

Safety and management recommendations are lifelong.

POSSIBLE COMPLICATIONS

Injuries to humans.

EXPECTED COURSE AND PROGNOSIS

• Lifelong management is necessary.
• Prognosis for improvement determined by severity of aggression; motivation; whether triggers can be identified, avoided, and safely managed; owner compliance; and level that might be achieved with behavior modification and medication. • Prognosis more favorable if aggression occurs at low intensity and in predictable situations.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other fear- or anxiety-related conditions; possessive and redirected aggression, impulsivity, reactivity.

ZOONOTIC POTENTIAL

Human injury/bite wounds.

PREGNANCY/FERTILITY/BREEDING

Do not breed dogs that exhibit aggressive behavior.

AGGRESSION TOWARD HUMANS—CATS

BASICS

DEFINITION
Human-directed aggression in cats.

PATHOPHYSIOLOGY
- Most common causes for human-directed aggression in cats include play, fear/pain-related, redirected, maternal, and petting intolerance.
- Context contributes greatly when making correct diagnosis. For example, play aggression is likely to be seen in young, solitary cat, while pain-related/fear aggression is common behavior seen in clinic setting.

SYSTEMS AFFECTED
- Behavioral.
- Gastrointestinal—decreased appetite if fear and/or pain related.
- Hemic/lymphatic/immune—chronic stress effects on immune function.
- Ophthalmic—dilated pupils in response to autonomic nervous system stimulation.
- Skin/exocrine—may show displacement behaviors such as overgrooming.

GENETICS
No known genetic basis.

INCIDENCE/PREVALENCE
Aggression is second to inappropriate elimination for feline cases seen by veterinary behavior specialists.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT
- Cats of any age, sex/neuter status, breed can be affected.
- Play-motivated aggression more likely in juvenile, solitary cat.

SIGNS
- Play motivated—cat approaches its "victim," crouches in wait, stalks and chases; tail is twitching and ears are forward. Typically will attack moving target.
- Fear/pain related—ears back, body and tail lowered, piloerection, pupils dilated; may hiss and growl. Avoidance of person(s) who elicit aggression. Attacks if approached and/or cornered. Extreme cases: expression of anal glands, urination, and/or defecation. Hiding behavior.
- Redirected—cat highly aroused by stimulus and seeks out alternate target. Aggression can be very severe given cat's level of arousal.
- Maternal—usually predictable and self-limiting. Queen will act to protect her kittens.
- Petting intolerance—cat signals its "displeasure" by twitching its tail and skin when being petted in an undesired location and/or for too long. Ears usually back; mydriasis; may hiss and growl before turning to bite person.

CAUSES & RISK FACTORS
- Play motivated—lacking in opportunities for normal play: solitary cat, insufficient and/or inappropriate toys; history of owner using hands/feet to play with kitten and/or playing roughly with kitten.
- Fear—poor socialization with humans and/or feral living, aversive event associated with a person, or people in general.
- Pain related—medical/physical condition such as abscess, especially in indoor/outdoor cat.
- Redirected—occurs during interference in, or interruption of, situations that have caused cat to become aggressively aroused, such as cat fight (between familiar household cats), presence of a cat outside, or noise.
- Maternal—recent birth of litter.
- Petting intolerance—etiology unknown. Cats tend to groom each other on head/neck, so human petting of cat in other locations may contribute to aggressive reaction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
See Causes & Risk Factors.

CBC/BIOCHEMISTRY/URINALYSIS
- To rule out contributing medical conditions and screening prior to drug use.
- Urinalysis if concurrent inappropriate elimination or marking.

OTHER LABORATORY TESTS
Middle age/senior cats—thyroid profile.

IMAGING
If indicated based on clinical examination and/or suspected pain.

DIAGNOSTIC PROCEDURES
Thorough behavioral history, including description of cat's postures during aggression and injuries inflicted, context, presence of outside cats, early historical information, litter box use, food consumption, and hiding behaviors.

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
Only if health/medical issue diagnosed.

NURSING CARE
Only if health/medical issue diagnosed.

ACTIVITY
- Play motivated—cat should be provided with increased opportunity for appropriate play, either in the form of toys, human interaction, or additional housemate.
- Redirected—cat should be denied access to windows where outside cats can be seen.

DIET
Potential anxiolytic effects of "calming" diets (see Supplements).

CLIENT EDUCATION
- Play motivated—normal play behavior and importance of opportunities for appropriate play.
- Fear—avoidance of fear-inducing situations: ongoing exposure may worsen signs, cause severe stress, and compromise welfare.
- Redirected—addressing primary stimuli, such as outside cats.
- Maternal—normal maternal and kitten-protective behavior; same as for fear-motivated aggression.
- Petting intolerance—normal feline grooming patterns; observation of cat's warnings so that behavior does not escalate.

Behavior Modification Exercises

Desensitization and Counter-Conditioning (DS&CC)
- Desensitization—exposing cat to fear-inducing stimulus (scary person) at a low level so cat does *not* react fearfully or aggressively. Over time, intensity of stimulus is increased (i.e., distance between cat and stimulus is decreased) without causing fearful responses.
- Operant conditioning (response substitution)—rewarding cat with special treat, toy, grooming, petting, for relaxation.

Classical Conditioning (CC)
Classical counter-conditioning conditioning—pairing threatening stimulus (e.g., a person) with tasty treat, toy, petting; example: scary person = tuna fish.

MEDICATIONS

Short-term use of medication may be necessary to decrease overall levels of anxiety and reactivity in more severe cases.

DRUG(S) OF CHOICE

Azapirones
- Buspirone 0.5–1.0 mg/kg PO q12h.
- Most useful for fearful and withdrawn cats; decreases anxiety and may increase "self-confidence."
- Anecdotal reports of "increase in affection," therefore might be useful in severe cases of petting intolerance.
- Response noted in 1–2 weeks.

Selective Serotonin Reuptake Inhibitors (SSRIs)
- Fluoxetine, paroxetine, sertraline 0.5–1.5 mg/kg PO q24h.
- SSRIs must be given daily; may take 4–8 weeks to reach peak effects.

Tricyclic Antidepressants (TCAs)
- Amitriptyline 0.5–2.0 mg/kg PO q12–24h.
- Clomipramine 0.25–1.0 mg/kg PO q24h.

A

AGGRESSION TOWARD HUMANS—CATS (CONTINUED)

• TCAs must be given daily; may take 4–8 weeks to reach peak effects.

Benzodiazepines
• Alprazolam 0.125–0.25 mg/cat PO q8–24h.
• Diazepam 0.1–1.0 mg/kg PO q12–24h (rarely used due to potential hepatopathies).
• Can be given "as needed" for specific encounters with people inducing fear response and during DS&CC and CC sessions.
• Can be used in conjunction with azapirones, SSRIs, and TCAs.

CONTRAINDICATIONS/PRECAUTIONS/POSSIBLE INTERACTIONS

• None of drugs listed are approved for use in cats.
• All medications to be administered orally, as have not been shown to reach therapeutic levels by transdermal dosing.
• Azapirones—side effects uncommon, but occasional excitement noted; should not be given in combination with monoamine oxidase (MAO) inhibitor; avoid use in the aggressor cat as may increase any "bully" behavior.
• Neither SSRIs nor TCAs should be given with each other, nor in combination with MAOIs.
• SSRIs—side effects include mild sedation and decreased appetite, constipation, and urinary retention; competitive inhibition of cytochrome P450 liver enzymes; when administered concurrently with medication utilizing P450 enzymes, elevated plasma levels of medications may increase.
• TCAs—side effects include sedation, constipation, diarrhea, urinary retention, appetite changes, ataxia, decreased tear production, mydriasis, cardiac arrhythmias, tachycardia, and changes in blood pressure.
• Benzodiazepines—side effects include sedation, ataxia, muscle relaxation, increased appetite, paradoxical excitation, and increased friendliness; idiopathic hepatic necrosis has been reported in cats following treatment with diazepam.
• Specific recommendations for the use of diazepam—baseline physical exam, CBC, and blood chemistries to confirm good health; repeat the blood chemistries at 3–5 days; if elevated alanine aminotransferase (ALT) or aspartate aminotransferase (AST), discontinue medication.

ALTERNATIVE DRUG(S)

Pheromones
• Used alone or concurrently with drugs.
• F3 facial pheromone (Feliway®) diffuser, spray, and wipes.
• Maternal pheromone—Feliway MultiCat (Friends) diffuser for feline social conflict.
• Maternal pheromone collar (NurtureCALM 24/7).

Supplements
Used alone or concurrently with drugs: L-theanine (Anxitane®); alpha-casozepine (Zylkene®); combination products also containing thiamine, whey protein, and calming plant extracts (Solliquin®); or diets supplemented with alpha-casozepine and l-tryptophan (Multifunction Urinary + Calm Diet, Royal Canin®).

FOLLOW-UP

PATIENT MONITORING
• Weekly follow-up recommended in early stages of treatment.
• For cats on medication, follow-up blood testing recommended every 6–12 months.

PREVENTION/AVOIDANCE
• Play motivated—provide opportunities for appropriate play.
• Fear—avoidance of fear-inciting stimuli; early socialization to people and events may help prevent some occurrences of fear-related responses to people.
• Pain—treat underlying conditions.
• Redirected—address possible arousing stimuli, indoors and outdoors.
• Maternal—as for fear.
• Petting intolerance—limit amount of time petting cat; DS&CC to petting.

POSSIBLE COMPLICATIONS
Potential human injury, especially if cat is approached, cornered, and/or highly aroused.

EXPECTED COURSE AND PROGNOSIS
• Progress occurs slowly; relearning is a process and each case is individual.
• If medications are indicated, begin at low dose and titrate up as necessary.
• To discontinue medication, wait until new behavior is stable (8–12 weeks) and wean off slowly, usually over weeks.
• If aggressive behavior recurs, return to lowest effective dose.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Play motivated—typically seen in young, solitary cat in household.

ZOONOTIC POTENTIAL
People injured during aggressive attack should seek prompt medical attention; infection by *Bartonella henselae* can result from cat scratch or bite.

PREGNANCY/FERTILITY/BREEDING
Avoid medications in breeding/nursing cats.

SYNONYMS
N/A

SEE ALSO
• Aggression, Overview—Cats.
• Fears, Phobias, and Anxieties—Cats.

ABBREVIATIONS
• ALT = alanine aminotransferase.
• AST = aspartate aminotransferase.
• CC = classical conditioning.
• DS & CC = desensitization and counter-conditioning.
• MAO = monoamine oxidase.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

AGGRESSION, FOOD AND RESOURCE GUARDING—DOGS

BASICS

OVERVIEW
• Aggression displayed while guarding food (e.g., in food bowl, dog "chews"), scavenged items, objects (e.g., toys, stolen objects), resting locations (e.g., bed, couch), or people. Usually within the range of normal behavior, but may be excessive or abnormal due to early experience, learning, genetic factors, or underlying medical conditions.

SYSTEM AFFECTED
Behavioral.

SIGNALMENT
No breed or sex predilections.

SIGNS
• Barking, growling, lip-lifting, snarling, snapping, lunging, biting, directed toward other dogs or people.
• Subtle communication signals may include blocking access to resources, hard stare, taller stance, tail elevated, and ears perked forward when in possession of valued resource.
• May be accompanied by fearful/submissive body postures/facial expressions (e.g., crouching, backing away, ears back, tail tucked, looking away, lip licking).
• Can be motivated by fear—defensive or offensive.
• Most common near valued resources (e.g., food), stolen items (e.g., tissues, owner clothing), scavenged items (e.g., garbage), and lasting items (e.g., chews).

CAUSES & RISK FACTORS
• Underlying medical conditions, especially pain, endocrinopathies, gastrointestinal disease, or those causing changes in appetite.
• May be a normal canine behavior, influenced by previous negative experience (e.g., lack of socialization, physically removing resources, punishment or confrontation) or other behavioral disorders, such as anxiety.
• Owner's inability to read and recognize signs of fear or conflict.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Fear aggression.
• Social status aggression.
• Conflict-related aggression.
• Generalized anxiety disorder.
• Pain-related aggression.
• Irritable aggression.

CBC/BIOCHEMISTRY/URINALYSIS
To rule out underlying contributing medical conditions.

OTHER LABORATORY TESTS
As needed to rule out underlying medical conditions, particularly if signs of polyphagia; thyroid screen.

IMAGING
As needed to rule out underlying medical conditions, (e.g., pain); MRI if CNS disease suspected.

DIAGNOSTIC PROCEDURES
Gastrointestinal diagnostics.

TREATMENT

GENERAL COMMENTS
• Treatment consists of a multifaceted approach including management to ensure safety and prevent recurrence, behavior modification, and medication (if indicated).
• A realistic expectation is for successful management, not full resolution. In most cases, owners will need to manage triggers for the rest of the dog's life.
• Successful treatment depends on the owner's understanding of canine social behavior and communication, identifying and preventing all aggression-eliciting stimuli (e.g., situations, people, resources), willingness and ability to follow safety recommendations, and effective implementation of reward-based behavior modification.
• Owners must be educated about the risks of using physical punishment and training techniques that use "dominating," such as alpha rolls, corrections with choke chains or prong collars, verbal punishment, and of physically taking away resources that can lead to increased aggression, anxiety, and resource guarding, and disruption of the human–animal bond.

SAFETY RECOMMENDATIONS
• Prevention/avoidance is essential to ensure safety, address the pet's welfare, and prevent further repetition and potential intensification of the problem.
• Safety measures include training dogs to wear a basket muzzle, placing head collars or harnesses with leashes attached, and the use of pet gates and confinement training to prevent access to resources that might be guarded.
• Confine the dog away from potential victims and items and/or keep people away from the dog when it is in possession of resources that might be guarded; alternately, the dog must be under direct physical control, (e.g., with leash attached), of a responsible adult.
• Identify and prevent or avoid any situation that might trigger aggression. Never forcibly remove objects in the dog's possession. Wait until the dog is finished with the resource and will walk away, or cue and reward the dog for an alternative behavior, (e.g., drop, touch) (see training below).
• If the dog is in possession of an object that must be removed for safety, offer a reward (e.g., treat, toy, walk) of higher value or use a stimulus (e.g., doorbell) that will move the dog away.
• If safety cannot be ensured, the dog should be removed from the household.

BEHAVIOR THERAPY
• Structured interaction programs where the dog is taught to consistently perform a desired behavior (e.g., sit) before receiving anything it values (e.g., attention, petting, treats, going for a walk) give the dog control of its resources for being calm, provide structure and predictability in all interactions, teach impulse control, and train the dog using positive interactions (e.g., good things happen by sitting calmly).
• Provide sufficient outlets for play, chew, and feeding, such as in food-filled toys in locations and at times where the dog can be left alone or physically confined, (e.g., to a room, behind a barrier, or in a safe haven (pen, crate)) until the dog finishes with the resource, will walk away, or can be cued away and rewarded.
• Training—focus on teaching behaviors in neutral situations using positive reinforcement (e.g., food, toys, play, petting) that can be used to:
  ◦ Keep the dog away from resources, (e.g., leave it, go to bed or crate, or watch).
  ◦ Move the dog away from resources, (e.g., touch (hand target), find it).
  ◦ Release the object (e.g., drop).
• Private sessions with a force-free trainer may provide the best guidance for successful training.
• Behavior modification—desensitization (DS) is the process by which dogs are exposed to their triggers under their threshold (e.g., distance, low-value resource). Food, toys, verbal praise, or attention/petting can be used as rewards for calm responses. Counter-conditioning (CC) is the process in which favored rewards are paired with the stimulus to change the emotional response to one that is positive.
• Gradually (baby steps) increase stimulus intensity, staying below the threshold that would result in fear and/or aggression, (e.g., decreasing distance, increasing resource value, changing environments).
• The owner can toss treats when walking by the food bowl at sufficient distance that the pet associates approach with a positive outcome in association with the food bowl and toys.
• Progress is slow (typically months). Carefully monitor body language to avoid setbacks.
• Owners must be vigilant to prevent approach in situations where dog might guard.

A

AGGRESSION, FOOD AND RESOURCE GUARDING—DOGS (CONTINUED)

• Discuss referral to a veterinary behavior specialist where recommended for assessment and counseling.

MEDICATIONS

DRUG(S) OF CHOICE

• Medications are generally not indicated for resource guarding.
• May be indicated for moderate to marked fear or anxiety, or when behavior is abnormal in intensity, reactivity, or impulsivity.
• Owners must receive informed consent of potential risks and side effects, that the use of a medication is off-label, and that medication does not insure safety.
• For ongoing medication, a selective serotonin reuptake inhibitor (SSRI; e.g., fluoxetine, paroxetine, sertraline) or clomipramine might be indicated.
• For situational or as needed use, trazodone, clonidine, or benzodiazepines might be considered alone or in conjunction with an ongoing medication.
• For doses, side effects, precautions, and contraindications, see Aggression toward Familiar People—Dogs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Use caution, as any psychotropic medication might cause undesirable changes in behavior, including increased irritability and aggression. Drugs that increase appetite (e.g., psychotropic drugs, steroids) may increase resource guarding.
• Corticosteroids can be contraindicated in food-aggressive dogs; could cause or contribute to polyphagia, resource guarding, and irritability.

FOLLOW-UP

PATIENT MONITORING

In most cases, follow-up should be within the first 1–3 weeks after consultation. Provisions for further follow-up should be made at that time.

PREVENTION/AVOIDANCE

Owner should receive counseling from first visit on socialization, making positive associations with handling, reward-based training to cues (including touch and drop), and never forcing a pet to relinquish resources.

POSSIBLE COMPLICATIONS

Injuries to dogs and humans.

EXPECTED COURSE AND PROGNOSIS

• Resolution may not be achievable and lifelong management is usually necessary.
• Prognosis for improvement depends on severity of aggression, number and type of resources guarded, and whether they can be effectively identified and prevented.
• Prognosis is highly dependent on owner compliance.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other fear- or anxiety-related conditions.

ZOONOTIC POTENTIAL

Human injury and bite wounds.

PREGNANCY/FERTILITY/BREEDING

Do not breed dogs that exhibit aggressive behavior.

SEE ALSO

• Aggression to Unfamiliar People and Unfamiliar Dogs—Dogs.
• Aggression toward Familiar People—Dogs.

BASICS

DEFINITION
Intercat aggression—offensive or defensive aggression between cats consisting of staring, displacing, vocalizing (growling, yowling, shrieking), spitting, hissing, swatting, lunging, chasing/stalking, and/or biting other cats.

PATHOPHYSIOLOGY
• May be normal behavior or abnormal. • May be caused by underlying medical disease (e.g., CNS) or concurrent medical disease that may lower the threshold for irritable responses (e.g., pain, hyperthyroid). • May be multiple motivations including predatory/play, disputes over territory, sexual, fear, anxiety, and redirected, fear, anxiety, non-recognition, and redirected.

SYSTEMS AFFECTED
• Behavioral. • Skin/exocrine—secondary to traumatic injury. • Immune—chronic stress may alter the immune response. • Secondary infection (cat bite abscesses) is not uncommon. • Nervous.

GENETICS
None. However, friendliness may be mostly related to paternal effects.

INCIDENCE/PREVALENCE
Unknown

SIGNALMENT

Breed Predilections
None

Mean Age and Range
• Can occur at any age due to changes in social environment or be redirected. • Previously stable relationships can deteriorate as cats reach social maturity (2–4 years of age).

Sex
• Intact males more likely to initiate intercat aggression (related to territory, and/or proximity to females). • Females will defend their young from unfamiliar individuals. • Male kittens more likely to initiate intercat aggression related to predatory components of play.

SIGNS

Historical Findings
• May arise spontaneously and vary in frequency and intensity. • Owners most likely to seek behavioral intervention if there are physical injuries, the welfare of the aggressor and/or victim is compromised, or fighting becomes sufficiently distressing. • Human attempts to interrupt fighting may trigger human-directed aggression/injury.

Aggressor (Usually Offensive)
• Covert signs—staring, displacing other cats, stiff body language/movements while approaching other cat. • Overt signs—growling, yowling, spitting, hissing, swatting, lunging, chasing/stalking, and/or biting other cats, dilated pupils, may be accompanied by body language of fear (e.g., classic Halloween cat stance: piloerection, back arched, tail up) or more offensive body language (tense muscles, tail head elevated but rest of tail down, back straight or slightly slanted toward head, ears forward or to the side), excessive facial marking, and perhaps urine marking.

Victim (Usually Defensive)
• Covert—avoidance of aggressor, hiding, change in grooming and eating habits, hypervigilance, dilated pupils. • Overt—hissing, swatting, running, vocalizing (including growling), Halloween cat stance, may escalate to defensive attack if cornered.

Elimination Outside of Litter Box
• Aggressors may block access to litter box area, forcing victims to choose alternative locations; secondary substrate and/or location preferences and aversions can develop. • Both victims and aggressors may urine mark. • Extremely fearful cats may urinate or defecate in midst of aggressive events.

Physical Examination
• Normal, except injury from fights or if underlying medical issues. • Stress may affect eating and self-grooming (increased or decreased).

CAUSES
• Lack of appropriate socialization to other cats prior to 7 weeks of age. • May be component of normal social behavior. • Social and environmental instability such as addition of new cat, loss of resident cat, odor stimuli (return of cat from veterinarian or giving one cat a bath), aging or illness of one or both cats, cats reaching social maturity. • Household change, e.g., moving, changing furniture or resting areas. • Genetically unrelated cats and cats that have recently moved in together are more likely to show aggressive behaviors toward each other. • Resident cats commonly need prolonged exposure to new cats before accepting them into group. • Resource limitation, e.g., vertical and/or horizontal space, hiding/resting areas, food, water, and litter boxes in multicat households. • Exposure to arousing stimuli (cats in yard, visitors, noises, scents, etc.) can cause redirected aggression, after which aggression might persist. • Medical problems including CNS disorders, hyperthyroidism, or any disorder that causes pain and/or increased irritability.

RISK FACTORS
• Singleton and/or bottle-raised kittens. • Lack of socialization exposure and experience with conspecifics during socialization period (2–7 weeks) and beyond. • Male intact cats. • Postpartum females with kittens. • Separating and returning housemate (e.g., following veterinary visit, groomer). • Changes in social group such as addition of "new" cat. • Scratching and biting during first introduction. • Access to outdoors and/or intrusion of unfamiliar cats onto territory. • Crowding or lack of adequate social space and access to resources.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Behavioral Differentials
• Fear-related aggression—cat may hiss, spit, arch the back, display piloerection, and attempt to flee unless escape is thwarted; pupil dilation will accompany a fear response. • Status-related aggression—may occur with change or instability of social hierarchy and control of access to resources; it is undecided if cats have dominance hierarchies or if conflict is better explained by territorial defense. • Territorial aggression—in response to threat to territory; boundaries marked with urine, feces, or scent glands. • Redirected aggression—exposure to agitating stimuli (cats in yard, visitors, noises, scents, etc.), with aggression directed toward target other than stimulus. • Failure of recognition—aggression between feline housemates after returning from separation (e.g., veterinary visit, grooming); most likely due to change in odor, visual cues, or stress of returning cat. • Maternal aggression—aggression during periparturient period; females guard kittens and nesting sites. • Intermale aggression—between males in response to territorial disputes, hierarchical status, or mates; may be more pronounced at social maturity. • Sexual aggression—male typical behavior of chasing, pouncing, biting on nape of neck, and mounting. • Predatory/play-related aggression—predatory components of play directed toward another cat; recipient often older cat that is not interested in playing.

Medical Differentials
• Any illness causing malaise, pain, or increased irritability. • Endocrine—e.g., hyperthyroidism. • Neurologic—e.g., neoplasia, seizures, cognitive decline. • Infectious—e.g., toxoplasmosis, feline immunodeficiency virus (FIV), feline leukemia virus (FeLV). • Iatrogenic—medications that increase irritability or disinhibit aggression (e.g., mirtazapine, benzodiazepines, buspirone). • Toxins—lead, illicit substances.

CBC/BIOCHEMISTRY/URINALYSIS
To rule out medical causes and as baseline if drug therapy indicated.

OTHER LABORATORY TESTS
• FeLV/FIV. • Total thyroxine (T_4) in cats >6 years.

A

AGGRESSION, INTERCAT AGGRESSION (CONTINUED)

IMAGING
As indicated based on history and physical signs.

DIAGNOSTIC PROCEDURES
• Detailed behavioral and medical history. • Identify if there is a clear aggressor and/or victim and if aggression is overt or covert. • If multiple cats, determine which cats spend time together and mutually groom, and which avoid each other. • Identify preferred core areas of each cat for feeding, play, and resting, and locations of any house soiling or marking. • Identify number, location, types of litter boxes, and their management. • Videos, photographs, and/or drawn floor plans can provide spatial details and information regarding body language during social interactions. • Note any other changes in demeanor, routine, eating, and grooming.

PATHOLOGIC FINDINGS
None unless concurrent medical diseases.

TREATMENT

APPROPRIATE HEALTH CARE
Treat as outpatient.

NURSING CARE
Supportive care if any injuries.

ACTIVITY
• May need to be restricted if confinement required to prevent perpetuation of aggression and negative emotional responses. • Provide sufficient alternate outlets for each cat during confinement and during release.

CLIENT EDUCATION
For chronic, severe cases or for aggression that does not respond to treatment, may require permanent separation, either by rehoming one of the cats or by confining them in separate parts of the home.

Cases with Low Frequency of Intense, Injurious Aggressive Outbursts
• Separate cats when they cannot be supervised (create "safe zones"). • Either keep separate in same areas each day in effort to form separate core territories for each cat, or "time share" space between cats. • Confine newly introduced cat or aggressor to smaller, less familiar area. • For multiple cats, separate by stability of relationship between cats. Any despotic/bully cats should be confined alone. • Consider "artificial allomarking" to form communal scent between cats that are fighting; a towel (facecloth) may be rubbed (cephalocaudally) to obtain scent of one cat and then rubbed onto other cat, and vice versa. • Towels should be left in environment to allow for habituation to each other's scent, especially if cats are kept separated. • Reward cats with food, play, and/or attention for being in same room together without having aggressive events. Cats should stay at a distance that allows for calm participation. • Engage cats in daily sessions of pleasurable activities (e.g., play, training, eating delectable food treats) at distances that do not incite aggression. Gradually move fun sessions closer to each other, making sure to stay at a distance that does not trigger overt/covert aggression. • Teach cats a "come and/or go to place" cue using positive reinforcement at times, in situations, and with sufficient rewards that cats are most able to learn. • Interrupt or redirect cats by cueing to come or go to their place, or by luring one or both cats to their safe zones with food, treats, wand toys, tossed toys, or laser pointers before aggression starts or as initial signs are seen (e.g., staring, tail twitching, pupil dilation). • Aversives and/or punishers can increase aggressive behavior and increase negative associations with other cats, so must be avoided. • Goal of management and safety is to prevent aggressive events. In an emergency, use of laundry basket or blanket placed between or over cats can stop aggression, and direct cat to its safe area until calm, but should not be considered as a standalone treatment. • Bell the aggressor (using quick release or safety collar) so both owners and victim can quickly identify his or her location. • Increase number of resources and locations (e.g., food, water, scratching, perching, bedding, play and feeding toys) throughout the residence, including each cat's core area. Efficacy of multimodal environmental enrichment should not be underestimated. • Increase litter boxes to number of cats plus one divided among multiple locations, so that one cat cannot keep another from accessing boxes; locations with more than one exit/entry are ideal. • Increase number of hiding and resting areas, especially by increasing vertical space (e.g., shelves, window sills). • No new cats should be added to the house.

Cases Where Cats Cannot be in Same Room without Immediately Becoming Agitated
• Separate cats completely when unsupervised. • Meet each cat's needs for play, litter boxes, food, water, perching, resting, and attention. • Large wire dog kennel or vertically oriented wire cat cage (with shelving) may be better tolerated than smaller cat kennels and can be used for controlled exposure. • Cats may be taught to tolerate harnesses and leashes so that they can be used during training and controlled reintroduction. This is especially valuable for the aggressor. • Set up desensitization and counter-conditioning sessions daily; initially utilize physical and visual barriers (e.g., opposite sides of solid door). • Proceed to controlled visual introduction, across glass or screen door, in their kennels, or on leash and harness, insuring they are at a distance that prevents overt/covert aggression. Feed cats or engage in play for classical counter-conditioning. • Over many sessions gradually reduce distance between cats, being careful to stay far enough apart during each session that no overt or covert behavioral signs of aggression and/or fear are seen. Start and end all sessions on successful note. • Teach each cat a "come and/or go to place" cue using operant counter-conditioning and positive reinforcement at times when cats are not stressed. Practice several times daily so each cat learns to respond reliably. • When ready to allow cats more freedom with each other, follow instructions for less severe intercat aggression (above).

SURGICAL CONSIDERATIONS
Neutering reduces roaming, intercat aggression, and urine spraying in approximately 90% of intact males. Neutering/spaying reduces mounting and sexual behavior.

MEDICATIONS

DRUG(S) OF CHOICE
As all medications are extra-label, insure client is informed, and review target desirable outcomes and potential adverse effects.

For Aggressor and/or Victim
Selective Serotonin Reuptake Inhibitors (SSRIs)
• Fluoxetine or paroxetine 0.5–1 mg/kg PO q24h. • Drugs of choice for aggression, anxiety, and/or urine marking; may decrease impulsivity. • Side effects may include gastrointestinal upset, decreased appetite, sedation, urinary retention, constipation, lowered seizure threshold, and increased agitation/irritability.

Tricyclic Antidepressants (TCAs)
• Clomipramine 0.25–0.5 mg/kg PO q24h—serotonin selective tricyclic, for anxiety and aggression. • Side effects include gastrointestinal upset, sedation, urinary retention, constipation, and lowered seizure threshold. Do not use in patients with arrhythmias or cardiomyopathies.

Pheromones
• Feliway® Multicat/Friends (Ceva)—synthetic feline mammary gland pheromone that may be helpful for reducing intercat social conflicts when combined with a multimodal plan. • Feliway Classic (Ceva)—synthetic feline facial pheromone that may be helpful in reducing stress and associated marking behavior.

For Victim

Azapirone

• Buspirone 0.5–1 mg/kg PO q8–24h—reserved for victims to increase social confidence. • Side effects rare; may include decreased sociability and increased agitation/irritability; victim may be more confident and fight back.

Benzodiazepines

• Lorazepam 0.125–0.25 mg/CAT PO up to q12–24h or oxazepam 0.2–0.5 mg/kg PO q12–24h for anxious or fearfully aggressive cats and as an appetite stimulant, helping to facilitate classical counter-conditioning; may be used as needed, with peak effects seen within 1 hour. • Side effects may include increased appetite, ataxia, inhibited learning, and disinhibition of aggression. • Note: controlled substance; dependence can develop; should be gradually weaned if used consistently for longer than 2 weeks.

CONTRAINDICATIONS

• Benzodiazepines should be used cautiously or avoided in cats with hepatopathies. • SSRIs and TCAs may produce anticholinergic side effects. • SSRIs and TCAs should be used with caution in patients with cardiac abnormalities, seizures, and liver disease.

PRECAUTIONS

• Any behavioral drug may produce paradoxical reactions, including fear, anxiety, hyperexcitability, and/or aggression. • Medications that alter serotonin levels have the potential to produce serotonin syndrome.

POSSIBLE INTERACTIONS

• Avoid concurrent use of SSRIs and TCAs; avoid using monoamine oxidase inhibitors (MAOIs, such as selegiline) with SSRIs and TCAs; use SSRIs and TCAs cautiously or avoid with buspirone, tramadol, and tryptophan due to possible serotonin syndrome. • Caution with concurrent medications considered substrates of cytochrome P450.

ALTERNATIVE DRUG(S)

• Amitriptyline (TCA) 0.5–1 mg/kg PO q12–24h—for anxious cats, especially if comorbid recurrent feline idiopathic cystitis/feline lower urinary tract disease (FIC/FLUTD); not selective for serotonin reuptake inhibition and likely less effective for aggressor. Side effects include sedation, decreased grooming, and increased weight. • Dietary supplementation with l-theanine (Anxitane, Virbac), or with alpha-casozepine (Zylkene®, Vetoquinol), Royal Canin Veterinary Diet Calm® (contains alpha-casezopine, l-tryptophan, and nicotinamide), or Hill's Prescription Diet® Multicare Feline Urinary Stress (contains l-tryptophan and milk protein hydrolysate).

FOLLOW-UP

PATIENT MONITORING

• Monitor patients 2 weeks after treatment initiation and monthly for first few months; follow-up visit should be scheduled 4–8 weeks into treatment if drugs dispensed to assess response and adjust dose if necessary. • Benzodiazepines may rarely cause cases of fatal hepatopathies; patients should be rechecked immediately if any adverse events occur, including anorexia. • Medication should be used for at least 4–6 weeks after resolution of signs, then gradually weaned by reducing dosage no faster than 25% per day on weekly basis. • Some patients require long-term medication; recheck laboratory work every 6 months to 1 year, depending on health and age.

PREVENTION/AVOIDANCE

• Proper socialization through 2–7 weeks of age and ongoing. • Gradual introduction more closely resembles natural process through which new cats enter existing group at the periphery and may be accepted over time. • Negative initial encounter often associated with future intercat aggression. • Related and familiar cats less likely to have intense intercat aggression. • In stable multicat households, avoid adding additional cats. • Avoid reintroduction aggression by avoiding separating cats when possible.

POSSIBLE COMPLICATIONS

Abrupt withdrawal of behavioral medications may result in aggression and rebound anxiety.

EXPECTED COURSE AND PROGNOSIS

• Prognosis for most cases is fair; complicated by prolonged duration, high intensity, underlying medical conditions, and incomplete owner compliance. In one study 62% were considered cured and 37% not cured (rehomed, euthanized, or permanently separated). • Recent and mild cases may have better long-term outcomes.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Urine marking/spraying. • House soiling. • Excessive grooming. • Fearful/anxiety-related behavior. • Human-directed or interspecies aggression.

AGE-RELATED FACTORS

Predatory/play-related aggression more common in young active and playful cats housed indoors with more sedentary or aged individuals.

ZOONOTIC POTENTIAL

Human intervention may lead to bite or scratch injuries.

PREGNANCY/FERTILITY/BREEDING

Most behavioral medications are contraindicated in breeding animals.

SYNONYMS

Feline intraspecies aggression.

A

AGGRESSION, OVERVIEW—CATS

BASICS

DEFINITION

• Aggression is a behavioral strategy used to manage aversive situations. • May be normal and appropriate in certain contexts. • May be abnormal with deleterious effects on cat's physical and emotional well-being. • Aggressive—describes both mood and temperament traits relating to propensity to show aggression when environmental circumstances dictate.

Play Aggression (toward People)

• Typically refers to cat who scratches and bites owners during play. • Not true aggression, but overzealous play without proper impulse control due to lack of training or proper intraspecific social feedback. • Cat's intent is not to harm the person. • Behavior encouraged and rewarded by owners through rough play with kitten; when larger and stronger, becomes perceived as aggression rather than overzealous play.

Predatory Aggression (toward People or Other Animals)

• Cats have innate drive to "hunt" or show predation, which includes stalk, hide, and pounce. • Predatory behavior is not a direct function of hunger. • Typically stimulated by fast movements and can progress to cat hiding and waiting for animal or person to walk by. • Play is way for young cats to perfect predation skills; play aggression and predatory aggression may overlap.

Redirected Aggression (toward People or Other Animals)

• Cats who see, hear, or smell a trigger and direct aggressive behavior toward the closest bystander. • In some cases, one person or animal in the home becomes designated victim, and cat may bypass a nearby individual and attack preferred target. • Cats may remain aroused for 24–72 hours after triggering event. • Common triggers inciting redirected aggression are seeing another cat or wildlife outside or loud noises.

Fear/Defensive Aggression (toward People or Other Animals)

• Cat will show body postures indicative of fear/anxiety and may use aggression as strategy to manage that aversive situation. • Typical behaviors include combination of any of the following: hissing, spitting, piloerection, arched back, turning away, running away, cowering, rolling on back, and pawing (defensive) if cornered. • With learning and repetition, may display more offensive signs.

Territorial Aggression (toward People or Other Animals)

• Some cats, particularly males, show territorial behavior in domestic home settings due to perceived need to defend multiple resources (e.g., people, food, resting areas, feeding areas, elimination sites, etc.). • Territorial behaviors include marking with urine and/or feces, bunting (rubbing of cheeks on surfaces to deposit pheromones), and scratching (also deposits pheromones and leaves visual mark) that may be associated with aggression. • In severe cases, aggressor may seek out the other individual and attack. • Body posture with territorial aggression is assertive and confident.

Pain Aggression (toward People and Animals)

Cats in pain may show aggression (hiss, growl, scratch, bite) when physically handled or immediately prior to or after activity such as jumping on or off a piece of furniture.

Maternal Aggression

Female cat may show aggressive behavior toward individuals approaching her kittens.

Impulse Control Aggression

Cats who show intense aggressive responses to mild stimuli without much or any warning may have impulse control disorder arising from dysfunctional serotonin neural circuits.

Frustration-Induced Aggression (to People and Other Animals)

Some cats with very outgoing, social personalities may exhibit aggression if restricted life indoors does not meet their behavioral needs.

Contact-Induced/Petting Aggression (toward People)

• Cats may show early signs of aversion during petting and handling with ears going back and tail swishing. • If physical contact continues, they may bite. • Owners often miss early warning signs. • When cats groom one another, they typically limit grooming to the head region. • Some cats appear to be particularly sensitive to being stroked along the dorsum.

Intercat Aggression within Home

• After introducing new cat to home, 50% of cat owners report fighting (scratching and biting). • Number of cats, sex, and age are not significant factors in predicting which cats will show aggression toward each other. • Any of the above categories of aggression are all possibilities for fights between or among cats. • Fear/anxiety is most common cause of intraspecific aggression. • Learning—consequences/outcome (reinforcement, punishment) further compound the problem.

PATHOPHYSIOLOGY

Behavior problems are typically multifactorial in cause. Figure 1 illustrates some of the common components that need to be evaluated to accurately diagnose and treat aggression cases.

SYSTEMS AFFECTED

• Behavioral—vary with type of aggression, occur alone or in combination: tail swishing/twitching, ears turned sideways or flattened, stiffening of shoulders/legs, crouching, dilation of pupils, hissing, spitting, growling, piloerection, staring, chasing, stalking, pawing, lunging. • Cardiovascular—signs associated with sympathetic activation and hypothalamic-pituitary-adrenal (HPA) activation. • Endocrine/metabolic—long-term aggression associated with fear/stress/anxiety, symptoms associated with long-term activation of HPA system. • Gastrointestinal (GI)—with chronic HPA stimulation: may see cat more prone to anorexia and GI ulcers; with acute fear aggression: evacuation of bowel and possible diarrhea; inflammatory bowel disease (IBD) possible in chronic stress. • Hemic/lymphatic/immune—decreased immune response with chronic HPA stimulation; stress leukogram. • Both victim and aggressor may suffer injuries; with chronic activation of HPA, muscle wasting may occur. • Nervous—increased reactivity up to 72 hours following aggressive event; may see increase in aggression with decreased provocation as synapses in amygdala become sensitized; in some animals may be associated with decreased serotonin, causing aggressive outbursts; may see ritualized motor patterns, shaking, or trembling. • Ophthalmic—dilated pupils with sympathetic stimulation. • Renal/urologic—may see spraying or small amounts of urine on horizontal surfaces; stress may be contributor to feline interstitial cystitis. • Respiratory—tachypnea in acute cases or when stressed. • Skin/exocrine—damage due to fights or to excessive grooming associated with fear/anxiety/distress.

SIGNALMENT

• Preliminary evidence that behavioral traits in cats vary by breed and sex. • Males more likely to show aggression toward other cats, while females more likely to show aggression toward owners. • Abyssinian, Russian blue, Somali, Siamese, and chinchilla breeds showed more aggression. • Maine Coon, ragdoll, and Scottish folds showed least aggressiveness.

SIGNS

• May appear at social maturity (2–4 years of age) except for play-related and should occur in specific social contexts/interactions. If onset occurs in older cat, medical causes should be ruled out first. • General comments—most owners able to detect overt signs of aggression (biting, hissing, growling), but may miss more subtle signs of aggression that typically occur between cats (staring) and resulting anxious behaviors that can result in aggression (meatloaf position, averting gaze, etc.). Videotapes of intercat interactions allow clinician to assess behavior.

CAUSES

• Underlying medical issues can cause aggression. • Temperament/behavior influenced by genetics, rearing, socialization, environment in which cat lives, and types of interactions cat has with people.

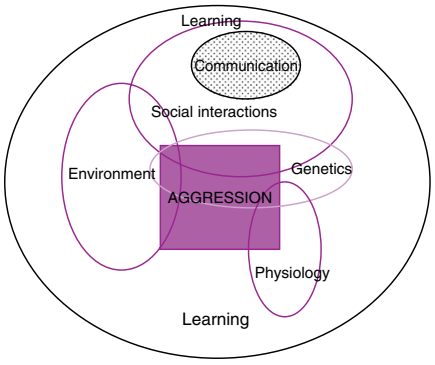

Figure 1.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• CNS diseases (e.g., infections, toxins, tumors, partial seizures, focal seizures). • Hyperthyroid. • Hepatic encephalopathy. • Any condition causing pain (e.g., arthritis, pancreatitis, dental disease, anal sacculitis, diabetic neuropathy). • Lead poisoning.

CBC/CHEMISTRY/URINALYSIS

Physical examination, baseline blood, and urine screening followed by additional diagnostics as indicated based on history, examination, and laboratory results.

OTHER LABORATORY TESTS

• Discuss *Bartonella* testing in any cat that bites or scratches people. • Thyroid levels. • Urinalysis ± culture if house soiling. • Feline serology—feline calicivirus (FCV), feline leukemia virus (FeLV), female immunodeficiency virus (FIV).

TREATMENT

• Never use physical correction/punishment; may escalate aggression. • Never try to physically handle or manipulate a cat in an aggressive state. • Avoid known triggers. • Identify triggers and desensitize and counter-condition to triggers. • Implement safety measures (nail caps, wearing long pants/long sleeves, keep flattened cardboard boxes around home to place between target and cat, redirect behavior in early arousal phase). • Behavior modifications to redirect cat and reduce arousal (specific plans dependent upon specifics of each case). • Train cat to commands such as "sit," "go to place," etc. • Environmental enrichment and meeting behavioral needs. • Teach owners to identify early signs of arousal so cat can be redirected or so they can avoid cat. • After aggressive outburst, keep aggressor isolated in a room for at least 24 hours (as long as cat remains aroused after attack). • Pheromones. • Medications.

MEDICATIONS

DRUG(S) OF CHOICE

• Selective serotonin reuptake inhibitors (SSRIs)—fluoxetine or paroxetine 0.5 mg/kg PO q24h. • Tricyclic antidepressants (TCAs)—clomipramine 0.25–1.0 mg/kg PO q24h. • Buspirone at 0.5–1.0 mg/kg q8–24h, benzodiazepines such as oxazepam at 0.2–0.5 mg/kg q12–24h, or lorazepam 0.125–0.25 mg/cat might reduce fear and build confidence and support counter-conditioning in fearful cat that avoids or retreats.

CONTRAINDICATIONS

• Cats with renal or hepatic disease. • Caution with TCAs and SSRIs in diabetics. • TCAs in patients with cardiac abnormalities.

POSSIBLE INTERACTIONS

• TCAs and SSRIs should not be used together. • Mirtazapine should be used cautiously in combination with TCA or SSRI. • Practitioner should evaluate all drugs and natural supplements administered to verify safety in combination.

ALTERNATIVE DRUG(S)

• Amitriptyline 0.5–1.0 mg/kg PO q12–24h. • S-adenosyl-L-methionine-tosylate disulfate (SAMe) 100 mg PO q24h. • Alpha-casozepine 75 mg (15 mg/kg or greater) PO q24h. • l-theanine 25 mg PO q24h. • Cat-appeasing pheromone (Feliway® Multicat or Friends). • F3 cheek gland pheromone (Feliway). • Calming and stress diets containing alpha-casozepine and l-tryptophan.

FOLLOW-UP

PATIENT MONITORING

• Call owners once every 1–2 weeks for first 2 months after treatment plan has been recommended; determine implementation of safety recommendations and behavioral plan. • If medication dispensed, dose should be reevaluated every 3–4 weeks. • Frequency of follow-up will be dictated by severity of case and owner compliance. • CBC, chemistry, T_4 prior to medication; recheck liver and kidney values 2–3 weeks after starting medication; recheck bloodwork annually in young healthy patients, semiannually in older patients. • Repeat physical exams in older patients semiannually, as painful conditions may exacerbate aggression.

EXPECTED COURSE AND PROGNOSIS

• Depends on type of aggression and compliance of clients with suggested behavior plan. • Most cases need combination of behavioral modification, environmental modification, training, and, when necessary, medication. • Some types of aggression can resolve or improve within a few weeks, whereas others may take several months or longer. • Some forms of aggression have poor prognosis.

MISCELLANEOUS

AGE-RELATED FACTORS

• Older cats—cognitive decline, CNS disease, arthritis, meningioma, other medical conditions. • Age 2–4 years—social maturity, when cats may start to show certain kinds of aggression.

SEE ALSO

• Aggression, Intercat Aggression. • Aggression Toward Humans—Cats.

ABBREVIATIONS

• FCV = feline calicivirus. • FeLV = feline leukemia virus. • FIV = feline immunodeficiency virus. • GI = gastrointestinal. • HPA = hypothalamic-pituitary-adrenal. • IBD = inflammatory bowel disease. • SAMe = S-adenosyl-L-methionine-tosylate disulfate. • SSRI = selective serotonin reuptake inhibitor. • TCA = tricyclic antidepressant.

A

AGGRESSION, OVERVIEW—DOGS

BASICS

DEFINITION

• Action by one dog directed against another organism with the result of limiting, depriving, or harming. Aggression refers to any behavior along an aggression continuum, from a stare to immobility (freeze), growl, snarl, lunge, air snap, single bite, multiple bite, multiple attacks, and chase and attack.
• Numerous functional types have been posited. Here, aggression is classified on the basis of (1) affective aggression, (2) predatory aggression, and (3) play-related aggression. Affective states, such as fear and arousal, and motivational factors, such as hunger and sexual drive, influence the probability of overt aggression, such as biting. Affective aggression may be human-directed or dog-directed. Within these contexts, there may be additional specificity, such as human-directed aggression toward unfamiliar persons, or human-directed aggression toward familiar persons. Often dogs display aggression in a single context.
• Human-directed aggression toward familiar persons in response to controlling gestures was historically called dominance aggression, although newer terminology, such as conflict aggression, may be used to avoid erroneous semantic assumptions inherent in the term "dominance."
• Human- or animal-directed aggression, generally toward unfamiliar individuals and specific to home location, is called territorial aggression. Location is commonly at door of entry, but may also involve defense of special favored locations such as beds.
• Predatory aggression refers to behaviors associated with chasing and hunting prey. It is often considered nonaffective and may be socially facilitated by other dogs. Predatory behaviors may be triggered by movement or high-pitched sounds, and may be redirected to humans or objects.
• Play-related aggression involves aggressive gestures, such as growling and biting, in the context of play and is commonly displayed toward other dogs or humans. It is often initiated by signs of play, such as the play bow.
• In all cases, medical factors that might contribute to aggression (including pain) must be evaluated.

PATHOPHYSIOLOGY

• Affective aggression involves arousal of the sympathetic nervous system. Some pathologic conditions are associated with an increase in aggression because of CNS effects such as pain or irritability.
• Abnormalities in the CNS serotonin neurotransmitter system have been implicated in one type of impulsive human-directed aggression, colloquially called "rage," directed toward familiar persons and triggered by controlling gestures.
• Aggression generally has a learned component, whereby dogs learn to use aggression to manage distance from fearful stimuli or control resources, as this behavior is often effective as a distance-increasing technique.

SYSTEMS AFFECTED

• Behavior.
• Other, if there is an underlying medical etiology.

GENETICS

• In some breeding programs, aggressive tendencies and bite styles have been selected for (or against).
• Behavioral genetics is an active area of research, with several genes identified that may be associated with fear and aggression in dogs.
• One study in the United States linked English springer spaniels that display human-directed dominance aggression to one breeding sire, implicating a heritable component.
• One study of human-directed dominance aggression among English cocker spaniels reported that males were more aggressive than females, and dogs with solid coat color were more aggressive than those with parti coat color.

INCIDENCE/PREVALENCE

• Reported problem by approximately 30% of owners.
• Most common diagnostic category seen by board-certified veterinary behaviorists in North America.
• According to Centers for Disease Control and Prevention, about 4.7 million people bitten by dogs each year in United States, although this number considered an underestimation as majority of dog bites not reported.
• In United States, estimated that one in five of those bitten require medical attention for dog bite–related injuries.
• Among children and adults, males more likely than females to be bitten.
• Based on emergency room data in United States, rate of dog bite–related injuries highest for children aged 5–9 years.
• In majority of cases, people are bitten by dogs that are known to them; this is not the case for dog injury–related fatalities.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog

Breed Predispositions

Any breed or breed mix.

Mean Age and Range

Any age, although some forms of aggression may arise more commonly at sexual or social maturity, while medical causes increasingly more likely in adult- or senior-onset aggression.

Predominant Sex

• Either sex.
• Males—intact or castrated, most commonly implicated in cases of human-directed "dominance"-type aggression. Intact males overrepresented in dog-bite fatalities, but covariables, such as owner management, are present.
• Females—spayed most commonly implicated in aggression to other female dogs in the home. In some studies, spayed females less likely than males to display human-directed aggression.

SIGNS

General Comments

• Any dog can display aggression. Many factors, including temperament, experience, and situational factors, influence propensity to bite.
• Dogs may display behavioral signals as warnings, including immobility, growls, snarls, or air snaps, which may provide time to avoid overt aggression. These signs should not be punished, as this might decrease the probability of warning signs without affecting the underlying risk, or may further intensify the aggressive (defensive) response. Instead, the animal should be safely removed from the situation and the underlying triggers for the affective state addressed.

Historical Findings

• Variable.
• Basis for risk analysis and details of treatment program. Important questions: Who/what was the target? Who was present to manage the dog? How severe were the resulting injuries? What are the circumstances (including location, time) in which aggression occurred? Are there any reliable triggers for aggressive behavior? Abnormalities in mentation or awareness might indicate a medical cause.

Physical Examination Findings

• Usually unremarkable.
• Use extreme care when handling aggressive dogs.
• A comfortable, well-fitting basket muzzle recommended prior to examination of any dog with history of human-directed aggression. Desensitize and countercondition to muzzle application and use. Basket-style muzzles allow dogs to pant.
• Abnormalities on physical or neurologic examination may suggest organic disease process (e.g., neurologic, pain, blindness). Dogs can display aggression during preictal, ictal, or posticta periods. Dogs with underlying

pain typically display defensive (body-protective) aggression.

CAUSES
- Part of normal range of behavior; strongly influenced by individual temperament, experience, early socialization (before 12 weeks), and other variables.
- Harsh handling and confrontational responses can escalate aggression and should be avoided.
- May be manifestation of organic condition, such as hepatic encephalopathy or pain.
- In all cases, evaluate medical causes of aggression.

RISK FACTORS
- Inadequate socialization during canine critical period (3–12 weeks).
- Traumatic/fearful/negative experience(s).
- Predisposing environmental conditions—lack of training, inadequate restraint, harsh handling.
- Inability of owner to safely confine or manage the dog in order to prevent future incidents. Helpful devices include barrier fence, muzzle, collar or head halter, leash.
- Previous aggression/bite history (number of incidents, number of bites per incident, target, severity of injury); legal citation for biting.
- Unpredictability of aggressive behaviors, lack of warning signals.
- Presence of children, elderly people, or other humans or animals at high risk living in or visiting household.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Thorough medical evaluation should be conducted on all cases of aggression.
- Identify pathologic conditions associated with aggression before making purely behavioral diagnosis.
- Rule out developmental abnormalities (e.g., hepatic shunts), metabolic disorders (e.g., hepatic encephalopathy), endocrinopathies (e.g., hypothyroidism, hyperadrenocorticism), dermatopathy, neurologic conditions (intracranial neoplasm, seizures), toxins, inflammatory diseases, cognitive dysfunction, acute or chronic pain, and iatrogenic causes, such as glucocorticoid administration.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually no significant findings unless underlying medical etiology.
- Indicated to evaluate dog as candidate for behavioral medications.

OTHER LABORATORY TESTS
- Thyroid testing.
- Others as indicated by history and physical exam.

IMAGING
- May be indicated to identify sources of pain or disease.
- MRI or CT—particularly if cerebral disease/neoplasia suspected.

DIAGNOSTIC PROCEDURES
- Collection of thorough behavioral history and evaluation of medical concerns.
- Postmortem fluorescent antibody test indicated for any aggressive dog for which rabies is differential diagnosis.

PATHOLOGIC FINDINGS
None

TREATMENT

APPROPRIATE HEALTH CARE
- Manage any underlying medical conditions.
- Management success—combination of multiple modalities: safe environmental control, behavior modification to teach animals appropriate behavior, and pharmacotherapy.
- Consult veterinarian with experience and training in aggression management.
- Euthanasia should be discussed or recommended when risk of injury is high. Note recommendation in medical record.
- Rehoming aggressive dogs may put those involved at liability risk.

NURSING CARE
A boarding facility able to safely manage the dog might be used until a safe management plan can be implemented, or until an outcome decision can be made.

ACTIVITY
Since frustration and arousal may increase incidence of aggression, appropriate and safe exercise regime should be incorporated into treatment program.

DIET
There is minimal evidence that a low-protein diet may reduce territorial aggression in dogs, an effect that might be enhanced with tryptophan supplementation.

CLIENT EDUCATION
- Safe practices should dictate all decisions. These practices include safe confinement, physical barriers, head halters, leash control, muzzle use, and supervision by a competent adult.
- Situations that have led to aggression in the past should be listed and a specific plan developed to avoid these situations and associated locations in the future, and a long-term management plan developed.
- The dog should calmly be removed from aggression-provoking situations.
- Safe, nonconfrontational techniques that manage resources and use positive reinforcement to teach the dog appropriate responses should be employed.
- Confrontational management techniques, such as roll-overs, or even verbal discipline increase the probability of a defensive aggressive response, may lead to human injury, and should be strictly avoided.
- Management ("dominance") techniques including punishment are associated with defensive fear responses by the dog and an increased risk of human-directed aggression. These should be avoided and replaced with positive management techniques.
- The client should be advised to consider personal and legal liability risks of keeping the dog. Human injury, bite-related lawsuits, and homeowner's insurance claims can result from canine aggression. Such risk assessment may help the client objectively evaluate the situation.
- Euthanasia should be considered if safe management cannot be employed, or when the risk of injury is high.

SURGICAL CONSIDERATIONS
Castration of males may reduce the incidence of intermale aggression.

MEDICATIONS

DRUG(S) OF CHOICE
- None approved by FDA for treatment of aggression.
- No drug will eliminate probability of aggression.
- Use drugs only when safe management plan has been implemented.
- Inform client of extra-label nature of medication and risk involved; document in medical record; obtain signed informed consent.
- Drugs that increase serotonin may be helpful to reduce anxiety, arousal, and impulsivity.
- Treatment duration—minimum 4 months, maximum lifetime.
- See Table 1 for drugs used to facilitate management of aggression in combination with safe management plan.

CONTRAINDICATIONS
- Fluoxetine should be used cautiously in cases of seizures.
- Clomipramine contraindicated in cases of cardiac conduction disturbances or seizures; in one open trial, clomipramine was no more effective than control in cases of human-directed aggression.

A

AGGRESSION, OVERVIEW—DOGS (CONTINUED)

Table 1

Drugs and dosages used to manage canine aggression.

Drug	*Drug Class*	*Oral Dosage in Dogs*	*Frequency*	*Side Effects—Usually Transient*
Fluoxetine	SSRI	1.0–2.0 mg/kg	q24h	Decreased appetite, sleepiness
Paroxetine	SSRI	1.0–2.0 mg/kg	q24h	Constipation
Sertraline	SSRI	2.0–4.0 mg/kg	q24h	Sleepiness
Clomipramine	TCA	1.0–3.0 mg/kg	q12h	Sleepiness, vomiting

PRECAUTIONS
Benzodiazepines (e.g., diazepam) may contribute to behavioral disinhibition. Aggression may increase when dogs lose their fear of the repercussions of biting.

POSSIBLE INTERACTIONS
Do not use selective serotonin reuptake inhibitors (SSRIs) or tricyclic antidepressants (TCAs) with monoamine oxidase inhibitors, including amitraz and selegiline, or with each other because of risk of serotonin syndrome. Caution when combining SSRI or TCA with any drug that might increase serotonin, including trazodone.

ALTERNATIVE DRUG(S)
- Trazodone (4–10 mg/kg PO q12h or PRN) may be used with drugs listed in Table 1 to reduce anxiety and arousal.
- Clonidine (0.01–0.05 mg/kg PO q12h or PRN) may be used with drugs listed in Table 1 to reduce anxiety and arousal.
- Natural products that may aid in reducing anxiety—l-tryptophan (10 mg/kg PO bid); alpha-casozepine (15 mg/kg or higher daily) alone or in diet combined with l-tryptophan; l-theanine alone (2.5–5 mg/kg bid) or in combination with products containing whey protein, *Phellodendron amurense*, and *Magnolia officinalis*; "calming" probiotic supplement; or dog-appeasing pheromone.

FOLLOW-UP

PATIENT MONITORING
Weekly to biweekly contact recommended in initial phases to guide clients with behavior modification plans and medication management.

PREVENTION/AVOIDANCE
- To prevent aggressive incidents, avoid all situations that have led to aggression in the past, using safe confinement, gates, halters, collars, leashes, muzzles.
- Reduce risk of aggression in young dogs (3–12 weeks) with positive socialization program; avoid intimidation techniques and negative, fear-inducing situations.

POSSIBLE COMPLICATIONS
- Injury to humans or animals.
- Liability to client, veterinarian.
- In cases of dog-directed aggression, although not the intended target, humans who interfere are often seriously injured, either by accident or by redirected aggression; owners should not reach for fighting dogs—pull apart with leashes.
- Aggressive dogs are at risk for relinquishment or euthanasia.

EXPECTED COURSE AND PROGNOSIS
- Aggressive dogs weighing over 18.5 kg are at increased risk for behavioral euthanasia.
- Aggressive dogs may be successfully managed, but should not be considered "cured."
- Prognosis is case dependent due to risk factors and management features of each situation.

MISCELLANEOUS

AGE-RELATED FACTORS
Onset of aggression in mature dogs suggests medical cause; carefully evaluate sensory acuity, sources of pain, endocrinopathy, cognitive function.

ZOONOTIC POTENTIAL
- Dog bites are significant public health risk.
- Rabies is potential cause of aggression.

PREGNANCY/FERTILITY/BREEDING
TCAs and trazodone are contraindicated in breeding males and pregnant females.

SYNONYMS
Biting

ALKALINE HYPERPHOSPHATASEMIA IN DOGS

BASICS

DEFINITION
Increase in serum alkaline phosphatase (ALP) activity above reference interval.

PATHOPHYSIOLOGY
• ALPs are heterogeneous group of isoenzymes that catalyze hydrolysis of organic phosphate esters in extracellular space. • Membrane-bound enzymes present in liver, bone, placenta, intestine, and kidney. • Total serum ALP attributed to liver (L-ALP), bone (B-ALP), and glucocorticoid-induced (G-ALP) isoenzymes; proportion of each isoenzyme changes with age in normal dogs. • Serum ALP activity increases with cholestatic, necroinflammatory, and neoplastic injury; many hepatic and nonhepatic causes; affected dogs often asymptomatic. • Anticonvulsants (phenobarbital, primidone, phenytoin) and steroids can induce L-ALP synthesis; steroids, inflammation, and chronic disease can induce G-ALP synthesis. • ALP has high sensitivity but poor specificity for hepatobiliary disease; reflects common induction of enzyme synthesis due to nonhepatic causes, i.e., "reactive hepatopathy." • Increased ALP activity with concurrent increase in GGT activity increases specificity for hepatobiliary disease.

SYSTEMS AFFECTED
• Multiple organ systems can influence ALP synthesis. • Increased ALP activity does not cause direct damage to other organ systems.

GENETICS
• Benign familial alkaline hyperphosphatasemia in Siberian huskies—presumed autosomal. • Vacuolar hepatopathy of Scottish terriers—breed relationship.

INCIDENCE/PREVALENCE
Increased ALP activity is common biochemical abnormality in dogs.

SIGNALMENT
• Any age, breed, or sex. • Young dogs, <1 year of age—increased B-ALP activity. • Siberian huskies and Scottish terriers. • Older dogs—conditions causing increased L-ALP, G-ALP, and/or B-ALP activity.

SIGNS

General Comments
• Many dogs with increased ALP activity are asymptomatic. • Dogs with hepatic or nonhepatic disorders causing increased ALP may be asymptomatic or have clinical signs related to underlying disorder. • Dogs with drug-induced elevations of ALP may have clinical signs related to drug side effects.

Historical Findings
• Dependent on cause. • Medication history important, including exposure to topical/ocular medications used by humans.

Physical Examination Findings
• Highly variable depending on cause; often normal. • Hepatomegaly or microhepatica. • Jaundice. • Abdominal pain. • Musculoskeletal—pendulous abdomen, muscle atrophy, lameness, difficulty walking, palpable bony swelling. • Dermatologic—alopecia, cutaneous hyperpigmentation, comedones, thin skin, pyoderma, calcinosis cutis.

CAUSES
• Age and breed (see Signalment). • Drug induced. • Bone-related disorders—neoplasia, osteomyelitis, hyperparathyroidism (primary or secondary), healing fractures. • Chronic stress, acute-phase response (endogenous cortisol). • Endocrinopathies (hyperadrenocorticism, diabetes mellitus, hypothyroidism). • Primary hepatobiliary disorders. • Extrahepatic disorders—extrahepatic biliary obstruction (EHBO), pancreatic/intestinal/other inflammation, neoplasia. • Infection—Leptospirosis, sepsis, viral. • Systemic inflammation/infection causing ischemic injury/cholestasis. • Hepatic or nonhepatic neoplasia (e.g., benign or malignant mammary tumors).

RISK FACTORS
• Age (young). • Breed—Siberian husky, Scottish terrier. • Breed association to conditions causing alkaline hyperphosphatasemia (e.g., Shetland sheepdog predisposition to gallbladder mucocele).

DIAGNOSIS

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
Corticosteroids, certain anticonvulsants.

Disorders That May Alter Laboratory Results
• Severe hemolysis (>500 hemolysis index) can falsely elevate ALP. • Lipemia and icterus have no significant effect on ALP.

CBC/BIOCHEMISTRY/URINALYSIS
• Thrombocytosis possible with hyperadrenocorticism and pancreatic, gastrointestinal disease. • Thrombocytopenia possible with leptospirosis, hepatic failure, neoplasia. • Leukocytosis or leukopenia with left shift, monocytosis with sepsis, systemic inflammation. • Stress leukogram with hyperadrenocorticism. • Concurrent elevation of other liver enzyme activities including alanine aminotransferase (ALT), aspartate aminotransferase (AST), and/or gamma glutamyltransferase (GGT), depending on underlying cause. • ± markers of hepatic synthetic dysfunction (hypoalbuminemia, hypoglycemia, hypocholesterolemia, decreased blood urea nitrogen [BUN]); many primary hepatic disorders. • Hyperbilirubinemia in EHBO, end-stage chronic hepatopathies, acute hepatic toxicities, infections. • Hypercholesterolemia with many causes of cholestasis, endocrinopathies. • Urinalysis—proteinuria with hyperadrenocorticism, other liver disorders; dilute urine, bacteriuria, pyuria with endocrinopathies; glucosuria with diabetes mellitus, copper-associated hepatopathy; ammonium biurate crystalluria with portosystemic vascular anomaly (PSVA; young dogs). • Conditions with often sole increase in serum ALP include idiopathic vacuolar hepatopathy, hepatic nodular hyperplasia, drug-induction breed-related disorders, some hepatic neoplasias, sudden acquired retinal degeneration (SARDS). • Hyperphosphatemia, hypercalcemia (young growing dogs, usually mild). • Hyperglycemia—mild with hyperadrenocorticism. • Azotemia—prerenal or renal with pancreatitis, pyelonephritis, Leptospirosis.

OTHER LABORATORY TESTS
• Serum bile acids; redundant test if hepatic hyperbilirubinemia. • Testing for endocrine disorders—hypothyroidism or hyperadrenocorticism based on clinical signs, physical exam findings, and associated laboratory abnormalities. • Infectious disease testing—leptospirosis PCR, microagglutination test (MAT), immunoglobulin (Ig) M; urine, bile cultures; tick-borne disease screening. • Blood pressure measurement. • Urine protein qualitative; quantitative with protein; creatinine if inactive sediment and culture negative.

IMAGING
• Radiographs—for liver most useful for hepatomegaly, microhepatica; nonhepatic findings may also be identified (pancreatitis, ascites, cystoliths, pyometra, pleural effusion). • Sonographic evaluation for hepatic parenchymal abnormalities (hyper- or hypoechoic nodules, heterogeneity, hyper- or hypoechoic hepatic echogenicity; changes in echodensity, echotexture; microhepatica, hepatomegaly, hepatic masses), biliary tract (gallbladder mucocele, gallbladder wall abnormalities, cholelithiasis, choledochitis, biliary tract neoplasia), pancreas, adrenal enlargement, neoplasia. • Abdominal CT ± angiography may be useful if suspicion of pancreatitis, gallbladder disease, or hepatic vascular disorders.

DIAGNOSTIC PROCEDURES
• Hepatic fine-needle aspirate (FNA) for cytology; caution as cytologic and histologic agreement may be as low as 30%; cytology is not diagnostic for many hepatobiliary conditions. • FNA of liver tends to agree with histology in cases of vacuolar hepatopathy, hepatic lipidosis, and some neoplasias (e.g., lymphoma). • If primary hepatobiliary

A

ALKALINE HYPERPHOSPHATASEMIA IN DOGS (CONTINUED)

disease suspected after elimination of other causes, hepatic biopsy may be warranted; biopsy at least three liver lobes; laparoscopic or wedge samples preferred; Tru-Cut® needle biopsy may be too small, use 14–16G needle.

PATHOLOGIC FINDINGS
Variable depending on cause; see specific chapters for pathologic findings.

TREATMENT

APPROPRIATE HEALTH CARE
• Dictated by underlying disorder.
• Asymptomatic dogs often do not require any specific treatment.

NURSING CARE
Variable as above.

ACTIVITY
Alteration of activity typically unnecessary.

DIET
• Dietary alteration unnecessary in most cases. • Dietary fat restriction in some cases (pancreatitis, hypertriglyceridemia, obesity, chronic EHBO). • Commercial liver diets *rarely* indicated (see Portosystemic Vascular Anomaly, Congenital; Hepatic Encephalopathy).

CLIENT EDUCATION
• Dictated by underlying disorder. • Clients with asymptomatic dogs should be counseled on potential for subsequent development of endocrine disease, neoplasia (Scottish terriers), other causes. • Liver biopsy necessary for definitive diagnosis if other underlying causes are ruled out and/or if ALP value continues to elevate; rarely pursued initially in asymptomatic dogs without other underlying disorder.

SURGICAL CONSIDERATIONS
• Refractory hypotension is common peri- and postoperative complication in dogs with obstructive cholestasis (see EHBO). • Dogs with end-stage hepatic disease (cirrhosis) may have alterations of coagulation and/or higher anesthetic risk.

MEDICATIONS

DRUG(S) OF CHOICE
• Specific for underlying cause. • Certain drugs/supplements have general hepatobiliary protective effects; see Hepatosupportive Therapies.

CONTRAINDICATIONS
Depending on cause, drugs requiring hepatic metabolism or capable of causing hepatotoxicity should be limited or avoided when possible.

PRECAUTIONS
Drugs known to induce elevation of ALP may confuse monitoring of underlying condition.

FOLLOW-UP

PATIENT MONITORING
• Dependent on the underlying cause.
• Suspected benign causes of ALP elevation can be monitored for elevations in other serum liver enzyme activities, further elevation in ALP, and/or synthetic hepatic function tests.

EXPECTED COURSE AND PROGNOSIS
• Dependent on underlying cause.
• Increased ALP activity for which underlying cause cannot be found after complete diagnostic evaluation may be benign.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Elevation of other serum liver enzymes, hyperbilirubinemia, alterations in hepatic synthetic function tests.

AGE-RELATED FACTORS
Young dogs (see Signalment).

ZOONOTIC POTENTIAL
Leptospirosis has high zoonotic potential; see Leptospirosis.

PREGNANCY/FERTILITY/BREEDING
Placental ALP can increase in late-term pregnant cats; not reported in dogs.

SYNONYMS
• Elevated ALP. • Serum alkaline phosphatase (SAP).

SEE ALSO
• Bile Duct Obstruction (Extrahepatic).
• Cholangitis/Cholangiohepatitis Syndrome.
• Cholecystitis and Choledochitis.
• Cholelithiasis.
• Copper Associated Hepatology.
• Glycogen-Type Vacuolar Hepatopathy
• Hepatic Failure, Acute.
• Hepatic Nodular Hyperplasia and Dysplastic Hyperplasia.
• Hepatitis, Chronic.
• Hyperadrenocorticism (Cushing's Syndrome)—Dogs.
• Leptospirosis.
• Pancreatitis—Dogs.

ABBREVIATIONS
• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• AST = aspartate aminotransferase.
• B-ALP = bone isoform.
• BUN = blood urea nitrogen.
• G-ALP = glucocorticoid isoform.
• EHBO = extrahepatic biliary obstruction.
• FNA = fine-needle aspirate.
• GGT = gamma glutamyltransferase.
• Ig = immunoglobulin.
• L-ALP = liver isoform.
• MAT = microagglutination test.
• PSVA = portosystemic vascular anomaly.
• SAP = serum alkaline phosphatase.
• SARDS = sudden acquired retinal degeneration.

Consulting Editor Kate Holan

BASICS

DEFINITION

A process in the body that leads to an increase in pH above the reference interval. An increase in blood pH is specifically termed alkalemia. Associated with an increase in plasma bicarbonate concentration (HCO_3^-; dogs, >24 mEq/L; cats, >22 mEq/L) and base excess (BE; >4 mmol/L) with a compensatory increase in carbon dioxide tension (PCO_2).

PATHOPHYSIOLOGY

• Metabolic alkalosis may develop from either a *gain of bicarbonate* or a *loss of acid*:
∘ *Bicarbonate gain* subsequent to: contraction alkalosis due to free water deficit; iatrogenic administration of alkalinizing therapy (e.g., $NaHCO_3^-$); metabolism of organic ions (lactate, citrate, acetate, and ketones); hypokalemia; and renal ammoniagenesis. ∘ *Acid loss* subsequent to: gastric or renal acid loss (loop or thiazide diuretic); mineralocorticoid excess; presence of nonreabsorbable anions; decreased weak acids (hypoalbuminemia, hypophosphatemia). ∘ Renal HCO_3^- excretion very efficient in eliminating an excess HCO_3^- load, but hindered by decreased effective circulating volume; hypokalemia, hypochloremia, and hyperaldosteronism; metabolic alkalosis persists only if renal excretion of HCO_3^- is impaired, which primarily occurs from continued high rate of alkali administration, or some stimulus for kidneys to retain Na^+ in presence of a relative Cl^- deficit. • *Hypochloremic (corrected)* metabolic alkalosis results from loss of fluid rich in Cl^- and hydrogen ion (H^+), primarily from alimentary tract or kidneys; loss of Cl^- and H^+ associated with increase in plasma HCO_3^- concentration; with Cl^- loss and volume depletion, kidneys reabsorb Na^+ with HCO_3^- instead of Cl^-, perpetuating metabolic alkalosis. Hypochloremic alkalosis divided into *chloride-responsive* and *chloride-resistant*:
∘ *Chloride-responsive* results primarily from loss of Cl^- rich fluid and characterized by decreased extracellular fluid volume, hypochloremia, and low urinary Cl^- concentration; this type of alkalosis responds to administration of chloride salt. ∘ *Chloride-resistant* characterized by excessive mineralocorticoid leading to increased effective circulating volume and is not responsive to chloride salt. • *Hypokalemia* may contribute to metabolic alkalosis by shifting H^+ intracellularly; stimulating apical H^+/K^+ ATPase in collecting duct; stimulating renal ammoniagenesis; impairing Cl^- reabsorption in distal nephron; and reducing glomerular filtration rate (GFR), which decreases filtered load of HCO_3^- and, in presence of volume depletion, impairs renal excretion of excess HCO_3^-. • *Hypoalbuminemic* alkalosis is due to decrease in plasma albumin concentration; plasma albumin is a weak acid. • *Compensatory* metabolic alkalosis occurs in response to respiratory acidosis; this is associated with low pH and increased PCO_2.

SYSTEMS AFFECTED

• Nervous—muscle twitching and seizures occur rarely in dogs. Metabolic alkalosis and associated hypokalemia may precipitate hepatic encephalopathy in patients with liver failure. • Urinary—kidneys rapidly and effectively excrete excessive alkali. In patients with Cl^- deficiency and volume depletion, kidneys cannot excrete excess alkali. Therefore, metabolic alkalosis is maintained. In these patients, Cl^- administration is required for renal compensation to occur. Volume expansion will hasten compensation. Patients with mineralocorticoid excess have excessive Cl^- loss. Therefore, Cl^- administration does not lead to hyperchloremia and correction of metabolic alkalosis (so-called chloride-resistant metabolic alkalosis). • Respiratory—low $[H^+]$ (increased pH) decreases alveolar ventilation. Hypoventilation increases PCO_2 and helps offset the effects of high plasma HCO_3^- on pH. In dogs, for each 1 mEq/L increase in plasma HCO_3^- there is an expected increase of approximately 0.7 mmHg in PCO_2. Limited data available for cats, but degree of respiratory compensation appears to be similar.

SIGNALMENT

Any breed, age, or sex of dog and cat.

SIGNS

Historical Findings

• Administration of loop diuretics (e.g., furosemide) or thiazides. • Vomiting.

Physical Examination Findings

• Signs related to underlying disease or accompanying potassium depletion (e.g., weakness, cardiac arrhythmias, ileus). • Muscle twitching caused by low ionized calcium concentration. • Dehydration in volume-depleted patients. • Muscle twitching and seizures in patients with neurologic involvement (rare).

CAUSES

• *Chloride-responsive*—gastrointestinal losses (e.g., gastric vomiting, nasogastric tube suctioning); renal losses (diuretic therapy); and rapid correction of chronic hypercapnia (respiratory acidosis). • *Chloride-resistant*—hyperadrenocorticism and primary hyperaldosteronism. • *Oral administration of alkalinizing agents*—sodium bicarbonate or other organic anions with Na^+ (e.g., lactate, acetate, gluconate); administration of cation-exchange resin with nonabsorbable alkali (e.g., phosphorus binders). • *Hypoalbuminemia*—liver disease, protein-losing nephropathy, protein-losing enteropathy. • *Free water deficit*—diabetes insipidus; water deprivation; postobstructive diuresis; polyuric renal failure. • *Hypokalemia*.

RISK FACTORS

• Administration of loop or thiazide diuretics. • Vomiting. • Stomach drainage. • Diseases associated with hypoalbuminemia (e.g., protein-losing nephropathy, liver failure).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

High plasma HCO_3^- and hypochloremia may also occur in animals compensating for chronic respiratory acidosis, in which PCO_2 is high and pH is low despite high HCO_3^- and low Cl^- concentration; blood gas determination is required to differentiate.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

None

Disorders That May Alter Laboratory Results

• Too much heparin (>10% of sample) decreases pH, PCO_2, and HCO_3^-. • Blood samples stored at room temperature for more than 15 minutes have low pH because of increased PCO_2. • Exposure to room air decreases PCO_2. • Venous samples may have pH 0.5–1 unit lower and PCO_2 5–10 mmHg higher than arterial sample.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

• High total CO_2 (total CO_2 in samples handled aerobically closely approximates HCO_3^-). • Low blood ionized calcium concentration. • Serum electrolyte abnormalities vary with underlying cause. • Hypochloremia—consider hypochloremic metabolic alkalosis, the most common reason for metabolic alkalosis in dogs and cats, which usually results from diuretic administration or vomiting of stomach contents. • High Na^+ but normal Cl^- concentration—consider chloride-resistant metabolic alkalosis (e.g., hyperadrenocorticism or primary hyperaldosteronism) or administration of alkali. • Hypoalbuminemia—consider hypoalbuminemic metabolic alkalosis (e.g., liver failure, protein-losing enteropathy, and protein-losing nephropathy). In vitro, a 1 g/dL decrease in albumin concentration is associated with an increase in pH of 0.093 in cats and 0.047 in dogs. • Hypokalemia—likely results from intracellular potassium shifting due to metabolic alkalosis or underlying problem (e.g., vomiting of stomach contents or loop diuretic administration). • Urinary Cl^- concentrations—chloride-responsive metabolic alkalosis characterized by urine Cl^- concentrations <10 mEq/L, whereas

A

ALKALOSIS, METABOLIC (CONTINUED)

chloride-resistant metabolic alkalosis associated with urine Cl^- concentrations >20 mEq/L.

OTHER LABORATORY TESTS

Blood gas analysis reveals high HCO_3^-, PCO_2, pH, and BE. Unlike HCO3-, BE is independent of changes in metabolic acid-base status, and is thus more reliable measure of metabolic acid-base changes.

IMAGING

None

DIAGNOSTIC PROCEDURES

• Blood pressure—combination of hypertension, hypernatremia, and hypokalemia with metabolic alkalosis may indicate presence of hyperaldosteronism. • Diagnostic testing for hyperadrenocorticism or primary hyperaldosteronism (e.g., plasma renin activity and aldosterone concentration).

TREATMENT

• Acid-base disturbances are secondary phenomena; diagnosis and treatment of underlying disease process are essential to successful resolution of acid-base disorders. • Severe alkalemia is uncommon, but may be life-threatening. Patients with chronic respiratory disease and respiratory alkalosis are at risk of developing severe alkalemia if they start vomiting or receive diuretics. • Discontinue drugs that may cause metabolic alkalosis. • *Chloride-responsive*—fluid of choice for patients with volume depletion is 0.9% saline or balanced isotonic replacement fluid supplemented with KCl; patients with hypokalemia may require large amounts of KCl (see Hypokalemia). • *Chloride-resistant* metabolic alkalosis can only be corrected by resolution of underlying disease; metabolic alkalosis usually mild in these patients. • If metabolic alkalosis associated with hypokalemia and total body potassium deficits, correcting deficit with KCl is particularly effective way to reverse alkalosis.

NURSING CARE

Supportive care to maintain normal hydration, plasma volume, and adequate nutrition.

MEDICATIONS

DRUG(S) OF CHOICE

Hypochloremic Alkalosis

• If chloride-responsive alkalosis occurs during edematous state (e.g., congestive heart failure), oral administration of compounds containing Cl^- without Na^+ is recommended to correct alkalosis; if diuresis needed due to volume overload, carbonic anhydrase inhibitor (e.g., acetazolamide) or potassium-sparing diuretic (e.g., spironolactone, amiloride) can be used to correct alkalosis. • H2-blocking agents such as famotidine decrease gastric acid secretion and may be considered as adjunctive therapy if gastric losses are ongoing. • Antiemetics may help prevent further gastric acid loss.

Hypoalbuminemic Alkalosis

• Treatment for hypoalbuminemic alkalosis should be directed at underlying cause and decreased colloid oncotic pressure. • Enteral nutrition will facilitate endogenous albumin production. • Consider species-specific plasma or albumin (e.g., canine albumin) therapy.

CONTRAINDICATIONS

• Avoid chloride-free fluids—they may correct volume depletion, but will not correct hypochloremic alkalosis. • Avoid using salts of potassium without Cl^- (e.g., potassium phosphate)—potassium will be excreted in urine and will correct neither alkalosis nor potassium deficit.

PRECAUTIONS

Do not use distal-acting, potassium-sparing diuretics (e.g., spironolactone) in volume-depleted patients.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

Acid-base status—frequency dictated by underlying disease and patient response to treatment.

POSSIBLE COMPLICATIONS

• Hypokalemia. • Neurologic signs.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Hypokalemia. • Hypochloremia.

AGE-RELATED FACTORS

None

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

• Nonrespiratory alkalosis. • Chloride-responsive metabolic alkalosis—metabolic alkalosis that responds to Cl^- administration. • Chloride-resistant alkalosis—metabolic alkalosis secondary to increased mineralocorticoid activity that does not respond to Cl^- administration. • Hypochloremic alkalosis—metabolic alkalosis caused by low Cl^- concentration. • Hypoalbuminemic alkalosis—metabolic alkalosis caused by low albumin concentration. • Concentration alkalosis—metabolic alkalosis resulting from decreased free water in plasma. • Contraction alkalosis—metabolic alkalosis formerly attributed to volume contraction, but now known to be caused by Cl^- depletion; volume depletion is common but not essential feature.

SEE ALSO

• Hypochloremia.
• Hypokalemia.

ABBREVIATIONS

• BE = base excess.
• GFR = glomerular filtration rate.
• H^+ = hydrogen ion.
• HCO_3^- = bicarbonate.
• PCO_2 = carbon dioxide tension.

BASICS

DEFINITION
Common problem, seen as abnormal lack of hair coat.

PATHOPHYSIOLOGY
Specific and unique for each cause.

SYSTEMS AFFECTED
- Endocrine/metabolic.
- Hemic/lymphatic/immune.
- Skin/exocrine.

SIGNALMENT
- Age, breed, or sex predilections specific to each condition.
- Neoplastic- and paraneoplastic-associated alopecias generally recognized in older cats.

SIGNS
Depends on specific diagnosis. Knowing whether cat is pruritic is a very important part of workup for alopecia.

CAUSES
- Infectious—dermatophytosis, parasitic (mites, fleas), superficial and deep bacterial infections, viral: herpesvirus, papillomaviral plaques, feline immunodeficiency virus (FIV)– and feline leukemia virus (FeLV)–associated giant cell dermatosis.
- Hypersensitivity—atopy/allergy, oral medication reaction, topical medication reaction.
- Disorders of hair follicle cycling—telogen effluvium, Cushing's (iatrogenic and hyperadrenocorticism), hypothyroidism (iatrogenic).
- Congenital—hair follicle dystrophy, alopecia universalis (normal in sphynx cats), feline hypotrichosis (Siamese and Rex cats), pinnal hypotrichosis.
- Environmental—solar damage, burns, frostbite, scarring.
- Ischemic—post matting alopecia, post traumatic.
- Autoimmune—alopecia areata, pemphigus foliaceus.
- Neoplastic—epitheliotropic lymphoma, mastocytosis, squamous cell carcinoma in situ.
- Manifestation of internal disease—sebaceous adenitis (thymoma-associated exfoliative dermatitis), paraneoplastic alopecia, mural lymphocytic folliculitis, hyperthyroidism, hyperadrenocorticism, diabetes.
- Psychogenic—compulsive disorder.

RISK FACTORS
FeLV/FIV—reported risk for demodicosis (not all cases associated with viral infection).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infectious
- Dermatophytosis.
- Parasites
  - Mites—*Demodex gatoi*, *cheyletiella*, *notoedres* are often pruritic and scaly; *Demodex cati* cause hair loss with minimal inflammatory change in many cases.
  - Fleas can cause alopecia if patient is hypersensitive and pruritic; severe on caudal dorsum, abdomen, and around ears.
  - Tick attachment sites can cause alopecic granuloma.
- Bacterial:
  - Alopecia secondary to deep bacterial infection.
  - Superficial bacterial infections secondary to underlying cause.
- Viral:
  - Herpesvirus can cause neuralgia, pruritus, alopecia, and ulcerated eosinophilic skin lesions, most commonly on the face.
  - FIV- and FeLV-associated giant cell dermatosis.
  - Papillomaviral plaques in older cats may transform to squamous cell carcinoma.

Hypersensitivities
- Food, flea bites, or environmental allergens (atopy)—ears, face, and abdomen are most affected.
- Oral medication reactions—severe facial pruritus caused by methimazole: symptoms resolve when medication discontinued.
- Topical parasite preventives—rare cause of alopecia at site of application; usually temporary.

Disorders of Hair Follicle Cycling
- Telogen effluvium:
  - Caused by severe stressful situation or hormonal change such as anesthesia/surgery, parturition, severe illness, drugs.
  - Sudden onset of large symmetric areas of hair thinning or alopecia.
  - Hair regrows over weeks.
- Cushing's syndrome:
  - Long-term (months) corticosteroid administration, oral or injectable.
  - Megestrol acetate administration.
  - Hyperadrenocorticism from adrenal tumor or pituitary tumor.
  - Causes symmetric alopecic and atrophic/thin skin, sometimes skin fragility/tearing, ear tips droop.
- Hypothyroidism—iatrogenic is most common cause, due to treatment of hyperthyroidism.

Congenital
- Hair follicle dystrophy/sebaceous gland dystrophy can cause thin hair diffusely or waxy accumulations on the hairs.
- Alopecia universalis (normal in sphynx cats):
  - Hereditary, complete absence of primary hairs; decreased secondary hairs.
  - Sebaceous and apocrine ducts open onto skin surface; oily feel to skin.
  - Wrinkled foreheads; gold eyes; no whiskers; downy fur on paws, tip of tail, and scrotum.
  - Comedones with or without secondary folliculitis.
- Feline hypotrichosis:
  - Siamese and Devon Rex cats (autosomal recessive alopecia).
  - Poorly developed primary telogen hair follicles.
  - Born with normal coat, which becomes thin and sparse as young adult.

Environmental
- Solar damage—skin can be damaged with prolonged sun exposure; most common in outdoor light-colored cats. Areas with thin hair most affected: ears, eyes, and nose; early signs alopecia, scaling, and erythema; can transform to squamous cell carcinoma.
- Burns/frostbite—burns are location dependent' sometimes have a drip-like pattern if caused by hot liquid; affect pressure points if due to heating pad. Third-degree burns will have permanent scars. Frostbite commonly affects ear tips and causes alopecia and necrosis.
- Scarring is loss of hair follicles and usually pigment from area of skin.

Ischemic
- Post matting/traction—caused by loss of blood supply to hair follicle due to tight prolonged matting or pulling of hair; usually hair regrows with time.
- Post traumatic—rare, alopecia with little inflammation can be seen with injuries where nerve or blood supply interrupted to the skin.

Autoimmune
- Alopecia areata—rare, alopecia with little outward inflammation, most common on face and head.
- Pemphigus foliaceus—crusting and alopecia on ears, sometimes nose, feet, and other areas; pruritus variable.

Neoplastic
- Epitheliotropic lymphoma—scaly alopecia, eventually plaques and nodules.
- Squamous cell carcinoma in situ—papillomaviral plaques: in older cats, scaly, crusty, often pigmented, multifocal, sometimes pruritic.

Manifestation of Internal Disease
- Thymoma-associated exfoliative dermatitis:
  - Nonpruritic dramatic scaling dermatitis that starts on head and neck.
  - Surgical removal of thymoma resolves dermatitis over 4–5 months.

A

ALOPECIA—CATS (CONTINUED)

- Paraneoplastic alopecia:
  - Most cases associated with pancreatic adenocarcinomas, bile duct carcinomas.
  - Nonpruritic alopecia has acute onset, progresses rapidly; bilaterally symmetric, ventrally distributed (also located along bridge of nose and periocular); hair epilates easily; dry fissuring footpads; skin often thin and hypotonic; rapid weight loss.
- Mural lymphocytic folliculitis—sometimes paraneoplastic: alopecia of face, eyelids, muzzle; skin has thick, waxy feel; histologic lymphocytic invasion of follicular outer root sheath and epidermis.
- Hyperthyroidism—alopecia due to self-barbering; can see weight loss as well.
- Hyperadrenocorticism—symmetric, nonpruritic; older cat if natural, any age if iatrogenic; can have severe skin fragility.
- Diabetes—unkempt and unhealthy coat, skin infections.

Psychogenic

Although anxiety may make overgrooming worse from any underlying condition, a pure compulsive disorder is very rare; all other causes of alopecia must be ruled out prior to considering.

CBC/BIOCHEMISTRY/URINALYSIS

Abnormalities may be noted with diabetes mellitus, hyperadrenocorticism, and hyperthyroidism.

OTHER LABORATORY TESTS

- FeLV and FIV—risk factors for demodicosis and other infections.
- Thyroid hormones—document hyperthyroidism/hypothyroidism.

IMAGING

- Abdominal ultrasound—assess adrenals in hyperadrenocorticism and look for neoplasia in animals with paraneoplastic syndrome.
- Chest radiographs/ultrasound to rule out thymoma.
- CT scan—look for pituitary or other neoplasia tumors in animals with hyperadrenocorticism.

DIAGNOSTIC PROCEDURES

- Skin scrapes.
- Dermatophyte culture.
- Parasite treatment trials, since negative skin scrapes do not rule out all parasites.
- Skin biopsy.
- Shirts/collar to prove self-trauma if pruritus is questioned.
- Food elimination trials if parasites and dermatophytes are ruled out.
- Intradermal allergy testing.

TREATMENT

- See specific chapters for full list of medications, doses, and other therapies.
- If pet is compliant, shampoo and topical therapy may relieve secondary problems such as hyperkeratosis, crusting, or secondary bacterial infections.

MEDICATIONS

DRUG(S) OF CHOICE

- Demodicosis—fluralaner topically as per label every 3 months; lime sulfur dips at weekly intervals for six dips; other mites and fleas also respond to appropriate topical or oral treatments.
- Allergic dermatitis—antihistamines only rarely helpful; novel restricted-ingredient diet; corticosteroids; cyclosporine (5–7 mg/kg/day initially); allergen-specific immunotherapy; ectoparasite control.
- Hyperthyroidism—methimazole, thyroidectomy, or radioactive iodine therapy.
- Diabetes mellitus—regulation of glucose levels (insulin, weight loss, diet).
- Hyperadrenocorticism—discontinue glucocorticoids if iatrogenic; if natural, trilostane, mitotane, and surgery are options.
- Paraneoplastic alopecia—surgical excision of neoplasia; but neoplasia often fatal.
- Epitheliotropic lymphoma—corticosteroids, lomustine.
- Sebaceous adenitis—surgical removal of thymoma, corticosteroids, cyclosporine.
- Squamous cell carcinoma in situ—surgical excision, retinoids (topical and oral), topical imiquimod cream.

PRECAUTIONS

Toxicity with griseofulvin and itraconazole (see Dermatophytosis).

FOLLOW-UP

PATIENT MONITORING

Determined by specific diagnosis.

PREVENTION/AVOIDANCE

Determined by specific diagnosis.

POSSIBLE COMPLICATIONS

Determined by specific diagnosis.

EXPECTED COURSE AND PROGNOSIS

Determined by specific diagnosis.

MISCELLANEOUS

ZOONOTIC POTENTIAL

BASICS

DEFINITION
- Common disorder.
- Characterized by complete or partial loss of hair in areas where it is normally present.
- May be associated with multiple causes, be the primary problem, or be secondary to an underlying cause.

PATHOPHYSIOLOGY
- Multiple causes.
- Represents removal of hair or disruption in the growth of the hair from hypersensitivity, infection, genetic abnormality, trauma, immunologic attack, mechanical "plugging," endocrine abnormalities, neoplasia, drug reaction, and/or blockage of receptor sites for stimulation of hair growth cycle.

SYSTEMS AFFECTED
- Endocrine/metabolic.
- Hemic/lymphatic/immune.
- Skin/exocrine.

SIGNALMENT
Age, breed, and sex predilections are specific to each cause listed.

SIGNS
- May be acute in onset or slowly progressive.
- Multifocal patches of alopecia are associated with folliculitis caused by demodicosis, dermatophytosis, or, most commonly, staphylococcus infection.
- Large, more diffuse areas of alopecia may indicate follicular dysplasia or metabolic component.
- Pattern and degree of hair loss, along with presence of pruritus, are important for establishing differential diagnoses.

CAUSES
- Infectious—dermatophytosis, parasitic (mites, fleas), superficial and deep bacterial infections.
- Hypersensitivity/reaction—atopy/allergy, oral medication reaction, topical medication reaction.
- Disorders of hair follicle cycling—telogen effluvium, Cushing's (iatrogenic and hyperadrenocorticism), hypothyroidism (iatrogenic), alopecia X, seasonal flank alopecia.
- Congenital—hair follicle dystrophy.
- Environmental—solar damage, burns, frostbite, scarring.
- Ischemic—post-matting alopecia, barrette or rubber band too tight, dermatomyositis, post vaccine, vasculitis.
- Autoimmune—alopecia areata, pemphigus foliaceus, sebaceous adenitis, vasculitis.
- Neoplastic—epitheliotropic lymphoma.
- Manifestation of internal disease—hypothyroidism, hyperadrenocorticism.

RISK FACTORS
Chronic corticosteroid use causes hair cycle arrest with other signs of iatrogenic Cushing's.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Multifocal Alopecia
- Demodicosis—partial to complete alopecia with erythema, comedones, and mild scaling; lesions may become inflamed and crusted.
- Dermatophytosis—partial to complete alopecia with scaling, with or without erythema, not usually ring-like.
- Staphylococcal folliculitis—circular patterns of alopecia with epidermal collarettes, erythema, crusting, and hyperpigmented macules.
- Injection/topical medication reactions—inflammation with alopecia and/or cutaneous atrophy from scarring.
- Rabies vaccine vasculitis—well-demarcated patch of alopecia observed 1–3 months post vaccination. Small-breed dogs more predisposed.
- Alopecia areata—noninflammatory areas of complete alopecia.
- Sebaceous adenitis of short-coated breeds—annular to polycyclic areas of alopecia and scaling.

Symmetric Alopecia
- Hyperadrenocorticism—truncal alopecia associated with atrophic skin, comedones, and pyoderma, as well as other systemic signs.
- Hypothyroidism—thinning of truncal haircoat; generalized alopecia is uncommon presentation; alopecic "rat" tail.
- Noninflammatory alopecia (alopecia X)—symmetric truncal alopecia associated with hyperpigmentation; alopecia often starts along collar area of neck; Pomeranian, chow chow, Akita, Samoyed, Keeshonden, Alaskan Malamute, and Siberian husky.
- Hyperestrogenism (females)—symmetric alopecia of flanks and perineal and inguinal regions with enlarged vulva and mammary glands; may also be associated with exogenous hormone exposure.
- Male feminization from Sertoli cell tumor—alopecia of perineum and genital region with gynecomastia.
- Seasonal/cyclic/flank alopecia—common, serpiginous flank alopecia with hyperpigmentation; boxer, English bulldog, Airedale terrier.
- Color mutant/dilution alopecia—brittle or coarse hair, thinning of blue or fawn-colored hair coat, and secondary folliculitis; other colors of hair normal.
- Follicular dysplasia—slowly progressive alopecia affecting one color of hair.
- Anagen defluxion and telogen defluxion—acute onset of alopecia due to stressful event.
- Epitheliotropic lymphoma—diffuse, generalized truncal alopecia with scaling and intense erythema; later nodule and plaque formation.
- Pemphigus foliaceus—hair loss associated with scale and crust formation.
- Sebaceous adenitis—hair straightening, thinning, with dry hyperkeratosis; standard poodles and crosses, Havanese, other breeds.
- Allergic dermatitis with secondary infections and self-trauma due to pruritus.

Specific Locations
- Pinnal alopecia/pattern baldness—miniaturization of hairs and progressive alopecia; dachshund, greyhound, American water spaniel, Portuguese water spaniel, Boston terrier, Manchester terrier, whippet, Italian greyhound, Chihuahua.
- Pinnal alopecia with crusting or necrosis—consider vasculitis, which can have many triggers.
- Traction alopecia—hair loss secondary to having barrettes or rubber bands applied to the hair, or prolonged tight matting of the hair.
- Post-clipping alopecia—failure to regrow after clipping associated with slow or arrested hair cycle.
- Melanoderma (alopecia of Yorkshire terriers)—symmetric alopecia of pinnae, bridge of nose, tail, and feet.
- Seasonal/cyclic/canine flank alopecia—serpiginous flank alopecia with hyperpigmentation; boxer, English bulldog, Airedale terrier.
- Black hair follicular dysplasia—alopecia of black-haired areas only.
- Dermatomyositis—alopecia of face, tip of ears, tail, and digits; associated with scale crusting and scarring.

Breed-Related Alopecia
- Alopecic breeds—Chinese crested, Mexican hairless, Inca hairless, Peruvian Inca orchid, American hairless terrier (often associated with comedones, folliculitis, and furunculosis).
- Congenital hypotrichosis—cocker spaniel, Belgian shepherd, poodle, whippet, beagle, French bulldog, Yorkshire terrier, Labrador retriever, bichon frise, Lhasa apso, basset hound.
- Color dilution alopecia—blue or fawn Doberman pinscher, silver Labrador, cream chow chow, blond Irish setter, blue pit bull terrier, other breeds with dilute coat colors.
- Melanoderma with alopecia—Yorkshire terrier.
- Seasonal/cyclic/canine flank alopecia—serpiginous flank alopecia with hyperpigmentation; boxer, English bulldog, Airedale terrier.
- Pinnal alopecia/pattern baldness—miniaturization of hairs and progressive alopecia; dachshund, greyhound, American water spaniel, Portuguese water spaniel, Boston

A

ALOPECIA—DOGS (CONTINUED)

terrier, Manchester terrier, whippet, Italian greyhound, Chihuahua.
• Noninflammatory alopecia (alopecia X)—symmetric truncal alopecia associated with hyperpigmentation; alopecia often starts along collar area of neck; Pomeranian, chow chow, Akita, Samoyed, keeshond, Alaskan Malamute, Siberian husky.

CBC/BIOCHEMISTRY/URINALYSIS
Rule out metabolic causes such as hyperadrenocorticism.

OTHER LABORATORY TESTS
• Thyroid panel—do not rely on low T_4 (total thyroxine) alone); diagnose hypothyroidism.
• Adrenocorticotropic hormone (ACTH)-response test, low-dose dexamethasone-suppression test (LDDST), and high-dose dexamethasone-suppression test (HDDST)—evaluate for hyperadrenocorticism.
• Sex hormone profiles (questionable validity, often not useful for diagnosis or therapy).

IMAGING
Ultrasonography—evaluate adrenal glands for evidence of hyperadrenocorticism.

DIAGNOSTIC PROCEDURES
• Cytology.
• Skin scraping.
• Fungal culture.
• Skin biopsy—very useful to evaluate status of follicle/hair growth as well as epidermal changes associated with specific conditions.

TREATMENT
• Treatments depend on the underlying causes of alopecia; see specific chapters for each condition.
• Bathing can be useful as adjunctive therapy for many conditions.

MEDICATIONS
DRUG(S) OF CHOICE
• Demodicosis or other external parasites — isoxazoline antiparasitics as per label.
• Dermatophytosis—terbinafine, ketoconazole, fluconazole, itraconazole, lime sulfur dips, griseofulvin.
• Staphylococcal folliculitis—investigate and treat underlying cause, shampoo and antibiotic therapy.
• Sebaceous adenitis—topical therapy, essential fatty acid supplementation, cyclosporine.
• Iatrogenic Cushing's—stop all glucocorticoids.
• Natural hyperadrenocorticism—trilostane, mitotane, surgical removal of tumor.
• Hypothyroidism—levothyroxine supplementation.
• Follicular dysplasia—control concurrent allergies and infections.
• Alopecia X and seasonal flank alopecia—sometimes responds to melatonin.
• Ischemic lesions—consider pentoxifylline.

CONTRAINDICATIONS
N/A

POSSIBLE INTERACTIONS
None

ALTERNATIVE DRUG(S)
None

ALOPECIA, NONINFLAMMATORY—DOGS

BASICS

DEFINITION

• Uncommon alopecic disorders that are associated with abnormal hair follicle cycling. • Both endocrine and nonendocrine diseases can be associated with alopecia. • Definitive diagnosis often requires ruling out the more common endocrine alopecias.

PATHOPHYSIOLOGY

• Many factors affect the hair cycle, both hormonal and nonhormonal. • Increased sex hormones can affect the hair cycle. Estrogen is a known inhibitor of anagen, the growth phase of the hair follicle. • The mechanism by which alopecia X influences the hair cycle is not known. • Exposure to human exogenous hormone replacement therapy.

SYSTEMS AFFECTED

• Behavioral. • Endocrine/metabolic. • Hemic/lymphatic/immune. • Skin/exocrine.

GENETICS

Breed predispositions exist for alopecia X; however, the mode of inheritance is unknown.

INCIDENCE/PREVALENCE

• Hyperestrogenism and hyperandrogenism are uncommon to rare causes of alopecia. • Alopecia X is relatively common in predisposed breeds.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Dogs

Breed Predilections

• Hyperestrogenism and hyperandrogenism—no breed predilections. • Alopecia X—miniature poodle and plush-coated breeds such as Pomeranian, chow chow, Akita, Samoyed, keeshond, Alaskan Malamute, and Siberian husky; recently described in Schipperke breed.

Mean Age and Range

• Hyperestrogenism and hyperandrogenism—middle-aged to old intact dogs. • Alopecia X—1–5 years of age; however, older dogs may develop the condition.

Predominant Sex

• Hyperandrogenism, primarily intact males. • Hyperestrogenism, primarily intact females or males. • Alopecia X, neutered or intact dogs of either sex.

SIGNS

Historical Findings

• Overall change in hair coat—dry or bleached because hairs not being replaced; lack of normal shed. • Males with hyperestrogenism may attract other male dogs.

Physical Examination Findings

• Alopecia—usually diffuse and bilaterally symmetric truncal alopecia sparing the head and distal extremities; uncommon with hyperandrogenism. • Hair coat—may be dry or bleached. • Secondary seborrhea, pruritus, pyoderma, comedones, ceruminous otitis externa, and hyperpigmentation—variable. • Enlargement of nipples, mammary glands, vulva, prepuce—may be associated with hyperestrogenism. • Macular melanosis and linear preputial dermatitis—may be associated with hyperestrogenism. • Abnormal-sized or different-sized testicles—may be associated with hyperestrogenism or hyperandrogenism. • Testicles may also appear normal in size. • Tail gland hyperplasia and perianal gland hyperplasia—usually associated with hyperandrogenism. • Systemic signs (polyuria/polydipsia [PU/PD]/polyphagia) are usually *not* present.

CAUSES

Hyperestrogenism—Females

Estrogen excess associated with cystic ovaries, ovarian tumors (rare), exogenous estrogen supplementation, or exposure to human topical hormone replacement.

Hyperestrogenism—Males

• Estrogen excess due to Sertoli cell tumor (most common), seminoma, or interstitial cell tumor (rare), or exposure to human topical hormone replacement. • Associated with male pseudohermaphrodism in miniature schnauzers.

Hyperandrogenism—Males

Androgen-producing testicular tumors (especially interstitial cell tumors).

Alopecia X

Hairs fail to cycle, but underlying endocrine cause has not been identified.

RISK FACTORS

• Intact male and female dogs at increased risk for developing testicular tumors and ovarian cysts/tumors, respectively. • Cryptorchid males at increased risk for developing testicular tumors. • Exogenous estrogen supplementation. • Exposure to human exogenous hormone replacement therapy. • No known risk factors for alopecia X other than breed predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Inflammatory causes of alopecia (pyoderma, demodicosis, and dermatophytosis)—usually cause patchy rather than diffuse pattern of alopecia. • Sebaceous adenitis—inflammatory cause of alopecia more common in specific breeds (Samoyed, Akita). • Hypothyroidism and hyperadrenocorticism—may cause very similar pattern of diffuse alopecia associated with lack of hair follicle cycling. • Follicular dysplasia including color dilution alopecia and black hair follicular dysplasia—alopecia should be color restricted. • Patterned alopecia of various breeds (dachshund, Boston terrier, greyhound, water spaniel, and others)—breed-specific alopecia of unknown cause. • Seasonal/cyclic/canine flank alopecia—alopecia of flank and dorsum, often serpiginous patterns with hyperpigmentation, more often in short-coated breeds (boxer, English bulldog, Airedale) and may recur seasonally. • Postclipping alopecia—hair fails to regrow following clipping; however, hair regrowth occurs within one year. • Telogen defluxion—alopecia occurs 1–2 months following illness or severe stressful episode and usually more sudden in onset, with relative ease of epilation.

CBC/BIOCHEMISTRY/URINALYSIS

• Usually unremarkable. • Anemia, hypercholesterolemia associated with severe hypothyroidism. • Anemia and/or bone marrow hypoplasia or aplasia can be associated with hyperestrogenism.

OTHER LABORATORY TESTS

• Serum sex hormone concentrations—often normal, treat according to suspected diagnosis based on clinical signs and ruling out other disorders. • Serum estradiol concentrations—sometimes elevated in male dogs with testicular tumors or female dogs with cystic ovaries; however, normal fluctuation of estradiol occurs throughout the day, making interpretation of estradiol concentrations difficult. • Adrenal sex hormone panel not useful for diagnosis of alopecia X.

IMAGING

Radiography, ultrasonography, and laparoscopy—identify cystic ovaries, ovarian tumors, testicular tumors (scrotal or abdominal), adrenal tumors, sublumbar lymphadenopathy, and possible thoracic metastases of malignant tumors.

DIAGNOSTIC PROCEDURES

• Preputial cytology—may demonstrate cornification of cells in males with hyperestrogenism (similar to bitch in estrus). • Skin biopsy.

PATHOLOGIC FINDINGS

Histologic changes associated with endocrine dermatoses (telogen hairs, follicular keratoses, hyperkeratosis, excess trichilemmal keratinization [flame follicles], thin epidermis, and thin dermis) may also be seen with noninflammatory alopecias including

A

ALOPECIA, NONINFLAMMATORY—DOGS (CONTINUED)

hyperestrogenism and alopecia X. Histopathology will help rule out inflammatory causes of alopecia (pyoderma, demodicosis, dermatophytosis, sebaceous adenitis) and some of the other differentials listed above.

TREATMENT

DIET
None

CLIENT EDUCATION
Alopecia X is a cosmetic condition resulting in coat loss only and there is no definitive cure for the hair loss. The risk of treatment should be emphasized. Hair regrowth will only occur in a portion of dogs regardless of treatment chosen, and hair loss may recur months to years later in spite of continued treatment.

SURGICAL CONSIDERATIONS

Hyperestrogenism/Hyperandrogenism
• Castration—scrotal testicular tumors. • Exploratory laparotomy—diagnosis and surgical removal (ovariohysterectomy and castration) for ovarian cysts and tumors and abdominal testicular tumors.

Alopecia X
• Neuter intact animals—a certain number will regrow hair following neutering; hair regrowth may take up to 3 months to become evident. • Microneedling technique may induce hair regrowth.

MEDICATIONS

DRUG(S) OF CHOICE

General Treatments
• Topical antiseborrheic shampoos—for comedones and seborrhea associated with alopecia. • Antibiotics and topical antimicrobial shampoos—for secondary skin infections associated with alopecia.

Alopecia X
• Melatonin—implants (8 mg or 18 mg every 4–6 months) or oral (3 mg q12h for small breeds and 6–12 mg q12h for large breeds); evidence of hair regrowth may take up to 3 months. Effective in approximately 40% of cases. Because this treatment is benign, it is considered the treatment of choice following neutering. Once hair regrowth has occurred, discontinue treatment. • Medroxyprogesterone acetate—5–10 mg/kg SC q4 weeks for 4 treatments. Hair regrowth can take up to 6 months. Effective in approximately 40–50% of cases.

CONTRAINDICATIONS
None

PRECAUTIONS
• Melatonin at high doses can cause insulin resistance. Use caution in treating dogs with diabetes mellitus. • Medroxyprogesterone acetate can cause mammary nodules and cystic endometrial hyperplasia with long-term use. Diabetes mellitus has been reported in a few dogs.

POSSIBLE INTERACTIONS
None

ALTERNATIVE DRUG(S)
• Mitotane—15–25 mg/kg once daily as induction for 5–7 days, followed by twice weekly maintenance; hair regrowth occurs in portion of dogs treated and can take up to 3 months to become evident. Use of this drug can result in an Addisonian crisis and other side effects, as for treatment of Cushing's syndrome. • Trilostane—dosages as described for treatment of Cushing's syndrome; hair regrowth occurs in a portion of dogs treated and can take up to 3 months to become evident. Use of this drug can result in an Addisonian crisis and other side effects, as for treatment of Cushing's syndrome.

FOLLOW-UP

PATIENT MONITORING
• Medroxyprogesterone acetate—complete physical examination and chemistry panel regularly. • Mitotane—electrolytes and cortisol with adrenocorticotropic hormone (ACTH) stimulation testing regularly. • Trilostane—electrolytes and cortisol with ACTH stimulation testing regularly.

PREVENTION/AVOIDANCE
None

POSSIBLE COMPLICATIONS
None

EXPECTED COURSE AND PROGNOSIS
• Estrogen- and androgen-secreting tumors—resolution of signs should occur within 3–6 months after castration or ovariohysterectomy. • Alopecia X—hair regrowth will occur in only a portion of dogs regardless of treatment chosen and hair loss may recur in spite of continued treatment. Therefore, if hair regrowth occurs, discontinue treatment to preserve treatment for future recurrence of alopecia. Risk of treatment should be weighed with the fact that this is a cosmetic disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Pyoderma, seborrhea, comedones may be associated with alopecia. • Behavioral changes associated with hyperestrogenism or hyperandrogenism.

AGE-RELATED FACTORS
None

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
N/A—neutering usually recommended for managing these conditions.

SYNONYMS
Alopecia X—growth hormone-responsive alopecia, castration-responsive alopecia, adrenal hyperplasia-like syndrome, adrenal sex hormone imbalance of plush-coated breeds, among others.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone.
• PU/PD = polyuria/polydipsia.

Client Education Handout available online

BASICS

OVERVIEW
- Common oral tumor of odontogenic (tooth structure) ectoderm origin.
- Biologically these tumors are benign histologically, but possess locally invasive properties.
- Tumors may arise anywhere within the dental arcade.
- Several histologic subtypes exist with similar invasive behavior.

SIGNALMENT
- Middle-aged and old dogs.
- Rare in cats.

SIGNS
- Dogs may present with a smooth, firm, gingival mass that is usually nonulcerated.
- May be incidental finding during dental prophylaxis/procedures. If involving rostral dental arcade, incisor teeth can be displaced and enveloped by proliferative tissue.

CAUSES & RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Epulis.
- Gingival hyperplasia.
- Squamous cell carcinoma.
- Amelanotic melanoma.
- Plasma cell tumor.
- Other tumors related to the odontogenic apparatus.

CBC/BIOCHEMISTRY/URINALYSIS
Unaffected

OTHER LABORATORY TESTS
N/A

IMAGING
- Dental radiographs may show bone lysis deep to the superficial mass. Not particularly useful for diagnostic or treatment planning.
- Regional and distant metastasis has not been described.
- CT is ideal for planning surgery or radiation therapy, especially in large or caudal tumors.

DIAGNOSTIC PROCEDURES
- Deep tissue biopsies are necessary and recommended for definitive diagnosis.
- Squamous cell carcinoma may be misdiagnosed as ameloblastoma.

TREATMENT
- Surgical excision such as hemi- or total mandibulectomy or maxillectomy with >1–2 cm margins is recommended as a curative treatment option. Always submit resected tissue for histopathology, in order to confirm the original diagnosis, and evaluate soft tissue and bone margins.
- Radiation therapy may provide long-term control in large tumors, or when owners decline surgery.
- Intralesional chemotherapy with bleomycin has been reported, but results are generally inferior to those of surgery or radiation.

MEDICATIONS

DRUG(S) OF CHOICE
N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
Careful oral examination at 1, 3, 6, 9, and 12 months after definitive treatment is recommended to monitor for local recurrence.

A

AMPHETAMINE AND ADD/ADHD MEDICATION TOXICOSIS

BASICS

DEFINITION
Acute neurologic, neuromuscular, and cardiac toxicosis as the result of excessive consumption of amphetamine or a derivative. May be due to ingestion of prescription medications or illegal drugs.

PATHOPHYSIOLOGY
- Amphetamine and its derivatives belong to the CNS stimulant class phenylethylamines. Various substitutions of the basic phenylethylamine structure account for many pharmaceutical and illicit compounds found today.
- Amphetamine is a sympathomimetic that is structurally related to norepinephrine.
- Central action—stimulates cortical centers including cerebral cortex, medullary respiratory center, and reticular activating systems.
- Peripheral action—directly stimulates alpha and beta receptors and stimulates release of norepinephrine from stores in adrenergic nerve terminals.
- Amphetamine may slow catecholamine metabolism by inhibition of monoamine oxidase.
- Several different product formulations, including immediate and extended release and topical patch.
- Amphetamines are well absorbed orally; peak plasma levels are generally reached in 1–3 hours; this may be delayed with extended release formulations.
- Metabolism is minimal.
- The half-life, which varies from 7 to 34 hours, and rate of excretion of unchanged amphetamine in the urine are both dependent upon urine pH, with shorter half-lives associated with more acidic urine.
- Clinical signs may be seen at doses below 1 mg/kg.
- Oral lethal dose in dogs for most amphetamines ranges from 10 mg/kg to 23 mg/kg and for methamphetamine sulfate it is 9–11 mg/kg. Oral lethal dose for amphetamine sulfate is 20–27 mg/kg.
- Amphetamine and its derivatives are used in humans to treat attention deficit disorder (ADD)/attention deficit hyperactivity disorder (ADHD), narcolepsy, and obesity.
- Illicit use of amphetamines in humans is also prevalent.

SYSTEMS AFFECTED
- Cardiovascular—stimulation most common: tachycardia and hypertension.
- Nervous—stimulation most common, depression uncommon.
- Neuromuscular—stimulation: muscle tremors and seizures.
- Respiratory—stimulation, tachypnea.
- Ophthalmic—mydriasis.
- Gastrointestinal (GI)—anorexia, vomiting, diarrhea.

INCIDENCE/PREVALENCE
N/A

SIGNALMENT

Species
Dogs and cats, although more prevalent in dogs.

Breed Predilections
N/A

Mean Age and Range
N/A

Predominant Sex
N/A

SIGNS

Historical Findings
- Abnormal behavior—usually hyperactivity, anxiety or pacing, anorexia, fast heart rate, panting; observed or evidence of exposure by owner/caretaker.
- Onset of signs typically begins within 30 minutes to 6 hours post ingestion; depends on product formulation.

Physical Examination Findings
- Nervous—hyperactivity, agitation, restlessness, head bobbing, pacing, circling, vocalization, disorientation, hyperesthesia, ataxia, lethargy or depression (less common).
- Cardiovascular—tachycardia or bradycardia (less common, may be reflexive), hypertension.
- Neuromuscular—muscle fasciculation or tremors, seizures.
- Gastrointestinal—vomiting, diarrhea, anorexia, excessive salivation.
- Respiratory—tachypnea.
- Ophthalmic—mydriasis with possibly poor to unresponsive pupillary light response.
- Other—hyperthermia.

CAUSES
Accidental ingestion or administration, malicious poisoning.

RISK FACTORS
Households with children or adults currently taking prescription or illicit amphetamine or derivative.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Strychnine.
- Organochlorine insecticides.
- Methylxanthine.
- 4-aminopyridine.
- Metaldehyde.
- Phenylpropanolamine.
- Albuterol.
- Nicotine.
- Tremorgenic mycotoxins.
- Hypernatremia.
- Pseudoephedrine, phenylephrine.
- 5-fluorouracil.
- Ma huang, guarana, or ephedra.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC—generally normal with mild to moderate intoxications; disseminated intravascular coagulopathy secondary to severe hyperthermia (rare).
- Chemistry—generally normal with mild to moderate intoxications.
- Azotemia—prerenal: secondary to dehydration; renal: secondary to rhabdomyolysis and myoglobinuria (rare).
- Elevated liver enzymes—secondary to seizures and/or hyperthermia (rare).
- Hypoglycemia.
- Urinalysis—evidence of myoglobinuria, urine specific gravity (high: prerenal azotemia; isosthenuria: renal failure).

OTHER LABORATORY TESTS
- Electrolytes—imbalances secondary to GI effects.
- Acid-base status—acidosis may occur.
- Over-the-counter urine drug screens—watch for false positive or negative; consult user handbook for further information.
- Amphetamines are present in blood, urine, and saliva; consult with local veterinary diagnostic lab or human hospital for availability and proper sample submission.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- ECG for presence of any tachyarrhythmia or less commonly bradyarrhythmia.
- Blood pressure—identification of hypertension.

PATHOLOGIC FINDINGS
On necropsy presence of amphetamines may be found in gastric contents, urine, plasma, liver, kidney, or muscle.

TREATMENT

APPROPRIATE HEALTH CARE
Majority of cases require emergency inpatient intensive care management.

NURSING CARE
- Intravenous fluid therapy to correct dehydration and electrolyte imbalances as well as support renal function and promote excretion of amphetamines; use blood pressure to help guide fluid rate.
- Cool intravenous fluids, fans, cool water baths for hyperthermia.

ACTIVITY
Minimize activity and stimuli.

DIET
Withhold food if moderately to severely affected. Bland diet for few days post exposure if significant GI signs were noted.

(CONTINUED) AMPHETAMINE AND ADD/ADHD MEDICATION TOXICOSIS

CLIENT EDUCATION
In case of exposure, owner should contact local veterinarian or veterinary poison center immediately.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE

Decontamination
- Induce emesis—if recent exposure and pet is not already symptomatic.
- Apomorphine—0.04 mg/kg IV, subconjunctival.
- Hydrogen peroxide 3%—2.2 mL/kg, maximum dose 45 mL.
- Gastric lavage if extremely large ingestion or patient is already symptomatic.
- Activated charcoal with cathartic.

CNS Signs of Stimulation
- Acepromazine 0.05–1.0 mg/kg IV/IM, start low and titrate to effect.
- Chlorpromazine 0.5 mg/kg IV, titrate up as needed.
- Cyproheptadine (serotonin antagonist)—dogs, 1.1 mg/kg orally or rectally, may be repeated q8h as needed for signs consistent with serotonin syndrome; cats, 2–4 mg/cat, may repeat q12h as needed for signs consistent with serotonin syndrome.
- Methocarbamol (for muscle tremors)—50–220 mg/kg IV, titrate to effect; do not exceed 330 mg/kg/day.

Cardiovascular Signs
- Tachyarrhythmia—beta blockers such as propranolol 0.02–0.04 mg/kg IV or esmolol or metoprolol; caution using propranolol in significantly hypertensive patient.
- Ventricular premature contractions—lidocaine: dogs at 2–4 mg/kg IV (to maximum of 8 mg/kg over 10-minute period); cats: start with 0.1–0.4 mg/kg and increase cautiously to 0.25–0.75 mg/kg IV slowly if no response; cats are reportedly very sensitive to lidocaine, so monitor carefully if used.

Promote Elimination
Ascorbic acid or ammonium chloride—for urinary acidification to promote elimination; however, only use if can measure acid-base status.

CONTRAINDICATIONS
- While diazepam has been successfully used to treat amphetamine exposures, there is evidence that benzodiazepines may intensify neurologic signs.
- Urinary acidification if unable to monitor acid-base status or if myoglobinuria is present.
- Inducing emesis in symptomatic patient.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
- Amphetamines inhibit metabolism of adrenergic blockers (doxazosin, phenoxybenzamine, prazosin, terazosin), phenobarbital, and phenytoin.
- Amphetamines potentiate metabolism of coumarin anticoagulants, monoamine oxidase inhibitors, opioid analgesics, and tricyclic antidepressants.

ALTERNATIVE DRUG(S)
Phenobarbital, pentobarbital, and propofol for CNS stimulatory signs.

FOLLOW-UP

PATIENT MONITORING
- Monitor in hospital until resolution of clinical signs.
- If severely affected, monitor liver and kidney values every 24 hours for 72 hours or until resolution.

PREVENTION/AVOIDANCE
All medications and illicit drugs should be kept out of pets' reach at all times.

POSSIBLE COMPLICATIONS
Acute renal failure secondary to myoglobinuria or disseminated intravascular coagulation (DIC; rare).

EXPECTED COURSE AND PROGNOSIS
- Expected course of clinical signs is 12–72 hours, depending on dose, product formulation, effectiveness of decontamination and treatment, and rate of elimination.
- Prognosis—most patients do well with prompt and appropriate veterinary care. Seizures or severe hyperthermia may be poor prognostic indicator.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
Pets exposed to human waste products from those taking amphetamines or derivatives could become symptomatic.

PREGNANCY/FERTILITY/BREEDING
Amphetamines are a known teratogen in humans. They have been found to cross the placenta in animals and may also be found in milk.

SYNONYMS
- Common brand names of prescription amphetamine drugs and their active ingredient—Adderall® (amphetamine and dextroamphetamine); Ritalin®, Metadate®, and Concerta® (methylphenidate); Daytrana® (methylphenidate transdermal patch); Focalin® (dexmethylphenidate); Vyvanse® (lisdexamfetamine); Cylert® (pemoline); Adipex-P® (phentermine); Dexedrine® (dextroamphetamine).
- Illicit drug street names—ice, glass, crank, speed, uppers, ecstasy, meth, and many others.

SEE ALSO
- Antidepressant Toxicosis—SSRIs and SNRIs.
- Antidepressant Toxicosis—Tricyclics.
- Pseudoephedrine/Phenylephrine Toxicosis.

ABBREVIATIONS
- ADD = attention deficit disorder.
- ADHD = attention deficit hyperactivity disorder.
- DIC = disseminated intravascular coagulation.
- GI = gastrointestinal.

Consulting Editor Lynn R. Hovda

A

AMYLOIDOSIS

BASICS

DEFINITION
Group of conditions of diverse causes in which extracellular deposition of insoluble fibrillar proteins (amyloid) in various organs and tissues compromises normal function.

PATHOPHYSIOLOGY
• Patients usually affected by reactive (secondary) amyloidosis; tissue deposits contain amyloid A protein (AA), fragment of acute-phase reactant protein called serum amyloid A protein (SAA). • Macrophage-derived cytokines, e.g., IL-1 and IL-6, stimulate hepatocytes to synthesize SAA. • Cellular and extracellular components involved in formation and deposition of AA. • Specific pathophysiology varies among different species and breeds; reactive amyloidosis occurs as familial disease in Chinese Shar-Pei dog and Abyssinian cat. • Chinese Shar-Pei dog—mutation involving overexpression of *HAS2* results in overproduction of hyaluronic acid, which acts as danger signal activating inflammasome pathway and IL-1 production; this mutation linked to increased likelihood of developing shar-pei autoinflammatory disease (SPAID), and also responsible for breed's meat-mouth phenotype; amyloid deposition occurs in medulla of all dogs, with majority of dogs also having glomerular involvement. • Non-shar-pei dogs—amyloid deposits found more commonly in glomeruli than medulla. • Abyssinian cat—amyloid deposits usually found in medulla, but may occur in glomeruli. • Siamese and oriental shorthair cats with familial amyloidosis—amyloid deposition occurs in liver. • Pancreatic islet amyloid polypeptide, or amylin, deposits in pancreas of old cats; amylin secreted with insulin by pancreatic beta cells; chronic increased stimulus for secretion of amylin by beta cells (e.g., states of insulin resistance) leads to pancreatic islet cell amyloidosis.

SYSTEMS AFFECTED
• Renal/urologic—predilection for renal AA deposition. • Liver, spleen, adrenal glands, pancreas, tracheobronchial tree, gastrointestinal tract also may be affected.

GENETICS
• Familial amyloidosis occurs in Chinese Shar-Pei, English foxhound, and beagle dogs, and in Abyssinian, oriental shorthair, and Siamese cats. • A genetic mutation that increases likelihood of SPAID in shar-pei dogs has been identified; chronic inflammatory episodes in SPAID result in renal amyloid deposition.

INCIDENCE/PREVALENCE
Uncommon, occurs mostly in dogs; rare in cats, except Abyssinian, Siamese, and oriental shorthair.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
• Dog—Chinese Shar-Pei, beagle, English foxhound, Walker hound, collies. • Cat—Abyssinian, Siamese, oriental shorthair.

Mean Age and Range
• Cats—mean age at diagnosis 7 years; range 1–17 years; Abyssinian cats with familial renal amyloidosis usually die by 5 years of age; Siamese cats with familial amyloidosis of liver and thyroid gland usually develop signs of liver disease when 1–4 years old. • Dogs—mean age at diagnosis 9 years; range 1–15 years; Chinese Shar-Pei affected younger, with median age at diagnosis of 5 years, range 3.6–17 years. • Prevalence increases with age.

Predominant Sex
None

SIGNS
General Comments
Clinical signs depend on organs affected; usually caused by kidney involvement.

Historical Findings
• No clear history of predisposing disorder in most cases. • Anorexia, lethargy, polyuria/polydipsia, weight loss, vomiting. • Owners may appreciate ascites and peripheral edema in animals with glomerular amyloidosis. • Chinese Shar-Pei dogs may have history of previous episodic joint swelling and high fever that resolves spontaneously within few days (SPAID). • Siamese and oriental shorthair cats may present with acute collapse and hemoabdomen due to spontaneous hepatic fracture.

Physical Examination Findings
• Related to primary inflammatory or neoplastic disease process. • Animals with renal disease may have muscle wasting, abnormal renal palpation, uremic ulceration, hypertensive fundic lesions. • Fluid retention may be present (ascites, peripheral edema). • Chinese Shar-Pei dogs may have evidence of SPAID if present during active flare-up (joint effusion and pain, fever). • Signs of thromboembolic disease may be present in up to 40% of dogs with renal amyloidosis (dyspnea with pulmonary embolism, caudal paresis with aortic embolism). • Siamese and oriental shorthair cats with hepatic dysfunction may have jaundice; pallor and abdominal fluid wave may be present with hepatic fracture and hemoabdomen.

CAUSES
• Neoplasia and chronic infectious and noninfectious inflammatory conditions can be found in 30–50% of dogs with reactive amyloidosis. • Chronic inflammation—systemic mycoses, chronic bacterial infections, parasitic infections (dirofilariasis, leishmaniasis, hepatozoonosis), inflammatory and immune-mediated diseases (SPAID, systemic lupus erythematosus, juvenile polyarteritis of beagle); amyloid deposits can be found in up to 35% of feline immunodeficiency virus (FIV)-positive cats. • Neoplasia (lymphoma, plasmacytoma, multiple myeloma, mammary tumors, testicular tumors). • Familial—Chinese Shar-Pei, English foxhound, and beagle dogs; Abyssinian, Siamese, and oriental shorthair cats. • Other—cyclic hematopoiesis in gray collies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Depends on organ affected. • Renal (glomerular) amyloidosis—immune-complex glomerulonephritis (GN; e.g., membrano-proliferative GN [MPGN], membranous GN [MGN]), non-immune-complex GN, glomerulosclerosis, focal segmental glomerulosclerosis, other glomerulopathies. • Renal (medullary) amyloidosis—other causes of medullary renal disease (e.g., pyelonephritis, chronic interstitial nephritis). • Hepatic amyloidosis—other causes of hepatic dysfunction (e.g., infectious, inflammatory, portosystemic shunt, neoplasia); in animals with hepatic fracture and hemoabdomen, consider other causes of hemoabdomen (e.g., hemangiosarcoma, hematoma).

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—nonregenerative anemia found in some dogs and cats. • Chemistry profile—changes reflect distribution of amyloid deposition; with renal medullary amyloidosis, azotemia, hyperphosphatemia, metabolic acidosis may be seen; hypoalbuminemia common with glomerular amyloidosis; hyperglobulinemia may be seen due to underlying inflammatory condition resulting in reactive amyloidosis. • Urinalysis—isosthenuria, proteinuria, cylindruria common with renal amyloidosis; proteinuria may be mild or absent in patients without glomerular amyloidosis; isosthenuria may not be present in patients without medullary involvement.

OTHER LABORATORY TESTS
• Urine protein–creatinine ratio (UPC) should be performed for quantification of proteinuria. • Urine sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE)—can differentiate between high and low molecular weight proteinuria; high molecular weight proteinuria expected with glomerular disease.

IMAGING
Abdominal Radiographic Findings
Kidneys—usually small in affected cats; small, normal size, or large in affected dogs.

Abdominal Ultrasonographic Findings

• Renal size, shape, and architecture variable; kidneys usually hyperechoic and small in affected cats; may be small, normal size, or large in affected dogs. • Echogenic effusion may be present in cats with hepatic amyloidosis, due to hepatic fracture and hemoabdomen.

DIAGNOSTIC PROCEDURES

Renal biopsy—histopathology required for definitive diagnosis, and to rule out other causes of GN; ultrasound-guided sampling preferred over surgical methods; samples should be assessed under dissecting microscope to ensure glomeruli present; risk factors for hemorrhage include body weight <5 kg, serum creatinine >5 mg/dL.

PATHOLOGIC FINDINGS

• Amyloid deposits appear homogeneous and eosinophilic when stained by hematoxylin and eosin and viewed by conventional light microscopy. • Demonstrate green birefringence after Congo red staining when viewed under polarized light; AA amyloid loses Congo red affinity after permanganate oxidation. • Ultrastructurally, fibrils are 9–11 nm in diameter, nonbranching, haphazardly arranged.

TREATMENT

APPROPRIATE HEALTH CARE

• Identify underlying inflammatory and neoplastic processes and treat if possible. • Animals symptomatic from uremia or clinically dehydrated may require hospitalization. • Stable, euhydrated animals can be managed as outpatients with standard therapy for proteinuria.

DIET

• Low-protein, low-phosphorous renal diets recommended for animals with proteinuria and/or renal dysfunction. • Esophageal feeding tube placement should be considered for enteral hydration and nutritional support.

CLIENT EDUCATION

• Discuss progression of disease and potential for underlying primary disease process. • Discuss familial predisposition in susceptible breeds.

MEDICATIONS

DRUG(S) OF CHOICE

Management of Proteinuria

• Animals with proteinuria should be treated with standard therapy for proteinuria (see Glomerulonephritis and Proteinuria). • Patients with evidence of active thromboembolic disease require antiplatelet drugs (clopidogrel or aspirin) and/or anticoagulant therapy (heparin, low molecular weight heparin, or factor Xa inhibitors).

Management of Renal Insufficiency and Hypertension

• As indicated by IRIS guidelines for stage of renal disease. • Amlodipine (0.3–0.8 mg/kg PO SID) as first-line therapy for management of hypertension.

Management of Amyloid Deposition

• Dimethylsulfoxide (DMSO; dogs—90% DMSO diluted 1 : 4 with sterile water subcutaneously at dosage of 90 mg/kg 3 times per week) may help patients by solubilizing amyloid fibrils, reducing serum concentration of SAA, and reducing interstitial inflammation and fibrosis in affected kidneys, though benefit of DMSO is controversial. • Colchicine (dogs—0.01–0.04 mg/kg PO q24h) impairs release of SAA from hepatocytes, and used for amyloidosis in humans with familial Mediterranean fever (familial amyloidosis similar in pathology to SPAID); no evidence for benefit once patient develops renal amyloidosis and dysfunction; colchicine used particularly in shar-pei dogs with episodic fever or polyarthritis before development of renal failure.

PRECAUTIONS

• Dose reduction of drugs may be needed in patients with renal insufficiency. • Use of nonsteroidal anti-inflammatory drugs (NSAIDs) should be avoided in patients with renal insufficiency; SPAID flare-ups usually resolve on their own, do not require NSAIDs. • Animals with glomerular disease are prone to overhydration due to abnormal renal sodium handling; fluid therapy should be used judiciously, only to correct dehydration; even patients with mild hypoalbuminemia can become significantly overhydrated from inappropriate fluid therapy.

FOLLOW-UP

PATIENT MONITORING

BUN, creatinine, albumin, electrolyte concentrations, 3-day pooled UPC, and blood pressure 1 month following medication changes, and every 3-4 months in stable patients.

PREVENTION/AVOIDANCE

Do not breed affected animals.

POSSIBLE COMPLICATIONS

• Renal insufficiency and progressive chronic kidney disease. • Nephrotic syndrome and fluid overload. • Thromboembolic disease occurs in up to 40% of dogs, but uncommon in cats. • Hepatic rupture causing hemoabdomen (hepatic amyloidosis). • Otic and airway hemorrhage (vascular amyloidosis) reported.

EXPECTED COURSE AND PROGNOSIS

• Disease is progressive and usually advanced at time of diagnosis. In one study, median survival time for all dogs with renal amyloidosis 5 days (range: 0–443 days), shorter in Chinese Shar-Pei dogs (2 days, range: 0–368 days). • Serum creatinine concentration has significant negative association with survival. • Cats with renal insufficiency because of amyloidosis usually survive <1 year; cats with systemic amyloidosis (i.e., liver, vascular) have grave prognosis due to complications such as hepatic fracture and pulmonary hemorrhage.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Shar-pei autoinflammatory disease. • Juvenile polyarteritis in beagles.

SEE ALSO

• Chronic Kidney Disease. • Glomerulonephritis. • Proteinuria.

ABBREVIATIONS

• AA = amyloid A protein. • BUN = blood urea nitrogen. • DMSO = dimethylsulfoxide. • FIV = feline immunodeficiency virus. • GN = glomerulonephritis. • MGN = membranous GN. • MPGN = membranoproliferative GN. • NSAID = nonsteroidal anti-inflammatory drug. • SAA = serum amyloid A protein. • SDS-PAGE = sodium dodecyl sulfate–polyacrylamide gel electrophoresis. • SPAID = shar-pei autoinflammatory disease. • UPC = urine protein–creatinine ratio.

A

ANAEROBIC INFECTIONS

BASICS

OVERVIEW

- Anaerobic bacteria require low oxygen tension to live, and constitute a large portion of the normal flora.
- May be Gram-positive or Gram-negative cocci or rods, and individual organisms vary in potential to withstand oxygen exposure.
- Most common genera—*Bacteroides*, *Fusobacterium*, *Actinomyces*, *Propionibacterium*, *Peptostreptococcus* (enteric *Streptococcus*), *Porphyromonas*, and *Clostridium*.
- Most anaerobic infections are polymicrobial and can contain anaerobes admixed with facultative anaerobes or aerobic bacteria (especially *E. coli*).
- Injurious toxins and enzymes elaborated by the organisms may allow extension of infection into adjacent, healthy tissue.

SIGNALMENT

Dog and cat.

SIGNS

General Comments

- Depend on body system involved.
- Areas associated with mucous membranes are more commonly associated with anaerobic infection.
- It is possible to overlook anaerobes in an infectious process, leading to confusion in interpreting culture results and selection of antimicrobials.

Physical Examination Findings

- Foul odor associated with wound or exudative discharge.
- Gas in the tissue or exudates.
- Discolored tissue.
- Ascites (peritonitis), pleural effusion (pyothorax), or signs of pyometra (vaginal discharge, palpable structure in caudal abdomen).
- Dental disease.
- Wounds or deep abscesses that do not heal as anticipated.

CAUSES & RISK FACTORS

- Usually caused by normal flora; break in protective barriers allows bacterial invasion.
- Predisposing factors—immunosuppression, bite wounds, dental disease, open fractures, abdominal surgery, migrating foreign bodies.
- Necrosis due to trauma or hypoperfusion.
- Neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection with aerobic or fungal organisms—culture recommended.

CBC/BIOCHEMISTRY/URINALYSIS

- Neutrophilic leukocytosis, monocytosis.
- Biochemical abnormalities depend on specific organ involvement.
- Sepsis suggested by leukocytosis/leukopenia, hypoglycemia, hypoalbuminemia.

OTHER LABORATORY TESTS

- Anaerobic bacterial culture often unrewarding because of fastidious growth requirements and errors in sample handling.
  - Appropriate media and containers should be available prior to sample collection.
  - Samples should not be refrigerated.
  - Suitable samples for culture include fluid or tissue.

IMAGING

As indicated for individual patient; gas may be apparent radiographically.

DIAGNOSTIC PROCEDURES

- Cytologic inspection of fluid or tissue reveals degenerate neutrophils with morphologically diverse intracellular and extracellular bacteria; presence of large filamentous bacteria is suggestive.
- Gram staining should be performed on sample.

TREATMENT

- Wound drainage/debridement should be established as soon as possible—including placement of drains or thoracostomy tubes, as indicated.
  - Combine with systemic antimicrobial therapy.
  - Devitalized tissue should be aggressively debrided.
  - Improves local blood flow and increases tissue oxygen tension.
- Exploratory surgery indicated when anaerobic organisms complicate osteomyelitis or intraabdominal disease (e.g., pyometra, peritonitis).

MEDICATIONS

DRUG(S) OF CHOICE

- Antimicrobial therapy alone is unlikely to be successful without debridement or drainage.
  - Antibiotic selection—largely empiric (difficult to isolate anaerobes).
  - Because most anaerobic infections are polymicrobial, therapy targeted against both anaerobes *and* aerobic organisms is indicated.
- Amoxicillin with clavulanate (22–30 mg/kg PO q12h)—antibiotic of choice; clavulanate improves activity against *Bacteroides*. Injectable potentiated beta-lactams include ampicillin/sulbactam, ticarcillin/clavulanate, and piperacillin/tazobactam.
- Cefoxitin (30 mg/kg IV/IM q6–8h)—reliable activity against anaerobes.
- Clindamycin (11–33 mg/kg PO q12–24h; 10 mg/kg IV q12h)—useful for respiratory tract infections.
- Chloramphenicol (25–50 mg/kg PO q8h, dogs only)—good tissue penetration but bacteriostatic; concern for human exposure.
- Metronidazole (10 mg/kg IV/PO q12h)—useful against all clinically significant anaerobes except *Actinomyces*.
- Cefovecin (8 mg/kg SC)—infections originating from the periodontal cavity, skin, or urinary tract.
- Imipenem—significant activity against serious, resistant infections, not first-line choice.
- Quinolones—newer third-generation quinolones (e.g., pradofloxacin) have some activity against anaerobes; others ineffective.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Varies with the circumstances of each patient.

POSSIBLE COMPLICATIONS

Localized infection may progress to systemic infection if not appropriately identified and treated.

EXPECTED COURSE AND PROGNOSIS

Dependent upon identification and resolution of the underlying cause; long-term antibiotic therapy may be required.

MISCELLANEOUS

ASSOCIATED CONDITIONS

See Causes & Risk Factors.

Suggested Reading

Greene CE, Jang SS. Anaerobic infections. In: Greene CE, ed., Infectious Diseases of the Dog and Cat, 4th ed. St. Louis, MO: Saunders Elsevier, 2011, pp. 411–416.

Author Sharon Fooshee Grace
Consulting Editor Amie Koenig

BASICS

OVERVIEW

• Anal sacs are reservoirs for secretions normally evacuated by compression during defecation. • Normal gland secretions vary widely in consistency and color. • Disorders include impaction, infection/sacculitis, and neoplasia. • Treatment options include manual expression, flushing, antibiotics, and surgical excision.

SIGNALMENT

Impaction/Infection

• Dogs and cats (rarely)—no age or sex predisposition. • Breeds predisposed (impaction)—smaller breeds (miniature/toy poodle, Chihuahua, American cocker and English springer spaniel).

Neoplasia

• Adenocarcinoma—English cocker spaniel most commonly reported.

SIGNS

Impaction/Infection

• Anal/perianal pruritus—often manifested by "scooting." • Hesitancy to defecate. • Tenesmus. • Tail chasing. • Foul-smelling, nonfeces anal discharge. • Refusal to sit and/or lift tail. • Cats—excessive licking of the ventral abdomen and tail head. • Abscess—often unilateral; localized pain and discharge.

Neoplasia

• Mass or swelling in perianal region. • Tenesmus, constipation, polyuria/polydipsia (due to hypercalcemia with adenocarcinoma). • L4-Cd myelopathy reported in one cat (adenocarcinoma).

CAUSES & RISK FACTORS

Impaction/Infection

• Predisposing factors—changes in muscle tone, fecal form (soft stool/diarrhea), secretion character/volume leading to decreased/lack of expression; intestinal disease, obesity, endocrine disease. • Infection/abscess—chronic or recurrent impactions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Impaction/Infection/Neoplasia

• Hypersensitivity (flea, atopy, food). • Tapeworm infestation. • Tail fold bacterial folliculitis. • Malassezia dermatitis. • Compulsive disorder (anal licking). • Colitis or other intestinal disorder. • Keratinization disorder. • Anal sac neoplasia (adenocarcinoma, squamous cell carcinoma, melanoma). • Perianal adenoma, adenocarcinoma. • Perianal fistulae.

CBC/BIOCHEMISTRY/URINALYSIS

Impaction/Infection

Usually normal.

Neoplasia

Hypercalcemia—anal sac adenocarcinoma.

OTHER LABORATORY TESTS

None unless indicated by an underlying cause.

IMAGING

None unless indicated by an underlying cause.

DIAGNOSTIC PROCEDURES

• Digital palpation of anal sacs—should not be palpable externally. • Expression of anal sac contents—varies widely in gross appearance and microscopic characteristics. • Cytology (normal dogs/cats)—one study reports Gram-positive cocci/rods, Gram-negative cocci/rods, yeast, nondegenerate neutrophils without phagocytosis, mononuclear cells, and corneocytes; erythrocytes uncommonly found in dogs, rare in cats. Another study had similar findings but with intracellular bacteria in clinically normal dog anal sacs.

Impaction/Infection

• Cytology—no statistically significant difference in bacterial counts or inflammatory cells found between normal dogs and those with clinical signs of anal sac disease. • Bacterial culture and susceptibility—*Bacillus*, *Escherichia coli*, *Micrococcus*, *Proteus mirabilis*, *Streptococcus* spp., others possible.

Neoplasia

• Surgical excision with histopathology.

TREATMENT

Impaction/Infection

• Gentle manual expression and/or flushing of contents. Sedation may be necessary to flush severely impacted or painful anal sacs. • Feeding high-fiber diets may help natural expression of anal sacs. • Identification of underlying causes of predisposing disease. • Chronic disease—anal sac excision. • Infection—infusion of antibiotic and/or corticosteroid medications directly into the anal sacs, drainage of abscesses, use of appropriate oral antibiotics and/or antiyeast medication.

Neoplasia

• Surgical excision and staging; combine with chemotherapy.

MEDICATIONS

DRUG(S) OF CHOICE

Infection

Use of appropriate oral antibiotics: cephalexin (dog, 22–30 mg/kg q12h), amoxicillin trihydrate–clavulanate potassium (dog, 13.75 mg/kg q12h; cat, 62.5 mg/cat q12h), clindamycin (dog, 11–22 mg/kg q24h; cat, 11–30 mg/kg q24h), trimethoprim–sulfamethoxasole (dog, 15 mg/kg q12h); metronidazole (dog, 15–25 mg/kg q12–24h); enrofloxacin (dog, 10–20 mg/kg q24h), orbifloxacin (dog/cat, 5 mg/kg q24h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Trimethoprim–sulfamethoxasole—Dobermans highly susceptible to type III hypersensitivity reactions.

FOLLOW-UP

Impaction/Infection

• Reassess patients weekly initially, then as necessary to monitor healing. • Manually express anal sac contents and/or flush contents until sacs empty without intervention. • Trimethoprim–sulfamethoxasole—monitor tear production, liver function; affects thyroid serum values.

MISCELLANEOUS

SEE ALSO

• Adenocarcinoma, Anal Sac
• Perianal Fistula

A

ANAPHYLAXIS

BASICS

DEFINITION
• Acute manifestation of a type I hypersensitivity reaction mediated through the introduction of an antigen into a host having antigen-specific antibodies of the immunoglobulin (Ig) E subclass.
• Binding of antigen to mast cells sensitized with IgE results in the release of preformed and newly synthesized chemical mediators.
• Anaphylactic reactions may be localized (atopy) or systemic (anaphylactic shock).
• Anaphylaxis not mediated by IgE is designated an anaphylactoid (nonimmunologic) reaction and will not be discussed; however, the treatment is the same for either reaction.

PATHOPHYSIOLOGY
• First exposure of the patient to a particular antigen (allergen) causes a humoral response and results in production of IgE, which binds to the surface of mast cells. The patient is then considered to be sensitized to that antigen.
• Second exposure to the antigen results in cross-linking of two or more IgE molecules on the cell surface, resulting in mast cell degranulation and activation. Release of mast cell granules initiates an anaphylactic reaction.
• Major mast cell–derived mediators include histamine, eosinophilic chemotactic factor, arachidonic acid and metabolites (e.g., prostaglandins, leukotrienes, and thromboxanes), platelet-activating factor, and proteases. Release of these mediators causes an inflammatory response characterized by increased vascular permeability, smooth muscle contraction, inflammatory cell influx, and tissue damage.
• Clinical manifestations depend on the route of antigen exposure, the dose of antigen, and the level and specificity of the IgE response.

SYSTEMS AFFECTED
• Gastrointestinal—salivation, vomiting, and diarrhea.
• Cardiovascular—hypotension, cardiac arrhythmias, shock.
• Respiratory—dyspnea, cyanosis/hypoxemia.
• Skin/exocrine—pruritus, urticaria, and edema.
• Hepatobiliary (dogs)—portal hypertension, vasoconstriction, ascites.

GENETICS
Familial basis reported for type I hypersensitivity reaction in dogs.

INCIDENCE/PREVALENCE
• Localized type I hypersensitivity reactions not uncommon.
• Systemic type I hypersensitivity reactions rare.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Dogs—numerous breeds documented as having a predilection for developing atopy.
• Cats—no breeds documented as having predilection for atopy.

Mean Age and Range
• Dogs—age of clinical onset ranges from 3 months to several years; most affected animals 1–3 years old.
• Cats—age of clinical onset ranges from 6 months to 2 years.

Predominant Sex
• Dogs—atopy more common in females, no predilection for acute anaphylaxis.
• Cats—no reported sex predilection.

SIGNS

General Comments
• Initial clinical signs vary depending on the route of exposure to the inciting antigen (allergen).
• Shock—a severe anaphylactic reaction attributable to cardiovascular collapse and impaired oxygen delivery.
• May be localized to the site of exposure, but may progress to a systemic reaction.

Historical Findings
• Onset of signs usually within minutes, history of exposure to insects or medications.
• Dogs—pruritus, urticaria, vomiting, defecation, urination, collapse if severe.
• Cats—intense pruritus about the head, dyspnea, salivation, vomiting, collapse if severe.

Physical Examination Findings
• Localized cutaneous edema and erythemia at the site of exposure, macropapular rash.
• Dyspnea, cyanosis, respiratory wheezes.
• Tachycardia, hypotension (poor pulses), pale or muddy mucous membranes in animals with shock.
• Conjunctivitis, lacrimation.
• Painful abdomen, hepatomegaly (dogs).
• Hyperexcitability possible in early stages, altered mentation from hypoperfusion in systemic anaphylaxis.

CAUSES
Virtually any agent; those commonly reported include venoms (bees, wasps and hornets, fire ants, etc.), blood-based products (including antivenom and other animal-derived products), vaccines, medications, and foods.

RISK FACTORS
Previous exposure (sensitization) increases the chance of the animal developing a reaction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other types of shock.
• Asthma.
• Depends on the major organ system involved or if reaction is localized; diagnosis can be made largely based on history and clinical signs.

CBC/BIOCHEMISTRY/URINALYSIS
Because of the acute onset of disease, no tests reliably predict individual susceptibility.

OTHER LABORATORY TESTS
• In heartworm-endemic areas, a positive heartworm test may indicate a worm embolus as a cause for anaphylaxis.
• If ascites is present, abdominocentesis may reveal hemoperitoneum.
• Intradermal skin testing to identify allergens.
• Radioallergosorbent test to quantify the concentration of serum IgE specific for a particular antigen.

IMAGING
• Radiographic findings—if hemoperitoneum is present, ascites may be apparent in abdominal radiographs.
• Ultrasonographic findings—may show presence of edema in the gall bladder wall ("halo sign") or peritoneal effusion.

DIAGNOSTIC PROCEDURES
Limited, because a severely allergic animal can develop an anaphylactic reaction when exposed to even small quantities of antigen.

PATHOLOGIC FINDINGS
• Lesions vary, depending on severity of reaction, from localized cutaneous edema to severe pulmonary edema (in cats) and visceral pooling of blood (in dogs).
• Other nonspecific findings vary and are characteristic of shock.
• Nonspecific characteristics of localized reactions include edema, vasculitis, and thromboembolism.

TREATMENT

APPROPRIATE HEALTH CARE
In an acutely affected animal, the reaction is considered a medical emergency requiring hospitalization and intensive care.

NURSING CARE
Elimination of inciting antigen, if possible.

Systemic Anaphylaxis
• Goal—emergency life support through the maintenance of an open airway, treating circulatory collapse, and reestablishing physiologic parameters.

• Administer fluids (isotonic crystalloids and/or colloids) intravenously to counteract hypotension; in severely affected animals, pressor agents (e.g., pinephrine) may be necessary to support blood pressure.
• In coagulopathic animals, transfusion with fresh frozen plasma or red blood cell–containing products may be indicated.

Localized Anaphylaxis

Goal—limit the reaction and prevent progression to a systemic reaction.

ACTIVITY
N/A

DIET
If a food-based allergen is suspected (uncommon), avoid foods associated with hypersensitivity reaction.

CLIENT EDUCATION
• Discuss the unpredictable nature of the disease.
• Discuss the need to recognize that the animal has an allergic condition that may require immediate medical care.

SURGICAL CONSIDERATIONS
None

MEDICATIONS

DRUG(S) OF CHOICE

Systemic Anaphylaxis

• Epinephrine hydrochloride (5–10 µg/kg [0.005–0.01 mg/kg] IV/IM).
• Corticosteroids—dexamethasone sodium phosphate (0.1–0.5 mg/kg IV), methylprednisolone sodium succinate (30 mg/kg IV).
• Isotonic crystalloid fluids (20–30 mL/kg IV over 15–20 minutes, followed by reassessment and additional boluses if necessary, targeting a maximum of 90 mL/kg in dogs and 60 mL/kg in cats) to treat hypotension and relative hypovolemia.
• Atropine (0.02–0.04 mg/kg IV) to treat symptomatic bradycardia.
• Bronchodilators—aminophylline (10 mg/kg IM or slowly IV) in severely dyspneic patients; albuterol inhalers (90 µg/actuation, via inhalation).
• Oxygen should be administered to hypoxemic patients, either by mask or a cage with an elevated oxygen content (targeting a 40% fraction of inspired oxygen [FiO_2]).
• Norepinephrine (0.5–3 µg/kg/min IV).

Localized Anaphylaxis

• Antihistamines—diphenhydramine hydrochloride (0.5–1.0 mg/kg IV/IM/PO); famotidine (0.5–1.0 mg/kg IV); ranitidine (0.5–2.5 mg/kg IV).
• Prednisolone (1–2 mg/kg PO).
• If shock develops, initiate treatment for a systemic anaphylaxis.

CONTRAINDICATIONS
None

PRECAUTIONS
Localized reaction can develop into systemic reaction.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Closely monitor hospitalized patients for 24–48 hours.
• In patients with systemic anaphylaxis, monitoring should focus on normalization and monitoring of blood pressure, heart rate and rhythm, urine output, coagulation status, and oxygenation.
• If patients have continued fluid loss (e.g., due to diarrhea or vomiting), fluid administration rates should be adjusted accordingly.

PREVENTION/AVOIDANCE
If inciting antigen (allergen) can be identified, eliminate or reduce exposure.

POSSIBLE COMPLICATIONS
None

EXPECTED COURSE AND PROGNOSIS
• If localized reaction is treated early, prognosis is good.
• Some patients with systemic anaphylaxis that respond initially can have a recurrence of shock, usually within 12 hours of initial presentation.
• If the animal is in shock on presentation, prognosis is guarded.

A

ANEMIA OF CHRONIC KIDNEY DISEASE

BASICS

OVERVIEW

• Progressive decrease in packed cell volume (PCV), red blood cell (RBC) count, and hemoglobin, and hypoplasia of erythroid elements of bone marrow are predictable features of chronic kidney disease (CKD).
• Anemia is normocytic, normochromic, nonregenerative, and proportional to stage of CKD; underlying cause of anemia is multifactorial.
• Gastrointestinal (GI) blood loss, reduced RBC survival, deficiencies in iron and/or folate, cytokines, and inflammatory mediators may be involved; however, primary cause of anemia in CKD is inadequate production of erythropoietin (EPO) by the kidneys.
• EPO is hormone that regulates bone marrow RBC generation and is produced in peritubular interstitial cells in response to decreased tissue oxygen.

SIGNALMENT

Any patient with advanced CKD—juvenile or acquired.

SIGNS

• Anemia contributes to anorexia, weight loss, fatigue, lethargy, depression, weakness, and behavior changes characterizing CKD.
• Pallor.
• Tachypnea.
• Tachycardia.
• Systolic murmur.

CAUSES & RISK FACTORS

• All inherited, congenital, and acquired forms of CKD.
• Exacerbated by iron deficiency, inflammatory or neoplastic disease, GI bleeding, hemolysis, and myeloproliferative disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Anemia of chronic infectious, inflammatory, or neoplastic disease; myeloproliferative disease; chronic blood loss; aplastic anemia; endocrine disease; drug reaction; chronic immune-mediated, toxic, viral, rickettsial, or parasitic anemia; hemodilution.
• Regenerative anemia excludes diagnosis of anemia of CKD.

CBC/BIOCHEMISTRY/URINALYSIS

• Normocytic, normochromic, hypoproliferative anemia.
• Reticulocytes—low corrected indices and absolute counts (≤10,000/μL).
• Typically, IRIS stage 3 or greater CKD.
• High blood urea nitrogen (BUN) : creatinine ratio may predict concurrent GI bleeding.

OTHER LABORATORY TESTS

• Serum iron—normal or variably low.
• Transferrin saturation—normal or variably low (<20%).
• Feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), mycoplasma, or rickettsial testing to exclude infection-induced myelodyscrasia.
• Serum EPO—inappropriately normal or low.

IMAGING

• Small, irregular kidneys with loss or disruption of renal architecture often seen.
• Less commonly enlarged, polycystic, hydronephrotic, infiltrative.

DIAGNOSTIC PROCEDURES

Bone marrow cytology—erythroid hypoplasia; myeloid : erythroid ratio normal or high; stainable iron normal or low.

TREATMENT

• Stabilize azotemia in patients with uremic crisis.
• Ensure adequate nutrition.
• Stabilize any metabolic derangement (e.g., acidosis) that could contribute to shortened RBC lifespan.
• Minimize micronutrient deficiencies that could reduce RBC production.
• Identify and manage GI bleeding.
• Parenteral iron supplementation if needed.
• Correct systemic hypertension.

MEDICATIONS

DRUG(S) OF CHOICE

Blood Transfusion

• Short-term, rapid correction needed if hypoxic distress (typically PCV ≤15%)—give compatible packed RBCs.
• May transfuse intermittently for prolonged management, although compatibility issues are likely to occur.
• Preferred treatment is EPO support for progressive or symptomatic anemia.

EPO Replacement

• Darbepoetin alfa (Aranesp®)—an analogue of recombinant human EPO (r-HuEPO) with prolonged half-life and sustained effects; very effective with less tendency for antibody induction; should be used preferentially to epoetin alfa.
• Target PCV—dogs, 30–35%; cats, 30%.
• Dosage—0.8–1.0 μg/kg SC once weekly until PCV reaches low end of target, then decrease to q2-4 weeks as needed to maintain target; check PCV first to avoid overtreatment.
• If PCV exceeds target, discontinue until upper target range is achieved, then increase dosing interval.
• Iron dextran (5–10 mg/kg IM) should be administered as needed to normalize serum iron and transferrin saturation before initiating and during EPO treatment; injectable iron more effective than oral preparations.
• r-HuEPO—original synthetic erythropoiesis-stimulating protein, replica of human EPO (Epogen® and Procrit®); higher potential for anti-r-HuEPO antibody production and pure red cell aplasia (PRCA); use no longer recommended,

Anabolic Steroids

Not indicated.

FOLLOW-UP

PATIENT MONITORING

• PCV and blood pressure.
• Iron and transferrin saturation—at 1, 3, and 6 months, then semiannually.
• Discontinue EPO if patient develops evidence of polycythemia, local or systemic sensitivity, PRCA, or refractory hypertension.

POSSIBLE COMPLICATIONS

EPO Related

• Development of polycythemia, seizures, hypertension, iron depletion, injection pain, and mucocutaneous reactions.
• Development of PRCA during epoetin alfa treatment suggests formation of anti-r-HuEPO antibodies, which neutralize r-HuEPO and native EPO, causing severe anemia in 20–30% of animals; often reversible with cessation of treatment.
• Development of anti-r-HuEPO antibodies occurs in <10% of patients receiving darbepoetin alfa.
• Signs associated with production of anti-r-HuEPO antibodies include decreasing PCV, erythroid hypoplasia, reticulocyte count nearing zero, and myeloid : erythroid ratio ≥8.
• EPO replacements should be used cautiously or withheld if hypertension or iron deficiency develops; treatment can be reinstituted once hypertension or iron deficiency is corrected.

Transfusion Related

• Incompatibility reaction.
• Circulatory or iron overload.
• Systemic hypertension.
• Transmissible infection.

EXPECTED COURSE AND PROGNOSIS

• Correction of anemia increases appetite, activity, and quality of life.

• Use of EPO replacement agents requires careful assessment of risks and benefits.
• Short-term prognosis depends on severity of CKD.
• Long-term prognosis is guarded to poor because of underlying CKD.

MISCELLANEOUS

ABBREVIATIONS

• BUN = blood urea nitrogen.
• CKD = chronic kidney disease.
• EPO = erythropoietin.
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• GI = gastrointestinal.
• PCV = packed cell volume.
• PRCA = pure red cell aplasia.
• RBC = red blood cell.
• r-HuEPO = recombinant human erythropoietin.

A

ANEMIA, APLASTIC

BASICS

OVERVIEW
• A disorder of hematopoietic precursor cells characterized by replacement of normal bone marrow with adipose tissue. There is decreased production of granulocytes, erythrocytes, and platelets, resulting in pancytopenia in the peripheral blood. The disease is sometimes also referred to as aplastic pancytopenia. • In the acute form, neutropenia and thrombocytopenia predominate because of the shorter life spans of these cells; in the chronic form, nonregenerative anemia also occurs. In both forms, the bone marrow exhibits variable degrees of panhypoplasia. • Precipitating causes can include infectious diseases, drug or toxin exposure, and starvation; immune-mediated mechanisms are often suspected. • Hemic/lymphatic/immune systems affected.

SIGNALMENT
Dogs and cats, no apparent breed or sex predilection. In one study, the mean age of nine affected dogs was 3 years.

SIGNS
• Acute form—fever, petechial hemorrhages, epistaxis, hematuria, melena; i.e., signs due to neutropenia and thrombocytopenia. • Chronic form—pale mucous membranes, weakness, lethargy; i.e., signs due to anemia, in addition to signs observed in acute forms.

CAUSES & RISK FACTORS
Often not identified.

Infectious Agents
• Feline leukemia virus (FeLV), feline immunodeficiency virus (FIV). • Canine and feline parvovirus. • Rickettsial organisms (e.g., *Ehrlichia* spp.)

Drugs and Chemicals
• Estrogen (exogenous administration, Sertoli and interstitial cell tumors). • Methimazole (cats). • Chemotherapeutic drugs, including azathioprine, cyclophosphamide, cytosine arabinoside, doxorubicin, vinblastine, and hydroxyurea. • Antibiotics, including trimethoprim–sulfadiazine, cephalosporins, and chloramphenicol. • Griseofulvin. • Nonsteroidal anti-inflammatory drugs (NSAIDs), including phenylbutazone and meclofenamic acid. • Fenbendazole, albendazole. • Captopril. • Quinidine. • Thiacetarsamide. • Ionizing radiation. • Mycotoxins (cats).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Causes of pancytopenia with normal to increased bone marrow cellularity (e.g., myelodysplastic syndromes, leukemias, myelofibrosis).

CBC/BIOCHEMISTRY/URINALYSIS
• Leukopenia characterized by neutropenia with or without lymphopenia. • Normocytic, normochromic, nonregenerative anemia. • Thrombocytopenia.

OTHER LABORATORY TESTS
• Immunologic tests for infectious diseases, e.g., serologic titers, ELISA, immunofluorescent antibody (IFA). • PCR for infectious agents. • Positive tests for antierythrocyte antibodies (Coombs' test) and/or antinuclear antibody (ANA) may indicate immune-mediated mechanisms.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Bone marrow aspiration—frequently an inadequate or fatty sample is obtained because of decreased hematopoietic tissue and replacement by adipocytes. • Bone marrow core biopsy—permits an evaluation of architecture and reveals hypoplasia of cell lines and replacement by adipose tissue.

TREATMENT
Supportive treatment, antibiotics, blood component therapy, as dictated by clinical condition and results of infectious disease testing.

MEDICATIONS

DRUG(S) OF CHOICE
• Cyclosporine A—10–25 mg/kg PO q12h (dogs), 4–5 mg/kg PO q12h (cats). • Mycophenolate mofetil—10 mg/kg PO/IV q12h. • Recombinant hematopoietic growth factors, e.g., recombinant human granulocyte colony-stimulating factor (rhG-CSF) 5 µg/kg/day SC. • Androgen and corticosteroid administration have been largely unsuccessful.

Other Drugs
• Antibiotics to treat secondary infections if fever and neutropenia present. • Whole or component blood transfusion if indicated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
• Daily physical examination. • CBC every 3–5 days. • Repeat bone marrow evaluation if necessary.

PREVENTION/AVOIDANCE
• Castration of cryptorchid males (to prevent development of Sertoli or interstitial cell tumors). • Vaccination for infectious diseases. • Frequent monitoring of CBC in cancer patients receiving chemotherapy or radiation.

POSSIBLE COMPLICATIONS
• Sepsis. • Hemorrhage.

EXPECTED COURSE AND PROGNOSIS
• Guarded to poor. • Recovery of hematopoiesis may take weeks to months, if it occurs at all. • Spontaneous recovery occasionally occurs, especially in younger animals.

MISCELLANEOUS

SEE ALSO
Pancytopenia.

ABBREVIATIONS
• ANA = antinuclear antibody.
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• IFA = immunofluorescent antibody (test).
• NSAID = nonsteroidal anti-inflammatory drug.
• rhG-CSF = recombinant human granulocyte colony-stimulating factor.

Author R. Darren Wood
Consulting Editor Melinda S. Camus

BASICS

OVERVIEW
• Heinz bodies occur in red blood cells (RBCs) following damage from chemical or dietary oxidants, can cause hemolytic anemia. • When oxidants overwhelm protective reductive pathways in RBCs, denaturation of hemoglobin (Hb) causes precipitation and attachment to cell membrane. • RBCs with Heinz bodies are removed by splenic macrophages, and occasionally undergo intravascular lysis, forming ghost cells. • The spleen may occasionally remove Heinz bodies, resulting in spherocytes. • Cats more susceptible to Heinz body formation because have less reductive enzymatic capacity and closed splenic circulation, preventing macrophages from removing Heinz bodies. • Healthy cats may have low numbers of Heinz bodies without anemia. • Heinz bodies reported in patients with hyperthyroidism, lymphoma, and diabetes mellitus. • Heinz bodies may be accompanied by methemoglobinemia (Hb containing Fe^{3+}) and/or eccentrocytes (indicating oxidative damage to RBC membranes).

SIGNALMENT
No species, sex, breed, or age disposition.

SIGNS
Historical Findings
• Oxidant exposure. • Sudden onset of weakness, lethargy, or anorexia secondary to anemia. • Signs related to underlying disease if present.

Physical Examination Findings
• Pale, occasionally icteric mucous membranes, dark or chocolate-colored if methemoglobinemia. • Tachypnea, tachycardia.

CAUSES & RISK FACTORS
• Dietary—onions (raw, cooked, dehydrated, powdered), garlic, propylene glycol (cats). • Drugs—acetaminophen, phenacetin (cats), phenazopyridine (cats), methylene blue, vitamin K1 or K3 (dogs), DL-methionine (cats), benzocaine, phenylhydrazine (dogs), propofol (cats). • Miscellaneous—zinc (bolts, pennies minted after 1982, dermatologic or sun creams), naphthalene (mothballs), skunk musk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Immune-mediated or hemoparasitic hemolysis.

CBC/BIOCHEMISTRY/URINALYSIS
• Diagnosis of Heinz body anemia requires regenerative anemia, evidence of hemolytic process, presence of Heinz bodies in peripheral blood, and elimination of other causes of hemolysis or blood loss. • Regenerative anemia; severity depends on dose and duration of oxidant exposure. • Hb concentration and mean corpuscular hemoglobin concentration (MCHC) may be falsely increased due to Heinz body interference with measurement. • Heinz bodies on routinely stained blood smear appear as small, nonstaining to pale red, round inclusions that may protrude from RBC surface. • Single, small (<0.5 µm) Heinz bodies may be found in cats without anemia, but large or multiple Heinz bodies in anemic cat suggest hemolytic anemia. • Dogs may have concurrent eccentrocytosis. • Hyperbilirubinemia, bilirubinuria, hemoglobinemia, and hemoglobinuria possible with intravascular hemolysis.

OTHER LABORATORY TESTS
• New methylene blue stains Heinz bodies blue, making them easy to identify and quantify on a blood smear. • Measure methemoglobin or perform spot test if blood is dark or chocolate-colored. • Serum zinc concentration.

IMAGING
Abdominal radiographs may reveal metallic foreign bodies contributing to zinc toxicity.

DIAGNOSTIC PROCEDURES
N/A

TREATMENT
• Immediate identification and removal of oxidant may be sufficient, though often takes several days after exposure for severity of anemia to reach nadir. • Treatment depends on severity and may include IV fluids, RBC transfusions, oxygen, and restricted activity. • Endoscopy or surgery to remove metallic items in gastrointestinal tract.

MEDICATIONS

DRUG(S) OF CHOICE
• Acetaminophen toxicity in cats—N-acetylcysteine (Mucomyst®) 140 mg/kg PO/IV, followed by seven additional treatments of 70 mg/kg PO/IV q8h). • Ascorbic acid (vitamin C) 30 mg/kg PO q6-12h, to reduce methemoglobin concentrations.

Alternative Drug(s)
Use of dietary antioxidants (e.g., bioflavonoids) is controversial, but may help prevent further formation of Heinz bodies.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Administration of methylene blue to treat methemoglobinemia may exacerbate Heinz body formation.

FOLLOW-UP

PATIENT MONITORING
Serial CBCs and review of blood smears to assess RBC regeneration and disappearance of Heinz bodies.

PREVENTION/AVOIDANCE
Counsel clients about identifying and preventing exposure to oxidant compounds.

POSSIBLE COMPLICATIONS
Without proper treatment and removal of oxidant, condition can be fatal.

EXPECTED COURSE AND PROGNOSIS
Prognosis is good with removal of oxidant and supportive care once hemolytic crisis is over.

MISCELLANEOUS

SEE ALSO
• Acetaminophen (APAP) Toxicosis.
• Methemoglobinemia.
• Zinc Toxicosis.

ABBREVIATIONS
• Hb = hemoglobin.
• MCHC = mean corpuscular hemoglobin concentration.
• RBC = red blood cell.

A

ANEMIA, IMMUNE-MEDIATED

BASICS

DEFINITION
Accelerated removal or hemolysis of red blood cells (RBCs) due to a type II hypersensitivity reaction.

PATHOPHYSIOLOGY
• Antibodies form against endogenous RBC antigens (primary/nonassociative immune-mediated hemolytic anemia [IMHA]), or RBC membrane antigens, or antigens altered by infectious organisms, drugs, or neoplasia (secondary/associative IMHA). • Immunoglobulin deposited on RBC membrane, causing either direct intravascular hemolysis or accelerated extravascular removal by monocyte/macrophage system. • Intravascular hemolysis occurs when adsorbed antibodies (especially immunoglobulin [Ig] M) activate complement. • Extravascular removal of RBCs occurs when RBCs coated with antibodies (especially IgG) are engulfed by splenic macrophages. • RBC agglutination occurs when IgM or high titers of IgG causes RBC bridging. • Nonregenerative IMHA caused by immune-mediated destruction of RBC precursors in bone marrow.

SYSTEMS AFFECTED
• Hemic/lymphatic/immune—destruction of RBCs, release of proinflammatory mediators, disseminated intravascular coagulation (DIC). • Cardiovascular—signs of anemia, thromboembolism. • Hepatobiliary—hyperbilirubinemia, icterus, bilirubinuria; centrilobular necrosis. • Respiratory—tachypnea (secondary to anemia or inflammation), hypoxemia (pulmonary thromboembolism [PTE]). • Integument—rare: cold-type IMHA causes necrosis of extremities and ear tips.

GENETICS
Cocker spaniels are at increased risk.

INCIDENCE/PREVALENCE
Most common hemolytic anemia of dogs, relatively rare in cats.

GEOGRAPHIC DISTRIBUTION
Secondary IMHA may have higher prevalence where associated infectious diseases endemic; incidence may vary seasonally.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Cocker spaniel, English springer spaniel, Old English sheepdog, Doberman pinscher, collie, bichon frise, miniature pinscher, Finnish spitz. • Domestic shorthair cats.

Mean Age and Range
• Dogs—mean age 5–6 years (range: 1–13 years). • Cats—mean age 2 years (range: 0.5–9 years).

Predominant Sex
• Female dogs at higher risk. • Male cats overrepresented.

SIGNS

Historical Findings
• Lethargy/weakness/collapse. • Anorexia. • Dyspnea, tachypnea. • Vomiting and/or diarrhea. • Pigmenturia. • Pica (cats).

Physical Examination Findings
• Pale mucous membranes, tachycardia, tachypnea. • Splenomegaly/hepatomegaly. • Icterus and pigmenturia (hemoglobin or bilirubin). • Fever/lymphadenopathy. • Systolic heart murmur. • Petechiae, ecchymoses, or melena (if concurrent thrombocytopenia or DIC). • Other findings possible (e.g., joint pain) when IMHA is component of systemic lupus erythematosus (SLE). • Necrosis of extremities and ear tips in cold-type IMHA (rare).

CAUSES & RISK FACTORS

Primary IMHA
Poorly characterized immune dysregulation.

Secondary IMHA
• Infectious causes—hemotrophic *Mycoplasma* spp., *Ehrlichia* spp., *Anaplasma phagocytophilum*, *Anaplasma platys*, *Babesia* spp., *Leishmaniasis*, *Dirofilaria immitis*, feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), chronic bacterial infection. • Neoplasia—lymphoma, lymphoid leukemia, hemangiosarcoma, hemophagic histiocytic sarcoma. • Drugs—penicillins, cephalosporins, propylthiouracil, methimazole, sulfonamides. • SLE. • Neonatal isoerythrolysis. • Dog erythrocyte antigen (DEA) incompatible blood transfusion. • Vaccination, surgery, hormonal changes, or other stressful events hypothesized as potential triggers.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs
• Toxicity (zinc, onions, garlic, naphthalene, skunk musk). • Snake/spider envenomation (coral snakes, recluse spiders). • Severe hypophosphatemia. • Anemia due to hemorrhage, hemoperitoneum. • Microangiopathic anemia due to splenic neoplasia or torsion. • Pyruvate kinase or phosphofructokinase deficiency.

Cats
• Toxicity (acetaminophen, zinc, onions, garlic). • Severe hypophosphatemia. • Congenital feline porphyria. • Increased osmotic fragility (Abyssinian, Somali).

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—anemia, normal to high mean cell volume (MCV), spherocytosis, polychromasia, ghost cells, leukocytosis with neutrophilia and left shift, monocytosis; anemia nonregenerative in 30% of dogs and 50% of cats. • Serum biochemistry—hyperbilirubinemia, high alanine aminotransferase (ALT). • Urinalysis—hemoglobinuria, bilirubinuria.

OTHER LABORATORY TESTS
• Positive saline agglutination test. • Direct antiglobulin (Coombs') test—positive in up to 75% of animals with IMHA. • Reticulocytosis if regenerative. • Thrombocytopenia—60% of dogs. • Prolonged activated partial thromboplastin time (APTT), ± prolonged prothrombin time (PT), increased fibrin degradation products (FDP) and d-dimer, decreased antithrombin in animals with DIC. • Blood smear—evidence of hematologic parasites. • Infectious disease testing—especially *Babesia* spp. (serology, PCR), *Mycoplasma hemofelis* (PCR), other vector-borne pathogens.

IMAGING
Abdominal radiography, ultrasonography—hepatomegaly/splenomegaly, neoplasia.

DIAGNOSTIC PROCEDURES
Bone marrow aspirate to identify nonregenerative (RBC precursor-directed) IMHA or myelofibrosis in chronic cases.

PATHOLOGIC FINDINGS
• Hepatosplenomegaly, centrilobular hepatic necrosis. • Splenic and hepatic extramedullary hematopoiesis. • PTE and DIC.

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient intensive care during acute hemolytic crisis and if complications such as DIC, PTE, thrombocytopenia, gastrointestinal (GI) bleeding, or need for multiple transfusions occur. • Outpatient when PCV stable, hemolysis controlled, and clinical signs of anemia resolved.

NURSING CARE
• Fluid therapy as needed. • Packed RBCs (or whole blood), fresh frozen plasma (FFP) if coagulopathic. • Oxygen therapy as needed. • Monitor for complications.

ACTIVITY
Cage rest.

DIET
N/A

CLIENT EDUCATION
• IMHA can be fatal and difficult to treat, with guarded prognosis. • Lifelong maintenance therapy may be needed; side effects may be severe. • Disease may recur.

SURGICAL CONSIDERATIONS
Splenectomy can be considered if medical management fails.

MEDICATIONS

DRUG(S) OF CHOICE
• Corticosteroids—prednisone 2–3 mg/kg/day PO; dexamethasone sodium phosphate (0.2–0.4 mg/kg IV q24h) can be used in patients unable to take oral medication. • Adjunctive immunosuppressants (if poor response to corticosteroids or to avoid side effects of prednisone)—cyclosporine 5 mg/kg PO q12h, cats: 0.5–3 mg/kg PO q12h; mycophenolate mofetil 8–12 mg/kg PO/IV q12h; azathioprine 2 mg/kg PO q24h, can decrease to 0.5–1.0 mg/kg PO q48h after 3 weeks or if bone marrow suppression occurs, monitor for side effects; *do not use in cats*. • Once PCV above 30%, decrease prednisone dosage to 1 mg/kg PO q12h; then taper by maximum rate of 25–50% per month over 3–6-month period, depending upon PCV and severity of side effects; additional immunosuppressant drugs may be tapered as well. • For prevention of thromboembolism consider unfractionated heparin 150–300 U/kg SC q6–8h (dose adjusted based on APTT prolongation or measurement of anti-Xa activity) and/or clopidogrel 1–2 mg/kg PO q24h; low molecular weight heparins (enoxaparin 0.8 mg/kg SC q6–8h or dalteparin 150 U/kg SC q8h) or rivaroxaban (0.5–1.0 mg/kg PO q24h) may be considered in lieu of unfractionated heparin. • Address underlying cause (secondary IMHA). • Therapeutic plasma exchange/plasmapheresis may be useful adjunctive therapy.

CONTRAINDICATIONS
Anticoagulant medications should be used cautiously in patients with thrombocytopenia (<40,000 platelets/µL).

PRECAUTIONS
• Prednisone/prednisolone can cause signs of hyperadrenocorticism and may increase risk of PTE, pancreatitis, diabetes mellitus, secondary infection, gastric ulcers (consider gastric protectants). • Immunosuppressive drugs can cause bone marrow suppression, secondary infection, pancreatitis (azathioprine), GI upset (cyclosporine, azathioprine, mycophenolate mofetil), gingival hyperplasia, papillomatosis (cyclosporine), infertility.

ALTERNATIVE DRUG(S)
• Chlorambucil—for cats, 0.1–0.2 mg/kg PO q24h initially, then q48h. • Human IV immunoglobulin (hIVIG; 0.5–1 g/kg IV) in dogs not responding to other therapies.

FOLLOW-UP

PATIENT MONITORING
• Monitor heart rate, respiratory rate, body temperature frequently. • Monitor for adverse reactions to treatment. • If PTE suspected, CT angiography indicated for diagnosis; oxygenation can be assessed with pulse oximetry or arterial blood gas analysis. • Initially, check packed cell volume (PCV) daily until stable, then every 1–2 weeks for 2 months; if still stable, recheck monthly for 6 months, then 2–4 times/year. • CBC and reticulocyte count at least monthly; if neutrophil count falls <3,000 cells/µL, discontinue cytotoxic drugs until count recovers; reinstitute at lower dosage.

PREVENTION/AVOIDANCE
Consider need for vaccination on case-by-case basis in dogs with IMHA; measurement of titers prior to elective vaccinations may be indicated.

POSSIBLE COMPLICATIONS
• Pulmonary/multiorgan thromboembolism. • DIC. • Centrilobular hepatic necrosis and renal tubular necrosis secondary to hypoxia. • Infection secondary to immunosuppressive therapy. • GI ulceration due to high-dose glucocorticoids. • Iatrogenic hyperadrenocorticism.

EXPECTED COURSE AND PROGNOSIS
• Mortality—30–70% (dog), 24% (cat). • Hyperbilirubinemia >5 mg/dL, autoagglutination, intravascular hemolysis, severe thrombocytopenia, hypoalbuminemia associated with poorer prognosis. • Response to treatment may take weeks to months; nonregenerative IMHA may have more gradual onset than typical IMHA and be slower to respond to treatment. Most patients receive immunosuppressive therapy for 4–8 months.

A

ANEMIA, IRON-DEFICIENCY

BASICS

OVERVIEW
Caused by chronic external blood loss or iron-limited erythropoiesis.

SIGNALMENT
- Fairly common in adult dogs, rare in adult cats.
- Transient neonatal iron-deficiency anemia may occur at 5–10 weeks of age in kittens.

SIGNS
- Signs of anemia (e.g., lethargy, weakness, tachypnea, pale mucous membranes).
- Cardiovascular—bounding pulses, tachycardia, systolic heart murmur.
- Gastrointestinal—intermittent melena or hematochezia, diarrhea.
- Integumentary—heavy hematophagous parasite burden (e.g., fleas), wounds.

CAUSES & RISK FACTORS
- Chronic external blood loss.
- Gastrointestinal—hookworms, lymphoma or other neoplasia, ulceration (related to medications, [e.g., non-steroidal anti-inflammatories] or disease [e.g., renal disease]).
- Less common—severe flea infestation, urinary tract hemorrhage.
- Iatrogenic—blood donor overuse, excessive diagnostic blood sampling.
- Inappropriate home-cooked diet (low dietary iron).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Any cause of anemia, especially hemorrhage.
- Microcytic anemia in portosystemic shunt disease may or may not be due to iron deficiency.
- Anemia of inflammatory disease—iron-limited erythropoiesis.

CBC/BIOCHEMISTRY/URINALYSIS
- Packed cell volume (PCV) variably decreased; may be within reference interval.
- Regenerative or nonregenerative anemia.
- Microcytosis—low normal or low mean cell volume (MCV), low mean reticulocyte volume (MCVr), anisocytosis, widened erythrocyte histogram, or increased red cell distribution width (RDW). Decreased mean cell hemoglobin concentration (MCHC) not sensitive or specific.
- Red blood cell (RBC) morphology—microcytosis, hypochromia, keratocyte (indicating oxidative damage), and schistocyte formation.
- Reticulocyte indices reticulocyte corpuscular hemoglobin concentration mean (CHCMr), reticulocyte hemoglobin content (CHr), hypochromic reticulocyte RBCs (%HYPOr), and %LowCHr are sensitive for detecting iron-limited erythropoiesis, but not specific.
- Lab tests indicating iron-limited erythropoiesis do not differentiate true from functional iron deficiency. Clinical findings of inflammatory disease are required to differentiate iron-limited erythropoiesis. Inflammatory disease and true iron deficiency may also occur concurrently.
- Thrombocytosis due to chronic blood loss.
- Hypoproteinemia—from blood loss.

OTHER LABORATORY TESTS
- Hypoferremia (serum iron <70 µg/dL) and transferrin saturation <15% support diagnosis.
- Serum iron values may be normal during iron repletion if blood loss is intermittent.
- Fecal exam for hookworms.
- Fecal examination for occult blood or melena.

IMAGING
Abdominal radiography, ultrasonography—abnormalities in gastrointestinal tract causing blood loss.

DIAGNOSTIC PROCEDURES
- Bone marrow aspirate, staining with Prussian blue (dogs only) to indicate body iron stores.
- Gastrointestinal endoscopy to identify sites of gastrointestinal blood loss.

TREATMENT
- Identify/correct cause of blood loss, treat underlying disease.
- Administer iron until hematologic features of iron deficiency resolve.
- If severe anemia (i.e., PCV <15%), transfusion may be required, using whole blood (10–30 mL/kg IV) or packed RBC (10 mL/kg IV).

MEDICATIONS

DRUG(S) OF CHOICE

Parenteral Iron Supplementation
- Iron therapy should begin with injectable iron.
- Iron dextran—10–20 mg/kg IM (dog), 50 mg IM (cat), followed by oral supplementation.

Oral Iron Supplementation—Dogs Only
- Animals with severe iron deficiency may have impaired intestinal iron absorption, making oral therapy of little value until partial iron repletion has occurred.
- Oral iron supplementation should continue 1–2 months, or until resolved.
- Ferrous sulfate powder—place in food or drinking water, 100–300 mg PO q24h.
- Ferrous gluconate—325 mg PO q24h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Oral iron is associated with unexplained death in kittens and should be avoided.
- Kittens undergo spontaneous iron replection beginning at 5–6 weeks of age.

FOLLOW-UP
- Monitor CBC every 1–4 weeks, more frequently as needed.
- Effective treatment associated with an increase in MCV and reticulocyte volume.
- Erythrocyte histogram—effective treatment reduces microcytic subpopulation over time (2–3 months).

MISCELLANEOUS

ABBREVIATIONS
- CHCMr = mean reticulocyte corpuscular hemoglobin concentration.
- CHr = reticulocyte hemoglobin content.
- HYPOr = hypochromic reticulocyte RBCs.
- MCHC = mean cell hemoglobin concentration.
- MCV = mean cell volume.
- MCVr = mean reticulocyte volume.
- PCV = packed cell volume.
- RBC = red blood cell.
- RDW = red cell distribution width.

Authors Glade Weiser and Melinda S. Camus
Consulting Editor Melinda S. Camus

ANEMIA, NONREGENERATIVE

BASICS

DEFINITION

Low red blood cell (RBC) mass due to low erythroid production, without evidence of polychromasia or reticulocytosis in peripheral blood. Anemia with reticulocyte counts <80 × 10^3/μL (dog) or 60 × 10^3/μL (cat) considered nonregenerative. Caused by altered erythropoiesis or bone marrow injury.

PATHOPHYSIOLOGY

- Alterations in erythropoiesis include deficient erythropoietin (EPO) production, nutritional deficiency, cytokine-mediated iron sequestration, disturbed metabolism in or destruction of RBC precursors (e.g., immune-mediated).
- Bone marrow injury usually caused by toxins, infection, or infiltrative processes.
- Anemia of inflammatory disease results from increased hepcidin production and release of cytokines from white blood cells (WBCs) leading to iron sequestration and decreased iron absorption. Low serum iron and transferrin, increased ferritin, decreased EPO production, shortened RBC lifespan result in anemia.

SYSTEMS AFFECTED

- Cardiovascular—shock from decreased systemic oxygen delivery.
- Hemic/lymph/immune.
- Hepatobiliary—from hypoxic injury.

SIGNALMENT

- Nonregenerative immune-mediated hemolytic anemia (IMHA)—middle-aged female dogs and male cats <3 years old.
- Congenital cobalamin malabsorption reported in Komondor, beagle, giant schnauzer, Australian shepherd, border collie, shar-pei.

SIGNS

General Comments

Usually secondary; signs associated with primary disease often precede signs of anemia.

Historical Findings

- Lethargy, exercise intolerance, inappetence, pica.
- Other findings reflect primary condition—polyuria/polydipsia (chronic kidney disease [CKD]), old paint exposure (lead poisoning), estrogen therapy or feminization in male dogs, failure to thrive (hereditary cobalamin malabsorption).

Physical Examination Findings

- Pallor, heart murmur (due to anemia), tachycardia, tachypnea, shock.
- Digital rectal examination may reveal melena if gastrointestinal (GI) blood loss.
- Signs reflecting primary condition—oral ulcerations (CKD), cachexia, organomegaly, GI or nervous system abnormalities (cobalamin malabsorption, lead poisoning), symmetric alopecia (hypothyroidism, hyperestrogenism).

CAUSES

Nonregenerative Anemia without Other Cytopenias

- Anemia of inflammatory disease (AID)—most common cause of mild nonregenerative anemia (also anemia of chronic disease).
- CKD—decreased EPO production by kidneys; uremic toxins shorten RBC lifespan and impair bone marrow response to EPO.
- Chronic liver disease—shortened RBC survival due to changes in RBC membrane lipids; functional iron deficiency due to decreased transferrin synthesis and impaired mobilization of hepatic iron.
- Hypothyroidism, hypoadrenocorticism—thyroid hormones and cortisol stimulate erythropoiesis.
- Immune-mediated destruction of precursors—spectrum from nonregenerative IMHA to pure red cell aplasia.

Nutritional or Mineral Deficiency/Toxicity

- Iron deficiency—usually due to chronic external blood loss.
- Copper deficiency—secondary to chelation therapy.
- Cobalamin (vitamin B_{12}) and/or folate deficiency—rare; can be caused by dietary insufficiency, malabsorption, congenital defects in cobalamin absorption.
- Disruption of precursor metabolism—chronic lead toxicity and possibly high concentrations of aluminum, arsenic, and cadmium inhibit heme synthesis; cadmium and lead cause renal toxicity, impaired EPO production.

Nonregenerative Anemia with Other Cytopenias

- Toxicities—drugs or chemicals, hormones (e.g., estrogen).
- Infections—feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), ehrlichiosis, babesiosis, *Cytauxzoon felis*, parvovirus (occasionally just erythroid line affected).
- Infiltrative processes—myelodysplasia, myeloproliferative and lymphoproliferative diseases, histiocytic sarcoma, metastatic neoplasia, myelofibrosis, osteosclerosis.

RISK FACTORS

- CKD.
- Inflammatory or chronic disease.
- Multicat household/cattery (infectious disease risk).
- Daily exposure to toxins (e.g., old homes with lead paint, environmental pollution).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Regenerative anemia can initially appear nonregenerative (especially in cats); exacerbation of chronic condition may produce appearance of acute onset.

CBC/BIOCHEMISTRY/URINALYSIS

CBC and Blood Smear

- Packed cell volume (PCV), hematocrit (HCT), RBC count, and hemoglobin concentration low.
- Anemia usually normocytic, normochromic, with normal mean cell volume (MCV) and mean corpuscular hemoglobin concentration (MCHC); occasionally severe vitamin B_{12} deficiency; characteristic large erythrocytes can be masked by presence of misshapen and/or small RBCs, giving normal MCV but widened red cell distribution.
- Macrocytosis (high MCV)—without polychromasia suggests nuclear maturation defect; seen in cats with FeLV.
- Microcytosis suggests maturation complete; iron deficiency most common cause; in late stages concurrent hypochromasia common in dogs.
- Characteristic RBC morphologies—schistocytes ± hypochromic RBCs common with iron deficiency; acanthocytes with liver disease; target cells with iron deficiency, liver disease, hypothyroidism.
- Inflammatory leukogram supports AID.
- Thrombocytosis common in iron deficiency.
- High number of nucleated red blood cells (NRBCs) without polychromasia or disproportionate to degree of anemia and polychromasia seen with lead toxicity, extramedullary hematopoiesis (EMH), heat stroke, bone marrow injury.
- RBC or WBC precursors in peripheral blood without orderly progression to more mature forms suggest myelodysplasia or myeloproliferative disease.
- Cobalamin malabsorption characterized by normocytic anemia, neutropenia, hypersegmented neutrophils; megaloblastic changes possible in marrow.
- RBC inclusions may be visible on blood smear with some infectious diseases (e.g., *C. felis*).

Serum Biochemistry and Urinalysis

- CKD—azotemia with isosthenuria, possible proteinuria, hypokalemia.
- Liver disease—elevated alanine aminotransferase (ALT) ± alkaline phosphatase (ALP) activities, elevated total bilirubin, bile acids, ammonia concentrations, hypoglycemia, hypoalbuminemia.
- Hypothyroidism—hypercholesterolemia (>500 mg/dL).

A

ANEMIA, NONREGENERATIVE (CONTINUED)

• Hypoadrenocorticism—hyponatremia, hyperkalemia, lymphocytosis, eosinophilia.

OTHER LABORATORY TESTS

• Reticulocyte count.
• Spherocytosis, autoagglutination, or positive Coombs' test supports immune-mediated destruction of erythroid precursors.
• Serum iron profile—with iron deficiency both serum iron and ferritin low, while total iron-binding capacity varies; with AID, serum iron low but serum ferritin high.
• Serum lead—indicated when NRBCs present; >30 µL/dL (0.3 ppm) strongly supports lead intoxication.
• Serologic testing—FeLV, FIV in cats; *Ehrlichia canis*, *Anaplasma phagocytophilia* in dogs, particularly if anemia with thrombocytopenia.
• Endocrine testing—adrenocorticotropic hormone (ACTH) stimulation test or thyroid function testing to rule out hypoadrenocorticism or hypothyroidism, respectively.
• Serum cobalamin, homocysteine, methylmalonic acid ± urine methylmalonic acid concentrations—to diagnose hereditary cobalamin malabsorption.

DIAGNOSTIC PROCEDURES

Cytologic Examination of Bone Marrow and Core Biopsy

• Cytologic examination of bone marrow aspirate indicated in all patients unless primary cause apparent, and bone marrow core biopsy useful in evaluation of bone marrow architecture and overall cellularity.
• Erythroid hypoplasia or aplasia confirms pure red cell aplasia; erythroid hyperplasia suggests IMHA; increased erythrophagia or incomplete maturation sequence suggests immune-mediated or toxic injury to specific maturation stage, or incomplete recovery from previous injury.
• Expanded erythron and high numbers of metarubricytes suggest iron deficiency; absence of iron stores supportive in dogs, but not cats.
• Disorderly maturation and atypical cellular morphology suggest myelodysplastic syndrome.
• Hypercellular marrow with increased blast cells consistent with hematopoietic neoplasia; immunophenotyping can identify affected cell line.
• Hypocellular sample can suggest aplastic marrow or myelofibrosis.

Abdominal Radiographs, Ultrasound

As part of evaluation for underlying causes such as neoplasia, CKD, or GI blood loss.

TREATMENT

• Anemia usually resolves with resolution of underlying disease.
• Conditions associated with severe anemia or pancytopenia often carry guarded to poor prognosis and may involve long-term treatment with incomplete resolution.
• Mild to moderate anemia (PCV >20%) generally requires no immediate supportive intervention.
• Patients with severe anemia (PCV <12–15%) require transfusion for stabilization (e.g., 6–10 mL/kg packed RBCs or 10–20 mL/kg whole blood).
• Determine blood type prior to transfusion (imperative for cats, ideal for dogs).
• If blood volume and tissue perfusion compromised by concurrent blood loss or shock, administer isotonic crystalloid solution (10–20 mL/kg IV, repeat as necessary) or isotonic colloid solution (2–5 mL/kg IV, to total 20 mL/kg/24h). See Shock, Hypovolemic.
• With chronic anemia, animals may be hypervolemic, and volume overload may be a concern during blood and fluid therapy.

MEDICATIONS

DRUG(S) OF CHOICE

• EPO or darbopoetin in patients with anemia of CKD.
• Iron supplementation in patients with iron deficiency anemia.
• Immunosuppressive drugs.
• May supplement with cobalamin (vitamin B_{12}) at rate of 100–200 mg PO q24h (dogs) or 50–100 mg PO q24h (cats); parenteral cyanocobalamin administration (50 µg/kg SC/IM weekly to monthly) needed in dogs with inherited cobalamin malabsorption.

PRECAUTIONS

Monitor for transfusion reactions.

FOLLOW-UP

PATIENT MONITORING

• With severe anemia—serial physical examinations, PCV/CBC, blood smear examination every 1–2 days.
• Stable animals with chronic or slowly improving disease course—reevaluate every 1–2 weeks.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Pregnant animals have mildly low PCV.

Consulting Editor Melinda S. Camus

ANEMIA, NUCLEAR MATURATION DEFECTS (ANEMIA, MEGALOBLASTIC)

BASICS

OVERVIEW

- Nonregenerative anemia characterized by impaired DNA synthesis in red blood cell (RBC) precursors (nuclear : cytoplasmic asynchrony).
- Affected RBC precursors fail to divide normally and thus are larger than corresponding normal precursors; their nuclei are deficient in chromatin with open and stippled appearance; these giant precursors with atypical nuclei are known as megaloblasts. Hemoglobin content in these precursors is normal.
- Asynchronous changes most prominent in RBC precursors, but white blood cell (WBC) and platelet precursors similarly affected.

SIGNALMENT

- Cats—often associated with feline leukemia virus (FeLV) infection.
- Dogs—usually acquired, but may be inherited.
- Breed predilection for inherited cobalamin malabsorption—giant schnauzers, Australian shepherds, Komondorok, and beagles—present as young as 8–12 weeks; border collies as young adults.
- Familial macrocytosis and megaloblastic change in toy/miniature poodles.

SIGNS

- In dogs, anemia often not symptomatic. For cobalamin deficiency, clinical signs include gastrointestinal signs and failure to thrive. Affected poodles usually not anemic.
- In cats, anemia may be mild to marked, if FeLV positive.

CAUSES & RISK FACTORS

- Infectious—FeLV most common cause in cats. Feline immunodeficiency virus (FIV) infrequently reported as causative agent.
- Nutritional—folic acid and cobalamin deficiencies, primarily in dogs with inherited cobalamin malabsorption (uncommon with other causes of cobalamin deficiency).
- Toxic—many drugs such as immunomodulators, chemotherapeutic agents, anticonvulsants, antibiotics.
- Congenital—toy/miniature poodles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- In dogs, all other mild to moderate nonregenerative anemias, including anemia of inflammatory disease and lead poisoning.
- Differentiation based on distinctive CBC and bone marrow findings.
- In cats, FeLV infection is primary differential.

CBC/BIOCHEMISTRY/URINALYSIS

- Classically, anemia macrocytic and normochromic, but often normocytic.
- Large, fully hemoglobinized RBC; few to many nucleated RBC precursors, no polychromasia.
- In dogs, mild to moderate anemia; may see neutropenia with hypersegmented neutrophils.
- In cats, mild to marked anemia.
- In cats with FeLV, anemia may occur with myelodysplastic syndrome or leukemia.
- In dogs with inherited cobalamin malabsorption, can see proteinuria and variable biochemistry derangements.

OTHER LABORATORY TESTS

- FeLV in blood and bone marrow.
- Genetic tests for dogs with inherited cobalamin malabsorption (available at University of Pennsylvania, PennGen).
- Serum cobalamin.
- Methylmalonic acid (MMA) in serum or urine (increase caused by inhibited cobalamin-dependent enzyme).

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Bone Marrow Biopsy

- In dogs, usually hyperplastic; may be hypocellular with hemosiderosis.
- In cats, may be hypo- or hyperplastic.
- Maturation arrest with nuclear : cytoplasmic asynchrony possible in all cell lines.
- Megaloblastic RBC precursors.
- Macrophage hyperplasia with phagocytosis of nucleated RBCs.

TREATMENT

- Anemia often mild and does not need specific therapy. FeLV-positive cats may require blood transfusion for stabilization.
- Target underlying cause and address concurrent signs.

MEDICATIONS

DRUG(S) OF CHOICE

- In animals with drug toxicity, discontinue offending drug.
- In animals with hypocobalaminemia, supplement with vitamin B_{12} (0.25–1 mg cyanocobalamin SC weekly to monthly or hydroxycobalamin IM every few months; oral may be effective in some patients—dogs, 250–1000 µg/day PO; cats, 250 µg/day PO).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid drugs known to cause megaloblastic anemia in patients whose condition results from other causes.

FOLLOW-UP

- Monitor response to treatment by CBC (weekly to every few months).
- Closely monitor FeLV-positive cats for disease progression.
- Prognosis depends on underlying cause; in FeLV-positive cats, prognosis poor; with drug-induced anemia, prognosis good if drug discontinued; inherited cobalamin malabsorption has good prognosis, with lifelong cobalamin supplementation.

A

ANEMIA, REGENERATIVE

BASICS

DEFINITION
Decreased circulating red blood cell (RBC) mass (indicated by low packed cell volume [PCV] or hematocrit [HCT], hemoglobin, and total RBC count) accompanied by appropriate, compensatory increase in RBC production by the bone marrow.

PATHOPHYSIOLOGY
- Caused by blood loss or hemolysis.
- Hemolysis—caused by intrinsic RBC defects (e.g., congenital RBC membrane defects or enzyme deficiencies) or extrinsic factors (e.g., RBC parasites, oxidative injury, hemolysins, osmotic changes, immune-mediated RBC destruction, hemophagocytic neoplasia, heat stroke, and severe hypophosphatemia).

SYSTEMS AFFECTED
- Cardiovascular—murmurs with marked anemia; tachycardia.
- Hemic/lymph/immune—erythroid hyperplasia in bone marrow; splenic extramedullary hematopoiesis (EMH).
- Hepatic—decreased oxygen delivery causes centrilobular degeneration of liver.
- Renal—severe intravascular hemolysis rarely leads to pigmentary nephropathy and acute renal failure.
- Musculoskeletal—progressive osteoclerosis seen in pyruvate kinase (PK)-deficient dogs.

SIGNALMENT
- PK deficiency—basenji, beagle, cairn terrier, Chihuahua, dachshund, Labrador retriever, labradoodle, miniature poodle, pug, West Highland white terrier, and American Eskimo; Somali, Abyssinian, domestic shorthair cats.
- PFK deficiency—Australian labradoodle, English springer spaniel, American cocker spaniel, cockapoo, English cocker spaniel, whippet, wachtelhund, and mixed breed dogs with spaniel parentage.
- Marked RBC osmotic fragility—English springer spaniel; Abyssinian, Somali, Siamese, and domestic shorthair cats.
- Feline congenital porphyria—Siamese and domestic shorthair cats.
- Heritable coagulopathies (e.g., factor VIII or IX deficiency), von Willebrand disease.
- Immune-mediated hemolytic anemia (IMHA)—middle-aged female dogs, especially American cocker spaniels, English springer spaniels, Irish setters, Old English sheepdogs, poodles, and Shetland sheepdogs.
- Hemophagocytic histiocytic sarcoma—Bernese mountain dog, Rottweiler, golden retriever, and flat-coated retriever.

SIGNS
- Pallor.
- Weakness, exercise intolerance, collapse.
- Anorexia.
- Possible heart murmur, tachycardia, bounding pulses (unless hemorrhage is present).
- Possible jaundice and hemoglobinuria.
- Petechiae, epistaxis, melena suggest blood loss due to vasculitis or thrombopathia.
- Hematomas or cavity bleeds suggest coagulation factor inhibition or deficiency.
- Clinical signs depend on degree of anemia and rapidity of onset.
- Rapid loss of 15–25% blood volume or acute hemolysis results in shock.
- With chronic anemia, compensatory increases in heart rate, and eventually heart size, occur; hemoglobin can drop to as low as 50% of minimum normal value without overt signs of shock or decreased oxygen delivery.

CAUSES
- Immune-mediated (IMHA).
- RBC toxins—snake venom and bee stings may cause RBC hemolysis; oxidants can cause Heinz body formation.
- Erythrocyte parasites—cats: *Mycoplasma* spp., *Cytauxzoon felis* (may be nonregenerative); dogs: *Mycoplasma haemocanis*, *Babesia* spp.
- Mechanical RBC fragmentation—caused by vasculitis, thromboembolic disease, or disease of any vascular organ; rare cause of significant anemia unless accompanied by hemorrhage.
- Inherited RBC abnormalities:
  - PK deficiency.
  - Phosphofructokinase (PFK) deficiency.
  - Increased RBC osmotic fragility (unknown RBC defect), leads to recurrent severe anemia and splenomegaly.
  - Feline congenital porphyria—enzyme deficiency in heme synthetic pathway leads to accumulation of heme precursors, hemolytic anemia, and brown-red discoloration of teeth and bones; Siamese tend to have severe hemolytic anemia, while domestic shorthair cats have less severe autosomal dominant trait that causes mild anemia.
- Hypophosphatemia—severe hypophosphatemia impairs adenosine triphosphate (ATP) production, leading to increased erythrocyte fragility and hemolysis; seen with refeeding syndrome and insulin administration.
- Blood loss:
  - Trauma.
  - Bleeding neoplasms.
  - Coagulopathies (e.g., warfarin toxicity, hemophilia, thrombocytopenia).
  - Blood-feeding parasites.
  - Gastrointestinal ulcers.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Differentiated from nonregenerative anemia by a reticulocyte count above the regenerative threshold for that species, generally above $80 \times 10^3/\mu L$ in dogs and $60 \times 10^3/\mu L$ in cats.

LABORATORY FINDINGS

Disorders That May Alter Laboratory Results
- Lipemia can cause mild in vitro hemolysis, without appreciable anemia, and may falsely elevate mean corpuscular hemoglobin concentration (MCHC).
- Autoagglutination may falsely decrease RBC count and increase MCV.
- Exercise and excitement can increase RBC count, PCV, and reticulocyte count through splenic contraction, masking severity of anemia.

Valid If Run in Human Laboratory?
- Dogs—yes.
- Cats—yes, if hematology instrument uses species-specific parameters; instruments designed for analysis of human specimens may undercount small feline RBCs and be unable to distinguish between erythrocytes and platelets.

CBC/BIOCHEMISTRY/URINALYSIS
- PCV, RBC count, and hemoglobin are below the reference interval.
- Total protein is often low with blood loss anemia and may be the only sign with acute blood loss due to splenic contraction, which elevates the circulating RBC count.
- RBC indices vary depending on the cause of anemia and degree of regenerative response:
  - Mean cell volume (MCV) is normal to high with regeneration, but low with iron deficiency.
  - MCHC is normal to low in most patients, low with iron deficiency, and artificially high with hemolysis.
- Specific RBC morphologies may suggest the cause of hemolysis:
  - Marked spherocytosis suggests immune-mediated disease in dogs.
  - Heinz bodies or eccentrocytes suggest oxidant injury.
  - Numerous schistocytes suggest microangiopathy.
  - RBC parasites may be found on or within RBC.
- Agglutinated RBCs indicate anemia is immune mediated; distinguish autoagglutination from rouleaux by saline agglutination test (see Appendix X).
- Hemolysis is often accompanied by an inflammatory leukogram.

• Animals with IMHA often have a concurrent thrombocytopenia, while iron deficiency is often accompanied by thrombocytosis.
• Hyperbilirubinemia and bilirubinuria accompany marked hemolysis; hemoglobinemia and hemoglobinuria can be seen following intravascular hemolysis.

OTHER LABORATORY TESTS

• Reticulocytosis may be absent in the first 3–5 days after onset of blood loss or hemolysis.
• Direct antiglobulin test (Coombs' test) is indicated when IMHA is suspected, in the absence of agglutination; a positive test is confirmatory.
• The rapid osmotic fragility test detects erythrocyte membrane defects and can help to discriminate hemolytic from nonhemolytic conditions.
• Coagulation testing may be indicated in cases of blood loss.
• PCR is more sensitive for diagnosis of *Babesia* and hemotropic *Mycoplasma* than microscopic blood smear exam; can differentiate between species.
• PCR for PK deficiency.
• PCR for PFK deficiency.

DIAGNOSTIC PROCEDURES

Fine-needle aspiration and cytologic exam of abnormal spleen, lung, or lymph nodes may help to diagnose hemophagocytic histiocytic sarcoma.

TREATMENT

• Emergency if anemia is severe or has developed rapidly.
• Massive hemorrhage leads to hypovolemic shock and decreased oxygen delivery to tissues; acute hemolysis also leads to decreased oxygen content in the blood.
• In cases of massive hemorrhage, crystalloid fluids can rapidly correct hypovolemia and restore circulation, but RBC replacement (and resolving the source of hemorrhage) is necessary for definitive therapy.
• RBC replacement (packed RBCs or whole blood) indicated with severe anemia (PCV <15%) or rapid drops (>15%) in HCT. Initial dosage depends on product selected; 1 mL/kg of packed RBCs will raise the HCT by approximately 1%; 3 mL/kg of whole blood will raise the PCV by approximately 1%, both depending on the PCV of the donor product.
• In cases of hemorrhage or coagulopathy, fresh whole blood will also provide volume expansion and coagulation factor replacement, compared to packed RBCs.
• Determine blood type prior to transfusion, especially in cats (who have preexisting autoantibodies to opposite blood types). Cross-match against donor blood if blood typing reagents not available, or if patient requires second transfusion more than 4 days after first transfusion.
• Animals with chronic blood loss or hemolytic anemias are generally normovolemic with increased cardiac output, therefore attention should be paid to transfusion volumes and rates.

MEDICATIONS

DRUG(S) OF CHOICE

• Iron may benefit animals with chronic blood-loss anemia (see Anemia, Iron-Deficiency).
• Hemolytic anemias—varies with cause of hemolysis.

FOLLOW-UP

PATIENT MONITORING

• Initially, monitor PCV and morphologic features of RBCs on a blood smear every 24 hours to evaluate effectiveness of treatment and bone marrow responsiveness; polychromasia may be seen as regenerative response starts.
• As regeneration becomes apparent, recheck every 3–5 days.
• During and following transfusion, monitor for transfusion reactions (see Blood Transfusion Reactions).

A

ANOREXIA

BASICS

DEFINITION
Anorexia is the lack or loss of appetite for food. Hyporexia is a reduction in appetite, while dysrexia is a change in appetite or lack of consistent appetite. Anorexia results in decreased food intake, which then leads to weight loss, dehydration, nutritional deficiencies, and/or sarcopenia.

PATHOPHYSIOLOGY
• The control of appetite is a complex interaction between the central nervous system, the environment, and the gastrointestinal (GI) tract. • The hypothalamus and brainstem contain feeding-regulatory neurons that act as input stations for sensory and metabolic signals. These cell populations project to several brain regions and interconnect extensively. • Sensory signals that affect appetite include the odor, taste, texture, and temperature of food, as well as gastric and duodenal distention. • Metabolic signals for hunger and satiety include a variety of peptides and hormones released during the fasting and fed states, as well as plasma concentrations of glucose, amino acids, and fatty acids. • Insulin, glucagon, somatostatin, cholecystokinin, peptide tyrosine tyrosine (PYY), and pancreatic peptide decrease hunger centrally. • Leptin, produced primarily by adipocytes, acts on specific hypothalamic receptors to increase metabolism and decrease appetite. • Neuropeptide Y, released from the GI tract after food restriction, induces hunger and decreases energy expenditure. • Ghrelin, produced by the stomach, is a prokinetic and increases appetite; it decreases leptin and increases neuropeptide Y production.
• Serotonin is an important central mediator and acts via a serotonergic tract that passes near the ventromedial hypothalamic nuclei (satiety center). • Dopaminergic tracts in the hypothalamus help regulate food intake and are closely associated with the lateral hypothalamic nuclei (feeding center). • Environmental factors including the location and timing of meals, as well as learned behaviors and circadian rhythms, modulate appetite. • Brain lesions that affect the hypothalamus can decrease or increase appetite; any disorder that decreases cerebral arousal will potentially decrease food intake. • Inflammatory and neoplastic diseases can cause hyporexia by the release of proinflammatory cytokines. • The expected upregulation of dietary intake in response to increased energy expenditure is frequently absent in patients with neoplastic and advanced cardiac diseases.
• Exogenous and endogenous toxins (e.g., renal and liver failure) cause hyporexia. • Neoplasia, metabolic disorders, pancreatitis, and primary GI diseases are associated with hyporexia.
• Fear, pain, and stress may decrease appetite.

SYSTEMS AFFECTED
All body systems.

GENETICS

Mean Age and Range
N/A

Predominant Sex
N/A

SIGNS

Historical Findings
• Refusal to eat is a common presenting complaint and causes owners significant distress. • Weight loss may be reported.

Physical Examination Findings
• Findings vary depending on the underlying cause. • Low body condition score and muscle wasting may be evident depending upon the duration of decreased food intake.
• Pseudoanorectic patients commonly display halitosis, excessive drooling, difficulty with prehension or mastication, and odynophagia (painful swallowing).

CAUSES

Anorexia/Hyporexia/Dysrexia
• Possible manifestations of a myriad of systemic disorders. • Psychological—food aversion, stress, alterations in routine or environment. • Pain.
• Toxicities and drug adverse effects. • GI and pancreatic diseases. • Acid-base disorders.
• Organ failure—e.g., cardiac, renal, hepatic.
• Endocrine and metabolic diseases. • Neoplasia.
• Infectious diseases. • Immune-mediated diseases. • Respiratory diseases. • Musculoskeletal diseases. • Neurologic diseases.
• Miscellaneous (e.g., motion sickness, high environmental temperature).

Pseudoanorexia
Any disease causing painful or dysfunctional prehension, mastication, or swallowing.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Pseudoanorexia is a term describing patients who are hungry but are unable to eat due to disorders causing dysfunction or pain of the face, neck, oropharynx, and esophagus.
• Animals lacking a sense of smell (anosmia) often show a lack of interest in food.

CBC/BIOCHEMISTRY/URINALYSIS
• Abnormalities vary with different underlying diseases. • May be normal.

OTHER LABORATORY TESTS
• Additional diagnostic tests may be necessary to investigate specific diseases suggested by history, physical examination, and preliminary tests. • Heartworm serology, tick serology, retrovirus serology, thyroid level, and histologic/cytologic examination of tissue/cell samples may be required to make a definitive diagnosis.
• A baseline cortisol or an adrenocorticotropic hormone (ACTH) stimulation test to rule out hypoadrenocorticism is warranted even when there are no significant laboratory changes.

IMAGING
• Thoracic and abdominal imaging (radiographs and ultrasound) studies are often included in the minimum database to detect anatomic or functional abnormalities.
• Videofluoroscopy and endoscopy may be indicated to specifically evaluate pharyngeal, esophageal, and GI function and appearance.

DIAGNOSTIC PROCEDURES
• Perform a nutritional assessment; collect a thorough dietary history, evaluate food intake, and obtain body and muscle condition scores.
• Elicit a thorough history regarding the patient's environment, changes in routine, people, or other pets, to help identify potential sources of psychologic stress.
• Observe the patient's interest in food and ability to prehend, masticate, and swallow food. • Complete a thorough physical examination including ophthalmic, oropharyngeal, neurologic, orthopedic, thoracic, abdominal, and rectal exam to determine the presence of disease.

PATHOLOGIC FINDINGS
Dependent on underlying disease.

TREATMENT

APPROPRIATE HEALTH CARE
• Assisted feeding (enteral and/or parenteral feeding) should be considered immediately for significantly malnourished patients (≥10% body weight loss, hypoalbuminemia, poor body condition score, evidence of muscle wasting, and/or chronic disease processes). In well-conditioned patients with decreased appetite, assisted feeding should be considered if food consumption is less than the resting energy requirement [RER = 70 x (body $\text{weight}_{kg}^{0.75}$)] for 3–5 days without trends toward improvement. • Force feeding should be avoided, particularly in cats, considering the association with conditioned food aversions.

NURSING CARE
• Medications the patient is receiving should be reviewed for possible side effects leading to reduced appetite. • Provide comfort and nutrition to the patient while efforts are directed at identifying and correcting the underlying disease so that more specific treatment can be provided. • Symptomatic therapy includes correcting fluid deficits and electrolyte derangements, control of pain and/or nausea, reduction in environmental stressors, and modification of the diet to improve palatability.

ACTIVITY
N/A

DIET
• Palatability can be improved by adding flavored toppings such as low-sodium broth, increasing the moisture, fat, or protein content of the food, and warming the food to body temperature. • When learned food aversion is suspected, food should be removed immediately at the first signs of aversion.

CLIENT EDUCATION
Depends on specific diagnosis.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Pharmacologic interventions aimed at improving appetite should not replace diagnostic efforts to identify the specific cause(s) of decreased appetite. • Mirtazapine antagonizes inhibitory, presynaptic, α2-adrenergic receptors, facilitating release of norepinephrine and serotonin (5-HT). It is also a 5-HT2 and 5-HT3 antagonist on the postsynaptic neuron. Stimulation of 5-HT1 produces antidepressant effects, while inhibition of 5-HT2 and 5-HT3 produces anti-emetic and appetite-stimulating effects. Canine dosing is 0.5 mg/kg q24h. Mirataz® is FDA approved for use in cats, with a recommended dose of a 1.5 in. strip applied to the inner pinna once daily for 14 days. Alternatively, 1.88 mg/cat PO q24–48h (for cats with chronic kidney disease) can be given to stimulate appetite. • Capromorelin is a ghrelin receptor agonist that stimulates appetite centrally in the hypothalamus. Entyce® is capromorelin, approved by the FDA for dogs as an appetite stimulant. A trial in healthy laboratory beagles demonstrated significant increases in food consumption and weight compared to placebo, and a clinical field trial in inappetent client-owned dogs demonstrated increases in appetite and body weight compared to placebo. Dosing at 3 mg/kg PO q24h is safe for long-term administration. Capromorelin is not approved for cats, though a safety trial has been published and clinical trials are underway. • Diazepam (0.1 mg/kg IV q24h) is a short-acting appetite stimulant with sedative properties. Oral diazepam should be avoided in cats due to possible idiosyncratic hepatotoxicosis. • Cyproheptadine (0.2–0.4 mg/kg PO, 10–20 minutes prior to feeding), an antihistamine with antiserotonergic properties, has been used as an appetite stimulant with mixed success. • Prokinetics such as metoclopramide (0.2–0.4 mg/kg SC/PO q8–12h), ranitidine (2 mg/kg SC/IV/PO q12h), or erythromycin (0.5–1 mg/kg PO q8–12h) are useful if anorexia is associated with ileus. • Antiemetics are useful in decreasing nausea or vomiting, but are not appetite stimulants. Ondansetron (0.5–1.0 mg/kg SC/IV/PO q12h) and dolasetron (0.6–1.0 mg/kg SC/IV/PO q24h) are potent antiemetics as 5-HT3 antagonists. Maropitant is a substance P analogue, which binds neurokinin-1 receptors in the chemoreceptor trigger zone (CRTZ) and vomiting center, inhibiting vomiting. Cerenia® is maropitant, approved by the FDA for dogs and cats as an antiemetic (dogs: 1 mg/kg SC/IV or 2 mg/kg PO q24h; cats: 1 mg/kg SC/IV/PO q24h). • Omega-3 fatty acids can reduce inflammatory cytokines and have modest benefit for appetite.

CONTRAINDICATIONS
Avoid antiemetics and prokinetics if GI obstruction is present or suspected.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
Mirtazapine should not be combined with drugs that interact with or affect serotoninergic systems including monoamine oxidase inhibitors (MAOIs), tricyclic antidepressants (TCAs), and selective serotonin reuptake inhibitors (SSRIs). Ondansetron and dolasetron, as well as metoclopramide, are 5-HT3 antagonists, and care should be used with combining these drugs with mirtazapine.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Body weight, body and muscle condition score, and hydration assessment. • Monitor caloric intake to ensure return of appetite is sufficient to meet nutritional needs.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• Dehydration, malnutrition, cachexia, and sarcopenia are sequelae of prolonged anorexia/hyporexia/dysrexia; these exacerbate the underlying disease. • A loss of more than 25–30% of body protein compromises the immune system and muscle strength, and death results from infection and/or cardiopulmonary failure. • Hepatic lipidosis is a possible complication of anorexia, particularly in cats. • Breakdown of the intestinal mucosal barrier further compromises debilitated patients.

EXPECTED COURSE AND PROGNOSIS
Depends on the underlying cause(s).

MISCELLANEOUS

ASSOCIATED CONDITIONS

ANTEBRACHIAL GROWTH DEFORMITIES

BASICS

DEFINITION
Abnormally shaped antebrachium and distal part of the thoracic limb, and/or malalignments of the elbow or antebrachiocarpal joints that result from maldevelopment of the radius or ulna in the growing animal.

PATHOPHYSIOLOGY
- Antebrachium—predisposed to deformities resulting from growth of one bone after premature growth cessation or growth retardation of the paired bone.
- Decreased rate of elongation in one bone behaves as a retarding strap; the growing paired bone must twist and curve around the short bone or overgrow at the elbow or carpus; causes joint malalignment.
- Normal growth—bones elongate through the process of endochondral ossification, which occurs in the physis; physis closure occurs when the germinal cell layer stops producing new cartilage and the existing cartilage hypertrophies, ossifies, and is remodeled into bone.
- Hereditary—may be a component of common elbow joint malalignment in many chondrodysplastic breeds (e.g., basset hound and Lhasa apso).
- Osteochondrosis (OC) or dietary oversupplementation—possibly associated with retardation of endochondral ossification (retained cartilaginous cores) in giant-breed dogs.
- Hypertrophic osteodystrophy (HOD)—juvenile growth syndrome with physeal and periosteal inflammation that may impede growth.
- Trauma—most common cause; if germinal cell layer of the physis is damaged, new cartilage production and bone elongation are stopped. Commonly occurs with injury (fractures or crushing injuries) involving the distal ulnar or radial growth plates.

SYSTEMS AFFECTED
Musculoskeletal

GENETICS
- Skye terriers—reported as a recessive inheritable trait.
- Chondrodysplastic breeds (dogs)—disturbed endochondral ossification results in asynchronous growth of the paired bone system, resulting in altered growth, angular deformity, and possible elbow malalignment.

INCIDENCE/PREVALENCE
- Traumatic—may occur in up to 10% of actively growing dogs that sustain injuries of the antebrachium; uncommon in cats.
- Elbow malalignment syndrome ± angular deformity (chondrodysplastic dog breeds)—fairly common and can be bilateral; clinical abnormality in affected individuals is variable.
- Nutritionally induced—incidence decreasing as nutritional standards are improved.
- Congenital agenesis of the radius (cats and rarely dogs)—occurs infrequently; results in severely bowed antebrachium and carpal subluxation.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- Skye terrier—recessive inheritable form.
- Chondrodysplastic and toy breeds (especially basset hound, dachshund, Lhasa apso, Pekingese, Jack Russell terrier)—may be predisposed to elbow malalignment and incongruity.
- Giant breeds (e.g., Great Dane, wolfhound)—may be induced by rapid growth owing to excessive or unbalanced nutrition, OC, or HOD.

Mean Age and Range
- Traumatic—any time during the active growth phase.
- Elbow malarticulations—during growth; may not be recognized until secondary arthritic changes become severe, occasionally at several years of age.

Predominant Sex
N/A

SIGNS

General Comments
- Longer-limbed dogs—angular deformities generally more common.
- Shorter-limbed dogs—tend to develop more severe joint malalignments.
- Age at time of premature closure—affects relative degree of deformity and joint malarticulation; dogs with more growth potential remaining tend to develop more severe deformity.

Historical Findings
- Traumatic—progressive limb angulation or lameness noticed 3–4 weeks after injury; owner may not be aware of causative event.
- Developmental elbow malalignments—insidious onset of lameness in one or both thoracic limbs; most apparent after exercise.

Physical Examination Findings

Premature Distal Ulnar Closure
- Results in three deformities of the distal radius—lateral deviation (valgus), cranial bowing (procurvatum), and external torsion resulting in supination of the manus.
- Relative shortening of limb length—if unilateral can compare to the contralateral normal limb.
- Caudolateral subluxation of the radiocarpal joint and malarticulation of the elbow joint—may occur; causes lameness and painful joint restriction.

Premature Radial Physeal Closure
- Affected limb—significantly shorter than the normal contralateral limb.
- Severity of lameness—depends on degree of joint malarticulation.
- Complete symmetric closure of distal physis—may note straight limb with a widened radiocarpal or radiohumeral joint space; may note caudal bow (recurvatum) to radius and ulna.
- Asymmetric closure of medial aspect of distal radial physis—varus angular deformity; occasionally internal torsion and pronation.
- Closure of lateral aspect of distal radial physis—valgus angular deformity; external torsion and supination.
- Closure of proximal radial physis with continued ulnar growth—malarticulation of the elbow joint; widened radiohumeral space; and proximal subluxation of the humeroulnar joint (increased humerus to anconeal process space).

CAUSES
- Trauma.
- Developmental basis.
- Nutritional basis.

RISK FACTORS
- Thoracic limb trauma.
- Excessive dietary supplementation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Elbow dysplasia.
- Fragmented medial coronoid process (FMCP).
- Ununited anconeal process (UAP).
- Panosteitis.
- Flexor tendon contracture.
- HOD.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
- Damage to growth potential of the physis—commonly cannot be seen at the time of trauma; usually 2–4 weeks before radiographically apparent.
- Craniocaudal and mediolateral radiographic views—include both entire elbow and carpal joints; compare with normal contralateral limb.
- Degree of angular deformities and relative shortening—determined by comparing relative lengths of radius and ulna within the deformed pair to the normal contralateral pair.
- Degree of torsional deformity—cross-sectional imaging and creation of models using stereolithography is most useful for full appreciation of torsional deformity.
- Elbow and carpal joints—evaluate for malalignment and degenerative change; presence of degenerative change is associated with less optimal outcome following surgical treatment.
- Elbow joint—evaluate for associated UAP and FMCP.

DIAGNOSTIC PROCEDURES
N/A

(CONTINUED) # ANTEBRACHIAL GROWTH DEFORMITIES

PATHOLOGIC FINDINGS
Cartilage of abnormal growth plate often replaced with bone. Angular deformity can occur due to retained cartilage core (OC) of the distal ulnar physis.

TREATMENT

APPROPRIATE HEALTH CARE
- Genetic predisposition—do not breed.
- Traumatic physeal damage—not seen at time of injury; revealed 2–4 weeks later.
- In young (<6 months) animals, surgical treatment is generally recommended as soon as possible following diagnosis; treatment may require multiple surgical procedures.

NURSING CARE
N/A

ACTIVITY
Exercise restriction—reduces joint malalignment damage; slows arthritic progression.

DIET
- Decrease nutritional supplementation in giant-breed dogs—slows rapid growth; may reduce incidence.
- Avoid excess weight—helps control arthritic pain resulting from joint malalignment and overuse.

CLIENT EDUCATION
- Discuss heritability in chondrodysplastic breeds.
- Explain that damage to physeal growth potential is not apparent at time of trauma and that the diagnosis is often made 2–4 weeks following an injury.
- Discuss the importance of joint malalignment and resultant osteoarthritis as primary causes of lameness.
- Emphasize that early surgical treatment leads to a better prognosis.
- Depending on the patient's age, treatment may involve multiple procedures.

SURGICAL CONSIDERATIONS
- Premature closure of the distal ulnar physis in a patient <5–6 months of age (significant amount of radial growth potential remaining)—treated with partial ulnar ostectomy; valgus deformities ≤25° may improve and may not require additional surgery; young patients and those with more severe deformities often require a second definitive correction after maturity.
- Radial or ulnar physeal closure in a mature patient (limited or no growth potential) requires definitive deformity correction, joint realignment, or both.
- Deformity (torsional and angular) correction—may be accomplished with a variety of osteotomy techniques; may be stabilized with several different internal or external fixation devices.
- Joint malalignment (particularly elbow)—must correct to minimize arthritis development (primary cause of lameness); typically performed via dynamic proximal ulnar osteotomy (use triceps brachii muscle traction and joint pressure) or shortening longer bone (radial or ulnar ostectomy).
- Significant limb length discrepancies—distraction osteogenesis; osteotomy of the shortened bone is progressively distracted at the rate of 1 mm/day with an external fixator system to create new bone length.

MEDICATIONS

DRUG(S) OF CHOICE
Anti-inflammatory drugs—symptomatic treatment of osteoarthritis.

CONTRAINDICATIONS
Corticosteroids—do not use owing to potential systemic side effects and cartilage damage seen with long-term use.

PRECAUTIONS
Nonsteroidal anti-inflammatory drugs (NSAIDs)—gastrointestinal irritation or renal/hepatic toxicity may preclude use in some patients.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
- Postoperative—depends on surgical treatment.
- Periodic checkups—evaluate arthritic status and anti-inflammatory therapy.

PREVENTION/AVOIDANCE
- Selective breeding of susceptible breeds.
- Avoid dietary oversupplementation in rapidly growing giant-breed dogs.

POSSIBLE COMPLICATIONS
Routinely seen with various osteotomy fixation techniques (e.g., infection, nonunion of osteotomy, fixator pin tract inflammation, undercorrection).

EXPECTED COURSE AND PROGNOSIS
- Best results seen with early diagnosis and surgical treatment—minimizes osteoarthritis.
- Premature ulnar closure—easier to manage than premature closure of the radial growth plates; prognosis dependent on severity of the deformity, joint congruity, and presence of degenerative joint disease; prognosis worsens with increasing severity.
- Limb lengthening by distraction osteogenesis—requires extensive postoperative management by the veterinarian and owner; high rate of complications.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- OC.
- HOD.
- UAP.

AGE-RELATED FACTORS
The younger the patient at the time of traumatically induced physeal closure, the more severe the deformity and malarticulation.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
N/A

SYNONYMS
Radius curvus.

ABBREVIATIONS
- FMCP = fragmented medial coronoid process.
- HOD = hypertrophic osteodystrophy.
- NSAID = nonsteroidal anti-inflammatory drug.
- OC = osteochondrosis.
- UAP = ununited anconeal process.

ANTERIOR UVEITIS—CATS

BASICS

DEFINITION
• Inflammation of the anterior uveal tissues, including iris (iritis), ciliary body (cyclitis), or both (iridocyclitis). • May be associated with concurrent posterior uveal and retinal inflammation (choroiditis; chorioretinitis). • Unilateral or bilateral.

PATHOPHYSIOLOGY
• Increased permeability of the blood–aqueous barrier due to infectious, immune-mediated, neoplastic, traumatic, or other causes; plasma proteins and blood cells enter aqueous humor. • Disruption of blood–aqueous barrier initiated and maintained by chemical mediators.

SYSTEMS AFFECTED
• Ophthalmic. • Other systems if underlying disease.

INCIDENCE/PREVALENCE
• Relatively common. • True incidence/prevalence unknown.

GEOGRAPHIC DISTRIBUTION
Geographic location may affect incidence of certain infections.

SIGNALMENT

Species
Cat

Mean Age and Range
• Mean age 7–9 years. • Any age may be affected.

Predominant Sex
Males more commonly affected than females.

SIGNS

Historical Findings
• Cloudy eye—corneal edema, aqueous flare, hypopyon. • Painful eye—blepharospasm, photophobia, or rubbing eye; usually less severe than dogs. • Red eye—conjunctival hyperemia and ciliary flush; usually less severe than dogs. • Vision loss—variable.

Physical Examination Findings
A thorough physical examination is crucial.

Ophthalmic Findings
• Ocular discomfort—manifest by blepharospasm and photophobia. • Ocular discharge—usually serous; sometimes mucoid to mucopurulent. • Conjunctival hyperemia—bulbar and palpebral conjunctiva affected. • Corneal edema—diffuse; mild to severe. • Keratic precipitates—multifocal aggregates of inflammatory cells adherent to corneal endothelium; most notable ventrally. • Aqueous flare—cloudiness of aqueous humor due to increased protein content and cellular debris; visualized with a bright, narrow beam of light shone through anterior chamber. • Ciliary flush—injection of deep perilimbal anterior ciliary vessels. • Deep corneal vascularization—circumcorneal distribution (brush border). • Miosis or resistance to pharmacologic dilation. • Iridal swelling—may be generalized or nodular. • Reduced intraocular pressure (IOP) consistent with anterior uveitis, but not uniform finding. • Posterior synechia—adhesions between posterior iris and anterior lens surface. • Fibrin in anterior chamber. • Hypopyon or hyphema—accumulations of white or red blood cells, respectively, in anterior chamber; usually settle in ventral aspect of chamber, but may be diffuse. • Chronic changes may include rubeosis iridis, iridal hyperpigmentation, secondary cataract, lens luxation, pupillary seclusion, iris bombé, secondary glaucoma, and phthisis bulbi.

CAUSES
• Infectious—mycotic (*Blastomyces* spp., *Cryptococcus neoformans*, *Coccidiodes immitis*, *Histoplasma capsulatum*); protozoal (*Toxoplasma gondii*, *Leishmania infantum*); bacterial (*Bartonella* spp., *Mycobacterium* spp., or other bacteria); viral (feline immunodeficiency virus [FIV], feline leukemia virus [FeLV], feline coronavirus [FCoV], feline herpesvirus type 1 [FHV-1]); parasitic (ophthalmomyiasis, ocular nematodiasis). • Idiopathic—lymphocytic-plasmacytic uveitis. • Immune-mediated—reaction to lens proteins (due to cataract or lens trauma/rupture). • Neoplastic—primary ocular tumors, metastasis to uveal tract. • Metabolic—hyperlipidemia, hyperviscosity, systemic hypertension. • Miscellaneous—trauma (blunt or penetrating), ulcerative keratitis, corneal stromal abscess, toxemia.

RISK FACTORS
Immune suppression and geographic location may increase risk for certain infectious causes of uveitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Conjunctivitis—redness limited to conjunctival hyperemia (no ciliary flush); discharge thicker and more copious than uveitis; discomfort alleviated by topical anesthetic. • Glaucoma—elevated IOP, dilated pupil, Haab's striae, and buphthalmos. • Ulcerative keratitis—corneal fluorescein staining detects ulcers; corneal edema is either localized to or most severe at site of ulcer; ocular discharge thicker and more copious than uveitis; discomfort alleviated by topical anesthetic. • Horner's syndrome—miosis, enophthalmos, and nictitans protrusion are similar, but Horner's is nonpainful without ocular discharge; ptosis with Horner's is not blepharospasm, as the latter is an active process; minor conjunctival hyperemia may be noted with Horner's, but cornea and anterior chamber are clear; clinical signs resolve with topical ophthalmic 1–10% phenylephrine.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—normal, or reflects underlying disease. • Biochemistry—most common abnormality is elevated serum proteins (usually due to polyclonal gammopathy). • Urinalysis—normal, or reflects underlying disease.

OTHER LABORATORY TESTS
• Serum titers for FeLV, FIV, and FCoV; FCoV titers not specific for feline infectious peritonitis (FIP), but very high titers may increase the index of suspicion; reverse transcription polymerase chain reaction (RT-PCR) testing can help support diagnosis, but not definitive. • *Toxoplasma gondii* serum immunoglobulin (Ig) M and IgG titers and/or PCR performed on serum and/or aqueous humor. • *Bartonella* spp. serology, PCR (serum or aqueous humor).

IMAGING
• Thoracic radiography—may show evidence of metastatic or infectious disease. • Ocular ultrasound—if opacity of ocular media precludes direct examination; may reveal intraocular neoplasm or retinal detachment.

DIAGNOSTIC PROCEDURES
• Tonometry—low IOP consistent with uveitis; elevated IOP indicates glaucoma (primary or secondary to uveitis). • Ocular centesis—if retinal detachment is present, cytology of subretinal aspirate may reveal causative agents; anterior chamber centesis for cytology, titers, or FCoV immunocytochemistry.

PATHOLOGIC FINDINGS
• Lymphoplasmacytic infiltrate of iris and ciliary body (either diffuse or nodular) is most common histopathologic finding. • Histopathologic—may observe corneal edema, peripheral corneal deep stromal vascularization, keratic precipitates, preiridal fibrovascular membrane, anterior or posterior synechia, entropion or ectropion uveae. Leukocyte accumulation in iris, ciliary body, sclera, choroid (lymphocytic, plasmacytic, suppurative, or granulomatous infiltrates, depending on etiology), secondary cataract, cyclitic membrane, vitreal traction bands, and retinal detachment.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient

ACTIVITY
No changes.

DIET
No changes.

CLIENT EDUCATION
• Systemic disease may cause ophthalmic signs; emphasize importance of appropriate diagnostic testing. • In addition to symptomatic treatment, treatment of underlying disease (when possible) is paramount. • Inform of potential complications and emphasize compliance with treatment and follow-up recommendations to reduce likelihood of complications.

SURGICAL CONSIDERATIONS
• None in most cases. • Specific instances include removal of ruptured lenses and surgical management of secondary glaucoma. • Chronic uveitis leading to secondary glaucoma commonly requires enucleation of the eye. • Enucleation is recommended in cats with uveitis related to diffuse iris melanoma or other intraocular tumors.

MEDICATIONS

DRUG(S) OF CHOICE

Corticosteroids

Topical

• Prednisolone acetate 1% or dexamethasone 0.1%—apply 2–8 times daily, depending on severity of disease; taper as condition resolves. • Stopping topical corticosteroids abruptly may result in rebound ocular inflammation.

Subconjunctival

• Often not required; indicated only in severe cases as one-time injection. • Triamcinolone acetonide—4 mg by subconjunctival injection. • Methylprednisolone—4 mg by subconjunctival injection.

Systemic

• Prednisone—1–3 mg/kg/day PO initially; taper dose after 7–10 days. • Only if infectious causes of uveitis have been ruled out.

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

Topical

• Flurbiprofen—apply 2–4 times daily, depending on severity of disease. • Diclofenac or ketorolac—apply 2–4 times daily, depending on severity of disease.

Systemic

• Meloxicam—0.3 mg/kg SC once. • Robenacoxib—1 mg/kg PO once daily; limit duration of use to 3 days.

Topical Mydriatic/Cycloplegic

Atropine sulfate 1%—apply 1–4 times daily, depending on severity of disease. Use lowest frequency adequate to maintain dilated pupil; taper medication as condition resolves. Ointment in cats causes less salivation.

CONTRAINDICATIONS
• Avoid the use of miotic medications, including topical prostaglandins (e.g., latanoprost), in the presence of uveitis. • Topical and subconjunctival corticosteroids are contraindicated with ulcerative keratitis. • Corticosteroids (especially systemic) should be avoided in cats with systemic hypertension. • Avoid systemic nonsteroidal anti-inflammatory drugs (NSAIDs) in cats with renal disease and in combination with corticosteroids.

PRECAUTIONS
Owing to concern for secondary glaucoma, topical atropine should be used judiciously and IOP monitored periodically.

POSSIBLE INTERACTIONS
Systemic corticosteroids and NSAIDs should not be used concurrently.

FOLLOW-UP

PATIENT MONITORING
Recheck in 3–7 days, depending on severity of disease. IOP should be monitored to detect secondary glaucoma. Frequency of subsequent rechecks dictated by severity of disease and response to treatment.

POSSIBLE COMPLICATIONS
• Secondary glaucoma—common complication of chronic uveitis in cats. • Secondary cataract. • Lens luxation. • Retinal detachment. • Phthisis bulbi.

EXPECTED COURSE AND PROGNOSIS
• Guarded prognosis for affected eyes; depends on underlying disease and response to treatment. • Cats with treatable underlying disease (e.g., toxoplasmosis) are more likely to have a favorable ophthalmic outcome than those with idiopathic lymphoplasmacytic uveitis or untreatable underlying condition (e.g., FIP, FIV).

MISCELLANEOUS

AGE-RELATED FACTORS
• Younger cats more likely to be diagnosed with infectious uveitis. • Older cats at higher risk of idiopathic lymphocytic-plasmacytic uveitis and intraocular neoplasia.

ZOONOTIC POTENTIAL
• None in most cases. • Some systemic infections causing uveitis may pose a risk to immunocompromised owners.

PREGNANCY/FERTILITY/BREEDING
Avoid systemic corticosteroids. Because of systemic absorption, topical corticosteroids may also pose a risk, especially with frequent application.

SYNONYMS
Iridocyclitis

SEE ALSO
• Horner's Syndrome.
• Red Eye.

ABBREVIATIONS
• FCoV = Feline coronavirus.
• FeLV = feline leukemia virus.
• FHV-1 = feline herpesvirus type 1.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.
• Ig = immunoglobulin.
• IOP = intraocular pressure.
• NSAID = nonsteroidal anti-inflammatory drug.
• RT-PCR = reverse transcription polymerase chain reaction.

ANTERIOR UVEITIS—DOGS

BASICS

DEFINITION
• Inflammation of anterior uvea, including iris (iritis), ciliary body (cyclitis), or both (iridocyclitis). • May be associated with posterior uveal and retinal inflammation (choroiditis; chorioretinitis). • Unilateral or bilateral.

PATHOPHYSIOLOGY
• Increased permeability of blood–aqueous barrier due to infectious, immune-mediated, traumatic, or other causes allows plasma proteins and blood cells to enter aqueous humor. • Disruption of blood–aqueous barrier is initiated and maintained by numerous mediators.

SYSTEMS AFFECTED
• Ophthalmic. • Other systems if systemic disease.

INCIDENCE/PREVALENCE
• Relatively common. • True incidence/prevalence unknown.

GEOGRAPHIC DISTRIBUTION
Geographic location may affect incidence of certain infections.

SIGNALMENT

Species
Dog

Breed Predilections
• None for most causes. • Uveitis associated with iridociliary cysts in golden retriever (golden retriever pigmentary uveitis) and Great Dane. • Increased incidence of uveodermatologic syndrome in Siberian husky, Akita, Samoyed, and Shetland sheepdog.

Mean Age and Range
• Any age. • Uveodermatologic syndrome—mean 2.8 years. • Golden retriever pigmentary uveitis—mean 8.6 years.

SIGNS

Historical Findings
• Red eye (conjunctival hyperemia, ciliary flush). • Cloudy eye (corneal edema, aqueous flare, hypopyon). • Painful eye (blepharospasm, photophobia, or rubbing eye). • Vision loss—variable.

Physical Examination Findings
Thorough physical examination is critical.

Ophthalmic Findings
• Ocular discomfort—blepharospasm, photophobia, and rubbing eye. • Ocular discharge—usually serous; sometimes mucoid to mucopurulent. • Conjunctival hyperemia—bulbar and palpebral conjunctiva affected. • Corneal edema—diffuse; mild to severe. • Keratic precipitates—aggregates of inflammatory cells adherent to corneal endothelium. • Aqueous flare—cloudiness of aqueous humor due to increased protein content and cellular debris; best seen with a bright, narrow beam of light shone through anterior chamber. • Ciliary flush—injection of deep perilimbal anterior ciliary vessels. • Deep corneal vascularization—circumcorneal distribution. • Miosis and/or resistance to pharmacologic dilation. • Iridal swelling. • Reduced intraocular pressure (IOP) is consistent with uveitis, but not a uniform finding. • Posterior synechia—adhesions between posterior iris and anterior lens surface. • Fibrin in anterior chamber. • Hypopyon or hyphema—accumulation of white or red blood cells, respectively, in anterior chamber; usually settles horizontally in ventral aspect of chamber, but may be diffuse. • Chronic changes may include rubeosis iridis, iridal hyperpigmentation, secondary cataract, lens luxation, pupillary seclusion, iris bombé, secondary glaucoma, and phthisis bulbi.

CAUSES
• Infectious—fungal (*Blastomyces dermatitidis*, *Cryptococcus neoformans*, *Coccidioides immitis*, *Histoplasma capsulatum*, *Candida* spp., *Aspergillus* spp., *Encephalitozoon cuniculi*), protozoal (*Toxoplasma gondii*, *Neospora caninum*, *Leishmania donovani*), rickettsial (*Ehrlichia canis*, *Rickettsia rickettsii*), bacterial (*Leptospira* spp., *Bartonella* spp., *Brucella canis*, *Borrelia burgdorferi*, and others), algal (*Prototheca* spp.), viral (adenovirus, distemper, rabies, herpes), parasitic (ocular filariasis, ocular nematodiasis, ophthalmomyiasis). • Immune-mediated—reaction to lens proteins (due to cataract or lens trauma), uveodermatologic syndrome, postvaccinal reaction to canine adenovirus vaccine, vasculitis. • Neoplastic—primary ocular tumors (uveal melanoma, iridociliary adenoma/adenocarcinoma), metastasis to uveal tract (e.g., lymphosarcoma). • Metabolic—hyperlipidemia, hyperviscosity, systemic hypertension. • Miscellaneous—idiopathic, trauma, golden retriever pigmentary uveitis, ulcerative keratitis, corneal stromal abscess, scleritis, lens instability/luxation.

RISK FACTORS
Immune suppression and geographic location may increase risk for infectious causes of uveitis; consider breed predispositions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Conjunctivitis—redness limited to conjunctival hyperemia (i.e., no ciliary flush); discharge usually thicker and more copious; discomfort alleviated with topical anesthetic. • Glaucoma—elevated IOP, diffuse corneal edema, dilated pupil, Haab's striae, buphthalmos. • Lens luxation—corneal edema may be localized to site of lens contact with endothelium or diffuse as a result of secondary uveitis and/or glaucoma; breed associated. • Ulcerative keratitis—corneal fluorescein stain detects ulcers; corneal edema localized to, or most severe at, site of ulcer; discomfort alleviated by topical anesthetic. • Corneal endothelial dystrophy or degeneration—diffuse corneal edema with normal IOP; conjunctival hyperemia and ocular discomfort generally absent. • Horner's syndrome—miosis, enophthalmos, and nictitans protrusion in both conditions, but Horner's is nonpainful without ocular discharge; ptosis with Horner's is distinguished from blepharospasm as the latter is an active process; minor conjunctival hyperemia may be noted, but cornea and anterior chamber are clear; clinical signs of Horner's syndrome resolve with topical ophthalmic 1–10% phenylephrine.

CBC/BIOCHEMISTRY/URINALYSIS
Normal, or reflect underlying disease.

OTHER LABORATORY TESTS
Serology for infectious diseases may be indicated, especially in patients with signs of systemic illness.

IMAGING
• Thoracic radiography and abdominal ultrasound may be warranted for systemic disease. • Ocular ultrasound is indicated if ocular media opacity precludes direct examination.

DIAGNOSTIC PROCEDURES
• Tonometry—low IOP consistent with uveitis; elevated IOP indicates glaucoma (primary disease or secondary to uveitis). • Ocular centesis—if retinal detachment is present, cytology of subretinal aspirate may reveal causative agents; anterior chamber centesis unrewarding, except in cases of lymphoma.

PATHOLOGIC FINDINGS
Histopathologic—may observe corneal edema, peripheral corneal deep stromal vascularization, keratic precipitates, preiridal fibrovascular membrane, anterior or posterior synechia, entropion or ectropion uveae. Leukocyte accumulation in iris, ciliary body, sclera, choroid may be lymphocytic, plasmacytic, suppurative, or granulomatous, depending on etiology. Secondary cataract, cyclitic membrane, vitreal traction bands, and retinal detachment may be present.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient

ACTIVITY
• No changes in most cases. • Reduced exposure to bright light may alleviate discomfort.

DIET
No changes.

CLIENT EDUCATION
• Systemic disease may cause ophthalmic signs; emphasize importance of appropriate diagnostic testing. • In addition to symptomatic uveitis treatment, treatment of underlying disease (when possible) is paramount. • Inform of potential complications and emphasize compliance with treatment and follow-up recommendations to reduce likelihood of complications.

SURGICAL CONSIDERATIONS
• None (most cases). • Specific instances include removal of ruptured lenses, removal of cataracts causing uveitis (if prognosis is otherwise favorable), surgical management of corneal disease causing uveitis, and surgical management of secondary glaucoma.

MEDICATIONS

DRUG(S) OF CHOICE

Corticosteroids

Topical
• Prednisolone acetate 1% or dexamethasone 0.1%—apply 2–8 times daily, depending on severity of disease; taper as condition resolves. • Stopping topical corticosteroids abruptly may result in rebound ocular inflammation.

Subconjunctival
• Often not required; indicated only in severe cases as one-time injection. • Triamcinolone acetonide—4–6 mg, subconjunctival injection. • Methylprednisolone—3–10 mg, subconjunctival injection.

Systemic
• Prednisone—0.5–2.2 mg/kg/day PO initially; taper dose after 7–10 days. Long-term treatment with immunosuppressive medication may be warranted for immune-mediated uveitis. • Use only if systemic infectious causes of uveitis have been ruled out.

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

Topical
• Less effective than topical corticosteroids; can be combined with topical steroids. • Flurbiprofen, diclofenac, ketorolac—apply 2–4 times daily, depending on severity of disease.

Systemic
• Do not use concurrently with systemic corticosteroids; avoid in presence of hyphema. • Carprofen—2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h. • Meloxicam—0.2 mg/kg on day 1, followed by 0.1 mg/kg PO q24h. • Deracoxib—1–2 mg/kg PO q24h. • Firocoxib—5 mg/kg PO q24h.

Topical Mydriatic/Cycloplegic

Atropine sulfate 1%—apply 1–4 times daily, depending on severity of disease; use lowest frequency adequate to maintain dilated pupil and ocular comfort; taper medication as condition resolves.

CONTRAINDICATIONS
• Avoid topical miotic medications (e.g., pilocarpine), including topical prostaglandins (e.g., latanoprost), in presence of uveitis. • Avoid topical atropine in cases of uveitis with secondary glaucoma. • Topical and subconjunctival corticosteroids are contraindicated with ulcerative keratitis. • Avoid systemic corticosteroids in dogs with systemic infection.

PRECAUTIONS
Out of concern for secondary glaucoma, topical atropine should be used judiciously and IOP should be monitored periodically.

POSSIBLE INTERACTIONS
Systemic corticosteroids and NSAIDs should not be used concurrently.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Recheck in 3–7 days, depending on severity of disease. IOP should be monitored to detect secondary glaucoma. Frequency of subsequent rechecks dictated by severity of disease and response to treatment.

POSSIBLE COMPLICATIONS
• Many systemic complications, including death, may occur due to systemic etiology of uveitis. • Ophthalmic complications include secondary cataract, secondary glaucoma, lens luxation, retinal detachment, phthisis bulbi.

EXPECTED COURSE AND PROGNOSIS
Extremely variable; depends on underlying disease and response to treatment.

MISCELLANEOUS

ZOONOTIC POTENTIAL
None in most cases. Some etiologies of systemic infection may pose a risk to immune-compromised owners.

PREGNANCY/FERTILITY/BREEDING
Avoid systemic corticosteroids. Because of possibility of systemic absorption, topical corticosteroids may also pose risk, especially with frequent application in small dogs.

SYNONYMS
Iridocyclitis

SEE ALSO
Red Eye.

ABBREVIATIONS
• IOP = intraocular pressure.
• NSAID = nonsteroidal anti-inflammatory drug.

ANTIDEPRESSANT TOXICOSIS—SSRIS AND SNRIS

BASICS

DEFINITION
• Toxicity secondary to the overdose of a selective serotonin reuptake inhibitor (SSRI), serotonin and norepinephrine reuptake inhibitor (SNRI), or coingestion of two types of serotonergic drugs.
• SSRIs include citalopram (Celexa®), escitalopram (Lexapro®), fluoxetine (Prozac®), fluvoxamine (Luvox®), paroxetine (Paxil®), sertraline (Zoloft®), vilazodone (Viibryd®), and vortioxetine (Brintellix®). SNRIs include desvenlafaxine (Pristiq®), duloxetine (Cymbalta®), levomilnacipran (Fetzima®), milnacipran (Ixel®, Savella®), tofenacin (Elamol®, Tofacine®), and venlafaxine (Effexor®).

PATHOPHYSIOLOGY
• SSRIs and SNRIs are antidepressants that inhibit reuptake of serotonin, a neurotransmitter involved in aggression, anxiety, appetite, depression, migraine, pain, and sleep. Antidepressant effects are secondary to inhibition of reuptake of serotonin into serotonergic neurons via binding to the serotonin transporter, resulting in increased synaptic availability of serotonin. SNRIs also inhibit the reuptake of norepinephrine by the same mechanism.
• Excessive stimulation of serotonin receptors can occur by enhanced serotonin synthesis, increased presynaptic serotonin release, inhibition of serotonin uptake into the presynaptic neuron, inhibition of serotonin metabolism, or serotonin agonism. Ingesting too much of one medication or a combination of medications that increase serotonin via different methods can lead to serotonin syndrome.
• Serotonin syndrome is characterized in humans as a combination of symptoms that include at least three of the following: myoclonus, mental aberration, agitation, hyperreflexia, tremors, diarrhea, ataxia, or hyperthermia.
• Toxic dosage varies widely among commonly available SSRIs and SNRIs and is not well defined in veterinary medicine.

SYSTEMS AFFECTED
• Cardiovascular—decreased vascular tone (hypotension), increased heart rate and stroke volume (tachycardia).
• Gastrointestinal—increased smooth muscle contractility (vomiting, diarrhea).
• Nervous—stimulation (agitation, restlessness, seizures) and altered mental status (vocalization, disorientation).
• Neuromuscular—autonomic dysfunction (hyperactivity) and neuromuscular hyperactivity (hyperreflexia, myoclonus, tremors).
• Ophthalmic—increased autonomic function (mydriasis).
• Respiratory—increased bronchial smooth muscle contraction (dyspnea).

INCIDENCE/PREVALENCE
Second most common human prescription medication toxicosis (after cardiac medications).

SIGNALMENT
Species
Dogs and cats.

Mean Age and Range
Any age can be affected.

SIGNS
Historical Findings
• Agitation or lethargy.
• Dilated pupils.
• Vomiting.
• Tremors.
• Hypersalivation.
• Diarrhea.
• Seizures.
• Nystagmus.

Physical Examination Findings
• Agitation.
• Ataxia.
• Mydriasis.
• Tremors.
• Vomiting.
• Disorientation.
• Hyperthermia.
• Vocalization.
• Depression.
• Tachycardia.
• Hypotension.
• Diarrhea.
• Blindness.
• Seizures.
• Hypersalivation.
• Death.

CAUSES
• SSRI/SNRI overdose—accidental exposure, inappropriate administration, or therapeutic use.
• Ingestion of an SSRI/SNRI along with another class of medications that increases serotonin (tricyclic antidepressants [TCAs], monoamine oxidase inhibitors [MAOIs], novel antidepressants, tramadol, fentanyl, meperidine, amphetamines, cocaine, dextromethorphan, 5-hydroxytryptophan [5-HTP], buspirone, bupropion, triptans, LSD).

RISK FACTORS
• Animals on a serotonergic drug.
• Underlying liver or kidney disease; cats are attracted to venlafaxine and will eat multiple capsules.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Toxicologic—TCAs, MAOIs, metaldehyde, lead, ethylene glycol, hops, anticholinergics, antihistamines.
• Nontoxicologic—meningitis (e.g., rabies, canine distemper), neoplasia, heat stroke, malignant hyperthermia.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC/biochemistry—no direct changes are expected, but creatine kinase (CK) may be elevated secondary to tremors.
• Urinalysis—myoglobinuria secondary to rhabdomyolysis may be seen.

OTHER LABORATORY TESTS
• Blood gas—metabolic acidosis may be seen.
• Testing for SSRIs/SNRIs can be performed, but the tests are not clinically useful.
• Note: venlafaxine will give a false positive for phencyclidine (PCP; angel dust) on many urine drug screens.

DIAGNOSTIC PROCEDURES
There are no diagnostic tests to confirm serotonin syndrome.

TREATMENT

APPROPRIATE HEALTH CARE
• Emesis (if asymptomatic and recent ingestion) or gastric lavage (if large number of pills ingested).
• Activated charcoal with cathartic (if severe signs are expected, may need to repeat due to long half-life).

NURSING CARE
IV fluids to help maintain blood pressure and body temperature, and to protect kidneys from myoglobinuria.

CLIENT EDUCATION
If animal appears blind, sight should return.

MEDICATIONS

DRUG(S) OF CHOICE
• Agitation:
  ○ Phenothiazines (acepromazine 0.025–0.05 mg/kg IV, titrate up as needed).
  ○ Cyproheptadine (dog, 1.1 mg/kg; cat, 2–4 mg PO q4–6h or can be given rectally if vomiting).
  ○ Benzodiazepines (diazepam 0.5–2 mg/kg IV; see Precautions).
  ○ Tremors—methocarbamol (50–150 mg/kg IV, titrate up as needed).

(CONTINUED)

ANTIDEPRESSANT TOXICOSIS—SSRIS AND SNRIS

CONTRAINDICATIONS

• High risk of serotonin syndrome—other SSRIs, SNRIs, MAOIs, TCAs, amphetamines, 5-HTP, clarithromycin, dextromethorphan, lithium, St. John's wort.
• Low risk of serotonin syndrome—tramadol, fentanyl, amantadine, bupropion, carbamazepine, codeine.

PRECAUTIONS

Benzodiazepines (e.g., diazepam) are reported by some sources to exacerbate serotonin syndrome and their use for SSRI/SNRI toxicosis is not universally recommended.

POSSIBLE INTERACTIONS

• Decreased metabolism of SSRIs/SNRIs—cimetidine, diuretics, quinidine, lithium.
• Increased levels of medications (decreased metabolism)—theophylline, coumadin, digoxin.

FOLLOW-UP

PATIENT MONITORING

Blood pressure, heart rate, urine color—monitor hourly, then less frequently as the animal remains stable.

PREVENTION/AVOIDANCE

• Keep medications out of the reach of animals.
• Follow label directions when giving serotonergic drugs to animals.

POSSIBLE COMPLICATIONS

Renal failure secondary to myoglobinuria from rhabdomyolysis; disseminated intravascular coagulation (DIC) secondary to hyperthermia.

EXPECTED COURSE AND PROGNOSIS

• Prognosis is good in most cases, with recovery in 12–24 hours.
• Patients that present in status epilepticus or with severe hyperthermia have a guarded prognosis.

MISCELLANEOUS

AGE-RELATED FACTORS

Young and elderly animals are more at risk for developing serious toxicosis.

PREGNANCY/FERTILITY/BREEDING

SSRIs and SNRIs can cause increased litter mortality and possible birth defects.

ABBREVIATIONS

• 5-HTP = 5-hydroxytryptophan.
• CK = creatine kinase.
• DIC = disseminated intravascular coagulation.
• MAOI = monoamine oxidase inhibitor.
• PCP = phencyclidine (angel dust).
• SNRI = serotonin and norepinephrine reuptake inhibitor.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

A

ANTIDEPRESSANT TOXICOSIS—TRICYCLIC

BASICS

DEFINITION
• Toxicity secondary to the acute or chronic ingestion of a tricyclic antidepressant (TCA).
• TCA medications include amitriptyline, amoxapine, clomipramine, desipramine, doxepin, imipramine, maprotiline (tetracyclic antidepressant), nortriptyline, protriptyline, trimipramine, and many others.

PATHOPHYSIOLOGY
• TCAs block the reuptake of norepinephrine, dopamine, and serotonin at the neuronal membrane. They also have anticholinergic activity and are thought to have membrane-stabilizing effects on the myocardium (particularly inhibiting fast sodium channels in the ventricular myocardium). They can also have slight alpha-adrenergic blocking activity and antihistaminic effects.
• TCAs are rapidly and well absorbed across the digestive tract. They can decrease GI motility and delay gastric emptying, resulting in delayed drug absorption.
• Lipophilic, protein bound, and well distributed across all tissues.
• They are metabolized by the liver and undergo enterohepatic recirculation. The inactive metabolites are eliminated in the urine.

SYSTEMS AFFECTED
• Nervous—increased dopamine, serotonin, and norepinephrine levels in the CNS contribute to CNS signs.
• Cardiovascular—anticholinergic effects and inhibition of norepinephrine reuptake contribute to tachycardia; alpha adrenergic blockade, cardiac membrane stabilization, and decreased cardiac contractility contribute to hypotension and arrhythmias.
• Gastrointestinal (GI)—anticholinergic effects may cause ileus and delayed gastric emptying.
• Ophthalmic—anticholinergic effects can cause pupillary dilation.
• Renal/urologic—anticholinergic effects may cause urinary retention.

GENETICS
Species and individual differences in absorption, metabolism, and elimination can be significant.

INCIDENCE/PREVALENCE
Incidence is unknown.

SIGNALMENT
Species
Dogs and cats.

Breed Predilections
None

Mean Age and Range
None

SIGNS
General Comments
• Signs can occur at therapeutic doses.
• Signs of toxicosis can occur within 30–60 minutes or be delayed by several hours.

Historical Findings
• Evidence of accidental consumption of the owner's or another pet's medication.
• CNS depression (lethargy, ataxia).
• Vocalization.
• Vomiting or hypersalivation.
• Panting.
• Agitation or restlessness.
• Tachypnea or dyspnea.
• Tremors.
• Seizures.

Physical Examination Findings
• CNS depression or stimulation.
• Tachycardia.
• Ataxia.
• Mydriasis.
• Hypothermia.
• Hypertension.
• Pallor.
• Cyanosis.
• Hyperthermia.
• Arrhythmias.
• Hypotension.
• Urinary retention.
• Constipation.

CAUSES
Accidental exposure, inappropriate administration, or therapeutic use.

RISK FACTORS
• Concurrent use of other antipsychotic medication.
• Preexisting cardiac disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Toxicity caused by other antipsychotic medication, stimulant substances (e.g., amphetamines, cocaine, methylxanthines, or pseudoephedrine), or substances capable of causing cardiac arrhythmias (e.g., quinidine, propranolol, albuterol, digoxin).
• Nontoxicologic differentials include hyperkalemia, cardiac ischemia, cardiomyopathy, and other diseases of cardiac conduction.

CBC/BIOCHEMISTRY/URINALYSIS
Expected to be normal.

OTHER LABORATORY TESTS
• Blood gases—metabolic acidosis may be noted.
• Over-the-counter (OTC) urine drug screen for TCAs—can be used to determine if exposure has occurred; not useful in determining degree of toxicity.
• Serum TCA levels—can be used to determine if exposure has occurred.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• ECG to monitor for arrhythmias.
• Blood pressure monitoring.

PATHOLOGIC FINDINGS
No specific lesions expected.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient—not recommended for symptomatic patients, patients with cardiac disease, or patients ingesting greater than a therapeutic dose of TCAs.
• Inpatient—asymptomatic:
  ◦ Decontamination with emesis (less than 15 minutes of exposure time), gastric lavage in large exposures, and activated charcoal.
  ◦ Monitor at a clinic for a minimum of 6 hours after exposure.
• Inpatient—symptomatic: stabilize the cardiovascular (CV) system and CNS and provide supportive care.

NURSING CARE
• Fluid therapy—restore hydration due to vomiting, regulate blood pressure when hypotension is noted.
• Thermoregulation as needed.
• Enema with warm water if not defecating within 6–12 hours.

ACTIVITY
N/A

DIET
NPO if vomiting.

CLIENT EDUCATION
• With a prescribed TCA, instruct client to monitor for adverse or idiosyncratic effects, and to stop the medication and contact the clinic if they occur.
• Prevent exposure to nonprescribed medication.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
Decontamination
• Emesis within 15 minutes of ingestion *only if asymptomatic*; induce emesis with either hydrogen peroxide (dog, 1–2 mL/kg PO),

apomorphine (dog, 0.03–0.05 mg/kg IV/IM, or 0.1 mg/kg SC, or 0.25 mg instilled in conjunctiva of eye), or dexmedetomidine (cat, 7 µg/kg IM or 3.5 µg/kg IV).
• Gastric lavage under anesthesia may be considered with large exposures.
• After emesis (or if >15 min of exposure), administer activated charcoal (1–2 g/kg PO) with a cathartic such as sorbitol (70% sorbitol at 3 mL/kg) or sodium sulfate (0.25 tsp/5 kg) if no diarrhea.
• Repeat one-half dose of activated charcoal in 4–6 hours if patient is still symptomatic.

Other
• Cyproheptadine—dogs, 1.1 mg/kg q8h PO or rectally; cats, 2–4 mg/cat q12–24h PO or rectally; used for treatment of serotonin syndrome.
• 20% intravenous lipid emulsion—prevents lipophilic TCAs from reaching site of action by acting as sequestrant in expanded plasma lipid phase; 1.5 mL/kg IV bolus followed by 0.25 mL/kg/min IV CRI for 1 hour. Can repeat bolus and CRI in 4–6 hours if serum is not lipemic and a poor response to treatment is seen.
• Sodium bicarbonate—used to maintain blood pH at 7.55; if not monitoring acid-base status, start with 2–3 mEq/kg IV over 15–30 minutes in a symptomatic patient.
• Diazepam—0.5–1 mg/kg IV, repeat if necessary; for agitation or seizures.
• Acepromazine—0.02 mg/kg IV, repeat if necessary; for agitation or mild hypertension.
• Phenobarbital—as needed for seizure control.

CONTRAINDICATIONS
• Atropine should not be used, because TCAs have anticholinergic effects that are exacerbated by atropine.
• Trazodone should not be used, because it can result in serotonin syndrome when given concurrently.
• Magnesium sulfate should not be used as a cathartic. Ileus or reduced GI motility will enhance absorption of magnesium and may result in magnesium toxicity.
• Beta blockers (e.g., propranolol, atenolol) should not be used for tachycardia because of their potential to exacerbate hypotension.
• Do not induce emesis in a patient already showing clinical signs.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
• TCAs increase risk of hyperthermia, seizures, and death with use of monoamine oxidase inhibitors (MAOIs).
• Sympathomimetic and anticholinergic medications increase the risk for arrhythmias or cardiac effects from TCAs.
• Levothyroxine increases the risk for arrhythmias when used with TCAs.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Acid-base status—monitor for acidosis and if implementing sodium bicarbonate therapy.
• Blood pressure—monitor until asymptomatic.
• ECG—monitor until asymptomatic.

PREVENTION/AVOIDANCE
Keep medications out of reach of pets.

POSSIBLE COMPLICATIONS
Pulmonary edema can occur secondary to aggressive fluid therapy.

EXPECTED COURSE AND PROGNOSIS
• Due to the variable half-lives of the different TCAs, signs can last 24 hours or longer.
• Prognosis is generally good in patients exhibiting mild to moderate signs.
• Prognosis is guarded in patients exhibiting severe signs such as seizures, arrhythmias, or hypotension that are poorly responsive to therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Serotonin syndrome may occur as a result of TCA ingestion.

AGE-RELATED FACTORS
None

PREGNANCY/FERTILITY/BREEDING
TCAs cross the placenta and can be found in breast milk; the significance of this is not known at this time.

SEE ALSO
• Antidepressant Toxicosis—SSRIs and SNRIs.
• Poisoning (Intoxication) Therapy.

ABBREVIATIONS
• CV = cardiovascular.
• GI = gastrointestinal.
• MAOI = monoamine oxidase inhibitor.
• OTC = over-the-counter.
• TCA = tricyclic antidepressant.

AORTIC STENOSIS

BASICS

DEFINITION
• A narrowing of the left ventricular outflow tract (LVOT) that restricts blood flow leaving the ventricle; most commonly congenital, often heritable. • Lesion is most commonly subvalvular in dogs, but may be valvular or supravalvular (more often in cats).
• Subvalvular aortic stenosis (SAS) in dogs is caused by fibrous tissue manifested as nodules, a ridge, a ring, or a tunnel-like lesion. SAS may be associated with other defects, including mitral valve dysplasia.

PATHOPHYSIOLOGY
• Restriction to outflow generates pressure overload of left ventricle (LV). • Degree of obstruction is related to severity of secondary changes. • LV pressure overload causes thickened LV walls, resulting in diminished blood supply relative to muscle demand and myocardial ischemia; this may result in arrhythmogenesis and, if severe or infarction occurs, mechanical dysfunction. • Restriction to blood flow causes high-velocity, turbulent flow across valve, which may cause endothelial damage, lead to aortic insufficiency (AI), and predispose to endocarditis. • SAS may lead to chamber enlargement, distortion of the mitral valve annulus, and mitral regurgitation, with possible sequela of left-sided congestive heart failure (CHF). • Sudden death is common with severe SAS and may be secondary to arrhythmias or infarction.

SYSTEMS AFFECTED
• Cardiovascular—LV pressure overload leading to arrhythmias, syncope, sudden death, heart failure, endocarditis. • Respiratory—possible pulmonary edema with CHF.
• Multisystemic—possible due to low cardiac output or endocarditis.

GENETICS
• SAS inherited in the Newfoundland, golden retriever, Rottweiler, bullmastiff, and dogue de Bordeaux. • Mutation in phosphatidylinositol-binding clathrin assembly protein gene (PICALM) reported in Newfoundlands; screening test is available. • Dominant inheritance patterns proposed for Newfoundlands with incomplete penetrance responsible for disease appearing to skip generations. • More than one gene or modifying genes may be involved. • Golden retrievers, Rottweilers, and bullmastiffs appear to inherit SAS in autosomal recessive pattern, but no associated mutation yet identified.

INCIDENCE/PREVALENCE
• SAS is one of most common congenital heart defects of dogs; it is reported as second most common, but difficulty in diagnosing mild disease may underestimate true prevalence.
• Aortic stenosis reported as small contributor of feline congenital heart disease, about 6%; approximately 2 out of 1,000 dogs and 0.2 per 1,000 cats evaluated at veterinary teaching hospitals are diagnosed with aortic stenosis, SAS most often in dogs and supravalvular aortic stenosis most often in cats.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Dog and cat.

Breed Predilections
• Newfoundland, bullmastiff, golden retriever, Rottweiler, bouvier des Flandres, dogue de Bordeaux, German shepherd, and boxer have highest incidence of SAS and familial component or heritability is reported.
• No breed predilection reported for cats.

Mean Age and Range
• Clinical signs may be seen at any age.
• Although often inherited, SAS becomes identifiable during first few weeks to months of life as subvalvular lesion progresses. • Full phenotype is appreciated by 1 year of age.

Predominant Sex
N/A

SIGNS
Historical Findings
• Many dogs show no clinical signs and have no relevant historical findings. • Historical findings related to disease severity and may include syncope, exercise intolerance, sudden death, and signs due to CHF such as respiratory distress and/or coughing if severe.

Physical Examination Findings
• Systolic left basilar ejection murmur; may radiate to apex, right side of thorax, include carotid arteries, and if very loud the cranium; precordial thrill may be palpable; murmur intensity loosely correlated to severity; as disease worsens during early life, some may have absence of or quiet murmur that develops to more characteristic finding by 1 year. • Diastolic murmur may be present with significant AI; combination of this diastolic murmur with systolic ejection murmur is to-and-fro murmur. • Arrhythmias may be ausculted. • Pulse deficits may be appreciated, often associated with ventricular arrhythmias.
• Weak pulses may be appreciated that are late or slow to rise with severe SAS (pulsus parvus et tardus). • Tachypnea, respiratory distress, and crackles may occur with CHF.

General Comments
• Boxers have relatively small aorta compared to other breeds, which can be difficult to distinguish from mild SAS. • Bull terriers overrepresented for combined mitral valve dysplasia and SAS. • Newfoundland dogs overrepresented for combined patent ductus arteriosus (PDA) and SAS. • Volume overload of PDA can cause relative aortic stenosis and be difficult to distinguish from PDA with mild SAS.

CAUSES
• Congenital heart disease. • Secondary to valvular change, as with aortic valve endocarditis or calcification. • Component of complex congenital heart disease, as with some cases of mitral valve dysplasia.

RISK FACTORS
• Familial history of SAS. • SAS predisposes to aortic valve endocarditis. • Aortic valve endocarditis predisposes to valvar aortic stenosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Systolic murmur must be differentiated from other causes of similar murmurs.
• Innocent or physiologic murmurs commonly ausculted in athletic dogs, or with anemia, fever, stress, or excitement.
• Pulmonic stenosis and tetralogy of Fallot cause similar murmur. • Weak pulses may also occur with conditions that reduce cardiac output, such as heart failure, cardiomyopathy, and severe pulmonic stenosis. • Other obstruction to flow may cause reduced pulse quality, such as aortic thromboembolism, or rarely aortic coarctation/tubular hypoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
Typically within normal limits.

OTHER LABORATORY TESTS
Genetic testing for mutation associated with Newfoundland SAS is breeding tool to reduce frequency in this breed.

IMAGING
Thoracic Radiography
• Mild disease may be radiographically silent.
• LV hypertrophy may be subtle, as pressure overload causes concentric hypertrophy. • Left heart enlargement. • Prominent aortic root and/or widened mediastinum. • Lung fields typically normal unless CHF with pulmonary venous distention and interstitial to alveolar infiltrates.

Echocardiography
• Findings variably present and associated with disease severity. • Ridge, ring, nodule, or tunnel-like narrowing below aortic valve with SAS. • Thickened LV free wall or interventricular septum. • Aortic valve thickening and increased echogenicity with valvar stenosis.
• Mitral regurgitation and thickening of valve leaflets possible. • Poststenotic aortic dilation.
• Hyperechoic myocardium associated with ischemia. • AI with secondary LV chamber enlargement and volume overload if significant.
• Left atrial enlargement may be seen with significant mitral valve regurgitation. • Elevated

LVOT flow velocity (>2.4 m/s), with acceleration proximal to stenosis and turbulent flow distal to obstruction and valve. • Transvalvular pressure gradient estimated by LVOT flow velocity (4 × flow velocity^2); estimated gradients of 25–49 mmHg considered mild, 50–79 mmHg moderate, and ≥80 mmHg severe. • With myocardial failure, estimated pressure gradient may be falsely low. • Effective valve orifice, if calculated, is reduced.

DIAGNOSTIC PROCEDURES
• ECG may show changes consistent with LV hypertrophy (tall R waves, widened QRS complexes, left axis deviation); signs of myocardial ischemia (ST segment deviation or slurring); ventricular arrhythmias may occur and contribute to syncope or sudden death. • Holter monitoring may be used to quantify arrhythmia severity and therapeutic response.

PATHOLOGIC FINDINGS
• Findings vary with severity, but typically include LV concentric or mixed (if significant AI) hypertrophy. • Variable subvalvular lesion of dense fibrous tissue is seen. • Myocardial ischemia, necrosis, and replacement fibrosis may be evident. • Poststenotic dilation of aorta, associated valvular endothelial damage, and sometimes left atrial enlargement are reported.

TREATMENT

APPROPRIATE HEALTH CARE
Therapy limited prior to onset of complications and aimed at preventing clinical signs.

NURSING CARE
Aimed at relieving symptoms and complications such as arrhythmias, syncope, and CHF.

ACTIVITY
Restriction warranted with severe disease; exertion may increase incidence of arrhythmias, syncope, and therefore risk of sudden death.

DIET
Modest salt restriction with CHF.

CLIENT EDUCATION
• SAS considered inherited disease; affected animals should not be bred. • Owners should be counseled on risk of endocarditis and appropriate antibiotics for any wounds, infections, or surgical procedures. • Alert owners to risks of sudden death, CHF, and increased anesthetic risk.

SURGICAL CONSIDERATIONS
• No surgical or interventional technique has been shown to extend life beyond medical therapy. • Balloon valvuloplasty or combined cutting and traditional balloon valvuloplasty may acutely reduce pressure gradient and temporarily alleviate some clinical signs; however, effects not yet shown to be beneficial beyond those achieved with beta blockers. • Currently, data does not support surgery or intervention, but this remains area of continued research.

MEDICATIONS

DRUG(S) OF CHOICE
• Beta adrenergic blockers advocated with moderate to severe SAS, particularly with ventricular arrhythmias, syncope, or ECG evidence of ischemia; may reduce myocardial oxygen demand, eliminate or protect against ventricular arrhythmias, and reduce heart rate; atenolol is most common (dogs, 0.5–1.5 mg/kg PO q12h; cats, 6.25 mg/cat PO q12–24h). • Therapy for ventricular arrhythmias, CHF, atrial fibrillation, or endocarditis may be required.

CONTRAINDICATIONS
• Beta blockers contraindicated in animals with bronchoconstriction such as asthmatic cats. • Starting beta blockers with CHF contraindicated and continued use in patients that develop CHF is controversial.

PRECAUTIONS
• Beta blockers negatively impact cardiac output and starting low doses with gradual up-titration warranted. • Positive inotropes may worsen fixed obstruction and are used with caution when treating CHF. • Anesthetic drugs that cause hypotension, arrhythmias, or cardiac depression should be avoided with severe SAS.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• Carvedilol (dogs, 0.5–1.5 mg/kg PO q12h). • Metoprolol tartrate (dogs, 0.5–1.5 mg/kg PO q12h).

FOLLOW-UP

PATIENT MONITORING
• Monitor by ECG, Holter monitor, thoracic radiography, and echocardiography. • Treatment of complications such as CHF and arrhythmias may necessitate additional monitoring for renal/electrolyte, blood pressure, and rhythm disturbances.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Ventricular arrhythmias, syncope, myocardial infarction, sudden death, AI, mitral regurgitation, endocarditis.

EXPECTED COURSE AND PROGNOSIS
• Mildly affected dogs may have normal lifespan and quality without therapy. • Severely affected dogs have limited lifespans and typically succumb to sudden death or CHF; in one study average lifespan for dogs with severe SAS on atenolol was about 4.5 years.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Increased risk of infective endocarditis.

AGE-RELATED FACTORS
SAS may not be immediately apparent at birth, but appears over first few weeks to months of life.

PREGNANCY/FERTILITY/BREEDING
Contraindicated

SYNONYMS
Subaortic stenosis, discrete subaortic stenosis.

SEE ALSO
• Cardiomyopathy, Hypertrophic—Cats.
• Cardiomyopathy, Hypertrophic—Dogs.
• Congestive Heart Failure, Left-Sided.
• Endocarditis, Infective.

ABBREVIATIONS
• AI = aortic insufficiency. • CHF = congestive heart failure. • LV = left ventricle. • LVOT = left ventricular outflow tract. • PDA = patent ductus arteriosus. • SAS = subvalvular aortic stenosis.

A

AORTIC THROMBOEMBOLISM

BASICS

DEFINITION
A thrombus or blood clot that is dislodged within the aorta, causing severe ischemia to the tissues served by that segment of aorta.

PATHOPHYSIOLOGY
• Aortic thromboembolism (ATE) is commonly associated with myocardial disease in cats, most commonly hypertrophic cardiomyopathy (HCM). It is theorized that abnormal blood flow (stasis) and a hypercoagulable state contribute to thrombus formation within the left atrium. The thrombus then embolizes distally to the aorta. The most common site of embolization is the caudal aortic trifurcation (hind legs). Other less common sites include the front legs, kidneys, gastrointestinal tract, or cerebrum.
• ATE in dogs typically is associated with neoplasia, sepsis, infectious endocarditis, Cushing's disease, protein-losing nephropathy and enteropathy, or other hypercoagulable states. However, in one recent retrospective study, no concurrent condition was identified in 58% of dogs.

SYSTEMS AFFECTED
• Cardiovascular—most affected cats have advanced heart disease and left heart failure.
• Nervous/musculoskeletal—severe ischemia to muscles and nerves served by segment of occluded aorta causes variable pain and paresis. Gait abnormality or paralysis results in leg or legs involved.

GENETICS
HCM, a common associated disease, is likely heritable. Additionally, a family of domestic shorthair cats with remodeled HCM who all died of ATE has been reported.

INCIDENCE/PREVALENCE
• In a recent observation study of over 1000 asymptomatic cats with HCM, nearly 12% developed ATE within 10 years after initial diagnosis. In two previous smaller case series of cats with clinical and preclinical HCM, 12–16% presented with signs of ATE; only 11–25% of cats had evidence of previously known heart disease.
• Rare in dogs.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Cat, rarely dog.

Breed Predilections
Mixed-breed cats most commonly affected. Abyssians, Birmans, and ragdolls overrepresented in one study. In dogs, no breed predilection identified in United States; European study suggested cavalier King Charles spaniels may be overrepresented.

Mean Age and Range
Age range—1–20 years. Median age—approximately 8–9 years (cats); 8–10 years (dogs).

Predominant Sex
Cats—males > females (2 : 1). Dogs—no sex predilection in United States; European study suggested male predilection.

SIGNS
Presence of 5 "Ps" is helpful to remember classic clinical signs associated with ATE—Pain, Paralysis or Paresis, Pulselessness, Pallor, and Poikilothermic (cold).

Historical Findings
• Acute onset paralysis and pain—most common in cats. Vocalization and anxiety also common.
• Lameness or gait abnormality, typically of several weeks' duration, more common in dogs.
• Tachypnea or respiratory distress common in cats.
• About 15% of cats may vomit prior to ATE.

Physical Examination Findings
• Usually paraparesis or paralysis of rear legs with signs of lower motor neuron injury. Less commonly, monoparesis of a front leg. In dogs, majority are paretic and ambulatory.
• Absent or diminished femoral pulses.
• Pain upon palpation of legs.
• Gastrocnemius muscle often becomes firm several hours after embolization.
• Cyanotic or pale nail beds and foot pads.
• Tachypnea/dyspnea and hypothermia are common in cats.
• Since commonly associated with heart disease in cats, cardiac murmur, arrhythmias, or gallop sound may be present.

CAUSES
• Cardiomyopathy (all types).
• Hyperthyroidism.
• Neoplasia.
• Sepsis (dogs).
• Hyperadrenocorticism (dogs).
• Protein-losing nephropathy and enteropathy (dogs).

RISK FACTORS
• In cats, cardiomyopathy, male sex, and gallop sound on exam are risk factors. Echocardiographic risk factors include enlarged left atrium, decreased left atrial function and left atrial appendage velocity, presence of spontaneous echocardiographic contrast (smoke) or left atrial thrombus, and restrictive left ventricular filling pattern.
• In dogs, hypercoagulable conditions, such as neoplasia, sepsis, endocarditis, protein-losing nephropathies/enteropathies, and hyperadrenocorticism are risk factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Hind limb paresis secondary to spinal neoplasia, trauma, myelitis, fibrocartilaginous infarction, or intervertebral disc protrusion. These conditions resulting in spinal cord injury present with signs of upper motor neuron disease, whereas ATE patients present with signs of lower motor neuron disease.

CBC/BIOCHEMISTRY/URINALYSIS
• High creatine kinase due to muscle injury.
• Higher blood lactate and lower blood glucose in affected limbs compared to normal limbs.
• High aspartate aminotransferase and alanine aminotransferase due to muscle and liver injury.
• Stress hyperglycemia.
• High blood urea nitrogen and creatinine due to low cardiac output and possible renal emboli.
• Electrolyte derangements, due to low output and muscle damage, such as hypocalcemia, hyponatremia, hyperphosphatemia, and hyperkalemia, are not uncommon.
• Nonspecific CBC and urinalysis changes.

OTHER LABORATORY TESTS
Routinely available coagulation profiles typically do not reveal significant abnormalities because hypercoagulability results from hyperaggregable platelets. In dogs, thromboelastrography may suggest hypercoagulable state with clot strength (increased maximum amplitude) or shortened clotting time (decreased R).

IMAGING

Radiography
• Cardiomegaly is common in cats.
• Pulmonary edema and/or pleural effusion in approximately 50% of cats.
• Rarely, a mass is seen in the lungs, suggestive of neoplasia.

Echocardiography
• In cats, changes consistent with cardiomyopathy. HCM is most common, followed by restrictive or unclassified cardiomyopathy, and then dilated cardiomyopathy.
• Most cases have severe left atrial enlargement (i.e., left atrial to aortic ratio of ≥2). Decreased left atrial function (fractional shortening) and decreased left atrial appendage velocity (<0.2 m/s).
• Left atrial thrombus or spontaneous echocardiographic contrast (smoke) may be seen.

Abdominal Ultrasonography
• May be able to identify the thrombus and visualize lack of blood flow in the caudal aorta.

• Typically unnecessary to reach a diagnosis in cats, but often needed to reach a diagnosis in dogs.

DIAGNOSTIC PROCEDURES

ECG

• Sinus rhythm and sinus tachycardia most common. Less common rhythms include atrial fibrillation, ventricular arrhythmias, supraventricular arrhythmias, and sinus bradycardia.
• Left ventricular enlargement pattern and left ventricular conduction disturbances (left anterior fascicular block) are common.

Doppler Blood Pressure

No or diminished audible blood flow in affected limbs.

PATHOLOGIC FINDINGS

• Thrombus typically identified at caudal aortic trifurcation.
• Occasionally, left atrial thrombus seen.
• Emboli of kidneys, gastrointestinal tract, cerebrum, and other organs also may be seen.

TREATMENT

APPROPRIATE HEALTH CARE

Initially, cats with ATE should be treated as inpatients, as many have concurrent congestive heart failure (CHF) and require injectable drugs, in addition to being in considerable pain and distress.

NURSING CARE

• Fluid therapy is cautiously used, as most cats have advanced myocardial disease. If in CHF, IV fluids may not be necessary.
• Supplemental oxygen or thoracocentesis may be beneficial if in CHF.
• Initially, minimally handle affected legs. However, as reperfusion occurs, physical therapy (passive extension and flexion) may speed full recovery.
• Do not perform venipuncture on affected legs.
• Animals may have difficulty posturing to urinate and may need bladder expression to prevent overdistention or urine scald.

ACTIVITY

Restrict activity and stress.

DIET

Initially, most cats are anorexic; tempt with any type of diet to keep them eating and avoid hepatic lipidosis.

CLIENT EDUCATION

• Short- and long-term prognosis is poor in both dogs and cats.
• Many cats do not survive their initial episode of ATE; if they survive, the cat will often reembolize or die of CHF within a few months to one year. Most cats that survive an initial episode will be on some type of anticoagulant and heart failure medications that may require frequent reevaluation and an indoor lifestyle.
• Most cats that survive an initial episode will recover complete function to the legs; however, if ischemia is severe and prolonged, sloughing of parts of the distal extremities or persistent neurologic deficits may result. In one study, approximately 15% of cats had permanent neuromucscular abnormalities after surviving the initial ATE.
• Prognosis in dogs is generally poor, but may be better in dogs presenting with chronic (vs. acute) lameness and dogs treated appropriately with warfarin.

SURGICAL CONSIDERATIONS

• Surgical embolectomy typically not recommended, since patients are high risk due to severe heart disease.
• Rheolytic thrombectomy has been used with limited success in a small number of cats with ATE.

MEDICATIONS

DRUG(S) OF CHOICE

Medical management focuses on (1) the thrombus, (2) analgesia, and (3) heart failure treatments (if needed).

Management of Thrombus

• Thrombolytic therapy (e.g., tissue plasminogen activator [TPA]) is used extensively in humans and infrequently in animals. These drugs are expensive and carry a significant risk for bleeding complications; to date, improved treatment efficacy is unproven and thus they are rarely used in general practice. TPA is theorized to be more beneficial if given early, ideally within the first few hours of the ATE.
• Unfractionated heparin is the preferred anticoagulant in general practice for initial management of feline ATE. Heparin has no effect on the established clot; however, it prevents further activation of the coagulation cascade. In either cat or dog, use an initial dose of 100–200 units/kg IV and then 200–300 units/kg SC q8h. Alternatively, heparin can be continued as a constant rate infusion, at a dose of 25–35 units/kg/h. Some advocate titrating the dose to prolong the activated partial thromboplastin time (APTT) approximately twofold.
• Clopidogrel is an antiplatelet aggregation drug. A loading dose may be chosen for treatment of an acute ATE. The loading dose in the cat is 75 mg/cat PO once, and then a maintenance dose of 18.75 mg/cat (one-fourth of a 75 mg tablet) PO q24h. The loading dose in the dog is approximately 10 mg/kg once, and then a maintenance dose of 1 mg/kg q24h. Compared to aspirin, clopidogrel was superior in preventing reembolization, resulting in improved survival times in cats that had survived an ATE. The combination of unfractionated heparin and clopidogrel is commonly used for the management of ATE in cats.

Other Options

• Aspirin is theoretically beneficial during and after an ATE event due to its antiplatelet effects. The dose in cats is an 81 mg tablet PO q48–72h. Vomiting and diarrhea are not uncommon. Some specialists advocate a mini dose of 5 mg/cat q72h. Antithrombotic dose recommendations for dogs range from 0.5 to 2 mg/kg q24h. Always give aspirin with food.
• Warfarin, a vitamin K antagonist, is the anticoagulant most widely used in humans and has been proposed for prevention of reembolization in cats surviving an initial episode. The initial dose is 0.25–0.5 mg/cat PO q24h, or 0.05–0.2 mg/kg PO q24h in the dog. Overlap with heparin therapy for 3 days. The dose is then adjusted to prolong the prothrombin time (PT) approximately twice its baseline value, or to attain an international normalized ratio (INR) of 2 to 3. Long-term management with warfarin can be challenging because of frequent monitoring and dose adjustments in addition to bleeding complications. In one study, dogs treated appropriately with warfarin had a better clinical outcome.
• Low molecular weight heparin (LMWH) has recently been proposed for the long-term prevention of feline ATE. LMWH has a more predictable relationship between dose and response than warfarin and does not need monitoring or dose adjustments. It also has a lower risk of bleeding complications. The main disadvantages are high drug cost and the injectable route of administration. The two LMWHs that have been used in feline ATE are dalteparin (100–150 units/kg SC q8–24h) and enoxaparin (1 mg/kg SC q12–24h). The best dose is unknown. LMWH is usually started q24h due to cost. Some studies suggest q6h dosing is necessary for stable blood levels, but may increase bleeding risk. LMWH can be used as an adjunctive anticoagulant combined with clopidogrel.
• Rivaroxaban, a newer anticoagulant drug, is an inhibitor of activated clotting factor X and prothrombinase activity that has shown promise for treatment and prevention of arterial thromboembolism in both dogs and cats. Rivaroxaban has a more predictable anticoagulant effect than warfarin and does not require any monitoring or dose adjustments. The cat dose is 1.25 mg/cat PO q24h. The dose recommended in dogs is 0.5–1 mg/kg PO q24h. The main disadvantage of rivaroxaban is its high cost at the time of this writing. However, it has the advantage of a shorter half-time than clopidogrel if there is a

A

AORTIC THROMBOEMBOLISM (CONTINUED)

need to discontinue the medication because of a bleeding complication or need to perform an invasive procedure. A clinical trial is currently ongoing to compare rivaroxaban and clopidogrel in cats that have survived an ATE.

Analgesics

- Buprenorphine in the cat is a useful and widely available drug for analgesia and sedation at a dose of 5–20 µg/kg IV, SC, or in cheek pouch q6–8h. For stronger analgesia, use fentanyl or hydromorphone. Butorphanol, while a good sedative, does not provide sufficient analgesia.
- Acepromazine may be cautiously used for its sedative and vasodilatory properties at a dose of 0.01–0.02 mg SC q8–12h. However, vasodilatory effects are mixed and therefore results are often variable.

CONTRAINDICATIONS
N/A

PRECAUTIONS
- Anticoagulant therapy with heparin, warfarin, or thrombolytics may cause bleeding complications.
- Avoid a nonselective beta blocker such as propranolol as it may enhance peripheral vasoconstriction.

POSSIBLE INTERACTIONS
Warfarin may interact with other drugs, which may enhance its anticoagulant effects.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
- ECG monitoring while cat in hospital is helpful to detect reperfusion injury and hyperkalemia-related ECG changes. Look for loss of P-waves and widening of QRS complexes.
- Monitoring electrolytes and renal parameters periodically may be helpful to optimize management of cardiac disease.
- Examine legs frequently to assess clinical response. Initially, APTT should be performed once daily to titrate heparin dose.
- If warfarin used, PT or INR is measured approximately 3 days after initiation of therapy and then weekly until desired anticoagulant effect reached. Thereafter, measure 3–4 times yearly or when drug regimen is altered.

PREVENTION/AVOIDANCE
Because of high rate of reembolization, prevention with either clopidogrel, aspirin, warfarin, or LMWH is strongly recommended.

POSSIBLE COMPLICATIONS
- Bleeding with anticoagulant therapy.
- Permanent neurologic deficits or muscular abnormalities in hind limbs may arise with prolonged ischemia.
- Recurrent CHF or sudden death.
- Reperfusion injury and death usually associated with hyperkalemic arrhythmias.

EXPECTED COURSE AND PROGNOSIS
- Expected course is days to weeks for full recovery of function to legs.
- Prognosis, both short and long term, is poor in cats.
- In two large studies, ~60% of cats were euthanized or died during initial thromboembolic episode. Long-term prognosis varies between 2 months and several years; however, average is a few months with treatment. Predictors of poorer prognosis include hypothermia (<99 °F) and CHF. One study demonstrated median survival time of 77 days in cats with CHF and 223 days in cats without CHF. Predictors of better prognosis include normothermia, single leg affected, and presence of motor function on initial exam.
- In dogs, the disease is rare and prognosis in general is also poor. One study suggested a better prognosis if the dog had chronic clinical signs and if treated with warfarin.
- Recurrence of ATE is common.

Client Education Handout available online

BASICS

OVERVIEW
• Tumors of endocrine cells that are capable of amine precursor uptake and decarboxylation (APUD) and secretion of peptide hormones. • APUD cells are generally found in gastrointestinal tract and CNS. • Hypergastrinemia from gastrin-secreting tumors (gastrinomas) causes gastritis and duodenal hyperacidity, which can cause gastric ulceration, gastric mucosal hypertrophy, esophageal dysfunction (chronic reflux), and intestinal villous atrophy. • Polypeptide-secreting tumors (polypeptidomas) may not cause clinical signs, but high concentration of pancreatic polypeptide may cause gastric hyperacidity and gastrointestinal ulceration.

SIGNALMENT
• Gastrinoma—rare in dogs, very rare in cats; age range 3–12 years, mean 7.5 years (dogs). • Pancreatic polypeptidoma—extremely rare in dogs.

SIGNS
• Vomiting. • Weight loss. • Anorexia. • Diarrhea. • Lethargy, depression. • Melena. • Abdominal pain. • Hematemesis, hematochezia. • Fever. • Polydipsia. • Polypeptidomas may not cause any clinical signs.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Conditions associated with hypergastrinemia, gastric hyperacidity, and gastrointestinal ulceration: ○ Uremia. ○ Hepatic failure. ○ Drug-induced ulceration, e.g., nonsteroidal anti-inflammatory drugs (NSAIDs) or steroids. ○ Inflammatory gastritis. ○ Stress-induced ulceration. ○ Mast cell disease.

CBC/BIOCHEMISTRY/URINALYSIS
• Normal or reflective of chronic disease or iron-deficiency anemia due to chronic gastrointestinal bleeding. • Regenerative anemia. • Increased blood urea nitrogen (BUN). • Hypoproteinemia. • Electrolyte abnormalities.

OTHER LABORATORY TESTS
• Serum gastrin concentration—normal or high normal if gastrinoma. Antacid treatment increases serum gastrin, resulting in false-positive diagnosis of gastrinoma; withdrawal of drugs for at least 7 days returns gastrin concentrations to baseline in dogs without gastrinoma. • Induced gastrin secretion—increased gastrin concentration after IV calcium gluconate or secretin suggests gastrinoma; rarely reported in veterinary medicine.

IMAGING
Abdominal ultrasound may demonstrate pancreatic mass or evidence of gastrointestinal ulceration/thickened gastric wall; frequently, the primary mass is too small to be detected.

DIAGNOSTIC PROCEDURES
• CT or MRI to identify pancreatic masses and/or metastatic lesions. • Endoscopy with gastric and duodenal biopsy. • Aspirate any detectable masses (rule out mast cell disease).

PATHOLOGIC FINDINGS
• Endoscopic biopsy—gastrointestinal ulceration. • Histopathology of pancreatic tumors—islet cell tumor (not specific for hormone type). • Immunocytochemical staining can aid specific diagnosis. • Liver and regional lymph node biopsies may reveal metastasis.

TREATMENT
• Most apudomas are malignant and have metastasized by the time of diagnosis; long-term control is difficult. • Aggressive medical management can palliate signs for months to years. • Surgical exploration and excisional biopsy/surgical debulking of a pancreatic mass are important both diagnostically and therapeutically. • Medical management for gastric hyperacidity.

MEDICATIONS

DRUG(S) OF CHOICE
• Omeprazole—proton pump inhibitor; potent inhibitor of gastric acid secretion; preferred. • Histamine H_2-receptor antagonists—cimetidine, ranitidine, famotidine; decrease acid secretion by gastric parietal cells. • Sucralfate—adheres to ulcerated gastric mucosa and protects from acid; promotes healing by binding pepsin and bile acids and stimulating local prostaglandins. • Octreotide–somatostatin analog—used successfully in 2 dogs and 1 cat with gastrinoma.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Because sucralfate may be less effective in an alkaline environment and may reduce absorption of other drugs, it should be given as a suspension, 1–2 hours prior to antacid drugs.

FOLLOW-UP

PATIENT MONITORING
• Physical examination and clinical signs are most useful measures of treatment effectiveness and disease progression. • Gastroscopy can monitor progression of gastritis, but is not necessary. • Abdominal radiography or ultrasound may detect development of abdominal masses. • Monitoring of CBC and serum protein levels may aid in assessing gastrointestinal hemorrhage.

POTENTIAL COMPLICATIONS
Gastrointestinal perforations may occur with severe ulceration.

EXPECTED COURSE AND PROGNOSIS
Survival time for gastrinoma ranges from weeks to years.

MISCELLANEOUS

SEE ALSO
Gastroduodenal Ulceration/Erosion.

ABBREVIATIONS
• APUD = amine precursor uptake and decarboxylation. • BUN = blood urea nitrogen. • NSAID = nonsteroidal anti-inflammatory drug.

A

ARTERIOVENOUS FISTULA AND ARTERIOVENOUS MALFORMATION

BASICS

OVERVIEW

- Abnormal, low-resistance connections between an artery and a vein (systemic or portal) that bypass a capillary bed.
- Arteriovenous malformation (AVM)—typically congenital, involving a vascular nidus, or complex network of communicating vessels.
- Arteriovenous fistula (AVF)—often acquired, direct, and singular connections.
- Large lesions cause marked drop in systemic vascular resistance and compensatory increase in cardiac output; this may cause circulatory volume overload and congestive heart failure (CHF).
- Variable location:
  - AVM most often reported in liver of dogs (termed arterioportal malformations/fistulas).
  - AVF more often in limbs or at sites of previous surgery/trauma.

SIGNALMENT

- Dog and cat (rare in both).
- No specific age, breed, or sex—AVMs typically in younger animals; 15% of hepatic AVMs found in Labrador retrievers in a recent multicenter study.

SIGNS

Historical Findings

- Depends on the lesion location (e.g., ascites with hepatic AVM).
- Often prior trauma to affected area with AVF.
- Warm, nonpainful swelling at site may be noted.
- Shunt may cause local organ dysfunction.

Physical Examination Findings

- Vary and depend on location.
- Signs of CHF (e.g., tachypnea, cough, exercise intolerance) may develop with chronic disease and high blood flow.
- Bounding pulses may be present due to high ejection volume and rapid runoff through AVM/AVF.
- Continuous murmur (bruit) at the site.
- Cautious compression of the artery proximal to the lesion abolishes the bruit. When blood flow is high, this may also elicit an immediate reflex decrease in heart rate (Branham's sign).
- Edema, ischemia, and congestion of organs and tissues caused by high venous pressure in proximity of lesion.
- If the lesion is on a limb, pitting edema, lameness, ulceration, scabbing, and gangrene may result.
- Lesions near vital organs may cause signs associated with organ failure, e.g., ascites (liver), seizures (brain), paresis (spinal cord).

CAUSES & RISK FACTORS

- AVM is rare; frequently congenital.
- Acquired AVF typically results from local vascular damage via trauma, surgery, venipuncture, perivascular injection, or neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Peripheral lesions (limb, ear) may look like a mass.
- Vascular aneurysm or pseudoaneurysm.
- Atypical clinical findings, depending on location, may suggest other disease processes; AVF/AVM may be a late diagnostic consideration.

CBC/BIOCHEMISTRY/URINALYSIS

May reflect damage to systems in vicinity of lesion, i.e., hepatic, renal, or other organ dysfunction.

OTHER LABORATORY TESTS

N/A

IMAGING

Thoracic Radiography

Cardiomegaly and pulmonary overcirculation with hemodynamically significant lesions. Microhepatica and loss of abdominal detail in hepatic AVMs.

Ultrasonography

- Lesions appear as cavernous, often tortuous, vascular structures.
- May observe high-velocity, turbulent flow on Doppler ultrasound.
- Hepatofugal flow in portal vein (away from the liver) nearly always apparent in hepatic AVM.
- Echocardiography may show four-chamber dilation and functional atrioventricular valve regurgitation due to increased circulating blood volume.

Cross-sectional Imaging

CT or MRI can aid in diagnosis, particularly when contrast is timed to highlight vascular anatomy.

Angiography

Selective angiography is the optimal test and is performed at time of intervention, if transcatheter therapy is pursued; digital subtraction angiography can improve visualization.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Surgery can be difficult, labor-intensive, and may require blood transfusion. Ligation or division of an AVF is often curative; *en bloc* resection of an AVM is necessary for cure.
- Transcatheter therapies with coils, devices, or glue are newer treatment options; potential advantages include less invasive therapy and intravascular access to remote lesions. Coils or occlusive devices are often sufficient for treatment of AVF; AVMs have been terminated by glue embolization of the arterial nidus, and more recently by embolization or ligation of the dominant outflow vein, which appears to limit shunt flow.
- Lesions may recur. In some cases, staged procedures or surgical removal of the affected limb or organ (e.g., amputation, liver lobectomy) may be necessary.

MEDICATIONS

DRUG(S) OF CHOICE

- Depend on site of lesion and secondary clinical features.
- Medical treatment for CHF or other organ dysfunction may be required before surgery.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid excessive fluid administration; patients are often volume overloaded and in a high cardiac output state.

FOLLOW-UP

Postoperative reevaluation and imaging needed to determine whether the lesion has recurred and if organ dysfunction has resolved.

ARTERIOVENOUS MALFORMATION OF THE LIVER

BASIC

OVERVIEW

• Intrahepatic arteriovenous (AV) malformations (also referred to as AV fistulae) are communications between proper hepatic arteries and intrahepatic portal veins; this anatomic union results in hepatofugal (away from the liver) splanchnic circulation.
• Blood flows directly from a hepatic artery into portal vasculature retrograde into the vena cava through multiple acquired portosystemic shunts (APSS).
• Associated with ascites.
• Uncommon, usually congenital, but may be acquired (surgical injury, trauma, neoplasia).

SIGNALMENT

• Dogs, less common in cats.
• Age-related presentation (congenital): <2 years.
• No sex or breed predilection.

SIGNS

General Comments

Vague or acute illness; present for signs caused by portal hypertension and APSS—ascites and hepatic encephalopathy (HE).

Historical Findings

• Dogs may have a normal transition to growth foods, unlike portosystemic vascular anomalies (PSVA) that demonstrate HE.
• May have an acute onset of ascites or HE.
• Vague signs include lethargy, anorexia, vomiting, diarrhea, weight loss, polydipsia, dementia, abdominal distention, and uroliths causing obstructive uropathy.

Physical Examination Findings

• Lethargic, poor body condition, ascites; enlarged liver lobe containing the AV malformation; rarely palpated on initial examination.
• Rarely, bruit auscultated over AV malformation.

CAUSES & RISK FACTORS

• Usually congenital vascular malformations (single or multiple vessels) reflecting failed differentiation of common embryologic anlage.
• Rare—secondary to abdominal trauma, inflammation, neoplasia, surgical interventions, or diagnostic procedures (e.g., liver biopsy).
• Portal hypertension—reflects arterialization of valveless portal system—establishing APSS.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• CNS signs—infectious disorders (e.g., distemper); toxicity (e.g., lead); hydrocephalus; idiopathic epilepsy; metabolic disorders (e.g., hypoglycemia, hypokalemia, or hyperkalemia); HE (e.g., acquired liver disease or PSVA).
• Abdominal effusion—pure transudate (ascites; protein-losing nephropathy, protein-losing enteropathy, liver disease); modified transudate (congenital cardiac malformations, right-sided heart failure, pericardial tamponade, supradiaphragmatic vena caval obstruction, neoplasia, portal vein thrombosis); hemorrhage.
• Portal hypertension—chronic hepatic disease, ductal plate malformations/congenital hepatic fibrosis, noncirrhotic or idiopathic portal hypertension, cirrhosis, portal thrombi.

CBC/BIOCHEMISTRY/URINALYSIS

• Erythrocyte microcytosis (APSS), target cells.
• Hypoalbuminemia with normal or low serum globulins; alkaline phosphatase (ALP) and alanine aminotransferase (ALT) activity normal or moderately increased; variable low blood urea nitrogen (BUN); hypocholesterolemia; anicteric.
• Hyposthenuria or isosthenuria.
• Ammonium biurate crystalluria.

OTHER LABORATORY TESTS

• Coagulation tests—variable, may be normal; low protein C activity reflects APSS.
• Total serum bile acids—preprandial values variable, postprandial values increased; classic shunting pattern.
• Plasma ammonia—usually increased, inferred by ammonium biurate crystalluria.
• Peritoneal fluid—pure transudate (total protein <2.5 g/dL) or modified transudate.

IMAGING

Radiography

• Abdominal effusion.
• Microhepatia or normal-sized liver due to enlarged lobe with AV malformation.
• Renomegaly.
• Normal thorax.

Abdominal Ultrasonography

• Abdominal effusion.
• Liver lobe with AV malformation—large compared to most other liver lobes that are atrophied due to portal hypoperfusion.
• Tortuous anechoic tubules represent AV structure with unidirectional pulsating or turbulent flow on color-flow Doppler.
• Hepatic artery and/or portal vein branches may appear tortuous.
• Hepatofugal portal flow (away from the liver)—through APSS.
• Renomegaly.
• Urolithiasis—urinary bladder or renal pelvis.
• Rule out portal thrombosis (luminal filling defect, abrupt blood flow termination).

Radiographic Contrast Angiography

• Not indicated in most cases.
• Venous portography—only confirms APSS.
• Hepatic arteriography—required to confirm AV communication (celiac trunk or anterior mesenteric artery contrast injection).

Multisector CT

Noninvasive contrast imaging of hepatic vasculature; arterial and venous phases; three-dimensional reconstruction illustrates AV malformation, large liver lobe, atrophied liver.

Echocardiography

Rule out right-sided heart disease, pericardial disease, and vena caval occlusion.

DIAGNOSTIC PROCEDURES

• Multisector CT and exploratory laparotomy.
• Liver biopsy—collect samples from *affected* and *unaffected* liver lobes; "normal" liver often demonstrates severe vascular arterialization (more severe than associated with PSVA).

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—treat HE and ascites prior to surgical approach or percutaneous selective acrylamide embolization.

NURSING CARE

• *Diet*—restrict nitrogen intake to ameliorate HE and hyperammonemia; restrict sodium to attenuate ascites formation.
• *HE*—resolve endoparasitism, electrolyte and hydration disturbances, treat infections, initiate treatments to alter enteric uptake and formation of HE toxins (see Hepatic Encephalopathy).
• *Ascites*—mobilize by restricting activity and sodium intake and instituting dual diuretic therapy (furosemide and spironolactone); reserve therapeutic abdominocentesis for tense ascites impairing ventilation, nutrition, sleep, or recumbent posture (see Hypertension, Portal; Portosystemic Shunting, Acquired; and below).

SURGICAL CONSIDERATIONS

• Resection of liver lobe containing AV malformation is complicated by coexistence of additional hepatic vascular malformations; clinical cure possible but unlikely.
• Percutaneous selective acrylamide vascular embolization; complicated by risk of thromboembolism of additional vasculature; temporary improvement, but treatment may be curative.
• Multiple microscopic vascular malformations continue portal hypertension and APSS.
• Do not ligate APSS nor band the vena cava.

A

ARTERIOVENOUS MALFORMATION OF THE LIVER (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

Hepatic Encephalopathy

See Hepatic Encephalopathy

Ascites

- Restrict sodium intake.
- Furosemide (0.5–2 mg/kg PO IM or IV q12–24h)—combine with spironolactone.
- Spironolactone (0.5–2 mg/kg PO q12h)—double initial dose as loading dose once.
- Chronic diuretic therapy—individualized to response, 4- to 7-day assessment intervals used to titrate dose to response, avoiding hydration, electrolyte, and HE complications.
- Diuretic-resistant ascites—may require therapeutic abdominocentesis; to initiate diuresis.
- Vasopressin V_2 receptor antagonists newly available may control ascites accumulation. (See Portosystemic Shunting, Acquired.)

Bleeding Tendencies

See Coagulopathy of Liver Disease.

Gastrointestinal Hemorrhage

- *Histamine type-2 receptor antagonists* (famotidine 0.5–2.0 mg/kg PO, IV, or SC q12–24h); or *HCl pump inhibitors* (omeprazole 1.0 mg/kg/24h PO or pantoprazole 1.0 mg/kg/24h IV; omeprazole may induce p450 cytochrome-associated drug interactions and may have a 24–48h delayed onset of action; some clinicians recommend chronic treatment to minimize GI bleeding and ulceration that may be chronic problems).
- *Gastroprotectant*—sucralfate: 0.25–1.0 g/10 kg PO q8–12h; titrate to effect, beware of drug interactions as sucralfate may bind other medications, reducing bioavailability.
- *Eliminate endoparasitism*.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid drugs dependent on hepatic biotransformation or first-pass hepatic extraction (reduced by APSS) or that react with γ-aminobutyric acid (GABA)-benzodiazepine receptors because of propensity for HE.

FOLLOW-UP

PATIENT MONITORING

Biochemistry—initially monthly until stabilized after surgery or AV malformation embolization, thereafter quarterly; monitor for hypoalbuminemia, infection, optimization of HE management, and control of ammonium biurate crystalluria.

EXPECTED COURSE AND PROGNOSIS

- Prognosis fair if patient survives surgical resection of AV malformation or embolization.
- Most patients require indefinite nutritional and medical management (HE, ascites) because of coexisting microscopic vascular malformations across the liver; APSS persists requiring continued management of HE.

MISCELLANEOUS

SEE ALSO

- Ascites.
- Coagulopathy of Liver Disease.
- Hepatic Encephalopathy.
- Hypertension, Portal.
- Portosystemic Shunting, Acquired.
- Portosystemic Vascular Anomaly, Congenital.

ABBREVIATIONS

- ALP = alkaline phosphatase.
- ALT = alanine aminotransferase.
- APSS = acquired portosystemic shunt.
- AV = arteriovenous.
- BUN = blood urea nitrogen.
- GABA = γ-aminobutyric acid.
- HE = hepatic encephalopathy.
- PSVA = portosystemic vascular anomalies.

ARTHRITIS (OSTEOARTHRITIS)

BASICS

DEFINITION

Osteoarthritis (OA) or degenerative joint disease is a chronic and progressive disease that leads to loss of articular cartilage and ultimately failure of the joint. OA is characterized as a noninfectious disorder of diarthrodial (synovial) joints, such that the disease process involves the entire joint, not just the articular cartilage. It is due to both primary (idiopathic) and secondary causes.

PATHOPHYSIOLOGY

- Ebb and flow characterization with periods of calmness followed by periods of exacerbation of clinical signs (flare-ups).
- OA initiated by mechanical stress—traumatic injury, instability, abnormal conformation, abnormal activity, etc.
- Inflammatory mediators and free radicals such as metalloproteinases, serine proteases, cysteine protease enzymes, and reactive oxygen species are released from damaged chondrocytes and synovium, resulting in breakdown of extracellular matrix of articular cartilage, causing collagen degradation and loss of collagen cross-linking.
- Collagen synthesis is altered, resulting in decreased collagen/proteoglycan interaction and reduced hydrophilic matrix properties.
- Extracellular matrix further compromised by increased breakdown of proteoglycans along with manufacture of poorer-quality proteoglycans.
- Nitric oxide released along with other free radicals, which mediates cartilage breakdown and supports chronic inflammation. Chondrocyte apoptosis facilitated by cyclooxygenase-2 enzymes and oxidative stress.
- Synovitis is driving force of the inflammatory cascade in OA, in addition to resulting in decreased viscosity of synovial fluid, reducing lubrication.
- Poorer-quality synovial fluid reduces oxygen and nutrient supply to chondrocytes as well as waste removal.
- Subchondral bone becomes sclerotic, worsening loading qualities of bone and overlying cartilage.
- Pain of OA results from distention of the joint capsule and stimulation of pain receptors, inflammation of synovium, increased mechanical loading of subchondral bone, alteration of function of surrounding tendons and ligaments, as well as development of periarticular fibrosis.
- The result of these processes is progressive cartilage degradation ranging from fibrillation to deep fissuring of cartilage. Full-thickness cartilage loss can eventually occur.
- Periarticular fibrosis occurs, resulting in a reduction of joint motion (and pain), leading to poorer vascularity of synovial membrane as well as lack of functionality of synovium due to lack of motion in joint.
- Osteophytes and enthesiophytes develop around and within joint to increase load-bearing surface area.
- These changes reduce functionality and may eventually lead to ankylosis.

SYSTEMS AFFECTED

Musculoskeletal—diarthrodial joints.

GENETICS

- Primary OA rare, occurring more commonly in cats or in smaller (manus, pes) joints of dogs.
- Dogs—causes of secondary OA are varied, including hip and elbow dysplasia, osteochondritis dessicans (OCD), patellar luxations, congenital shoulder luxation, Legg-Perthes, cranial cruciate ligament rupture, intra-articular fractures, obesity, as well as many other causes.
- Cats—causes of secondary OA are patellar luxation, hip dysplasia, obesity, and arthropathy.

INCIDENCE/PREVALENCE

- Dog—very common; 20% of dogs older than 1 year have some degree of OA.
- Cat—90% of cats over 12 years of age had evidence of OA on radiographs.
- Clinical problems are more prevalent in larger, overweight, and very active animals.
- Primary OA is rare.

SIGNALMENT

Species

Dog and cat.

Mean Age and Range

- Secondary OA due to congenital disorders (OCD, hip dysplasia) seen in immature animals; some present with OA signs when mature (hip and elbow dysplasia).
- Secondary to trauma—any age.

SIGNS

Historical Findings

- Dogs—decreased activity level, unwilling to perform certain tasks; intermittent lameness or stiff gait that slowly progresses; possible history of joint trauma, OCD, or developmental disorders; may be exacerbated by exercise, long periods of recumbency, and cold weather.
- Cats—overt lameness may not be seen. Reduction in activity, reluctance to jump, unkempt appearance, difficulty accessing litter box, and increased irritability.

Physical Examination Findings

- Stiff-legged or altered gait or nonuse of leg.
- Decreased range of motion.
- Crepitus.
- Joint swelling (effusion and/or thickening of the joint capsule).
- Joint pain.
- Joint instability.

CAUSES

- Primary—no known cause.
- Secondary—results from initiating cause: abnormal wear on normal cartilage (e.g., joint instability, joint incongruity, trauma to cartilage or supporting soft tissues, obesity) or normal wear on abnormal cartilage (e.g., osteochondral defects).

RISK FACTORS

- Working, athletic, and obese dogs place more stress on their joints.
- Dogs with disorders that affect collagen or cartilage (Cushing's disease, diabetes mellitus, hypothyroidism, hyperlaxity, prolonged steroid use).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Neoplastic (synovial sarcoma; rarely, chondrosarcoma; osteosarcoma).
- Septic arthritis (caused by bacteria; spirochetes; L forms in cats; *Mycoplasma*; *Rickettsia*; *Ehrlichia*; viruses such as feline calicivirus; fungi and protozoa).
- Immune-mediated arthritis (erosive vs. nonerosive).
- Other musculoskeletal conditions that cause lameness.
- Neurologic conditions causing lameness or decreased activity/weakness.

OTHER LABORATORY TESTS

- Coombs' test, antinuclear antibody (ANA), and rheumatoid factor may help to rule out immune-mediated arthritis.
- Serum titers for *Borrelia*, *Ehrlichia*, and *Rickettsia* to evaluate for infectious arthritis.

IMAGING

- Radiographic changes—include joint capsular distention, osteophytosis, enthesophytosis, soft-tissue thickening, and narrowed joint spaces. In severely affected patients: subchondral sclerosis and intra-articular calcified bodies (joint mice).
- Radiographic severity often does not correlate with clinical severity.
- Stress radiography may identify underlying instability and accentuate joint incongruity (e.g., distraction index, passive hip laxity of coxofemoral joint is predictive of hip OA).
- Bone nuclear scintigraphy can assist in localizing subtle OA.
- Arthroscopy can allow direct observation of cartilage and characterization by Modified Outerbridge Score.

DIAGNOSTIC PROCEDURES

- Arthrocentesis and synovial fluid analysis—cell counts are normal or slightly increased (<2,000–5,000 cells/mL) predominantly

A

ARTHRITIS (OSTEOARTHRITIS) (CONTINUED)

mononuclear (macrophages) and occasional synovial lining cells.
• Bacterial culture of synovial fluid or synovium—negative.
• Biopsy of synovial tissue to rule out neoplasia or immune-mediated arthropathy (lymphocytic plasmacytic synovitis, systemic lupus erythematosus).

PATHOLOGIC FINDINGS
• Fibrillation or erosion of articular cartilage.
• Eburnation and sclerosis of subchondral bone.
• Thickening and fibrosis of joint capsule.
• Synovial fluid can be grossly normal to thin and watery, usually increased volume.
• Synovial villous hypertrophy and hyperplasia.
• Osteophytes and enthesiophytes at joint capsule attachments and adjacent to the joint.
• Neovascularization or pannus in severe cases over joint surfaces.

TREATMENT

APPROPRIATE HEALTH CARE
• Medical—usually tried initially.
• Surgical options—to improve joint geometry or remove bone-on-bone contact areas through total joint arthroplasty, ostectomy, or joint fusion.

NURSING CARE
• Physical rehabilitation—very beneficial during periods of flare-ups.
• Maintaining or increasing joint motion—active and passive range of motion exercises, stretching, massage, therapeutic exercises, and hydrotherapy.
• Pain management—cold and heat therapy, transcutaneous electrical stimulation (TENS), and acupuncture.
• Muscle tone/strengthening—daily leash walking, incorporation of inclines/declines, stair ascent and stair descent, walking on uneven terrain, open water swimming, underwater and land treadmill.
• Maintenance of a lean body weight through both diet and daily exercise.

ACTIVITY
• During periods of calmness, daily leash walks to work up to twice-daily level flat ground for 20 minutes before incorporation of increased time or terrain.
• Limitation of daily activity that minimizes aggravation of clinical signs during periods of flare-up (avoidance of running, chasing, jumping, and playing).

DIET
• Weight reduction for obese patients—decreases stress placed on arthritic joints. Begin by feeding 60% of calories needed to maintain current body weight.
• Omega n-3 fatty acids decrease production of certain prostaglandins and modulate inflammation. Dosage should be 150–175 mg/kg DHA/EPA daily.

CLIENT EDUCATION
• Medical therapy is palliative and the condition is likely to progress.
• Describe identifying signs of flare-ups and importance of getting it under control quickly.
• Discuss management options, daily exercise, activity level, and diet.

SURGICAL CONSIDERATIONS
• Arthrotomy—used to remove aggravating causes (e.g., fragmented coronoid process, ununited anconeal process, osteochondral flaps).
• Arthroscopy—used to diagnose and remove aggravating causes.
• Reconstructive procedures—used to eliminate joint instability and correct anatomic problems (cruciate ligament rupture, patella luxation, angular deformity).
• Joint removal—femoral head and neck ostectomy, temperomandibular joint arthroplasty.
• Joint replacement—total hip replacement is widely used, total elbow and stifle replacement are used with less frequency, total ankle and shoulder replacment are experimental and used infrequently at this time.
• Joint fusion (arthrodesis)—in selected chronic cases and for joint instability, complete or partial; carpus, hock: generally excellent outcome; shoulder, elbow, stifle: less predictable outcome.

MEDICATIONS

DRUG(S) OF CHOICE

Nonsteroidal Anti-inflammatory Drugs (NSAIDs)
• Inhibit prostaglandin synthesis through cyclooxygenase enzymes.
• Deracoxib (3–4 mg/kg PO q24h, chewable).
• Carprofen (2.2 mg/kg PO q12h or q24h).
• Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h, liquid).
• Tepoxalin (load 20 mg/kg, then 10 mg/kg PO q24h).
• Cats—meloxicam (0.1 mg/kg PO q24h, liquid) or robenacoxib (1 mg/kg PO q24h for 3 days).
• Inhibit prostaglandin synthesis at receptor specific sites.
• Grapiprant (2.0 mg/kg PO q24h, chewable).

Disease-Modifying Osteoarthritis Agents (DMOAs)
• Host of products, many with little production oversight so effects vary widely. Supply polysulfated glycosaminoglycan (PSGAG) molecules to repair and regenerate cartilage.
• Adequan®—clinical study in dogs with hip dysplasia; 4.4 mg/kg IM every 3–5 days for 8 injections had positive, temporary effect.
• Glucosamine and chondroitin sulfate—oral Cosequin®, oral methylsulfonylmethane (MSM), mixtures with MSM, or other supplements (e.g., Dasuquin® Advanced, GlycoFlex® 2, Synflex).

CONTRAINDICATIONS
• NSAIDs must not be given with steroids.
• Acetaminophen must not be given to cats.

PRECAUTIONS
• NSAIDs may cause gastric ulceration.
• Cyclooxygenase-2 (COX-2)-selective drugs may interfere with liver function when used outside of dosage range
• When switching NSAIDs—wait 3 days for washout before starting new drug.

POSSIBLE INTERACTIONS
Steroids with NSAIDS.

ALTERNATIVE DRUG(S)
• Free-radical scavengers.
• Amantadine (3–5 mg/kg PO q24h)—best used in combination with another analgesic such as NSAID. Only analgesic (other than NSAID) with scientific evidence for usage with OA.
• Gabapentin (5–10 mg/kg PO q8-12h)—no scientific evidence for usage with OA.
• Codeine (1–2 mg/kg PO q 8–12h)—no scientific evidence for usage with OA; suggested for short-term use during flare-ups.
• Glucocorticoids—inhibit inflammatory mediators and cytokines; however, chronic use delays healing and initiates damage to articular cartilage; potential systemic side effects documented; goal is low dose (dogs, 0.5–2 mg/kg; cats, 2–4 mg/kg) q48h.
• Prednisone—initial dose 1–2 mg/kg PO q24h for dogs and 4 mg/kg PO q24h for cats.
• Triamcinolone hexacetonide—intra-articular injection of 5 mg in dogs showed a protective and therapeutic effect in one model.
• Hyaluronic acid—intra-articular injection (15–30 mg/joint) used as a series of 3 separated by 1 week or in combination with an intra-articular steroid.
• Platelet-rich plasma—intra-articular injection to decrease inflammatory mediators; many patients need more than 1 injection separated by 2 weeks; weak scientific evidence for efficacy.

FOLLOW-UP

PATIENT MONITORING
• During flare-up recheck 2 weeks later; pain should be better controlled at this time; then recheck every 4–6 weeks until flare-up under control.
• Recheck OA patients every 4–6 months for life.
• Any clinical deterioration could indicate a flare-up—need to change drug selection or dosage; may indicate need for intra-articular

injection, formal rehabilitation therapy, or surgical intervention.

PREVENTION/AVOIDANCE

Early identification of predisposing causes and prompt treatment to help reduce progression of secondary conditions, e.g., surgical removal of osteochondral lesions.

EXPECTED COURSE AND PROGNOSIS

- Slow progression of disease likely.
- Some form of medical or surgical treatment usually allows a good quality of life when managed appropriately and aggressively.

MISCELLANEOUS

SYNONYMS

- Degenerative arthritis.
- Degenerative joint disease.
- Osteoarthritis.
- Osteoarthrosis.

ABBREVIATIONS

- ANA = antinuclear antibody.
- COX-2 = cyclooxygenase-2.
- DMOA = disease-modifying osteoarthritis agent.
- MSM = methylsulfonylmethane.
- NSAID = nonsteroidal anti-inflammatory drug.
- OA = osteoarthritis.
- OCD = osteochondritis dessicans.
- PSGAG = polysulfated glycosaminoglycan.

Client Education Handout available online

A

ARTHRITIS, SEPTIC

BASICS

DEFINITION
Pathogenic microorganisms within the closed space of one or more synovial joints.

PATHOPHYSIOLOGY
• Usually caused by contamination associated with traumatic injury (e.g., a direct penetrating injury such as bite, gunshot wound, foreign object), a sequela to surgery, arthrocentesis or joint injection, hematogenous spread of microorganisms from a distant septic focus, or less commonly the extension of primary osteomyelitis. • Primary sources of hematogenous infection—urogenital, integumentary (including ears and anal sacs), respiratory, cardiac, and gastrointestinal systems.

SYSTEMS AFFECTED
Musculoskeletal—usually affects one joint.

GENETICS
N/A

INCIDENCE/PREVALENCE
Relatively uncommon cause of monoarticular arthritis in dogs and cats.

GEOGRAPHIC DISTRIBUTION
May be an increased incidence in areas with endemic Lyme disease.

SIGNALMENT

Species
• Most common in dogs. • Rare in cats.

Breed Predilections
Any; medium to large breeds—most commonly German shepherds, Dobermans, and Labrador retrievers.

Mean Age and Range
Any age; usually between 4 and 7 years. Hematogenous—more common in immature animals.

Predominant Sex
Male

SIGNS

General Comments
Always consider the diagnosis in patients with acute, monoarticular lameness associated with soft tissue swelling, heat, and pain.

Historical Findings
• Lameness—acute onset most common, but can present as chronic lameness. • Lethargy. • Anorexia. • May report previous trauma—dog bite, penetrating injury, prior surgery or other invasive procedure of the joint.

Physical Examination Findings
• Monoarticular lameness, rarely polyarticular. • Joint pain and effusion—commonly carpus, stifle, hock, shoulder, or cubital joint. • Localized joint heat. • Decreased range of motion. • Local lymphadenopathy. • Pyrexia.

CAUSES
• Aerobic bacterial organisms—most common: staphylococci, streptococci, coliforms, and *Pasteurella*. • Anaerobic organisms—most common: *Propionibacterium*, *Peptostreptococcus*, *Fusobacterium*, and *Bacteroides*. • Spirochete—*Borrelia burgdorferi*. • *Mycoplasma*. • Fungal agents—*Blastomyces*, *Cryptococcus*, and *Coccidioides*. • *Rickettsial—Anaplasma*, *Ehrlichia*, *Rickettsia*. • *Leishmania*. • Feline calicivirus.

RISK FACTORS
• Predisposing factors for hematogenous infection—diabetes mellitus, hypoadrenocorticism (Addison's disease), immunosuppression. • Penetrating trauma to the joint including surgery. • Existing osteoarthritis or other joint damage. • Intra-articular injection, particularly if steroid injected.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Osteoarthritis. • Trauma. • Immune-mediated arthropathy. • Postvaccinal transient polyarthritis. • Greyhound polyarthritis. • Feline progressive polyarthritis. • Crystal-induced joint disease. • Synovial sarcoma.

CBC/BIOCHEMISTRY/URINALYSIS
• Hemogram—inflammatory left shift in some cases. • Other results normal.

OTHER LABORATORY TESTS
Serologic testing for specific pathogens.

IMAGING

Radiography
• Early disease—may reveal thickened and dense periarticular tissues; may see evidence of synovial effusion. Often difficult to diagnose early disease radiographically. • Late disease—reveals bone destruction, osteolysis, irregular joint space, discrete erosions, and periarticular osteophytosis.

DIAGNOSTIC PROCEDURES

Synovial Fluid Analysis
• Increased volume. • Turbid fluid. • Decreased viscosity. • Decreased mucin clot reaction. • Make slides immediately; if additional fluid is obtained, place in EDTA tube. • Elevated white blood cell (WBC) count—i.e., >80% neutrophils with >40,000/mm^3 (normal joint fluid <10% neutrophils and <3,000/mm^3) • Neutrophils may show degenerative changes (chromatolysis, vacuolation, nuclear swelling, loss of segmentation). • Neutrophils with phagocytosed bacteria—definitive diagnosis or bacteria in the synovial fluid.

Synovial Fluid Culture
• Positive culture is definitive but not necessary for diagnosis; negative culture does not rule out infection. • Must be collected aseptically; requires heavy sedation or general anesthesia. • Place fluid sample in aerobic and anaerobic culturettes and in blood culture medium. • Use 1 : 9 dilution of synovial fluid to blood culture media. • Culturette samples—cultured immediately upon arrival at the laboratory. • Blood culture medium—reculturing after 24 hours of incubation increases accuracy by 50% and is the preferred method. • *Mycoplasma*, bacterial L-forms, and protozoa require specific culture procedures—contact laboratory prior to sample collection.

Other
• Synovial biopsy—to rule out immune-mediated joint disease; no more effective than incubated blood culture medium for growing bacterial organisms. • Blood and urine cultures if hematogenous source is suspected.

PATHOLOGIC FINDINGS
• Synovium—thickened; discolored; often very proliferative. • Histology—evidence of hyperplastic synoviocytes. • Increased numbers of neutrophils, macrophages, and fibrinous debris. • Cartilage—loss of proteoglycan, destruction of articular surface, pannus formation.

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient—initial stabilization; initiate systemic antibiotic therapy as soon as fluid is obtained for bacterial culture; consider joint drainage/lavage as soon as possible to minimize intra-articular injury. • Analgesia with anti-inflammatory medications if appropriate, and intravenous opioid. • Identify and treat source if hematogenous spread is suspected. • Outpatient—long-term management.

NURSING CARE
Alternating heat and cold packing—beneficial in promoting increased blood flow and decreased swelling.

ACTIVITY
Restricted until resolution of symptoms.

DIET
N/A

CLIENT EDUCATION
• Discuss probable cause. • Warn client about the need for long-term antibiotics and the likelihood of residual degenerative joint disease.

SURGICAL CONSIDERATIONS
• Acute disease with minimal radiographic changes—joint drainage and lavage via needle arthrocentesis, arthroscopic lavage,

or arthrotomy; an irrigation catheter (ingress/egress) can be placed in larger joints. • Chronic disease—may require open arthrotomy with debridement of the synovium and copious lavage; if appropriate, an irrigation catheter (ingress/egress) may be placed to lavage the joint postoperatively. • Lavage—use warmed physiologic saline or lactated Ringer's solution (2–4 mL/kg q8h) until effluent is clear; do not add povidone/iodine or chlorhexidine to lavage fluid. • Effluent fluid—cytologically monitored daily for existence and character of bacteria and neutrophils. • Removal of catheters—when effluent fluid has no bacteria and the neutrophils are cytologically healthy. • Arthroscopy allows for visual assessment of articular cartilage, lavage, and biopsy, and is a less invasive method of thorough joint lavage than arthrotomy. • Recent reports suggest there may be no difference between combined medical and surgical management and medical management alone.

MEDICATIONS

DRUG(S) OF CHOICE
• Pending culture susceptibility data—bactericidal antibiotics, such as first-generation cephalosporin or amoxicillin–clavulanic acid, preferred. • Choice of antimicrobial drugs—primarily depends on in vitro determination of susceptibility of microorganisms; toxicity, frequency, route of administration, and expense also considered; most penetrate the synovium well; need to be given for a minimum of 4–8 weeks. • Nonsteroidal anti-inflammatory drugs (NSAIDs)—may help decrease pain and inflammation.

CONTRAINDICATIONS
Avoid fluorinated quinolones in pediatric patients, as their use has induced cartilage lesions experimentally.

PRECAUTIONS
Failure to respond to conventional antibiotic therapy—may indicate anaerobic disease, other unusual cause (fungal, spirochete), or aseptic arthritides.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• If drainage and irrigation catheters have been placed—may be removed after 4–6 days or after reassessment of synovial fluid cytology. • Duration of antibiotic therapy—2 weeks following resolution of clinical signs; total treatment may be 4–8 weeks or longer, depending on clinical signs and pathogenic organism. • Persistent synovial inflammation without viable bacterial organisms (dogs)—may be caused by antigenic bacterial fragments or antigen antibody deposition. • Systemic corticosteroid therapy (after joint sepsis has been resolved) and aggressive physical therapy—may be needed to maximize normal joint dynamics.

PREVENTION/AVOIDANCE
If clinical signs recur, early (within 24–48 hours) treatment provides the greatest benefit.

POSSIBLE COMPLICATIONS
• Chronic disease—severe degenerative joint disease. • Recurrence of infection. • Limited range of joint motion. • Generalized sepsis. • Osteomyelitis.

EXPECTED COURSE AND PROGNOSIS
• Acutely diagnosed disease (within 24–48 hours) responds well to antibiotic therapy. • Delayed diagnosis or resistant or highly virulent organisms—guarded to poor prognosis.

ASCITES

BASICS

DEFINITION
The escape of fluid, either transudate or exudate, into the abdominal cavity between the parietal and visceral peritoneum.

PATHOPHYSIOLOGY
- Ascites can be caused by the following:
  - Congestive heart failure (CHF) and associated interference in venous return.
  - Depletion of plasma proteins associated with inappropriate loss of protein from renal or gastrointestinal disease—protein-losing nephropathy or enteropathy, respectively.
  - Obstruction of the vena cava or portal vein, or lymphatic drainage due to neoplastic occlusion.
  - Overt neoplastic effusion.
  - Peritonitis—infective or inflammatory.
  - Electrolyte imbalance, especially hypernatremia.
  - Liver cirrhosis.

SYSTEMS AFFECTED
- Cardiovascular.
- Gastrointestinal.
- Hemic/lymph/immune.
- Renal/urologic.

SIGNALMENT
- Dog and cat.
- No species or breed predisposition.

SIGNS
- Episodic weakness.
- Lethargy.
- Abdominal fullness.
- Abdominal discomfort when palpated.
- Dyspnea from abdominal distension or associated pleural effusion.
- Anorexia.
- Vomiting.
- Weight gain.
- Scrotal or preputial edema.
- Groaning when lying down.

CAUSES
- Nephrotic syndrome.
- Cirrhosis of liver.
- Right-sided CHF.
- Hypoproteinemia.
- Ruptured bladder.
- Peritonitis.
- Abdominal neoplasia.
- Abdominal hemorrhage.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating Abdominal Distension without Effusion
- Organomegaly—hepatomegaly, splenomegaly, renomegaly, and hydrometra.
- Abdominal neoplasia.
- Pregnancy.
- Bladder distension.
- Obesity.
- Gastric dilatation.

Differentiating Diseases
- Transudate—nephrotic syndrome, cirrhosis of liver, right-sided CHF, hypoproteinemia, and ruptured bladder.
- Exudate—peritonitis, abdominal neoplasia, and hemorrhage.

CBC/BIOCHEMISTRY/URINALYSIS
- Neutrophilic leukocytosis occurs in patients with systemic infection.
- Albumin is low in patients with impaired liver synthesis, gastrointestinal loss, or renal loss.
- Cholesterol is low in patients with impaired liver synthesis.

Liver Enzymes
- Low to normal in patients with impaired liver synthesis.
- High in patients with liver inflammation, hyperadrenocorticism, gallbladder obstruction, and chronic passive congestion.

Total and Direct Bilirubin
- Low to normal in patients with impaired liver synthesis.
- High in patients with biliary obstruction caused by tumor, gallbladder distension, or obstruction.

Blood Urea Nitrogen (BUN) and Creatinine
- High in patients with renal failure.
- BUN low in patients with impaired liver synthesis or hyperadrenocorticism.

Glucose
Low in patients with impaired liver synthesis.

OTHER LABORATORY TESTS
- To detect hypoproteinemia—protein electrophoresis and immune profile.
- To detect proteinuria—urinary protein : creatinine ratio (normal <0.5 : 1).
- To detect liver ascites—analysis of serum ascites albumin gradient.

IMAGING
- Thoracic and abdominal radiography is sometimes helpful.
- Ultrasonography of the liver, spleen, pancreas, kidney, bladder, and abdomen can often determine cause.
- Stages of ascites:
  - Stage I—minimal ascites: detected by ultrasound only.
  - Stage II—moderate ascites: abdominal distention visible and/or noted on ballottement.
  - Stage III—significant ascites: marked abdominal distention; patient uncomfortable, possibly with labored breathing.

DIAGNOSTIC PROCEDURES

Ascitic Fluid Evaluation
Exfoliative cytologic examination and bacterial culture and antibiotic sensitivity—remove approximately 3–5 mL of abdominal fluid via aseptic technique.

Transudate
- Clear and colorless.
- Protein <2.5 g/dL.
- Specific gravity <1.018.
- Cells <1,000/mm^3—neutrophils and mesothelial cells.

Modified Transudate
- Red or pink; may be slightly cloudy.
- Protein 2.5–5 g/dL.
- Specific gravity >1.018.
- Cells <5,000/mm^3—neutrophils, mesothelial cells, erythrocytes, and lymphocytes.

Exudate (Nonseptic)
- Pink or white; cloudy.
- Protein 2.5–5 g/dL.
- Specific gravity >1.018.
- Cells 5,000–50,000/mm^3—neutrophils, mesothelial cells, macrophages, erythrocytes, and lymphocytes.

Exudate (Septic)
- Red, white, or yellow; cloudy.
- Protein >4.0 g/dL.
- Specific gravity >1.018.
- Cells 5,000–100,000/mm^3—neutrophils, mesothelial cells, macrophages, erythrocytes, lymphocytes, and bacteria.

Hemorrhage
- Red; spun supernatant clear and sediment red.
- Protein >5.5 g/dL.
- Specific gravity 1.007–1.027.
- Cells consistent with peripheral blood.
- Does not clot.

Chyle
- Pink, straw, or white.
- Protein 2.5–7 g/dL.
- Specific gravity 1.007–1.040 and above.
- Cells <10,000/mm^3—neutrophils, mesothelial cells, and large population of small lymphocytes.

• Other—fluid in tube separates into cream-like layer when refrigerated; fat droplets stain with Sudan III.

Pseudochyle
• White.
• Protein >2.5 g/dL.
• Specific gravity 1.007–1.040.
• Cells <10,000/mm^3—neutrophils, mesothelial cells, and small lymphocytes.
• Other—fluid in tube does not separate into cream-like layer when refrigerated; does not stain with Sudan III.

Urine
• Clear to pale yellow.
• Protein >2.5 g/dL.
• Specific gravity 1–1.040 and above.
• Cells 5,000–50,000/mm^3—neutrophils, erythrocytes, lymphocytes, and macrophages.
• Other—if the urinary bladder ruptured <12 hours before, urinary glucose and protein could be negative; if bladder ruptured >12 hours before, urine becomes a dialysis medium with ultrafiltrate of plasma, and urine contains glucose and protein.

Bile
• Slightly cloudy and yellow.
• Protein >2.5 g/dL.
• Specific gravity >1.018.
• Cells 5,000–750,000/mm^3—neutrophils, erythrocytes, macrophages, and lymphocytes.
• Other—bilirubin confirmed by urine dipstick; nonicteric patient may have gallbladder rupture, biliary tree leakage, or rupture in the proximal bowel.

TREATMENT

• Can design treatment on an outpatient basis, with follow-up or inpatient care, depending on physical condition and underlying cause.
• If patients are markedly uncomfortable when lying down or become more dyspneic with stress, consider removing enough ascites to reverse these signs.
• Dietary salt restriction may help control transudate fluid accumulation due to CHF, cirrhosis, or hypoproteinemia.
• For exudate ascites control, address the underlying cause; corrective surgery is often indicated, followed by specific therapeutic management (e.g., patient with splenic tumor: tumor removed, abdominal bleeding controlled, blood transfusion administered).

Large-Volume Paracentesis
• Stage III treatment.
• Pretreat patient with hetastarch (6%) @ 1–2 mL/kg for 2 hours.
• Abdominal tap (paracentesis), until drainage slows.
• Post-treat patient with hetastarch (6%) @ 1–2 mL/kg for 4 hours.

MEDICATIONS

DRUG(S) OF CHOICE

• Patients with liver insufficiency or CHF—restrict sodium and give a diuretic combination of furosemide (1–2 mg/kg q8h PO) and spironolactone (1–2 mg/kg q12h PO); if control is inadequate, hydrochlorothiazide (1–4 mg/kg q12h PO) can be added (*cautiously*); must monitor serum potassium concentration to prevent potassium imbalances.
• Additionally for patients in CHF—pimobendan (0.3 mg/kg q12h PO) and an angiotensin-converting-enzyme inhibitor (e.g., enalapril 0.25-0.5 mg/kg q12h PO).
• Patients with hypoproteinemia, nephrotic syndrome, and associated ascitic fluid accumulation—can treat as above with the addition of hetastarch (6% hetastarch in 0.9% NaCl); administer an IV bolus (dogs, 20 mL/kg; cats, 10–15 mL/kg) slowly over ~1 hour; hetastarch increases plasma oncotic pressure and pulls fluid into the intravascular space for up to 24–48 hours.
• Systemic antibiotic therapy is dictated by bacterial identification and sensitivity testing in patients with septic exudate ascites.

FOLLOW-UP

PATIENT MONITORING

• Varies with the underlying cause.
• Check sodium, potassium, BUN, creatinine, and weight fluctuations periodically if the patient is maintained on a diuretic.

POSSIBLE COMPLICATIONS

Aggressive diuretic administration may cause hypokalemia, which could predispose to metabolic alkalosis and exacerbation of hepatic encephalopathy in patients with underlying liver disease; alkalosis causes a shift from ammonium (NH_4) to ammonia (NH_3).

A

ASPERGILLOSIS, DISSEMINATED INVASIVE

BASICS

OVERVIEW

- Opportunistic fungal infection caused by *Aspergillus* spp., common molds that are ubiquitous in the environment, forming spores in dust, straw, grass clippings, hay.
- Disseminated disease does not appear to be related to nasal form of disease.
- Disseminated disease—usually *A. terreus* or *A. deflectus*, but other *Aspergillus* species have also been described; *A. fumigatus* causes nasal or pulmonary disease; typically does not disseminate.
- Portal of entry not definitively established, possibly through respiratory tract or gastrointestinal tract, with subsequent hematogenous spread.
- Most commonly affects intervertebral discs, bones, thoracic lymph nodes, lung, renal pelvis; localized respiratory (bronchopulmonary aspergillosis) or, rarely, cornea or ear canal disease can occur, often with *Aspergillus* species other than *A. terreus* or *A. deflectus*.
- Sinoorbital aspergillosis has been described in cats; may be caused by variety of species including *Aspergillus felis*.

SIGNALMENT

Dogs

- Considerably more common in dogs than in cats.
- German shepherd dogs, and less so Rhodesian ridgebacks, overrepresented, but reported sporadically in many breeds; average age 3 years (range 2–8 years); females three times more likely to develop disease than males.

Cats

- Persians—overrepresented for sinoorbital aspergillosis.
- Disseminated cases mostly affect lungs and/or gastrointestinal tract.

SIGNS

Dogs

- May develop acutely or slowly over a period of several months.
- Lameness—fungal osteomyelitis, with focal pain and swelling.
- Neurologic—fungal discospondylitis causing paraparesis, paraplegia, spinal pain; central signs—vestibular signs, circling, seizures, hemiparesis, mental dullness, ataxia, vision impairment.
- Renal involvement—polyuria/polydipsia, vomiting, inappetence, weight loss.
- Respiratory—cough, increased respiratory effort, decreased lung sounds due to pleural effusion.
- Cardiac—arrhythmias.
- Gastrointestinal—abdominal distension, anorexia, vomiting, diarrhea.
- Ocular—uveitis, chorioretinitis, hyphema, panophthalmitis.
- Nonspecific—fever, weight loss, weakness, vomiting, lymphadenopathy.

Cats

- Usually nonspecific signs (e.g., lethargy, vomiting, and diarrhea).
- Ocular—exophthalmos.

CAUSES & RISK FACTORS

- Caused by *Aspergillus* species, most commonly *A. terreus or A. deflectus*, but other species have also been described (e.g., *A. niger*, *A. flavipes*, *A. versicolor*, *A. lentulus*, *A. alabamensis*).
- *A. felis* recently reported to cause fungal rhinosinusitis in cats, sinoorbital aspergillosis in cats, disseminated disease in dogs, pulmonary aspergillosis in humans.
- German shepherd dogs, purebred dogs, immunosuppressed animals at higher risk.
- Geographic/environmental conditions—may be factor, as some regions have higher incidence (e.g., California, Louisiana, Michigan, Georgia, Florida, Virginia in the United States; Western Australia; Barcelona; Milan).
- Cats—described in association with feline infectious peritonitis (FIP), feline panleukopenia virus, feline leukemia virus (FeLV), diabetes mellitus, chemotherapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial osteomyelitis/discospondylitis.
- Spinal neoplasia.
- Intervertebral disc disease.
- Skeletal neoplasia.
- Bacterial pyelonephritis.
- Bacterial pneumonia.
- Other causes of vestibular abnormalities or seizures.
- Other causes of uveitis (see Anterior Uveitis—Cats; Anterior Uveitis—Dogs).

CBC/BIOCHEMISTRY/URINALYSIS

- Nonspecific.
- CBC:
  - Dogs—mature neutrophilic leukocytosis, sometimes with eosinophilia and monocytosis; one-third have normocytic, normochromic, nonregenerative anemia.
  - Cats—may have nonregenerative anemia, leukopenia.
- Biochemistry—variable hyperglobulinemia, increases in activity of alkaline phosphatase (ALP), alanine aminotransferase (ALT), and amylase; increased concentrations of serum, creatinine, phosphate, blood urea nitrogen (BUN), and calcium.
- Urinalysis—possible isosthenuria, microscopic hematuria, pyuria, fungal hyphae in sediment.

OTHER LABORATORY TESTS

- Methods of detection include cytology, culture, histopathology.
- Definitive diagnosis by fungal culture from normally sterile body fluids and tissues (urine, bone, cerebrospinal fluid (CSF), blood, lymph node, pleural effusions, intervertebral disc aspirates, kidney, spleen); urine culture positive in 50% of dogs.
- Culture on Sabouraud's dextrose agar (requires 5–7 days).
- Antibody serology is highly insensitive for diagnosis of disseminated aspergillosis.
- Galactomannan antigen ELISA (urine or serum)—good sensitivity (89%) and specificity (89%); pulmonary and ocular infections have lower sensitivity; false positive in dogs treated with Plasmalyte or with other mycotic infections (*Penicillium*, *Paecilomyces*, *Cladosporidium*, *Geotrichum*, *Histoplasma*, *Cryptococcus*).
- Cats—test for FeLV and feline immunodeficiency virus (FIV).

IMAGING

Radiographic Findings

- Spinal views may show end-plate lysis, productive lesions with bridging spondylosis, lysis of vertebral bodies.
- Bony proliferation, lysis, periosteal reaction typical of osteomyelitis of diaphyseal region of long bones.
- Pulmonary involvement rare; mixed interstitial/alveolar pattern, enlarged sternal and/or tracheobronchial lymph nodes, pleural effusion; productive and destructive lesions of sternebrae; cavitary pulmonary lesions in dogs with chronic pulmonary localization.

Ultrasonographic Findings

- Kidneys—most common site to detect changes; renal pelvis dilation ± echogenic debris within pelvis, loss of corticomedullary distinction, renal distortion with mottled appearance of parenchyma, dilation of proximal ureter, renomegaly, nodules or masses, hydronephrosis.
- Spleen—hypoechoic, lacy, sharply demarcated areas with no Doppler signal (suggestive of infarct), nodules/masses, mottled parenchyma, splenic venous thrombosis.
- Other—abdominal lymphadenomegaly, diffuse hepatic hypoechogenicity, ascites, or evidence of venous thrombosis.

MRI Findings

Useful for further defining brain lesions in animals with CNS abnormalities; changes similar to other infectious and noninfectious inflammatory brain diseases; may identify subtle vertebral lesions in dogs with discospondylitis.

DIAGNOSTIC PROCEDURES

Area to collect sample relies on clinical presentation, but may include CSF tap, intervertebral disc space aspirates, abdominocentesis/thoracocentesis, aspirate of various organs (spleen, liver, kidney) or lymph nodes.

PATHOLOGIC FINDINGS

- Hyphae that branch at 45-degree angle; special stains assist organism detection.
- Focal osteomyelitis with multiple pale granulomas in kidneys, spleen, lymph node, myocardium, pancreas, liver.
- Pyogranulomatous inflammation can be found in lungs, eyes, thyroid, uterus, brain, prostate; contain numbers of septate, branching hyphae that may have characteristic lateral branching aleuriospores (*A. terreus*).
- Best visualized with periodic acid-Schiff, Gomori's methenamine silver, or Crocott's stain.

TREATMENT

DOGS

- Treatment rarely curative; may result in partial clinical remission or halt progression of clinical signs; severely ill dogs have poor prognosis.
- Fluid therapy—indicated by volume status, degree of renal compromise.
- Pulmonary lobectomy followed by systemic antifungals has been successful in dogs with cavitary lesions without evidence of dissemination.

CATS

Disseminated—likely difficult to treat; limited data.

MEDICATIONS

DRUG(S) OF CHOICE

- Combination itraconazole (5–10 mg/kg PO q24h or divided q12h) and amphotericin B (dogs, 2–3 mg/kg IV 3 days/week for 9–12 treatments, to cumulative dose of 24–27 mg/kg)—treatment of choice.
- Itraconazole monotherapy has achieved remission for months to 1–2 years in small number of dogs.
- New triazoles—voriconazole and posaconazole both have activity against *Aspergillus*; some dogs treated with them have gone into remission for many months; *Aspergillus* spp. and other molds are intrinsically resistant to fluconazole, so it should not be used.
- Terbinifine (5–10 mg/kg PO q24h) alone or in combination with triazoles has been used to treat resistant infections, with unclear benefit.
- β-glucan synthase inhibitors caspofungin, micafungin, anidulafungin—limited clinical information in dogs, but efficacious in invasive aspergillosis in humans.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Amphotericin B—contraindicated in dogs with preexisting renal compromise or failure; amphotericin B lipid complex reduces likelihood of nephrotoxicity.
- Oral azoles—nausea, intermittent anorexia, liver enzyme elevation.
- Avoid midazolam and cisapride with azoles—fatal drug reactions noted in humans.
- Hepatotoxicity and ulcerative dermatitis more likely to occur at doses of itraconazole ≥10 mg/kg/day; discontinue itraconazole if adverse effects occur; may be able to reinstitute at lower dose once side effects have resolved.

FOLLOW-UP

- Disseminated—monitor serial radiographs every 1–2 months, renal function, and urine cultures.
- Prognosis poor, especially in purebred dogs that lack other reasons for immune compromise.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None

Client Education Handout available online

A

ASPERGILLOSIS, NASAL

BASICS

DEFINITION
Nasal fungal disease caused by opportunistic ubiquitous saprophytic fungi that are members of the *Aspergillus fumigatus* species complex.

PATHOPHYSIOLOGY
- Inhalation of fungus leads to disease in the nasal cavity with destruction of turbinates, formation of plaque lesions, and overproduction of mucus, causing clinical signs of nasal disease; does not result in systemic mycosis.
- In dogs, confined to nasal cavity and frontal sinus—sinonasal form.
- In cats, can result in sinonasal or sino-orbital disease.

SYSTEMS AFFECTED
- Respiratory—sinonasal form in dogs and cats.
- Ophthalmic—sino-orbital form in cats.

GENETICS
Unknown

INCIDENCE/PREVALENCE
Unknown, but a common diagnosis in dogs with nasal discharge in many locations.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dogs and cats (less common).

Breed Predilections
- Dogs—dolichocephalic and mesocephalic breeds.
- Cats—brachycephalic breeds may be overrepresented.

Mean Age and Range
Predominantly young to middle-aged.

Predominant Sex
None identified.

SIGNS

Historical Findings
- Unilateral or bilateral nasal discharge—typically mucoid, mucopurulent, or serosanguinous; may be primarily epistaxis.
- Sneezing.
- Typically chronic signs—several months.
- Many patients will have been treated with antibiotics for a possible bacterial infection, with variable response.

Physical Examination Findings
- Unilateral or bilateral nasal discharge.
- Typically increased nasal airflow on the affected side.
- Depigmentation with ulceration of the nasal planum.
- Facial pain.
- Ipsilateral mandibular lymphadenopathy.
- Sino-orbital disease in cats—stertor, exophthalmos, exposure keratitis, hard palate ulceration, facial asymmetry, loss of nasal airflow.

CAUSES
- No underlying cause identified, although preexisting foreign body or trauma is occasionally implicated.
- Likely due to inhalation of a large bolus of fungus from the environment, most commonly from the *Aspergillus fumigatus* species complex—*A. fumigatus* in sinonasal disease, *A. felis* in sino-orbital disease.

RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Foreign body.
- Oronasal fistula.
- Lymphoplasmacytic rhinitis.
- Neoplasia.
- Nasopharyngeal polyp or cryptococcosis—cats.

CBC/BIOCHEMISTRY/URINALYSIS
- Often normal.
- Possible inflammatory leukogram.

OTHER LABORATORY TESTS

Serology
- Detects fungi-specific serum antibodies.
- Agar gel immunodiffusion (AGID)—commercially available; 98% specificity, 67% sensitivity in dogs; 43% sensitivity in cats. Serial serology does not appear to correlate with clinical status.
- ELISA—88% sensitivity, 97% specificity in dogs; 90% sensitivity in cats.
- Counter-immunoelectrophoresis—85% specificity in dogs.
- Serum galactomannan—unreliable.

Culture
- Tissue fungal culture—visualized biopsy sample taken from a region of suspected fungal growth showed 100% specificity, 81% sensitivity in dogs.
- Culture of nasal discharge is less sensitive and specific.

IMAGING

CT
- Imaging method of choice.
- Allows for evaluation of the cribriform plate.
- Cavitated turbinate lysis, thickening of the mucosa along the nasal turbinates.
- Frontal sinus proliferative mass effect.
- Cats—soft tissue mass in the choana or nasopharynx.

Skull Radiography
- Intraoral dorsoventral radiograph of the nasal cavity shows turbinate lysis.
- Rostrocaudal or skyline frontal sinus view may show increased soft tissue density in the frontal sinus.
- Cannot evaluate cribriform.

DIAGNOSTIC PROCEDURES

Rhinoscopy
- Allows for visualization of fungal plaques (white, yellow, black, or light green) on the mucosa of the nasal cavity and/or frontal sinus.
- Rigid rhinoscopy—examination of the nasal cavity alone; good visualization is possible due to large airspaces caused by turbinate lysis; excessive mucus and bleeding can make full examination difficult.
- Flexible rhinoscopy in dogs allows examination of the nasopharynx and frontal sinus if the opening of the nasofrontal duct is destroyed by fungal infection.
- Sinuscopy—may be required to confirm the diagnosis in dogs that lack nasal cavity plaques.

PATHOLOGIC FINDINGS
- Biopsies obtained of affected area under direct rhinoscopic visualization using cup biopsy instruments.
- Samples placed in formalin, routinely processed.
- Identification of septate, branching hyphae, and conidia on histopathology with surrounding inflammation.
- Blind biopsies in an unaffected area of the nasal cavity can result in a false diagnosis of inflammation.

TREATMENT

APPROPRIATE HEALTH CARE
Overnight hospitalization advised after topical treatment or surgery.

NURSING CARE
Maintain the nares free of nasal discharge.

ACTIVITY
Restriction of activity is not required if no bleeding is documented.

DIET
N/A

CLIENT EDUCATION
- Dogs—inform client that multiple topical treatments may be necessary for cure.
- No established protocols for treatment in cats.

SURGICAL CONSIDERATIONS

Endoscopic Debridement
Extensive curettage and removal of fungal material from the nose and frontal sinus are essential for efficacy of topical medication.

Trephination of the Frontal Sinus
- May be required for dogs with frontal sinus involvement where access cannot be established via rhinoscopy.

• Performed using a Jacob's chuck and intramedullary pin.

Surgical Debridement and/or Exenteration

• Rhinotomy for debridement in some dogs.
• Exenteration in some cats with sino-orbital disease.

MEDICATIONS

DRUG(S) OF CHOICE

• Clotrimazole and enilconazole are the most widely used drugs topically in different formulations and protocols.
• Treatment is usually performed during the same anesthesia as diagnostics, after debridement.
• No consensus regarding the most effective therapy; three protocols are described here.

Clotrimazole Solution Infusion

• Clotrimazole solution 1% infused through catheters placed into the nasal cavity and frontal sinus via trephination, or in the nasal cavity only; reported efficacy of up to 87% in dogs with multiple treatments.
• Has been used in cats with sinonasal disease with varying success.

Combined Clotrimazole Irrigation and Depot Therapy

Frontal sinus trephination with flushing of 1% clotrimazole solution followed by 1% clotrimazole cream instilled as a depot agent; reported efficacy of 86% with multiple treatments needed in one dog.

Debridement and Clotrimazole Depot Therapy under Rhinoscopic Guidance

Debridement and sinus and nasal depot therapy with 1% clotrimazole cream under rhinoscopic guidance; reported efficacy of 100% with multiple treatments.

Systemic Therapy

• Antifungal triazole drugs should be considered if the cribriform is not intact; can also be combined with topical therapy.
• Used as primary therapy in some cats.
• May be cost-prohibitive.
• Itraconazole 5 mg/kg PO q12h in dogs; reported efficacy of 60–70%; 10 mg/kg PO q24h in cats.
• Posaconazole 5 mg/kg PO q12h with terbinafine 30 mg/kg PO q12h and doxycycline 5 mg/kg PO q12h for refractory disease; complete remission reported in 7/10 dogs, partial clinical remission in 3/10 dogs; 2/10 dogs relapsed after cessation of therapy.
• Voriconazole 5 mg/kg PO q12h in dogs; efficacy has not been established; neurotoxic in cats.
• Fluconazole is not recommended due to resistance.

CONTRAINDICATIONS

• A breach in the cribriform plate was thought to be a contraindication to topical treatment; two recent retrospective studies showed no adverse neurologic effects after topical treatment in dogs with lysis of the cribriform and/or frontal sinus floor.
• Sino-orbital disease in cats necessitates the use of systemic therapy.

PRECAUTIONS

Topical clotrimazole and enilconazole are caustic to mucosal surfaces; all staff in close contact should wear protective gear.

ALTERNATIVE DRUG(S)

Homeopathic remedy—aurum metallicum reported to have resulted in a resolution of clinical signs and clearance of organisms in a dog unresponsive to topical therapy.

FOLLOW-UP

PATIENT MONITORING

Dogs

• Reduction of clinical signs does not establish resolution of disease.
• Follow-up rhinoscopy with possible histopathology and culture is recommended to establish a response to treatment.
• Serial serology (AGID) appears not to correlate with disease status.
• Repeat CT should be considered for reassessment of the cribriform plate before repeat topical treatment if worsening clinical signs are seen.

Dogs and Cats

• Monitor liver enzymes on triazole therapy.
• Monitor renal parameters on amphotericin B.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

• Topical therapy—monitor for any complications such as swelling of oropharynx, neurologic signs, infection/swelling of trephine site.
• Triazoles can cause anorexia and can be hepatotoxic.
• Amphotericin B can be nephrotoxic.

EXPECTED COURSE AND PROGNOSIS

• The prognosis in dogs is good, though multiple topical treatments may be needed; recurrence or reinfection can occur years after supposedly successful therapy.
• The prognosis for cats with sinonasal disease is better than with the sino-orbital form.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

ZOONOTIC POTENTIAL

No documented cases of human infection from an affected dog or cat.

Author Jill S. Pomrantz
Consulting Editor Elizabeth Rozanski

A

ASPIRIN TOXICOSIS

BASICS

OVERVIEW
- Given for its antipyretic, analgesic, anti-inflammatory, and antiplatelet effects.
- Aspirin inhibits cyclooxygenase, reducing the synthesis of prostaglandins and thromboxanes.
- Gastric irritation and hemorrhage can occur.
- Repeated doses can produce gastrointestinal ulceration and perforation and hepatic injury; renal injury is uncommon.
- Toxic hepatitis, marked metabolic acidosis, and anemia can occur, especially in cats (long half-life).
- Hepatic damage may not be dose related.

SIGNALMENT
Cats and less commonly dogs.

SIGNS
- Depression, lethargy.
- Anorexia.
- Vomiting ± blood.
- Diarrhea ± blood; melena.
- Tachypnea.
- Hyperthermia.
- Pallor.
- Polyuria/polydipsia (rare).
- Muscular weakness and ataxia.
- Ataxia, coma, seizures, and death in 1 or more days.

CAUSES & RISK FACTORS
- Owners employing human dosage guidelines to medicate cats and dogs.
- Dogs—single 25 mg/kg dose has resulted in gastric bleeding.
- Cats have a decreased ability to conjugate salicylate with glycine and glucuronic acid due to a deficiency in glucuronyl transferase.
- Half-life increases with dosage—cats, 22–27 hours for 5–12 mg/kg and approximately 44 hours for 25 mg/kg; responsible for higher risk in cats. Dogs, half-life = 7.5 hours.
- Elimination is slower in neonatal and geriatric patients.
- Patients with hypoalbuminemia may be at higher risk of toxicity because aspirin is highly protein bound to plasma albumin.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Ethylene glycol or alcohol.
- Anticoagulant rodenticides.
- Other causes of liver failure, including acetaminophen, iron, metaldehyde, and blue-green algae.

CBC/BIOCHEMISTRY/URINALYSIS
- Cats—prone to Heinz body formation.
- Decreased packed cell volume (PCV); may be marked, especially in cats.
- Leukocytosis.
- Hypoproteinemia.
- Elevated liver enzymes.
- Elevated renal values (rare).

OTHER LABORATORY TESTS
- Initial respiratory alkalosis followed by marked metabolic acidosis.
- High ketones and pyruvic, lactic, and amino acid levels.
- Decreased sulfuric and phosphoric acid renal clearance.

IMAGING
- Abdominal imaging (perforation).

DIAGNOSTIC PROCEDURES
- Salicylic acid concentrations in serum.

TREATMENT
- Inpatient—following general principles of poisoning management.
- Induced gastric emptying—gastric lavage or induced emesis.
- Correction of acid-base balance—continuous IV fluids; assisted ventilation and supplemental oxygen for severely affected animals.
- Whole blood transfusions for severe cases of hemorrhage and hypotension.
- Peritoneal dialysis and hemodialysis are advanced procedures that will increase salicylate clearance in severe cases.

MEDICATIONS

DRUG(S) OF CHOICE
- No specific antidote available.
- Activated charcoal—1–2 g/kg PO with a cathartic (sorbitol); monitor sodium concentration.
- 5% dextrose IV to correct dehydration.
- Gastrointestinal protectants—sucralfate and an H2 blocker or proton pump inhibitor; misoprostol for patients at higher risk for gastrointestinal hemorrhage.
- Sodium bicarbonate 1 mEq/kg IV in severe ingestions—alkalinizes urine; must closely monitor acid-base status.
- Diazepam 0.5–1 mg/kg IV or rectal as needed for seizures.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
- Maintaining renal function and acid-base balance is vital.
- Severe acid-base disturbances, severe dehydration, toxic hepatitis, bone marrow depression, and coma are poor prognostic indicators.

MISCELLANEOUS
- Be sure that history of "aspirin" medication does not refer to other available pain medications.
- Question owner about any preexisting painful condition that may have prompted the aspirin administration.

ABBREVIATIONS
- PCV = packed cell volume.

Author Lisa A. Murphy
Consulting Editor Lynn R. Hovda

BASICS

DEFINITION
• Chronic bronchitis—neutrophilic inflammation of the lower airways (bronchi and bronchioles) lacking a specific etiology; chronic daily cough of greater than 2 months in duration. • Asthma—acute or chronic airway inflammation associated with increased airway responsiveness to various stimuli, airway narrowing due to smooth muscle hypertrophy or constriction, reversibility of airway constriction, and presence of eosinophils, lymphocytes, and mast cells within the airways. • Bronchitis is thought to result in airflow obstruction due to airway remodeling, while asthma is associated with airway constriction; however, clinically the two disease processes can appear similar. No physical examination findings or biomarkers can distinguish between the two syndromes, although reversal of airflow obstruction following administration of a beta-agonist is suggestive of the asthmatic form of disease.

PATHOPHYSIOLOGY
• Lower airway inflammation likely results from inhalation of irritant substances. • Bronchiolar smooth muscle constriction—can resolve spontaneously or with treatment. • Increase in mucosal goblet cells, mucus production, and edema of bronchial wall associated with inflammation. • Excessive mucus can cause bronchiolar obstruction, atelectasis, or bronchiectasis. • Smooth muscle hypertrophy implies chronicity—usually not reversible. • Chronic inflammation leads to airway remodeling and irreversible airflow obstruction.

SYSTEMS AFFECTED
• Respiratory. • Cardiac—pulmonary hypertension rarely.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Cat

Breed Predilections
Siamese overrepresented.

Mean Age and Range
Any age; more common between 2 and 8 years.

Predominant Sex
One study showed females overrepresented.

SIGNS
Historical Findings
• Coughing, tachypnea, labored breathing or wheezing. • Signs are typically episodic and can be acute or chronic.

Physical Examination Findings
• Severely affected cats present with open-mouth breathing, tachypnea, and cyanosis.
• Increased tracheal sensitivity is common.
• Chest auscultation may reveal crackles and/or expiratory wheezes, but can be normal.
• Labored breathing with an abdominal push on expiration, increase in expiratory effort.

CAUSES
Triggers of airway inflammation unknown.

RISK FACTORS
• Cigarette smoke, poor environmental hygiene, dusty cat litter, hair sprays, and air fresheners can exacerbate disease. • Use of potassium bromide—implicated in causing signs of bronchitis/asthma in some cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Rule out infectious pneumonia (*Mycoplasma*, *Toxoplasma*, bacterial or fungal pneumonia). • Consider *Dirofilaria immitis* and primary lung parasites (*Aelurostrongylus abstrusus*, *Capillaria aerophilia*, *Paragonimus kellicotti*, *Troglostrongylus brevior*). More common in southern and midwest United States, and in outdoor and hunting cats in some geographic regions. • Primary or metastatic neoplasia can have similar clinical and radiographic appearance. • Clinical presentation of idiopathic pulmonary fibrosis may appear similar to feline bronchitis.

CBC/BIOCHEMISTRY/URINALYSIS
Frequently normal; ~40% of cats with bronchial disease have peripheral eosinophilia.

OTHER LABORATORY TESTS
• Fecal exams—flotation for *Capillaria*, sedimentation for *Paragonimus*, Baermann for *Aelurostrongylus*; false-negative results are common. • Heartworm antigen and antibody testing, particularly if coughing occurs in conjunction with vomiting. • Radioallergosorbent testing or intradermal skin testing—no correlation between skin allergies and respiratory disease currently documented.

IMAGING
Radiography
• Classically, diffuse bronchial wall thickening; interstitial or patchy alveolar patterns also possible. • Severity of radiographic changes does not necessarily correlate with clinical severity or duration, and normal radiographs can be found. • Hyperinflation of lung fields—flattened and caudally displaced diaphragm, increased distance between the heart and diaphragm, extension of lungs to the first lumbar vertebrae thought to reflect bronchoconstriction. • Collapse of right middle lung lobe due to mucus plugging and atelectasis reported in 11% of cases.
• Pulmonary lobar arterial enlargement is suspicious for heartworm disease.

CT
Bronchial wall thickening, patchy alveolar patterns, and bronchiectasis.

Echocardiography
Useful to document heartworm disease or secondary pulmonary hypertension.

DIAGNOSTIC PROCEDURES
Transoral Tracheal Wash (TOTW)
Use a sterile endotracheal tube and polypropylene or red rubber catheter to collect airway fluids at the level of the carina.

Bronchoscopy
Allows visualization of trachea and bronchi. Excessive amounts of thick mucus are common with bronchitis. Mucosa of the airways is typically hyperemic and edematous.

Cytology of TOTW or Bronchoscopy/Bronchoalveolar Lavage (BAL)
• Eosinophils and neutrophils are most prominent cell types. • Up to 20% eosinophils on BAL cytology can be found in normal cats. • A mixed inflammatory cell population occurs in about 21% of cats.

Bacterial Cultures
• Quantitated cultures recommended; positive cultures frequently encountered, but bacterial colony counts >100–300 cfu/mL uncommon with bronchitis. • Specific *Mycoplasma* cultures and PCR for species detection.

Biopsy
Keyhole biopsy—can differentiate between idiopathic pulmonary fibrosis, neoplasia, and bronchitis if needed; rarely performed.

PATHOLOGIC FINDINGS
Hyperplasia/hypertrophy of goblet cells, hypertrophy of airway smooth muscle, epithelial erosion, and inflammatory infiltrates.

TREATMENT

APPROPRIATE HEALTH CARE
• Remove patient from environment that exacerbates disease. • Hospitalize for acute respiratory distress.

NURSING CARE
• Oxygen therapy, bronchodilators, and sedatives in an acute crisis. • Minimize manipulation in order to lessen stress and oxygen needs of the animal.

ACTIVITY
Usually self-limited by patient.

DIET
Calorie restriction for obese cats.

CLIENT EDUCATION
• Most causes are chronic and progressive.
• Do not discontinue medical therapy when clinical signs have resolved—subclinical inflammation is common and can lead to

A

ASTHMA, BRONCHITIS—CATS (CONTINUED)

progression of disease; lifelong medication and environmental changes usually necessary. • Some clients can be taught to give terbutaline subcutaneously and corticosteroid injections at home for a crisis situation.

MEDICATIONS

DRUG(S) OF CHOICE

Emergency Treatment

• Oxygen and a parenteral bronchodilator—injectable terbutaline (0.01 mg/kg IV/SC); repeat if no clinical improvement (decrease in respiratory rate or effort) in 20–30 minutes. • A sedative can aid in decreasing anxiety (butorphanol tartrate at 0.2–0.4 mg/kg IV/IM, buprenorphine at 0.01 mg/kg IV/IM, or acepromazine at 0.01–0.05 mg/kg SC). • A short-acting parenteral corticosteroid may also be required—dexamethasone sodium phosphate (0.1–0.25 mg/kg IV/SC).

Long-Term Management

Corticosteroids

• Decrease inflammation. • Oral treatment is preferred over injectable for closer monitoring of dose and duration. • Prednisolone—0.5–1 mg/kg PO q12h; begin to taper dose (50% each week) after 1–2 weeks if clinical signs have improved; maintenance therapy 0.5–1 mg/kg PO q24–48h. • Longer-acting parenteral steroids (Vetalog® or Depo-Medrol®) should be reserved only for situations where owners are unable to administer oral or inhaled medication on a routine basis.

Inhaled Corticosteroids

• Requires a form-fitting facemask, spacer, and metered-dose inhaler (MDI); veterinary brand—Aerokat ® (Trudell Medical). • The most common corticosteroid used as an MDI is fluticasone propionate (Flovent®)—110 µg Flovent MDI is recommended (1–2 actuations, 7–10 breaths q12h); in one study, use of 44 µg Flovent decreased BAL eosinophil counts in cats with experimentally induced lower airway disease. • Flovent is used for long-term control of airway inflammation; takes 10–14 days to reach peak effect; use oral steroids concurrently during this time. • Results in some suppression of the hypothalamic–pituitary axis, but systemic side effects appear to be limited.

Bronchodilators

• Methylxanthines—sustained-release theophylline formulations recommended, and pharmacokinetics can vary greatly; only compounded generic currently available; dose at 15–20 mg/kg PO once daily in the evening. • Beta-2 agonists (terbutaline, albuterol)—reverse smooth muscle constriction; oral terbutaline dose is 1/4 of a 2.5 mg tablet; initial albuterol dose is 1–2 puffs; avoid giving beta-2 agonists daily as tachyphylaxis may develop.

Anthelminthics

• Empirical therapy is indicated for cats with clinical signs of bronchial disease and eosinophilic airway cytology in an appropriate geographic location. • Consider fenbendazole, ivermectin, praziquantel, or milbemycin.

Antibiotics

Use based on a positive quantitative culture and susceptibility testing or *Mycoplasma* isolation.

CONTRAINDICATIONS

Beta-2 antagonists (e.g., propranolol) are contraindicated because of their ability to block sympathetically mediated bronchodilation.

PRECAUTIONS

• Long-term use of steroids increases risk of development of diabetes mellitus and predisposes to immunosuppression. • Use of corticosteroids in cats may precipitate congestive heart failure. • Beta agonists could cause tachycardia and exacerbate underlying cardiac disease.

ALTERNATIVE DRUG(S)

• Leukotriene receptor blockers and inhibitors of generation—no evidence to support use. • Tyrosine kinase inhibitors—masitinib is no longer on the market; side effects were dose limiting. • Antiserotonin and antihistamine drugs—no evidence to support use. • Immunotherapy—allergen-specific rush immunotherapy (RIT) shows promise in treating asthma. • Omega 3 fatty acids/neutraceuticals—diminished hyperresponsiveness of airway, but did not resolve airway eosinophilia.

FOLLOW-UP

PATIENT MONITORING

• Owners should report any increase in coughing, sneezing, wheezing, or respiratory distress; medications should be increased appropriately, or additional therapy initiated if clinical signs worsen. • Follow-up radiographs may be helpful to detect onset of new disease. • Owner should watch for signs of polyuria/polydipsia (PU/PD) that could indicate diabetes mellitus or renal disease; monitor blood glucose and urine cultures.

PREVENTION/AVOIDANCE

Eliminate any environmental factors that can trigger a crisis situation (see Risk Factors); change furnace and air-conditioner filters on a regular basis; consider dust-free litters.

POSSIBLE COMPLICATIONS

• Acute episodes can be life-threatening. • Right-sided heart disease develops rarely as a result of long-term bronchitis.

EXPECTED COURSE AND PROGNOSIS

• Long-term therapy should be expected. • Most cats do well if recurrence of clinical signs is carefully monitored and medical therapy appropriately adjusted. • A few cats will be refractory to treatment; these carry a much worse prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Cor pulmonale can be a sequela to chronic lower airway disease.

PREGNANCY/FERTILITY/BREEDING

Glucocorticoids are contraindicated in the pregnant animal; bronchodilators should be used with caution.

SYNONYMS

• Allergic bronchitis. • Asthmatic bronchitis. • Feline lower airway disease. • Extrinsic asthma. • Eosinophilic bronchitis.

SEE ALSO

Client Education Handout available online

BASICS

OVERVIEW

• Glial cell neoplasm, most commonly affecting the brain and rarely the spinal cord. • Neoplastic cells are of astrocytic origin. • The most common intraaxial (situated inside of the brain parenchyma) intracranial neoplasm of dogs, but is rarely diagnosed in cats. • Tumors are often located in the pyriform area of the temporal lobe, the cerebral hemispheres, the thalamus, hypothalamus, or midbrain. • Biologic behavior of this tumor is dictated by the histopathologic grade (I–IV, from best to worst prognosis) and anatomic involvement. • Tumors typically do not penetrate the ventricular system or metastasize outside of the cranial vault.

SIGNALMENT

• Dog—often brachycephalic breeds >5 years of age; no sex predilection reported. • Cat—usually >9 years; no sex or breed predilection reported.

SIGNS

• Location and growth kinetic dependent. • Seizures. • Behavioral changes. • Apathy toward normal activities, including eating, playing, and societal interactions. • Disorientation. • Loss of conscious proprioception. • Cranial nerve abnormalities. • Head muscle atrophy. • Upper motor neuron tetraparesis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other primary tumors arising from tissues of the central nervous system. • Metastatic neoplasia with brain tropism such as hemangiosarcoma. • Granulomatous meningoencephalitis. • Trauma. Cerebrovascular infarction. • Meningitis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually unremarkable.

OTHER LABORATORY TESTS

Cerebrospinal fluid (CSF) analysis may show albumin-cytologic dissociation (high protein with low number of nucleated cells). The CSF analysis is indicated to exclude infectious etiology, not to diagnose astrocytoma.

IMAGING

• MRI of brain is ideal for mass lesion confirmation, as it is superior to CT scanning for detecting lesions in the middle and caudal fossae. MRI is more sensitive than CT for detection infarcts, bleeding, and edema. • Brain MRI is useful in establishing a tentative differential diagnosis of a glial tumor, based on tumor characteristics highlighted in specific sequences.

DIAGNOSTIC PROCEDURES

• Neurologic exam. • Ophthalmic exam. • MRI. • CSF analysis. • Tumor biopsy for definitive diagnosis, when specific antineoplastic treatment is sought (surgery, curative-intent radiation therapy, experimental therapies).

TREATMENT

• Surgery. • Radiation therapy can be very effective in improving neurologic signs. • Chemotherapy with lomustine, procarbazine, or temozolomide might exert cytoreductive activities. • Anti-inflammatory dosing with corticosteroids to reduce peritumoral edema. • Consultation with a neurosurgeon and a radiation oncologist is essential for appropriate patient management.

MEDICATIONS

DRUG(S) OF CHOICE

Seizure Control

• Status epilepticus—diazepam (0.5–1 mg/kg IV, up to three times to achieve effect); if no response to diazepam, use pentobarbital (5–15 mg/kg IV slowly to effect). • Long-term management—phenobarbital (1–4 mg/kg PO q12h) with or without adjuvant potassium bromide (20 mg/kg PO q24h).

Tumor Control

• Timely consultation with a neurosurgeon is of paramount importance for appropriate management of the patient. • Radiation therapy may be effective, and consultation with a radiation oncologist is recommended. Stereotactic radiosurgery or intensity-modulated radiation therapy may be considered as first-line treatment options. • Chemotherapy may be effective for treating dogs. Potential drugs that may exert measurable anticancer effects include CCNU (60–70 mg/m^2 PO every 3 weeks) or temozolomide (100–120 mg/m^2 PO q24h for 5 days every 3 weeks). • Prednisone (1 mg/kg q24h) may be effective in reducing peritumoral edema and improving neurologic signs. Patients may need to be on steroids long term, even after the definitive treatment of the tumor.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Prednisone and phenobarbital may cause polyphagia, polydipsia, and polyuria. • Phenobarbital may cause sedation for up to 2 weeks after initiation of treatment, and increase in hepatic enzymes on serum biochemical panel. • CBC and platelet count are recommended 7–10 days after chemotherapy and immediately before each dose of chemotherapy to monitor myelosuppression. • Chemotherapy has the potential to be synergistic with radiation therapy. Timely referral to a specialty center with neurosurgery, radiation therapy, and medical oncology capabilities is important for patients seeking more than palliative care.

FOLLOW-UP

PATIENT MONITORING

• Blood phenobarbital concentration should be assessed after 7–10 days of treatment, with modifications to dosages for achieving target plasma concentrations. • Serial MRIs should be considered for documenting response if multimodality therapy is used. • Serial CBC and platelet counts should be performed to monitor myelotoxicity associated with chemotherapy.

EXPECTED COURSE AND PROGNOSIS

• Long-term prognosis is guarded. • Median survival after chemotherapy plus medical management may be up to 7 months. • Median survival after radiation therapy has been reported to be as high as 12 months.

A

ATAXIA

BASICS

DEFINITION

• A sign of sensory dysfunction causing loss of coordination of the limbs, head, and/or trunk.
• Three clinical types—sensory (proprioceptive), vestibular, and cerebellar. All cause limb incoordination, but only vestibular and cerebellar ataxia cause head and neck incoordination.

PATHOPHYSIOLOGY

Sensory (Proprioceptive)

• Proprioceptive pathways in the spinal cord (i.e., fasciculus gracilis, fasciculus cuneatus, and spinocerebellar tracts) relay limb and trunk positions to the brain.
• When the spinal cord is slowly compressed, proprioceptive deficits are usually the first signs observed, because these tracts or pathways are located more superficially in the white matter and their larger axons are more susceptible to compression than are other tracts.
• Limb weakness (paresis) will occur if more centrally located motor tracts or pathways become involved; weakness is not always obvious early in the course of the disease.
• Ataxia can occur with spinal cord, brainstem, and cerebral lesions. Ataxia can be mild to absent with unilateral brainstem lesions, and subtle to absent with unilateral cerebral lesions.

Vestibular

• Changes in balance and head and neck positions are detected by vestibular receptors of the inner ear, relayed to the vestibulocochlear nerve, which is connected to vestibular nuclei in the brainstem.
• The inner ear's vestibular receptors and nerve are components of the peripheral nervous system, whereas brainstem vestibular nuclei are components of the central nervous system.
• Vestibular ataxia should be localized to either the peripheral or central vestibular nervous system, because prognosis and rule-outs differ for these two locations.
• Both locations of vestibular disease cause various degrees of vestibular ataxia, often manifested by head tilt and leaning, falling, or even rolling toward the side of the lesion.
• Central vestibular disease usually has vertical nystagmus or changing types of nystagmus; somnolence, stupor, or coma (due to involvement of the nearby ascending reticular activating system); multiple cranial nerve signs (e.g., trigeminal or facial nerve deficits); proprioceptive deficits and quadriparesis or hemiparesis.
• Peripheral vestibular disease does not typically show changes in mental status, vertical nystagmus, proprioceptive deficits, quadriparesis, or hemiparesis.
• Bilateral vestibular disease is uncommon and most often peripheral in origin. Typical vestibular signs are absent. Wide swinging back and forth head motions and poor to absent physiologic nystagmus are characteristic.

Cerebellar

• The cerebellum regulates, coordinates, and modulates motor activity.
• Proprioception is normal because the ascending proprioceptive pathways to the cortex are intact; weakness does not occur because the upper motor neurons are intact.
• While strength is preserved, affected animals have uncoordinated motor activity of limbs, head, and neck manifested by hypermetria; dysmetria; head tremors; intention tremors; and truncal sway. Menace responses may be absent without visual dysfunction.

SYSTEMS AFFECTED

Nervous—spinal cord (and brainstem and cortex), cerebellum, vestibular system.

SIGNALMENT

Any age, breed, or sex.

SIGNS

• Important to define the type of ataxia to localize the problem.
• Only one limb involved—rule out a musculoskeletal problem.
• Only hind limbs affected—likely a spinal cord disorder affecting the spinocerebellar tracts.
• All limbs or ipsilateral limbs affected—cervical spinal cord or cerebellar localization.
• Head tilt and/or nystagmus—vestibular localization.

CAUSES

Cerebellar

• Degenerative—abiotrophy (Kerry blue terrier, Gordon setter, rough-coated collie, Australian kelpie, Airedale, Bernese mountain dog, Finnish harrier, Brittany spaniel, border collie, beagle, Samoyed, wirehaired fox terrier, Labrador retriever, Great Dane, chow chow, Rhodesian ridgeback, domestic shorthair cats); storage diseases often have cerebellomedullary involvement.
• Anomalous—hypoplasia secondary to perinatal infection with panleukopenia virus (cats); malformed cerebellum due to herpesvirus infection (newborn puppies); arachnoid or epidermoid cyst located near fourth ventricle.
• Neoplastic—any CNS tumor (primary or secondary) localized to the cerebellum.
• Infectious—canine distemper virus; feline infectious peritonitis (FIP); and any other CNS infection affecting the cerebellum.
• Inflammatory, idiopathic, immune-mediated—meningoencephalomyelitis of undetermined etiology.
• Toxic—metronidazole.

Vestibular—CNS

• Infectious—FIP; canine distemper virus; rickettsial diseases.
• Inflammatory, idiopathic, immune-mediated—meningoencephalomyelitis of undetermined etiology.
• Nutritional—thiamine deficiency.
• Toxic—metronidazole.

Vestibular—Peripheral Nervous System

• Infectious—otitis media interna; *Cryptococcus* granuloma (cats).
• Inflammatory—nasopharyngeal (middle ear) polyps (cats).
• Idiopathic—geriatric vestibular disease (dogs); idiopathic vestibular syndrome (cats).
• Metabolic—hypothyroidism.
• Neoplastic—squamous cell carcinoma, bone tumors.
• Traumatic.

Spinal Cord

• Degenerative—degenerative myelopathy (old German shepherd, pug, boxer, Welsh corgi, others); degenerative disc disease.
• Vascular—fibrocartilaginous embolic myelopathy.
• Anomalous—hemivertebrae; dens hypoplasia with atlantoaxial subluxation-luxation; Chiari-like malformation; cervical spondylomyelopathy; spinal subarachnoid diverticulum; other spinal cord and vertebral malformation.
• Neoplastic—primary bone tumors; multiple myeloma and metastatic tumors that infiltrate the vertebral body; meningioma; others.
• Infectious—discospondylitis; myelitis.
• Traumatic—intervertebral disc herniation; fracture or luxation; atlantoaxial subluxation-luxation.

Metabolic

• Anemia.
• Polycythemia.
• Electrolyte disturbances—especially hypokalemia, hypocalcemia, and hypoglycemia.

Miscellaneous

• Drugs—acepromazine; antihistamines; antiepileptic drugs; flea and tick products.
• Respiratory compromise.
• Cardiac compromise—reverse patent ductus arteriosus, aortic thromboembolism.

RISK FACTORS

• Intervertebral disc disease—dachshund, poodle, cocker spaniel, beagle, and others.
• Cervical spondylomyelopathy—Doberman pinscher and Great Dane.
• Fibrocartilaginous embolism—young, large-breed dogs and miniature schnauzers.
• Dens hypoplasia and atlantoaxial luxation—small-breed dogs, poodles.
• Chiari-like malformation—cavalier King Charles spaniel, small-breed dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differentiate the types of ataxia.
- Differentiate from other disease processes that can affect gait—musculoskeletal, metabolic, cardiovascular, respiratory.
- Musculoskeletal disorders—typically produce lameness, pain, and a reluctance to move; degenerative joint disease signs often improve with increased movements.
- Systemic illness and endocrine, cardiovascular, and metabolic disorders—can cause intermittent ataxia, especially of the pelvic limbs; with fever, weight loss, murmurs, arrhythmias, hair loss, or collapse with exercise, suspect a non-neurologic cause; obtain minimum data from hemogram, biochemistry, and urinalysis.
- Head tilt or nystagmus—likely vestibular localization.
- Intention tremors of the head or hypermetria—likely cerebellar localization.
- All four limbs affected—lesion is in the cervical spinal cord, cerebellum, or is multifocal to diffuse.
- Only pelvic limbs affected—lesion is anywhere below the second thoracic vertebra.

CBC/BIOCHEMISTRY/URINALYSIS

Normal unless metabolic cause (e.g., hypoglycemia, electrolyte imbalance, anemia, polycythemia).

OTHER LABORATORY TESTS

- Hypoglycemia—determine serum insulin concentration on sample that has low glucose value; low glucose and higher than expected insulin value suggest insulin-secreting tumor.
- Anemia—differentiate as nonregenerative or regenerative on the basis of the reticulocyte count.
- Electrolyte imbalance—correct the problem; see if ataxia resolves.
- Antiepileptic drugs—if being administered, evaluate serum concentration for toxicity.

IMAGING

- Spinal radiography, myelography, CT, or MRI—if spinal cord dysfunction suspected.
- Bullae radiography—if peripheral vestibular disease suspected; CT or MRI superior; for inner ear disease, MRI superior to CT.
- Thoracic radiography—for older patients and patients suspected to have neoplasia or systemic fungal infection.
- CT or MRI—if cerebellar disease suspected; MRI superior to CT.
- Abdominal ultrasonography—if hepatic, renal, adrenal, or pancreatic dysfunction suspected.

DIAGNOSTIC PROCEDURES

- Cerebrospinal fluid analysis—helps confirm nervous system etiology.
- Cerebrospinal fluid culture, antibody titer, or polymerase chain reaction—helps confirm nervous system infectious etiology.

TREATMENT

- Usually outpatient, depending on severity and acuteness of clinical signs.
- Exercise—decrease or restrict if ataxia originates from spinal cord disease.
- Client should monitor gait for increasing dysfunction or weakness; if paresis worsens or paralysis develops, other testing is warranted.
- Avoid drugs that could contribute to the problem; may not be possible in patients on antiepileptic drugs for seizures.

MEDICATIONS

DRUG(S) OF CHOICE

Not recommended until the source or cause of the problem is identified.

FOLLOW-UP

PATIENT MONITORING

Periodic neurologic examinations to assess condition.

POSSIBLE COMPLICATIONS

- Spinal cord—progression to weakness and possibly paralysis.
- Hypoglycemia—seizures.
- Cerebellar disease—head tremors and bobbing.
- Brainstem disease—stupor, coma, death.

MISCELLANEOUS

SEE ALSO

- Cerebellar Degeneration.
- Head Tilt.
- Paralysis.

ABBREVIATIONS

- FIP = feline infectious peritonitis.

Client Education Handout available online

A

ATLANTOAXIAL INSTABILITY

BASICS

OVERVIEW

• Results from malformation or disruption of the articulation between the first and second cervical vertebrae (atlas and axis, respectively); causes spinal cord compression.
• Can result in spinal cord trauma or compression at the junction between atlas and axis—may cause neck pain and/or varying degrees of general proprioceptive (GP) ataxia/upper motor neuron (UMN) tetraparesis, tetraplegia (with or without nociception), and death from respiratory arrest.

Etiology

• Congenital—anomaly of the dens (aplasia, hypoplasia, or malformation [dorsal angulation] of the dens) and its ligamentous attachments.
• Acquired—consequence of traumatic injury.

SIGNALMENT

• Congenital—toy-breed dogs (Yorkshire terrier, miniature or toy poodle, Chihuahua, Pekingese, and Pomeranian).
• Age at onset—usually before 12 months.
• Uncommon in larger-breed dogs, dogs >1 year old, and cats.
• No sex predilection.

SIGNS

• Intermittent or progressive ambulatory tetraparesis, usually with neck pain—most common.
• Neurologic signs vary from mild to moderate GP/UMN ambulatory tetraparesis to nonambulatory GP/UMN tetraparesis, or tetraplegia, depending on degree of spinal cord compression and secondary pathology (i.e., edema, hemorrhage, or gliosis).
• Animals may have only neck pain without concurrent neurologic deficits.
• Episodes of collapse secondary to weakness.
• Abnormal postural reactions with spinal reflexes that are normal to exaggerated, with normal to increased muscle tone in all four limbs.
• Acute death may occur when accompanied by trauma and respiratory arrest (uncommon).

CAUSES & RISK FACTORS

• Usually caused by abnormal development of the dens and/or ligamentous support structures, resulting in subluxation of the atlantoaxial joint.
• Fracture of the axis.
• Clinical signs often occur as a result of mild or insignificant trauma (e.g., jumping or playing).
• Clinical signs may be exacerbated by activity such as flexion of the neck.
• Toy-breed dogs—at risk for congenital malformation of the dens.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Differential diagnoses are consistent with various causes of cervical myelopathies, including:
  ◦ Other congenital malformation.
  ◦ Trauma.
  ◦ Meningitis or meningomyelitis, infectious or noninfectious (granulomatous meningoencephalomyelitis).
  ◦ Fibrocartilaginous embolic myelopathy.
  ◦ Disk herniation.
  ◦ Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

IMAGING

• Plain radiography of the cervical vertebral column:
  ◦ Lateral view—caudal and dorsal displacement of the axis in relationship to the atlas, resulting in increased distance between vertebrae.
  ◦ Ventral dorsal or oblique view—may reveal absence, hypoplasia, or malformation (dorsal angulation) of the dens.
• Cross-sectional imaging:
  ◦ MRI.
  ◦ Diagnosis based on observation of caudal and dorsal displacement of the axis in relationship to the atlas, as evidenced by the following features of the atlantoaxial articulation: (1) dorsal: displacement of the spinous process of the axis; (2) ventral: increased size of the occipito-atlas-axis joint cavity.
  ◦ Allows identification of spinal cord compression.
  ◦ Allows recognition of secondary spinal cord pathology such as edema, hemorrhage, or gliosis, which may impact prognosis.
• CT—may provide detailed visualization of bony structures, which allows for creation of three-dimensional reconstructed image to help surgical planning.
• Precautions:
  ◦ Proper positioning will require sedation or general anesthesia.
  ◦ Sedation or general anesthesia carries significant risk for iatrogenic trauma.
  ◦ Care needs to be exercised when positioning animals.
  ◦ *Avoid excessive flexion of the neck!*
  ◦ Flexion may exacerbate compression, which may worsen clinical signs or cause death due to spinal cord trauma.
  ◦ To protect against neck flexion during recovery, affected animals should be closely monitored until they are capable of maintaining normal head and neck carriage.

TREATMENT

• Prior to treatment, consultation with a board-certified neurologist or surgeon should be pursued.
• Improper treatment can lead to irreversible deterioration in neurologic function.

MEDICAL

• Neck brace (splint) to stabilize cervical vertebral column in extension.
  ◦ Fiberglass cast material positioned ventrally from rostral aspect of mandible to xiphoid and incorporated into bandage material, which immobilizes head and neck.
  ◦ Strict exercise restriction (cage confinement) for minimum of 8 weeks.
  ◦ Frequent bandage/splint changes are needed.
• Adjunctive medication (see below).

Overall Prognosis

• Successful outcome observed in 62.5% of dogs.
• Improved prognosis associated with acute onset and short duration of clinical signs (<30 days).
• Surgery recommended to treat animals that fail to improve or experience recurrence of signs following medical treatment.

SURGERY

• Treatment of choice in majority of cases.
• Surgical approach; *ventral method is preferred.*
• Ventral approach—variety of methods:
  ◦ Transarticular pinning or lag screw technique; ventral tips of pins incorporated in polymethylmethacrylate to prevent pin migration.
  ◦ Transarticular pinning and ventral cortical screws or K-wires in bodies of atlas and axis ± K-wires applied longitudinally and wired to screws; screw heads and K-wires incorporated in polymethylmethacrylate to provide fixation.
• Dorsal approach—use wire or synthetic suture material to fix spinous process of axis to dorsal arch of atlas; provides less rigid fixation and may be associated with greater implant failure.
• Strict exercise restriction required for first month postoperatively, followed by gradual return to activity over additional month.
• Adjunctive medication (see below).
• Overall prognosis ranges from 63% to 91% success—improved prognosis associated with young (<24 months) dogs, duration of clinical signs <10 months, and mild neurologic deficits.

- Complications:
  - Failure to improve/worsening of neurologic deficits.
  - Implant failure/infection.
  - Respiratory—respiratory arrest, dyspnea, cough, and aspiration pneumonia.
  - Death.

MEDICATIONS

DRUG(S) OF CHOICE

- Anti-inflammatory medication:
  - Corticosteroids—prednisone 0.5–1.0 mg/kg PO divided twice daily for 2 weeks, followed by tapering regime. Suggested protocol following initial dose: 0.5 mg/kg PO daily for 5 days, followed by 0.5 mg/kg PO every other day for 5 days.
  - Nonsteroidal anti-inflammatory drug (NSAID)—1- to 4-week course.
- Analgesia:
  - Tramadol 2.0–4.0 mg/kg PO q6–8h—questionable efficacy.
  - Gabapentin 10–20 mg/kg PO q6–8h.
  - Pregabalin 3–4 mg/kg (begin with 2 mg/kg) PO q8–12h.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Corticosteroid—use caution when given in conjunction with medical treatment; may reduce pain, resulting in increased activity and spinal cord trauma.
- Avoid NSAIDs in combination with corticosteroids in all patients—increases risk of life-threatening gastrointestinal hemorrhage.

FOLLOW-UP

- Dogs treated medically require frequent (weekly) bandage changes for associated soft tissue trauma.
- All dogs should be reevaluated at 1 and 3 months (postoperatively or after neck brace removal) and then monthly until neurologic deficits resolve or remain static over 2–3 months.
- More frequent rechecks may be needed for dogs experiencing complications or recurrence of signs.
- Untreated animals may experience deterioration in neurologic function, catastrophic acute spinal cord trauma, respiratory arrest, and death.

MISCELLANEOUS

- Rehabilitation may play a significant role in ultimate neurologic functional level of patient.
- Rehabilitation should only be considered in dogs >30 days postoperatively or after neck brace (splint) removal.

ABBREVIATIONS

- GP = general proprioceptive.
- NSAID = nonsteroidal anti-inflammatory drug.
- UMN = upper motor neuron.

A

ATOPIC DERMATITIS

BASICS

DEFINITION

• Genetically predisposed skin disease characterized by inflammation and pruritus. Clinical signs associated with immunoglobulin (Ig) E and most commonly directed against environmental allergens. • Differentiate from atopic-like dermatitis, in which clinical signs identical to atopic dermatitis but IgE response to environmental or other allergens cannot be demonstrated.

PATHOPHYSIOLOGY

• Allergen exposure in susceptible animals results in IgE production. Upon reexposure to allergen, mast cell degranulation and activation of T_H2 lymphocytes allow release of inflammatory cytokines, chemokines, histamine, proteolytic enzymes, and other chemical mediators. • Genetic defects—dogs: gene expression upregulated or downregulated; cats: not well documented. • Barrier function defects—dogs: impaired epidermal lipid barrier can lead to enhanced allergen penetration and increased transepidermal water loss (TEWL); filaggrin defect thought to be associated; cats: may not be as relevant as with dogs. • Immunologic defects—dogs: acute lesions characterized by increased T_H2 lymphocyte activity, while T_H1 cytokines predominate in chronic lesions; T_H2:T_H1 imbalance proposed; aberrant regulatory T-cell function reported; cats: T_H2-mediated dysfunction suspected, but cytokine pathways need further investigation. • Bacterial superantigens, auto-antigens released via keratinocyte damage, and *Malassezia* may play role in inflammation.

SYSTEMS AFFECTED

• Ophthalmic. • Respiratory. • Skin/exocrine.

GENETICS

• Dogs—inherited predisposition. • Cats—inherited predisposition less clear.

INCIDENCE/PREVALENCE

• Canine—3–27% of canine population estimated. • Feline—lower than for dogs.

GEOGRAPHIC DISTRIBUTION

Canine—worldwide; local factors influence seasonality, severity, and duration of signs.

SIGNALMENT

Species

Dogs and cats.

Breed Predilections

• United States—Boston terrier, boxer, Cairn terrier, Chinese Shar-Pei, cocker spaniel, Dalmatian, English bulldog, English and Irish setter, American Staffordshire terrier, Lhasa apso, miniature schnauzer, pug, Sealyham terrier, Scottish terrier, West Highland white terrier, wirehaired fox terrier, Labrador retriever. • Feline—Abyssinian, Devon Rex, domestic shorthaired cats.

Mean Age and Range

• Canine—6 months to 3 years. • Feline—6 months to 2 years, commonly under 3 years.

Predominant Sex

None reported.

SIGNS

General Comments

Cutaneous changes caused by self-induced trauma; primary lesions usually unrecognized.

Historical Findings

• Pruritus. • Early age of onset. •History in related individuals. • May be initially seasonal. • Recurring skin or ear infection. • Temporary response to glucocorticosteroids. • Signs worsen with time.

Physical Examination Findings

• Most common (dogs)—interdigital spaces, carpal/tarsal areas, muzzle, periocular, axillae, abdomen, pinnae; >40% can be generalized. • Most common (cats)—head and neck, mouth, abdomen, lateral thorax, hind limbs. • Lesions (dogs)—none to salivary staining, alopecia, erythema, papules, crusts, hyperpigmentation, lichenification, seborrhea sicca/oleosa, and/or hyperhidrosis. • Lesions (cats)—miliary dermatitis (small crusted papules), alopecia, eosinophilic granuloma complex (indolent ulcers, eosinophilic granulomas, eosinophilic plaques). • Chronic relapsing bacterial and yeast skin/ear infections (common). • Respiratory symptoms, conjunctivitis, and blepharitis possible.

CAUSES

• Pollens. • Mold spores. • *Malassezia*. • House dust and storage mites. • Animal/human dander. • Insects.

RISK FACTORS

• Environments with long allergy seasons and high pollen and mold spore levels. • Concurrent hypersensitivities (summation effect). • Born during allergy season. • Breed predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Adverse food reaction. • Flea bite hypersensitivity. • Sarcoptic mange. • Bacterial folliculitis. • Yeast dermatitis. • Contact dermatitis (allergic or irritant).

CBC/BIOCHEMISTRY/URINALYSIS

Eosinophilia—rare in dogs without concurrent flea infestations; common in cats.

DIAGNOSTIC PROCEDURES

• Diagnosis made by history, physical examination, and ruling out differential diagnoses. • Serology/intradermal test (IDT) *not* meant for diagnosis. • Greatest treatment success noted when immunotherapy based on results of both serum and intradermal testing.

Serologic Allergy Tests

• Measures allergen-specific IgE in serum. • Advantages—readily available; clipping/sedation not required; concurrent/recent medications and infections less likely to affect results; similar hyposensitization success to IDT. • Disadvantages—fewer allergens tested; quality control/reliability varies with laboratory.

IDT

• Test allergens injected intradermally causing wheal formation. • Advantages—tests affected organ, results available immediately, many allergens tested; preferred where available. • Disadvantages—requires experience to interpret results, clipping and sedation needed, difficult to interpret in cats; drug withdrawal periods recommended, concurrent infection may affect results.

PATHOLOGIC FINDINGS

Skin biopsy—rule out other differential diagnoses; results not pathognomonic; superficial perivascular dermatitis with lymphocytic exocytosis ± eosinophils, mast cells; often with secondary bacterial folliculitis.

TREATMENT

APPROPRIATE HEALTH CARE

Outpatient

ACTIVITY

Avoid offending allergens when possible.

DIET

Diets rich in essential fatty acids may be beneficial.

CLIENT EDUCATION

Explain inheritable, progressive, and incurable nature of condition.

MEDICATIONS

DRUG(S) OF CHOICE

Immunotherapy (Hyposensitization)

• Subcutaneous or sublingual administration of causative allergens. • Allergen selection based on allergy test results, patient history, and knowledge of local exposure. • Immunotherapy protocols not standardized and vary widely between clinicians. • Preferred treatment in most cases. • Successfully reduces pruritus in 50–90% of dogs and cats. • 3 months to 1 year for full effect. • May continue lifelong if effective.

Cyclosporine (Atopica® Preferred)
• Cyclosporine, modified (dogs, 5 mg/kg/day; cats, 7 mg/kg/day). • 1–4 weeks for effect—frequency of dosing may be reduced to maintain control of symptoms. • Monitoring recommended. • Cats—drug blood level monitoring recommended; keep indoors, do *not* feed raw meat.

Corticosteroids
• For short-term relief or taper to lowest dosage/frequency. • Dogs—e.g., prednisolone (1 mg/kg PO q24h). • Cats—e.g., prednisolone (2 mg/kg q24h).

Antihistamines
• Less effective than corticosteroids. • 2 weeks for effect. • Dogs—cetirizine (1 mg/kg PO q12–24h), chlorpheniramine (0.4 mg/kg PO q8–12h), diphenhydramine (2.2 mg/kg PO q8–12h), amitriptyline (1–2 mg/kg q12h). • Cats—cetirizine (5 mg/cat q24h), chlorpheniramine (2 mg/cat PO q12h), amitriptyline (5–10 mg/cat q24h); diphenhydramine may cause paradoxical excitation in cats.

Oclacitinib (Apoquel®)
• Dogs—onset time/response similar to glucocorticoids (0.4–0.6 mg/kg q12h for 14 days, then q24h for maintenance). • Cats—not licensed; limited short-term studies report effectiveness, but higher doses may be needed.

Lokivetmab (Cytopoint®)
Dogs only—anti-IL-31 monoclonal antibody injectable; repeated as needed up to frequency of every 4–6 weeks.

PRECAUTIONS
• Immunotherapy—anaphylaxis rare (accompanied by diarrhea, weakness, collapse), hives, facial swelling; monitor for 1 hour post injection; increased pruritus after injection may indicate change in schedule needed; pain or swelling at injection site uncommon. • Cyclosporine—may affect glucose homeostasis; increased incidence of urinary tract infection; vomiting and diarrhea most common side effects; gingival hyperplasia, papillomavirus, and hirsutism possible; risk of fatal toxoplasmosis in naïve cats. • Corticosteroids—avoid iatrogenic hyperglucocorticism/hyperadrenocorticism; possible aggravation of pyoderma and induction of demodicosis. • Antihistamines—can produce drowsiness, rarely anorexia, vomiting, diarrhea, increased pruritus; use with caution in patients with cardiac arrhythmias. • Oclacitinib—not for use in dogs under 1 year of age; may cause existing parasitic skin infestations and/or prevent resolution of infections.

POSSIBLE INTERACTIONS
Concurrent use of cyclosporine and ketoconazole permits 50% dose reduction of each drug.

ALTERNATIVE DRUG(S)
• Frequent bathing (once to twice weekly) in cool water with antipruritic, antibacterial, antifungal, and/or moisturizing shampoos can be beneficial. • Fatty acids—diets rich in essential fatty acids typically provided higher amounts than with oral supplements. • Pentoxifylline 25 mg/kg q12h. • Topical hydrocortisone or triamcinolone spray 0.015% (short-term use).

FOLLOW-UP

PATIENT MONITORING
• Examination every 2–8 weeks initially; once acceptable level of control achieved, examine every 3–6 months. • Monitor pruritus, self-trauma, development of secondary infection, possible adverse drug reactions. • CBC/blood chemistry/urinalysis with culture—recommended every 3–12 months for patients on chronic corticosteroid, cyclosporine, or oclacitinib therapy.

PREVENTION/AVOIDANCE
• Avoidance of allergens seldom possible. • Minimize other sources of pruritus.

POSSIBLE COMPLICATIONS
• Secondary bacterial folliculitis or *Malassezia* dermatitis. • Concurrent hypersensitivities.

EXPECTED COURSE AND PROGNOSIS
• Pruritus and duration of signs usually worsen over time without intervention. • Some cases spontaneously resolve.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Hypersensitivity (flea, food). • Bacterial folliculitis. • *Malassezia* dermatitis. • Otitis externa.

AGE-RELATED FACTORS
Severity worsens with age.

PREGNANCY/FERTILITY/BREEDING
• Corticosteroids—contraindicated during pregnancy. • Affected animals should not be used for breeding.

SYNONYMS
• Atopy. • Canine atopic disease.

SEE ALSO
• Eosinophilic Granuloma Complex.
• Flea Bite Hypersensitivity and Flea Control.
• Food Reactions, Dermatologic.
• Otitis Externa and Media.
• Pyoderma.

ABBREVIATIONS
• IDT = intradermal test.
• Ig = immunoglobulin.
• TEWL = transepidermal water loss.

ATRIAL FIBRILLATION AND ATRIAL FLUTTER

BASICS

DEFINITION

• Atrial fibrillation—rapid, irregularly irregular supraventricular rhythm. Two forms recognized: primary atrial fibrillation, an uncommon disease that occurs mostly in large dogs with no underlying cardiac disease; and secondary atrial fibrillation, which occurs in dogs and cats secondary to underlying cardiac disease. • Atrial flutter is similar to atrial fibrillation, but the atrial rate is generally slower and is characterized by saw-toothed flutter waves in the baseline of the ECG. The ventricular response is generally rapid, but may be regular or irregular.

ECG Features

Atrial Flutter

• Atrial rhythm usually regular; rate approximately 300–400 bpm. • P waves usually discerned as either discrete P waves or "saw-toothed" baseline. • Ventricular rhythm and rate generally depend on atrial rate and atrioventricular (AV) nodal conduction, but are generally regular or regularly irregular and rapid. • Conduction pattern to ventricles is variable—in some cases every other atrial depolarization produces a ventricular depolarization (2 : 1 conduction ratio), giving a regular ventricular rhythm (Figure 1); other times the conduction pattern appears random, giving an irregular ventricular rhythm that can mimic atrial fibrillation.

Secondary Atrial Fibrillation

• No P waves present—baseline may be flat or may have small irregular undulations ("f" waves); some undulations may look like P waves. • Ventricular rate often elevated—usually 180–240 bpm in dogs and >220 bpm in cats. • Interval between QRS complexes is irregularly irregular; QRS complexes usually appear normal (Figure 2).

Primary Atrial Fibrillation

Similar to secondary atrial fibrillation, except ventricular rate usually in normal range.

PATHOPHYSIOLOGY

• Atrial fibrillation—caused by numerous small reentrant pathways creating a rapid (>500 depolarizations/minute) and disorganized depolarization pattern in the atria that results in cessation of atrial contraction. Depolarizations continuously bombard the AV nodal tissue, which acts as a filter and does not allow all depolarizations to conduct to the ventricles. Many atrial depolarizations activate only a part of the atria, because the rapid rate renders portions of the atria refractory, and thus they cannot reach the AV junction. Other atrial impulses penetrate into the AV junctional tissue, but do not penetrate the entire length. Blocked impulses affect the conduction properties of the AV junctional tissue and alter conduction of subsequent electrical impulses; electrical impulses are conducted through the AV junction irregularly, producing an irregular ventricular rhythm. • Atrial flutter—probably originates from one site of reentry that moves continuously throughout the atrial myocardium and frequently and regularly stimulates the AV node. When the atrial rate becomes sufficiently fast, the refractory period of the AV node exceeds the cycle length (P to P interval) of the supraventricular tachycardia (SVT), and some atrial depolarizations are blocked from traversing the AV node (functional second-degree AV block).

SYSTEMS AFFECTED

Cardiovascular

Loss of atrial contraction may result in decreased stroke volume and cardiac output, depending on heart rate; high heart rate may result in deterioration in myocardial function (tachycardia-induced myocardial failure).

GENETICS

No breeding studies available.

SIGNALMENT

Species

Dog and cat.

Breed Predilections

Large- and giant-breed dogs more prone to primary atrial fibrillation.

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

General Comments

• Generally relate to underlying disease process and/or congestive heart failure (CHF) rather than arrhythmia itself, but previously stable animals may decompensate. • Patients with primary atrial fibrillation are generally asymptomatic, but may demonstrate mild exercise intolerance.

Historical Findings

• Coughing/dyspnea/tachypnea. • Exercise intolerance. • Rarely, syncope. • Dogs with primary atrial fibrillation are typically asymptomatic.

Physical Examination Findings

• On auscultation, patients with atrial fibrillation have an erratic heart rhythm that sounds like "tennis shoes in a dryer." • First heart sound intensity in atrial fibrillation is variable; second heart sound only heard on beats with effective ejection, not on every beat. • Third heart sounds (gallop sounds) may be present. • Patients with atrial fibrillation have pulse deficits and variable pulse quality. • Signs of CHF often present (e.g., cough, dyspnea, cyanosis).

CAUSES

• Myxomatous valve disease. • Cardiomyopathy. • Congenital heart disease. • Digoxin toxicity. • Idiopathic. • Ventricular preexcitation (atrial flutter).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Frequent atrial (supraventricular) premature depolarizations. • Supraventricular tachycardia with AV block. • Multifocal atrial tachycardia (irregular).

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

• Echocardiography and radiography may characterize type and severity of underlying cardiac disease; moderate to severe heart enlargement common. • Typically normal in patients with primary atrial fibrillation, although mild left atrial enlargement may accompany hemodynamic alterations imposed by arrhythmia.

DIAGNOSTIC PROCEDURES

A baseline 24-hour Holter is recommended to determine if arrhythmia is chronic or paroxysmal. If it is chronic, drug therapy may be indicated.

TREATMENT

APPROPRIATE HEALTH CARE

• Patients with fast (secondary) atrial fibrillation are treated medically to slow the ventricular rate. Converting the atrial fibrillation to sinus rhythm would be ideal, but such attempts in patients with severe underlying heart disease or left atrial enlargement are generally futile because of a low success rate and high rate of recurrence. Consider electrical cardioversion to sinus rhythm for a dog with primary atrial fibrillation and minimal structural heart disease. • Patients with primary atrial fibrillation may be converted back to normal sinus rhythm. The success rate depends on chronicity. Patients that have been in atrial fibrillation for >4 months generally have a lower success rate and a higher rate of recurrence. In these patients, rate control, if necessary, is the recommended treatment. • Electrical (DC) cardioversion—application of a transthoracic electrical shock at a specific time in the cardiac cycle; requires special equipment, trained personnel, and general anesthesia. Using a monophasic defibrillator: start with 4 J/kg; if no conversion occurs,

(CONTINUED) ATRIAL FIBRILLATION AND ATRIAL FLUTTER A

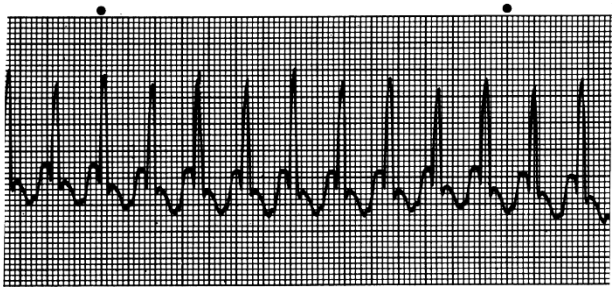

Figure 1.

Atrial flutter with 2 : 1 conduction at a ventricular rate of 330/minute in a dog with an atrial septal defect. This supraventricular tachycardia was associated with a Wolff-Parkinson-White pattern. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore, MD: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

increase dose by 50 J and repeat until a max of 360 J. Using a biphasic defibrillator: start with 1–2 J/kg; if no cardioversion occurs, increase dose by 50 J and repeat until max of 360 J.
• For atrial flutter, conversion to sinus rhythm can be accomplished by drug therapy, electrical cardioversion, or rapid atrial pacing (transvenous pacing electrode).

NURSING CARE
As indicated for CHF.

ACTIVITY
Restrict activity until tachycardia is controlled.

DIET
Mild to moderate sodium restriction if CHF.

CLIENT EDUCATION
• Secondary atrial fibrillation and atrial flutter are usually associated with severe underlying heart disease; goal of therapy is to lower heart rate and control clinical signs. • Sustained conversion to sinus rhythm is unlikely with secondary atrial fibrillation.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Digoxin, β-adrenergic blockers, esmolol, and calcium channel blockers (diltiazem) are frequently used to slow conduction through the AV node; definition of an adequate heart rate response varies among clinicians, but in dogs is generally 130–150 bpm. • For atrial flutter, therapy is aimed at suppressing the atrial reentry circuit using sotalol, amiodarone, or procainamide.

Dogs
• Digoxin—maintenance oral dose 0.005–0.01 mg/kg PO q12h; to achieve therapeutic serum concentration more rapidly, maintenance dose can be doubled for the first day. If digoxin is administered alone and heart rate remains high, check digoxin level and adjust dose to bring level into therapeutic range. If heart rate remains high, consider adding calcium channel blocker or β-adrenergic blocker.
• Diltiazem—initially administered at dose of 0.5 mg/kg PO q8h, then titrated up to maximum of 1.5 mg/kg PO q8h or until adequate response is obtained. • Therapy for atrial flutter is aimed at suppressing atrial reentry circuit using sotalol, amiodarone, or procainamide. Conversion to normal sinus rhythm is usually unsuccessful.

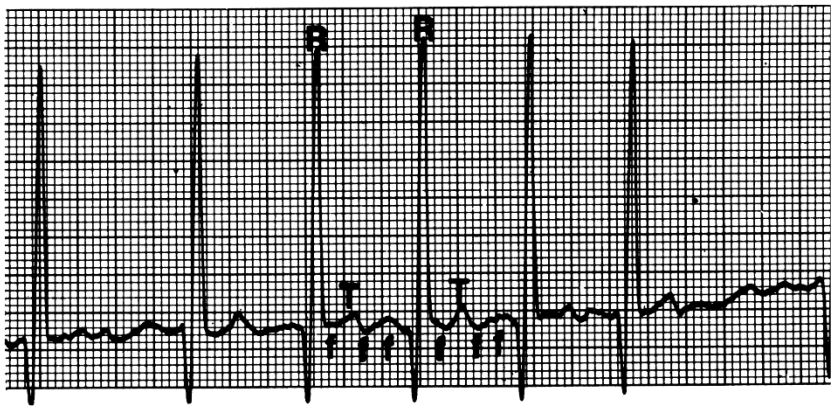

Figure 2.

"Coarse" atrial fibrillation in a dog with patent ductus arteriosus. The f waves are prominent. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore, MD: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

A

ATRIAL FIBRILLATION AND ATRIAL FLUTTER (CONTINUED)

Cats

• Diltiazem (1–2.5 mg/kg PO q8h) or atenolol (6.25–12.5 mg/cat PO q12–24h) are drugs of choice in most cats. • If the heart rate is not sufficiently slowed with these drugs or myocardial failure is present, digoxin (5 µg/kg PO q24–48h) can be added.

CONTRAINDICATIONS

• Digoxin, diltiazem, propranolol, and atenolol should not be used in patients with preexisting AV block. • Use of calcium channel blockers in combination with beta blockers should be avoided because clinically significant bradyarrhythmias and/or AV block can develop.

PRECAUTIONS

• Calcium channel blockers and β-adrenergic blockers, both negative inotropes, should be used cautiously in animals with myocardial failure. • Using high-dose oral quinidine for conversion to sinus rhythm carries a risk of quinidine toxicity (e.g., hypotension, weakness, ataxia, and seizures)—administration of diazepam intravenously controls seizures; other signs abate within several hours of discontinuing quinidine administration.

POSSIBLE INTERACTIONS

Quinidine raises the digoxin level, generally necessitating a digoxin dose reduction.

FOLLOW-UP

PATIENT MONITORING

• Monitor heart rate and ECG closely. • As heart rates in the hospital and those measured on the surface ECG may be inaccurate (due to patient anxiety and other environmental factors), Holter monitoring provides a more accurate means for assessing the need for heart rate control and/or the efficacy of medical therapy for heart rate control.

POSSIBLE COMPLICATIONS

Worsening of cardiac function with onset of arrhythmia.

EXPECTED COURSE AND PROGNOSIS

• Secondary atrial fibrillation—often associated with severe structural heart disease, so a guarded to poor prognosis. • Primary atrial fibrillation with normal ultrasound findings—generally a good prognosis.

MISCELLANEOUS

ABBREVIATIONS

• AV = atrioventricular.
• CHF = congestive heart failure.
• SVT = supraventricular tachycardia.

ATRIAL PREMATURE COMPLEXES

BASICS

DEFINITION

Premature atrial complexes or beats (APC) that originate outside the sinoatrial node and disrupt the normal sinus rhythm for 1 or more beats.

ECG Features

• Heart rate usually normal; rhythm irregular due to the premature P wave (called a P′ wave) that disrupts the normal P wave rhythm (Figure 1). • Ectopic P′ wave—premature; configuration differs from that of the sinus P waves and may be negative, positive, biphasic, or superimposed on the previous T wave. • QRS complex—premature; configuration usually normal (same as that of the sinus complexes). If the P′ wave occurs during the refractory period of the atrioventricular (AV) node, ventricular conduction does not occur (nonconducted APCs), so no QRS complex follows the P′ wave. If there is partial recovery in the AV node or intraventricular conduction systems, the P′ wave is conducted with a long P′–R interval or with an abnormal QRS configuration (aberrant conduction). The more premature the complex, the more marked the aberration. • In the P–QRS relationship, the P′–R interval is usually as long as, or longer than, the sinus P′–R interval. • A noncompensatory pause—when the R–R interval of the two normal sinus complexes enclosing an APC is less than the R–R intervals of three consecutive sinus complexes—usually follows an APC (Figure 2). The ectopic atrial impulse discharges the sinus node and resets the cycle.

PATHOPHYSIOLOGY

• Mechanisms—an increase in automaticity of atrial myocardial fibers or a single reentrant circuit. • May be normal finding in aged dogs; commonly seen in dogs with atrial enlargement secondary to chronic mitral valvular insufficiency; may also be observed in dogs or cats with any atrial disease. • May not cause hemodynamic problems; the clinical significance relates to their frequency, timing relative to other complexes, and the underlying clinical problems. • Can presage more serious rhythm disturbances (e.g., atrial fibrillation, atrial flutter, or atrial tachycardia).

SYSTEMS AFFECTED

Cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

Not documented.

SIGNALMENT

Species

Dog and cat.

Breed Predilections

Small-breed dogs.

Mean Age and Range

Geriatric animals, except those with congenital heart disease.

SIGNS

Historical Findings

• No signs. • Congestive heart failure (CHF). • Coughing and dyspnea. • Exercise intolerance. • Syncope.

Physical Examination Findings

• Myxomatous valve disease. • Cardiac murmur. • Gallop sound. • Signs of CHF.

CAUSES & RISK FACTORS

• Chronic valvular disease. • Congenital heart disease. • Cardiomyopathy. • Atrial myocarditis. • Electrolyte disorders. • Neoplasia. • Hyperthyroidism. • Toxemias. • Drug toxicity (e.g., digitalis). • Normal variation in aged animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Marked sinus arrhythmia. • Ventricular premature complexes when aberrant ventricular conduction follows an APC.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

Echocardiography and Doppler ultrasound may reveal the type and severity of the underlying heart disease.

DIAGNOSTIC PROCEDURES

• ECG. • Holter monitor to quantify APC frequency and event monitor/Holter ECG to correlate symptoms with rhythm.

PATHOLOGIC FINDINGS

Atrial enlargement; other features vary depending on underlying cause.

TREATMENT

APPROPRIATE HEALTH CARE

• Treat animal as inpatient or outpatient. • Treat the underlying CHF, cardiac disease, or other causes.

NURSING CARE

Usually not necessary; varies with underlying cause.

ACTIVITY

Restrict if symptomatic.

DIET

No modifications unless required for management of underlying condition (i.e., low-salt diet).

Figure 1.

APCs in a dog. P′ represents the premature P wave. The premature QRS resembles the normal (sinus) QRS. The upright P′ wave is superimposed on the T wave of the preceding complex. ATRIAL PREMATURE COMPLEXES (CONTINUED)

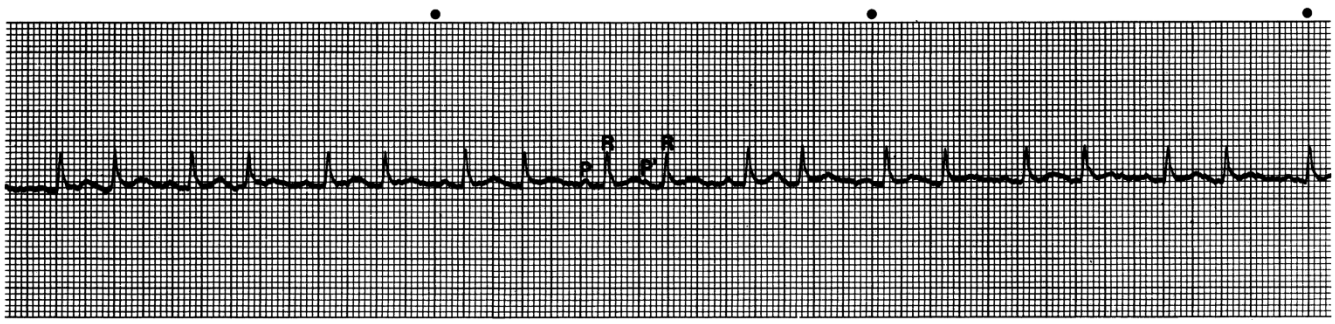

Figure 2.

APCs in bigeminy in a cat under general anesthesia. The second complex of each pair is an APC and the first is a sinus complex. The abnormality in rhythm disappeared after the anesthetic was stopped. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

CLIENT EDUCATION
APCs may not cause hemodynamic abnormalities; may be precursors of serious arrhythmias.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
Treat CHF and correct any electrolyte or acid/base imbalances.

Dogs
• Digoxin (0.005–0.01 mg/kg PO q12h, maintenance dosage), diltiazem (0.5–1.5 mg/kg PO q8h), or atenolol (0.25–1 mg/kg PO q12h) are used to treat clinically significant arrhythmias. • Digoxin—treatment of choice. • CHF is treated with appropriate dosage of diuretic, angiotensin-converting enzyme inhibitor, and pimobendan; appropriate management of CHF may reduce APC frequency.

Cats
• Cats with hypertrophic cardiomyopathy—diltiazem (1–2.5 mg/kg PO q8h) or atenolol (6.25–12.5 mg PO q12–24h). • Cats with dilated cardiomyopathy—digoxin (one-fourth of a 0.125 mg digoxin tablet q24h or q48h).

CONTRAINDICATIONS
Negative inotropic agents (e.g., propranolol) should be avoided in animals with CHF.

PRECAUTIONS
Use digoxin, diltiazem, atenolol, or propranolol cautiously in animals with underlying atrioventricular block or hypotension.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Monitor heart rate and rhythm with serial ECG.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Frequent APCs may further diminish cardiac output in patients with underlying heart disease and worsen clinical symptoms.

EXPECTED COURSE AND PROGNOSIS
Even with optimal antiarrhythmic drug therapy, some animals have an increased frequency of APCs or deteriorate to more severe arrhythmia as the underlying disease progresses.

MISCELLANEOUS

ASSOCIATED CONDITIONS
None

AGE-RELATED FACTORS
Typically occurs in geriatric dogs.

PREGNANCY/FERTILITY/BREEDING
N/A

SYNONYMS
• Atrial extrasystoles. • Atrial premature contractions. • Atrial premature impulses. • Premature atrial complexes/contractions.

SEE ALSO
Supraventricular Tachycardia.

ATRIAL SEPTAL DEFECT

BASICS

OVERVIEW

• Congenital defect in which interatrial septum fails to develop normally, resulting in communication between atria. Unknown cause; genetic basis suspected. Acquired atrial septal defects (ASD) secondary to atrial rupture reported with canine degenerative mitral valve disease. • Comprises 0.7–3.7% of congenital heart defects in dogs, <10% of congenital heart defects in cats. Significantly higher incidence (37.7%) noted in one study. • Three major types of ASD classified based on the location of the defect within the interatrial septum—ostium primum ASD (most apical portion of septum, adjacent to the atrioventricular [AV] valves), ostium secundum ASD (central portion of the septum, region of fossa ovalis), and sinus venosus ASD (adjacent to cranial or caudal vena cava). • Secundum ASD with left-to-right shunting is most common (98.7% in one study of dogs and cats). • Ostium primum ASD typically large; possible component of AV canal defect. • Sinus venosus ASD typically located at junction of cranial vena cava (less commonly caudal vena cava) and right atrium. Right pulmonary veins may be directed at right atrium through the defect. May be associated with anomalous pulmonary venous connections of some/all pulmonary veins. • Isolated ASD typically shunts left to right. Magnitude of flow dependent on ASD size, relative systemic and pulmonary resistance, and relative ventricular compliance. Small restrictive defects allow atria to maintain normal differential pressure. Large defects may have significant left-to-right shunting, causing volume overload to right heart and pulmonary vessels. Secondary pulmonary hypertension can reverse shunting (i.e., right to left), termed Eisenmenger's physiology. ASD with concurrent defects causing increased right atrial pressure (i.e., pulmonic stenosis, tricuspid valve dysplasia, tricuspid valve stenosis) may have balanced or reversed shunting.

SIGNALMENT

• Dog and cat. • Various breeds affected; higher prevalence in boxer and standard poodle. • No sex predisposition.

SIGNS

General Comments

• Typically asymptomatic (73.7% in one study). • Severe cases may show signs of congestive heart failure (CHF). • Generalized cyanosis possible with reversed shunting.

Historical Findings

Clinical signs related to concurrent heart disease, CHF, or cyanosis; exercise intolerance, syncope, and dyspnea.

Physical Examination Findings

• Soft systolic murmur over left base due to increased blood flow across normal pulmonic valve. • Split S2 (fixed) due to delayed closure of pulmonic valve. • Cyanosis with right-to-left shunting. • Ascites and jugular vein distension with right CHF.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

• Typically normal. • Polycythemia with right-to-left shunting.

IMAGING

Radiographic Findings

• None with small defects. • Right heart enlargement and vascular pattern (pulmonary overcirculation) with significant shunting.

Echocardiographic Findings

• Right atrial and/or right ventricular dilation. • Septal dropout (artifactual septal dropout is common and may lead to misdiagnosis). • Shunting across ASD by color-flow or spectral Doppler. • Increased pulmonic flow velocity. • Dilation of pulmonary trunk.

DIAGNOSTIC PROCEDURES

Electrocardiography

• Usually normal. • Right atrial and ventricular enlargement (tall P wave, deep S waves in lead II), right axis deviation. • Arrhythmias and intraventricular conduction disturbances possible.

TREATMENT

GENERAL

• Long-term prognosis for small ASD is good; treatment typically unnecessary. • Large ASD with hemodynamically significant shunting and right-sided enlargement warrants closure.

MEDICAL THERAPY

• Standard treatment of CHF—furosemide, pimobendan, angiotensin-converting enzyme (ACE) inhibitor). • Treatment of polycythemia (right-to-left shunting) if clinically indicated.

SURGICAL THERAPY

• Open heart surgery under cardiopulmonary bypass (surgical closure using patch graft). • Pulmonary artery banding as palliative measure to limit left-to-right shunting.

CATHETER-BASED THERAPY

• Amplatzer® atrial septal occluder (ASO) device delivered percutaneously through jugular vein possible for some secundum-type defects. • Hybrid procedure involving surgical access and transatrial delivery of ASO device under inflow occlusion reported.

MEDICATIONS

See Congestive Heart Failure, Left-Sided; Congestive Heart Failure, Right-Sided; and Hypertension, Pulmonary.

FOLLOW-UP

PATIENT MONITORING

• Periodic evaluation to assess cardiac structure and function. • Recheck when decompensation or other clinical signs develop.

EXPECTED COURSE AND PROGNOSIS

• Dependent on ASD size and coexisting defects. • Small, isolated defects unlikely to cause clinical signs. • Defects >12 mm more likely to cause CHF.

MISCELLANEOUS

SEE ALSO

• Congestive Heart Failure, Left-Sided. • Congestive Heart Failure, Right-Sided. • Hypertension, Pulmonary.

ABBREVIATIONS

• ACE = angiotensin-converting enzyme. • ASD = atrial septal defect. • ASO = atrial septal occluder. • AV = atrioventricular. • CHF = congestive heart failure.

A

ATRIAL STANDSTILL

BASICS

DEFINITION
ECG rhythm characterized by absence of P waves; condition can be temporary (e.g., associated with hyperkalemia or drug induced), terminal (e.g., associated with severe hyperkalemia or dying heart), or persistent.

ECG Features

Persistent Atrial Standstill
- P waves absent.
- Heart rate usually slow (<60 bpm).
- Rhythm regular with supraventricular-type QRS complexes.
- Heart rate does not increase with atropine administration.

Hyperkalemic Atrial Standstill
- Heart rate normal or slow.
- Rhythm regular or irregular.
- QRS complexes tend to be wide and become wider as the potassium level rises; with severe hyperkalemia (potassium >10 mEq/L), the QRS complexes are replaced by a smooth biphasic curve.
- Heart rate may increase slightly with atropine.

PATHOPHYSIOLOGY

Persistent Atrial Standstill
Caused by an atrial muscular dystrophy/cardiomyopathy; skeletal muscle involvement common.

Hyperkalemic Atrial Standstill
Generally occurs with serum potassium levels >8.5 mEq/L; value influenced by serum sodium and calcium levels and acid-base status. Hyperkalemic patients with atrial standstill have sinus node function, but impulses do not activate atrial myocytes; thus, the associated rhythm is termed a sinoventricular rhythm. Since the sinus node is functional, an irregular rhythm may be due to sinus arrhythmia.

SYSTEMS AFFECTED
Cardiovascular

GENETICS
None

INCIDENCE/PREVALENCE
Rare rhythm disturbance.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Persistent atrial standstill—most common in English springer spaniels; other breeds occasionally affected.

Mean Age and Range
Most animals with persistent atrial standstill are young; animals with hypoadrenocorticism are usually young to middle-aged.

Predominant Sex
Hypoadrenocorticism more common in females (69%).

SIGNS

Historical Findings
- Vary with underlying cause.
- Lethargy common; syncope may occur.
- Patients with persistent atrial standstill may show signs of congestive heart failure (CHF).

Physical Examination Findings
- Vary with underlying cause.
- Bradycardia common.
- Patients with persistent atrial standstill may have skeletal muscle wasting of the antebrachium and scapula.

CAUSES
- Hyperkalemia.
- Atrial disease, often associated with atrial distension (e.g., cats with cardiomyopathy).
- Atrial myopathy (persistent atrial standstill).

RISK FACTORS
- Hyperkalemic atrial standstill.
- Hypoadrenocorticism.
- Conditions leading to obstruction or rupture of the urinary tract.
- Oliguric or anuric renal failure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Slow atrial fibrillation.
- Sinus bradycardia with small or hidden P waves.

CBC/BIOCHEMISTRY/URINALYSIS

Persistent Atrial Standstill
Normal

Hyperkalemic Atrial Standstill
- Hyperkalemia.
- Hyponatremia and sodium : potassium ratio <27 if atrial standstill secondary to hypoadrenocorticism.
- Azotemia and hyperphosphatemia with hypoadrenocorticism, renal failure, and rupture or obstruction of the urinary tract.

OTHER LABORATORY TESTS
Adrenocorticotropic hormone (ACTH) stimulation test if hypoadrenocorticism suspected.

IMAGING
Echocardiogram and electromyography if persistent atrial standstill suspected—cardiomegaly and depressed contractility may be seen.

DIAGNOSTIC PROCEDURES
Skeletal muscle biopsy in animals with persistent atrial standstill, particularly if skeletal muscle wasting noted.

PATHOLOGIC FINDINGS

Persistent Atrial Standstill
- Greatly enlarged and paper-thin atria; usually biatrial involvement, although one case of only left atrial involvement was reported.
- Severe scapular and brachial muscle wasting in some dogs.
- Marked fibrosis, fibroelastosis, chronic mononuclear cell inflammation, and steatosis throughout the atria and interatrial septum.

TREATMENT

APPROPRIATE HEALTH CARE

Persistent Atrial Standstill
Not life-threatening condition; animal can be treated as an outpatient.

Hyperkalemic Atrial Standstill
Potentially life-threatening; often requires aggressive treatment.

NURSING CARE
Aggressive fluid therapy with 0.9% saline often required to correct hypovolemia and lower serum potassium levels (see Hyperkalemia) in patients with hyperkalemic atrial standstill.

ACTIVITY
Restrict activity in patients with persistent atrial standstill and signs of CHF or syncope.

DIET
N/A

CLIENT EDUCATION

Persistent Atrial Standstill
Clinical signs generally improve after pacemaker implantation; signs of CHF may develop, and weakness and lethargy may persist even after heart rate and rhythm are corrected with the pacemaker.

SURGICAL CONSIDERATIONS

Persistent Atrial Standstill
Implant permanent ventricular pacemaker to regulate rate and rhythm.

Hyperkalemic Atrial Standstill
Hyperkalemia secondary to urinary tract obstruction or rupture may require surgery.

(CONTINUED) ATRIAL STANDSTILL A

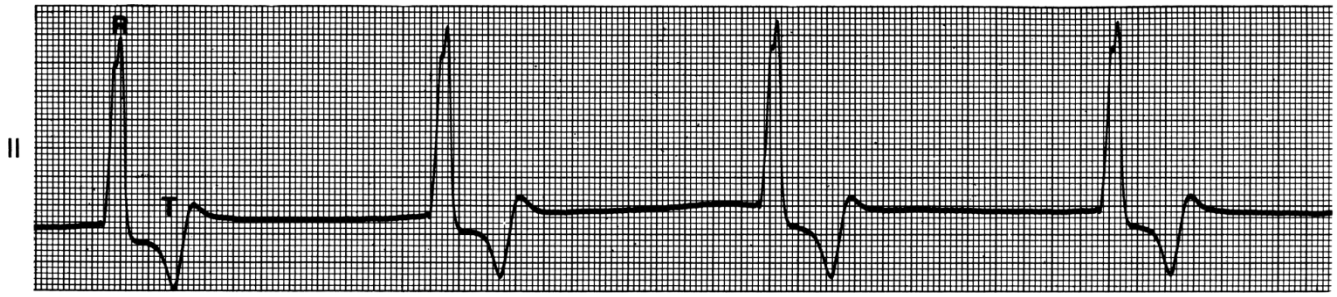

Figure 1.

Atrial standstill in a dog with a potassium of 9 mEq/L. Note the absence of P waves and wide QRS complexes.

MEDICATIONS

DRUG(S) OF CHOICE

Persistent Atrial Standstill

Treat with standard therapy (pimobendan, diuretics, and angiotensin-converting enzyme (ACE) inhibitor, e.g., enalapril or benazepril) if CHF develops.

Hyperkalemic Atrial Standstill

- Treat the underlying cause (e.g., oliguric renal failure, hypoadrenocorticism).
- Aggressive fluid therapy with 0.9% saline and possibly sodium bicarbonate or insulin with dextrose, as discussed under Hyperkalemia.
- Calcium gluconate—counters the cardiac effects of hyperkalemia; can be used in life-threatening situations while instituting treatment to lower potassium concentration.

CONTRAINDICATIONS

Avoid potassium-containing fluids or medications that increase potassium concentration in hyperkalemic patients.

PRECAUTIONS

Diuretics lower preload and may worsen weakness in dogs with persistent atrial standstill and CHF unless a pacemaker has been implanted.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

- Monitor ECG during treatment of hyperkalemia and periodically in animals with a permanent ventricular pacemaker.
- Monitor electrolytes in patients with hyperkalemic atrial standstill.
- Monitor patients with persistent atrial standstill for signs of CHF.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

CHF in patients with persistent atrial standstill.

EXPECTED COURSE AND PROGNOSIS

Persistent Atrial Standstill

- Clinical signs generally improve after pacemaker implantation. Signs of CHF may develop, and weakness and lethargy may persist even after heart rate and rhythm are corrected with the pacemaker.
- Signs related to muscular dystrophy may persist.
- Median survival in 20 dogs with atrial standstill treated with a pacemaker was 866 days and was not influenced by breed or presence of heart failure at time of implantation.

Hyperkalemic Atrial Standstill

Long-term prognosis is excellent if underlying cause can be corrected and hyperkalemia reversed.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Diseases causing hyperkalemia (e.g., hypoadrenocorticism, urethral obstruction or urinary tract tear, acidosis, and drugs).

AGE-RELATED FACTORS

Persistent atrial standstill—usually diagnosed in young animals; hypoadrenocorticism—usually diagnosed in young to middle-aged animals.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

Silent atrium.

SEE ALSO

- Digoxin Toxicity.
- Hyperkalemia.
- Hypoadrenocorticism (Addison's Disease).
- Urinary Tract Obstruction.

ABBREVIATIONS

- ACE = angiotensin-converting enzyme.
- ACTH = adrenocorticotropic hormone.
- CHF = congestive heart failure.

A

ATRIAL WALL TEAR

BASICS

DEFINITION
• Endocardial splitting is a linear defect limited to the atrial endocardium (typically left atrium [LA]) resulting from distension of the atrial wall beyond its elastic limits.
• Atrial tear results if the split extends through the myocardium and epicardium, resulting in a full-thickness atrial wall defect and hemorrhage into the pericardial space.

PATHOPHYSIOLOGY
• Endocardial splitting typically results from increased LA pressure secondary to severe mitral regurgitation and mechanical trauma from the regurgitant jet; primary endocardial degeneration may also play a role.
• If split is incomplete, fibrin may seal the defect temporarily; either heals as a linear depression in endocardial surface or subsequently extends through myocardium, resulting in complete tear.
• LA tear results in peracute bleeding into pericardial sac and acute cardiac tamponade.
• If tear occurs in interatrial septum, an acquired atrial septal defect may form.
• Tearing of either atrium may also rarely occur secondary to blunt trauma, or iatrogenically during pericardiocentesis or cardiac catheterization.

SYSTEMS AFFECTED
• Cardiovascular.
• Respiratory.

GENETICS
Unknown

INCIDENCE/PREVALENCE
A rare cause of hemorrhagic pericardial effusion in the dog encompassing approximately 2% of pericardial effusion cases.

SIGNALMENT

Species
Dog; uncommon in cat.

Breed Predilections
• Any breed predisposed to degenerative valve disease.
• If traumatic, any breed may be represented.

Mean Age and Range
Middle-aged to older dogs.

Predominant Sex
Male dogs may be overrepresented.

SIGNS

Historical Findings
• Acute weakness and collapse; may progress quickly to respiratory or cardiopulmonary arrest.
• History of chronic cardiac disease; signs of congestive heart failure (CHF) in most patients.
• Acute worsening of cough or dyspnea is commonly observed.
• Possible history of blunt trauma.

Physical Examination Findings
• Collapse.
• Tachycardia.
• Weak pulses or pulsus paradoxus.
• Pale, muddy, or ashen mucous membranes; prolonged capillary refill time (CRT).
• Other signs of significant cardiac disease (e.g., murmur, gallop sound, arrhythmia, cough, dyspnea) typically present.
• May have signs of right CHF (e.g., ascites, jugular venous distension).
• Heart sounds may be muffled, or if murmur was heard before atrial wall tear occurred, it may be reduced in intensity.

CAUSES
• Myxomatous mitral valve disease.
• Chordae tendineae rupture.
• Chest trauma.
• Cardiac catheterization.

RISK FACTORS
• Severe mitral regurgitation; LA enlargement.
• May be precipitated by excitement, stress, or activity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other causes of acute cardiovascular collapse or syncope.
• Pericardial effusion from other causes (e.g., neoplastic, idiopathic).
• CHF.
• Severe arrhythmias.

CBC/BIOCHEMISTRY/URINALYSIS
• Elevations in serum lactate; metabolic acidosis.
• Increased alanine aminotransferase/aspartate aminotransferase in some patients.
• Prerenal azotemia; hyponatremia or other electrolyte derangements may be seen.

OTHER LABORATORY TESTS
NT-proBNP and cardiac troponin I (cTnI) levels may be elevated.

IMAGING

Radiography
• Usually moderate to severe LA enlargement; cardiac silhouette may be rounded and further enlarged compared with previous radiographs.
• Interstitial to alveolar pulmonary infiltrates if left-sided CHF present.
• Pleural effusion, ascites, hepatomegaly, and large caudal vena cava if right-sided CHF.

ECG
• Pericardial effusion—volume may be relatively small as pericardium remains inelastic due to acute nature of bleed; characteristic linear, hyperechoic thrombus may be seen within pericardial sac.
• Actual tear often not identified, though associated thrombus occasionally visualized within LA.
• Evidence of cardiac tamponade.
• Signs of advanced myxomatous mitral valve disease with moderate to severe LA enlargement expected.

DIAGNOSTIC PROCEDURES

ECG
• Sinus tachycardia.
• Atrial or ventricular arrhythmias.
• Possible dampened QRS complexes.
• Electrical alternans.
• ST-segment abnormalities.
• Possible left ventricular or LA enlargement pattern.

PATHOLOGIC FINDINGS
• Endocardial splitting is noted grossly as pale linear depression in atrial endocardium.
• Atrial wall tears appear as full-thickness defects extending through atrial endocardium, myocardium, and epicardium; associated thrombus may or may not be present. Caudolateral aspect of LA most commonly affected, with many tears occurring at atrio-auricular junction.
• Hemorrhagic pericardial effusion or pericardial thrombus with acute tears.
• Myxomatous valve disease characterized by thickened leaflets with rolled edges; may have chordae tendineae rupture; possibly atrial jet lesions.
• Cardiomegaly with severe LA enlargement expected.

TREATMENT

APPROPRIATE HEALTH CARE
• If LA tear suspected, perform pericardiocentesis only if effusion causing symptomatic, life-threatening cardiac tamponade, since further hemorrhage into pericardial sac or exsanguination may occur once pericardial fluid removed; remove only enough fluid to improve clinical signs.
• Pericardiocentesis likely difficult given small volume of effusion typically present, severe cardiomegaly, and small size of most dogs with LA rupture; ultrasound guidance and continuous ECG monitoring highly recommended.
• Best practices for management of LA tear have not been clearly established; however, aggressive medical management to lower LA pressure using afterload and preload reducers recommended based on author's clinical experience.
• If fibrin clot forms over defect, patient may stabilize and recover.

NURSING CARE
• Administer oxygen to dyspneic or hemodynamically unstable dogs.

• Administer IV fluids only if evidence of hypovolemia present; most dogs volume overloaded and further intravascular volume expansion will increase LA pressure and potentially worsen tamponade.

ACTIVITY
Strict cage rest in acute period, followed by chronic exercise restriction.

DIET
Sodium restriction may be indicated for animals with advanced myxomatous valve disease with cardiomegaly.

CLIENT EDUCATION
LA tear typically accompanies advanced cardiac disease and chronic medical therapy is necessary; though prognosis is guarded for surviving acute event, some dogs have lived more than a year after the incident.

SURGICAL CONSIDERATIONS
Exploratory thoracotomy may be considered if hemorrhage persists or recurs, but should be undertaken cautiously given advanced state of cardiac disease typically present.

MEDICATIONS

DRUG(S) OF CHOICE
• Atrial tears occur secondary to elevated LA pressure; thus medical therapy should be focused on lowering LA pressures to reduce continued hemorrhage into pericardial space and permit fibrin clot formation at the tear; this may be accomplished with preload (e.g., diuretics, nitroglycerin paste) and/or afterload reducers (arterial vasodilators).
• Preload and afterload reduction must be undertaken cautiously to avoid worsening of hemodynamic compromise.
• If concurrent CHF present, afterload reduction may be achieved by conservative doses of sodium nitroprusside; low starting CRI dose of 0.5–1 µg/kg/min recommended to decrease LA pressure without precipitating significant hypotension; dose may be uptitrated as necessary every 15–30 min up to maximum of 10 µg/kg/min to improve clinical signs and/or reduce blood pressure by 10–15 mmHg.
• Alternatively, amlodipine may be started at 0.1–0.2 mg/kg PO q24h; chronic amlodipine therapy may be implemented in normotensive or hypertensive animals to reduce regurgitant fraction and lower LA pressure.
• Cautious diuretic use, if needed, to treat dyspnea associated with concomitant CHF (e.g., 1–2 mg/kg furosemide IV as needed); signs of left-sided CHF may worsen as cardiac tamponade resolves due to augmented preload—more aggressive diuretic therapy may then be required.
• Pimobendan (0.25–0.3 mg/kg PO q12h) may result in further LA pressure reduction, though studies have not specifically examined its use in setting of LA rupture.
• Once patient is stable, angiotensin-converting enzyme inhibitors (e.g., enalapril 0.5 mg/kg q12–24h) should be implemented for chronic management of accompanying CHF.

CONTRAINDICATIONS
• Antithrombotic medications.
• Arterial vasodilators, if significant hypotension present.

PRECAUTIONS
• Aggressive fluid therapy unwarranted; further volume expansion may increase LA pressure, worsen cardiac tamponade, and contribute to hemodynamic compromise.
• Best practices for management of LA tear not clearly established; choice of whether to perform pericardiocentesis, and whether to administer preload and/or afterload reducers, should be based on assessment of volume status, blood pressure, and clinical stability of patient.

POSSIBLE INTERACTIONS
Sodium nitroprusside should not be administered concurrently with phosphodiesterase-V inhibitors (e.g., sildenafil, tadalafil) due to potential for life-threatening systemic hypotension.

ALTERNATIVE DRUGS
N/A

FOLLOW-UP

PATIENT MONITORING
• Recommend close monitoring of respiratory rate and effort, mucous membrane color and CRT, pulse quality, and heart rate; blood pressure monitoring recommended if arterial vasodilators are implemented.
• Follow-up examination with echocardiography helps determine resolution of pericardial effusion and resorption of atrial or pericardial clot.
• Close follow-up every 2–3 months thereafter recommended for repeat pericardial fluid checks and medication adjustments as indicated.

PREVENTION/AVOIDANCE
Avoid strenuous physical activity and excitement.

POSSIBLE COMPLICATIONS
• Even if the tear seals, patient is prone to further tears because of underlying cardiac disease.
• Most dogs have or will develop concurrent CHF.

EXPECTED COURSE AND PROGNOSIS
Prognosis is guarded; however, some animals can do well for several months or more with exercise restriction and optimal medical management.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Myxomatous mitral valve disease.
• CHF.
• Mainstem bronchial compression.

AGE-RELATED FACTORS
Middle-aged to older dogs are predisposed.

A

ATRIOVENTRICULAR BLOCK, COMPLETE (THIRD DEGREE)

BASICS

DEFINITION
• All atrial impulses are blocked at the atrioventricular (AV) junction; atria and ventricles beat independently. A secondary "escape" pacemaker site (junctional or ventricular) stimulates the ventricles. • Atrial rate normal. • Idioventricular escape rhythm slow.

ECG Features
• Ventricular rate slower than atrial rate (more P waves than QRS complexes)—ventricular escape rhythm (idioventricular) usually <40 bpm; junctional escape rhythm (idiojunctional) 40–60 bpm in dogs and 60–100 bpm in cats. • P waves—usually normal configuration (Figures 1 and 2). • QRS complex—wide and bizarre when pacemaker located in the ventricle, or in the lower AV junction in a patient with bundle branch block; normal when escape pacemaker in the lower AV junction (above the bifurcation of the bundle of His) in a patient without bundle branch block. • No conduction between the atria and the ventricles; P waves have no constant relationship with QRS complexes; P–P and R–R intervals relatively constant (except for a sinus arrhythmia).

PATHOPHYSIOLOGY
Slow ventricular escape rhythms (<40 bpm) result in low cardiac output and eventual heart failure, often when animal is excited or exercised, since demand for greater cardiac output is not satisfied. As the heart fails, signs increase with mild activity.

SYSTEMS AFFECTED
Cardiovascular

GENETICS
Can be an isolated congenital defect.

INCIDENCE/PREVALENCE
Not documented.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Cocker spaniel—can have idiopathic fibrosis. • Pug and Doberman pinscher—can have associated sudden death, AV conduction defects, and bundle of His lesions.

Mean Age and Range
Geriatric animals, except congenital heart disease patients. Median age for cats—14 years.

Predominant Sex
Intact female dogs.

SIGNS

Historical Findings
• Exercise intolerance. • Weakness or syncope. • Occasionally, congestive heart failure (CHF).

Physical Examination Findings
• Bradycardia. • Variable third and fourth heart sounds. • Variation in intensity of first heart sounds. • Signs of CHF possible. • Intermittent "cannon" A waves in jugular venous pulses. • Often bounding arterial pulses.

CAUSES & RISK FACTORS
• Isolated congenital defect. • Idiopathic fibrosis. • Infiltrative cardiomyopathy (amyloidosis or neoplasia). • Hypertrophic cardiomyopathy in cats. • Digitalis toxicity. • Hyperthyroidism in cats. • Myocarditis. • Endocarditis. • Electrolyte disorder. • Myocardial infarction. • Other congenital heart defects. • Lyme disease. • Chagas disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Advanced second-degree AV block. • Atrial standstill. • Accelerated idioventricular rhythm.

CBC/BIOCHEMISTRY/URINALYSIS
• Abnormal serum electrolytes (e.g., hyperkalemia, hypokalemia) possible. • High white blood cell count with left shift in animals with bacterial endocarditis.

OTHER LABORATORY TESTS
• High serum digoxin concentration if AV block due to digoxin toxicity. • Lyme titer and accompanying clinical signs if AV block due to Lyme disease.

IMAGING
Echocardiography and Doppler ultrasound to assess cardiac structure and function.

DIAGNOSTIC PROCEDURES
• Electrocardiography. • His bundle electrogram to determine the site of the AV block is possible. • Long-term (Holter) ambulatory recording if AV block is intermittent.

PATHOLOGIC FINDINGS
Degeneration or fibrosis of the AV node and its bundle branches, associated with endocardial and myocardial fibrosis and organized endomyocarditis.

TREATMENT

APPROPRIATE HEALTH CARE
• Temporary or permanent cardiac pacemaker—only effective treatment in symptomatic patients. • Carefully monitor asymptomatic patients without a pacemaker for development of clinical signs.

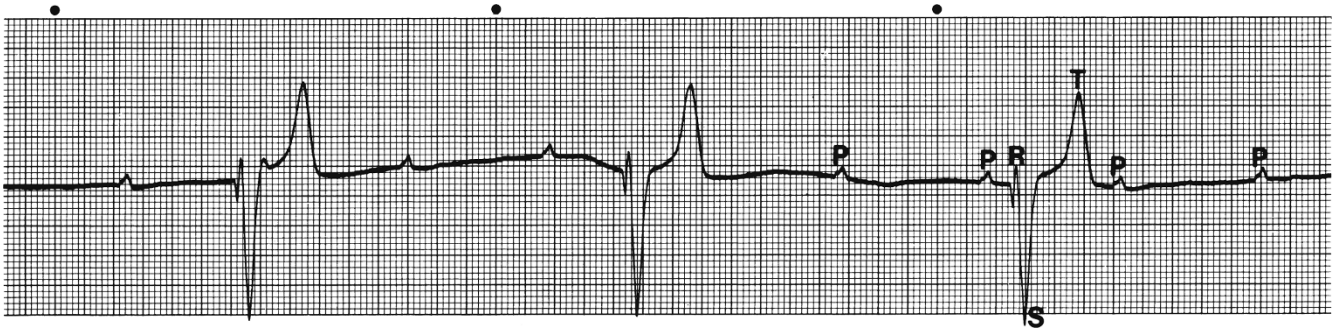

Figure 1.

Complete heart block in a dog. The P waves occur at a rate of 120, independent of the ventricular rate of 50. The QRS configuration is a right bundle branch block pattern. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

(CONTINUED) # ATRIOVENTRICULAR BLOCK, COMPLETE (THIRD DEGREE)

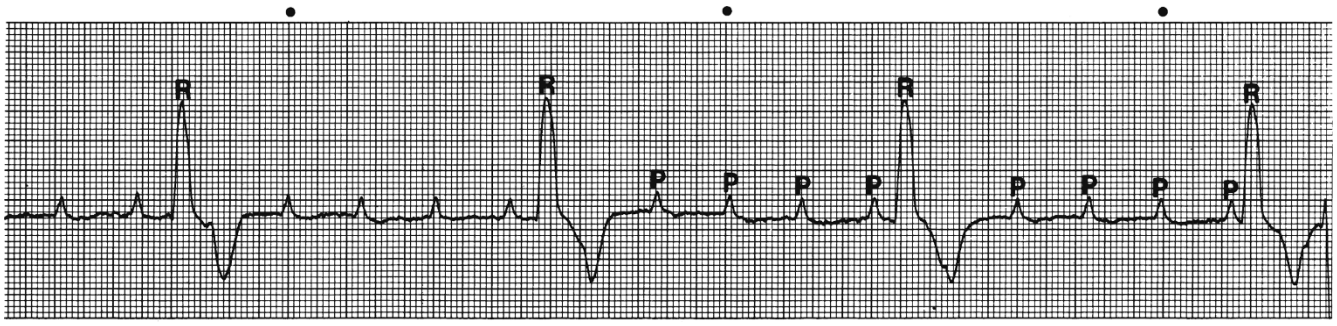

Figure 2.

Complete heart block in a cat. The P wave rate is 240/minute, independent of the ventricular rate of 48/minute. QRS configuration is a left bundle branch block pattern. (Source: From Tilley LP. Essentials of Canine and Feline Electrocardiography, 3rd ed. Baltimore: Williams & Wilkins, 1992. Reprinted with permission of Wolters Kluwer.)

NURSING CARE
Cage rest prior to pacemaker implantation; when the pulse generator is implanted into a subcutaneous pocket, a nonconstricting bandage is placed around the ventral neck or abdomen for 3–5 days to prevent seroma formation or pacemaker movement.

ACTIVITY
Restrict if symptomatic.

DIET
No modifications unless required to manage underlying condition (e.g., low-salt diet).

CLIENT EDUCATION
• Temporary or permanent cardiac pacemaker—only effective treatment in symptomatic patients. • Asymptomatic patients without a pacemaker—must be carefully monitored for development of clinical signs.

SURGICAL CONSIDERATIONS
• Most patients—at high anesthetic cardiopulmonary risk; usually paced preoperatively with a temporary external pacemaker system. • The small size of cats makes pacemaker implantation more difficult than in dogs.

MEDICATIONS

DRUG(S) OF CHOICE
• Treatment with drugs—usually of no value. Traditionally used to treat complete AV block: atropine, isoproterenol, corticosteroids, and dobutamine. • Intravenous isoproterenol infusion may help increase the rate of the ventricular escape rhythm to stabilize hemodynamics. • If CHF—diuretic and vasodilator therapy may be needed before pacemaker implantation.

CONTRAINDICATIONS
Avoid digoxin, xylazine, acepromazine, beta blockers (e.g., propranolol and atenolol), and calcium channel blockers (e.g., verapamil and diltiazem); ventricular antiarrhythmic agents are dangerous because they suppress lower escape foci.

PRECAUTIONS
Vasodilators—may cause hypotension in animals with complete AV block; monitor closely if used, especially prior to pacemaker implantation.

FOLLOW-UP

PATIENT MONITORING
• Monitor—pacemaker function with serial electrocardiograms. • Radiographs—following pacemaker implantation, to confirm the position of the lead and generator.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Pulse generators—pacemaker replacement necessary if battery becomes depleted, pulse generator malfunction occurs, or exit block develops; pacemaker leads can become dislodged and infected.

EXPECTED COURSE AND PROGNOSIS
Poor long-term prognosis if no cardiac pacemaker implanted, especially when the animal has clinical signs. Cats can sometimes survive >1 year without a permanent pacemaker.

MISCELLANEOUS

ASSOCIATED CONDITIONS
None

ABBREVIATIONS
• AV = atrioventricular.
• CHF = congestive heart failure.

A

ATRIOVENTRICULAR BLOCK, FIRST DEGREE

BASICS

DEFINITION
Refers to a delay in conduction that occurs between atrial and ventricular activation.

ECG Features
- Rate and rhythm—usually normal.
- Usually there are regularly occurring normal P waves and QRS complexes (Figures 1 and 2).
- Prolonged, consistent PR intervals—dogs, >0.13 sec; cats, >0.09 sec (Figures 1 and 2).

PATHOPHYSIOLOGY
- Virtually never causes clinical signs.
- May become a more severe atrioventricular (AV) conduction disturbance in some animals.
- Normally the PR interval tends to shorten with rapid heart rates.
- May be the result of intra-atrial conduction delay (prolongation of the PA interval on surface ECG and simultaneous His bundle electrogram) or delay of conduction within the AV node itself (prolongation of the AH interval on His bundle electrogram).

SYSTEMS AFFECTED
Cardiovascular

GENETICS
N/A

INCIDENCE/PREVALENCE
Common

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT

Species
Dog and cat.

Breed Predilections
American cocker spaniel, dachshund, brachycephalic dogs, Persian cats.

Mean Age and Range
- May occur in young, otherwise healthy dogs as a manifestation of high vagal tone.
- Intra-atrial conduction delay involving the right atrium may be seen with congenital heart disease, especially AV septal defects.
- May be noted in aged patients with degenerative conduction system disease, particularly cocker spaniels and dachshunds.
- Persian cats of any age with high vagal tone and in cats of any age with hypertrophic cardiomyopathy.

SIGNS

Historical Findings
- Most animals are asymptomatic.
- If drug induced, may have a history of clinical signs related to drug toxicity—anorexia, vomiting, and diarrhea with digoxin; weakness with calcium channel blockers or β-adrenergic antagonists.

Physical Examination Findings
Normal—unless also signs of more generalized myocardial disease, drug toxicity, or noncardiac disease.

CAUSES
- May occur in normal animals.
- Enhanced vagal stimulation resulting from noncardiac diseases—usually accompanied by sinus arrhythmia, sinus arrest, and/or Mobitz type I second-degree AV block.
- Pharmacologic agents—e.g., digoxin, β-adrenergic antagonists, calcium channel blocking agents, propafenone, amiodarone, α_2-adrenergic agonists, parasympathomimetic agents (bethanechol, physostigmine, pilocarpine), and severe procainamide or quinidine toxicity.
- Degenerative disease of the conduction system.
- Hypertrophic cardiomyopathy.
- Myocarditis (especially *Trypanosoma cruzi*, *Borrelia burgdorferi*, *Rickettsia rickettsii*).
- Infiltrative diseases (tumors, amyloid).
- Atropine administered intravenously may briefly prolong the PR interval.

RISK FACTORS
Any condition or intervention that raises vagal tone.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
P waves superimposed upon preceding T waves because of first-degree AV block should be differentiated from bifid T waves.

CBC/BIOCHEMISTRY/URINALYSIS
- Serum electrolytes—hypokalemia and hyperkalemia may predispose to AV conduction disturbances.
- Leukocytosis—may be noted with bacterial endocarditis or myocarditis.

OTHER LABORATORY TESTS
- Serum digoxin concentration—may be high.
- *T. cruzi*, *B. burgdorferi*, *R. rickettsii* titers—may be high.
- Thyroxine (T_4)—may be high in cats if associated with thyrotoxic myocardial disease.

IMAGING
Echocardiographic examination—may reveal hypertrophic or infiltrative myocardial disorder.

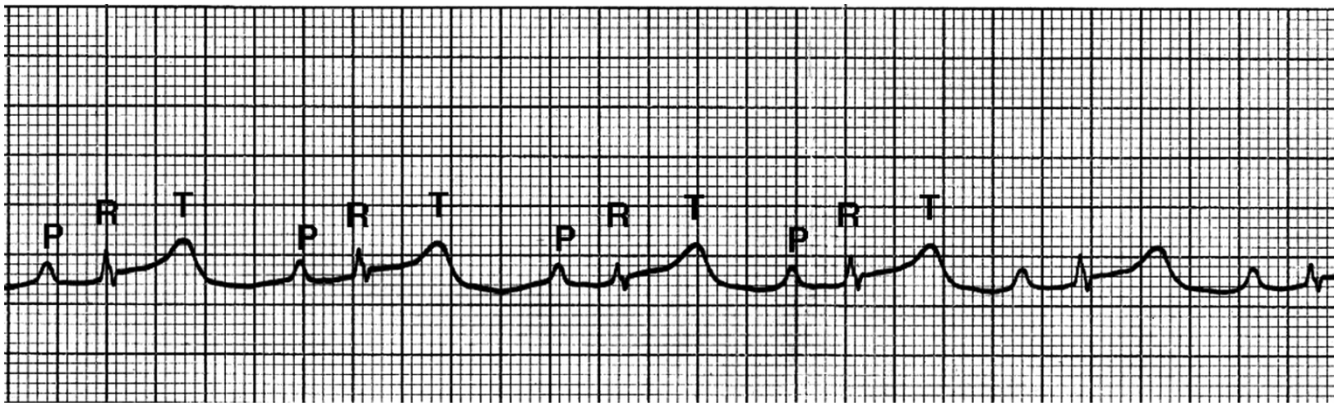

Figure 1.

Lead II ECG rhythm strip recorded from a cat with hypertrophic cardiomyopathy. There is sinus bradycardia (120 bpm) and first-degree AV conduction block. The PR interval is 0.12 second (paper speed = 50 mm/s).

(CONTINUED) # ATRIOVENTRICULAR BLOCK, FIRST DEGREE

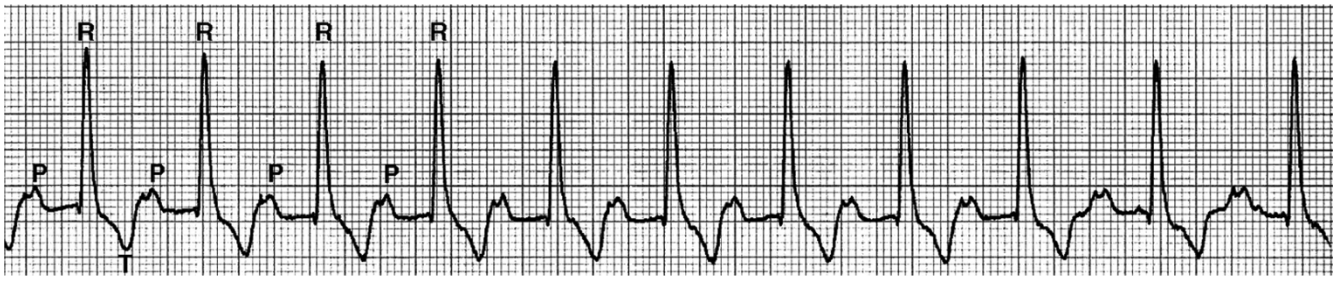

Figure 2.

Lead II ECG rhythm strip recorded from a dog showing sinus tachycardia (175 bpm) and first-degree AV conduction block. Because the heart rate is rapid, P waves are superimposed on the downslope of the preceding T waves. The PR interval exceeds 0.16 second (paper speed = 50 mm/s).

DIAGNOSTIC PROCEDURES
May be needed to identify causes of high vagal tone—upper airway disease, cervical and thoracic masses, gastrointestinal disorders, and high intraocular pressure.

PATHOLOGIC FINDINGS
Variable—depend on underlying cause.

TREATMENT

APPROPRIATE HEALTH CARE
- Remove or treat underlying cause(s).
- Hospitalization may be necessary to manage the underlying cause (e.g., cardiomyopathy, gastrointestinal disease, airway disease).

NURSING CARE
N/A

ACTIVITY
Unrestricted; unless restriction required for an underlying condition.

DIET
No modifications or restrictions, unless required to manage an underlying condition.

CLIENT EDUCATION
Generally unnecessary.

SURGICAL CONSIDERATIONS
None, unless required to manage an underlying condition.

MEDICATIONS

DRUG(S) OF CHOICE
Medications used only if needed to manage an underlying condition.

CONTRAINDICATIONS
- Avoid hypokalemia—increases sensitivity to vagal tone; may potentiate AV conduction delay.
- Avoid drugs likely to impair impulse conduction further (calcium channel blocking agents, β-adrenergic antagonists, α_2-adrenergic agonists, amiodarone, propafenone).

PRECAUTIONS
Drugs with vagomimetic action (e.g., digoxin, bethanechol, physostigmine, pilocarpine) may potentiate first-degree block.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Except in healthy young animals, monitor ECG to detect any progression in conduction disturbance.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
- Depends on underlying cause.
- Prognosis usually excellent if no significant underlying disease is present.

MISCELLANEOUS

ASSOCIATED CONDITIONS
None

AGE-RELATED FACTORS
PR interval—tends to lengthen with advancing age.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
N/A

A

ATRIOVENTRICULAR BLOCK, SECOND DEGREE—MOBITZ TYPE I

BASICS

DEFINITION
Second-degree atrioventricular (AV) block refers to failure of one or more P waves but not all P waves to be conducted. Mobitz type I second-degree AV block occurs when AV transmission is progressively delayed prior to a blocked P wave.

ECG Features
- PR interval—becomes progressively longer prior to the appearance of a P wave that is not followed by a QRS complex (Figure 1).
- Heart rate and QRS morphology—usually normal.
- Often cyclic.

PATHOPHYSIOLOGY
- Frequently associated with high resting vagal tone and sinus arrhythmia in dogs.
- Generally not pathologic or hemodynamically significant.
- This type of AV block usually results from conduction delay within the AV node itself (rather than delay in other segments of the AV conducting system) and is characterized by a progressive increase in AH interval, with eventual block between the A and H deflections on a His bundle recording.

SYSTEMS AFFECTED
Cardiovascular

GENETICS
N/A

INCIDENCE/PREVALENCE
Radiotelemetry studies have shown that this arrhythmia occurs in 64% of healthy adult dogs and 100% of healthy puppies 8–12 weeks of age.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog; uncommon in cat.

Breed Predilections
N/A

Mean Age and Range
- Usually occurs in young, otherwise healthy dogs as a manifestation of high vagal tone.
- Occasionally occurs in older dogs with abnormally strong vagal tone.
- Rarely noted in old dogs with degenerative conduction system disease.

SIGNS

Historical Findings
- Most animals are asymptomatic.
- If drug induced, owner may report signs of drug toxicity—anorexia, vomiting, and diarrhea with digoxin; weakness with calcium channel blockers or β-adrenergic antagonists.
- If heart rate is abnormally slow, syncope or weakness may occur.

Physical Examination Findings
- May be normal unless signs of more generalized myocardial disease or noncardiac disease are present.
- Intermittent pauses in the cardiac rhythm.
- First heart sound may become progressively softer, followed by a pause.
- An audible S4 may be heard unaccompanied by S1 and S2 when block occurs.

CAUSES
- Occasionally noted in normal animals.
- Enhanced vagal stimulation resulting from noncardiac diseases—usually accompanied by sinus arrhythmia, sinus arrest.
- Pharmacologic agents—digoxin, β-adrenergic antagonists, calcium channel blocking agents, propafenone, amiodarone, α_2-adrenergic agonists, opioids.

RISK FACTORS
Any condition or intervention that enhances vagal tone.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Nonconducted P waves from supraventricular premature impulses or supraventricular tachycardias should be distinguished from second-degree AV block.
- Type II second-degree AV block (no variation in PR intervals).

CBC/BIOCHEMISTRY/URINALYSIS
Hypokalemia may predispose to AV conduction disturbances.

OTHER LABORATORY TESTS
Serum digoxin concentration—may be high.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- May be necessary to identify specific causes of enhanced vagal tone (e.g., upper airway disease, cervical and thoracic masses, gastrointestinal disorders, and high intraocular pressure).
- Atropine response test—administer 0.04 mg/kg atropine IM and repeat ECG in 20–30 minutes; may be used to determine whether AV block is due to vagal tone; resolution of AV block with atropine supports vagal cause.
- Electrophysiologic studies are generally unnecessary, but will confirm this type of second-degree AV block if surface ECG is equivocal.

PATHOLOGIC FINDINGS
Generally, no gross or histopathologic findings.

TREATMENT

APPROPRIATE HEALTH CARE
- Treatment usually unnecessary.
- Treat or remove underlying cause(s).

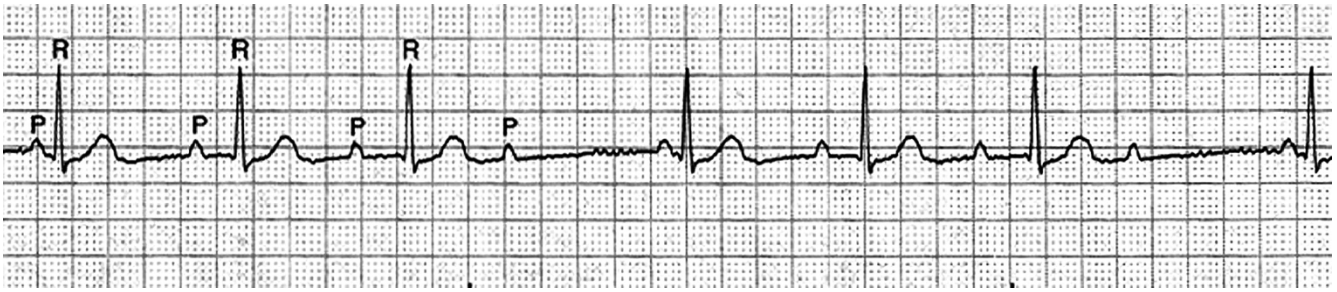

Figure 1.

Lead II ECG strip recorded from a dog with Mobitz type I, second-degree AV block. The PR intervals become progressively longer, with the longest PR intervals preceding nonconducted P waves (typical Wenckebach phenomenon) (paper speed = 50 mm/s).

(CONTINUED) ATRIOVENTRICULAR BLOCK, SECOND DEGREE—MOBITZ TYPE I

NURSING CARE
Generally unnecessary.

ACTIVITY
Unrestricted

DIET
Modifications or restrictions only to manage an underlying condition.

CLIENT EDUCATION
Explain that any treatment is directed toward reversing or eliminating an underlying cause.

SURGICAL CONSIDERATIONS
N/A except to manage an underlying condition.

MEDICATIONS

DRUG(S) OF CHOICE
Only as needed to manage an underlying condition.

CONTRAINDICATIONS
Drugs with vagomimetic action (e.g., digoxin, bethanechol, physostigmine, pilocarpine) may potentiate block.

PRECAUTIONS
Hypokalemia increases the sensitivity to vagal tone and may potentiate AV conduction delay.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Typically not necessary.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
N/A

ATRIOVENTRICULAR BLOCK, SECOND DEGREE—MOBITZ TYPE II

BASICS

DEFINITION
Second-degree atrioventricular (AV) block refers to failure of one or more P waves, but not all P waves, to be conducted. Mobitz type II second-degree AV block occurs when one or more P waves are blocked without a preceding progressive delay in AV transmission.

ECG Features
- One or more P waves not followed by a QRS complex; PR interval is constant, but may be either normal or consistently prolonged (Figure 1).
- Ventricular rate—usually slow.
- Fixed ratio of P waves to QRS complexes may occur (e.g., 2 : 1, 3 : 1, 4 : 1 AV block).
- High-grade (advanced) second-degree AV block is characterized by two or more consecutively blocked P waves.
- In second-degree AV block with a 2 : 1 conduction ratio or higher, it is impossible to observe prolongation of the PR interval before the block, so a designation of Mobitz type I vs. II is not appropriate.
- QRS complexes may appear normal, but may also be wide or have an abnormal morphology due to aberrant intraventricular conduction or ventricular enlargement.
- Abnormally wide QRS complexes may indicate serious, extensive cardiac disease.

PATHOPHYSIOLOGY
- Rare in healthy animals.
- May be hemodynamically important when ventricular rate is abnormally slow.
- May progress to complete AV block, particularly when accompanied by wide QRS complexes.
- Typically this type of AV block results from conduction delay within the AV node itself (rather than delay in another segment of the AV conducting system) that is characterized by normal or prolonged AH intervals, with intermittent block between A and H deflections on a His bundle electrogram.

SYSTEMS AFFECTED
- Cardiovascular.
- Central nervous or musculoskeletal systems if inadequate cardiac output.

GENETICS
May be heritable in pugs.

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
American cocker spaniel, pug, dachshund, Airedale terrier, Doberman pinscher.

Mean Age and Range
Generally occurs in older animals.

Predominant Sex
N/A

SIGNS

Historical Findings
- Presenting complaint may be syncope, collapse, weakness, or lethargy.
- Some animals are asymptomatic.
- Animals may show signs of the underlying disease process if present.

Physical Examination Findings
- ± weakness.
- Bradycardia common.
- May be intermittent pauses in the cardiac rhythm.
- An S4 may be audible in lieu of the normally expected heart sounds (i.e., S1, S2) when the block occurs.
- If associated with digoxin intoxication, there may be vomiting, anorexia, and diarrhea.
- May be other abnormalities reflecting the underlying etiology.

CAUSES
- Heritable in pugs.
- Enhanced vagal stimulation from noncardiac diseases.
- Degenerative change within the cardiac conduction system—replacement of AV nodal cells and/or Purkinje fibers by fibrotic and adipose tissue in old cats and dogs.
- Pharmacologic agents (e.g., digoxin, β-adrenergic antagonists, calcium channel blocking agents, propafenone, α_2-adrenergic agonists, muscarinic cholinergic agonists, or severe procainamide or quinidine toxicity).
- Infiltrative myocardial disorders (neoplasia, amyloid).
- Endocarditis (particularly involving the aortic valve).
- Myocarditis (viral, bacterial, parasitic, idiopathic).
- Cardiomyopathy (especially in cats).
- Trauma.
- Atropine administered intravenously may cause a brief period of first- or second-degree heart block before increasing the heart rate.

RISK FACTORS
Any condition or intervention that enhances vagal tone.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- High-grade (advanced) form must be distinguished from complete AV block.
- Nonconducted P waves arising from refractoriness of the conduction system during supraventricular tachycardias must be differentiated from pathologic conduction block.

CBC/BIOCHEMISTRY/URINALYSIS
- Serum electrolytes—hypokalemia and hyperkalemia may predispose to AV.
- Conduction disturbances.
- Leukocytosis—may be noted with bacterial endocarditis or myocarditis.
- Electrolyte abnormalities (e.g., severe hypokalemia, hyperkalemia, or hypercalcemia) may predispose to AV block.

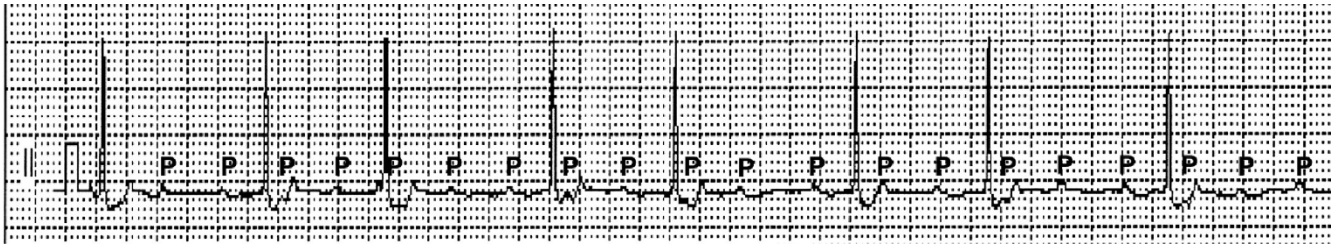

Figure 1.

Lead II ECG rhythm strip recorded from a dog with both first- and second-degree AV block. The second-degree AV block is high grade, with both 2 : 1 and 3 : 1 block resulting in variation in the RR intervals. The PR interval for the conducted beats is prolonged but constant (0.28 second) (paper speed = 25 mm/s).

(CONTINUED) ATRIOVENTRICULAR BLOCK, SECOND DEGREE—MOBITZ TYPE II

OTHER LABORATORY TESTS
- Serum digoxin concentration—may be high.
- High thyroxine (T_4) in cats—if associated with hyperthyroidism.
- High arterial blood pressure—if associated with hypertensive heart disease.
- Positive *Borrelia*, *Rickettsia*, or *Trypanosoma cruzi* titers—if associated with one of these infectious agents.
- Blood cultures may be positive in patients with vegetative endocarditis.

IMAGING
Echocardiographic examination may reveal structural heart disease (e.g., endocarditis, neoplasia, or cardiomyopathy).

DIAGNOSTIC PROCEDURES
- Atropine response test—administer 0.04 mg/kg atropine IM and repeat ECG in 20–30 minutes; may be used to determine whether AV block is due to high vagal tone.
- Electrophysiologic testing is generally unnecessary, but can be done to confirm this type of AV block if surface ECG findings are equivocal.

PATHOLOGIC FINDINGS
- Variable—depend on underlying cause.
- Old animals with degenerative change of the conduction system may have focal mineralization of the interventricular septal crest visible grossly; chondroid metaplasia of the central fibrous body and increased fibrous connective tissue in the AV bundle is noted histopathologically.

TREATMENT

APPROPRIATE HEALTH CARE
- Treatment—may be unnecessary if heart rate maintains adequate cardiac output.
- Positive dromotropic interventions are indicated for symptomatic patients.
- Treat or remove underlying cause(s).

NURSING CARE
Generally unnecessary.

ACTIVITY
Cage rest advised for symptomatic patients.

DIET
Modifications or restrictions only to manage an underlying condition.

CLIENT EDUCATION
- Need to seek and specifically treat underlying cause.
- Pharmacologic agents may not be effective long term.

SURGICAL CONSIDERATIONS
Permanent pacemaker may be required for long-term management of symptomatic patients.

MEDICATIONS

DRUG(S) OF CHOICE
- Atropine (0.02–0.04 mg/kg IV/IM) or glycopyrrolate (5–10 µg/kg IV/IM) may be used short term if positive atropine response.
- Chronic anticholinergic therapy (propantheline 0.5–2 mg/kg PO q8–12h or hyoscyamine 3–6 µg/kg q8h)—indicated for symptomatic patients if improved AV conduction with atropine response test.
- Isoproterenol (0.04–0.09 µg/kg/min IV to effect) or dopamine (2–5 µg/kg/min IV to effect) may be administered in acute, life-threatening situations to enhance AV conduction and/or accelerate an escape focus.

CONTRAINDICATIONS
- Drugs with vagomimetic action (e.g., digoxin, bethanechol, physostigmine, pilocarpine) may potentiate block.
- Avoid drugs likely to impair impulse conduction further or depress a ventricular escape focus (e.g., procainamide, quinidine, lidocaine, calcium channel blocking agents, β-adrenergic blocking agents).

PRECAUTIONS
Hypokalemia—increases sensitivity to vagal tone and may potentiate AV conduction delay.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Periodic ECG because risk of progression to complete (third-degree) AV block.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Prolonged bradycardia may cause secondary congestive heart failure or inadequate renal perfusion.

EXPECTED COURSE AND PROGNOSIS
Variable—depends on cause. If degenerative disease of the cardiac conduction system, often progresses to complete (third-degree) AV block.

MISCELLANEOUS

ASSOCIATED CONDITIONS
May be noted in cats with primary or secondary myocardial disease.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
N/A

SEE ALSO
- Atrioventricular Block, Complete (Third Degree).
- Atrioventricular Block, Second Degree—Mobitz Type I.

A

ATRIOVENTRICULAR VALVE DYSPLASIA

BASICS

DEFINITION
A congenital malformation of the mitral or tricuspid valve apparatus.

PATHOPHYSIOLOGY
• Atrioventricular valve dysplasia (AVVD) can result in valvular insufficiency, valvular stenosis, or dynamic outflow tract obstruction, depending on the anatomic abnormality. AVVD may occur alone or in association with abnormalities of the ipsilateral outflow tract (e.g., valvular or subvalvular aortic or pulmonic stenosis). It is not uncommon for mitral and tricuspid valve dysplasia to occur together in the same patient.
• Valvular insufficiency results in ipsilateral atrial dilation, eccentric hypertrophy of the associated ventricle, and, if severe, signs of congestive heart failure (CHF). Cardiomyopathy of chronic volume overload and elevated atrial pressures are the end result, culminating in pulmonary congestion (with mitral valve dysplasia [MVD]) or systemic congestion (with tricuspid valve dysplasia [TVD]).
• Valvular stenosis results in atrial dilation and hypertrophy and, if severe, hypoplasia of the receiving ventricle. The end result is atrial pressure elevation, also resulting in pulmonary congestion (mitral stenosis) or systemic congestion (tricuspid stenosis). Right-to-left shunting may occur in cases of tricuspid stenosis if there is an atrial septal defect or patent foramen ovale. Pulmonary hypertension is a common complication in animals with mitral valve stenosis.
• Dynamic outflow tract obstruction may occur in patients with MVD, with resultant concentric left ventricular (LV) hypertrophy that is proportional to the severity of the obstruction.
• Ebstein's anomaly is a rare form of TVD, characterized by apical displacement of the basal tricuspid leaflet attachments and resultant right atrial (RA) enlargement, with a small right ventricle ("atrialized" right ventricle). It can be accompanied by varying degrees of insufficiency or stenosis.

SYSTEMS AFFECTED
• Cardiovascular—chronic volume overload from valvular insufficiency and/or inflow obstruction due to valvular stenosis result in elevated pulmonary (MVD) or systemic (TVD) venous pressures.
• Respiratory—pulmonary edema may develop secondary to MVD; pulmonary hypertension is a common complication in animals with mitral stenosis.
• Neurologic—collapse and/or loss of consciousness, most often with exercise, may occur with severe disease due to low cardiac output/hypotension or ventricular arrhythmias in cases with severe dynamic outflow obstruction.

GENETICS
TVD appears to be inherited as an autosomal recessive trait in dogues de Bordeaux and an autosomal dominant with incomplete penetrance trait in Labrador retrievers.

INCIDENCE/PREVALENCE
These are common congenital cardiac anomalies in cats (17% of reported congenital cardiac defects in one study). Mitral valve malformations often are noted in cats with hypertrophic cardiomyopathy. Less frequently diagnosed in dogs.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• TVD—increased risk for Labrador retriever, German shepherd dog, great Pyrenees, possibly Old English sheepdog; also common in cats.
• MVD—increased risk in bull terrier, Newfoundland, Labrador retriever, Great Dane, golden retriever, Dalmatian, and Siamese cat.

Mean Age and Range
Variable; signs most often manifest within the first few years after birth.

Predominant Sex
Males are more likely to experience CHF.

SIGNS

Historical Findings
• Exercise intolerance.
• Abdominal distention, weight loss, and stunting may be observed with severe TVD.
• Labored respiration common with severe MVD.
• Syncope and collapse if critical atrioventricular (AV) valve stenosis, severe outflow tract obstruction, associated arrhythmias, or CHF.

Physical Examination Findings
• A holosystolic murmur is heard over the ipsilateral cardiac apex. In severe cases the murmur is accompanied by a thrill or gallop heart sounds. In animals with valvular stenosis, a soft diastolic murmur may be present in the same location, but many have no audible murmur. A labile systolic ejection murmur may be audible in animals with dynamic outflow tract obstruction. Silent tricuspid regurgitation is well documented in cats with a large regurgitant orifice and laminar regurgitant flow.
• Jugular venous distension/pulsation may be evident in patients with TVD.
• Evidence of left CHF (tachypnea, dyspnea, pulmonary crackles, cyanosis) in animals with severe MVD.
• Evidence of right CHF (ascites, peripheral edema) with severe TVD.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Except for age of onset, congenital AV valve insufficiency resembles acquired degenerative AV valve insufficiency with regard to history, physical examination findings, and clinical sequelae.
• The right-sided murmur of tricuspid insufficiency may be confused with the right-sided murmur of a ventricular septal defect.
• Ascites caused by silent tricuspid regurgitation or tricuspid valve stenosis is often attributed to pericardial effusion, hepatic disease, or caudal vena caval obstruction.
• Dogs and cats with cor triatriatum share many of the clinical features of AV valve stenosis.
• There is no certain way to distinguish outflow tract obstruction due to MVD and obstructive hypertrophic cardiomyopathy. If the obstruction can be abolished with adrenergic beta blockers and LV hypertrophy resolves, it is likely that the primary abnormality was MVD.

IMAGING

Radiographic Findings
• Ipsilateral atrial and ventricular enlargement with valvular insufficiency. Isolated atrial enlargement with valvular stenosis. Mild left atrial (LA) enlargement with dynamic LV outflow obstruction. Cardiac silhouette may appear globoid with pronounced enlargement in cases of severe TVD.
• Evidence of left CHF—distended pulmonary veins, interstitial or alveolar edema in severe MVD.
• Evidence of right CHF—dilated caudal vena cava, hepatosplenomegaly, or ascites in severe TVD.

Echocardiography
• Valvular insufficiency results in ipsilateral atrial dilation and eccentric ventricular hypertrophy. Doppler echocardiography demonstrates a high velocity retrograde systolic jet and modestly increased transmitral or transtricuspid inflow velocities.
• Valvular stenosis results in ipsilateral atrial dilation, while the associated ventricular dimensions are normal or small. Valve leaflets are often thickened, relatively immobile, and fused. Doppler echocardiography demonstrates a high-velocity transmitral or transtricuspid diastolic jet with a reduced EF slope. There may also be evidence of concurrent AV valvular insufficiency, secondary pulmonary hypertension (in cases of mitral stenosis), or right-to-left shunting across a patent foramen ovale or associated atrial septal defect (in cases of tricuspid stenosis).

• With MVD, the LV papillary muscles are typically flattened and displaced dorsally. Chordae tendineae are often short and thickened. With TVD, papillary muscles and chordae tendineae may be fused, creating a curtain-like appearance of the tricuspid valve.
• Dynamic LV outflow obstruction in patients with MVD is characterized by systolic motion of the anterior mitral leaflet toward the interventricular septum, increased LV outflow tract velocities, eccentric mitral regurgitation, and concentric LV hypertrophy.

Cardiac Catheterization

• Indicated only for cases in which diagnosis cannot be confirmed by echocardiography or if surgical correction anticipated.
• Hemodynamic measurements should include ipsilateral atrial and ventricular pressures. Additional measurements in cases of MVD include pulmonary capillary wedge pressure (in lieu of direct LA pressure measurement), pulmonary artery pressures, and, in cases of dynamic obstruction, simultaneous aortic and LV pressure recording with medical provocation. Contrast studies are best performed with ventricular injection in cases of valvular insufficiency, and direct atrial injection in cases of valvular stenosis.

DIAGNOSTIC PROCEDURES

ECG

• Findings usually reflect pattern of chamber enlargement.
• Severe defects may be accompanied by arrhythmias, particularly atrial premature beats, supraventricular tachycardia, or atrial fibrillation.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient treatment required for CHF.

DIET

Sodium restricted if overt or pending CHF.

CLIENT EDUCATION

Owners should be informed of heritability and advised against breeding.

SURGICAL CONSIDERATIONS

• Valve repair or replacement is available in a few centers.
• Balloon valvuloplasty is sometimes effective for valvular stenosis.

MEDICATIONS

DRUG(S) OF CHOICE

• For patients with CHF, furosemide (1–4 mg/kg q12–24h) and enalapril (0.5 mg/kg q12h) are used to control congestion, with the addition of pimobendan (0.3 mg/kg q12h) in cases of valvular insufficiency.
• Supraventricular tachyarrhythmias may be managed using digoxin (2–4 µg/kg q12h), a calcium channel blocker such as diltiazem (1–1.5 mg/kg q8h), or a beta blocker such as atenolol (0.5–1.5 mg/kg q12–24h). Heart rate should be maintained below 150 bpm.
• For dynamic outflow tract obstruction, beta blockers such as atenolol (0.5–1.5 mg/kg q12–24h) may be used to abolish or diminish severity of outflow obstruction; however, benefit has not been proven.

PRECAUTIONS

Standard patient monitoring for cardiac medication side effects (e.g., digitalis toxicity, azotemia).

FOLLOW-UP

PATIENT MONITORING

• Recheck yearly if no signs of CHF.
• Recheck every 3 months if signs of CHF (consider thoracic radiographs, ECG, and echocardiography).

PREVENTION/AVOIDANCE

Do not breed affected animals.

POSSIBLE COMPLICATIONS

• CHF—left-sided with MVD; right-sided with TVD.
• Collapse or syncope with exercise.
• Paroxysmal supraventricular tachycardia or atrial fibrillation with severe disease.

EXPECTED COURSE AND PROGNOSIS

• Depends on severity of underlying defect.
• Guarded to poor with serious defects.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• MVD commonly accompanies valvular or subvalvular aortic stenosis as well as TVD.
• TVD commonly accompanies pulmonic stenosis as well as MVD.

PREGNANCY/FERTILITY/BREEDING

Breeding should be avoided—heritable defect and possibility of causing decompensated or worsening CHF.

SEE ALSO

• Congestive Heart Failure, Left-Sided.
• Congestive Heart Failure, Right-Sided.

ABBREVIATIONS

• AV = atrioventricular.
• AVVD = atrioventricular valve dysplasia.
• CHF = congestive heart failure.
• LA = left atrial.
• LV = left ventricular.
• MVD = mitral valve dysplasia.
• RA = right atrial.
• TVD = tricuspid valve dysplasia.

A

ATRIOVENTRICULAR VALVULAR STENOSIS

BASICS

DEFINITION
Atrioventricular (AV) valvular stenosis is a pathologic narrowing of the mitral or tricuspid valve orifice or the presence of an obstructive, supravalvular ring.

PATHOPHYSIOLOGY
- AV stenosis increases the resistance to ventricular filling.
- Ventricular filling in clinically significant disease requires a persistent diastolic pressure gradient between atrium and ventricle.
- Concomitant valvular regurgitation is common.
- The increased atrial pressure leads to atrial dilation, venous congestion, and often to congestive heart failure (CHF). Pulmonary edema occurs with mitral stenosis (MS); whereas ascites, pleural effusion, and chylothorax can develop in cases of severe tricuspid stenosis (TS).
- The foramen ovale can remain patent (PFO) in patients with TS, allowing right-to-left shunting with signs of cyanotic heart disease.
- Partial AV septal defect (primum atrial septal defect [ASD] and abnormal AV valve) is observed in some cats with supravalvular mitral (ring) stenosis.
- Cardiac output and therefore exercise capacity are limited.
- The atrial pressure increases disproportionally with faster heart rates, thereby creating the risk for "flash" pulmonary edema in dogs or cats with MS.
- Development of atrial tachyarrhythmias, especially atrial fibrillation (AF), is associated with cardiac decompensation.
- Pulmonary hypertension (PH) can develop consequent to MS, leading to exercise intolerance and right ventricular hypertrophy. This can be severe, especially in cats.

SYSTEMS AFFECTED
- Respiratory—with MS: bronchial compression from enlarged left atrium, pulmonary edema from left heart failure; potential for hemoptysis due to rupture of pulmonary venous–bronchial venous connections; pleural effusion with atelectasis in TS or in long-standing MS complicated by PH or AF.
- Hepatobiliary—with TS: hepatic congestion, ascites.

GENETICS
- Uncertain in most cases.
- Tricuspid valve dysplasia in Labrador retrievers has been localized to a defect in dog chromosome 9, inherited as an autosomal dominant trait with reduced penetrance. In dogue de Bordeaux, tricuspid valve dysplasia has been identified as an autosomal recessive trait.

INCIDENCE/PREVALENCE
Rare

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Dog and cat.

Breed Predilections
- MS is overrepresented in bull terriers and Newfoundlands, and in Siamese cats.
- TS has been reported most often in Old English sheepdogs and Labrador retrievers.

Mean Age and Range
Most patients are presented at a young age, although exceptions occur, especially in cats.

Predominant Sex
N/A

SIGNS
Historical Findings
- Exercise intolerance.
- Syncope.
- Exertional dyspnea or tachypnea.
- Cough—MS.
- Cyanosis.
- Abdominal distention—TS.
- Acute posterior paresis—cats with MS and arterial thromboembolism.
- Stunted growth.
- Hemoptysis from rupture of intrapulmonary vessels—MS.

Physical Examination Findings
- Soft diastolic murmur with point of maximal intensity over left apex (MS) or right hemithorax (TS).
- Holosystolic murmur of mitral or tricuspid regurgitation is more often detected.
- Tachypnea, dyspnea from pulmonary edema or pleural effusion.
- Crackles from pulmonary edema.
- Jugular distention, jugular pulses, ascites, hepatomegaly with TS, or biventricular CHF associated with pulmonary hypertension and AF in chronic MS.
- Cyanosis from right-to-left shunting with TS and PFO or from pulmonary edema with MS.

CAUSES
- Usually due to congenital dysplasia of mitral or tricuspid valve.
- Supravalvular obstructing rings of tissue have been associated with AV stenosis; this is especially important in cats.
- Infective endocarditis, intracardiac neoplasia, and hypertrophic cardiomyopathy with scarring are rare causes of acquired AV valve stenosis.
- Acquired TS has been observed due to fibrous scarring of the tricuspid valve in dogs with transvenous pacing leads.

RISK FACTORS
Breed predispositions (see above); see Risk Factors for Endocarditis, Infective; permanent transvenous pacing.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
AV valvular stenosis must be differentiated from the more common causes of mitral and tricuspid regurgitation in the absence of stenosis. These include both congenital and acquired lesions of the AV valves and support apparatus. Cor triatriatum dexter, cor triatriatum sinister and double outlet right atrium can mimic some of the clinical findings of pure tricuspid and mitral valvular stenosis, respectively.

CBC/BIOCHEMISTRY/URINALYSIS
May be normal or reflect changes related to CHF or drug therapy for CHF.

IMAGING
Thoracic Radiography
- Atrial enlargement is the most common and outstanding feature; may see generalized cardiomegaly, especially with AV valve regurgitation.
- MS—may see pulmonary venous congestion and pulmonary edema; intrapulmonary hemorrhage can be misinterpreted as pneumonia or another parenchymal disease.
- TS—may see hepatomegaly; increased diameter of caudal vena cava.

Echocardiography
- Diagnostic test of choice.
- Two-dimensional echocardiography reveals a markedly dilated atrium and attenuated valve excursion during diastole, often with thickened, irregular AV valve leaflets; valve leaflets may appear to "dome" during diastole (see Web Video 1). A supravalvular obstructing ring also may be evident, as well as other lesions (see Causes).
- Color-flow imaging reveals a turbulent diastolic jet that originates proximal to the stenotic valve and projects toward the apex of the ventricle (see Web Video 2); AV valve regurgitation is often present (see Web Videos 3 and 4). Concurrent defects may also be noted, such as PFO, ASD, or bridging septal leaflet (see Web Video 5).
- M-mode studies show an enlarged atrium and concordant motion of the AV valve leaflets, indicating commissural fusion (see Web Figure 1); the E-to-F slope is decreased.
- Spectral Doppler studies show increased diastolic transvalvular flow velocities; prolonged calculated pressure half-time is a hallmark feature; E-wave/A-wave amplitude reversal is often evident in cases still in normal sinus rhythm (see Web Figures 2, 3, 4).

• Right-sided chamber enlargement in MS with pulmonary hypertension or with chronic AF (see Web Figure 4).

Angiography

• Right atrium—injection demonstrates markedly dilated atrium in TS; with concurrent PFO or ASD, opacification of the left atrium is also observed following right atrial injection.
• Might visualize thickened, irregular valve leaflets or a stenotic valve funnel.
• Ventricular injection often reveals valvular regurgitation.
• There can be delayed opacification of the ventricles and great vessels.

Cardiac Catheterization

• A diastolic pressure gradient is identified between atrium and ventricle. A large "A" wave is common if atrial function is preserved.
• High left atrial, pulmonary capillary wedge, and pulmonary artery pressures occur in MS.
• High right atrial and central venous pressures are present in TS.
• Ventricular pressure may be normal in the absence of concurrent defects.

DIAGNOSTIC PROCEDURES

ECG

• Variable enlargement and ventricular conduction patterns are observed. Widened or tall P-waves are commonly observed.
• Splintered R-waves are present in some dogs with tricuspid dysplasia.
• Axis deviation due to hypertrophy or ventricular conduction disturbances is relatively common in cats with mitral valve malformation.
• Ectopic rhythms, especially of atrial origin, are often observed. AF is the most important rhythm disturbance as atrial contribution to filling is lost and the R-to-R intervals vary with short cycles, increasing the mean diastolic gradient.

PATHOLOGIC FINDINGS

• The AV valve is abnormal, with thickened leaflets and fused commissures. Other lesions may be identified such as a supramitral ring (see Causes).
• Many cases also have abnormal chordae tendineae and papillary muscles.
• Atrial dilation and hypertrophy are common.
• PFO with TS or partial AV septal defect (primum ASD and bridging septal leaflet) with supravalvular mitral (ring) stenosis.

TREATMENT

APPROPRIATE HEALTH CARE

• Patients in overt CHF should be treated with inpatient medical management.
• Surgical or catheter-based interventions can be considered once heart failure has been stabilized.
• Control of heart rhythm disturbances, especially AF, is also important.
• These patients are typically complicated and consultation with a cardiologist is highly recommended.
• Electrocardioversion of AF should be considered, but advanced atrial disease can render the procedure less effective or limit the duration of sinus rhythm.

NURSING CARE

• Sedation with butorphanol is appropriate for dyspneic patients.
• Oxygen therapy should be administered to patients with dyspnea or hypoxemia from left-sided CHF.
• Fluid therapy is typically contraindicated in patients with overt CHF, except in cases of moderate to severe azotemia, renal compromise, or severe dehydration. Therapeutic paracentesis may be considered in patients with pleural effusion or tympanic ascites.

ACTIVITY

Exercise restriction is important to recommend for any animal with this condition, because tachycardia increases the mean gradient across the stenotic valve, predisposing to pulmonary edema or venous congestion (see Web Figures 3 and 4). Cage rest is ideal for patients with CHF.

DIET

Feed a sodium-restricted diet to patients in CHF.

CLIENT EDUCATION

Clients must be advised of symptoms associated with CHF and the urgency of treatment, particularly with left-sided CHF. Likelihood of recurrent bouts of CHF should also be discussed.

SURGICAL CONSIDERATIONS

• Surgical valve replacement or repair requires cardiopulmonary bypass or hypothermia; cost, availability, and high complication and mortality rates are greatly limiting factors.
• Balloon valvuloplasty is an alternative referral treatment and has been used successfully for managing some cases of AV stenosis.

MEDICATIONS

DRUG(S) OF CHOICE

CHF

• Diuretic—Furosemide: dogs, 2–4 mg/kg IV/IM/SC/PO q8–24h; cats, 1–4 mg/kg IV/IM/SC/PO q8–24h. Torsemide: dogs, 0.2–0.5 mg/kg PO q12–24h; cats, 1.25 mg PO q12–48h.
• Angiotensin-converting enzyme (ACE) inhibitor—enalapril or benazepril: dogs, 0.25–0.5 mg/kg PO q12h; cats, 0.25–0.5 mg/kg PO q12–24h; see Follow-Up for patient monitoring.
• Nitroglycerin paste (1/4 to 1 inch topically q12h) to reduce pulmonary venous pressures, but this has not been evaluated critically.

Atrial Tachyarrhythmias

• Digoxin—dogs, 3–5 µg/kg PO q12h; cats, one-fourth of a 0.125 mg tablet PO q24–48h; adjust dosage based on serum concentrations.
• Beta blockers such as atenolol or the calcium channel blocker diltiazem for suppression of frequent atrial premature complexes and for heart rate control in atrial tachyarrhythmias such as atrial tachycardia/flutter/fibrillation. Beware when using these drugs in uncontrolled CHF.
• Typical atenolol dosages—dogs, 0.25–1.0 mg/kg q12h; cats, 6.25–12.5 mg/cat q12–24h; start low and titrate to effect.
• Diltiazem dosages—dogs, 2–6 mg/kg daily in two (long-acting diltiazem) or three divided dosages; start low and titrate to effect; cats, 7.5 mg diltiazem HCl PO q8h. Higher dosages are sometimes needed.
• Sotalol for intractable/recurrent arrhythmias—dogs, 1–2.5 mg/kg PO q12h; cats, 10–20 mg/cat q12h.
• Dogs can be referred for electrocardioversion to convert AF to sinus rhythm (with follow-up therapy with sotalol or amiodarone); however, reversion to AF is common owing to marked atrial dilatation.

Pulmonary Hypertension

• Sildenafil—dogs, 0.5–3 mg/kg PO q8–12 hours.

CONTRAINDICATIONS

Primary afterload reducers such as hydralazine or amlodipine should be avoided in treatment of heart failure from pure MS due to risk of hypotension.

PRECAUTIONS

• As a general rule, pimobendan is relatively contraindicated in pure valvular stenosis; however, many dogs and cats with advanced CHF have been treated with this drug with apparent success, especially when there is combined stenosis/regurgitation of the valve.
• Use ACE inhibitors or other vasodilators judiciously in patients with CHF; cardiac output is limited and vasodilation may induce hypotension. Monitor arterial blood pressure and renal function.

POSSIBLE INTERACTIONS

• Furosemide and ACE inhibitors can affect kidney function, alter blood electrolytes, and reduce blood pressure; these parameters should be monitored.

A

ATRIOVENTRICULAR VALVULAR STENOSIS (CONTINUED)

• Sildenafil can also reduce systemic blood pressure and should not be used with nitroglycerin paste or other nitrates.

ALTERNATIVE DRUG(S)

Spironolactone (2 mg/kg PO q12–24h) should be considered as an ancillary diuretic and for its antifibrotic benefit (as an aldosterone antagonist).

FOLLOW-UP

PATIENT MONITORING

• Thoracic radiographs for pulmonary edema or pleural effusion.
• Echocardiography with Doppler studies—to estimate pulmonary pressures and subjectively assess right heart function if on sildenafil.
• Digoxin level—check 7–10 days following institution of therapy; 8- to 12-hour trough should be 0.8–1.5 ng/mL.
• Renal function, electrolyte status, and arterial blood pressure when on diuretic and/or ACE inhibitor.
• Standard rhythm ECG or Holter (ambulatory ECG) if arrhythmias are present.

POSSIBLE COMPLICATIONS

• CHF.
• Atrial fibrillation.
• Syncope.
• Arterial thromboembolism—cats with MS.
• Pulmonary hemorrhage with MS.

EXPECTED COURSE AND PROGNOSIS

• Morbidity is high; except for mild cases, prognosis is generally poor once an animal becomes symptomatic. However, some animals will live for many years even with relatively severe stenosis of the mitral or tricuspid valve.
• Surgical intervention or balloon valvuloplasty might alter course of disease, but data are limited.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Concurrent congenital defects are common, e.g., subaortic stenosis in MS, PFO in TS, primum ASD in cats with supravalvular mitral (ring) stenosis.

PREGNANCY/FERTILITY/BREEDING

The possibility that this may be a heritable defect must be considered in assessing suitability of the animal for breeding, particularly in breeds with a predilection for this defect. The additional hemodynamic burden of gestation may be poorly tolerated by an already compromised heart. In general, breeding is strongly discouraged.

SYNONYMS

• AV dysplasia with stenosis.
• Supravalvular mitral ring.

SEE ALSO

• Atrioventricular Valve Dysplasia.
• Endocarditis, Infective.

ABBREVIATIONS

• ACE = angiotensin-converting enzyme.
• AF = atrial fibrillation.
• ASD = atrial septal defect.
• AV = atrioventricular.
• CHF = congestive heart failure.
• MS = mitral stenosis.
• PFO = patent foramen ovale.
• PH = pulmonary hypertension.
• TS = tricuspid stenosis.

BASICS

DEFINITION

- Azotemia is an excess of urea, creatinine, or other nonprotein nitrogenous substances in blood, plasma, or serum.
- Uremia is the polysystemic toxic syndrome resulting from marked loss in kidney functions. Uremia occurs simultaneously in animals with increased quantities of urine constituents in blood (azotemia), but azotemia may occur in the absence of uremia.

PATHOPHYSIOLOGY

- Azotemia can be caused by (1) increased production of nonprotein nitrogenous substances, (2) decreased glomerular filtration rate (GFR), or (3) reabsorption of urine that has escaped from the urinary tract into the bloodstream. High production of nonprotein nitrogenous waste substances may result from high intake of protein (diet or gastrointestinal bleeding) or accelerated catabolism of endogenous proteins. GFR may decline because of reduced renal perfusion (prerenal azotemia), acute or chronic kidney disease (renal azotemia), or urinary obstruction (postrenal azotemia). Reabsorption of urine into the systemic circulation may also result from leakage of urine from the excretory pathways (also a form of postrenal azotemia).
- Pathophysiology of uremia—incompletely understood; may be related to (1) metabolic and toxic systemic effects of waste products retained because of renal excretory failure, (2) deranged renal regulation of fluid, electrolytes, and acid-base balance, and (3) impaired renal production and degradation of hormones and other substances (e.g., erythropoietin and 1,25-dihydroxycholecalciferol).

SYSTEMS AFFECTED

- Uremia affects all body systems.
- Cardiovascular—arterial hypertension, left ventricular hypertrophy, heart murmur, cardiomegaly, cardiac rhythm disturbances.
- Endocrine/metabolic—renal secondary hyperparathyroidism, inadequate production of calcitriol and erythropoietin, hypergastrinemia, weight loss.
- Gastrointestinal—anorexia, nausea, vomiting, diarrhea, uremic stomatitis, xerostomia, uremic breath, constipation.
- Hemic/lymph/immune—anemia and immunodeficiency.
- Neuromuscular—dullness, lethargy, fatigue, irritability, tremors, gait imbalance, flaccid muscle weakness, myoclonus, behavioral changes, dementia, isolated cranial nerve deficits, seizures, stupor, coma, impaired thermoregulation (hypothermia).
- Ophthalmic—scleral and conjunctival injection, retinopathy, acute-onset blindness.
- Respiratory—dyspnea.
- Skin/exocrine—pallor, bruising, increased

SIGNALMENT

Dog and cat.

SIGNS

General Comments

Azotemia may not be associated with historical or physical abnormalities. Unless patient has uremia, clinical findings are limited to disease responsible for azotemia.

Historical Findings

- Weight loss.
- Declining appetite or anorexia.
- Depression.
- Fatigue.
- Weakness.
- Vomiting.
- Diarrhea.
- Halitosis.
- Constipation.
- Polyuria.
- Changes in urine volume.
- Poor haircoat or unkempt appearance.

Physical Examination Findings

- Muscle wasting/sarcopenia/cachexia.
- Mental depression.
- Dehydration.
- Weakness.
- Pallor.
- Petechiae and ecchymoses.
- Dull and unkempt haircoat.
- Uremic breath.
- Uremic stomatitis (including oral ulcers, infarctions of the tongue).
- Scleral and conjunctival injection.
- Relative hypothermia.

CAUSES

Prerenal Azotemia

- Reduced renal perfusion due to low blood volume or low blood pressure.
- Accelerated production of nitrogenous waste products because of enhanced catabolism of tissues in association with infection, fever, trauma, corticosteroid excess, or burns.
- Increased gastrointestinal digestion and absorption of protein sources (diet or gastrointestinal hemorrhage).

Renal Azotemia

Acute or chronic kidney diseases (primary kidney disease affecting glomeruli, renal tubules, renal interstitium, and/or renal vasculature) that impair at least 75% of kidney function (GFR).

Postrenal Azotemia

Urinary obstruction; rupture of excretory pathway.

RISK FACTORS

- Medical conditions—kidney disease, hypoadrenocorticism, low cardiac output, hypotension, fever, sepsis, liver disease, pyometra, hypoalbuminemia, dehydration, acidosis, exposure to nephrotoxic chemicals, gastrointestinal hemorrhage, urolithiasis, urethral plugs in cats, urethral trauma, and neoplasia.
- Advanced age may be a risk factor.

nonsteroidal anti-inflammatory drugs, diuretics, antihypertensive medications; failure to adjust dosage of drugs primarily eliminated by the kidneys to correspond with decline in renal function.
- Toxins—ethylene glycol, grapes (dogs), lilies (cats).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dehydration, poor peripheral perfusion, low cardiac output, history of recent fluid loss, high-protein diet—rule out prerenal azotemia.
- Recent onset of altered urine output (high or low), clinical signs consistent with uremia, exposure to possible nephrotoxicants or ischemic renal injury, or kidney size normal or enlarged—rule out acute kidney injury (AKI).
- Progressive weight loss, polyuria, polydipsia, small kidneys, disparate kidney size (cats—big kidney and little kidney), pallor, and signs of uremia that have developed over several weeks to months—rule out chronic kidney disease (CKD).
- Abrupt decline in urine output and onset of signs of uremia; disparate kidney size, dysuria, stranguria, and hematuria; large urinary bladder or fluid-filled abdomen—rule out postrenal azotemia.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Nonregenerative anemia (normocytic, normochromic)—often present with CKD.
- Hemoconcentration—often present with prerenal azotemia; can also be seen with AKI and postrenal azotemia.

Biochemistry

- Serial determinations of serum urea nitrogen and creatinine concentrations may help differentiate the cause of azotemia. Appropriate therapy to restore renal perfusion typically yields a dramatic reduction in azotemia in patients with prerenal azotemia (typically within 24–48 hours). Correcting obstruction to urine flow or a rent in the excretory pathway typically is followed by a rapid reduction in the magnitude of azotemia.
- Hyperkalemia may be consistent with postrenal azotemia, primary renal azotemia due to oliguric renal failure, or prerenal azotemia associated with hypoadrenocorticism.
- Increased serum albumin and globulin concentration suggest prerenal component.

Urinalysis

- Urine specific gravity (USG) ≥1.030 (dog) and ≥1.035 (cat) supports a diagnosis of prerenal azotemia. Administration of fluid therapy before urine collection may interfere with interpretation of USG.
- Azotemic patients that have not been treated with fluids and have USG <1.030 (dog) and

A

AZOTEMIA AND UREMIA (CONTINUED)

disease, which is sometimes characterized by glomerulotubular imbalance, where adequate urine-concentrating ability may persist despite sufficient renal glomerular damage to cause primary renal azotemia; these patients are recognized by moderate to marked proteinuria in the absence of hematuria and pyuria.
• USG is not useful in identifying postrenal azotemia.

OTHER LABORATORY TESTS
Endogenous or exogenous creatinine, iohexol, or inulin clearance tests or other specific tests of GFR may be used to confirm that azotemia is caused by reduced GFR.

IMAGING
• Abdominal radiographs—used to determine kidney size (small kidneys consistent with CKD; mild-to-moderate enlargement of kidneys may be consistent with AKI or urinary obstruction) and to rule out urinary obstruction (marked dilation of urinary bladder or mineral densities within excretory pathway).
• Ultrasonography—may detect changes in echogenicity of renal parenchyma and size and shape of kidneys; useful to rule out postrenal azotemia characterized by distension of excretory pathway and uroliths or masses within or impinging on excretory pathway and intra-abdominal fluid accumulation (with rupture of excretory pathway).
• Excretory urography, pyelography, or cystourethrography—may help establish diagnosis of postrenal azotemia due to urinary obstruction or rupture of excretory pathway.

DIAGNOSTIC PROCEDURES
Renal biopsy can confirm the diagnosis of primary kidney disease, to differentiate acute from chronic kidney disease, and to attempt to establish the underlying disease process responsible for kidney disease.

TREATMENT
• Prerenal azotemia caused by impaired renal perfusion—correct the underlying cause of renal hypoperfusion; aggressiveness of treatment depends on severity of underlying condition.
• Primary renal azotemia and associated uremia—(1) specific therapy directed at halting or reversing primary disease process affecting the kidneys, and (2) symptomatic, supportive, and palliative therapies that ameliorate clinical signs of uremia; minimize clinical impact of deficits and excesses in fluid, electrolyte, acid-base balances; minimize effects of inadequate renal biosynthesis of hormones and other substances; and maintain adequate nutrition.
• Postrenal azotemia—eliminate urinary obstruction or repair rents in excretory

that may develop during solute diuresis that follows correction of postrenal azotemia.
• Fluid therapy—indicated for most azotemic patients; isotonic balanced crystalloid is preferred replacement fluid, followed by hypotonic maintenance fluid administration. Determine fluid volume to administer on basis of severity of dehydration or volume depletion. If no clinical dehydration is evident, cautiously assume that patient is <5% dehydrated and administer corresponding volume of fluid. Provide 25% of calculated fluid deficit in first hour. Thereafter, serially monitor perfusion (capillary refill time, pulse pressure, heart rate, and temperature of feet), blood pressure, and urine output to assess adequacy of fluid therapy. If perfusion has not improved, additional fluid should be administered. Provide the remaining fluid deficit over the next 12–24 hours. Fluid therapy should be cautiously administered to patients with overt or suspected cardiac failure and patients that are oliguric or anuric.
• Consider feeding diets formulated for kidney disease to reduce magnitude of azotemia, hyperphosphatemia, and acidosis.

MEDICATIONS
DRUG(S) OF CHOICE
• Symptomatic therapy for myriad manifestations of uremia.
• Omeprazole (1 mg/kg q12h) may be used to reduce gastric hyperacidity.
• Antiemetics such as maropitant (1 mg/kg q24h) are indicated for vomiting.

CONTRAINDICATIONS
Administration of nephrotoxic drugs.

PRECAUTIONS
• Use caution when administering drugs requiring renal excretion. Consult appropriate references concerning dose-reduction schedules or adjustments of maintenance intervals.
• Cautiously administer fluids to oligoanuric patients. Monitor urine production rates and body weight during fluid therapy to minimize likelihood of inducing overhydration.
• Stop fluid therapy in overhydrated oliguric/anuric patients. Use caution in administering drugs that may promote hypovolemia or hypotension (e.g., diuretics); carefully monitor response to such drugs by assessing hydration status, peripheral perfusion, and blood pressure, with serial evaluation of renal function tests.
• Corticosteroids may worsen azotemia by increasing catabolism of endogenous proteins.

ALTERNATIVE DRUG(S)

FOLLOW-UP
PATIENT MONITORING
Serum urea nitrogen and creatinine concentrations 24 hours after initiating fluid administration; also urine production, blood pressure, body weight, and hydration status.

POSSIBLE COMPLICATIONS
• Failure to correct prerenal azotemia caused by renal hypoperfusion rapidly could result in ischemic primary kidney disease.
• Primary renal azotemia can progress to uremia.
• Failure to restore normal urine flow in patients with postrenal azotemia can result in progressive renal damage or death due to hyperkalemia and uremia.

MISCELLANEOUS
ASSOCIATED CONDITIONS
An association may exist between hypokalemia and azotemia in cats.

AGE-RELATED FACTORS
Primary renal failure may occur in animals of any age, but geriatric dogs and cats appear to be at substantially higher risk for both acute and chronic kidney disease; these patients are also at higher risk for prerenal and postrenal causes of azotemia.

ZOONOTIC POTENTIAL
Leptospirosis

PREGNANCY/FERTILITY/BREEDING
• Data on azotemia and pregnancy are very limited.
• Pregnant azotemic animals—pharmacologic agents excreted by nonrenal pathways are preferred.

SEE ALSO
• Acute Kidney Injury.
• Chronic Kidney Disease.
• Urinary Tract Obstruction.

ABBREVIATIONS
• AKI = acute kidney injury.
• CKD = chronic kidney disease.
• GFR = glomerular filtration rate.
• USG = urine specific gravity.

BABESIOSIS

BASICS

OVERVIEW

• Caused by protozoal parasites of the genus *Babesia. Babesia* spp. infect mammalian red blood cells (RBCs). • Large *Babesia* spp. that infect dogs: ○ *Babesia vogeli* is transmitted by *Rhipicephalus sanguineus* and has a worldwide distribution. ○ *Babesia canis* is transmitted by *Dermacentor reticulatus* and is primarily found in Europe. ○ *Babesia rossi* is transmitted by *Haemaphysalis leachi* and is primarily found in Africa. ○ *Babesia* sp. (Coco)—tick vector is unknown; identified primarily in splenectomized and immune-suppressed dogs in the United States. • Small *Babesia* spp. (2–5 µm) that infect dogs: ○ *B. gibsoni*—worldwide distribution; most common *Babesia* sp. disease in the United States. ○ *B. conradae* (also *B. gibsoni* [United States/California])— only reported in California. ○ *Babesia vulpes* (also *Theileria Vulpes*, Spanish dog piroplasm, and *B. microti*-like parasite)—reported in Europe and the United States. • Several case reports of novel *Babesia* sp. and other piroplasms (i.e., *T. equi)* infecting dogs. • Small piroplasms (2–5 µm) that infect cats: ○ *B. felis*—reported in Africa. ○ *Cytauxzoon felis*—reported in the United States. • Infection may occur either by tick transmission, direct transmission via blood transfer during dog bites, blood transfusions, or transplacentally.
• Incubation period averages approximately 2 weeks, but some cases are not clinically diagnosed for months to years. • Piroplasms infect and replicate in red blood cells (RBCs), resulting in both direct and immune-mediated hemolytic anemia. • Immune-mediated hemolytic anemia is more clinically important than parasite-induced RBC destruction, since severity of signs does not depend on degree of parasitemia.

Systems Affected

• Hemic/lymphatic/immune—anemia, thrombocytopenia (bleeding tendencies rare), fever, splenomegaly, lymphadenomegaly, vasculitis. • Hepatobiliary—mild to moderate increase in liver enzyme activities.
• Nervous—cerebral babesiosis, weakness, disorientation, collapse (most common with *B. canis rossi*). • Renal/urologic—renal failure (*B. rossi* and *B. vulpes*).

SIGNALMENT

• Any age or breed of dog can be infected.
• *B. vogeli* infections are more prevalent in greyhounds. • *B. gibsoni* infections are more prevalent in American pit bull terriers. • Any age or breed of cat can be infected, but to date, only *C. felis* has been reported in the United States.

SIGNS

• Similar in dogs and cats. • Peracute, acute, or chronic. • Some carrier animals have no detectable clinical signs. • Dogs—lethargy, anorexia, pale mucous membranes, fever, splenomegaly, lymphadenomegaly, pigmenturia, icterus, weight loss, discolored stool.
• Cats—lethargy, anorexia, pale mucous membranes, icterus.

CAUSES & RISK FACTORS

• History of tick attachment. • Splenectomized animals develop more severe clinical disease.
• History of splenectomy or chemotherapy is risk factor for *Babesia* sp. (Coco) infection. • Immune suppression may cause clinical signs and increased parasitemia in chronically infected dogs. • History of recent dog-bite wound is risk for *B. gibsoni* (Asia) infection. • Recent blood transfusion from subclinically infected donor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Any cause of immune-mediated hemolytic anemia or thrombocytopenia, including idiopathic immune-mediated hemolytic anemia or thrombocytopenia, ehrlichiosis, Rocky Mountain spotted fever, systemic lupus erythematosus, neoplasia, endocarditis, hemotropic mycoplasmosis (haemobartonellosis), and cytauxzoonosis. • A positive Coombs' test does not rule out babesiosis, since many animals with babesiosis are also Coombs' positive. • Non-immune-mediated hemolytic anemia, including microangiopathic anemia, caval syndrome, splenic torsion, disseminated intravascular coagulation (DIC), Heinz body anemia, pyruvate kinase deficiency, phosphofructokinase deficiency. • Hepatic and posthepatic jaundice.

CBC/BIOCHEMISTRY/URINALYSIS

• Anemia—absent to severe; usually regenerative (reticulocytosis) unless signs are very acute; in severe cases, packed cell volume (PCV) <10%. • Thrombocytopenia—usually moderate to severe; some animals have thrombocytopenia without anemia; most common hematologic abnormality. • Both leukocytosis and leukopenia reported. • Hyperbilirubinemia, depending on rate of hemolysis.
• Hyperglobulinemia is common in chronic infections and may be the only biochemical abnormality in some animals. • Mildly elevated liver enzyme activities from anemia/hypoxia. • Proteinuria and hypoalbuminemia (protein-losing nephropathy) may occur.
• Azotemia and metabolic acidosis secondary to renal failure have been reported with *B. canis rossi*, *B. gibsoni*, and *B. vulpes*.
• Bilirubinuria is common.
• Hemoglobinuria is detected less commonly in United States than in Africa.

OTHER LABORATORY TESTS

• Microscopic examination of stained thin or thick blood smears—can provide definitive diagnosis (not to species level); sensitivity depends on microscopist experience and staining technique; most success using a quick modified Wright stain; capillary blood may enhance sensitivity. • Indirect fluorescent antibody (IFA)—serum antibody test; cross-reactive antibodies can prevent differentiation of species and subspecies; some infected animals, particularly young dogs, may have no detectable antibodies. • PCR—identifies presence of *Babesia* DNA in a biologic sample (usually ethylenediaminetetra-acetic acid [EDTA] anticoagulated whole blood); can differentiate subspecies and species.

TREATMENT

• Inpatient or outpatient care depending on severity of disease. • Hypovolemic animals should receive aggressive fluid therapy.
• Severely anemic animals require blood transfusion.

MEDICATIONS

DRUG(S) OF CHOICE

• Combination therapy of azithromycin (10 mg/kg PO q24h for 10 days) and atovaquone (13.5 mg/kg PO q8h for 10 days) is the treatment of choice and the only treatment that can potentially clear *B. gibsoni* (Asia) infections in dogs; in a controlled study, 85% of dogs cleared the infection after treatment. • Imidocarb dipropionate (FDA approved; 6.6 mg/kg SC/IM every 1–2 weeks) and diminazine aceturate (not FDA approved; 3.5–7 mg/kg SC/IM every 1–2 weeks) decrease morbidity and mortality in affected animals; they may completely clear *B. canis and B. vogeli* infections, but not *B. gibsoni*. • A combination of clindamycin (25 mg/kg PO q12h), metronidazole (15 mg/kg PO q12h), and doxycycline (5 mg/kg PO q12h) had been associated with elimination or reduction of parasite below the limit of detection of PCR testing in dogs; unfortunately, a well-defined treatment course has not been established, with treatment times ranging from 24 to 92 days; minimum duration of therapy of 90 days recommended. • Combination of doxycycline (7–10 mg/kg PO q24h), enrofloxacin (2–2.5 mg/kg PO q12h), and

BABESIOSIS (CONTINUED)

metronidazole (5–15 mg/kg PO q12h) for 6 weeks was associated with clinical remission in 85% of dogs, but PCR was not performed to assess effect on parasitemia. • Metronidazole (25–50 mg/kg PO q24h for 7 days), clindamycin (12.5–25 mg/kg PO q12h for 7–10 days), or doxycycline (10 mg/kg PO q12h for 7–10 days) as single-agent treatments may decrease clinical signs but not clear infections. • Primaquine phosphate (1 mg/kg IM single injection) is the treatment of choice for *B. felis*. • Since the anemia and thrombocytopenia are often immune mediated, immunosuppressive agents, such as prednisone (2.2 mg/kg/day PO), may be indicated in some cases that are not responding to antiprotozoal treatments alone; prolonged immune suppressive therapy *before* specific antiprotozoal therapy is contraindicated. • Antibabesial drugs (imidocarb and diminazene) can cause cholinergic signs that can be minimized by administering atropine (0.02 mg/kg SC 30 min prior to administration).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

High doses of antibabesial drugs (imidocarb and diminazene) have resulted in liver and kidney failure.

FOLLOW-UP

• Recheck CBC and biochemistry as needed to monitor resolution of anemia, thrombocytopenia, icterus, etc. • Most patients have clinical response within 1–2 weeks of treatment. • 2–3 consecutive negative PCR tests beginning 2 months post treatment should be performed to rule out treatment failure and persistent parasitemia; IFA titers are not recommended for follow-up because titers may persist for years. • Long-term follow-up of *B. conradae*, *B. vulpes*, or *B. felis* after treatment has not been reported. • When a dog housed in a multidog kennel is diagnosed with babesiosis, all dogs in that kennel should be screened, since there is a high percentage of carrier animals in kennel situations. • Coinfection with other vector-transmitted pathogens (e.g., *Ehrlichia*, hemotropic *Mycoplasma*, *Leishmania*) should be considered, especially in animals that fail to respond to treatment.

PREVENTION/AVOIDANCE

Recent studies suggest that using acaracides can reduce transmission with *Babesia* spp. All attached ticks should be removed as soon as possible. Vaccines for *B. canis* and *B. rossi* are available in Europe, but may not confer protection against other *Babesia* spp. Tick control is important for disease prevention.

MISCELLANEOUS

All potential blood donors should test negative for *Babesia* spp.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Transplacental transmission.

ABBREVIATIONS

• DIC = disseminated intravascular coagulation.
• EDTA = ethylenediaminetetra-acetic acid.
• IFA = indirect fluorescent antibody.
• PCV = packed cell volume.
• RBC = red blood cell.

BACLOFEN TOXICOSIS

BASICS

OVERVIEW

• Baclofen is centrally acting skeletal muscle relaxant used to prevent spasticity in people with multiple sclerosis, cerebral palsy, and spinal disorders. • Binds to gamma-aminobutyric acid ($GABA_B$) receptors and prevents release of inhibitory neurotransmitters and substances. • Has been used extra-label in dogs to reduce urethral resistance (1–2 mg/kg PO q8h), but is rarely recommended due to narrow margin of safety; use in cats not recommended. • Oral doses as low as 0.7 mg/kg in dogs have caused depression, dyspnea, and hypothermia. • Death has been documented in dogs at 2.3 mg/kg, but more likely at 8–16 mg/kg. • These organ systems are predominantly affected:
○ Cardiovascular. ○ Gastrointestinal.
○ Musculoskeletal. ○ Nervous. ○ Respiratory.

SIGNALMENT

• Accidental exposure in dogs is more frequently reported than in cats, but any animal may be at risk for poisoning.
• Cats are extremely sensitive to baclofen.

SIGNS

• Signs begin within 15–90 minutes of ingestion but, rarely, may be delayed several hours. • Common signs—vocalization, vomiting, ataxia, disorientation, hypersalivation, depression, weakness, coma, flaccid paralysis, recumbency, seizures, and hypothermia.
• Life-threatening signs—dypsnea, respiratory depression, and arrest secondary to diaphragmatic/intercostal muscle paralysis.

CAUSES & RISK FACTORS

Pet owners with medical conditions such as multiple sclerosis, cerebral palsy, and spinal disorders are more likely to have baclofen in the home.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Toxic—barbiturates, benzodiazepines, depressants, ethanol, ethylene glycol, cannabis/marijuana, illicit drugs (LSD, phencyclidine [PCP], hallucinogenic mushrooms), methanol, opioids, propylene glycol, tranquilizers, xylitol.
• Lower motor neuron disease (e.g., botulism, *Neospora*, tick paralysis, *Toxoplasma*). • Metabolic (e.g., hepatic encephalopathy, hypoglycemia, etc.).

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities expected, but should be used to rule out other causes.

OTHER LABORATORY TESTS

• Arterial blood gas analysis (hypoxemia, oxygenation, and ventilation). • Pulse oximetry (hypoxemia). • End tidal CO_2 (hypercapnia or hypoventilation).
• Baclofen serum or urine concentrations to confirm exposure; not helpful for case management.

IMAGING

Thoracic radiographs (aspiration pneumonia secondary to severe sedation).

TREATMENT

• Many cases quickly become serious and referral to a 24-hour critical care center should be considered. • Treatment focused on decontamination and supportive care.
• Induce emesis following recent (<1 hour) ingestion in asymptomatic patients only if have not already vomited; consider gastric lavage for very large ingestions. • One dose of activated charcoal with sorbitol. • IV fluid crystalloids at 1.5–2.5 × maintenance to support organ perfusion and enhance elimination.
• Monitor for cardiac arrhythmias, hypoventilation, and aspiration pneumonia.
• Oxygen if respiratory depression; ventilator support if severe respiratory depression/failure.
• Monitor body temperature and provide warming/cooling measures as needed.
• Hemodialysis and hemoperfusion have successfully shortened elimination half-life and led to full recovery.

MEDICATIONS

DRUG(S) OF CHOICE

• Atropine for bradycardia (0.02–0.04 mg/kg IM/IV/SC PRN for dogs or cats). • Antiemetics as needed (e.g., maropitant 1 mg/kg SC q24h).
• Diazepam (0.25–1.0 mg/kg IV to effect) or midazolam (0.1–0.3 mg/kg IV/IM) for seizures; use lowest effective dose. • For seizures refractory to bolus diazepam or midazolam, use CRI of diazepam (0.1–0.5 mg/kg/h), midazolam (0.05–0.5 mg/kg/h), levetiracetam (dogs, 30–60 mg/kg IV; cats, 20 mg/kg IV), propofol (1–8 mg/kg IV to effect, followed by CRI dose of 0.1–0.6 mg/kg IV for dogs or cats), or inhalant anesthesia. • Agitation may be treated with diazepam or midazolam; acepromazine (0.05–0.2 mg/kg IV/IM/SC PRN for cats or dogs) should be used with caution.
• Cyproheptadine for vocalization/disorientation (dogs, 1.1 mg/kg PO or rectally q4–6h; cats, 2–4 mg total dose q4–6h). • IV lipid emulsion (ILE) has successfully treated dogs suffering from baclofen intoxication; should be reserved for critical cases; doses vary; using 20% emulsion, give 1.5 mL/kg IV bolus followed by CRI of 0.25 mL/kg/min for 30–60 min; if initial bolus fails to produce desired effect, consider *additional* doses of 1.5 mL/kg IV q4–6h for initial 24 hours; if after 3–5 boluses no clinical response is seen, discontinue use; do not exceed 8 mL/kg/day.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Use acepromazine cautiously due to risk of hypotension. • Use all sedatives cautiously as baclofen also causes sedation. • Avoid drugs that cause respiratory depression (e.g., phenobarbital).

FOLLOW-UP

PATIENT MONITORING

• Serious cases require intense, consistent patient monitoring including vital signs, blood pressure, blood gas analysis, pulse oximetry, and end tidal CO_2. • Nursing care should include turning/repositioning q6h, ocular lubrication, keeping patient dry/clean, passive range of motion of limbs, and soft bedding.

PREVENTION/AVOIDANCE

Educate pet owners about risks of leaving prescription drugs accessible to pets.

POSSIBLE COMPLICATIONS

Aspiration pneumonia due to combination of vomiting, sedation, seizures, and paralysis of diaphragm/intercostal muscles.

EXPECTED COURSE AND PROGNOSIS

• Patients suffering serious intoxications may take 5–7 days to fully recover. • Recovery often occurs with no residual effects.
• Prognosis good with early and appropriate care, but becomes poor if medical care delayed; seizures and aspiration pneumonia associated with guarded prognosis.

MISCELLANEOUS

ABBREVIATIONS

• GABA = gamma-aminobutyric acid.
• ILE = intravenous lipid emulsion.
• PCP = phencyclidine.

BARTONELLOSIS

BASICS

OVERVIEW

• Small, facultative, fastidious intracellular argyrophilic, hemotrophic Gram-negative rod (bacilli) bacteria. • Emerging, vector-transmitted (fleas, ticks); adapted to reservoir hosts, establishes chronic, intraerythrocytic bacteremia. • Cats—usually asymptomatic, reservoir host. • Dogs—emerging clinical syndrome. • Seasonal—more cases reported between July and January. • Human syndrome—variable; cat scratch disease most common; worldwide, estimate >25,000 cases/year in United States; few fatalities.

SIGNALMENT

Dogs and cats.

SIGNS

Cats

• May have no clinical signs. • Lymphoid hyperplasia, uveitis, endocarditis (rare), self-limiting fever. • Between 5 and 60% seropositive, depending on geographic area.

Dogs

Nonspecific; include lethargy, fever, lymphadenomegaly, uveitis, or chorioretinitis, and may include signs consistent with endocarditis (e.g. weakness, cardiac arrhythmias), encephalitis (e.g. seizures, ataxia), myocarditis, vasculitis, rhinitis, angioproliferative lesions, or arthritis.

CAUSES & RISK FACTORS

• Dogs—flea and tick exposure, rural environment. • Bartonella associated with clinical illness in dogs and cats include *Bartonella henselae*, *B. clarridgeiae*, *B. koehlerae*, *B. quintana*, *B. vinsonii* ssp. *berkhoffii*, *B. rochalimae*, *B. elizabethae*.
• Human disease associated with contact with cats (>90%), particularly young cats with fleas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other tick-borne infections (*Ehrlichia*, *Babesia*). Due to the broad spectrum of diseases associated with Bartonella, many differentials possible.

CBC/BIOCHEMISTRY/URINALYSIS

• Anemia, thrombocytopenia, eosinophilia.
• Hyperglobulinemia, signs of liver dysfunction, hypoglycemia possible.

OTHER LABORATORY TESTS

• Serology—indirect fluorescent antibody, ELISA, and western immunoblot.
∘ Fourfold rise in antibody titer over a 2–3-week period consistent with infection.
∘ Good specificity, poor sensitivity. ∘ Acutely ill bacteremic animals may not have detectable antibodies.
• PCR amplification of bacterial DNA—on blood, body fluids, fresh or fresh frozen tissue; for cases with negative culture and serology. • *Bartonella* alpha proteobacteria growth medium (BAPGM) culture—of blood, cerebrospinal fluid, joint fluid, effusions, or tissue biopsies; enriched media, requires 14–30 days; obtain culture before antibiotic therapy. • Combination BAPGM and PCR enhances diagnostic sensitivity.

PATHOLOGIC FINDINGS

• Histopathology of lymph nodes—nonspecific inflammatory reaction: granulomas, microabscesses, and necrosis. • Warthin–Starry silver stain—bacilli in lesions.
• Immunohistochemistry, alone or with PCR to identify bacteria.

TREATMENT

Supportive care.

MEDICATIONS

DRUG(S) OF CHOICE

• Optimal protocols for treating *Bartonella* spp. have not been established; likely long-term (4–6 weeks) antibiotics required.
• Difficult to completely eliminate organism in cats; treatment reserved for symptomatic animals or those owned by immunocompromised people. • Single-agent antibiotic therapy not efficacious. • Antibiotic therapy: ∘ Cats—doxycycline, amoxicillin–clavulanate, fluoroquinolones, and azithromycin have been used. ∘ Dogs—fluoroquinolone + doxycycline good first choice; amoxicillin, gentamicin/amikacin, rifampin, erythromycin, azithromycin also options. ∘ Macrolides not recommended as first line due to rapid development of resistance.

FOLLOW-UP

PREVENTION/AVOIDANCE

• Immunocompromised people should avoid young cats. • Flea prevention.

POSSIBLE COMPLICATIONS

Caution with fluoroquinolones in cats and young dogs.

MISCELLANEOUS

• One episode appears to confer lifelong immunity. • Bacillary angiomatosis—vascular proliferative disease of skin; may be caused by *B. henselae*; responds to antimicrobial drugs.

ZOONOTIC POTENTIAL

• Risk of transfer of organisms from infected dogs and cats to people unknown. • Infected cats likely serve as source of organisms for fleas that transmit infection to humans (i.e., cat scratch disease). • Dogs may be chronically infected reservoirs for *Bartonella* species.
• Veterinarians are at occupational risk of infection from exposure. • Human disease manifested as erythema followed by unilateral regional lymphadenopathy (painful, often suppurative) in 3–10 days. Infection may be accompanied by fever, malaise, myalgia, nausea. Atypical infections may result in encephalopathy, meningitis, palpebral conjunctivitis, endocarditis, hepatitis, other systemic manifestations.

ABBREVIATIONS

• BAPGM = *Bartonella* alpha proteobacteria growth medium.

BASAL CELL TUMOR

BASICS

OVERVIEW
- Originates from the basal epithelial cells of both epidermal and adnexal origin.
- Majority of them are benign (e.g., basal cell epithelioma and basaloid tumor), with smaller occurrences of malignant (e.g., basal cell carcinoma) tumors.
- Metastasis is rare with the benign forms, and uncommon with malignant.

SIGNALMENT
- Most common skin tumor in cats (10–26%) and second to third most common skin tumor in dogs (4–12%).
- Median age—dogs, 6–9 years; cats, 10–11 years.
- Cocker spaniels, Kerry blue terriers, Siberian huskies, English springer spaniels, and poodles are predisposed for dogs. Persian, British Blue, Norwegian Forest Cat, Himalayan, and Siamese are predisposed for cats.

SIGNS
- Solitary, well-circumscribed, firm, often hairless, intradermal raised mass, typically located on the head, neck, limbs, or shoulders.
- Can vary greatly in size from a few millimeters to many centimeters in diameter.
- Feline basal cell tumors are frequently heavily pigmented, and occasionally cystic or ulcerated.

CAUSES & RISK FACTORS
- Breed (see Signalment).
- Contrary to human basal cell tumors, chronic ultraviolet exposure does not appear to play a role in pets.
- Possible association with papillomavirus in dogs and cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other skin tumors including mast cell tumor, extramedullary plasmacytoma, melanoma, hemangioma, hemangiosarcoma, histiocytoma.
- Melanoma is an especially important differential with the pigmented feline basal cell tumors.
- Intradermal cysts.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Cytologic evaluation of fine-needle aspiration sample reveals aggregates of round cells with basophilic cytoplasm; mitoses are not uncommon despite benign nature. In basal cell carcinomas, mitotic activity may be low to high with atypical mitotic figures.
- When clinically indicated, fine-needle aspiration of draining lymph nodes to confirm or deny the presence of regional metastases.
- Histopathologic examination required for definitive diagnosis; when highly pigmented, immunohistochemistry occasionally required to differentiate from melanoma.

PATHOLOGIC FINDINGS
- Histologic cellular patterns vary from solid to cystic to ribbon appearance.
- Tumor cells may contain melanin pigmentation; may have a fine eosinophilic stroma.
- Nuclear criteria might help predict risk of local recurrence in feline basal cell carcinomas.

TREATMENT
- Surgical excision treatment of choice and generally curative for fully resectable tumors.
- Cryosurgery or plesiotherapy with strontium-90 can be used for smaller, superficial lesions (<1 cm).

MEDICATIONS

DRUG(S) OF CHOICE
N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
- Complete surgical excision is usually curative and associated with an excellent prognosis.
- Majority of tumors are locally confined and nonmetastatic. Long-term follow-up is generally unnecessary.

BATTERY TOXICOSIS

BASICS

OVERVIEW

• Alkaline/acid-based batteries (generally referred to as dry cell batteries)—gastrointestinal tract (GIT) ulcers from leaking corrosive contents, oral injury from chewing on casing, rarely heavy metal toxicity from breakdown of casing in the GIT.
• Disc/button/lithium ion batteries—rapid necrosis to the esophagus and stomach due to electric current from the battery; significant necrosis can occur 15 minutes after contact.

SIGNALMENT

Dogs, cats, birds, and small mammals. Young animals are more commonly affected.

SIGNS

• Historical—finding chewed-up electronic equipment without the battery; chewed or mangled battery or battery packaging.
• Black debris in the oral cavity is evidence of leaked dry cell battery contents.
• Physical:
  ◦ Oral ulcerations.
  ◦ Oral injury from chewing on battery casing.
  ◦ Anorexia, drooling, regurgitation, vomiting, diarrhea, melena, progressive weakness, dyspnea, coughing, stridor, pleuritis, pyothorax, and pneumo-mediastinum.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Diagnosis based on history, complete oral exam, and full (esophagus and abdominal GIT) survey radiographs.
• Nonsteroidal anti-inflammatory drugs (NSAIDs), foreign body obstruction (FBO), pancreatitis, and other corrosive compounds (cleaning agents, drain cleaners, pool shocking agents, etc.).

CBC/BIOCHEMISTRY/URINALYSIS

• Anemia—secondary to bleeding GI ulceration.
• Leukocytosis—inflammation and secondary infection.
• Elevated total proteins/prerenal azotemia—secondary to dehydration.
• Elevated liver enzymes secondary to heavy metal toxicity from breakdown of casing.

IMAGING

• Full survey radiographs—determine if a battery was swallowed, assess location and condition of battery and casing; look for evidence of perforation and/or obstruction.
• Endoscopy—pending severity of signs, evaluate extent of damage to esophagus; may be able to remove battery or casing; use caution and do not damage esophagus.

TREATMENT

• Lavage oral cavity for 10–15 minutes for alkaline batteries; for disc batteries give 10–20 mL of water every 15 minutes until battery is out of esophagus.
• Do *not* induce vomiting, as this may expose esophagus to further injury.
• NPO or slurry feeding for 24–48 hours if oral ulcerations are present.
• Ulceration may not be visible in the oral cavity until 48 hours post exposure.
• Wear gloves when cleaning up battery debris, as leaked acid could cause injury to hands.
• Small, intact dry cell batteries in stomach should pass within 48 hours; evaluate all stools and if battery has not passed the pylorus in 48 hours, surgical removal is recommended.
• Punctured dry cell batteries and disc/button/lithium ion batteries should be immediately removed by endoscopy or surgery.

MEDICATIONS

DRUG(S) OF CHOICE

• Analgesics:
  ◦ Dogs—butorphanol 0.1–0.5 mg/kg IV/IM/SC; tramadol 4–10 mg/kg PO q6–8h.
  ◦ Cats—buprenorphine 0.01–0.03 mg/kg buccal/IV/IM q6–8h.
• Antiemetics—maropitant 1 mg/kg PO/SC/IV q12h PRN.
• H2 blockers—pantoprazole 0.7–1 mg/kg IV over 15 min q24h; ranitidine 1–2 mg/kg PO/SC/IM/IV q8–12h; famotidine 0.5–1.1 mg/kg PO q12h.
• Sucralfate 0.25–1 g PO q8h on empty stomach.
• Antibiotics—as needed to prevent secondary infection when ulcers are present.

CONTRAINDICATIONS/ POSSIBLE INTERACTIONS

• Emetics—emesis should not be performed as it may worsen damage to the esophagus.
• Steroids—may reduce risk of esophageal stricture, but expected to slow healing time.
• NSAIDs——aid in pain management and swelling reduction, but may increase risk of gastric ulceration/perforation.

FOLLOW-UP

PATIENT MONITORING

Consider endoscopy 2 weeks post exposure to assess condition of esophagus.

POSSIBLE COMPLICATIONS

Esophageal perforation, esophageal stricture, gastrointestinal obstruction, heavy metal toxicity.

EXPECTED COURSE AND PROGNOSIS

• Nonruptured dry cell battery—excellent; most pets pass on own within 48 hours.
• Ruptured dry cell battery—guarded, pending location of corrosive exposure and amount of time before removal; esophageal injury worsens prognosis.
• Disc/button/lithium ion battery—guarded, rapid removal is needed; significant injury, including esophageal or gastric perforation, can occur within 15 minutes of ingestion.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Heavy metal toxicity.
• Esophagitis.
• Esophageal stricture.
• Esophageal perforation.
• Gastrointestinal obstruction.

ABBREVIATIONS

• FBO = foreign body obstruction.
• GIT = gastrointestinal tract.
• NSAID = nonsteroidal anti-inflammatory drug.

Client Education Handout available online

BAYLISASCARIASIS

BASICS

OVERVIEW

- Disease caused by the raccoon roundworm, *Baylisascaris procyonis*.
- Two forms reported in dogs—intestinal infection occurring in adults; visceral disease caused by larval migration in puppies.
- Infection of raccoons occurs by ingestion of eggs or larvae in tissues of mammalian paratenic hosts.
- Dogs are infected by ingestion of infective eggs or paratenic hosts, from which they develop patent infections with adult worms in small intestine; puppies, probably infected by the ingestion of eggs, develop visceral disease.
- Dogs with intestinal infection are typically without signs; puppies with larval baylisascariasis show signs of neurologic disease.

SIGNALMENT

- Dogs.
- Intestinal form—adult animals.
- Larval form—puppies; suspect only severe cases have been reported; infection with only a few larvae probably does not cause severe disease in most puppies.

SIGNS

- Intestinal form—none.
- Larval form—weakness, ataxia, dysphagia, circling, recumbency.

CAUSES & RISK FACTORS

Sharing space with areas frequented by raccoons.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intestinal form—eggs in feces can be distinguished from those of either *Toxocara* or *Toxascaris*.
- Larval form—rabies, canine distemper, congenital neurologic defect, other infectious or inflammatory neurologic disease.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal; eosinophilia has been reported.

OTHER LABORATORY TESTS

N/A

IMAGING

- Larval form—based on lesions of toxocariasis or baylisascariasis in humans, lesions may appear on abdominal ultrasound or CT scans as small, single or multiple, ill-defined, oval or elongated, low-attenuating lesions in liver parenchyma.
- In neurologic lesions, MRI reveals diffuse periventricular white matter disease with atrophy.

DIAGNOSTIC PROCEDURES

- Intestinal form—direct fecal smear or fecal flotation (Web Figure 1).
- Larval form—ophthalmoscopic examination may show migratory tracks in retina, may use advanced imaging methods to visualize lesions in soft tissue or brain.

TREATMENT

- Intestinal form—may treat as inpatient to prevent environmental contamination with eggs and to ensure proper disposal (as biohazard) or destruction (incineration) of fecal material and worms after treatment.
- Larval form—no treatment to date.
- Client education—alert owner of potential risk to people who may frequent similar habitats to raccoons.

MEDICATIONS

DRUG(S) OF CHOICE

Intestinal Form

- Pyrantel pamoate—5–10 mg/kg PO.
- Fenbendazole (50 mg/kg q24h PO) for 3 days, repeat in 2 weeks.
- Febantel (25–35 mg/kg PO) with pyrantel pamoate (5–7 mg/kg PO) and praziquantel (5–7 mg/kg PO); Drontal Plus® label dose PO q24h for 5 days.
- Ivermectin (5 µg/kg PO) with pyrantel pamoate (5 mg/kg PO); Heartguard® approved label dosage, once monthly.
- Milbemycin (0.5–0.9 mg/kg PO), with lufenuron (10 mg/kg PO); Sentinel® approved label dosage, once monthly.

Larval Form

Corticosteroids and long-term albendazole (25–50 mg/kg/day PO for 10 days) may prove beneficial.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

- Intestinal form—check feces 2 weeks after deworming and again 1 month later.
- Larval form—disease has proven fatal.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Intestinal form—eggs are not infectious when passed, but can develop in the environment in several days; ingestion of eggs containing infective larvae by humans can cause severe disease, i.e., larval baylisascariasis.
- Larval form—infected puppies pose no zoonotic threat.
- Alert owner of potential risk to people who may frequent similar habitats to raccoons.

Suggested Reading

Author Dwight D. Bowman
Consulting Editor Amie Koenig

BENIGN PROSTATIC HYPERPLASIA

BASICS

OVERVIEW

- Age-related pathologic change in prostate gland, making it nonpainfully large.
- Occurs in two phases, glandular and complex.
- Glandular phase characterized by high number of large prostatic cells and symmetrically large prostate gland.
- Complex phase characterized by glandular hyperplasia and atrophy, small cyst formation, chronic inflammation, and squamous metaplasia of epithelium.

SIGNALMENT

Prevalence increases with age; 60% of intact male dogs affected by 6 years and 95% of intact male dogs affected by 9 years of age.

SIGNS

Historical Findings

- None in most dogs.
- Serosanguinous urethral discharge.
- Hemospermia.
- Hematuria.
- Dysuria.
- Dyschezia.
- Ribbon-like stools.

Physical Examination Findings

- Symmetric, nonpainfully enlarged prostate gland.
- Prostatic pain in dogs with complication of bacterial infection or prostatic carcinoma.

CAUSES & RISK FACTORS

- Dihydrotestosterone (DHT; strongly) and testosterone (weakly).
- Estrogens.
- Aging as intact male.
- Risk eliminated by castration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute bacterial prostatitis—fever, depression, pain on rectal palpation, neutrophilia, pyuria, and bacteriuria; occurs concurrently with and secondary to benign prostatic hyperplasia (BPH).
- Chronic bacterial prostatitis—recurrent lower urinary tract infections and subfertility; occurs concurrently with and secondary to BPH.
- Prostatic adenocarcinoma—poor appetite, weight loss, hind limb weakness, dysuria, hematuria, and dyschezia; may see carcinoma cells in urine sediment.
- Prostatic and paraprostatic cysts—can cause palpable abdominal cystic mass filled with yellow to orange fluid.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC and biochemistry—normal in BPH.
- Urinalysis—may be normal or reveal hematuria; pyuria and bacteriuria absent unless concurrent bacterial infection.

OTHER LABORATORY TESTS

Elevated serum concentration of canine prostate-specific arginine esterase correlates with histologic evidence of BPH.

IMAGING

- Radiography—abdominal radiographs reveal prostatomegaly.
- Ultrasonography—reveals enlarged prostate gland with uniform prostatic parenchymal echogenicity; small, fluid-filled cysts.

DIAGNOSTIC PROCEDURES

Prostatic fluid obtained by ejaculation or prostatic massage may be clear or hemorrhagic; red blood cell count high; white blood cell count normal; culture reveals <100,000 colony-forming units of bacteria/mL unless dog has concurrent bacterial infection.

TREATMENT

- Not required if asymptomatic.
- Castration—most effective and prevents recurrence; if BPH complicated by acute bacterial prostatitis, delay surgery until infection resolved.
- Finasteride, if castration not desired, as long as dog is to remain intact.

MEDICATIONS

DRUG(S) OF CHOICE

- If castration not acceptable, the following are the most available and clinically useful:
  - Finasteride (0.1 mg/kg/day, not to exceed 5 mg/dog/day) for as long as dog remains intact—inhibits conversion of testosterone to DHT by enzyme 5-α-reductase.
  - Osaterone acetate (0.25 mg/kg PO once daily for 7 days)—competitively binds to androgen receptors, reduces 5-α-reductase, inhibits testosterone transport into prostate cells.
  - Delmadinone acetate (3 mg/kg SC once)—antiandrogenic activity due to competitive binding to androgen receptors.
  - Deslorelin acetate (subcutaneous implant administered every 6–12 months)—gonadotropin-releasing hormone (GnRH) agonist to inhibit hypothalamic–pituitary–gondal axis by negative feedback.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Potential for glucocorticoid insufficiency during stressful events for unspecified period after delmadinone acetate treatment.
- GnRH agonists contraindicated in breeding dogs as will inhibit fertility.

FOLLOW-UP

- Castration is treatment of choice for nonbreeding dogs, will result in 80% reduction in prostate volume within 12 weeks.
- Finasteride is treatment of choice for breeding males. Side effects in dogs reported. Prostate reduced 50–70% between 16 and 53 weeks of treatment. Testosterone preserved, thus finasteride not associated with decline in libido or semen quality. BPH will recur after withdrawal of finasteride; time until clinical signs recur is variable.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Bacterial prostatitis and prostatic carcinoma.
- Prostatomegaly in castrated dog strongly suggests prostatic carcinoma, as other prostatic diseases unlikely to occur in absence of androgenic influence.

SEE ALSO

- Prostatic Cysts.
- Prostatitis and Prostatic Abscess.
- Prostatomegaly.

ABBREVIATIONS

- BPH = benign prostatic hyperplasia.
- DHT = dihydrotestosterone.
- GnRH = gonadotropin-releasing hormone.

BENZODIAZEPINE AND OTHER SLEEP AIDS TOXICOSIS

BASICS

DEFINITION
- Toxicosis due to ingestion of sleep aids or antianxiety medications commonly used in human and veterinary medicine.
- Benzodiazepine class—alprazolam (Xanax®), clonazepam (Klonopin®), diazepam (Valium®), lorazepam (Ativan®), midazolam (Versed®), temazepam (Restoril®), triazolam (Halcion®), and many more.
- Imidazopyridine class—eszopiclone (Lunesta®), zaleplon (Sonata®), and zolpidem (Ambien®, Ambien CR, Intermezzo®, Zolpimist®).

PATHOPHYSIOLOGY
- Benzodiazepines and imidazopyridines bind to receptors near the gamma-aminobutyric acid (GABA) receptor/chloride channel on neurons; they potentiate GABA's effect, which increases the opening of the chloride channel, leading to hyperpolarization of the nerve and decreased excitation.
- Imidazopyridines bind near the receptor subset that is responsible for sedation, while benzodiazepines bind to all receptor subsets and so not only mediate sedation, but are also anticonvulsant and anxiolytic.
- Paradoxical reactions can occur and are typically described as excitement, irritability, and aberrant demeanor in cats and excitement in dogs, when the expected effect is seizure control or sedation.
- Both classes are well absorbed orally and have rapid onset of actions, often less than 30 minutes.
- Duration of action depends on the drug and may last for hours to days.
- Both classes have wide margins of safety; lethal exposures are rare if a single agent is involved.
- Benzodiazepines—signs can be seen at therapeutic doses; however, the drugs have a wide margin of safety, with the minimal lethal dose being approximately 1,000 times the therapeutic dose. Cats may develop idiosyncratic hepatic failure with chronic oral dosing of diazepam and clonazepam.
- Zaleplon—based on a review of the American Society for the Prevention of Cruelty to Animals' Animal Poison Control Center (ASPCA APCC) Antox database: in dogs, doses >0.11 mg/kg have been associated with restlessness and hyperactivity; in cats, doses of >1.25 mg/kg caused paradoxical reactions.
- Zolpidem—based on a review of the ASPCA APCC Antox database: in dogs, dosages >0.2 mg/kg can cause mild sedation and ataxia; doses >0.6 mg/kg can cause paradoxical reactions. In cats, signs of paradoxical reactions were seen at 0.34 mg/kg or greater.

SYSTEMS AFFECTED
- Gastrointestinal—vomiting.
- Hepatic—acute necrosis and failure in cats with diazepam and clonazepam.
- Nervous—CNS depression and/or paradoxical reactions, ataxia, coma.
- Respiratory—depression.

GENETICS
N/A

INCIDENCE/PREVALENCE
Commonly prescribed drugs, so exposure is common.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT
Species
Dogs and cats—acute toxicity; cats—idiosyncratic hepatic failure with chronic oral dosing of diazepam or clonazepam possible.

Breed Predilections
None

Mean Age and Range
None

Predominant Sex
None

SIGNS
General Comments
- Benzodiazepines can cause sedation with virtually any exposure (even at therapeutic doses).
- Imidazopyridines cause sedation at low doses, but likelihood of paradoxical reaction increases with increasing dose, especially in dogs.

Historical Findings
- Evidence of accidental ingestion of medication.
- Therapeutic use of drug.
- Lethargy.
- Ataxia.
- Sedation.
- Agitation.

Physical Examination Findings
- Depression.
- Ataxia.
- Sedation.
- Hypothermia.
- Agitation.
- Hyperthermia (secondary to agitation).
- Tachycardia.
- Icterus (in cats with idiopathic liver failure).

CAUSES
Accidental exposure, inappropriate administration, or therapeutic use.

RISK FACTORS
- Younger and older animals.
- Animals with preexisting conditions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- CNS depression—barbiturates, ivermectin, ethylene glycol, alcohols (e.g., ethanol, methanol), marijuana, opioids, and antidepressants (low doses).
- Paradoxical reactions—amphetamines, pseudoephedrine, methylxanthines, cocaine, phenylpropanolamine, and serotonin syndrome (secondary to antidepressants).

CBC/BIOCHEMISTRY/URINALYSIS
- No abnormalities expected in acute overdoses.
- In cats with idiopathic liver failure, elevated liver enzymes and bilirubin.

OTHER LABORATORY TESTS
- Benzodiazepines can be detected in blood, urine, and liver; over-the-counter (OTC) drug-testing kits may be used to confirm exposure, but the label should be examined closely to be certain all benzodiazepines are included in the test kit.
- Imidazopyridines can be detected in blood and urine; OTC drug-testing kits are not yet readily available.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
No gross or histologic changes are expected.

TREATMENT

APPROPRIATE HEALTH CARE
- Outpatient—most mildly affected animals can be managed at home with confinement (to avoid injury due to falls) and minimizing stimulation.
- Inpatient—animals who are comatose or showing paradoxical reactions.

NURSING CARE
- Intravenous fluids.
- Monitor and control body temperature.
- Good bedding and frequent turning for recumbent patients.
- Minimize sensory stimulation, especially with paradoxical reactions.

ACTIVITY
Restrict until recovered to avoid injury.

DIET
Cats with liver failure may require forced or tube feeding for support.

CLIENT EDUCATION
- Make all clients aware of proper storage of all medications.
- If prescribing diazepam or clonazepam to cats, have owner closely monitor the cat for the first week.

BENZODIAZEPINE AND OTHER SLEEP AIDS TOXICOSIS (CONTINUED)

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
- Acepromazine 0.01–0.2 mg/kg IV/IM as needed to control paradoxical reactions.
- Cyproheptadine 1.1 mg/kg PO q4–6h or rectally for dogs; 2–4 mg/cat q4–6h for control of paradoxical reactions.
- Flumazenil—a benzodiazepine reversal agent: 0.01 mg/kg IV q1–2h as needed; it can be used to reverse both excessive sedation and paradoxical reaction; however, flumazenil can cause seizures, so its use is generally restricted to life-threatening situations.

CONTRAINDICATIONS
Do not give other benzodiazepines to control paradoxical reactions.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
Care when using other depressant medications (e.g., barbiturates, phenothiazines), as these can potentiate the depressant effects of these drugs.

FOLLOW-UP

PATIENT MONITORING
TPR, blood pressure, respiratory effort.

PREVENTION/AVOIDANCE
Secure medications out of reach of dogs and cats.

POSSIBLE COMPLICATIONS
No long-term complications expected.

EXPECTED COURSE AND PROGNOSIS
- Prognosis for acute overdose is excellent with symptomatic care.
- Prognosis for acute hepatic failure in cats with diazepam is poor.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
- Young animals and those with preexisting liver disease may have prolonged signs due to reduced ability to clear the drugs.
- Younger animals may be more prone to paradoxical reactions.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Benzodiazepines are considered teratogenic.

SEE ALSO
- Amphetamine and ADD/ADHD Medication Toxicosis.
- Antidepressant Toxicosis—SSRIs and SNRIs.
- Antidepressant Toxicosis—Tricyclic.
- Ethanol Toxicosis.
- Ethylene Glycol Toxicosis.
- Ivermectin and Other Macrocyclic Lactones Toxicosis.

ABBREVIATIONS
- ASPCA APCC = American Society for the Prevention of Cruelty to Animals' Animal Poison Control Center.
- GABA = gamma-aminobutyric acid.
- OTC = over-the-counter.

BETA RECEPTOR ANTAGONIST (BETA BLOCKERS) TOXICOSIS

BASICS

OVERVIEW

- Beta receptor antagonists—class II antidysrhythmics used to treat hypertrophic or hypertrophic obstructive cardiomyopathy in cats and hypertension and tachydysrhythmias in dogs and cats.
- β_1 receptors—primarily located in heart, eye, and kidney.
- β_2 receptors—primarily located in bronchial smooth muscle, gastrointestinal tract, pancreas, liver, skeletal muscle, vascular smooth muscle, and endothelium.
- Systems affected include:
  - Cardiovascular—bradycardia, hypotension.
  - Respiratory—bronchospasm.
  - Nervous—decreased mentation, seizures.
  - Endocrine/metabolic—hypoglycemia, metabolic acidosis secondary to hypoperfusion.
  - Renal/urologic—acute kidney injury secondary to prolonged hypoperfusion.

SIGNALMENT

Dogs and cats equally affected with no breed, age, or sex predilection.

SIGNS

- Bradycardia, atrioventricular (AV) block.
- Hypotension.
- Decreased mentation.
- Respiratory distress/bronchospasm.
- Seizures.
- Coma.
- Death.

CAUSES & RISK FACTORS

Therapeutic overdose or ingestion of medication.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Calcium channel blocker overdose.
- Cardiac disease with bradyarrhythmias.
- Cardiovascular drug overdose (e.g., clonidine, digoxin toxicosis).
- Sedative overdose (e.g., opioid or baclofen toxicosis).
- Sick sinus syndrome.
- Hyperkalemia.
- Decompensated shock.

CBC/CHEMISTRY/URINALYSIS

- Hypoglycemia.
- Hyperkalemia (mild).
- Azotemia and elevated liver enzymes with prolonged hypoperfusion.

OTHER LABORATORY TESTS

Blood gas—metabolic acidosis.

DIAGNOSTIC PROCEDURES

- ECG—first, second, and third degree AV block; prolonged PR, QRS, and QT intervals.
- Echocardiogram—negative inotropy, decreased cardiac output.

TREATMENT

- Emesis if asymptomatic and recent ingestion (<2 hours).
- Consider gastric lavage if decreased mental status and large number of pills ingested.
- Volume resuscitation with IV fluid bolus over 15–20 minutes for hypotension—cats, 10–20 mL/kg for cats; dogs, 20–30 mL/kg.
- Consider temporary cardiac pacing and hemodialysis (drug removal) in severe intoxications.

MEDICATIONS

DRUG(S) OF CHOICE

- Activated charcoal (1–2 g/kg) within 2 hours post exposure; repeat activated charcoal for ER formulations.
- Atropine (0.02–0.04 mg/kg IV) for sinus bradycardia.
- Intravenous fat emulsion (IFE)—may bind lipid-soluble drugs, increase Ca available for muscle contraction, and provide energy source for heart muscle. IFE 20% dose—1.5 mL/kg IV bolus over 1 min followed by CRI of 0.25 mL/kg/min for 30–60 min. Additional IV doses—1.5 ml/kg every 4–6 hours or CRI of 0.5 mL/kg/h; monitor serum for lipemia every 2–4 hours to determine if additional dosing needed.
- High-dose insulin euglycemia (HIE) treatment—may provide energy for heart muscle and increase Ca available for muscle contraction. Recommended treatment:
  - Check blood glucose (BG) concentration and administer dextrose if BG <100 mg/dL.
  - Administer regular insulin at 1 unit/kg IV followed by CRI at 0.5–2 units/kg/h. Increase every 10 min as needed up to maximum dose of 10 units/kg/h. When clinical signs resolve, decrease insulin by 1–2 units/kg/h.
  - Monitor BG every 10 min while titrating insulin dosing. Once insulin dosing is stabilized, check BG every 30–60 min. Dextrose supplementation IV will be needed to maintain normal BG concentrations. Central line placement recommended for frequent glucose monitoring and dextrose administration during HIE treatment. May need to continue dextrose supplementation up to 24 hours after discontinuation of insulin.
  - Monitor potassium concentration every hour during titration, then every 6 hours. Administer potassium chloride to keep potassium concentrations within normal range.
- Calcium gluconate 10% 0.5–1.5 ml/kg IV over 10–20 min, followed by CRI 0.1–0.15 ml/kg/h. May increase calcium available for heart muscle contraction.
- Glucagon—0.05–0.2 mg/kg slow IV bolus followed by CRI of 0.1–0.15 mg/kg/h. May not be as effective as IFE or HIE therapy.
- Sympathomimetics or vasopressin should only be used in cases refractory to other treatments.

CONTRAINDICATION/POSSIBLE INTERACTIONS

Vasopressors/sympathomimetics may not be as effective as other therapy and may make patients less responsive to treatment.

FOLLOW-UP

PATIENT MONITORING

- Monitor for 8 hours with immediate release preparations and 12–24 hours for extended release (ER) preparations.
- Heart rate/ECG.
- Blood pressure.
- Potassium levels.
- Blood glucose.

POSSIBLE COMPLICATIONS

Renal failure can occur secondary to prolonged hypoperfusion.

EXPECTED COURSE AND PROGNOSIS

- Ingestion of immediate release preparations typically result in clinical signs in 6 hours.
- Sustained release (SR) or ER preparations may take 12–24 hours for clinical signs to develop.
- Prognosis depends on dose ingested and response to therapy, but generally good.

MISCELLANEOUS

ABBREVIATIONS

- AV = atrioventricular.
- BG = blood glucose.
- ER = extended release.
- HIE = high-dose insulin euglycemia.
- IFE = intravenous fat emulsion.
- SR = sustained release.

Client Education Handout available online

BETA-2 AGONIST INHALER TOXICOSIS

BASICS

OVERVIEW

- Beta-2 agonist inhaler toxicosis occurs when dogs chew and puncture pressurized inhalers containing albuterol (salbutamol), levalbuterol, or salmeterol.
- Loss of beta-2 adrenergic selectivity with overdose results in beta-1 stimulation (sinus tachycardia). Failure of the myocardium to effectively oxygenate during extreme periods of tachycardia can result in other tachyarrhythmias such as ventricular premature contractions (VPCs) and ventricular tachycardia.
- Generalized adrenergic stimulation releases catecholamines that exacerbate cardiovascular (CV) stimulation, stimulate the CNS and respiratory systems, and can result in significant intracellular translocation of potassium and phosphorus.
- Propellants are now hydrofluoroalkanes (HFAs) and are expected to sensitize the myocardium less to catecholamines than older chlorofluorocarbon propellants.

Systems Affected

- Behavioral—hyperactivity, apprehension, nervousness, restlessness.
- Cardiovascular—sinus tachycardia, other tachyarrhythmias.
- Endocrine/metabolic—hypokalemia, hypophosphatemia.
- Gastrointestinal—mild vomiting.
- Musculoskeletal—tremors, weakness with catecholamine depletion.
- Nervous—anxiety, apprehension initially, depression with catecholamine depletion.
- Neuromuscular—tremors.
- Respiratory—tachypnea.

SIGNALMENT

Young dogs are overrepresented due to their predilection for dietary indiscretion.

SIGNS

- Tachycardia, other tachyarrhythmias.
- Lethargy, weakness, depression.
- Hyperactivity, apprehension, nervousness, restlessness.
- Tachypnea.
- Vomiting.
- Tremors.

CAUSES & RISK FACTORS

- Puncture of inhalers containing beta-2 agonists.
- Pets prone to dietary indiscretion with access to inhalers.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Amphetamines and related drugs such as those used for attention deficit hyperactivity disorder (ADHD).
- Sympathomimetics (e.g., phenylpropanolamine, pseudoephedrine, phenylephrine, ephedrine).
- Methylxanthines (e.g., caffeine, theobromine).
- Metaldehyde.
- Illicit drugs including methamphetamine.
- Thyroxine.
- Tremorgenic mycotoxins.
- Hops (*Humulus lupulus*).
- Nicotine.

CBC/BIOCHEMISTRY/URINALYSIS

- Hypokalemia.
- Hypophosphatemia.

DIAGNOSTIC PROCEDURES

ECG to confirm, monitor for arrhythmias.

TREATMENT

- Inpatient treatment—initiate medical management and emergency care as soon as possible following exposure.
- Nursing care required—fluid support.
- Altered activity—cage rest, quiet environment.
- NPO if vomiting.
- Discuss with owner timing of presentation relative to exposure; patients that have delayed presentation and prolonged, untreated CNS and CV stimulation may be at greater risk for more serious arrhythmias and slower recovery.
- No surgical or anesthetic considerations.

MEDICATIONS

DRUG(S) OF CHOICE

- Benzodiazepines PRN for anxiety, nervousness, tremors—diazepam: 0.5–1 mg/kg IV or 1 mg/kg rectally, repeat PRN; midazolam: 0.1–0.3 mg/kg IV, IM, repeat PRN.
- Beta blockers for severe tachycardia (HR >160 in large dogs; >200 in miniature breeds), hypokalemia—propranolol (preferred, nonspecific blocker): dogs, 0.02–0.06 mg/kg IV to effect; esmolol (blocks beta-1 only; ultra-short acting): dogs, 0.25–0.5 mg/kg IV as slow bolus then CRI of 0.01–0.2 mg/kg/min.
- Potassium chloride supplementation—up to 0.5 mEq potassium/kg/h IV maximum, based on degree of hypokalemia.
- Potassium phosphate if phosphorus <1 mg/dL—0.01–0.03 mM/kg/h IV.
- Lidocaine for ventricular arrhythmias—dogs, 2–4 mg/kg IV (max 8 mg/kg over 1–2 mins) followed by CRI of 25–100 µg/kg/min; cats, 0.25–0.5 mg/kg IV slowly (special caution for use in cats due to predilection for CNS and CV toxicity).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Electrolytes (potassium, phosphorus) q12h or PRN if ECG changes, weakness (potassium), hemolysis (phosphorus). *Note*: Monitor for rebound hyperkalemia.
- ECG.
- Mentation.

POSSIBLE COMPLICATIONS

- Rarely fatal. Persistent, severe tachycardia can result in myocardial hypoxia and more serious arrhythmias or other cardiac sequelae.
- Catecholamine depletion can result in weakness and depression once the stimulatory effects wane.

EXPECTED COURSE AND PROGNOSIS

Excellent prognosis with prompt and appropriate treatment in an otherwise healthy patient.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- Albuterol crosses the placenta. Overdose effects are expected to be similar for the fetus. Hypoxia with cardiac compromise in the bitch may harm the fetus.
- No adverse effects expected with regard to fertility.

ABBREVIATIONS

- ADHD = attention deficit hyperactivity disorder.
- CV = cardiovascular.
- HFA = hydrofluoroalkane.
- VPC = ventricular premature contraction.

BILE DUCT CARCINOMA

BASICS

OVERVIEW

• Epithelial neoplasia that arises from the cells lining the biliary ducts or gallbladder. • Second most common malignant hepatic tumor in dogs, representing 22–41% of all malignant canine liver tumors. • Most common malignant hepatobiliary tumor in cats, but less common than benign biliary cystadenoma. • Benign biliary cystadenomas may undergo malignant transformation into cystadenocarcinomas, although time period over which this occurs is unknown. • Common metastatic sites include lungs, regional lymph nodes, and peritoneum (carcinomatosis); other metastatic sites include intestine, pancreas, heart, spleen, kidney, spinal cord, urinary bladder, bone, and rarely bone marrow.

SIGNALMENT

• Dogs and cats. • Possible predilection for Labrador retrievers. • Affected animals typically >10 years of age. • Possible predisposition for female dogs.

SIGNS

Historical Findings

• Anorexia. • Lethargy. • Weight loss. • Vomiting. • Polyuria/polydipsia. • Icterus. • Abdominal distension.

Physical Examination Findings

• Hepatomegaly/cranial abdominal mass effect. • Ascites. • Icterus. • Paraneoplastic alopecia (ventral abdomen) associated with feline biliary carcinoma.

CAUSES & RISK FACTORS

• Potential association between canine cholangiocarcinoma and trematode (hookworms, whipworms) infection. • Canine biliary carcinoma has been experimentally induced by N-ethyl-N′-nitro-N-nitrosoguanidine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Hepatocellular adenoma (hepatoma). • Hepatocellular carcinoma. • Biliary adenoma/cystadenoma. • Nodular hyperplasia. • Cirrhosis. • Chronic active hepatitis. • Hepatic myelolipoma. • Carcinoids. • Hepatic abscess.

CBC/BIOCHEMISTRY/URINALYSIS

• Anemia. • Leukocytosis. • Elevated serum enzyme (alkaline phosphatase [ALP], gamma-glutamyl transferase [GGT], alanine aminotransferase [ALT], aspartate aminotransferase [AST]) activity. • Hyperbilirubinemia.

OTHER LABORATORY TESTS

• α-fetoprotein (an oncofetal glycoprotein) is elevated in 55% of dogs with bile duct carcinoma; may differentiate neoplastic from non-neoplastic lesions in dogs. • Coagulation profile (prothrombin time [PT], partial thromboplastin time [PTT]) recommended before biopsy or surgical procedures. • Pre- and postprandial bile acids can help assess hepatobiliary function.

IMAGING

• Abdominal radiography—may localize a mass to the liver, show displacement of the stomach, or demonstrate loss of detail in patients with peritoneal effusion. • Abdominal ultrasonography—can be used to assess location and character of lesion, detect and sample peritoneal effusion, and guide tumor biopsy. • Thoracic radiography—should be used to screen for pulmonary metastasis. • CT and MRI—more sensitive techniques that are more likely to detect smaller lesions not visible on ultrasound and radiography.

DIAGNOSTIC PROCEDURES

• Abdominocentesis and cytologic evaluation of peritoneal fluid. • Cytology or needle core (Tru-Cut®) biopsy samples via ultrasound guidance. • Laparoscopy or laparotomy may be needed to obtain larger samples for definitive diagnosis.

PATHOLOGIC FINDINGS

• Gross findings—morphologic types include massive (37–46%), nodular (0–21%), or diffuse (17–54%). Can be intrahepatic (most common in dogs), extrahepatic, or within the gall bladder (rare). • Histopathology findings—histologic subtypes include solid (cholangiocarcinoma) and cystic (biliary cystadenocarcinoma); subtype does not influence prognosis; immunohistochemistry (hepatocyte paraffin-1 and Claudin-7) can distinguish poorly differentiated hepatocellular carcinoma from biliary carcinoma.

TREATMENT

• Complete surgical excision is treatment of choice; surgery not applicable for nodular/diffuse forms. • Up to 80% of liver can be resected if remaining liver tissue is functional. • Interventional techniques (chemoembolization) may be utilized as palliative procedures for nonresectable solitary tumors.

MEDICATIONS

DRUG(S) OF CHOICE

• Chemotherapy—no effective protocol identified. Tyrosine kinase inhibitors have been used anecdotally.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Medications requiring metabolism by hepatobiliary system should be used with caution if evidence of dysfunction is present.

FOLLOW-UP

PATIENT MONITORING

Periodic physical examination, lab work, abdominal ultrasonography, and thoracic radiography after tumor resection.

PREVENTION/AVOIDANCE

Anthelmintic therapy is warranted due to potential association between canine bile duct carcinoma and infection with hookworms or whipworms.

POSSIBLE COMPLICATIONS

• Tumor rupture/hemorrhage, esp. if the massive form. • Biliary obstruction.

EXPECTED COURSE AND PROGNOSIS

• Aggressive tumor with a guarded to poor prognosis, especially if nonresectable. • High rate of metastasis (up to 88%) in both dogs and cats; widespread intraperitoneal carcinomatosis common in cats. • Most patients die within 6 months of surgery due to local recurrence or metastasis.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Chemotherapy drugs may be carcinogenic and mutagenic.

ABBREVIATIONS

• PT = Prothrombin time. • PTT = Partial thromboplastin time.

BILE DUCT OBSTRUCTION (EXTRAHEPATIC)

BASICS

DEFINITION
Extrahepatic bile duct obstruction (EHBDO) is biliary tree obstruction at the level of either the common bile duct (CBD) or the hepatic ducts, where it may involve one, several, or all hepatic ducts. Obstruction may be partial or complete.

PATHOPHYSIOLOGY
- EHBDO caused by abnormalities within biliary system or secondary to diseases affecting organs surrounding biliary tree; see Causes.
- Serious hepatobiliary injury follows within weeks of complete duct obstruction.
- Gallbladder (GB) bile may become colorless (white bile) if canalicular green pigmented hepatic bile not diverted into GB.
- Increased risk of bacterial infection of bile with stasis of bile flow.
- EHBDO progresses to biliary cirrhosis within 6 weeks; exception is pancreatitis causing EHBDO that may self-resolve within 2–3 weeks.

SYSTEMS AFFECTED
Hepatobiliary

SIGNALMENT

Species
Dog and cat.

Breed Predilection
- Some breeds predisposed to pancreatitis, choleliths, GB mucocele (GBM), dyslipidemias.
- Animals with large duct ductal plate malformation (DPM) phenotypes—predisposed to infection and cholelithiasis.
- Choleliths appear more common in small-breed dogs and cats.
- Neoplasia involving CBD more common in older animals and cats with chronic inflammation of biliary tree.

Mean Age and Range
Middle-aged to old animals with acquired disease; younger animals with DPM.

Predominant Sex
None

SIGNS

Historical Findings
- Depend on underlying disorder and "completeness" of EHBDO.
- Progressive lethargy and vague illness associated with progressive jaundice.
- Pale (acholic) stools—complete EHBDO in absence of enteric bleeding.
- Polyphagia—complete EHBDO causes nutrient malassimilation (fat).
- Bleeding tendencies—within 10 days of complete EHBDO, more severe/overt in cats.

Physical Examination Findings
- Depend on underlying cause.
- Weight loss.
- Severe jaundice.
- Hepatomegaly unless biliary cirrhosis.
- Cranial mass effect—extrahepatic biliary structures (small dogs and cats) or pancreatic involvement.
- Vague cranial abdominal discomfort.
- Acholic feces—unless enteric bleeding (hemoglobin pigment evolves pigmented feces).
- Bleeding tendencies and bruising—chronic EHBDO.
- Orange urine—severe bilirubinuria.

CAUSES & RISK FACTORS
- Diverse primary disorders.
- Cholelithiasis.
- Choledochitis.
- Neoplasia.
- Bile duct malformations—DPM phenotypes: choledochal cysts (cats), Caroli's malformation (dogs, cats), rare cystadenoma encroaching on porta hepatis (cats).
- Parasitic infestation—flukes (cats).
- Extrinsic compression—lymph nodes, neoplasia, pancreatitis, CBD entrapment in diaphragmatic hernia; foreign body obstruction of sphincter of Oddi in duodenum.
- Duct fibrosis—trauma, peritonitis, pancreatitis; major duct involvement in feline cholangitis/cholangiohepatitis syndrome (CCHS).
- Duct stricture—blunt trauma, iatrogenic surgical manipulations, e.g., after cholecystectomy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Mass lesions—primary or metastatic hepatobiliary neoplasia; adjacent viscera.
- Diffuse infiltrative liver disease—neoplastic, inflammatory, hepatic lipidosis (HL), amyloid (rare).
- Infectious hepatitis—bacterial, viral, trematodes, protozoal.
- Severe hepatic fibrosis/cirrhosis.
- Decompensated chronic hepatitis.
- Copper-associated hepatopathy.
- Fulminant hepatic failure.
- Biliary cysts—DPM phenotypes: choledochal (cats), cystadenoma compressing CBD at porta hepatis.
- Pancreatitis—CBD stenosis/stricture, choleliths in cats: fused bile and pancreatic ducts.
- HL—cats: canalicular collapse causes jaundice.
- CCHS—cats, lymphocytic sclerosing or destructive cholangitis.

CBC/BIOCHEMISTRY/URINALYSIS

CBC
- Anemia—mild nonregenerative (chronic disease) or regenerative (enteric bleeding, Heinz body hemolysis).
- Microcytosis—uncommon.
- Leukogram—variable, neutrophilic leukocytosis, left-shifted leukogram with sepsis.
- Plasma—markedly jaundiced.

Biochemistry
- Liver enzymes—variable; marked increases in alkaline phosphatase (ALP) and gamma glutamyltransferase (GGT) reflect ductal injury; high alanine aminotransferase (ALT) and aspartate transaminase (AST) reflect periportal hepatocyte injury or multifocal injury associated with sepsis.
- Total bilirubin—moderate to markedly high; less than observed with hemolysis or HL; hyperbilirubinemia markedly escalated subsequent to blood transfusion.
- Albumin—variable, usually normal except when EHBDO >6 weeks (biliary cirrhosis); low albumin reflects synthetic failure or loss into abdominal effusion if syndrome complicated by GB rupture, suppurative hepatitis, or hepatic fibrosis leading to ascites.
- Globulins—normal or increased.
- Glucose—normal or low if biliary cirrhosis or sepsis; high if diabetes with pancreatitis.
- Hypercholesterolemia—common.

Urinalysis
- Bilirubinuria and bilirubin crystal formation.
- Absence of urobilinogen—unless enteric bleeding; unreliable test for EHBDO.

OTHER LABORATORY TESTS
- Serum bile acids—always markedly increased; superfluous test if hepatobiliary jaundice already suspected.
- Coagulation abnormalities—within 10 days of EHBDO develop vitamin K deficiency; may develop disseminated intravascular coagulation (DIC).
- Fecal examination—acholic stools consistent with EHBDO, but may be masked by small-volume melena; trematode eggs may be verified in fluke infestation (cats).

IMAGING
- Abdominal radiography—inconsistent hepatomegaly; variable mass effect in area of gallbladder or CBD, pattern consistent with pancreatitis, mineralized cholelith(s).
- Cholecystography—rarely provides additional practical information.
- Abdominal ultrasonography—evidence of obstruction in 72–96 hours (distended, tortuous CBD, cystic duct, intrahepatic bile ducts); may disclose underlying or primary disorder (e.g., pancreatitis, cystic lesions, mass

(CONTINUED) # BILE DUCT OBSTRUCTION (EXTRAHEPATIC)

lesions, choleliths). *Caution*: GB bile "sludge" and full GB common in anorectic or fasted patients—do not mistake for EHBDO.
• *Caution*: Feline CBD serpiginous compared to canine—always inspect liver image for distended intrahepatic bile ducts and confirm that "tubes" are ducts rather than vasculature with color flow Doppler.

DIAGNOSTIC PROCEDURES

• Hepatic aspiration cytology—used to rule in HL (cats) or sample mass lesions; most clinicians avoid aspiration of obstructed biliary structures to avoid iatrogenic bile leakage and peritonitis.
• Ultrasound-guided needle biopsy—strongly contraindicated; may cause iatrogenic bile peritonitis.
• Laparotomy—best approach; allows tissue biopsy; biliary decompression; mass excision: cholelith or inspissated bile removal; cholecystectomy or creation of biliary-enteric anastomosis; CBD stent insertion.
• Laparoscopic procedures *not prioritized* because of need to completely evaluate biliary structures, ensure bile duct patency, and provide biliary decompressive surgeries.

PATHOLOGIC FINDINGS

• Gross—distended, tortuous bile duct, distended GB: cause often grossly apparent; obstruction >2 weeks: large, dark green to dark mahogany-colored liver; chronic complete obstruction often associates with white or clear GB bile.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—surgical intervention for EHBDO unless the cause is pancreatitis with prospect for resolution with supportive care.

NURSING CARE

• Fluid therapy—depends on underlying conditions; rehydrate and provide maintenance fluids before general anesthesia and surgical interventions.
• Water-soluble vitamins—in IV fluids; B complex (2 mL/L polyionic fluids).
• Initiate antibiotic therapy before surgery—see Drug(s) of Choice.
• Vitamin K_1—parenteral administration if EHBDO >5–7 days (see Drug(s) of Choice) before surgical interventions, abdominal or visceral aspiration cytology, placement of central lines or urinary catheters.

ACTIVITY

Depends on patient status and coagulopathy.

DIET

• Maintain nitrogen balance—avoid protein restriction.
• Restrict fat *if* overt fat malassimilation caused by lack of enteric bile acids in chronic EHBDO—rare.
• Supplement fat-soluble vitamins—vitamins E and K most urgent; supplements of vitamins D and A can lead to toxicity, thus careful use only in chronic unresolvable EHBDO.
• Water-soluble vitamin E—necessary in chronic EHBDO (see Drug(s) of Choice).
• Vitamin K—parenteral only, use SC or IM routes only.

CLIENT EDUCATION

• Inform client that surgical biliary decompression essential (unless resolvable pancreatitis or cholelith obstruction).
• Warn client that surgical success contingent on underlying cause, results of liver biopsy, infection, and individual variables.

SURGICAL CONSIDERATIONS

• Surgical exploration—imperative for determining underlying cause and for implementing definitive treatment unless obvious pancreatitis with hope for resolution.
• Excise masses, remove choleliths and inspissated bile; ensure common duct patency.
• Resect GB—if necrotizing cholecystitis, GBM, or GB cholelithiasis.
• Biliary-enteric anastomosis—if irresolvable occlusion of CBD: e.g., fibrosing pancreatitis, or neoplasia; anastomotic stoma at least 2.5 cm wide; chronic recurrent infection likely after biliary-enteric anastomosis; warn clients that temporary stenting instead of biliary-enteric anastomosis may be complicated by infection and stent obstruction, esp. in cats.
• Hypotension and bradycardia (vasovagal reflex)—may develop during biliary tree manipulation; ensure availability of emergency drugs (anticholinergics) and ventilatory support for rescue endeavors.
• Cholangiovenous reflux—bacteria and endotoxins during surgery from biliary tree manipulations in septic conditions; contributes to perioperative hypotension; all suspected EHBDO patients should be given broad-spectrum IV antimicrobials pre-, intra-, and postoperatively (during surgery after tissue and bile collection for bacterial culture).
• Ensure IV catheter access and volume expansion before surgery—use colloids only when plasma unavailable; be prepared for hemorrhage (have whole blood or packed red blood cells [RBCs] available).
• Surgical biopsies—submit tissue and particulate bile for aerobic and anaerobic bacterial culture; submit tissue for histology. Culture biliary debris; if GB removed, scrape wall to collect mucoid wall adherent material. Also collect GB wall, liquid bile, and liver tissue for culture. Combine all samples into a single culture for best bacterial recovery.
• Cytology—tissue and bile; cytology may detect bacterial infection and fluke eggs not recognized in biopsy sections; bile, biliary debris, and GB wall: more likely to harbor bacteria.
• Sclerosing or destructive feline cholangitis (intrahepatic ductopenia associated with lymphocytic or nonsuppurative or suppurative CCHS) may clinically emulate EHBDO; does not respond to biliary tree decompression; liver biopsy necessary for definitive diagnosis.

MEDICATIONS

DRUG(S) OF CHOICE

Vitamin K_1

• Provide 12–36h before surgery—0.5–1.5 mg/kg IM/SC, 3 doses at 12h intervals. *Caution*: avoid IV, may cause anaphylaxis.
• If chronic EHBDO not resolvable, parenteral vitamin K_1 given chronically with frequency titrated using prothrombin time (PT); too much vitamin K_1 causes hemolytic (Heinz body) anemia in cats.
• Oral vitamin K ineffectual owing to low bioavailability in EHBDO.

Vitamin E

• If chronic EHBDO nonresolvable, use water-soluble vitamin E (d-α-tocopheryl polyethylene glycol succinate [TPGS]-vitamin E)—10 U/kg/day PO.
• Treat early to allow response before invasive catheterizations, sampling, or surgical procedures.

Antibiotics

Before surgery—broad-spectrum antimicrobials for potential biliary infection because surgical manipulations may disseminate bacteremia; initially use antibiotics with wide spectrum, e.g., triad of ticarcillin 25 mg/kg IV q8h, metronidazole 7.5 mg/kg IV/PO q12h, enrofloxacin 5 mg/kg PO q12–24h (24h dose in cats no greater than 5 mg/kg/24h to avoid retinopathy).

Antioxidants

• Vitamin E (α-tocopherol acetate)—10–100 IU/kg; a larger than normal (normal = 10 IU/kg/day) oral dose needed in chronic EHBDO if fat-soluble vitamin used; lower dose used with water-soluble vitamin E (preferred, see previous).
• *S*-adenosylmethionine (SAMe)—20-40 mg/kg/day PO enteric-coated tablet 1–2h before feeding; choleretic with high-dose administration via glutathione (GSH) provoked bile flow.

Ursodeoxycholic Acid

• 10–15 mg/kg PO per day—*after biliary decompression* as a choleretic; ensure adequate hydration to achieve choleresis; *inappropriate before* biliary decompression: can accelerate liver injury in EHBDO.

BILE DUCT OBSTRUCTION (EXTRAHEPATIC) (CONTINUED)

• Beneficial effects: antifibrotic, anti-endotoxic, hepatoprotectant, anti-apoptotic, immunomodulator.

Bowel Preparation before Surgery

• Mechanical cleansing of colon with water or crystalloid fluids—may reduce endotoxemia potentiating perioperative hypotension.
• Acutely alter enteric flora to reduce enteric translocation of opportunistic pathogen with medications given either PO or by high enema instillation—neomycin 22 mg/kg q8h; lactulose 1–2 mL/kg q8h; metronidazole 7.5 mg/kg q12h; enrofloxacin 2.5 mg/kg q12h PO; rifaximin 5–10 mg/kg q12h, at present limited experience with rifaximin in dogs and cats; probiotic bacteria, empirical product dose but has unproven efficacy.

Gastrointestinal Protectants

• Agents reducing gastric acidity—omeprazole or pantoprazole (pump inhibitors) or famotidine (H2 blocker) combined with sucralfate for local cytoprotection if PO medications tolerated and enteric bleeding recognized (stagger sucralfate administration from other oral medications to avoid drug interactions).
• Antiemetics—maropitant (Cerenia®) or ondansetron.

CONTRAINDICATIONS

• Provide biliary decompression before institution of ursodeoxycholic acid.
• Take care to reduce drug dosages for medications eliminated in bile if EHBDO.
• Avoid invasive procedures—sampling, biopsy, surgical interventions before vitamin K_1.

PRECAUTIONS

See Surgical Considerations.

FOLLOW-UP

PATIENT MONITORING

• Depends on underlying condition.
• Total bilirubin values acutely reflect biliary decompression; values normalize within days.
• Liver enzyme activities—decline slowly.
• CBC—repeat q2–3 days initially if septic.
• Bile peritonitis—evaluate abdominal girth, body weight, and fluid accumulation.
• Determine necessity for pancreatic enzyme supplementation based on site of biliary-enteric anastomosis; patients with cholecystojejunostomy may benefit from enzyme supplementation; cannot rely on trypsin-like immunoreactive (TLI) substance to estimate pancreatic exocrine adequacy in this circumstance; sequentially evaluate body weight and condition, check feces for steatorrhea; only relevant if animal is fed a normal fat-containing diet; if steatorrheic after biliary-enteric anastomosis and patient is anicteric, reduce dietary fat intake and supplement pancreatic enzymes. *Warning*: pancreatic enzymes can induce oral or esophageal injury, especially in cats—must be mixed in food or administered in capsule or tablet form, followed by liquid or food to prevent mucosal adherence and injury.

POSSIBLE COMPLICATIONS

• Bile peritonitis.
• Restenosis of bile duct—if not bypassed and only stented to achieve biliary decompression.
• Stenosis of biliary-enteric anastomosis.
• Severe enteric hemorrhage with EHBDO—hypertensive enteric vasculopathy with coagulopathy (vitamin K deficiency).
• Hemorrhage during surgery.
• Septic bacteremia or systemic inflammatory response syndrome (SIRS) during or after surgery.
• Perioperative unresponsive hypotension—persistent vasovagal reflex or sepsis related.
• Vasovagal reflex.
• Cholangiovenous reflux.

EXPECTED COURSE AND PROGNOSIS

• Depends on underlying disease.
• Prognosis good if fibrosing pancreatitis and pancreatic inflammation resolve; bile duct patency may return without surgery.
• *Beware*: biliary tree distention often persists (ultrasound imaging) after EHBDO resolution.
• Permanent peribiliary fibrosis from EHBDO.
• Cats with sclerosing cholangitis or ductopenia mimic EHBDO but show no response to biliary decompression; liver biopsy is essential for diagnosis.

Considerations/Precautions

• Anticipate bleeding tendencies, vasovagal reflex, and cholangiovenous reflux during surgical procedures.
• Always submit liver and biliary tree biopsies for histology; all tissues, crushed cholеliths, and biliary debris for bacterial culture (aerobic, anaerobic).

MISCELLANEOUS

ASSOCIATED CONDITIONS

• See Causes.
• Sclerosing or destructive lymphocytic cholangitis (cats) and destructive suppurative cholangitis causing ductopenia and idiopathic or toxic ductopenia are confused with EHBDO.

SEE ALSO

• Cholangitis/Cholangiohepatitis Syndrome.
• Gallbladder Mucocele.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• AST = aspartate transaminase.
• CBD = common bile duct.
• CCHS = cholangitis/cholangiohepatitis syndrome.
• DIC = disseminated intravascular coagulation.
• DPM = ductal plate malformation.
• EHBDO = extrahepatic bile duct obstruction.
• GB = gallbladder.
• GBM = gallbladder mucocele.
• GGT = gamma glutamyltransferase.
• GSH = glutathione.
• HL = hepatic lipidosis.
• PT = prothrombin time.
• RBC = red blood cell.
• SAMe = *S*-adenosylmethionine.
• SIRS = systemic inflammatory response syndrome.
• TLI = trypsin-like immunoreactive.
• TPGS-Vitamin E = d-α-tocopheryl polyethylene glycol succinate.

BILE PERITONITIS

BASICS

OVERVIEW

- Chemical peritonitis due to release of free bile into the abdominal cavity.
- Can involve focal or diffuse peritoneal inflammation, depending on chronicity and causal factors, and omental adhesions.

SIGNALMENT

- More common in dog than in cat.
- No age, breed, or sex predilection.

SIGNS

Historical Findings

- Acute presentation if septic peritonitis.
- May have chronic illness if nonseptic.
- Rare asymptomatic biliary rupture associated with omental encapsulation of leakage.
- Abdominal discomfort—vague.
- Lethargy.
- Gastrointestinal signs—anorexia, vomiting, diarrhea.
- Weight loss.
- ± Abdominal distention.
- Variable jaundice.
- Collapse, if septic.

Physical Examination Findings

- Lethargy.
- Variable (cranial) abdominal pain.
- Jaundice.
- Abdominal effusion.
- ± Fever.
- ± Endotoxic shock, if septic.

CAUSES & RISK FACTORS

- Limited arterial perfusion (cystic artery) to gallbladder (GB) fundus predisposes to ischemic necrosis and GB rupture.
- Trauma to biliary structures—automobile injuries, surgical, animal bites, gunshot wounds, cystic artery laceration during cholecystocentesis.
- Common bile duct (CBD)—frequent site of rupture with blunt trauma.
- Cholecystitis/choledochitis—may derive from GB mucocele (GBM); sepsis more common with necrotizing cholecystitis.
- Extrahepatic bile duct obstruction (EHBDO)—may derive from neoplasia, cholelithiasis, pancreatitis, duct stricture.
- Focal, small-volume, bile peritonitis—associated with cholecystitis; may reflect omental entrapment of bile or transmural bile leakage without rupture.
- Chemical peritonitis due to bile—predisposes to septic peritonitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Conditions promoting inflammation/devitalization of biliary structures—e.g., cholecystitis, choledochitis, neoplasia, GBM, neoplasia, blunt trauma.
- Conditions causing EHBDO—e.g., neoplasia, choleliths, pancreatitis, duct stricture/fibrosis.
- Sepsis or endotoxemia.
- Ascites—in jaundiced cirrhotic patient.
- Nonhepatic conditions causing abdominal effusion and jaundice.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

Inflammatory leukogram—left shift and toxic neutrophils if necrotizing cholecystitis or sepsis; nonregenerative anemia if chronic inflammation.

Biochemistry

- High liver enzymes, especially alkaline phosphatase (ALP); hyperbilirubinemia; ± hypoalbuminemia; ± prerenal azotemia.
- Electrolyte, fluid, and acid-base disturbances; hyponatremia common.

Urinalysis

Bilirubinuria

OTHER LABORATORY TESTS

Coagulation tests—abnormal if sepsis syndrome, disseminated intravascular coagulation (DIC), or chronic EHBDO.

IMAGING

- Abdominal radiography—reduced abdominal detail, generalized or focal in GB area; cranial abdominal mass effect; rare mineralized cholelith or biliary gas (emphysematous cholecystitis).
- Thoracic radiography—rare bicavity effusion (pleural effusion), signs of trauma (e.g., fractured rib, hernia).
- Abdominal ultrasonography—effusion; EHBDO—distended GB or CBD; cholecystitis/choledochitis— thick GB or duct wall; necrotizing cholecystitis—segmental GB wall hyperechogenicity, laminated wall (represents necrosis); pericholecystic fluid; hepatic/pancreatic mass effect: common with bile peritonitis; choleliths or GBM ("kiwifruit sign"); gas in GB or bile ducts (emphysematous inflammation, implicates gas-forming organisms) casting acoustic shadow; ruptured GB may be difficult to image; liver size usually normal; variable parenchymal echogenicity reflects hepatic pathology (e.g., ascending cholangitis/cholangiohepatitis [CCHS]).

DIAGNOSTIC PROCEDURES

- Abdominocentesis—physicochemical, cytologic, and culture evaluations; ultrasound guidance optimizes sampling; sample close to biliary structures but avoid structure penetration.
- Cytology—impression smears of GB, liver, and bile (with particulate material) used for immediate detection of infection and neoplasia; modified transudate or exudate, phagocytized/free bile, and bilirubin.
- Acellular mucinous material reflects biliary mucin production; GBM material may be free within abdominal cavity.
- Ratio of bilirubin in effusion : serum usually ≥2–3 : 1.
- Bacterial aerobic/anaerobic culture and sensitivity—effusion, GB wall, liver, GB contents; Gram-negative enteric opportunists and anaerobes most common; polymicrobial infection possible.
- Exploratory laparotomy—appropriate for definitive diagnosis and treatment; permits cholecystectomy, cholecysto-enterostomy, duct or GB repair.
- Liver biopsy—important, evaluates for antecedent or coexistent disease, sample distant to the GB to avoid artifacts.

PATHOLOGIC FINDINGS

Depend on cause and site of rupture.

TREATMENT

- Inpatient—expediency of surgery depends on patient condition: achieve euhydration, correct electrolyte and acid-base status, provide preoperative antimicrobial treatment for best survival.
- Abdominal lavage to reduce peritoneal contamination if surgery delayed; use warm polyionic fluids and aseptic technique.
- Surgical experience important for best outcome—complicated resections and anastomoses may be required.
- Need for cholecystectomy decided at surgery; discolored GB wall indicates ischemic devitalized wall.

MEDICATIONS

DRUG(S) OF CHOICE

- Antimicrobials—in all patients, initiate broad-spectrum antimicrobials *before* surgical intervention; enteric Gram-negative and anaerobic organisms most common opportunists (good initial choices: ticarcillin, piperacillin, or third-generation cephalosporins, with enro-floxacin and metronidazole); customized antimicrobial treatment, thereafter based on cultures; continue antimicrobials ≥4–8 weeks if signs of infection confirmed by culture or on cytology.
- Vitamin K_1 (0.5–1.5 mg/kg IM/SC q12h for up to 3 doses)—all jaundiced patients *before* surgery.
- Prepare for blood component ± synthetic colloid therapy.
- Antiemetics if patient is vomiting—metoclopramide (0.2–0.5 mg/kg PO/SC q6–8h or 1–2 mg/kg/24h IV by CRI); ondansetron (0.5–1.0 mg/kg q12h IV/PO

BILE PERITONITIS (CONTINUED)

30 min before feeding); maropitant (1.0 mg/kg/day IV/SC/PO max 5 days).
• Proton pump inhibitor if gastric bleeding—pantoprazole (0.7–1.0 mg/kg IV q12–24h); omeprazole (0.5–1.0 mg/kg PO q12–24h); H2-receptor antagonists if proton pump inhibitor is not available: famotidine (0.5–2.0 mg/kg PO/IV/SC q12–24h); sucralfate (0.25–1.0 g PO q8–12h).
• Ursodeoxycholic acid as choleretic and hepatoprotectant if GBM, choleliths, CCHS, or chronic hepatitis—may administer chronically if GBM or cholelithiasis: 10–15 mg/kg PO daily, divided, with food for best bioavailability.
• Antioxidants—vitamin E (10 IU/kg/24h); *S*-adenosylmethionine (SAMe, with proven bioavailability and efficacy) 20 mg/kg PO daily 2h before feeding until enzymes normalize, indefinitely if chronic hepatitis or CCHS, GBM, inspissated bile syndrome; choleretic influence requires higher dose (40 mg/kg/day).

FOLLOW-UP

PATIENT MONITORING

• Sequential hematologic, biochemical, and imaging tests.
• Repeat abdominocentesis to assess continued infection and/or bile leakage as indicated.

POSSIBLE COMPLICATIONS

• Cholangitis/cholangiohepatitis.
• Pancreatitis.
• Recurrent bacterial cholangitis if biliary-enteric anastomosis required.

EXPECTED COURSE AND PROGNOSIS

• High survival rate for dogs with sterile bile peritonitis, if successful surgery, depending on underlying cause.
• Higher mortality in septic bile peritonitis (up to 73%).
• Anticipate slow clinical recovery and normalization of liver enzymes, but rapid resolution of hyperbilirubinemia with successful surgery.

MISCELLANEOUS

SEE ALSO

• Cholecystitis and Choledochitis.
• Cholelithiasis.
• Gallbladder Mucocele.

Consulting Editor Kate Holan

BILIOUS VOMITING SYNDROME

BASICS

OVERVIEW

• Bilious vomiting syndrome (BVS) is suspected to be secondary to alterations in normal gastrointestinal (GI) motility. BVS is associated with chronic intermittent vomiting of bile, thought to be the result of reflux of intestinal contents (bile) into the stomach. The normal aboral gastric and intestinal motility and functional pylorus prevent the reflux of bile back into the stomach. When bile is refluxed into the stomach it is normally rapidly removed by subsequent peristaltic contractions. Bile remaining in the gastric lumen along with gastric acid and pepsin can subsequently cause gastric mucosal damage. • Clinical signs often occur early in the morning, suggesting that prolonged fasting or gastric inactivity may modify normal motility patterns, resulting in bile reflux. • System affected—GI.

SIGNALMENT

• Commonly observed in dogs, rarely in cats.
• Most animals are young or middle-aged.
• No breed or sex predisposition.

SIGNS

• Chronic intermittent vomiting of bile associated with empty stomach. Signs generally occur late at night or early in morning. Signs may occur daily, but usually intermittent. Between episodes, animal appears normal and most dogs appear healthy immediately after vomiting episodes. • Results of physical examination usually unremarkable.

CAUSES & RISK FACTORS

• Cause unknown (idiopathic). • Primary gastric hypomotility or abnormal intestinal peristaltic motility are suspected as probable underlying causes. • Conditions causing gastritis, duodenitis, or intestinal obstructive disease may be responsible for altered proximal GI motility and can cause bile reflux; investigate for parasitism (e.g., *Giardia*), inflammatory bowel disease (IBD), intestinal neoplasia, or obstructions as possible etiologies.
• Previous pyloric opening or resection surgery can increase risk of enterogastric reflux.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Any number of GI and non-GI disorders can cause chronic vomiting. *Giardia* should be excluded since signs of this disease may mimic those of BVS. • IBD can result in bile reflux. • Intestinal obstruction or partial obstructions should be ruled out.

CBC/BIOCHEMISTRY/URINALYSIS

Results usually unremarkable.

OTHER LABORATORY TESTS

• Fecal examination to detect *Giardia* or other parasites. • Baseline cortisol to rule out hypoadrenocorticism. • GI panel—pancreatic lipase immunoreactivity (PLI), trypsin-like-immunoreactivity (TLI), cobalamin, folate.

IMAGING

• Barium contrast study may reveal delayed gastric emptying, although finding must be interpreted with caution. • Barium given with meals, radiopaque markers, or using special motility capsule (Smartpill®) may also demonstrate delayed gastric motility.

DIAGNOSTIC PROCEDURES

• Endoscopic findings frequently unremarkable and help rule out underlying GI disease. • May be evidence of bile in stomach or gastritis in antral region of stomach. • Endoscopy useful to rule out structural or inflammatory disease, since BVS is diagnosis of exclusion.

TREATMENT

• Generally not serious debilitating disorder if truly BVS, but important to rule out major conditions such as gastritis, IBD, or GI neoplasia. • Idiopathic bilious vomiting cases generally treated symptomatically on an outpatient basis and treatment response supports suspected diagnosis. • Feeding the animal small frequent meals, including late evening meal, often resolves clinical signs; food possibly could act as buffer to refluxed bile or may in some way enhance GI motility.
• Trial with hypoallergenic diet (novel protein or hydrolyzed protein) can also improve clinical signs, which may actually suggest underlying food-responsive enteropathy. • If diet modification fails, medical treatment should be considered.

MEDICATIONS

DRUG(S) OF CHOICE

• Choices include agents for gastric mucosal protection against refluxed bile or use of gastric prokinetic agents to improve motility.
• Often single evening dose of medication may be all that is required to prevent clinical signs if signs occur at night. • Drugs for gastric mucosal protection include various antacids or sucralfate (1 g/25 kg q8h).
• Drugs that block gastric acid production, including famotidine (0.5–1.0 mg/kg q12h–24h), ranitidine (1–2 mg/kg q8–12h), and omeprazole (0.7–1.5 mg/kg q12–24h) may be beneficial; ranitidine has mild gastric prokinetic effects in vitro and may be beneficial, but is less effective acid reducer.
• Specific gastric prokinetic agents include metoclopramide (0.2–0.4 mg/kg PO q6–8h) and cisapride (0.5 mg/kg PO q8–12h); cisapride only available through compounding pharmacies. • Erythromycin (0.5–1 mg/kg q8h) stimulates gastric motility by activation of motilin receptors and may also resolve signs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Gastric prokinetic agents should not be administered in patients with GI obstruction.
• Metoclopramide can cause nervousness, anxiety, or depression. • Cisapride at higher doses can cause vomiting, diarrhea, or abdominal cramping. • Erythromycin can cause vomiting.

FOLLOW-UP

• Most patients respond to one of these treatments and clinical response supports the diagnosis. • Failure to respond suggests another underlying or causative factor.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Gastroesophageal reflux.

SEE ALSO

• Gastric Motility Disorders.
• Gastroesophageal Reflux.

BLASTOMYCOSIS

BASICS

DEFINITION
A systemic, mycotic infection caused by the dimorphic soil organism *Blastomyces dermatitidis*.

PATHOPHYSIOLOGY
- A small spore (conidia) shed from the mycelial phase (*Ajellomyces dermatitidis*) of the organism growing in soil is inhaled, entering the terminal airway.
- At body temperature, spore transforms to its yeast form, which may initiate infection in lungs.
- From a focus of mycotic pneumonia, yeast may disseminate hematogenously throughout the body.
- Immune response produces pyogranulomatous inflammation.

SYSTEMS AFFECTED
- Respiratory—85% of affected dogs.
- Eyes, skin, subcutaneous tissues, lymphatic, and musculoskeletal—commonly affected.
- Reproductive, nasal cavity, and heart—less commonly affected.
- Subclinical infection is uncommon.

INCIDENCE/PREVALENCE
Depends on environmental and soil conditions that favor growth of *Blastomyces*. Growth of organism requires sandy, acidic soil and proximity to water.

GEOGRAPHIC DISTRIBUTION
Most common along the Mississippi, Ohio, and Tennessee river basins. Also reported in Great Lakes and St. Lawrence River areas, southern Canada, mid-Atlantic states; has been found outside endemic area in Colorado.

SIGNALMENT

Species
- Predominantly dog.
- Occasionally cat.

Breed Predilections
Large-breed dogs weighing ≥25 kg, especially sporting breeds; may reflect increased exposure rather than susceptibility.

Mean Age and Range
- Dogs—most common in those 1–5 years of age; uncommon after 7 years of age.
- Cats—no age predilection noted.

Predominant Sex
- Dogs—males in most studies.
- Cats—none noted.

SIGNS

Historical Findings
- Weight loss, hyporexia.
- Cough, dyspnea.
- Ocular inflammation/discharge.
- Draining skin lesions.
- Lymphadenitis.
- Lameness.
- Seizures or neurologic deficits with CNS involvement.
- Syncope if cardiac involvement.

Physical Examination Findings

Dogs
- Fever up to 104 °F (40 °C) in ~50% of patients.
- Harsh, dry lung sounds, increased respiratory effort.
- Generalized or regional lymphadenopathy with or without skin lesions or subcutaneous swellings.
- Uveitis with or without secondary glaucoma and conjunctivitis, ocular exudates, and corneal edema.
- Lameness—bone involvement in up to 30%.
- Testicular enlargement and prostatomegaly—occasional.
- Murmur and atrioventricular (AV) block—with endocarditis and myocarditis.

Cats
- Increased respiratory effort.
- Granulomatous skin lesions.
- Visual impairment.

RISK FACTORS
- Wet environment—banks of rivers, streams, lakes or swamps; most affected dogs live within 400 meters of water.
- Exposure to recently excavated areas.
- Reported in indoor-only cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Respiratory signs—bacterial pneumonia, metastatic neoplasia, heart failure, pleural effusion, or other fungal infection.
- Lymphadenopathy—similar to lymphoma.
- Combination of respiratory disease with ocular, bony, or skin/subcutaneous involvement in a young dog supports the diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC reflects inflammation; mild anemia in chronic cases.
- High serum globulins, borderline hypoalbuminemia with chronic infection.
- Hypercalcemia (generally mild) in some dogs.
- *Blastomyces* yeasts may be found in urine of dogs with prostatic involvement; mild proteinuria can be present.

OTHER LABORATORY TESTS
- Urine or serum antigen testing—sensitivity >90%; sensitivity greater with urine test; cross-reacts with other fungal infections (e.g., histoplasmosis).
- Agar gel immunodiffusion (AGID)—not sensitive early in disease, but very specific for infection.

IMAGING

Radiographs
- Lungs—generalized interstitial to nodular infiltrate, may be nonuniform distribution.
- Tracheobronchial lymphadenopathy.
- Changes may resemble metastatic neoplasia.
- Pleural effusion has been reported in dogs.
- Focal bone lesions—lytic and proliferative; can be mistaken for osteosarcoma.

DIAGNOSTIC PROCEDURES
- Cytology of lymph node aspirates, lung, or lytic bone aspirates, tracheal wash fluid, or impression smears of skin lesions—best method for diagnosis.
- Histopathology of bone biopsies or enucleated eyes.
- Organisms—usually plentiful in tissues; may be scarce in tracheal washes if there is no productive cough.

PATHOLOGIC FINDINGS
- Lesions—pyogranulomatous with budding 5–20 µm diameter yeast; thick, refractile, double-contoured cell wall; occasionally very fibrous with few organisms found.
- Special fungal stains—facilitate organism detection.

TREATMENT

NURSING CARE
Severely dyspneic dogs—require prolonged oxygen support; about 25% of dogs have worsening of respiratory disease during first days of treatment, attributed to an inflammatory response.

ACTIVITY
Patients with respiratory compromise must be restricted.

DIET
N/A

CLIENT EDUCATION
- Treatment is costly and long term.
- Infected dogs are not contagious to other animals or people.

SURGICAL CONSIDERATIONS
- Removal of abscessed lung lobe may be required if medical treatment ineffective.
- Blind eyes should be enucleated to remove potential sites of residual infection.

MEDICATIONS

DRUG(S) OF CHOICE

Itraconazole
- Dogs—5 mg/kg PO q12h with a fat-rich meal (e.g., canned dog food) for the first 3 days, then reduce to 5 mg/kg PO q24h.

• Cats—5 mg/kg PO q12h; open the 100 mg capsules containing pellets and mix with palatable food.
• Avoid antacid drugs as absorption best in acidic environment.
• Treat for minimum 90 days, or for 1 month after all signs of disease have resolved (whichever is longer).
• Absorption of compounded itraconazole is unreliable and use is not recommended.

Fluconazole
• Dogs—5 mg/kg PO q12h.
• Cats—5–10 mg/kg PO q12–24h; 50 mg/cat.
• Inexpensive, but may require longer treatment duration.

Amphotericin B
• For dogs with neurologic signs or life-threatening disease.
• 0.5–1.0 mg/kg IV q48h; use lipid complex for dogs with renal dysfunction.

CONTRAINDICATIONS
Corticosteroids—may allow continued proliferation of organisms; patients with previous steroid therapy require longer treatment duration; for dogs with life-threatening dyspnea, dexamethasone (0.1–0.2 mg/kg/day IV) for 2–3 days may be given with itraconazole treatment; taper and discontinue corticosteroids as soon as possible.

PRECAUTIONS

Itraconazole and Fluconazole Toxicity
• Anorexia—most common sign; attributed to liver toxicity; monitor serum alanine aminotransferase (ALT) activity monthly or when anorexia occurs; temporarily discontinue drug for patients with anorexia and moderate ALT activity elevation; after appetite improves, restart at half the previous dose.
• Ulcerative dermatitis—in some dogs due to vasculitis; dose related; temporarily discontinue drug until ulcers resolve, then restart at half the previous dose.

Amphotericin B Toxicity
• Only absolute contraindication to therapy is anaphylaxis, but major limiting factor is cumulative nephrotoxicity.
• Monitor serum creatinine concentration throughout therapy—elevation above normal or 20% greater than baseline considered significant.

FOLLOW-UP

PATIENT MONITORING
Serum chemistry—monthly to monitor for hepatic toxicity, or if anorexia develops.

Thoracic Radiographs
• Considerable permanent pulmonary changes (fibrosis/scarring) may occur after the infection resolves, making determination of persistent active disease difficult.
• At 90 days of treatment—if active pulmonary disease, continue treatment for additional 30 days.
• If lungs appear normal, stop treatment and repeat radiographs again in 30 days.
• At 120 days of treatment—if the lungs appear the same as day 90, changes are residual (fibrosis); if clearer than day 90, continue treatment for 30 more days. If lesions are significantly worse than at 90 days, consider a change in therapeutic agent.
• Continue treatment as long as improvement is noted in the lungs; if there is no further improvement and no indication of active disease, the lesions are likely the result of scarring.

Urine Antigen Testing
• Positive test is generally related to active disease.
• If other signs have resolved, a negative test supports treatment discontinuation.

PREVENTION/AVOIDANCE
• Location of environmental growth of *Blastomyces* organisms unknown, thus difficult to avoid exposure; exposure to lakes and streams may be restricted (but limited practicality).
• Dogs that recover from the infection may be immune to reinfection.

EXPECTED COURSE AND PROGNOSIS
• Death—25% of dogs die during first week of treatment; early diagnosis improves chance of survival.
• Severe pulmonary disease and CNS involvement decrease prognosis.
• Recurrence—approximately 20% of dogs; usually within 3–6 months after completion of treatment; may occur >1 year after treatment; a second course of azole treatment cures most patients; drug resistance has not been observed.
• With early detection of blastomycosis, the prognosis in cats appears similar to dogs.

MISCELLANEOUS

ZOONOTIC POTENTIAL
• Yeast form is not spread from animals to humans, except through bite wounds; inoculation of organisms from dog bites has occurred.
• Avoid cuts during necropsy of infected dogs and avoid needle sticks when aspirating lesions.
• Warn clients that blastomycosis is acquired from an environmental source and that they may have been exposed to the source; the incidence in dogs is 10 times that in humans.
• Encourage clients with respiratory and skin lesions to inform their physicians that they may have been exposed to blastomycosis.

PREGNANCY/FERTILITY/BREEDING
Azole drugs can have teratogenic effects (embryotoxicity found at high doses) and should ideally be avoided during pregnancy (but the risk of not treating the mother must be balanced with the theoretical risk of azole therapy to the fetuses).

ABBREVIATIONS
• AGID = agar gel immunodiffusion.
• ALT = alanine transaminase.
• AV = atrioventricular.

BLEPHARITIS

BASICS

DEFINITION
Inflammation of outer (skin) and middle (muscle, connective tissue, and glands) portions of eyelid, usually with secondary inflammation of palpebral conjunctiva.

PATHOPHYSIOLOGY
• Inflammation—immune mediated, infectious, endocrine mediated, self- and external trauma, parasitic, radiation, nutritional. Inflammatory response often exaggerated because conjunctiva is rich in mast cells and densely vascularized. • Meibomian gland dysfunction—bacterial lipases alter meibomian lipids and plug gland; produce irritating fatty acids, enhance bacterial growth, and destabilize tear film.

SYSTEMS AFFECTED
Ophthalmic

SIGNALMENT
See Causes.

SIGNS
• Serous, mucoid, or mucopurulent ocular discharge. • Blepharospasm. • Eyelid hyperemia, edema, and thickening. • Pruritus. • Excoriation. • Depigmentation—skin, hair (in Siamese-type cats with color points, lightening of hair on affected lids due to increased skin temperature). • Alopecia. • Swollen, cream-colored meibomian glands. • Elevated, pinpoint meibomian gland orifices. • Abscesses. • Scales, crusts, papules, or pustules. • Single or multiple nodular hyperemic swellings. • Concurrent conjunctivitis and/or keratitis.

CAUSES

Congenital
• Eyelid abnormalities—may promote self-trauma or moist dermatitis. • Prominent nasal folds, medial trichiasis, and lower lid entropion—shih tzu, Pekingese, English bulldog, Lhasa apso, pug; Persian and Himalayan cat. • Distichia—shih tzu, pug, golden retriever, Labrador retriever, poodle, English bulldog. • Ectopic cilia. • Lateral lid entropion—Chinese Shar-Pei, chow chow, Labrador retriever, Rottweiler. • Lagophthalmos—brachycephalic dogs; Persian, Himalayan, and Burmese cats. • Deep medial canthal pocket—dolichocephalic dogs. • Dermoids—Rottweiler, dachshund, and others; Burmese cat.

Allergic
• Type I (immediate)—atopy, food, insect bite, inhalant, *Staphylococcus* hypersensitivity (SH). • Type II (cytotoxic)—pemphigus, pemphigoid, drug eruption • Type III (immune complex)—systemic lupus erythematosus (SLE), SH, drug eruption. • Type IV (cell mediated)—contact and flea bite hypersensitivity; drug eruption.

Bacterial
• Hordeolum—localized abscess of eyelid glands, usually staphylococcal; may be external (sty in young dogs, glands of Zeis) or internal (in old dogs, meibomian glands). • Generalized bacterial blepharitis and meibomianitis—usually *Staphylococcus* or *Streptococcus*. • *Bartonella henselae*—chronic blepharoconjunctivitis in cats. • Pyogranulomas. • SH—young and old dogs.

Neoplastic
• Sebaceous adenomas and adenocarcinomas—from meibomian gland. • Squamous cell carcinoma—white cats. • Mast cell—may appear as swollen, hyperemic lesion.

Other
• External trauma—eyelid lacerations, thermal or chemical burns. • Mycotic—dermatophytosis; systemic fungal granulomas. • Parasitic—demodicosis; sarcoptic mange; *Cuterebra* and *Notoedres cati. Note: Demodex injai* has a propensity for sebaceous glands and can be associated with meibomian gland dysfunction in dogs, including chalazia and granulomatous blepharitis. • Chalazia—sterile, yellow-white, painless meibomian gland swellings caused by granulomatous inflammatory response to meibum in surrounding eyelid tissue. • Nutritional—zinc-responsive dermatosis (Siberian husky, Alaskan Malamute, puppies), fatty acid deficiency. • Endocrine—hypothyroidism (dogs); hyperadrenocorticism (dogs); diabetic dermatosis. • Viral—chronic blepharitis in cats (feline herpesvirus type 1 [FHV-1]). • Irritant—drug reaction (e.g., neomycin); smoke in environment; post-parotid duct transposition. • Familial canine dermatomyositis—collie and Shetland sheepdog. • Nodular granulomatous episclerokeratitis—fibrous histiocytoma and collie granuloma; may affect eyelids, cornea, or conjunctiva. • Eosinophilic granuloma—cats; may affect eyelids, cornea, or conjunctiva. • Eyelid contact with tear overflow and purulent exudate (tear burn). • Keratitis, conjunctivitis, dacryocystitis. • Dry eye. • Orbital disease. • Radiotherapy. • Idiopathic—especially Persians and Himalayans.

RISK FACTORS
• Breed predisposition to eyelid abnormalities (e.g., entropion, ectropion). • Hypothyroidism—may promote chronic bacterial disease in dogs. • Canine seborrhea—may promote chronic generalized meibomianitis, with predisposition for *Demodex injai* infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Clinical signs are diagnostic.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal unless metabolic cause (e.g., diabetic dermatosis).

OTHER LABORATORY TESTS
Indicated for systemic disorders, including hypothyroidism.

DIAGNOSTIC PROCEDURES
• Eye examination—inciting cause, corneal ulcer, foreign body, distichia, ectopic cilia, keratoconjunctivitis sicca (KCS). • Ancillary ocular tests— fluorescein, Schirmer tear test. • Thorough history and dermatologic exam: ○ Cytology—deep skin scrape, conjunctival scrape, or exudate from glands and pustules. ○ Wood's light evaluation, dermatophyte culture. ○ KOH preparation. ○ Intradermal skin testing, other testing for hypersensitivity-induced disease. ○ Consider referral to a dermatologist for refractory cases. • Aerobic bacterial culture and sensitivity—of exudate from skin, conjunctiva, expressed meibomian glands, or pustules; often will not recover *Staphylococcus* from patients with chronic meibomianitis and suspected SH. • Immunofluorescent antibody assay or PCR for FHV-1 and *Chlamydia*—in conjunctival scrapings from cats with primary conjunctivitis or keratitis. • Full-thickness wedge biopsy of eyelid.

PATHOLOGIC FINDINGS
Routine histopathology often nondiagnostic in chronic disease.

TREATMENT

APPROPRIATE HEALTH CARE
See Nursing Care.

NURSING CARE
• Prevent self-trauma—Elizabethan collar. • Cleanse eyelids—to remove crusts; warm compresses applied for 5–15 minutes 3–4 times daily, avoiding ocular surfaces. Use saline, lactated Ringer's solution, or a commercial ocular cleansing agent (e.g., I-Lid 'n Lash®); clip periocular hair short. • Common underlying cause in cats is FHV-1 infection; minimize stress.

DIET
Only if food allergy.

CLIENT EDUCATION
In cats with FHV-1-related blepharitis, inform client that there is no cure and that clinical signs often recur when animal is stressed.

SURGICAL CONSIDERATIONS

• Temporary everting eyelid sutures—spastic entropion; or in puppies before permanent surgical correction. • Repair eyelid lacerations. • Lancing—large abscesses only; lance and curette hordeola that resist medical treatment and chalazia that have hardened and cause keratitis; manually express infected meibomian secretions.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

• Systemic—for bacterial eyelid infections (e.g., cephalexin 20 mg/kg IV q8h). For *Bartonella henselae* infection in cats, therapy may include doxycycline (10 mg/kg PO q12h for 3 weeks), pradofloxacin (5–10 mg/kg PO q12–24h for 28–42 days), or azithromycin (10 mg/kg PO q24h for 3 weeks). • Topical—neomycin, polymyxin B, and bacitracin combination or chloramphenicol.

Congenital

• Topical antibiotic ointment—q6–12h to prevent frictional rubbing of eyelid hairs or cilia on ocular surface. • Regularly flush debris from deep medial canthal pocket using saline, lactated Ringer's solution, or ocular irrigant.

External Trauma

• Topical antibiotic ointment—q6–12h; in patients with spastic entropion and blepharospasm until surgical correction. • Systemic antibiotics.

Allergic

• SH blepharitis—systemic broad-spectrum antibiotics and systemic corticosteroids (prednisolone 0.5 mg/kg PO q12h for 3–5 days, then taper); many patients respond to systemic corticosteroids alone; systemic cyclosporine (5 mg/kg PO q24h until remission, then q48–72h) if refractory to corticosteroids; failure of treatment—consider injections of *Staphylococcus aureus* bacterin (Staphage Lysate®). • Infected meibomian glands—oral tetracycline (15–20 mg/kg PO q8h), doxycycline (3–5 mg/kg PO q12h), or cephalexin (22 mg/kg PO q8h) for 3 weeks (the former two are lipophilic and cause decreased production of bacterial lipases and irritating fatty acids); topical polymyxin B and neomycin with 0.1% dexamethasone (q6–8h) or topical 0.02% tacrolimus compounded ointment (q8–12h). *Some affected dogs might also require treatment for demodecosis*. • Eyelid lesions associated with puppy strangles—treat generalized condition. • Atopy—see Atopic Dermatitis.

Bacterial

• Based on culture and sensitivity or serologic testing. • Pending results—topical polymyxin B and neomycin with 0.1% dexamethasone ointment (q4–6h) and systemic broad-spectrum antibiotic.

Mycotic

Microsporium canis infection—see Dermatophytosis.

Parasitic

Demodicosis, *Notoedres* infection, sarcoptic mange—see relevant chapters.

Idiopathic

Clinical signs often controlled with topical polymyxin B and neomycin with 0.1% dexamethasone (q8–24h or as needed); occasionally may need prednisolone (0.5 mg/kg PO q12h for 3–5 days, then taper) and/or systemic antibiotic.

CONTRAINDICATIONS

• Topical corticosteroids—do not use with corneal ulceration. • Many cats with presumed idiopathic blepharoconjunctivitis have FHV-1 infection; topical and systemic corticosteroids may exacerbate infection. • Oral tetracycline and doxycycline—do not use in puppies and kittens. • Neomycin—avoid topical use if possible cause of blepharitis. • Neomycin, bacitracin, and polymyxin—avoid topical ophthalmic use in cats due to rare but potentially fatal anaphylactic reaction.

PRECAUTIONS

• Ectoparasitism—wear gloves; do not contact ocular surfaces with a drug topically applied to skin; apply artificial tear ointment to eyes for protection. • Topical gentamicin, neomycin, terramycin, and most ointments—may cause irritant blepharoconjunctivitis (rare); withdrawal may resolve condition.

POSSIBLE INTERACTIONS

Staphylococcal bacterin may cause anaphylactic reaction (rare).

FOLLOW-UP

PATIENT MONITORING

• Depends on cause, therapy. • Bacterial—systemic and topical treatment for at least 3 weeks; should notice improvement within 10 days. • Most common causes of treatment failure—use of subinhibitory antibiotic dosages, failure to correct one or more predisposing factors, early discontinuation of medications.

PREVENTION/AVOIDANCE

Depends on cause.

POSSIBLE COMPLICATIONS

• Cicatricial lid contracture—results in trichiasis, ectropion, or lagophthalmos. • Spastic entropion—because of blepharospasm and pain. • Qualitative tear film deficiency—loss of proper meibum secretion. • Recurrence of bacterial infection or FHV-1 blepharoconjunctivitis.

EXPECTED COURSE AND PROGNOSIS

Depend on cause.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Dermatophytosis.
• Sarcoptic mange.

SEE ALSO

• Atopic Dermatitis.
• Conjunctivitis—Cats.
• Conjunctivitis—Dogs.
• Dermatophytosis.
• Epiphora.
• Keratitis—Nonulcerative.
• Keratitis—Ulcerative.
• Red Eye.

ABBREVIATIONS

• FHV-1 = feline herpesvirus type 1.
• KCS = keratoconjunctivitis sicca.
• SH = *Staphylococcus* hypersensitivity.
• SLE = systemic lupus erythematosus.

BLIND QUIET EYE

BASICS

DEFINITION
Loss of vision in one or both eyes without ocular vascular injection or other externally apparent signs of ocular inflammation.

PATHOPHYSIOLOGY
Results from abnormalities in focusing images on the retina, the retina detecting an image, optic nerve transmission, or the brain not interpreting images correctly.

SYSTEMS AFFECTED
• Nervous. • Ophthalmic.

SIGNALMENT
• Dog and cat. • Any age, breed, or sex.
• Many causes (e.g., cataracts and progressive retinal atrophy) have a genetic basis and are often highly breed and age specific.
• Sudden acquired retinal degeneration syndrome (SARDS)—tends to occur in older dogs. • Optic nerve hypoplasia—congenital.

SIGNS
Historical Findings
• Vary with underlying cause. • Bumping into objects. • Clumsy behavior. • Reluctance to move. • Impaired vision in dim light.

Physical Examination Findings
• Vary with underlying cause. • Decreased or absent menace or dazzle response. • Impaired visual placing responses.

CAUSES
• Cataracts—entire lens must become opaque to produce complete blindness; incomplete opacification may reduce performance of visually demanding tasks. • Loss of focusing power of the lens—rarely completely blinding; substantial hyperopia (far-sightedness) occurs when the optical power of the lens is not replaced after lens extraction or if the lens luxates posteriorly out of the pupillary plane and into the vitreous. • Retina—SARDS, progressive retinal atrophy (PRA), retinal detachment, taurine deficiency (cats), enrofloxacin toxicity (cats), ivermectin toxicity (dogs, cats). • Optic nerve—optic neuritis, neoplasia of the optic nerve or adjacent tissues, trauma, optic nerve hypoplasia, lead toxicity, excessive traction on the optic nerve during enucleation resulting in trauma to the contralateral optic nerve or optic chiasm (especially cats and brachycephalic dogs). • CNS (amaurosis)—lesions of the optic chiasm or tract, optic radiation, or visual cortex. CNS-associated vision loss that occurs at a level higher than the optic chiasm often has vague visual disturbances in which the patient has some vision, but clearly does not have normal vision.

RISK FACTORS
• Poorly regulated diabetes mellitus—cataracts.
• Related animals with genetic cataracts or PRA.
• Systemic hypertension—retinal detachment.
• CNS hypoxia—blindness may become apparent after excessively deep anesthesia or revival from cardiac arrest.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Signs
• Anterior segment inflammation and glaucoma—conjunctiva typically injected.
• Young patients—may lack menace responses, but will successfully navigate a maze or visually track hand movements or cotton balls.
• Postictal period—transient vision loss.
• Abnormal mentation—may be difficult to determine whether an animal is visual; other neurologic abnormalities help localize the lesion.

Causes
• Optic neuritis, retinal detachment, SARDS, or visual cortex hypoxia—sudden vision loss (over hours to weeks). • SARDS—often preceded by polyuria, polydipsia, polyphagia, and weight gain. • PRA—gradual vision loss, especially in dim light; apparently acute vision loss with sudden change in environment. • Cataract—either gradual or rapidly increasing opacification and vision loss in a quiet eye. • Optic nerve hypoplasia—congenital; may be unilateral or bilateral.
• Optic neuropathy or CNS disease—other signs of neurologic abnormalities. • Pupillary light responses—usually normal with cataracts or visual cortex lesions; sluggish to absent with retinal or optic nerve diseases.
• Ophthalmoscopy—normal with early SARDS, retrobulbar optic neuritis, and higher visual pathway lesions; abnormal with retinal detachment and disorders of optic nerve head.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually normal, unless underlying systemic disease. • Hyperglycemia or glucosuria—may note with diabetic cataracts. • Elevated alkaline phosphatase (ALP) enzyme activity and changes consistent with hyperadrenocorticism (Cushing's syndrome)—suggest SARDS.
• Retinal detachment secondary to systemic hypertension (cats)—azotemia or changes consistent with hyperthyroidism.

OTHER LABORATORY TESTS
• Blood lead and serology for deep fungal or viral infections—consider for suspected optic neuritis (see Optic Neuritis and Papilledema).
• Low-dose dexamethasone suppression test—may help rule out Cushing's syndrome with SARDS. • Sex hormone abnormalities are common in patients with SARDS.

IMAGING
• Ocular ultrasound—may demonstrate retinal detachment (especially if the ocular media are opaque) or optic nerve mass lesion.
• Plain skull radiographs—seldom informative. • CT or MRI—often helpful with orbital or CNS lesions.

DIAGNOSTIC PROCEDURES
See Figure 1.
• Ophthalmic examination with a penlight—usually permits diagnosis of cataracts or retinal detachments severe enough to cause blindness.
• Ophthalmoscopy—may show PRA, late SARDS, or optic nerve disease; normal exam suggests early SARDS, retrobulbar optic neuritis, or a CNS lesion. • Systemic arterial blood pressure—determine in patients with retinal detachment. • Electroretinography—differentiates retinal from optic nerve or CNS disease. • Cerebrospinal fluid (CSF) tap—may be of value with a neurogenic cause of vision loss.

TREATMENT
• Try to obtain a definitive diagnosis on an outpatient basis before initiating treatment.
• Consider referral before attempting empirical therapy. • Most causes are not fatal, but must perform a workup to rule out potentially fatal diseases. • Reassure client that most causes of a blind quiet eye are not painful and that blind animals can lead relatively normal and functional lives.
• Warn client that the environment should be examined for potential hazards to a blind animal. • Advise client that patients with PRA or genetic cataracts should not be bred and related animals should be examined.
• Retinal detachment—restrict exercise until the retina is firmly reattached. • Calorie-restricted diet—to prevent obesity owing to reduced activity level. • Cats with nutritionally induced retinopathy—ensure diet has adequate levels of taurine. • SARDS, PRA, optic nerve atrophy, and optic nerve hypoplasia—no effective treatment.
• Cataracts, luxated lenses, and some forms of retinal detachment—best treated surgically.

MEDICATIONS

DRUG(S) OF CHOICE
• Depend on cause. • If workup is declined, infectious disease is unlikely, and the likely diagnosis is either SARDS or retrobulbar optic neuritis—consider systemic prednisolone (1–2 mg/kg/day PO for 7–14 days, then taper); may concurrently administer oral broad-spectrum antibiotic.

(CONTINUED) BLIND QUIET EYE

B

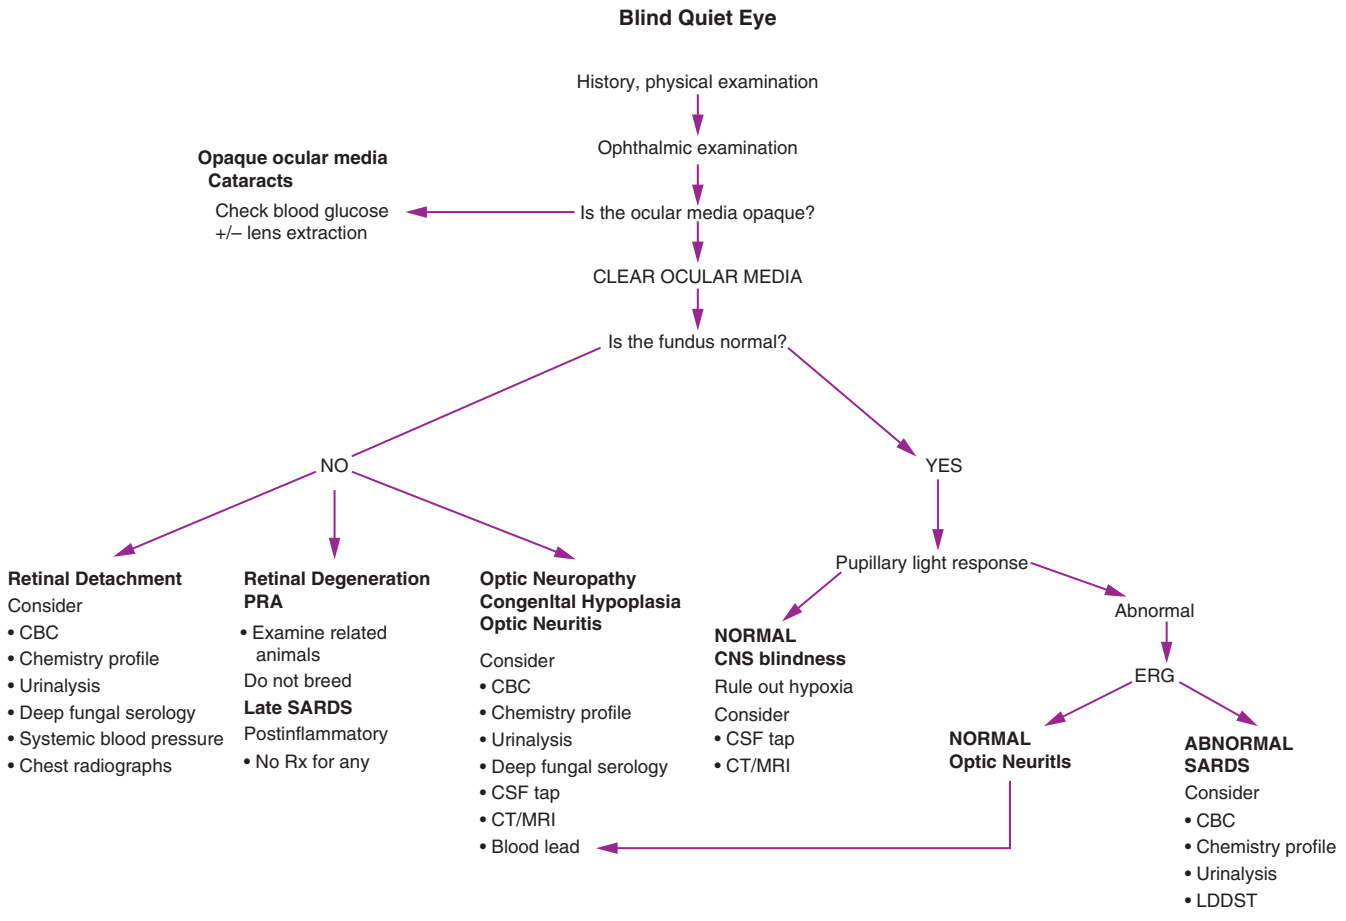

Figure 1.

CONTRAINDICATIONS
Do not use systemic corticosteroids or other immunosuppressive drugs with optic neuritis and retinal detachments that are infectious in origin.

PRECAUTIONS
Pretreatment with corticosteroids may mimic or mask liver enzyme changes in SARDS.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Oral azathioprine 1–2 mg/kg/day PO for 3–7 days, then taper; may be used to treat immune-mediated retinal detachments if systemic corticosteroids are not effective; perform a CBC, platelet count, and liver enzyme every 1–2 weeks for the first 8 weeks, then periodically.

FOLLOW-UP

PATIENT MONITORING
• Repeat ophthalmic examinations—as required to ensure that ocular inflammation is controlled and, if possible, vision is maintained. • Recurrence of vision loss—common in optic neuritis; may occur weeks, months, or years after initial presentation.

POSSIBLE COMPLICATIONS
• Death. • Permanent vision loss. • Loss of the eye. • Chronic ocular inflammation and pain. • Obesity from inactivity or as a sequela of SARDS.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• SARDS (dogs)—signs similar to those of hyperadrenocorticism. • Neurologic disease—may note seizures, behavior or personality changes, circling or other CNS signs. • Cardiomyopathy (cats)—taurine deficiency.

AGE-RELATED FACTORS
• PRA and many cataracts—breed-specific ages of onset. • SARDS—tends to occur in older dogs. • Optic nerve hypoplasia—congenital.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Corticosteroids and immunosuppressive drugs may complicate pregnancy.

SEE ALSO
Optic Neuritis and Papilledema.

ABBREVIATIONS
• ALP = alkaline phosphatase. • CSF = cerebrospinal fluid. • PRA = progressive retinal atrophy. • SARDS = sudden acquired retinal degeneration syndrome.

BLOOD TRANSFUSION REACTIONS

BASICS

OVERVIEW

• Reaction to donor blood cells can result in minor (fever, urticaria) or major (hemolysis, anaphylactic shock) reactions, usually acute but can be delayed. • Can occur with administration of any blood-derived product.

SIGNALMENT

• Dogs and cats. • No sex predilection. • All ages affected.

SIGNS

Acute Nonhemolytic Reaction

• Fever, urticaria, erythema, pruritus (in 10–25% of transfusions). • Septic shock from bacterial contamination of blood products. • Transfusion-associated circulatory overload (TACO)—dyspnea, cough, cyanosis (congestive heart failure). • Transfusion-associated acute lung injury (TRALI)—dyspnea, cyanosis. • Citrate toxicity—facial pruritis, weakness. • Hyperammonemia—encephalopathy.

Acute Hemolytic Reaction

• Occurs in 1–5% of transfusions. • Tachycardia, shock, anaphylaxis, death. • Collapse, lethargy, weakness. • Vomiting, diarrhea. • Pigmenturia, potential for pigmentary nephropathy. • Restlessness, hypersalivation, urticaria, facial swelling. • Hemolysis of transfused red blood cells (RBCs).

Delayed Hemolytic Reaction

Clinical signs of anemia may recur.

Delayed Nonhemolytic Reaction

Signs of blood-borne disease (e.g., *Babesia*, *Mycoplasma haemofelis*, *Ehrlichia*).

CAUSES & RISK FACTORS

Cats and previously transfused dogs have higher risk of transfusion reactions.

Acute Nonhemolytic Reaction

• Anaphylaxis/immune reaction to donor cells, major histocompatibility complex (MHC) or plasma antigens, release of inflammatory mediators and pyrogens. • RBC membrane fragility (from depleted adenosine triphosphate [ATP]) can result in mechanical destruction during transfusion; degradation of ATP causes hyperammonemia in stored blood. • Contamination of blood can result from lack of aseptic collection or poor storage conditions. • TACO results from rapid transfusion or excessive transfusion volume. • Citrate toxicity causes hypocalcemia.

Acute Hemolysis

• Type II hypersensitivity reaction caused by naturally occurring or acquired antibodies against donor RBCs (cats have existing alloantibodies against other blood type, dogs require prior sensitization). • Transfusion of damaged RBCs.

Delayed Hemolysis

Immune reaction to RBC antigens (5–14 days after transfusion).

Delayed Nonhemolytic Reaction

Transmission of blood-borne disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Hemolysis—other hemolytic disease (e.g., immune-mediated hemolytic anemia, *Babesia*, zinc toxicity). • Fever, hypotension—infectious/inflammatory disease, contamination of IV catheter sites. • Urticaria/pruritis—allergic reaction; avoid coadministration of medications during transfusion to distinguish drug vs. transfusion reaction. • Pigmenturia—hematuria or myoglobinuria vs. hemoglobinuria.

CBC/BIOCHEMISTRY/URINALYSIS

Hemoglobinemia, leukocytosis, thrombocytopenia possible, bilirubinemia, pigmenturia (hemoglobin/bilirubinuria).

OTHER LABORATORY TESTS

• Cross-match to confirm incompatibility. • Bacterial culture or microscopic examination of blood may reveal contamination. • Centrifugation of donor blood may show hemolysis.

TREATMENT

• *Acute, nonhemolytic reaction*—stop transfusion: if signs resolve, restart at slower rate, if signs recur, discontinue transfusion; if dyspnea, supplemental oxygen; if volume overload/congestive heart failure, furosemide; animals with TRALI may require mechanical ventilation. • *Acute, hemolytic reaction*—stop transfusion and administer IV fluids to maintain blood pressure and treat shock; in hypotensive patients, administer isotonic crystalloids (20–30 mL/kg, repeat as necessary); epinephrine and vasopressor therapy for severe anaphylaxis.

MEDICATIONS

DRUG(S) OF CHOICE

• For anaphylaxis—IV crystalloid as above, epinephrine 0.01 mg/kg IV. • For urticaria, fever—diphenhydramine (1–2 mg/kg IM); dexamethasone sodium phosphate (0.1 mg/kg IV once). • If septic shock suspected—broad-spectrum IV antibiotics, IV fluid therapy. • Volume overload—furosemide 2–4 mg/kg IV, oxygen. • Hypocalcemia—calcium gluconate 50–150 mg/kg IV slowly (monitor ECG).

FOLLOW-UP

PATIENT MONITORING

• Check attitude, rectal temperature, and vital signs before, during, and after transfusion. • For acute hemolytic reactions or septicemia—intensive monitoring and supportive care required. • Measure PCV or hematocrit 2 hours post transfusion, sooner if clinical signs warrant.

PREVENTION/AVOIDANCE

• Record any transfusion reaction in the medical file. • Pretransfusion testing: ◦ Screen donors for infectious disease. ◦ Blood type donors and recipients (imperative in cats). ◦ Cross-match patients receiving repeated transfusions. • Have standard transfusion protocols, dedicated storage for blood products. • Transfusion administration should start slowly but be completed within 4 hours. • Leukoreduction of RBC-containing products may decrease incidence of reactions. • Older stored blood more likely to result in reaction.

POSSIBLE COMPLICATIONS

Fulminant hemolysis may cause acute renal failure, multiorgan dysfunction, coagulopathies, and cardiac arrhythmias.

EXPECTED COURSE AND PROGNOSIS

• Acute course in most animals; nonhemolytic reactions have good prognosis. • Prognosis guarded in animals with severe reactions or hemolysis.

MISCELLANEOUS

SEE ALSO

Sepsis and Bacteremia.

ABBREVIATIONS

• ATP = adenosine triphosphate. • MHC = major histocompatibility complex. • RBC = red blood cells. • TACO = transfusion-associated circulatory overload. • TRALI = transfusion-associated acute lung injury.

BLUE-GREEN ALGAE TOXICOSIS

BASICS

OVERVIEW

• Cyanobacterial blooms can occur in fresh and brackish waters, and in backyard ponds where algal material is concentrated. • Nutrient-rich runoff, increased water temperatures, and stagnant water conditions favor toxic bloom formation. • Blue-green algae exposure can lead to acute hepato- or neurotoxicosis in animals and humans. • Skin irritation following exposure to cyanobacteria-contaminated water may occur. • Hepatotoxic blue-green algae poisonings are more frequently reported than neurotoxic algal intoxication. • Toxin-producing cyanobacteria include *Microcystis*, *Anabena*, *Aphanizomenon*, *Oscillatoria*, *Lyngbya*, and *Planktothrix* spp. • Microcystins are hepatotoxic blue-green algae toxins that have been found worldwide. • Anatoxins, which include anatoxin-a and anatoxin-as, are neurotoxic blue-green algae toxins.

SIGNALMENT

• Dogs—no breed, sex, or age predilection.
• Cats—no cases reported.

SIGNS

Hepatotoxic

• Diarrhea, weakness, shock. • Rapid progression to depression, coma, and death.

Neurotoxic

• Onset of rigidity and muscle tremors within minutes to a few hours after exposure.
• Rapid progression to paralysis, cyanosis, and death.

Dermatotoxic

• Pruritus, erythema, urticaria. • Secondary skin infection.

CAUSES & RISK FACTORS

• Access to and ingestion of toxin-contaminated water and/or algal material.
• Exposure to dietary supplements containing the blue-green algae *Spirulina platensis* and *Aphanizomenon flos aquae* that are contaminated with microcystins. • Blooms more common in nutrient-rich water in warmer months. • Blooms concentrated through wind or by removal into containers. • Certain algae reside in the benthic zone, e.g., in sediment; dogs mouthing material such as rocks from sediment can be at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hepatotoxic

• Amanitins, xylitol, cycad palms, acetaminophen, manganese, pennyroyal oil, cocklebur. • Other causes of acute liver

Neurotoxic

• Strychnine, metaldehyde, avitrol, pyrethrins/pyrethroids, zinc phosphide, bromethalin.
• Organophosphorus, carbamate, and organochlorine insecticides. • Penitrem A, methylxanthines. • Poisonous plants (*Brunfelsia* spp., cyanide, oleander, poison hemlock).
• Illicit substances (amphetamine and derivatives), ephedra-containing compounds.
• Neurotoxic mushrooms.

Dermatotoxic

Other causes of pruritus—allergies, infectious, parasitic, dietary, endocrine.

CBC/BIOCHEMISTRY/URINALYSIS

Hepatotoxic

• Elevated serum liver enzymes—alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase (ALP), bilirubin.
• Hypoalbuminemia. • Hypoglycemia.

Neurotoxic and Dermatotoxic

No specific changes.

DIAGNOSTIC PROCEDURES

Morphologic algal ID in suspect water, algal material, or stomach content. Positive ID confirms hazard but is not confirmatory for the toxin because toxicity is strain specific.

Hepatotoxic

• Detection of algal material on fur or in stomach contents. • Analysis of stomach contents and water/algal source for microcystins.

Neurotoxic

• Detection of anatoxin-a in gastric contents, urine, bile, and suspect source material.
• Depressed blood cholinesterase activity with anatoxin-as poisoning.

TREATMENT

• No antidote available. • Rapid onset typically prevents timely therapeutic intervention.
• Gastrointestinal decontamination with activated charcoal can be attempted, but efficacy not known. • Hepatotoxic—supportive care, close monitoring, and case-specific IV fluids to correct electrolytes and hypoglycemia, vitamin K_1, and plasma transfusions. • Neurotoxic—supportive care and seizure control.
• Dermatotoxic—supportive care and treatment for secondary skin infections.

MEDICATIONS

DRUG(S) OF CHOICE

• Activated charcoal—1 g/kg PO q6-8h until 2–3 days post ingestion; mix activated charcoal in water at 1 g/5 mL of water. • IV fluids—maintain hydration, induce diuresis, correct hypoglycemia. • Dextrose—50% dextrose 1 mL/kg IV slow bolus (1–3 min). • Vitamin K_1—0.5–1.5 mg/kg SC/IM q12h; 1–5 mg/kg hemostatic test results. • Diazepam (2–5 mg/kg IV, repeat in 30 min if necessary) for seizure control. • Phenobarbital (2–5 mg/kg IV q6–12h) for seizure control. • Methocarbamol (55–220 mg/kg IV) for muscle relaxation.

Alternative Drugs

• S-adenosylmethionine (SAMe)—antioxidant and hepatoprotectant; no data on efficacy in hepatotoxic cyanotoxin toxicosis available; dose 20 mg/kg PO q24h. • Ascorbic acid and cimetidine—hepatocyte protectors; no data on efficacy in hepatotoxic cyanotoxin poisoning available. • N-acetylcysteine (NAC)—antioxidant; no data on efficacy in hepatotoxic cyanotoxin toxicosis available; glutathione precursor that can be included in treatment regimen for acute hepatic failure at 140 mg/kg IV load, followed by 70 mg/kg IV q6h for 7 treatments.

FOLLOW-UP

PATIENT MONITORING

• Hepatotoxic—liver enzymes/function, coagulation status. • Neurotoxic—thermoregulation, respiratory function, blood gases.

PREVENTION/AVOIDANCE

• Deny access to water with visible algal blooms. • Remove algal blooms from ponds immediately and discard material safely.

EXPECTED COURSE AND PROGNOSIS

• Prognosis poor to guarded for hepatotoxic and neurotoxic; good for dermatotoxic.
• Rapid onset and progression; often lethal.

MISCELLANEOUS

ABBREVIATIONS

• ALP = alkaline phosphatase. • ALT = alanine transaminase. • AST = aspartate transaminase. • NAC = N-acetylcysteine.
• SAMe = S-adenosylmethionine.

BOTULISM

BASICS

OVERVIEW

• Paralytic illness caused by preformed neurotoxin produced by bacterium *Clostridium botulinum* (Gram +, anaerobe) contained in uncooked food, carrion, and contaminated or improperly stored silage. • Most cases in dogs caused by *Clostridium botulinum* neurotoxin serotype C; neurotoxin interferes with release of acetylcholine at neuromuscular junction, resulting in diffuse lower motor neuron signs. • Heavy molecular weight of the toxin seems to preclude its transfer to placenta.

SIGNALMENT

Dogs (naturally infected) and cats (experimentally infected except for one case report of natural *Clostridium botulinum* type C toxicosis).

SIGNS

Historical Findings

• Signs appear a few hours to 6 days after toxin ingestion. • Other dogs living in the same environment may be affected. • Acute, symmetric, progressive weakness develops, starting in the pelvic limbs and ascending to the trunk, thoracic limbs, neck, and muscles innervated by the cranial nerves; severe tetraparesis or tetraplegia ensues.

Physical Examination

• Possible increased or decreased heart rate. • In severe cases—diaphragmatic respiration.

Neurologic Examination Findings

• Mental status—normal. • Cranial nerves—may reveal sluggish pupillary light reflexes (PLR), diminished palpebral reflexes, decreased jaw tone, decreased gag reflex, salivation, and dysphonia. • Gait and posture—a stiff, short-stride gait (no ataxia) is initially observed until recumbence develops (usually within 12–24 hours). • Spinal reflexes—decreased to absent with decreased muscle tone (to atonia) and muscle atrophy. • Autonomic signs—mydriasis with decreased PLR, decreased lacrimation, ileus, and urine retention or frequent voiding of small volumes. • No hyperesthesia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Acute canine polyradiculoneuritis (coonhound paralysis). • Myasthenia gravis. • Tick bite paralysis. • Coral snake venom toxicity. • Dumb form of rabies. • Lasalocid (growth promoter in ruminants) toxicosis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

OTHER LABORATORY TESTS

• Definitive diagnosis is based on detection of botulinum toxin in serum, feces, vomitus, or ingested food sample; by neutralization test in small rodents; or by in vitro test that measures toxin antigenicity rather than toxicity. • Detection of anti-C botulinum neurotoxin antibodies may help support clinical diagnosis.

IMAGING

Thoracic radiographs—possible megaesophagus and/or signs of aspiration pneumonia.

DIAGNOSTIC PROCEDURES

• Electromyography may reveal fibrillation potentials and positive sharp waves in affected muscles. • Motor nerve conduction velocity may be normal or decreased, with reduced amplitude of evoked muscle action potentials; compound muscle action potentials can be decreased after low-frequency repetitive nerve stimulations.

TREATMENT

• If recent ingestion—gastric lavage, cathartics (avoid agents containing magnesium), or enemas may be useful. • Mildly affected dogs recover over a period of several days with supportive treatment including physical therapy, frequent turning, good bedding (to prevent decubital sores), bladder care (catheterization), artificial tears (to prevent corneal ulceration), and feeding from an elevated position (when megaesophagus present). • Dogs with respiratory difficulties require intensive care monitoring with arterial blood gas, intermittent esophageal suction, alimentation by nasogastric or gastrotomy tube, and eventually ventilatory support.

MEDICATIONS

DRUG(S) OF CHOICE

• Type C antitoxin may cause anaphylaxis; not effective when the toxin is already fixed at the nerve ending. • Antibiotics are not recommended since they might increase the release of toxins through bacterial lysis or by promoting intestinal infection; to be used only if secondary infections occur.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Aminoglycosides, procaine penicillin, tetracyclines, phenothiazines, antiarrhythmic agents, and magnesium should be avoided (neuromuscular transmission blockade).

FOLLOW-UP

PATIENT MONITORING

Monitor patients for respiratory failure, aspiration pneumonia, progressive lower motor neuron signs, urinary tract infection, and ocular complications.

PREVENTION/AVOIDANCE

• Prevent access to carrion and feed dogs cooked food. • Avoid contact with spoiled raw meat. • Samples should be refrigerated (not frozen) and manipulated with caution, since humans are also sensitive to the toxin.

POSSIBLE COMPLICATIONS

• Respiratory failure and death in severe cases. • Aspiration pneumonia from megaesophagus and regurgitations. • Keratoconjunctivitis sicca and corneal ulceration. • Prolonged recumbence—pulmonary atelectasia and infection; decubital sores; urine scalding.

EXPECTED COURSE AND PROGNOSIS

• Maximum severity of signs usually reached within 12–24 hours. • Neurologic signs disappear in reverse order of appearance; complete recovery usually occurs within 1–3 weeks, and requires the formation of new nerve terminals and functional neuromuscular junctions.

MISCELLANEOUS

SEE ALSO

• Coonhound Paralysis (Acute Polyradiculoneuritis). • Myasthenia Gravis. • Snake Venom Toxicosis—Coral Snakes. • Tick Bite Paralysis.

ABBREVIATIONS

• PLR = pupillary light reflex.

BRACHIAL PLEXUS AVULSION

BASICS

OVERVIEW

• Trauma with traction and/or severe abduction of a forelimb causes avulsion of nerve rootlets from their spinal cord attachment. • Ventral (motor) nerve roots are more susceptible than dorsal (sensory) roots. • It is important to rule out nerve root avulsions in traumatized animals that are not able to bear weight on a forelimb, especially before surgical repair of orthopedic injuries.

SIGNALMENT

• Dogs and cats. • No age, sex, or breed predilection.

SIGNS

• Depend on the extent and distribution of rootlet damage. • Motor signs—paresis/weakness (partial damage) to paralysis (complete ventral root avulsion). • Sensory signs—decreased to absent pain perception (dorsal root damage). • Muscle atrophy—begins within a week of injury. • Complete avulsion—spinal nerves C5 to T2; most common; combines cranial and caudal avulsion deficits. • Cranial avulsion—C5 to C7 nerves: supraspinatus and infraspinatus muscle atrophy, loss of shoulder and elbow movement flexion (dropped elbow), analgesia of craniodorsal scapula and medial forearm, possible diaphragm hemiplegia detected by fluoroscopy (phrenic nerve roots C5 to C7); if roots C8 to T2 are preserved, weight bearing remains almost normal. • Caudal avulsion—spinal nerves C7 to T2: inability to bear weight with knuckling over dorsum of paw; if C5 to C7 are spared, the limb is held in a flexed position and there is analgesia distal to the elbow (except for a small area on the medial aspect of the forearm); T1 to T2 involvement causes an ipsilateral partial Horner's syndrome (anisocoria only) and lack of ipsilateral cutaneous trunci reflex (reflex present contralaterally). • Bilateral avulsion—rarely encountered, caused by a significant fall with sternal landing and splaying of limbs. • Over time, complications of self-trauma may occur as a result of paresthesia in the most severe cases.

CAUSES & RISK FACTORS

Trauma—road accident; hung by foot; dragged; fall.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Brachial plexus trauma without avulsion—rare; temporary deficit owing to root contusion (neurapraxia). • Brachial plexus tumor—usually chronic, progressive onset. • Brachial plexus neuritis or neuropathy—rare, bilateral deficits, unknown etiology; acute onset; no trauma. • Fibrocartilaginous embolic myelopathy—deficits of ipsilateral hind limb and mild deficits of contralateral forelimb and hind limb are usually present. • Migrating foreign body – slow onset and no history of trauma. • Pure radial nerve paralysis caused by fracture of humerus or first rib—no nerve root sign. • Lateralized intervertebral disc protrusion.

IMAGING

CT or MRI—visualize lesion; rarely needed for diagnosis.

DIAGNOSTIC PROCEDURES

• Clinical—history of trauma with sudden onset of typical neurologic deficits. • Define involved spinal nerve roots—map motor and sensory deficits; note signs of Horner's syndrome; determine if cutaneous trunci reflex is present. • Electromyography (EMG) and nerve conduction studies (NCS) may help further define deficits and detect signs of recovery—from 5–7 days post injury, EMG shows denervation in affected muscles.

PATHOLOGIC FINDINGS

• Ventral and dorsal root avulsions—intradurally at level of root–spinal cord junction (most fragile area because it lacks protective perineurium). • Neuroma formation may develop over time on pial surface of spinal cord.

TREATMENT

Appropriate Health Care

• No specific treatment. • Outcome depends on initial damage. • Amputation of limb—may be necessary for patients showing complications (infections/self-mutilation, likely as a result of paresthesia) and no improvement. • Carpal fusion (arthrodesis) and transposition of biceps muscle tendon—consider only with adequate function of triceps and musculocutaneous muscles.

Nursing Care

• Protective wrap or boot to protect distal paw if patient walks a lot/walks on rough surfaces—increased skin fragility and lack of protective reflexes due to sensory deficits can result in severe excoriations when animal walks on affected limb. • Early and sustained physical therapy—crucial to prevent severe muscle atrophy and tendon contraction to keep joints and muscles mobile during recovery of reversible injuries; passive range of motion, massage therapy. • Monitor noncomplicated cases for 4–6 months before considering amputation.

MEDICATIONS

DRUG(S) OF CHOICE

Prednisolone (prednisone)—1-week anti-inflammatory course may decrease early edema and favor healing of reversible injuries.

FOLLOW-UP

POSSIBLE COMPLICATIONS

• Skin excoriation and secondary infection—from trauma to unprotected paw. • Trophic ulcers—thin, traumatized skin, especially over arthrodesis sites. • Paresthesia may lead to self-mutilation.

EXPECTED COURSE AND PROGNOSIS

• Preserved pain sensation (dorsal roots intact)—suggests less severe injury to ventral nerve roots. • Cranial avulsion—better prognosis with preserved sensation to distal limb and ability to bear weight. • Complete avulsion—poor prognosis for recovery, amputation likely. • Rarely, mild cases may resolve after 2–3 months.

MISCELLANEOUS

SEE ALSO

Polyneuropathies (Peripheral Neuropathies).

ABBREVIATIONS

• EMG = electromyography. • NCS = nerve conduction studies.

BRACHYCEPHALIC AIRWAY SYNDROME

BASICS

DEFINITION
Partial upper airway obstruction in brachycephalic dogs and cats caused by any of the following: stenotic nares, overlong soft palate, everted laryngeal saccules, and laryngeal collapse. Hypoplastic trachea can also be present and worsen respiratory distress.

PATHOPHYSIOLOGY
• In normal dogs, the upper airway accounts for 50–70% of total airway resistance. Brachycephalic breeds have increased upper airway resistance due to stenosis of nares, aberrant formation of nasal conchae, and presence of nasopharyngeal turbinates. Skull bones are shortened in length but normal in width, and soft tissues are not proportionately reduced, resulting in redundant tissue and narrowed air passages. • Increased airway resistance leads to more negative intra-airway pressures—may result in secondary eversion of laryngeal saccules, further elongation of palate, and laryngeal collapse. • Recruitment of pharyngeal dilator muscles (sternohyoid) becomes necessary to maintain airway patency; sleep apnea may occur secondary to relaxation of these muscles.

SYSTEMS AFFECTED
• Respiratory—respiratory distress, hypoxemia, hypercarbia, hyperthermia, aspiration pneumonia, noncardiogenic pulmonary edema from airway obstruction.
• Cardiovascular—cardiovascular collapse if complete airway obstruction or severe hyperthermia occurs. • Gastrointestinal—may be reluctant to eat or drink; increased airway resistance can exacerbate hiatal hernia, gastroesophageal reflux, and esophagitis.

GENETICS
Brachycephalic head shape—inherited defect in development of skull bones perpetuated by selective breeding.

INCIDENCE/PREVALENCE
• Dogs—common in brachycephalic breeds.
• Cats—less commonly severe enough to require treatment.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Dog and cat.

Breed Predilections
• Dogs—brachycephalic breeds (English bulldogs most common—up to 55% of breed, French bulldog, pug, Boston terrier); Norwich terriers and Cavalier King Charles spaniels affected by a variant of the syndrome.
• Cats—Persians and Himalayans.

Mean Age and Range
• Young adults, most diagnosed by 2–3 years. concurrent disease or exacerbating circumstances.
• Laryngeal collapse reported in brachycephalic breed puppies as young as 6–7 months.

Predominant Sex
No sex predilection.

SIGNS
Historical Findings
• Snoring, stridor, stertorous breathing.
• Tachypnea, frequent panting. • Coughing and gagging. • Difficulty eating and swallowing. • Ptyalism, regurgitation, and vomiting. • Syncope or collapse.

Physical Examination Findings
• Stridor and stertorous breathing.
• Stenotic nares—medial collapse of lateral nasal cartilage. • Increased respiratory effort—retraction of the commissures of lips, open-mouth breathing or constant panting, increased respiratory rate, abduction of forelimbs, increased abdominal component of respiration, recruitment of secondary muscles of respiration. • In severe distress, may see paradoxical abdominal movement, inward collapse of intercostal muscles during inspiration, orthopnea, and cyanosis. Hyperthermia may be present.

CAUSES
• Inherited or congenital defects in conformation. • Elongated soft palate—over 90% of surgical cases in dogs. • Stenotic nares—about 50% of dogs; most common defect in cats. • Aberrant formation of rostral and caudal nasal conchae. • Presence of nasopharyngeal turbinates (20% of dogs) and 100% of English bulldogs. • Laryngeal disease—everted laryngeal saccules (>50% of dogs) and/or laryngeal collapse (~10% of dogs).

RISK FACTORS
• Breed. • Obesity—worsens airway obstruction, associated with poorer outcome postoperatively, and may contribute to gastroesophageal reflux and aspiration pneumonia.
• Excitement and/or warm, humid weather—increased panting can lead to airway edema, further compromise of the lumen, and hyperthermia. • Exercise—dogs are often exercise intolerant due to airway compromise and hypoxia. • Sedation—relaxation of muscles of pharynx and palate can cause complete airway obstruction. • Respiratory infection or concurrent pulmonary disease—will cause further respiratory compromise.
• Endocrine disease (hypothyroidism and hyperadrenocorticism)—could worsen weight gain and panting.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Foreign bodies of nasopharynx, larynx, or trachea. • Infection—upper respiratory infection, nasopharyngeal abscess.
• Neoplasia obstructing the nasopharynx, glottis, larynx, or trachea. • Laryngeal paralysis. • Pharyngeal mucocoele.
• Nasopharyngeal polyp or cyst.

CBC/BIOCHEMISTRY/URINALYSIS
CBC—usually normal, but polycythemia can occur with chronic hypoxia, and leukocytosis if concurrent infection or severe stress.

OTHER LABORATORY TESTS
• Arterial blood gas—to diagnose respiratory acidosis and hypoxemia, and response to oxygen supplementation. • Pulse oximetry—to diagnose hypoxemia.

IMAGING
Radiographic Findings
• If stable, cervical and thoracic radiographs recommended. • Cervical radiographs may show thickened, elongated soft palate and suggest tracheal hypoplasia. • Thoracic radiographs can reveal aspiration pneumonia, pulmonary edema, air in esophagus, and hypoplastic trachea (TD/TI = tracheal diameter at the level of thoracic inlet/thoracic inlet distance, which is the distance from the sternum to the ventral surface of TI. A ratio <0.13 in bulldogs and <0.16 in other brachycephalic breeds suggests hypoplastic trachea).

Fluoroscopy
Gives information about degree of dynamic pharyngeal obstruction by palate and concurrent disease such as collapsing trachea (uncommon in brachycephalic dogs).

DIAGNOSTIC PROCEDURES
Laryngoscopy/Pharyngoscopy
• Performed under general anesthesia. • Due to risk of airway obstruction, owner should be prepared for surgical intervention if deemed necessary. • Overlong soft palate extends more than just a few millimeters beyond tip of epiglottis and hangs down into glottis. • Soft palate is often thickened and inflamed. • May have inflammation and edema of arytenoid cartilages. • Everted laryngeal saccules are diagnosed by visualizing two smooth, round, glistening masses in ventral half of laryngeal opening—they often obscure visualization of vocal folds.
• Laryngeal collapse can also be seen.
• Flexible endoscopy with retroflexed view of nasopharynx can detect nasopharyngeal turbinates.

Tracheoscopy
• Can reveal hypoplastic trachea with overlap of dorsal tracheal rings and dorsal tracheal membrane. • Collapsing trachea can also be diagnosed.

CT Scan
Can identify and grade aberrant nasopharyngeal turbinates.

(CONTINUED) BRACHYCEPHALIC AIRWAY SYNDROME

TREATMENT

APPROPRIATE HEALTH CARE

• Surgery recommended for patients with significant clinical signs or to prevent progressive respiratory dysfunction. • Severe respiratory distress requires rapid intervention including O_2 supplementation, cautious use of antianxiety medication. • If hyperthermic, cool via convective losses by wetting patient with cool water and placing fan to blow over them; administer IV fluids, up to a shock rate if extremely hyperthermic (T° >106 °F [41 °C]). • If complete airway obstruction, immediate orotracheal intubation and/or temporary tracheostomy is indicated. • Dexamethasone sodium phosphate can be administered (0.1 mg/kg IV) to reduce inflammation.

NURSING CARE

• Patients require 24-hour monitoring because of risk of acute airway obstruction and death. • Monitor respiratory rate, effort, heart rate, pulse quality, mucous membrane color, capillary refill time, temperature, and other physical parameters before and after surgery. • Pulse oximetry and arterial blood gases, depending on severity of condition. • Administer IV fluids at maintenance rate and minimize handling and stress. • O_2 therapy and cooling as necessary.

ACTIVITY

Usually self-limited.

DIET

• Weight loss is recommended if overweight. • For obese, stable patients, weight loss is recommended prior to surgery.

CLIENT EDUCATION

• Avoidance of risk factors is critical. • Inform owners that dogs with brachycephalic airway syndrome are at increased anesthetic risk, especially if obese, or have cardiac disease or aspiration pneumonia. • Inform owners that surgery often improves but does not normalize airway.

SURGICAL CONSIDERATIONS

• Evaluation for elongated soft palate performed under general anesthesia when patient is stable. • Temporary tracheostomy can be placed to facilitate exposure or to treat airway obstruction. • Stenotic nares are corrected by resection of a wedge of the dorsolateral nasal cartilage and planum; hemorrhage is controlled with pressure followed by closure of the surgical wound with 3 or 4 sutures of 3-0 or 4-0 absorbable suture material. • Elongated soft palate is resected using scissors, carbon dioxide laser, or bipolar sealing device; remove only enough to allow contact of center of soft palate with tip of epiglottis. • Sacculectomy performed by grasping tissue with Allis tissue forceps and trimming all mucosal tissue with curved scissors. • Severe laryngeal collapse might require cricoarytenoid and thyroarytenoid caudolateralization or permanent tracheostomy.

MEDICATIONS

DRUG(S) OF CHOICE

• Dexamethasone sodium phosphate for 12–24h pre- or postoperatively at 0.1 mg/kg IV q12–24h to reduce edema and inflammation. • Broad-spectrum antibiotics indicated if aspiration pneumonia present until culture and sensitivity results obtained. • Omeprazole 0.7 mg/kg q24h or pantoprazole 1 mg/kg q24h, cisapride 0.2 mg/kg q8h, and sucralfate 0.5–1 g q12h for dogs with concurrent esophagitis, gastritis, and/or duodenitis.

CONTRAINDICATIONS

Overuse of steroids can lead to panting, weight gain, and gastrointestinal ulceration, which can exacerbate signs of brachycephalic airway syndrome.

PRECAUTIONS

Sedation should be used with caution because of risk of upper airway obstruction with muscle relaxation.

FOLLOW-UP

PATIENT MONITORING

Postoperatively, 24-hour monitoring to observe for airway swelling and obstruction that may require temporary tracheostomy.

PREVENTION/AVOIDANCE

• Selection by breeders for dogs without severe conformational changes—difficult because breed standards encourage these. • Avoid risk factors, particularly weight gain.

POSSIBLE COMPLICATIONS

• Hyperthermia and heat stroke. • Aspiration pneumonia. • Death in about 10% of patients from airway disease. • Most common postoperative complication is airway swelling and obstruction within first 24 hours, may necessitate temporary tracheostomy. • Continued respiratory difficulty after corrective surgery. • Excessive resection of palate resulting in nasal aspiration of food contents due to inability to close pharynx during swallowing. • Progressive laryngeal collapse resulting in need for permanent tracheostomy.

EXPECTED COURSE AND PROGNOSIS

• Prognosis good for improvement in breathing (80% or more have good to excellent results), but airway still abnormal. • Prognosis better for dogs other than English bulldogs and for dogs that have correction of both stenotic nares and elongated soft palate. • Without surgery, prognosis poor due to continued progression of acquired components of brachycephalic airway syndrome. • Lifelong avoidance of risk factors recommended.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Aspiration pneumonia. • Heat stroke. • Hiatal hernia. • Hypoplastic trachea.

AGE-RELATED FACTORS

Older dogs may have a worse outcome postoperatively, but most have some improvement.

PREGNANCY/FERTILITY/BREEDING

Enlarged abdomen and pressure on the diaphragm in the pregnant bitch can further compromise respiratory function by decreasing tidal volume.

BRAIN INJURY

BASICS

DEFINITION

• Traumatic—external forces. • Nontraumatic—hypoxia, metabolic disorders, vascular disruption, infection, toxicity, neoplasia. • Primary—direct initial insult when tissue and vessels are stretched, compressed, or torn. • Secondary—alterations of brain vasculature and tissue following primary injury.

PATHOPHYSIOLOGY

• Acceleration, deceleration, and rotational forces traumatize brain tissue. • The brain has high oxygen and glucose requirements; reduced blood flow puts it at great risk for hypoxia. • Oxygen delivery dependent on cerebral blood flow (CBF) and cerebral perfusion pressure (CPP) (= mean arterial pressure [MAP] – intracranial pressure [ICP]). • Intracranial bleeding, edema (vasogenic and cytotoxic), vasodilation, and/or vasospasms increase ICP, causing low CBF, ischemia, brain swelling, and herniation; slow, progressive increase in ICP better tolerated than small, acute rise. • Hypotension, hypoxia—major contributors to secondary injury.

SYSTEMS AFFECTED

• Nervous—altered mentation, cranial nerve deficit, seizures, twitching, postural changes. • Cardiovascular—arrhythmia. • Endocrine/metabolic—alteration in antidiuretic hormone (ADH) release and sodium concentration; central temperature dysregulation; insulin resistance; depletion of cortisol. • Ophthalmic—changes in eye position, eye movements, pupillary light reflex, papilledema. • Respiratory—hyper- or hypocapnea; abnormal breathing patterns; neurogenic pulmonary edema.

INCIDENCE/PREVALENCE

• Head and neck injuries found in up to 34% of dogs and cats suffering blunt force trauma. • Head trauma reported in up to 25% of dogs with severe blunt force trauma and in 50% of dogs and cats injured by motor vehicles and crush injuries. • Additional causes—penetrating injuries, fall from heights, human-inflicted trauma. • Parenchymal and extradural hematomas found in 10% of dogs and cats with signs of mild head injury and in up to 80% with severe head injury.

SIGNALMENT

Species

Dog and cat.

SIGNS

Historical Findings

• Determine cause—trauma, cardiac arrest, heart failure, hypertension, toxins, vascular event, coagulopathy, severe respiratory compromise, prolonged seizures, hypoglycemia, jaundice. • Decline in neurologic condition—implies progression from intracranial bleeding, cerebral edema, ischemia. • Seizure activity—cerebral or diencephalon involvement.

Physical Examination Findings

• Evidence of head trauma—open wounds, epistaxis, blood in ear canal. • Cardiac or respiratory insufficiency—hypoxia, cyanosis, hypoventilation. • Poor perfusion—weak pulse, pale mucous membranes. • Skull palpation—fracture, open fontanelle. • Sustained bradycardia—midbrain, pontine, or medullary lesion. • Cushing reflex—bradycardia and hypertension. • Ecchymosis, petechiae, retinal hemorrhages, or distended vessels—hypertension, coagulopathy. • Papilledema—cerebral edema. • Retinal detachment—infectious, neoplastic, or hypertensive cause.

Neurologic Examination Findings

Mental Status

• Level of consciousness and cranial nerve deficits—cerebral cortex (better prognosis), midbrain/brainstem, or multifocal. • Postural changes—decerebrate rigidity with midbrain lesion; decerebellate rigidity with cerebellar lesion. • Peracute focal deficits—vascular or neoplastic causes.

Pupillary Light Reflexes

• Miotic responsive pupils—cerebral or diencephalic lesion (rule out traumatic uveitis, Horner's syndrome). • Pinpointed unresponsive pupils—diencephalic, pontine, or medullary lesion. • Dilated unresponsive pupil(s) or midpoint fixed unresponsive pupils—midbrain lesion.

Cranial Nerves

• Normal with altered mentation—cerebrum/diencephalic lesion. • CN II—loss of menace and dazzle response with dilated unresponsive pupils; cranial forebrain. • Loss of physiologic nystagmus—brainstem lesion. • CN III—midbrain lesion. • CN V–XII—pontine or medullary lesion.

Respiratory Patterns

• Cheyne-Stokes—severe diffuse cerebral or diencephalon lesion. • Hyperventilation—midbrain lesion. • Ataxic or apneustic—pontine or medullary lesion.

CAUSES

• Trauma. • Prolonged hypoxia or ischemia. • Prolonged shock. • Severe hypoglycemia. • Prolonged seizures. • Severe hyper- or hypothermia. • Alterations in serum osmolality. • Toxins. • Neoplasia. • Hypertension. • Hemorrhage. • Inflammatory, infectious, immune-mediated diseases. • Thiamin deficiency. • Hydrocephalus. • Parasitic migration.

RISK FACTORS

• Free-roaming—trauma, toxins. • Coexisting cardiac, respiratory, hematologic, hepatic disease. • Diabetes mellitus—insulin therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Systemic causes of altered states of consciousness or central vestibular signs—metabolic disease; toxins; drugs; infection.

CBC/BIOCHEMISTRY/URINALYSIS

• Reflect systemic effects of neurologic signs. • Alterations in serum sodium suggest central ADH abnormalities.

OTHER LABORATORY TESTS

• Arterial blood gas. • Coagulation profile. • Infectious disease titers.

IMAGING

• Skull radiographs—detect fractures, lytic lesion. • CT—detect acute hemorrhage, infarcts, fractures, lytic lesion, penetrating foreign bodies, hydrocephalus, herniation. • MRI—detect cerebral edema, hemorrhage, mass, hydrocephalus, infiltrative diseases, inflammation, herniation, fractures. • Ultrasound optic disk—more than 3 mm diameter may be associated with brain edema.

DIAGNOSTIC PROCEDURES

• ECG—detects arrhythmias. • BP—assess perfusion. • Cerebrospinal fluid (CSF) analysis—if cause unknown and no contraindications.

PATHOLOGIC FINDINGS

• Brain edema, inflammation. • Herniation. • Hemorrhage. • Hydrocephalus. • Infarct. • Laceration, contusion. • Hematoma. • Skull fracture, lytic lesion. • Necrosis. • Apoptosis.

TREATMENT

APPROPRIATE HEALTH CARE

• Goals of therapy—support oxygenation and ventilation; maintain BP and CPP; decrease ICP; decrease cerebral metabolic rate. • Maintain systolic BP >90 mmHg and partial pressure of carbon dioxide (PCO_2) at 35–40 mmHg; with suspected elevated ICP, hyperventilation to 32–35 mmHg. • Maintain partial pressure of oxygen (PaO_2) >60 mmHg, arterial oxygen saturation (SaO_2) >90%, peripheral oxygen saturation (SpO_2) >94%. • Avoid cough or sneeze reflex during intubation or nasal oxygen supplementation; lidocaine (dogs: topical and 1–2 mg/kg IV) before. • Do not compress jugular veins. • Orotracheal intubation if gag reflex lost.

NURSING CARE

• Aggressive therapy for midbrain/brainstem lesion or declining neurologic signs. • Overzealous fluid resuscitation can contribute to brain edema. • Small-volume fluid resuscitation techniques to maintain systolic BP >90 mmHg with normal heart rate. • Combination of

(CONTINUED) BRAIN INJURY

isotonic crystalloids (10–20 mL/kg increments) with hydroxyethyl starch (5 mL/kg increments) over 5–8 minutes. • Avoid hypertension. • Level head with body or elevate head and neck to 20° angle. • Keep airway unobstructed; use suction and humidify if intubated; hyperoxygenate, consider IV lidocaine prior to suctioning. • Lubricate eyes. • Reposition every 2–4 hours to avoid hypostatic pulmonary congestion, pressure sores. • Prevent fecal/urine soiling. • Maintain normal body temperature. • Maintain hydration with balanced crystalloid solution. • Rehabilitation exercises.

ACTIVITY

• Restricted. • Consult rehabilitation specialist for appropriate exercises to maintain muscle tone.

CLIENT EDUCATION

• Neurologic signs may worsen before improving. • Neurologic recovery may not be evident for several days; possibly >6 months for residual neurologic deficits. • Serious systemic abnormalities contribute to CNS instability.

SURGICAL CONSIDERATIONS

Depressed skull fracture, penetrating foreign body, uncontrollable ICP elevation (insufficient CSF drainage, hematoma/mass evacuation, herniation).

MEDICATIONS

DRUG(S) OF CHOICE

Elevated ICP

• Ensure systolic BP >90 mmHg; lower ICP by hyperventilation, drug therapy, drainage of CSF from ventricles, or surgical decompression. • 7% hypertonic saline—2–4 mL/kg IV. • Furosemide—0.75 mg/kg IV; may decrease CSF production. • Mannitol—0.5–1 g/kg IV bolus repeated at 2h intervals 3–4 times in dogs, and 2–3 three times in cats; repeated doses must be given on time; improves CBF and lowers ICP; may exacerbate hemorrhage. • Glucocorticosteroids—no benefit in acute management and long-term outcome in human traumatic brain injury (TBI); anti-inflammatory doses (prednisone 1 mg/kg/day) may be of benefit with brain edema related to intracranial neoplasia and infectious meningoencephalomyelitis (MEM); immunosuppressive doses (2 mg/kg/day) in combination with additional immunosuppressive drugs in immune-mediated MEM. • Provide analgesia/sedatives (e.g., fentanyl 3–5 µg/kg IV, then 3–5 µg/kg/h CRI ± lidocaine 3–5 mg/kg/h) as indicated; avoid agents that can reduce CPP. Avoid ketamine with obstructive intracranial lesions. • Thrashing, seizures, or uncontrolled motor activity—diazepam CRI (0.5–1 mg/kg/h), midazolam CRI (0.2–0.4 mg/kg IV), or propofol (3–6 mg/kg IV titrated to effect; 0.1–0.6 mg/kg/min CRI); monitor for hypotension; intubate if unable to protect airway. • Levetiracetam—20–30 mg/kg IV/IM/PO/rectal q8h if seizure activity.

Other

• Reducing cerebral metabolic rate with heavy sedation using dexmedetomidine (3 µg/kg slow bolus followed by 3–7 µg/kg/h CRI IV) with ketamine (1 µg/kg slow bolus followed by 1 µg/kg/h CRI IV) with uncontrolled seizures or propofol (2–4 mg/kg IV then 0.1–0.4 mg/kg/min); must intubate and support blood pressure, oxygenation, and ventilation. • Cooling patient to 32–33 °C (89–91 °F) for 48h may provide cerebral protection when administered within 6 hours of global ischemia or severe brain injury. • Glucose regulation. • Careful nasogastric tube feeding for early trickle flow feeding; cisapride (0.5 mg/kg PO q8–12h) and metoclopramide (1–2 mg/kg/day) may promote gastrointestinal motility. • Desmopressin for refractory hypernatremia; emergency dosage not established for animals (dogs: 4 µg topical conjunctival q12h; cats: 5 µg SC q12h).

CONTRAINDICATIONS

Drugs that cause hypertension, hypotension, hyperexcitability, or increase in metabolic rate.

PRECAUTIONS

• Avoid hypotension, hypoxemia, hypertension, hyperglycemia, hypoglycemia, hypernatremia, hypo- or hypervolemia. • Keep head and neck above plane of body. • Do not compress jugular veins. • Furosemide, mannitol, and hypertonic saline—can cause hypovolemia and hypotension. • Maintain PCO_2 >32 mmHg; avoid hyperventilation in the first 24–8h and do not perform therapeutic hyperventilation (32–35 mmHg) for extended periods (>48h).

FOLLOW-UP

PATIENT MONITORING

• Repeated neurologic examinations—deterioration warrants aggressive therapeutic intervention. • BP—maintain systolic BP >90 mmHg. • Blood gases, pulse oximetry, end-tidal CO_2—to assess need for oxygen supplementation or ventilation. • Blood glucose—avoid severe persistent hyperglycemia and hypoglycemia. • ECG—arrhythmias may affect perfusion, oxygenation, and CBF. • ICP—to detect elevations and monitor response to therapy.

PREVENTION/AVOIDANCE

Keep pets in a confined area or leashed.

POSSIBLE COMPLICATIONS

• Seizures. • Brain herniation. • Intracranial hemorrhage. • Progression from cerebral cortical to midbrain signs. • Malnutrition. • Aspiration pneumonia. • Hypostatic pulmonary congestion. • Corneal desiccation. • Urine scalding. • Airway obstruction from mucus. • Arrhythmias. • Hypotension. • Hypernatremia. • Hypokalemia. • Respiratory failure. • Residual neurologic deficits. • Death.

EXPECTED COURSE AND PROGNOSIS

• Young animals, minimal primary brain injury, secondary injury consisting of cerebral edema—best prognosis. • No deterioration for 48 hours—better prognosis. • Rapid resuscitation of systolic BP to >90 mmHg and avoiding hypoxemia—better neurologic outcome. • Modified Glasgow Coma Score may offer prognostic insight.

MISCELLANEOUS

SYNONYMS

• Head trauma. • TBI.

SEE ALSO

Stupor and Coma.

ABBREVIATIONS

• ADH = antidiuretic hormone. • CBF = cerebral blood flow. • CPP = cerebral perfusion pressure. • CRI = continuous rate infusion • CSF = cerebrospinal fluid. • ICP = intracranial pressure. • MAP = mean arterial pressure. • MEM = meningoencephalomyelitis. • PaO_2 = partial pressure of oxygen. • PCO_2 = partial pressure of carbon dioxide. • SaO_2 = arterial oxygen saturation. • SpO_2 = peripheral oxygen saturation. • TBI = traumatic brain injury.

BRAIN TUMORS

BASICS

DEFINITION

• Brain tumors of cats and dogs may be classified as either primary or secondary, depending on the cell type of origin. • Primary brain tumors originate from cells normally found within the brain and meninges, including the neuroepithelium, lymphoid tissues, germ cells, endothelial cells, and malformed tissues. • Secondary tumors are either neoplasms that have reached the brain by hematogenous metastasis from a primary tumor outside the nervous system, or neoplasms that affect the brain by local invasion, or extension, from adjacent non-neural tissues such as bone. • Pituitary gland neoplasms (adenomas or carcinomas) and tumors arising from cranial nerves (e.g., nerve sheath tumor of trigeminal, oculomotor, or vestibulocochlear nerves) are considered secondary brain tumors.

PATHOPHYSIOLOGY

• Brain tumors result in cerebral dysfunction by causing both primary effects, such as infiltration of nervous tissue or compression of adjacent anatomic structures, and secondary effects, such as hydrocephalus. • Additional primary effects include disruption of cerebral circulation and local necrosis, which may result in further damage to neural tissue. • The most important secondary effects of a primary brain tumor include disturbance of cerebrospinal fluid (CSF) flow dynamics, elevated intracranial pressure (ICP), cerebral edema, or brain herniation. • Secondary effects usually are more diffuse or generalized in their clinical manifestations and may mask the precise location of a focal intracranial lesion.

SYSTEMS AFFECTED

Nervous (brain).

GENETICS

• An unusually high incidence of meningiomas has been reported in cats with mucopolysaccharidosis type I. • Specific genetic factors associated with breed predisposition have not been identified. • Brachycephaly provisionally has been associated with the *SMOC*-2 and *thrombospondin-2* genes on canine chromosome 1, and a component of glioma susceptibility provisionally has been mapped to a region on canine chromosome 2. • Molecular and genetic classification of brain tumors may permit targeted therapies in the future.

INCIDENCE/PREVALENCE

• Brain tumors appear to be more common in dogs than in other domestic species. • Reported incidence in dogs is 10–20 per 100,000 animals, or 1–3% of all deaths where necropsy was done. • Primary nervous system tumors in dogs account for 60–80% of all such tumors reported in domestic animals (10–20% in cats; 10–20% in other species). • The most common sites for neoplasia to occur in immature dogs (<6 months), in decreasing order, are the hematopoietic system, brain, and skin. • Reported incidence in cats is 3.5/100000.

SIGNALMENT

Breed Predilections

• Meningiomas occur most frequently in dolichocephalic breeds of dog. • Glial cell tumors and pituitary tumors occur commonly in brachycephalic breeds of dog. • Canine breeds overrepresented include boxer, golden retriever, Doberman pinscher, Scottish terrier, and Old English sheepdog. • There does not appear to be a breed predisposition for development of brain tumors in cats.

Mean Age and Range

• Brain tumors occur in dogs and cats of any age. • Most frequent in older dogs, with greatest incidence in dogs >5 years of age. • Median age for diagnosis of meningiomas, gliomas, and choroid plexus tumors in dogs has been reported as 10–11 years, 8 years, and 5–6 years, respectively.

Predominant Sex

Older male cats appear to be most susceptible to meningiomas.

SIGNS

• Vary with tumor location. • The most frequently recognized clinical sign associated with a brain tumor of a dog or cat is seizures, particularly should first seizure occur after 5 years of age. • Other clinical signs frequently associated with brain tumor are abnormal behavior and mentation, visual deficits, circling, ataxia, head tilt, and cervical spinal hyperesthesia. • Signs that result from disease in given location in nervous system are similar, regardless of precise cause. • On basis of signalment, history, and results of complete physical and neurologic examinations, it is possible to localize a problem to the brain and, in some cases, to determine the approximate location.

CAUSES

• Uncertain. • Dietary, environmental, genetic, chemical, viral, traumatic, and immunologic factors may be considered.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Categories of disease that may result in clinical signs similar to those of a brain tumor include congenital disorders, infections, immunologic and metabolic disorders, toxicities, nutritional disorders, trauma, vascular disorders, degeneration, and idiopathic disorders.

CBC/BIOCHEMISTRY/URINALYSIS

The major objective in the completion of these tests is to eliminate extracranial causes for signs of cerebral dysfunction.

OTHER LABORATORY TESTS

N/A

IMAGING

• Survey radiographs of the thorax and abdominal ultrasound—to rule out primary malignancy elsewhere in body. • Skull radiographs—of limited value; may detect neoplasms of skull or nasal cavity that involve brain by local extension. • Occasionally, lysis or hyperostosis of skull may accompany primary brain tumor (e.g., meningioma of cats), or there may be radiographically visible mineralization within a neoplasm. • CT—provides accurate determination of presence, location, size, and anatomic relationships of many intracranial neoplasms. • MRI—considered superior to CT in localization and characterization of most brain tumors.

DIAGNOSTIC PROCEDURES

CSF Analysis

• CSF—may help to rule out inflammatory causes of cerebral dysfunction: in some cases may support diagnosis of brain tumor. • Care should be used in collection of CSF, because increased ICP may be present in association with brain tumor, and pressure alterations associated with CSF collection may lead to brain herniation. • CSF collection usually delayed until advanced imaging has been completed to evaluate factors such as presence of cerebral edema or hemorrhage. • In general, increased CSF protein content and normal to increased CSF white blood cell count have been considered "typical" of a brain neoplasm.

Biopsy

• Cytologic evaluation of smear preparations from biopsy tissue, rapidly fixed in 95% alcohol and stained with hematoxylin and eosin, may be done within minutes of biopsy collection. • Tissue biopsy remains sole method available for definitive diagnosis of brain tumor type in cats or dogs, and is essential consideration prior to any type of therapy. • Biopsy not always attempted because of practical considerations, such as cost and morbidity. • CT-guided stereotactic biopsy systems provide relatively rapid and extremely accurate means of tumor biopsy, with low rate of complications.

PATHOLOGIC FINDINGS

• Classification of CNS tumors in dogs and cats primarily is based on the characteristics of their constituent cell type, pathologic

behavior, topographic pattern, and secondary changes present within and surrounding the tumor. • Meningioma is most common intracranial neoplasm of dogs and cats. • Classification of glial subset of neuroepithelial tumors is based on predominant cell type (e.g., astrocyte or oligodendrocyte).

Dogs

• Embryonal tumors have been consolidated under single term "primitive neuroectodermal tumors" (or PNETs) to accommodate their anaplastic nature. • Brain tumors arising from lymphoreticular cells traditionally have been grouped under a heading of reticulosis or histiocytic lymphoma. • Skull tumors that affect the brain by local extension include osteosarcoma, chondrosarcoma, and multilobular osteochondrosarcoma. • The most frequently seen secondary tumors of dogs include local extension of nasal adenocarcinoma; metastases from mammary, prostatic, or pulmonary adenocarcinoma; metastases from hemangiosarcoma; and extension of pituitary adenoma or carcinoma. • Nerve sheath tumors arising from cranial nerves (particularly oculomotor nerve and trigeminal nerve) may occur in dogs.

Cats

• Meningiomas involving multiple intracranial sites (including third ventricle) relatively common in cats. • Primary brain tumors other than meningiomas occur infrequently in cats. • Tumors that have been reported include astrocytoma, ependymoma, oligodendroglioma, choroid plexus papilloma, medulloblastoma, lymphoma, olfactory neuroblastoma, and gangliocytoma. • Lymphoma of the brain may be primary or secondary, or may be an aspect of multicentric lymphoma of cats. • Secondary tumors that have been reported to occur in the brain of cats include pituitary macroadenomas and macrocarcinomas, and metastatic carcinoma. • Local extension may occur either from tumors of middle ear cavity (e.g., squamous cell carcinoma), nasal cavity (e.g., nasal adenocarcinoma), or skull (e.g., osteosarcoma).

TREATMENT

APPROPRIATE HEALTH CARE

• Beyond general efforts to maintain homeostasis, major goals of therapy for brain tumor are to control secondary effects, such as increased ICP or cerebral edema, and to eradicate the tumor or reduce its size. • Beyond palliative care, three methods of therapy for a brain tumor currently are available for use in dogs and cats: surgery, irradiation, and chemotherapy.

Surgery

• Neurosurgical intervention is an essential consideration in management of brain tumors in cats or dogs, whether for complete excision, partial removal, or biopsy. • Meningiomas, particularly those located over cerebral convexities or in frontal lobes of cerebrum, may be completely (or almost completely) removed by surgery, especially in cats. • Primary calvarial tumors also may be removed surgically prior to other types of therapy.

Radiation Therapy

• Irradiation may be used either alone or in combination with other treatments for either primary or secondary brain tumors. • Careful treatment planning by qualified and experienced radiation therapist is essential to success of radiation therapy. • A major development in radiation therapy is emergence of more precise protocols that spare tissues surrounding the brain tumor (e.g., stereotactic radiotherapy).

Chemotherapy

Alkylating agents (e.g., carmustine [BCNU], lomustine [CCNU], and temozolomide), antimetabolic agents (e.g., cytosine arabinoside), and ribonucleotide reductase inhibitors (e.g., hydroxuurea) may result in reduction of tumor size and improvement of clinical signs in dogs with glial cell tumors; however, evidence of efficacy in animals is lacking.

MEDICATIONS

DRUG(S) OF CHOICE

• Glucocorticoids may be used for edema reduction and, in some cases (e.g., lymphoma), for retardation of tumor growth. • Some animals with brain tumor demonstrate dramatic improvement in clinical signs for weeks or months with sustained glucocorticoid therapy. • Antiepileptic drugs (e.g., phenobarbital, bromide, levetiracetam) may be utilized for control of generalized seizures. • Mannitol and hypertonic saline are agents best suited for effective reduction of increased ICP.

FOLLOW-UP

PATIENT MONITORING

• Serial neurologic examinations. • Serial CT or MRI examinations.

POSSIBLE COMPLICATIONS

• Aspiration pneumonia due to depressed swallowing reflexes associated with increased ICP. • Seizures.

EXPECTED COURSE AND PROGNOSIS

• Little information available concerning survival times of dogs or cats with brain tumor that have received only palliative therapy (i.e., therapy to control secondary effects of a tumor without an attempt to eradicate the tumor). • Results of one study indicate mean and median survival of 81 days and 56 days, respectively, following CT diagnosis of primary brain tumor in each of 8 dogs. • Results from several studies confirm that prognosis for a dog or cat with a primary brain tumor may be significantly improved by surgical removal and irradiation, either alone or in combination.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Dogs that have been treated for a brain tumor may develop a second type of tumor elsewhere in the body.

ABBREVIATIONS

• CSF = cerebrospinal fluid.
• ICP = intracranial pressure.
• PNET = primitive neuroectodermal tumor.

BREEDING, TIMING

BASICS

DEFINITION
Timing of insemination(s) to maximize pregnancy risk and litter size.

PATHOPHYSIOLOGY

Dogs
• Must determine ovulation day so that breeding(s) occur(s) at proper time. • Fresh, chilled, or frozen semen—usually limited to one or two inseminations; insemination must be timed relative to ovulation for maximum fertility. • Ovulation may vary relative to onset of heat (proestrus), standing heat (estrus), vaginal cytology. • Luteinizing hormone (LH)—controls ovulation; peaks on same day or after full cornification is observed; ovulation occurs approximately 2 days after peak; 2–3 days (54–72 hours) more required for oocyte maturation; mature oocytes viable for minimum 2–3 days; thus fertile period is 4–8 days after LH peak, and maximum fertility is 5–6 days after LH peak. • Serum progesterone concentration—increase closely associated with LH peak.

Cats
• Ovulation—usually induced; timing of breeding is not as critical as with dogs; depends on adequate gonadotropin-releasing hormone (GnRH) and then LH release triggered by vaginal stimulation. • Adequate stimulation—characterized by copulatory cry and postcoital reaction; frequency of coital stimuli important in determining adequacy of coital contact. • LH—peak concentration and duration of elevation determine number of follicles ovulating; higher concentration with multiple copulations; response to copulation depends on day of estrus (greater release on estrus day 3 than on estrus day 1); release partially depends on duration of exposure to estrogen.

SYSTEMS AFFECTED
Reproductive

GENETICS
N/A

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Dog and cat.

SIGNS

General Comments

Dogs
• Onset of estrus—usually associated with a change in the vaginal discharge from sanguineous to barely red and decreased vulvar edema; sanguineous discharge may continue during estrus and cease only at the onset of diestrus. • Physical signs alone—unreliable for precise determination of fertile period. • Receptivity—may be detected by touching the perineum near the vulva; if receptive, female will "flag" by elevating the tail to one side and lifting the vulva dorsally.

Cats
LH response to a single mating—may vary substantially.

Historical Findings

Dogs
Sanguineous vulvar discharge during estrus.

Cats
Return to estrus in <30 days may indicate failure to ovulate; interestrus usually 8–10 days, but highly variable even within queen; some queens will breed while pregnant.

Physical Examination Findings

Dogs
• Interest shown by male. • Vulva less turgid. • Vaginal discharge—less color and amount. • Flagging. • Females show mounting behavior. • Fully cornified and crenulated pale vaginal epithelium. • Digital palpation of vagina may be resented by bitch in proestrus, improving throughout proestrus until estrus. May feel edematous mass on floor of caudal vagina, just cranial to urethral os, that should shrink as optimal breeding period approaches.

Cats
• Fully cornified vaginal epithelium. • Interest shown by male. • No changes in external genitalia. • Vocalizes, rubs objects. • Lordosis.

CAUSES

Dogs
• Limited number of breedings. • Female unreceptive to male. • Artificial insemination (fresh, chilled, or frozen semen).

Cats
• Coitus—too early or too late in estrus; too few times. • Artificial insemination.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Vaginal discharge—proestrus or estrus; vaginitis; neoplasia, pyometra, urinary tract infection. • Refusal to allow intromission—anatomic abnormalities of Mullerian duct development, vulvovestibular or vestibulo-vaginal junction, acquired abnormality from dystocia or breeding trauma, vaginal hyperplasia, behavioral.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS

Dogs
• Semi-quantitative progesterone ELISA—adjunct to vaginal cytologic examination. • Quantitative serum progesterone testing—preferred when breeding with frozen semen; especially useful in animals with reduced fertility. Commercial labs or in-house machines available. ○ Progesterone concentration <1 ng/mL (3.18 nmol/L) before LH peak, 1.5–4 ng/mL (4.8–12.7 nmol/L) at LH peak, 4–10 ng/mL (12.7–31.8 nmol/L) at ovulation; continues to rise during diestrus/pregnancy. ○ Commercial laboratories use various methods of progesterone concentration measurement, so values indicative of LH and ovulation vary among labs. ○ Documenting rapid rise in progesterone concentration subsequent to initial rise is more reliable indicator of ovulation than single measurement of LH peak or initial rise in progesterone. • LH testing—must sample daily to observe LH peak; can use serum progesterone to signal when to start testing or use the initial rise in progesterone concentration as surrogate for LH peak.

Cats
Serum progesterone testing to verify ovulation.

IMAGING
Ultrasonographic imaging of ovaries—may help determine ovulation; perform daily, best if using color flow Doppler.

DIAGNOSTIC PROCEDURES

Dogs
• Vaginal cytologic examination—imprecise indicator of fertile period; cornification of vaginal epithelium with clear background usually coincides with sexual receptivity. ○ Proestrus (in breeder terms, "day 1," first sign of hemorrhagic vaginal discharge)—most epithelial cells are noncornified. ○ Percentage of cornified cells (cells with angular cytoplasm and pyknotic nuclei or nuclei that fail to take up stain) increases during proestrus. ○ Estrus—90% or more cornified cells, background of slide free of debris. ○ Breeders refer to estrus by day, usually occurs day 10–18 in breeder terms. ○ Diestrus—abrupt decline in percentage of cornified cells (20–50%) in a single day: day 1 of diestrus (D1); normal to see neutrophils on days 1–4 of diestrus. • Vaginoscopy—edematous vaginal folds until LH peak, then vagina pale with slight wrinkling (crenulation) as edema decreases with estradiol decline; by optimum breeding period crenulation is obvious, until diestrus when folds are flat and edema disappears.

TREATMENT

APPROPRIATE HEALTH CARE

Dogs

• Fresh semen, multiple breedings—inseminate q48h, starting 48–96h after initial rise in serum progesterone concentration is observed until D1. • Fresh semen, two breedings—inseminate either on days 3 and 5 or on days 4 and 6 after LH peak or initial rise in serum progesterone concentration; use standard artificial insemination (AI) pipettes or modified Foley catheters (several sizes available); vaginal insemination on or after day 5 may be associated with reduced pregnancy rates and litter sizes due to beginning of cervical closure. • Frozen or chilled semen—frozen semen is less viable than chilled, thus timing is more critical; one or two intrauterine inseminations most common: inseminate on day 5 or 6 after LH peak or initial rise in serum progesterone concentration (day 0) or 3 days after serum progesterone concentration ≥5 ng/mL (16 nmol/L); for intrauterine insemination via transcervical endoscopy (TCI) or surgical insemination, serum progesterone concentration on day of insemination should be ≥12 ng/mL (38 nmol/L; value is laboratory dependent). • Timing insemination based on serum progesterone concentration improves chance of conception and increased litter size. • Blood collection and vaginal examination q48h are adequate in most cases.

Cats

• Increase likelihood of ovulation and litter size by maximizing number of matings; breed on successive days. • Breed at least 4 times daily at least 2–3 hours apart on days 2 and 3 of estrus to maximize LH release. • May induce ovulation by administration of exogenous hormones—GnRH or human chorionic gonadotropin (hCG) after mating.

ACTIVITY

• No alteration in activity necessary except confinement—bitch will search for male. • Keep strictly away from unintended sexually intact males.

CLIENT EDUCATION

Client education on physical, behavioral, and endocrinologic changes that occur during estrous cycle, and how variable timing of these changes can be from animal to animal, can improve owner compliance and satisfaction.

SURGICAL CONSIDERATIONS

Surgical AI requires standard postoperative care.

MEDICATIONS

DRUG(S) OF CHOICE

Cats—hCG (100–500 IU/cat IM); GnRH (25–50 µg/cat IM).

FOLLOW-UP

PATIENT MONITORING

• Dogs—serial vaginal cytology to determine D1; ovulation is ~6 days before D1. • Dogs—whelping is 65 ± 1 days from LH peak, 63 ± 1 days from ovulation, or 57 ± 1 days from D1; for fresh, chilled, or frozen semen: repeat quantitative serum progesterone measurement after initial progesterone rise or LH peak to verify >10 ng/mL (32 nmol/L). • Cats—use serum progesterone assay 1 week post insemination to verify ovulation. • Cats—queening is 62–71 days from first breeding.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Dogs

• Vaginal cytologic examinations—compare D1 with prospective estimation based on progesterone; if estimates differ, pregnancy rates are reduced. • Semi-quantitative progesterone kits—must come to room temperature before use; concentrations falsely elevated when using a cold kit. • Serum progesterone concentration—allow blood to clot at room temperature; separate cells from serum 20 minutes after collection; falsely low concentrations occur when using serum mixed with red blood cells (progesterone binds to erythrocytes). • Hemolyzed or lipemic specimen—may give falsely low progesterone concentration. • Quantitative (chemiluminescence assay, fluorescence, ELISA) progesterone assay—more accurate than semi-quantitative kits; several in-house analyzers available; turnaround times should be less than 24 hours. • Serum separator tubes cause false elevations in chemiluminescence progesterone assay; anticoagulant may affect reported concentration (serum > heparin plasma > EDTA plasma).

MISCELLANEOUS

AGE-RELATED FACTORS

Split heats in young bitches—period of proestrus (may be prolonged to 6 weeks or more), followed by cessation of signs, and subsequent resumption of estrus cycle (1–3 weeks later); no initial rise in progesterone or LH concentration occurs with first proestrus/estrus; subsequent estrus usually normal.

PREGNANCY/FERTILITY/BREEDING

Ultrasound—conceptuses can first be detected 18–20 days after LH peak (requires high-resolution, high-frequency probe, easier in toy breeds) or 2–3 days earlier in cats; commonly done 4 weeks post breeding; recommend earlier exam in bitches with history of pregnancy loss or infertility.

BRONCHIECTASIS

BASICS

OVERVIEW
- Clinical condition seen primarily in dogs; irreversible dilatation of the bronchi; caused by chronic infectious or inflammatory airway disease, foreign body pneumonia, or associated with primary ciliary dyskinesia.
- Occurs in cats as a sequela to longstanding inflammatory lung disease or neoplasia.
- Airways are pulled open by surrounding lung tissue; pooling of secretions can occur, which perpetuates lung damage and allows colonization by bacteria.
- Can be cylindrical or saccular, focal or diffuse.

SIGNALMENT
- Primarily dogs but radiographically detected in many cats.
- Cocker spaniels and perhaps West Highland white terriers predisposed.
- Young animals (<1 year) with primary ciliary dyskinesia.
- Middle-aged to old dogs with chronic pulmonary disease.

SIGNS
- Chronic cough—usually moist and productive; hemoptysis.
- Recurrent fever.
- Exercise intolerance.
- Tachypnea or respiratory distress.
- Chronic nasal discharge or sinusitis, particularly with primary ciliary dyskinesia.
- Moist, harsh inspiratory crackles; loud expiratory lung sounds or wheezes on physical exam.
- Tracheal hypersensitivity.

CAUSES & RISK FACTORS
- Primary ciliary dyskinesia.
- Inadequately treated infectious or inflammatory lung conditions (pneumonia, bronchitis, or eosinophilic lung disease).
- Smoke inhalation, chronic aspiration pneumonia, radiation injury, and inhalation of environmental toxins—predispose animal to airway injury and colonization by bacteria.
- Chronic bronchial obstruction or foreign body pneumonia—development of bronchiectasis distal to the obstructed region common.
- Signs related to bronchiectasis may not be recognized until long after the primary injury.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Recurrent bacterial bronchopneumonia.
- Fungal pneumonia.
- Chronic bronchitis.
- Infectious or parasitic bronchitis.
- Foreign body pneumonia.
- Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
- Neutrophilia and monocytosis.
- Hyperglobulinemia.
- Proteinuria—can be seen with secondary amyloidosis, glomerulonephritis, or sepsis.

OTHER LABORATORY TESTS
Arterial blood gas analysis—hypoxemia; widened alveolar–arterial oxygen gradient.

IMAGING
- Radiography—insensitive for the diagnosis. Abnormalities visible late in the course of disease include dilatation of the lobar bronchi with lack of normal tapering in the periphery; diffuse thickening of bronchial walls; mixed bronchial, interstitial, and alveolar pattern.
- Changes can be focal or diffuse.
- CT—bronchus >2 times the width of the adjacent pulmonary artery in dogs, abnormally dilated bronchi near the lung periphery; thickened airways; cystic dilatations of the bronchi with or without pulmonaray consolidation.

DIAGNOSTIC PROCEDURES
- Bronchoscopy—saccular or tubular dilatation of the airways.
- Airway sampling—cytologic examination of bronchoalveolar lavage fluid or tracheal wash specimens; culture for aerobic and anaerobic bacteria and *Mycoplasma*; typically find suppurative inflammation with high numbers of neutrophils, or increased eosinophils indicating eosinophilic bronchopneumopathy; may culture a mixed population of bacteria; some cases appear to have sterile inflammation.

PATHOLOGIC FINDINGS
- Dilated bronchi.
- Diffuse peribronchial and alveolar inflammation and fibrosis.
- Squamous metaplasia of bronchial epithelium.

TREATMENT
- Inpatient—severe condition: intravenous fluids and antibiotics; oxygen administration.
- Airway nebulization and coupage to facilitate removal of viscid pulmonary secretions, often lifelong.
- Gentle activity enhances clearance of secretions.
- Long-term antibiotic administration.
- Stress to owner the importance of appropriate follow-up care.
- Single affected lung lobe or bronchial obstruction—lung lobectomy can be curative.

MEDICATIONS

DRUG(S) OF CHOICE
- Intravenous antibiotics—may be required initially; good choices: ampicillin (10–20 mg/kg IV q6–8h) and enrofloxacin (5–10 mg/kg q24h).
- Broad-spectrum agents with efficacy against both aerobes and anaerobes and that offer good penetration of pulmonary tissue—preferred; combination of enrofloxacin (5–20 mg/kg PO q24h) and clindamycin (5–11 mg/kg PO q12h) or amoxicillin–clavulanate often effective.
- Azithromycin can be a good alternative antibiotic for outpatient care.
- Long-term use of antibiotics (2 months to lifelong)—based on bacterial culture and sensitivity testing; may be required even if culture of airway specimens yields no growth.
- Bronchodilators—may be beneficial, although animals usually have irreversible airflow limitation; extended release theophylline advised.
- Eosinophilic lung disease requires treatment with glucocorticoids.
- Saline nebulization and coupage highly beneficial in removing secretions.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Theophylline derivatives and fluoroquinolones—concurrent use causes high and possibly toxic plasma theophylline concentration.
- Furosemide—avoid; dries airway secretions.
- Cough suppressants—avoid; will trap secretions and bacteria in lower airway and perpetuate damage.

FOLLOW-UP

PATIENT MONITORING
- Clinical response—outpatient.
- Serial CBC, blood gas analysis, and thoracic radiographs.

PREVENTION/AVOIDANCE
- Antibiotics—complete a full course of therapy in patients that appear to have parenchymal involvement.
- Early recognition and resolution of foreign body pneumonia.
- Appropriate treatment of eosinophilic pneumonia.

POSSIBLE COMPLICATIONS
Chronic recurrent pulmonary infection likely.

EXPECTED COURSE AND PROGNOSIS
- Chronic and recurrent clinical signs expected; some degree of coughing will always be present.

• Animals can live for years with bronchiectasis if managed properly.
• Some patients succumb to respiratory failure.
• Other organs may fail if bacteremia or glomerulonephritis develops.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Primary ciliary dyskinesia.
• Chronic sinusitis.
• Chronic bronchitis.
• Pneumonia—bacterial, eosinophilic aspiration, foreign body.
• Smoke inhalation.

Consulting Editor Elizabeth Rozanski

BRONCHITIS, CHRONIC

BASICS

DEFINITION
• Chronic coughing for longer than 2 months that is not attributable to another cause (e.g., neoplasia, congestive heart failure, eosinophilic pneumonia, or infectious bronchitis). • Partly nonreversible and often slowly progressive condition owing to accompanying pathologic airway changes.

PATHOPHYSIOLOGY
• Recurrent airway inflammation suspected, but a specific cause is rarely determined. • Persistent tracheobronchial irritation—causes chronic coughing; leads to changes in tracheobronchial epithelium and submucosa. • Airway inflammation, epithelial edema, and thickening—prominent. • Excess production of thickened mucus is a hallmark. • In severe, very chronic cases—probable increased lung resistance; decreased expiratory airflow, especially in cats; in dogs, possible sequelae such as broncholamacia and bronchiectasis.

SYSTEMS AFFECTED
• Respiratory • Cardiovascular—pulmonary hypertension, cor pulmonale. • Nervous—syncope (infrequent).

INCIDENCE/PREVALENCE
Common in dogs and cats.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
• Dogs—small and toy breeds common; also observed in large breeds. • Siamese cats and domestic shorthairs affected.

Mean Age and Range
Most often affects middle-aged and old animals.

Predominant Sex
N/A, although spayed females are often overrepresented (might be due to weight gain).

SIGNS

Historical Findings
• Coughing—hallmark of tracheobronchial irritation; usually harsh and dry; post-tussive gagging common (owners often misinterpret this as vomiting, especially in dogs). • Exercise intolerance, difficult breathing, wheezing (in cats). • Cyanosis and even syncope may be noted in severe cases.

Physical Examination Findings
• Patients usually bright, alert, and afebrile. • Tracheal palpation—typically results in coughing because of increased tracheal sensitivity. • Small airway disease—assumed when expiratory abdominal push (during quiet breathing) or end-expiratory wheezing is detected. • Bronchovesicular lung sounds, end-inspiratory crackles, and wheezing (result of airflow into obstructed airways) may be heard. • Loud end-expiratory snap is suggestive of concurrent airway collapse. • Cardiac auscultation—murmurs secondary to valvular insufficiency common in dogs, but not always associated with congestive heart failure; chronic bronchitis usually results in normal or slower than normal resting heart rate and pronounced sinus arrhythmia; in cats, tachycardia is possible. • Obesity— common; important complicating factor. • Severe dental disease may predispose to lower airway colonization and possible infection (dogs).

CAUSES
Chronic airway inflammation initiated by multiple causes, although specific cause rarely identified.

RISK FACTORS
• Long-term exposure to inhaled irritants. • Obesity. • Recurrent bacterial infection. • Dental disease and laryngeal disease—result in bacterial showering of lower airways.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Bronchiectasis. • Eosinophilic bronchopneumopathy. • Foreign bodies. • Heartworm disease. • Bacterial, pneumonia. • Neoplasia—metastatic more than primary. • Pulmonary parasites or parasitic larval migration. • Pulmonary fibrosis—cats and dogs. • Pulmonary granulomatosis. • Congestive heart failure—typically associated with high resting heart rate and left atrial enlargement, which may lead to collapse of left principal bronchus.

CBC/BIOCHEMISTRY/URINALYSIS
• Rarely diagnostic. • Neutrophilic leukocytosis common. • Absolute eosinophilia—suggests but not diagnostic for allergic bronchitis. • Polycythemia secondary to chronic hypoxia—may be seen. • Liver enzymes and bile acids may be elevated due to passive congestion.

OTHER LABORATORY TESTS
• Fecal and heartworm tests—rule out pulmonary parasites. • Pulse oximetry—useful for detecting hemoglobin desaturation. • Arterial blood gas analysis—collect, ice, and have analyzed at a local hospital; mild to moderately low partial pressure of oxygen (PaO_2) seen with severe condition; aids in prognosis and monitoring treatment. • As hyperadrenocorticism could be responsible for obesity and/or enlarged liver/abdomen, testing should be considered if clinically indicated.

IMAGING

Thoracic Radiography (High Resolution Computed Topography)
Common features (in descending order of frequency)—bronchial thickening; interstitial pattern; middle lung lobe consolidation (cats); atelectasis; hyperinflation and diaphragmatic flattening (primarily cats).

Echocardiography
• May reveal right heart enlargement with pulmonary hypertension. • Helps rule out cardiac disease as a cause of coughing. • Check for pulmonary hypertension via Doppler echocardiography.

DIAGNOSTIC PROCEDURES

Bronchoscopy
Preferred test for assessing the lower airways. • Allows direct visualization of structural as well as functional (dynamic) changes; allows selected airway sampling (e.g., biopsy and lavage). • Gross changes—excess mucoid to mucopurulent secretions; epithelial edema or thickening with blunting of bronchial bifurcations; irregular or granular mucosa; mucosal polypoid proliferations can indicate chronic bronchitis or chronic eosinophilic pneumonia. • Large airway caliber changes (e.g., static or dynamic airway collapse and bronchiectasis)—may be detected as complicating problems.

Evaluation of Airway Secretions
• Must collect from lower airways—helps to establish underlying cause if present or to determine the severity of inflammation. • Throat swab cultures are not representative of lower airway flora • Tracheal aspiration or bronchoalveolar lavage—collect specimens for cytologic examination and bacterial/mycoplasmal culture or qPRC assessment. • Quantitated aerobic bronchoalveolar lavage (BAL) cultures help differentiate infection versus airway colonization; reported cutoff is $>1.7 \times 10^3$ colony-forming units (CFU) for infection in dogs. Anaerobic and *Mycoplasma* cultures recommended as well. • Cytology—inflammation primary finding; most cells are neutrophils, eosinophils, or macrophages; evaluate for bacteria, parasites, neoplastic cells, and contamination with foreign material. • Recurrent infections—implicated in pathogenesis of bronchitis; however, positive cultures are not frequently reported; *Mycoplasma* infection discussed but rarely confirmed as a cause.

PATHOLOGIC FINDINGS
See Bronchoscopy under Diagnostic Procedures.

TREATMENT

APPROPRIATE HEALTH CARE

• Usually outpatient—oxygen can be given at home in chronic cases. • Inpatient—if requires oxygen therapy, parenteral medication, or aerosol therapy; patients that owners cannot keep calm at home during initial stages of therapy.

NURSING CARE

Consider saline nebulization followed by coupage and/or gentle exercise to encourage removal of airway secretions.

ACTIVITY

• Exercise—moderate (not forced) useful in clearing secretions; assists with weight loss.
• Limit if exertion causes excessive coughing.
• Use a harness instead of a collar.

DIET

Weight loss critical—improves PaO_2, attitude, and exercise tolerance in obese patients; reduces cough frequency.

CLIENT EDUCATION

• Warn client that chronic bronchitis is an incurable disease and complete suppression of all coughing is an unattainable goal. • Stress that aggressive treatment (including weight control, avoiding risk factors, and medical treatment) minimizes the severity of the coughing and slows disease progression in most patients.

SURGICAL CONSIDERATIONS

Treat severe dental disease to minimize secondary bacterial complications.

MEDICATIONS

DRUG(S) OF CHOICE

Corticosteroids

• Diminish airway inflammation and coughing regardless of the underlying cause.
• Indicated for noninfectious conditions.
• With allergic or hypersensitivity reactions—require long-term administration; attempt to wean off steroids or determine lowest effective dosage. • Prednisolone preferred in cats.
• Prednisone or prednisolone usually initiated at 0.5–1 mg/kg PO q12h for a variable time, with tapering of the dosage based on clinical signs. • Inhaled agents (e.g., budenoside or fluticasone 1–3 puffs using metered dose inhalers [variable concentrations exist] a day) are often effective and can be used to reduce systemic side effects of corticosteroids; they are delivered via a spacer chamber and face mask (e.g., AeroDawg); however, the most adequate dose is not clearly established.

Bronchodilators

Commonly prescribed, although limited evidence of efficacy.

Antibiotics

• Select on basis of quantitated culture and sensitivity test results.

Antitussives

• Indicated for nonproductive, paroxysmal, continuous, or debilitating cough. • Dogs—butorphanol (0.55 mg/kg PO q6–12h; 0.055–0.11 mg/kg SC); hydrocodone (0.1–0.3 mg/kg q6–8h PO). Over-the-counter cough suppressants are rarely effective; gabapentin 2–5mg.kg by mouth every eight hours (but unestablished efficacy).

CONTRAINDICATIONS

Lasix and atropine—do not use because of drying effects on tracheobronchial secretions.

PRECAUTIONS

• Beta agonists (e.g., terbutaline and albuterol)—may cause tachycardia, nervousness, and muscle tremors; typically transient. • Theophylline—may cause tachycardia, restlessness, excitability, vomiting, and diarrhea; evaluate ethylene diamine tetra-acetate (EDTA) plasma sample for peak plasma concentration (ideally 5–20 µg/mL); toxicity may be more common with generic formulations.

POSSIBLE INTERACTIONS

Fluoroquinolones decrease theophylline clearance in dogs and can result in theophylline toxicity.

ALTERNATIVE DRUG(S)

Maropitant (some antitussive properties suggested, but not advised yet).

FOLLOW-UP

PATIENT MONITORING

• Follow abnormalities revealed by physical examination and selected diagnostic tests—determine response to treatment. • Monitor weight; arterial blood gases usually improve after significant weight loss.

PREVENTION/AVOIDANCE

Avoid and address risk factors (see Risk Factors).

POSSIBLE COMPLICATIONS

• Syncope—possible complication of chronic coughing, particularly in toy-breed dogs. • Pulmonary hypertension and cor pulmonale—most serious complications. • Bronchectasis and airway remodeling.

EXPECTED COURSE AND PROGNOSIS

• Progressive airway changes—syncopal episodes, chronic hypoxia, right ventricular hypertrophy, and pulmonary hypertension.
• Acute exacerbations—common with seasonal changes, air quality changes, worsened inflammation, and potentially development of secondary infection.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Syncope—secondary to chronic coughing or development of pulmonary hypertension.
• Increased susceptibility to airway infection, chronic hypoxia, pulmonary hypertension, and cor pulmonale.

PREGNANCY/FERTILITY/BREEDING

Safety in pregnant animals not established for most of the recommended drugs.

SYNONYMS

Chronic bronchitis.

SEE ALSO

• Asthma, Bronchitis—Cats. • Bronchiectasis.
• Cough. • Hypoxemia. • Tracheal Collapse.

ABBREVIATIONS

• BAL = bronchoalveolar lavage. • CFU = colony-forming unit. • EDTA = ethylene diamine tetra-acetate. • PaO_2 = partial pressure of oxygen.

BRUCELLOSIS

BASICS

DEFINITION
• Contagious disease of dogs caused by *Brucella canis*. • Rarely caused by *B. suis*, *B. abortus*, *or B. mellitensis*. • Characterized by abortion and infertility in females, epididymitis and testicular atrophy in males.

PATHOPHYSIOLOGY
B. canis—a small, intracellular Gram-negative bacterium; has propensity for growth in lymphatic, placental, and male genital (epididymis and prostate) tissues.

SYSTEMS AFFECTED
• Hemic/lymph/immune—lymph nodes, spleen, bone marrow, mononuclear leukocytes. • Reproductive—target tissues of gonadal steroids (gravid uterus, fetus, testes epididymides, prostate gland). • Other tissues—intervertebral discs, anterior uvea, meninges (uncommon).

GENETICS
No known genetic predisposition.

INCIDENCE/PREVALENCE
• Incidence unknown. • Seroprevalence—not well defined; false-positive results common with agglutination tests. • Prevalence—1–18% in United States, Japan; higher in rural United States; 25–30% in stray dogs in Mexico, Peru.

GEOGRAPHIC DISTRIBUTION
United States, Mexico, Japan, South America; Spain, Tunisia, China, Bulgaria; individual outbreaks in Germany, Czech Republic.

SIGNALMENT

Species
Dogs

Breed Predilections
• No evidence of breed susceptibility, reportedly high prevalence in beagles. • Pure breeds in commercial kennels ("puppy mills").

Mean Age and Range
• Any age. • Most common in sexually mature dogs.

Predominant Sex
Most common in females.

SIGNS

General Comments
Suspect with abortions, reproductive failures, or genital disease.

Historical Findings
• Animals may appear healthy or have vague signs of illness. • Lethargy. • Loss of libido. • Swollen lymph nodes. • Back or neck pain. • Abortion—commonly 6–8 weeks after conception, although pregnancy may terminate at any stage.

Physical Examination Findings
• Peripheral lymphadenopathy. • Males—swollen scrotum with scrotal dermatitis, enlarged firm epididymides, orchitis, prostatitis. • Chronic infection—unilateral or bilateral testicular atrophy, spinal pain, discospondylitis, posterior weakness, ataxia. • Chronic recurrent anterior uveitis without signs of systemic disease; also iris hyperpigmentation, vitreal infiltrates, multifocal chorioretinitis. • Vaginal discharge—may last several weeks after abortion. • Fever (rare).

CAUSES
B. canis—Gram-negative coccobacillus; morphologically indistinguishable from other members of genus.

RISK FACTORS
• Breeding kennels, pack hounds. • Contact with strays in endemic areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Abortions—maternal, fetal, or placental abnormalities. • Systemic infections—canine distemper, canine herpesvirus, *B. abortus*, hemolytic streptococci, *E. coli*, leptospirosis, toxoplasmosis. • Inguinal hernia. • Discospondylitis—fungal infections, actinomycosis, staphylococcal infections, nocardiosis, streptococci, or *Corynebacterium* diphtheroids.

CBC/BIOCHEMISTRY/URINALYSIS
• Normal in uncomplicated cases. • Chronic infection—hyperglobulinemia and hypoalbuminemia. • Cerebrospinal fluid—neutrophilic pleocytosis, elevated protein (meningoencephalitis); normal in discospondylitis. • Urinalysis usually normal.

OTHER LABORATORY TESTS
Serologic testing—most common diagnostic method; subject to error due to false-positive reactions to several species of bacteria common with tube agglutination tests; chronically infected dogs may test negative.

Rapid 2-Mercaptoethanol Slide Agglutination Test (RSAT)
• Simple, inexpensive, rapid. • Detects infected dogs 3–4 weeks after infection; accurate in identifying noninfected dogs. • Screening test—sensitive, not specific; high rate (50%) of false-positive tests. • Confirm results with other tests.

Mercaptoethanol Tube Agglutination Test (2ME)
• Semi-quantitative—similar information to RSAT, but inactivates immunoglobulin (Ig) M. • Good screening test (lacks specificity). • If positive RSAT and negative 2ME, retest in 2–4 weeks.

Agar Gel Immunodiffusion (AGID) Test
• Soluble antigen test—recommended; employs antigens highly specific for antibodies against *Brucella* spp. (including *B. canis*, *B. abortus*, and *B. suis*); reactive antibodies appear 4–12 weeks after infection and persist; may be positive after other tests become equivocal or negative. • ELISA—using purified cytoplasmic antigens; not yet commercially available. • PCR—available at some diagnostic laboratories; high sensitivity and specificity. • Cell wall antigen test—not recommended; highly sensitive but not standardized; frequent false positives.

IMAGING
Discospondylitis—radiographic changes slow to develop, may not be seen even when spinal pain is present.

DIAGNOSTIC PROCEDURES

Isolation of Organism
• Blood cultures—when clinical and serologic findings suggest diagnosis, can be isolated from blood of infected dogs if they have not received antibiotics; onset of bacteremia 2–4 weeks after oral-nasal exposure, persists for 8 months to 5.5 years. Culture is preferred method for diagnosis in endemic situations or with known exposure (1–8 weeks ago); must specifically request *Brucella* culture. • Culture or PCR of vaginal fluids or vaginal swab after abortion. • Semen or urine—PCR more practical than culture. • Tissue samples—culture or PCR of prostate, testicle, epididymis, lochia, or placenta. • Contaminated samples—media that contain antibiotics (e.g., Thayer–Martin medium) have proven useful.

Semen Quality
• Sperm motility, immature sperm, inflammatory cells (neutrophils) with epididymitis. • Abnormalities usually evident by 5–8 weeks post infection; conspicuous by 20 weeks. • Azoospermia without inflammatory cells common with bilateral testicular atrophy.

Lymph Node Biopsy
• Tissues (lymph node, uterus, testes) should be sterilely obtained, cultured on appropriate media, and submitted for histopathology. • Lymphoid hyperplasia—large numbers of plasma cells. • Intracellular bacteria—may be observed in macrophages with special stains (e.g., Brown–Brenn stain). • Histopathologic examination of testes—necrotizing vasculitis, inflammatory cells, granulomatous lesions.

PATHOLOGIC FINDINGS
• Gross findings—lymph node enlargement, splenomegaly, enlarged and firm epididymides, scrotal edema, or atrophy of one or both testes; chronic infection: anterior uveitis and discospondylitis. • Microscopic changes—

(CONTINUED) BRUCELLOSIS

B

diffuse lymphoreticular hyperplasia; chronic infection: lymph node sinusoids with plasma cells and macrophages that contain bacteria, diffuse lymphocytic infiltration and granulomatous lesions in all genitourinary organs (especially prostate, epididymis, uterus, and scrotum); inflammatory cell infiltration and necrosis of prostate parenchyma, seminiferous tubules. • Ocular changes—granulomatous iridocyclitis; exudative retinitis; leukocytic exudates in anterior chamber.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient

ACTIVITY
Restricted

CLIENT EDUCATION
• Goal is eradication of *B. canis* from animal (seronegative, no bacteremia for at least 3 months); sometimes result is persistent low antibody titers with no systemic infection. • Antibiotic treatment is expensive, time consuming, and controversial (because outcomes are uncertain, and organism has potential to recrudesce). • Euthanasia is strongly recommended for breeding or commercial kennels; treatment is only recommended for spayed or castrated dogs if the owner is willing to accept the ongoing zoonotic risk. • Before treatment is attempted for an intact household pet or breeding dog, client must clearly agree that animal will be neutered and potentially euthanized if treatment fails. • Zoonotic infection is a possibility; discuss proper sanitation and prevention of exposure.

SURGICAL CONSIDERATIONS
Neuter/spay plus treatment—when euthanasia is unacceptable to owner.

MEDICATIONS

DRUG(S) OF CHOICE
• Several therapeutic regimens have been evaluated, results have been equivocal; treatment duration longer than 30 days may be required. • Most successful—combination of a tetracycline (tetracycline hydrochloride, chlortetracycline, or minocycline: 25 mg/kg PO q8h for 4 weeks) or doxycycline (10 mg/kg PO q12h for 4 weeks) and dihydrostreptomycin (10 mg/kg IM q8h during weeks 1 and 4). • Enrofloxacin (10–20 mg/kg PO q24h for 30 days)—not recommended: variable results.

CONTRAINDICATIONS
Tetracyclines—do not use in immature animals.

ALTERNATIVE DRUG(S)
Gentamicin—6–15 mg/kg IM/SC q12h; limited success; insufficient data on efficacy combined with tetracycline.

FOLLOW-UP

PATIENT MONITORING
• Serologic tests—monthly at least 3 months after completion of treatment; continuous, persistent decline in antibodies to negative status indicates successful treatment. • Recrudescent infections (rise in antibody levels, recurrence of bacteremia after therapy)—retreat, neuter and retreat, or euthanize. • Blood cultures—negative for at least 3 months after completion of treatment.

PREVENTION/AVOIDANCE
• Vaccine—none. • Testing—all females before estrus if breeding is planned; breeding males at frequent intervals. • Quarantine and test all new dogs twice at monthly intervals before entering breeding kennel; test all breeding animals yearly.

POSSIBLE COMPLICATIONS
• Owner reluctance to neuter or euthanize valuable dogs, regardless of treatment failure. • Remind owners of ethical considerations, obligation not to sell or distribute infected dogs.

EXPECTED COURSE AND PROGNOSIS
• Prognosis guarded. • Infected for <3–4 months—likely to respond to treatment. • Chronic infections—may not respond to therapy. • Discospondylitis—may need repeated or long-term drug treatment, rarely surgical intervention. • Combination therapy with gentamicin or streptomycin, doxycycline, enrofloxacin, and rifampin has successfully treated ocular disease in dogs. • Successfully treated (seronegative) dogs are susceptible to reinfection.

MISCELLANEOUS

ZOONOTIC POTENTIAL
• Human infections possible; usually mild flu-like symptoms. • Severe infections, including hepatomegaly, splenomegaly, meningitis, endocarditis reported in immunocompromised children and adults.

PREGNANCY/FERTILITY/BREEDING
• Abortions at 45–60 days of gestation typical. • Pups from infected bitches may be infected or normal.

SYNONYMS
Contagious canine abortion.

ABBREVIATIONS
• 2-ME = mercaptoethanol tube agglutination test.
• AGID = agar gel immunodiffusion.
• Ig = immunoglobulin.
• RSAT = rapid 2-mercaptoethanol slide agglutination test.

CALCIPOTRIENE/CALCIPOTRIOL TOXICOSIS

BASICS

OVERVIEW

• Calcipotriene, also known as calcipotriol, is a synthetic analogue of calcitriol, an active metabolite of Vitamin D3. • Calcitriol activity: • Anti-psoriatic—increases epithelial cell differentiation and decreases keratinocyte proliferation. • Promotes calcium retention—triggers intestinal absorption, renal reabsorption, and mobilization of bone resorption of calcium. • Toxic exposure leads to hypercalcemia with soft tissue mineralization (hypercalcemic nephropathy), cardiac conduction disturbance, and gastrointestinal ulceration. • Cream, ointment, foam, and solution formulation for treatment of human psoriasis; common tradenames—Calcitrene®, Dovonex®, Sorilux®, Taclonex®. • Very low margin of safety—consider *all* exposures toxic. • Organ systems affected—cardiovascular, endocrine/metabolic, gastrointestinal, musculoskeletal, nervous, renal/urologic.

SIGNALMENT

Dogs and cats, with small or young animals at increased risk for toxicity.

SIGNS

• Early (0–24 hours)—vomiting, anorexia, diarrhea, depression, polyuria, polydipsia. • Late (18–72 hours)—hypercalcemia, hyperphosphatemia, azotemia/acute renal injury. • Other—bradycardia, arrhythmias, hematemesis, melena, abdominal pain, oliguria. • End stage—anuria, acute renal failure/dystrophic calcification of soft tissue, coma, death.

CAUSES & RISK FACTORS

Toxic exposure occurs when pets chew product tube/bottle or lick skin of human where product has been applied.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Vitamin D toxicity—vitamin D supplements, cholecalciferol rodenticide. • Ethylene glycol toxicity. • Grape/raisin toxicity. • Renal failure—acute or chronic. • Infectious disease—blastomycosis, heterobilharziasis, histomoniasis, bacterial osteomyelitis. • Hypoadrenocorticism. • Hypercalcemia of malignancy. • Hyperparathyroidism, primary. • Idiopathic hypercalcemia of cats. • Large-volume ingestion of calcinogenic plants—*Cestrum diurnum, Solanum malacoxylon*. • Severe dehydration.

CBC/CHEMISTRY/URINALYSIS

• Hyperphosphatemia. • Hypercalcemia. • Azotemia. • Hyposthenuria, isosthenuria. • Neutrophilia.

OTHER LABORATORY TESTS

Ionized calcium preferred over serum calcium.

IMAGING

Thoracic and abdominal radiographs—mineralization of soft tissue structure including kidneys, blood vessels, lungs, and intestine.

PATHOLOGIC FINDINGS

Coronary artery mineralization, gastrointestinal hemorrhage and mineralization, renal tubular necrosis and renal cortical mineralization, pulmonary mineralization.

TREATMENT

• Therapy immediately post ingestion focuses on decontamination and serial monitoring; if hypercalcemia occurs, weeks-long therapy is necessary due to slow release of stored product from fat/muscle tissue. • Oral irrigation with water if patient has recently licked product. • Early emesis or gastric lavage. • Activated charcoal (1–2 gm/kg) with a cathartic × 1, followed by activated charcoal only q6–8h × 2 doses; monitor sodium concentration. • Fluid therapy—if hypercalcemic: IV 0.9%NaCl rehydrate prn then 2× maintenance to encourage calciuresis; *if* normocalcemic: IV or SC fluids PRN to maintain hydration. • Diet—*if* hypercalcemic: calcium-restricted prescription diet or veterinary nutritionist-guided homemade diet.

MEDICATIONS

• Antiemetics PRN (e.g. maropitant 1mg/kg SC/IV, 2mg/kg PO q24h). • Proton pump inhibitor (e.g., omeprazole 1 mg/kg PO q24h) or H2 blocker (e.g., famotidine 1mg/kg IM/IV/PO/SC q 12-24h; slow IV administration advised for cats). • Sucralfate (0.25–1g PO q8h on empty stomach). • Cholestyramine (0.3–1 g/kg PO q8h × 4 days post ingestion); may reduce enterohepatic recirculation of vitamin D by reducing reabsorption of vitamin D–bound bile acids. • *If* hypercalcemic:
∘ Treatment goals—serum calcium <12.5 mg/dL or ionized calcium <1.33 mmol/L.
∘ Bisphosphonate tx (e.g., pamidronate sodium 1.3–2.0mg/kg diluted in 150cc saline IV CRI × 2–4 h or zoledronate 0.25 mg/kg in 50cc saline IV CRI x 15 min); bisphosphonates block dissolution of calcium hydroxyapatite and inhibit osteoclastic bone resorption; reduction in calcium level seen in 1–3 days; rebound hypercalcemia may occur and repeat dosing necessary in 3–7 days. ∘ Prednisone 1 mg/kg PO BID or dexamethasone 0.2 mg/kg IV BID; initially or at a later time; wean slowly. • Furosemide 1 mg/kg PO BID or 0.1–0.66mg/kg/h IV CRI- only in well-hydrated patients. • If hyperphosphatemic - aluminum hydroxide: 30–90 mg/kg/day divided; with meals.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Bisphosphonate use may result in hypocalcemia. • Long-term adverse effects from use of bisphosphonates in juvenile/growing dog or cat unknown.

FOLLOW-UP

PATIENT MONITORING

• Baseline CBC, serum chemistry, urinalysis; monitor renal values, hydration parameters, and calcium/phosphorous levels q12–24h × 4 days minimum; *if* hypercalcemia/hyperphosphatemia occurs continued monitoring of calcium/phosphorous, renal values, and hydration parameters advised until normalized—up to 3–4 weeks. • Urine output. • Appetite. • Heart rate/blood pressure.

PREVENTION/AVOIDANCE

• Do not allow pets to lick humans where calcipotriene was applied. • Keep medication inaccessible to pets.

POSSIBLE COMPLICATIONS

Dystrophic mineralization of soft tissue, acute kidney failure, death.

EXPECTED COURSE AND PROGNOSIS

Good prognosis if rapid, aggressive, and continuing therapy is provided and hypercalcemia/hypophosphatemia minimized. Guarded to poor prognosis if soft tissue mineralization occurs.

Consulting Editor Lynn R. Hovda

CALCIUM CHANNEL BLOCKER TOXICOSIS

BASICS

OVERVIEW

• Calcium channel blockers (CCBs): class IV antidysrhythmics used to treat systemic hypertension, cardiac disease, tachydysrhythmias, and oliguric/anuric renal failure in dogs and cats. • CCBs inhibit movement of Ca through L-type voltage-gated slow Ca channels located on cardiac muscle, atrioventricular (AV) and sinoatrial (SA) nodes, vasculature smooth muscle, and pancreatic beta cells. • Three classes of CCBs—phenylalkylamine, benzothiazepine, dihydropyridine; CCB class determines the effect on the body.

SIGNS

Systems affected include: • Cardiovascular—bradycardia, AV dissociation and AV block (first, second, or third degree), hypotension. • Gastrointestinal—vomiting, diarrhea, ileus. • Respiratory—pulmonary edema. • Nervous—decreased mentation, weakness, collapse, seizures. • Endocrine/metabolic—hyperglycemia, metabolic acidosis secondary to hypoperfusion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Beta blocker antagonist toxicosis. • Cardiac disease with bradyarrhythmias. • Cardiovascular drug overdose (e.g., clonidine, digoxin toxicosis). • Sedative overdose (e.g., opioid or baclofen toxicosis). • Sick sinus syndrome. • Hyperkalemia. • Decompensated shock.

CBC/CHEMISTRY/URINALYSIS

• Hyperglycemia. • Azotemia and elevated liver enzymes with prolonged hypoperfusion.

OTHER LABORATORY TESTS

Blood gas—metabolic acidosis.

IMAGING

Chest radiographs to evaluate for pulmonary edema with respiratory signs.

DIAGNOSTIC PROCEDURES

• ECG—first-, second-, and third-degree AV block; prolonged PR, QRS, and QT intervals. • Echocardiogram—negative inotropy, decreased cardiac output.

TREATMENT

• Emesis if asymptomatic and <2 hours after exposure. • Gastric lavage if decreased mental status and large number of pills ingested. • Temporary cardiac pacing when medical therapy fails. • IV fluid bolus over 15–20 min for hypotension—cats, 10–20 mL/kg; dogs, 20–30 mL/kg.

MEDICATIONS

DRUG(S) OF CHOICE

• Activated charcoal (1–2 g/kg) PO, repeat activated charcoal for extended-release (ER) formulations. • Atropine (0.02–0.04 mg/kg IV) for sinus bradycardia. • Calcium infusion—first-line therapy despite normocalcemia to increase Ca availability for muscle function and improve contractility. ◦ Ca gluconate 10% bolus 0.5–1.5 mL/kg IV over 5–10 min followed by CRI of 0.5–1.5 mL/kg/h, titrated to effect; monitor continuous ECG and infusion should be slowed or stopped if bradycardia or conduction blockade worsens. ◦ Ca chloride 10% bolus 0.15–0.5 mL/kg IV; central line recommended due to risk of tissue injury secondary to drug extravasation.
• Intravenous fat emulsion (IFE)—may bind lipid-soluble drugs, increase Ca available for muscle contraction, and provide an energy source for heart muscle. ◦ IFE 20% solution dose—1.5 mL/kg IV bolus over 1 min; follow with CRI of 0.25 mL/kg/min for 30–60 min; additional IV doses: 1.5 ml/kg every 4–6h or CRI of 0.5 mL/kg/h; monitor serum for lipemia every 2–4h to determine if additional dosing is needed. • High-dose insulin euglycemia (HIE) treatment—may provide energy for heart muscle and increase Ca available for muscle contraction. Recommended treatment: ◦ Check blood glucose (BG) concentration and administer dextrose if BG <100 mg/dL. ◦ Administer regular insulin at 1 unit/kg IV, followed by CRI at 0.5–2 units/kg/h; may increase every 10 min up to maximum dose of 10 units/kg/h; when signs resolve, decrease insulin by 1–2 units/kg/h. ◦ Monitor BG every 10 min while titrating insulin dose; once stabilized, check BG every 30–60 min; central line placement recommended for frequent glucose monitoring and dextrose administration during HIE treatment; dextrose supplementation will be needed to maintain normal BG concentrations and continued up to 24h after discontinuation of insulin therapy. ◦ Monitor potassium concentration every hour during titration, then every 6h; administer potassium chloride to keep potassium concentrations within normal range. • Glucagon—may not be as effective as HIE or IFE; dose is 0.05–0.2 mg/kg slowly IV bolus, followed by CRI of 0.05–0.1 mg/kg/h.

CONTRAINDICATION/POSSIBLE INTERACTIONS

Vasopressors/sympathomimetics may not be as effective as other therapy and may make patients less response to other therapy.

FOLLOW-UP

PATIENT MONITORING

Monitor heart rate/ECG, BP, and BG for 6–12h with immediate-release preparations and 12–24h for ER/sustained-release (SR) preparations, depending on peak drug levels.

EXPECTED COURSE AND PROGNOSIS

• Ingestion of immediate-release preparations typically result in clinical signs in 8–12h. • SR or ER preparations may take 12–24h for clinical signs to develop. • Prognosis depends on dose ingested and response to therapy. • Toxicosis normally results in bradycardia, hypotension, and in severe cases decreased mental status, coma, and apnea.

MISCELLANEOUS

ABBREVIATIONS

• AV = atrioventricular.
• BG = blood glucose.
• CCB = calcium channel blocker.
• ER = extended release.
• HIE = high-dose insulin euglycemia.
• IFE = Intravenous fat emulsion.
• SA = sinoatrial.
• SR = sustained release.

CAMPYLOBACTERIOSIS

BASICS

OVERVIEW

• *Campylobacter jejuni*—fastidious, microaerophilic, Gram-negative curved bacteria; often isolated from healthy dogs and cats; may cause superficial erosive enterocolitis. • Infection—fecal–oral route from contaminated food, water, raw meat (especially chicken), environment; localized in crypts of intestine; motile; produces multiple enterotoxins. • Invasion of gut mucosa—hematochezia, inflammation, ulceration, edema; bacteria shed in feces for weeks to months. • Up to 49% of dogs without diarrhea and 45% of normal cats carry *C. jejuni* and shed it in feces.

SIGNALMENT

• Dogs; less commonly cats. • Prevalence—higher in puppies and kittens up to 6 months. • Can cause chronic disease.

SIGNS

• Diarrhea—varies; mucoid and watery, hemorrhagic; may be chronic. • Tenesmus. • Fever, anorexia, intermittent vomiting possible. • Adults—may be asymptomatic carriers. • Abortion and perinatal death.

CAUSES & RISK FACTORS

• *C. jejuni*, *C. coli*, *C. upsaliensis*, *C. helviticus*, *C. lari*, and more uncommon species. • Kennels/intensive housing, poor sanitation/hygiene, fecal contamination in environment. • Young animals—debilitated, immunosuppressed, parasitized. • Nosocomial infection in hospitalized patients. • Adults—concurrent intestinal infections (e.g., *Salmonella*, parvovirus, hookworms). • Feeding homemade or commercially available raw meat–based diets.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Bacterial enterocolitis—*Salmonella*, *Yersinia enterocolitica*, *Clostridium difficile*, *Clostridium perfringens*. • Parasitic—helminths (whipworms); protozoa (*Giardia*, *Isospora*). • Viral—parvovirus; signs often more severe. • Dietary indiscretion, intolerance. • Drugs, toxins. • Pancreatitis. • Intussusception, other causes of abdominal pain. • Distinguish from other causes of chronic diarrhea. • Primary intestinal disease.

CBC/BIOCHEMISTRY/URINALYSIS

• Leukocytosis—possible. • Biochemistry abnormalities—effects of diarrhea, dehydration (e.g., azotemia, electrolyte disturbances).

DIAGNOSTIC PROCEDURES

• Fecal leukocytes—in gastrointestinal tract and stool. • Fecal culture—submit feces in Amies transport medium with charcoal or Cary-Blair medium kept refrigerated at 4 °C in transit. • Species-specific quantitative PCR—current methodology may be biased to detect *C. jejuni* and *C. coli*.

Direct Examination of Feces

• Gram stain—make smear; leave Gram safranin on for longer period. • Wet mount—large numbers of highly motile bacteria (characteristic darting motility).

PATHOLOGIC FINDINGS

• Gross—diffuse colon thickening, congestion/edema; hyperemia of small intestine; enlarged mesenteric lymph nodes. • Thickening of intestinal smooth muscle in cats.

TREATMENT

Mild Enterocolitis

• Outpatient. • Usually self-limiting.

Severe Enterocolitis

• Inpatient, especially if very young, fever, hematochezia, melena. • Severe neonatal disease—isolate; aggressive therapy. • NPO for 24 hours; then bland diet. • Mild dehydration—oral fluid therapy with enteric fluid replacement solution. • Severe dehydration—intravenous fluid therapy with balanced isotonic replacement solution. • Plasma transfusion may be required. • Locally acting intestinal adsorbents/protectants.

MEDICATIONS

DRUG(S) OF CHOICE

• Antibiotics—for systemic illness (e.g., high fever, dehydration), when diarrhea or abnormal clinical signs persist >7 days, in immune-suppressed patients. • Erythromycin 10–20 mg/kg PO q8h for 5 days; drug of choice. • Enrofloxacin—dog, 10 mg/kg PO/IV/IM q24h; cat, 5 mg/kg PO/IM/IV q24h. • Tylosin 11 mg/kg PO q8h for 7 days. • Septicemia—parenteral broad-spectrum antibiotics indicated. • Multidrug resistance (vs. macrolides, quinolones) becoming more common.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Antidiarrheal drugs that reduce intestinal motility are contraindicated. • Enrofloxacin—may induce arthropathy in dogs <28 weeks of age; caution with use in cats.

FOLLOW-UP

PATIENT MONITORING

Repeat fecal culture after treatment.

PREVENTION/AVOIDANCE

• Good hygiene (hand washing). • Routinely clean and disinfect runs, food and water bowls. • Do not feed raw-meat diets to companion animals.

EXPECTED COURSE AND PROGNOSIS

• Adults—usually self-limiting. • Juveniles with severe or persistent enterocolitis—prognosis good with appropriate intervention.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Concurrent infection with other pathogenic bacteria, enteric parasites, viruses.

ZOONOTIC POTENTIAL

High (*C. jejuni*, *C. coli*, *C. upsaliensis*).

PREGNANCY/FERTILITY/BREEDING

Erythromycin—safe in early pregnancy.

CANDIDIASIS

BASICS

OVERVIEW

- *Candida*—dimorphic fungus with the yeast phase (*Candida* spp.) being part of the normal flora of the mouth, nose, ears, and gastrointestinal (GI) and urogenital tracts of dogs and cats.
- *C. albicans* and *C. parapsilosis* most commonly cultured from clinically healthy dogs.
- Recovery from mucosal surfaces does not imply disease; organisms may cause opportunistic infection, colonize damaged tissues, or invade normal tissues of immunosuppressed animals.
- Pathogenic role determined by infiltration of organisms into tissues, or detection of organisms in presumed sterile sites (e.g., urinary bladder, peritoneal cavity).
- Organ systems most affected include GI, renal/urologic, skin, and respiratory.
- Conditions that suppress the immune system (e.g., feline immunodeficiency virus [FIV] infection) increase the likelihood of isolation in asymptomatic animals.

SIGNALMENT

Cats and dogs—any age and breed.

SIGNS

- Nonhealing ulcers in the oral, upper respiratory, GI, or urogenital mucosa—signs reflect location/extent of disease:
  - Cystitis—hematuria, stranguria, and pollakiuria.
  - Otitis—head shaking, scratching.
  - Oral cavity—drooling.
- Inflammation around IV catheters or gastrotomy tubes.
- Ulcerative, red skin lesions.
- Systemic disease with fever, cardiac and/or neurologic abnormalities can be seen.

CAUSES & RISK FACTORS

- Infection—rare; associated with neutropenia, parvovirus or FIV infection, endocrinopathies, glucocorticoid therapy, gastrotomy tubes, indwelling urinary catheters/urethrostomy, IV catheters, and incomplete bladder emptying.
- Lower urinary tract disease may predispose to candiduria.
- Administration of antibiotics in prior 30 days.
- Occasionally local or systemic infection is seen in animals without predisposing conditions.
- Skin damaged by burns, trauma, or necrotizing dermatitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Considered whenever the primary condition does not respond as expected.

CBC/BIOCHEMISTRY/URINALYSIS

- Reflect underlying inflammation and organ involvement (unless neutropenic).
- Urinalysis—may show yeast or clumps of mycelial elements (pseudohyphae) with inflammatory cells; concurrent bacterial urinary tract infection common.

OTHER LABORATORY TESTS

- Cytology—spherical to oval yeast cells 5–7 µm in diameter; pseudohyphae and septate hyphae 3–5 µm wide.
- Culture—grows well on blood agar and often is isolated from specimens submitted for bacterial culture; more easily isolated from urine than blood.
- PCR and antigen tests available.

DIAGNOSTIC PROCEDURES

- Lesions—to determine if *Candida* is truly a pathogen, requires demonstration of organisms penetrating the tissues.
- Urine sample—cystocentesis; culture of multiple colonies of *Candida* supports diagnosis.
- Otitis (dogs)—culture of *Candida* spp. or identification of yeast or mycelial elements on ear cytology suggests diagnosis.
- In febrile patients, culture catheter tips.

PATHOLOGIC FINDINGS

- White caseous foci in the infected tissue.
- Large numbers of both yeast and pseudohyphae in tissues surrounded by necrosis and suppurative inflammatory reaction.
- May be pyogranulomatous in more chronic infections.

TREATMENT

- Treat underlying causes of immunosuppression.
- Remove indwelling catheters, if possible.

MEDICATIONS

DRUG(S) OF CHOICE

- Topical therapy (mucosal lesions)—nystatin or amphotericin B.
- Fluconazole—5 mg/kg PO q12h; very effective and excreted unchanged in urine (high concentration in commonly infected sites).
- Itraconazole—5–10 mg/kg PO q12h; effective, can use if organism resistant to fluconazole; not recommended for urinary tract infection (poor urinary excretion).
- In lower urinary tract *Candida* infections resistant to fluconazole—infuse 10–30 mL of 1% clotrimazole into the bladder every other day for three treatments.
- *Candida* may develop drug resistance—consider drug sensitivity testing if suspected.
- Caspofungin—may be option for resistant isolates.

FOLLOW-UP

PATIENT MONITORING

- Fluconazole and itraconazole—hepatic toxicity; monitor serum alanine aminotransferase (ALT) activity monthly initially and check if patient becomes anorexic.
- After signs have resolved—reculture sites of infection; continue treatment for 2 weeks beyond negative culture; repeat cultures 2 weeks after completion of treatment and again if signs recur.

EXPECTED COURSE AND PROGNOSIS

- Should resolve within 2–4 weeks of treatment with correction of immunosuppression.
- Control of the underlying disease is necessary to prevent recurrence.
- May resolve spontaneously if the underlying condition is corrected.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Genetic similarities between human and animal isolates suggest a potential for transfer of *C. albicans* between species.

ABBREVIATIONS

- ALT = alanine aminotransferase.
- FIV = feline immunodeficiency virus.
- GI = gastrointestinal.

Consulting Editor Amie Koenig

CANINE CORONAVIRUS INFECTIONS

BASICS

OVERVIEW

- Canine enteric coronavirus (CCoV)—sporadic outbreaks of enteritis in dogs; worldwide distribution.
- Canine pantropic coronavirus (CPCoV)—variant of CCoV, fatal disease in dogs <6 months, described principally in Europe.
- CCoV, CPCoV—closely related to feline infectious peritonitis (FIP) virus, feline enteric coronavirus.
- Canine respiratory coronavirus (CRCoV)—associated with canine infectious respiratory disease complex (kennel cough); worldwide distribution; genetically and serologically distinct from CCoV.
- Incubation period 1–3 days.
- CCoV infection—usually inapparent; mild to severe enteritis possible; death reported in young pups; infects upper two-thirds of small intestine and associated lymph nodes; crypt cells spared.
- Simultaneous infection with canine parvovirus (CPV)-2 possible; severe, often fatal.
- CPCoV—infects intestinal tract, after short viremia distributes to organs like spleen, lungs, brain.
- Coronaviruses undergo rapid evolution, are highly variable; differences in virulence likely between isolates.

SIGNALMENT

- Dogs of all ages, breeds; disease more severe in young.
- CRCoV infections more common in winter, in shelters.

SIGNS

- Vary greatly—CPCoV virulent isolates cause systemic disease.
- Adults—most infections inapparent.
- Puppies—mild to severe, occasionally fatal, enteritis.
- Diarrhea—may be explosive; yellow-green or orange; loose or liquid; typically malodorous (characteristic); may persist for days to >3 weeks; may recur; young dogs may suffer severe, protracted diarrhea, dehydration.
- Vomiting.
- Coughing, dyspnea—CRCoV associated with kennel cough complex.
- Anorexia, lethargy.
- For CPCoV—pyrexia, anorexia, depression, vomiting, hemorrhagic enteritis, respiratory distress, and leukopenia that persists >1 week; ataxia, seizures, and death also possible.

CAUSES & RISK FACTORS

- Stress—greatest risk; sporadic outbreaks have occurred in dogs attending shows, in kennels where new dogs frequently introduced; crowding and unsanitary conditions promote illness.
- For CCoV, CPCoV—feces primary source of infection; virus shed for 2 weeks.
- For CRCoV—respiratory secretions, fomites likely sources of infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infections caused by enteric bacteria, protozoa, other viruses; canine kennel cough complex pathogens.
- Other mild to moderate upper respiratory disease.
- Food intoxication or intolerance.

CBC/BIOCHEMISTRY/URINALYSIS

Normal; lymphopenia with more virulent CCoV isolates.

OTHER LABORATORY TESTS

Serologic tests—available; not standardized, difficult to interpret due to frequent asymptomatic infection.

DIAGNOSTIC PROCEDURES

- Viral isolation for CCoV, CRCoV—possible but not recommended.
- Specific reverse transcriptase polymerase chain reaction (RT-PCR)—using feces for CCoV, respiratory swabs for CRCoV; CPCoV defined by presence of virus in extraintestinal organs.
- Immunofluorescence of small intestine—fatal cases; may show viral antigen in cells lining villous epithelium.

PATHOLOGIC FINDINGS

- Gross—dilated small intestine filled with gas, watery green-yellow material.
- Bowel loops congested, hemorrhagic; mesenteric lymph nodes enlarged, edematous.
- Histopathology—atrophy and fusion of intestinal villi, deepening of crypts, increased cellularity of lamina propria, epithelial cell flattening, increased goblet cells.
- CPCoV—hemorrhagic lesions in various organs (lungs, small intestines, spleen, lymph nodes).

TREATMENT

- Most dogs recover without treatment.
- CCoV—fluid, electrolyte treatment if dehydration severe.
- CRCoV—as for canine kennel cough complex.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics—not usually indicated, except with enteritis, sepsis, severe respiratory illness.

FOLLOW-UP

PREVENTION/AVOIDANCE

- CCoV vaccines—controversial; inactivated and live viral vaccines; appear safe; moderate efficacy may be due to variability of CCoV strains; not recommended; do not cross-protect against CPCoV, CRCoV.
- Strict quarantine, sanitation essential in kennels: susceptible to common disinfectants.
- CCoV, CRCoV—highly contagious; spread rapidly.

POSSIBLE COMPLICATIONS

Diarrhea with CCoV—may persist 10–12 days, may recur.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—good, except severe infections of young pups.
- Majority recover after short illness.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Concurrent infection with CPV or other agent.
- Infections with other respiratory pathogens with CRCoV.

ABBREVIATIONS

- CCoV = canine enteric coronavirus.
- CPCoV= canine pantropic coronavirus.
- CPV = canine parvovirus.
- CRCoV = canine respiratory coronavirus.
- FIP = feline infectious peritonitis.
- RT-PCR = reverse transcriptase polymerase chain reaction.

CANINE DEGENERATIVE MYELOPATHY

BASICS

DEFINITION
Canine progressive adult-onset fatal neurodegenerative disease that has recently been shown in many breeds to be a result of a mutation in the superoxide dismutase 1 gene (*SOD1*). Mutations in *SOD1* are known to cause some forms of amyotrophic lateral sclerosis (ALS), also known as Lou Gehrig's disease. Initial signs of progressive upper motor neuron spastic paresis and general proprioceptive ataxia in the pelvic limbs occur in older dogs. If euthanasia is delayed, clinical signs progress to flaccid tetraparesis/plegia and other lower motor neuron signs.

PATHOPHYSIOLOGY
- A *c.118 G>A* transition in Exon 2 of *SOD1* that predicts an E40K missense mutation underlies most degenerative myelopathy (DM); a second *SOD1* missense mutation (*c.52 A>T*) has been seen only in Bernese mountain dogs.
- Lesions may represent a multisystem central-peripheral axonopathy.
- Predilection for lesion severity in mid-thoracic spinal cord may be a result of lower percentages of radicular artery contributions and small-diameter vessels when compared to other spinal cord regions.
- Paucity of vascular supply in thoracic spinal cord may predispose it to damage from oxidative and metabolic disturbances.

SYSTEMS AFFECTED
- Central and peripheral nervous systems.
- Thoracolumbar spinal cord in early stage.
- Progresses to involve the cervical and lumbar spinal cord and peripheral nervous system later in the course of the disease.
- Neurons in the brainstem also may be affected.
- Disease also involves the sensory nerve roots and dorsal root ganglia.

GENETICS
- Most commonly autosomal recessive inheritance.
- Due to preponderance of purebred dogs affected, a familial inheritance is currently suspected.
- Mutations in *SOD1* are causative for DM but are incompletely penetrant.
- Dogs that are homozygous for the mutant allele are *at highest risk* for developing DM; not all dogs that test homozygous for the mutation will develop DM, but dogs that test normal (clear) are highly unlikely to develop DM; dogs that test carrier are less likely to develop DM, but this has been documented in some breeds.

INCIDENCE/PREVALENCE
Prevalence rate of DM reported for all dogs collected from the Veterinary Medical Database (1990–1999) was 0.19%.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Breed Predilections
So far the DM-associated *SOD1:c.118A* allele is in >150 breeds or varieties; a second *SOD1* mutation (*c.52 A>T*) was found only in Bernese mountain dogs. DM has been histopathologically confirmed in many purebred and mixed-breed dogs.

Mean Age and Range
- Mean—9 years of age in large dogs; mean age at onset is 11 years in Pembroke Welsh corgi.
- Range—between 8 and 14 years.

Predominant Sex
No known sex predilection.

SIGNS
- Early:
  - Upper motor neuron paraparesis.
  - Insidious, progressive, asymmetric general proprioceptive ataxia; gait shows long-strided spastic paraparesis.
  - Paw replacement deficits.
  - Spinal reflexes usually present or exaggerated (patellar reflex may be reduced).
  - Presence of crossed-extensor reflex is variable.
  - Lack of paraspinal hyperesthesia is key clinical feature.
- Later:
  - Pelvic limb paresis leading to plegia, eventually progressing to tetraparesis/plegia.
  - Mild to moderate loss of muscle mass in pelvic limbs due to neurogenic atrophy.
  - Reduced spinal reflexes in pelvic limbs.
  - ± Urinary and fecal incontinence.
- End stage:
  - Flaccid tetraplegia.
  - Difficulty with swallowing and tongue movements.
  - Absence of spinal reflexes in all limbs.
  - Reduced to absent cutaneous trunci reflex.
  - Profound generalized muscle wasting.
  - Urinary and fecal incontinence.

CAUSES
- Hereditary disease and genetic predisposition.
- Other hypothesized causes include immune-mediated, metabolic deficiencies, toxic, and oxidative stress.

RISK FACTORS
- Dogs homozygous for the mutant allele(s) are at highest risk.
- There may be other environmental factors and modifying genes; studies underway.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Type II intervertebral disc herniation.
- Intramedullary spinal cord neoplasia.
- Degenerative lumbosacral stenosis.
- Hip dysplasia.
- Other coexisting orthopedic disease.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Performed to rule out other underlying metabolic disease.
- Urinalysis may identify secondary urinary tract infection.

OTHER LABORATORY TESTS
- Urine culture and sensitivity testing.
- Thyroid function testing.
- Electrodiagnostic testing results are normal in early diagnosis of DM.
- Genetic testing—test result of at-risk can support a presumptive diagnosis of DM in light of typical clinical signs and normal findings on neuroimaging and cerebrospinal fluid analysis.

IMAGING
- Survey spinal radiography.
- Myelography evaluates for compressive spinal cord disease.
- Myelography combined with CT—more sensitive technique to evaluate suspicious lesions.
- MRI—preferred technique to evaluate for extramedullary compressive and intramedullary lesions.

DIAGNOSTIC PROCEDURES
- CSF analysis evaluates for inflammatory disease.
- Definitive diagnosis is determined by post-mortem histopathology of spinal cord.

PATHOLOGIC FINDINGS
- Spinal cord axons and myelin affected most severely in dorsal and dorsal portion of lateral funiculi.
- Vacuolated axon cylinders/myelin sheaths most extensive in mid-thoracic spinal cord.
- Astroglial proliferation is prominent in severely affected areas of lesion distribution.
- Usually, lesion distribution is described as asymmetric and discontinuous; however, more recent evidence describes lesion distribution as symmetric and continuous in dogs that survive for long periods with DM.
- Neuronal cell body loss in ventral horn is evident at terminal or end-stage disease.
- Nerve specimens show fiber loss resulting from axonal degeneration and secondary demyelination.
- Muscle specimens show large and small groups of atrophic fibers typical of denervation.

CANINE DEGENERATIVE MYELOPATHY (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE
- Supportive care.
- Breeds of small size may survive longer with DM because the pet owner is able to more easily give the appropriate care.

NURSING CARE
- When dog becomes nonambulatory, keep on a well-padded surface to prevent decubitus ulceration over bony prominences.
- Keep hair trimmed, and skin clean and dry to prevent urine scald secondary to incontinence.
- Urine should be monitored for odor and color change, which may indicate urinary tract infection.
- Physical therapy using range-of-motion and active exercises may help maintain limb mobility and muscle strength.

ACTIVITY
- Exercise is encouraged to slow disuse atrophy of pelvic limbs, but fatigue should be monitored and exercise intensity adjusted.
- Hydrotherapy can involve use of an underwater treadmill setup.
- A wheel cart may assist with patient mobility.

DIET
- Maintain balanced diet.
- Prevent weight gain.

CLIENT EDUCATION
- Long-term prognosis is poor.
- Meticulous nursing care is crucial to preventing secondary complications in a recumbent patient.

SURGICAL CONSIDERATIONS
None

MEDICATIONS

DRUG(S) OF CHOICE
Clinical trials are underway to determine effectiveness in slowing or halting disease progression.

FOLLOW-UP

PATIENT MONITORING
- Repeat neurologic examinations.
- Urine retention.
- Urinalysis and urine culture to monitor for urinary tract infection.

PREVENTION/AVOIDANCE
- Decubitus ulceration.
- Urine retention.
- Dermatitis from urine scald.
- Weight gain.

POSSIBLE COMPLICATIONS
- Urine retention may predispose to urinary tract infections.
- Local skin infections from decubitus ulceration.

EXPECTED COURSE AND PROGNOSIS
- Nonambulatory paraparesis occurs within 9–12 months from time of onset of signs.
- Tetraparesis may be evident within 3 years from time of onset of signs.
- Long-term prognosis is poor.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Other neurologic diseases associated with old-age onset.
- Spinal cord neoplasia.
- Intervertebral disc disease.
- Orthopedic disease.

AGE-RELATED FACTORS
Older dogs commonly affected.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
N/A

SYNONYMS
- Canine ALS.
- DM.
- Degenerative radiculomyelopathy.
- German Shepherd dog myelopathy.

SEE ALSO
- Intervertebral Disc Disease, Cervical.
- Intervertebral Disc Disease, Thoracolumbar.
- Lumbosacral Stenosis and Cauda Equina Syndrome.

Client Education Handout available online

CANINE DISTEMPER

BASICS

DEFINITION
• Acute to subacute, contagious, febrile, often fatal disease with respiratory, urogenital, gastrointestinal, ocular, and CNS manifestations.
• Caused by canine distemper virus (CDV), a *Morbillivirus* in the *Paramyxoviridae* family.
• Affects many Carnivora species; mortality rate varies greatly.

PATHOPHYSIOLOGY
• Natural route of infection—airborne and droplet exposure; from nasal cavity, pharynx, and lungs, virus replication occurs in local lymph nodes; within 1 week, viral shedding occurs (mainly in respiratory exudates but also urine) and virtually all lymphatic tissues become infected; spreads via viremia to surface epithelium of respiratory, gastrointestinal, and urogenital tracts and to CNS.
• Disease progression depends on virus strain and host immune response:
  ◦ Strong cellular and humoral immune response—subclinical infection.
  ◦ Weak immune response—subacute infection; longer survival.
  ◦ Failed immune response—death within 2–4 weeks after infection; frequently due to CNS manifestations.
• Viral excretion can occur for up to 2–3 months.

SYSTEMS AFFECTED
• Multisystemic—all lymphatic tissues, surface epithelium in respiratory, alimentary, and urogenital tracts, skin, endocrine and exocrine glands.
• CNS—brain and/or spinal cord.

INCIDENCE/PREVALENCE
• Dogs—sporadic outbreaks.
• Wildlife (raccoons, skunks, fox, tigers)—fairly common.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Most species of the order Carnivora; has been reported in large exotic cats.

Mean Age and Range
Young, especially unvaccinated animals are most susceptible.

SIGNS
• Fever—intermittent peaks starting 3–6 days after infection.
• Gastrointestinal and/or respiratory signs—nasal and ocular discharge, depression, anorexia, vomiting, diarrhea; often exacerbated by secondary bacterial infection.
• CNS—common; generally after systemic disease (depends on virus strain).
  ◦ Gray matter disease—affects cerebral cortex, brainstem, and spinal cord and may cause a nonsuppurative meningitis, seizures, mentation change, and ataxia; dogs may die in 2–3 weeks; some dogs recover (associated with prompt humoral and cell-mediated immunity), others develop white matter disease.
  ◦ White matter disease—multifocal disease, commonly cerebellovestibular signs, paresis, ataxia, occasionally myoclonus; some dogs die 4–5 weeks after initial infection with noninflammatory, demyelinating disease; some dogs may recover with minimal CNS injury.
• Optic neuritis and retinal lesions may occur; anterior uveitis, keratoconjunctivitis sicca possible.
• Hardening of footpads (hyperkeratosis) and nose—some virus strains; uncommon.
• Enamel hypoplasia of teeth after neonatal infection.

CAUSES
• CDV exposure.
• Incompletely attenuated vaccines (rare).

RISK FACTORS
Contact of nonimmunized animals with CDV-infected animals (dogs, wild carnivores).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Diagnosis based on clinical suspicion; combination of respiratory and gastrointestinal, ± CNS disease, in unvaccinated dog.
• Respiratory signs—can mimic kennel cough.
• Enteric signs—differentiate from canine parvovirus, coronavirus, parasitism (giardiasis), bacterial infections, gastroenteritis from toxin ingestion, inflammatory bowel disease.
• CNS form—differentiate from autoimmune meningoencephalitis (granulomatous meningoencephalomyelitis, necrotizing encephalitis, meningoencephalitis of unknown etiology), protozoal (e.g., toxoplasmosis, neosporosis), fungal (e.g., cryptococcosis), and rickettsial (e.g., ehrlichiosis, Rocky Mountain spotted fever) meningoencephalitis, rabies.

CBC/BIOCHEMISTRY/URINALYSIS
Lymphopenia in early infection; rare thrombocytopenia; intracytoplasmic inclusions in white and red blood cells.

OTHER LABORATORY TESTS
• Serology—positive antibody tests do *not* differentiate between vaccination and exposure to virulent virus; patient may die from acute disease before neutralizing antibody is produced. Immunoglobulin (Ig) M responses may occur up to 3 months after exposure to virulent virus, up to 3 weeks after vaccination; rising IgG titers in unvaccinated dog are suggestive of infection; may be useful for risk assessment of clinically healthy dogs in shelter environment.
• CDV antibody in cerebrospinal fluid (CSF)—indicative of distemper encephalitis, false negatives possible.

IMAGING
• Radiographs—evaluate pulmonary disease.
• CT and MRI—may or may not show lesions; MRI sensitive for demyelination.

DIAGNOSTIC PROCEDURES
• Immunohistochemical detection in haired skin, nasal mucosa, and footpad epithelium.
• Viral antigen or viral inclusions—in buffy coat cells, urine sediment, conjunctival or vaginal imprints, trans-tracheal wash (negative results do not rule out CDV).
• Reverse transcriptase polymerase chain reaction (RT-PCR)—on buffy coat, urine sediment cells, respiratory secretions, conjunctival swabs, CSF; false negatives possible, false positives with recent vaccination (uncommon).
• CSF—moderate mononuclear pleocytosis, elevated concentrations of CDV-specific antibody, interferon, and viral antigen early in disease course.

PATHOLOGIC FINDINGS
Gross
• Thymus—greatly reduced in size (young animals); sometimes gelatinous.
• Lungs—patchy consolidation.
• Footpads, nose—hyperkeratosis.
• Mucopurulent discharges—from eyes and nose, bronchopneumonia, catarrhal enteritis, skin pustules (secondary bacterial infection).

Histologic
• Intracytoplasmic eosinophilic inclusion bodies—in epithelium of bronchi, stomach, urinary bladder; also in reticulum cells and leukocytes in lymphatic tissues.
• Inclusion bodies in glial cells and neurons—frequently intranuclear; also in cytoplasm.
• Immunofluorescence and/or immunocytochemistry, virus isolation, and/or RT-PCR performed on tissues from lungs, stomach, urinary bladder, lymph nodes, brain.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient medical management to intensive care as indicated; isolate patient to prevent spread to other dogs.

NURSING CARE
• Symptomatic.
• IV fluids—for hypovolemia, support.
• Oxygen therapy, nebulization, and coupage—for pneumonia.
• Clean ocular, nasal discharges.

CANINE DISTEMPER (CONTINUED)

ACTIVITY
Limited, to reduce spread.

DIET
Depends on extent of gastrointestinal involvement.

CLIENT EDUCATION
- Inform client that mortality rate is about 50%.
- Inform client that dogs appearing to recover from early catarrhal signs may develop fatal CNS disease.
- Presenting neurologic abnormalities usually not reversible.

MEDICATIONS

DRUG(S) OF CHOICE
- Antiviral drugs—none known to be effective.
- Broad-spectrum antibiotics—for secondary bacterial infection (CDV is immunosuppressive), beta-lactams or cephalosporins are good initial choices.
- Anticonvulsant therapy—phenobarbital, potassium bromide, levetiracetam.
- Myoclonus—no proven treatment; single case report describes use of botulinum toxin type A.

CONTRAINDICATIONS
Corticosteroids—use anti-inflammatory dosages with caution; may provide short-term control. Immunosuppressive dosages may enhance viral dissemination.

PRECAUTIONS
Tetracycline, fluoroquinolones—avoid in growing animals.

FOLLOW-UP

PATIENT MONITORING
- Monitor for CNS abnormalities, particularly seizures.
- Monitor for respiratory distress or dehydration in acute phase.

PREVENTION/AVOIDANCE
- Vaccination.
- Isolate puppies to prevent infection from wildlife (e.g., raccoons, foxes, skunks), CDV-infected dogs, ferrets.
- Recovered dogs may shed virus for up to 4 months; isolate for this time period or until multiple negative RT-PCR tests.

Vaccines
- Duration of immunity from most vaccines is >3 years.
- Modified live vaccine for CDV (MLV-CD)—prevents infection and disease; two types available:
  - Canine tissue culture-adapted vaccines (e.g., Rockborn strain)—induce complete immunity in virtually 100% of susceptible dogs; rarely, a postvaccinal fatal encephalitis develops 7–14 days after vaccination, especially in immunosuppressed animals.
  - Chick embryo-adapted vaccines (e.g., Lederle strain)—safer; postvaccinal encephalitis does not occur; only about 80% of susceptible dogs seroconvert.
  - Other species—chick embryo can safely be used in variety of wildlife species (e.g., gray fox); Rockborn type fatal in these animals.
- Killed vaccines—useful for species in which either type of MLV-CD is fatal (e.g., red panda, blackfooted ferret).
- Canarypox recombinant CDV vaccine.

Maternal Antibody
- Important.
- Most puppies lose protection from maternal antibody at 6–12 weeks of age; 2–3 vaccinations should be given during this period.
- Heterotypic (measles virus) vaccination—recommended for puppies that have maternal antibody; induces protection from disease but not from infection.

POSSIBLE COMPLICATIONS
Possibility of CNS signs developing for 2–3 months after catarrhal signs have subsided.

EXPECTED COURSE AND PROGNOSIS
- Depends on strain and individual host response—subclinical, acute, subacute, fatal, or nonfatal infection.
- Mild CNS signs—patient may recover; myoclonus may continue for several months or indefinitely.
- Death—2 weeks to 3 months after infection; mortality rate ~50%.
- Euthanasia—owner may elect if or when neurologic signs develop; indicated if uncontrollable seizures occur.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Persistent or latent *Toxoplasma gondii* infections—may be reactivated due to immunosuppressive state.
- Respiratory infections with *Bordetella bronchiseptica* (kennel cough).

AGE-RELATED FACTORS
- Young puppies—more susceptible; mortality rate is higher.
- Nonimmunized old dogs—highly susceptible to infection and disease.

ZOONOTIC POTENTIAL
Possible that humans may become subclinically infected with CDV; immunization against measles virus also protects against CDV infection.

PREGNANCY/FERTILITY/BREEDING
In utero infection—occurs in antibody-negative bitches; rare; may lead to abortion or to persistent infection; infected neonates may develop fatal disease by 4–6 weeks of age.

SYNONYMS
- Canine distemper.
- Hard pad disease.

SEE ALSO
Myoclonus

ABBREVIATIONS
- CDV = canine distemper virus.
- CSF = cerebrospinal fluid.
- Ig = immunoglobulin.
- MLV-CD = modified live virus of canine distemper.
- RT-PCR = reverse transcriptase polymerase chain reaction.

CANINE INFECTIOUS DIARRHEA

BASICS

DEFINITION
• Viral, enteropathogenic bacterial, protozoal, or parasitic etiologies; small, large, or mixed-bowel diarrhea.
• Secondary systemic signs with canine parvovirus (CPV)-2 and salmonellosis.
• Presence of organisms on diagnostic screening does not indicate causation; patient factors (clinical signs, age, environmental exposure) should be considered before treatment.
• Some dogs will have self-resolution; diagnostic testing appropriate for more severely affected animals or if clinical signs are persistent having ruled out other causes of acute or chronic diarrhea.
• Puppies with acute diarrhea should be screened for CPV-2.

PATHOPHYSIOLOGY
• Typically, fecal–oral route of infection.
• Diarrhea from enterotoxins, osmotic diarrhea, or invasion of epithelium resulting in inflammation.
• Up to 50% of dogs may have coinfections.

SYSTEMS AFFECTED
• Gastrointestinal (GI)—vomiting, diarrhea.
• Cardiovascular—fluid balance.

INCIDENCE/PREVALENCE
• Prevalence of most pathogens similar in dogs with or without diarrhea.
  ◦ Coronavirus more common in dogs with diarrhea.
  ◦ Dogs with diarrhea more likely to have >1 enteropathogen.
• Specific prevalence in dogs in United States:
  ◦ 0–6%—CPV-2, Salmonella spp., Cystoisospora spp., Dipylidum caninum, Campylobacter spp., C. difficile toxin A and B, ascarids.
  ◦ 7–20%—whipworms, *Giardia* spp., *Cryptosporidium*, circovirus.
  ◦ 35–60%—*C. perfringens* enterotoxin A or alpha toxin gene, hookworm.

GEOGRAPHIC DISTRIBUTION
• Widespread.
• Prevalence of etiologies varies by location.

SIGNALMENT
• Species—dog.
• Breed predilections—none.
• Mean age and range—largely pediatric and young adult dogs; older animals if in high-risk environments.

SIGNS
• General comments—range from mild to severely affected.
• Historical findings—acute or chronic, small or large bowel diarrhea; possibly vomiting, weight loss, hyporexia; no history of dietary indiscretion.
• Physical examination findings—depends on etiology and severity; may include dehydration, poor body condition, borborygmus, flatulence, hematochezia, melena, visualization of worms on rectal exam or peri-anal, signs of sepsis or systemic inflammatory response syndrome (SIRS).

CAUSES
• Viral—coronavirus, CPV-2, circovirus.
• Bacterial—*Campylobacter spp*., *Clostridium perfringens* enterotoxin, *Clostridium difficile* toxins, *Salmonella* spp.
• Parasitic—*Toxocara* spp., *Ancylostoma* spp., *Toxascaris leonine, Dipyldium caninum, Trichuris vulpis*.
• Protozoal—*Giardia* spp.
• Coccidial—*Cryptosporidium* spp., *Cystoisospora* spp.

RISK FACTORS
• Pediatric and young adult dogs more commonly affected, particularly for viral enteritis, *Cryptosporidium* spp., roundworm (*Toxocara* and *Toxascaris*), *Cystoisospora* spp., and *Campylobacter* spp.
• Administration of antimicrobials and immunosuppressive drugs increase risk for hospital-associated colonization of *C. difficile*.
• Crowding and poor sanitation.
• Lack of regular parasiticide administration.
• Dogs with environmental exposure to livestock or wildlife for *Cryptosporidium* spp., *Campylobacter* spp., *Giardia* spp.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Acute diarrhea—dietary indiscretion, foreign body, pancreatitis, GI neoplasia; non-GI diseases: hepatotoxicity, renal disease, other systemic diseases (commonly other clinical signs such as hyporexia, vomiting, icterus).
• Chronic diarrhea—chronic enteropathy (dietary responsive, antibiotic responsive, or inflammatory bowel disease), chronic pancreatitis, primary GI neoplasia, and non-GI diseases of other organs.

CBC/BIOCHEMISTRY/URINALYSIS
• Eosinophilia—possible with intestinal parasitism.
• Anemia and/or microcytosis—GI hemorrhage or iron deficiency, particularly with high worm burden (e.g., *T. vulpis*) or GI mucosal shedding (e.g., CPV).
• Leukopenia—parvoviral enteritis (bacterial translocation or bone marrow suppression) or systemic salmonellosis.
• Hyponatremia and hyperkalemia with large bowel diarrhea—*T. vulpis*.
• Azotemia and electrolyte derangements with dehydration.
• Hypoglycemia—parvoviral enteritis and systemic salmonellosis.
• Panhypoproteinemia and hypocholesterolemia if secondary protein-losing enteropathy or GI blood loss.

IMAGING
• Abdominal radiographs if no response to symptomatic care to rule out other causes of diarrhea.
• Abdominal ultrasound recommended in nonpediatric patients with diarrhea that is nonresponsive to symptomatic care.

DIAGNOSTIC PROCEDURES
• Fecal flotation—for intestinal parasitism; false negatives possible (ova are intermittently shed); dogs suspected to have intestinal parasitism should have multiple fecal flotations performed or be treated with anthelmintics.
• Fecal cytology—bacterial morphology (frequent spirochetes, spores) or presence of fungal or protozoal organisms.
• *Giardia* ELISA.
• Infectious diarrhea PCR panels detect a range of possible causes of diarrhea; however, caution should be used in interpretation of these assays, as a positive result does not necessarily indicate causation and false-negative results are possible.

PATHOLOGIC FINDINGS
• Gross examination of intestinal mucosa may demonstrate parasites attached to intestinal mucosa with multifocal hemorrhagic ulcerations, submucosal congestion or hemorrhage, intestinal wall thickening.
• Histopathology of intestine may show eosinophilic, neutrophilic, or lymphoplasmacytic enteritis with varying degrees of hemorrhage and necrosis, depending on etiology.

TREATMENT

APPROPRIATE HEALTH CARE
• Mildly affected dogs—outpatient basis.
• Moderate to severely affected dogs may require IV administration of isotonic balanced electrolyte solution for dehydration.
• Electrolyte and acid-base imbalances should be corrected with fluid therapy and monitored closely.
• Dextrose should be supplemented parenterally in dogs with hypoglycemia.
• Packed red blood cell or plasma transfusions should be given as needed for severe anemia or coagulopathies from sepsis (rare).

DIET
• Easily digestible diets until clinical signs have resolved, followed by slow transition (3–4 days) to maintenance diet.
• In anorexic pediatric patients, nasogastric tube feeding of liquid diet recommended if anorexia persists ≥48 hours.

CANINE INFECTIOUS DIARRHEA (CONTINUED)

CLIENT EDUCATION

- For most infectious organisms, environmental decontamination prevents transmission to other pets/people and reinfection; isolation during hospitalization may be warranted depending on underlying cause.
- Appropriate vaccination and deworming schedules should be followed.
- Dogs with identified infectious causes of diarrhea should be isolated from other dogs if possible until clinical signs resolve.

SURGICAL CONSIDERATIONS

Viral and parasitic enterocolitis can result in intussusceptions, especially in puppies.

MEDICATIONS

DRUG(S) OF CHOICE

- Many cases will self-resolve with supportive care and time.
- Empiric therapy pending diagnostics, if clinical signs persist—probiotics, or metronidazole (10 mg/kg PO q12h) and fenbendazole (50 mg/kg PO q24h for 5 days).
- Anthelmintics—fenbendazole (50 mg/kg PO q24h for 5 days), pyrantel pamoate (5–10 mg/kg PO for 3 days).
- Coccidiostatic—sulfadimethoxine (50–60 mg/kg PO q24h for 5–10 days), ponazuril (50 mg/kg PO once).
- Antiprotozoal drugs—fenbendazole (50 mg/kg PO q24h for 5 days).
- Campylobacteriosis with persistent clinical signs—erythromycin (10–15 mg/kg PO q8h) or azithromycin (5–10 mg/kg PO q24h).
- Probiotics may be of benefit for dogs with bacterial enteritis with acute or chronic signs; probiotics should be selected with evidence of efficacy (e.g., Visbiome®).
- Patients with systemic illness, leukopenia, or suspected GI mucosal barrier breakdown (evidenced by blood in the feces) should be treated with broad-spectrum antimicrobial agents and as indicated by specific etiology.
- Dogs with confirmed salmonella should *not* be treated with antibiotics unless systemically ill.

PRECAUTIONS

Metronidazole dose should be reduced in animals with hepatic insufficiency.

POSSIBLE INTERACTIONS

- Metronidazole given at higher doses for giardiasis or long-term use can lead to vestibular signs.
- Some dogs may be sensitive to sulfa-containing medications used for treatment of coccidiosis.

FOLLOW-UP

PATIENT MONITORING

- Case-based, may include reassessment of anemia, leukopenia, or electrolyte derangements as appropriate.
- Persistent clinical signs after appropriate treatment is suggestive for alternative cause of diarrhea.
- Patients with recurrent clinical signs should be retested, particularly if environmental reinfection is possible (e.g., giardiasis, campylobacteriosis).

PREVENTION/AVOIDANCE

- Routine vaccination.
- Monthly flea/tick or heartworm preventative with combination anthelmintic therapy.
- Avoid subjecting poorly vaccinated or immunocompromised animals to high-traffic areas, including but not limited to pet supply stores, dog parks, or newly introduced poorly vaccinated pets.

POSSIBLE COMPLICATIONS

- Sepsis.
- Anemia.
- Electrolyte disturbances.
- Aspiration pneumonia if concurrent vomiting (uncommon).

EXPECTED COURSE AND PROGNOSIS

- Usually good to excellent; underlying immunosuppressive conditions may increase susceptibility to infection and worsen prognosis.
- Parvoviral enteritis carries guarded to poor prognosis without treatment; appropriate supportive care provides full recovery rates of 90% or more.

MISCELLANEOUS

AGE-RELATED FACTORS

Puppies and young dogs affected.

ZOONOTIC POTENTIAL

- Giardiasis—low risk of transmission.
- Cryptosporidiosis.
- Salmonellosis.
- *Campylobacter jejuni*.
- *Toxocara* spp. (ascarids)—visceral larval migrans in humans, most common in children.
- *Ancylostoma* (hookworms)—cutaneous larval migrans in humans, most common in children.

PREGNANCY/FERTILITY/BREEDING

If heavy endoparasite load, fenbendazole can be administered to pregnant bitches from 14th day of gestation through to 14th day of lactation. If risk of infection is high, all puppies (and mothers) should be treated with appropriate anthelmintics at 2, 4, 6, and 8 weeks of age.

SEE ALSO

- Acute Diarrhea.
- Campylobacteriosis.
- Canine Coronavirus Infections.
- Canine Parvovirus.
- Clostridial Enterotoxicosis.
- Coccidiosis.
- Diarrhea, Chronic—Dogs.
- Giardiasis.
- Hookworms (Ancylostomiasis).
- Roundworms (Ascariasis).
- Salmonellosis.
- Whipworms (Trichuriasis).

ABBREVIATIONS

- CPV-2 = canine parvovirus.
- GI = gastrointestinal.
- SIRS = systemic inflammatory response syndrome.

Authors Kasey E. Mabry and Tracy Hill
Consulting Editor Amie Koenig

CANINE INFECTIOUS RESPIRATORY DISEASE

BASICS

DEFINITION
A multifaceted disease whereby infectious disease and environment contribute to the genesis of cough and other respiratory signs in dogs.

PATHOPHYSIOLOGY
Initiated by injury to the respiratory epithelium by viral infection followed by invasion of damaged tissue by bacterial, mycoplasmal, or other virulent organisms, resulting in further damage and clinical signs.

SYSTEMS AFFECTED
Respiratory—upper and lower airways can be involved. Multisystemic—cases that develop sepsis.

GENETICS
None

INCIDENCE/PREVALENCE
Most common in areas of high density with immunologically naïve or immunosuppressed patients (i.e., training kennels, shelters, veterinary hospitals).

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dog

Breed Predilections
None

Mean Age and Range
• Most severe in puppies 6 weeks–6 months old. • Can develop in dogs of all ages, particularly with preexisting airway disease.

Predominant Sex
None

SIGNS

General Comments
• Related to the degree of respiratory tract damage and age of the affected dog and virulence of infectious organism. • Can be subclinical, mild, or severe with pneumonia. • Most viral, bacterial, and mycoplasmal agents spread rapidly from seemingly healthy dogs to others in the same environment; signs usually begin about 3–7 days after exposure to the infecting agent(s).

Historical Findings
• Uncomplicated—acute-onset cough in an otherwise healthy animal; dry and hacking, soft and dry, moist and hacking, or paroxysmal, followed by gagging, retching, and expectoration of mucus; excitement, exercise, and pressure on the trachea induce coughing spells. • Complicated (severe)—inappetence to anorexia; cough is moist and productive; lethargy, difficulty breathing, hemoptysis, and exercise intolerance can occur.

Physical Examination Findings
• Uncomplicated—cough readily induced with minimal tracheal pressure; lung sounds often normal; systemically healthy. • Complicated—low-grade or intermittent fever (39.4–40.0 °C; 103–104 °F); increased intensity of normal lung sounds, crackles or wheezes possible.

CAUSES
• Viral—canine distemper virus (CDV); canine adenovirus (CAV-2); canine parainfluenza (CPIV); canine respiratory coronavirus (CRCoV), canine reovirus; canine herpesvirus-1 (CHV-1); canine influenza virus (CIV; H3N8 or H3N2); canine bocavirus, canine hepacivirus; canine pneumovirus (CnPnV). • Most viral pathogens (except CHV and CDV) primarily infect epithelial and lymphoid tissue of the upper and lower respiratory tract; in severe cases, causing desquamation of the epithelium and aggregation of inflammatory cells in the lungs, leading to secondary bacterial colonization and infection; CRCoV infection leads to loss of cilia associated with the respiratory epithelium, increasing the severity and duration of secondary infections. • Bacterial—*Bordetella bronchiseptica*, with no other respiratory pathogens, produces clinical signs indistinguishable from those of other bacterial causes; *Streptococcus equi* subsp. *zooepidemicus* is associated with a particularly virulent course that can progress to death; *Pseudomonas*, *Escherichia coli*, *Klebsiella*, *Pasteurella*, *Streptococcus*, *Mycoplasma*, and other species equally likely.

RISK FACTORS
• Substandard hygienic conditions and overcrowding—encountered in some pet shops, shelters, research facilities, and boarding and training kennels. • Coexisting subclinical airway disease—congenital anomalies; chronic bronchitis; bronchiectasis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• In systemically well dogs—parasitic bronchitis, irritant tracheobronchitis, airway foreign body, airway collapse. • In a dog with systemic signs—fungal or bacterial (aspiration) pneumonia, primary or metastatic neoplasia, congestive heart failure, migrating foreign body. • Provisional diagnosis of infectious tracheobronchitis is made in a dog with compelling clinical signs and a history of exposure to the implicated organisms. • See Cough.

CBC/BIOCHEMISTRY/URINALYSIS
• Early, mild leukopenia (5,000–6,000 cells/dL)—can be detected; suggests viral cause. • Neutrophilic leukocytosis with a toxic left shift—frequently found with severe pneumonia.

OTHER LABORATORY TESTS
Pulse oximetry and arterial blood gas analysis—can reveal hypoxemia in pneumonia.

IMAGING
• Uncomplicated disease—radiographs: unremarkable; most useful for ruling out other differential diagnoses. • Complicated disease—radiographs: interstitial and alveolar lung pattern with a cranioventral distribution typical of bacterial pneumonia; can see diffuse interstitial lung pattern typical of viral pneumonia; mixed lung pattern can be present.

DIAGNOSTIC PROCEDURES
• In cases with severe disease—ideally perform bronchoalveolar lavage via bronchoscopy for cytology and microbial culture; tracheal wash sample acceptable, but increased likelihood for upper airway contamination. • Antimicrobial sensitivity pattern of cultured bacteria—identification aids markedly in providing an effective treatment plan. • PCR from bronchoalveolar lavage, nasal, ocular, or pharyngeal secretions can be used to detect virus, though there is difficulty in interpreting results as many healthy animals shed virus in the absence of clinical signs.

PATHOLOGIC FINDINGS
• CPIV—causes few to no clinical signs; lungs of infected dogs 6–10 days after exposure may contain petechial hemorrhages that are evenly distributed over the surfaces; detected by immunofluorescence in columnar epithelial cells of the bronchi and bronchioles 6–10 days after aerosol exposure. • CAV-2—lesions confined to the respiratory system; large intranuclear inclusion bodies found in bronchial epithelial cells and alveolar septal cells; clinical signs tend to be mild and short-lasting; lesions persist for at least a month after infection. • CIV (H3N8, H3N2)—fulminant disease characterized by secondary *Mycoplasma* or bacterial infection and pulmonary hemorrhage. • CRCoV—characterized by marked inflammation of the trachea and nares with cilia loss in the former; detected by immunohistochemistry of the trachea or bronchioles. • *Streptococcus equi* subsp. *zooepidemicus* infection—acute, fibrinosuppurative pneumonia with large numbers of cocci found within the pulmonary parenchyma and, often, septic thromboemboli. • Bordetellosis and severe bacterial infection—evidence of purulent bronchitis, tracheitis, and rhinitis with hyperemia and enlargement of the bronchial, mediastinal, and retropharyngeal lymph nodes; may see large numbers of Gram-positive or Gram-negative organisms in the mucus of the tracheal and bronchial epithelium.

CANINE INFECTIOUS RESPIRATORY DISEASE (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient—strongly recommended for uncomplicated disease. • Inpatient—strongly recommended for complicated disease and/or pneumonia.

NURSING CARE
Fluid administration—indicated for complicated disease and/or pneumonia.

ACTIVITY
Enforced rest—14–21 days with uncomplicated disease; for at least the duration of radiographic evidence of pneumonia in severely affected dogs.

DIET
Good-quality commercial food.

CLIENT EDUCATION
• Isolate patient from other animals; infected dogs can transmit the agent(s) before onset of clinical signs and afterward until immunity develops. • Dogs with uncomplicated disease should respond to treatment in 10–14 days. • Once infection spreads in a kennel, it can be controlled by evacuation for 1–2 weeks and disinfection with commonly used chemicals, such as sodium hypochlorite (1 : 30 dilution), chlorhexidine, and benzalkonium.

MEDICATIONS

DRUG(S) OF CHOICE
• Amoxicillin/clavulanic acid (12.5–25 mg/kg PO q12h) or doxycycline (5 mg/kg PO q12h or 10 mg/kg PO q24h)—initial treatment of uncomplicated disease. • Penicillin (ampicillin 10–20 mg/kg IV q6–8h or ticarcillin 40–50 mg/kg IV q6–8h) with aminoglycoside (gentamicin 2–4 mg/kg IV/IM/SC q6–8h or amikacin 6.5 mg/kg IV/IM/SC q8h) or fluoroquinolone (enrofloxacin 5–10 mg/kg PO/IM/IV q24h)—usually effective for severe disease. • Antimicrobial therapy—continue for at least 10 days beyond radiographic resolution. • *B. bronchiseptica* and other resistant species—some antimicrobials may not reach adequate therapeutic concentrations in the lumen of the lower respiratory tract, so oral or parenteral administration may have limited effectiveness; nebulization with gentamicin (3–5 mg/kg) can decrease bacterial numbers when administered daily for 3–5 days; use in conjunction with systemic antibiotics in dogs with parenchymal disease. • Butorphanol (0.55 mg/kg PO q8–12h) or hydrocodone bitartrate (0.22 mg/kg PO q6–8h)—effective suppression of dry, nonproductive cough not associated with bacterial infection. • Bronchodilators (e.g., terbutaline 0.625–5 mg/dog q8–12h)—may be used to control bronchospasm and wheeze.

CONTRAINDICATIONS
• Do not use cough suppressants in patients with pneumonia. • Employ glucocorticoids only in cases with significant inflammatory disease refractory to conventional supportive care.

PRECAUTIONS
None

POSSIBLE INTERACTIONS
Fluoroquinolones and theophylline derivatives—concurrent use causes high and possibly toxic plasma theophylline concentration. Dose reduce theophylline while concurrently administering fluoroquinolones.

ALTERNATIVE DRUG(S)
None

FOLLOW-UP

PATIENT MONITORING
• Uncomplicated disease—should resolve spontaneously or respond to treatment in 10–14 days; if patient continues to cough 14 days or more after establishment of an adequate treatment plan, question the diagnosis of uncomplicated disease. • Complicated disease—repeat thoracic radiography until at least 7 days beyond resolution of all clinical signs.

PREVENTION/AVOIDANCE
Shedding of the causative agent(s) of infectious respiratory disease in airway secretions of dogs undoubtedly accounts for the persistence of this problem in kennels, animal shelters, boarding facilities, and veterinary hospitals.

Viral and Bacterial Vaccines
• Modified live CDV and CAV-2 vaccines provide reliable protection and are considered core vaccines for all puppies; can be administered at 6 weeks of age, every 2–4 weeks. • *B. bronchiseptica* and CPIV vaccine—can vaccinate puppies mucosally or intranasally as early as 2–4 weeks of age without interference from maternal antibody and follow with annual revaccination; can vaccinate mature dogs with a one-dose intranasal vaccination (at the same time as their puppies or when they receive their annual vaccinations). • Inactivated *B. bronchiseptica* parenteral vaccine—administered as two doses, 2–4 weeks apart; initial vaccination of puppies is recommended at or about 6–8 weeks of age; revaccinate at 4 months of age. • Inactivated CIV vaccines (H3N2 and H3N8) available to reduce severity and duration of clinical signs but considered noncore; can be administered starting at 6 weeks as two doses, 2–4 weeks apart; results in seroconversion.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
• Natural course of uncomplicated disease, if untreated—10–14 days; simple restriction of exercise and prevention of excitement shortens the course. • Typical course of severe disease—2–6 weeks; patients that die often develop severe pneumonia that affects multiple lung lobes and multiple organ dysfunction due to sepsis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
May accompany other respiratory tract anomalies.

AGE-RELATED FACTORS
Most severe in puppies 6 weeks–6 months old and in puppies from commercial pet shops and humane society shelters.

ZOONOTIC POTENTIAL
Potential zoonotic risk of *Streptococcus equi* subsp. *zooepidemicus* and *B. bronchispetica* reported in single case reports.

PREGNANCY/FERTILITY/BREEDING
High risk in dogs on extensive medical treatment; especially risky for dogs in overcrowded breeding facilities.

SYNONYMS
• Kennel cough. • Infectious tracheobronchitis—uncomplicated disease.

ABBREVIATIONS
• CAV-2 = canine adenovírus. • CDV = canine distemper vírus. • CHV-1 = canine herpesvirus-1. • CIV = canine influenza virus. • CnPnV = canine pneumovirus. • CPIV = canine parainfluenza. • CRCoV = canine respiratory coronavirus.

CANINE PARVOVIRUS

BASICS

DEFINITION
- An acute systemic illness characterized by vomiting, hemorrhagic enteritis, and leukopenia.
- Myocardial form was observed in puppies in late 1970s, now rare.
- Most puppies protected against neonatal infection by maternal antibodies.
- Monoclonal antibodies have revealed antigenic changes in canine parvovirus (CPV)-2; CPV2a, b, and c strains have been identified.
- Original virus now virtually extinct in domestic dogs.
- CPV2c viruses are more virulent, and mortality rates higher.
- CPV-2 is closely related to feline panleukopenia virus (FPV).

PATHOPHYSIOLOGY
- Parvoviruses require actively dividing cells for growth.
- After ingestion of virus there is a 2–4-day period of viremia.
- Early lymphatic infection is accompanied by lymphopenia and precedes intestinal infection and clinical signs.
- By postinfection (PI) day 3, rapidly dividing crypt cells of small intestine are infected.
- Viral shedding in feces starts ~3–4 days PI, peaks with clinical signs.
- Virus ceases to be shed in detectable amounts by PI days 8–12.
- Absorption of bacterial endotoxins from damaged intestinal mucosa plays a role in CPV-2 disease.
- Intensity of illness related to viral dose and antigenic type.

SYSTEMS AFFECTED
- Cardiovascular—myocarditis (uncommon), hypovolemia.
- Gastrointestinal.
- Hemic/lymphatic/immune.

GENETICS
Unknown

INCIDENCE/PREVALENCE
Common in breeding kennels, animal shelters, pet stores.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dog

Breed Predilections
- Certain breeds are at increased risk, including Rottweiler, Doberman pinscher, American pit bull terrier, Labrador retriever, German shepherd dog, and Yorkshire terrier.
- Higher fatality rates are seen in hounds, gundogs, and nonsporting pedigree groups.

Mean Age and Range
- Illness occurs at any age.
- Most severe in dogs 6–24 weeks of age.

Predominant Sex
None

SIGNS

General Comments
Suspect CPV-2 infection whenever puppies have an enteric illness.

Historical Findings
- Sudden onset of bloody diarrhea, anorexia, and vomiting.
- Some dogs may collapse in a shock-like state and die without enteric signs.
- In breeding kennels, several littermates may become ill simultaneously or within a short period.
- Occasionally, one or two puppies in a litter have minimal signs, followed by death of littermates, which may reflect degree of virus exposure.

Physical Examination Findings
- Hypovolemic shock—weak pulse, tachycardia, dull mentation.
- Severe hemorrhagic diarrhea.
- Fluid-filled intestinal loops may be palpated.
- Dehydration, weight loss, abdominal discomfort.
- May have fever or hypothermia.

CAUSES
CPV-2.

RISK FACTORS
- Unvaccinated dogs.
- Dogs <4 months of age.
- Co-pathogens such as parasites, viruses, and certain bacterial species (e.g., *Campylobacter* spp., *Clostridium* spp.) may exacerbate illness.
- Severe, often fatal parvoviral infections have been demonstrated in puppies exposed simultaneously to CPV-2 and canine coronavirus.
- Crowding and poor sanitation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Canine coronavirus infection.
- Salmonellosis; colibacillosis; other enteric bacterial infections.
- Gastrointestinal foreign bodies.
- Gastrointestinal parasites.
- Acute hemorrhagic diarrhea syndrome (previously hemorrhagic gastroenteritis).
- Intussusception (may be concurrent).
- Toxin ingestion.

CBC/BIOCHEMISTRY/URINALYSIS
- Lymphopenia—characteristic; commonly occurs PI days 4–6.
- Severely affected dogs exhibit severe neutropenia with onset of intestinal damage.
- Leukocytosis during recovery.
- Serum chemistry profiles help assess electrolyte disturbances (especially hypokalemia), presence of azotemia, panhypoproteinemia, hypoglycemia.

OTHER LABORATORY TESTS
- Virus antigen detection in stool at onset of disease and for 2–4 days afterward; many commercial point-of-care ELISA assays available, also PCR and quantitative PCR methodologies.
- Serologic tests are not diagnostic because dogs often have high titers from vaccination and/or maternal antibodies.

IMAGING
- Abdominal radiographs—generalized small intestinal ileus; exercise caution to prevent misdiagnosis of intestinal obstruction, but intussusception may cause obstructive pattern.
- Abdominal ultrasound—fluid-filled, atonic small and large intestines, duodenal and jejunal mucosal layer thinning with or without indistinct wall layers and irregular luminal-mucosal surfaces, extensive duodenal and/or jejunal hyperechoic mucosal speckling, and duodenal and/or jejunal corrugations; intussusceptions can be identified.

DIAGNOSTIC PROCEDURES
- Electron microscopy detects fecal virus during early stages of infection.
- Samples for virus detection should be submitted during acute phase of infection; ship specimens refrigerated, not frozen.

PATHOLOGIC FINDINGS
- Gross changes include subserosal congestion and hemorrhage or frank hemorrhage into small intestinal lumen, or intestines that are empty or contain yellow or blood-tinged fluid.
- Mesenteric lymph nodes often enlarged and edematous, with hemorrhages in cortex.
- Thymic atrophy in young dogs.
- Pulmonary edema and hydropericardium may be only gross change in dogs with myocarditis and heart failure.
- Histopathology reveals intestinal inflammation and necrosis, with severe villus atrophy.

TREATMENT

APPROPRIATE HEALTH CARE
- Symptomatic and supportive (see Acute Vomiting; Acute Diarrhea; Gastroenteritis, Acute Hemorrhagic Diarrhea Syndrome), including IV fluids, antibiotics, antiemetics, and analgesics.
- Intensity depends on severity of signs; both in- and outpatient treatment protocols exist.

CANINE PARVOVIRUS (CONTINUED)

• Goals are to provide intestinal nutrients, restore and maintain fluid and electrolyte balance, and resolve shock, sepsis, and endotoxemia.
• Fecal microbiota transplant may speed resolution of diarrhea.
• Prompt, intensive inpatient care leads to treatment success.
• Proper, strict isolation procedures are essential.
• Exercise care to prevent spread of CPV-2, a very stable virus.
• Antiviral drugs have not yet been shown to be a critical part of treatment.

NURSING CARE
• Hospitalize patients and monitor for dehydration and electrolyte imbalance.
• Fluids are usually supplemented with potassium chloride, 5% dextrose, and possibly sodium bicarbonate (if severe metabolic acidosis due to bicarbonate loss).

ACTIVITY
Restrict until symptoms abate.

DIET
Puppies receiving early enteral nutrition via a nasoesophageal tube (compared to puppies that received nothing enterally until cessation of vomiting) showed earlier clinical improvement, significant weight gain, and improved gut barrier function, which could limit bacterial or endotoxin translocation.

CLIENT EDUCATION
• Inform about need for thorough disinfection, especially if other dogs are on premises; strict sanitation is essential; a 1 : 30 dilution of bleach (5% sodium hypochlorite) destroys CPV-2 in a few minutes.
• If possible, isolate puppies until they reach 3 months of age and vaccinate repeatedly; typical protocols involve vaccination at 6, 9, and 12 weeks of age.
• Puppies can be infected with virulent virus before any vaccine will confer immunity.
• CPV-2 is shed for less than 2 weeks after infection; no carrier state has been substantiated.

SURGICAL CONSIDERATIONS
• Exercise caution to prevent misdiagnosis of intestinal obstruction, especially if vomiting is only clinical sign.
• Intussusceptions can occur.

MEDICATIONS
See Acute Vomiting; Acute Diarrhea; Gastroenteritis, Acute Hemorrhagic Diarrhea Syndrome.

DRUG(S) OF CHOICE
Additional recommended drugs include parenteral antibiotics (ampicillin and gentamicin) and antiemetics (e.g., ondansetron, maropitant).

PRECAUTIONS
Gentamicin may cause renal toxicity in dehydrated puppies.

FOLLOW-UP
PATIENT MONITORING
There is an increased incidence of discospondylitis in puppies that had parvovirus infection.

PREVENTION/AVOIDANCE
• Inactivated and live vaccines are available for prophylaxis, and vaccines differ in their capacity to immunize puppies with maternal antibodies.
• Vaccination with a modified live vaccine at 4 weeks of age in puppies with high maternally derived antibody concentrations resulted in seroconversion rates of up to 80%; this may lead to a decreased window of susceptibility to CPV infection and might be an adjunct control method in contaminated environments.
• Control of CPV-2 requires efficacious vaccines, isolation of puppies, and stringent hygiene.

POSSIBLE COMPLICATIONS
• Septicemia/endotoxemia.
• Bacterial pneumonia.
• Intussusception.
• Discospondylitis.

EXPECTED COURSE AND PROGNOSIS
• Prognosis is guarded in severely affected puppies.
• Prognosis is good for dogs that receive prompt initial treatment and survive initial crisis—approximately 80% survival rate.
• Poor prognosis if a patient is purebred, has a low bodyweight, and if the following biomarker levels are present after 24 hours of intensive therapy: severe persistent leuko- and lymphopenia, persistently elevated or rising serum cortisol concentration (>8.1 µg/dL), severe hypothyroxinemia (<0.2 µg/dL), hypocholesterolemia (<100 mg/dL), and persistently elevated serum C-reactive protein (>97.3 mg/L).
• Conversely, puppies with a good prognosis are of mixed breed, >6 months old, and show the following biomarker values: total leukocyte count >4.5 × 10^3/µL, lymphocyte count >1 × 10^3/µL, and mature neutrophil count >3 × 10^3/µL. Additionally, a serum cortisol concentration <8.1 µg/dL at 48 hours after admission is associated with 96% survival, and a serum thyroxine concentration >0.2 µg/dL at 24 hours after admission is associated with 100% survival. An HDL-cholesterol concentration >50.2 mg/dL at admission is associated with 100% survival.

MISCELLANEOUS
ASSOCIATED CONDITIONS
Coinfection with intestinal helminths and *Giardia* are indicative of unhygienic housing conditions and can worsen clinical signs and contribute to morbidity.

AGE-RELATED FACTORS
Infection less likely in dogs >1 year of age, but can still occur, especially if unvaccinated.

ZOONOTIC POTENTIAL
Parvovirus per se is not zoonotic, but these puppies may harbor coinfections with *Giardia,* which can be zoonotic.

PREGNANCY/FERTILITY/BREEDING
Pregnant animals are likely to abort.

SEE ALSO
• Acute Diarrhea.
• Acute Vomiting.
• Canine Coronavirus Infections.
• Gastroenteritis, Acute Hemorrhagic Diarrhea Syndrome.
• Sepsis and Bacteremia.
• Shock, Septic.

ABBREVIATIONS
• CPV = canine parvovirus.
• FPV = feline panleukopenia virus.
• PI = postinfection.

CANINE SCHISTOSOMIASIS (HETEROBILHARZIASIS)

BASICS

OVERVIEW

• *Heterobilharzia americanum* is a trematode of the genus Schistosoma that has fresh water lymnaeid snails as intermediate hosts and raccoons as the natural definitive host.
• Eggs passed in the feces of raccoons hatch to release miracidia that penetrate freshwater snail hosts. After a period of development and asexual multiplication, the snails release cercariae that infect the next host by skin penetration. After penetrating skin, larvae undergo a migration to the lung and then make their way to mesenteric veins, where separate males and females form pairs. Eggs laid by female worms are carried to the intestinal wall, where they erode their way through to the lumen to be passed in the feces. Other eggs are carried to the liver or other organs by the bloodstream, where they lodge and cause granulomatous disease.
• Dogs become infected in contact with freshwater containing cercariae.
• Endemic in raccoons in southeastern United States; canine cases reported from Arkansas, Indiana, Florida, Georgia, Kansas, Louisiana, North Carolina, Oklahoma, and Texas.

SIGNALMENT

Dogs, typically adult, that have access to swampy areas or bayous.

SIGNS

• Lethargy (most common sign), weight loss, and decreased appetite.
• Other signs include vomiting, diarrhea, anorexia, polyuria/polydipsia; more rarely melena, borborygmus, ascites.

CAUSES & RISK FACTORS

Swimming in freshwater in areas contaminated with cercariae from miracidia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Coccidiosis.
• Bacterial diarrhea.
• Viral enteritis.
• Hepatopathies.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—anemia, lymphopenia, eosinopenia or eosinophilia, thrombocytopenia.
• Biochemistry—elevated liver enzyme activities, azotemia, hypercalcemia, hypernatremia, hyperglobulinemia, hypoalbuminemia.
• Urinalysis—proteinuria.

OTHER LABORATORY TESTS

• Elevated parathyroid hormone-related protein (PTH-rp) reported in dogs with hypercalcemia.
• PCR on feces (Texas A&M Gastrointestinal Laboratory).

IMAGING

Contrast radiographs and ultrasound may reveal thickened bowel walls; calcified eggs disseminated into tissues may give the false impression of soft tissue mineralization.

DIAGNOSTIC PROCEDURES

• Eggs with miracidia can be identified in feces, but feces must be kept in saline (not water) or miracidia will spontaneously hatch, making diagnosis impossible.
• Fecal direct or sedimentation methods are preferred to fecal flotation; routine fecal flotation will not detect these heavy eggs; if used, requires flotation with sugar solution with specific gravity of 1.3.
• Histopathology—trematode eggs in multiple organs (especially liver, intestine, pancreas, lymph nodes); lymphoplasmacytic, histiocytic, and eosinophilic to granulomatous enteritis, hepatitis with possible peri-portal fibrosis, dystrophic mineralization of multiple tissues.

TREATMENT

Inpatient care for the first few days of treatment may be warranted, as the response to worm kill may require supportive care.

MEDICATIONS

DRUG(S) OF CHOICE

• Praziquantel—25 mg/kg PO q8h for 2–3 days.
• Fenbendazole—50 mg/kg PO q24h for 10 days; clinical improvement without parasite elimination has been reported with fenbendazole.

FOLLOW-UP

• Check feces after treatment to ensure that it does not contain eggs.
• Reinfection from environment is possible.

MISCELLANEOUS

In Japan and other countries with endemic *Schistosoma japonicum*, dogs can be infected with this human and zoonotic species.

ZOONOTIC POTENTIAL

Stages in the dog pose no threat to people; with shared waterway exposure, cercariae can cause skin lesions in people.

SYNONYMS

• Schistosomiasis.
• Swimmer's itch (human, skin penetration of cercariae).

ABBREVIATIONS

• PTH-rp = parathyroid hormone-related protein.

CAR RIDE ANXIETY—DOGS AND CATS

BASICS

DEFINITION
Excessive or disruptive distress, fear, or panic associated with vehicle travel. Anxiety exhibited during travel can be mistaken for excitement.

PATHOPHYSIOLOGY
Unknown or not definitively determined. Lack of car ride experience, generalized anxiety disorder, nausea, previous negative experience with car rides; fear, anxiety, or arousal related to visual or auditory stimuli.

SYSTEMS AFFECTED
- Behavioral.
- Gastrointestinal.
- Neuromuscular.

GENETICS
May be genetic component, but experiential learning may be more significant.

INCIDENCE/PREVALENCE
Reported in over 50% of cats and over 20% of dogs.

SIGNALMENT
Dog and cat.

Breed Predilections
None

Mean Age and Range
Any. Young or ill animals may be predisposed to motion sickness.

Predominant Sex
None

SIGNS

Historical Findings
- May include pacing, restlessness, inappetence, vigilance, excitability, and vocalization including whining or high-pitched barking in dogs and growling, hissing, meowing, or yowling in cats.
- Locomotion varies between individuals—some may pace while others remain immobile; fear that manifests as freezing or hiding may be underrecognized and underreported.
- Pet-related panic, vocalization, and pacing may impair owner's ability to drive safely.
- Travel-related anxiety may prevent owners from taking pets to destinations (e.g., veterinary visits, grooming, social events, training).

Physiologic and Physical Signs
May include panting, rapid heart rate, drooling, urination, vomiting, defecation.

Physical Examination
Normal unless underlying medical problems.

CAUSES & RISK FACTORS
- Behavioral causes include unruliness, inadequate or poor prior experience traveling; insufficient adaptation to carriers, leashes, or restraint devices; fear and reactivity to visual stimuli such as people, animals, bikes, or cars; and generalized anxiety.
- Prior stressful or uncomfortable experiences following car rides such as veterinary visits, boarding, or shelter relinquishment.
- Traumatic events such as sudden stops or car accidents.
- Medical conditions may exacerbate or manifest as anxiety—motion sickness, musculoskeletal pain or discomfort, dental disease or pain, gastrointestinal upset, sensory hypersensitivity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Fear and anxiety-related behavior.
- Manifestation of pain, nausea, or physical discomfort.
- Acute onset or abrupt change in car ride anxiety warrants ruling out contributory medical conditions.

CBC/BIOCHEMISTRY/URINALYSIS
If indicated by clinical signs and prior to drug therapy.

OTHER LABORATORY TESTS
If indicated by clinical signs.

IMAGING
If indicated by clinical signs.

TREATMENT

ACTIVITY
Normal. Recommend adequate exercise and play before car ride.

DIET
- Normal.
- Providing highly palatable food during car travel may distract, reduce stress, and promote a positive association with car travel.
- If the pet has experienced nausea or vomiting in association with car travel, fasting is recommended.

CLIENT EDUCATION
A complete behavior program includes empathy, environmental management, and behavior modification together with supplements or medication where indicated.

Compassion
- Give thoughtful preparation and consideration for the pet's perspective before traveling; allow time for travel and be patient.
- Anticipate and avoid evoking the pet's fears to prevent exacerbating established fears; for example, when carrying a pet in a carrier, consider their viewpoint and the unsettling motion that may be experienced.
- Avoid reprimands or scolding.
- Avoid forcing pets that are unfamiliar or do not get along to be in close proximity.

Management and Safety
- Provide stable footing and secure resting locations.
- Consider crating if pet acclimated to crate confinement; pet seat belts, barriers, and seat slings can also be beneficial.
- A nondriver should accompany highly distressed pets.

Anxiety Reduction
- Multimodal comforting and anxiolytic support provides the best outcome.
- Window shades, covered crates, solid wall carriers, or products for dogs such as Doggles® or Thundercap® may alleviate anxiety related to visual stimuli.
- Classical music or psychoacoustically designed music for dogs or cats may help to calm; music or white noise may mute perception of fear-evoking sounds.
- Comforting pressure wraps may alleviate anxiety.
- Synthetic pheromone analogues (Adaptil®, Feliway®) sprayed into carriers, onto bedding, or on a bandana (for dogs) may reduce anxiety.
- Anxiety-reducing supplements or medications should be considered.

Behavior Modification
- Rehearse settle and relax positions when not traveling.
- Teach the dog to get in and out of the car by positive reinforcement (e.g., food or toy reward).
- Teach cats and small dogs to go in and out of carriers willingly; they should be acclimated to the motion of being in a carrier that is being carried.
- Practice training when travel is not imminent; use positive reinforcement training and avoid reprimand or intimidation training; animals should never receive corrections from shock, prong, or choke collars.
- During travel, provide comforting activities such as toys, food chews, or feeding puzzles that may distract the pet, reduce anxiety, or counter-condition the pet to car rides.

MEDICATIONS

DRUG(S) OF CHOICE

General Comments
- Psychotropic medication, supplements, or pheromones may be beneficial or necessary

(CONTINUED)

CAR RIDE ANXIETY—DOGS AND CATS

Table 1

Benzodiazepine doses

	Canine	*Feline*
Alprazolam	0.02–0.1 mg/kg PO q6–12h	0.025–0.1 mg/kg PO q8–24h
Clonazepam	0.1–1.0 mg/kg PO q8–12h	0.02–0.2 mg/kg PO q12–24h
Diazepam	0.5–2 mg/kg PO PRN (e.g., q6h)	
Lorazepam	0.025–0.2 mg/kg PO q24h to PRN	0.025–0.05 mg/kg PO 12–24h
Oxazepam	0.2–1 mg/kg PO q12–24h	0.2–0.5 mg/kg PO 12–24h

as an adjunct to the behavior program; short-acting anxiolytics are appropriate for pets traveling occasionally; administer anxiolytics so that optimal effect precedes onset of anxiety; the effect of anxiolytics may be overcome by severe anxiety or distress; high or repeated doses, extreme anxiety, and other medical conditions increase the risk for profound sedation and drug reactions.
- Drugs should be trial dosed in advance to determine effects, side effects, optimal dose, and duration.
- Address concurrent behavioral conditions (e.g., separation anxiety, fears, phobias, anxiety, reactivity) that may warrant ongoing anxiolytics (e.g., tricyclic antidepressants [TCAs] or selective serotonin reuptake inhibitors [SSRIs]) in conjunction with the treatment of travel-related anxiety.

Benzodiazepines
- Anxiolytic; see Table 1 for drug options and dosing information.
- Give 30–60 minutes prior to travel.
- Side effects—incoordination, hyperphagia, paradoxical excitability, muscle relaxation, possible amnesic effect that might interfere with learning.
- Hyperphagia may be advantageous for pets with stress anorexia.
- Oxazepam and lorazepam have no active intermediate metabolites and may be safer if hepatic function compromised; injectable midazolam may be useful if administered in the veterinary hospital before home travel.

Maropitant
- May be indicated for nausea related to travel and prior to opioid sedation.
- Dog—1–2 mg/kg PO 2h before travel; for motion sickness 8 mg/kg given with a small amount of food 1–2h before travel.
- Cat—1 mg/kg SC daily.

Trazodone
- Dog—2–5 mg/kg; titrate up to 5–10 mg/kg based on effect; higher doses may be utilized by experienced clinicians; may be started twice daily 12–48h in advance.
- Cat—25–50 mg/cat for car travel.
- Side effects—sedation, lethargy, incoordination, cardiac conduction disturbances, agitation.

Gabapentin
- Cat—20 mg/kg (50–150 mg/cat) 2–3h before travel.
- Dog—10–30 mg/kg PRN to BID; may be started twice daily 12–48h in advance.
- Side effects—sedation, ataxia.

Clonidine
- Dog—0.01–0.05 mg/kg PO; begin at low dose and titrate to most effective dose; maximum effect may take up to 2h with faster absorption on an empty stomach; may be started twice daily 12–48h in advance.
- Side effects—transient hyperglycemia, anticholinergic, hypotension, collapse, bradycardia, agitation; use with caution in cardiac disease or compromised renal or liver function.

Dexmedetomidine Oromucosal Gel
- Dogs—125 µg/m^2 onto oral mucosa 30–60 min prior to travel; can be repeated in 2h.
- Licensed for use in dogs with noise aversion.
- Side effects—sedation, paradoxical excitement, pale mucous membranes, emesis.

Acepromazine
- Dog and cat—0.5–2.2 mg/kg PO.
- Not for sole use; may be combined with anxiolytic medication for added sedation.
- Side effects—ataxia, inhibits thermoregulation, peripheral vasodilation, muscle tremor or spasm, altered noise reactivity.

Pheromone
F3 cheek gland pheromone or dog-appeasing pheromone given 30–60 min before travel.

Natural Supplements
- For mild to moderate anxiety or adjunctive therapy—alpha-casosopene alone or in a diet in combination with l-tryptophan; l-theanine alone or in combination products containing whey protein, *Phellodendron amurense*, and *Magnolia officinalis*; melatonin; *Souroubea* and *Plantanus*; or a calming probiotic supplement.
- Lavender essential oils may have a calming effect in dogs, but avoid in cats since floral scents may be aversive.

CONTRAINDICATIONS
Avoid use or use with caution in combination with any drug that enhances serotonin transmission (e.g., trazodone, SSRIs, TCAs) and that may pose an increased risk for serotonin syndrome.

PRECAUTIONS
All listed medications are extra-label or off-label (except maropitant). Use with informed consent.

FOLLOW-UP

PATIENT MONITORING
Ask about travel-related distress as part of wellness assessment, and recommend early intervention and prevention. Travel-related difficulties pose a barrier for bringing pets to the veterinary hospital.

PREVENTION/AVOIDANCE
- Provide preventive guidance on making travel positive and carrier training at first puppy or kitten visit.
- Avoid travel for severely affected pets.
- Use appropriate medication when travel required.

EXPECTED COURSE AND PROGNOSIS
Likely to worsen if untreated.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Generalized anxiety disorder, noise-related fears and phobias, separation anxiety; hyperattachment.
- Dental disease or pain.

AGE-RELATED FACTORS
Cognitive decline may exacerbate anxiety.

CAR RIDE ANXIETY—DOGS AND CATS (CONTINUED)

ZOONOTIC POTENTIAL

A distressed pet may cause distraction and put drivers at risk for accidents.

PREGNANCY/FERTILITY/BREEDING

Drug use in breeding, pregnant, or lactating animals should be avoided.

CARBON MONOXIDE TOXICOSIS

BASICS

OVERVIEW
- Carbon monoxide (CO)—odorless, colorless, nonirritating gas produced by inefficient combustion of carbon fuels.
- Common sources are fires, automotive exhaust, leaking coal, oil, or natural gas/propane furnaces, gas appliances or fireplaces, and some paint strippers and sprays.
- CO is absorbed into the blood, forming carboxyhemoglobin (COHb).
- Affinity of CO for hemoglobin is approximately 240 times that of oxygen.
- COHb cannot bind oxygen and impairs oxyhemoglobin from releasing oxygen to the tissues.
- Major effect is acute cellular hypoxia, leading to death.
- Survivors may have cardiac damage, acute and delayed neurotoxicity.
- Lethal concentration is approximately 1,000 ppm (0.1%) for 1 hour.

SIGNALMENT
Dogs and cats equally affected.

SIGNS
Acute Exposure
- Acute signs progress within minutes to hours.
- Neurologic signs—lethargy or agitation, weakness, ataxia, depressed mentation, deafness, coma, seizures.
- Respiratory—tachypnea and dyspnea.
- Cardiovascular—tachycardia, dysrhythmias, hypotension.
- Hyperemic skin and mucous membranes are rarely apparent in animals.

Chronic Exposure
- Nausea, vomiting, decreased activity, and cough; may mimic other diseases.
- Disturbance of postural and position reflexes and gait.

CAUSES & RISK FACTORS
- Housed in areas with blocked exhaust vents, furnaces, appliances, or chimneys; exposure to automobile exhaust or kerosene heaters in closed spaces with poor ventilation.
- Trapped in house or kennel fires.
- Animals with impaired cardiac or pulmonary function.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Sedatives, ethanol, ethylene glycol, petroleum hydrocarbons, lead poisoning; cyanide or hydrogen sulfide gas toxicosis.
- Smoke inhalation, primary neurologic disease, and severe metabolic disease.

CBC/BIOCHEMISTRY/URINALYSIS
Biochemistry—may see liver and kidney value elevations secondary to hypoxia.

OTHER LABORATORY TESTS
- Carboxyhemoglobin can be measured via co-oximetry; may return to normal within hours after removal from CO source. Available at human hospital or veterinary specialty/diagnostic lab.
- Blood gas—metabolic acidosis due to lactic acidosis; arterial blood gas may have normal partial pressure of oxygen (PaO_2).

IMAGING
Thoracic radiographs—evaluate for pulmonary injury and rule out other causes of respiratory signs.

DIAGNOSTIC PROCEDURES
- Pulse oximetry may overestimate hemoglobin saturation (SpO_2); COHb and oxyhemoglobin absorb light at the same wavelength.
- ECG—sinus tachycardia or cardiac dysrhythmia, ST-T depression with myocardial hypoxia/anoxia.
- Blood pressure—hypotension common in shock.

TREATMENT
- Supplemental oxygen (flow-by, mask, nasal, oxygen cage, or intubation ± mechanical ventilation)—improves oxygen delivery to vital organs, especially brain and heart; decreases half-life of COHb.
- Hyperbaric oxygen therapy use is controversial and not readily available in veterinary medicine, but will further reduce half-life of COHb.
- IV fluid therapy for hydration and perfusion and to correct metabolic acidosis.

MEDICATIONS

DRUG(S) OF CHOICE
- Sedatives and anxiolytics may be needed to allow oxygen supplementation—diazepam 0.1–0.5 mg/kg IV q6–8h.
- Short-acting opioids such as fentanyl (2–5 µg/kg IV followed by CRI 2–5 µg/kg/h) can be used for pain and sedation.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Limit 100% oxygen to <24 hours to avoid oxygen toxicosis.

FOLLOW-UP
- Patient monitoring—neurologic status, BP and ECG during hospitalization; frequency depends on stability of patient.
- Possible complications—delayed neurologic signs within days to weeks of initial improvement; deafness may occur/persist in survivors.
- Expected course and prognosis—respond and improve rapidly to oxygen therapy (within 30–60 minutes); prognosis guarded to poor with persistent or worsening respiratory and neurologic signs.
- Prevention—use adequate ventilation with use of kerosene heaters in kennels and use CO detectors.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Animals in house fires may have dermal burns, thermal and smoke inhalation injury to the airways, corneal ulcerations, or other injuries.

ZOONOTIC POTENTIAL
People and other pets in the same CO-contaminated environment are at risk.

PREGNANCY/FERTILITY/BREEDING
CO reduces oxygen-carrying ability of maternal blood, producing fetal hypoxia, abortion, or neurologic impairment of the fetus, often with minimal effects on the dam.

ABBREVIATIONS
- COHb = carboxyhemoglobin.
- PaO_2 = partial pressure of oxygen.
- SpO_2 = oxygen saturation.

CARCINOID AND CARCINOID SYNDROME

BASICS

OVERVIEW

• Carcinoid tumors are neuroendocrine tumors arising from amine precursor uptake and decarboxylation (APUD) cells.
• Carcinoids originate from enterochromaffin and enterochromaffin-like cells of the gastrointestinal tract, but can be found in the liver, gall bladder, pancreas, tracheobronchial tree and genitourinary system due to embryologic origins.
• Carcinoids may secrete amines such as histamine, serotonin, prostaglandin, and peptides such as bradykinins and tachykinins.
• In humans, secretion causes "carcinoid syndrome." This occurs in approximately 5–10% of patients with metastatic carcinoid tumors. Hepatic degradation of excess amines, notably seratonin, is bypassed, causing clinical signs. Human carcinoid syndrome is characterized by flushing, abdominal pain, diarrhea, bronchospasm, and cyanosis. This syndrome has not been reported in small animals, although a recent report describes a dog with episodic collapse and melena and an ileocecal carcinoid.
• Morbidity and mortality are more often a function of tumor size and gastrointestinal blockage.
• Primary carcinoid tumors in dogs have been reported in the stomach, small intestine, colon, lung, gallbladder, and liver. In cats, carcinoids have been found in the stomach, small intestine, liver, and heart.

SIGNALMENT

• Dog—rare, generally >8–9 years of age.
• Cat—rare, generally >7–8 years of age.

SIGNS

Clinical signs depend on the location of the primary tumor or metastases and may include anorexia, vomiting, dyschezia, melena, collapse, ascites, weight loss, and signs of hepatic failure or gall bladder obstruction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentials include primary gastrointestinal diseases—neoplasia, infection, inflammation, parasites, foreign body, dietary indiscretion, or hepatic/biliary disease.

CBC/BIOCHEMISTRY/URINALYSIS

• Normal, possible mild nonregenerative anemia.
• Electrolyte abnormalities, elevated liver enzyme activities, and hyperbilirubinemia can be present.

OTHER LABORATORY TESTS

• Serum serotonin, serum chromogranin A, and urinary 5-hydroxyindoleacetic acid are measured in humans suspected of carcinoid tumors; these tests are more diagnostic than direct measurement of serum amine and peptides.
• Serum serotonin levels were found to be increased tenfold in a dog with an intestinal carcinoid; other testing has not been documented in animals with carcinoid tumors.

IMAGING

• Radiography and ultrasound can identify primary tumors and metastases.
• CT scan and MRI may also be useful.
• In humans, more sensitive molecular imaging includes radiolabeled somatostatin receptor scintigraphy (OctreoScan); radioiodinated metaiodobenzylguanidine (MIBG) imaging; and PET scans.

DIAGNOSTIC PROCEDURES

• Biopsy often confirms diagnosis.
• If histopathologic results are equivocal, electron microscopy and/or immunohistochemistry (looking for chromogranin A and/or synaptophysin expression) may be used to confirm a carcinoid tumor.

PATHOLOGIC FINDINGS

Tumors have a fine fibrovascular stroma with minimal to moderate cellular pleomorphism. Cytoplasm is eosinophilic and usually contains secretory granules that stain argyrophilic and/or argentaffin-positive (silver stains).

TREATMENT

In some cases, surgical excision can be curative, especially if no metastasis. Debulking can decrease hormone secretion in humans, and it may relieve tumor-related gastrointestinal obstruction.

MEDICATIONS

DRUG(S) OF CHOICE

• Octreotide, a somatostatin analogue that inhibits hormone secretion from the tumor cells, is used in humans for palliative therapy; as carcinoid syndrome has not been reliably reported in animals with carcinoid tumors, octreotide may be of little benefit.
• High-dose radioiodinated MIBG is used in humans with nonresectable or metastatic carcinoid.
• Interferons have demonstrated limited success in humans with carcinoid tumors.
• Chemotherapy and radiotherapy have minimal efficacy in humans with carcinoid tumors.
• Adjuvant carboplatin therapy has been reported in a dog with a completely excised nonmetastatic jejunal carcinoid.

FOLLOW-UP

Abdominal ultrasound and thoracic radiographs should be performed regularly to identify metastasis.

EXPECTED COURSE AND PROGNOSIS

• Limited survival data exists (few reported cases).
• Survival of 18 months seen in dog with intestinal carcinoid treated with surgery and carboplatin.
• Survival of 12 months reported in cats with extrahepatic carcinoids.

MISCELLANEOUS

ABBREVIATIONS

• APUD = amine precursor uptake and decarboxylation.
• MIBG = metaiodobenzylguanidine.

CARDIAC GLYCOSIDE PLANT TOXICOSIS

BASICS

OVERVIEW
- Same toxic profile as digoxin, in particular cardiovascular (CV) and gastrointestinal (GI) signs.
- All plant parts, fresh or dry, are considered toxic, but the concentration varies depending on specific plant and plant part.
- Plants are best identified by scientific name.
- Common plants include *Adenium obesum* (desert rose); *Apocynum cannabinum* (dogbane); *Asclepias* spp. (milkweed); *Calatropis* spp. (giant milkweed); *Convallaria majalis* (lily of the valley); *Digitalis lanata* (wooly foxglove); *Digitalis purpurea* (common or purple foxglove); *Kalanchoe* spp. (mother of millions); *Nerium oleander* (oleander); *Ornithogalum umbellatum* (star of Bethlehem); *Thevetia peruviana* (yellow oleander).

SIGNALMENT
- Cats are more sensitive to some of the plant toxins than dogs.
- Dogs with the ABCB1-1Δ gene mutation *may* be more sensitive to toxins.

SIGNS
- CV—bradycardia (rarely tachycardia), atrioventricular (AV) block, all forms of arrhythmias, death from asystole.
- GI (most frequent)—hypersalivation, vomiting ± blood, diarrhea ± blood.
- Neuromuscular—coma, tremors, seizures (rarely); may be related to decreased cardiac output.

CAUSES & RISK FACTORS
- Cardiac glycoside–containing plants inhibit the ATPase sodium/potassium pump, resulting in an increase in intracellular sodium and a decrease in intracellular potassium; increased intracellular (myocyte) calcium results in increased cardiac contractions.
- Animals with a prior history of cardiac or renal disease and receiving digoxin or other cardiac glycoside drugs are at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Beta blocker or calcium channel blocker toxicosis.
- Cardiac disease in general.
- Digoxin/digitoxin toxicosis.
- Ingestion of medications with known cardiac effects.
- Ingestion of other plants with known cardiac effects such as *Taxus* spp. (yew), *Rhododendron* spp. (azalea, rhododendron), *Kalmia* spp. (mountain laurel, lambkill), and *Pieris japonica* (Japanese pieris).

CBC/BIOCHEMISTRY/URINALYSIS
Serum chemistry—hyperkalemia early and severe, may switch to hypokalemia.

OTHER LABORATORY TESTS
Serum digoxin levels may be useful in some ingestions.

DIAGNOSTIC PROCEDURES
- Presence of plant pieces in vomit or stool.
- ECG monitoring for cardiac arrhythmias.

PATHOLOGIC FINDINGS
Sudden death is common. Plant pieces are often found in the stomach and small intestine. Clotted blood may be present in the ventricles with a mottled appearance to the epicardium. Histopathology findings are similar to digoxin toxicosis.

TREATMENT
- Emesis *quickly after ingestion*.
- Activated charcoal (1–2 g/kg) with a cathartic × 1, followed by activated charcoal without a cathartic every 6–8 hours × 2 doses.
- Asymptomatic animals—hospitalize and monitor for 12 hours.
- Symptomatic animals—hospitalize and monitor with an ECG for 24 hours; administer appropriate IV fluids (dependent on serum potassium) to maintain blood pressure but not overload the CV system; monitor blood pressure closely, as hypotension may be persistent.

MEDICATIONS

DRUG(S) OF CHOICE
- Digoxin-specific fragment antigen binding (Fab; Digibind®) may be useful in some cases, especially oleander toxicosis.
- Antiemetics if vomiting is severe or persistent—maropitant 1 mg/kg SC/IV/PO q24h in dogs and cats; ondansetron 0.5–1 mg/kg IV, SC, PO q8–12h in dogs and cats.
- Bradycardia—atropine 0.02–0.04 mg/kg IV/IM/SC in dogs and cats; repeat q4–6h as needed.
- Antiarrhythmics may be necessary in patients with ventricular dysrhythmias, evidence of poor perfusion, or who remain tachycardic despite IV fluid therapy—lidocaine: dogs, 2–4 mg/kg IV to effect.
- GI protectants as needed—H2 blockers such as famotidine (0.5–1 mg/kg PO/SC/IM/IV q12h); omeprazole (0.5 mg/kg PO daily); or sucralfate (0.25–1 g PO q8h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Beta blockers and calcium channel blockers may have an additive effect on AV conduction and cause complete heart block.

FOLLOW-UP

PATIENT MONITORING
- ECG and blood pressure monitoring for first 24 hours, then PRN.
- Strict attention to serum electrolytes.

PREVENTION/AVOIDANCE
- Identify and recognize plants.
- Oleander grows seemingly everywhere in parts of the SW United States and off-leash dogs and cats should be monitored closely.

POSSIBLE COMPLICATIONS
Sudden death.

EXPECTED COURSE AND PROGNOSIS
- Good nursing care for 5–7 days.
- Prognosis is good with early and appropriate care.
- Cardiac arrhythmias prolong treatment and hospitalization.

MISCELLANEOUS

ABBREVIATIONS
- AV = atrioventricular.
- CV = cardiovascular.
- Fab = fragment antigen binding.
- GI = gastrointestinal.

CARDIOMYOPATHY, ARRHYTHMOGENIC RIGHT VENTRICULAR—CATS

BASICS

OVERVIEW

Arrhythmogenic right ventricular cardiomyopathy (ARVC) is a rare primary cardiomyopathy characterized by progressive atrophy of the right ventricular (RV) and/or right atrial (RA) myocardium, with replacement by fatty or fibrofatty tissue that may act as an arrhythmogenic substrate. The condition in cats typically manifests as signs of right-sided congestive heart failure (CHF) due to progressive RV dysfunction. A variety of arrhythmias have been observed in cats with ARVC; however, sudden death does not appear to be well recognized in this species.

SIGNALMENT

- Cats.
- One study reported mean age at presentation of 7.3 years (range: 1–20 years).
- Breed or sex predilections unknown.

SIGNS

General Comments

Compared to dogs and humans, sudden death does not appear to be as well recognized in cats with ARVC, despite the wide variety of arrhythmias documented with this condition.

Historical Findings

- Lethargy.
- Anorexia.
- Dyspnea.
- Tachypnea.
- Abdominal distention may be noted.

Physical Examination Findings

- Signs consistent with right-sided CHF.
- Dyspnea.
- Tachypnea.
- Jugular venous distention.
- Ascites.
- Heart and/or lung sounds may be muffled.
- Weak femoral pulses.
- Hepatosplenomegaly.
- Thoracic percussion may reveal presence of pleural effusion.
- May auscult arrhythmia.

CAUSES & RISK FACTORS

- Unknown.
- A genetic mutation in the striatin (desmosomal protein) gene is associated with ARVC in some dogs. Genetic mutations are identified in approximately 60% of humans with ARVC, with mutations identified in at least 13 genes. Genetic studies in feline ARVC are lacking.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Uhl's anomaly—a congenital abnormality characterized by partial or complete absence of myocardium in the RV free wall. Histopathology is required to distinguish this from ARVC and demonstrates apposing endocardial and epicardial surfaces, without any interposed adipose tissue or any evidence of inflammation or necrosis.

CBC/BIOCHEMISTRY/URINALYSIS

Alanine aminotransferase may be elevated secondary to hepatic congestion.

IMAGING

Radiographic Findings

- Cardiomegaly, typically in regions of right atrium and right ventricle; left atrial enlargement may also be noted.
- Pleural effusion.
- Ascites.
- Pericardial effusion.
- Caudal vena caval dilation.

Echocardiographic Findings

- Severe RA and RV dilation.
- RV systolic dysfunction/hypoknesis.
- Tricuspid regurgitation.
- Paradoxical septal motion.
- Focal aneurysms may be observed in the RV wall, often toward the apex.
- Left atrial enlargement sometimes seen.

DIAGNOSTIC PROCEDURES

ECG

- A variety of various arrhythmias have been observed in cats with ARVC.
- Ventricular premature complexes (right-sided or left-sided in origin).
- Ventricular tachycardia.
- Atrial fibrillation.
- Supraventricular tachycardia.
- Ventricular premature complexes.
- Right bundle branch block.
- First-degree atrioventricular block.
- Third-degree atrioventricular block.
- RA and RV enlargement (tall P wave, deep S waves in lead II), right axis deviation.

Paracentesis and Fluid Analysis

Fluid analysis of pleural or abdominal effusions typically reveals modified transudate consistent with right-sided CHF.

PATHOLOGIC FINDINGS

Gross Pathology

- Moderate-to-severe RA and RV dilation.
- Severe thinning of RA and RV walls, which are easily trans-illuminated.
- Left atrial dilation and rarely left ventricular dilation may be seen in some cats.
- Thrombi sometimes identified.

Histopathology

- RV myocardial atrophy with replacement by fatty or fibrofatty tissue.
- Fibrosis may also be observed in right atrium, left ventricular free wall, and interventricular septum.
- Focal or multifocal myocarditis.
- Apoptotic cardiomyocytes.

TREATMENT

- Medical management of right-sided CHF is the mainstay of treatment for clinically affected cats with ARVC.
- Anti-arrhythmic therapy is not routinely required, but in cases with hemodynamically significant arrhythmias, anti-arrhythmic drugs should be selected based on the suspected underlying mechanism of the arrhythmia.

MEDICATIONS

See Congestive Heart Failure, Right-Sided.

FOLLOW-UP

PATIENT MONITORING

Recheck when decompensation or other clinical signs develop.

EXPECTED COURSE AND PROGNOSIS

Prognosis appears to be very poor in cats identified with ARVC. Reported median survival time after development of clinical signs of approximately 1 month (range: 2 days to 4 months). Most cats die or are euthanized due to signs of right-sided CHF or thromboembolic complications.

MISCELLANEOUS

CARDIOMYOPATHY, ARRHYTHMOGENIC RIGHT VENTRICULAR—DOGS

BASICS

OVERVIEW

A myocardial disease commonly characterized by ventricular tachyarrhythmias that can be accompanied by syncope or sudden death. A small percentage (<5%) develop congestive heart failure with systolic dysfunction, comparable to the dilated cardiomyopathy observed in other breeds.

SIGNALMENT

- Dog.
- Specific to the boxer, although a similar presentation is infrequently observed in the English bulldog.
- Usually observed in mature dogs between 5 and 8 years of age. Dogs as young as 6 months have been reported and some affected dogs may not develop clinical signs until >10 years of age.

SIGNS

- Usually one of three presentations:
  - Asymptomatic dog with ventricular premature complexes (VPCs) detected on routine examination.
  - Syncope with VPCs detected on ECG or Holter monitor.
  - Signs of left heart failure (e.g., tachypnea, coughing) or biventricular failure (e.g., ascites, tachypnea, coughing) with VPCs; this presentation is least common.
- Sudden death may occur before development of obvious clinical signs.

CAUSES & RISK FACTORS

- Adult onset, inherited (autosomal dominant).
- A genetic mutation (deletion) in a cardiac desmosomal gene (striatin) is associated with the development of the disease. Dogs that are homozygous for the striatin deletion appear to be more likely to be more severely affected with a higher number of VPCs, and are more likely to have cardiac dilation and myocardial dysfunction. Sudden death is more common. It is not yet known if this is the only genetic cause or if additional genetic mutations will be identified.
- At least one family of boxers with VPCs, ventricular dilation, and systolic dysfunction was found to have decreased myocardial l-carnitine levels and demonstrated some clinical improvement when supplemented with l-carnitine. The cause and effect of this relationship is unclear, and response to this supplementation does not occur in all dogs with myocardial dysfunction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Aortic stenosis—moderate and severe forms can be associated with VPCs.
- Uncommon forms of acquired cardiac disease (neoplasia, endocarditis).
- Abdominal disease (especially splenic disease) can be associated with VPCs.
- Echocardiography and abdominal ultrasonography can be used to differentiate other causes of cardiac and abdominal disease.

OTHER LABORATORY TESTS

- Genetic testing can now be performed to screen for the genetic mutation (https://cvm.ncsu.edu/genetics) associated with arrhythmogenic right ventricular cardiomyopathy. Submission samples can be either a blood sample in an EDTA tube or a buccal swab of the oral mucosal surface.
- Plasma l-carnitine levels may be evaluated in boxers with ventricular dilation and systolic dysfunction. However, plasma levels are not always reflective of myocardial levels. If plasma levels are not low, it is still possible to have low myocardial levels, and supplementation with l-carnitine might be considered.

IMAGING

Thoracic Radiography

- Normal in most affected dogs.
- Dogs with ventricular dilation and systolic dysfunction may have cardiac enlargement and evidence of heart failure (e.g., pulmonary edema).

Echocardiography

- Normal in most affected dogs.
- A small percentage of dogs have ventricular dilation and systolic dysfunction, particularly if they are homozygous for the deletion mutation.

DIAGNOSTIC PROCEDURES

ECG

- Many dogs will not have VPCs on an ECG of brief duration since the arrhythmia can be intermittent. However, some dogs will have one or more upright VPCs on a brief lead II ECG.
- In either case, if suspicion of disease is present, Holter monitoring is recommended to determine the severity and complexity of the arrhythmia and to have a baseline for comparison once treatment is started. If Holter monitoring is not available and the dog is symptomatic with upright VPCs on an ECG, therapy should be considered.

PATHOLOGIC FINDINGS

- Gross pathology is nonspecific in most cases. In a small percentage of cases, left and right ventricular dilation may be observed.
- Histopathologic abnormalities include a fatty and fibrous infiltrate into the right ventricular (and sometimes interventricular and left ventricular) free wall.

TREATMENT

- The goals of therapy include reduction of the number of VPCs, reduction of clinical signs, and reduction of the risk of sudden cardiac death. Unfortunately, there is no evidence that therapy can reduce the risk of sudden death. The decision to start therapy in the asymptomatic boxer with VPCs is controversial, since all antiarrhythmics have the potential to make the arrhythmia worse. However, dogs with as few as 300 VPCs/24 hours have been observed to die suddenly. In general, initiate antiarrhythmic drugs if there are >1,000 VPCs/24 hours and/or significant runs of ventricular tachycardia or other signs of arrhythmia complexity (e.g., bigeminy, couplets), or clinical signs (syncope, exercise intolerance) related to the VPCs.
- Syncope and sudden cardiac death may be more frequently associated with stress and excitement. Reduce stress and effort when possible. There is no direct relationship between exercise restriction and survivability. Some dogs die while asleep. Thus, strict exercise restriction is not recommended.

MEDICATIONS

DRUG(S) OF CHOICE

- The two best choices for treating the ventricular arrhythmia are sotalol (1.5–2.0 mg/kg PO q12h) or mexiletine (5–6 mg/kg PO q8h). Some cases continue to have significant ventricular ectopy after treatment with one of these; such cases seem to respond well to the combination of sotalol and mexiletine. These drugs have different mechanisms and appear to work in a safe and complementary fashion.
- In dogs with systolic dysfunction and heart failure, consider treatment with furosemide, enalapril, pimobendan, spironolactone, and l-carnitine.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Any antiarrhythmic drug has the potential to make an arrhythmia worse.

FOLLOW-UP

- If possible, repeat the Holter monitor 2–3 weeks after starting therapy to evaluate for a response. Affected dogs can have an 85% day-to-day variability in VPC number before medications; therefore, a good response to therapy would be an 85% reduction in VPC number. It is also anticipated that the complexity of the arrhythmia (bigeminy,

CARDIOMYOPATHY, ARRHYTHMOGENIC RIGHT VENTRICULAR—DOGS (CONTINUED)

trigeminy, couplets, triplets, runs of ventricular tachycardia) will be reduced once on therapy. It may not always be possible to achieve an 85% reduction in VPC number; in those cases an improvement in arrhythmia complexity and clinical signs would be reasonable goals.
- Annual Holter monitoring and echocardiography are suggested, since in some cases the disease can be progressive.
- Advise owners that dogs are always at risk of sudden death. However, the majority of affected dogs can be maintained on antiarrhythmics for years with good quality of life. Dogs with systolic dysfunction and dilation have the worst prognosis, although some of these dogs do show improvement and a decreased rate of progression on l-carnitine supplementation.

MISCELLANEOUS

SYNONYMS
Boxer cardiomyopathy.

CARDIOMYOPATHY, DILATED—CATS

BASICS

DEFINITION

• Dilated cardiomyopathy (DCM) is a disease of the heart muscle characterized by systolic myocardial failure and a dilated, volume-overloaded heart that leads to signs of congestive heart failure (CHF) or low cardiac output.
• Before 1987, DCM was the second most commonly diagnosed heart disease in cats. Most cats had a secondary DCM as a result of taurine deficiency. Primary idiopathic DCM is now an uncommon cause of heart disease in cats.

PATHOPHYSIOLOGY

• Histopathologically, the myocardium of cats with idiopathic DCM has evidence of myocytolysis, fibrosis, myofibril fragmentation, and vacuolization. Gross examination reveals global eccentric enlargement of all four cardiac chambers.
• These anatomic changes are associated with progressive myocardial systolic failure, decreased contractility, decreased compliance, and secondary mitral valve regurgitation due to mitral valve annular dilation. These changes are typically identified by echocardiography.
• Eventually, the chronic myocardial dysfunction leads to CHF and clinical signs.

SYSTEMS AFFECTED

• Cardiovascular—DCM is a primary myocardial disease and primarily affects the heart and its ability to maintain an adequate cardiac output to maintain the body's needs.
• Musculoskeletal—cats with DCM can present with aortic thromboembolism (ATE), which causes acute paraparesis or monoparesis.
• Renal/urologic—cats with DCM and CHF often have poor renal perfusion and commonly have prerenal azotemia.
• Respiratory—cats usually present with tachypnea or dyspnea due to CHF with DCM. These cats can develop both pulmonary edema and pleural effusion.

GENETICS

Because of the human experience with DCM, it is likely that feline DCM also has a genetic basis, either inherited or de novo, as the cause of the disease. No definitive mutation has been identified in the cat to date; however, a quantitative genetic evaluation of a large cattery suggested an inherited factor in the development of DCM.

INCIDENCE/PREVALENCE

Idiopathic feline DCM is relatively uncommon now that taurine is adequately supplemented in cat foods. A retrospective survey of 106 cats with feline myocardial disease from 1994 to 2001 from Europe revealed that DCM was diagnosed in approximately 10% of the cases in this series. In the author's experience, the prevalence of feline idiopathic DCM may be less than 10%.

SIGNALMENT

Species

Cat

Breed Predilections

Because the prevalence is low, breed predilections are not clearly defined. That said, the Burmese cat may have an increased incidence.

Mean Age and Range

9 years (5–13 years).

Predominant Sex

None. (One study cites a male predisposition, while another states a female overrepresentation.)

SIGNS

General Comments

• Cats with idiopathic DCM usually present for signs of CHF.
• They are rarely diagnosed prior to onset of clinical signs.

Historical Findings

• Signs related to low cardiac output—anorexia, weakness, depression.
• Signs related to CHF—dyspnea, tachypnea.
• Signs related to ATE—sudden-onset pain and paraparesis.

Physical Examination Findings

• Heart rate can be fast, normal, or slow.
• Soft systolic heart murmur.
• Weak left cardiac impulse.
• Gallop sound.
• Possible arrhythmia.
• Hypothermia.
• Prolonged capillary refill time.
• Tachypnea.
• Quiet lung sounds (pleural effusion).
• Crackles (pulmonary edema).
• Ascites.
• Hypokinetic femoral pulses.
• Possibly, posterior paresis and pain as a result of ATE.

CAUSES

The underlying etiology of idiopathic DCM remains unknown, although a genetic predisposition has been identified in some families of cats. Taurine deficiency was a common cause of secondary myocardial failure before 1987.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Taurine deficiency DCM; because primary idiopathic DCM and taurine deficiency have similar clinical presentations, cats with myocardial failure should be assumed to have taurine deficiency until shown to be unresponsive to taurine.
• Myocardial failure secondary to long-standing congenital or acquired left ventricular volume overload diseases.
• End-staged remodeled hypertrophic cardiomyopathy may manifest with a dilated hypocontractile heart.
• Arrhythmogenic right ventricular cardiomyopathy.

CBC/BIOCHEMISTRY/URINALYSIS

Many cats will have prerenal azotemia related to low cardiac output.

OTHER LABORATORY TESTS

• Ensure that thyroid concentrations are normal.
• Plasma taurine concentrations less than 40 nmol/L or whole blood taurine concentrations less than 250 nmol/L, are subnormal and suggestive of taurine deficiency DCM. Taurine assays are performed at a limited number of institutions and require special handling.
• Cardiac biomarkers such as plasma amine terminal B-type natriuretic peptide (NT-proBNP) and cardiac troponin I (cTnI) concentrations would be elevated in a cat with CHF due to idiopathic DCM.

IMAGING

Radiography

• Radiography often shows pleural effusion or pulmonary edema.
• Generalized cardiomegaly.

Echocardiography

• Diagnostic modality of choice.
• Characteristic findings include thin ventricular walls, enlarged left ventricular end-systolic and end-diastolic dimensions, left atrial enlargement, and low fractional shortening.
• Pleural and pericardial effusion may be visualized.
• Spontaneous echocardiographic contrast or a thrombus may be visualized.

DIAGNOSTIC PROCEDURES

ECG

• ECG may be normal or may show left atrial or ventricular enlargement patterns.
• Both ventricular and supraventricular arrhythmias can be seen.

Pleural Effusion Analysis

• Pleural effusion typically is a modified transudate with total protein <4 g/dL and nucleated cell counts of less than 2,500/mL; chylous effusion may also be present.
• Analysis of the pleural effusion is important to rule out other causes of pleural effusion such as pyothorax, infectious peritonitis, or lymphosarcoma.

PATHOLOGIC FINDINGS

• Heart : body ratio is increased.
• All four cardiac chambers are dilated;

CARDIOMYOPATHY, DILATED—CATS (CONTINUED)

ventricular walls are thin and left ventricular lumen is enlarged.
• Valve anatomy is normal.
• Histopathology shows myocytolysis and myocardial fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE
These cats usually present in CHF and should be treated as inpatients, typically in an intensive care setting until more stable.

NURSING CARE
• Thoracocentesis is often utilized for both therapeutic and diagnostic purposes.
• Supplemental oxygen therapy is beneficial for cats in CHF to decrease the work of breathing.
• If hypothermic, cautious external heat (incubator or heating water pad) is recommended.

ACTIVITY
Indoors only after hospital discharge to reduce stress. Let cat dictate its own activity.

DIET
These cats typically are anorexic, thus tempting their appetite with many types of food may be necessary. Eventually, a low-sodium diet is recommended.

CLIENT EDUCATION
Some cats will need chronic intermittent thoracocentesis to manage significant accumulations of pleural effusion despite medical therapy.

MEDICATIONS

DRUG(S) OF CHOICE
• Furosemide is recommended to manage pulmonary edema and pleural effusion. Recommended dose range is 1–4 mg/kg q8–12h. Initially, administer parenterally then switch to oral. Chronically the lowest effective dose of furosemide is recommended.
• Pimobendan, an inodilator, is also recommended to strengthen contractility and provide some vasodilation. Recommended dose range is 0.1–0.3 mg/kg PO q12h. Although pimobendan is not currently licensed for use in cats, several recent publications have demonstrated its safety in cats and possibly a beneficial effect, albeit in retrospective studies. One study in cats with non-taurine-responsive DCM that were treated with pimobendan had a median survival time that was four times longer than the cats not treated with pimobendan (49 vs. 12 days).
• Taurine supplementation is recommended initially in all cats with DCM at 250 mg PO q12h, until it is demonstrated that the patient is unresponsive to taurine or is not taurine deficient based on diagnostic testing.
• Nitroglycerin (2% ointment) one-fourth to one-half inch applied topically can be used in conjunction with diuretics in the acute management of severe CHF to further reduce preload. Nitroglycerin will lower the dose of furosemide and is particularly useful in patients with hypothermia or dehydration.
• Enalapril or benazepril, at a dose of 0.25–0.5 mg/kg PO q24h, is recommended to reduce afterload and preload as soon as the cat is able to take oral medications and is clinically stable. Use with caution and possibly avoid if creatinine >2.5 mg/dL.
• Digoxin is optionally recommended to strengthen contractility and for its positive neurohumoral effects at a dose of 0.03 mg/cat (one-fourth of a 0.125 mg tablet) or 0.01 mg/kg PO q48h. Digoxin can be given concurrently with pimobendan. However, digoxin is often omitted when pimobendan is given because of the difficulties in giving a cat several pills and digoxin's side-effect profile.
• Dobutamine at extremely low dosages can be given to a patient with severe signs of CHF and low cardiac output that cannot take oral medications. Dose varies 0.25–5 µg/kg/minute IV CRI. ECG monitoring is recommended.
• Because ATE is a concern, an antithrombotic agent is also recommended. Clopidogrel given at a dose of 18.75 mg (one-fourth of a 75 mg tablet) PO q24h is generally the author's preferred antithrombotic agent. Other options include aspirin 81 mg PO q72h (with food) or low molecular weight heparin (e.g., dalteparin 100–150 units/kg SC q8–24h or enoxaparin 1 mg/kg SC q12–24h).
• Antiarrhythmic drugs may also be needed to control supraventricular or ventricular arrhythmias. If hemodynamically significant supraventricular tachycardia or rapid atrial fibrillation is present, diltiazem is recommended. Usually, diltiazem is given orally in either a non-sustained-release formulation (7.5 mg/cat PO q8h) or a sustained-release oral formulation (Cardizem CD® at 10 mg/kg PO q24h or Dilacor XR® 30 mg/cat [or 1/2 of an inner 60 mg tablet] PO q12h). Diltiazem is also available in an injectable formulation for urgent control of a supraventricular arrhythmia in a cat that cannot take oral medications (0.05–0.1 mg/kg slow IV, repeated PRN up to 0.25 mg/kg). If rapid and sustained ventricular tachycardia, lidocaine slow IV 0.2–0.5 mg/kg (repeat once or twice max) or sotalol PO 2 mg/kg q12h is recommended.
• Beta blockers, such as atenolol, may be useful in the chronic management of both supraventricular and ventricular arrhythmias. Beta blockers are used in the long-term management of DCM in humans because of their positive myocardial effects and survival benefit. Clinical experience is limited in feline DCM and they must be used cautiously, as they acutely decrease contractility and could worsen CHF. Recommended dose ranges from 3.125 to 6.25 mg PO q12–24h. Start low and titrate up based on heart rate and clinical signs.

PRECAUTIONS
• Unless needed for acute cardiac rhythm control, drugs such as calcium channel blockers (diltiazem) or beta-adrenergic blockers may reduce contractility and lower cardiac output. Use cautiously.
• Overzealous diuretic and vasodilation therapy may cause azotemia and electrolyte disturbances.
• Digoxin should not be used if renal insufficiency is documented or suspected.
• Enalapril or benazepril should be used with caution and possibly withheld if serum creatinine is >2.5 mg/dL.
• Dobutamine may cause seizures and cardiac tachyarrhythmias.

FOLLOW-UP

PATIENT MONITORING
• Repeat examination with ideally blood pressure, diagnostic imaging (either a thoracic radiograph or focused thoracic ultrasound for fluid assessment), and chemistry panel within 1 week to determine response of therapy.
• Home resting respiratory rate monitoring is helpful to determine need for diuretic dose adjustment or thoracocentesis.
• Periodically monitor electrolyte and renal parameters. Periodically monitor for CHF fluid accumulation with diagnostic imaging.
• If using digoxin, serum blood concentrations should be measured approximately 10–14 days after initiating therapy. Therapeutic range is 0.5–1.5 ng/dL 8–12 hours post-pill.
• Repeat diagnostic echocardiogram in 2–3 months after initiating taurine supplementation to determine echocardiographic response to therapy. Although echocardiographic response may take 2–3 months to assess, one should see dramatic clinical response within 2 weeks of initiating taurine therapy if cat has taurine-responsive DCM.

PREVENTION/AVOIDANCE
Ensure that cats eat a high-protein diet with sufficient dietary taurine. No vegetarian diets.

POSSIBLE COMPLICATIONS
ATE is the most feared complication of any feline myocardial disease.

EXPECTED COURSE AND PROGNOSIS
- These cats have a poor prognosis despite intensive therapy. If cat is not taurine responsive, survival is usually weeks to months.
- CHF can be medically refractory and recurrent despite appropriate medical therapy.
- Repeated thoracocentesis may be necessary.

MISCELLANEOUS

ASSOCIATED CONDITIONS

CARDIOMYOPATHY, DILATED—DOGS

BASICS

DEFINITION
Dilated cardiomyopathy (DCM) characterized by left- and right-sided dilation, normal coronary arteries, anatomically normal although commonly insufficient atrioventricular valves, significantly decreased inotropic state, and myocardial dysfunction occurring primarily during systole; however, progressive diastolic dysfunction with restrictive physiology may also be present and is a negative predictor of survival.

PATHOPHYSIOLOGY
- Myocardial failure leads to reduced cardiac output and congestive heart failure (CHF).
- Atrioventricular (AV) annulus dilation and altered papillary muscle function promote valvular insufficiency.
- Although left-sided signs commonly predominate, evidence of severe right-sided disease can occur and infrequently is the dominant clinical scenario.

SYSTEMS AFFECTED
- Cardiovascular.
- Renal/urologic—prerenal azotemia.
- Respiratory—pulmonary edema, infrequently pulmonary hypertension.
- All organ systems are affected by reductions in cardiac output.

GENETICS
- Genetic cause or heritable susceptibility strongly suspected in most breeds and documented in some (Portuguese water dog, boxer, and Doberman pinscher) with variable forms of inheritance.
- A genetic test is commercially available for causative mutations in boxer dogs (striatin) and Doberman pinscher (NCSU DCM 1—pyruvate dehydrogenase kinase; NCSU DCM 2—titin).
- These mutations are not causative in other predisposed breeds in which they have been evaluated.
- Correlations between genotype and phenotype have shown that Doberman pinschers with both mutations have, on average, an earlier onset of clinical disease with a predisposition to sudden death; boxers homozygous for the mutation are more likely to develop the DCM phenotype.

INCIDENCE/PREVALENCE
Estimated at 0.5–1.1% in predisposed breeds and perhaps higher in specific geographic regions.

GEOGRAPHIC DISTRIBUTION
None with the exception of Chagas' cardiomyopathy, which is limited to the southern United States (Gulf Coast) and both Central and South America.

SIGNALMENT

Species
Dog

Breed Predilections
- Doberman pinscher, boxer.
- Giant breeds—Scottish deerhound, Irish wolfhound, Great Dane, St. Bernard, Newfoundland.
- Cocker spaniel, Portuguese water dog (juvenile).

Mean Age and Range
4–10 years.

Predominant Sex
Males > females in most but not all breeds (minor predisposition).

SIGNS

Historical Findings
- Respiratory—tachypnea, dyspnea, coughing.
- Weight loss, typically of lean muscle mass.
- Weakness, lethargy, anorexia.
- Abdominal distention.
- Syncope, usually associated with arrhythmias (atrial fibrillation; ventricular tachycardia).
- Some dogs are asymptomatic, having what is termed preclinical DCM, the diagnosis of which in specific breeds is well described.
- Breed-specific echocardiographic parameters coupled with cardiac biomarkers (NT-proBNP; cardiac troponin I [cTnI]) may help identify dogs with preclinical DCM.

Physical Examination Findings
- May be completely normal with preclinical DCM.
- Weakness, possibly cardiogenic shock.
- Hypokinetic femoral pulse from low cardiac output.
- Pulse deficits with atrial fibrillation, ventricular or supraventricular premature contractions, and paroxysmal ventricular tachycardia.
- Jugular pulses from tricuspid regurgitation, arrhythmias, or right-sided CHF.
- Breath sounds—muffled with pleural effusion; crackles with pulmonary edema.
- S3 or summation gallop sounds.
- Mitral and/or tricuspid regurgitation murmurs are common but usually focal and soft.
- Auscultatory evidence of cardiac arrhythmia is common.
- Slow capillary refill time, infrequent cyanosis.
- Hepatomegaly with or without ascites.

CAUSES
- Majority of cases represent familial abnormalities of structural, energetic, or contractile cardiac proteins, some of which have been identified.
- Nutritional deficiencies (taurine and/or carnitine) have been documented in several breeds including golden retriever, boxer, Newfoundland, and cocker spaniel; diet-associated DCM, which may be associated with taurine deficiency, commonly secondary to boutique, exotic-ingredient, or grain free (BEG) diets, is increasing recognized and potentially reversible.
- Viral, protozoal, and immune-mediated mechanisms have been proposed but not proven.
- Doxorubicin toxicity.
- Hypothyroidism and persistent tachyarrhythmias (sometimes associated with congenital tricuspid valve malformation) may cause reversible myocardial failure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Myxomatous valvular degeneration.
- Congenital heart disease.
- Heartworm disease.
- Bacterial endocarditis.
- Cardiac tumors and pericardial effusion.
- Airway obstruction—foreign body, neoplasm, laryngeal paralysis.
- Primary pulmonary disease—bronchial disease, pneumonia, neoplasia, aspiration, vascular disease (e.g., heartworms).
- Noncardiogenic pleural effusions (e.g., pyothorax, hemothorax, chylothorax).
- Trauma resulting in diaphragmatic hernia, pulmonary hemorrhage, hemothorax, pneumothorax.

CBC/BIOCHEMISTRY/URINALYSIS
Routine hematologic tests and urinalysis are usually normal unless altered by severe reductions in cardiac output or severe elevations in venous pressures (e.g., prerenal azotemia, high alanine aminotransferase, hyponatremia), therapy for heart failure (e.g., hyponatremia, hypokalemia, hypochloremia, azotemia, and metabolic alkalosis from diuresis), or concurrent disease.

OTHER LABORATORY TESTS
Cardiac biomarkers including NT-proBNP and cTnI are elevated in both the preclinical and clinical stages of the disease. Clinical studies investigating use of these markers for diagnosis, prognosis, and optimization of therapy are ongoing.

IMAGING

Radiography
- Typically normal in the preclinical phase.
- Generalized cardiomegaly and signs of CHF are common.
- Left ventricular (LV) enlargement and left atrial enlargement may be most evident in early cases.
- In some cases, the degree of cardiomegaly may be less than expected for the severity of clinical signs; it is also often substantially less than would be expected in a dog with

primary valvular heart disease and comparable clinical signs.
• Pleural effusion, hepatomegaly, ascites.

Echocardiography
• Gold standard for diagnosis.
• LV dilation often precedes overt reductions in indices of systolic function.
• Ventricular and atrial dilation.
• Indices of myocardial systolic function (fractional shortening [FS%]), ejection fraction, area shortening, and mitral annular motion by tissue Doppler imaging may be reduced.
• Spectral Doppler studies may confirm decreased velocity and/or acceleration of trans-aortic flow as well as mitral regurgitation and/or tricuspid regurgitation.
• Doppler evidence of restrictive LV filling is associated with decreased survival.

DIAGNOSTIC TESTS

ECG
• Sinus rhythm or sinus tachycardia with isolated atrial or ventricular premature complexes.
• Atrial fibrillation and ventricular tachycardia (paroxysmal or sustained) are very common in Doberman pinschers.
• Boxers commonly have isolated ventricular arrhythmias without evidence of functional or anatomic heart disease.
• Prolonged QRS (>0.06 second), possible increased voltages (R >3 mV lead II), suggesting LV enlargement.
• May have "sloppy" R wave descent with ST-T coving, suggesting myocardial disease or LV ischemia.
• May have low voltages (pleural or pericardial effusion, concurrent hypothyroidism).

PATHOLOGIC FINDINGS
• Dilation of all chambers with or without thinning of chamber walls.
• Slightly thickened endocardium with pale areas within myocardium (necrosis, fibrosis).
• Two histologically distinct forms—fatty infiltration: degenerative type seen in boxers and Doberman pinschers; and attenuated wavy fiber type: seen in many giant-, large-, and medium-sized breeds, including some boxers and Doberman pinschers.

TREATMENT

APPROPRIATE HEALTH CARE
With the exception of severely affected dogs (life-threatening arrhythmias, severe pulmonary edema, cardiogenic shock), most therapy can be administered on an outpatient basis.

ACTIVITY
Allow the dog to choose its own level of activity.

DIET
• During initial therapy for clinical signs, simply maintaining adequate caloric intake is paramount.
• Goal—reduce dietary sodium intake to <12–15 mg/kg/day.
• Severe sodium restriction is typically not necessary when using potent cardioactive therapy and may adversely affect appetite.
• Best to use commercially prepared diets.

CLIENT EDUCATION
• Emphasize potential signs associated with progression of disease and adverse side effects of medication.
• Monitoring sleeping respiratory rate often gives insight into impending decompensation.

MEDICATIONS

DRUG(S) OF CHOICE
First identify patient problems—CHF (left or right-sided), arrhythmia, hypothermia, renal failure, shock.

Preclinical Disease
• There is clinical evidence (PROTECT Trial) that early intervention with pimobendan monotherapy substantially changes the course of preclinical disease in Doberman pinschers.
• These results are routinely extrapolated to other breeds, but have not been proven.
• Critical evaluation suggests that early intervention with monotherapy using an angiotensin-converting enzyme (ACE) inhibitor is of minimal or no survival benefit in preclinical disease.

Initial Stabilization
• Treat hypoxemia with oxygen administration; prevent heat loss if hypothermic (warm environment).
• If pulmonary edema—furosemide (1–4 mg/kg IM/IV, then 1–2 mg/kg q6–12h for first 1–3 days), or CRI 1–2 mg/kg/h (author's preference).
• 2% topical nitroglycerin for first 24–48h for severe pulmonary edema—apply 1 inch–2 inches q8h (beware of hypotension in both patients and staff).
• If significant pleural effusion—drain each hemithorax.
• If severe heart failure and cardiogenic shock—dobutamine may be indicated; this drug may exacerbate arrhythmias, particularly in hypoxic dogs; oral pimobendan (see dosing below) may have important acute (2–4h) hemodynamic benefit as well; IV pimobendan (0.15 mg/kg) is available in select countries.
• Dobutamine 5–15 µg/kg/min infused for 24–72h with care (start low and gradually up-titrate based on response).
• If paroxysmal ventricular tachycardia is present—administer lidocaine slowly in 2 mg/kg boluses (up to 8 mg/kg total over 30 min) to convert to sinus rhythm; follow with lidocaine infusion (50–100 µg/kg/min).
• If lidocaine is ineffective—administer procainamide slowly at dose of 2–5 mg/kg (up to 15 mg/kg) IV to convert to sinus rhythm; follow with 25–50 µg/kg/min CRI (beware of proarrhythmia and infrequently hypotension).

Maintenance Therapy
• ACE inhibitors (enalapril, benazepril, lisinopril) are considered cornerstone of therapy for DCM.
• Enalapril (0.25–0.5 mg/kg PO q12h), benazepril (0.5 mg/kg PO q12–24h), or lisinopril (0.5 mg/kg PO q 12–24h) should be initiated early in the therapeutic regimen.
• Furosemide (1–4 mg/kg PO q8–12h) is used to control signs of congestion.
• Torsemide (0.1–0.4 mg/kg PO q8–12h) is commonly employed as an alternative to furosemide, particularly in later-stage disease.
• Spironolactone (1–2 mg/kg PO q12h) may impart an independent survival benefit by blocking aldosterone; higher doses can be used for refractory heart failure (2–4 mg/kg PO q12h).
• Hydrochlorthiazide (1–2 mg/kg PO q12h) may be beneficial as a third diuretic.
• Beta blockers can be used cautiously once heart failure is controlled with other drugs (see Precautions); if tolerated, they may improve myocardial function with chronic use; carvedilol (0.25–1.25 mg/kg PO q12h) is an alpha and beta blocker with antioxidant activity: start at the low end of the dose range and gradually up-titrate over a 6-week period if tolerated; consult with a cardiologist before using beta blockers in clinical DCM patients as can result in rapid and profound clinical deterioration.
• Pimobendan (0.25–0.3 mg/kg PO q12h) is a calcium-sensitizing drug and a vasodilating, positive inotrope (inodilator) that, when added to furosemide, ACE inhibitors, and spironolactone improves functional heart failure class and in Doberman pinschers increases survival time; the author has administered pimobendan 0.5 mg/kg PO q8h in refractory cases with perceived clinical benefit.
• The role of carnitine and taurine in therapy of DCM remains controversial; however, American cocker spaniels with DCM generally respond favorably to taurine and l-carnitine supplementation, but still require additional cardiac medications.

Arrhythmias
• In atrial fibrillation, slowing of ventricular rate response typically achieved with chronic administration of extended-release diltiazem

CARDIOMYOPATHY, DILATED—DOGS (CONTINUED)

(Dilacor®) 2–7 mg/kg PO q12h, or atenolol 0.75–1.5 mg/kg PO q12h (never start in patient with active CHF), occasionally combined with digitalis at dose of 0.005 mg/kg PO q12h; therapeutic drug monitoring recommended when administering digoxin.
• Therapeutic goal is obtaining resting ventricular rate of 100–140 bpm.
• At-home monitoring with AliveCor Kardia device.
• This therapy merely controls ventricular rate, by depressing atrioventricular nodal conduction; generally does not convert rhythm from atrial fibrillation to sinus rhythm.
• Amiodarone (10–15 mg/kg PO q24h for 7–10 days followed by 5–10 mg/kg PO q24h) may either control ventricular response rate or in some cases result in conversion to normal sinus rhythm.
• Chronic oral therapy for ventricular tachycardia includes sotalol (1–2 mg/kg PO q12h), mexiletine (5–10 mg/kg PO q8h), or amiodarone (5–10 mg/kg PO q24h).
• Mexiletine can be combined with sotalol if necessary.

CONTRAINDICATIONS

Digoxin should be avoided in severe uncontrolled paroxysmal ventricular tachycardia, in animals with compromised renal function, and in animals with important hypokalemia.

PRECAUTIONS

• Calcium channel blockers and notably beta blockers are negative inotropes and may have acute adverse effect on myocardial function; numerous human studies, however, have suggested that chronic administration of beta blockers may be of benefit in DCM.
• Combination of diuretics and ACE inhibitors may result in azotemia, especially in patients with severe heart failure or preexisting renal dysfunction, and must be closely monitored.

POSSIBLE INTERACTIONS

• Quinidine, amiodarone, and diltiazem may increase serum digoxin levels and predispose to digitalis intoxication.
• Renal dysfunction, hypothyroidism, and hypokalemia predispose to digitalis intoxication.

ALTERNATIVE DRUG(S)

• Other vasodilators, including hydralazine and amlodipine, may be used instead of or in addition to ACE inhibitors (beware of hypotension).
• Role of co-enzyme Q10, fish oil, and arginine remains to be determined.

FOLLOW-UP

PATIENT MONITORING

• Serial clinical examinations, thoracic radiographs, blood pressure measurements, routine serum biochemical evaluations (including electrolytes), and electrocardiography are most helpful.
• Repeat echocardiography is rarely informative or indicated.
• Serial evaluation of serum digoxin levels (therapeutic range: 0.5–1 ng/mL) taken 6–8 hours post-pill and serum biochemistries may help prevent iatrogenic problems.

POSSIBLE COMPLICATIONS

• Sudden death due most commonly to arrhythmias.
• Iatrogenic problems associated with medical management (see above).

EXPECTED COURSE AND PROGNOSIS

• Always fatal unless associated with nutritional deficiencies.
• Death usually occurs 6–24 months following diagnosis.
• Dobermans typically have worst prognosis; however, with addition of pimobendan, survival following identification in *preclinical* phase averages over 700 days.
• Atrial fibrillation, paroxysmal ventricular tachycardia, Doppler evidence of restrictive LV filling, markedly decreased FS%, homozygosity for known mutations (boxer), or presence of multiple mutations (Doberman pinschers) are believed to be markers for shortened survival and increased risk for sudden arrhythmogenic death.

MISCELLANEOUS

CARDIOMYOPATHY, HYPERTROPHIC—CATS

BASICS

DEFINITION
Inappropriate concentric hypertrophy of the ventricular free wall and/or the interventricular septum of the nondilated left ventricle. The disease occurs independently of other cardiac or systemic disorders.

PATHOPHYSIOLOGY
- Diastolic dysfunction results from a thickened, less compliant left ventricle.
- High left ventricular filling pressure develops, causing left atrial (LA) enlargement.
- Pulmonary venous hypertension causes pulmonary edema. Some cats develop biventricular failure (i.e., pulmonary edema, pleural effusion, small volume pericardial effusion without tamponade, and infrequently ascites).
- Stasis of blood in the large left atrium predisposes the patient to aortic thromboembolism (ATE).
- Dynamic aortic outflow obstruction and systolic anterior mitral motion (SAM) with secondary mitral insufficiency may occur, but unlike in humans, appears not to affect prognosis.
- Recent evidence suggests that some cats with apparent hypertrophic cardiomyopathy (HCM) and congestive heart failure (CHF) actually have transient myocardial thickening, often associated with high serum troponin I concentrations. These cats are younger than average for HCM, with on average less severe left ventricular (LV) hypertrophy, and they can experience resolution of both CHF and LV hypertrophy.

SYSTEMS AFFECTED
- Cardiovascular—CHF, ATE, and arrhythmias.
- Pulmonary—dyspnea if CHF develops.
- Renal/urologic—prerenal azotemia.

GENETICS
Some families of cats have been identified with a high prevalence of the disease, and the disease appears to be an autosomal dominant trait in Maine coon cats and ragdoll cats, due to a mutation in the myosin-binding protein C (MyBPC) gene. The genetics have not been definitively determined in other breeds; however, the Maine coon and ragdoll mutations have not been identified in affected Sphynx, Norwegian forest cats, Bengals, Siberians, or British shorthair cats.

INCIDENCE/PREVALENCE
Unknown, but relatively common. May be as high as 15% of the population.

SIGNALMENT
Species
Cat

Breed Predilections
Maine coon cats, ragdolls, Sphynx, British and American shorthairs, and Persians.

Mean Age and Range
- 5–7 years, with reported ages of 3 months–17 years. Some breeds of cats including ragdolls and Sphynx may develop the disease at a younger age (average of 2 years).
- HCM is most often a disease of young to middle-aged cats; unexplained murmurs in geriatric cats are more likely associated with hyperthyroidism or hypertension.

Predominant Sex
Male

SIGNS
Historical Findings
- Dyspnea, tachypnea.
- Anorexia.
- Exercise intolerance.
- Vomiting.
- Collapse.
- Sudden death.
- Coughing is uncommon in cats with HCM and suggests primary pulmonary disease.

Physical Examination Findings
- Gallop rhythm (S3 or S4).
- Systolic murmur in approximately half of affected cats.
- Apex heartbeat may be exaggerated.
- Muffled heart sounds, lack of chest compliance, and dyspnea characterized by rapid shallow respirations may be associated with pleural effusion.
- Dyspnea and crackles if pulmonary edema is present.
- Weak femoral pulse.
- Acute pelvic limb paralysis with cyanotic pads and nailbeds, cold limbs, and absence of femoral pulse in animals with ATE; emboli rarely affect thoracic limbs.
- Arrhythmia in some animals.
- May have no clinical signs.

CAUSES
- Usually unknown—multiple causes exist.
- MyBPC mutations in some cats with HCM.

Possible Causes
- Abnormalities of contractile protein myosin or other sarcomeric proteins (e.g., troponin, myosin-binding proteins, tropomyosin).
- Abnormality affecting catecholamine-influenced excitation contraction coupling.
- Abnormal myocardial calcium metabolism.
- Collagen or other intercellular matrix abnormality.
- Growth hormone excess.
- Dynamic LV outflow obstruction may contribute to secondary LV hypertrophy.

RISK FACTORS
Offspring of animals with familial mutations of MyBPC.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other forms of cardiomyopathy.
- Hyperthyroidism.
- Aortic stenosis.
- Systemic hypertension.
- Acromegaly.
- Noncardiac causes of pleural effusion.

CBC/BIOCHEMISTRY/URINALYSIS
- Results usually normal.
- Prerenal azotemia in some animals.

OTHER LABORATORY TESTS
- MyBPC assay; mutation differs for Maine coon cats and ragdoll cats.
- In cats >6 years old, check thyroid hormone concentration; hyperthyroidism causes myocardial hypertrophy that might be confused with HCM.
- Serum NT-proBNP concentrations higher in cats with HCM than in normal cats, and higher still in cats with symptomatic HCM. SNAP NT-proBNP point-of-care testing is also available to help differentiate symptomatic cats with HCM from those that are symptomatic from other causes. Send-out serum NT-proBNP testing is useful in identifying cats with suspicion of HCM from asymptomatic cats with abnormal physical exam findings (e.g., murmur). Follow-up echocardiography indicated in cats with serum NT-proBNP concentrations in "equivocal" or "high" range, or positive SNAP results.

IMAGING
Radiography
- Dorsoventral radiographs often reveal a valentine-appearing heart because of atrial enlargement and a left ventricle that comes to a point.
- Pulmonary edema, pleural effusion, or both in some animals.
- Radiographs may be normal in asymptomatic cats.
- Different forms of cardiomyopathy cannot be reliably differentiated by radiography.

Echocardiography
- Hypertrophy of interventricular septum (IVS) or LV posterior wall (diastolic wall thickness >6 mm).
- Hypertrophy may be symmetric (affecting IVS and posterior wall) or asymmetric (affecting IVS or posterior wall, but not both).
- Hypertrophy of papillary muscles.
- Normal or high fractional shortening.
- Normal or reduced LV lumen.
- LA enlargement.
- Systolic anterior motion of mitral valve (some animals).
- LV outflow obstruction (some animals); specialized Doppler studies performed by

CARDIOMYOPATHY, HYPERTROPHIC—CATS (CONTINUED)

experienced sonographers often reveal LV relaxation abnormalities (e.g., mitral inflow E : A wave reversal).
• Thrombus in left atrium (rare).
• *Note:* there is some overlap between normal cats (especially ketaminized or dehydrated) and cats with mild HCM. Correlate echo findings with physical findings. Presence of LA enlargement favors HCM.

DIAGNOSTIC PROCEDURES

ECG

• Sinus tachycardia (heart rate >240) common with heart failure; however, some cats with severe heart failure and hypothermia are bradycardic.
• Atrial and ventricular premature complexes seen more often in cats with cardiomyopathy, but also occasionally seen in normal cats.
• Atrial fibrillation seen in some advanced cases.
• Left axis deviation often seen.
• Prolongation of QT interval and QTc (QT interval corrected for heart rate) often seen with LV hypertrophy.
• Cannot differentiate different forms of cardiomyopathy; may be normal.

Systemic Blood Pressure

• Normotensive or hypotensive.
• Evaluate blood pressure in all patients with myocardial hypertrophy to rule out systemic hypertension as cause of hypertrophy.

PATHOLOGIC FINDINGS

• Nondilated left ventricle with hypertrophy of IVS or LV free wall.
• Hypertrophy of papillary muscles.
• LA enlargement.
• Mitral valve thickening.
• Myocardial hypertrophy with disorganized alignment of myocytes (myofiber disarray).
• Interstitial fibrosis.
• Myocardial scarring.
• Hypertrophy and luminal narrowing of intramural coronary arteries.

TREATMENT

APPROPRIATE HEALTH CARE

Cats with CHF should be hospitalized.

NURSING CARE

• Minimize stress.
• Oxygen if dyspneic.
• Warm environment if hypothermic.

ACTIVITY

Restricted with CHF.

DIET

Modest to moderate sodium restriction in animals with CHF.

CLIENT EDUCATION

• Many cats diagnosed while asymptomatic eventually develop CHF and may develop ATE and die suddenly.
• If cat is receiving warfarin, dalteparin, enoxaparin (Lovenox®), or combination of clopidogrel and any of those medications, minimize potential for trauma and subsequent hemorrhage.

MEDICATIONS

DRUG(S) OF CHOICE

Furosemide

• Dosage—1–2 mg/kg PO/IM/IV q8–24h.
• Critically dyspneic animals often require high dosage (4 mg/kg IV); this dose can be repeated in 1 hour if cat still severely dyspneic; indicated to treat pulmonary edema, pleural effusion, and ascites.
• Cats are sensitive to furosemide and prone to dehydration, prerenal azotemia, and hypokalemia.
• Once pulmonary edema resolves, taper to lowest effective dose.

Pimobendan

• Dosage—0.25–0.3 mg/kg PO q12h.
• Appears to be useful in management of CHF (e.g., pulmonary edema or pleural effusion) in cats with HCM, possibly by enhancing diastolic function and LA fractional shortening; not used in management of asymptomatic HCM at this time.
• Not currently licensed for use in cats.

Angiotensin-Converting Enzyme (ACE) Inhibitors

• Dosage—enalapril or benazepril 0.25–0.5 mg/kg PO q24h.
• Indications in cats with HCM not well defined—authors currently use for CHF.

Beta Blockers

• Dosage—atenolol (6.25–12.5 mg/cat PO q12h).
• Beneficial effects may include slowing of sinus rate, correcting atrial and ventricular arrhythmias, platelet inhibition.
• More effective than diltiazem in controlling dynamic outflow tract obstruction.
• Role in asymptomatic patients unresolved, but many clinicians use if dynamic outflow obstruction and hypertrophy present.
• Contraindicated in presence of CHF.

Diltiazem

• Dosage—7.5–15 mg/cat PO q8h or 10 mg/kg PO q24h (Cardizem® CD) or 30 mg/cat q12h (Dilacor XR®).
• Beneficial effects may include slower sinus rate, resolution of supraventricular arrhythmias, improved diastolic relaxation, coronary and peripheral vasodilation, platelet inhibition.
• May reduce hypertrophy and LA dimensions in some cats.
• Role in asymptomatic patients unresolved.

Aspirin

• Dosage—81 mg/cat q2–3 days if severe atrial enlargement.
• Depresses platelet aggregation, hopefully minimizing risk of thromboembolism.
• Warn owners that thrombi can still develop despite aspirin administration; aspirin appears to be not as effective as clopidogrel (1/4 of 75 mg tablet PO q24h) in prevention of ATE, at least in cats with previous embolic episode.

Nitroglycerin Ointment

• Dosage—one-fourth inch/cat topically applied q6–8h or 2.5 mg/24h patch.
• Often used in acute stabilization of cats with severe pulmonary edema or pleural effusion.
• When used intermittently, may be useful for long-term management of refractory cases.

CONTRAINDICATIONS

Avoid beta blockers in cats with emboli; these agents cause peripheral vasoconstriction. If beta blockers must be used in this setting for arrhythmia control, choose beta-1 selective blocker such as atenolol.

PRECAUTIONS

Use ACE inhibitors cautiously in azotemic animals.

ALTERNATIVE DRUG(S)

Torsemide

• Dosage—0.1–0.5 mg/kg q24h, sometimes with dose escalation to q12h.
• Used as substitute for furosemide in refractory pulmonary edema or pleural effusion in cats with apparently normal (or at least stable) renal function.
• Monitor renal function closely in first days after switching to torsemide.

Spironolactone

• Dosage—1 mg/kg q12–24h.
• Used in conjunction with furosemide in cats with CHF, especially refractory effusions.
• May cause facial pruritis.

Warfarin and Low Molecular Weight Heparin

• Used sometimes in cats at high risk for thromboembolism.
• See Aortic Thromboembolism.

Clopidogrel

• Dosage—18.75 mg/cat/day.
• Platelet function inhibitor, superior to aspirin in cats with previous ATE.

Beta Blocker plus Diltiazem

• Cats that remain tachycardic on a single agent can be treated cautiously with a combination of a beta blocker and diltiazem.
• Monitor for bradycardia and hypotension.

FOLLOW-UP

PATIENT MONITORING

• Observe closely for dyspnea, lethargy, weakness, anorexia, and painful posterior paralysis or paresis.

(CONTINUED) # CARDIOMYOPATHY, HYPERTROPHIC—CATS

- If treating with warfarin, monitor prothrombin time.
- If treating with ACE inhibitor or spironolactone, monitor renal function and electrolytes.
- Repeat echocardiogram in 6 months to assess efficacy of treatment for hypertrophy. If beta blocker or diltiazem was prescribed in asymptomatic animal and there is evidence of progressive hypertrophy/LA enlargement, consider switching to another class of medications (or adding an ACE inhibitor) and recheck 4–6 months later.
- Echocardiographic evaluations that reveal LA diameters >2 cm or loss of LV systolic function should prompt more aggressive prophylaxis against ATE (e.g., clopidogrel with low molecular weight heparin).

PREVENTION/AVOIDANCE

Avoid stressful situations that might precipitate CHF.

POSSIBLE COMPLICATIONS

- Heart failure.
- ATE and paralysis.
- Cardiac arrhythmias/sudden death.

EXPECTED COURSE AND PROGNOSIS

- Animals homozygous for MyBPC mutations more likely to develop severe HCM and at earlier age than heterozygous animals.
- Prognosis varies considerably, probably because there are multiple causes. In one study of cats with HCM living at least 24 hours following presentation:
  - Asymptomatic cats—median survival 563 days (range: 2–3,778 days).
  - Cats with syncope—median survival 654 days (range: 28–1,505 days).
  - Cats with CHF—median survival 563 days (range: 2–4,418 days).
  - Cats with ATE—median survival 184 days (range: 2–2,278 days).
  - Older age and larger left atria predicted shorter survival.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Aortic thromboembolism.

PREGNANCY/FERTILITY/BREEDING

- High risk of complications.
- Avoid aspirin.

CARDIOMYOPATHY, HYPERTROPHIC—DOGS

BASICS

OVERVIEW

Hypertrophic cardiomyopathy (HCM) is defined as inappropriate myocardial hypertrophy of a nondilated left ventricle, occurring in the absence of an identifiable stimulus. HCM is rare in dogs, and is characterized by left ventricular (LV) concentric hypertrophy (increased wall thickness). The primary disease process is confined to the heart and only affects other organ systems when congestive heart failure (CHF) is present. Increased LV wall thickness leads to impaired ventricular filling (due to lack of compliance and abnormal relaxation), with resultant increases in LV end-diastolic pressure and left atrial (LA) pressure. LA enlargement is usually in response to increased LV end-diastolic pressure. Mitral insufficiency and/or dynamic LV outflow tract obstruction commonly occur secondary to structural and/or functional changes of the mitral valve apparatus caused by papillary muscle malalignment due to hypertrophy.

SIGNALMENT

- The incidence of HCM in dogs is very low, thus accurate accounts of signalment are lacking.
- Young (<3 years) male dogs.
- Rottweiler, Dalmatian, German shepherd, pointer breeds and Boston terriers have been reported.

SIGNS

Historical Findings

- Most are asymptomatic.
- Signs of left CHF predominate in symptomatic dogs.
- Syncope, generally during activity or exercise.
- Sudden death is the most commonly reported clinical sign.

Physical Examination Findings

- ± Systolic heart murmur.
- ± Gallop heart sound.
- ± Signs of left CHF (e.g., dyspnea, cyanosis, exercise intolerance, cough).

CAUSES & RISK FACTORS

The cause of canine HCM is unknown. Genetic abnormalities in genes coding for myocardial contractile proteins have been documented in humans and cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Systemic hypertension.
- Infiltrative cardiac disorders.
- Thyrotoxicosis.
- Mitral dysplasia.

IMAGING

Radiography

- May be normal or may show LA or LV enlargement.
- Pulmonary edema present with left CHF.

Echocardiography

- Severe cases usually have marked LV and papillary muscle hypertrophy, and LA enlargement. Hypertrophy is usually global, but can be more regional or segmental (asymmetric). Milder forms may have subtle LV hypertrophy.
- Systolic anterior motion of the mitral valve, suggesting dynamic LV outflow tract obstruction (LVOTO), is common in dogs with HCM.

DIAGNOSTIC PROCEDURES

ECG

- May be normal.
- ST segment and T wave abnormalities have been reported.
- Atrial or ventricular ectopic arrhythmias may rarely occur.

Blood Pressure

Usually normal. Should be evaluated to rule out systemic hypertension as the cause of LV hypertrophy.

PATHOLOGIC FINDINGS

- Abnormal heart : body weight ratio.
- LV concentric hypertrophy.
- The interventricular septum may have an impact lesion, varying from a small opaque lesion to a thickened plaque.
- The mitral valve is often thickened and elongated.
- Varying degrees of LA enlargement may be present.

TREATMENT

Treatment is generally only pursued if there is evidence of CHF, severe arrhythmias, or frequent syncope. Exercise restriction and sodium restriction are beneficial.

MEDICATIONS

DRUG(S) OF CHOICE

- In patients with left CHF, diuretics and angiotensin-converting enzyme (ACE) inhibitor therapy are advocated.
- In dogs with severe dynamic LVOTO, administration of beta blockers or calcium channel blockers has been advocated; however, benefit has not been proven.
- Beta blockers or calcium channel blockers may also improve myocardial oxygenation, reduce heart rate, improve LV diastolic function, and control arrhythmias, and therefore may be useful in dogs with left CHF; however, benefit has also not been proven.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Positive inotropes may worsen dynamic LVOTO.
- Avoid calcium channel blockers in combination with beta blockers, as clinically significant bradyarrhythmias can develop.
- Avoid potent arteriolar dilators in cases with dynamic LVOTO. The use of milder vasodilators such as ACE inhibitors in dogs with CHF is generally well tolerated.

FOLLOW-UP

- Depends on clinical severity. Serial radiography and/or echocardiography may help characterize disease progression and guide medication adjustments.
- Due to the rarity of canine HCM, prognostic information is lacking. In dogs with severe CHF or other complications, prognosis is generally guarded.

MISCELLANEOUS

ABBREVIATIONS

- ACE = angiotensin-converting enzyme.
- CHF = congestive heart failure.
- HCM = hypertrophic cardiomyopathy.
- LA = left atrial.
- LV = left ventricular.
- LVOTO = left ventricular outflow tract obstruction.

CARDIOMYOPATHY, NUTRITIONAL

BASICS

OVERVIEW

• Nutritional imbalances, such as taurine and L-carnitine deficiency, can lead to the development of dilated cardiomyopathy (DCM) in some dogs and cats. Deficiencies of other nutrients (e.g., selenium, zinc, vitamin E, thiamine, copper, iron) or nutrient toxicities (e.g., iron, cobalt) also have the potential to alter myocardial function, resulting in clinical manifestations of heart disease. Additionally, relative nutritional deficiencies or toxicities may interact with other toxic, infectious, or genetic insults in certain individuals to produce DCM.

• Taurine is the most abundant free amino acid found in cardiac muscle, playing an important role in myocardial calcium regulation. Taurine deficiency was first reported as a cause of reversible DCM in cats in 1987, prompting an increase in the dietary taurine requirement for commercial cat foods, and since then DCM in cats is uncommon. Unlike cats, dogs should be able to endogenously synthesize taurine; however, several breeds (e.g., American cocker spaniel, Newfoundland, Irish wolfhound, golden retriever) have reported predispositions to taurine deficiency and resultant DCM. Additionally, some commercial dog foods such as grain-free, high-legume, lamb and rice formulations and high-fiber foods, have been associated with taurine deficiency. Oral taurine supplementation can effect disease reversal in deficient cats and significant improvement in dogs.

• L-carnitine, a quaternary amine, is an important part of enzyme systems that transport fatty acids into mitochondria for oxidization to make energy. It also has other important cellular metabolic and scavenging functions. Carnitine deficiency complicates some cases of DCM in dogs. Plasma L-carnitine deficiency in association with cardiomyopathy does not mean that the deficiency is the sole cause of the myopathy, although correcting the deficiency, if possible, makes medical and physiologic sense. In the dog, dietary carnitine intake influences plasma concentrations significantly, and oral carnitine supplementation is usually an effective means of raising plasma and subsequently muscle carnitine levels.

• A perceived increase in recognition of DCM in dogs eating boutique, exotic-ingredient, or grain-free (BEG) dog foods in 2018 prompted an FDA investigation into a possible relationship between BEG diets and canine DCM. The majority of affected dogs eating BEG diets do not appear to be taurine or L-carnitine deficient; however, golden retrievers appear to be more susceptible to taurine deficiency when eating these foods. The underlying cause has not yet (as of writing) been identified, and causation has not been proven. Nutritional management, involving diet change and in some cases taurine supplementation, has resulted in improvement or resolution of cardiomyopathy over a period of 3–12 months. Investigations are ongoing.

SIGNALMENT

Dogs

• Golden retrievers, American cocker spaniels, Newfoundlands, English setters, St. Bernards, and Irish wolfhounds are reported to be predisposed to taurine-deficient DCM.

• L-carnitine deficiency has been reported in a family of boxers.

• Dogs eating BEG diets that are affected with suspected nutritional DCM have been of varied ages and breeds.

Cats

Taurine deficiency is rare in cats fed commercial, nutritionally balanced diets. Taurine-deficient DCM can occur in cats fed vegetarian or home-prepared diets.

SIGNS

• Clinical signs of taurine-deficient DCM are related to poor myocardial contractility, which can lead to congestive heart failure in some cases; these signs include lethargy, weakness, syncope, dyspnea and tachypnea.

• Cats may also present for reproductive failure, poor growth, or blindness due to central retinal degeneration.

• Clinical signs of carnitine deficiency can be diverse, ranging from clinical manifestations of DCM to skeletal muscle pain and exercise intolerance.

• See Cardiomyopathy, Dilated—Dogs.

CAUSES & RISK FACTORS

• Vegetarian and home-prepared diets increase the risk of taurine-deficient DCM in cats if taurine is not exogenously supplemented adequately.

• Factors predisposing to taurine deficiency in dogs include breed (possible genetic causes) and dietary components; high-fiber diets, low-protein diets, lamb and rice diets, and beet pulp ingredients have been associated with taurine deficiency; dietary predisposition to taurine deficiency with these factors could be a result of inadequate taurine precursors (methionine and cysteine), low bioavailability of taurine and/or precursors, reduced entero-hepatic bile acid recycling due to high dietary fiber, excessive urinary taurine wasting, or gastrointestinal microbial interaction with taurine.

• Some dogs with DCM have been documented to have carnitine transport defects, in which muscle carnitine is low despite adequate plasma concentrations. In cases in which a mitochondrial enzyme defect causes the accumulation of a metabolite to toxic levels within the mitochondria (e.g., multiple Co-A dehydrogenase defects), free L-carnitine is used to "scavenge" potentially toxic excess metabolites, which appear harmlessly in the plasma and eventually the urine as carnitine esters; in these cases, the total amount of carnitine (free carnitine plus that esterified to other molecules) in the plasma or muscle may be normal or even high, but the ratio of free to esterified carnitine is decreased; this situation is known as carnitine insufficiency (since although the concentration of free carnitine may be within the normal range, it is insufficient to meet the body's pathologically increased need for free carnitine).

• Certain families of boxers appear to be at especially high risk of developing symptomatic DCM in association with, and probably caused by, carnitine deficiency; a known first-degree relative with cardiomyopathy should increase the index of suspicion.

• The cause of the apparent, although unproven, link between BEG diets and canine DCM is unknown; however, the commonality of ingredients in these diets has drawn the attention of veterinary nutritionists; the high legume content of these foods (e.g., lentils and peas), less studied protein sources (e.g., kangaroo, alligator, bison), and other unusual ingredients (e.g., flaxseed) raise the possibility of a nutrient deficiency, toxicity, or nutrient–nutrient interaction that may predispose to the development of DCM in some dogs.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY TESTS

• Ideally, both whole blood and plasma taurine concentrations should be evaluated to assess for taurine deficiency in any dog with DCM; if only one blood sample can be analyzed, whole blood is considered a better indicator of long-term taurine status. Blood for taurine concentrations should be drawn into lithium heparin tubes and frozen immediately. The normal whole blood taurine concentration range for dogs (200–350 nmol/mL) has been questioned recently, especially in golden retrievers, where normal has been proposed to be 213–377 nmol/mL. Historically, taurine-deficient DCM is diagnosed when whole blood concentrations are <150 nmol/mL in dogs and <200 nmol/mL in cats, or when plasma taurine concentrations are <40 nmol/mL in both species; values ≤213 nmol/mL (whole blood) and ≤63 nmol/mL (plasma) have been proposed for DCM diagnosis in golden retrievers.

• Plasma carnitine concentrations appear to be a specific but insensitive indicator of

CARDIOMYOPATHY, NUTRITIONAL (CONTINUED)

myocardial or skeletal muscle carnitine deficiency. Plasma free carnitine concentrations of less than 8 µmol/L are considered diagnostic of systemic carnitine deficiency; plasma concentrations in the normal or supernormal range do not rule out myocardial carnitine deficiency or insufficiency.
• There is no confirmatory laboratory test currently available to diagnose nutritional DCM associated with BEG diets; dogs should be assessed for taurine and carnitine deficiency, and the diagnosis is solidified by response to nutritional management.

IMAGING
Echocardiography is used to diagnose DCM.

DIAGNOSTIC PROCEDURES
• Endomyocardial biopsy is the gold standard to assess myocardial carnitine levels, since plasma carnitine concentrations are an insensitive indicator of muscle carnitine deficiency.
• Myocardial free carnitine concentrations <3.5 nmol/mg of noncollagenous protein are considered diagnostic of myocardial carnitine deficiency.
• Ratio of esterified to free carnitine >0.4 is considered diagnostic of carnitine insufficiency.

TREATMENT
• Response to nutritional manipulation and supplementation can take months, so patients will require medications to support myocardial function (e.g., pimobendan), antagonize neurohormonal activation (e.g., angiotensin-converting enzyme inhibitors and spironolactone), and diuretic therapy if congestive heart failure is present (e.g., furosemide).
• Taurine supplementation if taurine deficiency is diagnosed; if blood concentrations are not measured, it is reasonable to trial with supplementation and assess response to treatment; taurine deficiency associated with DCM in American cocker spaniels is reported to respond to both taurine and L-carnitine supplementation.
• Treatment with L-carnitine is indicated in addition to conventional treatment for DCM; however, some dogs, including some families of carnitine-deficient boxers, fail to respond clinically to supplementation. While supplementation dramatically improves a small percentage of dogs with DCM, the overall efficacy of L-carnitine supplementation for treatment of DCM is untested. If a trial of metabolic supplementation is desired in the absence of known L-carnitine deficiency, the combination of L-carnitine with taurine and CoQ10 (100 mg as ubiquinol q8–12h) seems prudent.
• Transition to a high-quality, scientifically backed, grain-based food with a well-studied protein source is critical to the recovery of nutritional DCM associated with BEG diets. The role of taurine supplementation in the absence of deficiency is uncertain; however, there is no known detriment to empiric supplementation, and taurine may have therapeutic benefits apart from correction of deficiency.

MEDICATIONS
DRUG(S) OF CHOICE
Taurine
• Dogs—250 mg PO q12h if <10 kg; 500 mg PO q12h if 10–25 kg; 1000 mg PO q12h if >25 kg.
• Cats—250 mg PO q12h.

L-Carnitine
• Large-breed dogs—2 g (approximately 1 tsp L-carnitine powder) q8–12h.
• American cocker spaniels—(in combination with taurine) 1 g (approximately 0.5 tsp L-carnitine powder) q8–12h.

FOLLOW-UP
Repeat echocardiogram 3–6 months after nutritional manipulation, including amino acid supplementation and/or diet change. Improvement in myocardial function may take up to a year for dogs with nutritional cardiomyopathy.

MISCELLANEOUS

CARDIOMYOPATHY, RESTRICTIVE—CATS

BASICS

DEFINITION

A rare, primary heart muscle disease characterized *functionally* by severe diastolic dysfunction with restrictive left ventricular (LV) filling and normal to near normal systolic function, *morphologically* by a nondilated, nonhypertrophied left ventricle with increased endocardial and/or myocardial fibrosis and severe atrial enlargement, and *clinically* by congestive heart failure (CHF), thromboembolic disease, and cardiac death.

PATHOPHYSIOLOGY

• Increased cardiomyofilament Ca^{2+} sensitivity leading to severely impaired myocardial relaxation, high myocardial stiffness due to endomyocardial fibrosis (endomyocardial type) and/or interstitial fibrosis (myocardial type), and disorganized myofiber architecture (disarray) are main characteristics of primary restricted cardiomyopathy (RCM); RCM-like myocardial changes and clinical syndromes can result from myocardial remodeling and dysfunction secondary to other causes (e.g., endomyocarditis, immune-mediated disease, or end-stage hypertrophic cardiomyopathy). • Diastolic heart failure and cardiogenic arterial thromboembolism (ATE) lead to high mortality.

SYSTEMS AFFECTED

• Cardiovascular. • Respiratory.

GENETICS

Primary RCM can be a spontaneous or familial disease, but is generally considered of genetic cause in humans with an autosomal dominant pattern of inheritance; several genes encoding sarcomeric and nonsarcomeric proteins can be affected; RCM-causing mutations have not been identified in cats.

INCIDENCE/PREVALENCE

Primary feline RCM is rare—prevalence ranging from 1% to 5% of all myocardial diseases in cats.

SIGNALMENT

• Cats. • Higher prevalence in Siamese and oriental cats. • Middle-aged to older cats. • Male predisposition.

SIGNS

Historical Findings

• Lethargy. • Weight loss. • Paresis or paralysis (i.e., signs of ATE). • Labored breathing. • Tachypnea. • Ascites. • Jugular venous distension. • Cyanosis.

Physical Examination Findings

• If not in CHF—arrhythmias. ○ Prominent gallop sounds are a hallmark. ○ Heart murmur uncommon. • If in CHF—above signs plus the following: ○ Tachypnea. ○ Labored breathing. ○ Cyanosis. ○ Hepatomegaly or ascites with jugular venous distention. ○ Pulmonary crackles. ○ Muffled cardiac or respiratory sounds if pleural effusion. ○ Paralysis or paresis with loss of femoral pulses; one or more extremities cold and painful (ATE).

CAUSES

• Primary RCM—currently unknown; genetic cause documented in humans.
• Secondary RCM—late or end stage of underlying disease (e.g., hypertrophic cardiomyopathy); link between prior interstitial pneumonia and feline endomyocarditis leading to RCM suspected in one study.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Advanced stages of other feline cardiomyopathies: ○ Hypertrophic, dilated, arrhythmogenic right ventricular, non-specific phenotype, and tachycardia-induced cardiomyopathy. ○ Myocardial infarct. ○ CHF secondary to thyrotoxicosis or hypertensive heart disease.

CBC/BIOCHEMISTRY/URINALYSIS

Routine chemistry panel and urinalysis helpful to document concurrent or complicating conditions (e.g., renal failure and potassium depletion).

OTHER LABORATORY TESTS

• Plasma T_4 concentration in cats ≥6 years old. • Plasma cardiac troponin I concentration (more specific if ischemic heart disease or myocarditis suspected).

IMAGING

Thoracic Radiography

• Cardiomegaly with severe biatrial enlargement ("valentine" heart on v/d projections). • Interstitial or alveolar infiltrates or pleural effusion with pulmonary venous distention if in CHF.

Echocardiography

• *Note:* definitive diagnostic criteria are *poorly* defined and remain controversial. Early (noncongestive) RCM has rarely been documented in cats. • Anatomic findings characterizing the RCM phenotype include: ○ Severe biatrial enlargement. ○ Nonhypertrophied, nondilated left ventricle (normal chamber dimension, normal wall thickness). ○ Severe enlargement of the left atrium with spontaneous echocardiographic contrast or thrombi frequently seen. ○ Prominent, often diffuse echogenic scar ("moderator bands," false tendons) leading to a small LV lumen and narrowing at the midventricle (endomyocardial fibrosis or "bridging" fibrosis). ○ Focal areas of highly echogenic and often thin myocardium indicative of ischemia or scarring. ○ Myocardium can appear normal with pure myocardial form of RCM. ○ Pleural effusion and pericardial effusion may be present.
• Functional findings (echocardiographic): ○ Severe LV diastolic dysfunction on Doppler echocardiography—restrictive LV filling with a peak velocity of early : late transmitral flow (E : A) ratio >2.0, short isovolumic relaxation time (<37 msec), shortened deceleration time of E (<45 msec), low peak velocity of mitral annular motion (E′), and E : E′ ≫15. ○ Normal to low normal LV systolic function (in some cases LV systolic dysfunction is present). ○ Regional wall motion abnormalities possible. ○ Left atrial dysfunction. ○ Severe left atrial appendage enlargement with evidence of blood stasis. ○ Midventricular obstruction with flow turbulence in cats with bridging endomyocardial fibrosis. ○ In cats with other causes of restrictive physiology, characteristics of the underlying disease can predominate; however, severe atrial enlargement and restrictive LV filling will be present in nearly all cats.

DIAGNOSTIC PROCEDURES

ECG

• *Note*: ECG findings are neither sensitive nor specific. • Sinus tachycardia is common, but cats with severe CHF and hypothermia may be bradycardic. • Ventricular or supraventricular ectopic beats, paroxysmal or sustained supraventricular or ventricular tachycardia, or atrial fibrillation. • Atrial or ventricular enlargement patterns. • ST segment changes.

Pathology

• *Note*: histopathologic confirmation is needed to diagnose RCM. • Increased heart weight (>19 g). • Severe biatrial dilatation. • Locally or diffusely thickened opaque endocardium. • False tendons ("moderator bands") present in some cats. • Normal luminal size of the left and right ventricles. • Diffuse or focal cardiomyocyte disarray. • Increased interstitial and replacement fibrosis. • Abnormal intramural coronary arterioles with medial hypertrophy and narrowed lumen. • Increased number of inflammatory cells seen only in cats with acute endomyocarditis—this finding is commonly absent in cats with endocardial fibrosis.

TREATMENT

APPROPRIATE HEALTH CARE

• Patients with severe CHF are hospitalized for emergency care. • Mildly symptomatic animals can be treated with outpatient medical management.

NURSING CARE

• Cats with respiratory distress should receive oxygen. • Sedation is usually beneficial. • Thoracocentesis if relevant pleural effusion. • Maintain a low-stress environment (e.g., cage rest, minimize handling). • Heating pad for hypothermic patients. • Respiratory rate should be used to monitor immediate treatment success.

CARDIOMYOPATHY, RESTRICTIVE—CATS (CONTINUED)

ACTIVITY
Cage rest for CHF patients.

DIET
In acute heart failure, maintain intake with hand feeding if necessary.

CLIENT EDUCATION
Owner should be counseled regarding technique of pill administration in cats, possible adverse effects of medications, importance of maintaining stable food and water intake, and monitoring their cat's resting respiratory rate at home.

MEDICATIONS

DRUG(S) OF CHOICE

Acute CHF
• Parenteral administration of furosemide (1–2 mg/kg IV/IM/SC q2–6h); CRI may be considered. • Dermal application of nitroglycerin ointment (2%, one-fourth inch q12h). • Oxygen delivered by cage, mask, nasal prongs, or flow-by. • Thoracocentesis if relevant pleural effusion. • Dobutamine only if cats are hypotensive (systolic blood pressure <90 mmHg); 1–5 µg/kg/minute as CRI, start a lower dose and increase over 0.5–1h. • Severe supraventricular tachyarrhythmias can be treated with diltiazem CRI (2–6 µg/kg/min IV). • Ventricular tachycardia may resolve with resolution of CHF. • Acute therapy of ventricular tachycardia may include lidocaine (0.25–0.5 mg/kg IV *slowly*); monitor closely for neurologic signs of toxicity. • Pimobendan (0.25 mg/kg PO q12h) may be helpful to increase cardiac performance in acute heart failure, but is only used in animals that cannot be stabilized and systemic hypotension cannot be corrected. *Note*: pimobendan is not approved for clinical use in cats and clinical safety and efficacy data are limited. • Antiplatelet medication (clopidogrel bisulfate 18.75 mg PO q24h) or anticoagulants (e.g., unfractionated heparin 150–250 IU/kg SC q6h) may be administered, in particular in cats with severe left atrial enlargement and spontaneous echocardiographic contrast.

Chronic Therapy
• Furosemide is gradually decreased to lowest effective dose. • Angiotensin-converting enzyme (ACE) inhibitors may reduce fluid retention, decrease the need for diuretics, and counterbalance adverse effects of diuretics (e.g., enalapril 0.25–0.5 mg/kg PO q12–24h). • Diltiazem (1.5–2.5 mg/kg regular diltiazem or 10 mg/kg q24h extended-release diltiazem) decreases heart rate and improves supraventricular arrhythmias in affected cats; the addition of digoxin (0.007 mg/kg PO q48h) may allow better control of ventricular response rate in cats with atrial fibrillation; cats with hemodynamically important ventricular and supraventricular ectopy can also benefit from sotalol (1.0–2.0 mg/kg PO q12h). • Pimobendan (0.25 mg/cat PO q12h) may be helpful in the management of chronic heart failure; *note*: pimobendan is not approved for clinical use in cats. • Treat associated conditions (e.g., dehydration, hypothermia, hypokalemia). • Clopidogrel (one-fourth of a 75 mg tablet PO q24h) to inhibit platelets chronically; aspirin (25 mg/kg PO q72h) may also be considered, but efficacy is questionable; in cases of echogenic smoke or prior ATE, dual platelet inhibition (clopidogrel and aspirin) may be used. • Addition of low molecular weight heparin (enoxaparin [Lovenox®] at 1–2 mg/kg q12h SC) may be considered in cats at high risk for thromboembolic disease; apixaban (Eliquis®) at 0.625 mg/cat q12h in cats <5 kg bodyweight and 1.25 mg/cat q12h in cats ≥5 kg has been recommended, but published evidence is not available. • Treatment of cats with preclinical RCM has rarely been reported, but includes ACE inhibitors and antiplatelet drugs; there is currently no specific drug for LV diastolic dysfunction.

CONTRAINDICATIONS
• Beta blockers should never be administered in cats with RCM. • For diltiazem—bradycardia, atrioventricular block, myocardial failure, and hypotension. • For furosemide—severe dehydration, severe hypokalemia, and moderate to severe azotemia. • For ACE inhibitors—moderate to severe azotemia, hypotension, and hyperkalemia.

POSSIBLE INTERACTIONS
• Combination of ACE inhibitors and furosemide—hypotension and renal failure. • Chronic aspirin therapy may increase risk of renal side effects of ACE inhibitors and may lead to inappetence and gastrointestinal upset. • Combining antiplatelets and anticoagulants may increase risk of bleeding.

FOLLOW-UP

PATIENT MONITORING
• Frequent physical reexaminations to assess response to treatment. • Frequent reevaluation of hydration status and renal function, particularly in first few days of therapy to avoid dehydration, hypokalemia, and azotemia. • Repeated thoracocentesis if necessary. • "Hands-off" hourly assessment of respiratory rate in first 12–24 hours can be used to monitor efficacy of CHF therapy. • Radiographs may be repeated in 12–24 hours to monitor pulmonary infiltrate resolution. • Repeat physical examination and analysis of blood biochemistries after 3–7 days' treatment of acute CHF. • Stable patients reevaluated every 2–4 months or more frequently if problems occur.

PREVENTION/AVOIDANCE
No known preventative measures for RCM.

POSSIBLE COMPLICATIONS
Tissue necrosis or loss of function in limbs affected by thromboembolic complications, adverse effects of medications, sudden death, and euthanasia due to refractory heart failure.

EXPECTED COURSE AND PROGNOSIS
Variable, but most cats have a grave prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Aortic thromboembolism and CHF.

AGE-RELATED FACTORS
Hyperthyroidism should be ruled out with appropriate testing in feline patients with heart disease ≥6 years of age.

SYNONYMS
• Intermediate cardiomyopathy. • Unclassified cardiomyopathy.

SEE ALSO
• Aortic Thromboembolism. • Congestive Heart Failure, Left-Sided. • Congestive Heart Failure, Right-Sided.

ABBREVIATIONS
• A = peak velocity of late transmitral flow. • ACE = angiotensin-converting enzyme. • ATE = arterial thromboembolism. • CHF = congestive heart failure. • E = peak velocity of early transmitral flow. • E′ = peak velocity of mitral annular motion. • LV = left ventricular. • RCM = restrictive cardiomyopathy.

CARDIOPULMONARY ARREST

BASICS

DEFINITION
• Cessation of effective perfusion and ventilation because of loss of coordinated cardiac and respiratory function.
• Cardiac arrest invariably follows respiratory arrest if not recognized and corrected.

PATHOPHYSIOLOGY
• Generalized or cellular hypoxia may be cause or effect of sudden death.
• After 1–4 minutes of airway obstruction, breathing efforts stop while circulation remains intact.
• If obstruction continues for 6–9 minutes, severe hypotension and bradycardia lead to dilated pupils, absence of heart sounds, and lack of palpable peripheral pulse.
• After 6–9 minutes, myocardial contractions cease even though ECG may look normal—pulseless electrical activity (formerly electrical mechanical dissociation).
• Ventricular fibrillation, ventricular asystole, and pulseless electrical activity are rhythms indicating cessation of myocardial contractility.

SYSTEMS AFFECTED
• All systems are affected, but those requiring greatest supply of oxygen and nutrients affected first.
• Cardiovascular.
• Renal/urologic.
• Neurologic.

SIGNALMENT
• Dog and cat.
• Any age, breed, or sex.

SIGNS
• Lack of response to stimulation.
• Loss of consciousness.
• Dilated pupils.
• Cyanosis.
• Agonal gasping or absence of ventilation.
• Absence of peripheral pulses.
• Hypothermia.
• Absence of audible heart sounds.

CAUSES
• Hypoxemia caused by ventilation–perfusion mismatch, diffusion barrier impairment, hypoventilation, or shunting.
• Poor oxygen delivery due to anemia or vasoconstriction.
• Myocardial disease—infectious, inflammatory, infiltrative, traumatic, neoplastic, or embolic.
• Acid-base abnormalities.
• Electrolyte derangements—hyperkalemia, hypocalcemia, and hypomagnesemia.
• Hypovolemia.
• Shock.
• Anesthetic agents.
• Sepsis/septic shock.
• CNS trauma.
• Electrical shock.

RISK FACTORS
• Cardiovascular disease.
• Respiratory disease.
• Trauma.
• Anesthesia.
• Septicemia.
• Endotoxemia.
• Ventricular arrhythmias—ventricular tachycardia, R on T phenomenon, multiform ventricular complexes.
• Increased parasympathetic tone—gastrointestinal disease, respiratory disease, manipulation of eyes, larynx, or abdominal viscera.
• Prolonged seizing.
• Invasive cardiovascular manipulation—pericardiocentesis, surgery, angiography.

DIAGNOSIS

• Sudden cardiovascular collapse associated with inadequate cardiac output leading to severe consequences.
• Quick assessment and diagnosis are critical.
• Assess the ABCs—airway, breathing, circulation.

DIFFERENTIAL DIAGNOSIS
• Severe hypovolemia and absence of palpable pulses.
• Pericardial effusion with cardiac tamponade, decreased cardiac output, and muffled heart sounds.
• Pleural effusion with respiratory arrest.
• Respiratory arrest can be confused with cardiopulmonary arrest (CPA).
• Upper airway obstruction can rapidly progress to CPA.

CBC/BIOCHEMISTRY/URINALYSIS
May help identify underlying cause for CPA, but should not be part of initial triage.

OTHER LABORATORY TESTS
• Arterial blood gas evaluation may be useful during or after resuscitative procedures, but is not part of initial emergency management.
• Venous blood gas evaluation may be more useful during cardiopulmonary resuscitation (CPR) than arterial blood gas and provides electrolyte and lactate concentrations.

IMAGING
• Thoracic/abdominal focused assessment with sonography for trauma (TFAST®/AFAST®) may be useful in identifying underlying disease; additional terminology being introduced, such as POCUS (point of care ultrasound) and eFAST (extended FAST).
• Thoracic or abdominal radiographs or abdominal ultrasound may help identify underlying disease processes, but only consider after patient has been stabilized.
• Echocardiography may confirm pericardial effusion or underlying myocardial disease, but should not interfere with resuscitative procedures.

DIAGNOSTIC PROCEDURES
Once CPA has developed, continuous ECG monitoring, blood pressure monitoring, pulse oximetry, and capnography are useful in monitoring effectiveness of resuscitative procedures.

TREATMENT

Institute CPR immediately upon diagnosing CPA; CPR in veterinary patients should follow Reassessment Campaign on Veterinary Resuscitation (RECOVER) evidence-based guidelines, published in 2012 and divided into five domains. It is recommended the reader read the original publication.

Basic Life Support (Domain 2)

Immediate Recognition of CPA

If patient is identified as being nonresponsive and apneic, start CPR immediately, do not take time to confirm via palpation of pulse or ECG.

Chest Compressions

• Perform CPR in continuous, uninterrupted, 2-minute cycles when possible.
• Use the cardiac pump in patients weighing <10 kg bodyweight; with the patient in right lateral recumbency, perform compressions directly over the heart (intercostal spaces 3–5); this can be performed using one or two hands.
• Use the thoracic pump for patients weighing >10 kg bodyweight; with the patient in right lateral recumbency, apply thoracic compressions at the widest portion of the thorax.
• Different compression and ventilation regimes have been reported.
• Providing appropriate compressions (100–120 per minute) and appropriate ventilations (10 per minute) without stopping compressions for ventilations and without trying to synchronize ventilations with compressions is the goal; the chest should be displaced ~30–50%.
• Try to minimize discontinuing compressions to interpret ECG.
• Avoid leaning on the patient during chest compressions and allow full chest wall recoil.
• Interposing abdominal compressions between chest compressions enhances cerebral and coronary blood flow by increasing aortic diastolic pressure; this technique has not been shown to improve survival, but should be considered if adequate personnel are available.

Airway and Ventilation

• Visualize the airway by extending the patient's head and neck and pulling the tongue forward; clear any debris (e.g., secretions,

CARDIOPULMONARY ARREST (CONTINUED)

blood, or vomitus) manually or with suction; use of a laryngoscope is advised.
• Establish an airway by either oral endotracheal intubation or, if complete obstruction, emergency tracheostomy.
• Correct endotracheal tube placement should be confirmed visually, by auscultation and/or capnography.
• 10 breaths per minute with a tidal volume of 10 mL/kg and an inspiratory time of 1 second; peak airway pressures should not exceed 20 cm H_2O.
• Techniques for ventilation include mouth to mouth, mouth to nose, or mouth to endotracheal tube; these techniques provide ~16% oxygen; use of a mechanical resuscitator (Ambu® bag) and room air provides 21% oxygen.
• The preferred technique is endotracheal intubation and ventilation with 100% oxygen using an Ambu bag or an anesthesia machine.
• The suggested rate of oxygen administration is 150 mL/kg/minute.

Circulation
• Assessment—palpate peripheral pulses and auscultate heart to confirm CPA.
• External thoracic compression provides at best ~30% of normal cardiac output; internal cardiac compression is two to three times more effective in improving cerebral and coronary perfusion.

Open-Chest CPR
• Indicated if closed-chest CPR is ineffective or preexisting conditions such as flail chest, obesity, diaphragmatic hernia, pericardial effusion, or other significant intrathoracic disease preclude closed-chest techniques.
• Perform through a left thoracotomy at the fifth or sixth intercostal space.
• Perform a pericardectomy.
• The palmar surface of the fingers and thumb is used to push the ventricular blood toward the great vessel; digital compression of the descending aorta may help improve coronary and cerebral perfusion.

Advanced Life Support (Domain 4)
This includes drug therapy and additional resuscitation techniques. Drugs should be administered every other CPR cycle (~q4 minutes).

Epinephrine
• Epinephrine low dose—0.01 mg/kg IV (1 : 10,000) 1 mL/10 kg patient.
• Epinephrine high dose—0.1 mg/kg IV (1 : 1000) can be used in protracted CPR.

Vasopressin
May be used as alternative to epinephrine 0.8 U/kg IV (20 U/ml; ~0.5 ml/10 kg patient); may be used in combination with epinephrine, especially if protracted CPR.

Atropine
• Atropine—0.04 mg/kg IV (0.4 mg/mL) 1 mL/10 kg patient.
• Limited data to suggest benefit unless arrest is due to increased vagal tone.

Fluids
Administer fluids cautiously unless known hypovolemia has led to CPA. Crystalloids, colloids, or blood products may be considered, including Oxyglobin®.

MEDICATIONS

DRUG(S) OF CHOICE
• See Advanced Life Support.
• Administer drugs via intravenous, intraosseous, or intratracheal routes in descending order of preference; volumes should be doubled if administering via the intratracheal route and diluted in saline.
• Intracardiac administration should not be used unless open-chest CPR is being performed; administration of epinephrine into the left ventricle with concurrent digital or mechanical compression of descending aorta is optimal.

PRECAUTIONS
Fluid administration should be used cautiously and only if there is a known history of hypovolemia; excessive fluid administration may lead to decreased coronary perfusion.

FOLLOW-UP

PATIENT MONITORING
• Maintain normal heart rate and blood pressure with fluids and inotropic agents.
• Arterial blood pressure.
• Central venous pressure.
• Blood gas analysis.
• Support respiration with artificial ventilation and supplemental oxygen.
• Neurologic status—if signs of increased intracranial pressure develop, consider mannitol, corticosteroids, and furosemide.
• ECG—continuously.
• Urine output.
• Body temperature.
• Radiograph thorax to assess resuscitative injury.
• Diagnose and correct factors that led to initial CPA.

PREVENTION/AVOIDANCE
Careful monitoring of all critically ill patients.

POSSIBLE COMPLICATIONS
• Vomiting.
• Aspiration pneumonia.
• Fractured ribs or sternebrae.
• Pulmonary contusions and edema.
• Pneumothorax.
• Acute renal failure.
• Neurologic deficits.
• Cardiac arrhythmias.

EXPECTED COURSE AND PROGNOSIS
• Prognosis depends on underlying disease process.
• Rapid return to spontaneous cardiac and respiratory function improves the prognosis.
• Overall prognosis is poor; <10% of patients are discharged.

MISCELLANEOUS

ZOONOTIC POTENTIAL
None

SYNONYMS
• For CPA—cardiac arrest, heart attack.
• For CPR—cardiopulmonary cerebral resuscitation (CPCR).

SEE ALSO
• Ventricular Fibrillation.
• Ventricular Standstill (Asystole).

ABBREVIATIONS
• CPA = cardiopulmonary arrest.
• CPCR = cardiopulmonary cerebral resuscitation.
• CPR = cardiopulmonary resuscitation.
• FAST = focused assessment with sonography for trauma.
• POCUS = point of care ultrasound.
• RECOVER = Reassessment Campaign on Veterinary Resuscitation.

CATARACTS

BASICS

DEFINITION
Opacification of the lens (focal or diffuse).

PATHOPHYSIOLOGY
- The normal lens is composed of perfectly aligned lens fibers that create a transparent structure. A clear capsule surrounds the cortex and nucleus. New lens fibers are continually produced at the equator of the lens cortex throughout life. The aqueous humor provides nutrition to the lens.
- A cataract occurs when there is derangement of lens fibers due to changes in lens nutrition, energy metabolism, protein synthesis or metabolism, or osmotic balance.
- Anterior uveitis is a common cause of altered lens nutrition.
- Genetics can result in altered protein and energy metabolism, or protein synthesis, in the lens.
- Diabetes mellitus affects the osmotic balance in the lens. Hyperglycemia increases glucose in the aqueous and lens overwhelming the glycolysis pathway; glucose is shunted to the sorbitol pathway; sorbitol creates an osmotic gradient that draws water into the lens and rapid cataract formation. The sorbitol pathway requires aldose reductase enzyme and dogs have more aldose reductase than cats, making cats more resistant to developing diabetic cataracts. The enzyme levels vary between individuals, which may explain dogs that are resistant to cataract development.

SYSTEMS AFFECTED
Ophthalmic

GENETICS
- Inheritance has been established for many dog breeds; the most common mode of inheritance is autosomal recessive.
- Inheritance has been established in the Himalayan cat (autosomal recessive).

INCIDENCE/PREVALENCE
- One of the leading causes of blindness in dogs.
- The prevalence of genetic cataracts varies significantly; up to 10% in some breeds.
- Most diabetic dogs will develop cataracts regardless of their diabetic control.
- Cataracts are rare in cats.

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
Over 135 dog breeds are suspected as being predisposed to hereditary cataracts.

Mean Age and Range
Cataracts can develop at any age; genetic cataracts can develop as early as 6 months of age.

SIGNS

Historical Findings
- Cloudy/white appearance of the lens.
- Vision loss when the cataracts are bilateral and diabetic cataracts with a rapid, bilateral onset.
- Polyuria/polydipsia is noticed prior to cataract development in diabetic dogs.

Physical Examination Findings
- General physical examination findings—unremarkable unless the dog is an undiagnosed diabetic.
- Ophthalmic examination findings—opacification in one or both lenses.
  - Incipient stage—small, focal opacity/opacities in the lens that does not interfere with the view of the fundus; no vision deficits.
  - Immature stage—diffusely cloudy appearance to the lens with the tapetal reflection still visible and some portions of the fundus visible through a dilated pupil; the menace reflex is positive.
  - Mature stage—completely opaque lens with no tapetal reflection visible; blind.
  - Hypermature stage—wrinkled lens capsule, areas of dense white mineralization, may have portions of liquefied cortex (white, sparkly to clear); deep anterior chamber; blind unless there is a large area of clear liquefied cortex.
  - Intumescent mature cataract—opaque, swollen lens usually due to the hyperosmotic effect of diabetes; shallow anterior chamber.

CAUSES
- Hereditary—most common cause in dogs.
- Diabetes mellitus.
- Anterior uveitis—either by altered nutrition of the lens from the abnormal aqueous, or by posterior synechia and inflammatory debris causing opacification of the anterior lens capsule.
- Trauma—perforating injury that disrupts the anterior lens capsule, most commonly a cat claw injury, especially in puppies and kittens.
- Senile—slowly progressive cataract in geriatric animals, usually beginning as dense nuclear sclerosis followed by gradual spoke-like opacities extending into the cortex.
- Congenital—due to heredity, in utero insult, or associated with other congenital ocular anomalies such as persistent pupillary membranes, persistent hyperplastic primary vitreous/persistent tunica vasculosa lentis, or a hyaloid artery attachment.
- Surgery—transpupillary laser energy, intraocular instrument trauma.
- Toxic—long-term ketoconazole therapy; suspected secondary to toxic by-products of degenerating photoreceptors in dogs with progressive retinal atrophy.
- Radiation—when the eye is in the radiation treatment field for neoplasia of the mouth or head.
- Hypocalcemia—can cause bilateral, diffuse punctate or incipient cataracts.
- Nutritional—use of unbalanced milk replacers in bottle-fed puppies and kittens.
- Electrical shock—chewing electrical cords or lightning strike.

RISK FACTORS
- Diabetes mellitus (dogs).
- Chronic anterior uveitis.
- Progressive retinal atrophy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Lenticular nuclear sclerosis—normal aging change in the lens of dogs and cats starting at 6 years of age due to compression of older lens fibers in the center of the lens; gradually becomes more visible with age and can be mistaken for a cataract in geriatric patients; definitive diagnosis can be made using mydriasis (1% tropicamide) and the observation of a perfectly round, bilaterally symmetric, homogeneous nucleus in the center of each lens, and the ability to view the fundus through the lens; vision is rarely affected and treatment is not indicated.

CBC/BIOCHEMISTRY/URINALYSIS
Dogs with diabetic cataracts may have hyperglycemia and glucosuria.

IMAGING
Ocular ultrasound can be used to evaluate the posterior lens capsule for any sign of rupture and can evaluate for retinal detachment prior to cataract surgery.

DIAGNOSTIC PROCEDURES
ERG is performed prior to cataract surgery to evaluate for retinal degeneration when the fundus is not visible due to the cataract.

TREATMENT

ACTIVITY
For safety, blind animals should not be allowed access to an in-ground swimming pool or elevated decks with open railings; use caution near stairs; restrict outside activity to fenced yards or leash walks.

CLIENT EDUCATION
- Cataract surgery is routinely performed, with an overall 80–90% success rate.
- Once the cataracts are removed they cannot return.
- Artificial lens implants will restore essentially normal vision.
- Evaluation for surgery should be done early in the course of cataract development to avoid complications that may result in the cataract becoming inoperable, to allow time to plan

CATARACTS (CONTINUED)

for the surgery, and in some cases to eliminate the need and extra cost for an ocular ultrasound and ERG.

SURGICAL CONSIDERATIONS

- Phacoemulsification (removal of the cataract through a corneal incision using ultrasonic waves to emulsify and aspirate the lens) is the most common technique for cataract removal.
- The ideal time for cataract surgery is the immature/early mature stage.
- Inherited, diabetic, and senile cataracts are potentially good candidates for surgery; cataracts secondary to anterior uveitis are normally poor surgical candidates.
- Artificial intraocular lenses are routinely placed inside the patient's lens capsule; lens implants restore normal focus and help minimize posterior capsular fibrosis; if a lens cannot be implanted (e.g., due to an unstable lens capsule or luxated lens), the dog or cat will still have functional vision.
- Traumatic lens perforation with release of lens cortex into the anterior chamber may require surgery to remove the lens, depending on the size of the capsular tear.

MEDICATIONS

DRUG(S) OF CHOICE

- Topical anti-inflammatory medication is recommended q6–24h to help prevent or treat lens-induced uveitis with immature, mature, and hypermature cataracts; this can be a topical nonsteroidal anti-inflammatory drug (NSAID) such as flurbiprofen, diclofenac, or ketorolac, or a topical steroid such as prednisolone acetate 1% or dexamethasone 0.1%; topical NSAIDs may be preferable in diabetic patients.
- Topical atropine q8–24h is indicated for lens-induced uveitis; *contraindicated with glaucoma*.
- Oral NSAIDs (carprofen, meloxicam, deracoxib) are also used to treat lens-induced uveitis.
- Topical antioxidants are advertised as able to reverse cataract changes; to date there have been no published data conclusively showing a significant reversal, or delay in progression; time spent trying medical therapy will delay evaluation for surgery, resulting in surgery being performed at a suboptimal stage, or complications from the cataract making it inoperable.
- A topical aldose reductase inhibitor, Kinostat®, is in the final stage of FDA approval. When made available, it may prove helpful in delaying the onset of diabetic cataracts in dogs.

FOLLOW-UP

PATIENT MONITORING

- Incipient or early immature cataracts should be monitored regularly for progression in order to select the ideal time for surgery and to avoid complications associated with cataracts.
- Postoperative monitoring by the surgeon is critical for the success of surgery and should be clearly discussed with the owner prior to surgery.

PREVENTION/AVOIDANCE

Do not breed animals with cataracts.

POSSIBLE COMPLICATIONS

- Lens-induced uveitis—associated with hypermature cataracts and cataracts that progress rapidly; caused by antigenic lens proteins leaking through the lens capsule. Clinical signs can be subtle (e.g., low intraocular pressure) to extreme (granulomatous uveitis with aqueous flare, miosis, synechia, keratic precipitates); preoperative uveitis increases postoperative complications.
- Secondary glaucoma—impaired aqueous outflow from intraocular changes associated with lens-induced uveitis, or from an intumescent cataract causing a forward displacement of the iris, narrowing the iridocorneal angle.
- Retinal detachment—associated with hypermature cataracts and cataracts in young dogs with a rapid onset and cortical liquefaction.
- Lens luxation—associated with hypermature cataracts in which the lens and capsule shrink, causing the zonules to stretch and break, resulting in a lens subluxation or luxation.

EXPECTED COURSE AND PROGNOSIS

- Most cataracts are progressive, although the rate of progression can vary widely depending on age, breed, and location of the cataract.
- Long-term prognosis following cataract surgery is very good; however, some patients have increased risk for postoperative complications.
- Those that do not pursue surgery should be monitored for uveitis and glaucoma.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Retinal detachment.
- Lens-induced uveitis.
- Congenital ocular anomalies.

AGE-RELATED FACTORS

- Immediate referral for cataracts in young dogs (<2 years of age) is recommended because the cataract can progress very rapidly, with partial cortical liquefaction followed by retinal detachment.
- Nuclear sclerosis is prominent in geriatric animals; a dilated exam may be necessary to definitively distinguish nuclear sclerosis from cataract.

SEE ALSO

- Anterior Uveitis—Cats.
- Anterior Uveitis—Dogs.
- Diabetes Mellitus Without Complication—Cats.
- Diabetes Mellitus Without Complication—Dogs

ABBREVIATION

- NSAID = nonsteroidal anti-inflammatory drug.

Author Margi A. Gilmour
Consulting Editor Kathern E. Myrna

Client Education Handout available online

CEREBELLAR DEGENERATION

BASICS

OVERVIEW

• Progressive and non-progressive etiologies. Progressive - premature aging and neuronal death; may be due to failure of neuronal energy supply, ion regulation, excitotoxicity, autoimmunity/inflammation, or inappropriate apoptosis; neonatal, postnatal, and adult onset (rare). • Nonprogressive - due to abnormal cerebellar development following in utero or neonatal viral infection in cats (feline panleukopenia) and dogs (canine herpesvirus, canine parvovirus).

SIGNALMENT

Progressive

• Dog and cat. • Described in over 40 dog breeds, often affecting a single family or individual. • Eight causal mutations, all with autosomal recessive mode of inheritance, have been identified. Beagle (onset of clinical signs before 1 month); Finnish hound (2 months), Parson Russell terrier (2 months), Jack Russell terrier (2–12 months) Hungarian Vizsla (3 months); Kerry blue terrier and Chinese crested (3–4 months); Old English sheepdog and Gordon setter (6 months – 3 years). • Immune-mediated disorder described in Coton de Tulear (2 months). • Sporadic reports in miniature poodle (neonatal), papillon (5 months); Scottish terrier, Border Collie, Lagotto Romagnolo, Australian Kelpie, Labrador Retriever, Bavarian mountain dogs, Italian hound (2 months – 1 year); English bulldog (5–8 months); American Staffordshire terrier (2–9 years). • Late onset disorder described in Labrador Retriever, Bern running dog, Irish setter, and Brittany spaniel (signs at 5–13 years). • Cerebellar degeneration and coat color dilution reported in one family of Rhodesian ridgebacks. • X-linked mode of inheritance suspected in English pointer (only males affected). • Both early- (days to weeks) and late- (years) onset in domestic shorthair cat. • Described in two Havana brown kittens from the same litter. Signs observed at one month. Heritable nature suspected.

Nonprogressive

• Two causal mutations identified in two dog breeds. • Non-inflammatory disorder with autosomal recessive mode of inheritance reported in six litters of Coton de Tulear (signs by 2 weeks). • Eurasier dog (2 months).

SIGNS

• Cerebellar ataxia- hypermetria; broad-based stance; swaying of body, intention tremors. • Lack of menace responses with normal vision and pupillary light reflexes. • Head tilt and episodes of vestibular ataxia with resting or positional nystagmus. • Diffuse tapetal hyperreflectivity on funduscopic exam. • Decerebellate posture—opisthotonos with extensor rigidity of the forelimbs and flexed hind limbs. • Cerebellar degeneration is not characterized by altered mentation, proprioceptive deficits, or paresis. • Progression of signs varies. • Use caution in interpreting progression of clinical signs—cerebellar ataxia in a puppy or kitten with cerebellar degeneration caused by in utero or neonatal infection may appear to worsen as the animal grows and becomes more active; the underlying disease process itself is nonprogressive.

CAUSES & RISK FACTORS

• Causal mutations associated with progressive cerebellar degeneration have been identified in several breeds. • In utero or neonatal exposure to feline panleukopenia or canine herpesvirus infection. • Poor vaccination history or exposure to modified live virus during gestation. • A syndrome of hepatocerebellar degeneration has been described in a litter of Bernese mountain dogs. • Paraneoplastic cerebellar degeneration has been reported in humans.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Lysosomal storage diseases—diffuse diseases of the CNS; differentiate by presence of signs of involvement of parts of the CNS outside of the cerebellum. • Toxicity (e.g., hexachlorophene)—differentiate by history of exposure. • Inflammatory diseases—infectious (e.g., canine distemper and feline infectious peritonitis [FIP]) and immune-mediated (dogs). Differentiate from cerebellar degeneration by MRI and cerebrospinal fluid (CSF) analysis. Infectious diseases are frequently accompanied or preceded by systemic signs of illness. • Cerebellar cyst—differentiate by advanced imaging (MRI). • Medulloblastoma (cerebellar tumor)—reported in dogs and cats <1 year old; differentiate by advanced imaging (MRI) and CSF analysis. • Other primary and metastatic tumors in adult dogs.

IMAGING

• MRI is preferred imaging modality—cerebellum may be smaller than normal. • CT can aid in diagnosis of other conditions (e.g., cyst); if MRI is not accessible, CT may have some value.

DIAGNOSTIC PROCEDURES

• CSF analysis—normal with nonprogressive disease; normal-to-high protein concentration and normal cell counts with progressive disease. • Cerebellar biopsy—may be only definitive means of antemortem diagnosis.

TREATMENT

• Restrict to supervised activity in safe areas; leash-walks only; avoid stairs, furniture, proximity to swimming pools, etc. • Amantadine has potentiating effects on dopaminergic neurotransmission in CNS and anticholinergic activity; buspirone is serotonin agonist; research models demonstrate some potential benefit for progressive cerebellar degeneration; guidelines and clinical evidence are lacking. • Neuroprotective agents (such as coenzyme Q10 and acetyl-L-carnitine) may have promising effects.

MEDICATIONS

DRUG(S) OF CHOICE

N/A

FOLLOW-UP

• Neurologic status—examine at weekly-to-monthly intervals if progression of signs is uncertain; consider videotaping patient to determine progression objectively. • Progression of signs—rate varies depending on etiology; ranges from days to years. • Nonprogressive disease—patient may show improvements as they learn to compensate for deficits. • Do not vaccinate pregnant animals with modified live virus. • Do not breed animals with familial history of cerebellar disease.

MISCELLANEOUS

ABBREVIATIONS

• CSF = cerebrospinal fluid. • FIP = feline infectious peritonitis.

Authors Richard J. Joseph and Anne E. Buglione

CEREBELLAR HYPOPLASIA

BASICS

OVERVIEW
Caused by incomplete development of parts of the cerebellum owing to intrinsic (inherited) or extrinsic (infectious, toxic, or nutritional) factors.

SIGNALMENT
- Symptoms may not be visible until puppies and kittens begin to stand/walk (usually by 6 weeks old).
- Hereditary in Airedale, chow chow, Boston terrier, Labrador retriever, Weimaraner, shih tzu, miniature schnauzer, and bull terrier.

SIGNS
- Symmetric, nonprogressive cerebellar disorder—head bobbing; limb tremors; aggravated by movement or eating and disappear during sleep (intention tremors).
- Cerebellar ataxia, wide-base stance.
- Dysmetria and disequilibrium—falling, flipping over.

CAUSES & RISK FACTORS
- Cats—usually transplacental or perinatal infection with panleukopenia virus (wild or from modified live virus used in some vaccines), which selectively attacks rapidly dividing cells, e.g., external germinal layer of the cerebellum at birth and for 2 weeks postnatal.
- Dogs—hereditary in some breeds (autosomal recessive).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Age, breed, history, typical symmetric and nonprogressive symptoms—usually sufficient for tentative diagnosis.
- Early cerebellar abiotrophy—postnatal degeneration after normal development; slow progression of signs over weeks to months; neonatal onset (beagle, Samoyed, Rhodesian ridgeback, Irish setter, Jack Russell terrier, miniature poodle) or postnatal onset (Australian kelpie at 5–6 weeks; Kerry blue terrier at 8–16 weeks; rough-coated collie at 4–8 weeks; bullmastiff at 4–9 weeks).
- Neuroaxonal dystrophy—slowly progressive cerebellar signs starting around 5 weeks of age in cats and 7 weeks in Chihuahuas.
- Cerebellar sequels of systemic canine herpesvirus infection—follow systemic illness.
- Concomitant seizures or other cerebral signs—suggest other malformations, such as lissencephaly (wirehaired fox terrier and Irish setter) or hydrocephalus.
- Final diagnosis possible only at necropsy.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

IMAGING
MRI—cerebellar atrophy or malformation (incomplete or asymmetric filling of the caudal cranial fossa by the cerebellum); rule out other malformations.

PATHOLOGIC FINDINGS
- Cerebellum—normally very small in newborn kitten or puppy (cerebellar development continues for up to 10 weeks postnatal); subtle to marked atrophy; as necropsy is performed weeks to months after birth, there is no sign of active inflammation.
- Transverse fibers of the pons—decreased size associated with marked cortical cerebellar atrophy.
- Hydrocephalus—may be concomitant, resulting from multifocal inflammation or multiple malformations (e.g., Dandy–Walker syndrome).
- Microscopic—depletion of cerebellar cortex cellular layers.

TREATMENT

None

MEDICATIONS

DRUG(S) OF CHOICE
N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
Helps confirm the diagnosis (as necessary).

PREVENTION/AVOIDANCE
Avoid using modified live panleukopenia vaccines in reproducing female cats and keep cats vaccinated against panleukopenia.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
- Slight improvement may occur as patient compensates for deficits.
- Deficits—permanent; do not progress; compatible with a normal lifespan.
- Some patients may be acceptable indoor pets.

Care
- Restrict environment to prevent injuries and road accidents—no climbing, falling, or escaping.
- Nutritional support as needed.
- Euthanasia—severely affected animals that are unable to feed, groom, or be housetrained.

CEREBROVASCULAR ACCIDENTS

BASICS

DEFINITION
• Sudden onset of nonprogressive focal brain signs. • Signs must remain for >24 hours for a diagnosis of cerebrovascular accident (CVA). • Permanent brain damage usually ensues. • Called transient ischemic attack or TIA if clinical signs resolve within 24 hours.

PATHOPHYSIOLOGY
• Cerebrovascular diseases are the underlying cause of CVA. • Brain abnormality resulting from a pathologic process that compromises the blood supply to the brain. • Lesions affecting the cerebral blood vessels are divided into two broad categories: ○ Hemorrhagic stroke—ruptured blood vessel with hemorrhage into or around the brain. ○ Ischemic stroke—abrupt disruption of blood flow from blockage of an artery depriving the brain tissue of oxygen and glucose.

SYSTEMS AFFECTED
• Nervous. • Multisystemic—if underlying cause present.

INCIDENCE/PREVALENCE
Unknown; supposed low compared to human.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Ischemic stroke—cavalier King Charles spaniel and greyhound seem predisposed; small breed (≤15 kg) more likely to have cerebellar infarct; large breed (>15 kg) more likely to have midbrain or thalamic infarct. • Hemorrhagic stroke—unknown.

SIGNS

Historical Findings
• Ischemic stroke—peracute to acute nonprogressive focal brain signs. • Hemorrhagic stroke—acute to subacute focal or multifocal brain signs that can progress over a short period of time.

Physical Examination Findings
• Fundus examination—may reveal tortuous vessels (systemic hypertension), hemorrhage (coagulopathy or systemic hypertension), or papilledema (elevated intracranial pressure [ICP]). • Coagulation defects—may underlie hemorrhagic stroke and cause hemorrhage in any tissue or organ and anemia.

Neurologic Examination Findings
• Ischemic stroke—signs depend on the localization of the vascular insult (prosencephalon, midbrain, pons, medulla, cerebellum). • Hemorrhagic stroke—signs relate to increased ICP with nonspecific forebrain and/or brainstem disturbance.

CAUSES

Ischemic Stroke

Dogs
• Unknown in 50% of cases. • Endocrine diseases—hyperadrenocorticism, hypothyroidism, diabetes. • Embolism, thromboembolism—neoplastic (hemangiosarcoma, lymphoma), infectious (associated with bacterial endocarditis or other sources of infection), and aortic or cardiac. • Systemic hypertension—chronic kidney disease, protein losing enteropathy. • Fibrocartilaginous embolism. • Intravascular lymphoma. • Parasite migration (*Cuterebra*) or embolism (*Dirofilaria immitis*).

Cats
• High likelihood of concurrent disease. • Parasite migration (*Cuterebra* or heartworms). • Systemic hypertension—hyperthyroidism, chronic kidney disease, heart disease. • Neoplastic embolism. • Intracranial telangiectasia. • Hypertropic cardiomyopathy. • Hyperthyroidism. • Pulmonary disease. • Liver disease. • Neoplasia elsewhere in the body.

Hemorrhagic Stroke

Dogs
• Ruptured congenital vascular anomalies. • Primary and secondary brain tumors. • Inflammatory disease of arteries and veins (vasculitis). • Intravascular lymphoma. • Brain hemorrhagic infarction. • Impaired coagulation.

Cats
• Primary and secondary brain tumors. • Inflammatory disease of arteries and veins (vasculitis). • Brain hemorrhagic infarction. • Impaired coagulation—cerebral amyloid angiopathy. • Systemic hypertension.

RISK FACTORS
• Ischemic stroke—systemic hypertension, systemic conditions associated with hypercoagulability syndrome. • Hemorrhagic stroke—systemic hypertension, coagulopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Head trauma—history and physical findings suggestive of trauma. • Decompensation from primary or metastatic brain tumor—signs are progressive. • Infectious and noninfectious encephalitis—acute to subacute clinical signs that gradually worsen. • Neurotoxicity—bilateral, symmetric neurologic deficits.

CBC/BIOCHEMISTRY/URINALYSIS
Most often normal; may show changes reflecting underlying cause.

OTHER LABORATORY TESTS
• Cerebrospinal fluid—unlikely to confirm CVA, may help rule out inflammatory CNS disease. Variable findings; either normal, or mild mononuclear or neutrophilic pleocytosis; protein concentration occasionally elevated. • Prothrombin time—screening test for extrinsic mechanism defects. • Activated partial thromboplastin time—screening test for intrinsic mechanism defects. • Bleeding time—prolonged in patients with von Willebrand's disease; normal with most other coagulation defects, except disseminated intravascular coagulation. • Thromboelastography, D-dimer assay, and antithrombin III—screening tests for hypercoagulability syndrome as possible cause of ischemic stroke. • Endocrine testing—hyperadrenocorticism, thyroid disease, and pheochromocytoma. • Renal disease—urine protein/creatinine ratio.

IMAGING

Ischemic Stroke
• CT—often normal during acute phase. • MRI—within 12–24 hours of onset to distinguish hemorrhage from infarction; T2-weighted and fluid-attenuated inversion recovery (FLAIR) images particularly useful; T2*-weighted (gradient echo) images to show presence of or exclude intracranial hemorrhage; diffusion-weighted imaging (DWI) sequence: ideal for identification of hyperacute stroke, excluding stroke mimics; perfusion-weighted MRI can be used to depict brain regions of hypoperfusion and derive the tissue at risk by comparing the results with the findings on DWI. • Time of flight magnetic resonance angiography (MRA) and contrast-enhanced MRA can be used to assess intracranial vascular status of stroke patients.

Hemorrhagic Stroke
• CT—very sensitive for detection of acute hemorrhage; hyperdensity due to hyperattenuation of X-ray beam by the globin portion of blood; attenuation decreases until the hematoma is isodense at about 1 month from onset; periphery of hematoma contrast-enhances from 6 days to 6 weeks after onset due to revascularization. • MRI—signal intensity of intracranial hemorrhage is influenced by several intrinsic (time from ictus, source, size and location of hemorrhage) and extrinsic (pulse sequence and field strength) factors; as hematoma ages, oxyhemoglobin in blood breaks down sequentially into several paramagnetic products (deoxyhemoglobin, methemoglobin, hemosiderin), each with different MRI signal intensities; compared to other conventional sequences, T2*-weighted (gradient echo) images demonstrate readily detectable hypointensity regardless of time from ictus, source and location of hemorrhage, or field strength. • Multiple hemorrhagic lesions <5 mm—most often associated with hyperadrenocorticism, hypertension, chronic

CEREBROVASCULAR ACCIDENTS (CONTINUED)

kidney disease, or hypothyroidism. • Single hemorrhagic lesion—most often associated with *Angiostrongylus vasorum*. • Multiple hemorrhagic lesions ≥5 mm—most often associated with *Angiostrongylus vasorum*, primary extracranial neoplasia with metastases (haemangiosarcoma).

DIAGNOSTIC PROCEDURES

Diagnosis of potential underlying causes.

Ischemic Stroke

Evaluate for hypertension (and potential underlying causes), endocrine disease (hyperadrenocorticism, hypothyroidism, hyperthyroidism, diabetes mellitus), chronic kidney disease (especially protein-losing nephropathy), protein-losing enteropathy, heart disease, and metastatic diseases (particularly hemangiosarcoma).

Hemorrhagic Stroke

Evaluate for coagulopathy (and potential underlying causes), hypertension (and potential underlying causes), and metastatic diseases (particularly hemangiosarcoma).

PATHOLOGIC FINDINGS

Ischemic Stroke

• Ischemic necrosis centered on gray matter due to selective vulnerability. • Lesions limited to brain area vascularized by the affected vessel with sharply demarcated borders; normal surrounding brain tissue; minimal to no mass effect. • Global brain ischemia usually affects a dense area of selectively vulnerable neurons; specific anatomic areas including cerebral cortex, hippocampus, certain basal nuclei (e.g., caudate nuclei), thalamus, and cerebellar Purkinje cell layers are more susceptible to hypoxic injury. • Early ischemic cell changes occur rapidly and are a result of energy deprivation with swelling of the mitochondria and endoplasmic reticulum, which causes cytoplasmic microvacuolation; more chronic lesions are characterized by postnecrotic atrophy of the brain parenchyma, endothelial proliferation in viable capillaries, and accumulation of Gitter cells.

Hemorrhagic Stroke

• Parenchymal bleeding results from rupture of the small penetrating brain arteries; most acute cases reveal fresh hemorrhage and acute neuronal necrosis that is slowly removed by macrophages, leaving over time a cystic cavity lined by fibrillary astrocytes. • Histology is characterized by presence of edema, neuronal damage, macrophages, and neutrophils in the region surrounding the hematoma. • While some cerebral hemorrhages stop quickly as a result of clotting and tamponade by the surrounding regions, others tend to expand over time; the latter is a result of continued bleeding from the primary source and to the mechanical disruption of surrounding vessels; the hemorrhage spreads between planes of white matter cleavage with minimal destruction, leaving nests of intact neural tissue within and surrounding the hematoma.

TREATMENT

NURSING CARE

Ischemic Stroke

• Monitoring and correction of basic physiologic variables (e.g., oxygen level, fluid balance, blood pressure, body temperature). • Maintenance of systemic arterial blood pressure within physiologic range; aggressive lowering of blood pressure should be avoided during acute stages unless the patient is at high risk of end-stage organ damage (systolic blood pressures >180 mmHg); hypertension can develop as a physiologic response to a stroke to ensure adequate cerebral perfusion pressure; elevated blood pressure can persist for up to 72 hours after the onset of injury. • No evidence that glucocorticoid provides beneficial neuroprotection; most neuroprotective agents tested have either failed to prove their efficacy in clinical trials or are awaiting further investigation.

Hemorrhagic Stroke

• Patient stabilization (airway protection, monitoring and correction of vital signs). • Assessment and monitoring of neurologic status. • Determination and treatment of potential underlying causes of hemorrhage. • Assessment for the need of specific treatment measures including management of raised ICP, which revolves around reducing cerebral edema, optimizing cerebral blood volume, and eliminating space-occupying mass. • Risk of neurologic deterioration and cardiovascular instability highest during the first 24 hours after onset of intracranial hemorrhage, as the space-occupying lesion slowly expands and cerebral vasogenic edema develops.

MEDICATIONS

DRUG(S) OF CHOICE

Ischemic Stroke

• Antihypertensive—consider if systemic BP >180 mmHg on serial evaluation and/or severe ocular manifestations of hypertension. • Angiotensin-converting enzyme (ACE) inhibitor—enalapril (0.25–0.5 mg/kg q12h) or benazepril (0.25–0.5 mg/kg q12h) and/or calcium channel blockers such as amlodipine (0.1–0.25 mg/kg q24h); amlodipine is more effective in severe hypertension. • Prevention of clot formation—consider in proven cardiac sources of embolism; antiplatelet therapy with low-dose aspirin (0.5 mg/kg PO q24h) or clopidogrel (2–4 mg/kg PO q24h) and low molecular weight heparin can be used prophylactically; low molecular weight heparin 80–150 IU/kg SC can be used in suspected or confirmed case of hypercoagulable state; anti-factor Xa activity should be monitored, although this may not be practical.

Hemorrhagic Stroke

Mannitol—if suspected elevated ICP unresponsive to extracranial stabilization measures (0.25–2 g/kg IV over 10–20 min up to q4-8h).

FOLLOW-UP

PATIENT MONITORING

Frequent neurologic evaluations in the first 48–72 hours to monitor progress.

EXPECTED COURSE AND PROGNOSIS

• Maximum severity of signs usually reached within 24h for ischemic stroke. • Resolution of signs—gradual within 2–10 weeks; some dogs/cats may be left with permanent neurologic signs due to irreversible brain damage. • Dogs with causal medical condition significantly more likely to relapse and have significant shorter survival time than dogs with no identifiable medical condition. • Despite having a high likelihood of concurrent disease, cat with ischemic stroke have been reported to have a favorable short-term outcome, if neither clinical presentation nor concurrent disease was severe. • Prognosis for global brain ischemia difficult to predict as there are no controlled studies.

MISCELLANEOUS

SYNONYMS

Stroke

ABBREVIATIONS

• ACE = angiotensin-converting enzyme. • CVA = cerebrovascular accident. • DWI = diffusion-weighted imaging. • FLAIR = fluid-attenuated inversion recovery. • ICP = intracranial pressure. • MRA = magnetic resonance angiography. • TIA = transient ischemic attack.

Author Laurent Garosi

CERUMINOUS GLAND ADENOCARCINOMA, EAR

BASICS

OVERVIEW
• Most common primary malignant tumor of the external ear canal, arising from modified apocrine sweat glands (ceruminous glands).
• Often locally invasive, but associated with a low metastatic rate.

SIGNALMENT
• Uncommon overall, but the most common malignant tumor of the ear canal in both dogs and cats, followed by carcinoma of undetermined origin and squamous cell carcinoma.
• Cocker spaniels and German shepherd dogs are overrepresented.
• Mean age—dogs, 10 years; cats, 11 years.
• No known sex predisposition.

SIGNS
• Progressive hearing loss.
• Similar to chronic, recurrent otitis externa—discharge, odor, pruritus, inflammation.
• Early appearance—pale pink, friable, ulcerative, bleeding nodular mass(es) within the external ear canal.
• Late appearance—large mass(es) filling the canal and invading through canal wall into surrounding structures.
• Regional lymph node enlargement.
• Neurologic signs (vestibular signs, Horner's syndrome) may be present secondary to middle ear involvement.
• Signs of pain and discomfort; pain upon opening the mouth.

CAUSES & RISK FACTORS
Chronic inflammation and ceruminous gland hyperplasia/dysplasia appear to play a role in tumor development.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Proliferative chronic otitis externa with ceruminous gland hyperplasia.
• Inflammatory polyps.
• Other tumors including squamous cell carcinoma, basal cell tumor, mast cell tumor, papilloma, sebaceous gland tumor, ceruminous gland adenoma.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
• Ear swab cytology for bacteria and yeast.
• Bacterial culture and sensitivity as needed.

IMAGING
• Skull radiography to assess potential involvement of the tympanic bulla, but this is difficult to interpret due to superimposition of bones in the skull.
• Thoracic radiography to evaluate for pulmonary metastasis.
• CT or MRI is most useful for loco-regional staging and before surgery and radiation therapy, providing greater detail than with radiographs.

DIAGNOSTIC PROCEDURES
• Cytologic examination of aspirate from regional lymph nodes.
• Cytologic examination of fine-needle aspirate from mass.
• Biopsy and histopathology.

PATHOLOGIC FINDINGS
• Cytology from fine-needle aspirate—round to polygonal epithelial cells arranged both singly and in large clusters with deep blue to lavender-gray cytoplasm and a variable quantity of black, intracytoplasmic granular material; unable to differentiate adenocarcinoma from adenoma consistently with cytology.
• Histopathologic characteristics—apocrine type differentiation from ceruminous glands and local invasion into stroma; neoplastic cells show moderate to marked nuclear atypia with frequent mitotic figures.

TREATMENT
• Total ear canal ablation and lateral bulla osteotomy (TECABO) is the preferred surgical approach over lateral ear resection.
• Radiation therapy may be considered for either large (palliative intent) or incompletely excised masses (curative intent).

MEDICATIONS

DRUG(S) OF CHOICE
• Chemotherapy not evaluated, but occasionally considered based on histologic information and clinical staging results.
• Multimodal therapy incorporating corticosteroids or nonsteroidal anti-inflammatory drugs (NSAIDs) and other analgesics.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
• Physical examination and thoracic radiography at regular intervals following therapy (every 3–4 months) is recommended for the first year postoperatively.
• Serial CT or MRI to monitor for local tumor regrowth may be recommended.

POSSIBLE COMPLICATIONS
• Permanent or transient Horner's syndrome secondary to surgery.
• Permanent or transient facial paralysis following surgery (more frequent in cats).

EXPECTED COURSE AND PROGNOSIS
• Median survival after lateral ear resection is around 10 months for both dogs and cats.
• Median survival after TECABO is >3 years in both dogs and cats.
• Median survival after radiation therapy is >3 years, but published information is on small numbers only.
• Poor prognosis associated with extensive tumor involvement (advanced stage), preoperative neurologic signs, and conservative therapy (e.g., lateral ear canal ablation alone).

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Otitis externa.
• Peripheral vestibular disease, Horner's syndrome.
• Chronic pain.

ABBREVIATIONS
• NSAID = nonsteroidal anti-inflammatory drug.
• TECABO = total ear canal ablation and bulla osteotomy.

CERVICAL SPONDYLOMYELOPATHY (WOBBLER SYNDROME)

BASICS

DEFINITION
• Cervical spondylomyelopathy (CSM) or wobbler syndrome is a disease of the cervical spine of large- and giant-breed dogs.
• CSM is characterized by compression of the spinal cord and/or nerve roots associated with neurologic deficits and/or cervical pain.

PATHOPHYSIOLOGY
• Compressive lesion caused by intervertebral disc herniation, osseous malformation, thickened ligaments, or a combination, in a stenotic vertebral canal.
• Disc-associated compression—dogs >3 years; intervertebral disc degeneration and subsequent protrusion might be secondary to abnormal articular facet articulation in Doberman pinschers, which predisposes to increased rotational strain in the intervertebral discs.
• Vertebral malformation (bony-associated compression)—most commonly seen in giant breeds of dogs, usually in young adult dogs (<4 years); the osseous malformation can compress the spinal cord dorsoventrally (vertebral arch malformation), dorsolaterally (articular process malformation/osteoarthritic lesions), or laterally (pedicular malformation/osteoarthritic lesions).
• Dynamic spinal cord compression (one that changes with movements of the cervical spine) is always a component of the pathophysiology with any type of compression.
• Current evidence does not suggest that instability has a primary role in the pathogenesis of CSM.

SYSTEMS AFFECTED
Nervous

GENETICS
• Heritable basis proposed for borzoi and basset hound.
• Recent evidence suggests that the disease is inherited as an autosomal dominant trait (with incomplete penetrance) in Doberman pinscher.

INCIDENCE/PREVALENCE
CSM is probably the most common neurologic disorder of the cervical spine of large- and giant-breed dogs.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Breed Predilections
• Doberman pinscher and Great Dane are the most commonly affected breeds, with approximately 60–70% of cases seen in these breeds.
• Other breeds with a high incidence include Rottweiler, German shepherd, Weimaraner, Labrador, and Dalmatian.
• CSM can be seen in any breed, including small-breed dogs.

Mean Age and Range
• Doberman pinschers and other large-breed dogs are usually presented >3 years of age, with a mean age of 6 years.
• Giant-breed dogs are usually presented <3 years of age, although late presentations can be seen.

Predominant Sex
Males overrepresented, primarily in giant-breed dogs.

SIGNS

General Comments
The classic clinical presentation is a slowly progressive pelvic limb ataxia with less severe thoracic limb involvement.

Historical Findings
• Chronic, slowly progressive gait dysfunction is characteristic; acute presentations are usually associated with neck pain; occasionally, acute worsening of a dog with chronic history is observed.
• Neck pain or cervical hyperesthesia is a common historical finding; it occurs in approximately 65–70% of Dobermans, and 40–50% of other breeds.

Neurologic Examination Findings
• Cervical pain is the primary complaint in only approximately 5% of patients.
• Gait changes are characterized by proprioceptive ataxia and paresis (weakness); the ataxia and paresis are more obvious in the pelvic limbs, with lesions in the caudal cervical spine (C5–6, C6–7); compressive lesions in the mid-cervical spine tend to cause ataxia in all four limbs.
• The thoracic limb gait can appear short-strided, spastic with a floating appearance, or very weak.
• Proprioceptive positioning deficits are usually present, but dogs with chronic ataxia may not display them; the gait exam (presence of ataxia) provides a more sensitive indication of myelopathy than proprioceptive positioning deficits.
• Dogs can present nonambulatory.
• Supraspinatus muscle atrophy and worn toenails can be seen in some cases.
• Extensor muscle tone is commonly increased in all four limbs.
• Patellar reflexes are normal or increased; flexor reflex may be difficult to elicit in the thoracic limbs due to increased extensor tone.

CAUSES
• Nutrition—excess protein, calcium, and caloric intake were proposed in Great Danes; nutrition does not appear to play a role in the development of CSM in large-breed dogs.
• The cause of CSM is likely multifactorial.

RISK FACTORS
• Body conformation—large head and long neck have been proposed, but later studies found no correlation between body dimensions and incidence of CSM.
• Fast growth rate has been proposed, but not confirmed by other studies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Orthopedic conditions such as hip dysplasia and cruciate ligament rupture; differentiated by neurologic examination (absence of ataxia).
• Spinal neoplasia, spinal subarachnoid diverticulum, spinal synovial cysts, discospondylitis, osteomyelitis, meningomyelitis, trauma; differentiated by results of survey radiographs, cerebrospinal fluid (CSF), myelography, CT, CT myelography, or MRI findings.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

IMAGING

Survey Cervical Radiographs
• Survey radiographs serve as a screening tool to rule out bony disorders; although intervertebral disc narrowing or vertebral tipping can be seen, these findings are not specific for CSM since they can be observed in clinically normal large-breed dogs.
• Osteoarthritic changes of the articular processes can be seen in giant breeds.

Myelography
• Myelography can define the location(s) and direction (ventral, dorsal, lateral) of the spinal cord compression.
• Stressed views (flexion or extension) may cause significant risk of neurologic deterioration.
• Linear traction myelography is a safer procedure and can distinguish a static from a dynamic lesion.

Advanced Imaging
• CT myelography—cross-sectional visualization of the spinal cord compression and determination of sites with spinal cord atrophy.
• MRI—visualization of the spinal cord parenchyma, intervertebral disc, soft tissues, and nerve roots; images can be obtained in sagittal, transverse, and dorsal planes; spinal cord signal changes allow more precise identification of the main site of compression than CT and myelography; kinematic MRI is a novel procedure that allows more precise identification of dorsal and ventral lesions, primarily when the vertebral column is placed in extension.

DIAGNOSTIC PROCEDURES
CSF analysis—usually normal; mild mixed or neutrophilic pleocytosis can be seen in dogs with acute presentations; elevated protein concentrations can be observed with chronic presentations.

(CONTINUED) CERVICAL SPONDYLOMYELOPATHY (WOBBLER SYNDROME)

PATHOLOGIC FINDINGS
- Spinal cord white matter tract demyelination at the site of spinal cord compression; axonal damage can lead to Wallerian degeneration in the ascending and descending white matter tracts.
- Neuronal loss, gliosis, and necrosis can be observed in the gray matter.
- Chronic severe focal spinal cord compression can lead to focal myelomalacia.

TREATMENT

APPROPRIATE HEALTH CARE
- Inpatient if surgical treatment is elected.
- Outpatient if medical management is chosen.

NURSING CARE
- Nonambulatory dogs—keep patients on soft bedding and alternate recumbence side every 4 hours to avoid bed sores.
- Bladder catheterization.
- Physical therapy is essential to avoid muscle atrophy and ankylosis, and to hasten recovery.

ACTIVITY
- Medically treated dogs should have restricted activity for at least 2 months.
- Restriction of activity is also important for the first 2 or 3 months postoperatively to allow bone fusion and prevent implant displacement.

DIET
Avoid excess of protein, calcium, or caloric intake in giant-breed dogs with osseous compression.

CLIENT EDUCATION
Inform that surgery offers the best chance of improvement (approximately 80%), but there is a 1–5% risk of significant complications associated with cervical surgical procedures.

SURGICAL CONSIDERATIONS
- Ventral slot—commonly used and recommended for single ventral compressions; could also be used for two ventral compressions.
- Dorsal laminectomy—primary indication for dorsal or dorsolateral compressions; can also be used for multiple ventral compressions; hemilaminectomy is an alternative for lateralized osseous compressions.
- Distraction/stabilization/fusion techniques are recommended primarily for single dynamic ventral compressions, but could be used for multiple compressions.
- Cervical disc arthroplasty—novel technique that appears safe and as effective as the traditional procedures; it can be used for multiple compressions.
- Recurrence rate is approximately 20% with any surgical technique.
- Fenestration provides a very low success rate and is not recommended.

MEDICATIONS

DRUG(S) OF CHOICE
- Corticosteroids—prednisone 1 mg/kg q24h or 0.5 mg/kg q12h, progressively decreasing dosage and frequency; most dogs can have prednisone discontinued after 4–8 weeks of treatment; dexamethasone 0.1–0.25 mg/kg q24h can be used as an alternative to prednisone in dogs severely affected; corticosteroids act by reducing the vasogenic edema often present in chronic compressive spinal cord lesions.
- Gabapentin—10 mg/kg q8–12h can be used for analgesia in cases of more severe cervical pain.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Monitor for signs of gastroenteritis, gastric hemorrhage, and cystitis. A proton pump inhibitor may be used to minimize the risk of gastrointestinal bleeding.

POSSIBLE INTERACTIONS
Do not use corticosteroids in combination with nonsteroidal anti-inflammatory drugs (NSAIDs).

ALTERNATIVE DRUG(S)
NSAIDs (all kinds) can be used in dogs with only cervical hyperesthesia or mild ataxia.

FOLLOW-UP

PATIENT MONITORING
Repeat neurologic evaluation as often as needed to monitor response to treatment.

PREVENTION/AVOIDANCE
- Excessive activity, jumping, and running should be avoided.
- Avoid use of neck collars; use a body harness instead.

POSSIBLE COMPLICATIONS
Recurrence of clinical signs can occur in dogs treated medically or surgically.

EXPECTED COURSE AND PROGNOSIS
- About 80% of patients improve with surgery.
- Approximately 50% of patients improve with medical treatment (restricted activity ± corticosteroids) and 25% remain stable.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Dilated cardiomyopathy, hypothyroidism, and von Willebrand's disease are common in Doberman pinscher dogs; these diseases can affect diagnostic and treatment options. Doberman pinschers suspected of having CSM should be routinely evaluated for these conditions.

AGE-RELATED FACTORS
- Young giant- or large-breed dogs—vertebral malformation and compression.
- Older dogs—disc-associated compression.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
N/A

SYNONYMS
- Cervical malformation-malarticulation.
- Cervical spondylopathy.
- Cervical vertebral instability.

SEE ALSO
Intervertebral Disc Disease—Cats.

Client Education Handout available online

CHAGAS DISEASE (AMERICAN TRYPANOSOMIASIS)

BASICS

OVERVIEW

- Caused by hemoflagellate protozoan *Trypanosoma cruzi*.
- Transmission through contact with infected feces of the Reduviid ("kissing") bug, ingestion of bug vector, through blood transfusion, or vertical transmission to offspring.
- After multiplication at entry site (5 days postinfection [PI]), hematogenous spread to heart, brain, and other organs.
- Maximal parasitemia at 14 days PI; associated with acute myocarditis and (less commonly) encephalitis.
- Infection becomes subpatent 30 days PI.
- Dogs then enter long asymptomatic period (months to years); subset develop cardiomyopathy.
- South and Central America—endemic in humans and pets; infected animals are sentinels for human risk.
- United States—in southern states with infected vectors and reservoir hosts (raccoons, opossums, armadillos, mice, rats, squirrels).

SIGNALMENT

- Dogs of any age, breed:
  - Acute infection—more severe in dogs <2 years old.
  - Chronic infection—adults.
  - Sporting breeds and outdoor-housed dogs more likely to be in contact with vectors or reservoir host.
- Cats—more recent evidence of infection and organ pathology.

SIGNS

General Comments

Two syndromes can be difficult to distinguish—acute myocarditis/encephalitis and chronic arrhythmias and myocardial dysfunction.

Historical Findings

- Lethargy, weakness.
- Anorexia.
- Abdominal distension (ascites).
- Cough, dyspnea.
- Syncope, sudden death.
- Ataxia, seizures.

Physical Examination Findings

- Tachy- or bradyarrhythmia.
- Heart murmur.
- Congestive heart failure (tachypnea, dyspnea, ascites).
- Hepatomegaly.
- Generalized lymphadenopathy (acute).
- Neurologic—weakness, ataxia, seizures (acute).

CAUSES & RISK FACTORS

Lives in or travels to endemic area.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cardiomyopathy.
- Congenital heart defect (tricuspid valve dysplasia).
- Myocarditis.
- Distemper, other causes of meningoencephalitis.

CBC/BIOCHEMISTRY/URINALYSIS

Generally normal.

OTHER LABORATORY TESTS

- Cardiac troponin I—elevation indicates myocardial damage.
- Serology—presence of *T. cruzi* serum antibodies (present by 16 days PI) confirms infection, but not necessarily clinical disease.
- Tests can cross-react with *Leishmania*.
- Cytology—trypomastigote (blood form) occasionally on blood smear, lymph node aspirate, abdominal effusion, or buffy coat during period of high parasitemia.
- Cytology—amastigote (intracellular form) identified on lymph node aspirate or impression.
- PCR—detect parasite DNA in blood or tissue with high specificity; low sensitivity in chronic stage if parasite levels low.

IMAGING

- Thoracic radiography—cardiomegaly, pulmonary edema, pleural effusion.
- Echocardiography—dilation of heart chambers, systolic dysfunction.

DIAGNOSTIC PROCEDURES

ECG

- Supraventricular and ventricular arrhythmias, atrioventricular block (any degree), bundle branch block.
- Ambulatory ECG (Holter) to document abnormalities.

PATHOLOGIC FINDINGS

- Acute—diffuse granulomatous myocarditis, myocardial necrosis, parasitic pseudocysts with intracellular amastigotes.
- Chronic—lymphoplasmacytic inflammation, loss of myocardial fibers, severe interstitial fibrosis.
- *T. cruzi* amastigotes in heart, lymph nodes, liver, spleen, brain.

TREATMENT

- No currently approved treatment for *T. cruzi*.
- Manage heart failure (see Congestive Heart Failure, Left-Sided; Congestive Heart Failure, Right-Sided).
- Tachyarrhythmias—anti-arrhythmic drugs.
- Bradyarrhythmias—pacemaker implantation.

Client Education

- Test housemates/littermates of infected dogs.
- Take measures to eliminate the insect vector—remove brush, pyrethroid insecticide.
- Alert owner to possible zoonotic risk and potential for sudden death.
- Infected female can transfer infection to offspring.
- Cardiology tests (ECG, echocardiography) can identify dogs at risk of developing clinical signs or sudden death.

MEDICATIONS

DRUG(S) OF CHOICE

Limited therapeutic options for treating infection. Variable clinical response to Benznidazole; treated dogs still develop myocardial damage. Other drug protocols under investigation.

FOLLOW-UP

- Monitor positive dogs for clinical disease.
- Prognosis unknown for asymptomatic, positive dogs.
- Dogs with clinical signs or arrhythmias have guarded prognosis.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- Public health concern with limited treatment options.
- Risk of human acquiring infection directly from infected dog is low, but infected animal indicates presence of infected vectors or reservoir hosts.

ABBREVIATIONS

- PI = postinfection.

CHEDIAK-HIGASHI SYNDROME

BASICS

OVERVIEW
- Autosomal recessive inherited disorder of Persian cats characterized by abnormalities in cellular morphology and pigment formation.
- Large intracytoplasmic granules in circulating leukocytes and melanocytes formed by fusion of preexisting granules.
- Storage pool deficiency of adenosine diphosphate (ADP), adenosine triphosphate (ATP), magnesium, and serotonin results from lack of platelet-dense granules.
- Prolonged bleeding from trauma, venipuncture, or minor surgery occurs because of impaired platelet aggregation and release reaction.
- Normal coagulation times.
- Depressed chemotaxis.
- No change in rates of infection.
- Mildly depressed neutrophil count, but within reference interval.
- In humans, it is associated with one of eight mutations in the LYST gene.

SIGNALMENT
- Persian cats with dilute smoke-blue coat color and yellow-green irises (and white tigers).
- Not reported in dogs.

SIGNS

Historical Findings
Prolonged bleeding from trauma, venipuncture, or minor surgery.

Physical Examination Findings
- Red fundic reflex (lack of choroidal pigment).
- Dilute smoke-blue coat color and yellow-green irises.
- Photophobia (blepharospasm and epiphora) in bright light.

CAUSES & RISK FACTORS
Genetic disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Lysosomal storage diseases (e.g., mucopolysaccharoidoses), therapy with antiplatelet agents (e.g., aspirin, clopidogrel), other inherited platelet function defect.

CBC/BIOCHEMISTRY/URINALYSIS
Romanowsky-stained blood smear—leukocytes, especially neutrophils, contain pink to magenta cytoplasmic inclusions approximately 2 µm in diameter.

OTHER LABORATORY TESTS
None

IMAGING
N/A

DIAGNOSTIC PROCEDURES
Advanced platelet function testing or electron microscopy of platelets may provide additional evidence for diagnosis.

TREATMENT
- Provide ascorbic acid (vitamin C) to increase cyclic guanosine monophosphate (cGMP) concentration and to improve cell and platelet function (no controlled studies in cats).
- Transfusion of platelet-rich plasma or fresh whole blood from healthy cats will temporarily normalize bleeding time in affected individuals.
- Experimentally, bone marrow transplantation has restored neutrophil and platelet function in cats, but is impractical for general clinical use.

MEDICATIONS

DRUG(S) OF CHOICE
Ascorbic acid (100 mg PO q8h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
None

FOLLOW-UP

PATIENT MONITORING
None

PREVENTION/AVOIDANCE
Advise owner of potential for prolonged bleeding after trauma, venipuncture, or minor surgery.

POSSIBLE COMPLICATIONS
Prolonged bleeding time.

EXPECTED COURSE AND PROGNOSIS
Normal lifespan, with avoidance of trauma or other situations that may predispose to bleeding.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
- Provide genetic counseling to eliminate Chediak-Higashi syndrome from animals used for breeding.
- Neuter affected and carrier animals or advise owner not to breed.

ABBREVIATIONS
- ADP = adenosine diphosphate.
- ATP = adenosine triphosphate.
- cGMP = cyclic guanosine monophosphate.

Suggested Reading

CHEMODECTOMA

BASICS

OVERVIEW
- Chemodectomas are tumors arising from the chemoreceptor cells (such as in the aortic body and the carotid body).
- Other names—aortic body tumors, cardiac paraganglioma, APUDoma (amine precursor uptake decarboxylase), and glomus body tumor.
- Aortic body tumors more common (80–90%) in dogs than carotid body tumors (10–20%).

SIGNALMENT
- Rare in cats.
- Dogs—age 6–15 years.
- Any breeds—but brachycephalic breeds predisposed, especially boxers, Boston terriers, English bulldogs, and German shepherd dogs.
- Males predisposed for aortic body tumors; no sex predilection for carotid body tumors.

SIGNS
- Nonspecific and dependent upon tumor size and anatomic localization, and can include lethargy, anorexia, weakness, collapse, coughing, respiratory distress, exercise intolerance, distended abdomen, vomiting, sudden death.
- Carotid body tumor—may notice neck mass, regurgitation, dyspnea, Horner's syndrome, head tilt, facial nerve paralysis, or laryngeal paralysis.
- May be associated with pericardial effusion and cardiac tamponade—muffled heart sounds, poor pulses, tachycardia, tachypnea, weak pulses, slow capillary refill time, ascites.
- May be associated with cranial vena cava syndrome (edema of head, neck, and forelimbs).
- May be associated with ascites secondary to right heart failure.
- May be associated with pleural effusion—decreased lung sounds ventrally, cyanosis.
- Cardiac arrhythmias with pulse deficits.

CAUSES & RISK FACTORS
Chronic hypoxia may play a role in the development of this disease in brachycephalic breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other masses located at the heart base (i.e., hemangiosarcoma, thymoma, ectopic thyroid carcinoma, mesothelioma, abscess, and granuloma).
- Idiopathic pericardial effusion.
- Pericarditis.
- Cardiomyopathy.
- Valvular insufficiency.

CBC/BIOCHEMISTRY/URINALYSIS
Typically normal, but 36% of patients can have nucleated red blood cells without anemia.

OTHER LABORATORY TESTS
N/A

IMAGING
- Thoracic radiography—to evaluate for mass in the region of the heart base, pericardial effusion, metastatic lesions in the lungs.
- Cervical ultrasound, CT, or MRI—to evaluate for masses arising in the neck.
- Echocardiography—to image mass and aorta/pulmonary arteries/veins.

DIAGNOSTIC PROCEDURES
- Biopsy of mass.
- ECG—if evidence of arrhythmia, may see low-amplitude QRS complexes with pericardial or pleural effusion, or electrical alternans with pericardial effusion.

TREATMENT

Aortic Body Tumors
- Surgical removal of mass—if possible.
- Subphrenic pericardectomy has been shown to prolong survival.
- Symptomatic pericardiocentesis or thoracocentesis.
- Conformal radiation therapy or stereotactic body radiation therapy—discuss with owners possible complications including cough, tachyarrhythmias, and congestive heart failure.
- Palliative thoracoscopic-guided pericardial window.

Carotid Body Tumors
Surgical removal if possible—discuss with owners possibility of postoperative Horner's syndrome and laryngeal paralysis.

Both
Possible role of chemotherapy (doxorubicin)—however, definitive studies are lacking.

MEDICATIONS

DRUG(S) OF CHOICE
- The role of chemotherapy in this disease has not been published.
- Pharmacologic intervention for cardiac insufficiency.

FOLLOW-UP

PATIENT MONITORING
Serial thoracic radiography or advanced imaging for monitoring tumor progression and metastasis.

EXPECTED COURSE AND PROGNOSIS
- Carotid body tumors treated with surgery—median survival time (MST) 25.5 months.
- Aortic body tumors—animals treated with pericardectomy MST 730 days vs. animals that did not have pericardectomy MST 42 days. Larger tumors (as determined by tumor weight to body weight ratio) more likely associated with metastasis.
- Conformal radiation therapy in 1 dog—survival >42 months.
- Stereotactic body radiation therapy in 6 dogs—tumor reduction by 30–76% in 4 dogs, 3 dogs alive 408–751 days post radiation therapy, 2 dogs died suddenly at 150 days and 294 days post radiation therapy, and 1 dog died of unrelated causes 1228 days post radiation.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
It is not recommended to breed animals with cancer. Chemotherapy is teratogenic—do not give to pregnant animals.

SEE ALSO
Pericardial Disease.

ABBREVIATIONS
- APUD = amine precursor uptake decarboxylase.
- MST = median survival time.

Consulting Editor Timothy M. Fan

CHEYLETIELLOSIS

BASICS

OVERVIEW

- Contagious parasitic skin disease caused by surface-living mites.
- Signs of mild pruritus and scaling resemble other more common dermatoses.
- Potential zoonosis.
- System affected—skin/exocrine.

SIGNALMENT

- Dogs and cats.
- More severe in young animals.
- Cocker spaniels, poodles, and longhaired cats may be inapparent carriers.

SIGNS

Historical Findings

- Referred to as "walking dandruff," because of the large mite size and excessive scaling.
- Prevalence varies by geographic region owing to mite susceptibility to common flea-control insecticides and differences in climate.
- Pruritus—usually absent to mild, but can be severe: hypersensitivity to mite allergens may develop, producing clinical signs similar to infestations with *Sarcoptes* or *Notoedres* mites.
- Infestation often suspected only after lesions in human beings develop (pseudoscabies).

Physical Examination Findings

- Scaling— diffuse or plaque like; more severe in chronically infested or debilitated animals.
- Lesions—dorsal orientation commonly noted; head can be affected in cats.
- Underlying skin irritation may be minimal.
- Cats may exhibit bilaterally symmetric alopecia, bizarre behavior, head shaking, or excessive grooming.

CAUSES & RISK FACTORS

- Partial host specificity—dogs: *C. yasguri*. Cats: *C. blakei*. Rabbits: *C. parasitovorax*.
- Cheyletiellosis should be considered in every animal that shows scaling, with or without pruritus.
- Contagion by direct contact or by fomites.
- Common sources of infestation—animal shelters, breeders, and grooming facilities.
- Adult female mites may survive in the environment up to 10 days.
- Eggs can be found on shed hair.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Keratinization disorders.
- Cutaneous hypersensitivity.
- *Sarcoptes* and *Notoedres* spp. mite infestation; other fur mites.
- Endocrinopathy.
- Dermatophytosis.
- Pediculosis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

DIAGNOSTIC PROCEDURES

- Examination of epidermal debris—*Cheyletiella* mites are large and can be visualized with a hand lens or microscope (10× objective); scales and hair may be examined under low magnification; finding mite eggs is diagnostic.
- Mite numbers may be low—concentration of debris for examination increases the likelihood of diagnosis; collection of debris: flea combing (most effective), skin scraping, hair plucking, acetate tape preparation, scale collection, and fecal flotation.
- Response to insecticide treatment may be required to definitively diagnose suspicious cases in which mites cannot be identified.

TREATMENT

- All animals in the same household must be treated.
- Clip long coats to facilitate treatment.
- Weekly baths to remove scale, followed by rinses with an insecticide.
- Lime-sulfur rinses—cats, kittens, dogs, and puppies.
- Routine flea sprays—not always effective: treat all animals in the home before introducing a new pet.
- Environmental treatment with frequent cleanings and insecticide sprays—reduces possibility of reinfestation.
- Continue treatment for at least 6–8 weeks to prevent reinfestation from shed eggs.
- Combs, brushes, and grooming tools—discard or thoroughly disinfect before reuse.

MEDICATIONS

DRUG(S) OF CHOICE

- Amitraz rinses—dogs only; 2-week intervals for 4 applications.
- Fipronil—2-week intervals for 1–4 applications.
- Ivermectin—300 µg/kg PO/SC 3 times at 2-week intervals; dogs and cats >3 months old; pour-on forms have shown efficacy in cats (500 µg/kg 2 times at 2-week intervals; non-FDA-approved usage; see Contraindications/Possible Interactions).
- Selamectin—apply every 2–4 weeks for 3 applications (non-FDA-approved usage).
- Imidacloprid/moxidectin—apply every 2 weeks for 3 applications (non-FDA-approved usage); imidacloprid alone: not effective.
- Milbemycin oxime—2 mg/kg PO once weekly for 4 weeks.
- Moxidectin—subcutaneous injection every 2 weeks for 3 treatments (non-FDA-approved usage: dogs).
- Doramectin—subcutaneous injection every week for three treatments (non-FDA-approved usage: dogs).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Prevent ingestion/avoid use of avermectins in sensitive dogs (*MDR1*/*ABCB1* gene mutation, collie, sheltie, Australian shepherd, Old English sheepdog)—selamectin may be used in these dog breeds.

FOLLOW-UP

- Treatment failure requires a thorough reevaluation for other causes of pruritus and scaling.
- Reinfestation may indicate contact with an asymptomatic carrier or the presence of an unidentified source of mites

MISCELLANEOUS

ZOONOTIC POTENTIAL

Pruritic papular rash may develop in human beings.

CHLAMYDIOSIS—CATS

BASICS

DEFINITION
A chronic respiratory infection of cats caused by an intracellular bacterium, characterized by mild to severe conjunctivitis, mild upper respiratory signs, and mild pneumonitis.

PATHOPHYSIOLOGY
• *Chlamydophila felis* (previously *Chlamydia psittaci var. felis*)—a Gram-negative, obligate intracellular bacterium spread through close contact, aerosolization, or genital contact during parturition.
• Replicates on the mucosa of the upper and lower respiratory epithelium; produces a persistent commensal flora that causes local irritation, resulting in mild upper and lower respiratory signs and conjunctivitis; can also colonize the mucosa of the gastrointestinal and reproductive tracts.
• Incubation period—7–10 days (longer than that of other common feline respiratory pathogens).

SYSTEMS AFFECTED
• Gastrointestinal—cat: infection without clinical disease; other species: may have clinical gastroenteritis.
• Ophthalmic—acute or chronic conjunctivitis, unilateral often progresses to bilateral.
• Reproductive—infection without clinical disease.
• Respiratory—mild rhinitis, bronchitis, and bronchiolitis.

GENETICS
None

INCIDENCE/PREVALENCE
• Incidence of clinical disease—sporadic; outbreaks of respiratory disease may occur, especially in multicat facilities.
• Prevalence of *C. felis* in the feline population: ~5–10% chronically infected.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
• Cat
• Human

Breed Predilections
None

Mean Age and Range
Usually cats >8 weeks and <1 year of age; any age of cat possible.

Predominant Sex
None

SIGNS

General Comments
• Commonly associated with feline conjunctivitis.
• Infection often subclinical.
• Clinical disease—commonly coinfection with other organisms, such as feline herpesvirus (FHV) and feline coronavirus (FCV).

Historical Findings
• Primarily signs of ocular discharge, blepharospasm.
• Mild upper respiratory infection, with possible sneezing and oculonasal discharge.
• Varying degrees of anorexia, lethargy.
• Lameness possible (uncommon).

Physical Examination Findings
• Conjunctivitis—unilateral or bilateral chemosis, blepharospasm, conjunctival and third eyelid hyperemia; serous to mucopurulent discharge without keratitis.
• Mild nasal discharge.
• Fever.
• Dyspnea and cough extremely unlikely; rales with pneumonitis.

CAUSES & RISK FACTORS
• Concurrent infections with other respiratory pathogens (FHV, FCV, *Bordetella bronchiseptica*, *Mycoplasma felis*).
• Lack of vaccination.
• Multicat facilities, especially adoption shelters and breeding catteries.
• Stress.
• Presence of asymptomatic shedders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Feline herpesvirus infection—short incubation period (4–5 days), rapid bilateral conjunctivitis, severe sneezing, and ulcerative keratitis.
• Feline calicivirus infection—short incubation period (3–5 days), ulcerative stomatitis, and potentially pneumonia.
• *Mycoplasma felis*.

CBC/BIOCHEMISTRY/URINALYSIS
Leukocytosis possible.

IMAGING
Thoracic radiographs—consolidation of lung tissue with pneumonia.

DIAGNOSTIC PROCEDURES
• PCR—preferred; best sensitivity; submit conjunctival swab in a sterile red top tube with a small amount of sterile saline.
• Culture—obtain conjunctival swab with vigorous exfoliation and submit on ice within 24 hours in special transport media such as 2-sucrose-phosphate (2-SP).
• Conjunctival cytology—characteristic intracytoplasmic basophilic inclusions may be seen with Giemsa staining early in disease.
• Serum antibody titers—limited diagnostic value.
• ELISA kits—variable sensitivity and specificity.

PATHOLOGIC FINDINGS
• Gross—chronic conjunctivitis with mucopurulent ocular discharge; minor rhinitis with nasal discharge; sometimes lung changes indicative of pneumonitis.
• Histopathologic (conjunctiva)—an early intense infiltration of neutrophils; inflammatory response changes to lymphocytes and plasma cells; inclusions detected with special stains (inclusions invisible with routine H&E stains).

TREATMENT

APPROPRIATE HEALTH CARE
Generally outpatient.

NURSING CARE
• Clean eyes and nose as necessary with warm water or saline.
• Provide access to steam, such as in a bathroom, to clear secretions.
• Provide palatable, soft foods; warming food can improve cat's olfaction.
• Generally does not require other supportive therapy (e.g., fluids), unless complicated by concurrent infections.

ACTIVITY
• Quarantine affected cats from contact with other cats.
• Do not allow affected cats to go outside.

DIET
• No restrictions.
• Special diets—to entice anorectic cats to resume eating.

CLIENT EDUCATION
Inform clients of the causative organism, the anticipated chronic course of disease, and the opportunity to vaccinate other cats before exposure.

MEDICATIONS

DRUG(S) OF CHOICE
• Ophthalmic ointments—usually beneficial; oxytetracycline 3-4 times daily for 3 weeks; preparations with polymyxin may be irritating for cats; alternatively erythromycin or fluoroquinolone ointment; resistant to bacitracin, neomycin, gentamicin.
• Systemic antibiotics—tetracyclines are antibiotic of choice; doxycycline (10 mg/kg PO q24h or 5 mg/kg PO q12h for 4 weeks to prevent recrudescence); amoxicillin-clavulanate (20–25 mg/kg PO q12h) as alternative for young kittens.

CONTRAINDICATIONS
Tetracyclines—risk for esophagitis; may affect growing teeth of young kittens.

PRECAUTIONS
Colonies/shelters/breeding catteries—all cats may have to be treated; treatment should be continued for 4 weeks.

POSSIBLE INTERACTIONS
None

ALTERNATIVE DRUG(S)
None

FOLLOW-UP

PATIENT MONITORING
Monitor for improved health as treatment proceeds.

PREVENTION/AVOIDANCE

Vaccines
- Both inactivated and modified live vaccines available.
- Vaccines do not prevent infection; rather, they reduce severity and duration of clinical disease.
- American Association of Feline Practitioners—noncore vaccine; for at-risk cats, give a single vaccination at initial visit as early as 9 weeks of age, repeat in 3–4 weeks; revaccinate annually where *C. felis* is endemic.
- Adverse vaccine reactions—mild clinical disease with modified live vaccines in small percentage of vaccinated cats.

Environmental Management
- Quarantine affected cats by >4 ft perimeter.
- Practice appropriate hygiene and beware of fomites.
- *C. felis* readily inactivated with common disinfectants.

POSSIBLE COMPLICATIONS
- If kittens are affected <2 weeks of age, eyelids may need to be surgically opened to allow for drainage of purulent material (ophthalmia neonatorum).
- If entire course of antibiotics are not completed, persistently infected cats can become asymptomatic shedders.
- Coinfections increase morbidity.

EXPECTED COURSE AND PROGNOSIS
- Without treatment, tends to be chronic, lasting for several weeks or months.
- Prognosis good with appropriate antibiotic therapy.
- Improvement in 1–2 days with therapy; 28 days of treatment needed to clear organism.
- Look for coinfections if not improving as expected.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Affected cats may be concurrently infected with FHV or FCV, especially in multicat and breeding facilities.

AGE-RELATED FACTORS
Primarily a disease of young cats.

ZOONOTIC POTENTIAL
C. felis can infect humans, especially immunocompromised individuals; limited number of reports of mild conjunctivitis in humans transmitted from infected cats.

PREGNANCY/FERTILITY/BREEDING
- Endemic breeding catteries—treat all cats with doxycycline for at least 4 weeks; then vaccinate.
- Role of *C. felis* as a pathogen during pregnancy—unclear; can colonize the reproductive mucosa; severe ophthalmia neonatorum can occur in neonatal kittens infected at or shortly after birth.

SYNONYMS
Feline pneumonitis.

SEE ALSO
- Conjunctivitis—Cats.
- Feline Calicivirus Infection.
- Feline Herpesvirus Infection.
- Feline (Upper) Respiratory Infections.
- Mycoplasmosis.
- Ophthalmia Neonatorum.

ABBREVIATIONS
- 2-SP = 2-sucrose-phosphate.
- FCV = feline calicivirus.
- FHV = feline herpesvirus.

CHOCOLATE TOXICOSIS

BASICS

DEFINITION

• Chocolate, derived from the seed of the *Theobroma cacao* plant, contains the naturally occurring methylxanthine alkaloids theobromine and caffeine. • Excessive intake can lead to dose-dependent gastroenteric, cardiac, and neurologic toxicosis. • Theobromine is the largest fraction of methylxanthines in chocolate products; lower concentration of caffeine is present (Table 1). Other sources of methylxanthines include coffee, tea, diet pills, over-the-counter (OTC) stimulants, and herbal medications.

PATHOPHYSIOLOGY

• Variably absorbed orally (caffeine <1 hour; theobromine 10 hours), metabolized by liver, undergo enterohepatic recirculation; metabolites primarily excreted via urine and may be reabsorbed from urinary bladder. • Estimated theobromine and caffeine half-lives in dogs 17.5 hours and 4.5 hours, respectively. • Methylxanthines inhibit phosphodiesterase to increase intracellular cyclic adenosine monophosphate (cAMP), stimulate catecholamine release, and increase intracellular calcium, which results in vasoconstriction, increased myocardial and skeletal muscle contractility, and CNS stimulation. • Toxic dosages: ◦ Theobromine—LD_{50} (dog) 250–500 mg/kg; LD_{50} (cat) 200 mg/kg. Mild signs (agitation, vomiting, diarrhea): 20 mg theobromine/kg. Moderate signs (tachycardia): 40–50 mg theobromine/kg. Severe signs (seizures): 60 mg theobromine/kg. ◦ Caffeine—LD_{50} (dog) 140 mg/kg; LD_{50} (cat) 80–150 mg/kg. Clinical signs: >15 mg caffeine/kg. Moderate signs: >25 mg caffeine/kg. Cardiotoxic signs: >50 mg caffeine/kg. • Several aids to assess canine risk from chocolate can be found online—see Internet Resources.

SYSTEMS AFFECTED

• Cardiovascular—tachycardia, hypertension, ventricular premature contractions (VPCs), other tachyarrhythmias, bradycardia (rare). • Gastrointestinal (GI)—vomiting, diarrhea, regurgitation. • Metabolic—hypokalemia, hyperthermia, dehydration. • Nervous—agitation, tremors, seizures, ataxia, muscle rigidity, hyperreflexia. • Renal/urologic—polyuria, polydipsia. • Respiratory—panting, tachypnea, cyanosis, respiratory failure.

INCIDENCE/PREVALENCE

• Dogs—among 10 most common poisonings reported by small animal practices and animal poison control centers. • More common at holidays when chocolate products readily available.

GEOGRAPHIC DISTRIBUTION

Indoor dogs at risk owing to closer proximity to chocolate products.

SIGNALMENT

Species

• Dogs most frequently poisoned based on proximity to methylxanthine products and propensity for dietary indiscretion leading to excessive ingestion. • Cats rarely affected.

Breed Predilections

• Small dogs may be at higher risk due to smaller body weight relative to amount of chocolate consumed. • Breeds prone to dietary indiscretion, such as Labrador retrievers.

SIGNS

Historical Findings

• History of ingestion. • Evidence of chewed packaging. • Vomiting and diarrhea—vomit often contains evidence of chocolate and may be first sign noted. • Early restlessness and hyperactivity. • Polydipsia.

Physical Examination Findings

• Physical exam may be normal after recent ingestion (<1–2 hours). • Vomiting. • Diarrhea. • Restlessness and hyperactivity. • Panting. • Polyuria/polydipsia. • Dehydration. • Tachycardia. • Cardiac arrhythmias such as VPCs. • Hypertension. • Hyperthermia. • Tremors. • Hyperreflexia and muscle rigidity. • Seizures. • Advanced signs with severe toxicosis—cardiac failure, weakness, cyanosis, coma, and death. • Death—12–48 hours after ingestion.

CAUSES

Excessive ingestion of chocolate and other methylxanthine products.

RISK FACTORS

• Access to chocolate, which is palatable and attractive to dogs, often readily available, and unprotected in homes and kitchens. • Dogs with preexisting heart disease may be more sensitive to cardiac effects.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Convulsant or excitatory alkaloids—strychnine, amphetamine, nicotine, 4-aminopyridine. • Convulsant pesticides such as pyrethroids, organochlorines, bromethalin, zinc phosphide, metaldehyde. • Tremorgenic mycotoxins. • Acute psychogenic drugs—LSD, cocaine. • Medications such as phenylpropanolamine, pseudoephedrine, tricyclic and selective serotonin reuptake inhibitor antidepressants. • Cardioactive glycosides—*Digitalis* spp., *Nerium oleander*. • Primary GI, cardiac, or neurologic disease.

CBC/BIOCHEMISTRY/URINALYSIS

• Hyperglycemia or hypoglycemia. • Hypokalemia, especially with caffeine overdose. • Urine may be dilute due to polydipsia.

OTHER LABORATORY TESTS

• Methylxanthine assay—rarely necessary as history and clinical signs usually sufficient for diagnosis; can be performed on stomach contents, plasma, serum, urine, or liver.

DIAGNOSTIC PROCEDURES

• ECG monitoring—sinus tachycardia, VPCs, and ventricular tachyarrhythmias. • Blood pressure monitoring.

PATHOLOGIC FINDINGS

• Presence of chocolate in GI tract. • Nonspecific gastroenteritis. • No distinctive microscopic lesions.

TREATMENT

APPROPRIATE HEALTH CARE

• Emesis in stable patients considered low risk for aspiration; chocolate is slowly absorbed from a dog's stomach, so emesis may be rewarding up to 6–8 hours after ingestion. • Gastric lavage with cuffed tube in symptomatic patients with large-volume ingestions once stabilized. • Activated charcoal may not be necessary with lower-dose exposures or in cases where most of the chocolate was recovered by induction of vomiting or gastric lavage; monitor electrolytes for hypernatremia if giving multiple doses of activated charcoal. • IV fluid therapy to correct dehydration, promote urinary excretion of methylxanthines, and avoid hypernatremia; SC fluids may suffice with lower-dose exposures; potassium may be supplemented in fluids, if needed. • Control hyperthermia. • Urine voiding every 4 hours or urinary catheterization may reduce urinary bladder resorption. • GI support as needed (see Medications). • Control hyperactivity and agitation, tremors, seizures (see Medications). • Treat tachycardia with beta blockers, if sedation not effective; treat arrhythmias with anti-arrhythmic drugs as appropriate (see Medications).

NURSING CARE

Fluid therapy used to correct electrolyte disturbances and dehydration and to enhance excretion of methylxanthines.

ACTIVITY

Avoid stress and limit activity until recovered.

DIET

• No food until vomiting is controlled. • Convalescence—bland, low-fat diet to aid recovery from gastroenteritis and/or pancreatitis.

CLIENT EDUCATION

Warn owners about toxicologic hazards of chocolate, and advise keeping chocolate out of reach of dogs.

MEDICATIONS

DRUG(S) OF CHOICE

• Induce emesis—*only if patient is stable with low risk of aspiration*; apomorphine

(CONTINUED) CHOCOLATE TOXICOSIS

Table 1

Comparative concentrations of caffeine and theobromine

Caffeine Source	*Amount (mg/g)*	*Amount (mg/oz)**
Coffee beans	10–20	284–570
Drip coffee	90–100 mg/6 oz cup	15–20
Cola drinks	30–71 mg/12 oz can	2.5–6
Baking chocolate (unsweetened)	0.8	23
Dark chocolate	0.43–0.8	12–23
Milk chocolate	0.2	6
Cocoa powder (unsweetened)	2.3	70
Guarana	30–50	850–1,400
Caffeine stimulant tablets	50–200 mg/tablet	————
OTC migraine pain control	65 mg/tablet	————
Theobromine Source	*Amount (mg/g)*	*Amount (mg/oz)*
Cacao beans	10–50	300–1500
Baking chocolate (unsweetened)	13–16	370–454
Milk chocolate	1.5–2	42–57
Cacao bean hulls	5–9	142–256
Cacao bean mulch	2–30	57–852
Cocoa powder (unsweetened)	14–29	398–832

* To convert mg/g to mg/oz, multiply by 28.4.

(0.02–0.04 mg/kg IV); hydrogen peroxide 3% (1–2 mL/kg PO); do not exceed 50 mL in dogs. • Activated charcoal 1–2 g/kg PO with cathartic × 1 dose. With large ingestions, repeat activated charcoal (no cathartic) q8 up to 24h to prevent enterohepatic recirculation. • Hyperactivity—acepromazine (0.02–0.04 mg/kg IV/IM/SC) or butorphanol (0.2–0.5 mg/kg IM/IV), with doses repeated/titrated to effect. • Seizures—diazepam (0.5–1 mg/kg IV) or phenobarbital (2–6 mg/kg IV) as needed to effect. • Tremors—diazepam (0.5–1 mg/kg IV) or methocarbamol (50–220 mg/kg IV slowly, up to daily dose of 330 mg/kg). • Vomiting—maropitant (1 mg/kg SC or IV) q24h as needed. • Persistent ventricular tachycardia—metoprolol (0.04–0.06 mg/kg IV), esmolol (initial loading dose 0.25–0.5 mg/kg IV slowly over 1–2 min, followed by CRI at 10–200 µg/kg/min) or propranolol (0.02–0.06 mg/kg IV); metoprolol or esmolol preferred but may be difficult to obtain. • Ventricular arrhythmias (dogs)—lidocaine (2–4 mg/kg IV followed by 25–100 µg/kg/min IV CRI); lidocaine not recommended in cats. • In rare instance of bradycardia—atropine 0.02–0.04 mg/kg IV/IM/SC; rule out reflex bradycardia from hypertension before use.

CONTRAINDICATIONS

• Do not use epinephrine concurrent with lidocaine. • Avoid erythromycin and corticosteroids, which may reduce excretion of methylxanthines. • Do not use lidocaine in cats due to risk of seizures.

PRECAUTIONS

Keep patient under observation until recovered and treatment no longer needed.

FOLLOW-UP

PATIENT MONITORING

Monitor heart rate, blood pressure, ECG, mentation, and temperature closely while hospitalized.

PREVENTION/AVOIDANCE

Warn owners about toxicologic hazards of chocolate and advise keeping chocolate out of reach of dogs.

POSSIBLE COMPLICATIONS

• Aspiration can occur rarely secondary to vomiting. • Pancreatitis can occur in some patients that consume chocolate.

EXPECTED COURSE AND PROGNOSIS

• Expected course—12–36 hours, up to 72 hours in severe cases, depending on dosage and effectiveness of decontamination and treatment. • Successfully treated patients—usually recover completely. • Prognosis—good if prompt oral decontamination occurs, but guarded with advanced signs of seizures and arrhythmias.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Methylxanthines cross the placenta and are excreted in milk.

CHOLANGITIS/CHOLANGIOHEPATITIS SYNDROME

BASICS

DEFINITION
- Cholangitis—bile duct inflammation.
- Cholangiohepatitis—inflammation of bile ducts and adjacent liver parenchyma.
- Cholangitis/cholangiohepatitis syndrome (CCHS)—more common in cats; histologically classified as suppurative (predominant neutrophilic inflammation, S-CCHS); nonsuppurative (lymphocytic, plasmacytic, NS-CCHS); lymphoproliferative (may transition to lymphosarcoma); or granulomatous.

PATHOPHYSIOLOGY
- Antecedent or coexisting conditions—inflammation or obstruction involving extrahepatic bile duct (EHBDO) or pancreatic duct (cat), pancreatitis or inflammatory bowel disease (IBD; dog, cat); chronic interstitial nephritis (CIN; cat).
- Bacterial infection may be primary or secondary.
- Acute or chronic cholangitis—associates with biliary epithelial hyperplasia and ductular reaction.
- Chronic inflammation—may cause bile duct dystrophic mineralization or cholelithiasis.
- S-CCHS—usually positive bacterial culture or bacteria observed cytologically (tissue or bile); rarely observed in liver tissue, may observe in gallbladder (GB).
- NS-CCHS—immune-mediated and self-perpetuating, may evolve from S-CCHS.
- Sclerosing or destructive cholangitis—bile duct involution/destruction, may be immune mediated or infectious; leads to loss of small and medium-sized bile ducts (ductopenia) with "sclerosing" circumferential fibrosis; ductopenia is severe lesion.
- Pyogranulomatous CCHS—infectious or immune mechanisms (dog or cat).
- Lymphoproliferative disease—speculated transition stage of inflammation to neoplasia.

SYSTEMS AFFECTED
- Hepatobiliary—liver and biliary system.
- Gastrointestinal (GI)—pancreas and intestines.

INCIDENCE/PREVALENCE
NS-CCHS—most common chronic liver disorder in cats.

SIGNALMENT
Species
Cat (common), dog (uncommon).

Breed Predilections
Possibly Himalayan, Persian, Siamese cats.

Mean Age and Range
- S-CCHS—range: 0.4–16 years; mostly young to middle-aged cats.
- NS-CCHS—range: 2–17 years; mostly middle-aged cats.

Predominant Sex
- S-CCHS—male cats may be predisposed.
- NS-CCHS—no sex prevalence.

SIGNS
General Comments
- S-CCHS—most severe clinical illness, acute onset (often <5 days); abdominal pain, pyrexia; associated with EHBDO and cholelithiasis.
- NS-CCHS—ill >3 weeks (months to years).

Historical Findings
Feline CCHS—cyclic illness with chronic vague signs: lethargy, vomiting, anorexia, weight loss; ductopenic cats demonstrate polyphagia, acholic stools, variable steatorrhea, reduced uptake of fat-soluble substances.

Physical Examination Findings
- S-CCHS—fever; painful abdomen; ± jaundice; dehydration; shock.
- NS-CCHS—few physical abnormalities other than variable hepatomegaly; thickened intestines with IBD; variable jaundice; rare abdominal effusion.
- Ductopenia (cats)—unkempt coat, cyclic lateral thoracoabdominal alopecia; jaundiced; acholic feces (may be cyclic).

CAUSES
Suppurative CCHS
- Infections acquired as result of ductal plate malformations (DPM), all phenotypes but most commonly choledochal cyst and caroli phenotypes.
- Bacterial infection—more common in cats: *E coli and Enterococcus* most common, but numerous bacteria (e.g., *Enterobacter*, β-hemolytic *Streptococcus*, *Klebsiella*, *Actinomyces*, *Clostridia*, *Bacteroides*); rare toxoplasmosis; dogs: usually enteric opportunists; rare *Campylobacter*, *Salmonella*, *Leptospirosis*, others.
- Aerobic infections commonest, polymicrobial infections in ~30%.
- May represent sequela to intermittent mechanical bile flow stasis or EHBDO; DPM with cholelithiasis most common associated disorder.

Nonsuppurative CCHS
Concurrent disorders—cholecystitis, cholelithiasis, pancreatitis, EHBDO, IBD (dogs, cats); CIN (cats).

RISK FACTORS
- S-CCHS—EHBDO; cholelithiasis; DPM; other causes of cholestasis; infections elsewhere (dental, splenic abscess, pyelonephritis).
- Feline NS-CCHS—IBD, pancreatitis, EHBDO, cholelithiasis, CIN; may evolve from chronic intermittent S-CCHS.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
- Feline hepatic lipidosis (FHL)—may coexist; similar enzyme patterns with jaundice but low γ-glutamyl transferase (GGT) unless concurrent biliary or pancreatic inflammation.
- EHBDO and obstructive cholelithiasis; variable jaundice, increased alkaline phosphatase (ALP), GGT, transaminase activities; increased cholesterol.
- Pancreatitis—may reflect cholelithiasis-initiated CCHS in cats; lipemia, high cholesterol, hyperbilirubinemia; inconsistent high feline pancreatic lipase activity (fPLI); high fPLI implicates pancreatic inflammation but also may reflect IBD, pancreatic duct inflammation/obstruction from cholelithiasis; ultrasound may differentiate.
- Lymphoproliferative disease and lymphoma—may involve any enteric segment, mesenteric/thoracic lymphadenopathy; shares clinical features with CCHS; hepatic infiltrates may require immunohistochemical characterization and clone evaluation to differentiate lymphoproliferative or lymphoma from NS-CCHS.
- Jaundice of septicemia—hyperbilirubinemia dominates clinical biochemical features, usually disproportionate to magnitude of liver enzyme activity unless concurrent CCHS.
- DPM occur in dogs, cats, esp. longhaired cats (Persian and Himalayan)—normal or modestly increased liver enzymes (see Ductal Plate Malformations); variable mild to moderate suppurative or nonsuppurative portal aggregates, cholangitis, or CCHS.

CBC/BIOCHEMISTRY/URINALYSIS
CBC
- Poikilocytes; nonregenerative anemia; anemia of chronic disease; Heinz body hemolysis.
- S-CCHS—variable neutrophilic leukocytosis, left shift, toxic neutrophils; NS-CCHS—may be normal; lymphoproliferative disorder or lymphoma may have lymphocytosis ± abnormal cell morphology.

Serum Biochemistry
- Consistent findings—high alanine aminotransferase (ALT), aspartate aminotransferase (AST), ALP, variable GGT.
- Variable findings—high total serum bile acids, bilirubin, cholesterol: depends on severity and extent of cholestasis, coexistent illness, liver dysfunction, cholelithiasis, DPM-associated hepatic fibrosis.

(CONTINUED) # CHOLANGITIS/CHOLANGIOHEPATITIS SYNDROME

OTHER LABORATORY TESTS

- Species-specific PLI—may be high with pancreatitis, enteritis, or cholelith occlusion of bile duct ampulla in cats.
- Vitamin B_{12}—low values indicate small bowel malabsorption, exocrine pancreatic disease, chronic oral antimicrobials (dysbiosis).
- Coagulation tests—variable results; prothrombin time most sensitive for vitamin K_1–induced coagulopathy.
- T_4—rules out hyperthyroidism as cause of increased liver enzyme activity in cats.

IMAGING

- Thoracic radiography—sternal lymphadenopathy may reflect abdominal inflammation or lymphoma, general lymphadenopathy suggests lymphoma.
- Abdominal radiography—normal to large liver in NS-CCHS; mineralized choleliths or biliary structures in S-CCHS or NS-CCHS.
- Abdominal US—normal to large liver; thick extrahepatic bile duct or GB wall if choledochitis or cholecystitis; echogenic intraluminal debris; choleliths; focal parenchymal lesions (abscess, infiltrates: inflammation, neoplasia); lymphadenopathy suggests pancreatic, liver, intestinal inflammation or neoplasia; hepatic parenchymal hyperechogenicity (concurrent FHL, fibrosis); hypoechogenicity (inflammation); cysts (DPM, cystadenoma). *Note*: no US lesions apparent in some animals with CCHS.

DIAGNOSTIC PROCEDURES

Fine-Needle Aspiration Cytology

- Hepatic aspiration—for culture and diagnosis of FHL; cytology may reveal bacteria not visualized by light microscopy of biopsy sections. *Note*: cytology is diagnostic for FHL but unreliable for diagnosis of NS-CCHS; hepatocyte vacuolation common in ill cats, may implicate FHL as primary process when consequence of primary hepatic disease.
- Cholecystocentesis—may disclose suppuration, bacteria, trematode eggs, or neoplasia.

Percutaneous Biopsy

- US-guided core-needle biopsy—small sample size may misdiagnose CCHS; need min 15 portal triads for accuracy; if 18-G core needle used, collect min 4 samples.
- Inaccuracy with needle biopsy in feline CCHS reflects biopsy of single liver lobe in syndrome with differential lobe involvement or small sample size.
- Postbiopsy complications—esp. cats: collapse due to vasovagal response; biliary trauma; cats and tiny dogs: unintentional sampling of nonhepatic tissues.

Laparoscopy

- Permits direct visualization of GB, common bile duct (CBD), porta hepatis, pancreas, perihepatic and peripancreatic lymph nodes; allows biopsy of multiple liver lobes, pancreas, aspiration collection of bile.
- In EHBDO—not recommended, see Laparotomy.

Laparotomy

- Esp. if suspected EHBDO or choleliths in CBD or GB.
- Permits inspection and flushing of extrahepatic biliary conduits; biliary decompression and biliary enteric anastomosis.
- May be preferable approach in cats with CCHS as allows biopsy of liver, biliary structures, pancreas, intestines, lymph nodes, bile collection.

Tissue Sampling

If NS-CCHS suspected, also biopsy bowel, pancreas, and suspicious lymph nodes.

Bile and Tissue Cultures

- Aerobic and anaerobic bacterial cultures—of liver, bile, any choleliths (crushed); bile sample should include particulate debris (empty GB to collect mucin-laden bile: site of bacterial biofilm).
- If cholecystectomy done—scrape portion of GB wall and cut section of GB wall for culture.
- Put bile, GB wall, crushed cholelith, liver in same culture transport medium.

Molecular Genetics

Genetic test for feline polycystic disease may be appropriate if DPM diagnosis, especially if breeding animal.

PATHOLOGIC FINDINGS

- S-CCHS—normal or swollen liver, sharp or blunt edges, focal discolorations; may note erythematous, necrotic, or thick-walled GB; peripancreatic steatonecrosis or fat saponification (pancreatitis); perihepatic and peripancreatic lymphadenopathy; EHBDO: may observe choleliths or cystic lesions (DPM) or neoplastic mass lesions.
- NS-CCHS—variable liver size, normal to firm texture; sharp or blunt margins; variable surface irregularity; choleliths or cystic lesions (DPM phenotypes).
- If concurrent FHL—pale yellow friable parenchyma, liver floats in formalin.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient Management

- *S-CCHS with acute febrile illness, painful abdomen, left-shifted leukogram*—hydration support, "best guess" bactericidal antimicrobials: initially based on cytology and Gram stain or start trimodal antibiotics, esp. if EHBDO or cholecystitis suspected. Antibiotics essential *before* surgery; continue antibiotics ≥4 weeks with choleretic therapy until enzymes normalize or signs resolve (see Medications).
- *NS-symptomatic cats*—fluid therapy as necessary; if jaundiced: vitamin K_1 (0.5–1.5 mg/kg SC/IM q12h for 3 doses) before invasive diagnostics; cats with CCHS may need blood transfusion consequent to surgery or biopsy.
- Polyionic fluids—with B-soluble vitamins (2 mL/L), KCl, and K phosphate if refeeding syndrome possible; avoid dextrose supplements unless hypoglycemia (see Hepatic Lipidosis).

Outpatient Management

- S-CCHS—after acute crisis managed.
- NS-CCHS—after resolution of acute crisis, provide lifelong immunomodulation (if no bacteria observed or cultured), antioxidants, hepatoprotectants.

ACTIVITY

Restricted while symptomatic.

DIET

Nutritional support—avoid FHL in cats by feeding balanced high-protein, high-calorie feline diet; supplement water-soluble vitamins; antigen-restricted diet if concurrent IBD; fat-restricted diet if steatorrhea due to chronic EHBDO or severe ductopenia or chronic pancreatitis causing maldigestion; may require feeding tube; rarely require parenteral nutrition (may provoke FHL).

CLIENT EDUCATION

Emphasize chronic nature of NS-CCHS and requirement for lifelong therapy.

SURGICAL CONSIDERATIONS

- Cholecystectomy—if cholecystitis.
- Cholecystoenterostomy—may be necessary for some causes of EHBDO; if choleliths in GB: perform cholecystectomy.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics: S-CCHS

- Bactericidal—against enteric opportunists; initial combination of ticarcillin or clavamox with enrofloxacin and metronidazole (7.5–15 mg/kg PO q12h; low dose if jaundiced).
- Modify initial empiric antimicrobials based on culture and sensitivity reports; resistant enterococcus may require vancomycin (10 mg/kg q12h IV slow infusion for 7–10 days).

Immunomodulation: NS-CCHS

- Glucocorticoids—prednisolone (dogs: 2 mg/kg/day prednisone or prednisolone; cats: 2–4 mg/kg/day prednisolone only) for 14–21 days, taper to lowest effective alternate-day dose based on ALT and clinical signs.

CHOLANGITIS/CHOLANGIOHEPATITIS SYNDROME (CONTINUED)

• Metronidazole—used for cell-mediated immunomodulation, antiendotoxin and antibacterial effects, esp. for IBD; as chronic bacterial involvement possible in feline NS-CCHS, chronic antibiotic treatment may be beneficial.
• Cats with confirmed ductopenia—aggressive immunomodulation; *do not use azathioprine*; clinical experience suggests combination of prednisolone, metronidazole with pulsed methotrexate (see below) *or* chlorambucil 1–2 mg per cat, load q24h for 3 days then every 3 days.
• *Methotrexate protocol feline destructive or sclerosing NS-CCHS:* 0.4 mg *total dose* given in 3 divided doses *on 1 day* (0.13 mg total at 0, 12, and 24h), repeated at 7–10-day intervals), PO/IV/IM (parenteral routes require 50% dose reduction); concurrently provide folate (folinic acid) 0.25 mg/kg daily. If lymphoproliferative or neoplastic infiltrates, use chemotherapy protocols developed for enteric lymphoma.

Antioxidants

• Vitamin E (α-tocopherol acetate)—10 IU/kg), using oral water-soluble form in chronic EHBDO or ductopenia (fat malabsorption).
• S-adenosylmethionine (SAMe)—20 mg/kg/day enteric-coated tablet PO 2h before feeding; benefits include anti-inflammatory influence; high dose for glutathione choleresis: 40 mg/kg/day.

Other

• Ursodeoxycholic acid (UDCA)—10–15 mg/kg/day PO divided, given with food for best bioavailability; provides immunomodulatory, hepatoprotectant, choleretic, antifibrotic, antioxidant effects; in immune-mediated NS-CCHS with developing ductopenia, use is controversial based on work in humans and animal models of immune-mediated destructive cholangitis: findings indicate may hasten small duct injury; liver biopsy recommended before prescribing UDCA for cats with "suspected" chronic CCHS; taurine supplementation (250 mg/day) should be considered in cats with poor appetite given chronic UDCA because of obligatory bile acid taurine conjugation.
• B vitamin supplementation—thiamine (B_1) and B_{12}: thiamine 50–100 mg PO q24h for 3 days, then in water-soluble vitamin supplements while hospitalized; B_{12} 0.25–1.0 mg SC if suspect gut malabsorption, using initial and sequential plasma B_{12} concentrations to guide need for chronic supplementation.

CONTRAINDICATIONS

Adjust drug dosages with regard to liver function and cholestasis. Caution with metronidazole to avoid neurotoxicity—if jaundiced use 7.5 mg/kg PO BID.

FOLLOW-UP

PATIENT MONITORING

• S-CCHS—follow body temperature, CBC, biochemical profile initially q7–14 days; continue antibiotics until clinical features normalize; if DPM may require lifelong antimicrobials.
• Animals with intrahepatic cholelithiasis and S-CCHS require long-term antibiotics, UDCA, high-dose SAMe, and monitoring for recurrent sepsis, stone migration (e.g., CBD, EHBDO).
• NS-CCHS—initially monitor enzymes and bilirubin q7–14 days, then monthly for 3 months to judiciously adjust immunomodulatory protocol, then quarterly.
• Serum bile acid measurements complicated by ursodeoxycholic acid administration and superfluous in circumstance of hepatobiliary jaundice

PREVENTION/AVOIDANCE

• Control IBD.
• If S-CCHS in animals with DPM—manage long term with appropriate antibiotics (see Ductal Plate Malformation).
• If choleliths in CBD or GB—surgically intervene: cholecystectomy if GB choleliths; flushing CBD free of lithic material essential if EHBDO.

POSSIBLE COMPLICATIONS

• S-CCHS may transform to NS-CCHS or sclerosing CCHS.
• Diabetes mellitus develops in ~30% of cats with sclerosing CCHS treated with prednisolone.
• FHL may develop due to inadequate nutritional intake or as side effect of glucocorticoids.

EXPECTED COURSE AND PROGNOSIS

• S-CCHS—may be cured.
• NS-CCHS—chronic, long-term, vacillating illness or remission possible (survival >8 years documented in some cats).

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Pancreatitis.
• Hepatic lipidosis.
• DPM.
• Lymphosarcoma.
• Lymphoproliferative disease.
• Cholangiocarcinoma—may develop in some cats with chronic NS-CCHS or DPM.

SEE ALSO

CHOLECYSTITIS AND CHOLEDOCHITIS

BASICS

OVERVIEW

• Cholecystitis = gallbladder (GB) inflammation. • Choledochitis = large bile duct inflammation. • Associated with cholelithiasis; secondary to GB mucocele (GBM); extrahepatic bile duct obstruction (EHBDO); inflammation of intrahepatic biliary structures (common in ductal plate malformation [DPM]). • Severe GB inflammation can lead to rupture and subsequent bile peritonitis, necessitating combined surgical and medical interventions. • Bile duct obstruction increases risk for biliary infection: enteric bacteria transmigrate bowel wall, pass into portal circulation, disseminate within liver, bile, and then GB, dispersing endotoxins and bacteria that may cause systemic sepsis or septic peritonitis.

SIGNALMENT

• Dog and cat. • No breed or sex predilection. • Necrotizing cholecystitis (dogs)—usually middle-aged or older animals. • GBM—predisposition for elderly dogs, dogs with hyperlipidemia or hypercholesterolemia (e.g., endocrinopathies [hyperadrenocorticism, hypothyroidism, diabetes mellitus]), pancreatitis, glucocorticoid administration, nephrotic syndrome, idiopathic hyperlipidemia (e.g., Shetland sheepdogs, miniature schnauzers, beagles, others); leads to cholestasis and possible cholecystitis (see Gallbladder Mucocele).

SIGNS

• Choledochitis—vague signs, variable icterus. • Sudden onset—inappetence, lethargy, vomiting, vague abdominal pain (may be postprandial with cholecystitis or GBM, reflecting post-meal GB contraction). • Chronic postprandial discomfort/distress—position of comfort, stretching, pacing, panting. • Mild to moderate jaundice and fever common. • Severe disease—shock due to endotoxemia, bacteremia, hypovolemia. • Soft tissue mass in right cranial abdomen palpable in small dogs and cats, reflecting inflammation or adhesions between GB and pericholecystic tissues.

CAUSES & RISK FACTORS

• Impaired bile flow at cystic duct or GB (cholelithiasis, mass lesions), GB dysmotility, or ischemic insult to GB wall (from GB distention)—may precede cholecystitis ± necrotizing lesions. • Irritants in sludged bile (e.g., lysolecithin, prostaglandins, choleliths, flukes) or retrograde flow of pancreatic enzyme into bile duct in cats may initiate/augment GB or duct inflammation. • Previous enteric disorders, trauma, abdominal surgery—may be contributing factors. • Anomalous GB or duct development—DPM lesions including choledochal cysts (cats > dogs). • Bacterial infection—common; retrograde duct bacterial invasion from intestines or hematogenous dispersal from splanchnic circulation. • Toxoplasmosis and biliary coccidiosis—rare causes. • Necrotizing cholecystitis (dogs)—ruptured GB (common, often secondary to cholelithiasis or hypermature GBM); *E. coli* and *Enterococcus* spp.: common isolates. • Emphysematous cholecystitis/choledochitis—rare, associated with diabetes mellitus, traumatic GB ischemia, acute cholecystitis (with or without cholelithiasis); common gas-forming organisms: *Clostridia* spp. and *E. coli*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• EHBDO. • GBM. • Cholelithiasis. • Cholangitis/cholangiohepatitis. • Pancreatitis. • Focal or diffuse peritonitis. • Bile peritonitis. • Gastroenteritis with biliary involvement. • Hepatic necrosis or abscessation. • Septicemia.

CBC/BIOCHEMISTRY/URINALYSIS

• Variable leukocytosis with toxic neutrophils and inconsistent left shift if necrosis or sepsis. • High bilirubin and bilirubinuria common. • High alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), and γ-glutamyl transferase (GGT) activity. • Low albumin with peritonitis. • High cholesterol and bilirubin if EHBDO. • Hypercholesterolemia and/or hypertriglyceridemia—breed related, endocrine related, pancreatitis, nephrotic syndrome, EHBDO, GBM.

OTHER LABORATORY TESTS

• Abdominocentesis—inflammatory effusion (see Bile Peritonitis). • Bile culture (dogs and cats)—*E. coli*, *Enterococcus* spp., *Klebsiella* spp., *Pseudomonas* spp., *Clostridium* spp., many others. • Coagulation tests—abnormal if chronic EHBDO (vitamin K deficiency) or disseminated intravascular coagulation (DIC) in severe conditions with sepsis; cats display coagulopathy with EHBDO early.

IMAGING

• Abdominal radiography—may reveal loss of cranial abdominal detail with focal or diffuse peritonitis or effusion; ileus; radiodense choleliths; gas in biliary structures; radiodense GB (dystrophic mineralization due to chronic inflammation; porcelain GB is rare). • Ultrasonography—diffusely thick GB wall, segmental hyperechogenicity and/or laminated wall or double-rimmed GB wall observed with necrotizing cholecystitis; double-rimmed GB wall also observed with acute cholecystitis, hepatitis, cholangiohepatitis; GB lumen filled with amorphous echogenic stellate or finely striated pattern, resembling sliced kiwi fruit ("kiwi sign") in mature GBM; GB rupture implicated by discontinuous GB wall, pericholecystic fluid, or generalized effusion, and hyperechogenicity of pericholicystic tissue; failure to image GB: may implicate rupture or agenesis; mineralized GB wall may indicate dystrophic mineralization (limey or porcelain GB) due to chronic cholecystis often associated with sacculated GB or bile ducts in DPM: Caroli's phenotype; intrahepatic bile ducts may be difficult to visualize or be thick and prominent: ascending cholangitis or EHBDO (dilated ducts, "too many tubes signs" defined with color-flow Doppler); pericholecystic fluid: necrotizing cholecystitis and surgical emergency. • Choledochitis involving common bile duct (CBD)—thick wall, intraluminal debris, extends into hepatic ducts.

PATHOLOGIC FINDINGS

• Gross appearance—erythematous GB; may appear green-black if necrotizing lesion; tenacious "inspissated" biliary material common with GBM; pigmented choleliths if infection; dark black or frank blood if hemobilia; CBD with thick wall, variable intraductal debris (e.g., biliary particulates, cholelithiasis, suppurative inflammation). • Microscopic features of GBM without cholecystitis are benign, with wall thinning, mucosal cystic hyperplasia, elongated mucosal fronds extending from flattened mucosa, without granulation response in GB wall; if chronic GBM may involve arterial thrombi and/or transformation to chronic cholecystitis. • Microscopic features of cholecystitis include inflammatory infiltrates in lamina propria (lymphoplasmacytic or suppurative with macrophages, rarely eosinophilic, occasional lymphoid follicular hyperplasia), intraluminal suppurative/necrotic debris; if chronic cholecystitis—submucosal granulation tissue with variable ulcerative/necrotic mucosa, occasional hemobilia, occasional arterial thrombi; if cholelithiasis—hyperplastic mucosa with dense elongated mucosal fronds and glands contrasting with flattened appearance of GBM.

TREATMENT

• Inpatient—provision of critical care during diagnostic/presurgical evaluations or if septic. • Place IV catheter in peripheral vein for polyionic fluids and blood component therapy as needed. • Restore fluid and electrolyte balance; monitor electrolytes frequently. • Vitamin K—if jaundiced; give parenterally (see Medications) before surgical interventions, cystocentesis, jugular venipuncture, other iatrogenic trauma. • Plasma—preferred colloid; indicated if hypoalbuminemia *and* coagulopathy or if anticipated surgical

CHOLECYSTITIS AND CHOLEDOCHITIS (CONTINUED)

interventions and complicating coagulopathy uncorrected. • Whole blood or fresh frozen plasma—for surgical cases with bleeding tendencies; if septic, artificial colloids may delay recovery; if bleeding, some artificial colloids impair platelet aggregation. • Monitor urine output. • Remain vigilant for vasovagal reflex (abrupt bradycardia, hypotension, cardiac arrest) during biliary tree manipulation or cholecystocentesis; be prepared with anticholinergics (atropine) and pressor drugs. • Remain vigilant for cholangiovenous reflux—systemic dispersal of endotoxin or bacteria while handling septic biliary tree: give IV antibiotics promptly (but after culture collection). • GB resection advised for cholecystis, best based on surgical evaluations, ultrasound images, bedside cytology of bile—bacterial infection mandates cholecystectomy.

MEDICATIONS

DRUG(S) OF CHOICE

• Antibiotics—*before surgery*; broad spectrum; surgical manipulations may cause bacteremia; select antibiotics for *Enterococcus* spp., enteric Gram-negative and anaerobic flora; refine treatment using culture and sensitivity results; good initial choice is triad combination of metronidazole, ticarcillin (or clavamox), and a fluorinated quinolone; reduce standard dose for metronidazole by 50% if cholestatic jaundice. • Ursodeoxycholic acid—10–15 mg/kg PO daily divided BID with food; requires decompression of EHBDO *prior to treatment*. • Antioxidants—vitamin E (α-tocopherol acetate): 10 IU/kg (see Bile Duct Obstruction (Extrahepatic); use water-soluble form if EHBDO); S-adenosylmethionine (SAMe): use enteric-coated bioavailable product; on empty stomach: used as glutathione (GSH) donor (20 mg/kg PO q24h), 2h before feeding; nonbile acid-dependent (GSH) choleresis (40 mg/kg PO q24h); n-acetylcysteine (NAC) IV if oral administration of antioxidants not possible; loading dose 140 mg/kg IV over 20 min, follow by 70 mg/kg over 20 min q6–8h. • Vitamin K_1—0.5–1.5 mg/kg SC/IM q12h for 3 doses; *caution*: never administer IV (anaphylactoid reaction); treat early to allow response before surgical manipulations.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Ursodeoxycholic acid—contraindicated in uncorrected EHBDO or bile peritonitis.

FOLLOW-UP

PATIENT MONITORING

• After critical crisis resolution and surgery—physical examination and pertinent diagnostic testing: repeat every 1–2 weeks until abnormalities resolve. • If septic—continue antibiotics until enzymes, hyperbilirubinemia, leukocytosis, left shift, and fever resolve.

POSSIBLE COMPLICATIONS

Anticipate protracted clinical course with ruptured biliary tract or peritonitis; postoperative pancreatitis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Cholelithiasis. • DPM. • EHBDO. • GBM. • Bile peritonitis.

AGE-RELATED FACTORS

Congenital malformations of biliary structures do not predispose patients to cholecystitis, but do predispose to choledochitis and cholelithiasis that lead to GB disease and infection.

ZOONOTIC POTENTIAL

Campylobacter and *Salmonella* may cause cholecystitis in dogs; advise owner if diagnosed.

CHOLELITHIASIS

BASICS

OVERVIEW

- Radiopaque or radiolucent calculi in common bile ducts (CBD), gallbladder (GB), or less commonly in intrahepatic bile ducts (hepatolithiasis); gallbladder mucocele (GBM) qualifies as a form of cholelithiasis (see Gallbladder Mucocele).
- May be asymptomatic.
- Symptomatic—signs reflect sludging of bile, extrahepatic bile duct obstruction (EHBDO), cholecystitis, cholangiohepatitis, or bile peritonitis.
- Primary constituents of choleliths—mucin, glycoprotein, calcium carbonate, and bilirubin pigments; while dog bile is less lithogenic than human bile (lower cholesterol saturation), dog bile forms calcium bilirubinate sludge upon fasting.
- 50% feline choleliths are mineralized; may be radiographically visible (calcium carbonate).
- Surgical treatment—not recommended without clinical signs or clinicopathologic abnormalities (current or historical), with the exception of preemptive GBM removal.

SIGNALMENT

- Cat and dog.
- Small-breed dogs may be predisposed; animals with ductal plate malformations (DPM) predisposed: particularly Caroli DPM phenotypes (i.e., malformative dilated large ducts causing bile stasis in sacculated ducts); microhepatolithiasis encountered more often in DPM.
- Hyperlipidemic and hypercholesterolemic dogs—predisposed to GBM; may relate to endocrine disorders, idiopathic condition, or other disorders (see Gallbladder Mucocele).

SIGNS

- May be asymptomatic.
- When accompanied by infection or causing intermittent or complete EHBDO (with or without peritonitis)—vomiting; meal-related discomfort, vague abdominal pain; fever; ± jaundice.
- Episodic vague peri- or postprandial abdominal pain or behavior seeking position of relief.

CAUSES & RISK FACTORS

- Predisposing factors—stasis of bile flow: GB dysmotility, choledochal cysts (cat especially, form of DPM); lith nidus may evolve from inflammatory debris, infection, epithelial irregularity/exfoliation, neoplasia, residual suture material; bile supersaturation: heme-bilirubin pigments, hemobilia, calcium-bilirubinate, enhanced mucin production (inflammation, prostaglandins), cholesterol.
- Fused feline pancreatic and bile duct predisposes to concurrent biliary/pancreatic cholelithiasis, choledochitis, and bile stasis progressing to EHBDO as well as cholelith-initiated pancreatitis or signs mistaken for pancreatitis.
- Bile sludge associated with GB distention—may enhance mucin production and coalescence of bile particulates increasing risk for choleliths; but EHBDO does not cause choleliths.
- Inflammatory mediators and bacterial enzymes associated with cholecystitis—increase risk for stone precipitation.
- Hemobilia—bleeding into GB or bile ducts or chronic hemolysis can lead to heme-initiated cholelith formation.
- Low-methionine and high-cholesterol experimental diet in dogs is proven lithogenic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- EHBDO—inflammatory, infectious, or neoplastic conditions involving liver, CBD, or extrahepatic tissues adjacent to porta hepatis; suggested by marked increases in alkaline phosphatase (ALP), γ-glutamyltransferase (GGT), bilirubin, and gradual increase in cholesterol.
- Cholangiohepatitis.
- Cholecystitis/choledochitis.
- Bile peritonitis.
- GBM.
- Consequence of DPM.
- Chronic hypercalcemia may increase risk.

CBC/BIOCHEMISTRY/URINALYSIS

- May have no clinicopathologic abnormalities—asymptomatic cholelithiasis.
- CBC—may be normal; may reflect bacterial infection, endotoxemia, biliary obstruction, or other underlying causal factors; inflammatory leukogram in some cases.
- Biochemistry—if symptomatic: variable hyperbilirubinemia, increase ALP, GGT, alanine aminotransferase (ALT), and aspartate aminotransferase (AST) activities; also see Bile Duct Obstruction (Extrahepatic).

OTHER LABORATORY TESTS

- Bacterial culture—bile: aerobic and anaerobic bacteria often confirmed in symptomatic patients if crushed cholelith, sludged bile, ± GB wall (if cholecystectomy) submitted for cultures.
- Cholelith nidus—may house associated bacterial infection.
- Coagulation profile—bleeding associated with prolonged clotting times may develop with EHBDO of ≥7–10 days; see Bile Duct Obstruction (Extrahepatic); responsive to parenteral vitamin K_1 administration.
- Cholelith analysis—infrequently done; submit to laboratory equipped for cholelith analyses.

IMAGING

- Abdominal radiography—limited value in delineating GB structure/content; choleliths often small, may be radiolucent; rarely mistaken for dystrophic biliary mineralization in animals with chronic cholangitis or Caroli DPM phenotype.
- Ultrasonography—can detect: choleliths ≥2 mm diameter, thickened GB wall, distended biliary tract, increased hepatic parenchymal echogenicity and extrahepatic ductal involvement; may facilitate specimen collection for culture, cytology, and histopathology; may detect evidence of EHBDO within 72h; *caution*: distended GB with bile "sludge" is common in anorectic or fasted patients; do not mistake for GB obstruction. Hepatolithiasis usually casts acoustic shadows. Imaging of choleliths within extrahepatic ducts may be difficult owing to enteric gas obstructing imaging "window"; confirmation of distended intrahepatic bile duct done with color-flow Doppler.

DIAGNOSTIC PROCEDURES

Histopathologic evaluation of liver necessary in patients undergoing surgical cholelith removal to detect comorbid conditions influencing treatment and prognosis, i.e., suppurative cholangitis, nonsuppurative cholangitis, DPM, neoplasia.

TREATMENT

- Controversial whether choleresis with ursodeoxycholate (UDCA) is beneficial in animals lacking clinical or clinicopathologic signs; can resolve cholesterol choleliths in humans, but these are rare in dogs or cats; choleresis with UDCA may help move sludged biliary debris.
- Supportive fluids—if hospitalized, according to hydration, electrolyte, and acid-base status.
- If hyperlipidemia coexistent—prescribe fat-restricted diet, identify and manage endocrinopathies; if failure to control hyperlipidemia, may require additional medical management.
- Control predisposing conditions, especially biliary tree infection (with antimicrobials) and GB dysmotility (by GB removal).
- Exploratory surgery, choledochotomy, cholecystotomy, and possibly cholecystectomy or biliary-enteric anastomosis—indicated in symptomatic cases according to circumstances.
- Warn client that cholelithiasis is chronic problem and that stones may reform even after surgical removal despite chronic medical treatment; choleliths in GB is strong

CHOLELITHIASIS (CONTINUED)

indication for cholecystectomy unless GB needed for biliary enteric anastomosis in certain conditions.

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics—based on culture of bile, tissue, and cholelith nidus, cytology and Gram staining of biliary debris or crushed lith if cultures negative; if culture negative then directed against enteric microbial opportunists; initial treatment with Timentin or Clavamox® with metronidazole, combined with a fluoroquinolone, usually successful.
- Ursodeoxycholic acid—10–15 mg/kg/day PO, divided BID, given with food to increase bioavailability; provides choleretic, hepatoprotectant, anti-endotoxic, antifibrotic effects, and may facilitate cholesterol stone dissolution; therapy often continued lifelong if no cause for cholelithiasis identified to augment choleresis thwarting bile stasis.
- Vitamin K_1—parenterally; 0.5–1.5 mg/kg to max 3 doses in 24–36h in jaundiced patients; do not administer IV (anaphylaxis).

Antioxidants

- Vitamin E (α-tocopherol acetate)—10 IU/kg per day for patients with high liver enzymes or confirmed hepatobiliary inflammation; use water-soluble form if EHBDO.
- S-adenosylmethionine (SAMe; use form with proven bioavailability and efficacy)—glutathione (GSH) donor (important hepatic antioxidant, GSH also provides driving force for non-bile acid–dependent choleresis) and thus is potential choleretic for patients with high liver enzymes or confirmed hepatobiliary inflammation; 20–40 mg/kg using enteric-coated tablet PO q24h, administer 2h before feeding; higher dose recommended for choleresis; also provides antifibrotic and antiinflammatory benefits.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Ursodeoxycholic acid—contraindicated with EHBDO before biliary decompression.

FOLLOW-UP

PATIENT MONITORING

- Physical examination and pertinent diagnostic testing q2–4 weeks postoperatively until clinical signs and clinicopathologic abnormalities resolve.
- Periodic ultrasonography—assess cholelith status, integrity/distention of biliary tract, hepatic parenchymal changes.

POSSIBLE COMPLICATIONS

Sudden onset of fever, abdominal pain, and malaise—may signify bile peritonitis and/or sepsis from breakdown in bile containment, or recurrent cholelith lodged in sphincter of Oddi (duodenal papilla) or obstructing pancreatic duct (cats only).

EXPECTED COURSE AND PROGNOSIS

- May be asymptomatic.
- Symptomatic disease—reflects existing infection, EHBDO, cholecystitis, DPM, or bile peritonitis.

MISCELLANEOUS

SEE ALSO

- Bile Duct Obstruction (Extrahepatic).
- Cholecystitis and Choledochitis.
- Ductal Plate Malformation (Congenital Hepatic Fibrosis).

CHONDROSARCOMA, BONE

BASICS

OVERVIEW

• Chondrosarcoma (CSA) is a malignant mesenchymal tumor arising from cartilage and characterized by production of chondroid and fibrillar matrix. • CSA is the second most common primary bone tumor in dogs and accounts for 5–10% of all primary bone tumors; primary bone tumors are uncommon in cats, and CSA is third in incidence behind osteosarcoma and fibrosarcoma. • Dogs—majority of CSAs arise from flat bones (axial skeleton); approximately 30% occur in nasal cavity and 20% of CSAs arise from ribs; 20% of CSAs in dogs arise from appendicular skeleton; sites are generally similar to where osteosarcoma typically occurs. • Cats: 66% of CSAs arise in appendicular skeleton, with 33% occurring in the axial skeleton. • Rarely, CSA can arise in soft tissue (extraskeletal) sites.

SIGNALMENT

• Dogs—medium- to large-breed dogs, with mixed-breed dogs, golden retrievers, boxers, and German shepherd dogs overrepresented; median age is 8 years (range: 1–15 years). • Cats—median age is 9 years (range: 2–18 years), with males twice as likely to be affected.

SIGNS

Historical Findings

• Patients often present with a visible mass at the affected site. • History of lameness if involvement of weight-bearing bone. • Rarely, CSA of the rib may be associated with respiratory signs. • Additional clinical signs vary with site of involvement.

Physical Examination Findings

• Findings depend on anatomic location. • A firm to hard mass often is palpable, with variable degrees of pain elicited on palpation. • CSA of the rib occurs most commonly at the costochondral junction; dyspnea is rare and associated with space-occupying effect.

CAUSES & RISK FACTORS

• Etiology largely unknown. • Osteochondromatosis (multiple cartilaginous exostosis) lesions can transform into CSA.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other primary bone tumors (osteosarcoma, fibrosarcoma, hemangiosarcoma). • Metastatic bone tumors (transitional cell, prostatic, mammary, thyroid, apocrine gland, anal sac carcinomas). • Tumors that locally invade adjacent bone (especially oral, nasal, digital, and joint tumors). • Fungal osteomyelitis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

IMAGING

• Radiographs of affected area show features of aggressive bone lesion (cortical lysis, nonhomogenous reactive bone formation, ill-defined zone of transition). • Thoracic radiographs recommended to screen for pulmonary metastasis. • CT recommended for axial tumors to more accurately stage local disease and plan for surgery and/or radiation therapy; concurrent CT imaging of thorax recommended as more sensitive way to screen for pulmonary metastasis. • MRI, alone or in combination with CT, may be recommended for treatment planning for vertebral CSA.

DIAGNOSTIC PROCEDURES

• Histopathology needed for definitive diagnosis. • Fine-needle aspirate bone cytology may provide supportive diagnosis; differentiation of CSA from other sarcomas may be challenging if sample contains sparse amounts of matrix.

TREATMENT

• Amputation recommended for appendicular tumors. • For axial tumors, wide surgical excision recommended whenever possible. • Stereotactic radiation therapy provides effective local control for canine osteosarcoma and might be alternative to surgery for patients with CSA. • Palliative therapy recommended for patients with nonresectable local disease or gross metastasis, or when definitive therapy is declined; palliative care focuses on pain control.

MEDICATIONS

DRUG(S) OF CHOICE

Pain Management

• Nonsteroidal anti-inflammatory drugs (NSAIDs). • Tramadol. • Gabapentin. • IV aminobisphosphonates (e.g., pamidronate, zoledronate) might alleviate bone pain and slow pathologic bone resorption.

Chemotherapy

Role of chemotherapy has not been defined in veterinary oncology, but does not improve outcome in humans.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Use NSAIDs cautiously in all cats and in dogs with renal insufficiency. • Do not combine NSAIDs with corticosteroids.

FOLLOW-UP

PATIENT MONITORING

Physical examination every 2–3 months and thoracic radiographs every 3–4 months to monitor for local tumor control and distant metastases, respectively.

EXPECTED COURSE AND PROGNOSIS

• Overall, 15–30% of dogs will develop metastatic disease, with lungs being most commonly affected site; metastatic rates approach 50% for high-grade canine tumors; development of metastasis rare for cats with CSA. • With curative-intent surgery, median survival >3 years; depending on tumor location and completeness of excision, up to 40% will develop local recurrence. • With palliative care alone, survival times of >1 year still possible.

MISCELLANEOUS

SEE ALSO

• Chondrosarcoma, Nasal and Paranasal Sinus.
• Chondrosarcoma, Oral.
• Fibrosarcoma, Bone.
• Osteosarcoma.

ABBREVIATIONS

• CSA = chondrosarcoma.
• NSAID = nonsteroidal anti-inflammatory drug.

CHONDROSARCOMA, NASAL AND PARANASAL SINUS

BASICS

OVERVIEW

• Chondrosarcoma (CSA) is a malignant mesenchymal tumor arising from cartilage and characterized by production of chondroid and fibrillar matrix. • Nasal CSA arises most commonly from the nasal turbinates. • In dogs, CSA accounts for 15% of all nasal tumors.

SIGNALMENT

• Mixed-breed dogs, Labrador retrievers, golden retrievers, boxers, and German shepherd dogs are overrepresented. • Median age is 7 years (range: 2–13 years). • CSA tends to develop at a younger age than other nasal tumors. • Rare in cats, with no obvious breed or sex predilections.

SIGNS

Historical Findings

• Intermittent unilateral epistaxis and/or mucopurulent discharge, may progress to bilateral involvement. • Sneezing, stertorous breathing, and/or facial deformity. • Decreased appetite and/or halitosis secondary to oral cavity invasion. • Seizures, behavior changes, and/or obtundation secondary to cranial invasion.

Physical Examination Findings

• Epistaxis and/or nasal discharge, initially unilateral but can progress to bilateral. • Decreased nasal air flow (unilateral or bilateral). • Pain on nasal or paranasal sinus palpation or percussion. • Facial deformity, decreased ocular retropulsion, exophthalmia, or epiphora. • Visible mass effect protruding through the palate into the oral cavity.

CAUSES & RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other nasal tumors—adenocarcinoma, squamous cell carcinoma, osteosarcoma, fibrosarcoma, lymphoma, transmissible venereal tumor (dogs), nasopharyngeal polyp (cats). • Fungal rhinitis—aspergillosis and penicilliosis (dogs), cryptococcus (cats), sporotrichosis (both). • Rhinosporidiosis (dogs). • Foreign body. • Thrombocytopenia or other coagulopathy. • Tooth root abscess. • Oronasal fistula.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal—evaluate for thrombocytopenia if signs of epistaxis.

OTHER LABORATORY TESTS

• Nasal flush for cytology and culture—rarely helpful. • Coagulation profile. • Buccal mucosal bleeding time.

IMAGING

• Thoracic radiographs to screen for pulmonary metastasis (uncommon). • CT for detecting soft tissue opacity within nasal cavity and surrounding sinuses, bony destruction, and extension through cribriform plate into brain. • If CT scan is not accessible, skull radiographs can be performed to assess for soft tissue opacity in nasal cavity and/or frontal sinuses.

DIAGNOSTIC PROCEDURES

• Blood pressure, to rule out systemic hypertension as cause for epistaxis. • Mandibular lymph node cytology to screen for possible metastasis. • Rhinoscopy is helpful for visualization of mass or fungal plaque and guiding subsequent tissue biopsy. • Tissue biopsy and histopathology needed for definitive diagnosis; biopsy instrument should not pass caudal to level of medial canthus of eye to avoid penetrating cribriform plate. • Intranasal approach to obtaining tissue biopsy preferable if treatment radiation therapy planned.

TREATMENT

• Radiation therapy is treatment of choice. • Conventional linear accelerator used most commonly; however, if available, stereotactic radiation therapy can reduce number of radiation treatments and reduce adverse effects. • Palliative radiation protocols (fewer treatments and lower total radiation dose) might be preferable for dogs with very advanced disease.

MEDICATIONS

DRUG(S) OF CHOICE

• Nonsteroidal anti-inflammatory drugs (NSAIDs) for pain control. • Prednisone (0.5–1 mg/kg PO q24h) to help relieve nasal congestion. • Phenylephrine nasal spray can be used intermittently to help with epistaxis. • Empiric antibiotic therapy can be considered for secondary bacterial infections.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Use NSAIDs cautiously in all cats and in dogs with renal insufficiency. • Do not combine NSAIDs with corticosteroids.

FOLLOW-UP

PATIENT MONITORING

• Physical examinations every 2–3 months and thoracic radiographs every 3–4 months. • CT of skull can be considered when clinical signs recur or progress.

EXPECTED COURSE AND PROGNOSIS

• <10% develop metastasis (lungs affected most commonly). • Median survival with palliative care alone is 3 months. • With definitive daily radiation therapy, median survival is around 17 months, and 2-year survival rate is around 30%; median survival with palliative radiation protocols is about 9 months. • Recurrence/progression of tumor and recurrence of clinical signs generally life-limiting event for nasal CSA. • Brain involvement is poor prognostic sign. • Unilateral versus bilateral involvement is not significant prognostic factor.

MISCELLANEOUS

SEE ALSO

• Adenocarcinoma, Nasal.
• Chondrosarcoma, Bone.
• Chondrosarcoma, Oral.
• Epistaxis.

ABBREVIATIONS

• CSA = chondrosarcoma.
• NSAID = nonsteroidal anti-inflammatory drug.

CHONDROSARCOMA, ORAL

BASICS

OVERVIEW

• Chondrosarcoma (CSA) is a malignant mesenchymal tumor arising from cartilage and characterized by production of chondroid and fibrillar matrix.
• CSA accounts for 5–10% of all primary bone tumors; mandibular and maxillary CSAs have been reported in dogs, but these are not common locations for this tumor (see Chondrosarcoma, Bone, and Chondrosarcoma, Nasal and Paranasal Sinus).

SIGNALMENT

• Dogs—medium- to large-breed dogs, with mixed-breed dogs, golden retrievers, boxers, and German shepherd dogs overrepresented; median age is 8 years (range: 1–15 years).
• Cats—rarely affected.

SIGNS

Historical Findings

• Visible mass involving the mandible or maxilla.
• Halitosis, dysphagia, and/or hypersalivation.
• Bloody oral discharge and oral pain.
• Weight loss secondary to a prolonged decrease in food intake.

Physical Examination Findings

• A firm to hard mass centered on the maxilla or mandible is seen most commonly.
• The overlying gingival mucosa usually is intact, although trauma and ulceration from the occlusal teeth are common with larger tumors.
• Loose or missing teeth.
• Difficulty or pain when opening the mouth (especially caudal tumors).
• Facial deformity.
• Mandibular lymphadenopathy.
• Nasal discharge, epistaxis, or decreased air flow through the nares (maxillary tumors).

CAUSES & RISK FACTORS

None identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other primary oral tumors, including melanoma, fibrosarcoma, squamous cell carcinoma, osteosarcoma, and acanthomatous ameloblastoma.
• Maxillary invasion of primary nasal CSA.
• Craniomandibular osteopathy.
• Dentigerous cyst, tooth root abscess, or osteomyelitis.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

IMAGING

• Thoracic radiographs are recommended to screen for pulmonary metastasis.
• Skull radiographs often will show features of an aggressive bone lesion (bone lysis, cortical destruction, nonhomogenous bone formation, ill-defined zone of transition); however, normal radiographs do not exclude bone involvement.
• High-detail dental radiographs may be appropriate for imaging smaller lesions.
• CT imaging can more accurately determine extent of local disease and is useful for surgical planning, particularly caudal lesions; CT is generally required for radiation therapy planning.

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration (FNA) and cytology of the mass may provide provisional diagnosis. FNA and cytology are recommended for mandibular lymph nodes, especially if they are enlarged.
• Histopathology is required to reach a definitive diagnosis; preoperative incisional biopsy is recommended.
• If curative-intent surgery is performed, all excised tissue should be submitted to the pathologist *en bloc* for evaluation of surgical margin.

TREATMENT

• Surgical excision—removal of the affected segment of bone (maxillectomy or mandibulectomy) with a margin of at least 2 cm is recommended whenever possible.
• If excision is incomplete, adjuvant radiation therapy might help improve local control, although there is little information regarding efficacy.
• Radiation therapy can be considered as a sole local treatment modality but, because of the chondroid matrix produced by CSAs, radiation therapy likely will stabilize tumor size and not necessarily cause substantial shrinkage.
• Chemotherapy has not been evaluated, but is not thought to be effective.
• Palliative care focuses on pain control.

MEDICATIONS

DRUG(S) OF CHOICE

• Nonsteroidal anti-inflammatory drugs.
• Tramadol.
• Gabapentin.
• Intravenous aminobisphosphonates (pamidronate or zoledronate) might alleviate bone pain and attenuate bone resorption.
• Empiric antibiotic therapy can be considered for secondary bacterial infections.

FOLLOW-UP

PATIENT MONITORING

Physical examination with thorough oral examination every 2–3 months and thoracic radiographs every 3–4 months to monitor for local tumor control and distant metastases, respectively.

EXPECTED COURSE AND PROGNOSIS

• Prognosis depends on tumor size and location, and surgical resectability; with complete excision, long-term control may be possible.
• Most patients die or are euthanized due to local disease progression.
• Overall CSA metastatic rate is 15–30%, with the lungs being affected most commonly; metastatic rates approach 50% for high-grade tumors.

MISCELLANEOUS

SEE ALSO

• Chondrosarcoma, Bone.
• Chondrosarcoma, Nasal and Paranasal Sinus.

ABBREVIATIONS

• CSA = chondrosarcoma.
• FNA = fine-needle aspiration.

CHORIORETINITIS

BASICS

DEFINITION
- Inflammation of the choroid and retina.
- Choroid is also called posterior uvea.
- Diffuse inflammation may result in retinal detachment.

PATHOPHYSIOLOGY
- Caused by infectious agents, neoplastic cells, or immune complexes (immune-mediated diseases); hematogenous pathogenic factors inducing choroidal inflammation is most common.
- Choroid and retina—closely apposed; physiologically interdependent; inflammation of one usually results in inflammation of the other.
- May also occur as a retinochoroiditis—retinal inflammation preceding and inducing choroidal inflammation.

SYSTEMS AFFECTED
- Nervous.
- Ophthalmic.
- Other systems if underlying disease is systemic.

INCIDENCE/PREVALENCE
- Fairly common.
- Exact incidence unknown.

GEOGRAPHIC DISTRIBUTION
Varies with endemic infectious diseases (e.g., systemic mycoses, rickettsial disease).

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- Systemic mycoses—more common in hunting dogs.
- Uveodermatologic syndrome—Akita, chow chow, and Siberian husky predisposed.
- Chorioretinopathy—borzoi, border collie, beagle, German shepherd dog.
- Systemic histiocytosis—Bernese mountain dog, golden retriever.

Mean Age and Range
Depends on underlying cause.

Predominant Sex
Uveodermatologic syndrome—more common in young male dogs.

SIGNS
- Not usually painful, except with concurrent anterior uveitis, secondary glaucoma, or inflammatory retrobulbar disease.
- Vitreous abnormalities—may note exudate, hemorrhage, or syneresis (liquefaction).
- Interruption or alteration of the course of retinal blood vessels—due to retinal elevation.
- Ophthalmomyiasis (cats)—curvilinear tracts from migrating larvae.
- Others—related to underlying systemic disease, retrobulbar disease.

Lesions
- Active—indistinct margins, tapetal hyporeflectivity, white-gray color, altered course of retinal blood vessels.
- Few or small lesions—no apparent visual deficits.
- Extensive lesions involving larger areas of the retina—blindness or reduced vision.
- Inactive (scars)—discrete margins, tapetal hyperreflectivity with hyperpigmented central areas, depigmented in the nontapetum and some surrounding or central hyperpigmentation.

CAUSES

Infectious

Dogs
- Viral—canine distemper, herpesvirus (rare, usually neonates), rabies.
- Bacterial—leptospirosis, brucellosis, pyometra (toxic uveitis), borreliosis, ehrlichiosis, Rocky Mountain spotted fever, bartonellosis; discospondylitis, endocarditis may be present with bacteremia.
- Fungal—aspergillosis, blastomycosis, coccidioidomycosis, histoplasmosis, cryptococcosis, acremoniosis, pseudallescheriasis, candidiasis, geotrichosis.
- Algal—protothecosis.
- Protozoal—toxoplasmosis, leishmaniasis (rare), neosporosis, and sarcocystosis (dogs).
- Parasitic—ocular larval migrans (*Strongyles*, *Ascarids*, *Baylisascaris*), *Sarcocystis neurona*, and ophthalmomyiasis interna (Diptera larval migrans).
- Retrobulbar abscess/cellulitis—uncommon.

Cats
- Viral—feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), feline infectious peritonitis (FIP).
- Bacterial—septicemia or bacteremia, bartonellosis.
- Fungal—cryptococcosis, histoplasmosis, blastomycosis.
- Parasitic—toxoplasmosis, ophthalmomyiasis interna (Diptera, Cuterebra), ocular larval migrans, leishmaniasis (rare).
- Protozoal—toxoplasmosis.

Idiopathic
- Common.
- Multifocal chorioretinitis or chorioretinopathy—acquired syndrome; affected dogs have multifocal retinal edema or chorioretinal atrophy.
- German shepherd dog—choroidal scars in police dogs: possibly due to physical exertion or circulatory disorders; affected dogs had lower amplitude ERG.

Immune
- Any immune-mediated disease may cause vasculitis or inflammation, resulting in exudative retinal detachment or chorioretinitis. Thrombocytopenia may result in small multifocal or large retinal or vitreal hemorrhages with inflammation.
- Dogs—Vogt-Koyanagi-Harada-like (uveodermatologic) syndrome: target is melanin pigment granule (abundant in uveal tissue), leading to severe anterior and posterior inflammation (affected dogs may also exhibit depigmentation of the skin, especially at mucocutaneous junctions); systemic lupus erythematosus (SLE).
- Cats—periarteritis nodosa, SLE.

Metabolic
Early hypertensive retinopathy may result in multifocal localized lesions.

Neoplastic
Neoplasia (multiple myeloma, lymphoma, malignant histiocytosis) can metastasize to the eye.

Toxic
- Ethylene glycol, idiosyncratic drug reactions (e.g., trimethoprim-sulfa), ivermectin.
- Photic injury—exposure to bright light can burn the retina.

Trauma
Perforating wound or migrating foreign body.

RISK FACTORS
- FeLV or FIV infection—may predispose cat to ocular toxoplasmosis or other infectious disease.
- Immunosuppressive therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Blindness or impaired vision—optic neuritis, CNS disease, diffuse retinal inflammation.
- Retinal dysplasia—bilateral, symmetric folds or geographic clumps of pigment or altered fundus reflectivity; no associated signs of inflammation in the eye.

CBC/BIOCHEMISTRY/URINALYSIS
Normal if problem confined to the eye, otherwise may have signs of systemic disease.

OTHER LABORATORY TESTS
- Anti-nuclear antibody (ANA)—for suspected SLE.
- Bence-Jones proteinuria—for multiple myeloma.
- Skin biopsy—SLE, uveodermatologic syndrome.
- Coagulation profile.
- Bacterial culture of ocular or body fluids.
- Serologic or PCR testing—infectious disease (see Causes).
- Cytology of lymph node, mass, or organ aspirates.
- Histopathology of enucleated eyes.
- Bartonella—PCR, culture on special media (BAPGM).

(CONTINUED) CHORIORETINITIS

IMAGING
- Thoracic radiography—may show infectious or neoplastic disease.
- Spinal radiography— may show discospondylitis or multiple myeloma.
- Ocular ultrasound—retinal detachment, intraocular masses; especially helpful if the ocular media are not clear; can identify retrobulbar disease.
- Abdominal ultrasound—screen for neoplasia, systemic disease.
- CT/MRI—if signs of retrobulbar or CNS disease.

DIAGNOSTIC PROCEDURES
- Indirect ophthalmoscopy—screens a large area of the retina.
- Direct ophthalmoscopy—facilitates examination of suspicious areas.
- Cerebrospinal fluid (CSF) tap—indicated for diagnosis of some CNS disease or optic neuritis.
- Vitreocentesis or subretinal aspirate—if other diagnostic tests fail or to identify infectious agent or neoplasia; vitreocentesis may worsen inflammation or induce hemorrhage or retinal detachment, reducing chances for restoration of vision.
- Choroidal aspirate—of thickened areas, ideally ultrasound guided; procedure may aggravate inflammation, induce hemorrhage or retinal detachment.
- Measurement of blood pressure.

PATHOLOGIC FINDINGS
- Masses or retinal or choroidal exudates.
- Fungal organisms in exudates and inflammatory cells.
- Perivascular inflammation with vasculitis, FIP.
- Inactive lesions—retinal and choroidal atrophy (thinning); may note retinal pigment epithelium hyperpigmentation and tapetal destruction.

TREATMENT

APPROPRIATE HEALTH CARE
Depends on physical condition of patient, usually outpatient.

NURSING CARE
Therapy for systemic disease, depending on patient status.

CLIENT EDUCATION
- Chorioretinitis may be a sign of systemic disease, so diagnostic testing is important.
- Immune-mediated disease requires lifelong therapy.
- Dogs with uveodermatologic syndrome may have anterior uveitis and secondary glaucoma, which necessitate treatment or eye removal; dermatitis may also require management.

MEDICATIONS

DRUG(S) OF CHOICE
- Identify and treat underlying systemic disease (see specific chapters).
- Topical medications—not effective in dogs with intact lenses; systemic therapy required.
  - 1% prednisolone acetate or 0.1% dexamethasone q6–8h to treat anterior uveitis.
  - Parasympatholytics (e.g., 1% atropine) can be given at a frequency that dilates the pupil and reduces pain.
  - 0.5% timolol maleate or 2% dorzolamide may be used to treat secondary glaucoma.
- Corticosteroids at anti-inflammatory doses—prednisone 0.5–1 mg/kg PO q24h (dog), prednisolone 1–2 mg/kg q24h (cat), then taper; avoid use unless large areas of the retina are affected and vision is severely threatened.
- Prednisone for immunosuppression—2–4 mg/kg PO divided q12 for 3–10 days (dog, cat), then taper slowly over months (do not exceed 80 mg per day).

CONTRAINDICATIONS
Systemically administered corticosteroids—do not use if systemic infectious disease is present. Exception: sometimes steroids are used when infectious cause has been identified and is being treated.

ALTERNATIVE DRUG(S)
Uveodermatologic syndrome or known autoimmune etiology—may require corticosteroids and concurrent use of or transition to other immunosuppressive medications (e.g., azathioprine, cyclosporine, leflunomide, or mycophenolate mofetil; see Retinal Detachment).

FOLLOW-UP

PATIENT MONITORING
- As appropriate for underlying cause and type of medical treatment.
- For bartonella treatment in cats, consider follow-up testing to help assess response.
- CBC, platelet count, and liver enzymes—monitor for side effects of systemic immunosuppressive drugs.
- Intraocular pressure monitoring—for anterior uveitis.

PREVENTION/AVOIDANCE
Tick and flea control measures.

POSSIBLE COMPLICATIONS
- Permanent blindness.
- Cataracts.
- Glaucoma.
- Chronic ocular pain.
- Death—secondary to systemic disease.

EXPECTED COURSE AND PROGNOSIS
- Prognosis for vision—guarded to good, depending on amount of retina affected; visual deficits or blindness if large areas of the retina were destroyed; focal and multifocal disease do not markedly impair vision but do leave scars.
- Prognosis for life—guarded to good, depending on underlying cause.
- Prognosis for globe—secondary glaucoma may necessitate removal of blind painful eye.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Several systemic diseases.

ZOONOTIC POTENTIAL
- Toxoplasmosis—may be transmitted to humans if patient is shedding oocysts in feces.
- Vector-borne diseases—infected animals may act as reservoirs, i.e., bartonella (cat scratch disease), rickettsia, others.

SYNONYMS
Retinochoroiditis

SEE ALSO
- Retinal Degeneration.
- Retinal Detachment.
- Uveodermatologic Syndrome (VKH).

ABBREVIATIONS
- ANA = antinuclear antibody.
- CSF = cerebrospinal fluid.
- FeLV = feline leukemia virus.
- FIP = feline infectious peritonitis.
- FIV = feline immunodeficiency virus.
- SLE = systemic lupus erythematosus.

CHRONIC KIDNEY DISEASE

BASICS

DEFINITION
Chronic kidney disease (CKD) encompasses functional or structural lesions (in one or both kidneys as detected by blood or urine tests, imaging studies, or kidney biopsy) that have been present for >3 months. This definition includes all cases previously described by the terms renal insufficiency or renal failure, as well as less advanced forms of kidney disease. Patients are categorized into stages along a continuum of progressive CKD (IRIS CKD stages 1–4; www.iris-kidney.com) based on >2 serum creatinine values obtained over several weeks when the patient is fasted and well hydrated. The IRIS system uses the term "kidney" rather than "renal" because it is more universally recognized by pet owners.

PATHOPHYSIOLOGY
More than ~67–75% reduction in renal function results in impaired urine-concentrating ability (leading to polyuria/polydipsia [PU/PD]) and retention of nitrogenous waste products of protein catabolism (azotemia). CKD is progressive; more advanced CKD results in uremia. Decreased renal erythropoietin and calcitriol production results in hypoproliferative anemia and renal secondary hyperparathyroidism, respectively.

SYSTEMS AFFECTED
- Cardiovascular—hypertension; uremic pericarditis.
- Endocrine/metabolic—renal secondary hyperparathyroidism, activation of renin-angiotensin-aldosterone system, erythropoietin deficiency.
- Gastrointestinal—uremic stomatitis and halitosis, nausea, vomiting, anorexia, gastrointestinal bleeding, diarrhea.
- Hemic/lymphatic/immune—anemia; hemorrhagic diathesis.
- Musculoskeletal—renal osteodystrophy; sarcopenia.
- Neuromuscular—seizures and other neurologic signs, muscle tremors, muscle wasting.
- Ophthalmic—retinal detachment, hemorrhage, or edema due to hypertension.
- Reproductive—impaired reproductive capacity.
- Respiratory—uremic pneumonitis.

GENETICS
- Inherited in these breeds (mode of inheritance indicated in parentheses)—Abyssinian cat (dominant with incomplete penetrance); Persian cat (dominant); bull terrier (dominant); Cairn terrier (recessive); German shepherd (dominant); Samoyed (X-linked dominant); English cocker spaniel (recessive).
- Renal dysplasia—shih tzu, Lhasa apso, golden retriever, Norwegian elkhound, chow chow, standard poodle, soft-coated wheaten terrier, Alaskan Malamute, miniature schnauzer, Dutch kooiker, and many other breeds.

INCIDENCE/PREVALENCE
- 9 cases per 1,000 dogs and 16 cases per 1,000 cats examined.
- Prevalence increases with age—age >15 years, reportedly 57 cases per 1,000 dogs and 153 cases per 1,000 cats examined.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Dog and cat.

Breed Predilections
See Genetics.

Mean Age and Range
Mean age at diagnosis is 7 years in dogs and 9 years in cats. Animals of any age can be affected; prevalence increases with age.

Predominant Sex
None

SIGNS

General Comments
- Clinical signs related to stage of CKD and complications such as proteinuria and hypertension.
- CKD stages 1 and 2 may be asymptomatic; overt clinical signs typically become apparent in stages 3 and 4.
- Animals with stable CKD (particularly stages 3 and 4) may decompensate, resulting in uremic crisis.

Historical Findings
- PU/PD.
- Anorexia.
- Lethargy.
- Vomiting.
- Weight loss.
- Nocturia.
- Constipation.
- Diarrhea.
- Acute blindness.
- Seizures or coma.
- Cats may have ptyalism and muscle weakness with cervical ventroflexion.

Physical Examination Findings
- Kidneys may be small, irregular, enlarged (secondary to polycystic kidney disease or lymphoma), or normal.
- Dehydration.
- Cachexia.
- Weakness.
- Mucous membrane pallor.
- Oral ulceration.
- Uremic halitosis.
- Hypertensive retinopathy.
- Renal osteodystrophy may manifest as bone pain, particularly in skull.
- Reduced body temperature with uremia.

CAUSES
- Unknown in most cases due to late diagnosis.
- Familial and congenital renal disease, nephrotoxins, hypercalcemia, hypokalemic nephropathy, glomerulopathies, amyloidosis, pyelonephritis, polycystic kidney disease, nephroliths, chronic urinary obstruction, drugs, lymphoma, leptospirosis (following acute kidney injury [AKI]), feline infectious peritonitis.

RISK FACTORS
Age, proteinuria, hypercalcemia, hypokalemia, hypertension, urinary tract infection (UTI).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- See Polyuria and Polydipsia for differential diagnosis.
- Azotemia—includes causes of prerenal and postrenal azotemia, AKI, and hypoadrenocorticism.
- Prerenal azotemia—azotemia with urine specific gravity (USG) >1.030 in dogs and >1.035 in cats; rapid reduction in azotemia after correcting hypoperfusion indicates prerenal azotemia; prerenal azotemia commonly occurs concurrent with primary renal azotemia when gastrointestinal signs of uremia are present.
- Postrenal azotemia—obstruction or rupture of excretory system; rapid correction of azotemia following elimination of obstruction or resolution of leakage from urinary tract supports postrenal azotemia.
- AKI—differentiated by normal to large renal size, cylindruria, lack of indications of chronicity, and history of recent nephrotoxin exposure or hypotensive episode; AKI can also occur in patients with CKD where rapid developing increase in serum creatinine concentration and uremic signs suggests acute-onset CKD.
- Hypoadrenocorticism—characterized by hyponatremia and hyperkalemia with hypocortisolemia.

CBC/BIOCHEMISTRY/URINALYSIS
- Hypoproliferative anemia.
- High blood urea nitrogen (BUN), creatinine, and symmetric dimethylarginine (SDMA).
- Hyperphosphatemia.
- Metabolic acidosis (normal or high anion gap).
- Hypokalemia or hyperkalemia.
- Hypercalcemia or hypocalcemia.

(CONTINUED) CHRONIC KIDNEY DISEASE

• USG <1.030 in dogs and <1.035 in cats.
• Proteinuria.

OTHER LABORATORY TESTS
Urinary protein : creatinine ratio to assess proteinuria.

IMAGING
• Abdominal radiographs may demonstrate small kidneys, or large kidneys secondary to polycystic kidney disease or lymphoma.
• Ultrasound demonstrates small kidneys and hyperechoic renal parenchyma with less apparent distinction between cortex and medulla in some animals. Animals with lymphoma often have renomegaly with hypoechoic renal parenchyma.

DIAGNOSTIC PROCEDURES
• Blood pressure measurement to detect hypertension.
• Measurement of glomerular filtration rate may be useful for detection of loss of kidney function before onset of azotemia.
• Renal biopsy may be indicated in proteinuric patients with normal to large kidneys.

PATHOLOGIC FINDINGS
• Gross—small kidneys with irregular surface; fewer glomeruli found on visualizing cut across renal cortex.
• Histopathologic—variable; complete evaluation of biopsy material requires light, immunofluorescent, and electron microscopy; advanced CKD has nonspecific changes including interstitial fibrosis and foci of interstitial mononuclear cells, chronic generalized nephropathy.
• Findings may be specific for diseases causing CKD in some patients with less advanced disease.

TREATMENT

APPROPRIATE HEALTH CARE
Patients with compensated CKD may be managed as outpatients; patients in uremic crisis should be managed as inpatients.

NURSING CARE
• Uremic crisis—correct fluid and electrolyte deficits with IV fluids, providing 25% of calculated fluid deficit in first hour; thereafter, serially monitor perfusion, blood pressure, and urine output to assess adequacy of fluid therapy; if perfusion not improved, additional fluid should cautiously be administered. Provide remaining fluid deficit over next 12–24 hours. Overhydration can result in anuria; once patient has been hydrated, only sufficient fluid to sustain hydration should be administered.
• Subcutaneous fluid therapy may benefit patients with moderate to severe CKD. Continue therapy only if clinical improvement noted.

ACTIVITY
Unrestricted

DIET
• Diets designed for CKD delay onset of uremic crisis and extend survival in dogs and cats with CKD stages 2–4; they are standard of care for these patients.
• Important components of renal foods—reduced protein, phosphorus, sodium, and net acid content, supplementation of n-3 fatty acids and antioxidants.
• Free access to fresh water.

CLIENT EDUCATION
• CKD typically progresses to terminal kidney failure over months to years, but may not be progressive in some cats, which may live for years
• Higher levels of proteinuria associated with shorter survival; may be mitigated by anti-proteinuria therapy.
• Heritability of familial renal diseases.

SURGICAL CONSIDERATIONS
• Avoid hypotension during anesthesia.
• Renal transplantation has been successfully performed in cats with CKD.

MEDICATIONS

DRUG(S) OF CHOICE

Uremic Crisis
• Antiemetics (maropitant 1 mg/kg q24h; or ondansetron 0.2–1 mg/kg IV q12h) to minimize vomiting and hyporexia due to nausea.
• Potassium chloride in IV fluids or potassium gluconate PO (2–6 mEq/cat/day) as needed to correct hypokalemia.
• Sodium bicarbonate to correct metabolic acidosis (IV to raise blood pH >7.1).

Compensated CKD
• Antiemetic (maropitant) and potassium gluconate as above.
• Mirtazapine (cats, 1.88 mg PO q 24–47h) to promote appetite.
• Intestinal phosphate binders as needed to correct hyperphosphatemia (see Hyperparathyroidism, Renal Secondary).
• Darbepoetin (see Anemia of Chronic Kidney Disease).
• Amlodipine (dogs, 0.1–0.6 mg/kg PO q24h; cats, 0.625–1.25 mg/cat PO q24h) or angiotensin-converting enzyme (ACE) inhibitors (0.5 mg/kg PO q24h) or angiotensin receptor blockers (ARB; e.g., telmisartan 1–3 mg/kg PO q24h) as needed for hypertension; amlodipine and telmisartan are more effective than ACE inhibitors for CKD-induced hypertension; if refractory to monotherapy, consider combination of amlodipine and ACE inhibitor or ARB, with frequent monitoring of blood pressure and electrolytes.
• ACE inhibitor (start at 0.5 mg/kg PO q24h; increase to 1 mg/kg PO q12h) or ARB (telmisartan 1–3 mg/kg PO q24h) for proteinuria.

CONTRAINDICATIONS
Avoid nephrotoxic drugs (aminoglycosides, cisplatin, amphotericin B) and corticosteroids.

PRECAUTIONS
• Drug dosage or dosing interval may need to be modified for some drugs eliminated by the kidneys.
• Use ACE inhibitors and ARB cautiously; monitor for worsening of azotemia,
• Generally avoid nonsteroidal anti-inflammatory drugs.

POSSIBLE INTERACTIONS
Cimetidine or trimethoprim may cause artifactual increases in serum creatinine concentration by reducing tubular secretion in dogs with CKD.

ALTERNATIVE DRUG(S)
• Metoclopramide (0.2–0.4 mg PO/SC q6–8h) can be used to treat uremic vomiting.
• Hemodialysis and renal transplantation are available at selected referral hospitals.

FOLLOW-UP

PATIENT MONITORING
• Monitor at regular intervals; initially weekly for patients receiving erythropoietin; every 1–3 months for stable patients with CKD stages 3 and 4.
• Proteinuric patients—monitor at least every 3–4 months (minimum: serum creatinine and urine protein : creatine ratio).

PREVENTION/AVOIDANCE
• Do not breed animals with familial renal disease.
• Include urinalysis and serum creatinine in yearly examination for older pets; if serum creatinine increases, increase frequency to every 4–6 months.

POSSIBLE COMPLICATIONS
• Systemic hypertension.
• Uremia.
• Anemia.
• UTI.
• Nephrouretrolithiasis.

EXPECTED COURSE AND PROGNOSIS
• Short term—depends on severity.
• Long term—guarded to poor in dogs (CKD tends to be progressive over months to years); poor to good in cats (CKD does not progress in some cats).

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Renal secondary hyperparathyroidism.
• Systemic hypertension.
• Nephroureterolithiasis.

CHRONIC KIDNEY DISEASE (CONTINUED)

AGE-RELATED FACTORS
Renal function may decrease with aging.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Patients with mild CKD may maintain pregnancy; those with moderate to severe disease may be infertile or have spontaneous abortions; breeding of females not recommended.

SYNONYMS
- Chronic kidney failure.
- Chronic renal disease or failure.

SEE ALSO
- Acute Kidney Injury.
- Anemia of Chronic Kidney Disease.
- Azotemia and Uremia.
- Congenital and Developmental Renal Diseases.
- Hydronephrosis.
- Hyperparathyroidism, Renal Secondary.
- Hypertension, Systemic Arterial.
- Nephrolithiasis.
- Polycystic Kidney Disease.
- Polyuria and Polydipsia.
- Proteinuria.
- Pyelonephritis.
- Urinary Tract Obstruction.

ABBREVIATIONS
- ACE = angiotensin-converting enzyme.
- AKI = acute kidney injury.
- ARB = angiotensin receptor blocker.
- BUN = blood urea nitrogen.
- CKD = chronic kidney disease.
- PU/PD = polyuria/polydipsia.
- SDMA = symmetric dimethylarginine.
- USG = urine specific gravity.
- UTI = urinary tract infection.

CHYLOTHORAX

BASICS

DEFINITION

• Accumulation of chyle in the pleural space. • Chyle—triglyceride-rich fluid from the intestinal lymphatics that empties into the venous system (usually cranial cava/jugular vein) in the thorax. • Pseudochylous effusion—effusion that contains less triglycerides and more cholesterol compared to serum, but appears fatty grossly. • Thoracic lymphangiectasia—tortuous, dilated lymphatics found in many animals with chylothorax. • Fibrosing pleuritis—condition in which pleural thickening leads to constriction of lung lobes; when severe, results in marked restriction of ventilation; can be caused by any chronic pleural exudate, but is most commonly associated with chylothorax and pyothorax.

PATHOPHYSIOLOGY

• Alteration of flow through thoracic duct (TD) leading to leakage of chyle—can be related to increased pressure or permeability in TD or venous obstruction downstream. • Can be caused by any disease or process that increases systemic venous pressure at the entrance of the TD to the venous system. • Cardiac causes—pericardial disease, cardiomyopathy, heartworm disease, other causes of right-sided heart failure; thrombosis around pacing lead wire. • Noncardiac causes—neoplasia (especially mediastinal lymphoma in cats), lung lobe torsion, diaphragmatic hernia, venous granuloma, venous thrombus. • Rare TD rupture/trauma—surgical (thoracotomy), nonsurgical (e.g., hit by car). • Idiopathic considered most common.

SYSTEMS AFFECTED

• Respiratory—due to reduced lung expansion. • Systemic signs can be present secondary to the respiratory distress (e.g., decreased appetite, weight loss).

GENETICS

Unknown

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat.

Breed Predilections

• Dogs—Afghan hound and Shiba Inu. • Cats—oriental breeds (e.g., Siamese and Himalayan).

Mean Age and Range

• Any age affected. • Cats—more common in older cats; could indicate an association with neoplasia. • Afghan hound—develop when middle-aged. • Shiba Inu—develop when young (<1–2 years of age).

Predominant Sex

None identified.

SIGNS

General Comments

• Signs will depend on the rate of fluid accumulation and volume of pleural effusion. • Usually not exhibited until there is marked impairment of ventilation. • Many patients appear to have the condition for prolonged periods before diagnosis.

Historical Findings

• Tachypnea and respiratory difficulty. • Coughing—can be present for months before examination, likely due to lung compression associated with pleural effusion. • Lethargy. • Anorexia and weight loss. • Exercise intolerance.

Physical Examination Findings

• Vary with cause of effusion. • Muffled heart and lung sounds ventrally. • Increased bronchovesicular sounds, particularly in dorsal lung fields. • Pale mucous membranes or cyanosis. • Arrhythmia. • Heart murmur. • Signs of right-sided heart failure (e.g., jugular pulses, ascites, hepatomegaly). • Decreased compressibility of anterior chest—common in cats with a cranial mediastinal mass.

CAUSES

• Cranial mediastinal masses—lymphoma, thymoma. • Cardiac disease—heartworm, cardiomyopathy, pericardial disease, congenital diseases. • Lung lobe torsion. • Venous obstruction—granuloma, thrombi. • Congenital abnormality of TD. • Cardiac or thoracic surgery. • Idiopathic—most common cause.

RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of pleural effusion—neoplasia, pyothorax, heart failure, feline infectious peritonitis (FIP).

CBC/BIOCHEMISTRY/URINALYSIS

• Often normal. • Lymphopenia and hypoalbuminemia—can be found; hyponatremia and hyperkalemia sometimes noted due to fluid shifts with repeat thoracocentesis.

OTHER LABORATORY TESTS

Heartworm testing.

Fluid Analysis

• Classified as an exudate. • Color will depend on fat content from diet and presence of concurrent hemorrhage—usually milky white and opaque, but can appear serosanguinous and range from yellow to pink. • Protein content varies, and high lipid content will make refractive index inaccurate. • Total nucleated cell count—usually <10,000 cells/μL. • Fluid triglycerides—higher compared to serum. • Fluid cholesterol—lower compared to serum.

Cytology

• Place sample in an EDTA tube to allow cell count to be performed. • Initially, cytology comprises primarily small lymphocytes, neutrophils, and macrophages containing lipid. • Chronic effusions contain fewer lymphocytes due to continued loss and more nondegenerate neutrophils due to inflammation from multiple thoracocenteses or irritation of pleural lining by chyle. • Atypical lymphocytes—suggestive of underlying neoplasia.

IMAGING

Thoracic Radiography

• Two to four views if patient is stable—pleural effusion. • Dorsoventral view associated with less stress than ventrodorsal view in animal with respiratory difficulty. • Repeat radiographs after thoracocentesis to assess for underlying causes of effusion or evidence of fibrosing pleuritis; if collapsed lung lobes do not appear to reexpand after pleural fluid is removed or if respiratory distress persists with only minimal fluid present, suspect underlying pulmonary parenchymal or pleural disease (e.g., fibrosing pleuritis).

Ultrasonography/Echocardiography

• Should be performed before thoracocentesis if patient is stable—fluid acts as an acoustic window, enhancing visualization of thoracic structures. • Assess for underlying causes—detect abnormal cardiac structure and function, pericardial disease, and mediastinal masses.

CT Lymphangiography

• Can quantify TD branches more accurately than standard radiographic lymphangiography. • In dogs, percutaneously inject 1–2 mL of nonionic contrast material into mesenteric lymph nodes using ultrasound or CT guidance. • Acquire helical thoracic CT images before and after injection of contrast media. • Can document location and character of TD and its tributary lymphatics; likely useful for surgical planning.

PATHOLOGIC FINDINGS

• Lymphatics (including TD)—difficult to identify at necropsy. • Fibrosing pleuritis—lungs appear shrunken; pleural layers (visceral and parietal) are diffusely thickened. • Fibrosing pleuritis—characterized histologically by diffuse, moderate to marked thickening of the pleura by fibrous connective tissue with moderate infiltrates of lymphocytes, macrophages, and plasma cells.

CHYLOTHORAX (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

• Dyspneic animal—immediate thoracocentesis; removal of even small amounts of pleural effusion can markedly improve ventilation. • Identify and treat the underlying cause, if possible. • Medical management—usually treated on outpatient basis with intermittent thoracocentesis as needed based on clinical signs (see Medications). • Chest tubes—place *only* in patients with suspected chylothorax secondary to trauma (very rare), in cases with rapid fluid accumulation, or after surgery. • Surgery if medical management does not resolve the problem in 2–3 months (see Surgical Considerations); some clinicians believe earlier intervention is better to avoid potential for development of restrictive pleuritis.

NURSING CARE

• Patients undergoing multiple thoracocenteses can rarely develop electrolyte abnormalities (hyponatremia, hyperkalemia) that may need to be corrected with fluid therapy. • Thoracocentesis—perform under aseptic conditions to reduce risk of iatrogenic infection; antibiotic prophylaxis generally unnecessary if proper technique is used.

ACTIVITY

Patients will usually restrict their own exercise as pleural fluid volume increases or if they develop fibrosing pleuritis.

DIET

• Low fat—potentially decreases the amount of fat in the effusion, which would improve the patient's ability to resorb fluid from the thoracic cavity; not a cure; may help in management by facilitating reabsorption. • Medium-chain triglycerides are transported via the TD in dogs and are no longer recommended.

CLIENT EDUCATION

• Inform client that no specific treatment will stop the effusion in all patients with the idiopathic form of the disease. • Inform client that the condition can spontaneously resolve in some patients after several weeks or months.

SURGICAL CONSIDERATIONS

TD Ligation and Pericardiectomy

• Recommended in patients that do not respond to medical management. • The duct usually has multiple branches in the caudal thorax where ligation is performed; failure to occlude all branches results in continued pleural effusion. • Always perform in conjunction with lymphangiography; methylene blue injected in the mesenteric lymph node greatly facilitates visualization and complete occlusion of all branches. • Thickening of the pericardium can prevent formation of lymphaticovenous communications—perform pericardiectomy simultaneously with TD ligation; reports of up to 100% success rate when both techniques are performed; second surgery can be necessary if all branches are not occluded. • Video-assisted thorascopic surgery for thoracic duct ligation and pericardiectomy is reported to have similar success rates to thoracotomy (86%).

Other

• Success rates of 83–88% reported for cysterna chyli ablation in combination with TD ligation. • Salvage procedures for recurrence after TD ligation include cisterna chyli and TD glue embolization, pleuroperitoneal or pleurovenous shunts, or placement of a PleuralPort®.

MEDICATIONS

DRUG(S) OF CHOICE

• Rutin 50–100 mg/kg PO q8h; believed to increase macrophage removal of proteins, which promotes absorption of fluid; complete resolution of effusion appears to occur in some patients; further study is required to determine whether resolution occurs spontaneously or in response to this therapy. • Somatostatin analog (octreotide)—a naturally occurring substance that inhibits gastric, pancreatic, and biliary secretions and prolongs gastrointestinal transit time, decreases jejunal secretion, and stimulates gastrointestinal water absorption; in traumatic chylothorax, reduction of gastrointestinal secretions may aid healing of the TD by decreasing TD lymphatic flows; resolution of pleural fluid has occurred in dogs and cats with idiopathic chylothorax in which octreotide has been administered, but the mechanism is unknown; octreotide (Sandostatin®; 10 µg/kg SC q8h for 2–3 weeks) is a synthetic analog of somatostatin that has a prolonged half-life and minimal side effects.

CONTRAINDICATIONS

Cardiac disease or neoplasia—treat the underlying disease rather than the effusion (other than heartworm disease in cats where TD ligation may be beneficial while the heartworm infection clears).

FOLLOW-UP

PATIENT MONITORING

• Monitor for signs of recurrence of pleural effusion (tachypnea, labored breathing, respiratory distress)—perform thoracentesis as needed. • Periodically reevaluate for several years to detect recurrence.

POSSIBLE COMPLICATIONS

• Fibrosing pleuritis. • Iatrogenic infection with repeated thoracocentesis—important to use aseptic technique.

EXPECTED COURSE AND PROGNOSIS

• Can resolve spontaneously or after surgery. • Untreated or chronic disease—can result in severe fibrosing pleuritis and persistent dyspnea. • Euthanasia—frequently performed in patients that do not respond to surgery or medical management.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Diffuse lymphatic abnormalities (e.g., intestinal lymphangiectasia, hepatic lymphangiectasia, pulmonary lymphangiectasia, and chylous ascites)—may be noted; may worsen the prognosis.

AGE-RELATED FACTORS

Young patients may have a better prognosis than old animals because of the association of neoplasia with advanced age.

ABBREVIATIONS

• FIP = feline infectious peritonitis. • TD = thoracic duct.

CIRRHOSIS AND FIBROSIS OF THE LIVER

BASICS

DEFINITION

• Hepatic fibrosis—replacement/effacement of hepatic parenchyma, intrasinusoidal, variable zonal, deposition of extracellular matrix (ECM).
• Cirrhosis—regenerative nodules with dissecting fibrotic partitions and regions of parenchymal extinction, deranging hepatic architecture; usually reflects chronic necroinflammatory liver injury.

PATHOPHYSIOLOGY

• Fibrosis—usually reflects injury-associated release of cytokines/mediators stimulating production and accumulation of ECM; exception: ductal plate malformation (DPM), with congenital hepatic fibrosis (CHF) phenotype (severe portal-to-portal bridging fibrosis without chronic inflammation).
• Cirrhosis—consequence of chronic hepatic injury, fibrogenesis, and hepatic regeneration; typified by regenerative nodules, reduced functional hepatic mass, collagen deposition in sinusoids (space of Disse) or portal tracts, compromising parenchymal perfusion.
• Cirrhosis/fibrosis—leads to hepatic dysfunction, capillarization of hepatic sinusoids, collagenization of sinusoids, development of sinusoidal hypertension, intrahepatic shunting through collagenized sinusoids, recanalized vascular pathways in fibrotic partitions between regenerative nodules; these microcirculatory disturbances impair exchanges between blood and hepatocytes.
• Sinusoidal hypertension—leads to hepatofugal portal flow (away from liver); splanchnic hypertension; acquired portosystemic shunt (APSS) formation; episodic hepatic encephalopathy (HE); splanchnic pooling of blood, decreased effective systemic blood volume, stimulation of renal sodium and water retention, with ascites formation; hypertensive splanchnic vasculopathy predisposing to enteric bleeding.

SYSTEMS AFFECTED

• Gastrointestinal (GI)—splanchnic portal hypertension leads to ascites and propensity for enteric bleeding.
• Neurologic—HE.
• Hemic—red blood cell (RBC) microcytosis reflects APSS; bleeding tendencies: failed factor synthesis or activation, thrombocytopenia; reduced anticoagulants increases risk for thrombosis.
• Renal/urologic—ammonium biurate crystalluria; isosthenuria: polyuria/polydipsia (PU/PD); hepatorenal syndrome (rare) may follow therapeutic paracentesis of large-volume ascites (postcentesis hypotension syndrome [PHS]).
• Endocrine/metabolic—hypoglycemia if end-stage liver failure.
• Respiratory—tachypnea if tense ascites or pleural effusion.
• Skin—superficial necrolytic dermatitis, unkempt coat.

GENETICS

Familial predisposition for chronic hepatitis—Doberman pinscher, cocker spaniel, Labrador retriever, Maltese, Bedlington terrier (copper related), West Highland white terrier, others.

INCIDENCE/PREVALENCE

High in dogs with chronic necroinflammatory liver disease, animals with chronic extrahepatic bile duct occlusion (EHBDO), dogs with severe hepatic copper accumulation.

SIGNALMENT

Species

• Cirrhosis—dogs with chronic hepatitis; cats with chronic cholangitis/cholangiohepatitis; dogs and cats with chronic EHBDO.
• Severe fibrosis—dogs and cats with severe DPM-CHF phenotype.

Breed Predilection

• Many breeds and mixed-breed dogs.
• Copper associated hepatopathy (CuAH)—genetics proven only in Bedlington terriers and partially in Labrador retrievers; Doberman pinschers, West Highland white terriers, and Dalmatians appear predisposed; but all breeds at risk for CuAH due to dietary Cu intake.
• DPM-CHF phenotype—boxers may be predisposed, many breeds of dogs and cats; cats with polycystic malformations at risk.

Mean Age and Range

• Cirrhosis (dogs)—any age; more common in middle-aged to older; CuAH any age.
• Biliary cirrhosis (cats)—with chronic cholangiohepatitis often >7 years old.
• Fibrosis—DPM-CHF phenotype (dogs, cats)—ECM accumulates with aging (suspected), genetic cause (see Ductal Plate Malformation).

Predominant Gender

• Cocker spaniels—may be higher in males.
• Doberman pinschers and Labrador retrievers—no sex predilection.
• DPM—no gender predilection.

SIGNS

General Comments

• Initially—vague and nonspecific.
• Later—relate to complications of portal hypertension (e.g., HE, ascites, gastroduodenal bleeding) and impaired hepatic function.

Historical Findings

• Chronic intermittent lethargy, anorexia, reduced body condition.
• GI signs—vomiting, diarrhea or constipation. Melena—late stage or as APSS develop.
• PU/PD.
• Late onset—ascites, bleeding, HE.
• Jaundice—with necroinflammatory disease; DPM usually anicteric.
• Cats—ascites uncommon with acquired necroinflammatory disease, more common with DPM; ptyalism, aggression, seizures with HE.

Physical Examination Findings

• Lethargy.
• Poor body condition/coat.
• ± Variable jaundice.
• ± Ascites.
• ± HE.
• Obstructive uropathy—ammonium biurates.
• Anasarca—rare; may develop with overzealous fluid therapy.
• Liver size—dogs: microhepatia; cats: variable.
• Coagulopathy—variable, uncommon in DPM.
• Cutaneous lesions—superficial necrolytic dermatitis.

CAUSES

• Chronic necroinflammatory, oxidant, or immune-mediated liver injury has many causes; may develop subsequent to chronic inflammatory bowel disease (IBD) or pancreatitis.
• CuAH.
• Drug- or toxin-induced liver injury—anticonvulsants; azole antifungals; nonsteroidal anti-inflammatory drug (NSAID) oxibendazole; trimethoprimsulfamethoxazole; chronic food-borne toxins (aflatoxins), others.
• Infections—leptospirosis, canine adenovirus I, leishmanial, histoplasmosis, protozoal (toxoplasmosis).
• Chronic cholangiohepatitis (cats).
• Chronic EHBDO (>6 weeks, dogs and cats).
• Single episode of massive hepatic necrosis; sago palm (cycad toxicity), xylitol, NSAIDs in dogs with substantial Cu accumulation.

RISK FACTORS

• Breed predisposition.
• Dietary Cu intake >patient tolerance.
• Hepatic iron accumulation—supplementation.
• Chronic hepatobiliary inflammation.
• Chronic EHBDO.
• Chronic phenobarbital administration (dogs).
• NSAIDS—dogs, especially carprofen.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Chronic hepatitis—common in dogs.
• Cholangiohepatitis—common in cats.
• Noncirrhotic portal hypertension—dogs.
• Chronic EHBDO.
• Chronic IBD or pancreatitis.
• Hepatic neoplasia.
• Metastatic neoplasia or carcinomatosis.
• Congenital portosystemic vascular anomaly (shunt).
• Congenital portal atresia—intrahepatic or extrahepatic.
• Right-sided heart failure, pericardial disease.

CIRRHOSIS AND FIBROSIS OF THE LIVER (CONTINUED)

• Cats—hepatic lipidosis, feline infectious peritonitis, toxoplasmosis.
• Hemolytic anemia (jaundice differential).

CBC/BIOCHEMISTRY/URINALYSIS

CBC

• Microcytic RBCs: APSS; mild anemia: small RBCs with normal cell count; anemia of chronic disease; microangiopathic shearing: sinusoidal fibrosis, APSS.
• Mild thrombocytopenia variable.
• Leukogram variable.

Biochemistry

• Bilirubin variable.
• Liver enzyme activities—high (alanine transaminase [ALT] > alkaline phosphatase [ALP]) noted before clinical signs or liver dysfunction; at end-stage enzymes may decline.
• Normal to hypoalbuminemia.
• Normal to hyperglobulinemia.
• Hypocholesterolemia—reflects APSS.
• Low blood urea nitrogen (BUN)—reduced urea cycle activity, APSS, protein-restricted diet, PU/PD.
• Hypoglycemia—rare.
• Hypokalemia—may predispose to HE.
• Hyponatremia—fluid imbalance with ascites.

Urinalysis

• Isosthenuria—with PU/PD.
• Ammonium biurate crystalluria.
• Bilirubinuria, bilirubin crystalluria.

OTHER LABORATORY TESTS

• Ascitic fluid—pure or modified transudate.
• Coagulation tests—inconsistently prolonged prothrombin time (PT), activated partial thromboplastin time, buccal mucosal bleeding time (BMBT).
• Low protein C and antithrombin activity—reflects APSS, synthetic failure, or disseminated intravascular coagulation (DIC).
• Serum bile acids—high; reflects APSS or cholestasis in cirrhosis.
• Hyperammonemia—inferred from ammonium biurate crystalluria.

IMAGING

Radiography

Abdominal—small to normal-sized liver; ascites may obscure details; urate calculi radiolucent unless calcium complexed.

Ultrasonography

• Abdominal—hyperechoic or mixed echogenic liver parenchyma; ± nodularity; often small with cirrhosis; abdominal effusion (ascites); APSS (color-flow Doppler); enlarged portal lymph nodes; no parenchymal change in some cases.
• Doppler interrogation of portal vasculature—may confirm hepatofugal flow or nests of APSS, esp. near left kidney or splenic vessels.

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration cytology—helps rule out neoplasia; rule in bacterial infection; *cannot define fibrosis or parenchymatous*
• Liver biopsy—for definitive diagnosis; accuracy increased by multiple biopsy samples.
• Ultrasound guided—14–16G.
• Laparoscopy/laparotomy—best methods, permits gross visualization, documents APSS, biopsy access to multiple liver lobes and focal lesions.

PATHOLOGIC FINDINGS

Gross

• Fibrosis—small, firm irregular to finely nodular liver; DPM-CHF may not be small; fibrotic liver may display APSS, ± ascites.
• Cirrhosis—firm irregular liver; prominent micro- or macronodules, APSS, ± ascites.

Histopathology

• Immune-mediated hepatitis—periportal, lobular, or centrilobular lymphoplasmacytic infiltrates, hepatic cord disorganization, sinusoidal fibrosis, biliary hyperplasia.
• CuAH—initially centrilobular, may evolve immune-mediated hepatitis; single necrotic hepatocytes; significant fibrotic tissue may falsely decrease quantitative Cu concentration measurements in biopsy samples.
• DPM—bridging partitions with proliferative nonfunctional embryonic bile ducts embedded in ECM interconnecting portal regions.
• Postnecrotic fibrosis—fibrosis marks regenerative repair, disorganized wide hepatic cords; engorged lymphatics reflect sinusoidal hypertension.
• Cirrhosis—diffuse lesion; fibrosis, nodular regeneration distorting lobular architecture, periportal or sinusoidal fibrosis depending on zone of chronic injury, engorged lymphatics; single hepatocyte necrosis if active disease.

TREATMENT

APPROPRIATE HEALTH CARE

• Outpatient—minimally symptomatic patients.
• Inpatient—diagnostic tests; treatment for dehydration, severe HE, enteric bleeding, tense ascites.

NURSING CARE

• Fluids—avoid lactate if hepatic failure; avoid sodium loading if ascites.
• B complex vitamins (esp. cats)—2 mL/L fluid advised.
• Vitamin K_1—0.5–1.5 mg/kg SC q12h for 3 doses initially; titrate with proteins invoked by vitamin K absence or antagonism (PIVKA; if available) or PT.
• Glucose—if hypoglycemia; 2.5–5% dextrose in polyionic solution; titrate to response.
• Potassium chloride—in fluids, as needed.
• Avoid alkalosis—worsens HE.
• Therapeutic large-volume abdominocentesis if tense ascites nonresponsive to medical treatment; *caution*: PHS—hypotensive crisis and acute renal failure.

ACTIVITY

Limit

DIET

• Withhold oral food in acute severe HE if stupor, coma, or vomiting associated with enteric bleeding or pancreatitis.
• Consider partial parenteral nutrition or total parenteral nutrition.
• If HE—restrict protein intake, use soy or dairy protein sources (dogs) with medical interventions to increase nitrogen tolerance (see Hepatic Encephalopathy).
• Supplement water-soluble vitamins.

CLIENT EDUCATION

• Treatment palliative and symptomatic.
• Fibrosis diminished by control of inflammation and provocative diseases.
• Attenuate factors provoking HE—azotemia, dehydration; infection; catabolism; high-protein meals, hypokalemia; alkalemia; constipation, endoparasitism; enteric bleeding; certain drugs.

SURGICAL CONSIDERATIONS

• Cirrhosis—high anesthetic risk; gas anesthesia preferred: isoflurane or sevoflurane.
• Coagulopathy—predisposes to bleeding; BMBT may better assess risk for bleeding.
• Postoperative intensive care—avoid HE, maintain hydration, euglycemia, electrolytes, acid-base balance (avoid alkalemia).
• Predisposed to enteric bacterial translocation—judiciously administer antibiotics, esp. if surgical procedures involve alimentary canal or biliary structures.

MEDICATIONS

DRUG(S) OF CHOICE

• Treatments for specific etiologies—chelate Cu if CuAH; withdraw potentially hepatotoxic drugs, herbal or natural remedies.
• No clinical trials prove efficacy of specific regimens in animals.

Immune Modulation

• Prednisolone/prednisone—1–2 mg/kg q24h PO; taper to 0.5 mg/kg q48h; do not exceed 40 mg/day/dog.
• Azathioprine—2 mg/kg (or 50 mg/m^2) q24h for 14 days, then q48h; contraindicated in cats (toxic); dogs: with prednisone, antioxidants, antifibrotics, and polyenylphosphatidylcholine (PPC).
• Cyclosporine—5 mg/kg BID tapered to q24h; has been successful as single agent or with corticosteroids.
• Mycophenolate—10–15 mg/kg BID; has been successful as first- or second-line treatment with corticosteroids.

Antifibrotics

• Immunomodulation, S-adenosylmethionine (SAMe), silybin, vitamin E—considered

(CONTINUED)

CIRRHOSIS AND FIBROSIS OF THE LIVER

• Ursodiol—7.5 mg/kg/day PO q12h with food; use indefinitely.
• Polyunsaturated phosphatidylcholine with dilinolylphosphatidylcholine (PhosChol®)—25 mg/kg/q24h, mix with food.
• Colchicine—0.025–0.03 mg/kg q24–48h; no evidence of chronic benefit; side effects complicate use; no longer recommended.
• Losartan and telmisartan—losartan: 0.5 mg/kg/q24h; telmisartan: 0.5–1 mg/kg q24h initial dose; closely monitor blood pressure, renal function, and potassium, reducing dose if hypotension or hyperkalemia; angiotensin receptor blockers used in humans as antihypertensives and have been shown to be nephroprotective, to protect against some forms of drug-induced hepatotoxicity, and to inconsistently limit hepatic fibrosis.

Antioxidants

• Necroinflammatory disorders.
• SAMe—20 mg/kg q24h PO, *empty stomach*.
• Vitamin E mixed tocopherols—10 U/kg q24h PO with food.

Hepatoprotectants

• Necroinflammatory disorders.
• Ursodeoxycholate, vitamin E, SAMe.
• Silibinin—efficacy unclear, use PPC complexed form (bioavailable), 2–5 mg/kg q24h PO.
• Elemental zinc—1.5–3 mg PO q24h (if low liver zinc confirmed); adjust dose with plasma zinc measurements; avoid ≥800 µg/dL; contraindicated with concurrent d-penicillamine administration.

Gastroprotectants

• Gastric acid inhibitors—if enteric bleeding (see Hepatitis, Chronic).
• Eliminate endoparasitism.

Ascites

• Restrict activity and sodium intake combined with diuretic therapy.
• Dietary sodium restriction (0.2% dry matter basis or <0.05 g/100 kcal).
• Diuretics (see Hypertension, Portal; Hepatitis, Chronic); slowly mobilize effusion: furosemide (0.5–1 mg/kg IV/SC/PO q12h) with spironolactone (0.5–2 mg/kg PO q12h); adjust dose to response (7–10 day recheck; if no response titrate up q3–5d to max dose 4 mg/kg/day).
• Therapeutic large-volume abdominocentesis if nonresponsive ascites mobilization after 7–14 days of diuretics and sodium restriction.
• Consider vasopressin V_2 antagonists with low-dose diuretics for treatment-resistant ascites (no published data for dogs or cats).

CONTRAINDICATIONS

NSAIDs—avoid; potentiate enteric bleeding; may worsen ascites; potentiate centrilobular hepatic necrosis-hepatotoxic metabolites and CuAH.

PRECAUTIONS

• Diuretics—dehydration, hypokalemia, alkalemia worsen HE.
• Glucocorticoids—increase susceptibility to infection, enteric bleeding, sodium and water retention, ascites, protein catabolism, HE.
• Avoid drugs or reduce dose if first-pass hepatic extraction, if require hepatic conjugation or biotransformation (e.g., metronidazole—reduce conventional dose to 7.5 mg/kg PO q12h, as used for HE).

ALTERNATIVE DRUG(S)

• Dexamethasone—if ascites, replace prednisone/prednisolone to avoid mineralocorticoid effect); divide dose by 7–10, administer q3–4 days; taper dose to efficacy.

FOLLOW-UP

PATIENT MONITORING

• Liver enzymes, albumin, BUN, cholesterol, bilirubin—monthly to quarterly.
• Serial monitoring of total serum bile acids—adds no prognostic or diagnostic information.
• Body condition score, weight, muscle mass—reflects nutritional adequacy/nitrogen balance.
• Abdominal girth—reflects ascites volume.
• Azathioprine, mycophenolate, colchicine—monitor for bone marrow toxicity (serial CBCs) and other side effects.

POSSIBLE COMPLICATIONS

HE, septicemia, bleeding—may be life-threatening; DIC—may be terminal event.

EXPECTED COURSE AND PROGNOSIS

• Flare-ups of HE and ascites may require hospitalization to adjust nutritional and medical interventions.
• Sodium restriction and diuretics may require titration to achieve optimal control of ascites.
• Presence of ascites indicates severe disease.
• DPM—survival up to 12 years after diagnosis.
• Cirrhosis—variable: poor long-term prognosis in limited studies, <6 months; however, some can survive years (>5) with careful interventional management depending on whether histologic changes truly "end-stage" or not.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Dogs with leptospirosis-associated chronic liver disease (rare) may shed organisms.

SEE ALSO

• Coagulopathy of Liver Disease.
• Copper Associated Hepatopathy.
• Ductal Plate Malformation (Congenital Hepatic Fibrosis).
• Hepatic Encephalopathy.
• Hepatitis, Chronic.
• Hypertension, Portal.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALR = alanine transaminase.
• APSS = acquired portosystemic shunt.
• BMBT = buccal mucosal bleeding time.
• BUN = blood urea nitrogen.
• CHF = congenital hepatic fibrosis.
• CuAH = copper associated hepatopathy.
• DIC = disseminated intravascular coagulation.
• DPM = ductal plate malformation.
• ECM = extracellular matrix.
• EHBDO = extrahepatic bile duct occlusion.
• GI = gastrointestinal.
• HE = hepatic encephalopathy.
• IBD = inflammatory bowel disease.
• NSAID = nonsteroidal anti-inflammatory drug.
• PHS = postcentesis hypotension syndrome.
• PIVKA = proteins invoked by vitamin K absence or antagonism.
• PPC = polyenylphosphatidylcholine.
• PT = prothrombin time.
• PU/PD = polyuria/polydipsia.
• RBC = red blood cell.
• SAMe = S-adenosylmethionine.

CLAW AND CLAWFOLD DISORDERS

BASICS

DEFINITION
- Ungual fold—crescent-shaped tissue surrounding the proximal claw.
- Coronary band and dorsal ridge (dorsal ridge of the ungual crest)—produces most of the claw; contributes to the curvature of the claw.
- Paronychia—inflammation of soft tissue around the claw.
- Onychomycosis—fungal infection of the claw.
- Onychorrhexis—brittle claws that tend to split or break.
- Onychomadesis—sloughing of the claw.
- Onychodystrophy—deformity caused by abnormal growth; often a sequela of a disorder.
- Onychomalacia—softening of the claw.

PATHOPHYSIOLOGY
- Claws and ungual folds—subject to trauma, infection, vascular insufficiency, immune-mediated disease, parasites, neoplasia, defects in keratinization, and congenital abnormalities.
- A particular claw deformity may be caused by a variety of diseases—claw disease is most often associated with other dermatoses: rarely the only epithelial structure affected.
- A single disease can present with various claw lesions.
- One foot affected—top differentials include foreign body, neoplasia, trauma, fungal infection, bacterial infection.
- Multiple feet affected—allergy, endocrine, secondary infections, demodicosis, immune-mediated disorders, epidermolysis bullosa, symmetric lupoid onychodystrophy (SLO), plasma cell pododermatitis, superficial necrolytic dermatitis, nutritional deficiencies, psychogenic dermatoses, idiopathic.

SIGNALMENT
- Dog and cat.
- Claw and clawfold diseases—1.3% of dogs and 2.2% of cats.
- Mean age range—SLO 3–8 years.
- No predominant sex reported.
- Dachshunds—onychorrhexis.
- German shepherd dogs, Rottweilers, possibly giant schnauzers and Doberman pinschers—SLO.
- Siberian huskies, dachshunds, Rhodesian ridgebacks, Rottweilers, cocker spaniels—idiopathic onychodystrophy.
- German shepherd dogs, whippets, English springer spaniels—idiopathic onychomadesis
- Shorthair dog breeds—paronychia in multiple digits.
- Devon Rex cats—*Malassezia* paronychia.

SIGNS
- Licking at the feet and/or ungual folds.
- Lameness.
- Pain.
- Swelling, erythema, and exudate of ungual fold.
- Deformity or band formation of claw.
- Sloughing of claw.
- Discoloration of claw.
- Hemorrhage from claw or at loss of a claw.

CAUSES

Paronychia
- Infection—bacteria, dermatophyte, yeast (*Candida*, *Malassezia*).
- Demodicosis.
- Immune-mediated—pemphigus, bullous pemphigoid, systemic lupus erythematosus (SLE), drug eruption, SLO.
- Neoplasia—subungual squamous cell carcinoma, melanoma, eccrine carcinoma, osteosarcoma, subungual keratoacanthoma, inverted squamous papilloma.
- Arteriovenous fistula.

Onychomycosis
- Dogs—*Trichophyton mentagrophytes*—usually generalized.
- Cats—*Microsporum canis*.

Onychorrhexis
- Idiopathic—especially in dachshunds; multiple claws.
- Trauma.
- Infection—dermatophytosis, leishmaniasis.

Onychomadesis
- Trauma.
- Infection.
- Immune-mediated—pemphigus, bullous pemphigoid, SLE, drug eruption, SLO.
- Vascular insufficiency—vasculitis, cold agglutinin disease.
- Neoplasia—see above.
- Idiopathic.

Claw Dystrophy
- Acromegaly.
- Feline hyperthyroidism.
- Zinc-responsive dermatosis.
- Congenital malformations.
- Leishmaniasis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Trauma or neoplasia often affects a single claw.
- Involvement of multiple claws suggests a systemic disease.
- Immune-mediated diseases (except SLO) usually have other skin lesions in addition to claw or ungual fold lesions.

CBC/BIOCHEMISTRY/URINALYSIS
May show evidence of SLE, diabetes mellitus, hyperthyroidism, or other systemic illness.

OTHER LABORATORY TESTS
- Feline leukemia virus (FeLV).
- Serum thyroxine.
- Antinuclear antibody (ANA) titer.

IMAGING
Radiographs—osteomyelitis of third phalanx, neoplastic change.

DIAGNOSTIC PROCEDURES
- Biopsy—often involves a third phalanx amputation; inclusion of the coronary band required for diagnosis of most diseases; punch biopsy of the claw (onychobiopsy).
- Cytology of exudate from the claw and/or fold.
- Skin scraping.
- Bacterial and fungal culture.

TREATMENT

PARONYCHIA
- Surgical removal of claw plate (shell).
- Antimicrobial soaks.
- Systemic antibiotics as per culture results.
- Identify underlying condition and treat specifically.

Onychomycosis
- Antifungal soaks—chlorhexidine, povidone iodine, lime sulfur.
- Surgical removal of claw plate—may improve response to systemic medication.
- Amputation of third phalanx.

Onychorrhexis
- Repair with fingernail glue (type used to attach false nails in humans).
- Remove splintered pieces and maintain with rotary sander (Dremel).
- Treat underlying cause.
- Amputate third phalanx, last resort.

Onychomadesis
- Antimicrobial soaks.
- Treat underlying cause.

Neoplasia
- Determined by biologic behavior of specific tumor.
- Surgical excision.
- Amputation of digit or leg.
- Chemotherapy and/or radiation therapy.

Claw Dystrophy
Treat underlying cause.

MEDICATIONS

DRUG(S) OF CHOICE
- Bacterial paronychia—systemic antibiotics based on culture and sensitivity.
- Yeast paronychia—*Candida* or *Malassezia* paronychia: ketoconazole (5–10 mg/kg PO q12–24h); topical nystatin or miconazole.

• Onychomycosis—griseofulvin (50–150 mg/kg PO/day) or ketoconazole (5–l0 mg/kg PO q12h) for 6–12 months until negative cultures; itraconazole (10 mg/kg PO q24h) for 3 weeks and then pulse therapy until resolved.
• Onychomadesis—determined by cause; immunomodulation therapy for immune-mediated diseases (e.g., SLO); options include essential fatty acid supplementation; cycline antibiotics: tetracycline 250 mg PO TID for dogs <10 kg; 500 mg PO TID dogs >10 kg); doxycycline 10 mg/kg PO q24h; minocycline 5 mg/kg PO BID, often administered with niacinamide 250 mg PO for dogs <10 kg and 500 mg PO for dogs >10 kg; pentoxifylline 10–15 mg/kg PO BID to TID; corticosteroids and cyclosporine 5 mg/kg PO q24h; vitamin E; appropriate chemotherapeutic agents (e.g., azathioprine, chlorambucil).
• Nonsteroidal anti-inflammatory drugs (NSAIDs) or tramadol if pain is present.

PRECAUTIONS

• Griseofulvin—teratogenic; may cause bone marrow suppression, anorexia, vomiting, and diarrhea; absorption enhanced if given with a high-fat meal.
• Ketoconazole—avoid use in cats; may cause anorexia, gastric irritation, hepatic toxicity, and lightening of the hair coat.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Slow claw growth cycle may require 6–8 months of therapy to fully correct an abnormality; improvement may be noted after 6–8 weeks of appropriate treatment.
• Bacterial or yeast paronychia and onychomycosis—treatment may be prolonged and response may be influenced by underlying factors; weight reduction in obese patients.
• Onychorrhexis—may require amputation of the third phalanx for resolution.
• Onychomadesis—prognosis determined by underlying cause; immune-mediated diseases and vascular problems carry a more guarded prognosis than do trauma or infectious causes.
• Neoplasia—excised by amputation of the digit; malignant tumors metastasize by the time of diagnosis.

MISCELLANEOUS

ABBREVIATIONS

• ANA = antinuclear antibody.
• FeLV = feline leukemia virus.
• NSAID = nonsteroidal anti-inflammatory drug.
• SLE = systemic lupus erythematosus.
• SLO = symmetric lupoid onychodystrophy.

CLOSTRIDIAL ENTEROTOXICOSIS

BASICS

DEFINITION
A complex disorder characterized by diarrhea in dogs and cats associated with *Clostridium perfringens* enterotoxins (CPEs).

PATHOPHYSIOLOGY
• *Clostridium perfringens* (CP) is a Gram-positive, spore-forming, strictly anaerobic bacterium. • CP is a normal commensal organism found in the intestinal tract of humans and animals. • A strong link between canine acute hemorrhagic diarrhea syndrome (AHDS; formerly hemorrhagic gastroenteritis [HGE]) and the presence of CP has been identified. • Certain strains of CP (primarily Type A) produce a potent enterotoxin (CPE) as well as pore-forming toxins (NetE and NetF). • CPE is a cytotoxic enterotoxin that causes tissue destruction; it has been identified in the feces of up to 14% of dogs without diarrhea, thus its role in causing diarrhea is unclear. • NetF-producing CP isolates have not been found in healthy dogs. • Not all strains of CP produce CPE or NetF and not all dogs that have CPE in feces are clinical, therefore it is undetermined why some develop diarrhea. • CPE production is coregulated with sporulation of the organism; conditions that precipitate sporulation in animals include a sudden change in diet, dietary indiscretion, injudicious use of antibiotics causing a severe dysbiosis, and underlying intestinal disease.

SYSTEMS AFFECTED
Gastrointestinal (GI).

INCIDENCE/PREVALENCE
Incidence is unknown; up to 34% of canine diarrhea cases are suspected to be CP related. The infection is far less common in cats.

SIGNALMENT

Species
Dog and cat.

Mean Age and Range
Any age.

SIGNS

General Comments
Can include both large and small bowel diarrhea.

Historical Findings
• Large bowel diarrhea—tenesmus, mucous, frank blood, and increased frequency of defecation. • Small bowel diarrhea—large volumes of soft to liquid diarrhea. • Vomiting and abdominal discomfort. • Severity varies from mild, self-limiting diarrhea to fatal, acute, hemorrhagic diarrhea.

Physical Examination Findings
• Abdominal discomfort. • Hematochezia. • Mucoid feces. • Dehydration if there has been voluminous diarrhea or vomiting. • Fever is uncommon. • Evidence of systemic illness or debilitation is rare.

CAUSES
• In humans, CP-associated diarrhea is usually due to ingestion of enterotoxigenic isolates. In dogs, it is thought to be secondary to disruption of the intestinal microenvironment. • Anything that disrupts normal enteric microbiota can lead to CP overgrowth and diarrhea. • CP toxins have been implicated in dogs with AHDS.

RISK FACTORS
• Dietary changes. • Antibiotic use. • Stress. • Primary small intestinal bacterial overgrowth.

DIAGNOSIS

• Diagnostic testing should occur during the acute phase. • In the absence of sepsis, antibiotic therapy has not been shown to alter resolution of clinical signs, therefore response to antibiotics cannot be used as diagnostic criterion.

DIFFERENTIAL DIAGNOSIS
Any cause of diarrhea can be considered, including, but not limited to, viral, bacterial, or parasitic infection, dietary indiscretion, chronic enteropathy, metabolic disease, neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS
• If dehydration is present—increased packed cell volume (PCV) from hemoconcentration, increased total plasma protein, increased amylase, and increased blood urea nitrogen (BUN) from prerenal azotemia. • Dogs with AHDS will often have increased PCV with discordantly low total plasma protein. • Leukocytosis with neutrophilia and monocytosis. • Decreased albumin secondary to loss and decreased production. • Increased alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities from organ hypoxia secondary to hypovolemia.

OTHER LABORATORY TESTS
There is no gold standard diagnostic test for confirming CP-associated diarrhea.

Microbiology
• Fecal culture alone should not be used to diagnose CP-associated illness because the organism is a normal commensal; CP can be isolated from feces of >80% of healthy dogs and 43–63% of normal cats. • Fecal endospore cultures are not useful, as sporulation of enterotoxigenic strains of CP occurs in dogs with and without diarrhea.

Enterotoxin Assay
• Fecal ELISA for identification of CPE in patients with diarrhea suspected to be due to CP is the current recommendation; since CPE is present in the feces of 5–14% of clinically normal dogs, this may or may not be clinically useful. • Fecal ELISA should be run in conjunction with PCR to detect enterotoxigenic strains. • Real-time polymerase chain reaction (RT-PCR) for detection of the CPE gene and the alpha toxin gene is available; the CPE gene has been found in up to 33.7% of healthy dogs, therefore its presence in a dog with GI disease does not confirm that CP is the cause.

Fecal Cytology
• CP endospores, characterized by "safety-pin" appearance with oval form and dense body at one end of spore wall, can be seen on microscopic evaluation of heat-fixed thin fecal smear stained with Romanowsky-type stain (e.g., Diff-Quik®), Wright's stain, or new methylene blue. • High numbers of CP endospores on fecal cytology correlates poorly with clinical disease or fecal CPE activity. • High numbers of fecal endospores can be found in feces of healthy dogs.

DIAGNOSTIC PROCEDURES
• Abdominal ultrasound can help rule out other causes of GI disease. • Colonoscopy and endoscopy with biopsy can be used to confirm presence of acute mucosal necrosis and neutrophilic infiltration, as well as adherence of rod-shaped bacteria to these necrotic areas, and can rule out other causes of GI disease.

PATHOLOGIC FINDINGS
• Grossly hyperemic or ulcerated mucosa. • Acute intestinal mucosal destruction and neutrophilic infiltration. • Immunohistochemical staining of bacterial plaques on necrotic areas may be clostridial antigen positive.

TREATMENT

APPROPRIATE HEALTH CARE
• There are no research-based recommendations for optimal treatment of patients with CP-associated illness. • If vomiting or diarrhea is not severe, animals may be treated as outpatients with antiemetics and subcutaneous fluids. • If more severe diarrhea, vomiting, dehydration, or evidence of hypovolemia, hospitalization with IV replacement crystalloids and antiemetics is recommended.

DIET
• Diet change plays a role in treatment and management of cases with chronic recurring disease; diets high in either soluble (fermentable) or insoluble fiber often result in clinical improvement by reducing enteric CP

number, possibly through acidification of the distal intestine, which limits CP sporulation and enterotoxin production.
• Commercial diets can be supplemented with psyllium (1/2–2 tsp/day) as a source of soluble fiber.
• Diets low in fiber should be supplemented with fiber (coarse bran 1–3 tbs/day) as a source of insoluble fiber or psyllium added as a source of soluble fiber. • Probiotics might help restore the normal intestinal microbiota, thereby reducing risk of recurrent CP-associated diarrhea.

CLIENT EDUCATION

• Acute disease is often self-limiting. • There have been no documented reports of transmission of CP from animals to humans; however, if there are immunosuppressed members in the household, strict hygiene protocols should be followed.

MEDICATIONS

DRUG(S) OF CHOICE

Antiemetics

• Maropitant—1 mg/kg IV/SC q 24h.
• Ondansetron—0.5–1 mg/kg IV/PO q24h.

Antibiotics

• Antibiotics are unnecessary in animals with mild disease as the infection is typically self-limiting. • If signs of systemic disease or sepsis are present, antibiotics should be administered. • Antibiotics that are recommended are ampicillin: 22 mg/kg IV q8h; amoxicillin: 22 mg/kg PO q8h; metronidazole: 10–25 mg/kg IV/PO q12h for 5–7 days; tylosin: 5–10 mg/kg PO q24h.
• Tetracyclines are no longer recommended due to resistance of CP isolates.

ALTERNATIVE DRUGS(S)

• Probiotics (e.g., lactobacillus) may alter the intestinal microbiota, reducing likelihood of recurrences. • One study reported faster resolution of clinical signs with use of probiotics than with no treatment. • Diet change can be instituted following resolution of clinical signs.

FOLLOW-UP

PATIENT MONITORING

• Ensure adequate hydration and intravascular volume, with replacement fluid administration as needed. • Monitor PCV, total plasma protein, acid-base balance, and electrolyte concentrations.

PREVENTION/AVOIDANCE

• Regular use of high-fiber diets or probiotics. • Avoiding or anticipating stressful events (e.g., kenneling) and using anxiolytics.

EXPECTED COURSE AND PROGNOSIS

• Overall excellent prognosis; many animals will have resolution of clinical signs without in-hospital treatment. • Acute hemorrhagic diarrheal events should be addressed with aggressive resuscitation and hospitalization; if the animal responds to therapy, the prognosis is good.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• CP enterotoxicosis can be associated with AHDS. • The connection to chronic enteropathies is less well understood.

ZOONOTIC POTENTIAL

Unknown

PREGNANCY/FERTILITY/BREEDING

Antibiotic therapy may be contraindicated.

SEE ALSO

• Colitis and Proctitis.
• Small Intestinal Dysbiosis.

ABBREVIATIONS

• AHDS = acute hemorrhagic diarrhea syndrome.
• ALT = alanine aminotransferase.
• AST = aspartate aminotransferase.
• BUN = blood urea nitrogen.
• CP = *Clostridium perfringens*.
• CPE = *Clostridium perfringens* enterotoxin.
• GI = gastrointestinal.
• HGE = hemorrhagic gastroenteritis.
• PCV = packed cell volume.
• RT-PCR = real-time polymerase chain reaction.

COAGULATION FACTOR DEFICIENCY

BASICS

DEFINITION
Hemostatic defects characterized by a lack of one or more procoagulant proteins (coagulation factors).

PATHOPHYSIOLOGY
- Coagulation involves a complex series of enzymatic reactions that generate a burst of thrombin (factor IIa) at sites of blood vessel injury; thrombin then cleaves plasma fibrinogen into fibrin monomers that subsequently polymerize and cross-link to form an insoluble fibrin clot.
- Functional and/or quantitative coagulation factor deficiencies cause a failure of fibrin clot formation.
- The liver is the sole or primary site of synthesis of most coagulation factors; after synthesis, factors II, VII, IX, and X require a vitamin K–dependent modification to become fully active.

SYSTEMS AFFECTED
- Coagulation factor deficiency can cause spontaneous hemorrhage, prolonged post-traumatic hemorrhage, and ultimately blood loss anemia.
- Spontaneous hemorrhage—often develops in body cavities or potential spaces (i.e., hemothorax, hemoperitoneum, hemarthrosis, subcutaneous, or intramuscular hematoma).

GENETICS
- Hemophilia A and B (factor VIII and IX deficiencies)—X-linked recessive traits.
- All other factor deficiencies are autosomal traits.
- Specific defects are more likely to be propagated within a single breed, but all breeds are at risk for developing new mutations.

SIGNALMENT
- Dog and cat.
- Hereditary factor deficiencies—severe defects manifest by 3–6 months of age, milder hemostatic defects manifest after surgery or trauma.
- For X-linked recessive traits, males express the bleeding tendency, female carriers are clinically normal.
- For autosomal traits, males and females express signs with equal frequency.
- Hemophilia A is a common hereditary factor deficiency and may be seen in all breeds and mixed-breed dogs and cats.
- Factor XII deficiency is common in cats, but does not cause a clinical bleeding tendency.
- Acquired factor deficiencies—depends on underlying disease process.

SIGNS
- Hematoma formation.
- Intracavitary hemorrhage.
- Prolonged hemorrhage after surgery or trauma.
- Blood loss anemia.

CAUSES
- Acquired—synthetic failure (liver disease); vitamin K deficiency (cholestasis, anticoagulant rodenticide toxicity, malabsorption, long-term antibiotics, coumadin); factor inhibition (anticoagulant overdose, envenomation, auto- or alloantibodies); factor consumption and depletion (disseminated intravascular coagulopathy [DIC]); factor dilution (high-volume transfusion, crystalloid, or colloid fluid therapy); hyperfibrinolysis (secondary fibrinogen depletion).
- Hereditary—distinct mutations in coagulation factor genes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Thrombocytopenia should be the first rule-out for any patient with abnormal hemorrhage; thrombocytopathies may also cause bleeding (see Thrombocytopenia, Thrombocytopathies).
- Hereditary coagulation factor deficiencies cause prolongation of coagulation screening tests, whereas vonWillebrand disease (vWD) does not.
- Hyperfibrinolysis may cause hemorrhage in patients with hypovolemic shock, acute blood loss, or trauma, but generally does not cause prolongation of activated partial thromboplastin time (APTT) or prothrombin time (PT) tests; a breed predisposition for hyperfibrinolysis may exist in sighthounds.
- Acquired coagulopathies often develop because of liver disease, anticoagulant rodenticide ingestion, or DIC.
- Liver disease is accompanied by changes in the chemistry profile (see Coagulopathy of Liver Disease).
- Anticoagulant rodenticide toxicity prolongs the PT and/or APTT, but does not affect thrombin clotting time (TCT) or fibrinogen concentration.
- DIC always develops secondary to systemic disease (especially sepsis, neoplasia, other inflammatory conditions) and is often accompanied by low or falling platelet count.
- Massive transfusion (>1 blood volume) with stored blood products may dilute functional factors, fibrinogen, and platelets below hemostatic levels; hypocalcemia may also result.
- Contamination of blood samples (e.g., with heparin flush) or delayed processing can generate spurious PT and APTT abnormalities.

CBC/BIOCHEMISTRY/URINALYSIS
- Regenerative anemia develops over the course of days after blood loss.
- Platelet count is normal unless the patient has DIC or massive bleeding.
- Resorption of blood from a large hematoma may cause hyperbilirubinemia.

OTHER LABORATORY TESTS
- Coagulation screening tests (activated clotting time [ACT], APTT, PT, TCT) are functional tests that measure the time for in vitro clot formation; coagulation factor and fibrinogen deficiencies prolong clotting time (see Figure 1).
- ACT is a point-of-care screening test that detects severe deficiencies of all factors (except factor VII); ACT may be influenced by anemia, thrombocytopenia, and changes in blood viscosity.
- APTT is a screening test of the contact pathway (prekallikrein, high molecular weight kininogen, factor XII), intrinsic system (factors XI, IX, VIII), common system (factors X, V, II), and severe fibrinogen deficiency.
- PT is a screening test of factor VII, common system, and severe fibrinogen deficiency.
- The TCT is a screening test of functional fibrinogen and is sensitive to the presence of fibrinogen inhibitors.
- Acquired coagulation factor deficiencies generally cause prolongation of more than one screening test; the most common hereditary factor deficiencies (hemophilia and factor XII deficiency) specifically prolong APTT.
- Individual factor assays can be performed for definitive diagnosis of hereditary or complex coagulopathies.

Drugs That May Alter Laboratory Results
Therapeutic dosages of unfractionated heparin, coumadin, and plasma expanders (dextran, hetastarch) prolong coagulation screening tests.

Disorders That May Alter Laboratory Results
- Improper sample collection (poor venipuncture technique, partially or overfilled citrate collection tubes, use of heparin or clot activator tubes) will invalidate coagulation test results.
- Extreme lipemia, hemoglobinemia, or icterus may interfere with clot detection by photo-optical coagulation analyzers.
- Because of factor lability, samples should be assayed on site or plasma separated and sent on ice to the laboratory.

Valid if Run in Human Laboratory?
- Interpretation of coagulation assay results requires same-species reference intervals and controls; for example, human APTT values are generally twice those of dogs and cats.
- The laboratory should confirm cross-reactivity of antigenic assays and optimization of functional tests for animal species.

DIAGNOSTIC PROCEDURES
Buccal mucosal bleeding time (BMBT) is prolonged in patients with severe thrombocytopenia, platelet dysfunction, vWD, and fibrinogen deficiency, but BMBT is insensitive to coagulation factor deficiencies.

(CONTINUED) COAGULATION FACTOR DEFICIENCY

C

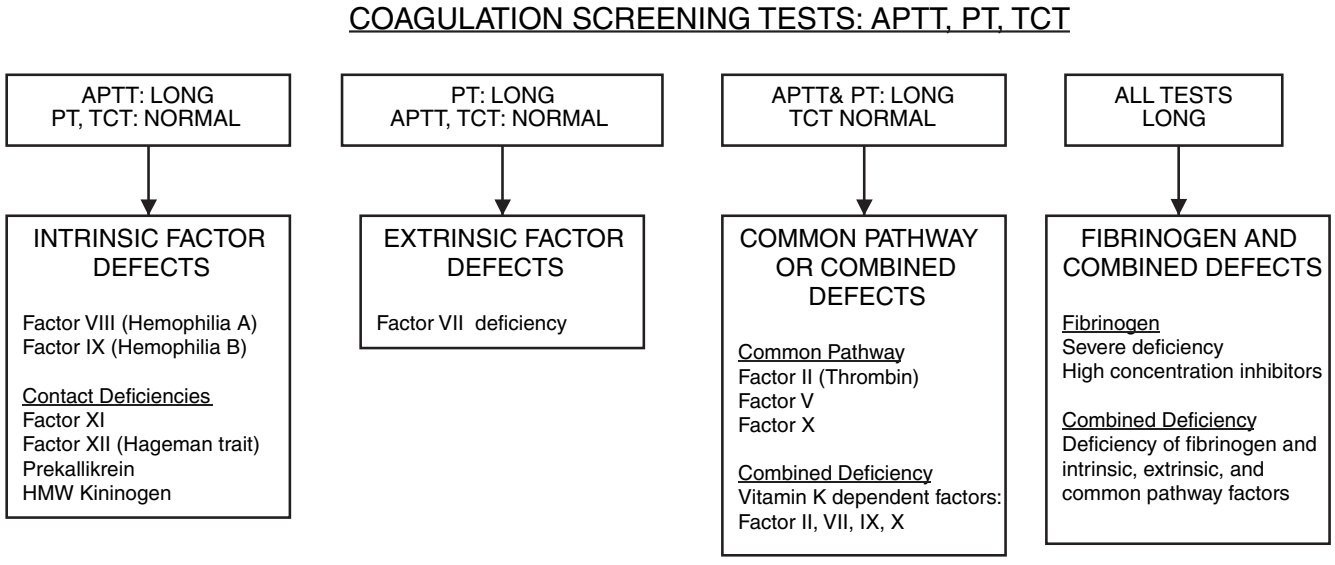

Figure 1.
Diagnostic algorithm for coagulation factor deficiencies

TREATMENT

- Transfusion of fresh whole blood, fresh plasma, and fresh frozen plasma will supply all coagulation factors.
- Cryoprecipitate is a specific source of factor VIII, fibrinogen, and von Willebrand factor; cryo-supernatant plasma supplies all other factors.
- Component therapy is preferred for surgical prophylaxis and nonanemic patients to prevent red cell sensitization and volume overload.
- Patients with severe acquired or hereditary factor deficiencies may require repeated transfusion (q8–12h) to control or prevent hemorrhage.

MEDICATIONS

DRUG(S) OF CHOICE

Vitamin K_1 (1.0 to 2.0 mg/kg SQ using a small needle, or preferably PO q24h) is an effective treatment for patients with anticoagulant rodenticide poisoning and other causes of vitamin K deficiency.

CONTRAINDICATIONS

Nonsteroidal anti-inflammatory drugs (NSAIDs), anticoagulants, and plasma expanders should be avoided to prevent further compromise of hemostasis.

PRECAUTIONS

- IM injections and jugular venipuncture should be avoided, when possible, because of the risk of inducing additional bleeding.
- Intravenous administration of vitamin K is not recommended because of the risk of anaphylaxis.

ALTERNATIVE DRUG(S)

Antifibrinolytic drugs (aminocaproic acid and tranexamic acid) help correct coagulopathy due to acute trauma and reduce transfusion requirements for orthopedic procedures in humans, and have shown benefit to prevent postoperative bleeding in greyhounds. These drugs may also be used topically (e.g., bleeding from tooth extraction).

FOLLOW-UP

PATIENT MONITORING

- PT or factor VII assays can be used to monitor effectiveness of vitamin K administration in animals with anticoagulant toxicity; test results should normalize after 24–48 hours of initiating therapy.
- ACT is a less specific but reasonable substitute for monitoring response to vitamin K.
- Hereditary defects can be monitored by cessation of bleeding, stabilization of hematocrit, resolution of hematoma, and, if needed, specific factor analyses.

POSSIBLE COMPLICATIONS

Transfusion poses a risk of immune and nonimmune reactions (see Blood Transfusion Reactions).

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Patients with hereditary factor deficiencies should not be bred.

SYNONYMS

- Coagulation defects.
- Coagulopathies.

SEE ALSO

COAGULOPATHY OF LIVER DISEASE

BASICS

OVERVIEW

- The liver is the sole/primary site of synthesis of procoagulant, anticoagulant, and fibrinolytic proteins, except factors V, VIII, von Willebrand factor (vWF), tissue plasminogen activator (TPA).
- Some patients develop prolonged in vitro clotting times, but few exhibit spontaneous bleeding.
- Causes of hemostatic imbalance:
  - reduced synthesis or activation of procoagulant proteins;
  - vitamin K deficiency;
  - dysfibrinogenemia due to abnormal fibrin polymerization;
  - reduced clearance of fibrin/fibrinogen degradation products (FDP);
  - thrombocytopenia or thrombocytopathy;
  - enhanced fibrinolysis.
- Vitamin K deficiency—linked to severe intra- or extrahepatic cholestasis, steatorrhea, or prolonged oral antibiotic administration.

SIGNALMENT

Dog and cat of any age, breed, or sex.

SIGNS

- Often minor or absent.
- Melena, hematemesis, hematochezia, hematuria.
- Prolonged bleeding if provoked—venipuncture, cystocentesis, biopsy, surgical wounds.
- Spontaneous bruising/hematomas—rare unless severe vitamin K deficiency or fulminant disseminated intravascular coagulation (DIC).

CAUSES & RISK FACTORS

- Severe hepatic failure of any etiology.
- Acute viral liver disease.
- Extrahepatic bile duct obstruction (EHBDO).
- Chronic liver disease—especially cirrhosis.
- Concurrent small bowel disease (e.g., cats with cholangiohepatitis or hepatic lipidosis) predisposing to vitamin K deficiency.
- High central venous pressure (CVP) and portal hypertension.
- Portosystemic vascular anomaly (PSVA)—asymptomatic factor deficiency common; overt bleeding uncommon.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxicities—see Hepatotoxins.
- Hereditary hemostatic defects.
- Thrombocytopenia.
- DIC—any cause.
- Hepatic amyloidosis.
- Abdominal trauma, gastrointestinal infiltrative disorders.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—normal or regenerative anemia; microcytosis; thrombocytopenia.
- Biochemistry—high liver enzymes; bilirubinemia; low albumin; hypoglobulinemia; low cholesterol.
- Urinalysis—hematuria; bilirubinuria.

OTHER LABORATORY TESTS

Hemostatic tests—thrombocytopenia; prolonged APTT (activated clotting time [ACT]), prothrombin time (PT), thrombin clotting time (TCT), and proteins induced by vitamin K absence (PIVKA); low fibrinogen and coagulation factors; low anticoagulant factors (antithrombin [AT], protein C); high FDP and D-dimer.

IMAGING

Abdominal Ultrasonography

- Effusion (ascites, hemorrhage).
- Liver changes—variable.
- Abnormal enteric motility, thickening in area of bleeding.

TREATMENT

- Not necessary unless invasive procedures planned or spontaneous hemorrhage noted.
- Fresh whole blood—provides replacement of red cells, coagulation factors, functional platelets.
- Fresh frozen plasma—provides coagulation factors, other hemostatic proteins, and reduces risk of red cell sensitization or volume overload.
- Cryoprecipitate—for severe hypofibrinogenemia or bleeding with coexistent von Willebrand's disease (vWD).
- Platelet-rich plasma—rarely indicated.
- Avoid synthetic colloids if bleeding tendencies observed.

Biopsy

- High risk for bleeding—PIVKA, PT, APTT, or ACT prolonged by >50%; thrombocytopenia <50,000/µL; prolonged mucosal bleeding time.
- Iatrogenic hemorrhage—grave prognosis if spontaneous bleeding with undetermined cause.
- Hemostasis support—postprocedure bleeding.
- Ultrasound-guided needle core—highest risk; observe biopsy site for 15 minutes, then sequentially over several hours postprocedure.
- Laparoscopy—affords visibility and allows hemostasis (cautery, Gelfoam pack biopsy site).
- Laparotomy—wedge biopsy; ill-advised in patients with overt bleeding.

MEDICATIONS

DRUG(S) OF CHOICE

- Based on cause of hepatic abnormality.
- Vitamin K deficiency—parenteral vitamin K_1 (0.5–1.5 mg/kg q12h SC up to 3 doses in 24h interval initially); vitamin K_1 PO (Mephyton®, 1 mg/kg q24h) if normal enteric bile acid uptake.
- DIC—correct primary disease; consider heparin for overt thrombosis (unfractionated heparin [UFH]: 200 U/kg q6–12h; or low molecular weight heparin [enoxaparin]: 1 mg/kg q12–24h), dose titration based on clinical status and laboratory monitoring (ACT, APTT [UFH], heparin anti-Xa activity [all heparins]).
- Blood products—fresh whole blood: 12–20 mL/kg q24h; fresh frozen plasma: 10–20 mL/kg q12h; plasma cryosupernatant (albumin, vitamin K–dependent factors): 10–20 mL/kg q12h; cryoprecipitate (fibrinogen, vWF, factor VIII): 1 U/10 kg or dose to effect.
- Desmopressin acetate (DDAVP)—0.5–1 µg/kg IV in saline; may increase coagulation factors, shortens bleeding times, reduces bleeding tendencies; empirically used for biopsy-induced bleeding.
- Antifibrinolytics—epsilon aminocaproic acid (EACA): 100 mg/kg loading, 30 mg/kg/h up to 8h; tranexamic acid: 25 mg/kg q8h; if evidence of hyperfibrinolysis.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Stored whole blood—may provoke hepatic encephalopathy (HE).
- Vitamin K_1 (cats)—high dose causes Heinz body hemolysis and oxidant liver injury.
- Aspirin or other nonsteroidal anti-inflammatory drugs (NSAIDs)—may predispose to renal failure, worsen ascites, provoke emesis and spontaneous bleeding,
- High-volume transfusion in citrate-based anticoagulants (especially in animals <5 kg) may induce symptomatic hypocalcemia.
- Avoid provocative procedures—e.g., jugular venipuncture or catheter placement, cystocentesis, if recognized bleeding tendencies.

FOLLOW-UP

PATIENT MONITORING

- PT, PIVKA (limited availability), factor VII—most sensitive coagulation tests to detect vitamin K deficiency; if no improvement after 48h of vitamin K_1 injection, unlikely correction by further dosing.

(CONTINUED) COAGULOPATHY OF LIVER DISEASE

• Heart rate, blood pressure, mucous membrane color and refill, packed cell volume (PCV), and total solids to monitor response if active bleeding.
• Biopsy site—observe immediately and sequentially (ultrasonography) for hemorrhage.
• Sample abdominal effusion to differentiate hemorrhage from ascites.

PREVENTION/AVOIDANCE

• Well-balanced diet replete with vitamins.
• Consider impaired vitamin K availability or synthesis from chronic oral antimicrobials.
• Invasive procedures—anticipate bleeding; pretreat with vitamin K_1; give DDAVP within 20 min of anticipated biopsy or if bleeding tendencies persist despite vitamin K_1 therapy (repeated DDAVP of no use); fresh frozen plasma for factor/fibrinogen replacement and active bleeding; avoid volume overload and increased CVP.
• Eliminate enteric parasitism.

POSSIBLE COMPLICATIONS

Hemorrhage, anemia, hypovolemia, HE.

EXPECTED COURSE AND PROGNOSIS

Spontaneous hemorrhage, refractory coagulopathy, and DIC—poor prognosis.

MISCELLANEOUS

SEE ALSO

• Hepatotoxins.

ABBREVIATIONS

• ACT = activated clotting time.
• APTT = activated partial thromboplastin time.
• AT = antithrombin.
• CVP = central venous pressure.
• DDAVP = desmopressin acetate.
• DIC = disseminated intravascular coagulation.
• EACA = epsilon aminocaproic acid.
• EHBDO = extrahepatic bile duct obstruction.
• FDP = fibrin/fibrinogen degradation product.
• HE = hepatic encephalopathy.
• NSAID = nonsteroidal anti-inflammatory drug.
• PCV = packed cell volume.

Consulting Editor Kate Holan

COBALAMIN DEFICIENCY

BASICS

OVERVIEW

- Cobalamin deficiency occurs in patients with cobalamin malabsorption when all body stores of cobalamin have been utilized and cobalamin is deficient on a cellular level.
- Cobalamin is required by virtually all cells in the body and plays a major role in beta-oxidation, conversion of certain amino acids, and the formation of tetrahydrofolate, and is thus crucial for energy production, amino acid metabolism, and DNA and RNA synthesis.
- Cobalamin deficiency is associated with gastrointestinal (GI) signs and systemic complications, such as immunodeficiencies, central neuropathies, and peripheral neuropathies.
- Cobalamin is absorbed exclusively in the ileum of dogs and cats via a receptor-mediated mechanism.
- The main causes of cobalamin deficiency in dogs and cats include chronic GI disease involving the ileum (e.g., inflammatory bowel disease, small intestinal dysbiosis, intestinal lymphoma), exocrine pancreatic insufficiency (EPI), short bowel syndrome, and, in rare cases, inherited cobalamin malabsorption or dietary deficiencies.

SIGNALMENT

- In the United States, Chinese Shar-Pei have a high prevalence of cobalamin deficiency. Isolated families of other breeds, such as the giant schnauzer, beagle, border collie, and Australian shepherd dog, have also been described as having cobalamin deficiency.
- No other breed, sex, or age predilections are known for canine or feline patients with cobalamin deficiency.

SIGNS

- Clinical signs attributable to the underlying disease process:
  - Chronic enteropathy—diarrhea, weight loss, vomiting, poor appetite, or others.
  - EPI—weight loss, failure to thrive, loose stools, steatorrhea, polyphagia or pica, borborygmus, flatulence.
- Clinical signs attributable to cobalamin deficiency—weight loss, failure to thrive, poor hair coat, lethargy, anorexia; less commonly signs of peripheral and central neuropathy such as a plantigrade stance or encephalopathy.

CAUSES & RISK FACTORS

- Intestinal disease involving the distal small intestine (i.e., the ileum)—inflammatory bowel disease, food-responsive enteropathy, lymphoma, others.
- EPI.
- Short bowel syndrome.
- Hereditary (Chinese Shar-Pei, giant schnauzer, beagle, border collie, Australian shepherd dog).
- Dietary—being fed exclusively vegan or vegetarian diet without concurrent supplementation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other diseases causing chronic GI disease, immunosuppression, central neuropathies, or peripheral neuropathies.

CBC/BIOCHEMISTRY/URINALYSIS

- May be within normal limits.
- May show changes associated with underlying disease process (e.g., hypoalbuminemia in patients with severe inflammatory bowel disease).
- May show anemia, neutrophilia with left shift, or neutropenia. Rubricytes have been documented in cobalamin-deficient dogs and have been interpreted as evidence of ineffective erythropoiesis. Hypersegmented neutrophils can also be observed.

OTHER LABORATORY TESTS

- Serum and urine methylmalonic acid concentrations are increased in patients with cobalamin deficiency.
- Decreased or low normal serum cobalamin concentrations. Studies measuring methylmalonic acid in serum from dogs and cats have shown that patients with low normal serum cobalamin concentrations may be cobalamin deficient on a cellular level. Note that all assays used for the measurement of serum cobalamin concentration in dogs and cats have been developed for use in humans and thus must be analytically validated for dogs and cats before routine clinical use. In addition, each laboratory should develop specific reference intervals.

IMAGING

Not useful, other than for evaluation of underlying intestinal disease.

DIAGNOSTIC PROCEDURES

None for the diagnosis of cobalamin deficiency. However, intestinal biopsies may be useful to confirm and characterize chronic enteropathies.

TREATMENT

Treatment of the underlying disease process, if identified (e.g., inflammatory bowel disease, EPI, lymphoma, small intestinal dysbiosis).

MEDICATIONS

DRUG(S) OF CHOICE

- Cobalamin supplements:
  - Cyanocobalamin—usually at 1,000 µg/mL for parenteral use; or 1,000 µg tablets or 250 µg and 1000 µg chewable tablets for oral use.
  - Hydroxocobalamin—usually at 1,000 µg/mL; for parenteral use.
  - Methylcobalamin—usually 1 mg capsule; for oral use.
- Traditionally, cobalamin supplementation in cobalamin-deficient patients has been administered parenterally (usually SC) using cyanocobalamin or rarely hydroxocobalamin.
  - Cats receive 250 µg/injection; dogs receive between 250 µg (small dog) and 1,500 µg (giant dog) per injection; doses should approximate 50 µg/kg per injection within this dose range.
  - In either species there are 6 weekly injections, one more injection a month later, and reevaluation of serum cobalamin concentration a month later.
- Recent studies have shown that oral cobalamin supplementation with cyanocobalamin is equally efficacious regardless of the underlying cause of cobalamin deficiency.
  - Cats receive 250 µg/day; dogs receive between 250 µg (small dog) and 1,000 µg (giant dog) per day.
  - Reevaluation of serum cobalamin concentration 2–4 weeks after the last dose.
- Continue therapy at the original dosing scheme if serum cobalamin is still low; continue at a decreased interval if cobalamin is in the mid-normal range; discontinue if serum cobalamin is in the high end of the reference interval.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

None known.

FOLLOW-UP

Depending on the severity of the underlying disease process, the complications from cobalamin deficiency, and treatment response.

PATIENT MONITORING

- See above; reevaluation of serum cobalamin concentration either 1 month after the last cobalamin injection or 2–4 weeks after the last oral dose of cobalamin.
- Additional monitoring as required for the underlying disease process.

MISCELLANEOUS

SEE ALSO

- Diarrhea, Chronic—Cats.
- Diarrhea, Chronic—Dogs.

COCCIDIOIDOMYCOSIS

BASICS

DEFINITION
A systemic mycosis caused by the inhalation of infective arthroconidia of the soil-borne fungus *Coccidioides immitis*.

PATHOPHYSIOLOGY
• Grows in soil in the mycelial state. • Inhalation of infective arthroconidia is the primary route of infection; at body temperature, all but one nucleus is shed and an immature spherule is produced within 2–3 days. • Spherule matures and ruptures, releasing 200–300 endospores that can produce new spherules. • Neutrophils cannot penetrate the spherule wall but can phagocytize the endospores. • Fewer than 10 inhaled arthrospores are sufficient to cause disease in susceptible animals. • Respiratory signs are often noted 1–3 weeks after exposure; signs of dissemination may not be evident for several months. • Most infections are mild or subclinical, although dogs appear more susceptible than cats to development of disseminated disease. • Fever, lethargy, inappetence, coughing, and joint pain or stiffness may be noticed. • Dissemination may occur within 10 days, resulting in signs related to the organ system involved; skin lesions are usually associated with dissemination.

SYSTEMS AFFECTED
• Respiratory—site of initial infection. • Extrapulmonary—musculoskeletal, ophthalmic, cardiovascular, skin, neuromuscular, reproductive, and visceral organs.

INCIDENCE/PREVALENCE
Not an uncommon disease in endemic areas, rare in nonendemic areas. It occurs more commonly in dogs and rarely in cats.

GEOGRAPHIC DISTRIBUTION
• *C. immitis* is found in the southwestern United States in the geographic Lower Sonoran life zone. • More common in southern California, Arizona, and southwest Texas. • Less prevalent in New Mexico, Nevada, and Utah.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
Though most commonly diagnosed in young animals (<4 years of age), it is seen in animals of all ages.

Predominant Sex
None

SIGNS

Historical Findings
• Coughing (ranges from dry/harsh to wet/productive). • Fever unresponsive to antibiotics. • Anorexia, weight loss. • Weakness, lameness (bone or joint involvement). • Seizures, paraparesis, back and neck pain (CNS involvement). • Visual changes (ophthalmic involvement).

Physical Examination Findings

Dogs
• Signs with pulmonary involvement—coughing and dyspnea. • Fever. • Bone swelling, joint enlargement, and lameness. • Lymphadenomegaly, skin lesions, and draining tracts. • Neurologic dysfunction including ataxia, spinal or cranial nerve deficits, and behavioral changes. • Blindness, uveitis, keratitis, and iritis.

Cats
Like dogs, although skin lesions are most common type of infection in cats.

CAUSES
C. immitis grows several inches deep in the soil, where it survives high ambient temperatures and low moisture. After a period of rainfall, the organism returns to the soil surface where it sporulates, releasing many arthroconidia that disseminate by wind and dust storms.

RISK FACTORS
• Aggressive nosing in contaminated soil and underbrush may expose susceptible animals to large numbers of arthroconidia. • Dust storms after the rainy season; increased incidence noted after earthquakes. • Land development with earth disruption may lead to increased exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Pulmonary lesions may resemble those of other systemic mycoses (e.g., histoplasmosis, blastomycosis) or neoplasia (single mass or multiple nodules). • Lymphadenomegaly may be seen in lymphoma, other systemic mycoses, and localized bacterial infections. • Bone lesions may resemble those caused by primary or metastatic bone tumors or bacterial osteomyelitis. • Skin lesions must be differentiated from routine abscesses or other infective processes. • For seizures and ataxia, consider inflammatory and neoplastic etiologies.

CBC/BIOCHEMISTRY/URINALYSIS
• Hemogram—mild nonregenerative anemia, neutrophilic leukocytosis, monocytosis. • Serum chemistry profile—hyperglobulinemia, hypoalbuminemia, other changes may be consistent with organ of involvement. • Urinalysis—proteinuria with inflammatory glomerulonephritis.

OTHER LABORATORY TESTS
• Serologic tests (generally by agar gel immunodiffusion [AGID] or ELISA) for antibody to *C. immitis* may provide a presumptive diagnosis; may aid in monitoring response to therapy. • Antigen testing has not proven to be sensitive.

IMAGING
• Radiography of lung (interstitial infiltrates, granulomas, tracheobronchial lymphadenopathy) and bone lesions (osteolysis) may aid in diagnosis. • MRI may help in diagnosing granulomas in the CNS.

DIAGNOSTIC PROCEDURES
• Serologic testing; repeat serology titers in 4–6 weeks when low titers are accompanied by clinical signs. • Microscopic identification of the large spherule form of *C. immitis* in lesion or biopsy material is the definitive method of diagnosis (large 10–80 µm round, double-walled structure containing endospores). • Lymph node aspirates and impression smears of skin lesions or draining exudate may yield organisms. • Cultures should be performed by trained laboratory personnel using protective hoods. • Biopsy of infected tissue often is preferred to avoid false-negative results; tissues involved, however, may not be readily accessible and finding the organism can be challenging; therefore, serologic testing is often a more logical approach.

PATHOLOGIC FINDINGS
• Granulomatous, suppurative, or pyogranulomatous inflammation present in many tissues. • Presence of the characteristic spherule forms in affected tissues.

TREATMENT

APPROPRIATE HEALTH CARE
• Generally treated as outpatient. • Concurrent clinical symptoms (e.g., seizures, pain, coughing) should be treated appropriately.

ACTIVITY
Restrict activity until clinical signs begin to subside.

DIET
Feed a high-quality palatable diet to maintain body weight.

CLIENT EDUCATION
• Treatment is potentially long (>6–9 months) and expensive. • Relapse (especially with disseminated disease) is common. • Reassure client that infection is not zoonotic.

SURGICAL CONSIDERATIONS
In cases of focal granulomatous organ involvement (e.g., consolidated pulmonary lung lobe, eye, kidney), surgical removal of the affected organ may be indicated.

(CONTINUED) COCCIDIOIDOMYCOSIS

C

MEDICATIONS

DRUG(S) OF CHOICE

Coccidioidomycosis is considered one of the most severe and life-threatening of the systemic mycoses. Treatment of disseminated disease often requires at least 1 year of aggressive antifungal therapy.

Dogs

• Ketoconazole (KTZ)—5–10 mg/kg PO q12h; ideally given with food; treatment typically requires at least 1 year of therapy; if titers rise or clinical signs deteriorate over first 4–6 weeks of treatment, alternative therapy should be considered. • Fluconazole (FCZ)—10 mg/kg PO q12h; noted to greatly increase success of treatment; cost of the drug has significantly decreased with availability of medical-grade generic compound; treatment failures have been noted with use of chemical-grade compounded formulations.
• Itraconazole (ITZ)—5 mg/kg PO q12h; administered similarly to KTZ, it has been reported to have higher penetration rate than KTZ; some suggest greater efficacy of ITZ over FCZ. • Amphotericin B (AMB) is rarely recommended because most patients do not require this aggressive therapy and effective oral medications are readily available; AMB can be administered at a dosage of 0.5 mg/kg IV 3 times per week, for a total cumulative dosage of 8–10 mg/kg; given IV either as a slow infusion (in dogs that are gravely ill) or as a rapid bolus (in fairly healthy dogs); for slow infusion, add AMB to 250–500 mL of 5% dextrose solution and administer as a drip over 4–6 hours; to lessen adverse renal effects of AMB, consider 0.9% NaCl (2 mL/kg/h) for several hours before initiating AMB therapy.

Cats

Any of the following azoles may be used in cats: KTZ 50 mg total dose PO q12h; FCZ 25–50 mg total dose PO q12h; ITZ 25–50 mg total dose PO q12h.

CONTRAINDICATIONS

• Drugs metabolized primarily by the liver should be used with caution alongside azole drugs.
• Drugs metabolized primarily by the kidneys should be used with caution alongside AMB.

PRECAUTIONS

• Side effects of azoles include inappetence, vomiting, and hepatotoxicity (typically alanine transaminase [ALT] > alkaline phosphatase [ALP]); liver values should be monitored monthly initially; drugs may be stopped until signs abate and restarted at a lower dose, which may be slowly increased to the recommended dose if the animal is able to tolerate the drug; newer azoles (ITZ and FCZ) have fewer side effects. • Side effects of AMB therapy can be severe, especially renal dysfunction, fever; use with caution if patient is azotemic, but not an absolute contraindication if the infection is life-threatening.

FOLLOW-UP

PATIENT MONITORING

• Serologic titers should be monitored every 3–4 months; animals should be treated until clinical and radiographic signs resolve/stabilize and their titers ideally fall to less than 1 : 4; titers frequently do not become negative throughout treatment. • Consider ITZ levels (2–4h post pill) in patients showing poor response to ITZ therapy, especially if using generic or compounded formulation.
• Creatinine and urinalysis should be monitored in all animals treated with AMB; treatment should be temporarily discontinued if creatinine rises above reference range or greater than 20% above baseline, or if granular casts are noted in urine.

PREVENTION/AVOIDANCE

• No vaccine is available for dogs or cats.
• Contaminated soil in endemic areas should be avoided, particularly during dust storms after the rainy season.

POSSIBLE COMPLICATIONS

Pulmonary disease resulting in severe coughing may temporarily worsen after therapy is begun owing to inflammation in the lungs. Anti-inflammatory short-term (2 weeks to 2 months) oral prednisone and cough suppressants may be required to alleviate the respiratory signs.

EXPECTED COURSE AND PROGNOSIS

• Prognosis for localized respiratory disease is good. • Prognosis for disseminated disease is guarded; many dogs will improve following oral therapy with resolution of signs reported in up to 90% cases; however, relapses may be common, especially if therapy is shortened; overall recovery rate has been estimated at 60%. • Prognosis with CNS involvement may be guarded to poor. • Prognosis for cats is not well documented, but long-term therapy should be anticipated and relapses are common. • Serologic testing every 3–4 months after completion of therapy is recommended to monitor possibility of rising titer and potential relapse. • Spontaneous recovery from disseminated coccidioidomycosis without treatment is extremely rare.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• The spherule form of the fungus, as found in animal tissues, is not directly transmissible to humans or to other animals. • Under certain rare circumstances, however, there could be reversion to growth of the infective mold form of the fungus on or within bandages placed over a draining lesion or in contaminated bedding; draining lesions can lead to contamination of the environment with arthrospores; care should be exercised whenever handling an infected draining lesion. • Special precautions should be recommended to households in which the owners may be immunosuppressed.

PREGNANCY/FERTILITY/BREEDING

Azole drugs can be teratogenic and should be used in pregnant animals only if the potential benefit justifies the potential risk to offspring.

SYNONYMS

• Desert rheumatism (in humans).
• San Joaquin Valley fever. • Valley fever.

ABBREVIATIONS

• AGID = agar gel immunodiffusion.
• ALP = alkaline phosphatase.
• ALT = alanine transaminase.
• AMB = amphotericin B.
• FCZ = fluconazole.
• ITZ = itraconazole.
• KTZ = ketoconazole.

Client Education Handout available online

COCCIDIOSIS

BASICS

OVERVIEW
- An enteric infection, traditionally associated with *Cystoisospora canis* (dogs) and *Cystoisospora felis* (cats) as potential pathogens; other species of *Cystoisospora* may be present.
- Strictly host specific (i.e., no cross-transmission).
- *Eimeria* spp. are not parasitic for dogs or cats.
- *Cryptosporidium* can cause an acute, life-threatening coccidiosis (cryptosporidiosis) in neonatal pups and kittens; can also cause non-life-threatening small bowel diarrhea in dogs and cats (see Cryptosporidiosis)
- Voluminous watery diarrhea is characteristic; auto-infection and recycling within the intestinal tract result in a rapid loss of mucosal lining with cryptosporidiosis.

SIGNALMENT
Dog and cat (especially puppies and kittens).

SIGNS
- Watery to mucoid, sometimes blood-tinged, diarrhea; vomiting; abdominal discomfort; inappetence.
- Weak puppies and kittens.
- Immunocompromised animals.

CAUSES & RISK FACTORS
- Infected dogs or cats contaminating environment with oocysts of *Cystoisospora* spp. or *Cryptosporidium* spp.
- Stress.
- Immunocompromise.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Enteric viral infections and other intestinal parasites.

CBC/BIOCHEMISTRY/URINALYSIS
Usually unremarkable; may be hemoconcentrated if dehydrated.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Fecal flotation (preferably centrifugation flotation technique) for oocysts (distinguish from pseudoparasitic *Eimeria* sp.); use sucrose solution or zinc sulfate; acid-fast stains should be considered for detection of *Cryptosporidium* spp.
- Direct fluorescent antibody (DFA) assay is a sensitive dual assay (can detect *Giardia* cysts and *Cryptosporidium* oocysts very well) and can be performed at reference laboratories or university parasitology laboratories.
- *Cystoisospora* oocysts should be 40 µm long; cysts of *Cryptosporidium* are approximately 5 µm diameter.

TREATMENT
- Usually treated as an outpatient.
- Inpatient if debilitated.
- Fluid therapy if dehydrated.

MEDICATIONS

DRUG(S) OF CHOICE
- Sulfadimethoxine—55 mg/kg PO on the first day, then 25–50 mg/kg PO q24h for up to 10–14 days, or until dog is asymptomatic for *Cystoisospora* and fecal examination is negative for oocysts.
- Sulfadiazine/trimethoprim—15–30 mg/kg sulfadiazine PO q24h up to 10 days.
- Amprolium (extra-label)—dogs: 100–400 mg (total dose) PO q24h for 7 days; cats with *Cystoisospora*: 60–100 mg (total dose) PO q24h for 7 days.
- No effective or approved treatment for *Cryptosporidium*—paromomycin 165 mg/kg PO q12h for 5 days has been suggested (extra-label); however, the drug is potentially nephrotoxic and ototoxic in cats and should not be used; azithromycin has been used at a dosage of 7–10 mg/kg PO q12h for 7 days for eradication of *Cryptosporidium* spp. in dogs and cats; however, efficacy is unknown.
- Ponazuril at 30–50 mg/kg PO q24h for 1–7 consecutive days in dogs, or 15 mg/kg PO q24h for 7 consecutive days in cats; treatment can be repeated after 3- to 5-day break to increase efficacy; single doses of the drug are generally ineffective.
- Toltrazuril—10–30 mg/kg PO q24h for 1–6 consecutive days in dogs.

Precautions
- Mild gastrointestinal upset with antibiotics.
- Amprolium—not recommended to be used for more than 12 consecutive days in puppies, exogenous thiamine in high doses may decrease efficacy; neurologic abnormalities have been reported in some dogs: if observed, discontinue medication and begin thiamine supplementation.
- Sulfadimethoxine—caution with diminished hepatic or renal function.
- Sulfadiazine/trimethoprim—potentially teratogenic; dog: associated with irreversible keratoconjunctivitis sicca, type 1 or type 3 hypersensitivity (especially in larger-breed dogs), thrombocytopenia; cat: anorexia, leukopenia, anemia, hematuria.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Sulfa medications—caution in patients with preexisting renal or hepatic disease.

FOLLOW-UP
Fecal flotation (for *Cystoisospora* spp. oocysts) or DFA (for *Cryptosporidium* spp. oocysts) 1–2 weeks following treatment.

MISCELLANEOUS

AGE-RELATED FACTORS
More severe disease in young or immunocompromised patients.

SEE ALSO
- Cryptosporidiosis.
- Toxoplasmosis.

ABBREVIATIONS
- DFA = direct fluorescent antibody.

COGNITIVE DYSFUNCTION SYNDROME

BASICS

DEFINITION
Syndrome associated with brain aging. Leads to alterations in awareness, decreased responsiveness to stimuli, deficits in learning and memory, agitation, and anxiety. Subtle signs seen in early stages of cognitive decline may include alterations in activity, social interactions and increasing anxiety.

PATHOPHYSIOLOGY
• Neuronal loss, decreased frontal lobe volume, increased ventricular volume, and neurotoxic deposits including lipofuscin and beta-amyloid. • Toxic free radicals (reactive oxygen species) increase with age because of illness and stressors, age-related decline in mitochondrial efficiency, and decreased clearance mechanisms. • Unclear which changes are associated with the clinical signs; possible correlation between cognitive decline, amount of beta-amyloid in the cerebral cortex, and increases in toxic free radicals. • Compromised cerebral vascular blood flow and infarcts may be contributory. • Neurotransmission is compromised; may be a decline in catecholamine and cholinergic transmission.

SYSTEMS AFFECTED
• Behavioral. • Nervous.

GENETICS
Unknown; may be genetic factors contributing to beta-amyloid deposition and the age at which it begins to accumulate.

INCIDENCE/PREVALENCE
• Clinical signs of cognitive dysfunction syndrome (CDS) have been reported to arise in 41–68% (or higher) of dogs over 14. • Overall prevalence in dogs over 10 estimated as at least 14.2%. • Clinical signs reported to arise in 50% of cats over 15. • Prevalence in cats over 10 estimated at 35%. • Progressive—over 6 months, 24% of dogs with mild signs progressed to moderate and 42% with no impairment progressed to mild.

SIGNALMENT

Species
Dogs and cats.

Mean Age and Range
• Increased prevalence with increasing age. • Neuropsychological testing in dogs and cats has identified a decline in memory and learning as early as 6–8 years of age. • Initial signs may not be noticed by pet owners, except perhaps in dogs trained to perform more specialized tasks (e.g., guide and hearing dogs, drug detection, agility).

SIGNS

Historical Findings
• Clinical signs have been categorized using the acronym DISHAA. • **D**isorientation, including getting lost in familiar environments, confusion, inability to navigate through familiar routes (e.g., goes to hinge side of door), dropping food and not retrieving. • **I**nteractions with humans or other animals may be altered (irritability, decreased interest in play/affection, or increased attention seeking). • **S**leep–wake cycle alterations including night waking, vocalization, and/or increased sleep during the day. • **H**ousetraining and other previously learned behaviors might deteriorate. • **A**ctivity may be altered—including a decline in activity level, exploration, and self-care; however, as the condition progresses, activity may increase with signs of restlessness, pacing, aimless wandering, vocalization, or excessive licking. • **A**nxiety and agitation.

Physical Examination
• No specific abnormalities associated with cognitive dysfunction. • Other age-related medical disorders might be noted.

CAUSES
• Exact cause is unknown and animals are variably affected. • Environmental factors may contribute to age-related degeneration. • May be predisposing genetic factors. • Diet, enrichment, and stress management may be in part preventive. • See Pathophysiology.

RISK FACTORS
• Chronic oxidative stress and chronic low-grade inflammation. • Conditions that affect cerebral vascular blood supply (e.g., systemic hypertension, anemia). • Deficiency in docosahexaenoic acid (DHA), B6, B12, and folic acid, high homocysteine, low-quality diets.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Any medical condition that affects the pet's mental attitude or behavior must be ruled out. • Pain (e.g., arthritis, dental disease) can lead to increased irritability, anxiety, and altered response to stimuli. • If mobility is affected, the pet may be less able to avoid fearful stimuli and less able to access its elimination area. • Impaired sight or hearing might lead to decreased responsiveness or increased reactivity to stimuli. • Diseases of the urinary or gastrointestinal tract can cause house-soiling. • Organ failure, tumors, immune diseases, and endocrinopathies can also affect behavior. • Diseases that affect the CNS or its circulation can affect behavior.

CBC/BIOCHEMICAL/URINALYSIS
Normal with CDS, but concurrent disease processes common in aged dogs.

OTHER LABORATORY TESTS
Normal with CDS.

IMAGING
• Used to rule out primary organic/structural cause. • Most important when there are abnormalities on the neurologic examination or when the onset is sudden; less likely to be of diagnostic value if signs are slowly progressive in the absence of other neurologic findings.

DIAGNOSTIC PROCEDURES
• Diagnosis is based on identifying clinical signs on screening questionnaire, e.g., DISHAA (Pan et al.), CADEs (Madari et al.), and CCDR (Salvin et al.), ruling out possible medical causes. • Early and mild signs not likely to be reported; therefore veterinarians must ask (e.g., with screening questionnaire). • Endoscopy, radiography, ultrasound, and other specialized diagnostic procedures may be necessary to rule out other causes of the clinical signs. • Further ophthalmic and neurologic assessment if indicated to rule out visual or auditory deficits and neurologic disease. • Therapeutic trial might be considered to rule out and treat other potential causes of the signs, e.g., pain.

PATHOLOGIC FINDINGS
Loss of frontal and temporal lobe volume, neuronal loss, meningeal calcification, microhemorrhage and infarcts, beta-amyloid deposition and hyperphosphorylated tau.

TREATMENT

NURSING CARE
Support and home care by pet owners.

ACTIVITY
• Maintain exercise, play, reward-based training, work, feeding enrichment (e.g., food-filled toys), and daily routines that are appropriate for the pet's age and health. • Maintaining mental stimulation and physical activity have been shown to reduce or slow progression of cognitive decline.

DIET
• Diet should be fed that meets and prioritizes medical and cognitive health care needs. • For dogs, diet supplemented with antioxidants including vitamins E and C, selenium, beta carotene, and flavonoids and carotenoids, omega-3 fatty acids, and carnitine and alpha lipoic acid (for mitochondrial health) has been shown to improve memory, learning ability, and clinical signs of cognitive dysfunction (Hills Prescription Diet b/d). • As cerebral glucose metabolism declines with increasing age in dogs, a diet

COGNITIVE DYSFUNCTION SYNDROME (CONTINUED)

supplemented with 5.5% medium-chain triglyceride (MCT) oil to provide ketone bodies as an alternative source of energy for aging neurons has been demonstrated to improve cognitive function in middle-aged and senior dogs (e.g., Purina ProPlan Bright Mind 7+®). • A brain support blend containing arginine (to enhance nitrous oxide synthesis), antioxidants including vitamins C, E, and selenium; B vitamins; and omega-3 fatty acids has been demonstrated to improve cognitive function in laboratory studies in senior dogs and middle-aged cats. • A combination of the brain support blend and 6.5% MCT supplementation has been demonstrated to improve clinical signs of cognitive dysfunction in dogs (Purina Pro Plan Veterinary Diets NC NeuroCare®). • For dogs—supplements containing phosphatidylserine (Senilife, CEVA Animal Health and Activait, VetPlus), S-adenosyl-L-methionine-tosylate disulfate (SAMe; Novifit, Virbac Animal Health), and apoaequorin have demonstrated some evidence of efficacy. • For cats—SAMe and diets containing fish oil, arginine, B vitamins, and antioxidants have demonstrated beneficial effects.

CLIENT EDUCATION

• Lifelong therapy is required, and concurrent medications may be necessary if the pet has multiple problems. • Any changes in the pet's health or behavior should be reported immediately, as this may be due to cognitive dysfunction or new health problems. • Considering the pet's health and cognitive status, the owner must be advised on any limitations on what might be achieved. • Signs are generally progressive; treatment is aimed at slowing the progression of the disease, not cure.

MEDICATIONS

DRUG(S) OF CHOICE

Dogs

• Selegiline—monoamine oxidase (MAO) B inhibitor, may contribute to improved catecholamine transmission, decrease in free radicals, and neuroprotective effect; 0.5–1 mg/kg PO q24h in the morning and maintained if effective; reevaluate clinical signs for improvement after 1–2 months; side effects might include occasional gastrointestinal upset and restlessness, and repetitive behavior at higher doses. • Propentofylline—not licensed in North America but is licensed in other countries; xanthine derivative; purported to inhibit platelet aggregation and thrombus formation, make the red cells more pliable, and increase blood flow; may increase oxygen supply to CNS without increasing glucose demand; 3–5 mg/kg PO q12h. • Nicergoline—alpha-adrenergic antagonist that may improve cognitive function through vasodilatory effects on cerebral circulation; 0.25–0.5 mg/kg PO q24h.

Cats

• No therapeutic agents licensed for treatment of CDS. • Selegiline (0.5–1 mg/kg PO q24h), propentofylline (1/4 of 50 mg tablet PO q24h), and nicergoline (0.25–0.5 mg/kg PO q24h) have been used off-label in cats, with anecdotal evidence of effect.

CONTRAINDICATIONS

• Selegiline should not be used concurrently with MAO inhibitors such as amitraz, narcotics, alpha-adrenergic agents such as phenylpropanolamine or ephedrine, or selective serotonin reuptake inhibitors (e.g., fluoxetine) or tricyclic antidepressants (e.g., clomipramine). • A 2-week washout is suggested following most tricyclic antidepressants and up to 5 weeks following fluoxetine before starting selegiline.

PRECAUTIONS

• Choose medications that are least sedating and least anticholinergic. • Potential drug interactions must be considered with concurrent use of drugs and over-the-counter medications.

POSSIBLE INTERACTIONS

See Contraindications.

ALTERNATIVE DRUG(S)

• Consider potential benefits vs. risks including contraindications, side effects, off-label use, and evidence of effect. • Anti-inflammatory medications and natural supplements such as gingko biloba and curcumin might be considered based on preliminary work in other species. • Medication used in humans for Alzheimer's disease to enhance cholinergic transmission might be useful, but doses and pharmacokinetics in dogs have not been determined; side effects might include nausea, vomiting, diarrhea, and sleep-wake disturbances. • For anxiety, agitation, apathy, and night waking consider adjunctive therapeutics including buspirone or fluoxetine for ongoing use, or trazodone, benzodiazepines, and alpha-2 agonists for as needed use. • Natural supplements including pheromones, melatonin, valerian, l-theanine, alpha-casozepine, γ-aminobutyric acid (GABA), magnolia and phellodendron (Solliquin®), or Souroubea (Zentrol®) might help to reduce signs related to anxiety and night-time waking.

FOLLOW-UP

PATIENT MONITORING

• If a drug or diet for CDS is dispensed, therapeutic response should be evaluated after 30–60 days and the dose adjusted or treatment changed if there is insufficient improvement. • If the pet is stable, twice-yearly checkups are recommended unless new problems arise before reassessment is due.

PREVENTION/AVOIDANCE

• Providing an enriched environment, ongoing training, and physical activity that is appropriate and practical for the pet's age and health may help to prevent or delay the onset of cognitive decline. • Early CDS dietary intervention may address risk factors and slow the progression of disease.

EXPECTED COURSE AND PROGNOSIS

Diet and medication may improve signs and slow progression in most cases; however, with increasing age, CDS may progress and other concurrent health problems will ultimately arise.

MISCELLANEOUS

SYNONYMS

• Age-related cognitive and affective disorders, involutional depression, dysthymia. • Dementia. • Senility.

ABBREVIATIONS

• CDS = cognitive dysfunction syndrome. • DHA = docosahexaenoic acid. • GABA = γ-aminobutyric acid. • MAO = monoamine oxidase. • MCT = medium-chain triglyceride. • SAMe = S-adenosyl-L-methionine-tosylate disulfate.

COLD AGGLUTININ DISEASE

BASICS

OVERVIEW

- Rare type II autoimmune disorder in which anti-erythrocyte antibodies have enhanced activity at temperatures <99 °F (37.2 °C).
- Cold agglutinins are typically immunoglobulin (Ig) M, although IgG alone and in combination with IgM may result in disease.
- Cold agglutinins cause direct erythrocyte agglutination at low body temperatures (primarily peripheral microvasculature), leading to vaso-occlusive disease, initiated or intensified by cold exposure.
- Fixation of complement and hemolysis is a warm reactive process occurring at higher body temperatures; at those temperatures cold agglutinins have eluted off the red blood cells (RBCs), lowering the rate of complement binding; therefore, acute hemolytic anemias are uncommon with this condition.
- Most cold agglutinins cause little or no shortening of erythrocyte lifespan.
- High thermal amplitude cold agglutinins (rare)—may cause mild chronic hemolysis, but exposure to cold may greatly augment binding of cold agglutinins and cause intravascular hemolysis.

SIGNALMENT

- Rare; genetics, age, breed, and sex predilections unknown.
- Low titer of cold agglutinins (1 : 32 or less) may be found in healthy pets without clinical significance.
- More likely to occur following exposure to cold temperatures.

SIGNS

- Cyanosis of the extremities associated with sludging of erythrocyte agglutinates in microvasculature.
- Erythema, skin ulceration with secondary crusting.
- Dry, gangrenous necrosis of ear tips, tail tip, nose, and feet.
- Anemia may cause signs of pallor, tachycardia, tachypnea, icterus, and pigmenturia.

CAUSES & RISK FACTORS

- Idiopathic; cold exposure is a risk factor.
- Secondary disease—associated with upper respiratory infection (cats), neonatal isoerythrolysis, lead intoxication (dogs), *Mycoplasma* pneumonia, and neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Skin lesions—vasculitis, hepatocutaneous syndrome, toxic epidermal necrolysis, dermatomyositis, systemic lupus erythematosus (SLE), lymphoma, frostbite, lead poisoning, and pemphigus.
- Other causes of anemia (including hemolytic anemias).

CBC/BIOCHEMISTRY/URINALYSIS

- Laboratory abnormalities secondary to hemolysis, if present.
- Autoagglutination of RBCs may be observed at room temperature.

OTHER LABORATORY TESTS

- Cold agglutinins should be suspected when blood in heparin or EDTA on a glass slide agglutinates spontaneously at room temperature with enhancement at 39 °F (3.9 °C), and the erythrocytes disperse again upon warming to 99 °F (37.2 °C).
- If no agglutination can be induced in vitro, it will not occur in vivo in extremities.
- Coombs' test at 99 °F—cold agglutinins usually not detected because they may be eluted off the erythrocytes during washing; thus test requires the use of anti-complement factor serum.
- Coombs' test at 39 °F—incidence of a positive result in healthy dogs has been reported to be >50%, which may be caused by unspecific binding of the reagent itself or by binding of naturally occurring nonpathogenic low-titer cold agglutinins.
- The globulin class can be established by immunoelectrophoresis of the patient's erythrocytes, which may be important for prognosis and treatment.

PATHOLOGIC FINDINGS

- Dermal necrosis and ulceration with possible opportunistic infections.
- Vascular thrombosis, ischemic necrosis.

TREATMENT

- Hospitalization in a warm environment until the disease is nonprogressive.
- Supportive care and wound management.
- Splenectomy is of little benefit in patients with IgM-mediated hemolysis, but may be helpful in those with IgG-mediated hemolysis.
- Inform the client to keep the patient in a warm environment at all times to prevent relapse.
- Exercise restriction.
- In humans, plasmapheresis, IV gamma globulins, and rituximab with or without fludarabine have been tried.

MEDICATIONS

DRUG(S) OF CHOICE

- IgM cold agglutinins—immunosuppressive therapy not very effective against IgM-mediated disorders, but can be tried (i.e., corticosteroids, leflunomide, cyclosporine).
- IgG cold agglutinins—immunosuppressive therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Use warmed IV fluids if indicated.

FOLLOW-UP

- Keep patient in warm environments.
- Cold agglutinin disease usually characterized by acute onset and rapid progression.
- Prognosis is guarded to fair; recovery may take weeks.

MISCELLANEOUS

SEE ALSO

Anemia, Immune-Mediated.

ABBREVIATIONS

- Ig = immunoglobulin.
- RBC = red blood cell.
- SLE = systemic lupus erythematosus.

COLIBACILLOSIS

BASICS

DEFINITION

• *Escherichia coli* (EC)—Gram-negative member of the *Enterobacteriaceae*; normal inhabitant of intestine of most mammals.
• Acute infection of puppies and kittens in first week of life characterized by septicemia and multiple organ involvement.
• Isolation from stool of young animals—inconclusive evidence of pathogenic potential because it is normal flora; molecular methods can assess virulence potential.
• Isolation from blood cultures or internal organs—better evidence of causality.
• Infection of older dogs and cats—documented; virulence of individual strains poorly characterized.

PATHOPHYSIOLOGY

• Virulence factors—not well defined; likely EC as a cause of septicemia in neonatal dogs and cats reflects balance between immunologic immaturity and intestinal barrier function of host and resident enteric EC rather than a single virulent strain.
• Enterotoxigenic EC (ETEC), attaching and effacing EC (AEEC), uropathogenic EC (UPEC), cytotoxic necrotizing factor (CNF) + EC strains—recovered from dogs, similar in cats.
• Intestinal strains colonize and multiply in small intestine; ETEC then elaborates uncharacterized adhesins and enterotoxins (STa); attaching and effacing factor of AEEC (intimin [eae]+).
• Many strains of EC from dogs and cats are hemolytic.
• An EC reported in boxer dogs with granulomatous colitis characterized by ability to adhere, invade, and replicate in macrophages, resulting in massive inflammatory response within intestinal wall.

SYSTEMS AFFECTED

• Neonates—small intestine (enteritis); multiple body systems (septicemia).
• Puppies/kittens and adults—small intestine (enteritis); urogenital (cystitis, endometritis, pyelonephritis, prostatitis); mammary gland (mastitis); large intestine (colitis).

GENETICS

Boxer dogs may be predisposed.

INCIDENCE/PREVALENCE

• Few statistics available.
• More common in neonatal puppies and kittens <1 week old that have not received any or adequate amounts of colostrum.
• Problem in overpopulated kennels and catteries.
• Sporadic accounts in older dogs and cats (mainly diarrhea and urogenital problems).
• Purulent skin disease, otitis, meningoencephalomyelitis.

Dogs

• ETEC—2.7–29.5% of diarrheic dogs; strains: STa/STb+/–, and CNF+ isolated from diarrheic dogs along with hemolysin.
• β-hemolytic EC—major cause of septicemia in newborn puppies exposed in utero, during birth, or from mastitic milk.

Cats

• AEEC/enteropathic EC (EPEC)—diarrheic cats; strains: eae+, hemolysin.
• Extraintestinal pathogenic EC (ExPEC)—acute necrotizing and hemorrhagic pneumonia and pleuritis; strains: CNF-1 plus other adhesions.
• UPEC—cystitis; strains: CNF-1+, P-fimbria, hemolysin.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Dog and cat.

Breed Predilections

Boxer dogs may be predisposed to colitis.

Mean Age and Range

• Neonatal infections common (diarrhea, septicemia) up to 2 weeks of age.
• Puppies/kittens and adult animals—sporadic disease often associated with other infectious agents.

Predominant Sex

None

SIGNS

General Comments

One of the most common causes of septicemia and death in puppies and kittens.

Historical Findings

• Neonates—sudden-onset vomiting, weakness/lethargy, diarrhea, cold skin; one or more animals affected in a litter.
• Puppies/kittens and adults—vomiting and diarrhea.

Physical Examination Findings

• Neonates—acute depression, anorexia, vomiting, tachycardia, weakness, hypothermia, cyanosis, watery diarrhea.
• Puppies/kittens and adults—ETEC associated with acute vomiting, diarrhea, anorexia, rapid dehydration, fever.

CAUSES

• EC—endogenous microbial flora of adult gastrointestinal tract, prepuce, and vagina.
• Many strains; poorly characterized regarding virulence factors; need molecular methods to assess virulence.
• Often found in older dogs and cats concurrently with other infectious agents.

RISK FACTORS

Neonates

• Bitch/queen in poor health and nutritional status—unable to provide good care and colostrum.
• Lack of colostrum or insufficient colostrum.
• Dirty birthing environment.
• Difficult or prolonged labor and birth.
• Crowded facilities—feces in environment, chance for fecal–oral spread.

Puppies/Kittens and Adults

• Concurrent disease—parvovirus, heavy parasitism.
• Antimicrobial drugs—upset gastrointestinal microbial flora.
• Immunosuppression.
• Postparturient mastitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Infectious enteritis—viral: feline panleukopenia, feline leukemia virus, feline immunodeficiency virus, enteric coronavirus, canine parvovirus, rotavirus, canine distemper; bacterial: *Salmonella*, *E. coli*, *Campylobacter jejuni*, *Yersinia enterocolitica*, bacterial overgrowth syndrome, *Clostridium difficile*, *Clostridium perfringens*; parasitic: hookworms, ascarids, whipworms, *Strongyloides*, *Giardia*, coccidia, cryptosporidia, rickettsiae (salmon poisoning).
• Dietary-induced enteritis—overeating, abrupt changes, starvation, thirst, food intolerance or allergy, indiscretions (e.g., foreign material, garbage).
• Drug- or toxin-induced enteritis—antimicrobial agents, antineoplastic agents, anthelmintics, heavy metals, organophosphates.
• Extraintestinal disorders or metabolic diseases—acute pancreatitis; hypoadrenocorticism; liver or kidney disease; pyometra; peritonitis.
• Functional or mechanical ileus— gastrointestinal obstruction, intussusception, electrolyte disorder, gastrointestinal foreign body.
• Neurologic disorders—vestibular disease, psychogenic (e.g., fear, excitement, pain).
• Fading neonates.

CBC/BIOCHEMISTRY/URINALYSIS

• Few abnormalities noted, owing to rapidity of death in puppies.
• Adults with enteritis may show nonspecific abnormalities, depending on condition.

DIAGNOSTIC PROCEDURES

• Routine bacterial culture and identification of EC from blood (antemortem) or necropsy tissue (bone marrow, heart blood, liver, spleen, brain, mesenteric lymph node) required.

(CONTINUED) COLIBACILLOSIS

• False-negative results can occur if antimicrobials are used before obtaining bacterial cultures.
• Appropriate testing of strains—identify adhesins and toxins (by DNA colony hybridization, PCR) in ETEC and verotoxigenic EC (VTEC) strains.

PATHOLOGIC FINDINGS
• Acute enteritis.
• Inflammation of small intestinal mucosa.
• Petechiae and hemorrhagic lesions on serosal surface of gastrointestinal mucosae and all body cavities.
• Fibrin on abdominal wall.
• Necrosis of liver/spleen.

TREATMENT

APPROPRIATE HEALTH CARE
Acutely ill puppies/kittens—inpatient care.

NURSING CARE
• Balanced parenteral polyionic isotonic solution (e.g., lactated Ringer's)—restore fluid balance.
• Oral hypertonic glucose solution—for secretory diarrhea, as indicated.

ACTIVITY
Acutely ill immature puppies/kittens (bacteremic/septicemic)—restricted activity, cage rest, monitoring, and warmth.

DIET
Puppies—likely to still be nursing when affected; good nursing care needed with bottle-feeding and/or IV nutrients.

CLIENT EDUCATION
Neonates—life-threatening with poor prognosis.

MEDICATIONS

DRUG(S) OF CHOICE
• Antimicrobial therapy—septicemia.
• Guided by culture and susceptibility (and minimal inhibitory concentration) testing of EC; empiric therapy until results available. Extended-spectrum β-lactamase (ESBL) and/or plasmid mediated AmpC (pAmpC) strains becoming more common.
• Amikacin—dog and cat: 15–20 mg/kg IV q24h.
• Cefazolin—dog and cat: 15–35 mg/kg IV q6–8h.
• Cefoxitin—dog and cat: 30 mg/kg IV once, then 15 mg/kg IV q6–8h.
• Enrofloxacin—dog: 10–15 mg/kg IM/IV q24h; cat: 5 mg/kg IV q24h.
• Ticarcillin–clavulanate—dogs and cats: 50 mg/kg IV q6h.

CONTRAINDICATIONS
Fluoroquinolones—avoid use in pregnant, neonatal, or growing animals (medium-sized dogs <8 months of age; large or giant breeds <12–18 months of age) because of potential cartilage lesions.

PRECAUTIONS
Ensure adequate hydration and perfusion when using aminoglycosides.

FOLLOW-UP

PATIENT MONITORING
• Physical exam—mentation, rectal temperature, pulse quality.
• Behavior—puppies should be eating, drinking, and/or nursing; adequate weight gain.

PREVENTION/AVOIDANCE
• Bitch/queen—good health; vaccinated; good nutritional status.
• Clean and disinfect parturition environment (1 : 32 dilution of bleach); clean bedding frequently after birth.
• Ensure adequate colostrum intake of all littermates.
• Separate mother with nursing litter from other cats or dogs.
• Keep density low in kennel or cattery rooms.
• Wash hands and change clothes and shoes after handling other cats/dogs and before dealing with neonates.

EXPECTED COURSE AND PROGNOSIS
• Neonates—life-threatening; prognosis often poor; neonate may rapidly succumb; quick treatment with supportive care essential for survival.
• Adults—self-limiting with supportive care, depending on degree of dehydration and existence of other diseases.

MISCELLANEOUS

AGE-RELATED FACTORS
Neonates—greatest risk of infection and subsequent septicemia.

ZOONOTIC POTENTIAL
• Little information of virulence potential of EC strains from dogs or cats for humans, although recently similarities have been found between canine fecal and UPEC and human EC associated with urinary tract infections, sepsis, and meningitis.
• Growing concern for presence of multidrug resistance determinants in EC strains from companion animals.
• Children and immunosuppressed persons should be kept away from pets with diarrhea.
• Whole genome sequencing has linked commercially available raw meat diets to pathogens found in dogs and cats, including EC, *Salmonella*, and *Listeria*.

SYNONYMS
• *E. coli* septicemia.
• Neonatal enteritis.

ABBREVIATIONS
• AEEC = attaching and effacing *E. coli*.
• CNF = cytotoxic necrotizing factor.
• EC = *Escherichia coli*.
• EPEC = enteropathogenic *E. coli*.
• ESBL = extended spectrum beta-lactamase.
• ETEC = enterotoxigenic *E. coli*.
• ExPEC = extraintestinal pathogenic *E. coli*.
• UPEC = uropathogenic *E. coli*.
• VTEC = verotoxigenic *E. coli*.

COLITIS AND PROCTITIS

BASICS

DEFINITION
• Colitis—inflammation of the colon (large intestine); colitis may be acute and self-limiting or chronic. • Colitis does not infer causality, and an underlying cause of the colitis should be investigated, particularly in chronic cases. • Proctitis—inflammation of the rectum.

PATHOPHYSIOLOGY
• Inflammation of the colon causes accumulation of inflammatory cytokines, disrupts tight junctions between epithelial cells, stimulates colonic secretion, stimulates goblet cell secretion of mucus, and disrupts motility. • These mechanisms reduce the ability of the colon to absorb water and electrolytes, and store feces, which causes frequent diarrhea, often with mucus and/or frank blood.

SYSTEMS AFFECTED
Gastrointestinal

GENETICS
• Breeds predisposed to histiocytic ulcerative colitis (granulomatous colitis [GC]) include boxers, French bulldogs, and, less commonly, border collies. • German shepherd dogs are predisposed to perianal fistulae (anal furunculosis) that can be associated with colitis.

INCIDENCE/PREVALENCE
• Approximately 30% of dogs with chronic diarrhea examined at one university hospital. • 71% of dogs with a food-responsive enteropathy had clinical signs of colitis (either alone or in association with enteritis (enterocolitis). • Prevalence of colitis probably higher than perceived, because many diarrheic dogs and cats manifesting small bowel diarrhea have evidence of colitis histopathologically when biopsied.

GEOGRAPHIC DISTRIBUTION
• N/A except for certain infectious diseases. • Pythiosis—predominantly Gulf Coast and southeast United States, although becoming more widespread, including California. • Histoplasmosis—Midwest, eastern United States. • *Prototheca* spp.—ubiquitous in nature, especially prevalent in warm, humid climates (e.g., southern and southeastern United States, northeastern Australia, southern continental Europe, Japan) in aqueous environments where decaying organic matter present. • *Entamoeba histolytica*—prevalent in tropical and subtropical regions worldwide; in United States, much higher rate of amebiasis-related mortality in California and Texas, which might be caused by their proximity to *E. histolytica*-endemic areas, such as Mexico, other parts of Latin America, and Asia. • *Tritrichomonas blagburni*—widespread distribution in North America, Australasia, Europe, and Asia.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Boxers, French bulldogs, border collies (GC). • German shepherd dogs—perianal fistulas and concurrent colitis.

Mean Age and Range
• Any age; boxers and French bulldogs are typically younger (<2 years). • Cats infected with *Tritrichomonas blagburni* are typically younger (<2 years), but can also be infected when older.

SIGNS

Historical Findings
• Fecal consistency can be variable from semi-formed to liquid. • Marked increase in frequency of defecation (6–15 times per day) with small fecal volume. • Tenesmus. • Increased fecal mucus. • Hematochezia; cats may have formed feces with hematochezia. • Occasional dyschezia (painful defecation). • Increased urgency to defecate. • Vomiting in approximately 30% of dogs and cats with colitis.

Physical Examination Findings
• Usually unremarkable. • Rectal examination may reveal thickened and irregular colorectal mucosa. • Dogs with GC may show systemic signs of weight loss and anorexia.

CAUSES
• Dietary—food-responsive enteropathy is common and important cause of colitis; dietary indiscretion; food intolerance. • Drug administration (antibiotics, nonsteroidal anti-inflammatory drugs [NSAIDs]). • Infectious—*Trichuris vulpis*, *Entamoeba histolytica*, *Balantidium coli*, *Tritrichomonas blagburni*, *Clostridium perfringens and Clostridium difficile*, *Campylobacter jejuni and Campylobacter coli*, *Yersinia enterocolitica*, *Prototheca*, *Histoplasma capsulatum*, pythiosis/phycomycosis. • Traumatic—foreign body, abrasive material. • Inflammatory—secondary to pancreatitis (transverse colitis). • Inflammatory/immune—inflammatory bowel disease (lymphoplasmacytic, eosinophilic, granulomatous) colitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Neoplasia—colonic lymphoma, adenocarcinoma, sarcomas. • Irritable bowel syndrome. • Colorectal polyps do not typically cause signs of colitis, but instead cause hematochezia in association with formed stool defecated at normal frequency. • Cecal inversion. • Ileocecocolic intussusception.

CBC/BIOCHEMISTRY/URINALYSIS
• Results usually unremarkable; neutrophilia with left shift can be seen with severe inflammatory causes; eosinophilia secondary to eosinophilic colitis, parasitism, histoplasmosis, pythiosis/phycomycosis. • Mild microcytic, hypochromic anemia may occur secondary to chronic intestinal bleeding and iron deficiency. • Hyperglobulinemia in some patients (especially cats) with chronic disease.

OTHER LABORATORY TESTS
• Examination of fecal centrifugation flotation, direct fecal smear (only on fresh diarrheic feces), detection of netE and netF toxin genes of *C. perfringens* and *C. difficile* toxins A and B genes via PCR, serum ELISA test for *Pythium* when indicated. • Rectal scraping for cytology for *Histoplasma* organisms and *Prototheca* spp. • Biopsy of colon or regional lymph nodes for detection of *Prototheca* spp., or biopsy of gastrointestinal tract and regional lymph nodes for detection of *Histoplasma* organisms. • Microscopic examination of urine sediment or cerebrospinal fluid (CSF) in dogs with disseminated protothecosis and associated clinical signs can be excellent means of detecting organisms. • Culture and sensitivity testing for diagnosis of *Prototheca* spp. • MVista® Histoplasma quantitative antigen test performed on serum, plasma, urine, or CSF can aid diagnosis and management of histoplasmosis. • Fecal PCR or In Pouch TF medium for culture of *Tritrichomonas foetus*.

IMAGING
• Abdominal radiographs—usually unremarkable. • Abdominal ultrasonography—may reveal masses, diffuse thickening or altered architecture of the colon, or enlarged associated lymph nodes. • Contrast studies—barium may be administered transcolonically to evaluate colorectal mucosa for irregularities or filling defects and colorectal strictures; however, procedure rarely indicated in dogs and cats with colitis and of low sensitivity in general.

DIAGNOSTIC PROCEDURES
• Colonoscopy with biopsy—procedure of choice for diagnosis of chronic or refractory cases; animals must be adequately prepared for colonoscopy by being fasted and administered osmotic cathartics such as OsmoPrep® or GoLYTELY®; mucosal changes visible grossly in animals with colitis include disappearance of submucosal blood vessels, granular appearance of mucosa, hyperemia, excessive mucus, ulceration, pinpoint hemorrhage (small ulcerations), or mass(es). • Always obtain multiple biopsy specimens from multiple locations (ascending colon, transverse colon, descending colon, rectum)

because extent of mucosal change assessed histologically does not necessarily reflect severity of colitis or proctitis.

PATHOLOGIC FINDINGS

Histopathologic findings depend on histologic type of colitis—lymphoplasmacytic, eosinophilic, or histiocytic represent most common subtypes; hyperplastic mucosa may be seen with irritable bowel syndrome; various infectious agents may be seen with special stains.

TREATMENT

DIET

• No inherent benefit to fasting patients with diarrhea, unless cause of diarrhea has osmotic component. • Animals that do not have severe clinical signs can be managed with elimination diet or hypoallergenic diet for 2 weeks; response to dietary therapy typically seen within first 5–7 days following dietary implementation; obtain comprehensive dietary history to optimize selection of novel, single protein source diet; strict dietary compliance pivotal during this trial period to optimize interpretation of response. • Fiber supplementation with poorly fermented fiber (e.g., bran and alphacellulose) recommended to increase fecal bulk, improve colonic muscle contractility, and bind fecal water to produce formed feces. • Some fermentable fiber sources (e.g., psyllium or diet containing beet pulp or fructooligosaccharides) may be beneficial—short-chain fatty acids produced by fermentation may be beneficial for colonocyte function.

SURGICAL CONSIDERATIONS

Segments of colon severely affected by fibrosis from chronic inflammation and subsequent stricture formation may need surgical excision, especially in patients with granulomatous form of disease; cecal inversion and ileocecocolic intussusception require surgical intervention; pythiosis/phycomycosis often requires surgical excision or debulking.

MEDICATIONS

DRUG(S) OF CHOICE

Antimicrobial Drugs

• *Trichuris*—fenbendazole (50 mg/kg PO q24h for 5 consecutive days, repeat in 3 months). • *Entamoeba*, *Balantidium*—metronidazole (25 mg/kg PO q12h for 5–7 days). • *Tritrichomonas blagburni*—ronidazole (30 mg/kg q24h for 14 days). • *Clostridium perfringens*—metronidazole (10 mg/kg PO q12h for 5 days), tylosin (5–10 mg/kg PO q24h for 5 days), ampicillin or amoxicillin (20 mg/kg PO q8h for 5 days); diarrhea, including acute hemorrhagic diarrheal syndrome, can be self-limiting and avoidance of antimicrobials recommended whenever feasible. • *Clostridium difficile*—metronidazole (10 mg/kg PO q12h for 5 days). • *Campylobacter jejuni*—erythromycin (10–15 mg/kg PO q8h) or azithromycin (5–10 mg/kg PO q24h) can be given for 7–10 days; azithromycin better tolerated than erythromycin. • *Yersinia* spp.—select drug on basis of bacterial culture and sensitivity testing. • *Prototheca*—combination therapy with amphotericin B and itraconazole, although disseminated cases typically fatal. • *Histoplasma*—itraconazole (dogs: 10 mg/kg PO q24h; cats: 5 mg/kg PO q12h; several months of therapy necessary); amphotericin B (0.25–0.5mg/kg slow IV q48h up to cumulative dose of 4–8 mg/kg) in advanced cases. • Pythiosis—itraconazole (10 mg/kg PO q24h) and terbinafine (10 mg/kg PO q24h) are drugs of choice following surgical debridement of affected portions of bowel; however, combination of itraconazole, terbinafine, and prednisone (without surgical resection) was shown to be highly effective in small cohort of dogs with focal involvement of colon; antifungal therapy often administered for 3–4 months or longer in affected animals.

Anti-inflammatory and Immunosuppressive Drugs for Inflammatory/Immune Colitis

• Sulfasalazine (dogs: 25–40 mg/kg PO q8h for 3–6 weeks with progressive tapering of dose throughout course of drug therapy; cats: 20 mg/kg PO q12h for 3 weeks); use with caution, particularly in cats, in which adverse effects on gastrointestinal tract and kidneys can be observed; sulfasalazine has been associated with irreversible keratoconjunctivitis sicca (KCS). • Corticosteroids—prednisone for dogs and prednisolone for cats: 1–2 mg/kg PO q12h for 5–7 weeks with gradual, progressive tapering of dose; most cats can be started on 5 mg (per cat) q12h with gradual taper; never use more than 50 mg total of prednisone (per day) for any animal, regardless of size. • Azathioprine (dogs) 1–2 mg/kg PO q24h for 10–14 days, followed by taper to 1–2 mg/kg q48h for 4–6 weeks; drug is markedly myelosuppressive in cats and should be avoided even though lower dose (0.3 mg/kg PO q48h) for this species has been published. • Chlorambucil—effective immunomodulator in both dogs and cats and usually administered in conjunction with prednisone or prednisolone; several dosing regimens have been published—cats: 2 mg per cat q3–4 days for 2–3 months (or longer if managing lymphoma) or 15 mg/m^2 given for 4 consecutive days every 3 weeks for 2–3 months; dogs: 0.1–0.2 mg/kg PO q24h for 8–12 weeks for immune disease, with gradual tapering of dose over course of therapy. • Cyclosporine (5 mg/kg PO q12–24h for 6 weeks for immune disease). • GC (histiocytic ulcerative colitis) usually managed with fluoroquinolones such as enrofloxacin at 10 mg/kg q24h for 6–8 weeks; however, evidence of marked increase in antimicrobial resistance to this class of drugs underscores importance of culture and sensitivity testing to optimize antimicrobial therapy. • Reconsider diagnosis of food-responsive colitis or nonspecific colitis carefully in dogs that do not respond to dietary therapy, fenbendazole administration, and tylosin therapy.

Motility Modifiers

• Indicated for symptomatic relief only in animals with intractable diarrhea; must be avoided in all animals with suspected infectious enteropathy. • Loperamide—0.1 mg/kg PO q8–12h. • Diphenoxylate—0.1–0.2 mg/kg PO q8h. • Propantheline bromide—0.25–0.5 mg/kg PO q8h, if colonic spasm contributing to clinical signs.

Anthelminthics

• Broad-spectrum anthelminthics such as fenbendazole (50 mg/kg q24h for 5 consecutive days) or Drontal® Plus in conjunction with dietary therapy (elimination diet) for first 2 weeks is mainstay of therapy for most patients with chronic colitis, unless a boxer breed that should have endoscopy and biopsy to confirm presence of GC, which has different therapy and prognosis. • Tylosin is highly effective antimicrobial that can be administered following assessment of response to dietary and anthelminthic therapy.

PRECAUTIONS

• Monitor patients on sulfasalazine for signs of KCS; measure tear production (Schirmer tear test) at baseline and every 2 weeks throughout course of therapy; discontinue drug if tear production decreases; use of sulfasalazine therapy has decreased markedly over past decade in light of excellent response to dietary and tylosin therapy in most dogs. • Monitor patients on azathioprine for bone marrow suppression—CBC every 2–3 weeks; stop treatment or go to alternate day if white blood cell count falls below 3,000 cells/µL. • Azathioprine can also increase risk of pancreatitis and should be used extremely cautiously in any dog at increased risk for pancreatitis; azathioprine can also cause hepatopathy. • Chlorambucil can cause progressive neutropenia and CBC should be repeated q2–3 weeks in all animals receiving this drug. • Cyclosporine can cause hepatotoxicity and chemistry panel should be performed as baseline before starting the drug and repeated q2–3 months. • Amphotericin B is nephrotoxic and requires close assessment of renal function

COLITIS AND PROCTITIS (CONTINUED)

via urinalyses and serum biochemistry panels. • Enrofloxacin-resistant cases of GC are increasing in prevalence due to antimicrobial resistance, necessitating alternative antimicrobial therapy in select cases.

FOLLOW-UP

PATIENT MONITORING

• Infrequent recheck examinations or client communication by phone. • Recheck of CBC is important for animals on immunomodulatory therapy.

EXPECTED COURSE AND PROGNOSIS

• Most bacterial and parasitic infectious causes have excellent prognosis, with high likelihood of cure following therapy. • *Prototheca*—grave; no known treatment except excision and itraconazole and amphotericin B following early diagnosis and before dissemination. • *Histoplasma* spp.—poor in advanced or disseminated disease; mild to moderate cases generally respond to therapy. • Pythiosis/phycomycosis—poor long-term prognosis in most animals, despite surgical intervention, given advanced stage of disease at diagnosis; addition of anti-inflammatory dose of prednisone with antifungal therapy appears to enhance effectiveness and benefit of therapy. • Cecal inversion, ileocecocolic intussusception—good with surgical resection if diagnosed in timely fashion. • Inflammatory—fair to good with treatment in patients with lymphoplasmacytic or eosinophilic colitis or GC. • Most dogs with mild to moderate nonspecific colitis respond favorable to combination of fenbendazole, feeding of elimination or hypoallergenic diet, and tylosin therapy.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Entamoeba, *Balantidium*, *Campylobacter jejuni*, *Yersinia* in immunosuppressed individuals.

SYNONYMS

• Inflammatory bowel disease. • Large bowel diarrhea.

ABBREVIATIONS

• CSF = cerebrospinal fluid.
• GC = granulomatous colitis.
• KCS = keratoconjunctivitis sicca.
• NSAID = nonsteroidal anti-inflammatory drug.

COLITIS, HISTIOCYTIC ULCERATIVE

BASICS

OVERVIEW
• Relatively common cause of colitis in Boxer breeds and infrequently seen in French bulldogs and border collies. • Boxer colitis is also referred to as granulomatous colitis (GC) in light of the granulomatous inflammation (macrophages) in the colon. • Etiology of GC is an adherent-invasive *E. coli* (AIEC) strain.

SIGNALMENT
• Dogs—primarily affects young Boxers, usually <3 years of age. • Reported in French bulldogs and border collies less frequently.

SIGNS
• Bloody, mucoid diarrhea with marked increase in frequency of defecation. • Tenesmus. • Weight loss and anorexia can occur and debilitation may develop.

CAUSES & RISK FACTORS
GC appears to be a genetic disorder in boxer breeds associated with reduced macrophage phagocytic function and inability to kill AIEC.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other causes of colitis—nonhistiocytic inflammatory bowel disease (IBD), lymphocytic, plasmacytic, eosinophilic colitis, other infectious causes of colitis (pythiosis, protothecosis, entamoeba), parasitic colitis (whipworms), food-responsive diarrhea. • Cecal inversion. • Ileocolic intussusception. • Neoplasia—lymphoma, adenocarcinoma. • Foreign body. • Colorectal polyps—dogs with colorectal polyps do not have diarrhea or increased mucus in stools, and instead have normal defecation frequency with formed stools (can have altered shape) coated with frank blood. • Irritable bowel syndrome. • Differentiate by clarifying history (colitis vs. colorectal neoplaia), fecal flotations, abdominal imaging, and colonoscopy or proctoscopy and biopsy.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually unremarkable; microcytic anemia may be present in Boxer dogs with GC secondary to intestinal bleeding. • Chemistry panel may reveal hypoalbuminemia, electrolyte abnormalities, and prerenal azotemia in dogs with severe diarrhea and anorexia.

IMAGING
Abdominal ultrasound in Boxer dogs with GC often reveals mild or moderate mesenteric or sublumbar lymphadenomegaly, and colonic wall can appear thickened.

DIAGNOSTIC PROCEDURES
• Proctoscopy or colonoscopy to obtain colonic biopsies. • Most Boxer dogs with GC have involvement of descending colon, underscoring diagnostic utility of proctoscopy. • Common changes in appearance to colonic wall include erythema, irregularity, and ulceration of colonic and rectal wall.

Microbiologic Testing
E. coli commonly isolated on routine bacteriologic media from feces of both healthy dogs and dogs with diarrhea; however, attempts to isolate *E. coli* from colonic biopsies is recommended for sensitivity testing and optimization of antimicrobial therapy.

PATHOLOGIC FINDINGS
• Histopathologic lesions include neutrophilic inflammation, epithelial ulceration, crypt hyperplasia and distortion, decreased numbers of goblet cells, and large numbers of macrophages that stain positive with periodic acid–Schiff (PAS) stain. • Presence of *E. coli* within macrophages can be confirmed using fluorescent in-situ hybridization (FISH).

TREATMENT
• Outpatient medical management following confirmation of diagnosis. • Antimicrobial therapy utilizing fluoroquinolones (unless resistance is observed) is mainstay of therapy. • Diet change to include moderately fermentable fiber source can be used in cases that do not show complete resolution of diarrhea.

MEDICATIONS

DRUG(S) OF CHOICE

Antimicrobials—First-Line Therapy
• Enrofloxacin (10 mg/kg q24h) for minimum duration of 6–8 weeks is typically associated with rapid resolution of clinical signs and resolution of histopathologic abnormalities. • Because enrofloxacin resistance has been documented in up to 70% of isolates from dogs with GC, attempts to isolate *E. coli* from colonic biopsies before treatment recommended such that antimicrobial susceptibility testing can be performed. • Antimicrobials that penetrate intracellularly, such as fluoroquinolones, chloramphenicol, rifampin, or trimethoprim-sulfonamides, should be preferentially chosen for treatment based on results of antimicrobial susceptibility testing. • Chloramphenicol, trimethoprim-sulfa, clarithromycin, imipenem, and meropenem should be considered for cases resistant to fluoroquinolones.

Anti-inflammatory/Immunosuppressive Drugs
• Rarely indicated in dogs with GC, and used at anti-inflammatory dose in conjunction with appropriate antimicrobial therapy. • Diagnosis must be reconsidered if no dramatic improvement in clinical signs following administration of fluoroquinolone therapy, because not all boxers with signs of colitis have GC.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Avoid anticholinergics or other motility modifiers such as Imodium® in dogs with infectious cause of diarrhea.

FOLLOW-UP

PATIENT MONITORING
• Monitor clinical signs, stool consistency and frequency, and body weight. • Dogs showing favorable response should improve within 5 days of starting effective antimicrobial therapy.

EXPECTED COURSE AND PROGNOSIS
• Generally good prognosis following appropriate antimicrobial therapy. • Increasing injudicious administration of fluoroquinolones to dogs is increasing resistance of *E. coli* to this class of antimicrobials, necessitating use of alternative antimicrobials in a subset of dogs.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Boxers, French bulldogs, and border collies with GC should not be bred.

SEE ALSO
Colitis and Proctitis.

ABBREVIATIONS
• AIEC = adherent-invasive *E. coli*. • FISH = fluorescent in-situ hybridization. • GC = granulomatous colitis. • IBD = inflammatory bowel disease. • PAS = periodic acid–Schiff.

COMPULSIVE DISORDERS—CATS

BASICS

DEFINITION
• Compulsive disorders are relatively invariant exaggerated behavior patterns, often derived from normal behaviors but out of context and repetitive, without apparent function; may be performed to the exclusion of other normal behaviors or to the detriment of the animal. • May be a heterogeneous group of conditions with differing pathologies including compulsive, stereotypic, and neurologic; therefore abnormal repetitive behaviors might be used to describe the clinical presentation. • Considered here are psychogenic dermatitis/alopecia, compulsive fabric chewing/sucking, and hyperesthesia syndrome.

PATHOPHYSIOLOGY
• Diagnosis of exclusion; must rule out pathophysiologic causes, including psychomotor seizures, before a presumptive diagnosis is made. • Can be a behavioral response to confinement, specific anxiety-producing event, or undefined environmental conditions (e.g., conflict, stress, anxiety, frustration); over time, can become fixed and independent of the environment; affected cats may lack control of onset or termination. • Behaviors may be self-reinforcing—allowing some animals to cope with conditions that do not meet their species-specific needs.

SYSTEMS AFFECTED
• Behavioral. • Gastrointestinal—fabric chewing/sucking. • Musculoskeletal—feline hyperesthesia (involves cutaneous trunci muscle), tail attack/mutilation. • Skin/exocrine—psychogenic dermatitis/alopecia. • Nervous—feline hyperesthesia syndrome.

GENETICS
None identified, although the association of compulsive fabric chewing/sucking with Asian breeds suggests a heritable component.

INCIDENCE/PREVALENCE
Unknown, uncommon.

SIGNALMENT

Species
Cat

Breed Predispositions
Siamese, Burmese, Birman, and crosses may be overrepresented for fabric chewing and sucking.

Mean Age and Range
• Compulsive disorders can develop at any time, generally not seen in kittens. • Psychogenic dermatitis/alopecia—6 months to 12 years. • Fabric chewing/sucking—12–49 months; generally around 24 months. • Hyperesthesia syndrome—1–5 years.

Predominant Sex
None

SIGNS

General Comments
• Behaviors may quickly increase in frequency if reinforced with attention by owner. • Scolding or punishment may increase cat anxiety and stress and worsen expression of behavior.

Historical Findings
• Onset may be coincident with environmental change (e.g., move or new household member) suggesting stress effect; cat may hide to avoid punishment. • Psychogenic dermatitis/alopecia—may be associated with excessive grooming to exclusion of other activities; may be history of flea exposure or diet change. • Compulsive fabric chewing/sucking—some patients show preference for specific fabric type such as wool or may have general texture preference; grind fabric with molars; may ingest fabric leading to foreign body obstruction. • Hyperesthesia syndrome—may be triggered by tactile contact (petting along dorsum and rump); may be episodic; flea exposure.

Physical Examination Findings
• Psychogenic dermatitis/alopecia—focal, partial, and bilateral dermatitis or alopecia; most common locations: groin, ventrum, and medial or caudal thigh regions; appearance of skin variable (normal or abnormal; erythematous to abraded). • Fabric chewing/sucking—often normal; secondary gastrointestinal inflammation or obstruction may occur if cat ingests material. • Hyperesthesia syndrome—episode may be prompted by petting or scratching dorsum; signs may include dilated pupils, salivation, alarming vocalization, "rippling skin" (hyperresponsive cutaneous trunci muscle), inappropriate urination or defecation, tail twitching, frantic grooming, self-directed (especially to tail) or owner-directed aggression, escape behavior.

CAUSES
Unidentified

RISK FACTORS
• Changes in environment might predispose cat to compulsive disorder. • More commonly reported in indoor cats. • Cats fed ad libitum may have lower prevalence of fabric chewing/sucking; must be balanced with nutritional needs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Rule out medical, including psychomotor seizures, before behavioral diagnosis is made.

Psychogenic Dermatitis/Alopecia
• Skin conditions—especially if associated with pruritus including external parasites; hypersensitivity to parasites, fleas, or food; atopy; neoplasia; fungal or bacterial dermatitis. • Nervous system disorders. • Disk rupture and associated neuritis. • Feline hyperesthesia syndrome. • Pain/neuropathy.

Fabric Chewing/Sucking
• Lead intoxication. • Hyperthyroidism. • Thiamin deficiency. • Gastrointestinal upset.

Hyperesthesia Syndrome
• Seizure disorder. • Skin disorders including external parasites, hypersensitivity to food, flea bites, and parasites; atopy. • Spinal disorder/neuropathy. • Myositis, myopathy.

CBC/BIOCHEMISTRY/URINALYSIS
Minimum database to rule out metabolic abnormalities. No consistent clinicopathologies associated with compulsive disorders.

OTHER LABORATORY TESTS

Psychogenic Alopecia
Microscopic examination of hairs (trichogram), skin scraping, skin biopsy, fungal culture, bacterial culture, examination for external parasites, exclusion diet to rule out dermatologic condition.

Fabric Chewing
• Serum lead level—if indicated for pica. • Serum T_4.

Hyperesthesia Syndrome
Rule out dermatologic conditions as above.

IMAGING
• CT or MRI—if indicated by abnormalities on examination, i.e., to diagnose neurologic, pain. • Fabric chewing/sucking—imaging gastrointestinal tract if obstruction or foreign body suspected.

DIAGNOSTIC PROCEDURES

Psychogenic Alopecia
Complete dermatologic evaluation.

Hyperesthesia Syndrome
Skin and/or muscle biopsy (as necessary).

PATHOLOGIC FINDINGS

Psychogenic Alopecia
• Microscopic examination of hairs—typically shafts are cleanly broken off at variable length as a result of trauma from the tongue. • If primarily behavioral, results of other dermatologic testing will be generally normal.

TREATMENT

APPROPRIATE HEALTH CARE
Supportive care.

NURSING CARE
Fabric chewing/sucking—create a "safe place" for when the cat is left alone, devoid of fabric of the sort favored for chewing.

ACTIVITY
Increase opportunities for play and social interactions by providing outlets favored by the affected cat. Insure environmental needs are fully addressed.

(CONTINUED) COMPULSIVE DISORDERS—CATS

C

Table 1

Drugs and dosages used to manage feline compulsive disorder.

Drug	*Drug Class*	*Oral Dosage in Cats*	*Frequency*	*Side Effects—Usually Transient*
Fluoxetine	SSRI	0.5–1.0 mg/kg	q24h	Decreased appetite, sleepiness
Paroxetine	SSRI	0.25–0.50 mg/kg	q24h	Constipation
Clomipramine	TCA	0.25–1.0 mg/kg	q24h	Sleepiness, urine retention
Amitriptyline	TCA	0.25–1.0 mg/kg	q24h	Sleepiness, urine retention
Gabapentin	Anticonvulsant	3–5 mg/kg	q12h	Sleepiness, sedation

DIET
• Fabric chewing—increasing fiber in the diet has been suggested. • Presumptive psychogenic alopecia—exclusion diet.

CLIENT EDUCATION
• Identify and remove triggers for the behavior, if applicable. • Do not reward the behavior. • Ignore the behavior as much as possible; distract the cat and initiate an acceptable behavior. • Note details of the time, place, and social milieu so that an alternative behavior (play or feeding or food-dispensing toy) may be scheduled prior to initiation of the compulsive behavior. • Punishment is contraindicated and can increase the unpredictability of the patient's environment, increase patient fear or aggressive behavior, and disrupt the human–animal bond. • Reduce environmental stress—increase the predictability of household events (feeding, play, exercise, and social time with the client); eliminate unpredictable events as much as possible.

SURGICAL CONSIDERATIONS
N/A unless obstructed.

MEDICATIONS

DRUG(S) OF CHOICE
• If a specific etiology cannot be identified, anti-compulsive or anti-anxiety drugs may be helpful; relatively high doses may be required (Table 1). • Goal—use the drugs until control is achieved for 2 months; attempt gradual withdrawal by decreasing dosage at 2-week intervals; treatment should be resumed at the last effective dose at the first sign of relapse; may be life-long. • Drugs are listed with dosage used to manage behavior and common side effects. • Hyperesthesia syndrome—gabapentin has been reported anecdotally to reduce the frequency and intensity of bouts.

CONTRAINDICATIONS
• Selective serotonin reuptake inhibitors (SSRIs)—depending on agent: poor appetite, constipation, sedation. • Tricyclic antidepressants (TCAs)—cats with history of cardiac conduction disturbances, urinary or fecal retention, megacolon, lower urinary tract blockages, seizures, and glaucoma. • Transdermal route does not appear to

PRECAUTIONS
• Start behavioral drugs at low dose to avoid side effects; may give at bedtime to reduce complaints of sedation; may be given with food. • No drugs approved by FDA for treatment of these disorders in cats; inform client of extra-label use and risks involved; document the discussion in the medical record or with a release form.

POSSIBLE INTERACTIONS
Do not use TCAs or SSRIs with monoamine oxidase inhibitors, including selegiline.

ALTERNATIVE DRUG(S)
• Phenobarbital if seizure disorder suspected. • Selegiline if cognitive dysfunction. • Presumptive psychogenic alopecia—exclusion diet, parasite treatment/preventative, trial course of steroids.

FOLLOW-UP

PATIENT MONITORING
• Before initiating treatment, record frequency of compulsive behavior so that progress can be monitored. • Successful treatment requires a schedule of follow-up examinations; a recommended schedule is a phone check 1 week after the initial consultation and an office recheck 4–6 weeks later; if improvement is evident, the treatment regime should be continued; if there is no improvement, differential diagnoses should be considered or an alternative drug should be considered. • If a medication is not effective after dosage adjustment, select an agent from another drug class.

PREVENTION/AVOIDANCE
Create an enriched environment with distributed resources, safe and accessible elevated resting sites, exercise and play opportunities, and predictable social interactions with people.

POSSIBLE COMPLICATIONS
• Treatment failure. • Realistic expectations must be created; immediate control of a longstanding problem is unlikely.

EXPECTED COURSE AND PROGNOSIS
With treatment, prognosis for improvement is good; treatment can be lifelong.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Avoidance behavior or aggression toward the owner—if the owner punishes the patient when it exhibits a compulsive behavior.

AGE-RELATED FACTORS
None

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
• Do not breed animals that display compulsive behavior. • TCAs—contraindicated in pregnant animals.

SYNONYMS
• Psychogenic alopecia—barbering, overgrooming. • Hyperesthesia syndrome—rippling skin disease, neurodermatitis.

SEE ALSO
Compulsive Disorders—Dogs.

ABBREVIATIONS
• SSRI = selective serotonin reuptake inhibitor. • TCA = tricyclic antidepressant.

COMPULSIVE DISORDERS—DOGS

BASICS

DEFINITION

• Heterogeneous group of abnormal repetitive behaviors with differing pathologies (compulsive, stereotypic, neurologic). • Categorized as locomotor (spinning, tail chasing, circling, fence running, pacing, light/shadow chasing); oral (licking, sucking/mouthing an object/body part, e.g., flank, tail, limb; pica, excessive drinking, "fly biting"); or hallucinatory ("fly biting," hind end checking, freezing, staring), with/without vocal and affective responses. • Compulsive disorders (CDs) are abnormal, repetitive, exaggerated, and/or sustained, variable in form and fixated on a goal; they are derived from normal maintenance behaviors (e.g., grooming, predation, ingestion); motivational conflict or frustration appears to trigger the behaviors in specific contexts often associated with high arousal; with repeated/sustained conflict, the behavior becomes emancipated from the original trigger(s) and displayed in diverse contexts; the animal may lack control of onset or termination. • Stereotypies are repetitive behaviors that are unvaried in sequence and have no obvious function or purpose; they may arise in situations of conflict/frustration related to confinement or husbandry practices, when the environment lacks sufficient outlets for the normal behavior repertoire, and with maternal deprivation.

PATHOPHYSIOLOGY

• Alterations in brain neurotransmitter functions likely—primarily serotonin; also dopamine, glutamate, endorphins; different CDs may preferentially involve different brain regions. • Abnormal serotonin transmission has been identified as a primary mechanism by which compulsive disorders are induced; stereotypies might be induced by dopaminergic stimulation.

SYSTEMS AFFECTED

• Behavioral—fear, anxiety, aggression. • Cardiovascular—tachycardia. • Endocrine/metabolic— hypothalamic–pituitary–adrenal (HPA) axis upregulation. • Gastrointestinal—inappetence, gastroenteritis, foreign body obstruction. • Hemic/lymphatic/immune—stress leukogram. • Musculoskeletal—weight loss, self-injury. • Respiratory—tachypnea. • Skin/exocrine—abrasions/wounds/infections secondary to self-trauma.

GENETICS

• Higher than expected occurrence among first-generation relatives (manifestations may differ). • Certain breeds overrepresented for specific CDs. • Genetic studies implicate N-methyl-D-aspartate (NMDA) glutamatergic neurotransmission, particularly via neural cadherin (*CDH2*); also serotonergic transmission via the 5-HT3 receptor, as well as other aspects of synaptic transmission.

INCIDENCE/PREVALENCE

Generally uncommon, although recent studies report in up to 16%; more common in certain breeds/families.

SIGNALMENT

Species

Dog

Breed Predispositions

Bull terrier—spinning, freezing/"trancing"; German shepherd—spinning, tail chasing; Great Dane, German shorthaired pointer—self-directed oral behaviors, fence running, hallucinations; Doberman—flank/blanket sucking; miniature schnauzer—hind end checking; border collie—light/shadow chasing; cavalier King Charles spaniel—fly catching.

Mean Age and Range

May be presented at any age; usually develops from onset of sexual (6 months) to social (12–24 months) maturity; earlier onset (3–6 months) reported for some CDs.

Predominant Sex

Some CDs may be more common in males.

SIGNS

General Comments

• Wide variety of manifestations—behaviors may be repetitive or static (e.g., freezing). • Signs may not be observed during examination; descriptions may be unclear; video aids diagnosis and treatment planning.

Historical Findings

• May be other signs of anxiety/concurrent behavioral diagnoses (e.g., separation anxiety, fears, aggression) and/or a history of stress (e.g., inadequate stimulation, punishment, change in routine/household). • Behavior may first be displayed as play or in situations of high arousal/stress; eventually may occur in multiple contexts independent of identifiable triggers. • Certain repetitive behaviors are expressed in situations with little to no external stimulation or evidence of arousal (e.g., blanket sucking). • May occur whether or not the owner is present; if punished, pet may avoid detection. • Hallmarks—behavior is ritualized, often exaggerated in form, and with time increases in frequency, intensity, and duration. • Behavior may be difficult/impossible to interrupt. • Behavior may interfere with normal functioning (e.g., eating, sleeping, social interactions).

Physical Examination Findings

• May be unremarkable. • May see skin lesions/injuries related to self-trauma (especially tail, forelimbs, distal extremities); excessive tooth wear/damage; lameness or poor body condition.

CAUSES

No direct cause.

RISK FACTORS

• Environmental stress (e.g., kenneling—spinning), management. • Owner/environmental reinforcement of the behavior. • Punishment of the behavior further contributing to stress and conflict. • Medical disease, pain, neuropathy—may increase anxiety or may be primary cause. • Sensory abnormalities (e.g., visual deficits) may contribute.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Dermatologic (e.g., atopy). • Gastrointestinal (e.g., inflammatory bowel disease [IBD], neoplasia, gastroesophageal reflux). • Metabolic/endocrine (e.g., Cushing's). • Neurologic (e.g., seizure focus, forebrain neoplasia, neurodegenerative disorder). • Orthopedic (e.g., degenerative joint disease [DJD]). • Any disorder causing abnormalities of sensation such as dysesthesia, paresthesia (e.g., sensory neuropathy). • Other problem behaviors—displacement/conflict behaviors, play and attention seeking, behaviors occurring secondary to lack of stimulation or due to resource restriction (e.g., water restriction—excessive drinking). • Rule out physical/medical causes.

CBC/BIOCHEMISTRY/URINALYSIS

• Usually within reference range—use for general health screening; prior to drug use. • Hematocrit, cholesterol, triglyceride increases have been reported.

OTHER LABORATORY TESTS

Specific to differential diagnoses (e.g., endoscopy, biopsy, echocardiography).

IMAGING

• For neurologic differentials, CT or MRI to rule out structural brain/spinal disease; altered brain/gray matter volume/density reported in CD. • Radiography, ultrasound if needed to rule out underlying physical causes.

DIAGNOSTIC PROCEDURES

History, video clips.

TREATMENT

Repetitive behaviors may represent a normal coping mechanism. If not harmful nor interfering with normal functioning, health, or human–animal bond, intervention may be unnecessary or contraindicated.

APPROPRIATE HEALTH CARE

• Generally outpatient. • Sedation—stop-gap measure; if needed to stop serious self-mutilation. • Treat associated physical conditions (primary or secondary). • Combination of environmental modification, behavior modification, and

pharmacologic treatment. • Pharmacologic intervention—implement early; reduction of anxiety facilitates behavioral therapy. • Environmental modification—reduce stress and anxiety; identify and remove sources (e.g., triggers) and/or begin desensitization and counter-conditioning exercises. • Punishment—contraindicated; increases anxiety, may worsen behavior and increase patient secrecy. • Provide structured, consistent interactions, routine, and sufficient exercise, enrichment/mental stimulation appropriate to species and individual; includes interactive play, food puzzles, and reward-based training. • Behavior modification—teach the patient to relax in a variety of settings; also teach a calm, desirable behavior incompatible with the stereotypic one, coupled to a verbal cue (e.g., for circling, teach to lie down with head and neck outstretched in response to "Head down"). In some cases, a head collar (e.g., Gentle Leader, Halti) left on the dog (when the owner is home) in the problem contexts may allow the owner to use gentle physical guidance along with verbal encouragement/cues to interrupt the behavior and redirect it more effectively; monitor for situation in which behavior occurs and preempt it by engaging the pet in an incompatible activity; if behavior occurs, disrupt immediately, redirect the animal to alternative incompatible activity and reward (with food/play/other reinforcer); dogs with CD may be more perseverant and thus not respond well to extinction procedures. • Have clients monitor behaviors via videos and written logs (e.g., rate severity) for objective assessment of response to therapy; improvement may be seen in frequency and/or intensity. • Bandages, collars, braces, and crates increase distress, do not address the behavioral condition, and may worsen it; if needed to ensure healing, use as briefly as possible.

ACTIVITY
Environmental enrichment.

CLIENT EDUCATION
• Cure unlikely; usually requires lifelong management. • Teach client to recognize all body language/behaviors reflecting anxiety.

SURGICAL CONSIDERATIONS
Tail/limb mutilation—avoid amputation unless medically indicated; will not resolve the CD.

MEDICATIONS

DRUG(S) OF CHOICE
• Selective serotonin reuptake inhibitors (SSRIs) and tricyclic antidepressants (TCAs)—CNS serotonin effects. • Generally treat at low end of dose range for 4–6 weeks; gradually increase dosage if ineffective and no adverse events. • SSRIs—fluoxetine 1–2 mg/kg q24h; sertraline 1–3 mg/kg q24h; paroxetine 1–2 mg/kg q24h. • TCAs—clomipramine is most serotonergic (most effective, fewest side effects): 2–3 mg/kg q12h. • If symptoms resolve, continue medication for >1 month; taper dose no faster than 25% every two weeks; recurrence common.

CONTRAINDICATIONS
• Hepatic or renal compromise—medications metabolized by these organs. • Cardiac conduction anomalies—TCAs. • Use extreme care combining serotonergic drugs (e.g., SSRI with tramadol); risk of serotonin syndrome. • Do not use SSRIs or TCAs within 2 weeks of monoamine oxidase (MAO) inhibitors (e.g., selegiline, amitraz).

PRECAUTIONS
• Use of listed medications for CD is extra- or off-label. • TCA overdose—cardiac conduction disturbances. • TCA/SSRI overdose—serotonin syndrome. • Side effects of SSRIs and TCAs—most common: lethargy, appetite change; less common: increased anxiety/reactivity, vomiting/diarrhea; severe side effects may necessitate discontinuation.

POSSIBLE INTERACTIONS
SSRIs competitively inhibit cytochrome P450 enzymes: may increase warfarin, many TCAs, some benzodiazepines and anticonvulsants, other medications; check compatibility and adjust dosage if necessary.

ALTERNATIVE DRUG(S)
• Synthetic pheromones (Adaptil), l-theanine, or alpha-casozepine—may reduce anxiety. • Adjunctive use of memantine (NMDA receptor antagonist) 0.3–1 mg/kg q12h; second-line TCAs, e.g., amitriptyline 1–6 mg/kg q12h. • Selegiline (MAO inhibitor) 0.5–1 mg/kg q24h—may be effective in some cases. • Narcotic antagonists (e.g., naltrexone, naloxone)—may be effective but not a practical therapeutic option. • Antipsychotics (e.g., thioridazine, haloperidol)—not recommended: risk of adverse effects, efficacy undocumented.

FOLLOW-UP

PATIENT MONITORING
• CBC, biochemistry, T_4 (TCAs may artificially lower), and urinalysis—semi-annually to yearly if chronic treatment; adjust dosages accordingly. • Medications may take 8–12 weeks or longer to affect CDs; first sign of efficacy may be reduced duration/frequency. • Relapses common during stressful situations; manage with increased intensity of behavior modification, addition of short-term, shorter-acting anxiolytics (e.g., benzodiazepines).

PREVENTION/AVOIDANCE
Monitor for affected relatives; early recognition and intervention.

POSSIBLE COMPLICATIONS
Dermatologic/musculoskeletal injury; gastrointestinal disorders.

EXPECTED COURSE AND PROGNOSIS
• Untreated CDs almost always progress. • >50% reduction in CD in approximately two-thirds of cases with appropriate medication and behavioral and environmental modification.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Various; specific to type of CD.

PREGNANCY/FERTILITY/BREEDING
• Listed medications not evaluated/contraindicated in pregnant animals; avoid use. • Do not breed affected animals.

SYNONYMS
Obsessive-compulsive disorder.

SEE ALSO
Acral Lick Dermatitis.

ABBREVIATIONS
• CD = compulsive disorder. • DJD = degenerative joint disease. • HPA = hypothalamic–pituitary–adrenal. • IBD = inflammatory bowel disease. • MAO = monoamine oxidase. • NMDA = N-methyl-D-aspartate. • SSRI = selective serotonin reuptake inhibitor. • TCA = tricyclic antidepressant.

CONGENITAL AND DEVELOPMENTAL RENAL DISEASES

BASICS

DEFINITION

• Functional or morphologic abnormalities resulting from heritable (genetic) or acquired disease processes affecting differentiation and growth of the developing kidney. • Renal agenesis—complete absence of one or both kidneys. • Renal dysplasia—disorganized renal parenchymal development. • Renal ectopia—congenital malposition of one or both kidneys. • Glomerulopathy—glomerular disease of any type. • Polycystic renal disease—formation of multiple, variable-sized cysts throughout the renal medulla and cortex. • Renal telangiectasia—multifocal vascular malformations involving the kidneys and other organs. • Renal amyloidosis—extracellular deposition of amyloid in glomerular capillaries, glomeruli, and interstitium. • Nephroblastoma—congenital renal neoplasm arising from the pluripotent metanephric blastema. • Multifocal renal cystadenocarcinoma—hereditary renal neoplasm in dogs. • Fanconi syndrome—generalized renal tubular functional anomaly characterized by impaired reabsorption of glucose, phosphate, electrolytes, amino acids, and uric acid. • Primary renal glucosuria—defect in renal tubular reabsorption of glucose. • Cystinuria—excessive urinary excretion of cystine due to defect in renal tubular reabsorption of cystine and other amino acids. • Xanthinuria—excessive urinary excretion of xanthine caused by a deficiency in xanthine oxidase. • Hyperuricuria—excessive urinary excretion of uric acid, sodium urate, or ammonium urate. • Primary hyperoxaluria—intermittent hyperoxaluria, l-glyceric aciduria, and oxalate nephropathy. • Congenital nephrogenic diabetes insipidus—polyuria caused by diminished renal responsiveness to antidiuretic hormone.

PATHOPHYSIOLOGY

Many congenital and developmental renal disorders are caused by genetic abnormalities that disrupt the normal development and interaction of multiple embryonic tissues involved in formation of the mature kidney. Nongenetic factors are also possible.

SYSTEMS AFFECTED

Renal/urologic.

GENETICS

• Familial renal disorders have been reported in the following breeds: ◦ Renal agenesis—beagle, Doberman pinscher, Shetland sheepdog. ◦ Renal dysplasia—Alaskan Malamute, border terrier, boxer, bullmastiff, bulldog, Cairn terrier, cavalier King Charles spaniel, chow chow, cocker spaniel, Dutch kookier, golden retriever, Finnish harrier, keeshond, Lhasa apso, miniature schnauzer, Norwegian elkhound, Rhodesian ridgeback, shih tzu, soft-coated wheaten terrier, standard poodle. ◦ Glomerulopathy—Airedale terrier, beagle, Belgian shepherd, Bernese mountain dog, Brittany spaniel, bull terrier, bullmastiff, Dalmatian, Doberman pinscher, English cocker spaniel, Newfoundland, Pembroke Welsh corgi, Rottweiler, Samoyed, soft-coated wheaten terrier. ◦ Polycystic renal disease—beagle, bull terrier, Cairn terrier, West Highland white terrier; Persian, exotic shorthair, Himalayan, British blue cats. ◦ Renal telangiectasia—Pembroke Welsh corgi. ◦ Renal amyloidosis—Abyssinian, oriental shorthair, Siamese cats; beagle, English foxhound, shar-pei. ◦ Renal cystadenocarcinoma—German shepherd. ◦ Fanconi syndrome—basenji and border terrier. ◦ Primary renal glucosuria—Norwegian elkhound, Scottish terrier, basenji. ◦ Cystinuria—American pit bull terrier, basset hound, English bulldog, dachshund, mastiff, Newfoundland, Rottweiler, among others. ◦ Xanthinuria—cavalier King Charles spaniel, wirehaired dachshund; domestic shorthair cats. ◦ Hyperuricuria—Dalmatian, black Russian terrier, English bulldog. ◦ Primary hyperoxaluria—domestic shorthair cats; Tibetan spaniel.

INCIDENCE/PREVALENCE

Uncommonly recognized, but occur more frequently in related animals from more than one generation than in the general population.

SIGNALMENT

Species

Dog and cat.

Breed Predilections

Sporadic cases can occur without apparent familial predisposition in any breed of dog or cat.

Mean Age and Range

Most are <5 years old at time of diagnosis.

Predominant Sex

• Familial cystinuria occurs primarily in male dogs. • Samoyed hereditary glomerulopathy more common in males. • Familial glomerulonephropathy of Bernese mountain dogs is more common in females.

SIGNS

General Comments

Most congenital and developmental disorders cannot be distinguished from acquired renal disease without kidney biopsy.

Historical Findings

• Indicate chronic kidney disease. • Some glomerulopathies associated with abdominal distension, edema, or other signs of nephrotic syndrome. • Abdominal distension in some patients with polycystic kidneys or renal neoplasms. • Hematuria or abdominal pain in some patients with renal telangiectasia or renal neoplasms. • Patients with unilateral renal agenesis, ectopic kidneys, and isolated renal tubular transport defects are frequently asymptomatic.

Physical Examination Findings

• Signs associated with advanced chronic kidney disease. • Ascites or pitting edema in some patients with protein-losing glomerulopathies or amyloidosis. • Renomegaly or abdominal mass lesions in some patients with polycystic kidneys, renal neoplasms, or fused ectopic kidneys.

CAUSES

Nonhereditary

• Infectious agents—feline panleukopenia virus and canine herpesvirus infection associated with renal dysplasia. • Drugs—corticosteroids, diphenylamine, and biphenyls associated with polycystic kidneys; chlorambucil and sodium arsenate associated with renal agenesis. • Dietary factors—hypo- or hypervitaminosis A associated with renal ectopia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Rule out acquired and nondevelopmental causes of primary renal disease. • Rule out nonrenal causes of hematuria, proteinuria, glucosuria, abdominal distention, or ascites.

CBC/BIOCHEMISTRY/URINALYSIS

• Nonregenerative anemia. • Azotemia and urine specific gravity <1.030 in dogs and <1.035 in cats. • Proteinuria, hypoalbuminemia, and hypercholesterolemia with nephrotic syndrome. • Normoglycemic glucosuria in Fanconi syndrome or primary renal glucosuria. • Hematuria with congenital renal neoplasia or renal telangiectasia. • Cystine crystalluria with cystinuria. • Xanthine crystalluria with xanthinuria. • Urate crystalluria with hyperuricuria.

OTHER LABORATORY TESTS

Genetic tests are available for some specific genetic mutations associated with hereditary renal disorders.

IMAGING

Survey abdominal radiography, renal ultrasonography, and excretory urography may identify and characterize congenital and developmental renal disorders and their associated sequelae.

DIAGNOSTIC PROCEDURES

Consider light microscopic evaluation of kidney biopsy specimens from patients with morphologic or functional abnormalities of the kidney for which a definitive diagnosis has not been established.

(CONTINUED) # CONGENITAL AND DEVELOPMENTAL RENAL DISEASES

PATHOLOGIC FINDINGS

• Renal dysplasia—primary lesions include immature glomeruli, persistent mesenchyme, persistent metanephric ducts, atypical tubular epithelium, and dysontogenic metaplasia; primary lesions usually associated with, and may be obscured by, secondary degenerative, inflammatory, and compensatory lesions. • Glomerulopathies—usually normal-to-small kidneys; most are characterized by a primary membranoproliferative glomerulonephritis with variable degrees of tubulointerstitial disease, others have cystic atrophic membranous glomerulopathy. • Polycystic renal disease—see Polycystic Kidney Disease. • Renal amyloidosis—see Amyloidosis. • Renal telangiectasia—multiple, variable-sized, red-black, blood-filled nodules and clots in the renal cortex and medulla, interstitial fibrosis, interstitial mononuclear cell infiltrate, and hydronephrosis. • Nephroblastoma—unilateral renal mass; contains both embryonic mesenchymal and epithelial tissue components. • Multifocal renal cystadenocarcinoma—bilaterally enlarged kidneys with irregular protruding cystic structures or multifocal neoplastic renal tubular epithelial cell proliferations. • Renal ectopia—kidneys abnormally located in the retroperitoneal space or abdomen; horseshoe kidneys are symmetrically fused along the medial border of either pole. • Fanconi syndrome—inconsistent findings of tubular atrophy, interstitial fibrosis, and acute papillary necrosis. • Primary hyperoxaluria—large, irregularly shaped kidneys; renal tubular deposition of calcium oxalate crystals and variable interstitial and periglomerular fibrosis.

TREATMENT

• Congenital and developmental renal disorders often have no specific treatment. • Supportive strategies are similar to those for acquired chronic kidney disease and may improve quality of life and minimize progression in patients with renal dysfunction. • Refer to chapters describing specific renal diseases or clinical syndromes.

MEDICATIONS

DRUG(S) OF CHOICE

Refer to chapters describing specific renal diseases or clinical syndromes.

CONTRAINDICATIONS

Avoid potentially nephrotoxic drugs or anesthetic agents that decrease renal function.

PRECAUTIONS

Avoid drugs requiring renal excretion in patients with renal failure; if necessary, modify dosage regimens to compensate for decreased renal clearance of drugs and other metabolites.

FOLLOW-UP

PATIENT MONITORING

Refer to chapters describing specific renal diseases or clinical syndromes.

PREVENTION/AVOIDANCE

Congenital and developmental renal disorders are irreversible, so control lies in preventing breeding of affected animals.

POSSIBLE COMPLICATIONS

• Acute or chronic renal failure. • Nephrotic syndrome. • Urolithiasis. • Hydronephrosis. • Urinary tract infection.

EXPECTED COURSE AND PROGNOSIS

• Highly variable; depends on the specific disorder, the extent of primary lesions, and the severity of renal dysfunction. • Congenital and developmental disorders are irreversible and may result in advanced chronic kidney disease; some patients with mild to moderate renal dysfunction may remain stable for long periods. • Patients with some disorders may remain asymptomatic unless the disorder is complicated by urolithiasis, infection, or other disease processes that promote progressive renal dysfunction.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Polycystic renal disease associated with hepatic biliary cysts. • Cystinuria, xanthinuria, and hyperuricuria associated with formation of uroliths. • Amyloidosis in Chinese Shar-Pei dogs associated with intermittent pyrexia or swelling of the hocks. • Renal neoplasms associated with hypertrophic osteoarthropathy, polycythemia, or other paraneoplastic syndromes.

SYNONYMS

• Familial renal disease. • Juvenile renal disease.

CONGENITAL OCULAR ANOMALIES

BASICS

DEFINITION
Solitary or multiple abnormalities that affect the globe or its adnexa; observed in dogs and cats at birth or within the first 6–8 weeks of life.

PATHOPHYSIOLOGY
- Breed-related inherited defects.
- Spontaneous malformations.
- In utero systemic infections and inflammations, exposure to toxic compounds, and lack of specific nutrients in pregnant dams or bitches.

SYSTEMS AFFECTED
Ophthalmic—entire eye or any part; unilateral or bilateral.

GENETICS
- * Indicates availability of genetic testing for all or most affected breeds.
- Congenital keratoconjunctivitis sicca (KCS) and KCS ichthyosiform dermatosis (KCSID)*—cavalier King Charles spaniel (dry eye and curly coat syndrome): recessive trait.
- Persistent pupillary membranes (PPM)—Basenji and other breeds: unknown mode of inheritance.
- Persistent hyperplastic tunica vasculosa lentis (PHTVL) and persistent hyperplastic primary vitreous (PHPV)—Doberman pinscher and Staffordshire bull terrier: dominant allele with variable expression.
- Retinal dysplasia—English springer spaniel: recessive trait.
- Collie eye abnormality (CEA)*—collie and other dog breeds: recessive trait.
- Merle ocular dysgenesis (MOD)—Australian shepherd: autosomal recessive trait with incomplete penetrance.
- Oculo-skeletal dysplasia (OSD)*—Labrador retriever and Samoyed: autosomal dominant trait with incomplete penetrance.
- Retinal dystrophy*—Briard: recessive trait.
- Rod cone dysplasia*—collies, Irish setter, Cardigan Welsh corgi, sloughi: recessive traits; nonallelic disease.
- Early retinal degeneration*—Norwegian elkhound: recessive trait.
- Photoreceptor dysplasia—Belgian shepherd.
- Cone rod dystrophy*—American pit bull terrier, American Staffordshire terrier, springer spaniel, long-, short- and wirehaired dachshunds: recessive traits; nonallelic disease.
- Cone degeneration, achromatopsia, or day blindness*—Alaskan Malamute, Australian shepherd, German shepherd dog, miniature American shepherd, German shorthaired pointer, Australian cobberdog, Labrador retriever and Labrador crosses (incl. Labradoodles): recessive traits.
- Optic nerve hypoplasia—miniature and toy poodle, sporadically in other breeds: unknown mode of inheritance.
- Photoreceptor dysplasia*—Abyssinian, Somali, and Ocicat cat breeds: dominant trait.

INCIDENCE/PREVALENCE
- Incidence—low; dogs > cats.
- CEA—>50% in collies, lower in other breeds.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
See Genetics.

SIGNS

General Comments
- Depends on defect.
- May cause no signs of disease; often incidental finding.
- May be congenitally blinding disease.

Historical Findings
Ranges from none to severe visual impairment to blindness.

Physical Examination Findings
- Anophthalmos—congenital lack of globe; rare.
- Microphthalmos—congenitally small eye; often associated with other hereditary defects, including MOD.
- Eyelid agenesis or colobomas of eyelids in cats—result in congenitally open eyelids; affects temporal portion of upper eyelid; may cause blepharospasm, epiphora, and corneal changes as result of trichiasis.
- Dermoids—islands of aberrant skin tissue involving either eyelids, conjunctiva, or cornea; may cause blepharospasm and epiphora (see Web Figure 1).
- Atresia and imperforate puncta of lacrimal system, common in dogs—results in tear streak at nasal canthus.
- Congenital KCS—usually unilateral; affected eye appears smaller; thick mucous discharge from red and irritated eye.
- KCSID—therapy-resistant KCS, curly coat and progressive dermatologic signs, including footpad hyperkeratosis that can cause lameness.
- PPMs—remnants of pupillary membrane spanning from iris collarette to another portion of iris, lens, or cornea; may coexist with other defects (see Web Figures 2 and 3).
- Iris cysts—pigmented or nonpigmented spherical structures may float freely in anterior chamber or be attached to posterior iris, ciliary body, or corneal endothelium (see Web Figure 4).
- Congenital glaucoma—rare; buphthalmic eye, often associated with multiple anterior segment changes.
- Pupillary abnormalities—polycoria, acorea, aniridia, or dyscoria.
- Congenital cataracts—primary, inherited, or developmental defect; associated with anomalies of lens, including microphakia, lenticonus or lentiglobus, and coloboma (see Web Figures 5 and 6).
- PHTVL and PHPV—persistence of parts of hyaloid vasculature; developmental aberrations of vitreous, lens, and lens capsule; may show leukocoria as result of retrolental fibrovascular plaques and/or cataracts, or reddish sheen from pupillary area with intralenticular bleeding.
- Retinal dysplasia—effect on retinal structure depends on severity; ranges from focal neuroretinal folds (multifocal defects often along major blood vessels in central tapetal fundus) to geographic dysplasia (abnormal central tapetal fundus area with elevated retina and surrounding hyperpigmentation and scarring) to complete retinal detachment.
- CEA—bilateral area of choroidal hypoplasia temporal to optic nerve head: focal increased visibility of white sclera and scarce, irregularly shaped choroidal blood vessels; visual impairment or blindness can be caused by optic nerve coloboma and retinal detachment.
- MOD—microphthalmia, microcornea, heterochromia irides, pupillary abnormalities, cataract, fundus coloboma, retinal detachment, intraocular hemorrhage.
- Coloboma of posterior segment—primary or in conjunction with CEA or MOD; focal, well-defined tissue depression, typically at 6 o'clock position in optic nerve head in CEA, or in fundus periphery in MOD; may be in other locations of fundus near optic nerve head.
- OSD—heterozygous carriers typically display signs of focal/multifocal retinal dysplasia, whereas homozygous animals display complete phenotype, including skeletal (short-limbed dwarfism) and ocular defects (ranging from retinal dysplasia to retinal detachments; corneal and lens opacities also possible).
- Retinal dystrophy—congenital night blindness, variable severity and progression of day blindness.
- Rod cone dysplasia, early retinal degeneration, photoreceptor dysplasia, and cone rod dystrophy—pupillary abnormalities and visual impairment in first few months of life; disease progression depends on specific disease and breed affected.
- Cone degeneration—apparent day blindness from 8–10 weeks of age; vision in dim light never affected.
- Retinal detachment—often in conjunction with other hereditary ocular diseases; signs depend on extent of detachment and include widely dilated pupils, weak to absent

(CONTINUED) # CONGENITAL OCULAR ANOMALIES

pupillary light reflexes; presence of fundus areas that appear out of focus, vascularized membranous structure (retina) visible within pupillary aperture behind lens, blindness with complete bilateral detachment.
• Optic nerve hypoplasia—avascular, dark, abnormally small, circular optic nerve head, may result in blindness.

CAUSES
• Genetic.
• Spontaneous malformations.
• Infections or inflammation during pregnancy.
• Toxicity during pregnancy.
• Nutritional deficiencies.

RISK FACTORS
Breeding dogs or cats that are homozygous or heterozygous for hereditary disease with recessive inheritance, or affected animals where disease has dominant inheritance.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Infectious and inflammatory processes in adnexa—may mimic and mask congenital abnormalities.
• Cataracts induced at early age may be interpreted as congenital.
• Postinflammatory ophthalmic lesions with anterior or posterior synechia—easily confused with iris to cornea or iris to lens PPMs.
• Tumors of anterior segment may be confused with iris cysts.
• Focal, multifocal, or generalized retinopathy of inflammatory origin—resulting retinal atrophy may appear to be retinal dysplasia or photoreceptor dysplasia.
• Retinal detachment as result of trauma or uveitis in young dogs.
• Optic nerve atrophy due to inflammatory process may be difficult to differentiate from congenital optic nerve hypoplasia.

IMAGING
• Routine ophthalmic ultrasound—use of 10–20 MHz probes for evaluation of intraocular changes in case of opacities that prevent proper ophthalmic examination.
• High-resolution ultrasound—use of 20–50 MHz probes for evaluation and measurement of corneal and anterior chamber structures, e.g., anterior chamber cysts or iridocorneal angle.

DIAGNOSTIC PROCEDURES
• Examination with diffuse and focal illumination, including slit-lamp biomicroscopy—evaluation of adnexal and anterior segment anomalies, including lens and anterior vitreous (following pharmacologic pupil dilation).
• Schirmer tear test—evaluate tear production.
• Tonometry—when glaucoma or uveitis suspected.
• Direct and/or indirect ophthalmoscopy—evaluation of posterior segment anomalies; pharmacologic pupil dilation necessary; difficult to perform in patients with opacities in cornea, anterior chamber, lens, or anterior vitreous.
• Gonioscopy—evaluation of width of and presence of signs of dysgenesis in iridocorneal angle when glaucoma suspected; critical to include examination of unaffected eye.
• Electroretinography (ERG).
• Optical coherence tomography (OCT).
• Referral to ophthalmologist necessary for gonioscopic, ERG, and OCT examinations.

TREATMENT

APPROPRIATE HEALTH CARE
• Patients usually referred to ophthalmologist.
• No treatment for most congenital abnormalities, except symptomatic treatment or surgery.

NURSING CARE
• In KCS—removing discharge and flushing with saline.
• Accommodate handicap of blind animals—leash walking, supervision.

ACTIVITY
Visually impaired or blind animals need adequate exercise.

DIET
Provide diet adequate in vitamins, antioxidants, and omega-3 fatty acids, especially in photoreceptor degenerations.

CLIENT EDUCATION
Discuss visual capacity, possible progression, and sequelae.

SURGICAL CONSIDERATIONS
• Adnexal abnormalities—surgery as soon as possible.
• Congenital KCS—parotid duct transposition.
• Cataract extraction—congenital cataract may be associated with other anomalies, decreasing chances for visual rehabilitation or causing surgical complications; presurgical evaluation should include imaging and ERG.
• Congenital glaucoma—surgical options depend on presence of vision, size of patient/eye, and level of motivation of owners; enucleation or intrascleral prosthesis typical treatments of choice; consider euthanasia if bilateral.
• Barrier retinopexy to prevent occurrence of retinal detachments with large colobomatous or dysplastic lesions of fundus—carries risk of inducing retinal detachment.

MEDICATIONS

DRUG(S) OF CHOICE
• Congenital KCS—frequent application of tear substitutes; antibiotics may be added; cyclosporine ophthalmic ointment q12h.
• Congenital cataracts—if only in nuclear region of lens, mydriatics used to increase visual capability.

FOLLOW-UP

PATIENT MONITORING
• Congenital KCS—repeated monitoring of tear production and status of external eye.
• Congenital cataracts and severe PHTVL and PHPV—regular checkups, usually on 6-month basis; monitor progression.
• Large colobomatous defects of the fundus and geographic retinal dysplasia—regular checkups to monitor possible retinal detachment.

PREVENTION/AVOIDANCE
Restrict breeding of affected animals and of known carriers of hereditary defects; DNA-based tests available for various diseases (see Internet Resources).

POSSIBLE COMPLICATIONS
• In congenital KCS with parotid duct transposition, keratitis and dermatitis may occur due to excessive deposition of minerals from saliva.
• Cataract surgery can result in glaucoma, retinal detachment, and corneal scarring in puppies and kittens; surgery seldom recommended before age 8–12 weeks.

EXPECTED COURSE AND PROGNOSIS
• Most abnormalities affecting adnexa can be corrected in young dogs and cats.
• Prognosis for most anterior segment abnormalities good to fair.
• Prognosis for glaucoma poor.
• For photoreceptor abnormalities prognosis for vision poor, but eyes should remain comfortable.
• For most other abnormalities prognosis depends on severity of condition.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
• Dogs and cats affected with congenital ocular anomalies resulting in blindness and/or pain should not be used for breeding.
• Many congenital ocular anomalies are hereditary and use of affected animals in breeding should be prohibited or severely

CONGENITAL OCULAR ANOMALIES (CONTINUED)

restricted. Breeding advice should be sought from kennel club and breed associations.

ABBREVIATIONS

- CEA = collie eye anomaly.
- ERG = electroretinography.
- KCS = keratoconjunctivitis sicca.
- KCSID = KCS ichthyosiform dermatosis.
- MOD = merle ocular dysgenesis.
- OSD = oculo-skeletal dysplasia.
- PHPV = persistent hyperplastic primary vitreous.
- PHTVL = persistent hyperplastic tunica vasculosa lentis.
- PPM = persistent pupillary membrane.

CONGENITAL SPINAL AND VERTEBRAL MALFORMATIONS

BASICS

DEFINITION
Anomalous development of spinal structures, which are apparent at birth or within the first weeks of life.

PATHOPHYSIOLOGY
- Malformation of the occipital bones, atlas, and axis; malformation of the odontoid process; occipitoatlantoaxial malformation; and occipital dysplasia—may cause atlantoaxial subluxation with secondary compression and trauma to the first segments of the cervical spinal cord.
- Other embryonic or developmental anomalies of the vertebrae such as hemivertebra, transitional vertebra, block vertebra, and butterfly vertebra—these defects cause deformity and instability of the vertebral canal and, on rare occasions, compression of the associated spinal cord or nerve roots.
- Sacrococcygeal dysgenesis—characterized by absence or partial development of the sacrocaudal spinal cord segments; often associated with additional malformations (e.g., spina bifida).
- Spina bifida—caused by failure of fusion of the vertebral arches; may be associated with protrusion of the spinal cord and meninges; other malformations often linked to this syndrome include spinal dysplasia, dysraphism, syringomyelia/hydromyelia, and myelodysplasia.
- Congenital spinal stenosis—can occur when vertebral malformations cause segmental or diffuse narrowing of the spinal cord; inborn errors in skeletal growth, hypertrophy of ligamentum flavum, and bony proliferation may also contribute to the stenosis.

SYSTEMS AFFECTED
Nervous—spinal cord; spinal nerve roots; and vertebral column.

GENETICS
- A genetic background, with unknown mode of inheritance, is suspected in most congenital spinal diseases.
- Sacrococcygeal dysgenesis—autosomal dominant.
- Thoracic hemivertebra of German shorthaired pointers—autosomal recessive.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species and Breed Predilections
- Malformation of the occipital bones, atlas, and axis—most common in small-breed dogs.
- Hemivertebra, transitional vertebra, block vertebra, and butterfly vertebra—most common in brachycephalic, "screw-tailed" breeds (e.g., French and English bulldog, pug, Boston terrier).
- Sacrococcygeal dysgenesis—Manx cat.
- Spina bifida—bulldog, Manx cat, and other screw-tailed breeds.
- Spinal dysraphism—Weimaraner.
- Congenital spinal stenosis—Doberman pinscher; chondrodystrophic breeds.

Mean Age and Range
- Often silent, vertebral malformation may cause clinical disease during the rapid growth of the animal (e.g., 5–9 months of age).
- Spinal cord anomalies cause clinical disease from birth on.

SIGNS
- Distortion of the spinal column—lordosis; kyphosis; and scoliosis in cases of vertebral malformations.
- Ataxia and paresis associated with spinal cord compression and trauma.
- Signs vary with spinal cord segment(s) involved.

CAUSES
Breed-related inherited defects are suspected for most congenital spinal abnormalities, although interactions between several genes and environmental factors (e.g., teratogenic compounds, nutritional deficiencies) are likely involved and would explain some of these complex pathologic changes.

RISK FACTORS
- Teratogenic compounds.
- Toxins.
- Nutritional deficiencies.
- Stress.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Metabolic disease (e.g., storage diseases).
- Nutritional disease (e.g., hypovitaminosis and hypervitaminosis A, thiamine deficiency).
- Early-onset inflammatory or infectious processes (e.g., viral, protozoal, and rarely bacterial).
- Toxin exposure (e.g., lead, organophosphates, hexachlorophene, organochlorine).
- Trauma.

CBC/BIOCHEMISTRY/URINALYSIS
Usually within normal limits.

OTHER LABORATORY TESTS
N/A

IMAGING
- Survey radiography—to reveal vertebral malformation(s) and deviation of the spinal column.
- Myelography—to determine the level(s) of spinal cord compression; flexed and extended views may cause neurologic deterioration if instability present.
- CT myelography and 3D reconstructed imaging—to characterize bony abnormalities and associated spinal cord compression.
- MRI—sensitive modality to visualize abnormalities of spinal cord parenchyma, cauda equina, nerve roots, and surrounding soft tissues.

DIAGNOSTIC PROCEDURES
Cerebrospinal fluid analysis to rule out infectious/inflammatory conditions.

PATHOLOGIC FINDINGS
- Multiple congenital malformations—often present concomitantly; pathologic changes reflect several disease processes.
- Acute compression of the spinal cord secondary to congenital malformation(s)—may result in spinal cord ischemia, hemorrhage, ballooning of the myelin sheath at the point of compression or trauma, and axonal swelling or loss; in chronic spinal cord compression, myelin degeneration, astrocytosis, and fibrosis are more prominent; at spinal sites, cranial and caudal to the primary injury, Wallerian degeneration can be observed in ascending or descending pathways, respectively.
- Chronic changes—may result from vertebral malformations secondary to bony proliferation, thickening of the joint capsule, hypertrophy of articular processes, and thickening of the ligaments surrounding the spinal cord.
- Atlantoaxial subluxation—congenital aplasia or hypoplasia of the odontoid process and surrounding ligaments.
- Occipitoatlantoaxial malformations—fusion of the atlas to the occipital bone (cats) and dorsal angulation of the dens (dogs).
- Occipital dysplasia—anomaly of the foramen magnum in which the occipital bone is incompletely formed and fibrous tissue membrane covers the caudal cerebellum.
- Sacrococcygeal dysgenesis—caudal vertebral aplasia or hypoplasia.
- Spina bifida—incomplete fusion of the dorsal vertebral arches where the meninges or spinal cord can protrude; most commonly seen in the caudal lumbar or sacral area; a dimple can be observed in a few cases secondary to the lack of separation between the neuroectoderm and other ectodermal structures, leaving a small attachment between the spinal cord or meninges and the skin; often seen with myelodysplasia, central canal defects, syringomyelia or hydromyelia, and abnormal gray-matter differentiation.
- Spinal stenosis—pathologic changes observed within the spinal cord are most commonly chronic and are caused by focal or diffuse narrowing of the spinal canal.

CONGENITAL SPINAL AND VERTEBRAL MALFORMATIONS (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE
- Depends on severity of neurologic deficits.
- Outpatient—if animal is ambulatory.
- Inpatient—if animal is nonambulatory or requires emergency surgical treatment (e.g., for atlantoaxial subluxation).

NURSING CARE
- Restricted activity combined with physical therapy—may help neurologically disabled patients in the postoperative period; a cart may be necessary for severely affected patients.
- Management of urination—essential for cases in which disorders of micturition accompany the spinal injury.

ACTIVITY
Restricted, especially if vertebral subluxation is present.

DIET
Maintaining a lean bodyweight limits stress on the spinal column.

CLIENT EDUCATION
- Many congenital vertebral malformations are clinically silent.
- Perform a thorough workup when a congenial malformation results in neurologic abnormalities.
- Heritability is suspected; avoid breeding.
- Many neurologically affected dogs and cats left untreated are euthanized.
- Early surgical intervention often necessary to alleviate compression of the spinal cord and prevent further damage.

SURGICAL CONSIDERATIONS
- In general, surgical decompression is required when congenital malformation(s) cause narrowing of the spinal canal and compression of the spinal cord. In cases of chronic or diffuse spinal cord compression, improvement following surgery is minimal.
- Atlantoaxial subluxation—surgical ventral decompression combined with stabilization of the atlantoaxial joint with pins or screws is the treatment of choice.
- Spina bifida—meningoceles can be closed surgically to prevent leakage of cerebrospinal fluid and infections; surgery usually not attempted when the spinal cord parenchyma is involved.

MEDICATIONS

DRUG(S) OF CHOICE
Corticosteroids may be used in some cases, with variable results.

CONTRAINDICATIONS
Avoid steroids with concomitant infections.

PRECAUTIONS
Steroids may cause ulcerations of the gastrointestinal tract and inhibit bone growth.

POSSIBLE INTERACTIONS
Steroids reduce immune response following vaccination.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
- Frequent neurologic examinations—to monitor the progression of clinical signs in developing animals (e.g., every 4–6 weeks).
- Neuroimaging—repeat as needed.

PREVENTION/AVOIDANCE
Avoid breeding affected animals.

POSSIBLE COMPLICATIONS
- Depend on the type and severity of neurologic signs. In cases of subluxation of the atlantoaxial joint, acute death may occur.
- Acute paralysis can also be seen with vertebral subluxation, with further trauma and spinal cord compression.
- Implant failure may be observed after surgical decompression/stabilization.

EXPECTED COURSE AND PROGNOSIS
- Prognosis varies depending on the type of malformation, degree of spinal cord compression or injury, and surgical decompression or stabilization techniques.
- Vertebral malformation without compression of the spinal cord—prognosis is good.
- Atlantoaxial subluxation following surgical decompression or stabilization—prognosis is fair to good.
- Spinal cord compression treated surgically—prognosis is fair.
- Spina bifida associated with spinal cord malformation, chronic neurologic disease despite surgical treatment, and lower motor neuron incontinence—prognosis is poor.
- Medical treatment usually is insufficient to alleviate moderate to severe neurologic signs caused by spinal cord compression secondary to congenital vertebral malformation(s).

Client Education Handout available online

CONGESTIVE HEART FAILURE, LEFT-SIDED

BASICS

DEFINITION
Failure of the left side of the heart to advance blood at a sufficient rate to meet the metabolic needs of the patient or to prevent blood from pooling within the pulmonary venous circulation.

PATHOPHYSIOLOGY
• Low cardiac output causes lethargy, exercise intolerance, syncope, and prerenal azotemia. • High hydrostatic pulmonary venous pressure causes leakage of fluid from pulmonary venous circulation into pulmonary interstitium and alveoli; when fluid leakage exceeds ability of lymphatics to drain affected areas, pulmonary edema develops.

SYSTEMS AFFECTED
• All systems can be affected by poor perfusion. • Respiratory—increased rate and effort because of elevated pulmonary venous pressures/edema. • Cardiovascular.

GENETICS
Some congenital heart defects, cardiomyopathies, and valvular heart disease have genetic basis in some breeds.

INCIDENCE/PREVALENCE
Common

GEOGRAPHIC DISTRIBUTION
Seen everywhere; prevalence of causes varies with location.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Varies with cause.

Mean Age and Range
Varies with cause.

Predominant Sex
Varies with cause.

SIGNS

General Comments
Signs vary with underlying cause and species.

Historical Findings
• Weakness, lethargy, exercise intolerance. • Coughing (dogs with large left atria, concurrent tracheobronchial disease, or such severe edema that large airways affected) and dyspnea (increased respiratory rate and effort); respiratory signs often worsen at night and may require assuming standing, sternal, or "elbows abducted" position (orthopnea). • Cats rarely cough from heart failure; coughing should prompt search for primary airway disease.

Physical Examination Findings
• Tachypnea and dyspnea. • Coughing, often soft in conjunction with tachypnea (dogs). • Pulmonary crackles and wheezes. • Pale/gray/cyanotic mucous membranes. • Prolonged capillary refill time. • Possible

CAUSES

Pump (Muscle) Failure of Left Ventricle
• Dilated cardiomyopathy (DCM)/diet-induced DCM. • Trypanosomiasis (rare). • Doxorubicin cardiotoxicity (dogs). • Hypothyroidism (rare). • Hyperthyroidism (rarely causes pump failure; more commonly causes high output failure). • Tachycardia-induced cardiomyopathy (caused by persistent pathologic supraventricular or ventricular tachyarrhythmia).

Pressure Overload of Left Heart
• Systemic hypertension (uncommon cause of heart failure in animals). • Subaortic stenosis. • Aortic coarctation (rare; Airedale predisposed). • Left ventricular tumors (rare).

Volume Overload of Left Heart
• Degenerative mitral valve disease (dogs). • Mitral valve dysplasia (cats and dogs). • Patent ductus arteriosus (dogs). • Ventricular septal defect, especially if complicated by aortic valve insufficiency. • Aortic valve insufficiency secondary to endocarditis (dogs). • Chronic, severe anemia. • Inadvertent high-volume fluid administration. • Steroid administration (cats, often with previously asymptomatic underlying hypertrophic cardiomyopathy [HCM]).

Impediment to Filling of Left Ventricle
• Restrictive cardiomyopathy (rare in dogs, more common in cats). • Pulmonary vein stenosis (rare). • HCM. • Left atrial masses (e.g., tumor or thrombus). • Mitral stenosis (rare). • Cor triatriatum sinister (cats, rare).

Rhythm Disturbances
• Bradyarrhythmia (high-grade atrioventricular block). • Tachyarrhythmia (e.g., atrial fibrillation, sustained supraventricular tachycardia, ventricular tachycardia).

RISK FACTORS
Conditions causing chronic high cardiac output (e.g., hyperthyroidism and anemia).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Must differentiate from other causes of coughing, dyspnea, and weakness.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC usually normal; maybe stress leukogram. • Mild to moderate liver enzyme elevation; bilirubin generally normal. • Prerenal azotemia in some animals.

OTHER LABORATORY TESTS
• Thyroid disorders may be detected. • Serum NT-proBNP and cardiac troponin I concentrations higher in animals with left-sided congestive heart failure (L-CHF) than in normal animals.

IMAGING

Radiography
• Left heart and pulmonary veins enlarged. involving right caudal lung lobe in acute edema of dog, but may be patchy, especially in cats; acute pulmonary edema may begin in right caudal lung lobe.

Echocardiography
• Findings vary markedly with cause, but left atrial enlargement relatively consistent finding in cardiogenic pulmonary edema. • Diagnostic test of choice for documenting congenital defects, cardiac masses, and pericardial effusion.

DIAGNOSTIC PROCEDURES

ECG
• Atrial or ventricular arrhythmias. • Evidence of left cardiomegaly (e.g., wide P waves, tall and wide QRS complexes, and left axis orientation). • May be normal.

PATHOLOGIC FINDINGS
Cardiac findings vary with disease.

TREATMENT

APPROPRIATE HEALTH CARE
• Usually treat as outpatient unless dyspneic or severely hypotensive. • Identify and correct underlying cause whenever possible. • Minimize handling of critically dyspneic animals—stress can kill!

NURSING CARE
Oxygen supplementation and postural support in dyspneic patients.

ACTIVITY
Restrict activity when dyspneic or tachypneic.

DIET
Initiate moderately sodium-restricted diet with adequate protein and calories. Severe sodium restriction indicated with advanced disease.

CLIENT EDUCATION
With few exceptions (e.g., animals with thyroid disorders, anemia, arrhythmias, nutritionally responsive heart disease, congenital heart disease), L-CHF is not curable.

SURGICAL CONSIDERATIONS
• Surgical intervention, coil embolization, Amplatz occluder placement, or balloon valvuloplasty may benefit selected patients with some forms of congenital and acquired valvular heart disease; response to these interventions varies. • Pericardiocentesis in animals with pericardial effusion.

MEDICATIONS

DRUG(S) OF CHOICE

Diuretics
• Furosemide (1–2 mg/kg q8–24h) or other loop diuretic is initial diuretic of choice; diuretics indicated to reduce preload and remove pulmonary edema; critically dyspneic animals

CONGESTIVE HEART FAILURE, LEFT-SIDED (CONTINUED)

stabilize; dose can be repeated in 1h if animal still severely dyspneic; IV bolus of 0.66 mg/kg followed by CRI of 0.66–1 mg/kg/h for 1–4h causes greater diuresis than equal dose divided into two IV boluses given 4h apart; once edema resolves, taper to lowest effective dose.
• Spironolactone (0.5–2 mg/kg PO q12–24h) increases survival in humans with CHF and is in clinical trials in dogs; use in combination with furosemide. • Thiazide diuretics can be added to furosemide and spironolactone in refractory heart failure cases. • Torsemide (0.2–0.8 mg/kg q24h) may be useful as substitute for furosemide in animals requiring daily furosemide dosing in excess of 12 mg/kg, and it may be more effective than furosemide at delaying death due to cardiac disease in dogs with CHF secondary to degenerative valve disease.

Angiotensin-Converting Enzyme ACE) Inhibitors

• ACE inhibitors such as enalapril (0.5 mg/kg q12–24h) or benazepril (0.25–0.5 mg/kg q12–24h) indicated in most animals with L-CHF. • ACE inhibitors improve survival and quality of life in dogs with L-CHF secondary to degenerative valve disease and DCM.

Positive Inotropes

• Pimobendan (0.25–0.3 mg/kg PO q12h) is a calcium channel sensitizer that dilates arteries and increases myocardial contractility; first-line agent in treating DCM or CHF due to degenerative valve disease efficacy in cats with CHF is not known, but possibly beneficial. • Dobutamine (dogs: 2.5–10 µg/kg/min; cats: 0.5–5 µg/kg/min) is a potent positive inotropic agent that may provide valuable short-term support of a heart failure patient with poor cardiac contractility. • Positive inotropes in general are potentially arrhythmogenic—monitor carefully.

Venodilators

• Nitroglycerin ointment (one-fourth inch/5 kg q6–8h) causes venodilation, lowering left atrial filling pressures. • Used for acute stabilization of patients with severe pulmonary edema and dyspnea, but uncertain benefit.

Antiarrhythmic Agents

Treat arrhythmias if clinically indicated.

CONTRAINDICATIONS

Avoid vasodilators in patients with pericardial effusion or fixed outflow obstruction.

PRECAUTIONS

• ACE inhibitors and arterial dilators must be used with caution in patients with possible outflow obstruction. • Pulmonary hypertension, hypothyroidism, and hypoxia increase risk for digoxin toxicity; hyperthyroidism diminishes effects of digoxin. • ACE inhibitors and digoxin—use cautiously in patients with renal disease. • Dobutamine—use cautiously in cats. • Spironolactone—may cause facial pruritis in cats.

POSSIBLE INTERACTIONS

• Combination of high-dose diuretics and ACE inhibitors may cause azotemia, especially in animals with severe sodium restriction. • Combination diuretic therapy adds to risk of dehydration and electrolyte disturbances. • Combination vasodilator therapy predisposes animal to hypotension.

ALTERNATIVE DRUG(S)

Arterial Dilators

• Hydralazine (0.5–2 mg/kg PO q12h; 0.5 mg/kg PO to start when added to ACE inhibitor) or amlodipine (0.05–0.2 mg/kg PO q24h) can be substituted for ACE inhibitor in patients that do not tolerate the drug or have advanced renal failure; monitor for hypotension and tachycardia; can be cautiously added to ACE inhibitor in animals with refractory L-CHF. • Nitroprusside (1–10 µg/kg/min) is potent arterial dilator usually reserved for short-term support of patients with life-threatening edema.

Digoxin

• Digoxin (dogs: 0.22 mg/m^2 q12h; cats: 0.01 mg/kg q48h) is used in animals with atrial fibrillation and myocardial failure (e.g., DCM); commonly used in combination with diltiazem to control rate of atrial fibrillation. • Digoxin is also indicated to treat dogs with refractory heart failure from either myocardial failure or volume loads; however, its use as a primary agent in myocardial failure has been replaced by pimobendan.

Calcium Channel Blockers

Diltiazem (0.5–1.5 mg/kg PO q8h) is frequently used in L-CHF patients for rate control in animals with supraventricular arrhythmias.

Beta Blockers

• Atenolol and metoprolol are sometimes used for rate control in animals with supraventricular tachycardia, hypertrophic cardiomyopathy, and hyperthyroidism. • Used alone or with a class 1 antiarrhythmic drug for control of ventricular arrhythmias; these drugs depress contractility (negative inotropes), so use cautiously in patients with myocardial failure or active signs of CHF. • On basis of human studies, may enhance survival in animals with idiopathic DCM; treatment is best initiated under guidance of a cardiologist, starting with very low dosage and gradually increasing; carvedilol is sometimes used for this purpose, starting at 0.1 mg/kg q24h and titrating to 0.5 mg/kg q12h.

Nutritional Supplements

• Potassium and magnesium supplementation if deficiency is documented; use potassium supplements cautiously in animals receiving ACE inhibitor or spironolactone. • Taurine supplementation in cats with DCM and dogs with DCM and taurine deficiency (e.g., American cocker spaniels) • L-carnitine supplementation may help some dogs with DCM. • Coenzyme Q_{10} is of potential value based on results in humans with DCM. • Ensure animal receiving a nutritionally balanced diet (see Cardiomyopathy, Nutritional).

FOLLOW-UP

PATIENT MONITORING

• Monitor resting respiratory rate and effort, appetite, renal status, electrolytes, hydration, heart rate, bodyweight. • If azotemia develops, reduce diuretic dose; if azotemia persists and animal is also on ACE inhibitor, reduce or discontinue ACE inhibitor; use digoxin with caution if azotemic. • Monitor ECG if arrhythmias suspected. • Check digoxin concentration (0.5–1.5 ng/mL, 8–10 hours post dose).

PREVENTION/AVOIDANCE

• Minimize stress, exercise, and sodium intake in patients with heart disease.
• Pimobendan delays onset of CHF in Doberman pinschers, and in dogs with hemodynamically significant myxomatous mitral valve regurgitation; prescribing an ACE inhibitor with pimobendan early in course of heart disease in patients with DCM may slow progression of heart disease and delay onset of CHF; role of ACE inhibitors in asymptomatic animals with mitral valve disease remains controversial.

POSSIBLE COMPLICATIONS

• Syncope. • Aortic thromboembolism (cats).
• Arrhythmias. • Electrolyte imbalances.
• Digoxin toxicity. • Azotemia and renal failure.

EXPECTED COURSE AND PROGNOSIS

Prognosis varies with underlying cause; cats and dogs that survive initial episode of pulmonary edema and can be reliably medicated often survive months to more than a year with good quality of life. Animals with reversible causes of L-CHF may recover to normal lives.

MISCELLANEOUS

AGE-RELATED FACTORS

• Congenital causes seen in young animals.
• Degenerative heart conditions and neoplasia generally seen in old animals.

SEE ALSO

Pulmonary Edema, Noncardiogenic.

ABBREVIATIONS

• ACE = angiotensin-converting enzyme.
• DCM = dilated cardiomyopathy.
• HCM = hypertrophic cardiomyopathy.
• L-CHF = left-sided congestive heart failure.

Authors Francis W.K. Smith, Jr. and Bruce W. Keene
Consulting Editor Michael Aherne

Client Education Handout available online

CONGESTIVE HEART FAILURE, RIGHT-SIDED

BASICS

DEFINITION
Failure of the right side of the heart to advance blood at a sufficient rate to meet the metabolic needs of the patient or to prevent blood from pooling within the systemic venous circulation.

PATHOPHYSIOLOGY
• High hydrostatic pressure leads to leakage of fluid from venous circulation into the pleural and peritoneal space and potentially into the pericardium and interstitium of peripheral tissue. • When fluid leakage exceeds ability of lymphatics to drain the affected areas, pleural effusion, ascites, pericardial effusion, and peripheral edema develop.

SYSTEMS AFFECTED
All systems can be affected by either poor delivery of blood or the effects of passive congestion from backup of venous blood.

GENETICS
• Some congenital cardiac defects have a genetic basis in certain breeds. • Arrhythmogenic right ventricular cardiomyopathy (ARVC) appears to have a genetic basis in boxers and possibly some cats.

INCIDENCE/PREVALENCE
Common

GEOGRAPHIC DISTRIBUTION
Syndrome seen everywhere; prevalence of various causes varies with location.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Vary with cause.

Mean Age and Range
Vary with cause.

Predominant Sex
Varies with cause.

SIGNS

General Comments
• Signs vary with underlying cause and between species. • Pleural effusion without ascites and hepatomegaly is rare in dogs with right-sided congestive heart failure (R-CHF). • Ascites without pleural effusion is rare in cats with R-CHF. • Small-volume pericardial effusion without tamponade is relatively common in cats with R-CHF. • Interstitial peripheral edema is a rare manifestation of R-CHF in both species.

Historical Findings
• Weakness. • Lethargy. • Exercise intolerance. • Abdominal distension. • Dyspnea, tachypnea.

Physical Examination Findings
• Jugular venous distention. • Hepatojugular reflux. • Jugular pulse in some animals. • Hepatomegaly. • Ascites common in dogs and rare in cats with R-CHF. • Possible regurgitant murmur in tricuspid valve region or ejection murmur at left heart base (pulmonic stenosis). • Muffled heart sounds if animal has pleural or pericardial effusion. • Weak femoral pulses. • Rapid, shallow respiration if animal has pleural effusion or severe ascites.• Peripheral edema (infrequent).

CAUSES

Pump (Myocardial) Failure of Right Ventricle
• Idiopathic dilated cardiomyopathy (DCM). • ARVC. • Hypertrophic cardiomyopathy (cats). • Restrictive cardiomyopathy (cats). • Trypanosomiasis. • Doxorubicin cardiotoxicity. • Chronic hyperthyroidism.

Volume Overload of Right Ventricle
• Chronic atrioventricular (AV) valve (mitral ± tricuspid) insufficiency due to myxomatous valvular degeneration. • Tricuspid valve dysplasia. • Large atrial septal defect.

Pressure Overload of Right Ventricle
• Heartworm disease. • Chronic obstructive pulmonary disease with pulmonary hypertension. • Pulmonary thromboembolism. • Pulmonic stenosis. • Tetralogy of Fallot. • Right ventricular tumors. • Heart base tumors (occasionally, compression of the pulmonary artery). • Primary pulmonary hypertension.

Impediment to Right Ventricular Filling
• Pericardial effusion (tamponade). • Constrictive/restrictive pericarditis. • Right atrial or caval masses. • Tricuspid stenosis. • Cor triatriatum dexter.

Rhythm Disturbances
• Bradycardia, generally complete AV block. • Tachyarrhythmias, generally sustained supraventricular tachycardia.

RISK FACTORS
• No heartworm prophylaxis. • Offspring of animal with right-sided congenital cardiac defect. • Conditions that augment demand for cardiac output (e.g., hyperthyroidism, anemia, pregnancy).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Must differentiate from other causes of pleural effusion and ascites; generally requires complete diagnostic workup including CBC, biochemistry profile, heartworm test, thoraco- or abdominocentesis with fluid analysis and cytology, and sometimes thoracic and abdominal ultrasound. • Animals with ascites or pleural effusion due to heart failure should have jugular venous distension.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC usually normal; animals with heartworm disease may have eosinophilia. • Mild to moderately high alanine aminotransferase, aspartate aminotransferase, and alkaline phosphatase due to passive liver congestion; bilirubin generally normal. • Prerenal azotemia in some animals.

OTHER LABORATORY TESTS
• Heartworm test may be positive. • NT-proBNP concentrations higher in animals with cardiac causes of fluid accumulation.

IMAGING

Thoracic Radiography
• Right cardiomegaly in some animals. • Dilated caudal vena cava (diameter greater than the length of the vertebra directly above the heart). • Pleural effusion (especially cats). • Hepatosplenomegaly and possible ascites (especially dogs).

Echocardiography
• Findings vary with underlying cause; especially useful for documenting congenital defect, cardiac mass, and pericardial effusion. • Abdominal ultrasound reveals hepatomegaly with hepatic vein dilation, flow reversal in the hepatic veins (Doppler), and possibly ascites.

DIAGNOSTIC PROCEDURES

ECG Findings
• Small (<1 mV) QRS complexes in all frontal axis leads if pericardial or pleural effusion. • Electrical alternans or elevated ST segment with pericardial effusion. • Evidence of right cardiomegaly (e.g., tall [>0.4 mV] P waves in lead II, deep S waves in leads I, II, aVF, and right axis deviation). • Atrial or ventricular arrhythmias. • ECG may be normal.

Abdominocentesis
Analysis of ascitic fluid in patients with R-CHF generally reveals modified transudate with total protein >2.5 mg/dL.

Thoracentesis
• Cats with pleural effusion associated with R-CHF may have transudate, modified transudate, or chylous effusion. • Dogs with pleural effusion and R-CHF may have transudate or modified transudate.

Central Venous Pressure
Central venous pressure is high (>9 cmH_2O) or rises dramatically to that level and remains elevated for more than 1h following a fluid bolus (e.g., 5–10 mL/kg IV).

PATHOLOGIC FINDINGS
• Cardiac findings vary with disease. • Hepatomegaly in animals with centrolobular necrosis (chronic condition).

CONGESTIVE HEART FAILURE, RIGHT-SIDED (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE
Most animals treated as outpatients unless dyspneic or collapsed (e.g., significant pleural or pericardial effusion).

NURSING CARE
Thoracentesis and abdominocentesis may be required periodically for patients no longer responsive to medical management or those with severe dyspnea due to pleural effusion or ascites.

ACTIVITY
Restrict activity.

DIET
Restrict sodium moderately; severe sodium restriction indicated for animals with advanced disease.

CLIENT EDUCATION
• With few exceptions (e.g., in heartworm disease, arrhythmias, hyperthyroidism, and idiopathic pericardial effusion), R-CHF is not curable. • Most patients improve with initial treatment but often have recurrent failure.

SURGICAL CONSIDERATIONS
• Surgical intervention or balloon valvuloplasty is indicated to treat certain congenital defects such as pulmonic stenosis or cor triatriatum dexter, and Amplatz occluder placement for morphologically appropriate atrial septal defects. • Pericardiocentesis or pericardectomy for pericardial effusion. • Removal of heartworms from the heart via the jugular vein in dogs with caval syndrome.

MEDICATIONS

DRUG(S) OF CHOICE
Drugs should be administered only after a definitive diagnosis is made.

Diuretics
• Furosemide (1–2 mg/kg q8–24h) or another loop diuretic is the initial diuretic of choice; diuretics are indicated to remove excess fluid accumulation. • Torsemide (0.2–0.8 mg/kg q24h) may be a useful substitute for furosemide in animals requiring a daily furosemide dose in excess of 12 mg/kg. • Spironolactone (2 mg/kg PO q12–24h) increases survival in humans with heart failure; use in combination with furosemide.

Vasodilators
• Angiotensin-converting enzyme (ACE) inhibitors such as enalapril (0.5 mg/kg q12–24h) or benazepril (0.25–0.5 mg/kg q24h) are helpful when CHF is secondary to DCM or chronic AV valve insufficiency. • Sildenafil (0.5–1 mg/kg PO q12h up to 2–3 mg/kg q8h) may be beneficial for pulmonary hypertension.

Pimobendan
• Calcium sensitizer that acts as an inodilator, causing arterial vasodilation and increasing myocardial contractility. • Especially useful in myocardial failure. • Dose—0.25–0.3 mg/kg PO q12h.

Digoxin
• Digoxin (dogs: 0.22 mg/m^2 q12h; cats: 0.01 mg/kg q48 h) is used in animals with myocardial failure (e.g., DCM) and atrial fibrillation. • Digoxin indicated in animals with refractory CHF that have supraventricular arrhythmias.

CONTRAINDICATIONS
• Avoid diuretics in patients with pericardial effusion/tamponade. • Avoid vasodilators in patients with pericardial effusion or fixed outflow obstructions.

PRECAUTIONS
• ACE inhibitors and arterial dilators must be used with caution in patients with possible outflow obstructions. • Pulmonary hypertension, hypothyroidism, and hypoxia increase risk for digoxin toxicity; hyperthyroidism diminishes effects of digoxin. • ACE inhibitors and digoxin—use cautiously with renal disease. • Dobutamine—use cautiously in cats. • Spironolactone—may cause facial pruritis in cats.

POSSIBLE INTERACTIONS
• Combination of high-dose diuretics and ACE inhibitors may alter renal perfusion and cause azotemia. • Combination diuretic therapy promotes risk of dehydration and electrolyte disturbances.

ALTERNATIVE DRUG(S)
• Patients unresponsive to furosemide, spironolactone, vasodilator, pimobendan, and digoxin (if indicated) may benefit from triple diuretic therapy by adding a thiazide diuretic, or substitution of torsemide for furosemide, generally at 0.1–0.2 mg of torsemide for each 1 mg of furosemide previously administered. • Potassium and magnesium supplementation if deficiency documented; use potassium supplements cautiously in animals receiving ACE inhibitors or spironolactone. • Treat arrhythmias if clinically indicated. • Taurine supplementation in cats with DCM and dogs with DCM and taurine deficiency. • Carnitine supplementation may help some dogs with DCM (e.g., cocker spaniels and boxers).

FOLLOW-UP

PATIENT MONITORING
• Monitor renal status, electrolytes, hydration, respiratory rate and effort, bodyweight, and abdominal girth (dogs). • If azotemia develops, reduce diuretic dosage; if azotemia persists and the animal is also on an ACE inhibitor, reduce or discontinue this drug; if azotemia develops, reduce digoxin dosage to avoid toxicity. • Monitor ECG periodically to detect arrhythmias. • Monitor digoxin concentrations—normal value 0.5–1.5 ng/mL for serum sample obtained 8–10h after dose is administered.

POSSIBLE COMPLICATIONS
• Pulmonary thromboembolism. • Arrhythmias. • Electrolyte imbalances. • Digoxin toxicity. • Azotemia and renal failure.

EXPECTED COURSE AND PROGNOSIS
Prognosis varies with underlying cause.

MISCELLANEOUS

AGE-RELATED FACTORS
• Congenital causes seen in young animals. • Degenerative heart conditions and neoplasia generally seen in old animals.

SEE ALSO
• Ascites.
• Chylothorax.
• Pleural Effusion.

ABBREVIATIONS
• ACE = angiotensin-converting enzyme.
• ARVC = arrhythmogenic right ventricular cardiomyopathy.
• AV = atrioventricular.
• DCM = dilated cardiomyopathy.
• R-CHF = right-sided congestive heart failure.

CONJUNCTIVITIS—CATS

BASICS

DEFINITION
Inflammation of the conjunctiva, the vascularized mucous membrane that covers the anterior sclera (bulbar conjunctiva), lines the eyelids (palpebral conjunctiva), and lines the third eyelid.

PATHOPHYSIOLOGY
May be primary or secondary to adnexal or ocular disease.

SYSTEMS AFFECTED
Ophthalmic

GENETICS
N/A

INCIDENCE/PREVALENCE
Common

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Cat

Breed Predilections
Infectious—purebred cats may be predisposed.

Mean Age and Range
Infectious—commonly affects young animals.

Predominant Sex
N/A

SIGNS
• Blepharospasm. • Conjunctival hyperemia. • Ocular discharge—serous, mucoid, or mucopurulent. • Chemosis. • Conjunctival follicles. • Upper respiratory infection—possible with infectious etiologies.

CAUSES

Viral
• Feline herpesvirus (FHV)—most common infectious cause; only one that leads to corneal changes (e.g., dendritic or geographic ulcers). • Calicivirus—may cause conjunctival ulcerations.

Bacterial
• *Chlamydophila felis*—chemosis is common clinical sign. • *Mycoplasma* spp.—may be overgrowth of normal flora. • Conjunctivitis neonatorum—accumulation of exudates under closed eyelids prior to natural opening; bacterial or viral component.

Immune-Mediated
• Eosinophilic. • Lipogranulomatous. • Allergic. • Related to systemic immune-mediated disease.

Trauma or Environmental Causes
• Conjunctival foreign body. • Irritation from dust, smoke, chemicals, or ophthalmic medications.

Secondary to Adnexal Disease
• May develop keratoconjunctivitis sicca (KCS) as a result of scarring. • Eyelid diseases (e.g., entropion, trichiasis, distichia, or eyelid agenesis)—cause frictional irritation or exposure. • Dacryocystitis or nasolacrimal system outflow obstruction.

Referred Inflammation from Other Ocular or Periocular Diseases
• Ulcerative keratitis. • Corneal sequestrum. • Anterior uveitis. • Glaucoma. • Orbital disease. • Pyoderma.

RISK FACTORS
Stress or immune system compromise (FHV).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Must distinguish primary conjunctivitis from secondary conjunctival hyperemia. • Thorough ophthalmic exam rules out other diseases (e.g., ulcers, uveitis, glaucoma, orbital disease); assess pupil size and symmetry, look for aqueous flare, perform intraocular pressure testing and fluorescein staining. • Deeper, darker, more linear and immobile blood vessel injection indicates episcleral vasculature congested due to intraocular disease. • Conjunctival mass biopsy will identify neoplasia (lymphoma and squamous cell carcinoma most common).

CBC/BIOCHEMISTRY/URINALYSIS
Normal, except with systemic disease.

OTHER LABORATORY TESTS
Infectious—serologic testing for feline leukemia virus (FeLV) and feline immunodeficiency virus (FIV).

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Thorough adnexal examination—rule out eyelid abnormalities and foreign bodies under eyelids or third eyelid. • Complete ophthalmic examination—rule out other ocular disease (e.g., uveitis, glaucoma). • Fluorescein stain—assess for corneal ulceration or dendritic lesions (FHV) and observe nares for stain passage to indicate nasolacrimal system patency. • Nasolacrimal flush—considered to rule out dacryocystitis or nasolacrimal system obstruction. • Schirmer tear test—measures aqueous tears to diagnose or rule out KCS; performed before anything is placed in the eye. • Conjunctival cytology—rarely reveals cause; eosinophils with eosinophilic conjunctivitis; degenerate neutrophils and intracytoplasmic bacteria indicate bacterial infection; intracytoplasmic inclusion bodies indicate chlamydial or mycoplasmal infection; rarely see intranuclear FHV inclusions.
• Conjunctival biopsy—"snip biopsy" may be useful with mass lesions and immune-mediated disease or chronic disease. • PCR testing for chlamydia or FHV. • Virus isolation or immunofluorescence antibody (IFA) testing for FHV; false-positive result if fluorescein staining is done before IFA testing.
• Serologic test for FHV antibodies—not useful (widespread exposure, vaccination).

PATHOLOGIC FINDINGS
• Biopsy—signs of inflammation, possible infectious agents. • Histopathology of mass lesions may reveal neoplasia (e.g., squamous cell carcinoma and lymphoma).

TREATMENT

APPROPRIATE HEALTH CARE
• Primary—often outpatient. • Secondary to other diseases (ulcerative keratitis, uveitis, glaucoma)—may need hospitalization to address severe underlying ophthalmic issue.

NURSING CARE
• Irritant-induced conjunctivitis—flush ocular surfaces and remove foreign body if observed.
• Topical hyaluronate-based artificial tear, q8h to benefit tear film. • Frequent cleaning of eyelid margins and periocular skin to remove ocular discharge.

ACTIVITY
• Generally, no restrictions. • Suspected contact irritant or acute allergic disease—prevent contact with the offending agent. • Suspected FHV—minimize stress. • Do not expose patients with infectious disease to susceptible animals.

DIET
• No change for most patients. • Suspected underlying skin disease and/or food allergy—food elimination diet.

CLIENT EDUCATION
• When solutions and ointments are prescribed, instruct the client to use solution(s) before ointment(s) and wait at least 5 minutes between treatments. • If copious discharge is noted, instruct client to clean eyes before giving medication. • Instruct client to call for instructions if condition fails to improve or worsens.

SURGICAL CONSIDERATIONS
• Lipogranulomatous conjunctivitis—surgical incision and curettage of glandular material and inflammatory infiltrates. • Entropion, distichia, or other eyelid disease—perform temporary or permanent surgery depending on the findings, signalment, and history.
• Nasolacrimal duct obstruction—difficult; treatment often not recommended (see Epiphora). • Conjunctival neoplasia—depending on tumor type and extent of involvement, may involve local excision and adjunctive therapy (β-irradiation, cryotherapy), enucleation, or exenteration. • Symblepharon

CONJUNCTIVITIS—CATS (CONTINUED)

(adhesions between the conjunctiva and cornea)—adhesions may require surgical resection (poor prognosis). • Corneal sequestration—keratectomy often recommended (see Corneal Sequestrum—Cats).

MEDICATIONS

DRUG(S) OF CHOICE

Herpetic

• Condition usually mild and self-limiting. • Antiviral treatment—indicated for severe intractable conjunctivitis, herpetic keratitis, and before keratectomy for corneal sequestra suspected to be related to FHV; for all antivirals treat 2 weeks past resolution of clinical signs. • 0.5% cidofovir solution (available from compounding pharmacies)—topical, q12h. • 0.1% idoxuridine solution or 0.5% ointment (compounding pharmacies)—topical, q4h. • Vidarabine 3% ointment—topical, q4h. • Trifluridine 1% solution—topical, q4h; potentially irritating. • Oral famciclovir is effective and safe; recommended dosage 90 mg/kg PO q12h. • Lysine 500 mg PO q12h for adult cat (250 mg PO q12h for kitten). • FortiFlora® probiotic PO q24h may decrease incidence of conjunctivitis associated with FHV.

Chlamydial or Mycoplasmal

• Tetracycline, erythromycin, or chloramphenicol ophthalmic ointment—topically q6–8h; continue for several days past resolution of all clinical signs; recurrence or reinfection common. • Topical ciprofloxacin ophthalmic solution q6–8h as alternative to ophthalmic ointment. • Doxycycline 10 mg/kg PO q24h for 3–4 weeks may be superior to or used along with topical treatment. • Based on bacterial culture and sensitivity results.

Neonatal

Carefully open the eyelid margins (medial to temporal), establish drainage, and treat with topical antibiotic ointment q6–8h and an antiviral for suspected FHV.

Eosinophilic

• Topical corticosteroid—0.1% dexamethasone sodium phosphate q6–8h generally effective; taper gradually to lowest effective dose or transition to cyclosporine. • Cyclosporine 0.2% ointment 1–2% compounded solution, or tacrolimus 0.03% compounded solution—topical therapy q8–24h. • Topical 0.5% megestrol acetate solution (available from compounding pharmacies)—q8–12h; safe with concurrent corneal ulceration and/or concurrent FHV ocular disease. • Oral megestrol acetate—may help resistant condition, but rarely used given possible systemic side effects.

CONTRAINDICATIONS

• Topical corticosteroids—avoid with known or suspected infectious conjunctivitis; may result in FHV recrudescence and predispose to corneal sequestrum formation; never use if corneal ulceration is noted. • Valacyclovir should never be used in cats.

PRECAUTIONS

• Topical medications may be irritating. • Monitor all patients treated with topical corticosteroids for signs of corneal ulceration; discontinue agent immediately if corneal ulceration occurs.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Other corticosteroids—1% prednisolone acetate.

FOLLOW-UP

PATIENT MONITORING

Recheck shortly after beginning treatment (at 5 days), then in 2 weeks or as needed.

PREVENTION/AVOIDANCE

• Treat any underlying disease that may be exacerbating the conjunctivitis. • Minimize stress for patients with herpetic disease. • Isolate patients with infectious conjunctivitis to prevent spread. • Prevent reexposure to infectious sources. • Vaccination recommended; infection is still possible if the cat was exposed to an infectious agent before being vaccinated (e.g., FHV infection from an infected queen).

POSSIBLE COMPLICATIONS

• Corneal sequestration (see Corneal Sequestrum—Cats)—usually requires surgical keratectomy. • Symblepharon—may require surgery. • KCS—most likely from chronic FHV.

EXPECTED COURSE AND PROGNOSIS

• FHV—most patients become chronic carriers; may see repeated exacerbations, but episodes less common as patient matures; more severe clinical signs at times of stress or immunocompromise. • Bacterial conjunctivitis—usually resolves with appropriate administration of antibiotic. • Immune-mediated diseases (e.g., eosinophilic)—control not cure; may require chronic treatment at lowest level possible. • If underlying disease is found (e.g., KCS, entropion), resolution may depend on appropriate treatment of the disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

FeLV and FIV—may predispose patient to chronic carrier state of FHV conjunctivitis.

AGE-RELATED FACTORS

FHV—tends to be more severe in kittens and in old cats with waning immunity.

ZOONOTIC POTENTIAL

Chlamydophila felis—low.

PREGNANCY/FERTILITY/BREEDING

Use topical and systemic medications with caution, if at all, in pregnant animals.

SEE ALSO

• Corneal Sequestrum—Cats.
• Keratoconjunctivitis Sicca.
• Ophthalmia Neonatorum.
• Red Eye.

ABBREVIATIONS

• FeLV = feline leukemia virus.
• FHV = feline herpesvirus.
• FIV = feline immunodeficiency virus.
• IFA = immunofluorescent antibody.
• KCS = keratoconjunctivitis sicca.

CONJUNCTIVITIS—DOGS

BASICS

DEFINITION
Inflammation of the conjunctiva, the vascularized mucous membrane that covers the anterior sclera (bulbar conjunctiva), lines the eyelids (palpebral conjunctiva), and lines the third eyelid.

PATHOPHYSIOLOGY
• Primary—allergic, infectious, environmental. • Secondary to other ocular disease—keratoconjunctivitis sicca (KCS), entropion, distichiasis.

SYSTEMS AFFECTED
Ophthalmic

GENETICS
N/A

INCIDENCE/PREVALENCE
Common

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog

Breed Predilection
Breeds predisposed to allergic or immune-mediated skin diseases (e.g., atopy) tend to have more problems with allergic conjunctivitis or KCS.

Mean Age and Range
N/A

Predominant Sex
None

SIGNS
• Blepharospasm. • Conjunctival hyperemia. • Ocular discharge—serous, mucoid, or mucopurulent. • Chemosis. • Follicle formation on posterior third eyelid surface. • Enophthalmos and third eyelid elevation.

CAUSES

Infectious
• Bacterial—rare as primary condition, usually secondary to KCS; conjunctivitis neonatorum involves accumulation of exudates under closed eyelids prior to natural opening. • Viral—canine herpes virus-1, canine distemper virus, or canine adenovirus-2. • Parasitic—*Leishmania*, *Onchocerca*, or *Thelazia*. • Conjunctival manifestation of systemic infectious disease

Immune-Mediated
• Allergic—especially in atopic patients. • Follicular conjunctivitis—common in dogs <18 months, secondary to chronic antigenic stimulation. • Lymphocytic/plasmacytic conjunctivitis—especially in German shepherd dogs with or without chronic superficial keratitis (pannus). • Systemic immune-mediated disease (e.g., pemphigus).

Trauma or Environmental Causes
• Conjunctival foreign body. • Irritation (dust, smoke, ophthalmic medications). • Toxin or chemical contact.

Other
Ligneous conjunctivitis—rare, young female Dobermans may be predisposed.

Secondary to Adnexal Disease
• Aqueous tear film deficiency (KCS) or qualitative tear deficiency. • Eyelid diseases—entropion, ectropion, medial canthal pocket syndrome, eyelid mass. • Hair or eyelash disorders—trichiasis, distichiasis, ectopic cilia. • Exposure—facial nerve paralysis, lagophthalmos. • Dacryocystitis or nasolacrimal system outflow obstruction (e.g., obstructed duct or imperforate punctum).

Referred Inflammation from Other Ocular or Periocular Diseases
• Ulcerative keratitis. • Nodular episcleritis. • Anterior uveitis. • Glaucoma. • Orbital disease. • Pyoderma.

RISK FACTORS
Atopy, KCS.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Distinguish primary conjunctivitis from secondary conjunctival hyperemia. • Thorough systematic ophthalmic exam identifies other potential diseases (e.g., KCS, ulcers, uveitis, glaucoma, orbital disease); assess pupil size and symmetry, look for aqueous flare, attempt globe retropulsion, perform Schirmer tear test, intraocular pressure measurement, and fluorescein staining. • Deeper, darker, more linear and immobile blood vessel injection indicates congested episcleral vasculature due to episcleritis or intraocular disease. • Mass biopsy will differentiate conjunctival neoplasia (rare: squamous cell carcinoma, melanoma, hemangioma/sarcoma, lymphoma, papilloma, mast cell tumor) or episcleritis.

CBC/BIOCHEMISTRY/URINALYSIS
Normal unless systemic disease.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
• Adnexal examination—rule out facial nerve paralysis, lagophthalmos, eyelid abnormalities, hair or eyelash disorders, and foreign bodies in cul-de-sacs or under third eyelid. • Schirmer tear test—rule out KCS; perform before anything else is placed in eye. • Fluorescein stain—no corneal retention rules out ulcerative keratitis; stain flow to nares rules out nasolacrimal disease. • Tear film breakup time—assesses tear film stability to rule out qualitative tear deficiency. • Intraocular pressures—rule out glaucoma. • Globe retropulsion—rule out orbital disease. • Examine for signs of anterior uveitis (e.g., hypotony, aqueous flare, miosis) or other intraocular disease (e.g., cataracts, lens luxation). • Consider nasolacrimal duct flush if fluorescein stain did not pass to nares. • Conjunctival cytology—lymphocytes and plasma cells diagnostic for lymphocytic/plasmacytic conjunctivitis; eosinophils in allergic conjunctivitis; degenerate neutrophils and intracellular bacteria with bacterial infection; rarely distemper virus intracytoplasmic inclusions. • Conjunctival biopsy—may be useful with mass lesions and nodular episcleritis or chronic undiagnosed disease. • PCR or viral isolation testing for canine herpesvirus-1. • Intradermal skin testing—if suspect allergic conjunctivitis.

PATHOLOGIC FINDINGS
• Biopsy—inflammation, may note infectious agents, neoplasia, or nodular episcleritis. • Ligneous conjunctivitis—thick, amorphous eosinophilic hyaline-like material.

TREATMENT

APPROPRIATE HEALTH CARE
• Primary—outpatient. • Secondary to other disease (e.g., ulcerative keratitis, uveitis, glaucoma, lens luxation)—may require hospitalization to address underlying ophthalmic issue.

NURSING CARE
• Irritant-induced conjunctivitis—flush ocular surfaces and remove foreign body if observed. • Allergic or follicular conjunctivitis—apply viscous artificial tear gel to both eyes before patient is active outdoors (q8–12h), then flush ocular surface with eye wash when returning indoors to remove "trapped" allergens. • Secondary to ectropion or medial canthal pocket syndrome—flush ocular surface with eye wash daily to remove dust, dirt, or other matter that collects ventrally. • Warm pack eyelids and periocular skin to soften crusted secretions and improve comfort.

ACTIVITY
• No restriction for most. • Suspected contact irritant or allergic disease—prevent contact with offending agent. • Do not expose patients with infectious viral disease to susceptible animals.

DIET
• No change for most. • Suspected underlying skin disease and/or food allergy—food elimination diet trial.

CONJUNCTIVITIS—DOGS (CONTINUED)

CLIENT EDUCATION

• When solutions and ointments are prescribed, the client should use solution(s) before ointment(s) and wait 5 minutes between treatments. • If copious discharge is noted, clean eyes before giving medication. • Call for instructions if condition fails to improve or worsens. • An Elizabethan collar should be placed on the patient to prevent self-trauma.

SURGICAL CONSIDERATIONS

• Follicular conjunctivitis—if follicles are unresponsive to medication, consider debridement. • Entropion, distichia, ectopic cilia, or other eyelid disease—perform temporary or permanent surgery depending on findings, signalment, and history. • Nasolacrimal duct obstruction—if repeated flushing attempts at weekly intervals along with medical therapy are unsuccessful, consider contrast study and surgery (see Epiphora). • Conjunctival neoplasia—depending on tumor type and extent of involvement, may involve local excision and adjunctive therapy (β-irradiation, cryotherapy), enucleation, or exenteration.

MEDICATIONS

DRUG(S) OF CHOICE

Bacterial

• Initial treatment—broad-spectrum topical triple antibiotic q6–8h continuing several days past resolution of clinical signs; revise based on bacterial culture and sensitivity results. • Systemic antibiotic (e.g., cephalosporin)—occasionally indicated, especially for more generalized disease (e.g., pyoderma).

Neonatal

Carefully open eyelid margins (medial to lateral), establish drainage, and treat with topical antibiotic ointment q6–8h.

Herpetic

• Condition usually mild and self-limiting. • Antiviral treatment—indicated for severe intractable canine herpesvirus-1 conjunctivitis or herpetic keratitis. • 0.15% ganciclovir gel—topical q4h for 7 days, then q8h. • 1% trifluridine solution—topical q4h for 2 days, then q6h. • 0.1% idoxuridine solution (compounding pharmacies)—topical q4h for 2 days, then q6h. • 0.5% cidofovir solution (compounding pharmacies)—topical q12h; generally avoided: reduces duration of shedding but may worsen clinical disease due to local ocular toxic effects.

Immune-Mediated

• Depends on severity. • Allergic and follicular conjunctivitis—attempt nursing care first with viscous artificial tear gel lubricants and ocular flushing q8–12h; if nonresponsive consider antihistamine eye drops (e.g., ketotifen) q8–12h, or topical corticosteroid (e.g., dexamethasone) q8–12h. • Lymphocytic/plasmacytic conjunctivitis—0.1% dexamethasone q8h, then taper gradually to lowest effective dose; could attempt transition to cyclosporine 0.2% ointment, cyclosporine 1–2% compounded solution q12–24h, or tacrolimus 0.03% compounded solution q12–24h. • Treatment of any underlying disease (e.g., atopy) often improves clinical signs of allergic conjunctivitis.

Tear Deficiencies

• Aqueous tear film deficiency (see Keratoconjunctivitis Sicca). • Qualitative tear deficiency—cyclosporine 0.2% ointment, cyclosporine 1–2% compounded solution q12h, or tacrolimus 0.03% compounded solution q12–24h, and viscous artificial tear lubricants q6–12h.

CONTRAINDICATIONS

Topical corticosteroids—avoid if corneal ulceration is present, patient is at high risk for ulceration (e.g., entropion, lagophthalmos, severe KCS), or with known or suspected infectious conjunctivitis.

PRECAUTIONS

• Topical medications may be irritating. • Topical corticosteroids—monitor all patients carefully for signs of corneal ulceration; discontinue agent immediately if corneal ulceration occurs.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

Other corticosteroids—1% prednisolone acetate, betamethasone, hydrocortisone.

FOLLOW-UP

PATIENT MONITORING

Recheck shortly after beginning treatment (at 5 days), then recheck in 2 weeks or as needed.

PREVENTION/AVOIDANCE

Treat any underlying disease that may be exacerbating the conjunctivitis (e.g., KCS, allergic or immune-mediated skin disease).

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

• Good prognosis when underlying cause identified and treated (e.g., KCS, adnexal disease, eyelash disorder). • Bacterial—usually resolves with appropriate antibiotics; may depend on control of underlying disease (e.g., KCS). • Allergic or follicular—nursing care or medical treatment may be needed during peak allergy times. • Lymphocytic/plasmacytic—tend to be controlled and not cured; may require chronic treatment at lowest level possible.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Atopy. • Pyoderma.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Use topical and systemic medications with caution, if at all, in pregnant animals.

SEE ALSO

• Epiphora.
• Keratoconjunctivitis Sicca.
• Red Eye.

ABBREVIATIONS

• KCS = keratoconjunctivitis sicca.

CONSTIPATION AND OBSTIPATION

BASICS

DEFINITION

• *Constipation* is defined as infrequent, incomplete, or difficult defecation with passage of hard or dry feces. This does not imply abnormal motility or loss of function. • *Obstipation* denotes intractable constipation that has failed several consecutive treatments; defecation is impossible in the obstipated patient.

PATHOPHYSIOLOGY

• Constipation can develop with any disease that impairs the passage of feces through the colon. Potential causes include congenital vertebral malformation, spinal cord disease, pelvic canal narrowing (trauma), rectal mass lesions causing obstruction, and perianal disease causing painful defecation. Often in cats no underlying etiology can be identified. • Delayed fecal transit allows removal of additional salt and water, producing drier feces. Clinical signs are attributable to dehydration and potential toxemia resulting from fecal retention. • Peristaltic contractions may increase during constipation, but eventually motility diminishes because of smooth muscle degeneration secondary to chronic overdistension.

SYSTEMS AFFECTED

Gastrointestinal.

GENETICS

N/A

INCIDENCE/PREVALENCE

Common clinical problem in older cats; less common in dogs.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

• Dog and cat. • More common in cat.

Breed Predilections

N/A

Mean Age and Range

Any age; most common in older cats.

Predominant Sex

N/A

SIGNS

Historical Findings

• Reduced, absent, or painful defecation. • Hard, dry feces. • Small amount of liquid, mucoid stool, sometimes with blood present produced after prolonged tenesmus. • Occasional vomiting, inappetence, and/or lethargy.

Physical Examination Findings

• Colon filled with hard feces. Severe impaction may cause abdominal distention. • Other findings depend on underlying cause. • Rectal examination may reveal mass, stricture, perineal hernia, anal sac disease, foreign body or material, prostatic enlargement, or narrowed pelvic canal.

CAUSES

Dietary

• Bones. • Hair. • Foreign material. • Excessive fiber. • Inadequate water intake.

Environmental

• Lack of exercise. • Change of environment—hospitalization, dirty litter box. • Inability to ambulate.

Drugs

• Anticholinergics. • Antihistamines. • Opioids. • Barium sulfate. • Sucralfate. • Antacids. • Kaopectolin. • Iron supplements. • Diuretics.

Painful Defecation (Dyschezia)

• Anorectal disease—anal sacculitis, anal sac abscess, perianal fistula, anal stricture, anal spasm, rectal foreign body, rectal prolapse, proctitis. • Trauma—fractured pelvis, fractured limb, dislocated hip, perianal bite wound or laceration, perineal abscess.

Mechanical Obstruction

• Extraluminal—healed pelvic fracture with narrowed pelvic canal, prostatic hypertrophy, prostatitis, prostatic neoplasia, intrapelvic neoplasia, sublumbar lymphadenopathy. • Intraluminal and intramural—colonic or rectal neoplasia or polyp, rectal stricture, rectal foreign body, rectal diverticulum, perineal hernia, rectal prolapse, congenital defect (atresia ani).

Neuromuscular Disease

• Central nervous system—paraplegia, spinal cord disease, intervertebral disc disease, cerebral disease (lead toxicity, rabies). • Peripheral nervous system—dysautonomia, sacral nerve disease, sacral nerve trauma (e.g., tail fracture/pull injury). • Colonic smooth muscle dysfunction—idiopathic megacolon in cats.

Metabolic and Endocrine Disease

• Impaired colonic smooth muscle function—hyperparathyroidism, hypothyroidism, hypokalemia (chronic renal failure), hypercalcemia. • Debility—general muscle weakness, dehydration, neoplasia.

RISK FACTORS

• Manx cats may be predisposed due to vertebral (sacral) abnormalities. • Drug therapy—anticholinergics, narcotics, barium sulfate. • Metabolic disease causing dehydration. • Feline dysautonomia. • Intact male—perineal hernia, benign or infectious prostatic disease. • Castrated male—prostatic neoplasia. • Perianal fistula.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Dyschezia and tenesmus (e.g., caused by colitis or proctitis)—unlike constipation, associated with increased frequency of attempts to defecate and frequent production of small amounts of liquid feces containing blood and/or mucus; rectal examination reveals diarrhea and lack of hard stool. • Stranguria (e.g., caused by cystitis/urethritis)—unlike constipation, can be associated with hematuria and abnormal findings on urinalysis (pyuria, crystalluria, bacteruria).

CBC/BIOCHEMISTRY/URINALYSIS

• Usually unremarkable. • May detect hypokalemia, hypercalcemia. • High packed cell volume (PCV) and total protein in dehydrated patients. • High white blood cell (WBC) count in patients with severe obstipation secondary to bacterial or endotoxin translocation, abscess, perianal fistula, prostatic disease. • Pyuria and hematuria with prostatitis.

OTHER LABORATORY TESTS

• If patient is hypercholesterolemic, consider thyroid panel to rule out hypothyroidism. • If patient is hypercalcemic, consider parathyroid hormone assay.

IMAGING

• Abdominal radiography documents severity of colonic impaction. Other findings may include colonic or rectal foreign body, colonic or rectal mass, prostatic enlargement, fractured pelvis, dislocated hip, or perineal hernias. • Pneumocolon (after enemas to clean colon) may better define intraluminal mass or stricture. • Ultrasonography may help define extraluminal mass and prostatic disease.

DIAGNOSTIC PROCEDURES

Colonoscopy may be needed to identify a mass, stricture, or other colonic or rectal lesion; rectal/colonic mucosal biopsy specimens should always be obtained.

PATHOLOGIC FINDINGS

Dependent on underlying disease process.

TREATMENT

APPROPRIATE HEALTH CARE

• Remove or ameliorate any underlying cause if possible. • Discontinue any medications that may cause constipation. • May need to treat as inpatient if obstipation and/or dehydration present.

CONSTIPATION AND OBSTIPATION (CONTINUED)

NURSING CARE
Dehydrated patients should receive IV (preferably) or SC balanced electrolyte solutions (with potassium supplementation if indicated).

ACTIVITY
Encourage activity.

DIET
Dietary supplementation with a bulk-forming agent (bran, methylcellulose, canned pumpkin, psyllium) is often helpful, though they can sometimes worsen colonic fecal distension; in this instance, feed a low-residue diet.

CLIENT EDUCATION
• Feed appropriate diet and encourage activity. • Survey cat boxes daily to ensure level of defecation activity.

SURGICAL CONSIDERATIONS
• Manual removal of feces through the anus with the animal under general anesthesia (after rehydration) may be required if enemas and medications are unsuccessful. • Subtotal colectomy may be required with recurring obstipation that responds poorly to assertive medical therapy.

MEDICATIONS

DRUG(S) OF CHOICE
• Emollient laxatives—docusate sodium or docusate calcium (dogs: 50–100 mg PO q12–24h; cats: 50 mg PO q12–24h). • Stimulant laxatives—bisacodyl (5 mg/animal PO q8–24h). Ensure that animal is not obstructed prior to use of stimulant laxatives. • Saline laxatives—isosmotic mixture of polyethylene glycol and poorly absorbed salts; usually administered as a trickle amount via nasoesophageal tube over 6–12h. • Disaccharide laxative—lactulose (1 mL/4.5 kg PO q8–12h to effect). • Warm water enemas may be needed; a small amount of mild soap or docusate sodium can be added but is usually not needed; sodium phosphate retention enemas (e.g., Fleet®) are contraindicated because of their association with severe hypocalcemia. • Suppositories can be used as a replacement for enemas; use glycerol, bisocodyl, or docusate sodium products. • Motility modifiers can be administered—cisapride (dogs: 0.3–0.5 mg/kg PO q8–12h; cats: 2.5–10 mg/cat PO q8–12h) may stimulate colonic motility; indicated with early megacolon.

CONTRAINDICATIONS
• Lubricants such as mineral oil and white petrolatum are *not* recommended because of the danger of fatal lipid aspiration pneumonia due to their lack of taste. • Fleet (sodium phosphate) enemas. • Anticholinergics. • Diuretics.

PRECAUTIONS
Cisapride and cholinergics—can be used with caution; contraindicated in obstructive processes. Avoid the use of metoclopramide because it does not affect the colon.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• Ranitidine causes contraction of colonic smooth muscle in vitro. • Misoprostol causes contraction of colonic smooth muscle in vitro. • Newer-generation cisapride-like drugs may be available soon. • One recent pilot study using multistrain probiotic SLAB51® showed clinical improvement in a feline cohort having chronic constipation and idiopathic megacolon.

FOLLOW-UP

PATIENT MONITORING
Monitor frequency of defecation and stool consistency at least twice a week initially, then weekly or biweekly in response to dietary and/or drug therapy.

PREVENTION/AVOIDANCE
Keep pet active and feed appropriate diet. Subcutaneous fluids to ensure hydration can help reduce frequency of constipation, particularly in cats.

POSSIBLE COMPLICATIONS
• Chronic constipation or recurrent obstipation can lead to acquired megacolon. • Overuse of laxatives and enemas can cause diarrhea. • Colonic mucosa can be damaged by improper enema technique, repeated rough mechanical breakdown of feces, or ischemic necrosis secondary to pressure of hard feces. • Perineal irritation and ulceration can lead to fecal incontinence.

EXPECTED COURSE AND PROGNOSIS
• Fair to good prognosis with early diagnosis and intervention. • Recurring bouts of constipation/obstipation may occur dependent on underlying cause.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Vomiting—with severe/prolonged obstipation.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
N/A

SYNONYMS
• Colonic impaction. • Fecal impaction.

CONTACT DERMATITIS

BASICS

OVERVIEW

• Irritant and allergic contact dermatitis—rare syndromes with similar clinical signs but different pathophysiology; differentiation may be more conceptual. • Irritant contact dermatitis (ICD)—direct damage to keratinocytes by exposure to particular irritant or sensitizer induces inflammatory response directed at skin without prior sensitization. • Allergic contact dermatitis (ACD)—type IV (delayed) hypersensitivity: immunologic event requiring sensitization and elicitation; Langerhans cells and keratinocytes interact with environmental haptens to create antigens, leading to sensitization of T-lymphocytes and activation following reexposure with release of cytokines (mainly tumor necrosis factor alpha • [TNF-α], IL1βGM-CSF). • Recent reports blur distinction between ICD, ACD, and atopic dermatitis.

SIGNALMENT

• ICD—Any age as direct result of irritation from offending chemical. • ACD—older dogs; chronic exposure to antigen (months to years); extremely rare in cats, (except exposure to d-limonene-containing insecticides). • ACD—German shepherd dog, poodle, wirehaired fox terrier, Scottish terrier, West Highland white terrier, Labrador and golden retriever.

SIGNS

Lesions

• Location determined by antigen contact; commonly limited to glabrous skin and regions frequently in direct contact with the environment. • Extreme erythroderma stops abruptly at hairline. • Initial erythema, edema, and papules leading to crusts and excoriations; lichenification and hyperpigmentation with chronicity; vesicles uncommon.

Others

• Localized reactions to topical medications. • Generalized reactions to shampoos or insecticide sprays. • Pruritus—moderate to severe (most common). • Seasonal incidence may indicate plant or outdoor antigen.

CAUSES & RISK FACTORS

• Reported offending substances—plants, mulch, cedar chips, fabrics, rugs, carpets, plastics, rubber, leather, nickel, cobalt, concrete, soaps, detergents, floor waxes, epoxy resin, carpet and litter deodorizers, herbicides, fertilizers, insecticides (including topical flea treatments), flea collars, topical preparations (neomycin). • Increased incidence with atopic disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Hypersensitivity dermatitis. • Drug reaction. • Pelodera dermatitis. • Hookworm dermatitis. • Pyoderma. • *Malassezia* dermatitis. • Demodicosis. • Solar dermatitis. • Thermal injuries. • Trauma from rough surfaces.

DIAGNOSTIC PROCEDURES

• ACD—closed-patch test (corticosteroids and nonsteroidal anti-inflammatory drugs [NSAIDs] must be discontinued for 3–6 weeks); materials taken from environment or home applied to upper thorax skin under bandage; examine for erythema, edema, pruritus at 48, 72 hours, and 7 days. • ICD—eliminate exposure to contact irritant or antigen, followed by provocation. • Open patch test—apply substance to inside pinnae; monitor for mild erythema, edema, pruritus; examine daily for 5–15 days. • Human patch test kits (TRUE Test®). • Skin biopsy.

PATHOLOGIC FINDINGS

• Intraepidermal vesiculation and spongiosis; superficial dermal edema with perivascular mononuclear cell infiltrate in ICD and ACD; polymorphonuclear cell infiltrate in ICD; leukocyte exocytosis common. • Lymphocytic spongiotic or eosinophilic and lymphocytic spongiotic infiltrate with intraepidermal eosinophilic pustules in canine ACD.

TREATMENT

• Eliminate offending substance(s). • Bathe with hypoallergenic shampoos to remove antigen from skin. • Create mechanical barriers, if possible—socks, shirts, restriction from environment.

MEDICATIONS

DRUG(S) OF CHOICE

• Prednisolone (1 mg/kg PO q24h for 5–7 days, then q48h for 2 weeks). • Topical corticosteroids for focal lesions. • Topical tacrolimus. • Pentoxifylline (10–25 mg/kg PO q8–12h initially). • Cyclosporine (modified, 5 mg/kg q24h).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Pentoxifylline—do not administer with alkylating agents, cisplatin, or amphotericin B; cimetidine may increase serum levels of pentoxifylline.

FOLLOW-UP

PREVENTION/AVOIDANCE

Remove offending substances from the environment.

EXPECTED COURSE AND PROGNOSIS

ICD

• Acute condition—may occur after only one exposure; can be manifested within 24 hours of exposure. • Corticosteroids rarely helpful. • Lesions resolve 1–2 days after irritant removal.

ACD

• Requires chronic exposure for hypersensitivity to develop. • Reexposure results in development of clinical signs within 1–5 days; signs may persist for several weeks. • Responds well to corticosteroids; pruritus returns after discontinuation if antigenic stimulus persists. • Hyposensitization not effective. • Prognosis—good if allergen is identified and removed, otherwise poor: may require lifelong treatment.

MISCELLANEOUS

ABBREVIATIONS

• ACD = allergic contact dermatitis. • ICD = irritant contact dermatitis. • NSAID = nonsteroidal anti-inflammatory drug. • TNF-α = tumor necrosis factor alpha.

COONHOUND PARALYSIS (ACUTE POLYRADICULONEURITIS)

BASICS

DEFINITION
• Acute inflammatory disorder involving the axons and myelin of nerve roots, spinal nerves, and peripheral nerves in dogs, with or without a previous history of contact with raccoon saliva, vaccination, or a gastrointestinal or respiratory infection. • Proposed animal model for Guillain-Barré syndrome in humans.

PATHOPHYSIOLOGY
• Etiology uncertain, appears to be immune mediated. • Immune-mediated inflammation develops 7–14 days after antecedent event (delayed hypersensitivity reaction?).
• Thought to be the dog's immune system reaction to a cross-reacting antigen (suspect molecular mimicry phenomenon between external antigen and gangliosides from dog's neural tissue, with the development of antiganglioside autoantibodies). • Coonhound paralysis (CHP)—antecedent event is recent contact with raccoon saliva. • Acute canine idiopathic polyradiculoneuritis (ACIP)—affected dogs with identical clinical signs to those with CHP but without a history of raccoon exposure; may have history of recent respiratory or gastrointestinal infection.
• Postvaccinal polyradiculoneuritis—antecedent event is recent vaccination (rare).
• *Toxoplasma gondii* infection—dogs with ACIP more likely to have positive titers than control dogs (possible triggering factor?).

SYSTEMS AFFECTED
• Peripheral nervous system—most severe involvement in the ventral (motor) nerve roots and ventral root components of the spinal nerves; lumbosacral nerve roots affected more severely than cervical and thoracic nerve roots. • Cranial nerves—nerve VII often affected; nerves IX, X occasionally affected. • Respiratory failure—secondary to intercostal and/or phrenic nerve involvement in some patients.

GENETICS
No proven basis.

INCIDENCE/PREVALENCE
• Most commonly recognized acute polyneuropathy in dogs. • Low incidence.

GEOGRAPHIC DISTRIBUTION
• CHP—relative to distribution of raccoons (e.g., North and Central America; parts of South America). • ACIP—worldwide.

SIGNALMENT
Species
Dog, very occasionally cat.

Breed Predilections
• CHP—Coonhounds; any breed in contact with raccoons susceptible. • ACIP, postvaccinal polyradiculoneuritis—none.

Mean Age and Range
N/A

Predominant Sex
N/A

SIGNS
Historical Findings
• Appear 7–14 days after contact with raccoon saliva (bite or scratch), receipt of vaccination, or development of respiratory or gastrointestinal infection. • Initial signs—stiff, stilted gait in all limbs, typically starting in the pelvic limbs and eventually progressing to the thoracic limbs. • Rapid progression (2–4 days) to a flaccid, lower motor neuron tetraparesis to tetraplegia. • Owners may notice loss or change of voice. • Appetite and water consumption—usually normal.
• Urination and defecation—normal.
• Progressive phase of the disease—clinical signs can continue to worsen up to 5–10 days after onset.

Neurologic Examination Findings
• Usually symmetric. • Stiff, stilted gait that usually progresses rapidly to lower motor neuron tetraparesis or tetraplegia; some dogs may remain ambulatory tetraparetic.
• Generalized hyporeflexia to areflexia, with the exception of a normal perineal reflex.
• Generalized hypotonia to atonia, severe neurogenic muscle atrophy. • Affected dogs often show inability to hold the head up.
• Aphonia or dysphonia common; no megaesophagus. • Facial paresis—bilateral incomplete palpebral closure in some patients. • Respiration—labored in severely affected dogs; occasional progression to respiratory paralysis. • Pain sensation intact; hyperesthesia common—may reflect variable dorsal nerve root inflammation. • Motor dysfunction—always predominates; even tetraplegic patient can usually wag its tail.
• Mental status, urination, and defecation—unaffected.

CAUSES
• CHP—contact with a raccoon; perhaps more important, contact with raccoon saliva.
• ACIP—none proven; possibly previous respiratory or gastrointestinal viral or bacterial infection. • Postvaccinal polyradiculoneuritis—recent vaccination (rare).

RISK FACTORS
• CHP—coonhounds tend to be predisposed primarily because of the nature of their activities; previous disease does not confer immunity and may increase risk of redevelopment; multiple bouts not uncommon. • ACIP—unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other acute polyneuropathy (i.e., paraneoplastic neuropathy). • Distal denervating disease. • Botulism. • Tick bite paralysis.
• Fulminant myasthenia gravis. • Black widow spider bite envenomation, coral snake envenomation. • Intoxications (lasalocid, blue-green algae). • Generalized (diffuse) or multifocal myelopathy (involving both cervical and lumbosacral intumescences).

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
• Serum immunoglobulins (Ig)—high serum IgG but not IgM in some patients.
• Immunologic—serum reaction to raccoon saliva on ELISA; dogs with CHP have a strong positive reaction that decreases in intensity over time; dogs without disease but with raccoon contact have a strong positive reaction; dogs with ACIP but with no raccoon contact have a negative reaction. • Immunologic—for dogs with ACIP, identification of anti-GM2 ganglioside antibodies reached a diagnostic sensitivity of 60% and a specificity of 97%.

IMAGING
Thoracic radiographs and abdominal ultrasound—normal.

DIAGNOSTIC PROCEDURES
Cerebrospinal Fluid Analysis
• Lumbar—high protein without an increase in leukocytes at all stages of disease. • Albumin leakage across the disrupted blood–nerve barrier of the affected ventral nerve roots is the primary cause of the protein increase.

Electrodiagnostics
• Electromyography (EMG)—generalized spontaneous activity (fibrillation potentials and positive sharp waves) consistent with denervation; EMG normal in first 4–5 days. • Markedly low compound muscle action potential amplitudes after motor nerve stimulation. • F waves (late waves that indicate proximal motor nerve and ventral nerve root function)—prolonged minimum latencies, increased F ratio, decreased amplitudes. • Motor nerve conduction velocities—usually normal; severely affected patients may have mildly decreased values. • Sensory nerve function—usually normal. • Abnormalities provide evidence of severe peripheral motor axonopathy (more severe in proximal portions of nerves and ventral nerve roots), along with demyelination in the proximal motor nerves and ventral nerve roots.

(CONTINUED) COONHOUND PARALYSIS (ACUTE POLYRADICULONEURITIS)

PATHOLOGIC FINDINGS
• Ventral nerve roots and the ventral root components of the spinal nerves—most severe lesions, various degrees of axonal degeneration, paranodal and segmental demyelination, and leukocyte infiltration (predominantly monocytes and macrophages). • Peripheral nerves—affected to a lesser degree; might be normal. • Dorsal nerve roots—much less severely affected.

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient—closely monitor patients in the progressive phase of the disease (especially during first 5 days) for respiratory problems. • Severe respiratory compromise—mechanical ventilation as required. • IV fluid therapy—administer if patient is dehydrated. • Outpatient—once patient is stable and the progressive phase of the disease is over.

NURSING CARE
• Patients are usually able to eat and drink; hand feed in sternal position until able to reach food and water. • Intensive physical therapy—important to decrease muscle atrophy; severe neurogenic muscle atrophy is inevitable. • Frequent turning and excellent padding—essential to prevent pressure sores.

ACTIVITY
Encourage as much movement as possible.

DIET
• No restrictions. • Make sure patient is able to reach food and water. • Cervical weakness—may need to hand feed patient in sternal position.

CLIENT EDUCATION
• Inform client that good nursing care is essential. • Discuss importance of preventing pressure sores and urine scalding and of limiting the degree of muscle atrophy by frequent daily physical therapy (passive limb movement, swimming as the patient's strength begins to improve). • Patient needs soft bedding that must be kept free of urine and feces, frequent turning (every 3–4 hours), frequent bathing, and adequate nutrition.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• None proven effective. • Immunoglobulin—1 g/kg IV daily for 2 consecutive days, 0.5 g/kg IV daily for 3 consecutive days, or 0.4 g/kg IV daily for 5 consecutive days; given early may shorten recovery time in ACIP.

CONTRAINDICATIONS
Corticosteroids—do not improve clinical signs or shorten course of disease; may reduce survival in humans with Guillain-Barré syndrome.

PRECAUTIONS
Monitor for possible adverse reactions (anaphylaxis, hematuria) after IV immunoglobulin administration.

FOLLOW-UP

PATIENT MONITORING
• Outpatient—keep in close contact with client regarding complications or changes in the patient's condition. • Urinalysis—perform periodically to check for cystitis in tetraplegic or severely tetraparetic patients. • Ideally, reevaluate at least every 2 weeks.

PREVENTION/AVOIDANCE
• CHP—if possible, avoid contact with raccoons. • Postvaccinal polyradiculoneuritis—if strong association with a specific vaccination, avoid that particular vaccine in the future.

POSSIBLE COMPLICATIONS
• Respiratory paralysis—in progressive phase of disease. • Pressure sores, urine scalding, cystitis—common in chronically recumbent dogs.

EXPECTED COURSE AND PROGNOSIS
• Signs stabilize once progressive phase of disease is over. • Most affected dogs recover fully over 3–6 weeks; severely affected cases may take up to 3–4 months to recover; incomplete recoveries can happen.

COPPER ASSOCIATED HEPATOPATHY

BASICS

DEFINITION

- Severe hepatic accumulation of copper (Cu) causes acute or chronic hepatitis leading to cirrhosis or death from liver failure.
- Mild to moderate hepatic Cu accumulation augments oxidative injury and increases risk for liver disease caused by other hepatobiliary insults, notably hepatotoxicity from nonsteroidal anti-inflammatory drugs (NSAIDs).
- *Primary copper associated hepatopathy* (CuAH) depicts copper accumulation in the absence of other liver disorders or *as the major cause of liver injury*.
- *Secondary CuAH* depicts Cu accumulation caused by severe chronic cholestasis in cats (not dogs) or fulminant hepatic failure (rare).
- *Genetic primary CuAH*—only proven in Bedlington terriers.
- *Acquired primary CuAH*—most common canine cause of CuAH, reflects dietary Cu availability in commercial dog food that exceeds individual's tolerance limit.
- *Congenital primary CuAH* (no gene mutation characterized)—comparatively rare in cats.
- Some animals with primary CuAH accumulate Cu without histologic evidence of liver damage despite vacillating liver enzyme activity (alanine aminotransferase [ALT] most common); in absence of inflammation or hepatocyte necrosis, the term *hepatopathy* is most correct.

PATHOPHYSIOLOGY

- Hepatic Cu homeostasis involves complex regulatory system including protein transporters, chaperones, membrane receptors, intracellular binding proteins, canalicular egress pumps; Cu absorbed from small intestine, stored in liver, with excess excreted in bile.
- A single gene mutation (*COMMD1*) causes genetic primary CuAH in Bedlington terriers.
- More commonly, canine hepatic Cu accumulation reflects Cu intake exceeding capacity to maintain neutral Cu balance; suspected pharmacogenetic basis.
- Secondary CuAH reflects reduced canalicular Cu egress associated with severe cholestasis (cats only) or severe panlobular liver injury (fulminant hepatic failure, rare).
- Primary CuAH—hepatocyte cytosolic Cu first accumulates in zone 3 (centrilobular region).
- Secondary CuAH (cats)—hepatocyte cytosolic Cu accumulates in zone 1 (periportal) or adjacent to injured regions.
- Hepatic Cu concentrations widely variable—primary CuAH: range 500 to >10,000 µg/g dry weight liver (DWL); secondary CuAH in cats rarely exceeds 1,000 µg/g DWL.
- Cu accumulation causes oxidative membrane injury—cell and organelles; high hepatic Cu concentration not always associated with histologic evidence of liver injury.
- Focal hepatitis initiated by Cu may progress to chronic hepatitis, eventually cirrhosis.
- Rarely, acute severe hepatic necrosis releases Cu into systemic circulation causing hemolysis and/or acute-onset acquired Fanconi syndrome (proximal renal tubular injury causing euglycemic glucosuria).

SYSTEMS AFFECTED

- Hepatobiliary—centrilobular hepatitis, chronic hepatitis, eventual cirrhosis.
- Hemic/lymphatic—hemolytic anemia rare sequel to acute hepatic necrosis in dogs.
- Renal—rare reversible Fanconi syndrome causes euglycemic glycosuria, granular casts, ± clinicopathologic evidence of compromised renal function.

GENETICS

- Autosomal recessive *COMMD1* mutation in Bedlington terriers reduces biliary Cu excretion.
- Gene mutations remain unproven in other breeds and in cats; gene associations may modify susceptibility in Labrador retrievers, but no genetic test and liver biopsy remains gold standard for diagnosis of CuAH.
- Predisposition to CuAH recognized in Labrador retriever, West Highland white terrier, Doberman pinscher, Dalmatian, keeshond, corgi, Staffordshire terrier, and other breeds.

INCIDENCE/PREVALENCE

- Bedlington terrier—at one time up to 2/3 of dogs carried *COMMD1* mutation; incidence significantly declined with genetic testing.
- Prevalence of excess hepatic Cu remains high in West Highland white terrier, Labrador retriever, Doberman pinscher, and other breeds.
- CuAH currently most common cause of chronically increased ALT activity in dogs (since mid-1990s) likely caused by increased Cu availability in manufactured dog foods.
- CuAH comprises ≥20% of liver biopsy submissions for abnormal enzyme activity in dogs.
- Primary congenital CuAH occurs in cats but comparatively rare.

GEOGRAPHIC DISTRIBUTION

Reported worldwide.

SIGNALMENT

Species

Dog and cat; more common in dog.

Breed Predilections

Bedlington terrier, West Highland white terrier, Labrador retriever, Doberman pinscher, Dalmatian, Welsh corgi, keeshond, Staffordshire terrier with observed increased incidence of high hepatic Cu concentrations; no canine breed exempt.

Mean Age and Range

- Bedlington terrier—Cu slowly accumulates to max at ~6 years of age; dogs can be clinically affected at any age; most present as middle-aged to older dogs with chronic hepatitis.
- West Highland white terrier—maximum Cu accumulation observed by 12 months of age and may vacillate or decline with clinical disease at any time; *however*, some dogs with high hepatic Cu survive to old age (15 years) without evidence of liver injury.
- Labrador retriever, Doberman pinscher, Dalmatian, other breeds—young adult to middle-aged at diagnosis for chronic hepatitis.
- Doberman pinscher—often develop hepatitis with ALT increases and Cu accumulation at 1–3 years of age; clinical signs of liver disease often recognized by 5–7 years of age.

Predominant Sex

None

SIGNS

Historical Findings

- Primary CuAH—4 categories:
  - no clinical signs;
  - subclinical disease: increased ALT activity with no clinical illness;
  - acute disease associated with severe acute hepatic necrosis;
  - chronic progressive hepatitis eventually evolving cirrhosis.
- Secondary CuAH accompanies feline cholestatic necroinflammatory liver disease (cholangiohepatitis) or rarely in dogs with fulminant liver necrosis.
- Acute signs—with extreme hepatic Cu accumulation, sudden-onset lethargy, anorexia, vomiting; may have rapid course, dogs succumb despite intensive supportive care.
- Chronic signs—variable, intermittent lethargy, hyporexia, weight loss, vomiting, diarrhea, with later polydipsia and polyuria; eventual liver injury leads to ascites, jaundice, bleeding tendencies, hepatic encephalopathy (HE).

Physical Examination Findings

- Acute signs—lethargy, weakness, jaundice, pallor (anemia), vomiting, diarrhea, dark urine (bilirubinuria); rare hemoglobinemia and hemoglobinuria if intravascular Cu-mediated hemolysis.
- Chronic signs—weight loss, ascites, jaundice, nodular microhepatia; melena and petechial hemorrhage in animals with significant panlobular injury.

CAUSES

- Genetic primary CuAH—single gene mutation in Bedlington terriers.
- Acquired primary CuAH—either Bedlington mutation or suspected pharmacogenetic differences involving regulatory pathways influencing Cu homeostasis, making them intolerant to current levels of dietary Cu supplementation.
- Secondary acquired CuAH—necroinflammatory chronic cholestatic liver disease in cats or diffuse severe panlobular injury in dogs or cats (rare).

(CONTINUED)

COPPER ASSOCIATED HEPATOPATHY

RISK FACTORS

- Primary—feeding diets or providing water with Cu concentrations exceeding individual's tolerance to maintain neutral Cu balance.
- Stress or concurrent illnesses may precipitate acute illness in dogs with hepatocyte Cu accumulation.
- Asymptomatic dogs with primary CuAH may become symptomatic when additional disease processes or toxicities (e.g., NSAID administration; CCNU chemotherapy) impose oxidative challenge, expose hepatocytes to inflammatory cytokines, or another primary liver disease develops.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute diseases—infectious (e.g., infectious canine hepatitis, leptospirosis, septicemia, suppurative bacterial cholangiohepatitis), acute hepatic necrosis, hepatic abscess, drug- or toxin-induced hepatic injury, acute pancreatitis, hepatic lymphoma, immune-mediated hemolytic anemia, zinc toxicity.
- Chronic diseases—chronic hepatitis or cholangiohepatitis of any other cause, drug- or toxin-induced liver injury, severe diffuse glycogen-type vacuolar hepatopathy (dogs), infectious hepatitis, chronic obstructive biliary disease, chronic fibrosing pancreatitis, congenital portosystemic shunt, primary or metastatic hepatic neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

- *CBC*—may be normal; regenerative anemia, leukocytosis, neutrophilia if acute Cu-associated hemolysis; microcytic or normocytic, normochromic nonregenerative anemia in chronic progressive liver injury; microcytosis usually reflects acquired portosystemic shunting.
- *Biochemistry*—increased liver enzymes (ALT, aspartate transaminase [AST], γ-glutamyl transferase [GGT], and alkaline phosphatase [ALP] with increase in ALT > ALP); hyperbilirubinemia in dogs with severe liver injury; increased ALT without clinical signs increases suspicion for early or cyclic CuAH necrosis.
- As hepatic function deteriorates—onset of hypoalbuminemia, ± hyperglobulinemia, low blood urea nitrogen (BUN), hypoglycemia, hypocholesterolemia.
- *Urinalysis*—usually normal, bilirubinuria escalates with hyperbilirubinemia; hepatic insufficiency: dilute urine, ammonium biurate crystalluria reflects acquired portosystemic shunts (APSS); glucosuria, granular casts if acquired Fanconi syndrome.

OTHER LABORATORY TESTS

- High fasting or postprandial total serum bile acid (TSBA) values—dogs with severe liver injury, remodeling, or portal hypertension associated with APSS.
- Prolonged prothrombin time (PT), activated partial thromboplastin time (APTT), activated clotting time (ACT), mucosal bleeding time in severe liver injury.
- Rare increased serum Cu concentration—dogs with acute severe CuAH liver necrosis; otherwise serum Cu does not reflect liver Cu concentrations; low-yield screening test.
- Hepatic Cu measurements *must* be reconciled with histopathologic findings.
- Genetic marker testing in Bedlington terrier—microsatellite markers or specific *COMMD1* mutation; however, kindreds of Bedlington terriers with CuAH have had negative PCR-based gene tests.

IMAGING

- Radiography—unremarkable in most dogs; small liver in chronic hepatic injury, poor abdominal detail if ascites.
- Ultrasonography—early: normal hepatic imaging; later: hyperechoic to heterogeneous nodular echogenicity; ascites in some cases.

DIAGNOSTIC PROCEDURES

- *Liver biopsy*—gold standard diagnostic test; confirms and characterizes liver injury; needle samples may not provide adequate liver lobe assessment as Cu is differentially distributed across lobes and liver sections; biopsy at least 3 lobes.
- Routine H&E staining—can overlook pathologic Cu accumulation.
- Cu-specific staining—rhodanine (preferred); confirms Cu-protein aggregates, details zonal distribution.
- Semi-quantitative scoring system—estimates severity of Cu accumulation; variation among interpreters confounds comparisons between biopsy reports.
- Cu measurements—can be completed on fresh, frozen, formalin fixed liver, liver tissue extracted from paraffin blocks, or liver sections.
- Distribution of hepatocytes with cytosolic Cu granules and quantification of Cu should be reconciled—areas of dense fibrosis, parenchymal extinction, regenerative nodules contain lower Cu concentrations than unremodeled liver tissue; this phenomenon causes discordance between measured and assessed Cu accumulations.
- In dogs with severe illness with high risk for general anesthesia and liver biopsy, hepatic aspiration cytology with samples stained with rhodanine may identify Cu accumulation; qualitative with variable accuracy; *not* recommended method for definitive diagnosis.

Cu Measurement

- *Atomic absorption spectroscopy*—gold standard method of Cu determination; requires at least full needle biopsy (≥16 g) sample; larger samples improve accuracy.
- Cu must be expressed per DWL.
- *Digital scanning of rhodanine-stained biopsy sections*—validated against atomic absorption spectroscopy, accurately quantifies liver Cu (Cornell University) on biopsy sections; allows rhodanine staining of all sections to determine accurate hepatic Cu distribution and quantification.

Hepatic Cu Concentrations (DWL)

- Normal hepatic Cu ≤400 μg/g.
- Hepatic Cu concentration in dogs with primary diet-induced or genetic CuAH (μg/g DWL)—Bedlington terrier (*COMMD1* mutation): 850–12,000; West Highland white terrier: up to 3,500; Labrador retriever: 400–9,000; Doberman pinscher: 1,000–10,000; Dalmatian: 750–22,000; cat: 700–8,000.
- *Avoid* analytic methods "estimating" sample hydration or reporting Cu on wet weight basis.

PATHOLOGIC FINDINGS

- Cu accumulates in lysosomes and mitochondria in zone 3 (centrilobular) hepatocytes in dogs.
- Oxidative injury—mechanism of hepatocellular injury.
- In some cases, apparent immune-mediated hepatitis accompanies CuAH injury.
- Rhodanine Cu staining confirms affiliation of Cu with histologic injury.
- Histologic features commonly include formation of "copper granulomas" in areas of hepatocyte necrosis—reflects response to oxidatively mediated hepatocyte necrosis; adjacent copper-laden hepatocytes.
- Chronic untreated necroinflammatory injury progresses to chronic hepatitis, parenchymal extinction, liver fibrosis, eventually to cirrhosis and formation of APSS.
- CuAH causing necroinflammatory liver injury leads to development of microhepatia, regenerative nodules, fibrotic "firm" liver texture.

TREATMENT

APPROPRIATE HEALTH CARE

- Outpatient for most dogs.
- Inpatient evaluation and treatment for dogs with hepatic failure or severe acute hepatitis.
- See Hepatitis, Chronic; Cirrhosis and Fibrosis of the Liver for detailed management of liver disease.

NURSING CARE

- Animals in liver failure require fluid and electrolyte correction; may require treatment for HE and coagulopathies and should be treated with IV N-acetylcysteine (NAC) for oxidative injury, d-penicillamine chelation protocol started as soon as oral treatment possible.
- Dogs with hemolytic anemia may require whole or packed red blood cell (RBC) transfusion, IV NAC.

COPPER ASSOCIATED HEPATOPATHY (CONTINUED)

• Dogs with acquired Fanconi syndrome require IV fluid therapy and IV NAC to protect against acute renal failure.

ACTIVITY

Normal; rest if severe acute hepatic necrosis.

DIET

• Feed Cu-restricted diets to all affected dogs *for their lifetime*.
• Merely feeding Cu-restricted diet is unreliable intervention for dogs with pathologic hepatic Cu accumulation (see Suggested Reading).
• Avoid Cu in water if copper pipes—run water for 5 min to remove eluted Cu; restrict access to water with Cu >0.2 ppm.
• Prescription-type liver diets contain lowest Cu content, only provide 2.2–2.5 g protein/kg body weight when fed for maintenance energy requirements; *however*, dietary protein content should *only be reduced* for dogs exhibiting signs of HE or developing ammonium biurate crystalluria.
• Supplemental protein added to base prescription "liver" diets to increase protein intake by 0.5 g up to 1.5 g protein/kg body weight using low Cu-containing foods; select supplemental low Cu-containing protein sources using USDA food tables (freely available on internet).
• Alternative dietary management—balanced homemade Cu-restricted diets (*avoid* organ meats, nuts, certain grains) formulated by veterinary clinical nutritionist.
• Supplement water-soluble vitamins but avoid ascorbate (vitamin C supplements) during Cu hepatotoxicity as may augment oxidative injury.
• Avoid mineral supplements containing Cu if homemade diet; use specifically formulated supplements (e.g., Balance-It®).
• Chelation protocol must be adjunctively used with commercial diets for initial Cu removal.

CLIENT EDUCATION

• Educate all Bedlington terrier owners about genetic basis of CuAH in this breed and appropriate genetic testing, but inform that some dogs require liver biopsy for diagnosis.
• Other breeds—monitor for increased ALT activity with liver biopsy.
• Dogs receiving NSAIDs with circumstantial increase in ALT activity should be investigated for potential asymptomatic or "silent" hepatic Cu accumulation.
• Dietary management and chronic intermittent chelation or zinc administration needed for life in most dogs rescued from CuAH.

SURGICAL CONSIDERATIONS

• Animals with hepatic failure are surgical and anesthetic risks.
• Hypoxia encountered during anesthesia or surgery can provoke Cu-driven oxidative injury.

MEDICATIONS

DRUG(S) OF CHOICE

See other liver topics for specific treatments of chronic hepatitis and cirrhosis.

Chelation

d-Penicillamine
• 10–15 mg/kg PO q12h on empty stomach (1h before feeding); bioavailability reduced 50% if given with food.
• Mechanism—chelates Cu, promotes urinary excretion of Cu, other Cu-protective effects.
• Supplement vitamin B6 (pyridoxine)—25 mg PO q24h for duration of d-penicillamine treatment.
• Initiate treatment in dogs with increased ALT activity associated with biopsy-confirmed centrilobular Cu accumulation in >25% centrilobular hepatocytes or that reconciles with lobular injury/remodeling and Cu affiliation.
• Hepatic Cu as low as 600 µg/g DWL may require chelation and chronic management.
• Dogs with hepatic Cu <1,500 µg/g DWL usually cleared with 6 months of d-penicillamine chelation based on cases with biopsy-proven response.
• Dogs with hepatic Cu >3,000 µg/g may require ≥9–12 months chelation or longer.
• Drug-associated vomiting or hyporexia—abated with starting ½ dose d-penicillamine and titrating upward or concurrent low-dose prednisone; giving with morsel of meat anecdotally reported to solve nausea but may compromise drug bioavailability.
• Monitoring—most clinicians use ALT as surrogate marker because of cost and risks associated with follow-up liver biopsy; post-treatment biopsy optimal.
• Expect substantial decline in ALT by 8 weeks of chelation; do not discontinue daily chelation until ALT within normal range for several months, coordinating with anticipated chelation duration based on hepatic biopsy Cu quantification.
• Successful chelation achieves remarkable histologic improvement and resolution of ALT activity.

Trientine hydrochloride
• Alternative Cu chelator—as effective as d-penicillamine with similar guidelines; dose: 5–7 mg/kg PO q12h given 1h before meals; higher dosing associated with acute renal injury.
• Trientine currently restrictively expensive and difficult to acquire.
• Ammonium tetrathiomolybdate—alternative method for chelating Cu in circulation, from liver, and blocking enteric uptake in humans with Wilson's disease; limited use in dogs.

Zinc—Blocking Enteric Cu Uptake
• Zinc oral administration may assist in chronic control of CuAH; zinc use predicated on study of only 6 dogs.
• Reduces intestinal Cu absorption—study demonstrated reduced hepatic Cu concentrations after 2 years.
• 100 mg elemental zinc PO q12h 1h before feeding as loading dose for 2 months, then 25–50 mg PO q12h for Bedlington terrier-sized dog; zinc acetate best tolerated as zinc source.
• In humans, zinc therapy *less effective* than chelation for chronic management.
• May be useful in early CuAH with lower hepatic Cu concentrations: <1,000 µg/g DWL.
• Effects too slow to achieve therapeutic utility in dogs with high Cu concentrations and hepatitis where chelation therapy required for acute Cu mobilization and elimination.
• Coadministration of zinc and Cu *strongly contraindicated* as will negate efficacy of each treatment.
• Vomiting and inappetence commonly associated with zinc-induced gastritis.
• Evidence suggests low zinc utility in CuAH in dogs—low concentrations of oral zinc concurrent with Cu-restricted diet in previously chelated Labrador retrievers provided no additional benefit (see Suggested Reading).

Antioxidants

• d-α-tocopherol (vitamin E)—10 U/kg q24h PO; may be mixed in food.
• S-adenosylmethionine (SAMe)—20 mg/kg q24h, given on empty stomach.

Hepatoprotectants

• Silibinin (milk thistle extract, form bound to phosphatidylcholine [PPC] improves bioavailability)—5 mg/kg PO q24h; no proven benefit aside from high-dose IV silibinin for Amanita toxicity.
• Ursodeoxycholic acid—10–15 mg/kg PO divided BID given with food for best bioavailability (see Hepatitis, Chronic).
• Polyunsaturated PPC (dilinolylphosphatidylcholine [DLPC])—20–50 mg/kg PO q24h (soy bean extract; PhosChol® form providing 52% DLPC) mixed with food, advised for membrane-protectant and antifibrotic effects; apparent benefit with described chelation protocol based on post-treatment biopsy evaluations.

CONTRAINDICATIONS

• Ascorbic acid (vitamin C) may augment Cu hepatotoxicity.
• Avoid treatment with NSAIDs in affected dogs.

PRECAUTIONS

• Remain aware of altered drug metabolism related to reduced first-pass extraction if APSS develop or altered hepatic metabolism/biotransformation in dogs with severe centrilobular necrosis and remodeling.
• Avoid NSAID administration.

(CONTINUED) # COPPER ASSOCIATED HEPATOPATHY

POSSIBLE INTERACTIONS
Penicillamine or trientine may not be effective if giving concurrent zinc therapy.

FOLLOW-UP

PATIENT MONITORING
- Liver enzymes initially q2–4 weeks for 8 weeks, then q2-4 months.
- Evaluate body weight and condition.
- Optimal reassessment—hepatic biopsy with determination of hepatic Cu concentration within 1 year of initiated treatment.
- If using zinc therapy—assess serum zinc concentrations initially, then during first 2–3 weeks until stable to insure values increase but remain within nontoxic range (200–500 µg/dL), then q6 months; plasma zinc does not reflect liver zinc concentrations.

PREVENTION/AVOIDANCE
- Breed only Bedlington terriers without *COMMD1* mutation; liver registry available for Bedlington terriers proven unaffected on basis of hepatic Cu concentration <400 µg/g DWL at 1 year of age or by gene testing.
- Other breeds noted previously may have recognized kindred predispositions.

POSSIBLE COMPLICATIONS
- d-Penicillamine can cause anorexia and vomiting; start at low end of dose range for first week; give 1h before meals; small amount of food may reduce nausea but reduces treatment efficacy.
- d-Penicillamine can induce glycogen-type vacuolar hepatopathy and ALP activity.
- d-Penicillamine side effects—glomerulonephritis, polyarthritis, drug-associated hepatopathy, or autoimmune-like vesicular disease of mucocutaneous junctions that resolves on drug withdrawal; *note*: assess urine for proteinuria before initiating therapy; rare hepatotoxicity: indicated by escalation of ALT activity; drug known to induce ALP.
- Excess zinc (oral dose >200 mg/day or blood concentration >800 µg/dL) can cause hemolytic anemia.

EXPECTED COURSE AND PROGNOSIS
- Prognosis poor in acutely affected young dogs with fulminant hepatic failure or older dogs with cirrhosis; however, some respond to acute care and chelation.
- Dogs with mild to moderate acute hepatic injury usually have good prognosis.
- Even dogs with nodular hepatopathy and microhepatia and ascites can respond well to described protocol with resolution of many histologic changes, including fibrosis.
- Good prognosis warranted if CuAH detected before liver remodeling or development of hepatitis.

MISCELLANEOUS

AGE-RELATED FACTORS
- Health evaluations that include ALT measurement help identify at-risk dogs.
- Important to evaluate ALT in any dog placed on chronic NSAIDs where Cu retention appears to augment centrilobular hepatotoxicity; measure ALT before and 2–4 weeks after NSAID initiation (sooner if patient demonstrates inappetence, vomiting, lethargy).

PREGNANCY/FERTILITY/BREEDING
- Do not breed affected Bedlington terriers or carriers.
- Genetics of other at-risk breeds unknown—some kindred predispositions recognized.

SYNONYMS
- Bedlington hepatitis.
- Chronic active hepatitis.
- Chronic Cu toxicity.
- Cu toxicosis.

COPROPHAGIA AND PICA

BASICS

DEFINITION
Pica is an abnormal ingestive behavior in which nonfood items are consumed. Coprophagia is a form of pica in which feces is consumed.

PATHOPHYSIOLOGY
• The pathophysiology of pica is unclear. • Coprophagia is not usually a pathologic condition. • Pica is a sign that may be associated with a variety of different conditions—any medical condition leading to nutritional deficiencies, electrolyte imbalances, gastrointestinal (GI) disturbances, polyphagia, or CNS disturbances may lead to pica and/or coprophagia. • Severely calorie-restricted diets or imbalanced diets leading to insufficiencies may also lead to pica and/or coprophagia.

SYSTEMS AFFECTED
GI—foreign body obstruction, GI upset leading to vomiting and diarrhea; increased chance of GI parasitism with coprophagia.

GENETICS
None known.

INCIDENCE/PREVALENCE
• Pica—unknown. • Coprophagia—occurrence has been estimated at 16–23% in dogs.

SIGNALMENT

Species
Coprophagia is common in dogs but rare in cats. Pica is seen in both dogs and cats.

Breed Predilections
Oriental cat breeds such as Siamese may be at greater risk of pica.

Mean Age and Range
Pica occurs more often in puppies than in adult dogs. Pica in cats is most likely to begin prior to 18 months of age.

SIGNS

Historical Findings
• In dogs, ingestion of inappropriate items such as rocks, clothing, and/or feces. • In cats, ingestion of fabrics, plastic, shoelaces, string, thread, or other inappropriate items.

Physical Examination Findings
• Halitosis if coprophagia is the presenting problem. • Dental trauma if the dog targets hard objects. • Pallor or weakness if anemia is a contributing condition. • Poor body condition if malabsorption or maldigestion is a contributing condition. • Neurologic signs if caused by neurologic disease. • May be abnormalities on abdominal palpation if gastroenteritis or foreign body.

CAUSES

Behavioral Causes
• Coprophagia is considered normal maternal behavior; the dam or queen licks the anogenital region of the neonate to stimulate elimination and then consumes the excreta. • Coprophagia may be considered a normal exploratory behavior in puppies; it has been postulated that high levels of deoxycholic acid in feces may contribute to neurologic development. • It is normal for dogs to seek out cat feces because it is high in protein—odor and taste may also be appealing. • Ungulate feces is also appealing to dogs, apparently due to partially digested vegetable matter. • Dogs described as "greedy eaters" have higher incidence of coprophagy; therefore a voracious appetite may predispose to coprophagia. • Feces may be appetizing to some dogs, so the behavior might be self-rewarding. • Dogs that have been punished for eliminating in the house could learn to eat their own feces in an apparent attempt to avoid punishment. • Dogs may also eat their own feces as a form of "nest cleaning." • Coprophagia may be attention-seeking behavior if a dog learns that it reliably leads to immediate owner attention. • Coprophagia may also develop in response to anxiety or frustration. • Pica may occur secondary to stealing behavior when the dog is highly motivated to prevent the owner from retrieving the stolen object or when the object has ingestive appeal. • Pica may develop as a result of anxiety or frustration that leads to destruction and subsequent consumption of an item.

Medical Causes
• Anemia. • Malnutrition leading to polyphagia. • Endocrinopathies—hyperthyroidism, diabetes mellitus, hyperadrenocorticism. • Maldigestion/malabsorption (e.g., exocrine pancreatic insufficiency). • Inflammatory bowel disease. • Small intestinal bacterial overgrowth. • CNS disease. • Portosystemic shunt. • Intestinal parasitism.

Drug-Induced Causes
Administration of drugs such as corticosteroids, progestins, phenobarbital, or benzodiazepines can lead to polyphagia.

RISK FACTORS
• Early weaning of kittens has been postulated to lead to sucking and ingestion of fabrics. • Cats fed low-roughage diets and/or not allowed access to roughage sources such as grass. • Dogs lacking appropriately stimulating environment, adequate activity, or social interactions may be at risk for pica and/or coprophagia. • Long periods of confinement, especially in a barren environment, may predispose to coprophagia. • Dogs in multidog households may be at higher risk of demonstrating coprophagia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Diagnosis is based on history and description of the behavior. • History should include: ○ Description of the problem—when and where it happens. ○ Age of onset. ○ Owner's usual response, any corrections attempted so far, and their results. ○ Changes in household, schedule, diet, or health associated with onset of problem. ○ Feeding routine of pets—when, where fed, by whom. ○ Any other unusual oral behaviors. ○ Other behavioral problems. ○ House training status—when and where the pet eliminates. ○ How the pet was house trained. ○ Relationships with other pets. • Environment, including daily schedule for play, exercise, attention, or training. • Medical health should be evaluated, including appetite and weight, any signs of nausea or GI upset such as excessive lip licking or surface licking, and color, consistency, and frequency of feces. • Pica must be differentiated from destructive chewing, where items may be torn apart but not consumed. • Pica must also be differentiated from instances where an animal consumes a nonfood item because the item smells and/or tastes appealing.

CBC/BIOCHEMISTRY/URINALYSIS
• Results suggesting diabetes mellitus, hyperadrenocorticism, hyperthyroidism, or drug-induced causes of polyphagia. • Anemia or hypoproteinemia. • Results suggesting presence of a portosystemic shunt—microcytosis, target cells, hypoalbuminemia, low blood urea nitrogen (BUN), ammonium biurate crystalluria. • Peripheral eosinophilia may occur due to gastrointestinal parasitism or eosinophilic inflammatory bowel disease.

OTHER LABORATORY TESTS
• Trypsin-like immunoreactivity (TLI)—may be low if exocrine pancreatic insufficiency exists. • Serum folate and cobalamin to evaluate for small intestinal bacterial overgrowth and small intestinal mucosal disease. • Fecal fat and fecal trypsin may help to evaluate for exocrine pancreatic insufficiency and other malabsorption/maldigestion-related conditions. • Thyroid panel to determine if hyperthyroid. • Fecal examinations to screen for intestinal parasites; *note*: coprophagia can result in false-positive tests for helminths in dogs. • Bile acids to evaluate for presence of a portosystemic shunt. • Adrenocorticotropic hormone (ACTH) stimulation if hyperadrenocorticism a consideration.

(CONTINUED)

COPROPHAGIA AND PICA

IMAGING
Survey abdominal radiographs and/or abdominal ultrasonography if indicated to rule out foreign body obstruction. May also demonstrate microhepatica if a portosystemic shunt is present.

DIAGNOSTIC PROCEDURES
• GI scoping and biopsy may be needed to evaluate for gastric and small bowel disease. • Cultures if indicated to evaluate for small intestinal bacterial overgrowth.

TREATMENT

APPROPRIATE HEALTH CARE

Treatment of Pica
• Prevent access to nonfood items that are likely targets—physical barriers to prevent access or confine animal away from targeted nonfood items; teach dog to wear basket muzzle. • Change to diet higher in fiber. • Provide feeding toys and acceptable foraging opportunities (e.g., green plants such as grass or catnip for cats). • Teach dogs a "Drop it" or "Leave it" command so the owner can prevent consumption of inappropriate items. • If diagnosis consistent with compulsive disorder, see appropriate section in text for treatment.

Treatment of Coprophagia
• Prevent access to feces. • Walk dog on leash and pick up feces immediately. • Teach dog to wear basket muzzle. • Head collar for increased ability to guide pet away from feces and reward "turning away" after defecation; dogs should then be rewarded with a tasty treat for returning to the owner on command. • There is no evidence that changing the taste or texture of the stool helps to decrease coprophagia or that any product marketed for the treatment of coprophagia reliably stops the behavior. • Taste aversion might be taught by treating the feces with a strongly distasteful substance (e.g., hot sauce, cayenne pepper, etc.); all feces that the dog can come in contact with must be treated in order for this to be effective; however, even if effective, dogs can learn to recognize which feces are treated, and ingest untreated feces.

ACTIVITY
• Increased mental and physical enrichment may help in treatment and prevention of pica and coprophagia and keep the pet engaged in alternative desirable activities. • Regular, predictable schedules of interaction and exercise can decrease anxiety and may aid in treatment of pica and coprophagia.

DIET
Dietary changes may be helpful in some cases of coprophagia. A more highly digestible diet or the addition of plant-based enzyme supplements or meat tenderizers is rarely successful in decreasing coprophagia.

CLIENT EDUCATION
• Owners should be counseled that coprophagia is, in most cases, normal canine behavior and not harmful unless the dog consumes feces containing pathogens or infective parasites. • Owners should avoid the use of any form of direct or confrontational punishment for pica or coprophagia due to the risk of increasing anxiety, possibly worsening the behavior, and/or leading to other problem behaviors. Close supervision and prevention of access are the best approach.

MEDICATIONS

DRUG(S) OF CHOICE
If the behavior is determined to be a compulsive disorder or secondary to anxiety, psychoactive drugs or anxiolytic drug therapy may be indicated.

CONTRAINDICATIONS
The use of any drugs that might contribute to polyphagia should be avoided when possible.

PRECAUTIONS
If drugs are indicated, precautions should be considered for the specific drug.

POSSIBLE INTERACTIONS
If drugs are prescribed, interactions should be considered for the specific drug.

FOLLOW-UP

PATIENT MONITORING
• Client should be contacted in 1–2 weeks to verify compliance and determine if there is improvement. • If no or minimal improvement, further diagnostics should be recommended.

PREVENTION/AVOIDANCE
• Prevent access to the items likely to be consumed. • Careful supervision during house training may help to prevent puppy exploration of feces and reinforcement of coprophagia. • Administration of monthly parasiticide to control GI parasites.

POSSIBLE COMPLICATIONS
Foreign body obstruction is most common sequela to pica in both dogs and cats.

EXPECTED COURSE AND PROGNOSIS
◦ Prognosis is guarded if the condition has been present for a long period of time; or the owner is not willing to closely supervise the dog when it eliminates or prevent access to inappropriate items that the pet attempts to consume. • If owner is willing to supervise the dog and comply with treatment recommendations, prognosis improves.

MISCELLANEOUS

AGE-RELATED FACTORS
In adult or geriatric onset of pica or coprophagia, primary underlying medical conditions should be strongly suspected.

PREGNANCY/FERTILITY/BREEDING
• Owners of wool-sucking cats should be cautioned that the behavior appears to have a breed disposition, so avoiding breeding of this individual may be prudent and responsible action. • If this behavior is believed to be associated with a compulsive disorder, the animal should not be bred, as compulsive disorders appear to have a hereditary basis.

SYNONYMS
• Depraved appetite. • Wool sucking or wool chewing in cats.

SEE ALSO
• Compulsive Disorders—Cats.
• Compulsive Disorders—Dogs.
• Fear, Phobias and Anxieties—Cats.
• Fear, Phobias, and Anxieties—Dogs.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone.
• BUN = blood urea nitrogen.
• GI = gastrointestinal.
• TLI = trypsin-like immunoreactivity.

CORNEAL AND SCLERAL LACERATIONS

BASICS

DEFINITION
• Penetrating—a wound or foreign body enters but does not pass through the cornea or sclera. • Perforating—a wound or foreign body completely passes through the cornea or sclera; greater risk of vision loss than penetrating. • Simple—only the cornea or sclera, penetrating or perforating, other eye structures intact. • Complicated—perforating, involves other ocular structures, uveal, vitreal, or retinal incarceration or prolapse through the wound, traumatic cataract, hyphema, lid lacerations.

PATHOPHYSIOLOGY
• Sharp trauma—wounds by an outside-in mechanism. • Blunt trauma—wounds by an inside-out mechanism; eye undergoes sudden changes in its equatorial and axial dimensions and intraocular pressure (IOP); actual wound may be distant from point of impact; often more damaging than sharp trauma. • All or a portion of foreign object initiating injury may be retained in wound or eye.

SYSTEMS AFFECTED
• Musculoskeletal—surrounding skull or orbital tissue. • Nervous—brain injury. • Ophthalmic.

INCIDENCE/PREVALENCE
Common

SIGNALMENT
Species
Dog and cat.

SIGNS
Historical Findings
• Usually acute onset. • History of running through vegetation, hit by projectiles (gunshot etc.), scratched by a cat. • Trauma may not be observed.

Physical Examination Findings
• Varies with tissues affected. • Corneal, scleral, or eyelid deformity, edema, or hemorrhage. • May see retained foreign body. • Often rapidly seals; may appear only as subconjunctival hematoma. • May also see iris defects, pupil distortion, hyphema, cataract, vitreal hemorrhage, retinal detachment, and exophthalmia.

CAUSES
Blunt or sharp trauma.

RISK FACTORS
• Preexisting visual impairment. • Young, naïve, or highly excitable animals. • Hunting or running through heavy vegetation. • Fighting.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Traumatic event not observed and no foreign body found—consider nontraumatic causes of ocular injury. • Traumatic hyphema—generally accompanied by corneal or scleral lesions and subconjunctival or periocular hemorrhage. • Traumatic cataracts—disrupted lens capsule. • Traumatic retinal detachment—accompanied by intraocular hemorrhage.

CBC/BIOCHEMISTRY/URINALYSIS
Normal, or related to other injuries.

OTHER LABORATORY TESTS
• Cytologic examination and aerobic culture and sensitivity of the wound and foreign body—recommended even if infection is not apparent; specimen may be collected under general anesthesia at time of surgery. • Consider other tests (platelet count, coagulation profile, etc.) if nontraumatic causes possible.

IMAGING
• Ocular ultrasonography—if ocular media are opaque; may clarify extent and nature of intraocular disease, may detect foreign body. • Orbital radiographs, CT, or MRI (if nonmetallic)—may help determine projectile's course; may detect foreign body.

DIAGNOSTIC PROCEDURES
• Determine nature, force, and direction of impact of object—to identify which tissues may be involved. • Do not put pressure on eye until rupture or laceration of globe has been ruled out. • Assess vision—menace response; aversion to bright light. • Periocular skin and orbit—examine for lacerations or deformities; suspect globe involvement if lid laceration crosses eyelid margin or penetrates orbital septum; entry sites often small and quickly seal. • Abnormal ocular motility—suggests extraocular muscle trauma, orbital hemorrhage or edema, retained foreign bodies, or peripheral nerve or CNS damage. • Scleral rupture—consider if subconjunctival hemorrhage, especially if anterior chamber is deep or shallow, there is vitreal hemorrhage, or eye is abnormally soft. • Pupils—assess size, shape, symmetry, direct and consensual light reflexes. • Detailed ophthalmoscopy—assess clarity of ocular media and fundus integrity, rule out intraocular foreign body. • Seidel test—if any question of corneal or scleral leaking; use a dry to slightly moist fluorescein strip to paint a thin coat of fluorescein over the surface of the defect; leaking aqueous combines with the orange fluorescein, forming a bright green rivulet (seen best with cobalt illumination).

PATHOLOGIC FINDINGS
• Depends on wound and affected tissues. • Usually correlates with clinical examination findings. • Vitreal hemorrhage—may organize into a fibrous band that causes traction retinal detachment. • Post-traumatic sarcoma (cats)—may occur months to years after severe ocular trauma.

TREATMENT

APPROPRIATE HEALTH CARE
• Depends on severity. • Outpatient—if integrity of globe is ensured.

NURSING CARE
• Sedation—consider for excited or fractious patients. • When walking—apply an Elizabethan collar (E-collar) and use a harness or put ipsilateral foreleg through the leash to avoid increasing IOP in affected eye.

Injuries Considered for Medical Treatment
• Complicated wounds, those with retained plant material, and those caused by blunt trauma with tissue devitalization—infection common. • Bacterial endophthalmitis—5–7% of perforations; very rare in wounds that only penetrate but do not perforate the cornea. • Nonperforating wounds with no wound edge override or gape—apply an E-collar; give topical antibiotic or atropine ophthalmic solutions. • Nonperforating wounds with mild wound gape or shelved edges—apply a therapeutic soft contact lens and an E-collar; give topical antibiotic or atropine ophthalmic solutions. • Simple full-thickness, pinpoint corneal perforation with a negative Seidel test that has a formed anterior chamber and no uveal prolapse—sedentary patients; use a therapeutic soft contact lens and an E-collar; give topical antibiotic or atropine ophthalmic solutions; reexamine a few hours after applying the lens and at 24 and 48 hours.

ACTIVITY
• Usually confined indoors (cats) or limited to leash walks until healing is complete. • A harness is preferred to a collar to reduce pressure on the neck and the risk of increased IOP and wound leaks.

CLIENT EDUCATION
Warn client that the full extent of the injury (cataracts, retinal detachment, infection) may not be apparent until days or weeks after the injury and that long-term follow-up is necessary.

(CONTINUED)

CORNEAL AND SCLERAL LACERATIONS

SURGICAL CONSIDERATIONS

Injuries Requiring Surgical Exploration or Repair

• Full-thickness corneal lacerations with a positive Seidel test. • Full-thickness wounds with iris incarceration or prolapse. • Full-thickness scleral or corneoscleral lacerations. • Suspected retained foreign body or posterior scleral rupture. • Simple nonperforating wound with edges that are moderately or overtly gaping and that are long or more than two-thirds the corneal thickness.

Injuries Considered for Surgical Exploration or Repair

• Small full-thickness corneal lacerations with a negative Seidel test and no uveal prolapse. • Large conjunctival lacerations. • Partial-thickness corneal or scleral lacerations in an active patient.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

• Penetrating—topical antibiotics alone (e.g., neomycin, polymyxin B, and bacitracin) or gentamicin solution q6–8h; usually sufficient. • Perforating wounds with negative Seidel test—systemic ciprofloxacin (dogs: 10–20 mg/kg PO q24h); topical cefazolin (add injectable cefazolin to artificial tears to concentration of 33 mg/mL) and either topical ophthalmic ciprofloxacin or ofloxacin; both drugs q4–6h. • Perforating wounds with positive Seidel test—systemic ciprofloxacin (dogs: 10–20 mg/kg PO q24h); topical antibiotics as noted above, only after defect has been made watertight.

Anti-Inflammatories

• Topical 1% prednisolone acetate or 0.1% dexamethasone solution q6–12h; as soon as wound is sutured or has epithelialized (becomes fluorescein stain negative), as long as infection is not present. • Systemic prednisone 0.5–1 mg/kg PO q12–24h; for sutured or epithelialized wounds when inflammation is severe, when lens or posterior structures are involved, or when wound is infected or not epithelialized and control of inflammation is mandatory to preserve the eye. • Topical nonsteroidal anti-inflammtory drugs (NSAIDs)—flurbiprofen or others; if topical corticosteroids are contraindicated and control of inflammation is mandatory to preserve the eye.

Mydriatics

1% atropine ophthalmic solution q6–12h—when there is significant miosis.

Analgesics

• Topical atropine may provide sufficient pain relief. • Carprofen 2.2 mg/kg PO q12h or 4.4 mg/kg PO q24h. • Tramadol—2–5 mg/kg PO q12h.

CONTRAINDICATIONS

• Topical ophthalmic ointments—avoid in Seidel-positive perforations until wound closed. • Systemic ciprofloxacin—avoid in young dogs.

PRECAUTIONS

• Aminoglycosides—topical application may be irritating and may impede reepithelization if used frequently or at high concentrations; possibility for renal toxicity. • Topical solutions may be preferable to ointments if corneal integrity is questionable. • Atropine—may exacerbate keratoconjunctivitis sicca and glaucoma. • Topical or systemic NSAIDs—use cautiously with hyphema; unknown safety in cats.

POSSIBLE INTERACTIONS

Systemic NSAIDs—may potentiate nephrotoxicity of aminoglycosides; ensure good hydration and adequate renal function.

ALTERNATIVE DRUG(S)

Topical ciprofloxacin ophthalmic solution—may be used instead of combination of topical cefazolin and fortified aminoglycoside; some streptococcus are resistant.

FOLLOW-UP

PATIENT MONITORING

• Deep or long penetrating wounds that have not been sutured and perforating wounds—recheck q24–48h for first several days to ensure integrity of globe, to monitor for infection, and to check control of ocular inflammation. • Superficial penetrating wounds—usually recheck at 3–5-day intervals until healed. • Antibiotic therapy—alter according to culture and sensitivity.

PREVENTION/AVOIDANCE

• Take care when introducing new puppies to households with cats. • Minimize running through dense vegetation; owner should consider having bottle of saline eyewash to irrigate foreign debris from eye. • Minimize visually impaired dog's exposure to dense vegetation.

POSSIBLE COMPLICATIONS

• Loss of eye or vision. • Chronic ocular inflammation or pain. • Post-traumatic sarcoma—may develop in cat eyes following trauma.

EXPECTED COURSE AND PROGNOSIS

• Most eyes with corneal lacerations or a retained corneal foreign body are salvageable. • The more posterior the injury, the poorer the prognosis for retention of vision. • Poor prognosis—scleral or uveal involvement, no light perception, perforating injuries involving the lens or with significant vitreal hemorrhage or retinal detachment. • Penetrating injuries usually better prognosis than perforating injuries. • Blunt trauma carries poorer prognosis than sharp trauma.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Depends on nature and extent of injury.

PREGNANCY/FERTILITY/BREEDING

• Systemic corticosteroids—may complicate pregnancy. • Systemic ciprofloxacin—should be avoided during pregnancy.

SEE ALSO

• Cataracts.
• Hyphema.
• Keratitis—Ulcerative.
• Proptosis.
• Retinal Detachment.

ABBREVIATIONS

• E-collar = Elizabethan collar.
• IOP = intraocular pressure.
• NSAID = nonsteroidal anti-inflammatory drug.

CORNEAL OPACITIES—DEGENERATIONS AND INFILTRATES

BASICS

OVERVIEW
Acquired corneal disorder characterized by lipid or calcium deposition. May be unilateral or bilateral, have distinct margins, and occur secondary to other ocular or systemic disorders.

SIGNALMENT
Primarily in dogs, uncommon in cats. Lipid deposition most common in geriatric dogs. May be associated with systemic hyperlipoproteinemia.

SIGNS
• Lipid deposits—gray-white or crystalline; band-shaped, irregular, or circular. • Calcium deposits—dense white to crystalline; irregular, punctate to band-shaped lesions in the superficial stroma. • Frequently associated with inflammatory disorders such as keratitis or uveitis. • Corneal vascularization, edema, and pigmentation often present. • With progression the cornea may develop a roughened appearance; disruption of epithelium can lead to ulceration. • Associated ocular conditions that may lead to corneal degeneration—corneal scars, keratoconjunctivitis sicca (KCS), exposure keratitis, chronic uveitis, episcleritis, phthisis bulbi, chronic topical steroid therapy, limbal neoplasia. • When lipid deposition occurs secondary to hyperlipoproteinemia, perilimbal annular ring may form with clear zone between affected cornea and limbus; often bilateral but may be asymmetric; vascularization is variable.

CAUSES & RISK FACTORS
• Lipid—hyperlipoproteinemia may increase risk or worsen existing deposits; can be secondary to hypothyroidism, diabetes mellitus, hyperadrenocorticism, diet, pancreatitis, nephrotic syndrome, liver disease, hyperlipidemia of miniature schnauzers. • Calcium—hypercalcemia, hyperphosphatemia, hypervitaminosis D, hyperadrenocorticism, uremia. • Lipid and calcium deposits are frequently seen together.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Corneal scar—nonpainful lesion, gray to white; fluorescein negative; relatively smooth corneal surface; distinct margins. • Corneal stromal dystrophies—bilateral, often symmetric foci of gray to white deposition, distinct margins; heritable, not associated with ocular inflammation; do not retain fluorescein stain; often occur away from the limbus. • Edema—bluish to gray; usually homogeneous; varies in size depending on severity; indistinct margins; can retain fluorescein stain if corneal erosion/ulceration present. • Corneal ulcer—ocular pain, retains fluorescein stain, varying degrees of edema around the lesion. • Inflammatory cell infiltrates—ocular pain, gray to tan to yellow with indistinct margins; cytologic examination of cornea reveals white blood cells, microorganisms.

CBC/BIOCHEMISTRY/URINALYSIS
• *Systemic tests only necessary if hyperlipidemia is suspected; no systemic tests necessary for most cases.* • Lipid—evaluate fasting cholesterol, triglyceride, blood glucose concentrations. • Calcium—evaluate ionized calcium concentration.

OTHER LABORATORY TESTS
Endocrinopathy testing—thyroid function, adrenocorticotropic hormone (ACTH) stimulation test.

DIAGNOSTIC PROCEDURES
Fluorescein staining—may retain dye around margins of deposit if raised.

TREATMENT
• Treat primary ocular disease if present. • Corneal deposits causing patient discomfort or impaired vision may benefit from corneal debridement or superficial keratectomy followed by medical treatment; deposits likely to recur if underlying cause not corrected. • Hyperlipoproteinemia may resolve with low-fat diet and treatment of systemic disease if present; both may slow or stop progression of ocular disease.

MEDICATIONS

DRUG(S) OF CHOICE
• Topical broad-spectrum antibiotics (i.e., triple antibiotic) for ulcerated cornea; frequency depends on severity; usually uncomplicated ulcers treated q8–12h. • Topical nonsteroidal anti-inflammatory drug q8–12h—indicated if uveitis noted. • Topical 0.2% cyclosporine—to improve tear film quality, reduce inflammation. • Topical 1% atropine q8–24h—indicated to reduce pain if uveitis or ulceration is present. • Topical ethylene diamine tetra-acetate (EDTA) solution 0.5–3% q6h; may help minimize calcium deposits; usually used following debulking procedure to improve efficacy. • Artificial tear ointment q6–12h; may prevent or reduce frequency of secondary corneal ulceration; provides lubrication and improves comfort when corneal surface is irregular.

CONTRAINDICATIONS/POSSIBLE COMPLICATIONS
• Topical corticosteroids—not recommended, may worsen severity; contraindicated with corneal ulceration. • Topical atropine—contraindicated with KCS, glaucoma, lens luxations.

FOLLOW-UP

PATIENT MONITORING
Monitor serum cholesterol and triglycerides to assess efficacy of dietary management in hyperlipidemic patients; monitor treatment of primary disease if present.

EXPECTED COURSE AND PROGNOSIS
• Corneal ulceration—associated with worsening of disease. • Vision—may be affected in advanced disease; may be severe if primary ocular disease (e.g., uveitis) present. • Deposits may recur following superficial keratectomy.

MISCELLANEOUS

SEE ALSO
• Corneal Opacities—Dystrophies.
• Keratitis—Ulcerative.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone.
• EDTA = ethylene diamine tetra-acetate.
• KCS = keratoconjunctivitis sicca.

CORNEAL OPACITIES—DYSTROPHIES

BASICS

OVERVIEW

• Primary, inherited (or familial), bilateral, and often symmetric condition of the cornea that is not associated with other ocular or systemic diseases. • Three types based on anatomic location—epithelial: characterized by dyskeratotic and necrotic epithelial cells, focal absence of epithelial basement membrane, and cell infiltrate in anterior corneal stroma; stromal: lipid deposition within corneal stroma; endothelial: characterized by abnormal, dystrophic endothelial cells.

SIGNALMENT

Usually dogs; rare in cats.

Epithelial

Shetland Sheepdogs—age of onset 6 months–6 years; slow progression.

Stromal

• Usually young adult dogs at age of onset. • Affected breeds—Afghan hound, Airedale terrier, Alaskan Malamute, American cocker spaniel, beagle, bearded collie, bichon frisé, cavalier King Charles spaniel, German shepherd, Lhasa apso, mastiff, miniature pinscher, rough collie, Samoyed, Siberian husky, Weimaraner, whippet, and others; inheritance pattern identified in few breeds.

Endothelial

• Dogs—primarily Boston terriers, Chihuahuas, and dachshunds; may affect other breeds; typically middle-aged or older at onset of clinical signs; female predilection suggested. • Cats—affects young animals; described most often in domestic shorthairs; a similar condition without endothelial disease is inherited as an autosomal recessive disorder in Manx.

SIGNS

All cause some degree of opacity in cornea.

Epithelial

• Can be asymptomatic or have blepharospasm; multifocal white or gray circular to irregular opacities or rings; sometimes associated with multifocal corneal erosions. • Vision usually not affected.

Stromal

• Usually asymptomatic without inflammation. • Central—most common; gray, white, or silver oval to circular opacity of central or paracentral cornea; with magnification may note multiple fibrillar to coalescing opacities that have crystalline or ground-glass appearance (crystalline corneal dystrophy). • Diffuse—affects Airedales; more diffuse, dense opacity than with central dystrophy. • Annular—commonly affects Siberian huskies; doughnut-shaped opacity of paracentral or peripheral cornea. • Vision—usually not affected; visual deficit possible with advanced or diffuse disease.

Endothelial

• Asymptomatic in early stages. • Edema of temporal or inferio-temporal cornea that usually progresses to entire cornea after months to years. • Corneal epithelial bullae (bullous keratopathy) and subsequent corneal erosion ulceration may develop; erosions or ulceration may cause blepharospasm due to pain. • Vision—may be impaired with advanced disease.

CAUSES & RISK FACTORS

• Epithelial—result of degenerative or innate abnormalities of corneal epithelium and/or basement membrane. • Stromal—innate abnormality or localized error in corneal lipid metabolism; may be affected by hyperlipoproteinemia (may increase opacity). • Endothelium—degeneration of endothelial cell layer; subsequent loss of endothelial cell pump function results in corneal edema.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Epithelial, stromal—other causes of corneal opacity: corneal degenerations, ulcers, scars, inflammatory cell infiltrates. • Endothelial—other causes of diffuse corneal edema: uveitis and glaucoma.

CBC/BIOCHEMISTRY/URINALYSIS

Epithelial, stromal—high concentrations of cholesterol and triglyceride levels may modify course of disease, but are not the cause.

DIAGNOSTIC PROCEDURES

• Stromal—usually does not retain fluorescein stain. • Epithelial or endothelial—may retain fluorescein stain, often in multifocal punctate areas, particularly with advanced disease. • Tonometry—to eliminate glaucoma as cause of corneal edema.

TREATMENT

• Advanced epithelial or endothelial disease with ulceration—may require treatment for ulcerative keratitis. • Stromal—usually none required; may perform superficial keratectomy to remove lipid deposits if severe, but usually unnecessary and deposits may recur. • Inform client that some corneal dystrophies are inherited. • Advanced endothelial dystrophy—may use therapeutic soft contact lens with or without debridement of redundant corneal epithelial tags, conjunctival flap surgery, or thermal cautery of cornea.

MEDICATIONS

DRUG(S) OF CHOICE

• Corneal ulceration—topical antibiotics and possibly atropine (see Keratitis—Ulcerative). • Epithelial—1–2% cyclosporine in oil or 0.2% ointment q8–24h to relieve clinical signs. • Endothelial—topical 5% sodium chloride ointment; palliative treatment; does not markedly clear cornea, but may prevent progression and rupture of corneal epithelial bullae.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Topical corticosteroids—no benefit to lipid (stromal) dystrophy, of questionable benefit to other forms of dystrophy.

FOLLOW-UP

• Reexamination—necessary only if ocular pain or corneal ulceration develops. • Corneal opacity—may wax and wane with lipid dystrophy; unlikely to resolve. • Corneal ulceration—may accompany progression of epithelial or endothelial dystrophy. • Vision—not substantially affected except in advanced cases.

MISCELLANEOUS

SEE ALSO

• Corneal Opacities—Degenerations and Infiltrates.
• Keratitis—Ulcerative.

Author Ellison Bentley
Consulting Editor Kathern E. Myrna

CORNEAL SEQUESTRUM—CATS

BASICS

OVERVIEW
- A focal, light brown to black, plaque-like area of stromal coagulation necrosis usually located axially.
- Usually caused by chronic corneal ulceration, trauma, or exposure.
- Synonym—keratitis nigrum.

SIGNALMENT
- Cats—any breed, age.
- Brachycephalic breeds, Siamese predisposed.
- Colorpoints may be genetically predisposed.

SIGNS
- Unilateral or bilateral, focal round to oval, variably sized areas of corneal discoloration ranging from translucent golden-brown (early) to opaque black (chronic).
- Often with chronic nonhealing corneal ulcer.
- Corneal vascularization and edema.
- History of feline herpesvirus-1 (FHV-1) keratoconjunctivitis.
- Blepharospasm or ocular discharge.
- Conjunctival hyperemia and chemosis.
- Miotic pupil.
- May be static for long periods or may rapidly progress.
- With chronicity, corneal vascularization may extrude plaque.

CAUSES & RISK FACTORS
- Thought to involve chronic mechanical corneal irritation or ulceration with corneal necrosis and desiccation.
- Risk factors include chronic corneal ulceration, chronic trichiasis or entropion, brachycephalic conformation, lagophthalmia, keratoconjunctivitis sicca (KCS), qualitative tear film disorders (lipid or mucin deficiency), FHV-1 infection, topical corticosteroids, and iatrogenic trauma (grid keratotomy).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Corneal perforation/iris prolapse—protruding iris is fleshy and yellow to light brown.
- Corneal foreign body.
- Corneal pigmentation—rare in cats.
- Corneal neoplasia—melanocytoma occurs at limbus and is typically nonpainful.

CBC/BIOCHEMISTRY/URINALYSIS
No specific abnormalities.

OTHER LABORATORY TESTS
- Schirmer tear test—very low values suggest KCS, but some normal cats have low values.
- Corneal culture and cytology to rule out corneal infection.
- Fluorescein stain.
- Tear film breakup time (TBUT)—normal time to breakup of fluorescein-stained tear film is 21 seconds; TBUT may be decreased in cats with sequestra or FHV-1 due to mucin tear film deficiency or secondary to corneal disease.
- Corneal histopathology—confirm diagnosis and evaluate completeness of excision.
- PCR for FHV-1— limited value.
- Conjunctival biopsy—goblet cell numbers may decrease with conjunctival inflammation or FHV-1.

TREATMENT
- Lesion depth, degree of ocular pain, and cost are important factors.
- Medical—supportive care, wait for sequestrum to spontaneously slough; ocular pain may persist for months and sloughing of sequestrum may lead to deep corneal ulceration or perforation.

Surgical Considerations
- Lamellar keratectomy—if performed early, can relieve ocular pain, promote corneal healing, and may prevent lesion from involving deeper corneal stroma.
- Corneal grafting should be performed if ≥50% of corneal stroma has been excised; options include conjunctival pedicle grafting, grafting with synthetic, autogenous, or heterologous biomaterials, and corneoscleral transposition.
- Diamond burr debridement may be used to remove superficial sequestra.
- Postoperative management—broad-spectrum topical antibiotic, atropine ointment, and tear supplement.

MEDICATIONS

DRUG(S) OF CHOICE
- Topical oxytetracycline with polymyxin B or bacitracin-neomycin-polymyxin B q6–8h (prophylactic).
- Topical 1% atropine sulfate ointment q12–24h (improve ocular comfort).
- Topical lubricants (e.g., carboxymethylcellulose gel) q6–8h (reduce mechanical irritation and corneal desiccation); may prevent progression of nonulcerated sequestra.
- Topical or systemic antiviral therapy in cats with history or clinical signs of FHV-1 infection.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Topical antibiotics (neomycin) may be irritating and cause chemical conjunctivitis.

FOLLOW-UP

PATIENT MONITORING
- If managing medically, examine as needed to monitor progression and for complications associated with sloughing of sequestrum.
- If managed by keratectomy, examine q5–7 days until corneal defect has reepithelialized (usually 7–14 days).
- Sequestra may recur or occur in contralateral eye; recurrence more likely in cats with low Schirmer tear tests, full-thickness lesions, or in cases in which keratectomy did not result in complete excision of pigmented corneal tissue or predisposing cause was not addressed.

POSSIBLE COMPLICATIONS
Corneal perforation may occur if sequestrum sloughs, leaving full-thickness defect, or if sloughing results in deep stromal corneal ulcer that becomes malacic or infected.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Corneal ulceration—cats.
- Eyelid conformational abnormalities (trichiasis, entropion, etc.).

ABBREVIATIONS
- FHV-1 = feline herpesvirus-1.
- KCS = keratoconjunctivitis sicca.
- TBUT = tear film breakup time.

Consulting Editor Kathern E. Myrna

COUGH

BASICS

DEFINITION

• A sudden and often repetitively occurring defense reflex that helps clear large airways of excess secretions, irritants, foreign particles, and microbes, or clear foreign material from upper airways. • The cough reflex consists of three phases: inhalation, forced exhalation against a closed glottis, and violent expulsion of air from the lungs following opening of the glottis, usually accompanied by a sudden noise. Coughing can happen voluntarily as well as involuntarily, although in dogs and cats it is presumed to be essentially involuntary. Coughing should not be confused with other airway sounds (cf differential diagnosis).

PATHOPHYSIOLOGY

• A physiologic reflex in healthy animals that protects the lower airways from inhalation of foreign particles and helps clear particles that have been entrapped in the mucus; acts in conjunction with the mucociliary clearance mechanism. • The cough pathway includes cough receptors, which are made up of sensory nerves in the airways, the vagus nerve, the central cough center, and effector muscles. • The cough pathway can be stimulated by mechanical or chemical factors; endogenous triggers include airway secretions and inflammation; exogenous triggers include smoke and aspirated foreign material. • Cough receptors include rapidly adapting stretch receptors (sensitive to mechanical stimuli) that are located within the mucosa of the tracheobronchial tree (especially larynx and trachea), and pulmonary/bronchial C-fibers, which are more sensitive to chemical stimulation; coughing mechanisms and pathways are very complex and are not fully understood, even in humans.

SYSTEMS AFFECTED

• Respiratory—cough of any origin can be an inciting factor for aggravation or precipitation of signs associated with tracheal collapse in susceptible breeds. • Cardiovascular—enlargement or impaired function of the right ventricle can result from a respiratory disorder causing tissue damage, hypoxic injury, and/or chronic hypoxic pulmonary vasoconstriction (cor pulmonale).

SIGNALMENT

• Dogs and cats of all ages and breeds. • Much more common clinical sign in dogs than in cats. • Cough of tracheal origin is less common in cats than in dogs. • Age, breed, and sex predispositions vary with inciting cause.

SIGNS

• Cough must be differentiated from similar signs such as reverse sneezing, gagging, retching. • Description of the cough and/or smartphone recording of suspect sounds are helpful in identification of the anatomic structures involved in dogs (i.e., honking cough is typical of tracheal collapse, harsh sonorous cough followed by terminal retch characterizes cough of tracheal or bronchial origin, faint moist cough is heard in moderate to severe pneumonia). • Cough can be described as dry or moist, productive, honking, short or harsh, faint or sonorous, followed by gagging or retching. • Cough can be elicited by traction on the collar (laryngeal or tracheal origin), aggravated by exercise or excitation (tracheal collapse), or can occur after a period of rest (cough due to heart failure). • Can be accompanied by stertor or stridor (laryngeal, tracheal origin) or dyspnea (many areas).

CAUSES

Upper Respiratory Tract Diseases

• A variety of sinonasal conditions cause extension of inflammation and/or secretions into the pharynx and/or larynx and can lead to the upper airway cough syndrome (UACS), previously referred to as postnasal drip syndrome. • Laryngeal and/or pharyngeal disease (inflammation, paralysis, tumor, granuloma, collapse). • Tracheal disease (inflammation, infection, foreign body, collapse, stenosis, tumor).

Lower Respiratory Tract Diseases (Tracheobronchial or Bronchopulmonary Disease)

• Inflammatory (feline bronchitis syndrome; dogs: chronic bronchitis, eosinophilic bronchopneumopathy). • Infectious—bacterial, viral (dog: distemper, kennel cough; cat: feline leukemia virus [FeLV], feline immunodeficiency virus [FIV], feline infectious peritonitis [FIP], calicivirus, herpesvirus), parasitic (dog: *Filaroides* spp., *Angiostrongylus vasorum*, *Capillaria aerophilia*, *Crenosoma vulpis*; cat: *Aerulostrongylus abstrusus*; dog, cat: *Paragonimus kellicotti*, *Dirofilaria immitis*), protozoal (cat: toxoplasmosis; dog: pneumocystosis), fungal (blastomycosis, histoplasmosis, coccidiomycosis, cryptococcosis, aspergillosis). • Neoplastic (primary, metastatic, compression due to enlarged lymph nodes). • Chemical or traumatic (aspiration, near drowning, noxious fumes, foreign body, trauma, hemorrhage). • Chronic disorders of unknown origin (interstitial pulmonary fibrosis).

Other Diseases

• Cardiovascular diseases (pulmonary edema, left atrial enlargement, heart-base tumor, embolism). • Gastroesophageal reflux. • Compression of respiratory structures by adjacent organs (cardiomegaly, megaesophagus, hilar lymph node enlargement). • Noncardiogenic pulmonary edema (multiple causes). • Passive smoking inhalation. • Adverse drug reaction—potassium bromide in cats.

RISK FACTORS

Breed

• Toy and miniature breeds at risk for tracheal collapse. • Terrier breeds at risk for pulmonary fibrosis. • Husky, Rottweiler, Labrador, and Jack Russell terrier at risk for eosinophilic bronchopneumopathy. • Giant breeds at risk for dilated cardiomyopathy. • Labrador retriever, large breeds at risk for laryngeal paralysis. • Siamese cats at risk for feline bronchitis syndrome.

Environmental Factors

Longhaired cats that are infrequently groomed will periodically retch, cough, and vomit up mats of hair.

Drugs

Potassium bromide in cats.

Geographic Area (or Travel History)

Certain diseases are common in specific areas (e.g., dirofilariasis, angiostrongylosis).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Similar signs. • Coughing may be confused with other signs such as sneezing, reverse sneezing, gagging, panting, retching, and vomiting; presence of terminal retch is often misinterpreted as vomiting. • Honking noise coughing in case of severe tracheal collapse can be descried by owners as severe stertor.

CBC/BIOCHEMISTRY/URINALYSIS

Minimum database may suggest acute bacterial infection (leukocytosis with left shift) or eosinophilic airway disease (peripheral eosinophilia).

OTHER LABORATORY TESTS

• Filter test for microfilaria and/or heartworm antigen serology—for heartworm disease. • Serum antibody titer—toxoplasmosis, FIV, FIP, distemper, *Angiostrongylus vasorum*. • Coagulation profile—for any patient that presents with cough associated with either epistaxis or hemoptysis. • Feces examination (Baermann test: identification of *Angistrongylus* (dogs), *Aerulostrongylus* (cat), or other parasites (*Filarial*, *Crenosoma*). • PCR diagnosis available for several microorganisms. • Tests for evaluation of possible hyperadrenocorticism (potentially causing pulmonary thromboembolism).

IMAGING

• Thoracic radiographs are first step prior to any additional test—provide essential information about intrathoracic airways, lung parenchyma, pleural space, mediastinum, and cardiovascular system. • Thoracic computed tomography is being more and more often used for identification of respiratory intrathoracic problems. • Fluoroscopy—helpful to investigate diseases in which dynamic obstruction is

COUGH (CONTINUED)

suspected (tracheal collapse, bronchial collapse, bronchomalacia). • Echocardiography—helpful when heart failure or dysfunction is suspected. • Thoracic ultrasonography—in case of pleural effusion or when a pulmonary or mediastinal mass is suspected.

DIAGNOSTIC PROCEDURES

• Endoscopy allows visualization of both static (tumor, granuloma, abnormal mucosa, excessive secretions) and dynamic (laryngeal paralysis, dynamic airway collapse) airway abnormalities. • When bronchial and/or alveolar infiltrates are present—samples from lower airways can be obtained for diagnostic purpose (cytology, bacterial/mycologic cultures) by bronchoalveolar lavage or tracheal wash. • Transthoracic (fine-needle aspiration) biopsy or thoracoscopy—allows biopsy sample when interstitial infiltration is prominent. • Thoracocentesis—allows sampling of pleural fluid, can be performed under ultrasonographic guidance. • Pulse oximetry and blood gas determination. • Pulmonary function tests—require sophisticated material and/or experienced technicians, not readily available in private practice.

TREATMENT

• Usually treated as outpatient. • Most successful management of cough involves treatment and resolution of underlying cause rather than use of medications that suppress signs. • If chronic cough is related to acute or chronic inflammation, anti-inflammatory therapy preferred to cough suppressant therapy. • Use of cough suppressant therapy must be limited to cases in which the cause of the cough can neither be treated medically nor resolved, and in which excessive coughing leads to exhaustion of the patient or insomnia of the owners, as well as aggravation of the disease.

MEDICATIONS

DRUG(S) OF CHOICE

Antimicrobial Therapy

Indicated for tracheo-broncho-pulmonary disease of bacterial origin. Better selected based in culture and antimicrobial susceptibility testing.

Anti-inflammatory Therapy

• Indicated in feline bronchitis syndrome, canine chronic bronchitis, or canine eosinophilic bronchopneumopathy. • Oral prednisolone 0.5 mg/kg q12h in dogs and cats, then taper the dose progressively to q48h. • Nebulized fluticasone or budesonide 100–200 µg q12h with metered dose inhaler including spacer with face mask and inspiratory valve.

Antitussives

• Hydrocodone (dog only)—0.2–0.3 mg/kg PO q 6–12h. • Butorphanol (dog only)—0.25–1.1 mg/kg every 8–12h. • No antitussive available for cats. • In humans, gabapentin (neuromodulator) recently described to treat refractory chronic cough. • Gabapentin in dogs, 2–5 mg/kg by mouth every 8h, but unestablished efficacy.

Bronchodilators

Theophylline (for Dogs and Cats)

• Pharmacokinetics are form and species dependent; slow-release formulations exist. • Beneficial effects of theophylline include relaxation of bronchial smooth muscle, improved diaphragmatic contraction, and probably some anti-inflammatory effects but primary antitussive action not demonstrated. • Side effects are related to inotropic and chronotropic effects, as well as to an increase in blood pressure; can also cause nausea, diarrhea, arrhythmias, and CNS excitation.

Beta-2 Agonists (Cats Only)

• Delivered mostly via a meter dose inhaler (MDI); administered IV in emergency situations. Short-acting (salbutamol, terbutaline, fenoterol) or long-acting (salmeterol, formoterol) drugs. • May be administered temporarily to cause immediate and temporary relief, but not as long-term management; have limited effect. • Side effects include dry mouth, tachycardia, nausea; regular inhalation of racemic and S-albuterol (but not R-albuterol) induces airway inflammation in both healthy and asthmatic cats.

Expectorants

Guafenesin—included in some preparations but benefit not extensively studied or proven.

CONTRAINDICATIONS

Antitussive agents are strictly contraindicated when cough is needed to clean the airways, i.e., in infectious or inflammatory airway disease.

PRECAUTIONS

See side effects of respective drugs.

POSSIBLE INTERACTIONS

Theophylline—clearance may be inhibited by other drugs such as fluoroquinolones, increasing risk of theophylline toxicity.

FOLLOW-UP

PATIENT MONITORING

• Acute cough must be adequately treated in order to avoid chronic cough, leading to possibly irreversible lesions. • Conditions leading to chronic cough sometimes can only be alleviated but not cured; communicate with client to ensure successful management of cough.

POSSIBLE COMPLICATIONS

• Aggravation of tracheal collapse. • Progression toward chronic bronchitis, chronic obstructive pulmonary disease, lung emphysema, irreversible bronchial and parenchymal remodeling, bronchiectasis. • Acute severe cough might lead to syncope, rib fracture, or pneumothorax. • Right heart dysfunction.

MISCELLANEOUS

AGE-RELATED FACTORS

• In dogs with anatomic disorders of inherited (e.g., primary ciliary dyskinesia) or congenital origin, signs might start early in life. • Puppies and kittens more likely to suffer from infectious disease. • Inflammatory disorders affect middle-aged adults. • Heart failure and tumors more frequent in older animals.

PREGNANCY/FERTILITY/BREEDING

• Dogs affected with primary ciliary dyskinesia. • Possible decreased fertility (in male and female dogs) as cilia from urogenital tract and flagellated cells can be affected. • Proven hereditary in some breeds (Old English sheepdog; carrier test detection exists).

SEE ALSO

• Asthma, Bronchitis—Cats.
• Bronchitis, Chronic.
• Congestive Heart Failure, Left-Sided.
• Hypoxemia.
• Nasal Discharge.
• Pneumonia, Bacterial.
• Pneumonia, Eosinophilic.
• Respiratory Parasites.
• Sneezing, Reverse Sneezing, Gagging.
• Tracheal Collapse.

ABBREVIATIONS

• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.
• UACS = upper airway cough syndrome.

CRANIOMANDIBULAR OSTEOPATHY

BASICS

OVERVIEW

• A non-neoplastic, noninflammatory proliferative disease of the bones of the head. • Primary bones affected—mandibular rami; occipital and parietal; tympanic bullae; zygomatic portion of the temporal. • Bilateral symmetric involvement most common. • Affects musculoskeletal system.

SIGNALMENT

• Scottish, Cairn, and West Highland white terrier breeds—most common. • Labrador retrievers, Great Danes, Boston terriers, Doberman pinschers, Irish setters, English bulldogs, bullmastiffs, Shetland sheepdogs, and boxers—may be affected. • Usually growing puppies 4–8 months of age. • No gender predilection. • Neutering may increase incidence.

SIGNS

Historical Findings

• Usually relate to pain around the mouth and difficulty opening the mouth progressively worsening. • Difficulty in prehension and mastication—may lead to starvation.

Physical Examination Findings

• Temporal and masseter muscle atrophy—common. • Palpable irregular thickening of mandibular rami and/or temporomandibular joint (TMJ) region. • Inability to fully open jaw, even under general anesthesia. • Intermittent pyrexia. • Bilateral exophthalmos.

CAUSES & RISK FACTORS

• Believed to be hereditary—occurs in certain breeds and families. • West Highland white terriers—autosomal recessive trait. • Scottish terriers—possible predisposition. • Young terrier with periosteal long bone disease—monitor for disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Osteomyelitis—bones not symmetrically affected; generally not as extensive; lysis; lack of breed predilection; history of penetrating wound. • Traumatic periostitis—bones not symmetrically affected; generally not as extensive; history of trauma. • Neoplasia—mature patient; not symmetrically affected; more lytic bone reaction; metastatic disease. • Calvarial hyperostosis—young patient: frontal, parietal, and occipital bones; does not involve mandible; may have long bone involvement.

CBC/BIOCHEMISTRY/URINALYSIS

• Serum alkaline phosphatase (ALP) and inorganic phosphate—may be high. • May note hypogammaglobulinemia or α_2-hyperglobulinemia.

OTHER LABORATORY TESTS

Serology—rule out fungal agents; indicated in atypical cases.

IMAGING

• Skull radiography—reveals uneven, bead-like osseous proliferation of the mandible or tympanic bullae (bilateral); extensive, periosteal new bone formation (exostoses) affecting one or more bones around the TMJ; may show fusion of the tympanic bullae and angular process of the mandible. • CT—may help evaluate osseous involvement of TMJ.

DIAGNOSTIC PROCEDURES

Bone biopsy and culture (bacterial and fungal)—necessary only in atypical cases; rule out neoplasia and osteomyelitis.

PATHOLOGIC FINDINGS

• Bone biopsy—reveals normal lamellar bone being replaced by enlarged coarse-fiber bone and osteoclastic osteolysis of periosteal or subperiosteal region. • Bone marrow—replaced by vascular fibrous-type stroma. • Inflammatory cells—occasionally seen at periphery of bony lesion.

TREATMENT

• Palliative only. • Surgical excision of exostoses—results in regrowth within weeks. • High-calorie, protein-rich gruel diet—helps maintain nutritional balance. • Surgical placement of pharyngostomy, esophagostomy, or gastrostomy tube—considered to help maintain nutritional balance.

MEDICATIONS

DRUG(S) OF CHOICE

• Analgesics and anti-inflammatory drugs—palliative use warranted. • Nonsteroidal anti-inflammatory drugs (NSAIDs)—inhibit cyclooxygenase enzymes. • Deracoxib (1–2 mg/kg PO q24h, chewable). • Carprofen (2.2 mg/kg PO q12h or 4.4 mg/kg q24h). • Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h, liquid). • Grapiprant (2 mg/kg PO q24h). • Firocoxib (5 mg/kg PO q24h).

FOLLOW-UP

PATIENT MONITORING

Frequent reexaminations—mandatory to ensure adequate nutritional balance and pain control.

PREVENTION/AVOIDANCE

• Do not repeat dam–sire breedings that resulted in affected offspring. • Discourage breeding of affected animals.

EXPECTED COURSE AND PROGNOSIS

• Pain and discomfort may diminish at skeletal maturity (10–12 months of age); exostoses may regress. • Prognosis—depends on involvement of bones surrounding TMJ. • Elective euthanasia may be necessary.

MISCELLANEOUS

SYNONYMS

• Lion jaw. • Craniomandibular osteoarthropathy. • Craniomandibular osteodystrophy. • Mandibular periostitis. • Westie jaw. • Scotty jaw.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• NSAID = nonsteroidal anti-inflammatory drug.
• TMJ = temporomandibular joint.

CRUCIATE LIGAMENT DISEASE, CRANIAL

BASICS

DEFINITION
The acute or progressive failure of the cranial cruciate ligament (CrCL), which results in partial to complete instability of the stifle joint.

PATHOPHYSIOLOGY
• Function of the CrCL includes passive constraint of the stifle joint by limiting internal rotation of the tibia, hyperextension of the stifle, and cranial displacement of the tibia relative to the femur. • Two distinct bands—craniomedial band is taut on both flexion and extension of the joint (primary check) and caudolateral band is taut in extension and lax in flexion (secondary check).
• Types of injury:
○ Avulsion—skeletally immature animals in which acute load results in avulsion of the origin or insertion of the ligament.
○ Acute (traumatic) rupture—result of hyperextension, limb overloading, or internal rotation; mid-substance tear of the CrCL; most common cause in cats.
○ Progressive (chronic) degeneration pathogenesis remains elusive; decreases in elasticity, stress/strain energy, failure to maintain collagen fiber organization, and chondroid metaplasia—most common cause in dogs.
• Repetitive subclinical injury may be due to neuromuscular incoordination, aging, conformational abnormalities (excessive tibial plateau angle (TPA), medial luxating patella, narrow intercondylar notch), breed variations, poor muscle tone related to sedentary habits or limb immobilization, and possibly immune-mediated damage. • Complete and partial tears exist in varying degrees. • Untreated instability leads to degenerative osteoarthritic changes within a few weeks; severe within a few months. • Medial meniscal (caudal horn) damage occurs in 33.2–77% of cases—due to shearing force during drawer.

SYSTEMS AFFECTED
Musculoskeletal, ± neurologic.

GENETICS
Suspected

INCIDENCE/PREVALENCE
Most common cause of hind limb lameness in dogs; major cause of degenerative joint disease (DJD) in the stifle joint.

SIGNALMENT

SPECIES
Dog and cat.

Breed Predilections
• All susceptible. • Rottweiler and Labrador retriever—increased incidence when <4 years of age. • West Highland white terrier—over-represented affected small breed.

Mean Age and Range
• Incidence increases with age >5 years.
• Large- to giant-breed dogs may present earlier in life; approx. 2 years of age.

Predominant Sex
Female—neutered.

SIGNS

General Comments
Severity of lameness—related to degree of rupture (partial vs. complete), mode of rupture (acute vs. chronic), occurrence of meniscal injury, and severity of inflammation and DJD. Condition and therefore lameness may be bilateral.

Historical Findings
• Athletic or traumatic events—generally precede acute injuries. • Normal activity resulting in acute lameness—suggests degenerative rupture. • Subtle to marked intermittent lameness (for weeks to months)—consistent with partial tears that are progressing to complete rupture.

Physical Examination Findings
• Varying degrees of lameness and joint effusion, pain, and/or crepitus; affected limb generally held in partial flexion while standing. • Cranial drawer test—diagnostic for rupture; test in flexion, normal standing angle, and extension. • Tibial compression test—cranial movement of tibia relative to femur when tightening gastrocnemius by flexing hock. • Medial periarticular thickening (medial buttress). • Presence of click or pop—63% accurate in detecting meniscal injury. • Hind limb muscle atrophy—especially quadriceps muscle group. • False-negative drawer or compression tests with chronic or partial tears and in painful or anxious patients that are not sedated or anesthetized. • Earliest sign of partial rupture is pain on hyperextension of stifle.

CAUSES
• Trauma. • Repetitive microinjury; excessive stifle loading. • Progressive degeneration.

RISK FACTORS
• Obesity. • Patella luxation. • Conformational abnormalities. • Excessive caudal slope of tibial plateau. • Narrowed intercondylar notch.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Puppy laxity—positive drawer motion that stops abruptly as CrCL is stretched taut.
• Patella luxation (medial or lateral). • Collateral ligament injury, long digital extensor tendon injury. • Osteochondritis dissecans of femoral condyle. • Neoplasia (e.g., synovial sarcoma, osteosarcoma, chondrosarcoma). • Traumatic fractures or avulsions. • Caudal cruciate ligament rupture—uncommon and generally only seen with significant trauma.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING

Radiography
• Verify secondary intra-articular changes such as DJD and rule out other differentials.
• Common findings—joint effusion with capsular distention and effacement of infrapatellar fat pad; periarticular osteophytes; enthesiophytes; CrCL avulsion fractures; calcification of CrCL and/or menisci. • Cats commonly have mineralized menisci present (incidental finding). • Necessary for preoperative planning with osteotomy procedures.

Alternative Diagnostic Imaging
Ultrasound and MRI—facility and operator dependent.

DIAGNOSTIC PROCEDURES
• Arthrocentesis—rule out sepsis or immune-mediated disease. • Arthroscopy—gold standard; direct visualization and magnification of cruciate ligaments, menisci, and other intra-articular structures.

PATHOLOGIC FINDINGS
• Varying degrees of synovitis, cartilage fibrillation, and erosion. • Periarticular osteophyte formation. • Meniscal damage.
• Ruptured fibers of CrCL—hyalinization; fibrous tissue invasion; necrosis; loss of parallel orientation of ligament bundles.

TREATMENT

APPROPRIATE HEALTH CARE
• Stabilization surgery—recommended; speeds rate of recovery; reduces degenerative changes; enhances function. • Conservative management—diet, nonsteroidal anti-inflammatory drugs (NSAIDs), physical rehabilitation, weight loss; approx. 66% of patients have improved function over course of >1 year; DJD is progressive; not generally recommended.

NURSING CARE
Postsurgery—restricted activity with physical rehabilitation (e.g., ice packing, range-of-motion exercises, massage, and muscle electrical stimulation); important for improving mobility and strength.

ACTIVITY
Restricted—duration depends on method of treatment and progress of patient.

(CONTINUED) # CRUCIATE LIGAMENT DISEASE, CRANIAL

DIET
• Weight control—important for decreasing load and thus stress on stifle joint. • Joint-health diets rich in omega-3 fatty acids and chondroprotectants may support overall joint health.

CLIENT EDUCATION
• Regardless of treatment, DJD is common and progressive. • Return to full athletic function is possible, but requires early surgical intervention and rehabilitation. • Rupture of contralateral CrCL can occur in 37–48% of patients.

SURGICAL CONSIDERATIONS
• No one technique has proven consistently superior, clinically or radiographically. • Recent force plate studies show slight differences between common techniques; dogs with tibial plateau leveling osteotomy (TPLO) procedure achieve normal limb loading faster than with extracapsular procedure.

Extra-articular Methods
• Wide variety of techniques that use an implant to mimic CrCL and restore stability; these techniques rely on periarticular fibrosis for long-term stability. • Alternative method includes fibular head transposition to realign and tension lateral collateral ligament in order to restrict internal rotation and cranial drawer.

Intra-articular Methods
Designed to replace CrCL anatomically with autografts (patellar ligament, fascia), allografts, xenografts, and synthetic materials.

Osteotomy Procedures

Cranial Tibial Closing Wedge Osteotomy
• Levels TPA by removing cranially based wedge of bone from proximal tibia and eliminates cranial thrust. • Held in place with bone plate and screws. • Can potentially shorten tibia and alter stifle biomechanics.

TPLO
• Rotational osteotomy of proximal tibia to level TPA and neutralize cranial tibial thrust. • Held in place with bone plate and screws. • Can accomplish correction for angular and torsional deformities.

Tibial Tuberosity Advancement
• Tibial crest osteotomy; crest is held in advanced position with cage and plate; bone graft fills defect. • Active control of cranial tibial displacement improved, which helps stabilize stifle. • Can combine technique with lateral transposition of tibial tuberosity to correct concurrent medial luxating patella.

MEDICATIONS

DRUG(S) OF CHOICE
NSAIDs—minimize pain; decrease inflammation.

CONTRAINDICATIONS
Avoid concurrent use of corticosteroids with NSAIDs.

PRECAUTIONS
NSAIDs—gastrointestinal irritation or renal/hepatic toxicity may preclude use in some patients.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• Chondroprotective drugs (polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate) may help reduce cartilage damage and improve regeneration.
• Omega-3 fatty acid supplementation to reduce inflammation is recommended.

FOLLOW-UP

PATIENT MONITORING
