VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Terbutaline Tablets: 2.5 mg and 5 mg; generic; (Rx)

Terbutaline Injection: 1 mg/mL in 1 mL single-dose vials; generic; (Rx)

Testosterone

(tess-***toss***-ter-ohn)

Androgenic Hormone

Prescriber Highlights

- ► Principal endogenous androgen used primarily for the treatment of testosterone-responsive urinary incontinence in neutered male dogs and cats; in bovine medicine, it is used to produce an estrus-detector animal.
- ► Contraindications include known hypersensitivity to the drug, pregnancy, and prostate carcinoma.
- ► Use with caution in animals with renal, cardiac, or hepatic dysfunction.
- ► Adverse effects are uncommon in males; however, perianal adenomas, perineal hernias, prostatic disorders, and behavior changes possible. Masculinization and aggression may occur in females.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies testosterone as a hazardous drug; use appropriate precautions when handling.
- ► DEA Schedule III (C-III) controlled substance

Uses/Indications

The use of injectable esters of testosterone in veterinary medicine is primarily limited to its use in dogs (and perhaps cats) for the treatment of testosterone-responsive urinary incontinence in neutered males. Testosterone has been used to treat a rare form of dermatitis (exhibited by bilateral alopecia) in neutered male dogs. Testosterone products are also used in bovine medicine to produce an estrus-detector (teaser) animal in cull cows, heifers, and steers.

The effectiveness of testosterone to increase libido and treat hypogonadism, aspermia, and infertility in domestic animals has been disappointing and is generally not recommended.

Theoretically, topically applied human transdermal products could be effective in animals, but no information was located on their efficacy or safety.

Pharmacology/Actions

Testosterone, the principal endogenous androgenic steroid, is responsible for many secondary sex characteristics of the male, as well as the maturation and growth of the male reproductive organs and increasing libido.

Testosterone has anabolic activity with resultant increased protein anabolism and decreased protein catabolism. Testosterone causes nitrogen, sodium, potassium, and phosphorus retention and decreases the urinary excretion of calcium. Nitrogen balance is improved only when an adequate intake of both calories and protein occurs. By stimulating erythropoietic stimulating factors, testosterone can stimulate the production of red blood cells. Large doses of exogenous testosterone can inhibit spermatogenesis through a negative feedback mechanism, inhibiting luteinizing hormone (LH).

Testosterone may help maintain the normal urethral muscle tone and integrity of the urethral mucosa in male dogs. It may also be necessary to prevent some types of dermatoses.

Pharmacokinetics

Orally administered testosterone is rapidly metabolized by the GI mucosa and the liver (first-pass effect); very little reaches the systemic circulation. The esterified compounds, testosterone enanthate and cypionate, are less polar than testosterone and more slowly absorbed from lipid tissue after IM injection.[1] The duration of action of these compounds may persist for 2 to 4 weeks after IM injection. Because

testosterone absorption is dependent upon several factors (volume injected, perfusion), the duration of action may be variable.

Testosterone is highly bound to a specific testosterone-estradiol globulin (98% in humans).[1] The quantity of this globulin determines the amount of drug that is in the free or bound form. The free form concentration determines the plasma half-life of the hormone.

Testosterone is metabolized in the liver and is, with its metabolites, excreted in the urine (≈90%) and feces (≈6%).[1] The plasma half-life of testosterone has been reported to be between 10 and 100 minutes in humans. The plasma half-life of testosterone cypionate has been reported to be 8 days.

Contraindications/Precautions/Warnings

Testosterone therapy is contraindicated during pregnancy and in patients with known hypersensitivity to the drug; it should not be used in males with prostate carcinoma.[1] It should be used with caution in patients with renal, cardiac, or hepatic dysfunction.

Testosterone depot formulations are formulated for deep IM injection and should not be given by the IV route.[1]

The National Institute for Occupational Safety and Health (NIOSH) classifies androgens as hazardous drugs representing an occupational hazard to healthcare workers; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[2]

Adverse Effects

Adverse effects are reportedly uncommon when injectable testosterone products are used in male dogs to treat hormone-responsive incontinence; however, perianal adenomas, perineal hernias, prostatic disorders, and behavior changes (aggression) are all possible. In bitches, testosterone can cause clitoral hypertrophy, masculinization, and aggression. In cats, behavioral changes have been reported. High doses or chronic use may result in priapism, oligospermia, or infertility in intact males.

Polycythemia, hepatitis, hepatocellular carcinoma, and reduced clotting factors have been reported in humans receiving high doses of testosterone.[1] Use in pediatric patients may result in early epiphyseal closure.

Reproductive/Nursing Safety

Testosterone use during pregnancy causes virilization of female fetuses. In humans, testosterone is contraindicated during pregnancy.[1] It is not known whether androgens are excreted in the milk; consider using milk replacer if using testosterone in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located; refer to ***Adverse Effects*** for further information.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving testosterone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Corticosteroids** (eg, **dexamethasone, fludrocortisone, prednis(ol)one**): Androgens may enhance the edema that can be associated with ACTH or adrenal steroid therapy.
- **Cyclosporine**: Increased risk for cyclosporine toxicity
- **Insulin; Oral Antidiabetic Agents**: May decrease serum glucose levels
- **Propranolol**: Testosterone cypionate may increase propranolol clearance.
- **Warfarin**: May increase anticoagulant effects

Laboratory Considerations

- Concentrations of **protein-bound iodine (PBI)** can be decreased in patients receiving testosterone therapy, but the clinical significance of this is probably not important. Androgen agents can decrease amounts of **thyroxine-binding globulin** and decrease **total T_4 concentrations** and increase resin uptake of **T_3 and T_4**. Free thyroid hormones are unaltered, and clinically, there is no evidence of dysfunction.
- Both **creatinine** and **creatine** excretion can be decreased by testosterone.
- Testosterone can increase the urinary excretion of **17-ketosteroids**.
- Androgenic/anabolic steroids may alter **blood glucose** levels.
- Androgenic/anabolic steroids may suppress **clotting factors II, V, VII, and X**.

Dosages

NOTE: Older references may list dosages using testosterone propionate (a shorter-acting injectable form), but commercially available products are no longer available in the United States.

DOGS:

Testosterone-responsive urinary incontinence (may be used with phenylpropanolamine) in males (extra-label): Testosterone cypionate 2.2 mg/kg IM once every 30 to 45 days[3]

Estrus control (extra-label): **NOTE**: Rarely recommended. Concerns have been expressed about adverse effects as well as the long-term suppression of estrous activity in bitches treated with testosterone. Research results disagree as to whether treatment with testosterone interferes with the subsequent ability to induce estrus in bitches.[4] Testosterone enanthate (or cypionate) 0.5 mg/kg IM once every 5 days.[5]

Reducing mammary gland enlargement seen in pseudopregnancy (extra-label): **NOTE**: Rarely recommended. Testosterone enanthate (or cypionate) 0.5 – 1 mg/kg IM once[5]

CATTLE:

Producing an estrus-detector (teaser) animal (cull cows, heifers, steers) (extra-label): Testosterone enanthate 0.5 g IM and 1.5 g SC (divided into 2 separate locations). After 4 days, attach the chin ball marker and put the animal in with the breeding herd. To maintain, give 0.5 – 0.75 g SC every 10 to 14 days[6]

Monitoring

- Efficacy
- Adverse effects
- Consider baseline and periodic CBC, serum chemistry profile with electrolytes especially with long-term administration or with high doses.

Chemistry/Synonyms

The esterified compounds, testosterone cypionate and enanthate, are available commercially as injectable (in oil) products.

Testosterone cypionate occurs as an odorless to having a faint odor, creamy white or white crystalline powder. It is insoluble in water, soluble in vegetable oils, and freely soluble in alcohol. Testosterone cypionate has a melting range of 98°C to 104°C (208°F-219°F). It may also be known as testosterone cyclopentyl propionate.

Testosterone enanthate occurs as an odorless to having a faint odor, creamy white or white crystalline powder. It is soluble in veg-

etable oils and insoluble in water and melts between 34°C and 39°C (93°F-102°F).

Storage/Stability

Store the commercially available injectable preparations of testosterone cypionate, enanthate, and propionate at room temperature (20°C-25°C [68°F-77°F]); avoid freezing or exposure to temperatures greater than 40°C (104°F). If exposed to low temperatures, a precipitate may form but should redissolve with shaking and rewarming. If a wet (aqueous) needle or syringe is used to draw up the parenteral solutions, cloudy solutions may result, but this will not affect the drug's potency.

Testosterone is a DEA Schedule III (C-III) controlled substance. Store it in a substantially constructed and securely locked area. Follow applicable local, state, and federal rules regarding the disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

No known testosterone products (with the exception of combinations with estradiol as growth promotant implants) that are FDA-approved for use in veterinary species were located. Testosterone propionate (200 mg) is available in combination with estradiol benzoate (20 mg) as a growth promotant. Trade names include *Component E-H*®; (OTC) and *Synovex-H*®; (OTC). For use in heifers weighing at least 181 kg (400 lb).

HUMAN-LABELED PRODUCTS:

Testosterone Cypionate (in oil) Injection: 100 mg/mL and 200 mg/mL in 1 mL and 10 mL vials; *Depo-Testosterone*® generic; (Rx, C-III)

Testosterone Enanthate (in oil) Injection: 50 mg, 75 mg, 100mg and 200 mg in 0.5 mL prefilled syringes, and 200 mg/mL in 5 mL multidose vials; generic; (Rx, C-III)

Testosterone Undecanoate solution for injection: 250 mg/ mL in 3 mL single-dose vials; *Aveed*®; (Rx; C-III)

Testosterone Pellets Implant for subcutaneous implantation: 75 mg in 1 pellet/vials; *Testopel*®; (Rx, C-III)

There are also testosterone transdermal patches, topical solutions and gels, and oral capsules available.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Tetracycline

(tet-ra-***sye***-kleen)

Tetracycline Antibiotic

Prescriber Highlights

- ► Prototype tetracycline antibiotic; many bacteria are now resistant, but may still be useful to treat *Mycoplasma* spp, *Rickettsia*, spirochetes, and *Chlamydia* spp. Used with niacinamide to help control sterile inflammatory skin conditions in dogs
- ► Doxycycline or minocycline are usually preferred antimicrobial indications in small animals due to more favorable dosing frequency and adverse effect profile.
- ► Extreme caution: pregnancy
- ► Caution: renal insufficiency
- ► Adverse effects: GI distress, staining of developing teeth and bones, photosensitivity; long-term use may cause uroliths. Cats: do not tolerate well. Horses: if stressed, diarrhea is possible (oral use). Ruminants: high oral doses can alter ruminal microbiota and cause ruminoreticular stasis

Uses/Indications

Although tetracycline is still used as an antimicrobial, its use has largely been supplanted by doxycycline or minocycline in dogs and cats, and oxytetracycline in most food animals. It is also used for non-antimicrobial effects in combination with niacinamide, which may be useful in controlling a variety of sterile inflammatory skin conditions in dogs including: discoid lupus erythematosus (DLE), sterile granulomatous/pyogranulomatous syndrome, sterile nodular panniculitis, cutaneous reactive histiocytosis, cutaneous vesicular lupus erythematosus, pemphigus erythematosus, pemphigus foliaceus, lupoid onychodystrophy/onychitis, German shepherd dog metatarsal fistulae, vasculitis, arteritis of the nasal philtrum, sebaceous adenitis, and dermatomyositis.[1] Controlled studies demonstrating clear efficacy are lacking, but anecdotally this combination appears effective in some patients, including up to ⅔ of dogs that are treated for DLE. Often used in conjunction with other immunomodulating drugs, especially in the initial treatment phase. Niacinamide/tetracycline may take 1 to 2 months before efficacy is noted.

Tetracycline soluble powder is labeled for treatment and control of bacterial enteritis and bacterial pneumonia in swine and calves; chronic respiratory disease, air sac disease, and infectious synovitis in chickens; and infectious synovitis and enteritis in turkeys that are caused by susceptible bacteria.[2] Tetracycline has also been used topically in an extra-label manner to treat digital dermatitis in cows.

The World Health Organization (WHO) has designated tetracycline as a Highly Important antimicrobial for human medicine.[3] The Office International des Epizooties (OIE) Antimicrobial Classification has designated tetracycline as a Veterinary Critically Important antimicrobial.[4]

Pharmacology/Actions

Tetracyclines generally act as time-dependent antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing binding to those ribosomes of aminoacyl transfer-RNA. Tetracyclines are bacteriostatic antibiotics at usual doses and may be bactericidal at higher doses or against susceptible bacteria. Tetracyclines are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. At high concentrations, tetracyclines can inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most *Mycoplasma* spp, spirochetes (including *Borrelia burgdorferi*), *Chlamydia* spp, and rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of *Staphylococcus* spp and *Streptococcus*

spp, but resistance of these organisms is increasing. Gram-positive bacteria that are usually susceptible to tetracyclines include *Bacillus anthracis*, *Clostridium perfringens* and *C tetani*, *Listeria monocytogenes*, and *Nocardia* spp. Gram-negative bacteria against which tetracyclines usually have in vitro and in vivo activity include *Bordetella* spp, *Brucella* spp, *Bartonella* spp, *Haemophilus* spp, *Pasteurella multocida*, *Shigella* spp, and *Yersinia pestis*. Many or most strains of *Escherichia coli*, *Klebsiella* spp, *Bacteroides* spp, *Enterobacter* spp, *Proteus* spp, and *Pseudomonas aeruginosa* are resistant to the tetracyclines. Hemoglobin at the site of the infection can reduce the antimicrobial activity of tetracycline.

Oxytetracycline and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance and a tetracycline susceptibility disk is usually used for in vitro testing for oxytetracycline susceptibility.

Tetracyclines have anti-inflammatory and immunomodulating effects. They can suppress antibody production and chemotaxis of neutrophils; inhibit lipases, collagenases, prostaglandin synthesis; and inhibit activation of complement component 3. The clinical relevance of these is largely unknown.

Tetracycline susceptibility cannot be predicted by susceptibility to doxycycline or minocycline. If doxycycline or minocycline resistance is present, tetracycline resistance is also present. However, doxycycline or minocycline susceptibility can be present in some tetracycline-resistant bacteria.

Pharmacokinetics

Both oxytetracycline and tetracycline are readily absorbed after oral administration to fasting animals. Bioavailabilities are ≈60% to 80%. The presence of food or dairy products can significantly reduce the amount of tetracycline absorbed, with reductions of 50% or more possible. After IM administration, tetracycline is erratically and poorly absorbed with serum concentrations usually lower than those attainable with oral therapy.

Tetracyclines, as a class, are widely distributed to the heart, kidneys, lungs, muscles, pleural fluid, bronchial secretions, sputum, bile, saliva, urine, synovial fluid, ascitic fluid, and aqueous and vitreous humor. Only small quantities of tetracycline and oxytetracycline are distributed to the CSF, and therapeutic concentrations may not be achievable. Although all tetracyclines distribute to the prostate and eye, doxycycline or minocycline penetrate better into these and most other tissues. Tetracyclines cross the placenta, enter fetal circulation, and are distributed into milk. The volume of distribution of tetracycline is ≈1.2 to 1.3 L/kg in small animals. The amount of plasma protein binding is ≈20% to 67% for tetracycline. In cattle, the volume of distribution for oxytetracycline is between 1 and 2.5 L/kg. Milk to plasma ratios for oxytetracycline and tetracycline are 0.75 and 1.2 to 1.9, respectively.

Both oxytetracycline and tetracycline are eliminated unchanged primarily via glomerular filtration and in the feces. Patients with impaired renal function can have prolonged elimination half-lives and accumulate the drug with repeated dosing. These drugs are not metabolized but are excreted unchanged into the urine as well as into the GI tract via both biliary and nonbiliary routes. The elimination half-life of tetracycline is ≈5 to 6 hours in dogs and cats.

Contraindications/Precautions/Warnings

Tetracycline is contraindicated in patients hypersensitive to it or other tetracyclines.

Use with caution in patients with renal insufficiency, as tetracycline can accumulate and lead to liver toxicity.[5] Dose reduction is recommended. In humans, tetracycline can cause an increase in BUN. In patients with impaired renal function, this can lead to azotemia, hyperphosphatemia, and acidosis. Avoid concurrent administration with other nephrotoxic drugs. Monitoring of serum tetracycline concentrations should be considered if long-term therapy is required.

In humans, tetracyclines can cause increased photosensitivity that presents as severe sunburns.[5] Limit sun exposure for patients with thin or light-colored coats while taking tetracycline.

Adverse Effects

Oxytetracycline and tetracycline given to young animals can cause discoloration (yellow, brown, or gray color) of teeth. High doses or chronic administration may delay bone growth and healing.

In small animal species, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Esophageal injuries (esophagitis, ulceration) have occurred with administration of capsule and tablet forms of tetracyclines; a water bolus after administering solid dosage forms is recommended.

Cats do not tolerate oral tetracycline well and may present with clinical signs of colic, fever, hair loss, and depression. There are reports that long-term tetracycline use may cause urolith formation in dogs. Tetracyclines have caused thyroid hyperpigmentation and induced thyroid hyperplasia in many small animal species. Horses that are stressed by surgery, anesthesia, or trauma, may develop severe diarrhea after receiving tetracyclines (especially with oral administration).

In ruminants, high oral doses can alter ruminal microbiota depression and cause ruminoreticular stasis. Rapid IV injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Propylene glycol-based products have also caused cardiodepressant effects when administered to calves. When administered IM, local reactions, yellow staining, and necrosis may be seen at the injection site.

Tetracycline therapy (especially long-term) may result in overgrowth of non-susceptible bacteria or fungi (superinfections).

Tetracyclines have also been associated with photosensitivity reactions and, rarely, hepatotoxicity, formation of anti-nuclear antibodies, or blood dyscrasias. Risk for hepatotoxicity may be increased with pre-existing renal or hepatic impairment.

Reproductive/Nursing Safety

Animal studies indicate that tetracyclines cross the placenta, are found in fetal tissues, and can have toxic effects on the developing fetus. Because tetracyclines can delay fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline and tetracycline are considered more likely to cause these abnormalities than either doxycycline or minocycline. Evidence of embryotoxicity has also been noted in animals when given tetracycline during early pregnancy.[5]

Tetracycline had no effect on fertility when administered in the diet to male and female rats at a daily intake of 25 times the human dose. Tetracyclines are excreted in milk but because much of the drug will be bound to calcium in milk, it is unlikely to be of significant risk to nursing animals. Short-term use of tetracycline is considered compatible with breastfeeding.[6]

Overdose/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

Rapid IV injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug

could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (in less than 5 minutes), some clinicians recommend pretreating the animal with IV calcium gluconate. Rapid IV injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

High oral doses given to ruminants can alter ruminal microbiota and cause ruminoreticular stasis.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tetracyclines and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Atovaquone**: Tetracyclines have caused decreased atovaquone concentrations.
- **Beta-Lactam or Aminoglycoside Antibiotics**: Bacteriostatic drugs, like the tetracyclines, have been historically thought to interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides but the clinical significance of this interaction is unknown.
- **Digoxin**: Tetracyclines have increased the bioavailability of digoxin in a small percentage of human patients and caused digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.
- **Divalent or Trivalent Cations** (eg, oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations): When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1 to 2 hours before or after the cation-containing products.
- **Methoxyflurane**: Fatal nephrotoxicity has occurred in humans when used with tetracycline.
- **Neuromuscular Blocking Agents**: Tetracyclines may potentiate neuromuscular blockade.
- **Sucralfate**: Sucralfate may impair the oral absorption of tetracycline; separate dosing by at least 2 hours to minimize this effect.
- **Warfarin**: Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment.

Laboratory Considerations

- Tetracyclines (not minocycline) may cause falsely elevated values of urine catecholamines when using fluorometric methods of determination.
- Tetracyclines can reportedly cause false positive urine glucose results if using the cupric sulfate method of determination (Benedict's reagent, *Clinitest®*), but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false negative results in determining urine glucose when using the glucose oxidase method (*Clinistix®*, *Tes-Tape®*).

Dosages

DOGS:

Adjunctive treatment of sterile inflammatory or autoimmune diseases (extra-label): Tetracycline is typically used in combination with niacinamide. Recommended dosages are empirical and vary.

- Dogs 10 kg (22 lb) or less: tetracycline 250 mg/dog (NOT mg/kg) PO 3 times daily in combination with niacinamide 250 mg/dog (NOT mg/kg) PO 3 times daily[7]
- Dogs more than 10 kg (22 lb): tetracycline 500 mg/dog (NOT mg/kg) PO 3 times daily in combination with niacinamide 500 mg/dog (NOT mg/kg) PO 3 times daily[7]

NOTES:

1. If efficacious, may reduce niacinamide dose to twice-daily administration and then taper further over time when possible.
2. Tetracycline may be replaced with doxycycline 5 – 10 mg/kg PO every 12 hours OR minocycline 5 – 10 mg/kg PO every 12 hours.[8]
3. Some clinicians have used 15 kg (33.1 lb) as the weight cutoff (ie, dogs 15 kg [33.1 lb] or less receive 250 mg/dog [NOT mg/kg]; dogs more than 15 kg [33.1 lb] receive 500 mg/dog [NOT mg/kg]).[9] Other clinicians have suggested niacinamide 45 mg/kg PO every 8 hours in combination with tetracycline 45 mg/kg PO every 8 hours.[10]

Susceptible infections (extra-label): 22 mg/kg PO every 8 hours for 14 to 28 days

CATS:

Susceptible infections (extra-label): 15 – 22 mg/kg PO every 8 hours for 14 to 28 days

FERRETS:

Susceptible infections (extra-label): 25 mg/kg PO 2 to 3 times daily[11]

RABBITS, RODENTS, SMALL MAMMALS:

a) **Rabbits**: 50 – 100 mg/kg PO every 8 to 12 hours[12]

b) **Chinchillas**: 50 mg/kg PO every 8 to 12 hours[13]

c) **Chinchillas, Guinea Pigs, Rats**: 20 mg/kg PO every 12 hours. **Mice**: 20 mg/kg PO every 12 hours or 50 – 60 mg/L of drinking water, **Hamsters**: 30 mg/kg PO every 6 hours or 400 mg/L of drinking water. **Gerbils**: 20 mg/kg PO or IM once a day.[14]

CATTLE:

Susceptible infections in calves (label dosage; FDA-approved): 22 mg/kg/day PO in drinking water for up to 5 days.[15] Prepare fresh solution once or twice daily.

Digital dermatitis in cow (extra-label): 2 – 25 g applied topically to affected foot as a paste or powder, with or without bandaging[16,17]

SHEEP:

Susceptible infections (extra-label): using previously available FDA-approved product, 11 mg/kg PO twice daily for up to 5 days[18]

SWINE:

Susceptible infections (label dosage; FDA-approved): 22 mg/kg/day PO in drinking water for 3 to 5 days.[15] Prepare fresh solution once or twice daily.

POULTRY:

Susceptible infections (label dosage; FDA-approved): 200 to 800 mg/gallon drinking water for 7 to 14 days[15]

BIRDS:

Chlamydiosis; mild respiratory disease (especially flock treatment) (extra-label):

a) Using tetracycline soluble powder containing 324 g tetracycline/pound, mix ¼ teaspoon of soluble powder per gallon of drinking water. Used as an adjunct for psittacosis with other

tetracycline forms. Will not reach therapeutic concentrations by itself. Prepare fresh solution twice daily, as potency is rapidly lost.[19]

b) Using tetracycline soluble powder containing 324 g tetracycline/pound, mix ¼ teaspoon of soluble powder per gallon of drinking water and administer for 5 to 10 days. Prepare fresh solution 2 to 3 times daily, as potency is rapidly lost. For converting regimen to pelleted feeds, administer oral suspension by gavage at 200 – 250 mg/kg once or twice daily until feeds are accepted; this is not an adequate therapy for long-term treatment of chlamydiosis (psittacosis).[20]

Monitoring

- Adverse effects
- Clinical efficacy
- Long-term use or in susceptible patients: periodic renal, hepatic, thyroid, and hematologic evaluations

Client Information

- This medicine is best given without food. Avoid giving this medicine orally within 1 to 2 hours of milk or other dairy products.
- If gastrointestinal upset occurs, giving with a small amount of food may help, but this may also reduce the amount of drug absorbed.

Chemistry/Synonyms

An antibiotic obtained from *Streptomyces aureofaciens* or derived semisynthetically from oxytetracycline, tetracycline HCl occurs as a moderately hygroscopic, yellow, crystalline powder. Approximately 100 mg/mL is soluble in water and 10 mg/mL soluble in alcohol.

Tetracycline base has a solubility of ≈0.4 mg per mL of water and 20 mg per mL of alcohol. Commercially available tetracycline HCl for IM injection also contains magnesium chloride, procaine HCl, and ascorbic acid.

Tetracycline may also be known as tetracyclini hydrochloridum; many trade names are available.

Storage/Stability

Unless otherwise instructed by the manufacturer, tetracycline oral tablets and capsules should be stored in tight, light-resistant containers at room temperature (15°C-30°C [59°F-86°F]).

Compatibility/Compounding Considerations

No specific information noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tetracycline HCl Soluble Powder (as a water additive): 324 g/lb in 5 lb containers; FDA-approved for use in swine, cattle, and poultry. (OTC at time of writing). Not to be used in pre-ruminating calves or calves to be processed for veal. Not for use in turkeys or chickens producing eggs for human consumption. Withdrawal times: swine, 4 days; calves, 5 days; chicken, 4 days. For topical applications, a milk withdrawal time of 24 hours is recommended[21]; however, it has been suggested that a more conservative 36-hour withdrawal may be needed.[22]

HUMAN-LABELED PRODUCTS:

Tetracycline HCl Capsules: 250 mg and 500 mg; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Theophylline

(thee-***off***-i-lin)

Phosphodiesterase Inhibitor Bronchodilator

Prescriber Highlights

- ► Bronchodilator with mild diuretic activity used as adjunctive therapy in dogs with cough and in cats with asthma.
- ► Narrow therapeutic index in humans, but dogs appear to be less susceptible to toxic effects at higher plasma concentrations
- ► Doses should be calculated using lean body weight in obese animals.
- ► Many drug interactions are possible; fluoroquinolones (eg, enrofloxacin) can increase theophylline concentrations substantially.
- ► Availability can be an issue; check with a reputable compounding pharmacy for availability.

Uses/Indications

Theophyllines (ie, aminophylline, theophylline) are used primarily for their bronchodilatory effects, especially in dogs with cough and cats with asthma. Theophylline may also be considered when managing sick sinus syndrome and other bradycardias.[1] In coughing dogs with heart disease and evidence of concurrent tracheal instability or chronic small airway disease, clinical improvement may be seen with a bronchodilator such as theophylline. Theophylline has also been used as a bronchodilator in horses; however, some do not recommend its use in this species due to its narrow therapeutic index.[2]

Pharmacology/Actions

Theophylline competitively inhibits phosphodiesterase (PDE) III (and PDE IV to a lesser extent), thereby increasing amounts of cyclic AMP (cAMP) that then increase the release of endogenous epinephrine. The elevated concentrations of cAMP may also inhibit the release of histamine and slow reacting substance of anaphylaxis (SRS-A). The myocardial and neuromuscular transmission effects of theophylline may be a result of translocating intracellular ionized calcium. Adenosine antagonism may contribute to CNS stimulant effects.

Theophylline directly relaxes smooth muscles in the bronchi and pulmonary vasculature; smooth muscle relaxant effects also occur in the uterus, biliary, and GI tracts. In addition, theophylline may induce diuresis, vasodilate arterioles and veins, increase gastric acid secretion and corticosteroid activity, improve mucociliary clearance, and inhibit mast cell release. Theophylline has weak chronotropic and inotropic action, improves diaphragm contractility, stimulates the CNS, and can cause respiratory stimulation (centrally mediated). Theophylline also has anti-inflammatory effects, including diminished activity of inflammatory and immune cells, especially eosinophils, within the airways.[3,4]

Pharmacokinetics

Oral absorption of theophylline from commercial extended-release formulations is variable.[5] Bioavailability of compounded modified-release theophylline products was ≈96% in dogs, and peak concentrations were reached 7.1 to 8.9 hours after administration.[6,7] Theophylline is distributed throughout extracellular fluids and body tissues. In dogs, only ≈10% is bound to plasma proteins at therapeutic serum concentrations.[8] The volume of distribution of theophylline in dogs has been reported to be 0.5 to 0.8 L/kg.[9] After IV administration of aminophylline (=7.88 mg/kg theophylline) to greyhounds, mean theophylline volume of distribution (steady-state) was 0.72 L/kg, mean clearance was 0.935 mL/minute/kg, and elimination half-life was ≈9 hours.[10] Clearance was 1.2 mL/minute/kg in puppies 1 week of age, and increased with age to peak at 7.1 mL/minute/kg in

puppies 16 weeks of age.[11] It has been shown that herbal medicines, such as fenugreek and garden cress, can alter theophylline pharmacokinetics in beagles.[12] Elimination half-life was 8.7 to 10.5 hours following administration of compounded modified-release theophylline products.[6,7]

In cats, bioavailability was 96% (with aminophylline)[13] and ≈80% with extended-release formulations.[14] The volume of distribution in cats was reported to be 0.46 L/kg, and protein binding was 12%.[13] Elimination half-life was ≈8 hours[13] but was prolonged to ≈20 hours when the drug was administered in the evening (8 to 9 PM).[15] Transdermal administration of theophylline (15 mg/kg/day in either PLO or *Lipoderm*®) produced a therapeutic theophylline concentration in 2 of 7 cats in each formulation, and only 7 of the 56 total measurements were within the therapeutic range.[16]

In horses, oral bioavailability of immediate-release and extended-release formulations were 87% and 97%, respectively.[17] Protein binding was ≈13% to 23%[18]; volume of distribution was 0.85 to 1.6 L/kg[17–19]; and elimination half-life was 12 to 17 hours.[18,19] Pharmacokinetic values in donkeys were found to be similar to those of horses.[20]

In ruminating calves, oral bioavailability was 93%, volume of distribution was 0.8 L/kg, and elimination half-life was 6.4 hours.[21] In adult camels, protein binding was ≈33%, volume of distribution was ≈0.8 L/kg, and elimination half-life was ≈11 hours.[22] Oral bioavailability in goats and camels was 90%.[23] In goats, volume of distribution was 1.4 L/kg and elimination half-life was ≈2 hours.[23]

Because of the low volume of distribution and theophylline's low lipid solubility, obese patients should be dosed on a lean body weight basis. Theophylline is metabolized primarily in the liver (in humans) to 3-methylxanthine, which has weak bronchodilator activity. Renal clearance contributes only ≈10% to the overall plasma clearance of theophylline. In humans, there are wide interpatient variations in serum half-lives and resultant serum concentrations. It could be expected that similar variability exists in veterinary patients, particularly those with concurrent illnesses. Note that the pharmacokinetics of long-acting theophylline products vary with the modified (ie, extended) release mechanism, and duration of effect may vary between 8 to 24 hours in humans.

Contraindications/Precautions/Warnings

Theophylline is contraindicated in patients that are hypersensitive to xanthines (eg, aminophylline, theobromine, caffeine). Use in dogs with a history of epileptiform seizures is contraindicated.[24]

Theophylline should be administered with caution in patients with severe cardiac disease, gastric ulcers, hyperthyroidism, renal or hepatic disease, severe hypoxia, or hypertension. Theophylline clearance is decreased by ≈50% in patients with hepatic disease or CHF, and a 50% reduction in dosage has been suggested for patients in hepatic failure.[25] Clearance is reduced to a lesser extent by hypothyroidism, fever, and sepsis. Because it may cause or worsen pre-existing arrhythmias, caution and enhanced monitoring are advised in patients with cardiac tachyarrhythmias that receive theophylline. Neonatal and geriatric patients may have decreased clearances of theophylline and be more sensitive to its toxic effects.

In humans, exposure to secondhand smoke may increase theophylline clearance; whether the same occurs in animals is unknown.

Adverse Effects

Theophylline can produce CNS stimulation and GI irritation after administration by any route. Most adverse effects are related to the serum concentration of the drug and may be indicative of toxic blood concentrations; dogs appear to tolerate concentrations that may be toxic to humans.

Dogs and cats can exhibit clinical signs of nausea and vomiting, insomnia, increased gastric acid secretion, diarrhea, polyphagia, polydipsia, polyuria, dyspnea, tremors, agitation, nervousness, restlessness, and increased activity. In dogs, tachycardia was noted at a dose of 40 mg/kg twice daily with corresponding plasma theophylline concentration greater than 30 µg/mL.[26]

Adverse effects in horses are generally dose related and may include nervousness, excitability (with auditory, tactile, or visual stimulation), tremors, diaphoresis, tachycardia, and ataxia.[27]

Administration of theophylline with high-fat foods (eg, cheese, peanut butter) may increase the rate of absorption of some extended-release products, increasing the risk for adverse effects and toxic concentrations.

Reproductive/Nursing Safety

Theophylline has been shown to reduce uterine contractions. Theophylline crosses the placenta and is distributed into milk (70% of serum concentrations). In humans, theophylline is considered compatible with nursing.[28] Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In humans, clinical signs of toxicity (see ***Adverse Effects***) are usually associated with serum drug concentrations greater than 20 µg/mL and become more severe as the serum concentration exceeds that value. Tachycardia, arrhythmia, and CNS effects (eg, seizures, hyperthermia) are considered the most life-threatening aspects of toxicity. Hypokalemia and acid-base disturbances may also occur. Dogs and cats appear to tolerate serum concentrations greater than 20 µg/mL. Common clinical signs associated with overdose may include tachycardia.

Treatment of theophylline toxicity is supportive. GI decontamination with activated charcoal, which blocks theophylline absorption, can be considered and is more effective in reducing theophylline exposure than inducing emesis. Patients with seizures should have an adequate airway maintained and be treated with an IV benzodiazepine (eg, diazepam, midazolam) as indicated. Patients should be continuously monitored for cardiac arrhythmias and tachycardia. Hydration status and electrolytes should be monitored and corrected as necessary. Hyperthermia may be treated with phenothiazines[29] and tachycardia treated with propranolol if either condition is considered life-threatening. Theophylline is removed by hemodialysis, which may be an option in cases in which activated charcoal cannot be administered.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving aminophylline or theophylline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- KETAMINE: Theophylline with ketamine can cause an increased incidence of seizures and cardiac arrhythmias.
- SYMPATHOMIMETICS (eg, **beta agonists** [eg, **albuterol**], **ephedrine, isoproterenol, phenylpropanolamine**): Toxic synergism (eg, CNS stimulation, arrhythmias) can occur if theophylline is used concurrently with sympathomimetics (especially ephedrine) or possibly isoproterenol. Concurrent use with beta-sympathomimetics is contraindicated.[24]

The following drugs can **decrease** theophylline concentrations:
- **Albendazole**
- **Barbiturates** (eg, **phenobarbital**): Can induce CYP enzymes and increase theophylline metabolism in dogs (not cats)
- **Beta-2-Adrenergic Receptor Agonists** (eg, **albuterol**)
- **Charcoal**
- **Herbal Agents** (eg, **fenugreek, garden cress**)[12]
- **Isoniazid**: May increase or decrease concentrations
- **Isoproterenol**
- **Ketoconazole**
- **Loop Diuretics** (eg, **furosemide**): May increase or decrease concentrations
- **Phenobarbital**
- **Phosphate Binders** (eg, **aluminum hydroxide, calcium carbonate**): Can form an insoluble complex in the GI tract and inhibit drug absorption; separate administration by 2 hours
- **Rifampin**
- **Sucralfate**: Can form insoluble complex in the GI tract and inhibit drug absorption; separate administration by 2 hours

The following drugs can **increase** theophylline concentrations:
- **Allopurinol**
- **Beta-Adrenergic Receptor Antagonists, Nonselective** (eg, **propranolol**): May also antagonize effects of theophylline
- **Calcium Channel Blockers** (eg, **diltiazem, verapamil**)
- **Chloramphenicol**: Consider reducing the dose of theophylline by 30% to 50% or extending the dosing interval
- **Cimetidine**
- **Corticosteroids** (eg, **dexamethasone, prednis[ol]one)**
- **Estrogen**
- **Fluconazole**
- **Fluoroquinolones** (eg, **ciprofloxacin, enrofloxacin, marbofloxacin**): Enrofloxacin reduced theophylline clearance by ≈50% in healthy beagles.[30] A similar effect was noted with oflaxacin.[31] Consider reducing the dose of theophylline by 30% to 50% or extending the administration interval. Monitor for toxicity and efficacy. Marbofloxacin reduces clearance of theophylline in dogs but not with clinical significance; however, in animals with renal impairment, marbofloxacin may interfere with theophylline metabolism in a clinically relevant manner.[32]
- **Interferon Alfa**
- **Macrolides** (eg, **clarithromycin, erythromycin**)
- **Methotrexate**
- **Mexiletine**
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine**)
- **Thiabendazole**
- **Thyroid Hormones** (in hypothyroid patients)

Theophylline may **decrease** the effects of the following drugs:
- **Benzodiazepines** (eg, **diazepam, midazolam)**
- **Macrolides** (eg, **azithromycin, erythromycin**)
- **Pancuronium**
- **Propofol**[33]

Laboratory Considerations

Theophylline can cause falsely elevated values of **serum uric acid** if measured by the Bittner or colorimetric methods. Values are not affected if using the uricase method.

Immunoassays are specific for theophylline. If using a spectrophotometric method of assay, theophylline serum concentrations can be falsely elevated by **furosemide**, **phenylbutazone**, **probenecid**, **theobromine**, **caffeine**, **sulfathiazole**, **chocolate**, or **acetaminophen**. **Cefazolin** may interfere with HPLC assays. The Schack and Wexler method of determining theophylline concentrations may be interfered with by large doses of **thiamine**.

Dosages

NOTES:
1. Theophyllines have a relatively low therapeutic index. Determine doses carefully; doses should be calculated using lean body weight in obese animals.
2. Extended-release oral dosage forms are generally used, but bioavailability of currently marketed human products can be variable in veterinary species; attentive monitoring for adverse effects and efficacy is recommended. Contact a pharmacist for the current availability of products. See ***Compatibility/Compounding***.
3. Dosage conversions between aminophylline and theophylline can be performed using the information found in ***Chemistry/Synonyms***.

DOGS:

Bronchodilator for small airway collapse/disease (extra-label):

a) Extended-release tablets: 10 mg/kg PO every 12 hours initially is recommended; titrate dosage to balance efficacy and tolerability. Dosages of 5 – 20 mg/kg PO every 12 to 24 hours can be used. Availability of commercial extended-release tablets may be problematic. Compounded modified-release theophylline products showed pharmacokinetic properties similar to previously available extended-release theophylline tablets.[6,34]

b) Immediate-release tablets: 9 mg/kg PO every 8 hours has been recommended.[35]

Bradyarrhythmias (eg, sick sinus syndrome, AV block) (extra-label): Using extended-release tablets, 10 mg/kg PO every 12 hours for sick sinus syndrome, as medical management may improve the clinical situation by reducing the impact of bradycardia episodes.[36] In one study, 54% of dogs with sinus node dysfunction had their clinical signs controlled with pharmacologic treatment; however, definitive treatment with recurrent episodes requires the placement of a pacemaker. In one case report in a German shepherd dog with syncope secondary to transient atrioventricular block with dilated cardiomyopathy and atrial fibrillation, an initial dose of 20 mg/kg once daily was used, but the dose was decreased to 10 mg/kg/day due to adverse GI effects; no syncope occurred after the dose reduction, and GI effects improved.[37]

CATS:

Bronchodilator (extra-label):

a) Extended-release tablets: 15 – 25 mg/kg (practically one 100 mg extended-release tablet/capsule) PO once daily in the evening has been suggested.[14] Some cats may only require dosing every other day.

b) Immediate-release tablets: 4.25 mg/kg PO every 12 hours. From a pharmacokinetic study using aminophylline[13,38]

HORSES:

Severe equine asthma (extra label): Loading dose of 12 mg/kg PO, followed by maintenance doses of 5 mg/kg PO every 12 hours

Monitoring

- Therapeutic efficacy and clinical signs of toxicity (eg, excitement, tremors, tachycardia, vomiting)
- Consider measuring serum theophylline concentrations for patients not responding to therapy or that have clinical signs of toxicity. Contact the laboratory for specific instructions on sample collection and handling as well as recommended therapeutic ranges. Therapeutic serum concentrations of theophylline in humans are ≈10 µg/mL. Dogs likely can tolerate higher peak con-

centrations. It is reported that sustained-release products peak 4 to 6 hours after administration in dogs and 8 to 12 hours after administration in cats, but variable bioavailability occurs.[25] Commercial immediate-release products generally peak 1.5 to 2 hours after administration.

Client Information

- This medicine can be given with or without food but giving with some food may prevent stomach upset or vomiting.
- Try to give the medicine in the same manner (ie, with or without food) and at the same time each day.
- Do not crush or allow animals to chew extended-release products.
- Report signs of agitation or excitement to your veterinarian.
- Keep out of reach of children and animals; overdose can be serious.

Chemistry/Synonyms

Theophylline is a naturally occurring xanthine derivative. Aminophylline differs from theophylline only by the addition of ethylenediamine to its structure and may have different amounts of molecules of water of hydration. 100 mg of hydrous aminophylline contains ≈79 mg of anhydrous theophylline; 100 mg of anhydrous aminophylline contains ≈86 mg anhydrous theophylline. Conversely, 100 mg of anhydrous theophylline is equal to 116 mg of anhydrous aminophylline and 127 mg of hydrous aminophylline.

Theophylline occurs as a bitter, odorless, white crystalline powder and has a melting point between 270°C and 274°C (518°F-525°F). It is sparingly soluble in alcohol and only slightly soluble in water at a pH of 7, but solubility increases with increasing pH.

Theophylline may also be known as anhydrous theophylline, teofillina, or theophyllinum; many trade names are available.

Storage/Stability

Theophylline oral dosage forms should be stored in tight containers at room temperature (15°C-30°C [59°F-86°F]). Avoid excessive heat.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist can be consulted for more specific information.

Theophylline for injection is reportedly **compatible** when mixed with chlorpromazine, fluconazole, furosemide, lidocaine, methylprednisolone sodium succinate, and verapamil.

Theophylline for injection is reportedly **incompatible** (or data conflict) with ascorbic acid injection, ceftazidime, ceftriaxone, and phenytoin.

Modified-release products from some veterinary compounding pharmacies and from a 503B outsourcing facility have been validated for use in dogs.[6,7,34] Transdermal gel formulations prepared with pluronic lecithin organogel (PLO) or *Lipoderm*® applied once daily to the inner pinna of a cat's ears did not achieve therapeutic theophylline concentration.[16]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for further information.

HUMAN-LABELED PRODUCTS:

Theophylline Extended-Release Capsules and Tablets: 100 mg, 200 mg, 300 mg, 400 mg, 450 mg, and 600 mg (**NOTE**: Different products have different claimed release rates that may or may not correspond to actual times seen in veterinary patients.); *Theo-24*®, *Theochron*®, generic; (Rx). Availability of commercial extended-release products in strengths that are suitable for veterinary patients has been problematic. Check with a reputable compounding pharmacy for availability.

Theophylline Elixir: 80 mg/15 mL (26.7 mg/5 mL); *Elixophyllin*®; generic; (Rx)

Thiamine

Vitamin B_1

(***thye***-a-min)

Nutritional; B Vitamin

Prescriber Highlights

► Used for treatment or prevention of thiamine deficiency
► Adverse effects include tenderness or muscle soreness after IM injection, as well as hypersensitivity and anaphylactic reactions (rare).

Uses/Indications

Thiamine is indicated in the treatment or prevention of thiamine deficiency that may be secondary to either a lack of thiamine in the diet or the presence of thiamine-destroying compounds in the diet (eg, bracken fern, raw fish, sulfites,[1] amprolium, thiaminase-producing bacteria in ruminants).[2] Clinical signs of thiamine deficiency can manifest as GI (eg, anorexia, salivation), neuromuscular/CNS (eg, ataxia, cervical ventriflexion, seizures, loss of reflexes), ocular (eg, nystagmus, anisocoria, blindness), or cardiac (eg, brady- or tachyarrhythmias, cardiac hypertrophy) effects. Cats are more susceptible to thiamine deficiency than dogs, as their daily requirements are 3 times higher.[3] Evaluation of many cat foods, including canned and dry food as well as home-prepared diets, has shown suboptimal concentrations of thiamine.[4–7]

Thiamine may be supplemented in camelids and other species when long-term amprolium is used.[8]

Thiamine has also been used in the adjunctive treatment of lead poisoning and ethylene glycol toxicity to facilitate the conversion of glyoxylate to nontoxic metabolites.[9]

In animal models (eg, dogs, mice) and humans, thiamine has been used as adjunctive therapy for septic shock.[10,11]

Pharmacology/Actions

Thiamine combines with adenosine triphosphate (ATP) to form thiamine diphosphate/thiamine pyrophosphate that is used for carbohydrate metabolism without affecting blood glucose concentrations.

Absence of thiamine results in decreased transketolase activity in red blood cells and increased pyruvic acid blood concentrations. Without thiamine triphosphate, pyruvic acid is not converted into acetyl-CoA and diminished NADH results, with anaerobic glycolysis producing lactic acid. Lactic acid production is further increased secondary to pyruvic acid conversion. Lactic acidosis may occur.

Pharmacokinetics

Thiamine is absorbed from the GI tract and is rapidly metabolized by the liver. In humans, thiamine is distributed to all tissues with the highest concentrations in the liver, brain, kidney, and heart. The majority of the drug is eliminated as metabolites via the kidney.

Contraindications/Precautions/Warnings

Thiamine injection is contraindicated in animals that are hypersensitive to it or to any component of it. Anaphylactic reactions to parenteral thiamine have occurred after IM and IV administration.[9]

Adverse Effects

Hypersensitivity reactions have occurred following injection. Rarely, a vasovagal anaphylactic response (eg, cardiac arrest or severe bradycardia, cardiac arrhythmias, apnea, hypotension, collapse, seizure, or protracted neuromuscular weakness) has been observed in a small number of cats when thiaminewas administered SC. Some tenderness or muscle soreness may result after SC or IM injection. Thiamine can be diluted with sterile 0.9% sodium chloride to reduce the discomfort associated with SC administration.[3]

Reproductive/Nursing Safety

Thiamine administration to pregnant women has not been shown to cause fetal abnormalities; however, the possibility cannot be ruled out.[9] It is not known whether this drug is excreted in milk, but thiamine is considered compatible with breastfeeding in humans.[12]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Large overdoses of thiamine in laboratory animals have been associated with neuromuscular or ganglionic blockade, but the clinical significance is unknown. Transient cardiovascular depression[13] and respiratory depression may also occur with massive parenteral doses. Generally, no treatment should be required with most overdoses as excess drug will be excreted in the urine.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

- None noted

Laboratory Considerations

- Thiamine may cause false positive **serum uric acid** results when using the phosphotungstate method of determination or urobilinogen urine spot tests using Ehrlich reagent.
- The Schack and Wexler method of determining **theophylline concentrations** may be interfered with by large doses of thiamine.

Dosages

NOTE: Some references discourage the use of the IV route of administration due to risk for adverse hemodynamic effects[3,13,14]; however, these adverse effects are associated with dosages that are much higher than commonly recommended. Adverse cardiovascular effects have not been reported with orally administered thiamine.[14]

DOGS/CATS:

Thiamine deficiency (extra-label): The ideal dose of thiamine is unknown and dosage recommendations vary widely; however, thiamine has a relatively large margin for safety. One dosage recommendation for cats is 50 – 100 mg/cat (NOT mg/kg) parenterally (eg, SC, IM, slow IV) every 12 to 24 hours for 3 to 5 days, followed by PO administration for an additional 2 to 4 weeks.[3,13,14] Until further research determines optimal dosing recommendations, this recommendation for cats could also be used in dogs.[1,3,13,15]

Ethylene glycol toxicosis (extra-label): 50 mg/animal (NOT mg/kg) slow IV ever 6 hours[16]

Adjunctive treatment of refeeding syndrome after critical illness (extra-label): 10 – 100 mg/animal (NOT mg/kg) SC daily during the refeeding period[17]

HORSES:

Thiamine deficiency (extra-label): 0.5 – 5 mg/kg IV, IM, or PO[18]; 100 – 1000 mg/horse (NOT mg/kg) IM, SC, or IV (depending on formulation)[19]

Adjunctive treatment of perinatal asphyxia syndrome (eg, **hypoxic ischemic encephalopathy) in foals** (extra-label): 1 g/foal (NOT g/kg) in 1 L of fluids IV once a day[20]

Part of a parenteral nutrition (PN) formula (extra-label): B complex vitamins (thiamine 12.5 mg/mL; niacinamide 12.5 mg/mL; pyridoxine 5 mg/mL; d-panthenol 5 mg/mL; riboflavin 2 mg/mL; cyanocobalamin 5 mg/mL) should be supplied at a rate of 1 – 2 mL/45 kg (99 lb) daily, diluted in fluids or PN. Vitamin C should be supplied at a rate of 20 mg/kg/day enterally whenever possible.[21]

CATTLE:

Thiamine deficiency (polioencephalomalacia): 10 mg/kg IV or IM every 6 hours for 1 to 3 days, then daily. Prognosis is fair if the animals are still standing with some improvement within 24 hours; if still standing after a week, prognosis is good for a complete recovery.[22]

SHEEP & GOATS:

Thiamine deficiency (polioencephalomalacia) (extra-label): 10 mg/kg IV initially, then 10 mg/kg IV, IM, or SC every 6 hours for the first day. Dosing intervals may be tapered depending on the response to treatment; regaining appetite is a positive indicator.[23]

NEW WORLD CAMELIDS:

Prophylaxis when animals treated with amprolium for *Eimeria macusaniensis* for more than 5 days (extra-label): 10 mg/kg SC once a day after the fifth day of amprolium[8]

SWINE:

Thiamine deficiency (extra-label): 5 – 100 mg IM, SC, or IV (depending on formulation)[19]

Monitoring

- Clinical efficacy

Client Information

- A reason for thiamine deficiency (eg, diet, plants, raw fish) should be found with changes made to prevent recurrence.

Chemistry/Synonyms

A water-soluble B vitamin, thiamine HCl occurs as bitter-tasting, white, small hygroscopic crystals, or crystalline powder that has a characteristic yeast-like odor. Thiamine HCl is freely soluble in water, slightly soluble in alcohol, and has pK_as of 4.8 and 9.0. The commercially available injection has a pH of 2.5 to 4.5.

Thiamine HCl may also be known as aneurine hydrochloride, thiamin hydrochloride, thiamine chloride, thiamini hydrochloridum, thiaminii chloridum, vitamin B_1; many trade names available.

Storage/Stability

Thiamine HCl for injection should be protected from light and stored at temperatures less than 40°C (104°F) and preferably between 15°C and 30°C (59°F-86°F); avoid freezing.

Thiamine HCl is unstable in alkaline or neutral solutions or with oxidizing or reducing agents. It is most stable at a pH of 2.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Thiamine HCl is reportedly physically **compatible** with all commonly used IV replacement fluids.

Do **not** mix thiamine with alkaline drugs or alkalinizing agents (barbiturates, citrates, carbonates, acetates, copper ions) or oxidizing/reducing agents (eg, sulfites).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Thiamine HCl for Injection: 500 mg/mL; generic; (Rx). Labeled for use in dogs, cats, and horses.

Thiamine HCl as a supplement: Numerous oral vitamin/mineral/nutritional supplement products in tablet, gel, oral drench, chewable, and powder formulations; (OTC). Labeled for use in multiple species.

Thiamine monohydrate supplement: A component in numerous vitamin/mineral formulations; *DERM-TABS*®; (OTC). Labeled for use in dogs. Calf colostrum replacer and supplement; (OTC). Labeled for use in calves. Pelleted formulation; *Compose® 2X*; (OTC). Labeled for use in horses.

Thiamine mononitrate: Included as an ingredient in numerous oral vitamin/mineral/nutritional supplement/milk replacer products in tablet, gel, oral drench, and milk replacer powder formulations; (OTC). Labeled for use in multiple species. Also available as a type B or type C medicated feed drug that may contain neomycin and oxytetracycline; *Super Guard Plus*®; (VFD). Also available as *Calf Solutions® Balansure®* medicated with *CLARIFLY®* larvicide. (VFD) Labeled for use in calves for treatment of coccidiosis and contains an ionophore and fly control.

HUMAN-LABELED PRODUCTS:

Thiamine Tablets: 50 mg, 100 mg, 250 mg, and 500 mg; generic; (OTC)

Thiamine Capsules: 50 mg; generic; (OTC)

Thiamine HCl Injection: 100 mg/mL in 1 mL and 2 mL multi-dose vials; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Thiopental

(thye-oh-***pen***-tal) *Pentothal®*

Ultra-Short-Acting Thiobarbiturate

Prescriber Highlights

- ► Used for anesthesia induction or anesthesia for very short procedures. Not available in the US or Canada.
- ► Absolute contraindications: absence of suitable veins for IV administration, history of hypersensitivity reactions to barbiturates, status asthmaticus. Relative contraindications: severe cardiovascular disease or pre-existing ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, and conditions where hypnotic effects may be prolonged (eg, severe hepatic disease, myxedema, severe anemia, excessive premedication). Greyhounds (and other sighthounds) metabolize thiobarbiturates much more slowly than other breeds; consider using methohexital instead. Horses: pre-existing leukopenia; thiopental alone may cause excessive ataxia and excitement.
- ► Avoid: Extravasation, intracarotid or intra-arterial injections. Too rapid IV administration can cause significant vascular dilatation and hypoglycemia.
- ► Adverse Effects: Dogs: Ventricular bigeminy. Cats: Apnea after injection, mild arterial hypotension. Horses: Excitement and severe ataxia (if used alone); transient leukopenias, hyperglycemia, apnea, moderate tachycardia, mild respiratory acidosis
- ► Severe CNS toxicity and tissue damage have occurred in horses receiving intracarotid injections of thiobarbiturates.
- ► DEA Schedule IV (C-IV) controlled substance

Uses/Indications

Because of its rapid action and short duration, in young, healthy animals, thiopental has been used as an induction agent (rapid IV bolus) for general anesthesia with other anesthetics or as the sole anesthetic agent for very short procedures. In sick or debilitated animals, thiopental may be used in a more cautious manner (IV, slowly to effect). Once widely used, thiopental is no longer available in many markets, including in the US and Canada.

Pharmacology/Actions

Because of their high lipid solubility, thiobarbiturates (also known as ultra short-acting barbiturates) rapidly enter the CNS and produce profound hypnosis and anesthesia. They act directly on the CNS neurons in a manner similar to that of the inhibitory transmitter GABA.

Pharmacokinetics

Following IV injection of therapeutic doses, hypnosis and anesthesia occur within 1 minute and usually within 15 to 30 seconds. The drug rapidly enters the CNS and then redistributes to muscle and adipose tissue in the body. The short duration of action (10 to 30 minutes) after IV dosing of thiopental is not due to rapid metabolism, but rather to this redistribution out of the CNS and into muscle and fat stores. Greyhounds and other sighthounds may exhibit longer recovery times than other breeds. This may be due to these breeds' low body fat concentrations and differences in the metabolic handling of the thiobarbiturates. Although anesthesia is short, recovery periods may require several hours. Prolonged recovery can also be noticed in horses[1] and bovine youngstock[2] when compared to ketamine.

Thiopental is metabolized by the hepatic microsomal system, and several metabolites have been isolated. The elimination half-life in dogs has been reported as being ≈7 hours and in sheep as 3 to 4 hours. Little of the drug is excreted unchanged in the urine (0.3% in humans), so dose adjustments are not necessary for patients with chronic renal failure.

Thiopental is highly protein-bound (75%).

Contraindications/Precautions/Warnings

The following are considered **absolute contraindications** to the use of thiopental: absence of suitable veins for IV administration, history of hypersensitivity reactions to the barbiturates, and status asthmaticus. **Relative contraindications** include severe cardiovascular disease or pre-existing ventricular arrhythmias, shock, hypotension, hypovolemia, increased intracranial pressure, myasthenia gravis, asthma, and conditions where hypnotic effects may be prolonged (eg, severe hepatic disease, myxedema, severe anemia, excessive premedication). The intracranial pressure (ICP) might increase due to respiratory depression and hypoventilation with a consequent increase in CO_2. If the patient is ventilated properly, thiopental decreases both ICP and cerebral metabolic oxygen consumption rate ($CMRO_2$), resulting in a neuroprotective effect. The decrease in mean arterial pressure (MAP) causes a decrease in cerebral blood flow (CBF), but the decrease in $CMRO_2$ helps maintain the ratio of CBF and $CMRO_2$ unchanged. Although MAP decreases, the cerebral perfusion pressure (CPP) remains unchanged due to the decrease in ICP (CPP = MAP – ICP). These relative contraindications do not preclude the use of thiopental, but dose adjustments and specific management of the patient must be considered, and the drug must be given cautiously.

Patients with renal dysfunction, acidemia, or hypoproteinemia may show increased sensitivity to thiopental.

Because greyhounds (and other sighthounds) metabolize thiobarbiturates much more slowly than methohexital, many clinicians recommend using methohexital instead. In horses, thiopental should not be used if the patient has pre-existing leukopenia. Some clinicians feel that thiopental should not be used alone in the horse as

it may cause excessive ataxia and excitement. In young cattle, it is recommended that thiopental be avoided due to slower metabolism and long recovery times.

Concentrations of less than 2% in sterile water should not be used as they may cause hemolysis. Extravasation and intra-arterial injections should be avoided because of the high alkalinity of the solution. Severe CNS toxicity and tissue damage have occurred in horses receiving intracarotid injections of thiobarbiturates.

Adverse Effects

In dogs, thiopental has an arrhythmogenic incidence of ≈40%. Ventricular bigeminy is the most common arrhythmia seen; it is usually transient and generally responds to additional oxygen. Administration of catecholamines, xylazine, halothane, and methoxyflurane may exacerbate the arrhythmogenic effects of the thiobarbiturates, while lidocaine may inhibit it. Cardiac output may also be reduced but is probably only clinically significant in patients experiencing heart failure. Dose-related apnea and hypotension may be noted.

Cats are susceptible to developing apnea after injection and may develop mild arterial hypotension.

Horses can exhibit clinical signs of excitement and severe ataxia during the recovery period if the drug is used alone. Horses can develop transient leukopenia and hyperglycemia after administration. A period of apnea, moderate tachycardia, and mild respiratory acidosis may also develop after dosing.

Too rapid IV administration can cause significant vascular dilatation and hypoglycemia. Repeated administration of thiopental is not advised as recovery time can become significantly prolonged. Parasympathetic adverse effects (eg, salivation, bradycardia) can be managed with the use of anticholinergic agents (atropine, glycopyrrolate).

Prolonged recoveries may occur when repeated dosages of thiopental are administered.

The high pH of thiopental (10 to 11) can cause significant tissue irritation and necrosis if administered perivascularly; administration through an IV catheter is advised.

Reproductive/Nursing Safety

Thiopental readily crosses the placental barrier and should be used with caution during pregnancy.

Small amounts of thiopental may appear in milk following administration of large doses but are unlikely to be of clinical significance in nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Treatment of thiobarbiturate overdosage consists of supporting respirations (eg, O_2, mechanical ventilation) and giving cardiovascular support; do not use catecholamines (eg, epinephrine).

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiopental and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Clonidine**: IV clonidine prior to induction may reduce thiopental dosage requirements by up to 37%.[3]
- **CNS Depressants, Other** (eg, **methocarbamol**): May enhance respiratory and CNS depressant effects
- **Diazoxide**: Potential for hypotension
- **Epinephrine, Norepinephrine**: The ventricular fibrillatory effects of epinephrine and norepinephrine may be potentiated when used with thiobarbiturates and halothane.
- **Ketoprofen**: Anesthesia recovery time was prolonged[4]
- **Metoclopramide**: Given prior to induction may reduce thiopental dosage requirements
- **Midazolam**: May potentiate hypnotic effects
- **Opioids** (eg, **buprenorphine, fentanyl, morphine, tramadol**): Given prior to induction may reduce thiopental dosage requirements
- **Phenothiazines** (eg, **acepromazine**): May potentiate thiopental effects; hypotension possible

Dosages

NOTE: Atropine sulfate (or glycopyrrolate) is often administered prior to thiobarbiturate anesthesia to prevent parasympathetic adverse effects; however, some clinicians question whether routine administration of anticholinergic agents is necessary. Thiobarbiturates are administered strictly to effect; listed dosages are guidelines only.

DOGS/CATS:

Labeled dose (No longer marketed in the US): 13.2 – 26.4 mg/kg IV depending on the duration of anesthesia required[5]

Extra-label doses:

a) Usually dosed at 12 – 15 mg/kg, with ⅓ of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate, resulting in prolonged recoveries; residual effects may last several hours.[6]

b) Dogs: 15 – 17 mg/kg IV; Cats: 9 – 11 mg/kg IV[7]

RABBITS, RODENTS, SMALL MAMMALS:

Chemical restraint (extra-label): **Mice**: 50 mg/kg IP; **Rats**: 40 mg/kg IP; **Hamsters/Gerbils**: 30 – 40 mg/kg IP; **Guinea pigs**: 15 – 30 mg/kg IV; **Rabbits**: 15 – 30 mg/kg IV[8]

CATTLE:

General Anesthesia in premedicated cattle (extra-label): Cattle: 8.1 – 9.9 mg/kg IV; calves: 4.5 mg/kg IV[7]

HORSES:

General Anesthesia in premedicated horses (extra-label): 5.9 – 12.9 mg/kg IV.[7] A dose of thiopental 4 mg/kg IV, after premedication with medetomidine and midazolam, achieved induction and recovery quality comparable to ketamine 2.5 mg/kg IV; however, the recovery was longer when thiopental was used.[1]

SWINE:

General Anesthesia (extra-label): 5 – 11 mg/kg IV[7]

SHEEP:

General Anesthesia (extra-label): 9 – 14 mg/kg IV[7]

Monitoring

- Level of hypnosis/anesthesia
- Respiratory status; cardiac status (eg, heart rate and rhythm and blood pressure)

Client Information

This drug should only be used by professionals familiar with its effects, and in a setting where adequate respiratory support can be performed.

Chemistry/Synonyms

Thiopental, a thiobarbiturate, occurs as a bitter-tasting, white to off-white, crystalline powder or a yellow-white hygroscopic powder. It is soluble in water (1 g in 1.5 mL) and alcohol. Thiopental has a pK_a of

7.6 and is a weak organic acid. Thiopental solutions are very alkaline (pH greater than 10).

Thiopental sodium may also be known as thiopentone sodium, natrium isopentylaethylthiobarbituricum, penthiobarbital sodique, thiomebumalnatrium cum natrii carbonate, thiopentalum natricum, thiopentobarbitalum solubile, tiopentol sodico, *Anesthal®*, *Bensulf®*, *Farmotal®*, *Hipnopento®*, *Inductal®*, *Intraval®*, *Nesdonal®*, *Pensodital®*, *Pentothal®*, *Sandothal®*, *Sodipental®*, *Thionembutal®*, *Thiopentax®*, *Tiobarbital®*, or *Trapanal®*.

Storage/Stability

When stored in the dry form, thiopental sodium is stable indefinitely. Thiopental should be diluted with only sterile water for injection, 0.9% sodium chloride or 5% dextrose. Do not use concentrations of less than 2% in sterile water as they may cause hemolysis. After reconstitution, solutions are stable for 3 days at room temperature and 7 days if refrigerated; however, as no preservative is present, consider using it within 24 hours after reconstitution. After 48 hours, there are reports of the solution attacking the glass bottle in which it is stored. Thiopental may also adsorb to plastic IV tubing and bags. Do not administer any solution that has a visible precipitate.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors, such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Preparation of Solution for Administration: Use only sterile water for injection, 0.9% sodium chloride, or 5% dextrose to dilute. A 5 g vial diluted with 100 mL will yield a 5% solution, and diluted with 200 mL will yield a 2.5% solution. Discard reconstituted solutions after 24 hours.

The following agents have been reported to be physically **compatible** when mixed with thiopental: aminophylline, chloramphenicol sodium succinate, hyaluronidase, hydrocortisone sodium succinate, neostigmine methylsulfate, oxytocin, pentobarbital sodium, phenobarbital sodium, potassium chloride, propofol (1:1 mixture), scopolamine HBr, sodium iodide, and tubocurarine chloride (recommendations **conflict** with regard to tubocurarine; some clinicians recommend not mixing with thiopental).

The following agents have been reported to be physically **incompatible** when mixed with thiopental: lactated Ringer's solution, amikacin sulfate, atropine sulfate, chlorpromazine, codeine phosphate, dimenhydrinate, diphenhydramine, ephedrine sulfate, glycopyrrolate, hydromorphone, insulin (regular), meperidine, morphine sulfate, norepinephrine bitartrate, penicillin G potassium, prochlorperazine edisylate, promazine HCl, promethazine HCl, succinylcholine chloride, and tetracycline HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None presently marketed in the United States

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Thiopental remains unavailable in the United States market.

Thyrotropin Alfa

(thye-roe-***troe***-pin) Thyroid-Stimulating Hormone, TSH Hormone

Prescriber Highlights

- ► Used for thyroid-stimulating hormone (TSH) test of thyroid function
- ► Contraindications include adrenocortical insufficiency, hyperthyroidism, coronary thrombosis, hypersensitivity to bovine thyrotropin. Cannot be used to evaluate thyroid function in patients receiving levothyroxine.
- ► Adverse effects include hypersensitivity (especially with repeated injections).
- ► Expense (human product) may be an issue.

Uses/Indications

The labeled indication for the formerly available bovine-source veterinary product *Dermathycin®* was *for the treatment of acanthosis nigricans and for temporary supportive therapy in hypothyroidism in dogs*. However, TSH is used more commonly as a diagnostic agent in the TSH stimulation test to diagnose primary hypothyroidism in many species. It can also be used for the diagnosis of congenital hypothyroidism. Commercially available TSH is supplied as a recombinant human product (rhTSH). While rhTSH enhances radioactive iodine uptake in hyperthyroid cats,[1] inconsistent results were noted when used to evaluate radioactive iodine uptake in dogs with thyroid tumors.[2]

Pharmacology/Actions

Thyrotropin increases iodine uptake by the thyroid gland and increases the production and secretion of thyroid hormones and thyroglobulin. With prolonged use, hyperplasia of thyroid cells may occur.

Pharmacokinetics

No specific information was located; exogenously administered TSH apparently exerts maximal increases in circulating T_4 ≈4 to 8 hours after IM or IV administration. In humans, peak TSH concentrations occur at ≈10 hours after administration and the elimination half-life is ≈25 hours.

Contraindications/Precautions/Warnings

A previous veterinary drug manufacturer (Coopers) listed adrenocortical insufficiency and hyperthyroidism as contraindications to TSH use for treatment purposes in dogs. In humans, TSH is contraindicated in patients with coronary thrombosis, untreated Addison's disease, or hypersensitivity to bovine thyrotropin.

Levothyroxine supplementation can cause thyroid atrophy and should be discontinued before thyroid testing with TSH. After discontinuing levothyroxine, a washout period of 6 to 8 weeks before performing the TSH stimulation test has been proposed.[3]

Adverse Effects

Because the commercially available product is derived from human sources, hypersensitivity reactions are possible in patients sensitive to human proteins, particularly with repeated use. To date, no reports of anaphylaxis in animals receiving rhTSH have been reported. Nausea, vomiting, diarrhea, and fatigue have been reported in humans.

Reproductive/Nursing Safety

It is not known whether the drug is excreted in milk, but it is unlikely to be clinically significant when used for diagnostic purposes.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Chronic administration at high dosages can produce clinical signs of hyperthyroidism. Massive overdoses can cause clinical signs resembling thyroid storm. Refer to the levothyroxine monograph for more information on treatment.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No specific drug interactions were reported, but see the information regarding levothyroxine (see ***Contraindications/Precautions/Warnings*** section). Concurrent use of levothyroxine while using thyrotropin alfa for provocative thyroid testing may skew test results.

Laboratory Considerations

- Prior or concurrent levothyroxine supplementation may skew results of TSH stimulation testing (see ***Contraindications/Precautions/Warnings*** section).

Dosages

DOGS:

TSH stimulation test (extra-label):

a) From two studies where dogs received either 75 µg/dog or 150 µg/dog (NOT µg/kg) IV of the human recombinant product. Blood samples were taken before and 6 hours after rhTSH administration for determination of total serum thyroxine (T_4) concentration. The authors concluded that the TSH-stimulation test with rhTSH is a valuable diagnostic tool to assess thyroid function in selected dogs in which a diagnosis of hypothyroidism cannot be based on basal T_4 and canine TSH concentrations alone. Using the higher dose of rhTSH resulted in a higher discriminatory power with regard to differentiating between primary hypothyroidism and non-thyroidal disease and the authors recommend the higher dose (150 µg/dog [NOT µg/kg]) of rhTSH for performing a TSH stimulation test in a diseased animal or an animal on medication, especially if testing cannot be delayed.[4,5]

b) Using rhTSH: 75 – 150 µg/dog (NOT µg/kg) IV. The higher dose of TSH is recommended in dogs with concurrent disease and those receiving medication that might suppress thyroid function. Measure serum total T_4 at 0 hours (presample) and 6 hours postdosing. Hypothyroidism is confirmed by a pre- and post-total T_4 concentration below the reference range for basal total T_4 concentration (less than 1.5 µg/dL). Euthyroidism is confirmed by a post total T_4 concentration greater than 2.5 µg/dL and at least 1.5 times the basal T_4 concentration.[6]

CATS:

TSH stimulation test (extra-label):

a) 25 µg/cat (NOT µg/kg) IV. Draw pre- and postdosing total T_4 levels. Can be useful for differentiating feline iatrogenic hypothyroidism from non-thyroidal illness.[3]

b) Using rhTSH: 25 µg/cat (NOT µg/kg) IV. Measure serum total T_4 at 0 hours (presample) and 6 hours postdosing.[7]

BIRDS:

TSH stimulation test (extra-label): 20 - 200 µg/kg IM. Draw T_4 sample at baseline (predose) and 4 to 6 hours after dose.[8]

FERRETS:

TSH stimulation test (extra-label): 100 µg/ferret (NOT µg/kg) IM. Postlevel (T_4) drawn at 4 hours. Authors concluded that the results suggested that rhTSH can be used for TSH testing in ferrets when administered IM. Based on the results, a euthyroid ferret should have an increase of ≈30% in plasma T_4 concentration 4 hours after rhTSH injection.[9]

SMALL MAMMALS:

TSH stimulation test (guinea pigs) (extra-label): 100 µg/guinea pig (NOT µg/kg) IM. Postlevel (T_4) drawn at 3 to 4 hours. Authors concluded that the results suggested that rhTSH can be used for TSH testing in guinea pigs when administered IM. Based on the results, authors suggest that the thyroxine concentration in a euthyroid guinea pig should at least double 3 to 4 hours after rhTSH injection.[10]

Chemistry/Synonyms

Commercially available thyrotropin (human; rhTSH) is now available only as a lyophilized powder for reconstitution obtained via DNA recombinant technology. Thyrotropin is a highly purified preparation of thyroid-stimulating hormone (TSH). Thyrotropin is a glycoprotein and has a molecular weight of ≈28,000 – 30,000. Thyrotropin is measured in International Units (IU), which is abbreviated as units in this reference. 7.5 µg of thyrotropin are ≈equivalent to 0.037 units. The formerly available veterinary product was obtained from bovine anterior pituitary glands.

Thyrotropin may also be known as thyroid-stimulating hormone, thyrotrophic hormone, thyrotrophin thyrotropin, TSH, *Thyrogen®*, or *Tirogen®*.

Storage/Stability

Thyrotropin alfa (non-reconstituted) should be stored between 2°C and 8°C (36°F-46°F). If necessary, the reconstituted solution can be stored up to 24 hours at 2°C to 8°C (36-46°F); avoid microbial contamination. However, it is reportedly stable if kept refrigerated (2°C-8°C [36°F-46°F]).) up to 4 weeks and up to 12 weeks if frozen (-20°C [-4°F). Protect from light.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

After reconstitution visually inspect each vial for particulate matter or discoloration before use. Do not use any vial exhibiting particulate matter or discoloration. Do not use after the expiration date on the vial.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Recombinant (human) Thyrotropin (Thyroid-Stimulating Hormone) Powder for Injection, Lyophilized: 1.1 mg per vial; *Thyrogen®*; (Rx)

Thyrotropin-Releasing Hormone (TRH)

(thye-roe-***troe***-pin ree-***lee***-seen ***hor***-mohn)

Hormone

Prescriber Highlights

- ► Most commonly used for diagnosing pituitary pars intermedia dysfunction (PPID) in horses. Can also be used for some thyroid-related tests.
- ► Adverse effects in horses include transient muscle trembling, yawning, lip smacking, flehmen, and coughing.
- ► In the United States, must be compounded

Uses/Indications

Thyrotropin-releasing hormone (TRH; protirelin) is most commonly used in veterinary medicine as a diagnostic agent (TRH stimulation test) for diagnosing pituitary pars intermedia dysfunction (PPID) in horses. While safe and fast, when measuring cortisol as the marker, false-positive results are relatively common. Combining this test with a dexamethasone suppression test can improve diagnostic test sensitivity and specificity, but increases testing times and sampling requirements.[1] Measuring plasma corticotropin (ACTH) instead of cortisol after TRH now appears to offer the highest diagnostic sensitivity compared with other tests for PPID and may allow for earlier detection.[2] Because of seasonal variations in ACTH levels, the TRH stimulation test should be performed during winter or spring.[3–6]

In dogs, the TRH test can potentially be used to differentiate primary from secondary hypothyroidism. It is not a reliable test to diagnose primary hypothyroidism.

TRH or its analogues may improve physical function after acute intervertebral disk herniation.

Pharmacology/Actions

Thyrotropin-releasing hormone directly stimulates thyrotropin secretion by the pituitary gland, thereby indirectly stimulating synthesis and secretion of thyroid hormones.

In horses, thyrotropin-releasing hormone (TRH) can stimulate the equine pars intermedia and appears to directly stimulate equine melanotropes. In healthy horses, plasma alpha-melanocyte-stimulating hormones can be increased more than 400% after TRH. Normal horses will have slight increases in ACTH after TRH administration, subclinical PPID horses have a moderate increase in ACTH, while clinically ill PPID horses have dramatic increases in ACTH after TRH. Response to TRH is greater in autumn months than at other times of the year.

Pharmacokinetics

No specific information for veterinary species was noted. Onset of action after IV administration appears to be within minutes. In humans, buccal administration yielded statistically significant increases in thyrotropin concentrations above baseline at 30 and 60 minutes, although at 30 minutes both the thyrotrophic effect and adverse effects were less in some subjects. Deamidase, peptidase, and imidopeptidase enzymes in the CNS and serum metabolize TRH to active and inactive metabolites. Elimination half-life is ≈5 minutes.

Contraindications/Precautions/Warnings

Contraindicated in patients that are hypersensitive to it. Use with caution in patients with seizure disorders as IV administration has rarely caused seizures in humans.

Adverse Effects

Hypersalivation, vomiting and restlessness were noted in healthy dogs.[7] In horses, IV administration of TRH can cause transient muscle trembling, yawning, lip-smacking, flehmen, and coughing.

In humans, TRH given by rapid IV injection or intranasally can cause nausea, a desire to urinate, flushing, dizziness, and a strange taste. Intranasal administration has rarely caused bronchospasm. IV administration can cause transient increases in pulse rate, and changes in blood pressure; convulsions have rarely occurred.

Reproductive/Nursing Safety

It is not known whether TRH is excreted in milk, but it is unlikely to be clinically significant when used for diagnostic purposes.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located; determine doses and drug volumes carefully.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving TRH and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Corticosteroids** (eg, **dexamethasone**): At high doses, may cause decreased thyrotropin response to TRH. Dexamethasone suppression test may be performed concurrently with TRH testing in horses.[8,9]
- **Cyproheptadine**: May cause decreased thyrotropin response to TRH
- **Dopamine Blocking Drugs** (eg, **domperidone, metoclopramide**): May cause increased thyrotropin response to TRH
- **Gonadorelin and Gonadorelin Analogues**: May cause increased thyrotropin response to TRH
- **Salicylates**: May cause decreased thyrotropin response to TRH
- **Thyroid Hormones** (eg, **levothyroxine**): May decrease thyrotropin response to TRH

Laboratory Considerations

- Contact your laboratory for specific sampling guidelines and shipping requirements.

Dosages

DOGS:

Assess pituitary and thyroid gland function:

a. **Differentiate primary from secondary hypothyroidism** (extra-label): Collect a pre-TRH blood sample; administer 0.2 mg/dog (NOT mg/kg) IV of TRH; collect a 4-hour post-TRH blood sample. Measure pre- and post-TRH serum T_4 concentrations. **NOTE**: For measurement of thyrotropin (TSH) collect blood samples pre- and 30 minutes post-TRH administration.[10]

b. **Differentiate primary hypothyroidism from nonthyroidal illness** (extra-label): Collect a pre-TRH blood sample; administer 0.01 mg/kg IV of TRH; collect a 30- minute post-TRH blood sample. Measure pre- and post-TRH serum TSH concentrations. TSH will be elevated in dogs without thyroidal illness.[7,11]

CATS:

Assess thyroid gland function for hyperthyroidism (extra-label): Collect a pre-TRH blood sample; administer 0.1 mg/kg IV of TRH; collect a 4-hour post-TRH blood sample. Measure pre- and post-TRH serum T_4 concentrations. Hyperthyroid cats have little to no post-TRH elevation in T_4.[12]

HORSES:

Diagnosis of pituitary pars intermedia dysfunction (PPID) using the TRH stimulation test (extra-label):

Using plasma ACTH as the marker:

Protocol 1: The most accurate results are obtained when diagnostic testing is performed winter or spring. Contact your diagnostic laboratory for specific sample requirements. Collect baseline (usually plasma) sample for ACTH analysis. Inject TRH 1 mg IV. Collect plasma sample at 10 and/or 30 minutes following TRH. A 10-minute and/or a 30-minute post-TRH ACTH level of 110 nanograms/L and 65 nanograms/L, respectively,[5,13,14] are the

current diagnostic cut-offs, but these may vary depending on the laboratory used.[2,3,15]

Protocol 2: An alternative testing procedure is as above, but TRH 0.5 mg IV is used for ponies and the post-TRH sample is drawn at 30 minutes. At Auburn University Endocrine Diagnostic Laboratory: ACTH concentrations at T = 0, 10, and 30 minutes should all be <35 picograms/mL, with even lower concentrations expected between December and June. Note: Can also be used to simultaneously rule out hypothyroidism by collecting samples for T_3 and T_4 at 0, 2, and 4 hours. Normal horse: A doubling of T_4 after 4 hours and ≈tripling of T_3 after 2 hours is expected. A normal horse will have a small increase in ACTH concentration after 30 minutes (refer to seasonal reference ranges). PPID horse: T_3 and T_4 will increase the same as a normal horse, and the ACTH at T = 0 will be elevated, and at 30 minutes ACTH will be markedly elevated. Hypothyroid horse: No marked increase in T_3 or T_4. (Resting T_3 and T_4 concentrations are not very useful.)[16]

Combined dexamethasone suppression/TRH stimulation test using plasma cortisol as the marker: Collect plasma between 8 AM and 10 AM. Administer dexamethasone 0.04 mg/kg IM. Three hours later administer TRH 1 mg IV. Collect plasma 30 minutes after TRH was given and again 24 hours after the dexamethasone dose (21 hours post-TRH). Compared to baseline, a plasma cortisol greater than 1 µg/dL at 24 hours post-dexamethasone sample or a greater than or equal to 66% increase for the 3-hour post-TRH sample suggests PPID. **NOTE**: Some diagnostic laboratories prefer to use serum for measurement of cortisol levels. The effect of season on the combined test has not been assessed but would likely result in similar incidence of false-positive results as each of the component tests do.[9,17]

Chemistry/Synonyms

TRH (protirelin) is a synthetic tri-peptide with the same sequence of amino acids as the natural hypothalamic neuro-hormone. It occurs as a white or yellowish-white hygroscopic powder that is very soluble in water and freely soluble in methyl alcohol.

Thyrotropin-releasing hormone may also be known as Abbott-38579, TRH, thyrotrophin-releasing hormone, lopremone, protirelin, thyroliberin, thyrotropin-releasing factor (TRF), *Antepan*®, or *Relefact*®.

Storage/Stability

TRH (protirelin) powder should be stored at 2°C to 8°C (36°C-46°C) and protected from light and moisture. If using a compounded preparation, store as labeled.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

There are no commercially available products marketed in the United States at present, but TRH may be available from compounding pharmacies.

For the complete list of references, see **wiley.com/go/budde/plumb**

Tiamulin

(tye-***am***-myoo-lin) *Denagard*®

Diterpine Pleuromutilin Antibiotic

Prescriber Highlights

- ► Antibiotic approved for use in swine; may be used extra-label in chickens and turkeys
- ► Contraindications include in animals with access to feeds containing polyether ionophores (eg, monensin, lasalocid, narasin, or salinomycin) and in swine over 113.4 kg (250 lb).
- ► Adverse effects are unlikely.
- ► Variable withdrawal times depending on dosage.

Uses/Indications

Tiamulin is FDA-approved for use in swine to treat pneumonia caused by susceptible strains of *Actinobacillus pleuropneumoniae* and swine dysentery caused by *Brachyspira hyodysenteriae*. Tiamulin has demonstrated activity against *Brachyspira hampsonii*.[1] In the UK, tiamulin is approved for use in turkeys and chickens for the reduction in the severity of disease caused by mycoplasmas; in pigs for dysentery, colitis, and pneumonia; and in rabbits for enterocolitis.[2]

The World Health Organization (WHO) has designated tiamulin as an Important antimicrobial for human medicine.[3] The Office International des Epizooties (OIE) Antimicrobial Classification has designated tiamulin as a Veterinary Highly Important antimicrobial.[4]

Pharmacology/Actions

Tiamulin is a pleuromutilin antibiotic that is usually bacteriostatic but can be bactericidal in high concentrations against susceptible organisms. The drug acts by binding to the 50S ribosomal subunit, thereby inhibiting bacterial protein synthesis; it has good intracellular penetration.

Tiamulin has good activity against many gram-positive cocci, including most staphylococci and streptococci (not group D streptococci). It also has good activity against *Mycoplasma* spp and spirochetes. With the exceptions of *Haemophilus* spp, most isolates of *Lawsonia intracellularis*, and some *Escherichia coli* and *Klebsiella* spp strains, tiamulin activity is quite poor against gram-negative organisms. Tiamulin does not have apparent efficacy against *Histomonas meleagridis*.

Pharmacokinetics

Tiamulin is well absorbed orally by swine. Approximately 85% of a dose is absorbed and peak levels occur between 2 to 4 hours after a single oral dose. Tiamulin is apparently well distributed, with the highest levels found in the lungs.

Tiamulin is extensively metabolized to over 20 metabolites, with some of the metabolites having antibacterial activity. Approximately 30% of these metabolites are excreted in the urine with the remainder excreted in the feces.

Contraindications/Precautions/Warnings

Tiamulin should not be administered to animals that have access to feeds containing polyether ionophores (eg, monensin, lasalocid, narasin, salinomycin), as adverse reactions may occur. Do not use tiamulin in swine over 113.4 kg (250 lb).

Tiamulin inhalation has been reported to result in QT prolongation and ventricular tachyarrhythmia in humans; wear appropriate protective equipment when handling.[5]

Reproductive/Nursing Safety

Teratogenicity studies done in rodents demonstrated no teratogenic effects at doses up to 300 mg/kg. The manufacturer has concluded that the drug is not tumorigenic, carcinogenic, teratogenic, or mutagenic.

Adverse Effects

Adverse effects occurring with this drug at usual doses are considered unlikely. Rarely, redness of the skin, primarily over the ham and underline, has been observed in swine. If this occurs, it is recommended to discontinue the medication, provide clean drinking water, and hose down the housing area or move affected animals to clean pens.

Overdose/Acute Toxicity

Oral overdoses in swine may cause transient salivation, vomiting, and CNS depression (calming effect). Discontinue drug and treat symptomatically and supportively if necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tiamulin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Polyether Ionophores** (eg, **monensin, lasalocid, narasin, salinomycin**): Tiamulin should not be administered to animals that have access to feeds containing polyether ionophores, as adverse reactions may occur.
- **Lincosamides, Macrolides** (eg, **clindamycin, lincomycin, erythromycin, tylosin**): Although not confirmed with this drug, concomitant use with other antibiotics that bind to the 50S ribosome could lead to decreased efficacy secondary to competition at the site of action.

Dosages

SWINE:

Swine dysentery (label dosage; FDA-approved): 7.7 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions.[6]

Swine pneumonia (label dosage; FDA-approved): 23.1 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions.[6]

Medicated premix: See the label for the product.

POULTRY:

***Mycoplasma* spp disease in chicken and turkey** (extra-label): 25 mg/kg bodyweight administered in drinking water as 0.025% solution for 3 – 5 days (chicken) or for 5 days (turkey)[2]

Monitoring

- Clinical efficacy

Client Information

- Prepare fresh medicated water daily.
- Avoid contact with skin or mucous membranes as irritation may occur.

Chemistry/Synonyms

A semisynthetic diterpene-class antibiotic derived from pleuromulin, tiamulin is available commercially for oral use as the hydrogen fumarate salt. It occurs as white to yellow, crystalline powder with a faint but characteristic odor. Approximately 60 mg of the drug are soluble in 1 mL of water.

Tiamulin may also be known as 81723-hfu, SQ-14055, SQ-22947 (tiamulin fumarate), or *Denagard*®.

Storage/Stability

Protect from moisture; store in a dry place at controlled room temperature (59°F-77°F [15°C-25°C]). In unopened packets, the powder is stable up to 5 years. Fresh solutions should be prepared daily when using clinically.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY APPROVED PRODUCTS:

Tiamulin Medicated Premix: 10 g/1 lb in 35 lb bags; *Denagard® 10*; (OTC). FDA-approved for use in swine not weighing over 113.4 kg (250 lb). Slaughter withdrawal period at the 35 g/ton use is 2 days; at the 200 g/ton dose it is 7 days.

Tiamulin Solution as tiamulin hydrogen fumarate in an aqueous base; *Triamulox® Liquid Concentrate* (12.3% solution in 32 oz bottles); *Denagard® Liquid Concentrate* (12.5% solution in 1000 mL and 5000 mL bottles; (OTC). FDA-approved for use in swine not weighing over 113.4 kg (250 lb). Slaughter withdrawal: treatment at 3.5 mg/lb = 3 days; at 10.5 mg/lb = 7 days. The UK label lists slaughter withdrawal of 2 days for chicken and 5 days for turkey; there is no withdrawal time for eggs laid by chickens.

Tiamulin solution for injection: 162 mg/mL; *Vetmulin®*; (Not available in the United States). For treatment and prevention of dysentery in swine in individuals with known exposure; not for herd-level treatment. Withdrawal time is 21 days.[7]

There is also a chlortetracycline/tiamulin premix approved by the FDA.

HUMAN APPROVED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Tigilanol Tiglate

(tih-g***il***-an-ol tig-late) *Stelfonta®*

Antineoplastic

Prescriber Highlights

- FDA-approved for intratumoral injection for treatment of dogs with nonmetastatic cutaneous mast cell tumors (MCTs) anywhere on the body and nonmetastatic subcutaneous MCTs at or distal to the elbow or the hock
- Destruction of the tumor produces a wound at the treatment site that typically heals within ≈6 weeks.
- Tigilanol tiglate **must** be used concomitantly with a corticosteroid (eg, prednis(ol)one), an H_1-receptor antagonist (eg, diphenhydramine), and an H_2-receptor antagonist (eg, famotidine) to minimize severe systemic reactions caused by mast cell degranulation.
- Has been used in an extra-label manner to treat skin tumors in horses; concomitant medications and dosages for horses differ from those used in dogs
- Contraindicated for treatment of subcutaneous MCT above the elbow or the hock, of MCT volume exceeding 10 cm^3, and in dogs with metastatic disease. Total dose must not exceed 5 mL/dog and 0.25 mL/kg.
- Do not administer into the tumor margin, beyond the tumor periphery, or by any route other than directly in the tumor.
- Use with extreme caution in MCTs that are ulcerated; use cautiously with mucocutaneous MCTs and in animals with conditions associated with impaired wound healing.
- Adverse effects include extensive wound formation, tissue sloughing, and cellulitis that occurs at, and may extend from, the tumor site. Injection site reactions (eg, pain, swelling, erythema, bruising) are common. In dogs, lameness in the treated limb and GI effects (eg, hyporexia/anorexia, vomiting, diarrhea) may also occur.
- Handle this drug with extreme caution, as accidental self-injection or needlestick injury may result in severe wound formation. Wear appropriate personal protective equipment when preparing or administering this drug. Those who are pregnant or planning to become pregnant should not handle this drug.
- Provide the manufacturer's client information sheet to owners before the drug is administered.

Uses/Indications

In dogs with a tumor volume less than 10 cm^3, tigilanol tiglate is administered via intratumoral injection to treat nonmetastatic cutaneous mast cell tumor (MCTs) located anywhere on the body or nonmetastatic **sub**cutaneous MCTs at or distal to the elbow or the hock. Intratumoral tigilanol tiglate administration destroys the tumor over ≈1 week, and the resulting wound typically heals within ≈6 weeks. In a field study, 75% of treated dogs achieved complete response in the target tumor 28 days after receiving 1 injection.[1] In dogs with an incomplete response, a second injection 1 month later resulted in a cumulative complete response rate of ≈87%. Efficacy proved higher in tumors of lower cytologic grade when compared with tumors of higher grade (ie, 72% vs 38%).[1] At 12 weeks after treatment, a complete response was maintained in 93% of dogs.[1] In a separate evaluation, 89% of evaluable dogs remained tumor free at the treatment site 12 months after treatment,[2] and most cases of recurrence were noted within 12 weeks after treatment.

Tigilanol tiglate **must** be used in combination with a corticosteroid and antihistamines (see ***Contraindications/Precautions/Warnings*** and ***Dosages***).[3]

Tigilanol tiglate was successfully used intratumorally in 2 horses to treat local disease (fibroblastic sarcoid, periocular squamous cell carcinoma); tumor response followed a pattern similar to that observed in dogs.[4]

Pharmacology/Actions

Tigilanol tiglate disrupts mitochondrial function, resulting in oncolysis.[3,5,6] This effect is immediate, short-lived, and limited to the area of injection. In addition, the drug preferentially activates beta II (alpha-, beta I-, and gamma-isoforms of protein kinase C [PKC] are also activated[3,7]), producing an acute (2 to 4 days) inflammatory response in and around the tumor that restricts tumor blood supply, as well as recruiting and activating the cellular immune response (ie, neutrophils and macrophages). Activating PKC also increases tumor vascular permeability that leads to destruction of the tumor vasculature.[3,5,6] Tumor destruction and necrosis are typically seen 4 to 7 days after administration.[3,5,6]

Tigilanol tiglate does not prevent MCT development in dogs.[5,6]

Pharmacokinetics

The pharmacokinetics of tigilanol tiglate have been described in dogs receiving intratumoral administration.[3,5,6] A relatively small amount of the drug is absorbed into systemic circulation. Peak plasma concentration (C_{max}) ranged from 0.356 to 13.8 ng/mL (mean 5.9 ng/mL), and elimination half-life was 2.85 to 36.87 hours. Tigilanol tiglate exposure (C_{max} and AUC_{last}) demonstrated no relationship with tumor location or total tigilanol tiglate dose.[3] The systemic exposure of tigilanol tiglate following intratumoral injection is not sufficient to treat MCT at other sites or to treat metastatic disease.[6]

Although tigilanol tiglate treatment is not administered by the IV route, following 0.025 – 0.075 mg/kg IV infusion in dogs, tigilanol tiglate C_{max} was 11 – 57 ng/mL,[8] and half-life was 0.54 hours.[5,6,8]

Contraindications/Precautions/Warnings

Tigilanol tiglate is contraindicated in patients hypersensitive to it or to propylene glycol, which is present in the commercial formulation. Do not inject tigilanol tiglate in MCTs with volume greater than 10 cm^3, or in the margins of a surgically resected MCT[5,6]; SC injection in locations above the elbow or hock may result in severe systemic reactions due to mast cell degranulation and must be avoided.[3] Use tigilanol tiglate with extreme caution in MCTs that are ulcerated or have broken skin, as drug leakage from the site could lead to an underdose and unintentional drug exposure[5,6]; consider applying a bandage to the treated area. Use tigilanol tiglate with caution in MCTs located in mucocutaneous regions (eg, conjunctiva, lip margins, vulva, prepuce, anus) and at the extremities (eg, tail, paws)[5,6] and in patients with conditions associated with impaired wound healing (eg, uncontrolled diabetes mellitus, hyperadrenocorticism).[3] In completely subcutaneous MCTs, an incision may be needed to allow drainage of necrotic tissue.[5,6] Safe use of tigilanol tiglate in dogs younger than 3.5 years old was not evaluated during United States approval studies,[3] but European Union authorization provides for use in dogs 12 months of age and older.[5]

When treating MCT in dogs, an anti-inflammatory dose of a corticosteroid **must** be started 2 days prior to tigilanol tiglate injection. Both H_1- and H_2-receptor antagonists (eg, diphenhydramine, famotidine) **must** be started the day of tigilanol tiglate injection. See ***Dosages.*** These concomitant treatments **must** continue for an additional 7 days after tigilanol tiglate administration (ie, 10 total days of corticosteroid and 8 total days of both antihistamines). Failure to administer these treatments for the full duration has resulted in death due to mast cell degranulation.[3]

Tigilanol tiglate does not treat metastatic disease, as it is only effective at the injection site.[5,6] Tumor necrosis and wound formation are expected outcomes of tigilanol tiglate administration and occur ≈ 4 to 7 days after injection. The size (ie, surface area) of the

resulting wound is increased with larger tumor volume, enlarged regional lymph nodes, and higher cytologic tumor grade.[9] Fully healed wounds were noted at 4, 6, and 12 weeks after administration in ≈58%, ≈75%, and ≈97% of dogs, respectively.[3,6,9] NOTE: Histologic tumor grading after tigilanol tiglate treatment is unlikely to be accurate following necrosis of the tumor. Cytologic grading prior to treatment is recommended.[3]

Tigilanol tiglate is a skin and eye irritant.[10] Wear appropriate personal protective equipment (eg, gloves, gown, eye protection) when preparing and administering tigilanol tiglate. Accidental human self-injection of tigilanol tiglate may cause severe wound formation. Do not recap needles. In case of accidental self-injection, the manufacturer advises that the area be rinsed with water and to immediately seek medical attention; give the package insert to the attending physician.[3]

Sedation of the patient may be necessary to reduce the risk for needlestick injury. A Luer-lock syringe must be used to administer tigilanol tiglate. If leakage occurs following removal of syringe, rinse injection site with saline to wash tigilanol tiglate from skin surface.

As there is little information available regarding the teratogenic potential of tigilanol tiglate, the manufacturer recommends those who are pregnant or planning to become pregnant avoid preparing or administering the drug.

Tigilanol tiglate is intended only for intratumoral administration. Severe systemic reactions may result from inadvertent IV injection.

Tigilanol tiglate dosage is based on tumor volume. Consider using calipers to measure tumor dimensions[8] and instituting practices such as redundant drug dosage, volume checking, and special alert labels.

Do not confuse *Stelfonta®* with *Stelazine®* or *Stelara®*—or tigilanol with tigecycline, timolol, or *Tigan®*.

Adverse Effects

Swelling and bruising at the injection site, which may occur as soon as 2 hours after administration, on the day of treatment occurs in over 90% of treated dogs, whereas pain and heat are noted in ≈50% to 70% of dogs ≈24 hours after injection. Treatment site exudate occurs ≈7 days after injection and may be serous, serosanguinous, sanguineous, seropurulent, or purulent. Wound size following administration is frequently, but not always, proportional to the tumor size.[6]

The most frequently reported adverse effects following tigilanol tiglate injection include (in decreasing order)[3]: injection site pain (52%), lameness in the treated limb (25%), vomiting (21%), diarrhea (21%), hypoalbuminemia (18%), anorexia/hyporexia (12%), regional lymph node enlargement (11%), tachycardia (10%), weight loss (10%), dermatitis (8%), injection site infection (7%), tachypnea (6%), lethargy (5%), and pyrexia (3%). Tachypnea and lethargy were transient in a pilot field study.[8] Most adverse effects occurred in the first 7 days after injection.[3]

Anemia, neutrophilia, hypoalbuminemia, leukocytosis, monocytosis, and elevated creatine kinase have been documented following intratumoral injection.[3,6]

Reproductive/Nursing Safety

Safe use of tigilanol tiglate in pregnant, breeding, or lactating dogs has not been evaluated.[3,6]

Overdose/Acute Toxicity

Tigilanol tiglate administered IV (**NOTE**: not labeled route of administration) across a range of doses resulted in retching and vomiting during or immediately following the infusion, salivation, tremors, swaying gait, tachypnea, and lateral recumbency.[3,5,6] These effects were dose-related and considered serious but self-limiting and typically resolved 1 to 4 hours postinfusion. Tachycardia was observed with 0.075 mg/kg IV infusion,[3] and seizures and death occurred following 0.225 mg/kg IV infusion.[5,6] Infusion site reactions, including wound formation, were noted.[3]

There is no known antidote for toxic tigilanol tiglate exposure; treat clinical signs with supportive therapy.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with the drug manufacturer, or if unavailable, contact one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Antibiotics, sedatives, and analgesics, including opioids, have been coprescribed for dogs receiving tigilanol tiglate.[3,6] The following drug interactions have either been reported or are theoretical in humans or animals receiving tigilanol tiglate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antineoplastic Agents** (eg, **toceranib, vinblastine**): Use of other antineoplastic agents 2 months prior to tigilanol tiglate was prohibited in field studies.[8] Use together cautiously, if at all.
- **Immunosuppressive Agents** (eg, **cyclosporine, lokivetmab, oclacitinib**): Use of immunosuppressive agents 14 days prior to tigilanol tiglate was prohibited in field studies. Use together cautiously.[8]
- **NSAIDs** (eg, **carprofen, deracoxib, firocoxib, meloxicam**): In dogs being treated for MCT, a corticosteroid must be administered concomitantly with tigilanol tiglate; therefore, NSAIDs may need to be avoided during periods of corticosteroid use. Use of NSAIDs 7 days prior to tigilanol tiglate administration was prohibited in field studies.[8]

Laboratory Considerations

Histologic tumor grading after tigilanol tiglate treatment is unlikely to be accurate due to tumor necrosis; cytologic grading prior to treatment should be considered.[3]

Dosages

DOGS:

Nonmetastatic cutaneous MCT anywhere on the body or nonmetastatic subcutaneous MCT at or distal to the elbow or hock (label dosage; FDA-approved): 0.5 mL/cm^3 of tumor volume injected into (not under) a single MCT[3] with maximum tumor volume of 10 cm^3

Concomitant medications

An anti-inflammatory dose of a corticosteroid ***must*** be started 2 days prior to tigilanol tiglate injection, and histamine H_1- and H_2-receptor antagonists ***must*** be started on the day of tigilanol tiglate injection (see ***Contraindications/Precautions/Warnings***). The manufacturer's protocol uses the following dosages:

- Prednis(ol)one 0.5 mg/kg PO twice daily for 7 days (2 full days before treatment, the day of treatment, and for 4 days after treatment), decreased to 0.5 mg/kg PO once daily for 3 additional days (10 days total)
- Diphenhydramine 2 mg/kg PO twice daily, beginning the morning of the day of treatment and for 7 additional days (8 days total)
- Famotidine 0.5 mg/kg PO twice daily beginning the morning of the day of treatment and for 7 additional days (8 days total)

Calculating the dose to be administered

1. Tumor volume is calculated as 0.5 × [length (cm) × width (cm) × height (cm)]; it is highly recommended to use calipers to obtain tumor measurements.[8]

2. Number of mL of tigilanol tiglate to administer = 0.5 mL × tumor volume.
3. Confirm that tigilanol tiglate dose does not exceed 0.25 mL/kg.
4. The minimum dose is 0.1 mL, and the maximum dose is 5 mL, regardless of body weight, tumor volume, or number of tumors. **NOTE**: In a small dose-finding study, using dosages less than what is listed on the label demonstrated lower efficacy and a higher rate of adverse effects.[11]

Administration

1. Shaving the tumor slightly beyond the margins is recommended, unless doing so requires excessive manipulation of the tumor or causes the dog stress.[11]
2. Consult the product label for administration technique. A Luer-lock syringe ***must*** be used with a 23-gauge needle to inject tigilanol tiglate into the tumor with a dispersed (ie, fanning) pattern such that the tumor is fully perfused. Do not inject in a blood vessel or tumor margins, beyond tumor periphery, or deep into the tumor. Avoid manipulation of the tumor prior to injection to minimize the risk for mast cell degranulation.
3. Sedation of the patient may be necessary to decrease risk of accidental self-injection.

Dogs with an incomplete response may be given a second dose 30 days after the first injection. The corticosteroid and antihistamines described above are also required for the second treatment. Tigilanol tiglate dose for the second treatment must be based on the tumor volume calculated at the time of the second treatment.

Nonresectable, nonmetastatic cutaneous MCT or nonmetastatic subcutaneous MCT at or distal to the elbow or hock (extra-label): 0.5 mL/cm^3 of tumor volume, following the calculations, limits, cautions, and techniques presented in the FDA-approved labeled-dosage protocol above, with the following exceptions: maximum tumor volume is 8 cm^3, maximum dosage is 4 mL/dog (not to exceed 0.15 mg/kg), and, if needed, a second dose may be repeated 28 days after the first dose. The tumor must be accessible for intratumoral injection. More than 1 MCT may be treated per dog provided the preceding limits are not exceeded.[5,6]

HORSES:

Treatment of equine sarcoid or squamous cell carcinoma (extra-label): 0.35 mg/cm^3 (not mL/ cm^3) of tumor volume injected with a Luer-lock syringe using a dispersed pattern to fully perfuse the lesion.[4] Minimum dose of 0.05 – 0.1 mg/horse and maximum dose of 0.2 – 2 mg/horse; dose may vary based on lesion location. Standing sedation and local or regional anesthesia may be used. Surgical excision of the sarcoid pedicle was performed to measure and treat the tumor base.

Concomitant medication

- Immediately following tigilanol tiglate injection, administer flunixin 1.1 mg/kg IV.
- After tigilanol tiglate treatment, administer phenylbutazone 4.4 mg/kg PO twice daily for 3 days, followed by 2.2 mg/kg PO twice daily for the next 7 days if required.
- For ocular mucocutaneous and peri-orbital lesions, a subpalpebral lavage system must be placed at the time of treatment to administer an ophthalmic NSAID (eg, ketorolac, 0.1 mL every 6 hours) *and* atropine 1% (0.1 mL every 6 hours); a UV-protecting head veil is required.

Monitoring

- Clinical efficacy
- Signs of systemic mast cell degranulation for up to 7 days after treatment may include vomiting, diarrhea, anorexia/hyporexia, lethargy, urticaria, hypotension, altered breathing, and edema or bruising at or away from the MCT treatment site
- CBC, general chemistry, albumin, creatine kinase

Client Information

- Your veterinarian will provide an information sheet prior to administration of this drug.
- Tigilanol tiglate will be administered by your veterinarian. Sedation of your dog may be required to allow safe administration of the drug.
- At least 3 other medications are used with tigilanol tiglate. It is absolutely essential that these medications are administered exactly as prescribed, as death has occurred when these medications were not used, or were used improperly (eg, not giving the full 8- or 10-day treatment).
- Tigilanol tiglate destroys the mast cell tumor. In doing so, a wound will form where the drug was administered within a week of administration. This is a normal and expected part of treatment.
- Reactions (eg, swelling, redness, heat, pain) at the treatment site may begin as soon as 2 hours after injection and may last up to 1 week or longer. These reactions may be painful; talk to your veterinarian if you think your dog may need pain relievers.
- As the tumor breaks down, the skin at the injection site may darken or break open. A pocket, or wound, with a red and healthy-appearing border will develop at the site and progressively heal over several weeks. In some cases, the size of the wound may exceed the size of the original tumor. Antibiotics may be required if an infection develops in or around the wound.
- The wound is typically left uncovered. Discharge from the treatment site can be cleaned with warm water when necessary. Wear disposable gloves while cleaning. Use of preventive measures (eg, Elizabethan collar, bandage) may be needed if your dog is excessively grooming (licking) the treatment site. Other pets should be prevented from grooming the treatment site.
- Wound healing typically occurs 4 to 6 weeks after injection but may take longer in some dogs.
- Drinking water should be made accessible to treated dogs.
- Contact your veterinarian if your dog stops eating, develops lameness, has repeated vomiting or diarrhea, has difficulty breathing, or shows signs of severe pain, or if the treatment site appears to be increasing in size, is irritated, or has extensive swelling, redness, or bruising.
- Thoroughly wash any human skin that comes in contact with the treatment site, wound discharge, or materials contaminated with wound discharge (eg, bedding). Wash soiled items separately from other laundry.
- If there are multiple animals in the house, they may need to be separated to prevent grooming or trauma to the treated site.

Chemistry/Synonyms

Tigilanol tiglate is a phorbol ester with a molecular weight of 563. The commercial product is a clear colorless solution that also contains propylene glycol (40% v/v). Tigilanol tiglate is an epoxytigliane isolated from the seed of *Fontainea picrosperma*, a tree native to Australia.[7]

Tigilanol tiglate may also be known as EBC-46, phorbol triacetate, tigliane, TT, or *Stelfonta*®.

Storage/Stability

Tigilanol tiglate injection must be stored refrigerated at 2°C to 8°C (36°F-46°F). Do not freeze. Store in the manufacturer's carton to protect from light. Discard unused portion in accordance with routine medical waste.

Compatibility/Compounding Considerations

None noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Tigilanol Tiglate Injection: 1 mg/mL solution in 2 mL single-use vials; *Stelfonta*®, (Rx). NADA# 141-541

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Tildipirosin

(til-di-***pir***-oh-sin) *Zuprevo*®
Macrolide Antibiotic

Prescriber Highlights

- ► Injectable macrolide antibiotic used as a single SC dose in beef and nonlactating dairy cattle
- ► Used as a single IM dose in swine (not approved in the United States)
- ► Precautions: do not use the cattle product in swine; do not administer IV; do not use in chickens or turkeys.
- ► Do not use in automatically powered syringes. In case of human injection, contact a physician immediately. Use precautions when handling any tildipirosin product.
- ► Pain and swelling at the injection site are the most common adverse effects.

Uses/Indications

Tildipirosin is an injectable macrolide antibiotic that is approved by the FDA for the treatment of bovine respiratory disease (BRD) associated with *Mannheimia haemolytica, Pasteurella multocida,* and *Histophilus somni* in beef and nonlactating dairy cattle and for the control of respiratory disease in beef and nonlactating dairy cattle at high risk for developing BRD associated with *Mannheimia haemolytica, Pasteurella multocida,* and *Histophilus somni.* A study in heifers comparing metaphylactic antimicrobial administration of tildipirosin, tulathromycin, or placebo administered 10 days before experimental inoculation with *Mannheimia haemolytica* concluded that tildipirosin-treated animals had less pulmonary damage and fewer clinical signs of illness when compared to the other groups.[1]

In the EU, tildipirosin is also approved for the treatment of swine respiratory disease (SRD) associated with *Actinobacillus pleuropneumoniae, Pasteurella multocida, Bordetella bronchiseptica,* and *Haemophilus parasuis* sensitive to tildipirosin.

The World Health Organization (WHO) has designated tildipirosin as a Critically Important, Highest Priority antimicrobial for human medicine.[2] The Office International des Epizooties (OIE) Antimicrobial Classification has designated tildipirosin as a Veterinary Critically Important antimicrobial.[3]

Pharmacology/Actions

Similar to other macrolides, the antimicrobial activity of tildipirosin is due to its binding to the ribosomal 50S subunit of bacterial cells and inhibiting bacterial protein synthesis. Tildipirosin is generally classified as a time-dependent antibiotic, although it may be concentration-dependent (AUC/MIC ratio) against some isolates of *Mannheimia haemolytica* and *Pasteurella multocida*.

Significant increases in MIC of *P multocida* and *M haemolytica* to tildipirosin can be conveyed by the presence of the *erm*(42) gene.[4]

Macrolides inhibit the secretion of proinflammatory cytokines, phospholipase activity, and the release of leukotrienes and have anti-inflammatory effects on bovine macrophages and neutrophils.[5]

Pharmacokinetics

In cattle, after a single 4 mg/kg SC injection, bioavailability was 78%, and peak plasma concentrations of 0.7 to 0.8 µg/mL occurred within 1 hour of dosing. Concentrations of tildipirosin in lung and bronchial fluid far exceed those in plasma. Lung:plasma ratios range from 28 times at 4 hours to 214 times at 240 hours. Bronchial fluid:plasma ratios are 5 times at 4 hours; up to 72 times at 240 hours. The elimination half-life was ≈9 days in plasma and 10 to 11 days in lung and bronchial fluid.[6,7] Because of the extensive partitioning of macrolides into tissues and because of their multi-fold greater concentrations in bronchial fluid relative to that observed in the blood, plasma drug concentrations underestimate concentrations at the site of action.

A research publication suggests that upon administration to beef cattle and pigs at the recommended dose, colonic tildipirosin activity remains at subinhibitory concentrations far below the MICs against bovine and porcine foodborne pathogens and commensal bacteria.[8]

In pigs, after 4 mg/kg IM, peak plasma concentrations occurred within 23 minutes. Only ≈30% is bound to porcine plasma proteins. The mean terminal half-life was ≈4.4 days. Concentrations in the lung peaked about 1 day after dosing, and the lung half-life was ≈7 days.[9,10]

Contraindications/Precautions/Warnings

Tildipirosin is contraindicated in animals hypersensitive to it or other macrolide antibiotics. Tildipirosin is **NOT** for use in chickens or turkeys, and the 18% product must **NOT** be used in swine. Tildipirosin must **NOT** be given IV.

Cross-resistance can occur with other macrolides, and use with other macrolides or lincosamides is not advised. SC injection in cattle may result in local tissue reactions that can persist beyond the slaughter withdrawal period and may result in trim loss of edible tissue at slaughter.

Care must be taken to avoid accidental injection in humans, as toxicology studies in laboratory animals (including dogs) showed cardiovascular effects after IM administration. Do not use automatically powered syringes that do not have an additional protection system. In case of human injection, seek medical advice immediately and show the package insert or label to the physician. Avoid direct contact with skin and eyes. If accidental eye exposure occurs, rinse eyes with clean water. If accidental skin exposure occurs, wash the skin immediately with soap and water. Wash hands after use. Tildipirosin may cause sensitization by skin contact.

Adverse Effects

In cattle, pain and swelling at injection sites are the most commonly reported adverse effects, with pain on palpation persisting for 1 day in most treated cattle. Swelling can last at the injection site for up to 21 days posttreatment, and tissue lesions have been noted at 35 days postinjection.[7,11] Swelling and inflammation, which may be severe, may be seen at the injection site after administration. SC injection may result in local tissue reactions, which persist beyond the slaughter withdrawal period. This may result in trim loss of edible tissue at slaughter.

In pigs, swelling at the injection site after IM injection can persist for up to 3 days but is not painful upon palpation. Injection site reactions resolved completely within 21 days of injection.[10] Shock-like reactions with fatal outcomes can occur rarely.[10]

Reproductive/Nursing Safety

The safety of the veterinary medicinal product has not been established during pregnancy and lactation; however, no evidence for any selective developmental or reproductive effects was noted in any of the laboratory studies.

The product is not labeled for use in lactating dairy cattle.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited information is available. In cattle, dosages up to 5 times recommended caused little demonstrable effects other than localized tissue reactions.[7]

Some piglets that were given 3 times (12 mg/kg) and 5 times (20 mg/kg) the normal doses IM developed muscle tremors, weakness, or showed subdued activity. One animal developed a shock-like syndrome after 20 mg/kg and was euthanized. Mortality was seen at dosages of 25 mg/kg or greater.[10]

Dogs given IM doses of 20 mg/kg caused a slight but significant decrease in blood pressure.[11,12]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No specific drug interactions were noted, although the EU label states: *There is cross resistance with other macrolides. Do not administer with antimicrobials with a similar mode of action such as other macrolides or lincosamides.*[13]

Laboratory Considerations

None were noted.

Dosages

CATTLE:

Treatment of bovine respiratory disease (BRD) associated with *Mannheimia haemolytica, Pasteurella multocida,* and *Histophilus somni* in beef and nonlactating dairy cattle and for the control of respiratory disease in beef and nonlactating dairy cattle at high risk for developing BRD associated with *Mannheimia haemolytica, Pasteurella multocida,* and *Histophilus somni* (label dose, FDA-approved): 4 mg/kg SC as a single dose in the neck. Do not inject more than 10 mL per injection site.[7]

SWINE:

Treatment of swine respiratory disease (SRD) associated with *Actinobacillus pleuropneumoniae, Pasteurella multocida, Bordetella bronchiseptica,* and *Haemophilus parasuis* sensitive to tildipirosin (extra-label): **NOTE**: The 18% cattle product must not be used in swine; the swine product (EU) is 40 mg/mL (4%). Administer 4 mg/kg IM once only. The injection volume should not exceed 5 mL per injection site. Start treatment in the early stages of the disease and re-evaluate within 48 hours; if clinical signs persist or increase, antibiotic treatment should be changed.[10]

Monitoring

Clinical efficacy. The product information for the UK products states: *In cattle, evaluate the response to treatment within 2 to 3 days after injection. If clinical signs of respiratory disease persist or increase, treatment should be changed to using another antibiotic.*[13] In pigs, it is recommended to evaluate the response to treatment within 48 hours after injection. If clinical signs of respiratory disease persist, increase, or if relapse occurs, treatment should be changed to using another antibiotic.[10]

Client Information

- Understand and follow use restrictions and withdrawal times for food animals.
- Humans with a known drug allergy to macrolide antibiotics (eg, erythromycin, clarithromycin) should avoid contact with the medication.
- Do not use automatically powered syringes that do not have an additional protection system. In case of accidental self-injection, seek medical advice immediately and show the package leaflet or label to the physician. In case of skin or eye exposure, wash/flush with clean water.

Chemistry/Synonyms

Tildipirosin (CAS Registry: 328898-40-4; ATCvet code: QJ01FA96) is a 16-membered semisynthetic macrolide antimicrobial agent.

The injectable solution is a clear, yellowish solution. Excipients in the injectable solution include citric acid monohydrate, propylene glycol, and water for injection.

Tildipirosin may also be known as 20, 23-di-piperidynyl-mycaminosyl-tylonolide, or PMT. The trade name is *Zuprevo*®.

Storage/Stability

Store the injectable solution at temperatures at or below 30°C (86°F). Do not freeze. The EU label states not to store above 25°C (77°F). The maximum storage time after the first puncture is 28 days at or below 25°C (77°F). Do not puncture 50 mL and 100 mL vial stoppers more than 8 times or the 250 mL vial stopper more than 16 times.

Compatibility/Compounding Considerations

No specific information was noted. The EU label states: *In the absence of compatibility studies, this veterinary medicinal product must not be mixed with other veterinary medicinal products.*

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tildipirosin Injection: 180 mg/mL (18%) in 50 mL, 100 mL, and 250 mL multidose vials; *Zuprevo*®; (Rx). FDA-approved (NADA# 141-334) for use in cattle. Not for use in female dairy cattle 20 months of age or older or in pre-ruminating calves. Do not use in calves to be processed for veal. Withdrawal time is 21 days. (Withdrawal time in EU label is 47 days.)

Tildipirosin 40 mg/mL injection for use in swine is available in EU (not available in the US).

HUMAN-LABELED PRODUCTS: NONE

Tiletamine/Zolazepam

(tye-***let***-a-meen/zoe-***laze***-a-pam) *Telazol*®

Injectable Anesthetic/Tranquilizer

Prescriber Highlights

- ► Combination similar to ketamine/diazepam but with a longer duration of effect
- ► Contraindications include pancreatic disease, New Zealand white rabbits, severe cardiac or pulmonary disease, or during pregnancy.
- ► Use with caution in patients that have renal disease and in large exotic cats.
- ► Apply ophthalmic lubricant after administration
- ► Dosages may need to be reduced in geriatric or debilitated animals, or in animals with renal dysfunction.
- ► Adverse effects include respiratory depression, pain after IM injection, athetoid movements, tachycardia (especially dogs), emesis during emergence, excessive salivation and bronchial/tracheal secretions, transient apnea, vocalization, erratic and/or prolonged recovery, involuntary muscular twitching, hypertonia, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, and either hypertension or hypotension.
- ► Monitor body temperature (may cause hypothermia)
- ► DEA Schedule III (C-III) controlled substance

Uses/Indications

In dogs, tiletamine/zolazepam is labeled for induction of anesthesia and for restraint and minor procedures of short duration (≈30 minutes) that require mild to moderate analgesia. Tiletamine/zolazepam is also labeled for restraint or anesthesia combined with muscle relaxation in cats. Although tiletamine/zolazepam is not FDA-approved for other species, it has been used in many domestic, exotic, and wild species. A potential disadvantage of this product is that it is a fixed-ratio combination and the pharmacokinetics of each drug can vary significantly among species.

Pharmacology/Actions

Tiletamine is a dissociative anesthetic and zolazepam is a benzodiazepine. The pharmacology of this drug combination is similar to that of ketamine combined with diazepam or midazolam.

In cats, tiletamine can briefly (≈1 minute) decrease blood pressure after IV injections, but this parameter increases above baseline after this brief period.[1] In dogs, a persistent tachycardia is followed by decreased blood pressure, although cardiac output typically remains unchanged. It can cause apneustic breathing (like ketamine); however, normal minute ventilation and pCO_2 is maintained.[2,3] In dogs, induction with tiletamine IV had no clinical effects on intraocular pressure.[4] The same outcomes were noted when this drug was administered IM and intranasal in cats.[5]

Pharmacokinetics

In dogs, the onset of action following IM injection averages 7.5 minutes. The mean duration of surgical anesthesia is ≈27 minutes, with recovery times averaging ≈4 hours. The duration of the tiletamine effect is longer than that of zolazepam, so there is a shorter duration of tranquilization and muscle relaxation than there is anesthesia. Less than 4% of the drugs are reported to be excreted unchanged in the urine in dogs. Reported elimination half-life for tiletamine is 1.25 to 2.5 hours, and 1.5 hours for zolazepam.

In cats, the onset of action is reported to be within 5 to 12 minutes after IM injection. Duration of anesthesia is dose dependent, but is usually≈21 to 60 minutes at peak effect, which is reported to be ≈3 times the duration of ketamine anesthesia. The duration of effect of the zolazepam component is longer than that of the tiletamine, so there is a greater degree of tranquilization than anesthesia during the recovery period. The recovery times vary in length from ≈1 to 5.5 hours. Reported elimination half-life for tiletamine is 2.5 hours and 4.5 hours for zolazepam. These differences in half-life result in less predictable anesthetic effects when multiple doses are administered.

In xylazine-sedated horses, tiletamine/zolazepam 1.5 mg/kg IV (over 15 seconds) produced the following pharmacokinetic data (means reported): For tiletamine and zolazepam: clearance, 96 mL/minute/kg and 6.7 mL/minute/kg; volume of distribution, 0.79 L/kg and 0.76 L/kg; terminal half-life, 29 minutes and 235 minutes. Tiletamine is cleared much more rapidly than zolazepam. At this dose, recumbency lasted for 30 to 43 minutes, and the mean time to standing was 39 minutes. The authors judged recoveries to be excellent.

In pigs, higher concentrations of zolazepam were observed in pig plasma and it was cleared more slowly compared with tiletamine. Apparent clearance was 11 L/hour (zolazepam) versus 134 L/hour (tiletamine); and half-life was 2.76 hours (zolazepam) versus 1.97 hours (tiletamine). Three metabolites of zolazepam and 1 metabolite of tiletamine were identified in pig urine, plasma, and microsomal incubations.[6]

Contraindications/Precautions/Warnings

Tiletamine/zolazepam should only be used in situations in which sufficient monitoring and patient-support capabilities (eg, intubation, ventilation) are available. Tiletamine/zolazepam is contraindicated in animals with pancreatic disease and severe cardiac or pulmonary disease. Animals with renal insufficiency may have prolonged duration of anesthetic action or recovery times.

Because tiletamine/zolazepam may cause hypothermia, susceptible animals (eg, small body surface area, low ambient temperatures) should be monitored carefully and a supplemental heat source should be provided if needed. Like ketamine, tiletamine/zolazepam does not abolish pinnal, palpebral, pedal, laryngeal, and pharyngeal reflexes, and its use (alone) may not be adequate if surgery is to be performed on these areas.

It has been reported that this drug is contraindicated in New Zealand white rabbits due to renal toxicity.[7] Other breeds seem to be unaffected.

Tiletamine/zolazepam is often avoided for use in large, exotic cats, as it reportedly can cause seizures, prolonged recovery, permanent neurologic abnormalities, or death. Although several clinicians have suggested that tiletamine/zolazepam is contraindicated in tigers (*Panthera tigris*), an evaluation of the literature suggests that although adverse effects can occur, tiletamine/zolazepam is not contraindicated.[8] A study found no major differences in pharmacokinetics between tigers and leopards (*Panthera pardus*).[9] A study evaluating the effects of tiletamine/zolazepam in combination with detomidine (TZD) in 9 tigers found it to be effective in immobilizing captive healthy tigers and no neurologic and/or important adverse reactions were noted; however, hypertension and ataxia may be seen during recovery.[10]

Animals' eyes remain open after receiving tiletamine/zolazepam; they should be protected from injury and an ophthalmic lubricant should be applied to prevent excessive drying of the cornea. When dissociative anesthetic agents (ie, ketamine, tiletamine) are used, animals maintain the swallowing reflex, making intubation challenging, especially in cats. The use of sedatives before the administration of tiletamine/zolazepam may improve the outcome. Topical lidocaine (on the arytenoid cartilages) or rocuronium IV (with ventilatory support)[11] has been used in cats to facilitate tracheal intubation.

The effects of tiletamine (eg, anesthesia with concurrent athetosis, muscle rigidity, convulsions) typically outlast the duration of zolazepam effects in dogs, which may cause agitated recoveries. See ***Adverse Effects***.

Dosages may need to be reduced in geriatric or debilitated animals or animals with renal dysfunction.

Adverse Effects

Respiratory depression is a possibility, especially when higher doses are administered. Apnea may occur; observe animal carefully. Pain after IM injection (especially in cats) has been noted, which may be a result of the low pH of the solution. Athetoid movements (eg, constant succession of slow, writhing, involuntary movements of flexion, extension, pronation) may occur; do not give additional tiletamine/zolazepam in an attempt to diminish these actions. Large doses given SC or IM (vs small doses given IV) may result in longer, rougher recoveries. Recoveries in dogs can be rougher than those usually seen in cats.

In dogs, tachycardia may be a common effect and last for 30 minutes. Insufficient anesthesia after recommended doses has been reported in dogs.

Tiletamine/zolazepam has been implicated in causing nephrosis in lagomorphs and prolonged recovery, neurologic signs, and death in large cats (specifically in tigers).

Other adverse effects include emesis during emergence, excessive salivation and bronchial/tracheal secretions (if atropine not administered beforehand), transient apnea, vocalization, erratic and/or prolonged recovery, involuntary muscular twitching, hypertonia, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, seizure activity, and either hypertension or hypotension.[12] Atropine 0.04 mg/kg IV, IM, or SC can be used concurrently to control hypersalivation.

Reproductive/Nursing Safety

Tiletamine/zolazepam crosses the placenta and may cause respiratory depression in newborns; use for cesarean sections is contraindicated.[12] The teratogenic potential of the drug is unknown, and it is not recommended for use during any stage of pregnancy or during lactation.

Overdose/Acute Toxicity

The manufacturer claims a 2 times margin of safety in dogs, and a 4.5 times margin of safety in cats. Lethal doses can occur at ≈5 to 10 times the labeled IM doses. A preliminary study in dogs suggests that doxapram 5.5 mg/kg will enhance respirations and arousal after tiletamine/zolazepam.[13] In massive overdoses, it is suggested that mechanically assisted ventilation be performed if necessary and other clinical signs treated supportively. Use of flumazenil to reverse zolazepam is not commonly done, as its use will exacerbate the effects of tiletamine, which cannot be reversed.

High doses of tiletamine have caused acute tubular necrosis in New Zealand white rabbits.[14,15]

Drug Interactions

Little specific information is available presently on drug interactions with this product. The following drug interactions either have been reported or are theoretical in animals receiving tiletamine/zolazepam and may be of significance. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, Inhalational** (eg, **isoflurane, sevoflurane**): Dose may need to be reduced when used concomitantly with tiletamine/zolazepam.
- **Barbiturates** (eg, **phenobarbital**): Dose may need to be reduced when used concomitantly with tiletamine/zolazepam.
- **Chloramphenicol**: In cats, anesthesia is prolonged an average of ≈30 minutes by chloramphenicol; however, in dogs, chloramphenicol apparently has no effect on recovery times.
- **Phenothiazines** (eg, **acepromazine**): Can cause increased respiratory and cardiac depression

The following are interactions for the related compounds ketamine and midazolam and could apply to tiletamine/zolazepam:

Ketamine:

- **Neuromuscular blockers** (eg, **succinylcholine, tubocurarine**): May cause enhanced or prolonged respiratory depression
- **Thyroid hormones**: Combination has induced hypertension and tachycardia in humans; beta-blockers (eg, **propranolol**) may be of benefit in treating these effects.

Midazolam:

- **Anesthetics, Inhalational** (eg, **isoflurane, sevoflurane**): Midazolam may decrease the dosages required.
- **Azole Antifungals** (eg, **fluconazole, itraconazole, ketoconazole**): May increase midazolam concentrations
- **Calcium Channel Blockers** (eg, **diltiazem, verapamil**): May increase midazolam concentrations
- **Cimetidine**: May increase midazolam concentrations
- **CNS Depressants, Other**: May increase the risk for respiratory depression
- **Macrolides** (eg, **clarithromycin, erythromycin**): May increase midazolam concentrations
- **Opioids**: May increase the hypnotic effects of midazolam; hypotension has been reported when used with meperidine.
- **Phenobarbital**: May decrease peak concentrations and AUC of midazolam
- **Rifampin**: May decrease peak concentrations and AUC of midazolam

Dosages

NOTE: Listed dosages are for the combined amounts of tiletamine/zolazepam.

DOGS:

NOTE: The label dosages for dogs is considered to be greater than is necessary for most indications. The label indications and dosages are provided below but the use of lower, extra-label dosages should be considered.

Restraint for diagnostic purposes (label dosage; FDA-approved): 6.6 – 9.9 mg/kg IM[12]

Minor procedures of short duration (label dosage; FDA-approved): 9.9 – 13.2 mg/kg IM.[12] If supplemental doses are necessary, give doses less than the initial dose; total dose should not exceed 26.4 mg/kg.

Induction of anesthesia (label dosage; FDA-approved): 2.2 – 4.4 mg/kg IV slowly over 30 to 45 seconds.[12] Additional drug may be given if the depth of anesthesia is not sufficient 60 seconds after administration; total dose of 4.4 mg/kg IV should not be exceeded. Maintain anesthesia with an inhalant anesthetic.[12]

Anesthetic induction (extra-label): 3 – 4.5 mg/kg IV followed by isoflurane anesthesia[16]

Aggressive (difficult to handle) dogs (extra-label): 1 – 2 mg/kg IM. Use only if there is insufficient sedation from a combination of opioid, higher dose medetomidine, and midazolam.[17] Anecdotally, 5 mg/kg IM in combination with an opioid (eg, morphine, hydromorphone)

CATS:

NOTE: The label dosages for cats is considered to be greater than is necessary for most situations. The label indications and dosages are provided below but the use of lower, extra-label dosages should be considered.

Procedures such as dentistry, abscess treatment, foreign body removal (label dosage; FDA-approved): 9.7 – 11.9 mg/kg IM [12]

Minor procedures of short duration that require mild to moderate levels of analgesia (eg, lacerations, castration) (label dosage; FDA-approved): 10.6 – 12.5 mg/kg IM[12]

Ovariohysterectomy and onychectomy (label dosage; FDA-approved): 14.3 – 15.8 mg/kg IM.[12] If supplemental doses are necessary, give doses in increments that are less than the initial dose; total dose should not exceed 72 mg/kg.

Procedures that require relief of mild pain (extra-label): 2 – 5 mg/kg IV or 5 – 10 mg/kg IM. The tiletamine/zolazepam vial can be reconstituted with butorphanol 2.5 mg (using 10 mg/mL solution) and dexmedetomidine 2.5 mL (using 0.5 mg/mL solution) and given IM.[18]

Procedures that require relief of moderate to severe pain (extra-label): Tiletamine/zolazepam 3 mg/kg IM in combination with methadone 0.2 mg/kg and given IM provided superior sedation and similar recovery when compared to acepromazine-methadone combination.[19]

Sedation of healthy cats prior to blood donation (extra-label): 5 mg/kg IM[20]

Oral transmucosal (OTM) administration (extra-label): 10 – 15 mg/kg OTM effectively restrained healthy cats under experimental conditions.[21]

Restraint of aggressive cats: Anecdotally, 3 – 5 mg/kg IM in combination with an opioid (eg, hydromorphone) results in profound sedation.

HORSES:

Anesthesia (extra-label): Xylazine 1.1 mg/kg IV, 5 minutes prior to tiletamine/zolazepam 1.65 – 2.2 mg/kg IV. Recumbency lasted 30 to 43 minutes, and mean time to stand was 39 minutes. Both induction and recovery quality were subjectively evaluated as excellent.[22,23]

Immobilization (extra-label): Tiletamine/zolazepam 2.4 mg/kg IM in combination with detomidine 0.04 mg/kg IM. Time to sternal recumbency was 76 minutes, and time to standing was 118 minutes.[24]

RUMINANTS:

Chemical restraint (extra-label):

Combining tiletamine/zolazepam with ketamine and xylazine (TKX-Ru) for capturing intractable ruminant patients and large exotic hoof stock: Reconstitute a 500 mg vial of tiletamine/zolazepam with ketamine 250 mg (2.5 mL) and large animal xylazine 100 mg (1 mL), yielding a final volume of 4 mL. Use 1.25 – 1.5 mL/110 to 115 kg (242.5 lb to 253.5 lb) body weight for smaller-sized ruminant patients, and 1 mL/110 to 115 kg (242.5 lb to 253.5 lb) body weight for large-sized ruminant patients. Typically administered via a dart gun or pole syringe. Patients generally become compliant and recumbent in 5 to 10 minutes.[25]

Combining tiletamine/zolazepam with ketamine and detomidine (TZDK) in free-range cattle: Prepare solution of tiletamine/zolazepam 52.6 mg/mL in combination with detomidine 4.2 mg/mL and ketamine 52.6 mg/mL. Administer 1 mL/100 kg (220.5 lb) body weight (body weight estimated visually) IM[26,27]

Sheep undergoing surgical procedures (extra-label):

a) 8 – 12 mg/kg IV[28]

b) 12 mg/kg IM yields surgical anesthesia lasting 30 minutes[28]

NEW WORLD CAMELIDS:

Sedative/analgesic with xylazine (extra-label): Tiletamine/zolazepam 2 mg/kg in combination with xylazine 0.2 or 0.4 mg/kg IM provided antinociceptive effects for ≈30 to 50 minutes.[29] Transient hypoxemia can be seen with xylazine administration; however, this is not clinically relevant in healthy llamas. Tiletamine/zolazepam alone was deemed suitable only for immobilization for non-painful procedures.

Sedative/analgesic with dexmedetomidine (extra-label): In adult male alpacas, tiletamine/zolazepam 2 mg/kg IM in combination with dexmedetomidine 0.01 – 0.02 mg/kg IM significantly increased the duration of lateral recumbency, time to standing, and response to painful stimuli compared with tiletamine/zolazepam alone.[30]

SWINE:

Sedative/analgesic in combination with ketamine and xylazine (extra-label): Reconstitute a 500 mg vial of tiletamine/zolazepam with ketamine 250 mg (2.5 mL) and large animal xylazine 250 mg (2.5 mL), yielding a final volume of 5 mL and a concentration of 50 mg/mL of each drug. For sedation: 0.01 mL/kg IM; for surgical anesthesia: 0.02 mL/kg IM. **WARNING**: Anecdotally, this combination has been associated with deaths after recovery.[31]

Sedative/analgesic in companion pigs (extra-label): For procedures of short duration (15 to 30 minutes), 2 mg/kg IM; procedures of longer duration (30 to 60 minutes): 3 – 4 mg/kg IM[32]

Anesthesia/sedation (extra-label):

a) A variety of protocols have been used in pigs. The use of tiletamine/zolazepam alone is not recommended due to insufficient CNS depression and analgesia, rough recovery, paddling, vocalization, and hypersalivation. Can be used in combination with ketamine and xylazine. Combine ketamine 250 mg (2.5 mL of 100 mg/mL) with xylazine 250 mg (2.5 mL of 100 mg/mL) to a vial of tiletamine/zolazepam. Use 1 mL per 35 to 75 kg IM, depending on sedation required. Use one-half of these doses when administering to pot-bellied pigs.[33]

b) Short-term anesthesia in domestic pigs: Tiletamine/zolazepam 8 mg/kg IM with methadone 0.2 mg/kg IM in neck muscles provided adequate anesthesia for minor procedures lasting ≈30 minutes but was associated with poor recovery.[34]

c) A study compared induction and anesthesia of tiletamine/zolazepam/ketamine/xylazine (4.4/2.2/2.2 mg/kg), tiletamine/zolazepam/xylazine (4.4/2.2 mg/kg), tiletamine/zolazepam/xylazine (4.4/4.4 mg/kg), and ketamine/xylazine (2.2/2.2 mg/kg). All combinations were administered IM. Both tiletamine/zolazepam/xylazine combinations were deemed to be superior.[35]

d) In miniature pigs, tiletamine/zolazepam 3.5 mg/kg IM has been combined with xylazine 1.32 mg/kg IM and tramadol 1.8 mg/kg IM to increase depth and duration of anesthesia.[36] This combination can be antagonized with atipamezole, flumazenil, and naloxone.[37]

FERRETS:

Sedative/analgesic (extra-label): Tiletamine/zolazepam 22 mg/kg IM.[38] Tiletamine/zolazepam 1.5 mg/kg in combination with xylazine 1.5 mg/kg IM; may reverse xylazine with yohimbine 0.05 mg/kg IM. Tiletamine/zolazepam 1.5 mg/kg with xylazine 1.5 mg/kg and butorphanol 0.2 mg/kg IM; may reverse xylazine with yohimbine 0.05 mg/kg IM.[39]

SMALL MAMMALS:

Chemical restraint in small rodents (extra-label): 6 – 10 mg/kg IM is adequate prior to inhalation anesthesia. Advantages over ketamine include better muscle relaxation, small volume of injection, rapid induction time, and a wide margin of safety. Disadvantages of this drug combination are increased respiratory secretions, variability in recovery times, and short shelf-life after reconstitution.[40] Not recommended for New Zealand white rabbits.[41]

REPTILES:

NOTE: Significant interspecies and interpatient differences in effectiveness can be seen.

a) **Large snakes**: 3 mg/kg IM to facilitate handling and anesthesia. Administer 30 to 45 minutes prior to handling. Sedation may persist for up to 48 hours. May also be used in crocodilians at 4 – 8 mg/kg[42]

b) 3 – 10 mg/kg IM. Lizards and snakes can generally be treated with lower end of dosage range and chelonians may require high end. If sedation is inadequate, may give incrementally up to the maximum dose. Monitor closely for apnea and ventilate if required[43]

c) At lower doses of 4 – 10 mg/kg, sedation may be sufficient for some procedures (eg, venipuncture, gastric lavage, intubation for inhalation anesthesia). At higher doses of 15 – 40 mg/kg, recovery may be greatly prolonged. Starting dose: 7 – 15 mg/kg[44]

d) Best used for sedation and tranquilization or to facilitate intubation, especially in large boas, crocodilians, and venomous species. Author starts with a dose of 5 mg/kg IM and repeats if needed. Higher doses of 6 mg/kg are associated with very long recovery times, especially in chelonians (72 hours).[45]

e) **Anesthetic induction of chelonians** (extra-label): Aquatic or box turtles, 5 mg/kg IM, SC; tortoises, 10 – 20 mg/kg IM in brachial muscle; intubation is usually possible 20 minutes after administration.[46]

Monitoring
- Depth of anesthesia and degree of analgesia
- Ventilation (eg, $ETCO_2$), pulse oximetry (PaO_2), cardiovascular status (eg, heart rate and rhythm, blood pressure)
- Monitor eyes to prevent drying out or injury
- Body temperature

Client Information
Tiletamine/zolazepam should only be administered by authorized veterinary professionals that are familiar with its use. Some manufacturers state that women who are pregnant, or are suspected to be pregnant, should not handle the product.

Chemistry/Synonyms
Tiletamine is an injectable anesthetic agent chemically related to ketamine. Zolazepam is a diazepinone minor tranquilizer. The pH of the injectable product (after reconstitution) is 2.2 to 2.8.

Tiletamine HCl may also be known as CI-634, CL-399, or CN-54521-2; zolazepam HCl may also be known as CI-716.

Tiletamine/zolazepam may also be known as *Telazol®*, *Tilzolan®*, *Tzed®*, or *Zoletil®*.

Storage/Stability
Tiletamine/zolazepam is a schedule III (C-III) controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Store unreconstituted vials at controlled room temperature (20°C-25°C [68°F-77°F]). After reconstitution with sterile water for injection, solutions may be stored for 7 days at room temperature and 56 days if refrigerated. Use only clear solutions; color may vary from colorless to light amber.

Compatibility/Compounding Considerations
Reconstitute with 5 mL sterile water.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Tiletamine/zolazepam has been designated as a Class 2 substance by the Association of Racing Commissioners International (ARCI). Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix***.

Tiletamine HCl (equivalent to 250 mg free base) and Zolazepam HCl (equivalent to 250 mg free base) as lyophilized powder/vial in 5 mL vials. When 5 mL of sterile diluent (sterile water) is added, a concentration of 50 mg/mL of each drug (100 mg/mL combined) is produced; *Telazol®*, generic; (Rx, C-III). FDA-approved for use in cats and dogs. NADA# 106-111

No guidelines for milk or meat withdrawal intervals are available.[47]

Tilmicosin

(til-mi-***coe***-sin) *Micotil®, Pulmotil®*

Macrolide Antibiotic

Prescriber Highlights
- ► Injectable macrolide antibiotic used in cattle, sheep, and sometimes rabbits; oral concentrate used in swine
- ► **Fatal to cattle and sheep when the injection is administered IV**; give by the SC route only. **May be fatal if injected** by any route in swine, horses, or goats. Severe reactions reported in camelids
- ► **Accidental injection can be fatal in humans.** Do not use in automatically powered syringes. In case of human injection, contact a physician immediately. Use precautions when handling any tilmicosin product.
- ► Adverse effects include SC injection site edema, lameness, and decreased food and water intake; accidental IM injection may cause a local tissue reaction, resulting in trim loss.

Uses/Indications
Tilmicosin injection is indicated for the treatment of bovine respiratory disease (BRD) associated with *Mannheimia haemolytica*, *Pasteurella multocida,* and *Histophilus somni,* for the treatment of ovine respiratory disease associated with *M haemolytica*, and for the treatment of swine respiratory disease (SRD) associated with *Mannheimia haemolytica*. It is also indicated for the control of respiratory disease in cattle at high risk for developing BRD associated with *Mannheimia haemolytica*. For oral use (in drinking water), tilmicosin is indicated for the control of swine respiratory disease associated with *Pasteurella multocida* and *Haemophilus parasuis* in groups of swine in buildings where a respiratory disease outbreak is diagnosed. It is also used for the control of SRD associated with *Mycoplasma hyopneumoniae* in the presence of porcine reproductive and respiratory syndrome virus (PRRSV) in groups of swine in buildings where a respiratory disease outbreak is diagnosed.

In other countries, tilmicosin injection is indicated for use in cattle for the treatment of interdigital necrobacillosis and in sheep for the treatment of foot rot or acute ovine mastitis,[1] and the oral concentrate is added to drinking water for the treatment and metaphylaxis of respiratory disease[2] in chickens and turkeys.

The World Health Organization (WHO) has designated tilmicosin as a Critically Important, Highest Priority antimicrobial for human medicine.[3] The Office International des Epizooties (OIE) Antimicrobial Classification has designated tilmicosin as a Veterinary Critically Important antimicrobial.[4]

Pharmacology/Actions
Like other macrolides, tilmicosin has activity primarily against gram-positive bacteria, although some gram-negative bacteria are affected, and the drug reportedly has some activity against mycoplasma. Preliminary studies have shown that 95% of studied isolates of *Pasteurella multocida* are sensitive. Bacterial isolates susceptible to tilmicosin at concentrations of less than or equal to 8 µg/mL are reported as susceptible to tilmicosin. The MIC_{90} value reported for *M. haemolytica* and *P. multocida* in cattle with BRD is 32 µg/mL. Oral tilmicosin does not have activity against *Cryptosporidium* spp in goats.[5]

Pharmacokinetics
Tilmicosin apparently concentrates in lung tissue. A single SC injection of *Micotil®* 10 mg/kg of body weight dose in cattle resulted in peak tilmicosin concentrations within 1 hour and detectable concentrations (0.07 µg/mL) in serum beyond 3 days. At 3 days postinjection, the lung:serum ratio is ≈60:1. MIC_{95} concentrations

(3.12 µg/mL) for *P. haemolytica* persist for a minimum of 3 days after a single injection.

Contraindications/Precautions/Warnings

Injections in humans can be fatal; exercise extreme caution when handling injectable products. Do not use in automatically powered syringes. Never carry a syringe of tilmicosin with a needle attached.[1] Keep needles capped until ready to use; only attach the needle to fill the syringe or administer injection; keep syringe and needle separate at all other times. Ensure animals are properly restrained before attempting to administer. Do not work alone when using tilmicosin injectable.[1] In case of accidental injection, seek medical attention immediately. Emergency treatment includes applying ice to the injection site and contacting a physician immediately. Elanco emergency medical telephone numbers are 1-800-722-0987 or 1-800-428-4441.

Avoid contact with eyes.

Do not inject by any route in swine, goats, nonhuman primates, or horses as fatalities may result. Do not administer IV to sheep or cattle, as deaths of cattle have been observed with a single IV dose of 5 mg/kg. There have been anecdotal reports of severe reactions in some camelids.

When using oral concentrate in drinking water, do not use rusty containers for medicated water as product integrity may be affected.[2] Oral concentrate must be diluted before administration. Do not allow horses or other equines access to water containing tilmicosin.

Adverse Effects

In cattle: injection site swelling and inflammation, lameness, collapse, anaphylaxis/anaphylactoid reactions, decreased food and water consumption, and death.

In sheep: dyspnea and death. Injection lesions are described as being generally more severe and occurred at higher frequency rates in the animals treated with higher doses of tilmicosin. If administered IM, a local tissue reaction may occur, resulting in the trim loss. Edema may be noted at the site of SC injection.

In swine: decreased water consumption has been observed in healthy pigs receiving tilmicosin via drinking water.

In rabbits receiving SC tilmicosin, local swelling and necrosis at the injection site, as well as weakness, pallor, tachypnea, and sudden death have been observed.[6]

Reproductive/Nursing Safety

Safe use in pregnant or lactating animals or animals to be used for breeding purposes has not been demonstrated.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The cardiovascular system is apparently the target of toxicity in animals. The primary cardiac effects are increased heart rate (tachycardia) and decreased contractility (negative inotropy). In cattle, doses up to 50 mg/kg IM did not cause death, but 150 mg/kg SC did cause fatalities, as well as 5 mg/kg IV. Doses as low as 10 mg/kg in swine caused increased respiration, emesis, and seizures; 20 mg/kg IM caused deaths in most animals tested. In monkeys, 10 mg/kg administered once caused no signs of toxicity, but 20 mg/kg caused vomiting; 30 mg/kg caused death.

In cases of human injection, contact a physician immediately. The manufacturer has emergency telephone numbers to assist in dealing with exposure: 1-800-722-0987 or 1-800-428-4441.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In swine, **epinephrine** increased the mortality associated with tilmicosin. No other specific information was noted; refer to the ***Erythromycin*** monograph for possible interactions.

Dosages

CATTLE:

Treatment of BRD associated with *Mannheimia haemolytica, Pasteurella multocida,* and *Histophilus somni* or control of respiratory disease in cattle at high risk for developing BRD associated with *Mannheimia haemolytica* (FDA-approved): 10 – 20 mg/kg SC as a single dose. Injection under the skin in the neck is suggested. If not accessible, inject under the skin behind the shoulders and over the ribs. Do not inject more than 10 mL per injection site. If no improvement is noted within 48 hours, the diagnosis should be re-evaluated.[7]

SHEEP:

Treatment of ovine respiratory disease associated with *Mannheimia haemolytica* (FDA-approved): In sheep greater than 15 kg (33 lb), 10 mg/kg SC as a single dose. Injection under the skin in the neck is suggested. If not accessible, inject under the skin behind the shoulders and over the ribs. Do not inject more than 10 mL per injection site. If no improvement is noted within 48 hours, the diagnosis should be re-evaluated.[7]

SWINE:

Control of SRD associated with *Pasteruella multocida* and *Haemophilus parasuis* in groups of swine in buildings where a respiratory disease outbreak is diagnosed (FDA-approved): Using oral concentrate, administer it in drinking water at a concentration of 200 mg tilmicosin per liter of drinking water for 5 consecutive days. Replace the water every 24 hours. One 960 mL bottle is sufficient to medicate 1200 L (320 gallons) of drinking water for pigs. When using water medicating pump with a 1:128 inclusion rate, add 1 bottle (960 mL) of *Pulmotil AC*® per 2.5 gallons of stock solution.[2]

SMALL MAMMALS:

Rabbits:

Pasteurellosis[6] (extra-label):

a) 25 mg/kg SC once[8]; repeat in 3 days if necessary

b) 5 mg/kg SC on day 0; if no reaction, give 10 mg/kg SC on days 7 and 14

Monitoring

- Efficacy
- Signs of water refusal or dehydration (medicated drinking water[2])
- Cardiovascular status following SC injection

Client Information

- If clients are administering the drug, warn them about the potential toxicity to humans, swine, and horses in case of accidental injection.
- Carefully instruct in proper injection techniques.
- Avoid contact with eyes.

Chemistry/Synonyms

Tilmicosin phosphate, a semisynthetic macrolide antibiotic, is commercially available in a 300 mg/mL (of tilmicosin base) injection with 25% propylene glycol.

Tilmicosin may also be known as EL-870, LY-177370, *Micotil*®, or *Pulmotil*®.

Storage/Stability

Store the injection at or below room temperature 30°C (86°F). Avoid exposure to direct sunlight. The UK label states to discard 28 days after the first puncture.

Store the oral liquid at or below 30°C (86°F). Protect from direct sunlight. The UK label states to use within 3 months of opening. Discard medicated water after 24 hours. Discard medicated milk replacer after 6 hours. Do not freeze; protect from frost.[2]

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tilmicosin for Subcutaneous Injection: 300 mg/mL in 250 mL multidose vials; *Micotil® 300 Injection*; (Rx). FDA-approved (NADA# 140-929) for use in cattle and sheep. Not FDA-approved for use in female dairy cattle 20 months or older. Do not use in lactating ewes if milk is to be used for human consumption. Do not use in veal calves. Slaughter withdrawal (at labeled doses) is 42 days.

Tilmicosin Phosphate 250 mg/mL Aqueous Concentrate for oral use in drinking water in 960 mL bottles; *Pulmotil® AC, Tilmovet® AC*; (Rx). FDA-approved (NADA# 141-361) for use in swine. Slaughter withdrawal is 7 days.

Tilmicosin medicated article is available for incorporation into the feed of swine, beef and nonlactating dairy cattle.

HUMAN-LABELED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Tiludronate

Tiludronic Acid

(til-yoo-***droe***-nate) *Tildren®*

Bisphosphonate; Bone Resorption Inhibitor

Prescriber Highlights

- ► Used as an IV treatment for navicular syndrome in horses
- ► Must be given slowly and evenly as an IV infusion over 90 minutes
- ► Contraindications include horses that are hypersensitive to tiludronate or mannitol and horses with a history of renal impairment.
- ► Use with caution in horses with conditions that cause mineral or electrolyte imbalance (eg, HYPP, hypocalcemia) and conditions that may be exacerbated by hypocalcemia (eg, cardiac disease).
- ► Adverse effects include signs of colic, muscle tremor (hypocalcemia), fatigue/lassitude, sweating, injection site effects, salivation, and tail hypertonia.

Uses/Indications

Tiludronate (tiludronic acid) is indicated for the control of clinical signs associated with navicular syndrome in horses.[1] It may be beneficial in managing lameness isolated to the navicular bone and distal tarsal osteoarthritis by decreasing bone resorption and inflammation.[2,3] Treatment earlier in the course of the disease apparently results in greater efficacy.

Tiludronate appeared to inhibit the radiographic progression of osteoarthritis after traumatic injury of the fetlock joint but was associated with increased markers of cartilage damage.[4]

Pharmacology/Actions

Tiludronate, like other bisphosphonates, inhibits osteoclastic bone resorption by inhibiting osteoclast function after binding to bone hydroxyapatite, thereby helping to regulate bone remodeling.

Pharmacokinetics

After IV injection in horses, the drug is rapidly distributed to the bone. Binding is greater to cancellous bone than cortical bone. Plasma protein binding is reported to be ≈85%, and the elimination half-life is ≈4 hours. Repeated daily doses do not result in accumulation in plasma. Tiludronate undergoes minimal metabolism. The unbound drug is eliminated unchanged in the urine. Approximately 25% to 50% of a single IV dose is eliminated in the urine over 96 hours. Quantifiable concentrations of tiludronate in the bone can be detected up to 1 year postdose,[1] and in the plasma for up to 3 years.[5]

Contraindications/Precautions/Warnings

Tiludronate is contraindicated in horses with known hypersensitivity to tiludronate disodium or to mannitol. It should not be used in horses with impaired renal function or a history of renal disease, as conditions causing renal impairment may increase plasma bisphosphonate concentrations, resulting in an increased risk for adverse reactions. Horses should be well hydrated prior to administration because of the potential nephrotoxic effects.[1]

Safe use has not been evaluated in horses less than 4 years of age. Bisphosphonates affect bone turnover and therefore may affect bone growth.[1] Increased bone fragility has been observed after high doses or a long duration of use.

Tiludronate can affect plasma concentrations of certain minerals and electrolytes, including calcium, magnesium, and potassium, immediately after treatment and can last up to several hours. Use caution when administering tiludronate to horses with conditions affecting mineral or electrolyte homeostasis (eg, hyperkalemic periodic paralysis (HYPP), hypocalcemia) and conditions which may be exacerbated by hypocalcemia (eg, cardiac disease).

Adverse Effects

Adverse effects reported in horses are most commonly seen during the infusion period or within 4 hours of beginning the infusion. Adverse effects include signs of abdominal pain or colic (eg, pawing, evidence of pawing, getting up and down, pacing, restlessness, rolling, trying to roll, looking at or biting at the side, stretching out/straining, kicking at belly/walls, and shifting weight), muscle tremors/fasciculation, fatigue/lassitude, and sweating. Colic signs occur in ≈30% to 45% of horses and generally resolve without treatment.[1] If these signs persist, conventional colic treatments (NOT including NSAIDs) are recommended. Muscle tremors may be treated with IV calcium if required. Horses with HYPP appear to be at increased risk for adverse effects.[1]

Adverse reactions occurring between 4 and 24 hours posttreatment include increased frequency of urination with or without increased drinking, reduced appetite, sore or stiff neck, fever, and uncomplicated colic.

Up to 9% of patients develop local reactions at the injection site (eg, phlebitis), particularly after the fourth injection. Other adverse effects reported include polydipsia/polyuria, decreased feed intake, recumbency, salivation, and tail hypertonia.

Tiludronate has caused acute renal failure.[6] Assess renal function and hydration status prior to administration.

The drug may be safely administered to horses within 24 to 36 hours after bone scintigraphy.[7]

Reproductive/Nursing Safety

Bisphosphonates should not be used in pregnant or lactating mares or mares intended for breeding.[1] Bisphosphonates have been shown to cause fetal developmental abnormalities in laboratory animals. The uptake of bisphosphonates into fetal bone may be greater than into maternal bone, creating a possible risk for skeletal or other abnormalities in the fetus.

Many drugs, including bisphosphonates, may be excreted in milk and may be absorbed by nursing animals.

Studies performed in male and female rats at tiludronate doses as high as 75 mg/kg/day demonstrated no effects on fertility. Studies in pregnant rabbits given 2 to 5 times the human-recommended dosages showed no skeletal abnormalities. Pregnant mice given 7 times the human-recommended dosages showed some adverse effects (eg, decreased litter size, malformed paws in 6 fetuses from 1 litter). Rat studies have shown decreased litter sizes[8] but no teratogenic effects.

Overdose/Acute Toxicity

Limited information is available. The manufacturer reports that dosing horses 3 times at monthly intervals caused an increased frequency of adverse effects, particularly signs of colic and muscle tremor. A dose-dependent increase in the frequency and severity of hypocalcemia and hyperphosphatemia was noted.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tiludronate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin**): Concurrent use may increase the risk for nephrotoxicity and hypocalcemia.
- **Amphotericin B**: Concurrent use with nephrotoxic drugs may increase the risk for nephrotoxicity.
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **flunixin**): The product label warns that NSAIDs should not be used concurrently with tiludronate. Concurrent use may increase the risk for renal toxicity and acute renal failure. Acute renal failure has been reported in horses concurrently administered NSAIDs and tiludronate within a 48-hour period. Additionally, horses concurrently administered both drugs in field studies demonstrated statistically significant increases in serum BUN and creatinine concentrations but were not always associated with clinical signs of renal dysfunction. Appropriate washout periods should be observed, and BUN and creatinine should be monitored. If treatment for discomfort is required after tiludronate administration, a non-NSAID treatment should be used.
- **Tetracyclines** (eg, **oxytetracycline**): May increase the risk for hypocalcemia

Laboratory Considerations

No specific concerns were noted.

Dosages

HORSES:

Control of clinical signs associated with navicular syndrome (label dose; FDA-approved): A single dose of 1 mg/kg as an IV infusion in 1000 mL of 0.9% sodium chloride. Administer slowly and evenly over 90 minutes (to minimize adverse reactions) through a suitable IV catheter inserted into a jugular vein and connected to the infusion bag using sterile infusion tubing.[1] Maximum effect may not occur until 2 months posttreatment. Infusion of the labeled dose diluted in 5000 mL of 0.9% sodium chloride solution appears to be a common practice.

Control of clinical signs associated with navicular syndrome (extra-label): Ten bolus doses of 0.1 mg/kg IV every 24 hours for 10 consecutive days.[9] Used in horses particularly sensitive to adverse effects of tiludronate

Monitoring

- Clinical efficacy
- Serum calcium
- BUN and serum creatinine prior to administration of NSAIDs following dosing
- Adverse effects (particularly within the first 4 hours after dosing)

Client Information

- A veterinary professional should administer this medication.
- Observe the animal for up to 4 hours postadministration for signs of hypocalcemia (eg, muscle tremors) or colic. Monitor food and water intake, urinary frequency, and body temperature for a few days after administration.
- Allow the horse to lie down, as this is an expected behavior after the infusion is complete.
- Consult with your veterinarian prior to giving anti-inflammatory medications (NSAIDs) following tiludronate administration.

Chemistry/Synonyms

Tiludronate disodium is a non-nitrogen-containing bisphosphonate that occurs as a white powder with a molecular weight of 380.6. Commercially available products contain the disodium salt of tiludronic acid. 120 mg of tiludronate disodium is equivalent to 100 mg of tiludronic acid.

Tiludronate disodium or tiludronic acid may also be known as ME-3737, SR-41319, acidum tiludronicum, *Tildren*®, or *Skelid*®.

Storage/Stability

Store unreconstituted powder at controlled room temperature 20°C to 25°C (68°F-77°F). After preparation, either administer the infusion within 2 hours of preparation or store it for up to 24 hours under refrigeration at 2°C to 8°C (36°F-46°F) and protect it from light.

Compatibility/Compounding Considerations

Do **not** reconstitute or mix this product with calcium-containing solutions or other solutions containing divalent cations, such as lactated Ringer's solution, as it may form complexes with these ions.

Preparation of the reconstituted solution (20 mg/mL): Use strict aseptic technique. Remove 25 mL of solution from a 1-liter bag of sterile 0.9% sodium chloride and add to a vial of *Tildren*®. Shake gently until the powder is completely dissolved. This reconstituted solution contains 20 mg of tiludronate disodium per mL. After reconstitution, further dilution is required before administration.

Preparation of the solution for infusion: Using strict aseptic technique, withdraw the appropriate volume of the reconstituted solution based on the horse's body weight. Inject that volume back into the 1-liter bag of sterile 0.9% sodium chloride. Horses greater than 550 kg (1210 lb) will require a second vial of reconstituted solution. Invert the infusion bag several times to mix the solution before infusion. Label the infusion bag to ensure proper use.

After preparation, the infusion should be administered either within 2 hours of preparation, or it can be stored for up to 24 hours under refrigeration at 2°C to 8°C (36°F-46°F) and protected from light.

Administer for infusion through a suitable IV catheter inserted into a jugular vein and connected to the infusion bag using sterile infusion tubing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tiludronic Acid: 500 mg (as tiludronate disodium) lyophilized powder for reconstitution per vial; *Tildren*®; (Rx). FDA-approved for horses. NADA #141-420

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Tinidazole

(tye-***ni***-dah-zole) *Tindamax®*

Nitroimidazole Antiprotozoal/Antibiotic

Prescriber Highlights

- ► Drug similar to metronidazole, but does not appear to have significant advantages over metronidazole or ronidazole
- ► Used primarily as an alternative treatment for giardiasis. Potentially useful for treating anaerobic infections (especially in the mouth), trichomoniasis, amebiasis, and balantidiasis.
- ► Little experience in veterinary medicine. Most likely adverse effects are GI-related; like other nitroimidazole agents, neurotoxicity is possible.

Uses/Indications

Little information is presently available on the use of tinidazole in veterinary species. Because of its antiprotozoal effects, it has been used as an alternative for treating giardiasis in small animals. Tinidazole could have efficacy against amebiasis, trichomoniasis, or balantidiasis, but documentation of efficacy is not available. Tinidazole potentially could be useful for treating anaerobic infections in small animals, particularly those associated with dental infections.[1] Tinidazole has a longer duration of action than metronidazole in dogs and cats.

In a small study done in cats experimentally infected with *Tritrichomonas foetus*, tinidazole 30 mg/kg PO once daily for 14 days decreased fecal shedding of *T foetus* but failed to eradicate the infection from 2 of 4 cats.[2] However, results from a pilot study indicated that tinidazole 30 mg/kg, formulated in a gastro-resistant capsule coated with guar gum, PO once daily for 14 days resolved *T foetus* infections and improved the clinical condition in 5 FIV-positive cats and was also effective against concomitant *Giardia duodenalis* infection in the 4 affected cats.[3]

In humans, oral tinidazole is FDA-approved for treating extraintestinal and intestinal amebiasis (ie, *Entamoeba histolytica*), giardiasis (ie, *Giardia duodenalis* and *G lamblia*), and trichomoniasis (ie, *Trichomonas vaginalis*).

The World Health Organization (WHO) has designated tinidazole as an Important antimicrobial for human medicine.[4]

Pharmacology/Actions

Tinidazole is a 5-nitroimidazole similar to metronidazole. It is bactericidal against susceptible bacteria. Its exact mechanism of action is not completely understood, but it is taken up by anaerobic organisms where it is reduced to an unidentified polar compound. It is believed that this compound is responsible for the drug's antimicrobial activity by disrupting DNA and nucleic acid synthesis in the bacteria.

Tinidazole has activity against many obligate anaerobes and *Helicobacter pylori*. It has excellent activity against *Porphyromonas* spp found in canine gingiva.[1]

Tinidazole is also trichomonacidal and amebicidal.[5] Its mechanism of action for its antiprotozoal activity is not well understood. It has therapeutic activity against *Entamoeba histolytica*, *Trichomonas* spp, and *Giardia* spp.

Pharmacokinetics

In dogs and cats,[6] tinidazole is practically completely absorbed after oral administration. Apparent volumes of distribution are 0.66 L/kg in dogs and 0.54 L/kg in cats. Dogs clear the drug about twice as fast as cats; elimination half-lives are ≈4.4 hours in dogs and 8.4 hours in cats.

In horses,[7] tinidazole is practically completely absorbed after oral administration. Apparent volume of distribution is 0.66 L/kg and elimination half-life is ≈5.2 hours.

Contraindications/Precautions/Warnings

Tinidazole is contraindicated in patients documented to be hypersensitive to it or other 5-nitroimidazoles (eg, metronidazole). In humans, tinidazole is contraindicated in the first trimester of pregnancy.

Tinidazole is metabolized by the liver; use with caution in patients with hepatic dysfunction. Tinidazole should be used with caution in patients with blood dyscrasias.

As other 5-nitroimidazoles (eg, metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats and seizures have been reported rarely with tinidazole use in humans, use with caution in animals susceptible to seizures.

The human labeling for tinidazole carries a black box warning stating: *Carcinogenicity has been seen in mice and rats treated chronically with another agent in the nitroimidazole class (eg, metronidazole). Although such data has not been reported for tinidazole, avoid unnecessary use of tinidazole. Reserve its use for the conditions for which it is indicated.*

Adverse Effects

The adverse effect profiles for dogs, cats, or horses are not well described since clinical use of this medication has been limited. GI effects including vomiting, inappetence, and diarrhea are most likely. Giving the medication with food may help alleviate these effects. Other 5-nitroimidazoles (eg, metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats.

Although metronidazole has been shown to significantly decrease food intake in chinchillas, equivalent doses of tinidazole did not affect food intake.[8]

In humans, tinidazole reportedly has fewer side effects than metronidazole.[9] GI effects (eg, dysgeusia, nausea, decreased appetite) are the most commonly reported adverse effects. Rare adverse effects in humans include seizures, transient myelosuppression, and hypersensitivity reactions.[5]

Reproductive/Nursing Safety

In studies performed on male rats, tinidazole decreased fertility and caused testicular histopathology.

Tinidazole crosses the placenta. While studies in mice and rats have not demonstrated significant fetal effects, because of its mutagenic potential, it is stated that it should **not** be used in women during the first trimester of pregnancy. If considering use of this product in a pregnant animal, weigh the potential benefits of treatment versus the risks.

Tinidazole is distributed into maternal milk at levels approximating those found in serum. It is suggested that milk replacer be used if tinidazole is necessary for treating a nursing dam.

Overdose/Acute Toxicity

Limited information is available. In studies done in rats and mice, the oral LD_{50} was greater than 3.6 g/kg for mice and greater than 2 g/kg for rats. Treatment of acute overdoses of tinidazole is symptomatic and supportive. Gastric lavage or induction of emesis may be helpful. Hemodialysis can remove ≈43% of the amount in the body (human) in a 6-hour session.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are

theoretical in humans or animals receiving metronidazole (a related compound) and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Busulfan**: Tinidazole may increase the serum concentration of busulfan.
- **Cholestyramine**: May decrease metronidazole absorption; interaction may apply to tinidazole
- **Cimetidine**: May decrease the metabolism of tinidazole and increase the likelihood of dose-related side effects occurring
- **Cisapride**: Tinidazole may increase the serum concentration of cisapride; contraindicated in humans.
- **Cyclosporine, Tacrolimus** (systemic): Tinidazole may increase the serum concentration of cyclosporine or tacrolimus.
- **Ethanol**: May induce a disulfiram-like (nausea, vomiting, cramps) reaction
- **Fluorouracil** (systemic): Tinidazole may increase the serum concentration of fluorouracil and increase the risk of toxicity.
- **Ketoconazole**: May decrease the metabolism of tinidazole and increase the likelihood of dose-related side effects occurring
- **Oxytetracycline**: Reportedly, may antagonize the therapeutic effects of metronidazole; interaction may apply to tinidazole
- **Phenobarbital**: May increase the metabolism of tinidazole, thereby decreasing blood concentration
- **Rifampin**: May increase the metabolism of tinidazole, thereby decreasing blood concentration
- **Warfarin**: Metronidazole (and potentially tinidazole) may prolong the prothrombin time (PT) in patients taking warfarin or other coumarin anticoagulants. Avoid concurrent use if possible; otherwise, intensify monitoring.

Laboratory Considerations

- **AST, ALT, LDH, Triglycerides, Hexokinase glucose**: Tinidazole, like metronidazole, may interfere with enzymatic coupling of the assay to oxidation-reduction of nicotinamide adenine. Falsely low values, including zero, may result.

Dosages

DOGS:

Giardiasis (extra-label): 44 mg/kg PO every 24 hours for 6 days. Potentially useful for treating trichomoniasis, amebiasis, and balantidiasis, but efficacy data are lacking for animals.[10] Another source lists the same dosage but treats for 3 days.[11]

CATS:

Giardiasis (extra-label): 30 mg/kg PO once daily for 7 to 10 days.[12] Another source lists the same dosage but treats for 3 days.[11]

Tritrichomonas foetus (extra-label): 30 mg/kg PO once daily for 14 days decreased detection of *T foetus* in 50% of experimentally infected cats

Monitoring

- Clinical efficacy in treating the infection

Client Information

- Give this medication with food.
- Animals should not have access to alcohol when receiving this medication.
- If gastrointestinal signs (eg, vomiting, lack of appetite, diarrhea) are severe or persist, contact your veterinarian.
- Contact your veterinarian immediately if animal shows signs of behavior changes, eyes moving back and forth (nystagmus), convulsions, or if it has difficulty walking, climbing stairs; these could be signs that drug toxicity is occurring.

Chemistry/Synonyms

Tinidazole occurs as an almost white or pale-yellow crystalline powder. It is practically insoluble in water, soluble in acetone, and sparingly soluble in methyl alcohol.

Tinidazole may also be known as CP-12574 or tinidazolum or tinidatsoli. International trade names include: *Estovyn-T®*, *Fasigyn®*, *Tindamax®*, *Tiniba®*, *Tiniameb®*, or *Tinidazol®*.

Storage/Stability

Store tinidazole tablets at controlled room temperature (20°C-25°C [68°F-77°F]) protected from light.

Compatibility/Compounding Considerations

The manufacturer label states an oral suspension can be made by pulverizing four 500 mg oral tablets with a mortar and pestle. Add ≈10 mL of cherry syrup to the powder and mix until smooth. Transfer the suspension to a graduated amber container. Use several small rinses of cherry syrup to transfer any remaining drug in the mortar to the final suspension for a final volume of 30 mL (67 mg/mL). This suspension is stable for 7 days at room temperature. When this suspension is used, it should be shaken well before each administration.[13]

Tinidazole reportedly is very bitter tasting. If using compounded products, consider using capsules or having a flavored suspension prepared.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

As tinidazole is a nitroimidazole, its use is prohibited in animals to be used for food.

HUMAN-LABELED PRODUCTS:

Tinidazole Tablets (scored): 250 mg and 500 mg; *Tindamax®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Tiopronin

(tye-oh-***proe***-nin) *Thiola®*

Antiurolithic (Cystine)

Prescriber Highlights

- ► Used in combination with dietary therapy, high fluid intake, and urinary alkalinization for prevention and dissolution of cystine urolithiasis in dogs
- ► Avoid use in cats.
- ► Use with caution in animals with agranulocytosis, aplastic anemia, thrombocytopenia or other significant hematologic abnormality, impaired renal or hepatic function, or sensitivity to either tiopronin or penicillamine.
- ► Adverse effects include Coombs-positive regenerative spherocyte anemia, aggressive behavior, proteinuria, thrombocytopenia, elevations in liver enzymes, dermatologic effects, and myopathy.
- ► Cost and availability may be problematic.

Uses/Indications

Tiopronin may be added to the treatment regimen for the prevention and dissolution of cystine urolithiasis in dogs when dietary therapy (ie, low-protein, low-sodium diet), high fluid intake, and urine alkalinization are not completely effective.[1–5]

Pharmacology/Actions

Tiopronin is a chelator that is considered an antiurolithic agent. It undergoes thiol-disulfide exchange with cystine (cysteine-cysteine

disulfide) to form tiopronin-cystine disulfide. This complex is more water-soluble and readily excreted thereby preventing cystine calculi from forming. Its effects on cystine reduction are dose-related and typically begin within the first day of treatment. Given the relatively rapid elimination of drug, twice daily dosing is recommended.

Pharmacokinetics

Tiopronin has a rapid onset of action, and in humans, up to 48% of a dose is found in the urine within 4 hours of dosing.[6] Tiopronin has a relatively short duration of action, and its effect in humans disappears in ≈10 hours. Elimination is primarily via renal routes.

Contraindications/Precautions/Warnings

Tiopronin is contraindicated in patients that are hypersensitive to it or in those patients with obstructive urolithiasis. Tiopronin's risks vs benefits should be considered before using in patients with agranulocytosis, aplastic anemia, thrombocytopenia, or other significant hematologic abnormalities. Use with caution in patients with impaired renal or hepatic function or sensitivity to penicillamine. In humans, it is recommended to start tiopronin at a lower dose in patients with history of severe toxicity to penicillamine.

Avoid use of tiopronin in cats as they reportedly do not tolerate the drug well and dissolution of cystine uroliths has not been successful.[7]

Adverse Effects

There is limited information available on the adverse effect profile of tiopronin in dogs. In a retrospective study evaluating tiopronin treatment for cystinuria, ≈13% of treated dogs experienced adverse events including proteinuria, thrombocytopenia, anemia, increased liver enzymes and bile acids, lethargy, dermatologic effects (small pustules of the skin, dry crusty nose), aggression, sulfur odor of the urine, or myopathy (noted as staggering and difficulty chewing).[3] Adverse effects manifested between 1 month and 36 months (mean of 7.8 months) of therapy and resolved with discontinuation of therapy. Tiopronin has been associated with Coombs-positive regenerative spherocyte anemia in dogs. If this effect occurs, the drug should be discontinued and appropriate treatment started as needed (eg, corticosteroids, blood component therapy).

If adverse reactions occur, stop treatment for 4 weeks. Check blood and urine analysis every 1 to 2 weeks until remission of signs. When the adverse reactions disappear, start tiopronin again, gradually increasing the dose from 10 – 15 mg/kg every 12 hours. If the adverse reactions reappear despite a lowered dose, tiopronin treatment has to be abandoned.[3]

In cats, GI signs, liver disease, and anemia have been reported.[7]

In humans, common adverse effects include dermatologic effects (ecchymosis, itching, rashes, mouth ulcers, jaundice) and GI distress. Less frequently reported adverse effects include allergic reactions (specifically adenopathy), arthralgias, dyspnea, fever, hematologic abnormalities, edema, and nephrotic syndrome.[6]

Reproductive/Nursing Safety

There is limited information on the reproductive safety of tiopronin. No adverse developmental outcomes were noted in rats given up to 4 times the recommended human dose.[8] Skeletal defects, cleft palates and increased resorptions were noted when rats were given 10 times the human dose of penicillamine and, therefore, may also be of concern with tiopronin. In humans, tiopronin is contraindicated during pregnancy except in severe cases of cystinuria in which the potential benefits outweigh possible hazards.

Because tiopronin may be excreted in milk, it is not recommended for use in nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

There is little information available. It is suggested to contact an animal poison control center for further information in the event of an overdose situation.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Potentially, use of tiopronin with **other drugs causing nephrotoxicity, hepatotoxicity, or myelosuppression** could cause additive toxic effects. Clinical significance is not clear.

Dosages

DOGS:

Prevention and dissolution of cystine urinary calculi (extra-label):

a) **Prevention of uroliths**: 15 mg/kg PO every 12 hours. Increase water intake and urine diuresis. Alkalinize urine (pH 6.5 to 7.0) using potassium citrate. In cases with low cystine excretion and low urolith recurrence rate, tiopronin dose may be individually decreased (less than 30 mg/kg) or stopped.[2–4]

b) **Dissolution of uroliths**: Approximately 20 mg/kg PO every 12 hours. Reevaluation of uroliths with ultrasound or radiography every 4th week. After urolith dissolution, give preventive dose of tiopronin. If urolith dissolution is not achieved after 2 to 3 months, surgery is recommended.[2–4]

Monitoring

- Re-examination is recommended 1, 3, 6, and 12 months after starting treatment, and if well controlled, every 6 to 12 months thereafter.
- Physical examination
- Ultrasonography/radiography of the urinary tract
- Urinalyses with sediment using first morning urine samples
- CBC with platelet count
- Liver enzymes (ALP, ALT)

Client Information

- Clients should be counseled on the importance of adequate compliance with this medicine to maximize efficacy and detailed on the clinical signs to watch for regarding adverse effects.
- Give this medicine at the same time each day, at least one hour before or two hours after meals.

Chemistry/Synonyms

A sulfhydryl compound related to penicillamine, tiopronin has a molecular weight of 163.2. It occurs as a white crystalline powder that is freely soluble in water.

Tiopronin may also be known as SF 522, N-(2-Mercaptopropionyl)-glycine (MPG), 2-MPG, thiopronine, *Acadione®*, *Captimer®*, *Epatiol®*, *Mucolysin®*, *Mucosyt®*, *Sutilan®*, *Thiola®*, *Thiosol®*, or *Tioglis®*.

Storage/Stability

Store tablets in tight containers at room temperature 25°C (77°F) with excursions permitted to 15°C -30°C (59°F -86°F).

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Tiopronin Tablets: 100 mg; *Thiola®*; (Rx)

Tiopronin Delayed Release Tablets: 100 mg, 300 mg; *Thiola EC*®; (Rx)

Tobramycin, Systemic

(toe-bra-***mye***-sin) *Nebcin*®

Aminoglycoside Antibiotic

See also ***Tobramycin Ophthalmic***

Prescriber Highlights

- ► Parenteral aminoglycoside antibiotic that is active against a variety of bacteria, predominantly gram-negative aerobic bacilli
- ► Because of potential adverse effects, systemic use is usually reserved for serious infections; may be less nephrotoxic than gentamicin.
- ► Adverse effects may include nephrotoxicity, ototoxicity, and neuromuscular blockade.
- ► Cats may be more sensitive to toxic effects.
- ► Risk factors for nephrotoxicity include pre-existing renal disease, age (both neonatal and geriatric), fever, sepsis, and dehydration.

Uses/Indications

Tobramycin can be useful clinically to treat serious gram-negative infections in most species. It is often used in settings where gentamicin-resistant bacteria are a clinical problem or when amikacin is unavailable. The inherent toxicity of the aminoglycosides limits their systemic use to serious infections when there is either a documented lack of susceptibility to other less potentially toxic antibiotics or when the clinical situation dictates the immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

Whether tobramycin is less nephrotoxic than either gentamicin or amikacin when used clinically is somewhat controversial, but in controlled laboratory animal studies, it was less nephrotoxic.

The World Health Organization (WHO) has designated tobramycin as a Critically Important, Highest Priority antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) Antimicrobial Classification has designated tobramycin as a Veterinary Critically Important antimicrobial.[2]

Pharmacology/Actions

Tobramycin, like the other aminoglycoside antibiotics, acts on susceptible bacteria, presumably by irreversibly binding to the 30S ribosomal subunit, thereby inhibiting protein synthesis. It is considered a bactericidal concentration-dependent antibiotic.

Tobramycin's spectrum of activity includes coverage against many aerobic gram-negative and some aerobic gram-positive bacteria, including most species of *Escherichia coli*, *Klebsiella* spp, *Proteus* spp, *Pseudomonas* spp, *Salmonella* spp, *Enterobacter* spp, *Serratia* spp, *Shigella* spp, *Mycoplasma* spp, and *Staphylococcus* spp. Tobramycin has more activity against *Pseudomonas* spp isolates than gentamicin.

The antimicrobial activity of the aminoglycosides is enhanced in an alkaline environment, but pus or cellular debris can reduce efficacy.

The aminoglycoside antibiotics are inactive against fungi, viruses, and most anaerobic bacteria.

Pharmacokinetics

Tobramycin, like the other aminoglycosides, is not appreciably absorbed after oral or intrauterine administration, but it is absorbed from topical administration (not skin or urinary bladder) when used in irrigations during surgical procedures. Patients receiving oral aminoglycosides with hemorrhagic or necrotic enteritis may absorb appreciable quantities of the drug. SC injection results in slightly delayed peak levels and more variability than after IM injection. Bioavailability from IM or SC injection is greater than 90%.

The pharmacokinetics of tobramycin in horses have been reported.[3–5] In a study where horses were given 4 mg/kg IV,[5] the following approximate values were reported (**NOTE**: First value is a calculated value from a microbiologic assay, and the second is from an HPLC assay): volume of distribution (steady-state) (Vd), 0.24 to 0.55 L/kg; clearance (Cl), 101 to 130 mL/kg/hour; and elimination half-life ($t_{1/2}$), 2.5 to 4 hours. Another study where horses were administered 4 mg/kg IV, IM, or IV with concurrent IA[3] reported the following (means) after IV administration: Vd, 0.18 L/kg; Cl, 1.18 mL/kg/minute; and $t_{1/2,}$ 4.6 hours. IM mean bioavailability was 81%, but there was wide variability (±44%). Concurrent IA administration did appear to alter IV pharmacokinetics.

A 2008 review article of pharmacokinetic studies of aminoglycosides in various mammals showed the following mean values for tobramycin: dogs: $t_{1/2}$, 56 minutes; Vd, 4.1 L/kg; Cl, 53.7 mL/kg/minute; cats: $t_{1/2}$, 1.5 hours; Vd, 0.8 L/kg; and Cl, 6.3 mL/kg/minute.[6]

After absorption, aminoglycosides are distributed primarily in the extracellular fluid. They are found in ascitic, pleural, pericardial, peritoneal, synovial, and abscess fluids and high levels are found in sputum, bronchial secretions, and bile. Aminoglycosides (other than streptomycin) are minimally protein-bound (less than 20%) to plasma proteins. Aminoglycosides do not readily cross the blood–brain barrier or penetrate ocular tissue. CSF levels are unpredictable and range from 0% to 50% of those found in the serum. Therapeutic levels are found in bone, heart, gallbladder, and lung tissues after parenteral dosing. Aminoglycosides tend to accumulate in certain tissues, such as the inner ear and kidneys, which may help explain their toxicity.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. Patients with decreased renal function can have significantly prolonged half-lives. In humans with normal renal function, elimination rates can be highly variable with the aminoglycoside antibiotics.

Contraindications/Precautions/Warnings

Aminoglycosides are contraindicated in patients that are hypersensitive to them. Because these drugs are often the only effective agents in severe gram-negative infections, there are no other absolute contraindications to their use; however, they should be used with extreme caution in patients with pre-existing renal disease, with concomitant monitoring and dosage interval adjustments made. Other risk factors for the development of toxicity include age (both neonatal and geriatric patients), fever, sepsis, and dehydration.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in working dogs (eg, seeing-eye dogs, herding, police dogs, and dogs for the hearing impaired). Topical preparations for the treatment of otitis externa should only be used when an intact tympanic membrane is present.

Aminoglycosides should be used with caution in patients with neuromuscular disorders (eg, myasthenia gravis) because of their neuromuscular blocking activity.

Aminoglycosides are generally considered contraindicated in rabbits and hares, as they adversely affect the GI flora balance in these animals.

Adverse Effects

The aminoglycosides possess nephrotoxic and ototoxic effects. The nephrotoxic (tubular necrosis) mechanisms of these drugs are not completely understood but are likely related to accumulation in the renal convoluted tubules, interfering with phospholipid metabolism

in the lysosomes of proximal renal tubular cells, resulting in leakage of proteolytic enzymes into the cytoplasm. Nephrotoxicity normally manifests by azotemia and decreases in urine specific gravity and creatinine clearance. Proteinuria and cells or casts may also be seen in the urine. Nephrotoxicity is usually reversible once the drug is discontinued. Although tobramycin may be less nephrotoxic than the other aminoglycosides, the potential for nephrotoxicity remains, and equal caution and monitoring are required.

Ototoxicity (eighth cranial nerve toxicity) from aminoglycosides can manifest with either auditory and/or vestibular clinical signs and may be irreversible.[7] Vestibular clinical signs are more frequent with streptomycin, gentamicin, or tobramycin. Auditory clinical signs are more frequent with amikacin, neomycin, or kanamycin, but any manifestation can occur with any of the drugs. Cats are apparently sensitive to the vestibular effects of aminoglycosides.

The aminoglycosides can also cause neuromuscular blockade, facial edema, pain or inflammation at the injection site, peripheral neuropathy, and hypersensitivity reactions. Rarely GI clinical signs, hematologic, and hepatic effects have been reported.

Reproductive/Nursing Safety

Aminoglycosides cross the placenta, and fetal concentrations range from 15% to 50% of those found in maternal serum. Tobramycin can concentrate in fetal kidneys and, although rare, cause eighth cranial nerve toxicity or nephrotoxicity in fetuses. Total irreversible deafness has been reported in some human babies whose mothers received tobramycin during pregnancy. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks.

Tobramycin is excreted in breast milk, but because of poor oral absorption, it is unlikely to have systemic effects on the infant. However, it could alter gut flora.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

If an inadvertent overdose is administered, hemodialysis is very effective in reducing serum levels of the drug. Peritoneal dialysis will also reduce serum levels but is much less efficacious.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tobramycin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, General** (eg, **alfaxalone, isoflurane, ketamine, propofol**): Concurrent use could potentiate neuromuscular blockade.
- **Beta-Lactam Antibiotics** (eg, **penicillins, cephalosporins**): May have synergistic effects against some bacteria; some potential for inactivation of aminoglycosides in vitro (do not mix together) and in vivo (patients in renal failure). Cephalosporins could cause additive nephrotoxicity when used with aminoglycosides, but this interaction has only been well documented with cephaloridine and cephalothin (both no longer marketed).
- **Diuretics, loop** (eg, **furosemide, torsemide**): Concurrent use may increase the risk for nephrotoxicity and/or ototoxicity.
- **Diuretics, Osmotic** (eg, **mannitol**): Concurrent use may increase the nephrotoxic or ototoxic potential of aminoglycosides.
- **Nephrotoxic Drugs, Other** (eg, **amphotericin B, cisplatin, cyclosporine, polymyxin B, vancomycin**): Increased risk for nephrotoxicity
- **Neuromuscular Blocking Agents** (eg, **atracurium**): Concurrent use could potentiate neuromuscular blockade.
- **Nonsteroidal anti-inflammatory drugs** (**NSAIDs**; eg, **carprofen, meloxicam, robenacoxib**): May increase tobramycin concentration

Laboratory Considerations

- Tobramycin serum concentrations may be falsely decreased if the patient is also receiving some **beta-lactam antibiotics** and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough level.

Dosages

NOTE: There is significant interpatient variability with aminoglycoside pharmacokinetic parameters. To ensure therapeutic levels and minimize the risks for toxicity, consider monitoring serum levels. See ***Monitoring***.

DOGS & CATS:

Susceptible infections (extra-label): Dogs: 9 – 14 mg/kg IV, IM, or SC once daily. Cats: 5 – 8 mg/kg IV, IM, or SC once daily

HORSES:

Susceptible infections (extra-label): 4 mg/kg IV once daily. IM administration will somewhat reduce peak concentration and corresponding efficacy against some Enterobacteriaceae.[3]

LLAMAS:

Susceptible infections (extra-label): 4 mg/kg IV once a day[8]

BIRDS:

Susceptible infections (extra-label):

a) 5 mg/kg IM every 12 hours[9]

b) 2.5 – 5 mg/kg/day; must be given parenterally[10]

REPTILES:

Susceptible infections (extra-label): 2.5 mg/kg once daily IM[11]

Monitoring

- Efficacy (cultures, clinical signs associated with infection)
- Gross monitoring of vestibular or auditory toxicity is recommended.
- Tobramycin serum concentration, if possible (see below)
- Nephrotoxicity (see below)

The following recommendations are from the International Renal Interest Society (IRIS) to prevent aminoglycoside-induced acute kidney injury (AKI; in dogs and cats).

Prior to aminoglycoside treatment*:

- Carefully consider the potential risk factors: dehydration, concomitant treatment with furosemide, use of other nephrotoxic drugs, arterial hypotension, hypokalemia, previous history of AKI, pre-existing chronic kidney disease (CKD). When such factors are identified, alternatives to aminoglycoside treatment should be considered.
- Perform urinalysis: measure urine specific gravity, examine for glycosuria, proteinuria (UPC), and abnormal sediment. If abnormalities are detected, investigate carefully to determine the underlying cause before deciding whether to prescribe aminoglycosides.
- Blood tests: determine blood creatinine concentration. Consider avoiding the use of aminoglycosides if the blood creatinine concentration is at the borderline between stage I and stage II or al-

ready in stage II. In borderline cases, further investigations might be considered to evaluate renal risk.
- Imaging: abdominal radiograph and/or ultrasonographic examination
- Measurement of arterial blood pressure: high-risk hypertension: systolic BP greater than 180 mm Hg is indicative of renal damage and risk.

**This list was adapted from IRIS. Preventing Aminoglycoside-induced AKI. http://www.iris-kidney.com/education/education/prevention.html.*

During the treatment*:
- Assess the hydration status of the patient (body weight, total plasma protein concentration, and hematocrit) once weekly.
- If therapeutic drug monitoring is available, ensure the plasma tobramycin concentration has decreased to below 1 mg/L (1 µg/mL) before the next dose is administered.
- Carefully re-assess the pretreatment urine and blood variables indicated above
- Repeat these assessments every 3 to 4 days to detect any change. If there is any doubt of renal damage, perform the GGT:creatinine ratio in the urine (when available in the laboratory); an increase is an early indicator of nephrotoxicity.
- Continue monitoring for 1 week after discontinuing the treatment, as AKI may occur later as aminoglycosides accumulate inside proximal tubular cells and persist for long periods after dosing.
- The risk for nephrotoxicity increases with the duration of the treatment, as aminoglycoside nephrotoxicity is cumulative.
- If findings suggest the development of AKI (urine: the presence of renal casts in the sediment, glycosuria, low specific gravity; blood: azotemia): Immediately stop aminoglycoside therapy. Hospitalize the patient and monitor urine production. Nonoliguric AKI generally occurs and is reversible. Oliguric AKI has a poor prognosis. Start adequate IV fluid therapy. Monitor BUN, creatinine, and electrolytes (hypokalemia is frequent in nonoliguric AKI and should be corrected)
- If AKI is worsening, consider renal substitutive therapy (hemodialysis). After apparent recovery from aminoglycoside-induced AKI, some dogs may remain renally impaired.

**This list was adapted from IRIS. Preventing Aminoglycoside-induced AKI. http://www.iris-kidney.com/education/education/prevention.html.*

Client Information
- Tobramycin must be injected if it is used for treating serious infections. It does not work if it is given by mouth.
- This medicine can damage the nerves, hearing, and kidneys. Monitor your animal for symptoms such as vomiting, not eating, lethargy, and difficulty walking.
- Cats may be more likely to have damage to their hearing.
- Give this medicine once daily either in the vein (by your veterinarian) or under the skin (subcutaneous).
- This medicine can be used topically (in the eye, ear, on the skin) for certain infections.
- While your animal is taking this medication, it is important to return to your veterinarian for blood and urine tests. Do not miss these important follow-up visits.

Chemistry/Synonyms
Tobramycin, an aminoglycoside derived from *Streptomyces tenebrarius*, occurs as a white to off-white, hygroscopic powder that is freely soluble in water and very slightly soluble in alcohol. The sulfate salt is formed during the manufacturing process. The commercial injection is a clear, colorless solution, and the pH is adjusted to 6 to 8 with sulfuric acid and/or sodium hydroxide.

Tobramycin sulfate may also be known as tobramycin sulphate, *Nebcin®, Nebcine®, Tobra®, or TOBI®*.

Storage/Stability
Store tobramycin sulfate for injection at room temperature (15°C to 30°C [59°F-86°F]); avoid freezing and temperatures above 40°C (104°F). Do not use the product if discolored. After reconstitution, keep the solution in a refrigerator and use it within 96 hours. If kept at room temperature, use the solution within 24 hours.

Compatibility/Compounding Considerations
Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Although the manufacturers state that tobramycin should not be mixed with other drugs, it is reportedly physically **compatible** and stable in most commonly used IV solutions (**NOT compatible** with dextrose and alcohol solutions, *Polysal®*, *Polysal® M*, or *Isolyte® E*, *M*, or *P*) and **compatible** with the following drugs: aztreonam, bleomycin sulfate, calcium gluconate, cefoxitin sodium, ciprofloxacin lactate, clindamycin phosphate (not in syringes), metronidazole (with or without sodium bicarbonate), ranitidine HCl, and verapamil HCl.

The following drugs or solutions are reportedly physically **incompatible** or only **compatible** in specific situations with tobramycin: furosemide and heparin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

In vitro inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well documented; see the information in the ***Drug Interactions*** and ***Laboratory Consideration*** sections.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Tobramycin Sulfate Solution for Injection: 10 mg/mL in 2 mL vials, and 40 mg/mL in 2 mL, 30 mL, and 50 mL vials; generic; (Rx)

Tobramycin Sulfate Powder for Injection: 1.2 g (40 mg/mL after reconstitution), preservative-free in 30 mL bulk package vial; generic; (Rx)

Also available in ophthalmic preparations as well as products (solution, powder [capsule]) for inhalation.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Toceranib

(toe-***ser***-a-nib) *Palladia®*

Tyrosine Kinase Inhibitor Antineoplastic

Prescriber Highlights
- ► FDA-approved for grades II or III canine mast cell tumors (MCTs) in dogs
- ► Discontinue toceranib therapy at least 3 days prior to, and 2 weeks following, surgery.
- ► Most common adverse effects are diarrhea, decreased/loss of appetite, lameness, weight loss, and hematochezia.
- ► Adverse effects can be serious and require treatment delay or dose reduction.
- ► Monitoring is essential.
- ► Toceranib should be handled as a hazardous drug; personal protective equipment (PPE) should be used accordingly.

Uses/Indications

Toceranib is indicated for the treatment of Patnaik grade II or III, recurrent, cutaneous mast cell tumors (MCTs) with or without regional lymph node involvement in dogs.

Toceranib may prove useful for treating a variety of tumors in dogs, including heart-base tumors,[1] sarcomas, carcinomas, melanomas, multidrug-resistant lymphoma,[2] and multiple myeloma. Toceranib has been investigated in combination with radiation therapy[3] and in combination with other targeted therapies such as calcitriol,[4] carboplatin,[5,6] low-dose continuous (metronomic) cyclophosphamide alone[7] or with piroxicam,[8] doxorubicin,[9] lomustine,[10–12] piroxicam,[13] prednisone, and vinblastine.[14–16]

Preliminary data suggest that toceranib is tolerated in cats at a similar dose range and schedule as that recommended for dogs.[17–22] Early evidence of biological activity against feline MCTs,[17,22] pancreatic carcinoma,[23,24] and oral squamous cell carcinoma[20] has been demonstrated.

Pharmacology/Actions

Toceranib is a small molecule tyrosine kinase inhibitor (TKI) that selectively inhibits the tyrosine kinase activity of several split receptor tyrosine kinases (RTKs), including vascular endothelial growth factor receptor-2 (VEGFR2), platelet-derived growth factor receptor-beta (PDGFR-beta), and KIT (stem cell growth factor receptor), among others. These kinases are believed to be involved in growth, pathologic angiogenesis, and metastatic processes of certain tumors. Toceranib competitively inhibits ATP binding in target RTKs, preventing receptor phosphorylation and subsequent downstream signal transduction. Toceranib can induce cell cycle arrest and apoptosis in canine tumor cell lines expressing activating mutations in KIT. As canine mast cell tumors (MCTs) universally express KIT and a subset possess activating mutations, toceranib administration can be associated with objective antitumor activity in a large minority of dogs with MCTs. Aberrant KIT localization and/or activation mutation may influence treatment response, although conflicting data exist.[3,25,26] Toceranib's activity against VEGFR2 and PDGFR-beta has the potential to exert antiangiogenic effects in multiple tumor types. Additional information suggests that toceranib administration may be associated with a reduction in immunosuppressive regulatory T cells in the peripheral blood.[7]

Pharmacokinetics

The oral bioavailability of toceranib phosphate in dogs is ≈77%. The presence of food does not significantly impact absorption. Binding to canine plasma proteins is ≈94%, and the volume of distribution is very large (ie, greater than 20 L/kg). The terminal elimination half-life is 31 hours after oral administration. Although the metabolic fate of toceranib has not been completely determined, it appears that the drug is metabolized via cytochrome P450 and/or flavin monooxygenase to an N-oxide metabolite in the liver.[27,28]

A study evaluating toceranib peak plasma concentrations after administration of lower oral dosages (2.5 – 2.75 mg/kg PO every other day) resulted in an average 6- to 8-hour postdose plasma concentration ranging from 100 – 120 ng/mL.[29] These were significantly above the 40 ng/mL concentration that is associated with inhibition of KIT phosphorylation, and the adverse event profile was substantially reduced from the one associated with the label dosage of 3.25 mg/kg every other day.

Contraindications/Precautions/Warnings

Toceranib use has not been evaluated in dogs less than 24 months of age or weighing less than 5 kg (11 lb). Because toceranib can cause vascular dysfunction leading to edema and thromboembolism (including pulmonary emboli) and may impair wound healing, it is recommended that toceranib be discontinued at least 3 days prior to, and 2 weeks following, surgery.

When toceranib is used for the treatment of bulky mast cell tumors (MCTs), significant mast cell degranulation may occur with resultant adverse effects; systemic mastocytosis should be ruled out prior to starting toceranib.[30]

Toceranib can cause clinical signs similar to those seen with aggressive MCTs. When these occur, the drug should be stopped and the patient re-evaluated. When signs resolve, treatment may be re-instituted at a lower dose or reduced frequency. The package insert has specific monitoring requirements with dose adjustment or therapy pause guidelines when certain adverse effects (eg, severe diarrhea, GI bleeding) occur or when laboratory monitoring indicates toxicity. See ***Monitoring***.

Toceranib in combination with lomustine and prednisolone in dogs with advanced MCTs caused severe adverse effects in all 10 enrolled dogs, including grade 3 and 4 neutropenia ($n = 9$), GI toxicity ($n = 5$), and hepatotoxicity and pancreatitis ($n = 1$ each), requiring temporary discontinuation of therapy in 9 dogs, and 4 dogs died or were euthanized due to treatment-related adverse effects.[12]

Toceranib should be handled as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[6] Refer to the Occupational Safety and Health Association (OSHA) website for more information.

Adverse Effects

The most common adverse effects observed with toceranib in dogs include diarrhea, decreased/loss of appetite, lameness, weight loss, and hematochezia. Severe diarrhea or GI bleeding requires immediate treatment and necessitates dose interruption or reduction (see ***Monitoring***). Other potential adverse effects include vomiting, anemia, thrombocytopenia, lethargy, azotemia, hyperphosphatemia, increased ALT, muscle cramping/pain, neutropenia, hypoalbuminemia, thromboembolic disease, vasculitis, pancreatitis, nasal depigmentation, change in coat or skin color, epistaxis, seizures, and pruritus. Increased systolic blood pressure (SBP) has been noted in dogs receiving toceranib, with an average increase of 11 to 16 mm Hg, and 37% to 45% of dogs developing SBP greater than 160 mm Hg.[31,32] Proteinuria occurred in 20% to 25% of dogs.[31,33] Over a 90-day study period, laboratory assessments of thyroid function remained with the laboratory reference interval but trended toward reduced thyroid dysfunction.[34] Case reports describe nephrotic syndrome developed in a dog after 328 days of toceranib treatment for a mast cell tumor,[35] as well as secondary lymphoma in another dog after 3 months of toceranib treatment for a GI stromal tumor.[36]

One source[37] suggests starting certain drugs 4 to 7 days prior to staring toceranib to reduce the likelihood of toxicity. These drugs include antacids (eg, famotidine, omeprazole), H_1 blockers (eg, diphenhydramine), prednisone (to reduce tumor inflammation and possibly decrease mast cell tumor mediators' effects), and sucralfate (if dog has a positive stool hemoccult). Additionally, in dogs that experience hyporexia or vomiting after therapy has begun, administration of metoclopramide, ondansetron, or maropitant may be effective. Loperamide can be given on toceranib dosing days to help prevent or lessen diarrhea; other clinicians have found metronidazole useful. Another study reported that continuation of prednisone after treatment was begun, but only given on days when toceranib is not given, was well tolerated.[3]

In cats that have received toceranib, reported adverse effects include GI toxicity, myelosuppression, azotemia, hepatopathy, and alopecia.[17–21]

Reproductive/Nursing Safety

Toceranib is a likely teratogen and should not be used in pregnant females. It is labeled as contraindicated in breeding, pregnant, or lactating bitches. For sexually intact patients, verify pregnancy status prior to administration.

Because reproductive/nursing safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No acute toxicity data are available, but toceranib has a narrow margin of safety. For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in animals receiving toceranib and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Calcitriol**: An in vitro study found that calcitriol had synergistic effects with toceranib against canine C2 mastocytoma cells. The authors concluded that calcitriol combination therapies might have significant clinical utility in the treatment of canine mast cell tumors (MCTs) but refinement of the calcitriol-dosing regimen must be carried out.[4]
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs**; eg, **carprofen, meloxicam**): The package insert states to use NSAIDs with caution in conjunction with toceranib due to an increased risk for GI ulceration or perforation. Although NSAIDs (eg, **piroxicam**) are sometimes used with toceranib as part of metronomic drug protocols,[13] it is recommended that they not be given on the same day as toceranib as GI toxicity can be exacerbated.[37]
- **CYP3A4 Inhibitors** (eg, **clarithromycin, fluconazole, grapefruit juice, itraconazole, ketoconazole, verapamil**): May increase toceranib concentrations. This interaction with toceranib has not been documented in dogs to date and presently is speculative; however, use caution.
- **Other Cytotoxic Antineoplastic Agents** (eg, **doxorubicin, lomustine, vinblastine**): Potentiation of myelosuppression (neutropenia) with toceranib co-administration, necessitating reductions in dosage and/or frequency of administration of the cytotoxic agent, has been reported.[9–11,14] Use in combination with caution.

Laboratory Considerations

- None noted

Dosages

NOTE: There is a significant amount of ongoing research evaluating toceranib for use with other drugs, other species, and for extra-label indications and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[38–42] are strongly recommended.

DOGS:

NOTE: The label dosage for dogs is considered by most clinicians to be greater than is necessary and is associated with more adverse effects. The label indications are provided below, but the use of lower, extra-label dosages is strongly recommended.

Patnaik grade II or III, recurrent, cutaneous mast cell tumors (MCTs) with or without regional lymph node involvement (label dosage; FDA-approved): Initial dose 3.25 mg/kg PO every other day (every 48 hours).[30] Dose reductions of 0.5 mg/kg (to a minimum dose of 2.2 mg/kg) every other day and dose interruptions (cessation of treatment) for up to 2 weeks may be utilized, if needed, to manage adverse reactions. May be administered with or without food. Do not split tablets.

Chemotherapeutic agent (extra-label): Clinical experience with toceranib in dogs suggests that 2.4 – 2.75 mg/kg every other day is better tolerated than the label dosage, resulting in less toxicity, better owner compliance, and fewer drug holidays.[29] Some dogs do not tolerate this dosing regimen even at the 2.4 mg/kg dose rate. Medical oncologists have found that a Monday/Wednesday/Friday schedule of dosing may be better tolerated by some dogs. This may be particularly useful when toceranib is combined with other drugs such as NSAIDs. When a dog cannot tolerate the Monday/Wednesday/Friday schedule, every-third-day dosing may be attempted, but this is not ideal and may result in subtherapeutic drug exposure.[37]

CATS:

Chemotherapeutic agent (extra-label): A target dosage of 3.25 mg/kg every other day or Monday/Wednesday/Friday appears to be tolerated. Practically, each dose equates to 10 mg/cat (NOT mg/kg), which results in doses ranging from 2 to 4 mg/kg for the average 2.5 to 5 kg (5.5 to 11 lb) cat and is tolerated by the majority of cats and is recommended by some clinicians.[22]

Monitoring

- Baseline and periodic CBC, hematocrit, and serum albumin, creatinine, and phosphate. The manufacturer recommends weekly (approximately) veterinary assessment for the first 6 weeks of therapy and approximately every 6 weeks thereafter. The package insert states:
  Temporarily discontinue drug if anemia, azotemia, hypoalbuminemia, and hyperphosphatemia occur simultaneously. Resume treatment at a dose reduction of 0.5 mg/kg after 1 to 2 weeks when values have improved and albumin is >2.5 g/dL. Temporary treatment interruptions may be needed if any one of these occurs alone: hematocrit <26%, creatinine ≥2 mg/dL, or albumin <1.5 g/dL. Then resume treatment at a dose reduction of 0.5 mg/kg once the hematocrit is >30%, the creatinine is <2.0 mg/dL, and the albumin is >2.5 g/dL. Temporarily discontinue the use of toceranib if neutrophil count is ≤1000/mL. Resume treatment after 1 to 2 weeks at a dose reduction of 0.5 mg/kg, when neutrophil count has returned to >1000/mL. Further dose reductions may be needed if severe neutropenia recurs.[30]
- Other laboratory tests that have been suggested for monitoring (every 6 to 8 weeks) include urinalysis, full chemistry panel, thyroid function, and urine protein:creatinine ratio.
- Adverse effects (diarrhea): If 4 or more watery stools/day or diarrhea persists for 2 days, stop drug and institute supportive care until formed stools recur. When dosing is resumed, decrease dose by 0.5 mg/kg.
- Adverse effects (eg, GI bleeding): If fresh blood in stool or melena for more than 2 days, or frank hemorrhage or blood clots in stool are noted, stop drug and institute supportive care until resolution of all clinical signs of blood in stool, then decrease dose by 0.5 mg/kg.
- Blood pressure (every 6 to 8 weeks)[31]
- Tumor size

Client Information

- Always provide Client Information Sheet with prescription. In addition, it is highly recommended to verbally reiterate some of the key points found on the client information sheet.
- This medication may be given with or without food; do not split or crush tablets.
- Toceranib is a chemotherapy (anticancer) drug. The drug can be

hazardous to other animals and people that come in contact with it. On the day your animal gets the drug and then for a few days afterward, all bodily waste (eg, urine, feces, litter), blood, or vomit should only be handled while wearing disposable gloves. Seal the waste in a plastic bag, then place both the bag and gloves in with the regular trash.

- Do not wash any items soiled with stool, urine, or vomit from your dog with regular laundry.
- Store toceranib out of the reach of children or pets.

Chemistry/Synonyms

Toceranib phosphate is an idolinone with a molecular weight of 494.46. Toceranib may also be known as PHA-291639, SU-11654, UNII-59L7Y0530C, toceranibum, or tocéranib.

Storage/Stability

Toceranib phosphate tablets should be stored at controlled room temperature 20°C-25°C (68°F-77°F).

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Toceranib Phosphate Oral Tablets: 10 mg, 15 mg, and 50 mg; *Palladia*®; (Rx) NADA # 141-295

HUMAN-LABELED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Tolazoline

(toe-***laz***-oh-leen) *Tolazine*®

Alpha-Adrenergic Antagonist

Prescriber Highlights

- ► Alpha-adrenergic antagonist used primarily in horses and other large animals as a reversal agent for xylazine or other alpha-2 agonists
- ► Reversal effects may be partial and transitory.
- ► Contraindications in horses include stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia, shock, hypersensitivity, or coronary artery or cerebrovascular disease.
- ► Use caution or avoid use in foals.
- ► Adverse effects in horses include transient tachycardia, peripheral vasodilation presenting as sweating and injected mucous membranes, hyperalgesia of the lips (eg, licking, flipping of lips), piloerection, clear lacrimal and nasal discharge, muscle fasciculations, and apprehensiveness.
- ► Ruminants and camelids may be more susceptible to the adverse effects of tolazoline, especially when given IV or at high doses.
- ► Availability may be an issue; may be obtained from compounding pharmacies.

Uses/Indications

Tolazoline is FDA-approved and indicated for the reversal of sedative and analgesic effects associated with xylazine in horses. Tolazoline antagonizes the effects of detomidine more completely, hastens recovery, and lasts longer than atipamezole[1]; however, effects can be transient, and sedative effects may reoccur.[2,3]

Tolazoline has also been used for reversing the effects of xylazine and other alpha-2 agonists (eg, dexmedetomidine, detomidine, medetomidine) in horses and in a variety of other species, but fewer safety and efficacy data are available.

Pharmacology/Actions

By directly relaxing vascular smooth muscle, tolazoline has peripheral vasodilating effects and decreases total peripheral resistance. Tolazoline also is a competitive alpha-1- and alpha-2-adrenergic blocking agent, helping explain its mechanism for reversing the effects of xylazine. It may stimulate GI secretions and motility via parasympathomimetic or histamine type-2 agonist effects.

Tolazoline is rapid-acting (usually within 5 minutes of IV administration) but may not fully reverse effects on sedation or heart rate and rhythm. It has a short duration of action; repeat doses may be required.

In horses that received detomidine 0.04 mg/kg sublingually (SL), then tolazoline 4 mg/kg IV 1 hour later, tolazoline's effect on detomidine-induced changes in the chin-to-ground distance was minimal, and detomidine-induced changes in heart rate and rhythm only persisted for 15 to 20 minutes.[2]

After tolazoline doses of 4 mg/kg IV in horses, average heart rate decreased beginning 2 minutes postinjection, with heart rate nadir at 45 minutes. No apparent effect on chin-to-ground distance was noted. PCV significantly increased in all horses throughout the times sampled with the maximal change at 15 minutes. Serum glucose concentrations increased significantly in all horses at the first time point measured through 1.5 hours postinjection.[4]

Pharmacokinetics

After a single tolazoline 4 mg/kg IV injection in 6 horses, tolazoline had a mean volume of distribution (steady-state) of 1.68 L/kg, clearance of 0.757 L/hour/kg, and elimination half-life of 2.08 hours.[4] In a subsequent study, after horses (n = 9) were first given detomidine 0.04 mg/kg SL, then tolazoline 4 mg/kg IV 1 hour later; mean tolazoline pharmacokinetic values included volume of distribution (steady-state) of 1.9 L/kg, clearance of 11.2 mL/minute/kg, and elimination half-life of 3.51 hours.[2] An older preapproval study done in ponies reported the elimination half-life of ≈1 hour.[5]

Animal studies have demonstrated that tolazoline concentrates in the liver and kidneys.

Contraindications/Precautions/Warnings

The manufacturer does not recommend use in horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia, or shock. Safe use for foals has not been established, and some clinicians believe it should not be used in foals, as adverse reactions and fatalities have been reported.

Tolazoline should be considered contraindicated in patients known to be hypersensitive to it or with coronary artery or cerebrovascular disease. Humans that have any of the conditions listed above should use extra caution when handling the agent.

Adverse Effects

In horses, adverse effects that may occur include transient tachycardia; peripheral vasodilatation presenting as sweating and injected mucous membranes of the gingiva and conjunctiva; hyperalgesia of the lips (eg, licking, flipping of lips); piloerection; clear lacrimal and nasal discharge; muscle fasciculations; and apprehensiveness. Adverse effects should diminish with time, and generally disappear within 2 hours of dosing. The potential for adverse effects increases if tolazoline is given at higher than recommended dosages or if xylazine has not been previously administered.

Ruminants and camelids appear to be more sensitive to tolazoline's effects than horses. In cattle, 1.5 mg/kg IV can cause coughing, increased frequency of defecation, and mild increases in breathing effort. At higher doses (2 – 10 mg/kg IV), bright red conjunctival mucous membranes, coughing, nasal discharge, salivation, labored breathing, CNS depression, signs of abdominal pain, straining, head pressing, restlessness, and severe diarrhea can be observed. Rapid IV injection has been reported to cause significant cardiac stimulation,

tachycardia, increased cardiac output, vasodilation, and GI distress.

Reproductive/Nursing Safety

Safety during pregnancy in breeding or lactating animals has not been established. It is unknown if the drug crosses the placenta or enters maternal milk.

Overdose/Acute Toxicity

In horses given tolazoline alone (no previous xylazine), 5 times the recommended doses resulted in GI hypermotility, with resultant flatulence and defecation or attempt to defecate. Some horses exhibited mild colic and transient diarrhea. Intraventricular conduction may be slowed when horses are overdosed, with a prolongation of the QRS-complex noted. Ventricular arrhythmias may occur, resulting in death with higher overdoses (5 times the recommended doses). In humans, ephedrine (**NOT** epinephrine or norepinephrine) has been recommended to treat serious tolazoline-induced hypotension.

A llama that received 4.3 mg/kg IV and again 45 minutes later (≈5 times overdose) developed signs of anxiety, hyperesthesia, profuse salivation, GI tract hypermotility, diarrhea, convulsions, hypotension, and tachypnea. Treatment, including IV diazepam, phenylephrine, IV fluids, and oxygen, was successful.[6]

Tolazoline 8 mg/kg IV has reportedly caused a fatality in a sheep.

Apnea, fasciculations, and muscle tensing were observed in mule deer that received dosages of 6.1 – 8.4 mg/kg IV; however, no adverse effects were observed in black-tailed deer that received an average dosage of 8.1 mg/kg IV.[7]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tolazoline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Dopamine**: Concurrent use may cause severe hypotension.
- **Epinephrine, Norepinephrine**: If large doses of tolazoline are given with either norepinephrine or epinephrine, a paradoxical drop in blood pressure can occur, followed by a precipitous increase in blood pressure.
- **Ethanol**: Accumulation of acetaldehyde can occur if tolazoline and alcohol are given simultaneously.

Dosages

DOGS/CATS:

Reversal of xylazine effects (extra-label): 2 – 4 mg/kg slow IV (administration rate should approximate 1 mL/second).[8] **WARNING**: If reversal is warranted, the high concentration (100 mg/mL) of the veterinary drug may make accurate dosing difficult. Tolazoline is not FDA-approved for use in dogs or cats, and the United States manufacturer does not recommend its use.

EQUINE:

Horses: **Reversal of xylazine effects** (label dosage; FDA-approved): 4 mg/kg slow IV; administration rate should approximate 1 mL/second. [9]

Horses: **Reversal of xylazine effects** (extra-label): 0.5 – 2 mg/kg IM (preferred) or slow IV; if administering IV, dividing the dose into multiple smaller doses has been suggested.[10]

Horses: **Reversal of low-dose alpha-agonist effects after dental procedures** (extra-label): Following sedation with 1.1 – 2.2 mg/kg IM xylazine, reverse with tolazoline 0.04 mg/kg slow IV; may repeat 0.02 mg/kg slow IV 20 to 30 minutes later if needed.[11]

Donkeys: **Reversal of detomidine** (extra-label): Tolazoline 4 mg/kg IV, given 15 minutes after detomidine 0.04 mg/kg IV, reduced the degree and duration of sedation, ataxia, and analgesia.[12]

RUMINANTS (CATTLE, SHEEP, GOATS):

NOTE: Not FDA-approved for use in cattle, sheep, goats, or other food animals

Reversal of alpha-2 agonists (extra-label): 0.5 – 1.5 mg/kg IV. Other clinicians have suggested that IV administration of tolazoline should be avoided, except in emergency situations, to prevent adverse effects such as cardiac asystole.[13,14]

CAMELIDS:

Reversal of alpha-2 agonists (extra-label):

a) Preferred reversal agent for xylazine is tolazoline 1 – 2 mg/kg IM or SC.[15–17]. IV administration (especially the labeled dose—4 mg/kg) should be avoided as adverse effects have occurred.[6]

b) 0.5 – 1.5 mg/kg IV. Today, these lower doses are now recommended for use in all ruminants, including camelids. Other clinicians have suggested that IV administration of tolazoline should be avoided, except in emergency situations, to prevent adverse effects such as cardiac asystole.[13]

SWINE:

Reversal of alpha-2 agonists (extra-label): 2 – 4 mg/kg IV or 2 mg/kg IM[18,19]

DEER:

NOTE: Not FDA-approved for use in food animals

Reversal of xylazine (extra-label):

a) 2 – 4 mg/kg slow IV; titrate to effect[8]

b) 2 – 4 mg/kg IV, or 50% of dose given IV, 50% given IM[7,20,21]

BIRDS:

Reversal of alpha-2-adrenergic agonists (eg, xylazine, detomidine) (extra-label): 15 mg/kg IV[22]

Monitoring

- Efficacy (ie, reversal of xylazine effects)
- Adverse effects (eg, tachycardia, sweating, mucous membrane injection, lip licking, ocular and nasal discharge, fasciculations, and restlessness)

Client Information

- Because of the risks associated with the use of xylazine and reversal by tolazoline, only veterinary professionals should administer and monitor these drugs.

Chemistry/Synonyms

Tolazoline HCl is an alpha-adrenergic blocking agent that is structurally related to phentolamine. It occurs as a white to off-white, crystalline powder possessing a bitter taste and a slight aromatic odor. Tolazoline is freely soluble in ethanol or water. The commercially available (human) injection has a pH between 3 and 4.

Tolazoline HCl may also be known as benzazoline hydrochloride, phenylmethylimidazoline, tolazolinium chloratum, *Priscol®*, *Priscoline®*, *Tolazine®*, or *Vaso-Dilatan®*.

Storage/Stability

Store commercially available injection products between 15°C and 30°C (59°F and 86°F) and protected from light. Color change or crystallization may occur with refrigeration.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

The drug is reportedly physically **compatible** with the commonly used IV solutions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Tolazoline HCl Injection: 100 mg/mL in 100 mL multi-dose vials; *Tolazine*®; (Rx). FDA-approved for use in horses; not to be used in foodproducing animals. Cattle slaughter withdrawal: 8 days; mild discard 2 days. Deer slaughter withdrawal = 30 days. While this product is still listed in FDA's Green Book of approved animal drugs, it may no longer be commercially available in the US. [11]

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS: NONE

Tolfenamic Acid

(tole-fen-***a***-mik) *Tolfedine*®

Nonsteroidal Anti-inflammatory Agent (NSAID)

Prescriber Highlights

- ► Oral and injectable NSAID approved in various countries for dogs, cats, cattle, and swine. No approved products in the United States
- ► Relatively safe for short-term use.
- ► Contraindicated in patients with active GI bleeding or ulceration and those that are hypersensitive to it or other drugs in its class
- ► Use caution in patients with renal or hepatic insufficiency and those that are dehydrated, hypovolemic, or hypotensive.
- ► Not recommended prior to surgery due to its effects on platelet function

Uses/Indications

Tolfenamic acid is an anti-inflammatory, antipyretic, and analgesic agent approved in other countries for use in dogs, cats, cattle, and swine.

Tolfenamic acid may be useful for the treatment of acute or chronic pain and/or inflammation in dogs and acute pain/inflammation in cats.

In some countries, tolfenamic acid is approved for the treatment of pneumonia and acute mastitis in cattle and metritis mastitis agalactia in swine.[1]

Pharmacology/Actions

Tolfenamic acid exhibits pharmacologic actions similar to those of aspirin. It is a potent inhibitor of cyclooxygenase, thereby inhibiting the release of prostaglandins. It also has direct inhibition of prostaglandin receptors. Tolfenamic acid has significant antithromboxane activity and is not recommended for use presurgically because of its effects on platelet function.

Pharmacokinetics

Tolfenamic acid is absorbed after oral administration. In dogs, peak concentrations occur from 2 to 4 hours after dosing. Enterohepatic recirculation is increased if given with food. This effect can increase the bioavailability but also creates more variability in bioavailability than when given to fasted dogs. The volume of distribution in dogs is reported to be 1.2 L/kg, and it has an elimination half-life of ≈6.5 hours. The duration of the anti-inflammatory effect is 24 to 36 hours. Dogs with experimentally induced renal failure had significantly increased clearances of the drug, presumably via increasing hepatic metabolism or enterohepatic recycling of tolfenamic acid.[2]

Contraindications/Precautions/Warnings

Tolfenamic acid is contraindicated in animals hypersensitive to it or to other drugs in its class (eg, meclofenamic acid). Like other NSAIDs, it should not be used in animals with active GI bleeding or ulceration. Use with caution in patients with decreased renal or hepatic function. Avoid use in dehydrated, hypovolemic, or hypotensive animals.[3]

Use in animals under 6 weeks of age is not recommended.[3]

Adverse Effects

Tolfenamic acid is relatively safe when given as recommended in dogs and cats. Vomiting and diarrhea have been reported after oral use. Experimental studies did not demonstrate significant renal or GI toxicity until doses were more than 10 times labeled. Potentially, long-term use could cause renal failure, especially in cats. However, 1 small (n = 7) study, where healthy cats received 4 mg/kg PO once daily for 14 days, did not find significant changes in renal scintigraphy or biochemical profiles when compared to baseline.[4]

Because of its anti-thromboxane activity and resultant effects on platelet function, tolfenamic acid is not recommended for use presurgically.

Reproductive/Nursing Safety

No specific information was located; like other NSAIDs, tolfenamic acid should be used with caution in pregnancy.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located. It is suggested that if an acute overdose occurs, treatment follows standard overdose procedures (empty gut following oral ingestion). Supportive treatment should be instituted as necessary, and diazepam IV used to help control seizures. Monitor for GI bleeding. Because tolfenamic acid may cause renal effects, monitor electrolyte and fluid balance carefully and manage renal failure using established guidelines.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tolfenamic acid or other NSAIDs and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aspirin**: May increase the risk for GI toxicity (eg, ulceration, bleeding, vomiting, diarrhea)
- **Corticosteroids**: As concomitant corticosteroid therapy may increase the occurrence of gastric ulceration, avoid the use of these drugs when also using tolfenamic acid.
- **Digoxin**: NSAIDs may increase serum levels.
- **Fluconazole**: Administration has increased plasma levels of celecoxib in humans and potentially could also affect tolfenamic acid levels in dogs.

- **Furosemide**: NSAIDs may reduce saluretic and diuretic effects; may increase the risk for nephrotoxicity.
- **Methotrexate**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution.
- **Nephrotoxic Drugs** (eg, **aminoglycosides, amphotericin B**): May enhance the risk for nephrotoxicity
- **NSAIDs, Other** (eg, **meloxicam, flunixin**): May increase the risk for GI toxicity (eg, ulceration, bleeding, vomiting, diarrhea)
- **Warfarin**: Closely monitor patients also receiving drugs that are highly bound to plasma proteins (eg, **warfarin**), as tolfenamic acid and its active metabolite are 98% to 99% protein-bound in the dog and may displace warfarin from plasma proteins.

Dosages

DOGS:

NSAID (extra-label):

a) Acute pain: 4 mg/kg once daily SC, IM, or PO for 3 to 5 days. Chronic pain: 4 mg/kg, PO once daily for 3 to 5 consecutive days per week. The injectable is suggested for the first dose only.[5]

b) Injectable: 4 mg/kg SC once; if necessary, can repeat 4 mg/kg SC once 24 hours after initial injection. Oral: 4 mg/kg PO once daily for 3 days; oral treatment may be repeated once a week (ie, 3 days of medication followed by 4 days without medication). Oral and injectable treatments may be combined (ie, give initial injection of 4 mg/kg once SC followed 24 hours later by 4 mg/kg PO once daily for 3 days).[6,7]

CATS:

Acute pain (extra-label): 4 mg/kg once daily SC, IM, or PO for 3 to 5 days. The injectable is suggested for the first dose only.[5]

Anti-inflammatory; Adjunctive treatment of upper respiratory disease in association with antimicrobial therapy (injectable) or for treatment of febrile syndromes (oral); (extra-label): 4 mg/kg SC or PO (with food) once a day for 3 to 5 days. Injectable is labeled as a single injection or can be repeated 1 time.[6,8]

CATTLE:

NOTE: Other countries may have different withdrawal requirements; refer to the product label. This drug is not approved in the US, and its administration would not be legal unless a veterinarian could provide justification for its use.[9]

Pneumonia (extra-label): 2 mg/kg by IM injection high in the neck.[7] Treatment may be repeated once only after 48 hours. Another course of treatment should not be administered within 28 days. **DO NOT** inject cattle other than into muscle tissues high on the side of the neck. Meat withdrawal = 10 days (IM); Milk withdrawal = 12 hours

Acute mastitis (extra-label): 4 mg/kg as a single IV injection.[7] Meat withdrawal = 4 days (IV); Milk withdrawal = 12 hours

SWINE:

NOTE: Other countries may have different withdrawal requirements; refer to the product label. This drug is not approved in the United States, and its administration would not be legal unless a veterinarian could provide justification for its use.[9]

Metritis-mastitis-agalactia (extra-label): 2 mg/kg IM into the rump once.[7] Another course of treatment should not be administered within 21 days. Meat withdrawal = 6 days.[8] (Label Information; *Tolfejec*®—Troy Labs, Australia)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- The weekly dosing regimen (3 to 5 consecutive days per week for dogs) is important to follow to minimize the risks for side effects. Do not give longer to cats than your veterinarian prescribes.
- Should give oral medicine with food.
- Vomiting and diarrhea have been reported as side effects in dogs and cats.
- Report any changes in appetite, water consumption, or GI distress to your veterinarian.

Chemistry/Synonyms

Tolfenamic acid, a nonsteroidal anti-inflammatory agent in the anthranilic acid (fenamate) category, is related chemically to meclofenamic acid.

Tolfenamic acid may also be known as acidum tolfenamicum, *Bifenac*®, *Clotam*®, *Clotan*®, *Fenamic*®, *Flocur*®, *Gantil*®, *Migea*®, *Polmonin*®, *Purfalox*®, *Rociclyn*®, *Tolfamic*®, *Tolfedine*®, *Tolfejec*®, or *Turbaund*®.

Storage/Stability

Unless otherwise labeled, store tolfenamic acid products at room temperature. Protect from light. Refer to the injectable product label for discard dating following the first vial puncture.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the United States; in New Zealand, Australia, UK, and/or Europe: Tolfenamic Acid Tablets: 6 mg, 20 mg, and 60 mg; Tolfenamic Acid Oral Suspension: 20 mg/mL; and Tolfenamic Acid Injection: 40 mg/mL are available.

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Toltrazuril

(tole-***traz***-yoo-ril) *Baycox*®

Antiprotozoal/Anticoccidial

Prescriber Highlights

- ► Approved in some countries for treating coccidial infections in calves, lambs, piglets, and poultry
- ► Not commercially available in the United States; must be legally imported or compounded by a reputable pharmacy
- ► May be considered as an alternative for treating coccidiosis in companion animals (eg, dogs, cats, and rabbits) and the oocyst shedding stage of toxoplasmosis in cats
- ► Adverse effect profile not well described, but appears relatively safe

Uses/Indications

Toltrazuril is an antiprotozoal agent that is approved in some countries to treat *Isospora suis* in piglets and coccidiosis in lambs (*Eimeria crandalis* and *Eimeria ovinoidalis*) and calves (*Eimeria bovis* or *Eimeria zuernii*). The drug also may be considered as an alternative treatment for coccidiosis in dogs, cats, camelids, birds, rabbits, mice, and reptiles.

Toltrazuril has activity against parasites of the genus *Hepatozoon* spp, but other drugs (eg, imidocarb, primaquine, doxycycline) are generally used. Toltrazuril can induce initial excellent clinical responses in dogs with American canine hepatozoonosis (ACH) but

cannot completely eliminate the parasites, and remission is transient in most dogs.[1] A combination of toltrazuril and emodepside (*Procox®*) with clindamycin reduced infectivity but did not completely clear the organism.[2] Toltrazuril has been used for treating the oocyst shedding stage of toxoplasmosis in cats.

Although toltrazuril has been used to treat equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*, the use of FDA-approved products (eg, ponazuril, pyrimethamine/sulfadiazine) is preferred.

Toltrazuril failed to eradicate *Neospora caninum* in congenitally infected lambs.[3]

Pharmacology/Actions

Toltrazuril is the parent compound to ponazuril (toltrazuril sulfone). Its mechanism of action is not well understood, but it appears to inhibit protozoal enzyme systems and cell division and damages intracellular structures. Light and electron microscope studies show that toltrazuril is active against all intracellular stages of coccidia, including schizonts and micro- and macrogamonts.[4] It interferes with the division of the protozoal nucleus and the activity of the mitochondria, and damages the wall-forming bodies in the microgametes. Toltrazuril produces severe vacuolization of the protozoal endoplasmic reticulum in all intracellular development stages.

Toltrazuril has activity against *Hepatozoon* spp, *Isospora* spp, *Sarcocystis* spp, *Toxoplasma* spp, and all intracellular stages of *Coccidia* spp.

Pharmacokinetics

Toltrazuril is slowly absorbed after oral administration. The highest concentrations are found in the liver; it is rapidly metabolized into the sulfone derivative (ponazuril). Plasma half-lives are 72 hours in calves, 170 hours in lambs, and 51 hours in piglets. There is little enterohepatic recirculation. It is primarily excreted in the feces.

In rabbits, the pharmacokinetics of toltrazuril were compared using a compounded toltrazuril formulation to improve solubility (prepared by solid dispersion technology using DMSO, PEG 400, and PEG 6000 as a carrier for drinking water) with a commercially available (in China) 0.5% premix product. With the compounded preparation, peak plasma levels were ≈3 times greater, and AUC was ≈2 times greater. The authors concluded that using toltrazuril prepared with solid dispersion technology could provide better anticoccidial activity via the attainment of higher blood concentrations.[5]

Contraindications/Precautions/Warnings

Toltrazuril should not be used in patients that have had prior hypersensitivity reactions to it or other triazinone (triazine) antiprotozoals (eg, ponazuril, diclazuril).

The principal metabolite of toltrazuril (toltrazuril sulfone, ponazuril) reportedly persists in the environment, and undiluted manure from treated animals can contaminate groundwater. There appears to be little risk for significant environmental contamination when toltrazuril is used in dogs, cats, or other companion animals (eg, pet birds, reptiles).

Do not confuse toltrazuril with toltrazuril sulfone (ponazuril) as the dosages differ.

Adverse Effects

Toltrazuril appears to be well tolerated in birds. An adverse effect profile in mammals is not well described. Potentially, GI signs could occur. Some horses receiving the related drug ponazuril developed blisters on their nose and mouth, and others developed a rash or hives during field trials.[6]

Reproductive/Nursing Safety

No reproductive or nursing safety information was located; weigh the potential risks versus benefits of use during pregnancy or lactation.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Doses up to 5 times the label recommendations in calves, lambs, and piglets resulted in no adverse hematologic or pathologic effects.[4] Doses of up to 10 times the label recommendations in horses were tolerated without significant adverse effects. Five times overdoses in poultry have been tolerated without clinical signs noted. Decreased water intake has been seen if overdoses are greater than 5 times.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

- None were reported.

Laboratory Considerations

- No issues were noted.

Dosages

DOGS:

Coccidiosis (extra-label): 10 – 30 mg/kg PO once daily for 1 to 3 days[7,8]

CATS:

Enteroepithelial cycle (oocyst shedding) of toxoplasmosis (extra-label): 5 – 10 mg/kg PO once daily for 2 days[9]

Coccidiosis (extra-label): 20 – 30 mg/kg PO once.[10] Repeating the dose in 10 days improves efficacy.

CATTLE:

Prevention of clinical signs of coccidiosis and reduction of coccidia shedding in calves on farms with a confirmed history of coccidiosis caused by *Eimeria bovis* or *Eimeria zuernii* (extra-label): 15 mg/kg PO once for each animal.[11] For the treatment of a group of animals of the same breed and same or similar age, the dosing should be done according to the heaviest animal of this group. To obtain maximum benefit, animals should be treated before the expected onset of clinical signs (ie, in the prepatent period). Not for calves weighing greater than 80 kg (176 lb) or in fattening units such as veal or beef calves. Not for dairy animals

SHEEP:

Prevention of clinical signs of coccidiosis and reduction of coccidian shedding in lambs on farms with a confirmed history of coccidiosis caused by *Eimeria crandallis* and *Eimeria ovinoidalis* (extra-label): 20 mg/kg PO as a single dose.[4] To obtain maximum benefit, sheep should be treated in the prepatent period before the expected onset of clinical signs. The prepatent period of *E ovinoidalis* is 12 to 15 days, and the prepatent period of *E crandalis* is 15 to 20 days. If animals are to be treated collectively rather than individually, they should be grouped according to their body weight and dosed accordingly. In order to maximize effectiveness, it is important to time therapy according to individual farm management and the lifecycle of the organism involved. Not for use in dairy sheep

CAMELIDS:

Coccidiosis caused by *Eimeria* spp (extra-label): 5 – 20 mg/kg PO once daily for up to 3 days. The higher doses and longer courses are for the treatment of individuals; the lower doses may be used for control.[12]

SWINE:

Preclinical coccidiosis due to *Isospora suis* in neonatal piglets

(extra-label): 20 mg/kg body weight PO once at 3 to 4 days of age.[4] Weigh 3 representative litters at 3 days of age to determine an average piglet weight. Not for use in suckling or barbecue pigs

BIRDS:

Coccidiosis in chickens and turkey (extra-label): 7 mg/kg per day orally in drinking water for 2 consecutive days.[13] Consult product label for instruction on preparing and administering medication via drinking water systems. Do not use in laying birds producing eggs for human consumption

Coccidiosis in raptors (extra-label): 7 mg/kg PO once daily for 2 to 3 days[14]

SMALL MAMMALS:

Coccidiosis (extra-label):

a) **Rabbits**: In the study, a single oral dose of toltrazuril 2.5 mg/kg or 5 mg/kg PO reduced oocyte counts by 98.1% and 99.6%, respectively.[15] The authors concluded that there appeared to be no advantage to using the higher dose and 2.5 mg/kg PO once recommended.

b) **Mice**: Toltrazuril 0.5% 10 – 20 mg/kg PO given for 3 days, pause for 5 days, and then repeat once more[16]

c) **Guinea pigs**: Coccidiosis, 2.5 – 5 mg/kg PO twice, 5 days apart[17]

REPTILES:

Parasitism in bearded dragons (extra-label): 5 – 15 mg/kg PO once daily for 3 days[18]

Coccidiosis in tortoises (extra-label): 15 – 20 mg/kg PO every 48 hours for 3 months reduced mortality.[19]

Monitoring

- Clinical efficacy: fecal egg count reduction testing before and up to 10 to 14 days after treatment

Client Information

- Used to treat certain types of protozoal infections found in your animal's feces. Not currently available in the United States but may be legally imported by your veterinarian.
- This medicine may be given with food or on an empty stomach. If your animal vomits or acts sick after getting it on an empty stomach, give it with food or a small treat to see if this helps. If vomiting continues, contact your veterinarian.
- Avoid direct contact with the medication. Wear disposable gloves and wash hands after giving medication.
- This medicine appears to be well tolerated by all animals.
- Manure from treated animals contains residual medication that can negatively affect groundwater and the growth of certain crops. Manure from treated animals must be diluted with 3 times the amount of manure from untreated animals before being spread onto land.

Chemistry/Synonyms

Related to other antiprotozoals, such as ponazuril, toltrazuril is a triazinone (triazine) antiprotozoal (anticoccidial) agent. The commercially available (in Europe) 2.5% oral solution is an alkaline, clear, colorless to yellow-brown solution that also contains triethanolamine 30 mg/mL and polyethylene glycol 80.7 mg/mL. Toltrazuril has a molecular weight of 425.4.

Toltrazuril may also be known as Bay-Vi-9142, toltrazurilo, toltrazurilum, and *Baycox®*, *Cevauril®*, *Chanox® Multi, Tolracol®*, *Zorabel®*.

Storage/Stability

Store the 2.5% solution at temperatures at 25°C (77°F) or below. Store oral 5% suspensions at temperatures at 30°C (86°F) or below.

Dilutions in drinking water more concentrated than 1:250 (4 mL of the 2.5% solution to 1 L of water) may precipitate. After dilution, the resulting solution is stable for 24 hours. It is recommended to discard medicated drinking water not consumed after 24 hours.

Compatibility/Compounding Considerations

Do not mix toltrazuril solution for drinking water with other medications.[11,13]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the United States; in some countries, toltrazuril 2.5% (25 mg/mL) solution for dilution in drinking water and/or 5% (50 mg/mL) oral suspension are available. Refer to the specific product label for withdrawal times or other restrictions for use.

A combination oral suspension for dogs and cats containing toltrazuril and emodepside (*Procox®*) is also available in some markets. A combination injection product (*Forceris®*) containing toltrazuril and iron (as gleptoferrin) for use in piglets also may be available.

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Topiramate

(toe-***pie***-rah-mate) *Topamax®*

Anticonvulsant

Prescriber Highlights

- ► May be useful for refractory seizure disorders in dogs, particularly for partial seizure activity; may be of benefit in treating cats, but little information is available.
- ► Very short half-life in dogs (2 to 4 hours), but therapeutic activity may persist secondary to high affinity for receptors in the brain.
- ► Adverse effects may include GI distress, sedation, ataxia, inappetence, and irritability in dogs; in cats, sedation and inappetence have been noted.
- ► Expense may be an issue, but generic products are now available.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies topiramate as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Topiramate may be useful for treating refractory seizures in dogs, particularly partial seizure activity. It may also be of benefit in treating cats, but little information is available. A case report of a cat with feline idiopathic ulcerative dermatitis treated with topiramate has been published.[1]

Pharmacology/Actions

Although the exact mechanism for its antiseizure action is unknown, topiramate possesses three properties that may play a role in its activity: Topiramate blocks, in a time-dependent manner, action potentials elicited repetitively by a sustained depolarization of neurons; it increases the frequency that GABA activates $GABA_A$ receptors; and it antagonizes the kainite/AMPA receptors without affecting the NMDA receptor subtype. Topiramate's actions are concentration-dependent; effects can first be seen at 1 micromole and maximize at 200 micromoles. Topiramate is a weak inhibitor of carbonic anhydrase isoenzymes CA-II and CA-IV; it is believed that this effect does not contribute significantly to its antiepileptic actions but may influence the drug's adverse effect profile.

Pharmacokinetics

In dogs, topiramate is rapidly absorbed after oral administration, but

absolute bioavailability varies between 30 and 60%. Half-life ranges from 2 to 4 hours after multiple doses.[2] Comparatively, the half-life in humans is ≈21 hours in adults, but shorter in children.[3] In humans, the drug is not extensively metabolized and is ≈70% is excreted unchanged in the urine.

No information on sustained-release topiramate product (eg, 24-hour topiramate sprinkles) pharmacokinetics in dogs or cats was located.

Contraindications/Precautions/Warnings

Topiramate is contraindicated in patients hypersensitive to it.[3] In humans, topiramate should be used with caution in patients with impaired hepatic or renal function.

The National Institute for Occupational Safety and Health (NIOSH) classifies topiramate as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[4]

Adverse Effects

Because this drug has not commonly been used in veterinary patients, an accurate adverse effect profile is not well described. In dogs, the most prevalent adverse effects reported include GI distress, sedation, ataxia, inappetence, weight loss and irritability; signs often subsided or lessened in severity over time.[5] In cats, sedation and inappetence have been noted.[1] A case of renal tubular acidosis in a cat has been reported, which resolved with discontinuation of topiramate and supportive care.[6]

In humans, the most likely adverse effects include somnolence, dizziness, nervousness, confusion, and ataxia. Rarely, acute myopia with secondary angle closure glaucoma has been reported. Incidence of kidney stones is ≈2 to 4 times higher in patients taking topiramate than in the general population. Topiramate can cause a hyperchloremic metabolic acidosis and reduce citrate excretion in the urine, thus increasing urine pH, leading to calcium phosphate renal calculi.

Reproductive/Nursing Safety

Teratogenic effects were noted in mice and rats given topiramate at dosages equivalent to those used in humans.[3] Topiramate enters maternal milk; use with caution in nursing patients.

Overdose/Acute Toxicity

Overdoses in humans have caused convulsions, drowsiness/lethargy, slurred speech, blurred and double vision, impaired mentation, stupor, ataxia, metabolic acidosis, hypotension, agitation, and abdominal pain.[3]

Clinical signs reported in dogs and cats with a topiramate overdose include lethargy, ataxia, and vomiting (cats).

Treatment consists of GI decontamination if the ingestion was recent, and supportive therapy. Hemodialysis enhances the elimination of topiramate from the body.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving topiramate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amitriptyline**: Topiramate may increase amitriptyline concentration.
- **Carbonic Anhydrase Inhibitors** (eg, **acetazolamide, dichlorphenamide**): Concurrent use may increase the risk for renal calculus formation.
- **CNS Depressant Drugs, Other** (eg, **acepromazine, cannabidiol, gabapentin, trazodone**): Other CNS depressant drugs may exacerbate the CNS adverse effects of topiramate.
- **Furosemide**: Concurrent use may increase the risk for hypokalemia.
- **Hydrochlorothiazide**: Concurrent use may result in increased topiramate exposure and increase the risk for hypokalemia.
- **Methenamine**: Topiramate may alter urine pH and decrease the efficacy of methenamine
- **Opioids** (eg, **buprenorphine, hydrocodone, tramadol**): May exacerbate the CNS adverse effects of topiramate
- **Phenobarbital**: Concurrent use may decrease topiramate serum concentration.
- **Posaconazole**: Concurrent use may result in increased topiramate plasma concentration and topiramate toxicity.

Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

Dosages

DOGS:

Add-on drug (to phenobarbital or bromides) for refractory epilepsy (extra-label): No controlled clinical studies were noted that support clinical use or any dosage. Initially, 2 mg/kg PO twice daily for 2 weeks, then increase to 5 mg/kg PO twice daily and continue for ≈2 months. If seizure frequency is not reduced by at least 50% (compared with prior to topiramate) and no adverse effects occurred, increase dose to 10 mg/kg PO twice daily. Reassess again after ≈2 months and if the prior criteria were met, increase dose to 10 mg/kg PO 3 times daily. Dogs that were responders received dosages within the range of 5 – 10 mg/kg PO twice daily.[5]

CATS:

Refractory epilepsy (extra-label): No controlled clinical studies were noted that support clinical use or any dosage. Anecdotally, 12.5 – 25 mg/cat (≈2.4 – 5 mg/kg) PO twice daily has been noted. To reduce adverse effects, dose is usually started low and increased as tolerated. Inappetence can be dose-limiting.

Feline idiopathic ulcerative dermatitis (extra-label): 5 mg/kg PO twice daily. From a case report, remission occurred within 4 weeks and control was maintained for 30 months. Two attempts to withdraw topiramate led to relapse within 24 hours.[1]

Monitoring

- Efficacy
- Adverse effects
- Plasma concentrations of topiramate are usually not monitored in humans, but therapeutic levels are thought to range from 2 to 25 mg/L.

Client Information

- Give this medicine as directed by your veterinarian. Do not skip doses. Try to give the medicine at the same time each day.
- This medicine may be given with or without food. If your animal vomits or acts sick after getting it on an empty stomach, give the medicine with food or small treat to see if this helps. If vomiting continues, contact your veterinarian.
- Do not suddenly stop giving this medicine to your animal or seizures may occur again.
- It is recommended to maintain a seizure diary to help determine how well this medicine is working.
- Possible side effects may include gastrointestinal distress (nausea, vomiting, loss of appetite) or sedation (sleepiness, lack of energy). Report these or any other unexpected changes to your veterinarian right away.

- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

A sulfamate-substituted derivative of D-fructose antiepileptic, topiramate occurs as a white crystalline powder with a bitter taste. Its solubility in water is 9.8 mg/mL; it is freely soluble in alcohol.

Topiramate may also be known as McN-4853, RWJ-17021, *Epitomax®*, *Topamac®*, *Topamax®*, or *Topimax®*.

Storage/Stability

Topiramate tablets should be stored in tight containers at room temperature (15°C-30°C [59°F-86°F]); protect from moisture. Topiramate sprinkle capsules should be stored in tight containers at temperatures below 25°C (76°F); protect from moisture.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Topiramate Oral Tablets and Caplets: 25 mg, 50 mg, 100 mg, and 200 mg; *Topamax®*, *Topiragen®*, generic; (Rx)

Topiramate Sprinkle Capsules: 15 mg and 25 mg; *Topamax® Sprinkle*, generic; (Rx)

Topiramate Sprinkle Capsules Extended-Release (24-hr for humans): 25 mg, 50 mg, 100 mg, 150 mg, and 200 mg; *Qudexy XR®*, *Trokendi® XR*, generic; (Rx)

Topiramate Oral Solution: 25 mg/mL in 473 mL bottle; *Eprontia®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Torsemide

(***tor***-se-myde) *Demadex®*

Loop Diuretic

Prescriber Highlights

- ► Used as adjunctive treatment of CHF in dogs and cats, especially in cases that have stopped responding to furosemide
- ► ≈10 to 20 times more potent than furosemide with longer diuretic action
- ► Contraindicated in patients with anuria, hypersensitivity, dehydration, or serious electrolyte depletion
- ► Adverse effects include GI (vomiting, diarrhea, anorexia) and renal effects (polyuria, increased renal values, renal insufficiency or failure).

Uses/Indications

Torsemide is a loop diuretic similar to furosemide but is ≈10 to 20 times more potent, and its diuretic effects can persist for a longer period (≈12 hours). Therefore, the starting dose should be 5% to 10% of the required furosemide dose, and dosing frequency may be reduced.[1] It may be a useful adjunctive treatment for congestive heart failure (CHF) in dogs and cats, particularly in patients that have become refractory to furosemide.

The parenteral form of torsemide has been discontinued in the US, so use is limited to oral therapy.[2]

In dogs, torsemide is an option for dogs with myxomatous mitral valve disease (MMVD) in stages C and D of heart failure, which are no longer responsive to furosemide.[3] A study in dogs with MMVD that compared oral furosemide vs oral torsemide (dosed at 10% of the furosemide dose divided into twice-daily doses) concluded that torsemide is equivalent to furosemide at controlling clinical signs of CHF and is likely to achieve greater diuresis vs furosemide.[4] Two larger-scale studies have also found that torsemide given every 24 hours is noninferior to furosemide for MMVD dogs with CHF.[5,6] In dogs with first-time CHF related to MMVD that were naïve to diuretics, torsemide was noninferior to furosemide for reducing pulmonary edema and clinical cough scores without worsening of dyspnea or exercise intolerance.[6] Torsemide was associated with a 64% reduction in risk for cardiac death, euthanasia due to worsening CHF, or study withdrawal due to worsening CHF. However, adverse effects were more frequent in dogs receiving torsemide. Another study in dogs with CHF related to MMVD found torsemide to be noninferior to furosemide based on clinical improvement or stabilization of CHF.[5] Additionally, torsemide was associated with a 2-fold reduction in risk for reaching the composite cardiac endpoint (spontaneous cardiac death, euthanasia for HF, or CHF class worsening) within the first 12 weeks of treatment compared to furosemide.[5]

A small retrospective study found that torsemide was tolerated in cats with spontaneous CHF as first-line and second-line treatments.[7]

One pharmacokinetic study in horses concluded that torsemide might be a reasonable alternative to furosemide because of good absorption after oral administration, reasonable half-life, and sustained diuretic effect.[8]

Pharmacology/Actions

Torsemide, like furosemide, inhibits sodium and chloride reabsorption in the ascending loop of Henle via interference with the chloride-binding site of the 1Na+, 1K+, 2Cl- cotransport system.

Torsemide increases renal excretion of water, sodium, potassium, chloride, calcium, magnesium, hydrogen, ammonium, and bicarbonate. Torsemide is able to suppress almost total water reabsorption in dogs.[1] In healthy dogs, diuretic resistance developed after 14 days of furosemide but not torsemide.[9]

In dogs, excretion of potassium is affected much less than sodium (20:1); this is ≈2 times the ratio of Na:K excreted than with furosemide. The diuretic activity begins within 1 hour of dosing, peaks at ≈2 hours, and persists for ≈12 hours. In dogs, torsemide appears to have differing effects on aldosterone than furosemide. When compared to furosemide, torsemide increases plasma aldosterone levels and inhibits the amount of receptor-bound aldosterone; however, additional research must be performed to determine the clinical significance of these effects.

In cats, torsemide's effects on potassium excretion appear to be similar to that of furosemide. Peak diuresis occurs ≈4 hours postdose and persists for 12 hours.[10]

Pharmacokinetics

Limited information is available. Oral bioavailability has been reported to be between 80% and 100% in dogs and cats. Plasma protein binding in dogs is greater than 98%. ≈60% of the dose is excreted unchanged in the urine.[11] Elimination half-life in dogs is ≈10 hours and is ≈13 hours in cats.[1,12]

In horses, 1 study found that torsemide was orally absorbed and reached plasma concentrations similar to those reported in dogs, rabbits, rats, and humans. A single dose of 6 mg/kg PO resulted in a maximum plasma concentration of 10.14 µg/mL ≈3 hours after dos-

ing and a half-life of 9.2 hours.[8]

In humans, torsemide has high oral bioavailability; patients may be switched between IV and PO forms with no change in dose. Bioavailability in dogs has been reported at 80% to 100%. It is extensively bound to plasma proteins in humans (greater than 99%). The major metabolite in humans is the carboxylic acid derivative, which is biologically inactive.

Contraindications/Precautions/Warnings

Torsemide should not be used in patients with known hypersensitivity to it or other sulfonylureas. Caution in patients with other sulfonamide hypersensitivities; cross-reactivity between antibiotic sulfonamides and non-antibiotic sulfonamides is theoretically possible.[13] Torsemide should not be used with other loop diuretics, in dehydrated or hypovolemic patients, or in anuric patients.[11]

Use torsemide cautiously in patients with significant hepatic dysfunction, hyperuricemia (may increase serum uric acid), or diabetes mellitus (may increase serum glucose). Torsemide can cause excessive diuresis that could potentially cause symptomatic dehydration, decreased blood volume and hypotension, and worsening renal function. Acute renal failure is possible; concomitant use of nephrotoxic drugs increases this risk. Symptomatic electrolyte abnormalities are possible. Use of torsemide at higher than recommended doses, in patients with severe renal impairment, or patients with hyponatremia may increase the risk for ototoxicity.[14]

Adverse Effects

Adverse effect profiles for dogs and cats have not been fully established because of the limited use of this drug in veterinary medicine. In clinical studies, the most common adverse effects seen were GI effects (vomiting, diarrhea, anorexia) and renal effects (polyuria, increased renal values, renal insufficiency or failure).[5,6] One study in healthy dogs given torsemide daily for 26 weeks reported dose-dependent adverse effects, including dryness of oral mucosa, decreased food intake, increased water intake, electrolyte imbalances, increased urine pH, decreased urine specific gravity, and increased serum aldosterone concentrations.[15] In healthy dogs, diuretic resistance developed after 14 days of furosemide but not torsemide, and both drugs were associated with increased BUN and plasma creatinine concentrations when compared with values before treatment.[9]

Torsemide can induce fluid and electrolyte abnormalities. Patients should be monitored for hydration status and electrolyte imbalances (especially potassium, calcium, magnesium, and sodium). Prerenal azotemia may result if moderate to severe dehydration occurs. Hyponatremia is probably the greatest concern, but hypocalcemia, hypokalemia, and hypomagnesemia may all occur. Animals with normal food and water intake are much less likely to develop water and electrolyte imbalances than those that do not.

Other potential adverse effects include hematologic effects (eg, anemia, leukopenia), weakness, and restlessness. Torsemide, unlike furosemide, apparently only rarely causes significant ototoxic effects in humans; high doses in laboratory animals have induced ototoxicity.

Reproductive/Nursing Safety

No effects on fertility were noted when female and male rats were administered up to 25 mg/kg/day.

No adverse teratogenic effects were seen when pregnant rats and rabbits were administered up to 15 times (human dose) and 5 times (human dose), respectively. Larger doses increased fetal resorptions, decreased average body weight, and delayed fetal ossification.

It is unknown if torsemide enters milk, but furosemide is distributed in milk. Clinical significance for nursing offspring is unknown.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In dogs, the oral LD_{50} is greater than 2 g/kg. Fluid and electrolyte imbalance is the most likely risk associated with an overdose. Consider GI decontamination for very large or quantity unknown ingestions. Acute overdoses should generally be managed by observation with fluid, electrolyte, and acid-base monitoring; supportive treatment should be initiated if required.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving torsemide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs**; eg, **enalapril, benazepril**): Slightly increased risk for hypotension, particularly in patients that are volume or sodium depleted secondary to diuretics
- **Aminoglycosides** (eg, **gentamicin, amikacin**): Other diuretics have been associated with increasing the ototoxic or nephrotoxic risks of aminoglycosides. It is unknown if torsemide can also have these effects and, if so, what the clinical significance may be.
- **Amphotericin B**: Loop diuretics may increase the risk for nephrotoxicity development.
- **Cholestyramine**: Concomitant administration may decrease torsemide absorption; administer separately.
- **Cisplatin**: Concomitant use may increase the risk for worsening renal function or renal failure.
- **Corticosteroids** (eg, **dexamethasone, predniso(lo)ne**): Increased risk of hypokalemia
- **Digoxin**: Can increase the area under the curve of torsemide by 50% but is unlikely to be of significance clinically; torsemide-induced hypokalemia may increase the potential for digoxin toxicity.
- **Iohexol**: Increased risk for nephrotoxicity
- **Nonsteroidal anti-inflammatory drugs** (**NSAIDs**; eg, **carprofen, flunixin**): NSAIDs may reduce the natriuretic effects of torsemide. Concomitant use with NSAIDs may increase the risk for worsening renal function or renal failure.
- **Probenecid**: Can reduce the diuretic efficacy of torsemide.
- **Salicylates** (eg, **aspirin**): Torsemide can reduce the excretion of salicylates.

Laboratory Considerations

Torsemide can affect **serum electrolytes, glucose, uric acid,** and **BUN** concentrations.

Dosages

DOGS/CATS:

Diuretic for adjunctive treatment of heart failure (extra-label): Initial dose 0.1 – 0.3 mg/kg PO every 24 hours.[3,5–7] Torsemide dosages are ≈5% to 10% of furosemide doses, as torsemide is ≈10 to 20 times more potent than furosemide; if switching from furosemide, torsemide dose should be started at 5% to 10% of the total daily furosemide dose.

HORSES:

Diuretic for fluid overload (extra-label): Based on a pharmacokinetic study, 0.5 – 1 mg/kg PO every 12 hours appears to be a reasonable starting dose.[8]

Monitoring
- Serum electrolytes, BUN, creatinine, glucose (if diabetic)
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema, patient weight, if indicated

Client Information
- While taking this medicine, your animal will drink and urinate more often than usual. Be sure your animal always has access to freshwater. You may give this medicine with or without food.
- While your animal is taking this medicine, your veterinarian will need to monitor your animal closely. Do not miss these important follow-up visits.
- Contact your veterinarian immediately if you notice excessive thirst, weakness, collapse (passing out), head tilt, lack of urination, or a racing heartbeat.

Chemistry/Synonyms
Torsemide is a lipophilic anilinopyridine sulfonylurea loop diuretic that occurs as white to off-white, crystalline powder. It is practically insoluble in water and slightly soluble in alcohol.

Torsemide may also be known as torasemide, AC-3525, AC 4464, BM-02.015, JDL-464, and *Demadex®*. International trade names include *Isemid®*, *Torem®*, and *Unat®*.

Storage/Stability
Store torsemide tablets below 40°C (104°F); preferably between 15°C and 30°C (59°F and 86°F).

Compatibility/Compounding Considerations
No specific information was noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE IN THE US.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Torsemide Oral Tablets: 5 mg, 10 mg, 20 mg, and 100 mg; *Demadex®*, generic; (Rx)

Torsemide Injection: 10 mg/mL; generic; (Rx). **NOTE**: This product has been discontinued.

Tramadol

(***tram***-ah-doll) *Ultram®*

Opioid Agonist

Prescriber Highlights
- ► Synthetic mu-receptor partial opioid agonist that also inhibits the reuptake of serotonin and norepinephrine
- ► Appears useful as an analgesic in cats, but studies in dogs provide conflicting evidence of analgesia; may take up to 2 weeks for full analgesic activity in chronic pain states
- ► It is contraindicated in patients hypersensitive to it and other opioids, and in those with GI obstruction. Use with caution in patients with a history of seizures or patients receiving other CNS or respiratory depressants.
- ► Appears well tolerated in dogs; sedation is the most likely adverse effect.
- ► Several potential clinically significant drug interactions exist; avoid use with selective serotonin reuptake inhibitors (SSRIs; eg, fluoxetine) or monoamine oxidase inhibitors (MAOIs; eg, selegiline).
- ► DEA Schedule IV (C-IV) controlled substance

Uses/Indications
Tramadol is used for adjunct treatment of postoperative or chronic pain in many species. It is most useful when used in combination with NSAIDs or other analgesic drugs (eg, amantadine, gabapentin, alpha-2 agonists).[1] Tramadol use as an analgesic was widely adopted in veterinary medicine in part based on its low cost and previous status as a noncontrolled drug; however, evidence of efficacy is conflicting and studies demonstrating tramadol's efficacy as a sole analgesic[2–5] are outweighed by studies that cite its limitations.[1,6–11] A meta-analysis that reviewed the efficacy of tramadol for postoperative pain management in dogs found that tramadol likely results in a decreased need for rescue analgesia compared to no treatment or placebo, but the certainty of the evidence was determined to be low.[12] Studies of tramadol in dogs with osteoarthritis did not show benefits compared to placebo.[10,13] Anecdotally, tramadol has also been used as an anti-tussive agent; however, evidence of efficacy is lacking.

Tramadol's efficacy as an analgesic in cats is more robust.[14–19]

In horses, tramadol administered as an epidural may also be useful as an analgesic, but no appropriate commercial dosage forms are available in the United States; however, studies evaluating the antinociceptive effects in horses after IV administration have found that IV tramadol is not an effective analgesic in horses when used alone.[20,21] Some studies have shown benefits when used in combination therapy.[21,22] In donkeys, tramadol used with lidocaine as an epidural has a shorter onset and longer duration of action than when lidocaine is used alone.[23]

Tramadol administered systemically in sheep, camels, and camelids has noticeable adverse effects and a lack of efficacy and should not be used in those species.[24–28]

Pharmacology/Actions
Tramadol is a centrally acting partial opioid agonist with primarily mu-receptor activity. It also weakly inhibits the reuptake of serotonin and norepinephrine. Analgesic activity is due to the parent compound and its active metabolite, M1 (O-desmethyltramadol [ODT]). When compared with tramadol in laboratory animal studies, M1 was 20 times more potent in binding to mu receptors and was 6 times more potent as an analgesic.

Naloxone only partially antagonizes the analgesic effects of tramadol; other partial antagonists include yohimbine and ondansetron.

Pharmacokinetics

Bioavailability is ≈65% after oral administration of immediate-release tablets in dogs, but there is significant interpatient variability. Rectal bioavailability is ≈10%. The volume of distribution (V_D), total body clearance, and half-life are 3.8 L/kg, 55 mL/kg/minute, and 1.7 hours, respectively.[29] Tramadol is extensively metabolized via several pathways to at least 20 metabolites. The active M1 metabolite is formed by cytochrome P450 2D15 (CYP2D15) but is a minor metabolite in dogs.[30,31] M1 has a half-life of ≈2 hours after oral tramadol administration.[29] Dogs appear to produce substantial quantities of the inactive metabolite M2 via CYP2B11. M1 and M2 are further metabolized to M5 (N,O-didesmethyltramadol) via CYP2C21 and 2D15.[30,32] Pharmacokinetics of tramadol have been reported for young and middle-aged dogs. After IV administration at 4 mg/kg, the V_D, elimination half-life, and total body clearance were 4.77 ± 1.07 L/kg, 1.91 ± 0.26 hours, and 29.9 ± 7.3 mL/kg/minute, respectively, in young dogs and 4.73 ± 1.43 L/kg, 2.39 ± 0.97 hours, and 23.7 ± 5.4 mL/kg/minute, respectively, in middle-aged dogs. Excretion was significantly prolonged in older animals.[33] In greyhounds, tramadol's half-life is slightly shorter (ie, 1.1 hours).[34]

After intranasal administration in dogs, tramadol was rapidly absorbed into the systemic circulation, becoming detectable after 5 minutes and reaching maximum concentrations ≈40 minutes after administration. Bioavailability was determined to range from 3.3% to 20.6%. In general, plasma concentrations were low and variable. Tramadol half-life was ≈1 hour. M1 was largely undetectable. Plasma concentrations were low, and because they did not correlate with analgesic effect it was hypothesized that tramadol bypassed systemic circulation and traveled directly to the CNS.

A study of 8 cats that received the immediate-release oral tablet showed high interpatient variability in absorption (2 cats had inadequate data and could not be analyzed). The main metabolite produced in cats is the active M1 metabolite. The elimination half-life for the parent compound was ≈2.25 to 3.5 hours and was 4.5 hours for the M1 metabolite.[35] Another study in 6 cats demonstrated the following approximate values: 60% oral bioavailability, 2 L/kg volume of distribution at steady state (V_{SS}), 12 mL/kg/minute clearance, and 3.2 hours terminal half-life. The terminal half-life of M1 after oral administration was ≈4.8 hours. After transdermal application of a compounded tramadol gel, a dose of ≈2.8 mg/kg resulted in undetectable or very low plasma concentrations.[36]

In adult horses, tramadol had relatively poor oral absorption (≈3% to 10%)[37,38] and an elimination half-life of ≈1.5 to 2.5 hours after IV or IM administration and up to 10 hours when given orally.[37–41] The M1 active metabolite half-life was ≈4 hours. Oral doses of 10 mg/kg yielded concentrations of tramadol and M1 that are believed to be therapeutic, whereas lower doses (3 to 6 mg/kg) were inconsistent and transient.[41–44] M2 appears to be the main metabolite produced by horses, with very low and variable M1 concentrations.[37,45] In donkeys given single IV doses of 2 mg/kg, the half-life of the parent compound was ≈1 hour, and the halflife of the M1 metabolite was ≈8.5 hours.[46]

Tramadol has different pharmacokinetics in neonatal and weaned foals. After oral administration, higher bioavailability (53% vs 20%), shorter time to peak concentration (1 hour vs 1.25 hours), and peak levels occurred with neonatal (2 weeks of age) vs weaned (4 months of age) foals. The elimination half-life did not significantly differ (≈2 hours). The active metabolite (M1) remained above the reported therapeutic concentration for humans for 3 hours in neonatal foals and 8 hours in weaned foals.[47] In another study, the elimination half-life was ≈1.5 hours in foals up to 6 weeks of age.[48]

In llamas administered 2 mg/kg IV, tramadol and M1 pharmacokinetics values (approximate means) were: V_{SS}, 4 L/kg and 26.5 L/kg; clearance, 1.7 L/kg/hour and 2.03 L/kg/hour; half-life, 2.1 hours and 10.4 hours. IM (2 mg/kg) bioavailability was high.[49] Data in camels were similar to those in llamas.[24] In alpacas, oral bioavailability was poor (6% to 19%).[28] After IV administration (3.4 to 4.4 mg/kg), V_D was 5.50 ± 2.66 L/kg, total body clearance was ≈4.6 L/kg/hour, and half-life was ≈0.9 hours. The M1 metabolite was not detected.

The elimination half-life of tramadol in sheep receiving IV tramadol (4 and 6 mg/kg) was 0.6 hours and 1.2 hours for M1.[27] Bioavailability in goats given tramadol at 2 mg/kg IV and PO was 37%, and the half-life was ≈1 hour (IV) and 2.7 hours (PO). The M1 half-life was 2.9 hours after IV administration but was undetectable after oral administration.[50]

In red-tailed hawks given an oral dose of 11 mg/kg, plasma levels of tramadol reached or exceeded concentrations associated with analgesia in humans for at least 4 hours after administration. The elimination half-lives were 1.3 hours (tramadol) and 1.9 hours (M1).[51] Single IV doses given to Hispaniolan Amazon parrots resulted in half-lives of 1.54 hours (tramadol) and 2.55 hours (M2). Oral bioavailability was ≈24%.[52]

Contraindications/Precautions/Warnings

Tramadol is contraindicated in patients that are hypersensitive to it or other opioids. The combination product containing acetaminophen is contraindicated in cats. In humans, the drug is contraindicated in patients with GI obstruction or paralytic ileus and in children younger than 12 or undergoing tonsillectomy or adenoidectomy.

Caution should be used when tramadol is given in conjunction with other drugs that can cause CNS or respiratory depression. Because tramadol has caused seizures in humans, it should be used with caution in animals with pre-existing seizure disorders, at increased risk for seizures (eg, head trauma, CNS infections), or receiving other drugs that may reduce the seizure threshold. Similar to other opioidlike compounds, tramadol should be used with caution in geriatric or severely debilitated animals and in those with severe asthma. Animals with impaired renal or hepatic function may need dosage adjustments.

Although the risk for physical dependence is less than that of several other opioids, it has been reported in humans. The drug should be withdrawn gradually in animals that receive it chronically. Humans can potentially abuse tramadol, and significant diversion of the drug reportedly occurs. Clinicians should be alert to pet owners seeking tramadol.

Extended-release tablets, which are not currently recommended or used in veterinary patients, should not be broken, crushed, or chewed because toxicity could occur.

Care should be taken not to confuse traMADol with traZODone.

Adverse Effects

Tramadol appears to be well tolerated in dogs and appears to have fewer adverse effects than methadone or morphine.[53] Tramadol has the potential to cause a variety of adverse effects associated with its pharmacologic actions, including CNS effects (eg, excessive sedation, agitation, anxiety, tremor, dizziness) or GI effects (inappetence, vomiting, constipation, diarrhea).

Limited information is available on the adverse effects in cats. Vomiting, sedation, mydriasis, dysphoria or euphoria, and constipation have been reported. In a study, neurologic effects (eg, mydriasis, dysphoria) were seen in 25% of cats, and the drug was observed to be unpalatable to cats.[54] Unpalatability may lead to dose avoidance.

In horses, tramadol 5 mg/kg IV caused excitement[20]; ataxia and muscle spasms were more frequently seen in donkeys after 4 mg/kg IV administration.[46]

In humans receiving tramadol, ≈10% develop pruritus. Injectable tramadol may cause respiratory and cardiac depression.

Reproductive/Nursing Safety

Laboratory animals have experienced embryotoxicity and fetotoxici-

ty at doses administered 0.6 to 3.6 times the maximum daily human dose. Chronic tramadol administration in pregnant patients may result in opioid withdrawal in the offspring. Tramadol was embryotoxic and fetotoxic in laboratory animals when given at dosages 3 to 15 times the recommendation.

Humans receiving long-term opioid therapy have experienced hypogonadism, resulting in an impairment of reproductive functions.

Tramadol and its active M1 metabolite enter maternal milk. This drug is not recommended for use while nursing.

Overdose/Acute Toxicity

Acute oral overdoses can cause signs of CNS depression or serotonin syndrome. Clinical signs associated with an overdose in dogs include sedation/lethargy, vomiting, tachycardia, vocalizing, ataxia, agitation, or tremor. In cats, mydriasis, hypersalivation, lethargy, ataxia, tachycardia, and vomiting have been reported. Signs of serotonin syndrome due to overdose (80 mg/kg PO) have been described in a cat.[55]

Treatment is primarily supportive (eg, maintaining respiration, treating seizures with benzodiazepines or barbiturates). Naloxone may NOT be useful in tramadol overdoses, as it may only partially reverse some of the effects of the drug and may increase the risk for seizures. Naloxone did not decrease the drug's lethality in tramadol overdoses given to mice. Cyproheptadine and phenothiazines can be used to treat stimulatory signs. Tramadol and the M1 metabolite are not removed by dialysis.[56]

For patients that have experienced or are suspected of having experienced an overdose, it is strongly encouraged to consult with a 24hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Tramadol is metabolized by CYP2B, CYP2D, and CYP3A enzyme families. The following drug interactions have either been reported or are theoretical in humans or animals receiving tramadol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amantadine**: Concomitant use with tramadol may increase the risk for seizures because tramadol at high doses has caused seizures in humans[56], and amantadine can lower the seizure threshold[57]; however, an increased risk for seizures with this drug combination appears unlikely in a clinical setting at recommended dosages. Monitor for sedation or other neurologic adverse effects if using this combination.
- **Amiodarone**: May increase tramadol concentrations and decrease M1 (active metabolite) concentrations
- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate**): Concurrent use may increase the risk for anticholinergic effects (eg, constipation, urinary retention).
- **Antidepressants, Miscellaneous** (eg, **mirtazapine, trazodone**): Increased risk for serotonin syndrome
- **Antihistamines** (eg, **diphenhydramine, hydroxyzine, promethazine**): Increased risk for CNS depression
- **Azole Antifungals** (eg, **fluconazole, ketoconazole**): Fluconazole inhibits tramadol metabolism to the inactive M2 metabolite without inhibiting the formation of the active M1 metabolite. In dogs that were receiving fluconazole and that were given tramadol, tramadol and M1 concentrations increased by 31-fold and 39-fold, respectively.[58] Ketoconazole may increase tramadol exposure and risk for toxicity.[59]
- **Benzodiazepines** (eg, **alprazolam, diazepam**): Increased risk for respiratory depression
- **Cimetidine**: May increase tramadol exposure and risk for toxicity[59]
- **CNS Depressants, Miscellaneous** (eg, **dexmedetomidine, gabapentin, levetiracetam, methocarbamol**): Increased risk for CNS depression
- **Cyproheptadine**: May decrease efficacy of tramadol
- **Digoxin**: In humans, tramadol has been rarely linked to digoxin toxicity.
- **Erythromycin**: May increase tramadol exposure and risk for toxicity
- **Iohexol**: Concurrent use may increase the risk for seizures.
- **Ketamine**: Increased risk for CNS and respiratory depression
- **Metoclopramide**: Increased risk for seizures
- **Mitotane**: May reduce tramadol levels and efficacy
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, selegiline**): Potential for serotonin syndrome; MAOI use within the past 14 days or use together should be avoided.
- **Ondansetron**: In humans, use together may reduce the effectiveness of both drugs.
- **Opioid Analgesics** (eg, **buprenorphine, butorphanol, methadone**): May increase the risk for seizures, serotonin syndrome, and CNS and respiratory depression; methadone may inhibit tramadol metabolism.
- **Phenobarbital**: Increased risk for CNS depression. Tramadol may lower the seizure threshold. Phenobarbital may decrease tramadol levels.
- **Quinidine**: May increase tramadol concentrations and decrease M1 (active metabolite) concentrations
- **Rifampin**: May reduce tramadol levels and efficacy
- **S-Adenosyl Methionine (SAMe)**: Theoretically, concurrent use of SAMe with tramadol could cause additive serotonergic effects.
- **Sevoflurane**: Pretreatment with tramadol reduced minimum alveolar concentration (MAC) values by 22% to 30% in dogs[60,61] and 40% in cats.[62]
- **Selective-Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine, paroxetine, sertraline**): Can inhibit the metabolism of tramadol to its active metabolites, thereby decreasing its efficacy and increasing the risk for toxicity (serotonin syndrome, seizures)
- **Terbinafine**: May increase tramadol levels and reduce the formation of M1 metabolite due to CYP2D6 inhibition. In humans, this effect may persist for weeks after discontinuing terbinafine.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Increased risk for seizures and serotonin syndrome; amitriptyline may inhibit tramadol metabolism.
- **Yohimbine**: May antagonize (partial) the pharmacologic effects of tramadol
- **Warfarin**: In humans, increased prothrombin time in patients taking tramadol has been reported (relatively rare).

Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

Dosages

DOGS:

Analgesic (extra-label): 4 – 10 mg/kg PO every 8 hours; pharmacokinetic data suggest administration every 6 hours may be necessary. Tramadol's efficacy as a single agent appears questionable. The long-term efficacy of tramadol may decrease with time.[10]

CATS:

Analgesic (extra-label): Most recommendations for administra-

tion in cats are 1 – 2 mg/kg PO every 12 hours. There is no clear dosage for tramadol in cats based on prospective studies. Some clinicians suggest that some cats may only need to be dosed every 24 hours; others suggest doses up to 4 mg/kg. Tramadol has an unpleasant taste, and avoidance may be an issue. Neurologic and opioid adverse effects can be seen, particularly in geriatric cats at doses greater than 2 mg/kg.[17]

HORSES:

Analgesic (extra-label):

a) Based on pharmacokinetic studies and treated patients: 10 mg/kg PO every 12 hours[41–44]

b) **Chronic laminitis pain**:

i. 5 – 10 mg/kg PO every 12 hours,[42,63] although the 5 mg/kg dose did not reliably produce analgesia.[42]

ii. Tramadol 5 mg/kg PO twice daily for 7 days—with ketamine 0.6 mg/kg/hour IV CRI over 6 hours each day for the first 3 days of treatment.[63]

BIRDS:

Analgesic (extra-label):

a) **Red-tailed hawks**: From a pharmacokinetic study, authors concluded that an oral dose of 15 mg/kg PO every 12 hours would be a reasonable starting point; additional pharmacodynamic and repeat dose pharmacokinetic studies are needed.[51]

b) **Hispaniolan Amazon parrots**: From pharmacokinetic and antinociceptive studies, 30 mg/kg PO every 6 to 8 hours may provide clinical analgesia. Further studies are needed to fully evaluate the analgesic effects of tramadol in psittacines.[52,64,65]

SMALL MAMMALS:

Analgesic (extra-label):

a) **Sugar gliders**: 2 – 6 mg/kg PO every 12 hours[66]

b) **Chinchillas, guinea pigs, rodents**: 5 – 10 mg/kg PO every 12 hours[67]

c) **Companion pigs**: 4 – 6 mg/kg PO every 12 hours[68]

REPTILES:

Analgesic (extra-label):

a) **Red-eared slider turtles**: 5 – 10 mg/kg PO[69]

b) **Reptiles/chelonians**: 5 – 10 mg/kg PO every 48 to 72 hours. Good analgesic efficacy with relatively long duration when administered PO in chelonians; less respiratory depression than other opioids[70]

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Contact your veterinarian if you suspect your animal's pain is not controlled.
- This medicine may be given with or without food. Putting the medicine in a small amount of canned food may hide its bitter taste. If your animal vomits or acts sick after receiving this drug on an empty stomach, give the medicine with food or a small treat. If vomiting continues, contact your veterinarian.
- This medicine may cause changes in alertness or behavior. Use it with caution in working or service dogs.
- The combination product with acetaminophen (*Ultracet®*) should NOT be used in cats.
- Tramadol is a controlled substance in the United States. It is against the law to give away or sell this medication and to use it without a prescription.

Chemistry/Synonyms

Tramadol HCl, a mu-receptor opioid agonist, occurs as a white crystalline powder that is freely soluble in water or alcohol and very slightly soluble in acetone. Tramadol is not derived from opium, nor is it a semisynthetic opioid, but it is entirely synthetically produced.

Tramadol HCl may also be known as CG-315, CG-315E, tramadoli hydrochloridum, or U-26225A; many trade names are available.

Storage/Stability

Unless otherwise labeled, store tramadol tablets at a controlled room temperature of 20°C to 25°C (68°F-77°F); excursions are permitted between 15°C and 30°C (59°F-86°F). Dispense in tight, light-resistant containers. Tramadol is a controlled substance and should be stored in an area that is substantially constructed and securely locked, in accordance with US Drug Enforcement Administration regulations.

Compatibility/Compounding Considerations

Tramadol suspensions, 5 mg/mL[71] and 10 mg/mL,[72] made by crushing tramadol tablets and suspending in appropriate vehicles, have demonstrated potency and stability for up to 90 days when refrigerated or stored at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Tramadol HCl Oral Tablets (film-coated): 50 mg; *Ultram®*, generic; (Rx); (C-IV)

Tramadol HCl Extended-Release Tablets and Capsule: 100 mg, 200 mg, and 300 mg; *Ultram ER®*, *Ryzolt®*, generic [tablets], *ConZip®* [capsules]; (Rx); (C-IV). **NOTE**: Dogs apparently do not absorb these products as well as humans and potentially could overdose if they chew on the tablets or capsules.

Tramadol HCl Oral Solution: 5 mg/mL; *Qdolo®*; (Rx); (C-IV)

Tramadol is also available in a fixed-dose combination of tramadol HCl 37.5 mg and acetaminophen 325 mg tablets. United States trade name is *Ultracet®*; (Rx); (C-IV). **WARNING**: This combination product should **not** be used in cats.

In several countries outside the United States, tramadol injection is available commercially.

Tranexamic Acid

(tran-ex-***am***-ik ***as***-id) *Cyklokapron®, Lysteda®*

Fibrinolysis Inhibitor

Prescriber Highlights

► Used to prevent or reduce bleeding in dogs and cats
► Contraindications include hypersensitivity and in patients with a history of, risk for, or active thromboembolic disease.
► Causes dose-dependent vomiting; may be useful as an emetic
► Thromboembolic events and visual disturbances have occurred in humans.
► Inadvertent intrathecal administration is rapidly fatal.

Uses/Indications

Tranexamic acid is used to prevent and reduce postoperative bleeding and to stop traumatic bleeding in dogs and cats. It may be effective in controlling hyperfibrinolysis associated with *Angiostrongylus vasorum* infection.[1] It has also been used as an emetic in dogs.[2]

Pharmacology/Actions

Tranexamic acid reduces bleeding by inhibiting the breakdown of fibrin. It reversibly binds to lysine binding sites on plasminogen to prevent the binding of plasminogen to fibrin and thus prevents the formation of plasmin. Inhibiting plasmin-mediated fibrin dissolution stabilizes the blood clot matrix. In horses, tranexamic acid is ≈10 times more potent in vitro than aminocaproic acid; in dogs, it is ≈4 times more potent.[3,4] The minimum plasma concentration of tranexamic acid required to completely inhibit experimentally induced hyperfibrinolysis is ≈145 µg/mL in dogs[3] and ≈6 µg/mL in horses.[4]

Tranexamic acid is emetogenic in dogs, causing dose-dependent vomiting within 2 to 3 minutes of administration. Dogs vomited only once or twice, and the emetogenic effect persisted for 4 to 5 minutes.[2] In a larger cohort of dogs, vomiting occurred in 85% of dogs receiving tranexamic acid. The median time to onset of vomiting was ≈2 minutes, median duration of emesis was ≈2.5 minutes, and median of 2 episodes of emesis.[5] Emetogenic effects of tranexamic acid may be mediated by NK1 receptors.[2] It can antagonize GABA and glycine receptors, and these actions may contribute to its proconvulsive effect.[6]

Pharmacokinetics

No veterinary pharmacokinetic information was located.

In humans, tranexamic acid is ≈45% bioavailable after oral administration, with peak concentrations occurring at 3 hours.[7] Absorption appears unaffected by food. It is widely distributed with a volume of distribution of ≈0.4 L/kg. It passes into aqueous humor, breast milk, and crosses the placenta. It does not bind to plasma proteins. Tranexamic acid is not appreciably metabolized and is excreted unchanged in the urine with a terminal elimination half-life of ≈2 hours after IV administration[8] and ≈11 hours after oral administration.[8]

Contraindications/Precautions/Warnings

Tranexamic acid is contraindicated in patients that are hypersensitive to it and in patients with a history of, risk for, or active thromboembolic disease. In humans, it is contraindicated in patients with subarachnoid hemorrhage as cerebral edema has occurred.[7,8] Patients with renal impairment require dosage reduction.

In humans, inadvertent intrathecal administration has resulted in seizures and cardiac arrhythmias.[8] Thrombosis and thromboembolism have been reported with IV administration. Tranexamic acid should be discontinued if ocular or vision disturbances occur. Patients treated for upper urinary tract bleeding have developed ureteral obstruction caused by clot formation.

Adverse Effects

Vomiting can occur immediately or within minutes of IV administration, is dose dependent, and more likely with rapid IV bolus administration.[2,9] Administration of maropitant IV 10 minutes before treatment with tranexamic acid has been shown to prevent emesis.[10] Tonic-clonic seizures have been reported in dogs.[11,12]

In humans, nausea, vomiting, and diarrhea are dose related; musculoskeletal pain, thrombosis, and visual changes, including ocular or retinal occlusion, have been reported.[7,8] Hypotension can occur when administered IV too rapidly. Anaphylactic reactions have been reported, and convulsions have been reported during surgery.

Reproductive/Nursing Safety

Tranexamic acid crosses the placenta and reaches concentrations approximating those found in maternal blood.[7,8] No impairment of fertility or evidence of fetal harm was observed in studies with laboratory animals, including doses up to 4 times the maximum human oral dose; however, safe use of tranexamic acid during pregnancy has not been established.

Tranexamic acid is distributed into milk; use with caution in lactating patients or consider milk replacer.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

GI distress, hypotension, myoclonus, and thromboembolic events may occur. Retinal changes, including degeneration, have occurred in dogs, cats, and rats that received 3 to 40 times the human dose for 6 days to 1 year.[7,8] GI decontamination should not be necessary but can be considered in patients that did not vomit. Provide supportive and symptomatic treatment.

Inadvertent intrathecal administration can be rapidly fatal; contact an animal poison control center immediately.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tranexamic acid and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Chlorpromazine**: May increase risk for bleeding
- **Estrogens**: Increased risk for thrombotic events with combined use
- **Thrombolytics** (eg, **alteplase**): Concomitant use may reduce efficacy of both agents.

Laboratory Considerations

- None noted

Dosages

DOGS:

Adjunctive treatment of bleeding (extra-label): 10 mg/kg IV over 2 minutes, followed by 10 mg/kg/hour IV CRI for 3 hours[9]

Control of hyperfibrinolysis associated with *Angiostrongylus vasorum* infection (extra-label): 10 – 20 mg/kg IV over 15 to 20 minutes; repeat 6 to 8 hours later based on thromboelastography (TEG) testing[1]

Induce emesis (extra-label): In one study, 50 mg/kg IV bolus induced vomiting in all dogs (n = 10) without adverse effects; lower doses (20 – 40 mg/kg IV) were not uniformly effective to induce emesis.[2]

CATS:

Control of bleeding during surgical carcinoma and sarcoma removal (extra-label): 15 mg/kg IV bolus given during anesthetic induction reduced surgical blood loss and shortened the activated clotting time (ACT) without altering prothrombin time (PT) or activated prothrombin time (aPTT).[13]

Monitoring

- Thromboelastography (TEG analysis)
- Baseline and periodic CBC and platelets as indicated by clinical condition

- Vision changes or deficits

Client Information

- Humans have rarely experienced changes in vision or vision loss with this drug. It is unclear if this occurs in veterinary patients. Contact your veterinarian if you are concerned that your animal is developing vision problems.

Chemistry/Synonyms

Tranexamic acid is a synthetic lysine derivative that occurs as a white, crystalline powder. It is freely soluble in water and practically insoluble in alcohol. The solution for injection has a pH of 6.5 to 8.

Tranexamic acid is also known as CL-65336, acidum tranexamicum, *Cyklokapron®*, *Hexakapron®*, and *Lysteda®*.

Storage/Stability

Tranexamic acid tablets and injection should be stored at room temperature (20°C-25°C [68°F-77°F]), with excursions permitted between 15°C-30°C (59°F-86°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

According to the manufacturer, tranexamic acid injection is **compatible** with most solutions for infusion, including saline or balanced electrolyte solutions, carbohydrate solutions, amino acid solutions, and Dextran solutions; heparin may be added to tranexamic acid injection. Tranexamic acid injection should **NOT** be mixed with blood and is **incompatible** with penicillins (eg, penicillin G, ampicillin, piperacillin).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Tranexamic Acid for Injection: 100 mg/mL in 10 mL ampules and single-dose vials; *Cyklokapron®*, generic; (Rx)

Tranexamic Acid Tablets: 650 mg; *Lysteda®*, generic; (Rx)

Trazodone

(***traz***-oh-done) *Desyrel®*

Serotonin (5-HT_{2A}) Antagonist/Reuptake Inhibitor

Prescriber Highlights

- ► Antidepressant used for adjunctive treatment of behavior disorders (particularly those that are anxiety- or phobia-related) and to facilitate postoperative confinement in dogs; also used for transport- and examination-related anxiety in cats
- ► Commonly used as an anxiolytic prior to veterinary appointments in dogs and cats
- ► Efficacy in facilitating postoperative confinement in dogs has been described, although there may be a large placebo effect.
- ► Well tolerated after oral administration. IV use of compounded formulations in dogs and horses has resulted in aggression and excitation.

Uses/Indications

Trazodone may be useful in treating behavior disorders in small animals, particularly when it is used as an adjunctive treatment in patients that do not adequately respond to conventional therapies.[1] Trazodone appears to be effective in providing short-term relief of anxiety during hospitalization and postoperative confinement after orthopedic surgery[2,3]; however, a placebo-controlled study found no difference between postoperative dogs given trazodone and those given a placebo to facilitate calmness and ease of confinement.[4]

Trazodone is commonly used as an anxiolytic prior to veterinary appointments[5]; it is also used to reduce anxiety in high-stress situations (eg, shelter housing).[6]

A recent study showed that when trazodone was administered before induction of general anesthesia in healthy dogs undergoing orthopedic surgery, the hemodynamic and propofol-sparing effects of trazodone were comparable to those of acepromazine.[7] The use of trazodone premedication also demonstrated an isoflurane minimum alveolar concentration (MAC)-sparing effect in dogs.[8]

Trazodone has been used anecdotally to decrease the hyperesthetic effects associated with strychnine toxicity.

Pilot studies in cats suggest trazodone is an effective sedative[9,10] or anxiolytic and may improve tractability during veterinary examinations.[11] Systolic blood pressure was significantly decreased in healthy cats undergoing an echocardiogram, with no altered echocardiographic results.[10]

Trazodone use in horses undergoing stall rest and exhibiting adverse behaviors resulted in significant calming in 17 out of 18 horses.[12]

In humans, trazodone is used for treating depression, aggressive behavior, alcohol or cocaine withdrawal, panic disorder, migraines, and insomnia.

Pharmacology/Actions

Trazodone is classified as a 5-HT_{2A} and 5-HT_{2C} antagonist/reuptake inhibitor (SARI) that primarily potentiates serotonin activity in the CNS. In laboratory animals, trazodone is shown to selectively inhibit serotonin uptake by brain synaptosomes and potentiate behavior changes induced by the serotonin precursor 5-hydroxytryptophan. Trazodone can antagonize alpha-1 adrenergic receptors and reduce blood pressure. Because trazodone can antagonize 5-HT_2 receptors and cause their downregulation, it can augment the efficacy of selective serotonin reuptake inhibitors (SSRIs).[13] It has fewer anticholinergic effects as compared with tricyclic antidepressants and is among the antidepressants with the lowest seizure risk.

Pharmacokinetics

In dogs, administration of 8 mg/kg IV resulted in a mean volume of distribution of 2.53 L/kg, a mean elimination half-life of 169 minutes, and a mean plasma total body clearance of 11.15 mL/minute per kg.[14] Administration of 8 mg/kg PO resulted in bioavailability of 85% and an elimination half-life of 166 minutes; peak plasma concentrations occurred at 445 minutes (mean), but there was wide intersubject variation (± 271 minutes).

In horses, the oral bioavailability of trazodone powder (4 mg/kg mixed into moistened feed) was 63%.[15] Peak concentrations of trazodone and its active metabolite (ie, m-chlorophenylpiperazine [m-CPP]) were reached within 1.7 to 2.5 hours and 0.5 to 1.8 hours, respectively, following 7.5 or 10 mg/kg.[12,15] Active metabolite accounted for ≈1% to 4% of total drug exposure.[12] The terminal half-life of trazodone was 7 to 8 hours; the m-CPP half-life was more variable (ie, 4 to 7 hours)[12,15] and concentration-dependent.[12] Half-life was prolonged in 2 horses, and the authors suggested genetic polymorphism of cytochrome P450 enzymes as a possible explanation.[15]

In humans, the oral bioavailability of trazodone (tablets) is ≈65%; the presence of food increases absorption (ie, area under the curve

[AUC] is increased) but decreases C_{max} (ie, peak plasma concentration) and delays T_{max} (ie, time of peak concentration).[16] Peak plasma concentrations occur ≈1 hour after a dose when trazodone is given on an empty stomach and after ≈2 hours when given with food. Trazodone is ≈90% to 95% bound to plasma proteins. The volume of distribution ranges from 0.47 to 0.84 L/kg. Metabolization is extensive and occurs primarily in the liver. m-CPP is also an active metabolite in humans and is formed via oxidative cleavage by CYP3A4 and further metabolized to inactive compounds via CYP2D6. Excretion is mostly (ie, 70% to 75%) via renal mechanisms, with only a small amount (ie, 0.13%) excreted unchanged in the urine. ≈21% of a dose is excreted in feces. The elimination half-life of the parent compound is ≈7 hours.

Contraindications/Precautions/Warnings

Trazodone is contraindicated in patients that are hypersensitive to it or in those receiving, or that have recently used, monoamine oxidase inhibitors (MAOIs; see ***Drug Interactions***). Trazodone should be used with caution in patients with severe cardiac disease or hepatic or renal impairment. Trazodone may dilate the pupils, which could trigger an acute crisis in patients with angle-closure glaucoma.

Do not confuse traZODone with traMADol.

Adverse Effects

Trazodone appears to be well tolerated in most patients. In dogs, the most common adverse effects are GI disturbances (eg, nausea, vomiting, diarrhea, or colitis), ataxia, and sedation.[1,3,14] Tachycardia, increased anxiety, behavior disinhibition, and aggression have also been reported. Trazodone appears to exert qualitatively different and less pronounced cardiac conduction effects in dogs than do tricyclic antidepressants. Transient priapism in a dog has also been reported.[7]

In pharmacokinetic studies in horses, excitation, tremors, and ataxia were observed after trazodone 1.5 mg/kg was given IV (over 1 minute)[15]; and sedation occurred following oral administration of 4 mg/kg[15]; and oversedation, muscle fasciculations, and transient arrhythmias occurred after oral administration of 7.5 or 10 mg/kg.[12,15]

Trazodone alone is unlikely to cause serotonin syndrome at clinically used dosages, but it is possible when trazodone is used with other serotonergic drugs. The most common clinical signs observed with serotonin syndrome in dogs include (in descending order) vomiting, diarrhea, seizures, hyperthermia, hyperesthesia, depression, mydriasis, vocalization, death, blindness, hypersalivation, dyspnea, ataxia/paresis, disorientation, hyperreflexia, and coma.[17]

In humans, the most common adverse effects include lethargy or somnolence, blurred vision, confusion, dizziness, dry mouth, orthostatic hypotension, sweating, and hyponatremia. QT prolongation can occur but is much less common in humans treated with trazodone than those treated with tricyclic antidepressants. Priapism has been reported rarely in men taking trazodone.

Reproductive/Nursing Safety

Trazodone appears to be relatively safe to use during pregnancy. At very high doses (ie, 15 to 50 times the recommended dose) in rats and rabbits, some increase in fetal death/resorption rates and congenital abnormalities were noted.[16]

Trazodone is excreted into human milk at very low concentrations.[16]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located regarding trazodone overdoses in veterinary patients. Clinical signs associated with an overdose in dogs and cats commonly include sedation or lethargy, ataxia, and vomiting. In humans, the incidence of serious toxicity from trazodone overdose (alone) was low as compared with tricyclic antidepressant overdoses; however, in the event of a substantial overdose of trazodone, it is recommended to contact an animal poison control center for further guidance.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trazodone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Aspirin**: Increased risk for GI bleeding; monitoring is needed
- **Azole Antifungals** (eg, **ketoconazole, fluconazole**): May increase trazodone blood concentrations; concurrent use is contraindicated in humans.
- **Cisapride**: Increased risk for QT prolongation. Concurrent use is contraindicated in humans, but the incidence of QT prolongation in dogs and cats is unknown.
- **CNS Depressants** (eg, **alpha-2 agonists** [eg, **dexmedetomidine**], **benzodiazepines, opioids**): Use with trazodone may cause additive CNS depressant effects.
- **Digoxin**: Trazodone may increase digoxin concentrations.
- **Diuretics** (eg, **furosemide**): May increase risk for hyponatremia
- **Fluoroquinolones** (eg, **ciprofloxacin**): Increased risk for QT prolongation
- **Hypotensive Drugs** (eg, **amlodipine, enalapril, telmisartan**): Trazodone may increase reductions in blood pressure and cause hypotension.
- **Isoflurane**: Premedication with trazodone (8 mg/kg) 2 hours prior to induction resulted in a mean MAC reduction of 17%.[8]
- **Linezolid**: Increased risk for serotonin syndrome; concomitant use is contraindicated in humans.
- **Macrolide Antibiotics**: (eg, **erythromycin, clarithromycin**): May increase trazodone blood concentrations
- **Methylene blue**: Increased risk for serotonin syndrome; concomitant use is contraindicated in humans.
- **Mirtazapine**: Increased risk for CNS depression, serotonin syndrome, and/or QT prolongation
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, selegiline**): Increased risk for serotonin syndrome; concurrent use is contraindicated in humans.
- **Metoclopramide**: Increased risk for serotonin syndrome
- **Ondansetron**: Increased risk for QT prolongation
- **Phenothiazines** (eg, **acepromazine**): May increase trazodone blood concentrations; can cause additive CNS effects
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine**): Increased risk for serotonin syndrome. Trazodone is commonly used together with SSRIs, but patients should be observed for signs associated with serotonin syndrome (see ***Adverse Effects***). Fluoxetine may also inhibit the metabolization of trazodone.
- **Tramadol**: Increased risk for serotonin syndrome
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Increased risk for serotonin syndrome

Laboratory Considerations

- None noted

Dosages

DOGS:

Adjunctive treatment of anxiety-related disorders (extra-label):

a) From a retrospective study of 56 dogs: The initial dose was ≈2.5 – 5 mg/kg PO every 12 to 24 hours for 3 days to allow dogs to become tolerant to the drug and avoid potential GI adverse effects.[1] The average final dose was ≈7.5 mg/kg/day PO, regardless of the dog's size. Wide interpatient dose variability existed, with oral doses ranging ≈2 – 19.5 mg/kg/day. The maximum individual dose was 300 mg. All dogs had an individually tailored behavior management program, and trazodone was added to other behavior-modifying drugs.

Body weight	Initial dose (total; NOT mg/kg) range	Target dose (total; NOT mg/kg)range
<10 kg (22 lb)	≤25 mg every 8-24 hours	≤50 mg every 8-24 hours
≥10-20 kg (22-44 lb)	50 mg every 12-24 hours	100 mg every 8-24 hours
≥20-40 kg (44-88 lb)	100 mg every 12-24 hours	200 mg every 8-24 hours
>40 kg (88 lb)	100 mg every 12-24 hours	200 – 300 mg every 8-24 hours

b) 2 – 10 mg/kg PO up to every 8 hours is recommended for daily modification of anxiety when the dog is at home in a low-stress situation and when sedation is undesired

c) Trazodone can be given as needed in addition to daily (or routine) use of another/different serotonergic agent (eg, clomipramine, fluoxetine). It is given ≈1 hour prior to the onset of anxiety, with a typical starting dose between 2 and 5 mg/kg and adjusting upward as necessary to get control (maximum dose, 14 mg/kg/day).[18] Because of the wide interpatient variability in metabolism of trazodone, test doses are recommended (when possible) to determine the time to onset of antianxiety effect before implementing its use for an expected/known anxiety-producing event.

Anxiolytic prior to veterinary visits (extra-label):

a) **As a single agent administered at least 90 minutes prior to travel**: 5 – 7.5 mg/kg PO[5] as needed up to 19.5 mg/kg PO daily[1] in aggressive dogs or those with high fear/anxiety/stress. 9 – 12 mg/kg PO also has been used.[19] The maximum recommendation is 300 mg/dose.[20] **NOTE**: Sedation may occur at the high end of the dose, which may be acceptable and preferred with high-anxiety situations (eg, transportation, hospitalization). In dogs with high fear/anxiety/stress or aggression, the same dose should also be administered the night before travel.

b) **In combination with gabapentin**: Trazodone 5 mg/kg PO in combination with gabapentin 10 mg/kg PO administered 2 hours prior to veterinary visits[21]

c) **As an adjunct to the Chill Protocol** (anecdotal):

i. <u>*Replace*</u> gabapentin with trazodone 5 – 10 mg/kg PO and administer the evening before the hospital visit and the morning of the hospital visit at least 2 hours prior to travel. Administer melatonin (small dogs, 0.5 – 1 mg PO; medium dogs, 1 – 3 mg PO; large dogs, 5 mg PO) with the morning dose of trazodone; administer acepromazine 0.025 – 0.05 mg/kg OTM 30 minutes before travel.

ii. Trazodone may be <u>*added*</u> to the Chill Protocol for dogs that do not experience adequate sedation or anxiolysis with the original Chill Protocol: Trazodone 5 – 10 mg/kg PO along with gabapentin 10 – 20 mg/kg PO administered the evening before the hospital visit and the morning of the hospital visit at least 2 hours prior to travel. Administer melatonin (small dogs, 0.5 – 1 mg PO; medium dogs, 1 – 3 mg PO; large dogs, 5 mg PO) with the morning dose of trazodone and gabapentin; administer acepromazine 0.025 to 0.05 mg/kg OTM 30 minutes before travel.

Anxiolytic for postsurgical confinement and stress during hospitalization (extra-label):

a) **As a single agent during hospitalization**: 4 mg/kg PO every 12 hours. Doses can be increased to 10 – 12 mg/kg, or the frequency of administration can be increased to every 8 hours when needed for desired calming and anxiolytic effects. The amount given did not exceed 300 mg/dose or 600 mg/24 hours.[20]

b) **In combination with tramadol**: Trazodone ≈3.5 mg/kg PO every 12 hours in combination with tramadol 4 – 6 mg/kg PO every 8 to 12 hours for the first 3 postoperative days (see ***Drug Interactions***), then tramadol discontinued, and trazodone increased to ≈7 mg/kg PO every 12 hours for at least 4 weeks.[3] A separate pharmacokinetic and hemodynamic study concluded that trazodone might be most useful in patients after surgery following complete recovery from anesthesia. In this study, trazodone doses of 8 mg/kg PO were well tolerated, but because of substantial variability in time to maximum plasma concentrations, individualized approaches to dose intervals may be necessary. At the authors' institution, trazodone treatment is instituted 12 to 24 hours after surgery for anxious patients, and clinicians often prescribe trazodone for a treatment duration of weeks to months for surgical patients to facilitate cage rest and activity restriction, particularly following orthopedic procedures. Further studies are warranted.[14]

CATS:

Anxiolytic prior to veterinary visits (extra-label):

a) **As a single agent administered at least 90 minutes prior to travel**: In a placebo-controlled study of 10 client-owned cats with a history of signs of anxiety during transport and/or veterinary examination, trazodone 50 mg/cat (NOT mg/kg) PO (equals 10.9 mg/kg based on average body weight [range, 7.7 – 15.2 mg/kg]) was given 60 to 90 minutes prior to a veterinary visit. No cat in the trazodone group displayed any signs of transportation- or examination-related anxiety, and stress scores and ease of examination were significantly better in cats treated with trazodone as compared with those receiving a placebo. Vocalization was common in both groups prior to transportation to the clinic and became less intense after trazodone administration.[11] A higher trazodone dose (100 mg/cat [NOT mg/kg] PO, ≈20 – 33 mg/kg) given to purpose-bred cats caused sedation and decreased activity level 2 hours after administration but did not improve behavioral response to physical examination.[9]

b) **In combination with gabapentin**: Trazodone 5 mg/kg PO in combination with gabapentin 10 mg/kg PO administered 2 hours prior to veterinary visits[21]

HORSES:

Facilitation of stall rest and treatment of abnormal behaviors (extra-label): 2.5 mg/kg PO once daily to 10 mg/kg PO twice daily depending on clinical reponse.[22] Duration of treatment lasted from 1 to 70 days.

Monitoring
- Clinical efficacy and adverse effects

Client Information
- Trazodone is used in dogs to treat anxiety-related conditions, including thunderstorms or firework phobias. The use of a combination of trazodone with other medications is common to help reduce anxiety.
- This medicine is also used when activity restriction (eg, cage rest) is needed after surgery.
- Trazodone may be given with food or on an empty stomach. If the animal vomits or acts sick after receiving trazodone on an empty stomach, give the medicine with a small amount of food or a small treat. It is important to contact your veterinarian if vomiting continues.
- Full calming effect may take up to 2 weeks of routine use, especially when trazodone is used alone.
- The most common side effects are sleepiness and decreased activity. Call your veterinarian if you observe shivering, dilated pupils, or agitation.
- Caution is advised when giving trazodone to working/service dogs, as they may be unable to perform their duties while on this medication.
- With chronic use, withdrawal signs may occur if the daily dose is not gradually reduced. Do not discontinue this medicine without first speaking with your veterinarian.

Chemistry/Synonyms
Trazodone is a triazolopyridine antidepressant agent. It occurs as an odorless, white to off-white crystalline powder and is sparingly soluble in water, alcohol, or chloroform. Trazodone tablets contain trazodone hydrochloride.

Trazodone may also be known as AF-1161, trazodona, trazodon, or sleepeasy. A common trade name is *Desyrel®*.

Storage/Stability
Store trazodone between 20°C and 25°C (68°F-77°F); excursions at 15°C to 30°C (59°F-86°F). Keep the medication in an airtight container and protect it from light.

Compatibility/Compounding Considerations
No specific information was noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Trazodone Oral Tablets: 50 mg, 100 mg, 150 mg, and 300 mg; generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Triamcinolone
Triamcinolone Acetonide
(trye-am-***sin***-oh-lone) *Vetalog®*

Glucocorticoid

Prescriber Highlights
- ► Oral, parenteral, topical, and inhaled glucocorticoid that is 4 to 10 times (some say up to 40 times) more potent than hydrocortisone; no appreciable mineralocorticoid activity. Commonly used for intra-articular injection (especially in horses)
- ► Contraindications include systemic fungal infections, viral infections, animals with arrested tuberculosis, peptic ulcer, corneal ulcer, or hyperadrenocorticism.
- ► Use cautiously in the presence of diabetes, osteoporosis, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, and active tuberculosis.
- ► If using systemically, the goal is to use as little as possible for as short a time as possible.
- ► Primary adverse effects with sustained use are cushingoid in nature (eg, polyuria, polydipsia, polyphagia, muscle wasting, osteoporosis).
- ► Many potential drug and laboratory interactions

Uses/Indications
Labeled indications include the treatment of inflammation and related disorders in dogs, cats, and horses; and management and treatment of acute arthritis, and allergic and dermatologic disorders in dogs and cats.[1,2]

Although glucocorticoids have been used to treat many conditions in humans and animals, triamcinolone has 4 primary uses with accompanying dosage ranges: 1) replacement or supplementation (eg, relative adrenal insufficiency associated with septic shock) for glucocorticoid deficiency secondary to hypoadrenocorticism; 2) anti-inflammatory agent; 3) immunosuppression, and 4) antineoplastic agent. High-dose use is not supported for hemorrhagic or hypovolemic shock, head trauma, spinal cord trauma[3], or sepsis. In general, when administering glucocorticoids, the following principles should be followed:
- A specific diagnosis is needed before glucocorticoids are administered as they can mask disease.
- A course of treatment should be determined prior to treatment.
- A therapeutic endpoint should be determined prior to treatment.
- The least potent glucocorticoid should be used at the lowest dose for a minimal amount of time.
- It is important to understand when glucocorticoid use is inappropriate (eg, acute infection, diabetes).[4]

See ***Glucocorticoid Agents, General Information.***

In working dogs with naturally occurring hip osteoarthritis, intra-articular (IA) injection of triamcinolone with hyaluronic acid into the hip joint reduced pain scores for up to 5 months.[5]

In horses, combining triamcinolone with a local anesthetic (eg, mepivacaine) has been shown to not alter the potency or duration of action of triamcinolone IA injections and may be useful to both confirm the joint causing lameness and to reduce synovitis.[6] In healthy horses, IA triamcinolone acetonide diffused directly from the distal interphalangeal joint with or without hyaluronic acid and may prove to be useful in treating navicular syndrome, but further studies are needed.[7] However, more lame horses receiving IA triamcinolone injection achieved clinical success 3 weeks after treatment than horses receiving the IA combination of triamcinolone and hyaluronate.[8] Triamcinolone given IM improves lung function in horses with severe equine asthma for up to 28 days.[9]

Intralesional injection of triamcinolone into esophageal[10,11] and rectal[12] strictures has been done in dogs and cats prior to dilation in an attempt to prolong the time needed between dilation procedures; more studies are needed to make specific recommendations for this use.[11]

Pharmacology/Actions

Triamcinolone acetonide is considered an intermediate-acting (metabolic activity of 24 to 48 hours when given orally) glucocorticoid that is ≈4 to 10 times more potent than hydrocortisone. Triamcinolone has negligible mineralocorticoid effects. When injected IM, duration of activity may persist for 4 to 6 (and sometimes up to 8) weeks. A study in cats with allergic pruritus found triamcinolone to be ≈7 times more potent than methylprednisolone.[13]

Intra-articular injection can reduce articular protein, inflammatory cell infiltration, intimal hyperplasia, and subintimal fibrosis, and increase synovial levels of hyaluronan and glycosaminoglycan.

Glucocorticoids have effects on virtually every cell type and system in mammals. For more information, refer to ***Glucocorticoid Agents, General Information***.

Pharmacokinetics

Like other corticosteroids, plasma concentrations are not a good indicator of biologic activity. A pharmacokinetic study to establish appropriate withdrawal times in thoroughbred horses after IM or intra-articular (IA) injection found: a plasma terminal elimination half-life of 11.4 (± 6.53) days for IM and 0.78 (±1) days for IA administration. Concentrations were below the limit of detection after IM injection by days 52 (plasma) and 60 (urine), and after IA injection by day 7 (plasma) and day 8 (urine). Triamcinolone acetonide was also undetectable in any of the joints sampled following IM administration and remained above the limit of quantitation for 21 days following IA administration.[14]

IA administration to horses results in systemic effects, including suppression of cortisol for up to 4 days following administration,[15] and improvement of lung function in horses with severe asthma.[9]

Contraindications/Precautions/Warnings

Triamcinolone is contraindicated in patients that are hypersensitive to it. Systemic use of glucocorticoids is generally considered contraindicated in viral or systemic fungal infections (unless used for replacement therapy in hypoadrenocorticism), in animals with tuberculosis, chronic nephritis, or hyperadrenocorticism when administered IM in patients with idiopathic thrombocytopenia. Sustained-release injectable glucocorticoid use is considered contraindicated for chronic corticosteroid treatment of systemic diseases.

Relative contraindications include the presence of diabetes mellitus, osteoporosis, or CHF. Corticosteroids should not be used to alleviate inflammation or pain caused by infections. Corticosteroids may mask signs of infection (eg, fever).

Patients that have received corticosteroids chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. If the animal undergoes a stressful event (eg, surgery, trauma, illness) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Aseptic preparation of the injection site should precede all intra-articular (IA) injections. Inadvertent administration into adjacent soft tissue is the most common reason for inadequate response after IA injection.[1] IA injections given to horses with undiagnosed asthma may mask clinical signs related to asthma and delay diagnosis.[9]

Triamcinolone induced rapid death of mesenchymal stem cells (MSC) in an in vitro cell culture,[16] and the authors concluded that concomitant use of corticosteroids is likely to have a detrimental effect on cell viability during MSC treatment.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if the drugs are administered at high doses or not on an alternate-day regimen. Effects typically manifest as clinical signs of hyperadrenocorticism. Glucocorticoids can delay growth when administered to young, growing animals. A list of potential effects is outlined in ***Glucocorticoid Agents, General Information***.

In dogs, polyuria (PU), polydipsia (PD), and polyphagia (PP) may occur during short-term burst therapy and on days when the drug is administered during alternate-day maintenance therapy. Other adverse effects in dogs receiving triamcinolone chronically can include dull/dry coat, weight gain, panting, vomiting, diarrhea, increased liver enzymes, GI ulceration (especially with high parenteral or oral dosages), hypercoagulability, hyperlipidemia, activation or worsening of diabetes mellitus, muscle wasting, and/or behavior changes (eg, depression, lethargy, aggression). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate adverse effects. Adverse effects associated with anti-inflammatory treatment are relatively uncommon, with the exception of PU, PD, and PP. Adverse effects associated with immunosuppressive dosages are more common and potentially more severe.

Glucocorticoids appear to have a greater hyperglycemic effect in cats than other species. Occasionally, PU, PD, and PP with weight gain, diarrhea, and/or depression will be present. Long-term, high-dose treatment can lead to cushingoid effects.

In horses, the potential for dexamethasone or triamcinolone playing a contributory role in the development of laminitis has been a traditional concern; however, a large, retrospective observational cohort study of horses found that intrasynovial triamcinolone administration did not increase the risk of laminitis.[17] Also there is no evidence that intra-articular corticosteroids cause harm to subchondral bone or promote catastrophic injury.[18] Another review article on this subject states:

Although the association of laminitis with elevated serum cortisol in pituitary pars intermedia dysfunction suggests that chronic exposure to glucocorticoids may be part of laminitis pathogenesis, review of published reports and databases suggests that glucocorticoid-induced laminitis is a relatively rare occurrence. . . . Generally, local glucocorticoid administration presents little risk as does systemic treatment of recurrent airway obstruction without concurrent disease. Caution should be used however in horses that are overweight and/or insulin resistant, or have had a recent bout of acute laminitis of alimentary or endotoxic origin.[19]

Reproductive/Nursing Safety

Endogenous glucocorticoids are likely necessary for normal fetal development. They may be required for adequate surfactant production and development of myelin, retinal tissue, the pancreas, and mammary tissue.

Glucocorticoids administered to pregnant dogs have resulted in congenital abnormalities, including deformed forelegs, phocomelia, and anasarca. Additionally, cleft palate has been reported in dogs, rabbits, and rodents. Systemic glucocorticoids administered to animals may induce the first stage of parturition when used during the last trimester of pregnancy and may precipitate premature parturition followed by dystocia, fetal death, retained placenta, and metritis.

Corticosteroids appear in milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects in the nursing offspring. Use with caution in nursing dams.

Overdose/Acute Toxicity

Glucocorticoids, when given short term, are unlikely to cause harmful effects, even in massive doses. If clinical signs occur, use supportive treatment if required.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving triamcinolone systemically and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amphotericin B**: When administered concomitantly with glucocorticoids, may cause hypokalemia
- **Anesthetics, Local** (eg, **epidural injections**): Combination with glucocorticoids in epidurals has caused serious CNS injuries and death.
- **Anticholinesterase Agents** (eg, **pyridostigmine, neostigmine**): In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**): May decrease the metabolism of glucocorticoids and increase triamcinolone blood concentrations; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis.
- **Cyclophosphamide**: Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **Cyclosporine**: Concomitant administration of glucocorticoids and cyclosporine may increase the blood concentrations of each, by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear.
- **Digoxin**: Secondary to hypokalemia, increased risk for arrhythmias
- **Diuretics, Potassium-Depleting** (eg, **furosemide, thiazides**): Administered concomitantly with glucocorticoids may cause hypokalemia
- **Ephedrine**: May increase metabolism of glucocorticoids
- **Estrogens** (eg, **DES, estriol**): The effects of triamcinolone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens.
- **Insulin**: Insulin requirements may increase in patients receiving glucocorticoids.
- **Isoniazid**: Triamcinolone may decrease isoniazid concentrations.
- **Macrolide Antibiotics** (eg, **clarithromycin, erythromycin**): May increase triamcinolone concentrations
- **Mitotane**: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **Nonsteroidal Anti-Inflammatory Drugs** (eg, **carprofen, flunixin, meloxicam, phenylbutazone**): Administration of ulcerogenic drugs with glucocorticoids may increase the risk for GI ulceration.
- **Opioids** (eg, **morphine**): Combination with glucocorticoids in epidurals has caused serious CNS injuries and death.
- **Phenobarbital**: May increase the metabolism of glucocorticoids and decrease triamcinolone blood concentrations
- **Rifampin**: May increase the metabolism of glucocorticoids and decrease triamcinolone blood concentration
- **Salicylates** (eg, **aspirin, bismuth subsalicylate**): Glucocorticoids may reduce salicylate blood concentrations.
- **Vaccines, Modified Live**: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids.
- **Warfarin**: Triamcinolone may affect clotting times; monitor.

Laboratory Considerations

- Glucocorticoids may increase **serum cholesterol**.
- Glucocorticoids may increase **serum and urine glucose** concentrations.
- Glucocorticoids may decrease **serum potassium**.
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce $\mathbf{T_3}$ and $\mathbf{T_4}$ values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I^{131} by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids.
- False negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids.
- Glucocorticoids may cause **neutrophilia** within 4 to 8 hours after dosing with return to baseline within 24 to 48 hours after drug discontinuation.
- Glucocorticoids can cause **lymphopenia**, which can persist for weeks after drug discontinuation in dogs.

Dosages

NOTE: When used systemically (PO, IM, or SC), initial doses of triamcinolone acetonide can be given at dosages that are ≈7 to 8 times lower than the prednis(ol)one dosage. For example: If the dosage of prednisone for the indication to be treated is 1 mg/kg PO, a corresponding dosage of triamcinolone acetonide would be ≈0.125 mg/kg PO. Triamcinolone has negligible mineralocorticoid effects, and its biologic activity may persist for 36 to 48 hours. If given on a daily basis, treatment for longer than 1 to 2 weeks will suppress the HPA axis and recovery will take longer than 1 week. Therefore, if triamcinolone is used for longer than a few days, when discontinuing, dosage should be tapered off using alternate-day, then every-third-day therapy.

DOGS/CATS:

Glucocorticoid effects (label dosage; FDA-approved):

a. **Using tablets**: 0.11 mg/kg PO initially once daily, may increase to 0.22 mg/kg PO once daily if initial response is unsatisfactory. As soon as possible, but not later than 2 weeks, reduce dosage gradually to 0.028 – 0.055 mg/kg/day.[20]

b. **Injectable product**: 0.11 – 0.22 mg/kg IM or SC for inflammatory or allergic disorders, and 0.22 mg/kg IM or SC for dermatologic disorders.[1] Effects generally persist for 7 to 15 days; if clinical signs recur, may repeat or institute oral therapy.

c. **Intralesional injection**: 1.2 – 1.8 mg/lesion (total dose; NOT mg/kg) is divided in several injections around the lesion at 0.5 to 2.5 cm intervals; administer well into the cutis.[1] When injecting, do not exceed 0.6 mg at any one site or a total dose of 6 mg when treating multiple lesions. May repeat after 3 or 4 days if indicated.

d. **Intra-articular (IA) and intrasynovial injection**: Dose for IA or intrasynovial administration is dependent on the size of the joint to be treated and on the severity of clinical signs. A single injection of 1 – 3 mg/dog (NOT mg/kg) IA.[1] After 3 to 4 days, dose may be repeated, depending on the severity of clinical signs and the clinical response. If initial results are inadequate or too transient, dose may be increased, but the recommended dose should not be exceeded. Routine aseptic preparation of

the area should be made prior to all IA injections. A thorough understanding of the pertinent anatomic relationships is essential. The inadvertent administration of the corticosteroid into the soft tissues surrounding a joint is not harmful but is the most common cause of failure to achieve the desired local results.

Anti-inflammatory agent (extra-label):

a) **Induction**: 0.05 – 0.22 mg/kg PO once daily. Maintenance: 0.05 – 0.1 mg/kg (or lower if possible) PO every 48 to 72 hours. Taper dose slowly if discontinuing.

b) **Adjunctive treatment of pruritus in allergic cats**: Initial induction dosage was 0.5 mg/cat (NOT mg/kg) PO once daily for cats weighing less than or equal to 5 kg (11 lb), and 0.75 mg/cat (NOT mg/kg) PO once daily for cats more than 5 kg (11 lb). Cats that did not achieve remission by day 7 had their once-daily induction dose doubled for the next 7 days. Mean dosage required for induction of remission was 0.18 mg/kg (range 0.09 – 0.26 mg/kg) PO once daily; 94% of treated cats achieved remission by the end of the second week. Dosages used to achieve remission were then given every other day and tapered (from 100% to 25% of induction dose in 25% increments) to the lowest every other day dosage that maintained remission. Mean alternate-day dosages were 0.08 mg/kg.[13]

c) **Canine hip osteoarthritis**: 0.2 mg/kg IA into the affected hip joint(s).[21] Alternatively, 20 mg/joint (NOT mg/kg) IA.[5] For both dosing options, administer IA triamcinolone injection in combination with 1 to 2 mL of hyaluronic acid IA.

Immunosuppressive agent (extra-label):

a) **Autoimmune skin diseases**: Induction: 0.4 – 0.6 mg/kg PO once daily. Maintenance: 0.1 – 0.2 mg/kg PO every 48 to 72 hours[22]

b) **Feline pemphigus foliaceus**: Induction: 0.6 – 2 mg/kg PO once daily. Maintenance: 0.6 – 1 mg/kg PO every 2 to 7 days. Cats receiving triamcinolone had significantly fewer adverse effects than cats receiving prednisolone and chlorambucil.[23]

Intralesional injection (extra-label):

a) **Preventing re-stricture after esophageal dilation**:
   i. Using an endoscopically directed needle, triamcinolone 2 – 10 mg (total dose; NOT mg/kg) is divided and injected submucosally into each of 4 quadrants (≈0.5 – 2.5 mg/quadrant), placed circumferentially around the stricture site *before* the balloon dilation procedure.[24–26]
   ii. Dilute triamcinolone 40 mg (total dose; NOT mg/kg) 1:1 with 0.9% sodium chloride and divide solution to inject submucosally into 4 quadrants (≈10 mg/quadrant), placed circumferentially around the stricture site *before* the balloon dilation procedure.[10]

b) **Preventing re-stricture after rectal dilation in dogs**: 5 – 10 mg (total dose; NOT mg/kg) divided and injected submucosally into 4 quadrants, placed circumferentially around the stricture site *before* the balloon dilation procedure[27]

c) **Preventing re-stricture after rectal dilation in cats**: 0.8 mg (total dose; NOT mg/kg) was injected submucosally into each of 4 quadrants, placed circumferentially around the stricture site *before* the balloon dilation procedure[12]

d) **Mast cell tumors**: 1 – 2 mg triamcinolone per cm of tumor length based on the longest tumor dimension. Treatment interval varied from weekly doses (20%), one-time doses (40%), or clinician's discretion (40%).[28]

e) **Ciliary body ablation for chronic glaucoma in dogs**: Triamcinolone 1 – 2 mg (total dose; NOT mg/kg) in combination with gentamicin 30 – 50 mg (total dose; NOT mg/kg) administered intravitreally[29]

HORSES:

Inflammation and related disorders (label dosage; FDA-approved):

a) **Oral**: 0.011 – 0.022 mg/kg PO twice daily[30]

b) **Injection**: 0.022 – 0.044 mg/kg IM or SC; usual dose, 12 – 20 mg/horse (NOT mg/kg)[1]

c) **Intra-articularly or intrasynovially**: 6 – 18 mg/joint (NOT mg/kg) IA, depending on the joint size and severity of inflammation. Do not exceed 18 mg/dose. May repeat after 3 or 4 days if indicated.[1]

Noninfectious synovitis or/and osteoarthritis (extra-label): 12 mg/horse (NOT mg/kg) as a single IA injection[8]

Severe equine asthma exacerbation (extra-label): 40 mg/horse (NOT mg/kg) IM improved lung function for 28 days[9]

Equine recurrent uveitis (extra-label): 5 mg/eye (NOT mg/kg) injected into the suprachoroidal space for horses that have responded poorly to other treatments[31]

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosing schedule (daily vs alternate-day therapy), route of administration, duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of fluid retention
- Serum and/or urine electrolytes
- Total plasma proteins and albumin
- Blood glucose
- Urine culture
- Growth and development in young animals

Client Information

- Give oral products with food.
- The goal of treatment is to find the lowest dose possible and use it for the shortest period of time. Follow your veterinarian's instructions on how to give this medicine.
- Many side effects are possible, especially when used long term or when given in higher doses. The most common side effects are increased appetite, thirst, and need to urinate.
- In dogs, stomach or intestinal ulcers, perforation, or bleeding can occur while taking this medicine. Contact your veterinarian right away if your animal stops eating or if you notice a high fever, black tarry stools, or bloody vomit (will look like coffee grounds).
- Do not stop treatment abruptly without your veterinarian's guidance, as serious side effects could occur.
- Be sure to tell your veterinarian what other medication (including vitamins, supplements, or herbal therapies) you give your animal.

Chemistry/Synonyms

Triamcinolone acetonide, a synthetic glucocorticoid, occurs as a slightly odorous, white to cream-colored, crystalline powder with a melting point between 290°C and 294°C (554°F-561°F). It is practically insoluble in water, very soluble in dehydrated alcohol and slightly soluble in alcohol.

The commercially available sterile suspensions have a pH range of 5 to 7.5.

Triamcinolone acetonide may also be known as triamcinoloni acetonidum; many trade names are available.

Storage/Stability

Triamcinolone acetonide products should be stored at room temperature (15°C-30°C [59°F-86°F]). The injection should be stored upright inside the manufacturer's carton, protected from light and freezing.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

Triamcinolone Acetonide Tablets: 0.5 mg and 1.5 mg; *Vetalog®*, generic; (Rx). FDA-approved for use in dogs and cats

Triamcinolone Acetonide Suspension for Injection: 2 mg/mL in 25 mL and 100 mL vials; 6 mg/mL in 3 mL, 5 mL and 25 mL vials; *Vetalog® Parenteral*; (Rx). FDA-approved for use in dogs, cats, and horses not intended for food

Triamcinolone Acetonide Oral Powder: 15 g of powder contains 10 mg of triamcinolone acetonide; *Vetalog®* Oral Powder; (Rx). FDA-approved for use in horses. Product is listed in the FDA Green Book but does not appear to be commercially available.

Triamcinolone is available as a topical spray, and in combination with other agents as a topical cream or ointment.

HUMAN-LABELED PRODUCTS:

Triamcinolone Acetonide Injection: 10 mg/mL and 40 mg/mL suspension in 1 mL, 5 mL, and 10 mL vials; *Kenalog®-10* and *-40*; (Rx)

Many topical preparations are available, alone and in combination with other agents. Oral mucosal paste and inhaled products are also FDA-approved. All are Rx.

Triamterene

(trye-***am***-te-reen) *Dyrenium®*

Potassium-Sparing Diuretic

Prescriber Highlights

- ► May be considered as an alternative to spironolactone for adjunctive treatment of CHF in dogs
- ► Rarely used in veterinary medicine; limited clinical experience in dogs and cats
- ► Contraindications include anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, or pre-existing hyperkalemia. Triamterene should not be used with other potassium-sparing agents (spironolactone, amiloride) or potassium supplements.
- ► Most common adverse effect is hyperkalemia; monitoring serum potassium is required.

Uses/Indications

Triamterene is a potassium-sparing diuretic that may be considered as an alternative to spironolactone for the adjunctive treatment of congestive heart failure in dogs; however, there is little experience associated with its use in dogs or cats and it is rarely recommended.

Pharmacology/Actions

By exerting a direct effect on the distal renal tubule, triamterene inhibits the reabsorption of sodium in exchange for hydrogen and potassium ions. It is a relatively weak diuretic since only ≈2% to 3% of filtered sodium is resorbed in the terminal portion of the distal tubule. Unlike spironolactone, it does not competitively inhibit aldosterone. Triamterene increases renal excretion of sodium, calcium, magnesium, and bicarbonate; urine pH may be slightly increased. Serum concentrations of potassium and chloride may be increased. When used alone, triamterene has little effect on blood pressure. Triamterene can reduce GFR slightly, probably by affecting renal blood flow; this effect is reversible when the medication is discontinued.

Pharmacokinetics

Pharmacokinetic data for dogs or cats were not located. In humans, triamterene is rapidly absorbed after oral administration and oral bioavailability is ≈85%. Onset of diuresis occurs in 2 to 4 hours, peaks at ≈6 hours and diuresis can persist up to 12 to 16 hours postdose. Triamterene is metabolized in the liver to 6-p-hydroxytriamterine and its sulfate conjugate. These metabolites are eliminated in the bile/feces and urine; elimination half-life is ≈2 hours.

Contraindications/Precautions/Warnings

Triamterene is contraindicated for human patients (and presumably dogs and cats) with anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, pre-existing hyperkalemia, or history of triamterene-induced hyperkalemia. Concurrent therapy with another potassium-sparing agent (spironolactone, amiloride) or potassium supplementation is also contraindicated.

In humans, hyperkalemia from potassium-sparing agents such as triamterene is more likely in patients with renal impairment and diabetes, and in elderly or severely ill patients.[1]

Adverse Effects

Because triamterene has been infrequently used in veterinary medicine, an accurate adverse effect profile for small animal species is not known. Hyperkalemia is possible and monitoring of electrolytes and renal function are necessary. In humans, hyperkalemia rarely occurs in patients with normal urine output and potassium intake.

Less common adverse effects reported in humans include headache, dizziness, GI effects (eg, nausea, vomiting, diarrhea), azotemia, hyponatremia, and an increased sensitivity to sunlight. Rarely, hypersensitivity reactions have occurred in human patients taking triamterene.[1] Other rare adverse effects include triamterene-nephrolithiasis, liver enzyme abnormalities, agranulocytosis, nephrotoxicity, thrombocytopenia, or megaloblastosis.

Reproductive/Nursing Safety

Studies to determine triamterene's effects on fertility in human have not been performed; however, studies in pregnant rats given triamterene at 6 to 20 times the human dose did not show adverse effects to the fetuses.[1] Triamterene crosses the placental barrier.

Triamterene is distributed into milk. Although unlikely to pose much risk to nursing animals, safety during nursing cannot be assured.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The oral LD_{50} for triamterene in mice is 380 mg/kg.[1] Fluid and electrolyte imbalance is the most likely risk associated with an overdose. GI effects or hypotension are also possible. Consider GI decontamination protocols for very large or quantity unknown ingestions. Acute overdoses should generally be managed by observation and supportive treatment with fluid diuresis as well as electrolyte (especially serum potassium) and acid-base monitoring.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving triamterene and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin Converting Enzyme Inhibitors (ACEIs**; eg, **enalapril, benazepril**): Increased risk for hyperkalemia
- **Antidiabetic Agents** (eg, **insulin, oral hypoglycemic agents** [eg, **glipizide**]): Triamterene may increase blood glucose levels.
- **Antihypertensive Agents**: Possible potentiation of hypotensive effects
- **Diuretics, Potassium-sparing** (eg, **spironolactone, amiloride**): Increase risk for hyperkalemia; use of these drugs with triamterene in humans is contraindicated.
- **Lithium**: Triamterene may reduce lithium clearance.
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)**: Triamterene with NSAIDs (especially indomethacin) may increase the risks of nephrotoxicity.
- **Potassium Supplements** or **High Potassium Foods**: Increased risk for hyperkalemia

Laboratory Considerations

- **Quinidine**: Triamterene may interfere with fluorescent assay of quinidine.

Dosages

DOGS:

Adjunctive treatment of heart failure (extra-label): Anecdotally, 1 – 2 mg/kg PO twice daily or 2 – 4 mg/kg PO daily. Limited published evidence to support use or any dosage; if a potassium-sparing diuretic is used, spironolactone is usually preferred.

Monitoring

- Baseline and periodic serum electrolytes (especially potassium), BUN, creatinine
- Hydration status; patient body weight
- Blood pressure, if indicated
- Signs of edema

Client Information

- Give this medication with food to help prevent stomach upset.
- Your animal's urine may develop a bluish hue while it is taking this medicine. This color change is normal and will go away when the medication is stopped.
- Because this medication has not been used very much in dogs or cats, report any unusual side effects to your veterinarian.

Chemistry/Synonyms

Triamterene is structurally related to folic acid and occurs as a yellow, odorless, crystalline powder. It is practically insoluble in water and very slightly soluble in alcohol. At 50°C, it is slightly soluble in water. In acidified solutions, triamterene gives off a blue fluorescence.

Triamterene may also be known as NSC-77625, KF-8542, FI-6143, triamteren, trimaterenum, triamtereen, or *Dyrenium*®. International trade names include *Dytac*® and *Triteren*®. There are many trade names for combination products with hydrochlorothiazide.

Storage/Stability

Triamterene capsules should be stored between 15-30°C (59-86°F) in tight, light-resistant containers.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix***.

HUMAN-LABELED PRODUCTS:

Triamterene Capsules: 50 mg and 100 mg; *Dyrenium*®; (Rx)

In humans, triamterene is often prescribed as a fixed-dose combination with hydrochlorothiazide; many preparations are available.

For the complete list of references, see **wiley.com/go/budde/plumb**

Trientine

(***trye***-en-teen) *Syprine*®

Chelating Agent

Prescriber Highlights

- ► Oral copper chelating agent for copper hepatopathy. Limited veterinary experience with this drug
- ► Give on an empty stomach, 1 to 2 hours prior to meals
- ► Likely fewer adverse effects than penicillamine, but acute kidney injury possible
- ► More expensive than penicillamine; not readily available commercially and may need to be compounded into smaller dosages

Uses/Indications

Trientine may be useful for the treatment of copper-associated hepatopathy in dogs,[1] particularly when dogs cannot tolerate the adverse effects (eg, vomiting) associated with penicillamine.

In humans, trientine is indicated for patients with Wilson disease who cannot tolerate penicillamine.

Pharmacology/Actions

Trientine is an effective chelator of copper and increases its elimination via urinary excretion. It apparently has a greater affinity for copper in plasma than penicillamine, but penicillamine has a greater affinity for tissue copper.

Pharmacokinetics

No animal data were located. In humans, trientine is poorly absorbed and then extensively metabolized, primarily by acetylation. The drug and metabolites are excreted in the urine, with an elimination half-life of ≈2 to 4 hours.

Contraindications/Precautions/Warnings

Trientine is contraindicated in patients that are hypersensitive to it. Patients receiving trientine should be closely monitored for evidence of iron deficiency anemia.

In case of skin contact, promptly wash the area with water as contact dermatitis is possible. Capsules should not be opened or chewed.[2]

Adverse Effects

Adverse effects of trientine in dogs treated for copper hepatotoxicity are minimal, but the veterinary experience is limited. Acute kidney injury has been reported, particularly when used in dogs with high liver copper levels and at higher doses.

In humans, nausea may occur, especially at the beginning of therapy.[3] Dystonias, muscle spasms, myasthenia gravis, and iron deficiency anemia have been noted after long-term use. Paradoxical neurologic deterioration has been reported.[4–6]

Reproductive/Nursing Safety

Trientine is a potential teratogen. It was teratogenic in rats that were given doses similar to those for humans.[2]

It is not known whether this drug is excreted in breast milk. Exercise caution when administering to nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Little information is available; a case of a human ingesting 30 g of trientine without significant morbidity has been reported.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trientine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Iron**: Iron and trientine inhibit the absorption of one another; if iron therapy is needed, give doses at least 2 hours apart from one another.
- **Zinc**: Because trientine may also chelate zinc or other minerals, avoid concomitant therapy (most do not recommend using zinc for copper reduction until copper chelation therapy with penicillamine or trientine is completed) or separate dosages by at least 2 hours.

Dosages

DOGS:

Chelator for copper hepatotoxicity (extra-label): 5 – 7.5 mg/kg PO twice daily.[1] Administer 1 to 2 hours prior to meals. Doses up to 10 – 15 mg/kg PO twice daily have been suggested.[7]

Monitoring

- Periodic liver biopsies for quantitative hepatic copper levels and response to therapy
- Free and total serum copper
- Baseline and periodic renal and hepatic function tests
- Iron status, anemia

Client Information

- It is best to give this medicine 1 to 2 hours before feeding or giving other medications. If your dog vomits after getting it, contact your veterinarian to see if giving it with a small amount of food is okay.
- Trientine may cause skin reactions. Administer as whole capsules. Wash any area that may come in contact with capsule contents.

Chemistry/Synonyms

Trientine HCl, an oral copper chelator, occurs as a white to pale-yellow crystalline powder. It is hygroscopic, freely soluble in water, and slightly soluble in alcohol.

Trientine HCl may also be known as MK-0681, TJA-250, 2,2,2-tetramine, TETA, trien hydrochloride, triethylenetetramine dihydrochloride, trientine hydrochloride, *Metalite*®, or *Syprine*®.

Storage/Stability

Store trientine capsules in the refrigerator at 2°C to 8°C (36°F-46°F) in tightly closed containers.

Compatibility/Compounding Considerations

Trientine may need to be compounded into smaller capsules to give appropriate doses to dogs.

One sources states: *Modification of 2,2,2-tetramine (trientine) to 2,3,2-tetramine increases potency as a copper-chelating agent. Use of 2,3,2-tetramine in affected Bedlington terriers reduced liver copper concentrations significantly after 200 days of treatment at a dose of 15 mg/kg body weight. This drug is not commercially available, but can be obtained from chemical supply companies in the form of N,N'-bis(2-aminoethyl)-1,3-propanediamine and prepared as a salt for oral administration.*[8]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Trientine HCl Oral Capsules: 250 mg; *Syprine*®, generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Trilostane

(***try***-low-stane) *Vetoryl*®

Adrenal Steroid Synthesis Inhibitor

Prescriber Highlights

- ► Reduces the synthesis of cortisol, aldosterone, and adrenal androgens via competitive inhibition of 3-beta hydroxysteroid dehydrogenase
- ► May be useful in dogs for the treatment of pituitary-dependent hyperadrenocorticism (PDH), hyperadrenocorticism caused by adrenocortical tumors when surgery is not an option, and alopecia X; in cats for the treatment of feline PDH; and in horses for the treatment of pituitary pars intermedia dysfunction (PPID)
- ► Treatment goals often include resolution of clinical signs and avoiding oversuppression of the adrenal axis. For safe administration, appropriate rechecks with laboratory testing are required. Ideally, for each individual patient, the timing of trilostane administration and ACTH stimulation testing should remain consistent when monitoring therapy.
- ► A lower, twice-daily regimen appears to be effective and associated with fewer significant adverse effects.
- ► Potential adverse effects in dogs include lethargy, inappetence, vomiting, electrolyte abnormalities, and diarrhea; iatrogenic hypoadrenocorticism and death have been reported.
- ► Give with food for improved bioavailability.
- ► Use of licensed product is recommended; use compounded products with caution.
- ► Do not handle trilostane if pregnant or trying to conceive.

Uses/Indications

Trilostane is approved for the treatment of pituitary-dependent hyperadrenocorticism (PDH) and for the treatment of hyperadrenocorticism (HAC) associated with adrenocortical tumors (AT) in dogs when surgery is not an option. Doses lower than the label-recommended amounts given twice daily appear to be as effective and better tolerated than the labeled dose.[1,2] Trilostane may also be useful in the treatment of alopecia X.[3–5]

Trilostane appears to be a viable, well-tolerated medical treatment option in cats with HAC.[6–8] Trilostane may be useful for the treatment of pituitary pars intermedia dysfunction (PPID) in horses.[9]

Pharmacology/Actions

Trilostane is a competitive inhibitor of 3-beta hydroxysteroid dehydrogenase and reduces synthesis of cortisol, aldosterone, and adrenal androgens. Inhibition is reversible and apparently dose dependent.

In dogs with PDH, cortisol concentrations decreased markedly

2 to 4 hours after trilostane administration. From baseline, significant increases occurred in endogenous adrenocorticotropic hormone (ACTH) concentrations between hours 3 and 12, significant increases in aldosterone concentrations occurred between hours 16 and 20 (not clinically significant), and significant increases in renin activity occurred between hours 6 and 20. Potassium concentrations decreased significantly between hours 0.5 and 2 but were not of clinical significance.[10] Another study in dogs with PDH assessed the effects of mitotane and trilostane on aldosterone secretory reserve and whether the aldosterone concentration correlates with serum electrolyte concentrations. Aldosterone concentrations in the mitotane- and trilostane-treated dogs at 30- and 60-minutes post-ACTH were significantly lower than in clinically healthy dogs, and treated dogs had a greater decrease in aldosterone secretory reserve at 30 minutes than at 60 minutes. No correlation between aldosterone and serum electrolyte concentrations was observed.[11]

Pharmacokinetics

In dogs, orally administered trilostane is rapidly but erratically absorbed, with peak concentrations occurring between 1.5 and 2 hours postadministration. Absorption is enhanced when given with food. Trilostane is metabolized in the liver to several metabolites, including ketotrilostane, which is active. An ex vivo study in canine adrenal glands found that ketotrilostane was 4.9 times and 2.4 times more potent than trilostane in inhibiting cortisol and corticosterone secretion, respectively.[12]

Contraindications/Precautions/Warnings

Trilostane is contraindicated in animals hypersensitive to it. The manufacturer cautions to not use the drug in patients with primary hepatic disease or renal insufficiency. In field studies, treated patients had a statistically significant decrease in RBC parameters (ie, hematocrit, hemoglobin, RBC count) as compared with pretreatment values; however, the posttreatment values remained within the normal range. Although this effect is not commonly reported, monitoring CBC in dogs with underlying anemia should be considered.

Hypoadrenocorticism can develop at any dose and at any time during therapy and does not appear to be dose dependent,[13,14] and although adrenal suppression caused by trilostane is reversible in most cases, adrenal necrosis and death have rarely occurred in dogs.[2,14] **Owners should be warned about this life-threatening complication**, counseled on the clinical signs of an Addisonian crisis, and, if there is any suspicion of an Addisonian crisis, instructed to discontinue trilostane therapy, administer glucocorticoids, and seek veterinary care immediately. Owners should always be provided a small supply of predniso(lo)ne or dexamethasone tablets when trilostane is prescribed in order to initiate emergency treatment for a possible Addisonian crisis. Dexamethasone is the preferred corticosteroid for treatment, as it will not interfere with the ACTH stimulation test. If prednisone or prednisolone are used, an ACTH stimulation test cannot be accurately performed for at least 24 hours after administration because of cross-reactivity of these drugs in cortisol assays.

When used to control clinical signs of HAC in dogs with adrenal tumors, trilostane does not shrink tumors, and adrenal glands may increase in size during treatment. Treatment with trilostane may not reduce the risk for HAC-induced pancreatitis.[15] HAC may mask signs of osteoarthritis or atopic dermatitis, and signs of these conditions may emerge during trilostane treatment as endogenous cortisol concentration decreases.

During periods of stress (eg, boarding, surgery), animals treated with trilostane may require short-term exogenous corticosteroid (see ***Dexamethasone***, ***Prednisolone/Prednisone***) supplementation.

Do not handle trilostane if pregnant or trying to conceive.[16] Trilostane has been associated with teratogenic effects and early pregnancy loss in laboratory animals.

Adverse Effects

Trilostane appears to be relatively well tolerated in dogs, but dogs can develop lethargy, mild electrolyte abnormalities (eg, hyponatremia, hyperkalemia), vomiting, diarrhea, and inappetence during the first few days of therapy secondary to steroid withdrawal.[17] These effects are usually mild and self-limiting; however, signs cannot be attributed to drug intolerance alone and could be indicative of hypoadrenocorticism.

In cats with HAC, adverse effects associated with trilostane therapy have included lethargy, anorexia, and dulled mentation.

No adverse effects were noted in a study of trilostane given to 20 horses with equine PPID.[18]

Reproductive/Nursing Safety

Trilostane is contraindicated during pregnancy. The drug can significantly reduce the synthesis of progesterone in vivo and is associated with teratogenic effects and early pregnancy loss in laboratory animals.[16] Safe use has not been evaluated in male dogs intended for breeding.

Because safety has not been established in lactating animals, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

Death occurred in 50% of healthy beagles administered 20.1 to 33.5 mg/kg PO twice daily for 90 days.[16] If clinical signs of hypoadrenocorticism are present, treatment with corticosteroids, mineralocorticoids, and IV fluids may be required; blood pressure, hydration status, and electrolyte balance should be monitored. Because the drug's effects are relatively short, monitoring of patients without complications should only be required for a few days after ingestion.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trilostane and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): May increase risk for hyperkalemia
- **Ketoconazole**: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- **Mitotane**: May potentiate the effects of trilostane and lead to hypoadrenocorticism. Wait at least 1 month after discontinuing mitotane before initiating trilostane.
- **Potassium-Sparing Diuretics** (eg, **spironolactone**): May increase risk for hyperkalemia
- **Potassium Supplements; High potassium foods**: May increase risk for hyperkalemia

Laboratory Considerations

- None

Dosages

CAUTION: Hypoadrenocorticism can develop at any dose and at any time during therapy and does not appear to be dose dependent. Animals should always be sent home with glucocorticoid supplementation in the event of an Addisonian crisis. See ***Contraindications/Precautions/Warnings***.

DOGS:

CAUTION: The label dosage for dogs is considered by most clinicians to be greater than is necessary for most patients. The label dosage is provided below; however, the use of lower, extra-label dosages (listed below label dosage) is recommended.
Hyperadrenocorticism (HAC) (label dosage; FDA-approved): Starting dose is 2.2 – 6.7 mg/kg (based on body weight and capsule size) PO once daily with food; after giving this dose for ≈10 to 14 days, re-examination is required and a 4- to 6-hour post-administration ACTH stimulation test and serum biochemical test (eg, electrolytes, renal and hepatic function) should be performed. If physical examination results are acceptable, adjust the dose according to post-ACTH serum cortisol based on Table 1 in the package insert.[16] Individual dose adjustments and close monitoring are essential. Re-examine and conduct an ACTH stimulation test 10 to 14 days after every dose alteration. Care must be taken during dose increases to monitor the dog's clinical signs and serum electrolyte concentrations. Once-daily administration is recommended; however, if clinical signs are not controlled for the full day, twice-daily dosing may be needed. To switch from a once-daily dosing regimen to a twice-daily dose, divide the total daily dose into 2 portions given 12 hours apart; it is not necessary for the doses to be equal. If applicable, the larger dose should be administered in the morning and the smaller dose in the evening.[16] **NOTE**: Extra-label use of twice daily doses permits use of a lower total daily trilostane dosage that appears equally effective and better tolerated.[19] See extra-label dosages below.

Hyperadrenocorticism (HAC) (extra-label):
Twice-daily administration:

a) In dogs weighing less than 5 kg: ≈0.5 – 1 mg/kg (0.78 ± 0.26 mg/kg) PO every 12 hours for 4 weeks, and then was adjusted based on clinical signs and ACTH stimulation testing.[1] No dogs required more than the manufacturer's lowest recommended starting dose of 3 mg/kg per day to control disease.[2] Slow adjustment of the treatment protocol to achieve clinical improvement may be needed on a case-by-case basis. There is some evidence that as body weight increases, especially in dogs weighing more than 30 kg (66 lb), the amount of trilostane (mg/kg/dose as well as mg/kg/day dosage) required to control clinical signs decreases.[5]
b) 0.21 – 1.1 mg/kg PO every 12 hours (mean, 0.86 mg/kg every 12 hours). Slow adjustment of the treatment protocol to achieve clinical improvement may be needed on a case-by-case basis. Most (≈75%) of the dogs in the study did not need more than 3 mg/kg per day to control disease throughout the 1-year follow-up. Author concluded that the results of the present study indicated that trilostane is both potent and effective in dogs at doses less than those recommended by the manufacturer and that a lower dose administered twice daily should be considered as it minimizes the incidence and severity of adverse effects and trilostane's effects have been shown to last less than 12 hours.[2]
c) Average initial dose of 0.78 – 3.1 mg/kg PO every 12 hours; average final dose of 1.43 – 3.75 mg/kg PO every 12 hours. It is recommended to start at a dosage of 0.5 – 1 mg/kg PO every 12 hours, with a maximum initial *daily* dose of 30 mg/dog (NOT mg/kg) for dogs weighing more than 30 kg (66 lb).[20]

Once-daily administration:

a) ≈2 mg/kg (based on body weight and available capsule sizes) PO once daily with food. Titrate dose slowly according to individual response, using lowest dose necessary to control clinical signs. If signs of HAC are not adequately controlled, increase dose by 50% and split into 2 evenly divided doses. Doses of 10 mg/kg per day or higher may be required in a small number of dogs.[15]
b) Average initial dose of 2.9 – 6.4 mg/kg PO every 24 hours; average final dose of 2.8 – 19 mg/kg PO every 24 hours[20]

Alopecia X (extra-label):

a) 3 – 3.6 mg/kg PO twice daily for 4 to 6 months. From a case series (n = 3)[3]; no adverse effects were reported.
b) In dogs weighing less than 10 kg (22 lb), average trilostane dose was 10.85 mg/kg PO per day given either once daily or divided and given twice daily for 4 to 8 weeks.[4]
c) A study in Pomeranians reported 1 mg/kg PO given twice daily to be a positive therapeutic option.[21]

CATS:

Hyperadrenocorticism (extra-label): Average dosages were 4.3 mg/kg PO once daily or 3.3 mg/kg PO twice daily; dosages ranged from 10 – 30 mg/cat (NOT mg/kg) PO every 12 to 24 hours to 12 mg/kg PO every 12 hours.[6–8,22]

HORSES:

Equine pituitary pars intermedia dysfunction (PPID; formerly known as equine Cushing's syndrome) (extra-label): 0.4 – 1 mg/kg (total dose of 120 – 240 mg/horse [NOT mg/kg]) PO once daily.[18] **NOTE**: Trilostane may be beneficial to those horses with PPID associated with adrenal gland hyperplasia and hypercortisolemia but has no effect on the excessive production of other pituitary-derived hormones.[23]

SMALL MAMMALS:

Hyperadrenocorticism in guinea pigs (extra-label): 2 – 6 mg/kg PO every 24 hours[24,25]

Monitoring

- Clinical effects. Clinical signs may correlate poorly with cortisol concentrations or ACTH stimulation test results.[26] Asking caregivers to keep a daily diary of their animal's clinical signs can help ascertain clinical control over time and help to make informed decisions about trilostane dosage adjustments.
- Adverse effects. Addisonian crisis is a life-threatening adverse effect of trilostane therapy. Monitor patients closely during therapy for this potential complication. Dispense oral dexamethasone at the time of discharge for owners to administer in case of an Addisonian crisis.
- Baseline and periodic (at 30 days, 90 days, and then every 3 months) history and physical examination[16]
- Baseline and periodic (at 30 days, 90 days, and then every 3 months) CBC and serum chemistry profiles with particular attention paid to electrolytes and renal and liver parameters[16]
- Urinalysis and (possibly) urine cortisol:creatinine ratio (UCCR). Of note, no advantage has been demonstrated in a UCCR evaluation on each re-evaluation, but measurement of urine specific gravity, glucose, and protein or checking for evidence of infection (ie, urine culture) may be helpful in assessing dogs treated long-term with trilostane.[2]
- ACTH stimulation testing is imperative to ensure safe continuation of trilostane therapy. Familiarity with and understanding of testing methods are necessary to ensure consistency of results and safe continuation of therapy. Ideally, for each individual patient, the timing of trilostane administration and ACTH stimulation testing should remain consistent when monitoring therapy. Different strategies include:
  - For long-term monitoring once an optimum dose has been reached, an ACTH stimulation test 4 to 6 hours after trilostane administration should be perfomed.[16] Results from 2 studies suggest the optimal time point for an ACTH stimulation test is

2 to 4 hours after trilostane administration.[10,27] A post-ACTH stimulation test that results in a cortisol of less than 1.45 µg/dL (less than 40 nmol/L), with or without electrolyte abnormalities, may precede the development of clinical signs of hypoadrenocorticism.[16] Good control is indicated by favorable clinical signs as well as post-ACTH serum cortisol of 1.45 – 9.1 µg/dL (40 to 250 nmol/L). If the ACTH stimulation test result is less than 1.45 µg/dL (less than 40 nmol/L) and/or if electrolyte imbalances characteristic of hypoadrenocorticism (eg, hyperkalemia, hyponatremia) are found, trilostane should be temporarily discontinued until recurrence of clinical signs consistent with hyperadrenocorticism and ACTH stimulation test results return to normal (1.45 – 9.1 µg/dL or 40 –250 nmol/L). Trilostane may then be re-introduced at a lower dose. One study concluded that a baseline cortisol concentration collected 4 to 6 hours after trilostane administration in dogs with hyperadrenocorticism provided clinically useful information about control of adrenal gland function,[28] but another study concluded baseline cortisol, endogenous ACTH, and the cortisol/ACTH ratio could not replace the ACTH stimulation test for monitoring trilostane therapy.[29]

- A second ACTH stimulation test performed 9 to 12 hours post-trilostane administration and ≈6 hours after the first ACTH stimulation test may provide additional therapy guidance in dogs that are clinically well-regulated and have cortisol less than 2 µg/dL before and after the first ACTH stimulation test.[30]
- Cortisol concentration measured pre-trilostane and 3-hours post-trilostane administration also may be a useful monitoring method,[31] although inconsistencies were noted in pre-trilostane cortisol measurements obtained 1 hour apart.[32]
- In dogs showing no signs of hypoadrenocorticism, cortisol concentrations in the normal range, measured by pre-trilostane cortisol concentration, could provide necessary information for management of the case. If the pre-trilostane cortisol concentration is low, additional cortisol testing (such as ACTH stimulation testing) should be performed to ensure safe continuation of therapy. Alternatively, if the pre-trilostane cortisol concentration is low in dogs showing no signs of hypoadrenocorticism, the trilostane dose could be decreased.[32]

Client Information

- Give this medicine exactly as prescribed by your veterinarian. Do not stop or give more of the drug unless you first talk to your veterinarian.
- Discontinue trilostane and contact your veterinarian immediately if any vomiting, diarrhea, lethargy, poor/reduced appetite, weakness, or collapse are observed.
- Give each dose with food, unless otherwise directed by your veterinarian. If directed to administer this medicine once daily, give it in the morning.
- If a dose is missed, give the dose at the next scheduled dose administration time.
- Wash your hands after handling this medicine. Do not empty capsule contents or do not attempt to divide the capsules. Do not handle the capsules if you are pregnant or trying to conceive.
- Report any side effects to your veterinarian.
- Keep this medicine out of reach of children and animals.
- Trilostane helps manage your animal's condition but is not a cure. Improvements in your animal's condition occur gradually and may be difficult to see on a daily basis.

Chemistry/Synonyms

Trilostane, a synthetic steroid analogue, has a molecular weight of 329.4 and its chemical name is 4-alpha, 5-alpha-epoxy-17-beta-hydroxy-3-oxoandrostane-2-alpha-carbonitrile. It is relatively insoluble in water.

Trilostane may also be known as WIN 24540, trilostaani, *Vetoryl*®, *Desopan*®, *Modrastane*®, or *Modrenal*®.

Storage/Stability

Commercially available trilostane capsules should be stored at room temperature (25°C [77°F]), with excursions between 15°C to 30°C (59°F-86°F) permitted.

Compatibility/Compounding Considerations

An evaluation of compounded trilostane capsules obtained from 8 compounding pharmacies found that 38% of compounded batches were outside the acceptance criteria for content (content ranged from 39% to 152% of stated label), and 20% did not meet the established criteria for dissolution. Reformulation of the licensed trilostane product into a novel capsule size by a trained pharmacist did not affect dissolution characteristics and the target dose was achieved. The authors concluded, *On the basis of these findings, compounded trilostane products should be used with caution as they may jeopardize the management of dogs with hyperadrenocorticism and potentially impact patient safety*.[33]

Trilostane 5 mg/mL oral suspension in cod liver oil (prepared using *Vetoryl*® capsules) retained potency within 90% to 105% of labeled value for 60 days when stored in amber glass vials at room temperature. Potency fell below 90% of the labeled value when stored in amber plastic bottles at room temperature.[34]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Trilostane Oral Capsules: 5 mg, 10 mg, 30 mg, 60 mg, and 120 mg packaged in aluminum foil blister cards of 10 capsules; *Vetoryl*®; (Rx). NADA 141-291

HUMAN-LABELED PRODUCTS:

Modrastane® was withdrawn from the United States market in 1994.

Prescriber Highlights

- ► Indicated for relief of pruritus and as an antitussive in dogs
- ► Goal of therapy should be to use the lowest dose possible for the least amount of time to treat and control patient's condition.
- ► Relatively contraindicated in animals with systemic fungal infection, hypovolemia, shock, tetanus, or strychnine intoxication
- ► Caution is advised in animals with hepatic dysfunction, cardiac disease, active bacterial or viral infections, peptic ulcer, corneal ulcer, hyperadrenocorticism (Cushing syndrome), diabetes, osteoporosis, predisposition to thrombophlebitis, hypertension, congestive heart failure, renal insufficiency, or general debilitation and in very young animals.
- ► Primary adverse effects include sedation, significant hypotension, cardiac rate abnormalities, hypo- or hyperthermia, and hyperadrenocorticism with sustained use.
- ► Many potential drug and laboratory interactions

Uses/Indications

Trimeprazine/prednisolone is indicated for treatment of pruritic and inflammatory conditions (especially if induced by allergic conditions such as atopic dermatitis) or as an antitussive.[1] There is anecdotal evidence that treatment with trimeprazine/prednisolone combinations require less prednisolone to control pruritus.[2,3]

Pharmacology/Actions

Trimeprazine has antihistaminic, sedative, antitussive, and antipruritic qualities. The veterinary FDA-approved product contains prednisolone in its formulation, providing additional antipruritic and anti-inflammatory effects.

See ***Glucocorticoid Agents, General Information***.

Pharmacokinetics

The pharmacokinetics of trimeprazine have apparently not been studied in animals. In humans, peak concentration occurs 3.5 to 4.5 hours after oral administration in adults and 1 to 2 hours in children. Protein binding is 90%. Half-life is ≈5 hours in adults and ≈7 hours in children.[4,5]

See ***Glucocorticoid Agents, General Information***.

Contraindications/Precautions/Warnings

Like other phenothiazines, trimeprazine is contraindicated in patients with a known hypersensitivity to it or other phenothiazines. It should not be used for patients in comatose states due to large amounts of CNS depressants or for tetanus or strychnine intoxication due to its effects on the extrapyramidal system. It is relatively contraindicated in patients with hypovolemia, dehydration, or shock, and should be used cautiously in animals with CNS depression, hepatic dysfunction, cardiac disease, or general debilitation.

Systemic use of glucocorticoids is generally contraindicated in animals with systemic fungal infections (with some exceptions such as when used for replacement therapy in animals with hypoadrenocorticism or to help reduce severe inflammation), corneal ulceration, or hypersensitivity to the drug. Use with caution in animals with concomitant renal disease, as they may be at increased risk for GI adverse effects. Animals, particularly cats, at risk for diabetes mellitus or with concurrent cardiovascular disease should not receive glucocorticoids or should receive them with caution because of the potent hyperglycemic effect of these agents. In humans, long-term glucocorticoids may increase intraocular pressure and increase the risk for cataracts and osteoporosis.

Systemic glucocorticoids suppress adrenal function. The drug should be tapered off slowly in animals receiving it chronically, as endogenous ACTH and corticosteroid function may return slowly. Additional glucocorticoids should be administered to animals undergoing a stressor (eg, surgery, trauma, illness) during the tapering process or until normal adrenal and pituitary functions resume.

Adverse Effects

For trimeprazine, possible adverse effects include sedation, depression, hypothermia, hypotension, and extrapyramidal reactions (eg, rigidity, tremors, weakness, restlessness).

For the product containing corticosteroids, additional adverse effects include elevated liver enzymes, weight loss, muscle wasting, polyuria/polydipsia, vomiting, and diarrhea. Iatrogenic hyperadrenocorticism may develop. Worsening of diabetes mellitus, GI ulceration and immunosuppression are possible, particularly at higher dosages.

Additional adverse effects of the combination product include sodium retention and potassium loss, negative nitrogen balance, suppressed adrenocortical function, delayed wound healing, osteoporosis, possible increased susceptibility to and/or exacerbation of bacterial infection, sedation, protruding nictitating membrane, and blood dyscrasias.[1] In addition, intensification and prolongation of the action of sedatives, analgesics, or anesthetics, as well as potentiation of organophosphate toxicity and procaine activity, may be noted.

Reproductive/Nursing Safety

Corticosteroids can induce the first stages of parturition if administered during the last trimester of pregnancy.[1] Small amounts of both trimeprazine and prednisolone are excreted into human milk; use with caution in nursing animals or consider milk replacer. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The most likely effects of an overdose include sedation and ataxia. Gut decontamination and supportive treatment should be used. It is especially advised to contact a veterinary poison center for treatment of seizures and/or hypotension that are nonresponsive to crystalloid fluid therapy.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving promethazine (a related phenothiazine antihistamine) or prednisolone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amphotericin B**: May cause hypokalemia when administered concomitantly with glucocorticoids
- **Antacids, Aluminum-, Calcium-, or Magnesium-Containing**: May cause reduced GI absorption of oral phenothiazines
- **Anticholinesterase Agents** (eg, **neostigmine, pyridostigmine**): In animals with myasthenia gravis, concomitant glucocorticoid use with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication

at least 24 hours prior to corticosteroid administration.

- **Antidiarrheal Mixtures** (eg, **bismuth subsalicylate mixtures, kaolin/pectin**): May cause reduced GI absorption of oral phenothiazines
- **Cholestyramine**: May reduce prednisolone absorption
- **Cisapride**: Increased risk for cardiac arrhythmia when used with phenothiazines
- **CNS Depressant Agents** (eg, **anesthetics, methocarbamol**): May cause additive CNS depression if used with phenothiazines
- **Cyclophosphamide**: Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **Cyclosporine**: Concomitant administration with glucocorticoids may increase blood concentrations of each by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear.
- **Digoxin**: Secondary to hypokalemia, increased risk for arrhythmia
- **Diuretics, Potassium-Depleting** (eg, **furosemide, thiazides**): May cause hypokalemia when administered concomitantly with glucocorticoids
- **Ephedrine**: May increase metabolism of glucocorticoids
- **Epinephrine**: Contraindicated in the treatment of acute hypotension produced by phenothiazine-derivative tranquilizers, as further depression of blood pressure can occur
- **Estrogens**: The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens.
- **Fluoroquinolones** (eg, enrofloxacin, marbofloxacin, pradofloxacin): Concurrent use may increase the risk for tendinitis and tendon rupture.
- **Insulin**: Insulin requirements may increase in patients receiving glucocorticoids.
- **Ketoconazole**: May decrease metabolism of glucocorticoids
- **Macrolide Antibiotics** (eg, clarithromycin, erythromycin): May decrease glucocorticoid metabolism
- **Metoclopramide**: Phenothiazines may potentiate the extrapyramidal effects of metoclopramide.
- **Mitotane**: May alter the metabolism of steroids; higher-than-usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency.
- **Mycophenolate**: Prednisolone increased the in vitro unbound (active) fraction of mycophenolic acid in dogs.6
- **Nonsteroidal Anti-Inflammatory Drugs** (NSAIDs; eg, carprofen, meloxicam): Administration of other ulcerogenic drugs with glucocorticoids may increase the risk for gastric ulcers.
- **Organophosphate Agents**: Phenothiazines should not be given within 1 month of deworming with these agents, as their effects may be potentiated.
- **Opioids** (eg, buprenorphine, morphine, tramadol): May cause additive CNS depression
- **Paraquat**: Toxicity of the herbicide paraquat may be increased by prochlorperazine.
- **Phenobarbital**: May increase the metabolism of glucocorticoids. Additive sedation may occur with phenobarbital.
- **Procaine**: Activity may be enhanced by phenothiazines.
- **Propranolol**: Increased concentrations of both drugs are possible.
- **Rifampin**: May increase the metabolism of glucocorticoids
- **Salicylates** (eg, aspirin, bismuth subsalicylate): Glucocorticoids may reduce salicylate blood concentrations.
- **Selective Serotonin Reuptake Inhibitors (SSRIs;** eg, fluoxetine, paroxetine): May increase phenothiazine plasma concentrations
- **Vaccines**: Animals receiving corticosteroids at immunosuppressive doses should generally not receive live attenuated virus vaccines, as virus replication may be augmented. A diminished immune response may occur after vaccine, toxoid, or bacterin administration in animals receiving glucocorticoids.

Laboratory Considerations

- Glucocorticoids may increase serum **cholesterol** and **alkaline phosphatase** concentrations.
- Glucocorticoids may increase **urine glucose** concentrations
- Glucocorticoids may decrease **serum potassium**.
- Glucocorticoids can suppress the release of **thyroid stimulating hormone (TSH)** and reduce T_3 and T_4 values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I^{131} by the thyroid may be decreased by glucocorticoids.
- Phenothiazine metabolites may darken the urine and cause false positive results for **amylase, urobilinogen, uroporphyrins, porphobilinogens,** and **5-hydroxyindolacetic acid**.
- Reactions to **allergen tests** may be suppressed by glucocorticoids and/or trimeprazine. The actual effect of trimeprazine with prednisolone on allergen-specific intradermal tests (IDT) and allergen-specific IgE serological (ASIS) tests has not been reported.[7] A 2- to 4-week withdrawal time prior to IDT or ASIS is recommended.[7,8]
- False negative results of the **nitroblue tetrazolium test for systemic bacterial infections** may be induced by glucocorticoids.

Dosages

DOGS:

Antipruritic and antitussive therapy (label dosage; FDA-approved): Dosed according to body weight: up to 4.5 kg (10 lb) = ½ tablet PO twice daily; 4.9 to 9 kg (11 to 20 lb) = 1 tablet PO twice daily; 9.5 to 18.1 kg (21 to 40 lb) = 2 tablets PO twice daily; over 18.1 kg (40 lb) = 3 tablets PO twice daily. After 4 days, reduce dose to ½ of initial dose or to an amount just sufficient to maintain remission of clinical signs; adjust as necessary.[1]

Adjunctive treatment of chronic pruritus (extra-label): 1 tablet/5 kg (11 lb) PO every 12 hours for 4 to 7 days, then 1 tablet/5 kg (11 lb) PO once daily for 4 to 7 days, and finally, 1 tablet/5 kg (11 lb) PO every other day. This schedule may be changed according to each animal's needs; however, the goal for long-term glucocorticoid therapy is to give the lowest dose possible to maintain control while administering the dose every other day or less frequently if possible. However, because antihistamines should be administered daily for optimal effect, this complicates the use of this fixed dose combination product.[8]

CATS:

Pruritus (extra-label): Anecdotally, trimeprazine 5 mg/prednisolone 2 mg has been used at 1 tablet/cat (NOT mg/kg) PO twice daily.

Monitoring

- Efficacy
- Degree of sedation and anticholinergic effects
- Adverse effects associated with corticosteroids
- Baseline and periodic (eg, every 6 to 12 months) CBC, serum chemistry profile, urinalysis, and urine culture (especially for geriatric animals) when used long-term[8]

Client Information

- Give this medicine as directed by your veterinarian. This med-

icine is a combination of an antihistamine and a cortisone-like steroid used to reduce itching. It may also be used to treat cough.
- This medicine can cause drowsiness, muscle tremors, and rigidity (stiffness), increased thirst, appetite, and amount of urine produced. It is important to not limit your animal's access to water to avoid these signs. Instead, make sure your animal has plenty of opportunities to eliminate outside to avoid accidents.
- Long-term use of this medicine can cause changes in the hair coat, thin skin, poor wound healing, potbellied appearance, muscle wasting, and increased chances for infection.
- This medicine is meant to be given for the shortest amount of time and at the lowest dose necessary to control your animal's signs.
- Contact your veterinarian if any of the side effects are worrisome.

Chemistry/Synonyms
Trimeprazine tartrate, a phenothiazine antihistamine related to promethazine, occurs as an odorless, white to off-white crystalline powder. It deteriorates on exposure to light and air. Approximately 0.5 gram is soluble in 1 mL water, and 0.05 gram is soluble in 1 mL of alcohol. Trimeprazine tartrate may also be known as alimemazine tartrate, *Panectyl*®, *Temaril*®, or *Vanectyl*®.

Prednisolone occurs as an odorless, white to practically white crystalline powder that is very slightly soluble in water and slightly soluble in alcohol. Prednisolone is also known as deltahydrocortisone or metacortandralone.

Storage/Stability
Store trimeprazine/prednisolone products in a cool, dry place at room temperature not above 25°C (77°F).

Compatibility/Compounding Considerations
No specific information noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
No single-agent trimeprazine products are FDA-approved for veterinary medicine.

Trimeprazine 5 mg with Prednisolone 2 mg Tablets; *Temaril-P*® *Tablets*; (Rx). FDA-approved for use in dogs. NADA# 012-437

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS: NONE

Tripelennamine
(tri-pel-***ehn***-a-meen) *Re-Covr*®
Antihistamine

Prescriber Highlights
- ► Injectable antihistamine FDA-approved for use in horses and cattle
- ► IV administration is contraindicated in horses
- ► Adverse effects include CNS stimulation (if given IV to horses), sedation, depression, ataxia, and GI effects.

Uses/Indications
Tripelennamine is a first-generation antihistamine that is FDA-approved for use in horses and cattle for treating conditions in which antihistaminic therapy may be expected to alleviate some signs of disease.[1] It has been used as a CNS stimulant in downer cows when administered slowly IV.

Pharmacology/Actions
Tripelennamine is a first-generation antihistamine that competitively inhibits histamine at H_1 receptor sites. It does not inactivate or prevent the release of histamine but can prevent histamine's action on the cell. Besides their antihistaminic activity, these agents also have varying degrees of anticholinergic and CNS activity (sedation). Tripelennamine is considered to have moderate sedative activity and minimal anticholinergic activity when compared with other first-generation antihistamines.

Pharmacokinetics
The pharmacokinetics of tripelennamine have apparently not been thoroughly studied in domestic animals or humans. One study performed on horses and camels showed that after IV administration, similar pharmacokinetic profiles were obtained for both species.[2] Terminal elimination half-lives were around 2-plus hours; volumes of distribution steady-state were ≈1.5 to 3 L/kg; protein binding was 80%, and total body clearance was ≈1 L/hour/kg.

Contraindications/Precautions/Warnings
Tripelennamine is contraindicated in patients that are hypersensitive to it. IV administration is contraindicated in horses (see ***Adverse Effects***).

Do not use tripelennamine in beef calves less than 2 months, dairy calves, or veal calves; it should not be used in horses intended for human consumption.

In humans, contraindications to tripelennamine included narrow-angle glaucoma bladder neck obstruction, pyloroduodenal obstruction, and asthma.

Adverse Effects
Adverse effects include CNS depression, ataxia, and GI disturbances. CNS stimulation (eg, hyperexcitability, nervousness, muscle tremors) lasting up to 20 minutes has been noted in horses after administration of label-recommended dosages.

Reproductive/Nursing Safety
No information was located. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity
Overdoses of tripelennamine reportedly can cause CNS excitation, seizures, and ataxia. Treat the patient supportively if clinical signs are severe.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving tripelennamine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.
- **CNS Depressants** (eg, **detomidine, methocarbamol**): Increased sedation can occur if tripelennamine is combined with other CNS depressant drugs.
- **Heparin**: Antihistamines may partially counteract the anticoagulation effects of heparin or warfarin.
- **Monoamine Oxidase Inhibitors (MAOIs;** eg, **amitraz,**

linezolid, selegiline): Concomitant use is considered contraindicated in humans; veterinary significance is unknown.

- **Warfarin**: Antihistamines may partially counteract the anticoagulation effects of heparin or warfarin.

Laboratory Considerations

- Antihistamines can decrease the wheal and flare response to **antigen skin testing**. In dogs, the recommended optimal withdrawal time of antihistamines prior to intradermal allergy testing is 7 days (the minimum recommended withdrawal time is 2 days).[3]

Dosages

NOTE: It is recommended to warm the solution to near body temperature before injecting; give IM injections into large muscle groups of the hind legs or cervical area.

HORSES:

Antihistamine (label dosage; FDA-approved): 1.1 mg/kg IM every 6 to 12 hours as needed.[1] **NOTE**: Do **NOT** administer IV to horses.

CATTLE:

Antihistamine (label dosage; FDA-approved): 1.1 mg/kg IV or IM every 6 to 12 hours as needed. Administer IV if more immediate effect is needed.

Monitoring

- Clinical efficacy
- Adverse effects

Chemistry/Synonyms

Tripelennamine HCl, an ethylenediamine-derivative antihistamine, occurs as a white, crystalline powder that will slowly darken upon exposure to light. It has a melting range of 188°C to 192°C (370°F-378°F) and pK_as of 3.9 and 9. One gram is soluble in 1 mL of water or 6 mL of alcohol.

Tripelennamine HCl may also be known as tripelennaminium chloride, *Pyribenzamine®*, or *Re-Covr®*.

Storage/Stability

Store the injection at room temperature (20°C-25°C [68°F-77°F]), with excursions permitted between 15°C to 30°C (59°F-86°F). Protect this product from light and avoid freezing or excessive heat. The vial should be punctured a maximum of 30 times.[1]

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tripelennamine HCl for Injection: 20 mg/mL in 100 mL, 250 mL, and 500 mL multiple-dose vials; *Re-Covr®*; (Rx). FDA-approved for use in cattle and horses. Not for use in horses to be used for food purposes. Not for use in beef calves less than 2 months, dairy calves, or veal calves. Meat withdrawal is 4 days; milk withdrawal is 24 hours.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix***.

HUMAN-LABELED PRODUCTS: NONE

Tulathromycin

(too-***la***-throe-***mye***-sin) *Draxxin®*

Injectable Macrolide Antibiotic

Prescriber Highlights

- ► Labeled for cattle and swine
- ► Single-dose treatment; long tissue half-lives
- ► Different withdrawal times in cattle based upon formulation of product used
- ► Not for lactating dairy cattle or veal calves
- ► Local injection site reactions most likely adverse effect

Uses/Indications

In beef and non-lactating dairy cattle, tulathromycin (100 mg/mL formulation) is indicated for the treatment of bovine respiratory disease (BRD) associated with *Mannheimia haemolytica, Pasteurella multocida*, *Histophilus somni* (*Haemophilus somnus*), and *Mycoplasma bovis*; and for the control of respiratory disease in cattle at high risk of developing BRD, associated with *Mannheimia haemolytica, Pasteurella multocida*, *Histophilus somni* (*Haemophilus somnus*), and *Mycoplasma bovis*. It is also FDA-approved for the treatment of bovine foot rot (interdigital necrobacillosis) associated with *Fusobacterium necrophorum* and *Porphyromonas levii* and for the treatment of infectious bovine keratoconjunctivitis (IBK) associated with *Moraxella bovis*.[1] In suckling calves, dairy calves and veal calves, tulathromycin (both 100 mg/mL and 25 mg/mL formulations) is indicated for the treatment of BRD associated with *M haemolytica, P multocida, H somni*, and *M bovis*.[1,2]

Tulathromycin (both 100 mg/mL and 25 mg/mL formulations) is indicated for the treatment of swine respiratory disease (SRD) associated with *Actinobacillus pleuropneumoniae, Pasteurella multocida, Bordetella bronchiseptica, Haemophilus parasuis,* and *Mycoplasma hyopneumoniae;* and for the control of SRD associated with *Actinobacillus pleuropneumoniae, Pasteurella multocida*, and *Mycoplasma hyopneumoniae* in groups of pigs where SRD has been diagnosed.[1,2]

Tulathromycin may be effective in treating various infections in commercial bison, white-tailed deer, small ruminants, and rabbits.

The World Health Organization has designated tulathromycin as a Critically Important, Highest Priority antimicrobial for human medicine.[3] The Office International des Epizooties (OIE) has designated tulathromycin as a Veterinary Critically Important Antimicrobial (VCIA) Agent in bovine and swine species.[4]

Pharmacology/Actions

Although tulathromycin is a macrolide antibiotic, it is structurally unique in that it has three amine groups (tribasic), while erythromycin and azithromycin have one (monobasic) and two (dibasic) groups, respectively. The tribasic group of compounds are called triamilide macrolides.

As with other macrolides, tulathromycin is effective against a range of gram-positive bacteria, with enhanced activity against-gram negatives. It is believed that tulathromycin's tribasic structure allows it to better penetrate gram-negative bacteria and its low affinity for bacterial efflux pumps may allow the drug to remain and accumulate within bacteria.

The mechanism of action of tulathromycin is similar to other macrolides. It inhibits protein synthesis by penetrating the cell wall and binding to the 50S ribosomal subunits in susceptible bacteria. It is considered a bacteriostatic antibiotic although there is the potential for time-dependent bactericidal action, particularly with high concentrations. The drug possesses bactericidal activity particularly for *Mannheimia haemolytica* and *Pasteurella multocida*. A postantibiotic effect can be produced; the duration is both drug and pathogen dependent.

Tulathromycin's efficacy is enhanced by its ability to accumulate and persist in pulmonary epithelial lining fluid, macrophages and neutrophils. The drug shows notable accumulation and long persistence in lung tissue. Neither time-dependent nor concentration-dependent models may accurately predict or describe the drug's efficacy. The efficacy of some modern macrolides (eg, azithromycin) may be more predictive by assessing the total drug exposure to the pathogen; the AUC:MIC ratio may be helpful.

Tulathromycin reportedly possesses immunomodulatory effects in leukocytes in vitro and anti-inflammatory effects in pigs in experimental models of *A pleuropneumoniae* infection and nonmicrobial-induced pulmonary inflammation. This suggests that in addition to its antimicrobial properties, tulathromycin may dampen severe proinflammatory responses and drive resolution of inflammation in pigs with microbial pulmonary infections.[5] The accumulation of macrolides in anti-inflammatory cells is widely recognized.[6]

Bacterial isolates susceptible to tulathromycin at concentrations of 16 µg/mL or less are reported as susceptible to tulathromycin. The MIC_{90} values reported for *M haemolytica* and *P multocida* in cattle with BRD are 2 µg/mL and 1 µg/mL, respectively. To date, resistance development to tulathromycin has not been a major problem; however, greater resistance against tulathromycin in *M haemolytica* isolates has been identified from 2013 to 2017 when compared to isolates from 2008 to 2012.[7]

Pharmacokinetics

In feeder calves given 2.5 mg/kg SC (in the neck), tulathromycin is rapidly and nearly completely absorbed (bioavailability greater than 90%). Peak plasma concentrations generally occur within 15 minutes after dosing. Volume of distribution is very large (≈11 L/kg) and total systemic clearance is ≈170 mL/hour/kg. This extensive volume of distribution is largely responsible for the long elimination half-life of this compound. In plasma, elimination half-life is ≈2.75 days, but in lung tissue it is ≈8.75 days. Tulathromycin is eliminated from the body primarily unchanged via biliary excretion with half of the dose being eliminated in the feces. Effective concentrations of tulathromycin against pathogens commonly associated with BRD are maintained for up to 10 days after administration to cattle.[8]

In a pharmacokinetic study of 6 healthy adult horses following IM administration of tulathromycin at 2.5 mg/kg, half-life was 54.8 hours, bioavailability was 99.4%, and time to peak concentration was 0.75 hours. After IV administration of the same dose, half-life was 59.8 hours and volume of distribution was 16.8 L/kg.[9] Tulathromycin reaches high concentrations in the pulmonary epithelial lining fluid (PELF) and bronchoalveolar lavage cells (BALC) in horses after both IM and IV administration of 2.5 mg/kg.

Following IM administration to feeder pigs at a dosage of 2.5 mg/kg, tulathromycin is readily and rapidly absorbed (bioavailability 88%) with peak levels occurring in ≈15 minutes. Tulathromycin rapidly distributes into body tissues, and the volume of distribution is 13 to15 L/kg. Plasma half-life is ≈60 to 90 hours, but lung tissue half-life is ≈5.9 days. Tulathromycin is eliminated from the body primarily unchanged via the feces and urine. In pigs, two-thirds of the dose is eliminated in the feces.

Results from a manuscript detailing the administration of a single injection of tulathromycin 2.5 mg/kg SC in deer reports similarity in maximal serum concentrations between deer and cattle and high lung concentrations in deer, suggesting the recommended cattle dosage is effective in deer. Tissue concentrations persisted for 56 days suggesting a need for longer withdrawal times in deer than cattle.[10]

The pharmacokinetics of tulathromycin in sheep appear to be similar enough to those in goats and cattle to recommend similar dosing (2.5 mg/kg SC), assuming that the target pathogens have similar inhibitory concentrations.[11]

Contraindications/Precautions/Warnings

Tulathromycin is contraindicated in animals with a prior hypersensitivity reaction to the drug.

Adverse Effects

At labeled dosages, adverse effects appear to be minimal in cattle and swine. At therapeutic doses, transient hypersalivation, head shaking, and pawing at the ground have been reported. One feeder calf in a field study developed transient dyspnea. Injection site reactions are most commonly reported and there have been some reports of anorexia in cattle to the FDA's Adverse Drug Reporting database. Subcutaneous or intramuscular injection can cause a transient local tissue reaction that may result in trim loss at slaughter.

In foals, self-limiting diarrhea, elevated temperature, and swelling at the injection site have been reported. In horses, significant injection site reactions and systemic reactions (sweating, pawing, lateral recumbency) have been documented following IM and SC injections.[9]

All goats used in a pharmacokinetic study developed injection site reactions.[12]

Reproductive/Nursing Safety

The effects of tulathromycin on reproductive performance, pregnancy and lactation have not been determined.[1,2]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In cattle (feeder calves), single SC doses of up to 25 mg/kg caused transient indications of pain at the injection site, including head shaking and pawing at the ground. Injection site swelling, discoloration of the subcutaneous tissues at the injection site and corresponding histopathologic changes were seen in animals in all dosage groups.

The SC administration of 12.5 to 15 mg/kg (5 to 6 times the labeled dosage) of tulathromycin to feeder calves caused no clinical signs of cardiovascular toxicity and no macroscopic tissue lesions. Minimal to mild myocardial degeneration was reported in 1 of 6 calves given a single dose of 12.5 mg/kg and 2 of 6 calves given 15 mg/kg.

In swine, single IM doses of up to 25 mg/kg caused transient indications of pain at the injection site, restlessness, and excessive vocalization. Tremors occurred briefly in one animal receiving 7.5 mg/kg BW.

No systemic treatment for single overdoses should be necessary; localized treatment at the injection site (eg, ice pack) to reduce swelling and pain as well as FDA-approved analgesic medications can be considered.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

- No drug interactions are noted in the product labels, and none could be found in other references for tulathromycin.

Laboratory Considerations

- None noted

Dosages

CATTLE:

Susceptible infections, labeled indications (label dosage; FDA-approved):

a) **Using 100 mg/mL product**: 2.5 mg/kg (1.1 mL/100 lb) SC as a single dose in the neck.[1] Do not inject more than 10 mL per

injection site.

b) **Using 25 mg/mL product**: 2.5 mg/kg (1 mL/22 lb) SC as a single dose in the neck.[2] Do not inject more than 11.5 mL per injection site.

SWINE:

Susceptible infections, labeled indications (label dosage; FDA-approved):

a) **Using 100 mg/mL product**: 2.5 mg/kg (0.25 mL/22 lb) IM as a single dose in the neck.[1] Do not inject more than 2.5 mL per injection site.

b) **Using 25 mg/mL product**: 2.5 mg/kg (1 mL/22 lb) IM as a single dose in the neck.[2] Do not inject more than 4 mL per injection site.

GOATS:

Pneumonia associated with *Mannheimia haemolytica*, *Pasteurella multocida*, and *Mycoplasma* spp. (extra-label): 2.5 mg/kg SC; repeat in 7 days if necessary.[12,13] Dosage is based on pharmacokinetic studies in meat and dairy goats. After a single dose, a 34-day meat withdrawal interval and a 45-day milk withdrawal time are recommended.[12–14]

DEER:

Susceptible infections (extra-label): Authors report using the cattle dose at 2.5 mg/kg SC once with the need to have a longer withdrawal time compared to cattle.[10]

Monitoring

- Clinical efficacy

Client Information

- Follow dosing guidelines exactly. Withdrawal times in cattle differ between products.
- Not for female dairy cattle 20 months or older or in poultry
- Cattle are dosed subcutaneously in the neck. Swine are dosed intramuscularly in the neck.

Chemistry/Synonyms

Tulathromycin is a semi-synthetic macrolide antibiotic of the subclass triamilide. It occurs as white to off-white crystalline powder that is readily soluble in water at pH less than 8. At a pH of 7.4 (physiological pH), tulathromycin (a weak base) is ≈50 times more soluble in hydrophilic than hydrophobic media.

The commercially available injections contain tulathromycin as the free base in an equilibrated mixture of the two isomeric forms of tulathromycin in a 9:1 ratio. The injectable vehicle consists of 50% propylene glycol, monothioglycerol (5 mg/mL); citric and hydrochloric acids are added to adjust pH, and it has a relatively low viscosity.

Tulathromycin may also be known as tulathromycine, tulathromycinum, CP-472295 (component A), CP-547272 (component B), or *Draxxin*®.

Storage/Stability

Tulathromycin injection should be stored at or below 25°C (77°F); some products allow for excursions up to 40°C (104°F). The number of times a vial may be punctured varies by vial size and by manufacturer, as does the length of time the vial may be used after first puncture; consult product labels for specific information.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tulathromycin Injection: 100 mg/mL in 50 mL, 100 mL, 250 mL, and 500 mL vials; *Draxxin*®, generic; (Rx). FDA-approved for use in beef and non-lactating cattle, and suckling calves, including dairy and veal calves, and swine. Cattle intended for human consumption must not be slaughtered within 18 days from the last treatment, and the swine withdrawal is 5 days. Do not use in female dairy cattle 20 months of age or older. NADA# 141-244

Tulathromycin Injection: 25 mg/mL in 50 mL, 100 mL, and 250 mL vials; *Draxxin® 25*; (Rx). FDA-approved for use in suckling calves, dairy calves, veal calves and swine. Not for use in ruminating cattle. When used as labeled; swine withdrawal = 5 days and calves = 22 days. NADA# 141-349

Tulathromycin and Ketoprofen Injection: Tulathromycin 100 mg/mL and Ketoprofen 120 mg/mL in 50 mL, 100 mL, 250 mL, and 500 mL vials; *Draxxin® KP*; (Rx). FDA approved for use in beef steers, beef heifers, beef calves 2 months of age and older, beef bulls, dairy bulls, and replacement dairy heifers. Not for use in reproducing animals over one year of age, or in dairy or veal calves less than 2 months of age. When used as labeled, withdrawal time is 18 days. NADA# 141-543

HUMAN-LABELED PRODUCTS: NONE

Tylosin

(***tye***-loe-sin) *Tylan*®

Macrolide Antibiotic

Prescriber Highlights

- ► Approved for use in cattle, swine, poultry, and honey bees; can be used in dogs and cats with diarrhea
- ► Contraindications include animals with a hypersensitivity to it or other macrolide antibiotics, and in horses and possibly other hindgut fermenters.
- ► Adverse effects include pain and local reactions after IM injection and GI upset (eg, anorexia, diarrhea) after PO administration; may cause severe diarrhea if administered orally to ruminants. Swine can experience edema of rectal mucosa and mild anal protrusion with pruritus, erythema, and diarrhea.
- ► Use in food animals (including honey bees) requires a prescription (soluble powder) or a veterinary feed directive (medicated feed).

Uses/Indications

Oral tylosin is commonly recommended for the adjunctive treatment of acute and chronic diarrhea in dogs, cats, and some small mammals. There is good evidence supporting the use of tylosin in the treatment of chronic diarrhea in dogs.[1–3]

Although oral tylosin has been anecdotally used in dogs to treat tear staining caused by chronic epiphora, supporting evidence for this use is weak, and there are concerns about the use of antimicrobials for nonantimicrobial indications.[4] Tylosin has demonstrated efficacy in the treatment of canine superficial and deep pyoderma caused by *Staphylococcus intermedius*.[5–8] Although tylosin is not commonly used as first-line therapy for treatment of pyoderma, it may be useful in cases for which resistance occurs.

In beef and nonlactating dairy cattle, tylosin is indicated for the treatment of bovine respiratory complex, foot rot, calf diphtheria, and metritis. In swine, it is indicated for the treatment of arthritis, pneumonia, erysipelas, and dysentery or enteropathies. Tylosin is also used clinically (extra-label) in cattle and swine for the treatment of infections caused by susceptible organisms; however, other approved antibiotics are generally preferred for systemic therapy.

The World Health Organization (WHO) has designated macrolides as Critically Important, Highest Priority antimicrobials for human medicine.[9] The Office International des Epizooties (OIE) has designated macrolides as Veterinary Critically Important Antimicrobial (VCIA) Agents in veterinary species.[10]

Pharmacology/Actions

Tylosin, a bacteriostatic antibiotic, is thought to have the same mechanism of action as erythromycin (ie, binds to 50S ribosome and inhibits protein synthesis) and exhibits a similar spectrum of activity. Tylosin has activity primarily against gram-positive bacteria, including streptococci and staphylococci (eg, *Staphylococcus pseudintermedius*).[7] There is some activity against gram-negative bacteria, but it is limited. Tylosin has some activity against *Campylobacter* spp but is not a recommended first-line agent for that bacteria. Good activity against *Mycoplasma* spp is present.[11] Over 50% of *Enterococcus faecalis* canine isolates from healthy dogs were resistant to tylosin in a study.[12] Tylosin may increase concentrations of enterococci in the jejunum, resulting in probiotic effects (ie, improved microbiota and clinical signs).[13,14] Tylosin may also have direct anti-inflammatory effects[15] and immunomodulatory effects on cell-mediated immunity.

Pharmacokinetics

In mammals, tylosin tartrate is well absorbed from the GI tract, primarily from the intestine. The phosphate salt is not as well absorbed after oral administration. Bioavailability after IM injection is ≈70% to 95%.[16,17] Peak concentration is reached in 1.5 to 2 hours in cows and swine[17–20] and ≈3 to 4 hours in sheep and goats.[16,21] Similar to erythromycin, tylosin is well distributed in the body after systemic absorption, with the exception of penetration into the CSF. The volume of distribution of tylosin is reportedly 1.7 L/kg in small animals and 1 – 2.3 L/kg in cattle.[18,22] In lactating dairy cattle, the milk to plasma ratio is ≈5.[18,20]

Tylosin is eliminated in the urine and bile, apparently as unchanged drug. The elimination half-life of tylosin is reportedly 54 minutes in dogs,[23] 139 minutes in newborn calves, 64 minutes in calves 2 months of age or older, and 80 to 97 minutes in cows.[18,24] The elimination half-life is ≈4.5 hours in swine, sheep, and goats.[16,17]

In chickens, oral bioavailability of tylosin tartrate is 27%. Peak concentration of 0.44 µg/mL is reached ≈1.3 hours after oral administration. Elimination half-life is 1.34 hours.[25]

Contraindications/Precautions/Warnings

Tylosin is contraindicated in patients that are hypersensitive to it or other macrolide antibiotics (eg, erythromycin). Tylosin is contraindicated in horses, as severe and sometimes fatal diarrhea may result; the drug should be used with extreme caution, if at all, in other hindgut fermenters (eg, rabbits).

Adverse reactions, including shock and death, may result from overdose in baby pigs.[26,27] Do not attempt injection into pigs weighing less than 11.4 kg (25 lb) with the 200 mg/mL formulation; in these pigs it is recommended to use the 50 mg/mL injection with a syringe that can accurately measure 0.1 mL.

Adverse Effects

The most likely adverse effects are pain and local reactions at IM injection sites and mild GI upset (eg, anorexia, diarrhea). Tylosin may induce severe diarrhea if administered orally to ruminants or by any route to horses. In swine, reported adverse effects include edema of rectal mucosa and mild anal protrusion with pruritus, erythema, and diarrhea.

Reproductive/Nursing Safety

Safety of tylosin in pregnant animals has not been established, but other macrolides are considered safe for use during pregnancy. Tylosin is excreted into milk at concentration up to 5 times higher than is found in serum.[18] Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Tylosin is relatively safe in most overdose situations. LD_{50} in pigs is greater than 5 g/kg PO and ≈1 g/kg IM. Dogs have been reported to tolerate oral doses of 800 mg/kg. Long-term (ie, 2-year) oral administration of up to 400 mg/kg produced no organ toxicity in dogs. Shock and death have been reported in piglets overdosed with tylosin.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center that specializes in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tylosin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate. Refer to ***Erythromycin*** for more information on potential interactions.

- **Bentonite**: Simultaneous administration of tylosin (in drinking water or feed) and bentonite (mixed in feed as a mycotoxin binder) should be avoided, as there is significant reduction in tylosin plasma levels and area under the curve (AUC) in chickens.[28]
- **Digoxin**: May increase digoxin blood concentrations with resultant toxicity

Laboratory Considerations

- Macrolide antibiotics may cause falsely elevated **ALT** (SGPT) and **AST** (SGOT) values when using colorimetric assays.
- Fluorometric determinations of **urinary catecholamines** can be altered by concomitant macrolide administration.

Dosages

DOGS/CATS:

NOTES:

1. Using volumetric containers (eg, teaspoons) to measure tylosin soluble powders is not necessarily accurate; however, 1 level teaspoon (5 mL) of powder contains ≈2.5 – 2.7 g of tylosin, and ⅛ level teaspoon contains ≈325 mg of tylosin.
2. Powder is unpalatable.

Antibiotic-responsive diarrhea and adjunctive treatment of inflammatory bowel disease (IBD) in dogs; (extra-label): 20 – 25 mg/kg PO once daily has been studied,[1–3] while 20 mg/kg PO every 8 to 12 hours has also been suggested.[29] Duration is poorly defined; 7 days has been used in some studies, but 4 to 6 weeks has been recommended.[30] Diarrhea often reappears within weeks after discontinuation (some dogs with tylosin-responsive diarrhea remain clinically normal while treatment continues). A lower dose of 5 – 15 mg/kg PO once daily has been effective in dogs that have relapsed.[1–3]

Adjunctive treatment of colitis (extra-label): 10 – 15 mg/kg PO every 8 hours for 14 to 28 days, then maintain with 5 mg/kg PO every 24 hours[31]

Campylobacteriosis (extra-label): 11 mg/kg PO every 8 hours[32]

***Clostridium perfringens*-associated diarrhea** (extra-label): Although there is little objective information on when and how to provide treatment, tylosin 10 – 20 mg/kg PO every 12 to 24 hours has been recommended.[32]

***Cryptosporidium* spp-associated diarrhea in cats** (extra-label):

10 – 15 mg/kg PO every 12 hours will sometimes resolve diarrhea. Tylosin can be a GI irritant; if a positive response has been noted in the first 7 days of therapy, and if there is no toxicity, continue treatment for 1 week after clinical resolution of diarrhea. Some cats with *Cryptosporidium* spp infection (with or without *Giardia* spp coinfection) require several weeks of treatment prior to resolution of diarrhea.[33]

Canine pyoderma (extra-label): 10 – 20 mg/kg PO every 12 hours; continue treatment for 7 days after resolution of active lesion.[6,8]

CATTLE:

Susceptible infections in beef and nonlactating dairy cattle (label dosage; FDA-approved): 17.6 mg/kg IM once daily. Continue treatment for 24 hours after clinical signs have resolved, not to exceed 5 days. Do not inject more than 10 mL per site. Use the 50 mg/mL formulation in calves weighing less than 91 kg (200 lb).[26]

SWINE:

Susceptible infections (label dosage; FDA-approved):

a) **Injection**: 8.8 mg/kg IM twice daily. Continue treatment for 24 hours after clinical signs have resolved, not to exceed 3 days.[26] Do not inject more than 5 mL per site. Use the 50 mg/mL formulation for piglets weighing less than 11.3 kg (25 lb).[27]

b) **In drinking water**: 250 mg tylosin soluble powder is added per gallon of sole source drinking water for 3 to 10 days; subsequent treatment with tylosin medicated feed may be necessary.[11]

POULTRY:

Chickens (label dosage; FDA-approved):

a) **Necrotic enteritis**: 851 – 1419 mg/gallon of sole source drinking water for 5 days[11]

b) **Chronic respiratory disease**: 2000 mg/gallon of sole source drinking water for 3 days; treatment duration of 1 to 5 days may be considered based on severity of infection.[11]

Turkeys (label dosage; FDA-approved): 2000 mg/gallon of sole source drinking water for 3 days; treatment duration of 2 to 5 days may be considered based on severity of infection.[11]

Reduction in severity of effects of infectious sinusitis associated with *Mycoplasma gallisepticum*: 2000 mg/gallon of sole source drinking water for 3 days; treatment duration of 2 to 5 days may be considered based on severity of infection.[11]

FERRETS:

Susceptible enteric infections (extra-label): 10 mg/kg PO once to twice daily[34]

RABBITS, RODENTS, SMALL MAMMALS:

NOTE: Use with caution in hindgut fermenters.
Rabbits: 10 mg/kg SC or IM every 12 to 24 hours[35]
Gerbils, Hamsters, Rats: 10 mg/kg SC once a day[36]

HONEY BEES:

Control of American foulbrood (label dosage; FDA-approved): 200 mg tylosin mixed in 20 g confectioners/powdered sugar and dusted over the top bars of the brood chamber once weekly for 3 weeks. Apply early in the spring or fall before the main honey flow begins.[11]

Monitoring

- Clinical efficacy
- Adverse effects, including signs of enterocolitis in hindgut fermenters

Client Information

- This medicine is most commonly used in dogs and cats to treat diarrhea and inflammation of intestines; it may also be used to treat respiratory infections in birds (including chickens) and reptiles.
- Do not give this medicine to horses or ponies.
- Oral doses may be given with or without food. Give this medicine with food if stomach upset or vomiting occurs.
- The powder has an extremely bitter taste. The animal may be more likely to accept the medication if the powder is placed in an empty gelatin capsule.
- Tylosin is usually well tolerated when it is given orally to small animals (ie, dogs and cats). Contact your veterinarian if your animal experiences side effects.
- When tylosin is given in drinking water, prepare a fresh solution every 3 days. First mix the appropriate amount of tylosin powder with 1 gallon of drinking water, then further dilute it according to the product label.

Chemistry/Synonyms

Tylosin, a macrolide antibiotic composite structurally related to erythromycin, is produced from *Streptomyces fradiae* and may contain tylosin B, C, and D in addition to the main component. It occurs as an almost white to buff-colored powder with a pK_a of 7.1. It is slightly soluble in water and soluble in alcohol. Tylosin is considered to be highly lipid soluble. The tartrate salt is soluble in water. The injectable form of the drug (as the base) is in a 50% propylene glycol solution.

Tylosin may also be known as desmycosin, tilosina, tylosiini, tylosinum, tylozin, tylozyna, or *Tylan*®.

Storage/Stability

Unless otherwise instructed by the manufacturer, injectable tylosin should be stored in well-closed containers at 25°C (77°F). Tylosin, like erythromycin, is unstable in acidic (pH less than 4) media.

Compatibility/Compounding Considerations

Because converting volume measurements into weights is not very accurate for powders, it is recommended to weigh powders when using them for pharmaceutical purposes. However, if this is not possible, 1 level teaspoon (5 mL) of commercially available tylosin tartrate (*Tylan*® *Soluble*) contains ≈2.5 to 2.7 g of tylosin; ⅛ level teaspoon contains ≈325 mg of tylosin.

Tylosin tartrate powder added to food can be unpalatable for dogs or cats. Placing the proper dose in a gelatin capsule may be more preferable than mixing it into food. Another suggestion for dogs or cats that absolutely will not eat food with tylosin in it is to melt ≈¼ teaspoon of butter, pour into mini ice tray compartments, add the appropriate dose of tylosin powder, mix well, and freeze. (**NOTE**: Stability information for this procedure has not been performed.) Alternatively, the medication can be compounded. See ***Appendix*** for finding a quality assured pharmacy.

It is not recommended to mix tylosin for injection with other drugs, as precipitation of tylosin may result.[26,27]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

A prescription or veterinary feed directive is required to treat any food animals (including honey bees) with tylosin.

Tylosin Injection: 50 mg/mL and 200 mg/mL; *Tylan*®, generic; (OTC). FDA approved for use in nonlactating dairy cattle, beef cattle, and swine. Slaughter withdrawal (at labeled doses): cattle = 21 days; swine = 14 days. Not for use in calves intended to be processed for veal, preruminating calves, or female dairy cattle 20 months of age or older (including dry cows).

Tylosin Tartrate Powder: (≈2.5 – 2.7 g/level teaspoon) in 100 g bottles; *Tylan*® *Soluble*, *generic*; (Rx). FDA-approved for use in turkeys

(not layers), chickens (not layers), swine, and honey bees. Slaughter withdrawal swine = 2 days; chickens = 1 day; turkeys = 5 days. Complete honey bee treatments at least 4 weeks prior to the main honey flow.

There are many FDA-approved tylosin phosphate products available via veterinary feed directive for use in beef cattle, swine, and honey bees. Many of these products have other active ingredients included in their formulations.

HUMAN-LABELED PRODUCTS: NONE

Ursodiol

Ursodeoxycholic acid (UDCA)

(ur-soe-***dye***-ole) *Actigall®, URSO®*

Choleretic; Bile Acid; Hepatoprotectant

Prescriber Highlights

- ► Bile acid that may be useful for adjunctive treatment of hepatobiliary disease in dogs and cats, particularly cholestatic disorders; may also be effective in treating biliary sludge (microlithiasis)
- ► Contraindicated in the presence of extrahepatic bile duct obstruction or vanishing bile duct syndrome; do not use in rabbits and other hindgut fermenters because of bacterial metabolism to the hepatotoxic bile acid, lithocholic acid.
- ► Appears to be well tolerated in dogs and cats; should be given with food

Uses/Indications

In small animal species, ursodiol may be useful as adjunctive therapy for the medical management of acute and chronic cholestatic hepatobiliary disorders by ameliorating the progression of inflammatory and degenerative changes associated with these conditions[1–7]; it may also aid in the resolution of biliary sludge accumulation (ie, microlithiasis).[8,9] Ursodiol can also be used as part of the medical management of gallbladder mucoceles by protecting against hepatobiliary epithelial damage that occurs with this condition; however, there is no evidence that ursodiol aids in the medical dissolution of mature gallbladder mucoceles and surgical correction is indicated in many patients.[10,11]

Although ursodiol is approved to dissolve cholesterol choleliths in humans,[12] it will not dissolve choleliths in small animal species as they are commonly composed of calcium carbonate (dogs) or calcium bilirubinate (cats), not cholesterol.

Pharmacology/Actions

Ursodiol is a noncytotoxic bile acid that has several pharmacologic actions.[13–15] After oral administration, ursodiol decreases intestinal absorption of cholesterol and suppresses hepatic synthesis and secretion of cholesterol, and ultimately reduces cholesterol saturation in the bile. In veterinary medicine, ursodiol is used for its choleretic (increased bile flow) properties. It increases the expression of membrane transport proteins on the canalicular membrane of hepatocytes that are responsible for the movement of bile acids from hepatocytes to the bile canaliculi. Secretion of ursodiol into the bile ducts stimulates the flow of bicarbonate-rich bile and promotes the elimination of toxic bile acids. A process known as cholehepatic shunting allows for the recirculation of ursodiol from the cholangiocytes back to the hepatocytes.

Ursodiol has antioxidant, anti-inflammatory, and some mild immunomodulatory effects. It promotes hepatobiliary cytoprotection by replacing the more toxic hydrophobic bile acids (eg, lithocholic acid, deoxycholic acid), which accumulate in the bile acid pool with cholestatic liver disease. Additionally, it is antiapoptotic through its ability to stimulate cell survival pathways; ursodiol also acts as a molecular chaperone and protects against endoplasmic reticulum-mediated hepatobiliary cellular stress caused by toxic bile acids.

Pharmacokinetics

Ursodiol is well absorbed from the small intestine after oral administration. In humans, up to 90% of the dose is absorbed from the small intestine into the portal circulation. Absorption is improved in the presence of food.[12] Once it reaches the liver, it is extracted from the portal circulation, conjugated with either taurine or glycine in hepatocytes, then secreted into bile. Ursodiol concentrates in the gallbladder, and the concentration in bile plateaus at ≈30% to 50% of total bile acid after ≈3 weeks. After biliary secretion into the duodenum, the majority of conjugated ursodiol is extracted by the apical bile acid transporter in the ileum, deposited into the portal circulation, and transported back to the liver. A small portion of conjugated ursodiol in the intestinal tract may be deconjugated by bacterial enzymes and either be absorbed there or pass to the colon where it may be eliminated or converted to other bile acids (including the potentially hepatotoxic bile acid, lithocholic acid), which also are eliminated in the feces. In most species, with the exception of hindgut fermenters, the amount of this hepatotoxic bile acid generated is minimal and inconsequential.

The very small quantities of unconjugated ursodiol that enter the systemic circulation are bound (70%) to plasma proteins, and less than 1% is excreted in the urine. Ursodiol has been detected in the serum of dogs and cats following oral administration.[3,16]

Contraindications/Precautions/Warnings

Ursodiol is contraindicated in rabbits and other hindgut fermenters as it is converted into the hepatotoxic bile acid, lithocholic acid.[17] It is also contraindicated in patients hypersensitive to it or other bile acid products and in patients with complete extrahepatic bile duct obstruction. Ursodiol should also be used cautiously in dogs and cats with histologically confirmed hepatic ductopenic disorders (eg, cholangitis, cholangiohepatitis) as it may lead to progressive biliary damage. The benefits of using ursodiol should be weighed against its risks in patients with complications associated with choleliths (eg, biliary obstruction, biliary fistulas, cholecystitis, pancreatitis, cholangitis). Ursodiol does not dissolve radiopaque, calcified cholesterol, or radiolucent bile pigment choleliths.[12]

Adverse Effects

Ursodiol appears to be well tolerated in dogs and cats.[16,18–20] A study in 20 healthy dogs given ursodiol 10 to 15 mg/kg PO daily showed no changes in hepatic ultrasound, serum liver enzymes, total bilirubin, cholesterol, or triglyceride concentrations after 6 to 8 weeks of administration.[20] An additional study in 12 healthy dogs at the same dose showed no changes in serum bile acids testing and hepatic histopathology after 7 days of therapy.[19] Two studies in normal cats given ursodiol showed no changes in CBC, biochemical panel, urinalysis, ultrasound, or hepatic histopathology, but a significant decrease in serum cholesterol was noted.[16,18] See ***Laboratory Monitoring***.

In humans taking ursodiol, elevated liver enzymes, diarrhea, abdominal pain, and other GI effects have rarely been noted.[12] Although hepatotoxicity has not been associated with ursodiol therapy in humans, there are some patients with an inability to sulfate lithocholic acid (a naturally occurring bile acid and also a metabolite of ursodiol). These patients are at risk for increased concentrations of lithocholic acid as bile acid sulfation is a mechanism for bile acid detoxification. The clinical significance of this information for dogs and cats is unclear.

Reproductive/Nursing Safety

No evidence of impaired fertility or fetal harm was found in pregnant rabbits or rats given ursodiol 7 times or 22 times, respectively, the maximum human labeled dose.[12] It does not cross the placenta and has been safely used in the treatment of intrahepatic cholestasis of pregnancy in women.[21]

It is not known whether ursodiol is excreted in breast milk. Because minimal drug is systemically absorbed, clinical effects on nursing animals are unlikely.

Overdose/Acute Toxicity

Overdoses of ursodiol would most likely cause diarrhea, although salivation and vomiting have been noted in dogs. Treatment, if required, could include supportive therapy, oral administration of an aluminum-containing antacid (eg, aluminum hydroxide suspension), or gastric emptying (if large overdose) with concurrent administration of activated charcoal or cholestyramine suspension.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ursodiol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aluminum-containing Antacids**: May bind to ursodiol, thereby reducing its efficacy
- **Cholestyramine**: May bind to ursodiol, thereby reducing its efficacy
- **Cyclosporine**: May increase cyclosporine serum concentrations
- **Estrogens**: May increase hepatic cholesterol secretion and counteract ursodiol effects in humans; significance in veterinary patients is unknown.
- **Fenofibrate**: Fibrates increase cholesterol formation and may counteract ursodiol effects in humans; significance in veterinary patients is unknown.
- **Gemfibrozil**: Fibrates increase cholesterol formation and may counteract ursodiol effects in humans; significance in veterinary patients is unknown.
- **Taurine**: Although not documented, concern has been raised that chronic administration of ursodiol in cats may lead to taurine deficiency.

Laboratory Considerations

- Ursodiol may falsely elevate total **serum bile acid test** results, although the magnitude of this change may not be clinically relevant.[16,19,20] It is recommended to stop ursodiol for a minimum of 2 to 3 days before performing total serum bile acid testing.

Dosages

DOGS:

Medical treatment of biliary sludge (microlithiasis) and adjunctive treatment of acute and chronic nonobstructive cholestatic disorders or chronic hepatitis (extra-label): 10 – 15 mg/kg PO with food once daily day or divided twice daily[22]

CATS:

Adjunctive treatment of nonobstructive acute and chronic cholestatic disorders (extra-label): 10 – 15 mg/kg PO with food once daily day or divided twice daily[6]

Lymphocytic cholangitis: 15 mg/kg PO with food daily produced morphologic and immunohistochemical improvements, although prednisolone reduced inflammation to a greater extent and promoted longer survival.[1,2]

BIRDS:

Adjunctive treatment of liver disease (extra-label): 10 – 15 mg/kg PO once daily[23]

Monitoring

- Periodic abdominal ultrasonography based on the clinical presentation of the underlying condition being treated (eg, biliary sludge)
- Baseline and periodic (eg, every 3 to 6 months) serum liver chemistry panel (eg, ALT, ALP, GGT, total bilirubin)

Client Information

- Ursodiol is used to help animals with liver, pancreas, and/or gallbladder problems.
- This medicine works best when given with food. It also has a bitter taste that can often be masked when the medicine is given with food.
- Ursodiol is usually well-tolerated by dogs and cats. Diarrhea is the most common side effect. Contact your veterinarian if you have any concerns about your animal's condition.
- Do not give this medicine to rabbits, guinea pigs, rodents, or horses.

Chemistry/Synonyms

Ursodiol, also known as ursodeoxycholic acid, is a naturally occurring bile acid. It occurs as a white or almost white, bitter-tasting crystalline powder that is practically insoluble in water and freely soluble in alcohol.

Ursodiol may also be known as acidum ursodeoxycholicum, UDCA, or ursodesoxycholic acid; many trade names are available, including *Actigall*®.

Storage/Stability

Unless otherwise specified by the manufacturer, store ursodiol at room temperature (20°C to 25°C [68°F-77°F]) in tight containers. Half tablets maintain acceptable quality for up to 28 days when stored in the bottle at room temperature. Because of the bitter taste, store the segments separately from whole tablets.

Compatibility/Compounding Considerations

Ursodiol 50 mg/mL oral suspension can be compounded from commercially available tablets. Triturate 20 ursodiol 250 mg tablets with 50 mL of *Ora-Plus*® and qs ad to 100 mL with *Ora-Sweet*®. The resulting suspension retains 90% potency for 90 days when stored at both 5°C (41°F) or 25°C (77°F). Compounded preparations of ursodiol should be protected from light and shaken well before use.[24]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Ursodiol Oral Capsules: 300 mg; *Actigall*®, generic; (Rx)

Ursodiol Oral Tablets: 250 mg and 500 mg; *URSO*®*-250* and *-Forte*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Valacyclovir

(***val***-ay-***sye***-kloe-veer) *Valtrex®*

Antiviral

Prescriber Highlights

- ► Potentially useful for treating equine herpes viral infection; however, definitive proof is lacking
- ► Prodrug of acyclovir with improved oral absorption
- ► Should not be used in cats due to lack of efficacy and profound toxicity (ie, nephrotoxicity, hepatotoxicity, myelosuppression)
- ► Use with caution and consider dose reduction in patients with renal insufficiency.
- ► Patients must be adequately hydrated during treatment.
- ► Appears to be well tolerated in horses, but experience is limited

Uses/Indications

Valacyclovir may be effective for treating equine herpesvirus 1 (EHV-1) infection, although evidence to support this use is limited. In horses experimentally exposed to EHV-1, valacyclovir was effective in reducing viral replication as measured by decreased viral load in blood, nasal secretions, and bronchoalveolar fluid; however, viral load in the CSF did not differ from placebo.[1] Clinical signs improved when valacyclovir was given prior to EHV-1 exposure as well when given up to 2 days after viral challenge. In ponies experimentally infected with EHV-1 that received valacyclovir 1 hour prior to inoculation, the drug reduced respiratory signs, but not other clinical signs.[2] These findings resemble the experience in humans, where treatment is more likely to be successful when initiated early (ie, with the earliest symptom or sign of disease).

Valacyclovir treatment was reported in a retrospective study of 7 naturally occurring cases of EHV-1.[3] Another report of 31 horses treated with valacyclovir also found a strong decrease of EHV-1 viral load in nasal secretions and blood in all treated horses.[4] Successful valacyclovir use was reported in 2 stallions during an outbreak of equine coital exanthema[5] and in a single case of equine multinodular pulmonary fibrosis[6]; however, valacyclovir failed to reduce viral load in 6 horses diagnosed with equine multinodular pulmonary fibrosis, and 5 horses were euthanized due to progression of clinical signs.[7]

Valacyclovir did not suppress FHV-1 replication in cats.[8]

In humans, valacyclovir is used for treatment, suppression, and/or prevention of herpes and varicella viral infections, and, at high doses, for prevention of cytomegalovirus infections in immunocompromised patients.

Pharmacology/Actions

As a prodrug, valacyclovir is rapidly and almost completely hydrolyzed to the nucleoside analogue acyclovir and L-valine. Viral-specific thymidine kinase then converts acyclovir to acyclovir monophosphate, which is further phosphorylated to the active acyclovir triphosphate. Acyclovir triphosphate is incorporated into the viral DNA to cause viral DNA chain termination and thereby inhibits viral DNA synthesis and replication. Variations in acyclovir sensitivity and resistance are likely mediated by differing sensitivity, or outright deficiency of, viral thymidine kinase.[9,10]

The primary goal of antiherpetic therapy is to decrease viral replication until the immune system mounts an appropriate response and controls active infection.[9]

In humans, valacyclovir has antiviral activity against herpes labialis, herpes simplex, herpes zoster, varicella zoster, and cytomegalovirus. Resistance of herpes simplex and varicella zoster to acyclovir has been reported in humans and can result from changes in thymidine kinase or DNA polymerase.[11]

Pharmacokinetics

In horses, oral absorption of valacyclovir is 8-fold greater than acyclovir,[12] with bioavailability reported as 26%[12] and up to 50% when the drug is administered after intragastric lavage.[13] The effect of food on oral absorption is uncertain. The pharmacokinetic profile of valacyclovir at 20 mg/kg PO was nearly identical to acyclovir at 10 mg/kg administered as an IV infusion over 1 hour.[12] Peak serum concentration was reached ≈50 minutes after administration.[12,13] Volume of distribution was 9.8 L/kg,[12] but penetration into the CSF was minimal.[10] Protein binding was low at 10% to 20%.[12] Elimination half-life of unbound acyclovir was 8.8 hours.[12] Following administration of valacyclovir 40 mg/kg PO every 8 hours (mixed in applesauce), acyclovir serum concentration remained above 3 µg/mL (the EC_{50}[12]) for 60% of the dosing interval,[10] and concentrations from nasal swabs were 50% to 100% of serum concentration.[2] Serum acyclovir concentration (mean peak concentration, 1.5 µg/mL on day 4) was lower than expected in 6 horses with EHV-5 that received valacyclovir 30 mg/kg PO every 8 hours for 48 hours, then 20 mg/kg every 12 hours for 8 additional days.[7]

After a single dose of valacyclovir 40 mg/kg was given orally in eastern box turtles, peak concentration of 1.9 µg/mL was reached 13 hours after dosing, and half-life was 15.2 hours. In this species, valacyclovir 40 mg/kg PO every 24 hours is predicted to maintain concentrations above 0.45 µg/mL.[14]

In humans, valacyclovir is rapidly absorbed, with peak concentrations reached after 1.5 hours. Bioavailability is ≈55% and is not affected by food. Conversion to acyclovir occurs with first-pass hepatic and intestinal metabolism. Acyclovir is widely distributed into most tissues, and protein binding is ≈15%. Acyclovir undergoes minimal hepatic metabolism and is excreted equally via the kidneys (47%) and in the feces (46%). Elimination half-life is ≈3 hours but increases to 14 hours in patients with end-stage renal disease. Hepatic impairment does not alter acyclovir pharmacokinetics.

Contraindications/Precautions/Warnings

Valacyclovir should not be used in patients that are hypersensitive to valacyclovir or acyclovir.[11] Valacyclovir should not be used in cats, as it has caused significant toxicity (eg, severe myelosuppression, coagulative necrosis of the renal tubular epithelium, centrilobular atrophy and hepatic necrosis) in this species.[8]

Valacyclovir should be used with caution in patients with renal insufficiency, and in those that are geriatric (with or without diminished renal function), dehydrated, or receiving nephrotoxic drugs, as use under these conditions has resulted in acute kidney injury in humans[11]; dosage modification may be considered in patients with significant renal impairment. Maintaining hydration in patients receiving valacyclovir is critical, as the drug may precipitate in—and cause damage to—the renal tubules.[11]

Do not confuse valACYclovir with valGANciclovir or VANcomycin.

Adverse Effects

Valacyclovir appeared to be well tolerated in horses enrolled in pharmacokinetic or experimental studies.

In cats infected with feline herpesvirus 1 (FHV-1), lethargy, dehydration, and significant decreases in WBC and neutrophil counts were noted 6 to 9 days after initiation of valacyclovir at 60 mg/kg PO every 6 hours; histologic changes included bone marrow suppression, coagulative necrosis in the renal tubules, centrilobular atrophy, and hepatic necrosis.[8] The drug did not suppress FHV-1 replication.

In humans, GI distress (eg, nausea, vomiting, abdominal pain), CNS depression, agitation, confusion, seizures, encephalopathy, and ophthalmologic, hematologic, and dermatologic conditions have also been reported.[11] CNS adverse reactions are more common in geriatric patients; however, they have also been reported in adults

and pediatric patients with or without reduced renal function. Increased liver enzymes and crystal formation in renal tubules has also occurred.

Reproductive/Nursing Safety

Valacyclovir is rapidly metabolized to acyclovir, which is found in amniotic fluid and crosses the placenta. No evidence of embryo-fetal toxicity or teratogenicity has been observed in animal studies.[11]

Although valacyclovir is not detected in milk, low levels of the metabolite acyclovir are present in breast milk of women taking valacyclovir. This drug should be used with caution in lactating patients.[11]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

Vomiting and diarrhea are the predominant signs of acyclovir toxicity; acute kidney injury is theoretically possible with higher doses. Acute oral overdose is unlikely to cause significant toxicity. Crystalluria and elevated renal values occurred after administration of acyclovir at 188.7 mg/kg in a dog.

GI decontamination can be considered with ingestions of valacyclovir at 150 mg/kg or higher if done within 60 to 90 minutes of ingestion. Below 150 mg/kg, GI signs (eg, vomiting, diarrhea) will likely predominate. Nephrotoxicity, hepatotoxicity, and myelosuppression occurred in cats receiving 240 mg/kg/day.[8] Acyclovir is removed via hemodialysis.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving valacyclovir and may be of significance in veterinary patients; unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring should be performed when appropriate:

- **Cimetidine**: Concurrent use in humans increases acyclovir area under the curve (AUC) by 32%, but this effect is considered to be clinically insignificant
- **Meperidine**: Concurrent use may increase risk for CNS stimulation and excitation.
- **Mycophenolate**: Concurrent valacyclovir and mycophenolate may increase serum concentration of each.
- **Nephrotoxic Medications** (eg, aminoglycosides, amphotericin B, cyclosporine, and ifosfamide): Concomitant administration of valacyclovir with nephrotoxic medications may increase the potential for nephrotoxicity.[11] Renal function should be monitored.
- **Probenecid**: Concurrent use in humans increases acyclovir AUC by 49%, but this effect is considered clinically insignificant.
- **Theophylline, Aminophylline**: May increase serum concentration of theophylline or theophylline derivatives
- **Vaccines For Viral Encephalomyelitis Infections (eg, EEE, VEE, WEE, West Nile virus)**: Concurrent valacyclovir may diminish vaccine effectiveness.
- **Zidovudine**: Concurrent use may increase risk for CNS depression.

Laboratory Considerations

- No specific laboratory interactions or considerations have been noted.

Dosages

HORSES:

Prevention or reduction of clinical signs in horses infected with equine herpesvirus 1 (EHV-1) (extra-label): 27 – 30 mg/kg PO every 8 hours for 6 doses, followed by 18 – 20 mg/kg PO every 12 hours for 1 to 2 weeks[1,3,10]

Equine coital exanthema (ECE) caused by equine herpesvirus 3 (EHV-3) (extra-label): 27 mg/kg PO every 8 hours for 6 doses, followed by 18 mg/kg PO every 12 hours for 10 or 11 days was believed to prevent lesions from expanding; stallions returned to mating 7 to 9 days after discontinuation of the drug.[5]

Monitoring

- Viral load in blood and nasal secretions via quantitative PCR[15]
- Clinical efficacy
- Adverse effects
- Baseline and periodic serum renal chemistries (eg, serum BUN and creatinine) and urinalysis
- Hydration status

Client Information

- This medicine can be given with or without food. If GI upset (eg, diarrhea, lack of an appetite) occurs, give the medicine with a small amount of food. Contact your veterinarian if the problem continues.
- Be sure your animal has access to fresh drinking water at all times.

Chemistry/Synonyms

Valacyclovir is the L-valine ester of acyclovir. Commercial dosage forms contain valacyclovir hydrochloride, which occurs as a white to off-white powder with aqueous solubility of 174 mg/mL at 25°C (77°F). 1 mg valacyclovir is equal to 1.11 mg valacyclovir HCl.

Valacyclovir may also be known as 256U87; *Valtrex®*, *Shilova®*, *Vaclovir®*, and *Valvir®* are examples of the many trade names available in different countries.

Storage/Stability

Valacyclovir tablets should be stored at a controlled room temperature of 15°C to 25°C (59°F-77°F) in a tightly closed container out of reach of children and animals.

Compatibility/Compounding Considerations.

A 50 mg/mL oral suspension may be made with caplets, *ORA-Plus®*, and either *ORA-Sweet®* or *ORA-Sweet® SF* (similar suspending vehicles may be used). Crush ten 500 mg tablets in a mortar and reduce to a fine powder. Sequentially add four 5 mL portions of *ORA-Plus®* (20 mL total) and mix to a uniform paste; transfer to an amber glass bottle calibrated to 100 mL, rinse mortar with 10 mL of *ORA-Plus®* 3 times, then add quantity of syrup (*ORA-Sweet®* or *ORA-Sweet® SF*) sufficient to make 100 mL. Label "shake well" and "refrigerate." Stable for 28 days refrigerated between 2°C to 8°C (36°F-46°F).[16] If a less concentrated suspension is desired, use five 500 mg tablets to make 25 mg/mL and follow previously described process for 100 mL total volume.[13]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Valacyclovir Oral Tablets: 500 mg and 1000 mg; *Valtrex®*, generic; (Rx). Some presentations may be scored.

For the complete list of references, see **wiley.com/go/budde/plumb**

Vancomycin

(van-koe-***mye***-sin) *Vancocin®*

Glycopeptide Antibiotic

Prescriber Highlights

- ► IV antibiotic reserved for life-threatening, multidrug-resistant staphylococcal or enterococcal infections. It may also be used PO to treat *Clostridioides difficile* diarrhea.
- ► When used systemically, must be given IV; severe pain and tissue injury occur with SC or IM injection.
- ► Oral vancomycin is not absorbed systemically and is only useful for treating intraluminal enteric infections.
- ► Nephrotoxic drug with limited understanding of optimal dosing regimens
- ► If decreased renal function, decrease dosage and/or frequency
- ► Use in veterinary medicine is controversial because of the drug's importance in human medicine. Veterinary infectious disease specialists should be consulted prior to treatment. Use should be reserved for infections with confirmed susceptibility and for infections that are resistant to first- and second-tier options.

Uses/Indications

Because vancomycin is used for severe multidrug-resistant infections in humans, its use in veterinary medicine should be reserved for confirmed infections where culture and susceptibility testing demonstrates resistance to all other options (usually methicillin-resistant *Staphylococcus* spp [eg, MRSA, MRSP] or multidrug-resistant *Enterococcus* spp) and when the infection is considered treatable and consultation with an infectious disease expert has concluded that vancomycin is a viable and reasonable treatment.[1–3] Empirical use should be discouraged. Oral vancomycin may be useful for oral treatment of *Clostridioides difficile* enteric infections, although treatment of this infection is rarely required and other treatment options (ie, metronidazole) are available for instances when treatment is indicated.

Vancomycin may also be useful for local therapy, such as through implantation of antimicrobial-impregnated substances (eg, PMMA beads, gels),[4,5] intra-articular injection, and regional limb perfusion. Uses that do not result in appreciable systemic or enteric concentrations are not associated with the same concerns of emergence of resistance in the patient's microbiome.

The World Health Organization (WHO) has designated vancomycin as a Critically Important, Highest Priority antimicrobial for human medicine.[6]

Pharmacology/Actions

Vancomycin inhibits cell wall synthesis and bacterial cell membrane permeability. It also affects bacterial RNA synthesis. It is only effective against gram-positive bacteria, including many strains of streptococci, staphylococci, and enterococci. Vancomycin is generally a bactericidal, time-dependent antibiotic, but is bacteriostatic against enterococci. Vancomycin also has activity against *Clostridioides (Clostridium) difficile*, *Rhodococcus equi*, *Listeria monocytogenes*, *Corynebacterium* spp, and *Actinomyces* spp. Vancomycin and aminoglycosides can have synergistic action against susceptible bacteria. Pus and cellular debris may bind to vancomycin and reduce its efficacy.

Resistance to vancomycin by certain strains of enterococci and staphylococci is an increasing concern in human medicine and potentially in veterinary patients. The global prevalence of vancomycin-resistant enterococci (VRE) in companion animals has been estimated to be 14.6%,[7] although regional variability exists.[8,9]

Pharmacokinetics

When given orally, vancomycin is not appreciably absorbed. A single dose study in dogs showed a bioavailability of 0.27% to 1.66% after oral administration.[10] After IV administration, vancomycin is widely distributed. Therapeutic concentrations can be found in pleural, ascitic, pericardial, and synovial fluids. At usual serum concentrations, it does not readily distribute into the CSF.

In humans, the elimination half-life of vancomycin in patients with normal renal function is ≈4 to 6 hours.[2] Prolonged dosing can allow the drug to accumulate. The drug is eliminated primarily via glomerular filtration; small amounts are excreted into the bile.

Contraindications/Precautions/Warnings

Vancomycin is an important antibiotic for treating multidrug-resistant infections in humans. It should not be used in veterinary patients when other antibiotics can be used to successfully treat the infection. Some clinicians believe that the drug should never be used in veterinary patients and its use in animals is banned in some countries. Nephrotoxicity is a concern.

IV vancomycin can be fatal in rabbits.

Patients with decreased renal function that require vancomycin should have doses reduced or dosing interval extended. Serum peak and trough concentrations should be monitored.

Adverse Effects

When given parenterally, nephrotoxicity and ototoxicity are the most serious potential adverse effects of vancomycin. In humans, the incidence of nephrotoxicity is relatively high in some patient populations[11]; however, it is usually reversible. In humans, dermatologic reactions and hypersensitivity can occur[2]; it is unknown if these effects are issues for veterinary patients. Reversible neutropenia has been reported in humans, particularly when the dose is high and prolonged.

Do not administer vancomycin IV rapidly or as a bolus; thrombophlebitis, severe hypotension, and cardiac arrest (rare) have been reported.[2] Vancomycin must be given over at least 30 minutes as a dilute solution. Do not give vancomycin IM, SC, or IP. Severe tissue damage and pain may occur.

Oral therapy may cause adverse GI effects (eg, nausea, inappetence, vomiting, diarrhea).

Reproductive/Nursing Safety

Because vancomycin should only be used for serious infections, the potential benefits of therapy will probably outweigh the risks in most circumstances.

Vancomycin is excreted into milk.[2] Because the drug is not appreciably absorbed through the GI tract, it is unlikely to pose significant harm to nursing animals, although diarrhea could occur.

Overdose/Acute Toxicity

IV overdoses of vancomycin may cause an increased risk for adverse effects, particularly ototoxicity and nephrotoxicity. Supportive care is advised. Hemodialysis does not appear to remove the drug in significant amounts.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vancomycin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: Vancomycin may increase the risk for aminoglycoside-related ototoxicity or nephrotoxicity. Because this combination of drugs may be medically required (there is evidence of synergy against staphylococci and enterococci), enhanced monitoring is suggested.
- **Anesthetic Agents**: In children, vancomycin used with anesthetic agents has caused erythema and a histamine-like flushing.
- **Nephrotoxic Drugs, Other** (eg, **amphotericin B, cisplatin**): Use with caution with other nephrotoxic drugs.

Laboratory Considerations

- No specific concerns were noted.

Dosages

DOGS/CATS:

Susceptible gram-positive, systemic, life-threatening infections (extra-label):

a) 15 mg/kg IV over 30 to 60 minutes every 6 to 8 hours[12]

b) 3.5 mg/kg IV and follow with 1.5 mg/kg/hour IV CRI[13]

Oral treatment of documented *Clostridioides difficile* infection unresponsive to metronidazole (extra-label): 10 – 20 mg/kg PO every 6 hours for 5 to 7 days. **NOTE**: Oral vancomycin is not appreciably systemically absorbed and is only effective for susceptible enteric infections.

HORSES:

Susceptible gram-positive, systemic, life-threatening infections (extra-label): Average dosage was 7.5 mg/kg IV over 30 minutes every 8 hours from a retrospective study in 15 horses. The authors recommend that the use of vancomycin in horses be limited to cases in which culture and susceptibility results clearly indicate that this agent is likely to be effective and in which there is no reasonable alternative.[14]

Susceptible gram-positive, systemic, life-threatening infections; **IV regional limb perfusion (IVRLP) or intraosseous regional limb perfusion (IORLP);** (extra-label): Vancomycin 300 mg diluted in 60 mL 0.9% sodium chloride and infused IV (using an IV pump) or IO (administered manually) over 30 minutes. IVRLP or IORLP administration maintained their targeted trough drug concentration in synovial fluid. The authors concluded that IVRLP and IOPLP were safe and may be clinically useful in horses. IVRLP may be better for distal interphalangeal (DIP) joints and IORLP for metacarpophalangeal (MTCP) joints. Mean vancomycin concentration in the MTCP joint was 4 µg/mL for 24 hours after IORLP. [5,15,16]

Monitoring

When used parenterally:

- Baseline and periodic serum renal chemistry profile
- Monitoring trough drug concentrations is sometimes used in human medicine, mainly in patients with decreased renal function, advanced age, or other complicating factors. The target is to achieve a trough vancomycin concentration between 10 – 15 µg/mL, with 15 – 20 µg/mL recommended for serious MRSA infections.[17,18] The low end, or slightly lower, may be appropriate if an aminoglycoside is being used concurrently. There is little indication for routine peak drug concentration monitoring. Whether the same concentrations apply to veterinary patients is unknown but if drug monitoring is performed, human targets are reasonable to apply to animals.
- Baseline and periodic CBC with prolonged therapy

Client Information

- This medicine is most commonly given in the vein, by your veterinarian, while your animal is hospitalized.
- Oral vancomycin may be used for outpatient treatment. Be sure to give this medicine as directed by your veterinarian. It may be given with a small amount of food.
- Your veterinarian will need to monitor your animal closely while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

A glycopeptide antibiotic, vancomycin HCl occurs as an odorless, tan to brown free-flowing powder. It is freely soluble in water. A 5% aqueous solution has a pH of 2.5 to 4.5.

Vancomycin may also be known as vanco, vancomycini, or *Vancocin*®; there are many registered international trade names available.

Storage/Stability

Vancomycin should be stored at room temperature in tight containers that are protected from light. Once reconstituted (see administration instructions in the product label or in ***Dosages***), the injectable or oral solutions are stable for 14 days if refrigerated. If diluted further with 5% dextrose or 0.9% sodium chloride for parenteral administration, solutions are stable for 24 hours at room temperature and 2 months if refrigerated. Vancomycin solution in 5% dextrose should be stored at or below -20°C (-4°F); once thawed they are stable at room temperature for 72 hours, or 30 days if refrigerated. Do not refreeze thawed solutions.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Vancomycin is **compatible** with 5% dextrose, 0.9% sodium chloride, and lactated Ringer's injection. To prepare a parenteral solution using vancomycin 500 mg or 1 g powder for injection: Reconstitute the 500 mg for injection vial by adding 10 mL of sterile water for injection; add 20 mL if using the 1 g vial. Before administering to patient, further dilute reconstituted solutions with (at least 100 mL for 500 mg; 200 mL for 1 g vial) a compatible diluent (eg, 5% dextrose, lactated Ringer's, 0.9% sodium chloride). Frozen containers of vancomycin solution in 5% dextrose should be thawed at room temperature (25°C[77°F]) or under refrigeration (5°C[41°F]); do not force thaw with hot water bath or by microwave.

Vancomycin injection is reportedly **Y-site compatible** with the following drugs: atropine sulfate, calcium salts, ciprofloxacin, clindamycin phosphate, dexamethasone sodium phosphate, diphenhydramine hydrochloride, famotidine, gentamicin, ketamine hydrochloride, metoclopramide, midazolam, ondansetron, potassium chloride, sodium bicarbonate, and tobramycin.

Vancomycin injection is reportedly **incompatible** with ampicillin, amphotericin B, cefazolin, ceftazidime, diazepam, furosemide, hydrocortisone sodium succinate, pantoprazole, and propofol.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Vancomycin HCl Powder for Injection (IV) Solution: 500 mg, 750 mg, 1 g, 5 g, and 10 g vials; (some preservative free); generic; (Rx)

Vancomycin for IV Injection in dextrose (frozen): 500 mg/100 mL, 750 mg/150 mL, 1 g/200 mL, 1.25 g/250 mL, 1.5 g/300 mL, and 2 g/400 mL; generic; (Rx)

Vancomycin HCl Oral Capsules: 125 mg and 250 mg; *Vancocin*®, generic; (Rx). **NOTE**: Not for systemic infections; not appreciably absorbed

Vancomycin Oral Solution: 25 mg/mL in 150 mL and 300 mL bot-

tles, and 50 mg/mL in 80 mL, 150 mL and 300 mL bottles; *First-Vancomycin®-25, -50*; (Rx). **NOTE**: Not for systemic infections; not appreciably absorbed

Vasopressin

(vay-soe-***press***-in) *Vasostrict®*

Hormone; Pressor Agent

Prescriber Highlights

- ► Used primarily as a diagnostic agent and for the adjunctive treatment of shock syndromes and cardiopulmonary resuscitation
- ► Contraindications include chronic nephritis until nitrogen retention is resolved to reasonable levels, and in patients that are hypersensitive to it. Use with caution in patients that have vascular disease, seizure disorders, heart failure, or asthma.
- ► Adverse effects include nausea, GI pain/cramping, local irritation at the injection site (including sterile abscesses), extravasation injuries, skin reactions, abdominal pain, hematuria, and, rarely, a hypersensitivity (urticarial) reaction.
- ► Overdoses can lead to exacerbation of adverse effects, and possibly water intoxication.
- ► Cost of the drug may be an issue.

Uses/Indications

Vasopressin is used as a diagnostic agent (after a modified water deprivation test) and for the adjunctive treatment of shock syndromes and cardiopulmonary resuscitation in small animal species. Vasopressin has some potential advantages over epinephrine for treatment of ventricular asystole or pulseless electrical activity. Vasopressin can act as a vasoconstricting agent even when acidosis is present, and it may cause less vasoconstriction of the coronary and renal vasculature, thereby increasing myocardial perfusion and reducing myocardial oxygen consumption. Additionally, it does not have the arrhythmogenic or chronotropic effects that are associated with epinephrine.

Vasopressin has been documented to increase blood pressure in dogs with systemic inflammatory response syndrome (SIRS) and sepsis-induced hypotension. A case report in 5 dogs with dopamine-resistant SIRS or sepsis-induced hypotension found, in all cases, that the mean arterial blood pressure increased within 15 minutes of adding vasopressin to the treatment regimen.[1] Vasopressin is a common second-line agent (after norepinephrine) for the treatment of vasodilatory hypotension in both dogs and cats.[2]

In human medicine, vasopressin has been used to treat acute GI hemorrhage and stimulate GI peristalsis. Vasopressin CRI is also being used for the treatment of hypotensive septic patients that are unresponsive to conventional vasopressor. Prior to radiographic procedures, it has been used in humans to dispel interfering gas shadows or help concentrate contrast media.[3,4]

Pharmacology/Actions

Vasopressin or antidiuretic hormone (ADH) acts through at least 5 different receptors (3 subtypes: V1, V2, V3; the oxytocin receptor; and the purinergic P2 receptor) to maintain serum osmolality. Via V2 receptors, vasopressin promotes the renal reabsorption of solutefree water in the distal convoluted tubules and collecting duct. ADH increases cyclic adenosine monophosphate (cAMP) at the tubule, which increases water permeability at the luminal surface, resulting in increased urine osmolality and decreased urine flow. Without vasopressin, urine flow can be increased up to 90% greater than normal.

At doses above those necessary for antidiuretic activity, vasopressin V1 receptor stimulation and blockade of K+ -sensitive ATP channels can cause smooth muscle contraction. Capillaries and small arterioles are most affected, with resultant decreased blood flow to several systems. Hepatic flow may actually be increased, however.

Vasopressin can cause contraction of the smooth muscle of the bladder and gall bladder and increase intestinal peristalsis, particularly of the colon. Vasopressin may decrease gastric secretions and increase GI sphincter pressure; gastric acid concentration remains unchanged.

Vasopressin possesses minimal oxytocic effects, but at large doses, it may stimulate uterine contraction. Vasopressin V3 receptor stimulation causes the release of corticotropin, growth hormone, and follicle-stimulating hormone (FSH).

Pharmacokinetics

Vasopressin is destroyed in the GI tract prior to being absorbed and therefore must be administered either intranasally or parenterally. After IM or SC administration in dogs, aqueous vasopressin has an antidiuretic activity for 2 to 8 hours. Vasopressin is distributed throughout the extracellular fluid. The hormone apparently is not bound to plasma proteins. Vasopressin is rapidly destroyed in the liver and kidneys. The plasma half-life has been reported to be only 10 to 20 minutes in humans.

Contraindications/Precautions/Warnings

In humans, vasopressin is contraindicated in patients that are hypersensitive to it, as well as in patients with chronic nephritis until nitrogen retention is resolved to reasonable levels.

Because of its effects on other systems, particularly at high doses, vasopressin should be used with caution in patients with vascular disease, seizure disorders, heart failure, or asthma.

In humans, IV or IO vasopressin is considered a high alert medication (medications that require special safeguards to reduce the risk for errors). Consider instituting practices such as redundant drug dosage and volume checking with special alert labels.

Adverse Effects

Vasopressin adverse effects include local irritation at the injection site (extravasation necrosis possible), bronchoconstriction, arrhythmias, skin reactions, platelet aggregation, hyperbilirubinemia, nausea, abdominal pain and cramping, hematuria, and, rarely, a hypersensitivity (urticarial) reaction.[5]

Reproductive/Nursing Safety

Although the drug has minimal effects on uterine contractions at usual doses, it should be used with caution in pregnant animals.

Information on vasopressin levels in maternal milk was not located. Because vasopressin is not orally absorbed, adverse effects on nursing animals would not be expected. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute overdoses would likely exacerbate the adverse effects listed above. Heart rate and rhythm as well as blood pressure should be monitored. Early clinical signs of overdose-induced water intoxication can include listlessness or depression. More severe intoxication clinical signs can include coma, seizures, and eventually death. Treatment for mild intoxication is stopping vasopressin therapy and restricting water access until it has resolved. Severe intoxication may require the use of osmotic diuretics (eg, mannitol, urea, dextrose) with or without furosemide.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and

toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vasopressin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

Isoflurane: In horses undergoing isoflurane anesthesia, IV administration of vasopressin raised blood pressure and caused mucous membrane ischemia within 1 minute, cardiac arrest within 5 to 10 minutes of administration in 8 of 10 horses.[6]

The following drugs may **inhibit** the antidiuretic activity of vasopressin:

- **Ethanol**
- **Epinephrine** (large doses)
- **Heparin**
- **Norepinephrine** (large doses)

The following drugs may **potentiate** the antidiuretic effects of vasopressin:

- **Cyclophosphamide**
- **Enalapril**
- **Fludrocortisone**
- **Furosemide**
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**)
- **Vincristine**

Dosages

NOTES:

1. Do not confuse dosages listed as units/kg/minute; units/kg per hour, milliunits/kg/minute.
2. Prior to IV administration, vasopressin should be diluted in 0.9% sodium chloride or 5% dextrose solutions to a final concentration of 0.1 – 1 unit/mL.[5]

DOGS/CATS:

Diagnostic agent for diabetes insipidus in conjunction with a modified water deprivation test (extra-label): A clear understanding of the limitations and risks for this test is required for patient safety during the test and to achieve an accurate diagnosis. Prior to administration, it is recommended to consult with a veterinary internal medicine specialist or refer to a current small animal endocrinology text for specific information about the protocol, precautions, endpoints, and contraindications for this type of testing.

a) 0.2 – 0.4 units/kg (maximum total dose of 5 units/animal [NOT units/kg]) IM[7]

b) **Dogs**: 2 – 3 units/dog (NOT units/kg) SC[8]

c) **Cats**: 0.55 units/kg SC [8]

Adjunctive treatment during cardiopulmonary resuscitation (extra-label):

a) 0.8 units/kg IV or IO as a substitute for or in combination with epinephrine every 3 to 5 minutes may be considered. Vasopressin is administered after every other basic life support cycle. If IV or IO access is not possible, intratracheal (IT) administration can be considered. Dilute in sterile saline or sterile water and administer via a catheter longer than the endotracheal tube. If giving IT, the dosage has not been fully determined, but 1.2 units/kg IT is currently recommended.[9]

b) With pulseless electrical activity or ventricular asystole, vasopressin may be beneficial for myocardial and cerebral blood flow: 0.2 – 0.8 units/kg, IV once[8]

c) In dogs, 0.4 – 0.8 units/kg IV, followed by 1 – 4 milliunits/kg per *MINUTE* IV CRI[10]

Adjunctive treatment of hypotension associated shock (extra-label):

a) **Adjunctive post-CPR treatment**: 0.5 – 5 milliunits/kg/*MINUTE* (0.03 – 0.3 units/kg/*HOUR*) IV CRI [9,10]

b) **Patients with vasodilatory shock unresponsive to fluid resuscitation and catecholamine (dobutamine, dopamine, norepinephrine) administration**: 0.01 – 0.04 units/*MINUTE* (NOT units/kg/*MINUTE*) IV. (**NOTE**: This dose is not dependent on patient weight.) DO NOT exceed 0.04 units/*MINUTE* (NOT units/kg/*MINUTE*), as there is a risk for myocardial ischemia. DO NOT use in patients with cardiogenic shock.[10,11]

c) **Adjunctive treatment of dogs with septic shock or severe systemic inflammatory response syndrome** (extra-label): The goal is to raise the diastolic pressure to 70 to 90 mm Hg, which is usually associated with a mean pressure of 110 to 140 mm Hg and a systolic of 140 to 180 mm Hg. If norepinephrine between 0.5 – 1 µg/kg/*MINUTE* IV CRI does not maintain the goal, consider adding vasopressin 1 – 4 milliunits/kg/*MINUTE* IV CRI. Infusion is started at the low end of the range and titrated upwards in response to need. Supplementation with low doses of vasopressin can restore catecholamine and hemodynamic response.[12]

d) **Hypotension that persists in dogs despite volume resuscitation** (extralabel): 0.5 – 5 milliunits/kg/*MINUTE* (0.03 – 0.3 units/kg/*HOUR*) IV CRI. Although arterial blood pressure may improve, it should be used cautiously, as excessive vasoconstriction (particularly to the splanchnic and renal circulation, thereby causing GI and renal ischemia) may occur. In the dog, splanchnic vasoconstriction may exacerbate the sepsis by promoting the loss of the gut barrier function and then bacterial translocation to the bloodstream.[13]

HORSES:

Refractory hypotension in critically ill neonatal foals (extralabel): 0.1 – 2.5 milliunits/kg/*MINUTE* IV CRI.[14] From the retrospective study, vasopressin dosages were titrated to the minimum infusion rate needed to achieve a mean arterial pressure (MAP) greater than 65 mm Hg. All foals also received dobutamine and other supportive treatment. Vasopressin use was associated with a significant increase in MAP and urinary output, and a significant decrease in heart rate.

Monitoring

- Blood pressure; heart rate and rhythm
- Hydration, body weight; fluid and electrolyte status
- Urine output, specific gravity, and/or osmolality
- Water consumption

Chemistry/Synonyms

Vasopressin, a hypothalamic hormone stored in the posterior pituitary, is a 9-amino acid polypeptide with a disulfide bond. In most mammals (including dogs and humans), the natural hormone is arginine vasopressin, while in swine, the arginine is replaced with lysine. Lysine vasopressin has only about ½ the antidiuretic activity of arginine vasopressin. Previously available vasopressin products were a combination of arginine or lysine vasopressin derived from natural sources or synthetically prepared, while the currently available product is synthetic arginine vasopressin. The products are standardized by their pressor activity in rats (USP posterior pituitary [pressor] units); their antidiuretic activity can be variable. Commercially available vasopressin has little, if any, oxytocic activity at usual doses.

Vasopressin occurs as a white to off-white amorphous powder. Vasopressin injection is a clear, colorless or practically colorless liquid with a faint, characteristic odor. Vasopressin is soluble in water.

Vasopressin may also be known as ADH, antidiuretic hormone, 8-arginine vasopressin, beta-hypophamine, *Neo-Lidocaton®*, *Pitressin®*, or *Pressyn®*.

Storage/Stability

Store vasopressin (aqueous) injection at controlled cold temperatures, 2°C to 8°C (36°F-46°F), but it may be stored at room temperature for up to 12 months or until the manufacturer's expiry date; avoid freezing. After first use, refrigerate the multiple-dose vial and discard it after 30 days. Discard the solutions diluted for IV infusion and kept at room temperature 18 hours after mixing or 24 hours if refrigerated.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Vasopressin is **Y-site compatible** with aminocaproic acid, amiodarone, buprenorphine, butorphanol, calcium gluconate/chloride, cefazolin, ciprofloxacin, dexamethasone sodium phosphate, diltiazem, dobutamine, dopamine, epinephrine, famotidine, fentanyl citrate, gentamicin, heparin, hydroxyethyl starch 130/0.4 in sodium chloride, imipenem/cilastatin, lidocaine, magnesium sulfate, mannitol, meropenem, metoclopramide, metronidazole, midazolam, morphine sulfate, nitroglycerin, norepinephrine, pantoprazole, phenylephrine, piperacillin/tazobactam, procainamide, sodium bicarbonate, and voriconazole. It is **incompatible** with ampicillin, diazepam, furosemide, insulin (regular), and phenytoin.

If the aqueous injection is to be administered as an IV or intra-arterial infusion, it should be diluted in either 5% dextrose or 0.9% sodium chloride. For infusion use in humans, it is usually diluted to a concentration of 0.1 to 1 unit/mL.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Vasopressin Injection: 20 pressor units/mL in 1 mL and 10 mL vials; *Vasostrict®*; (Rx)

Vasopressin Tannate Sterile Suspension in oil is no longer commercially available.

For the complete list of references, see **wiley.com/go/budde/plumb**

Vecuronium

(vek-yew-***roe***-nee-um) *Norcuron®*

Nondepolarizing Neuromuscular Blocker

Prescriber Highlights

- ► Used primarily in dogs and cats as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and facilitate endotracheal intubation
- ► Use with caution in animals with severe renal dysfunction, myasthenia gravis, or hepatic or biliary disease.
- ► Not for use as a single agent; no analgesic or sedative actions
- ► High alert drug; ensure appropriate respiratory support, reversal agents, and error-reducing safeguards are in place to minimize risk of patient harm.

Uses/Indications

Vecuronium is indicated as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and facilitate endotracheal intubation. In dogs it has been used during general anesthesia to decrease respiratory motion and allow for controlled respiratory cycles during radiation therapy of heart base tumors.[1] Vecuronium causes very minimal cardiac effects and generally does not cause the release of histamine. It has been used topically to cause mydriasis in birds to facilitate fundoscopic exam.[2]

Pharmacology/Actions

Vecuronium is a nondepolarizing neuromuscular blocking agent and acts by competitively binding at cholinergic receptor sites on the motor end-plate resulting in paralysis of striated muscles. Vecuronium, when compared to pancuronium (on a weight basis), has been described as being equipotent to up to 3 times more potent.

The potency of vecuronium as a neuromuscular blocker appears to be lower in horses than other species and some horses appear to be relatively resistant to its effect.[3,4]

Pharmacokinetics

The onset of neuromuscular blockade after IV injection is dose-dependent. Dogs given 50 µg/kg IV (also receiving halothane anesthesia) experienced complete paralysis.[5] Duration of effect is ≈20-30 minutes when given as a bolus. Vecuronium has a shorter duration of action than pancuronium (≈⅓ to ½ as long), but similar to that of atracurium.

In cats, after injection of vecuronium 0.6 mg/kg IV, the steady state volume of distribution was 0.23 L/kg, half-life was 31 minutes, and clearance was 11 mL/minute/kg. Vecuronium or its metabolites were recovered in the bile (40%), urine (15%), and liver (15%).[6]

Vecuronium is partially metabolized; it and its metabolites are excreted into the bile and urine. Prolonged recovery times may result in patients with significant renal or hepatic disease.

In humans, vecuronium is up to 80% bound to plasma proteins.[7] The half-life ranges from 65 to 75 minutes. Patients with hepatic function impairment or cirrhosis exhibited prolonged plasma half-lives and almost double the recovery time compared to patients with normal function.

Contraindications/Precautions/Warnings

Vecuronium is contraindicated in patients hypersensitive to it. Lower doses may be necessary in patients with hepatic or biliary disease. In patients with myasthenia gravis, neuromuscular blocking agents (NMBA) should be administered with caution using doses much lower than typical (15%-20% of recommended dose) and with continuous monitoring of neuromuscular transmission.[8]

Vecuronium should only be used in patients that are adequately anesthetized as it has no analgesic or sedative/anesthetic actions. Respiratory support (eg, intubation, mechanical ventilation), neuromuscular blocker reversal agents, and staff experienced in the use of of these agents must be readily available. Inadvertent administration of neuromuscular blocking agents to patients for which they were not intended may cause significant harm, including death. Neuromuscular blocking agents should be sequestered from other medications, and with access limited to those familiar with their use.[9] Prominent placement of warning labels (eg, "paralyzing agent- causes respiratory arrest," "causes respiratory paralysis; patient must be ventilated") on storage containers is highly recommended.

Vecuronium's duration of action is shorter in dogs with diabetes mellitus.[10]

In horses, vecuronium should be used with caution due to possible failure to produce complete paralysis and its prolonged action in this species.[3,11]

Adverse Effects

Other than the effects associated with pharmacologic neuromuscular blockade, vecuronium appears to be well tolerated in the limited number of animals studied.

Reproductive/Nursing Safety

It is unknown whether vecuronium causes fetal harm or if the drug is

excreted into maternal milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The LD_{50} reported for mice and rats following IV administration was 0.051 and 0.2 mg/kg, respectively. Overdoses with neuromuscular blocking agents may result in prolonged neuromuscular blockade. The primary treatment is maintenance of the patient's airway, mechanical ventilation and oxygenation, and adequate sedation until recovery function is assured. Only after evidence of recovery is seen should administration of an anticholinesterase drug with an anticholinergic agent be considered. Blood pressure, heart rate, ventilation and oxygenation (end tidal CO_2, SpO_2, and blood gas analysis) should be monitored during an overdose with any necessary supportive treatment performed.

Reversal of blockade might be accomplished by administering an anticholinesterase agent (eg, neostigmine) with an anticholinergic agent (eg, atropine, glycopyrrolate). See ***Neostigmine***. A case report of the anticholinesterase edrophonium (not currently commercially available) failing to reverse prolonged vecuronium-induced neuromuscular blockade in a dog has been published.[12] Vecuronium can be reversed by the drug sugammadex, a binding agent that is specific for vecuronium and rocuronium.[13]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vecuronium and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Medetomidine**: May shorten the duration of vecuronium effect[14]
- **Non-Depolarizing Muscle Relaxant Drugs, Other**: May have a synergistic effect if used with vecuronium
- **Succinylcholine**: May speed the onset of action and enhance the neuromuscular blocking actions of vecuronium; do not give vecuronium until succinylcholine effects have subsided.

The following agents may enhance or prolong the neuromuscular blocking activity of vecuronium:

- **Aminoglycoside Antibiotics** (eg, gentamicin)
- **Anesthetics, General** (eg, isoflurane)
- **Antiarrhythmic Agents** (eg, procainamide, quinidine)
- **Bacitracin, Polymyxin** B (systemic): Consider therapy modification.
- **Calcium Channel Blockers** (eg, amlodipine, diltiazem)
- **Cyclosporine** (systemic)
- **Lincosamide Antibiotics** (eg, clindamycin)
- **Magnesium Salts, Systemic**
- **Tetracycline Derivatives** (eg, doxycycline, minocycline)
- **Vancomycin**

Laboratory Considerations

- None noted

Dosages

DOGS:

Neuromuscular relaxation/blockade (extra-label):

a) 100 µg/kg (0.1 mg/kg) IV[15–17]; additional doses of 0.05 mg/kg IV can be administered if prolonged blockade is required.[15] Initial doses of up to 200 µg/kg (0.2 mg/kg) IV have also been used to prolong blockade; however, this higher dose will prolong the recovery period.[15]

b) From a study done in female beagles: 25 µg/kg (0.025 mg/kg) IV over 5 seconds. This dose of vecuronium was chosen after pilot studies and was expected to produce partial block without causing apnea. In 9 of the 10 dogs, vecuronium at this dose produced a twitch reduction of greater than 80%. Significant residual neuromuscular block could be measured at the hind limb with acceleromyography when ventilation spontaneously returned.[18] In another study, complete paralysis was induced at dosages of 50 µg/kg (0.05 mg/kg), suggesting that under inhalational anesthesia, the ED_{90} of vecuronium in dogs is likely much lower than the previously reported 90 µg/kg (0.09 mg/kg).[5] The authors concluded that monitoring spontaneous ventilation, including end-tidal CO_2, expired tidal volume, peak inspiratory flow or minute ventilation, cannot be used as a surrogate for objective neuromuscular monitoring, and this practice may increase the risk of postoperative residual paralysis.

c) **If using CRI propofol-fentanyl anesthesia**: vecuronium 0.2 mg/kg/*HOUR* IV CRI for maintenance[19]

d) **If using isoflurane or sevoflurane with fentanyl IV CRI anesthesia**: vecuronium 0.1 mg/kg/*HOUR* IV CRI for maintenance[20]

CATS:

Neuromuscular relaxation/blockade (extra-label): 20 – 40 µg/kg (0.02 – 0.04 mg/kg) IV[21–23]

Monitoring

- Degree of neuromuscular blockade; the manufacturer recommends use of a peripheral nerve stimulator to determine drug response, the need for additional doses, and to evaluate recovery.
- Cardiac rate and blood pressure

Client Information

- This drug should only be used by professionals familiar with using neuromuscular blocking agents in a supervised setting with adequate ventilatory support.

Chemistry/Synonyms

Structurally similar to pancuronium, vecuronium bromide is a synthetic, nondepolarizing neuromuscular blocking agent. It contains the steroid (androstane) nucleus but is devoid of steroid activity. It occurs as white to off-white or slightly pink crystals or crystalline powder. In aqueous solution, it has a pK_a of 8.97, and the commercial injection has a pH of 4 after reconstitution. 9 mg are soluble in 1 mL of water; 23 mg are soluble in 1 mL of alcohol.

Vecuronium bromide may also be known as Org-NC-45, *Curlem®*, *Norcuron®*, *Rivecrum®*, *Vecural®*, or *Vecuron®*.

Storage/Stability

The commercially available powder for injection should be stored at controlled room temperature (20°C-25°C [68°F-77°F]) and protected from light. After reconstitution with sterile water for injection, vecuronium bromide is stable for 24 hours at 2°C to 8°C (36°F-46°F).[5] As it contains no preservative, unused portions should be discarded after reconstitution.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration,

temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Compatible with 0.9% sodium chloride, 5% dextrose in water, 5% dextrose in 0.9% sodium chloride, and lactated Ringer's for dilution.

It should not be mixed in the same IV bag or syringe, or given through the same needle with alkaline drugs (eg, barbiturates) or solutions (eg, sodium bicarbonate) as precipitation may occur.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Vecuronium Bromide Powder for Injection: 10 mg and 20 mg in 10 mL and 20 mL vials; generic; (Rx)

Vecuronium Bromide Solution for Injection: 1 mg/mL in 10 mL prefilled syringes or 100 mL vials; generic; (Rx)

Verapamil

(ver-***ap***-a-mill) *Calan®, Verelan®*

Calcium Channel Blocker

Prescriber Highlights

- ► Used for supraventricular tachycardias in dogs and cats
- ► Contraindications include cardiogenic shock or severe CHF (unless secondary to a supraventricular tachycardia), hypotension, sick sinus syndrome, second- or third-degree AV block, digoxin intoxication, or hypersensitivity to verapamil. IV administration is contraindicated within a few hours of IV beta-blocker administration.
- ► Use with caution in patients with heart failure, hypertrophic cardiomyopathy, hepatic impairment, or renal impairment. Use cautiously in patients with atrial fibrillation and Wolff-Parkinson-White (WPW) syndrome.
- ► Verapamil is a P-glycoprotein substrate and should be used with caution in dogs with the *MDR1* gene mutation (also known as *ABCB1*-1delta).
- ► Adverse effects include hypotension, bradycardia, tachycardia, exacerbation of CHF, peripheral edema, AV block, pulmonary edema, nausea, constipation, dizziness, headache, or fatigue.
- ► Many possible drug interactions

Uses/Indications

In dogs and cats, verapamil may be useful for the treatment of supraventricular tachycardias and, possibly, treatment of atrial flutter or fibrillation. If systolic dysfunction is present, calcium channel blockers are often drugs of choice for atrial or AV nodal tachycardia. When oral therapy is indicated, most clinicians prefer using diltiazem instead of verapamil.

Pharmacology/Actions

Verapamil is a slow-channel calcium (L-type) blocking agent and a phenylalkylamine that is classified as a class IV antiarrhythmic drug. Verapamil exerts its actions by binding the L-type calcium channels and blocking the transmembrane influx of extracellular calcium ions across membranes of vascular smooth muscle cells and myocardial cells. The result of this blocking is inhibition of the contractile mechanisms of vascular, which causes systemic and coronary vasodilation, and inhibition of the contractile mechanisms of cardiac smooth muscle. Verapamil has inhibitory effects on the cardiac conduction system, and these effects produce its antiarrhythmic properties.

Electrophysiologic effects include an increased effective refractory period of the AV node, decreased automaticity, and substantially decreased AV node conduction. On ECG, heart rate and RR intervals can be increased or decreased; PR and AH intervals are increased. Verapamil has negative effects on myocardial contractility, and it decreases peripheral vascular resistance.

Verapamil is a P-glycoprotein inhibitor, which could increase toxicity risk for other substrate drugs but also could be used for therapeutic advantage (eg, overcoming P-glycoprotein-mediated multidrug resistance by blocking efflux of some chemotherapy drugs).

Pharmacokinetics

In dogs, 90% of an oral dose is absorbed, but because of a high first-pass effect, bioavailability is only 10% to 23%. The volume of distribution has been reported to be ≈4.5 L/kg in dogs. Serum half-lives of 1.8 hours and 2.5 hours have been reported in dogs, which appears to be significantly faster than in humans. Biotransformation occurs in the liver, and like humans, several metabolites are formed, including some that have activity. Elimination occurs primarily via the bile/feces in dogs.

No pharmacokinetic information was located for cats.

In humans, ≈90% of a dose of verapamil is rapidly absorbed after oral administration, but because of a high first-pass effect, only ≈20% to 30% is available to the systemic circulation. Patients with significant hepatic dysfunction may have considerably higher percentages of the drug systemically bioavailable. Food will decrease the rate and extent of absorption of the sustained-release tablets, but less so with the conventional tablets. Verapamil's volume of distribution is between 4.5 and 7 L/kg; ≈90% of the drug in the serum is bound to human plasma proteins. Verapamil crosses the placenta, and milk concentrations may approach those in the plasma.

Verapamil is metabolized in the liver to at least 12 separate metabolites, with norverapamil being the most predominant. The majority of the amounts of these metabolites are excreted into the urine. Only 3% to 4% is excreted unchanged in the urine. In humans, the half-life of the drug is 2 to 8 hours after a single IV dose, but it can increase after 1 to 2 days of oral therapy (presumably due to a saturable process of the hepatic enzymes).

Contraindications/Precautions/Warnings

Verapamil is contraindicated in patients with cardiogenic shock or severe CHF (unless secondary to a supraventricular tachycardia amenable to verapamil therapy), hypotension (less than 90 mm Hg systolic), sick sinus syndrome, second- or third-degree AV block, digoxin intoxication, or hypersensitivity to verapamil.

IV verapamil is contraindicated within a few hours of IV beta-adrenergic blocking agents (eg, propranolol), as they both can depress myocardial contractility and AV node conduction. The use of this combination in patients with wide complex ventricular tachycardia (QRS greater than 0.11 seconds) can cause rapid hemodynamic deterioration and ventricular fibrillation.

Verapamil should be used with caution in patients with heart failure, hypertrophic cardiomyopathy, and hepatic or renal impairment. Toxicity may be potentiated in patients with hepatic dysfunction. It should be used cautiously in patients with atrial fibrillation that have Wolff-Parkinson-White (WPW) syndrome, as fatal arrhythmias may result; this is considered a contraindication in humans.[1]

Verapamil should be used with caution in diabetic animals because it may increase blood glucose in dogs.[2,3]

Verapamil is a P-glycoprotein inhibitor, which could increase

the risk for toxicity in animals with the *MDR1* gene mutation (also known as *ABCB1*-1delta) that are concurrently receiving P-glycoprotein substrates.

Adverse Effects

Possible adverse effects include hypotension, bradycardia, tachycardia, exacerbation of CHF, peripheral edema, AV block, pulmonary edema, nausea, constipation, dizziness, or fatigue.

Reproductive/Nursing Safety

Verapamil crosses the placenta and can be detected in umbilical vein blood at delivery. Oral verapamil in rats with doses 1.5 to 6 times the human dose was embryocidal and retarded fetal growth and development, likely due to reduced weight gains in dams.[1]

Verapamil is excreted in milk.[1] Consider discontinuing nursing if the dam requires verapamil therapy.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs of overdose are extensions of verapamil's adverse effect profile, and may include lethargy, bradycardia, hypotension, QT interval prolongation, hyperglycemia, junctional rhythms, and second- or third-degree AV block.[4] Sinus tachycardia is also possible, presumably due to carotid sinus reflex stimulation. Other clinical signs that may be noted include GI upset, vomiting, hypothermia, CNS depression, noncardiogenic pulmonary edema, hypokalemia, metabolic acidosis, and increased lactate production. Rarely CNS stimulation (eg, seizures, agitation, ataxia, tremors) occurs.

If overdose is secondary to recent oral ingestion (less than 2 hours) and the patient is asymptomatic, GI decontamination (eg, emesis, activated charcoal ± sorbitol) should be considered. Treatment is generally supportive in nature; vigorously monitor cardiac and respiratory functions. IV calcium salts have been suggested to treat the negative inotropic clinical signs but may not adequately treat clinical signs of heart block. See ***Calcium, IV (-Borogluconate, -Chloride, -Gluconate)***. The use of fluids and pressor agents (eg, dopamine, norepinephrine) may be utilized to treat hypotensive clinical signs. The AV block and/or bradycardia can be treated with isoproterenol, norepinephrine, atropine, or cardiac pacing. Patients that develop a rapid ventricular rate after verapamil because of antegrade conduction in flutter/fibrillation with Wolff-Parkinson-White (WPW) syndrome have been treated with direct current (DC) cardioversion, lidocaine, or procainamide. Other therapies may include glucagon, insulin/glucose, and IV lipid emulsion.[4,5]

Because of the potential for severe toxic effects and the potentially complicated management of calcium channel blocker overdoses, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving verapamil and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin-Converting Enzyme Inhibitors (ACEIs;** eg, **benazepril, enalapril**): May cause additive hypotensive effects
- **Alpha-Adrenergic Receptor Antagonists** (eg, **prazosin**): May cause additive hypotensive effects
- **Beta-Adrenergic Receptor Antagonists** (eg, **propranolol**): May cause additive negative cardiac inotrope and chronotrope effects
- **Bupivacaine/Mepivacaine**: Concurrent use may increase the risk for heart block.
- **Buspirone**: Concurrent use may result in an increased risk for enhanced buspirone effects.
- **Calcium**: Concurrent use may result in reversal of hypotensive effects.
- **Clonidine**: Concurrent use may result in an increased incidence of sinus bradycardia.
- **Clopidogrel**: Concurrent use may result in decreased antiplatelet effect and increased risk for thrombotic events.
- **Cyclosporine**: Verapamil may increase levels and risk for toxicity.
- **Dantrolene**: Cardiovascular collapse is reported in animals when used with verapamil.
- **Digoxin**: Verapamil may increase the blood levels of digoxin; monitoring of digoxin levels is recommended.
- **Diuretics**: May cause additive hypotensive effects
- **Doxorubicin**: Verapamil may increase concentrations.
- **Erythromycin, Clarithromycin**: May increase verapamil levels
- **Fluconazole**: Concurrent use may result in increased verapamil exposure and risk for toxicity.
- **Fentanyl**: Concurrent use may result in increased risk for fentanyl toxicity.
- **Hydrocodone**: Concurrent use may increase hydrocodone exposure and risk for increased or prolonged opioid effects.
- **Ivermectin**: In rabbits, concurrent use increased ivermectin plasma concentration and AUC, and prolonged elimination half-life.[6] In vitro studies using canine cells demonstrate verapamil inhibits P-glycoprotein transport of ivermectin.[7,8]
- **Ketoconazole**: Concurrent use may result in increased ketoconazole and verapamil exposure.
- **Midazolam**: Concurrent use may result in increased/prolonged sedation.
- **Morphine**: Concurrent use may increase morphine exposure.
- **Neuromuscular Blockers** (eg, **atracurium**): Neuromuscular blocking effects of nondepolarizing muscle relaxants may be enhanced by verapamil.
- **P-Glycoprotein Substrates, Other** (eg, **butorphanol, loperamide, vincristine**): Because verapamil is a P-glycoprotein inhibitor, combination could increase the risk for toxicity for animals with the MDR1 gene mutation (also known as *ABCB1*-1delta) that are concurrently receiving P-glycoprotein substrates.
- **Phenobarbital**: May reduce verapamil concentrations
- **Quinidine**: Additive alpha-adrenergic blocking activity; increased hypotensive effect; verapamil can block quinidine's AV conductive effects and increase quinidine levels.
- **Rifampin**: May reduce verapamil levels
- **Theophylline, Aminophylline**: Verapamil may increase serum levels of theophylline and lead to toxicity.
- **Vincristine**: Calcium channel blockers may increase intracellular vincristine by inhibiting the drug's outflow from the cell.

Laboratory Considerations

- Verapamil may elevate blood glucose in dogs and confuse **blood glucose** determinations.

Dosages

DOGS:

Supraventricular tachycardia (extra-label): Initially, 0.05 mg/kg IV given over 1 to 2 minutes while continuously monitoring ECG. If not effective, may repeat dose every 5 to 10 minutes until a total dose of 0.15 mg/kg has been administered. If effective, control may last only for 30 minutes (or less). For longer control, a

2 – 10 µg/kg/minute IV CRI can be administered.[9,10]

CATS:

Supraventricular tachycardia (extra-label): Initially, 0.025 mg/kg IV given over 1 to 2 minutes while continuously monitoring ECG. If not effective, may repeat every 5 to 10 minutes until a total dose of 0.15 mg/kg has been administered. If effective, control may last only for 30 minutes (or less). For longer control, a 2 – 10 µg/kg per minute IV CRI can be administered.[11]

HORSES:

Controlling ventricular rate in atrial fibrillation (extra-label): 0.025 – 0.05 mg/kg IV every 30 minutes, not to exceed a total dose of 0.2 mg/kg[12]

SMALL MAMMALS:

a) **Hamsters**: 0.25 – 0.5 mg/hamster (NOT mg/kg) SC[13]

b) **Rabbits**: 8 – 16 mg/kg PO daily in combination with 0.5 – 2 mg/kg SC once daily[13,14]

Monitoring

- Heart rate and rhythm; blood pressure
- Clinical signs of toxicity (see ***Adverse Effects***)
- Blood pressure, particularly during acute IV therapy

Client Information

- This medicine is used in dogs and cats to treat heart rhythm problems.
- This medicine is not commonly used in animals, so side effects are not well known. Possible side effects include swelling of the limbs, too fast or too slow heartbeats, gastrointestinal effects (eg, vomiting, constipation), and drowsiness/tiredness/lack of energy. Contact your veterinarian if you have any concerns about your animal.
- It is very important that your animal receives each dose. If you miss a dose, give it when you remember, but it if it close to the time for the next dose, skip the dose you missed and give it at the next scheduled time. After that, return to the regular dosing schedule.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

Verapamil HCl is a calcium channel blocking agent that occurs as a bitter-tasting, nearly white, crystalline powder. It is soluble in water, and the injectable product has a pH of 4 to 6.5.

Verapamil HCl tablets should be stored at room temperature (15°C-30°C [59°F-86°F]); the injectable product should be stored at room temperature (15°C-30°C [59°F-86°F]) and protected from light and freezing.

Verapamil may also be known as CP-16533-1, D-365, iproveratril hydrochloride, or verapamili hydrochloridum; many trade names are available.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Verapamil HCl for injection is physically **compatible** when mixed with all commonly used IV solutions. However, a crystalline precipitate may form if verapamil is added to an infusion line with 0.45% sodium chloride with sodium bicarbonate running. Verapamil is reported to be physically **compatible** with the following drugs: amikacin sulfate, aminophylline, ampicillin sodium, ascorbic acid, atropine sulfate, calcium chloride/gluconate, cefazolin sodium, cefotaxime sodium, cefoxitin sodium, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dexamethasone sodium phosphate, diazepam, digoxin, dobutamine HCl (slight discoloration due to dobutamine oxidation), dopamine HCl, epinephrine HCl, furosemide, gentamicin sulfate, heparin sodium, hydrocortisone sodium phosphate, hydromorphone HCl, insulin, isoproterenol, lidocaine HCl, magnesium sulfate, mannitol, meperidine HCl, methylprednisolone sodium succinate, metoclopramide HCl, morphine sulfate, multivitamin infusion, nitroglycerin, norepinephrine bitartrate, oxytocin, pancuronium Br, penicillin G potassium/sodium, pentobarbital sodium, phenobarbital sodium, phentolamine mesylate, phenytoin sodium, potassium chloride/phosphate, procainamide HCl, propranolol HCl, protamine sulfate, quinidine gluconate, sodium bicarbonate, sodium nitroprusside, tobramycin sulfate, vasopressin, and vitamin B complex with C.

The following drugs have been reported to be physically **incompatible** with verapamil: albumin injection, amphotericin B, hydralazine HCl, and trimethoprim/sulfamethoxazole.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Verapamil HCl Tablets: 40 mg, 80 mg, and 120 mg; *Calan®*, generic; (Rx)

Verapamil HCl Sustained-Release Tablets: 120 mg, 180 mg, and 240 mg; *Calan® SR,* generic; (Rx); Tablets may be split in ½ without altering sustainedrelease characteristics.

Verapamil HCl Extended-Release Capsules: 100 mg, 120 mg, 180 mg, 200 mg, 240 mg, 300 mg, and 360 mg; *Verelan®*, *Verelan® PM*, generic; (Rx). Capsules may be opened, and contents sprinkled on soft food, but capsule contents should not be crushed or chewed.

Verapamil HCl for Injection: 2.5 mg/mL in 2 mL and 4 mL vials, ampules, and syringes; generic; (Rx)

Verdinexor

(ver-dih-***nex***-or) *Laverdia®-CA1*

Antineoplastic

Prescriber Highlights

- ► Conditionally approved oral treatment for dogs with lymphoma and must therefore only be used as labeled
- ► Must be administered immediately after feeding a small meal
- ► Contraindications include dogs with a hypersensitivity to the drug, or those that are pregnant, nursing, or intended for breeding. Dogs weighing less than 9 kg (19.8 lb) may not be accurately dosed or undergo dose adjustments.
- ► Adverse effects include anorexia, vomiting, diarrhea, weight loss, lethargy, polydipsia, polyuria, elevated liver enzymes, and thrombocytopenia.
- ► Disposable chemotherapy-resistant gloves should be used when handling verdinexor and the treated dog's bodily fluids and waste. Disposable chemotherapy-resistant gloves should also be worn when handling the dog's toys and food and water bowl. This medicine can affect male and female fertility. Women who are pregnant, may become pregnant, or breast-feeding should not handle the drug.
- ► Include the Client Information Sheet (CIS) when dispensing the drug. The CIS states that unused tablets are to be returned to the veterinarian for disposal.

Uses/Indications

Verdinexor is conditionally approved (pending a full demonstration of effectiveness) by the FDA for the treatment of lymphoma in dogs. In a field study, a complete response (CR) or partial response (PR) occurred in 20 of 58 dogs with T-cell or B-cell lymphoma (34.5%, CR = 1, PR = 19).[1] In dogs with lymphoma the median time to tumor progression (TTP) was 29.5 days (range, 7 to 244 days),[2] but TTP was 43 days in naïve lymphoma patients compared to 24 days for relapsed patients.[3] Clinical benefit (ie, CR, PR, or stable disease) was also demonstrated in 64% of dogs with non-Hodgkin lymphoma in a separate study.[4] In both studies,[3,4] concurrent corticosteroid use was allowable but was not part of the designed study protocol.

As a conditionally approved drug, it is a violation of US federal law to use this product other than as directed on the label.

Pharmacology/Actions

Verdinexor is a selective inhibitor of nuclear export (SINE) that reversibly inhibits chromosome region maintenance 1 (CRM1, also known as exportin-1 [XPO1]). CRM1 is an export protein responsible for transporting macromolecules, including RNA, tumor suppressor proteins (TSP; eg, p53, RB1), and growth regulatory proteins (GRP; eg, p21) from the cell nucleus into the cytoplasm.[5–7] Inhibition of CRM1 by verdinexor prevents the export of TSP and GRP, and the resulting restoration of TRP and GRP within the nucleus renders the cell susceptible to apoptosis.[4,8] As CRM1 is overexpressed and/or mutated in cancer patients,[7–9] verdinexor exerts its activity preferentially in cancer cells or in cells with genomic damage.[10,11] In addition to lymphomas, verdinexor has demonstrated biologic activity against cell lines for canine mammary carcinoma,[12] mast cell tumor,[4] melanoma,[9] osteosarcoma,[4] and transitional cell carcinoma.[12]

As a class, SINEs block thrombopoietin signaling and reversible thrombocytopenia is a common adverse effect.[13]

Verdinexor has demonstrated antiviral activity,[14,15] including against eastern and western equine encephalitis.[16]

Pharmacokinetics

The oral bioavailability of verdinexor in recently fed dogs is 3-fold to 5-fold greater than in fasted dogs.[1] In healthy and recently fed dogs receiving a single oral verdinexor dose, the time to peak plasma concentration is ≈1 to 4 hours after administration, and plasma half-life was ≈2 to 6 hours.[1] In dogs with lymphoma, at steady-state the mean peak verdinexor concentration of 278 ng/mL occurred ≈5 hours after administration, mean AUC was 1971 ng·t/mL, and half-life was ≈5 hours.[3] Verdinexor is thought to be metabolized by glutathione conjugation.[2]

Contraindications/Precautions/Warnings

Verdinexor is contraindicated in patients hypersensitive to it. Do not use the drug in dogs that are pregnant, lactating, or intended for breeding.[2]

Dogs weighing less than 9 kg (19.8 lb) may not be accurately dosed or undergo dose adjustments.[2] Dogs weighing 9 to 9.6 kg (19.8-21.1 lb) cannot undergo dosage increase from 1.25 mg/kg to 1.5 mg/kg. Verdinexor has not been evaluated in dogs younger than 7 months of age; with diabetes mellitus, cardiovascular, hepatic or renal disease; with concurrent serious infections or malignancy; or with clinically relevant hypercalcemia.

Oral absorption is dramatically increased when verdinexor is administered with food.[1] Because anorexia may be a dose-limiting adverse effect,[4] appetite stimulants appropriate for dogs and low-dose corticosteroids may be needed to maintain the dog's appetite during the course of therapy.[3,4]

Verdinexor has a narrow margin of safety. See ***Overdose/Acute Toxicity***.

Verdinexor is an antineoplastic agent, and disposable chemotherapy-resistant gloves are to be used when handling. Pregnant women, women who may become pregnant, and nursing women should not handle or administer verdinexor, or come in contact with the treated dog's waste or bodily fluids.

Adverse Effects

Adverse effects are dose-related.[4] All dogs in a field study of dogs with lymphoma experienced at least one adverse effect.[2] Common adverse effects included anorexia (45% to 74%), vomiting (26% to 59%), diarrhea (12% to 52%), weight loss (31% to 48%), and lethargy (17% to 41%).[1,3] Polydipsia (33%) and polyuria (31%) have also been observed,[1] although concurrent corticosteroid use was common. Other adverse effects seen in more than or equal to 10% of dogs in the field trial included fever, weakness, generalized pain, and cough/dyspnea. Hematological toxicity reported in a field study included thrombocytopenia (31%), lymphopenia (29%), neutrophilia (26%), anemia (22%), leukopenia (21%), and neutropenia (16%).[1] In the dogs with thrombocytopenia, 2 experienced bruising and 1 had epistaxis.[2]

Changes in serum chemistry values included elevated liver enzymes including ALP (48%), ALT (36%), and AST (10%); increased BUN (26%); hypercalcemia (17%); hypochloremia (14%); hyperphosphatemia (12%); and hypoproteinemia (10%). Prolonged partial thromboplastin time has also been noted.[1] A protein-losing nephropathy was reported in one dog.[23]

Hematuria, UTI, low urine specific gravity, and proteinuria were abnormalities noted on urinalysis.[2]

Reproductive/Nursing Safety

Verdinexor is contraindicated in dogs that are pregnant, lactating, or intended for breeding. The drug is embryotoxic and teratogenic in rats.[2] Reduced male and female fertility has been documented in animal studies and in humans.

Overdose/Acute Toxicity

In dogs given 1 – 1.75 mg/kg orally 3 times per week, in addition to the drug's typical adverse effects, other clinical signs included thin body condition, excessive shedding, loss of skin elasticity, lacrimation, slight depression, and slight decrease of forelimb strength.[2] Re-

duced lymphocytes, eosinophils, and monocytes were observed as was increased fibrinogen, albumin, and BUN.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The effects of concurrent drugs on verdinexor metabolism have not been studied. The product label states that verdinexor was administered concomitantly with other drugs such as corticosteroids (eg, predniso(lo)ne), proton pump inhibitors (eg, omeprazole), histamine H_2 receptor antagonists (eg, famotidine), antibiotics, antiemetics (eg, ondansetron), GI motility modifiers (eg, loperamide, metoclopramide), and opioids (eg, morphine).[1]

- **Chemotherapy, Other**: Safe and effective use of verdinexor with other chemotherapeutic agents has not been evaluated.[2]
- **Vaccines**: Verdinexor may diminish the response to vaccines.

The product label cautions that concurrent administration of verdinexor with drugs that undergo glutathione conjugation (eg, acetaminophen) should be minimized. Possible substrates of glutathione *S*-transferase include:

- **Acetaminophen** (metabolite)
- **Anthracyclines** (eg, **doxorubicin, mitoxantrone**)
- **Busulfan**
- **Cisplatin**
- **Cyclophosphamide**
- **Spinosad**
- **Thiotepa**

Laboratory Considerations

None noted

Dosages

DOGS:

Lymphoma (label dosage; conditionally approved by FDA): 1.25 mg/kg PO immediately after feeding twice per week with at least 72 hours between doses (eg, Monday and Thursday, or Tuesday and Friday)

- If tolerated after 2 weeks, increase dosage to 1.5 mg/kg PO twice per week with at least 72 hours between doses.
- To manage adverse effects, dosage may be reduced by increments of 0.25 mg/kg; dosage interruptions may also be considered. Minimum dosage is 1 mg/kg PO twice per week with at least 72 hours between doses.
- See product label for dosing tables with the necessary combinations of tablet strengths for 1 mg/kg, 1.25 mg/kg, and 1.5 mg/kg dosages.[2]

Monitoring

- Although the exact schedule for recheck appointments and blood work testing has not been determined, the phase II study performed rechecks weekly during the first 28 days, then every other week.[3]
- Baseline and periodic physical examinations and blood work (eg, CBC, serum chemistry [including liver enzymes, albumin, total protein]) are recommended as needed based on the patient's response to therapy (especially after starting therapy or increasing the dose) and occurrence of any adverse effects.
- Baseline and periodic (as clinically indicated) urinalysis, urine culture, and urine protein:creatinine (UPC) ratio
- Appetite, food intake, body weight
- Tumor dimensions, response to therapy

Client Information

- Verdinexor is an antineoplastic (anticancer) medicine. This medicine can be hazardous to other animals and people that come in contact with it. On the day of verdinexor treatment, and for 3 days afterward:
  - Chemotherapy-resistant gloves are to be worn (check with your veterinarian to ensure you have the appropriate gloves):
    - when handling or administering verdinexor (this is particularly important with broken tablets, or if your dog spits out verdinexor tablet(s))
    - to prevent contact with your dog's feces, urine, saliva, and vomit
    - when handling your dog's food and water dishes or toys
  - Clean wastes or bodily fluids using disposable absorptive materials (eg, paper towels) and discard in a securely sealed plastic bag.
  - Wash any items that come in contact with your dog's feces, urine, saliva, or vomit separately from normal household laundry.
- Children, as well as women who are nursing, pregnant, or attempting to become pregnant, should not handle verdinexor tablets, or the dog's waste or bodily fluids (saliva, vomit, urine). This medicine can also affect male fertility.
- Do not eat, drink, or smoke while handling this medicine.
- Do not store this medicine near food, in or near a food preparation area, or with medications intended for use in humans.
- Wash skin with soap and water in case of accidental contact with verdinexor tablets, or with your dog's feces, urine, saliva, or vomit within 3 days after verdinexor administration.
- With accidental eye exposure, rinse eyes with a large amount of tap water for 10 minutes while holding back the eyelid. Remove contact lenses. Seek medical advice immediately and show package insert or label to the physician.
- Seek medical attention in case of accidental human ingestion of verdinexor, or with significant exposure to your dog's feces, urine, vomit, or saliva on the day of treatment or for 3 days afterward.
- Do not crush or split tablets. Administer your dog's dose promptly after the tablets are removed from the bottle.
- Administer immediately after feeding. Ensure your dog consumes the entire dose. Placing tablets in your dog's food bowl is not recommended.
- There must be at least 72 hours separating each verdinexor dose. If you miss a dose, do not make up the dose, but give the next regularly scheduled dose.
- The most frequent side effects include reduced or loss of appetite, weight loss, vomiting, diarrhea, low energy level (weakness). Contact your veterinarian if you notice your dog refusing to eat for longer than 1 day, has repeated vomiting or diarrhea, has a low energy level, or any other changes that concern you.
- Overdoses can be very serious; administer each dose exactly as prescribed.
- Keep verdinexor tablets out of reach of children and animals.
- Your veterinarian will need to perform examinations and blood work on your dog while it is taking this medicine. Do not miss these important follow-up visits.
- Do not throw unused verdinexor tablet in the trash. Unused verdinexor tablets should be returned to your veterinarian for disposal.

Chemistry/Synonyms

Verdinexor occurs as a crystalline solid. It is soluble in DMSO and

sparingly soluble in ethanol.[17] It has an oil:water partition coefficient of 4.1.[18]

Verdinexor may also be known as KPT-335 or *Laverdia®-CA1*.

Storage/Stability

Store verdinexor tablets at room temperature between 20°C to 25°C (68°F-77°F). Store out of reach of children and pets. Do not store verdinexor tablets near other drugs, food, or in a food preparation area.

Compatibility/Compounding Considerations

No information available

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Verdinexor Coated Tablets: 2.5 mg, 10 mg, and 50 mg in 50-count bottles; *Laverdia®-CA1*, (Rx). Conditional Approval Application Number 141-526. Extra-label use of conditionally approved drugs is not permitted by FDA.

HUMAN-LABELED PRODUCTS: NONE

Vinblastine

(vin-***blas***-teen) *Velban®*

Antineoplastic

Prescriber Highlights

- ► Vinca alkaloid antineoplastic used for a variety of tumors in dogs and cats
- ► Contraindications include pre-existing leukopenia or granulocytopenia (unless a result of the disease being treated) or active bacterial infection; reduce dose if hepatic insufficiency. Use it with caution in herding breeds (eg, collies) that may have the *MDR1* mutation (also known as *ABCB1*-1delta).
- ► Adverse effects include nausea/vomiting (less than with vincristine), myelosuppression (more so than with vincristine); it may also cause constipation, alopecia, stomatitis, ileus, inappropriate ADH secretion, jaw and muscle pain, and loss of deep tendon reflexes.
- ► Cats can develop neurotoxicity, causing constipation or paralytic ileus and aggravating hyporexia; cats can also develop reversible axon swelling and paranodal demyelination.
- ► Extravasation can cause significant tissue irritation and cellulitis.
- ► Many drug interactions
- ► Hazardous drug; use appropriate precautions and wear gloves and protective clothing when preparing or administering. Potential teratogen

Uses/Indications

Vinblastine may be used in the treatment of lymphomas, carcinomas, and mast cell tumors in small animal species. It may be more effective than vincristine in the treatment of canine mast cell tumors.

The combination of vinblastine and toceranib for the treatment of canine mast cell tumors was evaluated in a phase I trial. Although an objective response rate of 71% was noted, vinblastine dosing required a 50% reduction due to dose-limiting toxicity when compared to single-agent use. The use of this combination is not supported based on current drug combination paradigms.[1]

A prospective clinical trial in cats (n = 40) to compare vincristine and vinblastine response rates, outcomes, and toxicity in a COP-based protocol for lymphoma found that both arms had similar response rates, progression-free survival (PFS) times, and lymphoma-specific survival (LSS) times, but vincristine-treated cats had a higher incidence of GI adverse effects.[2]

Vinblastine has been evaluated in a retrospective analysis for response in relapsed canine lymphoma. The approximate response rate was 25% and was short in duration, with a median of 29.5 days.[3]

A prospective clinical trial in dogs (n = 28) using vinblastine to treat bladder transitional cell carcinoma found that 36% had a partial response, 50% had stable disease, and 14% had disease progression. The majority of dogs (27 of 28) did not have clinically relevant adverse effects, but 61% required dosage reduction (from the initial 3 mg/m^2 IV every 2 weeks) due to neutropenia. The authors concluded vinblastine could be considered another treatment option.[2] Another study found that, when used in combination with piroxicam in dogs with urethral carcinoma, piroxicam enhanced the activity of vinblastine and extended the progression-free survival. However, overall survival was significantly longer in dogs receiving vinblastine monotherapy.[4] There was no added survival benefit found when combining vinblastine with toceranib.[5]

Pharmacology/Actions

Vinblastine binds to microtubular proteins (tubulin) in the mitotic spindle, thereby preventing cell division during metaphase. It also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle, and urea formation.

Pharmacokinetics

After IV administration, vinblastine is rapidly distributed to tissues. In humans, ≈75% is bound to tissue proteins, and the drug does not appreciably enter the CNS. Vinblastine is extensively metabolized by the liver and is primarily excreted in the bile/feces; lesser amounts are eliminated in the urine. CYP3A12 is the major cytochrome P450 isoform responsible for the metabolism of vinblastine in dogs.[6]

Contraindications/Precautions/Warnings

Vinblastine is contraindicated in patients with pre-existing leukopenia or granulocytopenia (unless a result of the disease being treated) or active bacterial infection. Doses of vinblastine should be reduced in patients with hepatic disease. In humans, a 50% reduction in dose is recommended when transaminases are 2 to 3 times the upper limit of normal.[7]

Because vinblastine is potentially neurotoxic as well as a substrate of P-glycoprotein, it should be used with caution in herding breeds (eg, collies) that may have *MDR1* mutation (also known as *ABCB1*-1delta) causing nonfunctional proteins. Myelosuppression and GI toxicity (anorexia, vomiting, diarrhea) are more likely to occur at standard dosages in dogs with the *MDR1* mutation. To reduce the likelihood of severe toxicity in these dogs (mutant/normal or mutant/mutant), the Veterinary Clinical Pharmacology Laboratory at Washington State University recommends reducing the dose by 25% to 30% and carefully monitoring these patients.[8]

Vinblastine is for IV use only and may be fatal if given by other routes.[9]

Do not confuse vinBLAStine with vinCRIStine; consider using "tall man lettering" when writing orders.

The National Institute for Occupational Safety and Health (NIOSH) classifies vinblastine as a hazardous drug[10]; wash hands after handling and use personal protective equipment (PPE) accordingly to minimize the risk for exposure.

Adverse Effects

Vinblastine can cause GI toxicity, including nausea and vomiting, which generally lasts less than 24 hours. Vinblastine is reported to cause less GI toxicity than vincristine.[2] It can be myelosuppressive at usual dosages (nadir at 4 to 9 days after treatment; recovery at 7

to 14 days). Vinblastine is considered more myelosuppressive than vincristine. Neutropenia is generally the doselimiting toxicity in dogs and humans.[9,11] At high doses, vinblastine may cause peripheral neurotoxic effects similar to those seen with vincristine. Additionally, vinblastine may cause constipation, alopecia, stomatitis, ileus, inappropriate ADH secretion, jaw and muscle pain, and loss of deep tendon reflexes.

Cats can develop neurotoxicity that can be associated with constipation or paralytic ileus, thereby aggravating anorexia. They may develop reversible axon swelling and paranodal demyelination.

Other adverse effects in humans include hypertension, ototoxicity, and acute shortness of breath or severe bronchospasm.[9]

Vinblastine is considered a vesicant, and extravasation may cause significant tissue irritation and cellulitis. If clinical signs of extravasation are noted, discontinue infusion immediately at that site and apply moderate heat to the area to help disperse the drug. Injections of hyaluronidase have also been suggested to help diffuse the drug. Ice is not recommended for vinca alkaloid extravasation as it has been shown to significantly increase skin ulceration.[12] Topical dimethyl sulfoxide (DMSO) has also been recommended by some to treat the area involved.

Reproductive/Nursing Safety

Little is known about the effects of vinblastine on developing fetuses, but it is believed that the drug possesses some teratogenic and embryotoxic properties. It may also cause aspermia in males.

It is not known whether vinblastine is excreted in milk, but because of the potential for serious adverse reactions in nursing offspring, the use of milk replacer is recommended if the dam requires vinblastine.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The LD_{50} in mice and rats following IV administration is 15 mg/mL and 2 mg/mL, respectively. In dogs, the lethal dose for vinblastine has been reported as 0.2 mg/kg. In addition to the exacerbations of the expected adverse effects, neurotoxicities similar to those associated with vincristine may also be noted.

In a cat that received 4 times the recommended IV dose, the following clinical signs were noted: within hours depression and inability to jump; Days 1 to 11 anorexia; Days 2 to 6 neutropenia with a fever on Day 4; Days 2 to 10 thrombocytopenia and anemia; Days 4 to 10 vomiting and diarrhea, and on Days 3 to 10 syndrome of inappropriate ADH (SIADH). Aggressive therapeutic interventions supporting the patient resulted in recovery.[13]

In humans, cardiovascular and hematologic monitoring is performed after an overdose. Treatment can include anticonvulsants and the prevention of ileus. Additionally, an attempt is made to prevent the effects associated with the syndrome of inappropriate antidiuretic hormone (SIADH) with fluid restriction and loop diuretics to maintain serum osmolality.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vinblastine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Ototoxic Drugs** (eg, cisplatin, carboplatin): May cause additive risk for ototoxicity
- **Immunosuppressive Drugs** (eg, azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk for infection.
- **Macrolide Antibiotics** (except azithromycin): Macrolide antibiotics may increase the serum concentration of vinblastine; consider therapy modification.
- **Myelosuppressive Agents** (eg, antineoplastics, immunosuppressants, iron chelators): Concurrent use with other bone marrow depressant medications may result in additive myelosuppression; avoid combination when possible.
- **Vaccines** (live and inactivated): Vinblastine may diminish vaccine efficacy and enhance adverse effects of vaccines.

Caution is advised if using other drugs that can inhibit **P-glycoprotein,** particularly in those dogs at risk for *MDR1* genetic mutation (eg, collies, Australian shepherds, shelties, long-haired whippets, "white feet" breeds), unless tested homozygous normal for the gene locus. Drugs and drug classes involved include:

- **Amiodarone**
- **Azole Antifungals** (eg, **ketoconazole, itraconazole**)
- **Carvedilol**
- **Cyclosporine**
- **Diltiazem**
- **Erythromycin; Clarithromycin**
- **Quinidine**
- **Spironolactone**
- **Tamoxifen**
- **Verapamil**

Laboratory Considerations

- Vinblastine may significantly increase both blood and urine concentrations of **uric acid** (potentially significant for Dalmatians).

Dosages

NOTE: Because of the potential toxicity of this drug to patients, veterinary personnel, and clients, and since chemotherapy indications, treatment protocols, and monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[14–18] are strongly recommended.

DOGS/CATS:

Antineoplastic agent (extra-label): Depending on the protocol and the disease treated, vinblastine doses are usually 1.5 – 3 mg/m^2 (NOT mg/kg) IV every 1 to 2 weeks, often in combination with other chemotherapy drugs (eg, cyclophosphamide and prednisolone in dogs).[19,20] One small observational study found that for mast cell tumors in dogs, a higher dose of 3 mg/m^2 (NOT mg/kg) resulted in a lower rate of recurrence than a lower 2 mg/m^2 (NOT mg/kg) dose.[21]

Monitoring

- Efficacy
- Baseline and periodic complete blood counts with platelets
- Baseline and periodic liver enzymes prior to therapy and repeated as necessary

Client Information

- Vinblastine is a chemotherapy (anticancer) medicine. The medicine can be hazardous to other animals and people that come in contact with it. On the day your animal gets the medicine and then for a few days afterward, handle all bodily waste (urine, feces, litter), blood, or vomit only while wearing chemotherapy-resis-

tant gloves. Seal the waste in a plastic bag and then place both the bag and gloves in with the regular trash. Those who are pregnant, attempting to conceive, or nursing should not clean up the animal's waste.

- Do not wash any items soiled with waste, vomit, or saliva from your dog with other laundry. Take precautions in handling the dog's toys, food bowl, and water bowl; wash separately from other items.
- Your veterinarian will need to perform regular monitoring, including blood tests and/or radiographs, to be sure this drug is not causing toxic effects to your animal. Do not miss these important follow up visits.
- Observe your dog for lack of appetite, vomiting, or diarrhea. If these signs are severe, or if you notice difficulty breathing or signs of infection, contact your veterinarian immediately.
- Bone marrow suppression can occur. The greatest effects on bone marrow usually occur within a week after treatment. Your veterinarian will do blood tests to watch for this, but if you see bleeding, bruising, fever (indicating an infection), or if your animal becomes tired easily, contact your veterinarian right away. Do not miss important follow-up visits with your veterinarian.
- Cats can develop nerve toxicity from vinblastine, resulting in severe constipation and loss of appetite.

Chemistry/Synonyms

Vinblastine sulfate, a vinca alkaloid, is isolated from the plant *Catharanthus roseus* (*vinca rosea Linn*) and occurs as a white or slightly yellow hygroscopic, amorphous, or crystalline powder that is freely soluble in water. The commercially available injection has a pH of 3 to 5.5.

Vinblastine may also be known as 29060-LE, NSC-49842, sulfato de vimblastina, vinblastini sulfas, vincaleukoblastine sulphate, VBL, *Alkaban®*, *Blastovin®*, *Cellblastin®*, *Cytoblastin®*, *Ifabla®*, *Lemblastine®*, *Periblastine®*, *Serovin®*, *Solblastin®*, *Velban®*, *Velbe®*, *Velsar®*, or *Xintoprost®*.

Storage/Stability

Store intact vials between 2°C to 8°C (36°F-46°F) and protect them from light. Dispose of any unused product or waste materials in accordance with proper procedures for cytotoxic drugs.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Vinblastine sulfate is reportedly **compatible** with 0.9% sodium chloride, lactated Ringer's, or 5% dextrose in water for dilution. It is also reportedly physically **compatible** with the following IV solutions and drugs: 5% dextrose with bleomycin sulfate and **compatible in syringes or at Y-sites** with bleomycin sulfate, cisplatin, cyclophosphamide, droperidol, fluorouracil, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, and vincristine sulfate.

Vinblastine sulfate **compatibility information conflicts** or is dependent on diluent or concentration factors with doxorubicin HCl and heparin sodium (in syringes).

Vinblastine sulfate is reportedly physically **incompatible** with furosemide and cefepime.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Vinblastine Sulfate Injection: 1 mg/mL in 10 mL and 25 mL vials; generic; (Rx)

Vinblastine Powder for Injection: 10 mg in vials; *Velban®*, generic; (Rx)

Vincristine

(vin-***kris***-teen) *Oncovin®, Vincasar PFS*

Antineoplastic

Prescriber Highlights

- ► Vinca alkaloid antineoplastic used for a variety of tumors (primarily lymphoid, hematopoietic neoplasms, and hemangiosarcoma) in dogs and cats
- ► Used for the treatment of immune-mediated thrombocytopenia and induces thrombocytosis when given at low doses
- ► Contraindications include patients with pre-existing leukopenia or granulocytopenia (unless as a result of the disease being treated) or active bacterial infection; reduce dose if hepatic disease is present.
- ► Use with caution in dogs that may have the *MDR1* genetic mutation.
- ► Less myelosuppressive than vinblastine but may cause more peripheral neurotoxic effects; neuropathic clinical signs can include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation.
- ► Cats can develop neurotoxicity causing constipation or paralytic ileus, aggravating anorexia; vinblastine may be substituted.
- ► Potentially teratogenic and embryotoxic. The National Institute for Occupational Safety and Health (NIOSH) classifies vincristine as a hazardous drug; use appropriate precautions when handling. Advise clients to use caution when handling animal waste.
- ► For IV use *only*. Vesicant, avoid extravasation

Uses/Indications

Vincristine is used as an antineoplastic primarily in combination drug protocols in the treatment of lymphoid hematopoietic neoplasms (CHOP) and hemangiosarcoma (VAC) in dogs and cats. In dogs, the drug may be used as a single agent in the therapy of transmissible venereal neoplasms.

A prospective clinical trial in cats ($n = 40$) to compare vincristine and vinblastine response rates, outcomes, and toxicities in a COP-based protocol for lymphoma, found that both arms had similar response rates, progression-free survival (PFS) times, and lymphoma-specific survival (LSS) times, but vincristine-treated cats had a higher incidence of GI adverse effects.[1] As a result, vinblastine is most commonly substituted for vincristine in cats.

Because vincristine can induce thrombocytosis (at low doses) and has some immunosuppressant activity, it may also be employed in the treatment of immune-mediated thrombocytopenia (ITP). A prospective, randomized study in dogs ($n = 20$) comparing the effect of hIVIG versus vincristine on platelet recovery in dogs with ITP found no significant differences in groups in platelet recovery time, hospitalization time, or survival at discharge or 6 months or 1 year after entry into the study. The authors concluded that because of lower cost and ease of administration, vincristine should be considered for first-line adjunctive treatment for the acute management of canine ITP.[2]

Pharmacology/Actions

By binding to beta-tubulin, vincristine blocks microtubule formation and prevents mitotic spindle formation; arresting cell division is thus arrested in metaphase. It also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle, and urea formation. Tumor resistance to

one vinca alkaloid does not imply resistance to another.

Vincristine can induce thrombocytosis (mechanism unknown) and has some immunosuppressant activity.

Pharmacokinetics

After IV administration, vincristine is rapidly distributed to tissues. In humans, ≈75% is bound to tissue proteins, and the drug does not appreciably enter the CNS. Vincristine is extensively metabolized by the liver and primarily excreted in the bile and/or feces; lesser amounts are eliminated in the urine. In dogs, the pharmacokinetics are reportedly biphasic with a volume of distribution of 0.66 L/kg and elimination half-life of ≈48 minutes.[3] Vincristine residue was detected in urine for 3 days after administration to dogs.[4]

Contraindications/Precautions/Warnings

Vincristine is contraindicated in patients with pre-existing leukopenia or granulocytopenia (unless as a result of the disease being treated) or active bacterial infection and should be used with caution in patients with hepatic diseases, biliary obstruction (hepatic, posthepatic), leukopenia, infection, or pre-existing neuromuscular disease.

Doses of vincristine should be reduced in patients with hepatic disease and/or biliary obstruction (hepatic, posthepatic). Complete avoidance or an empirical 50% reduction in dose should be considered if serum bilirubin concentrations are greater than 2 mg/dL.

Because vincristine is a substrate of P-glycoprotein, it should be used with caution in dogs (eg, Australian shepherds, collies) that may have the *MDR1* genetic mutation.[5] Bone marrow suppression (eg, decreased blood cell counts, particularly neutrophils) and GI toxicity (eg, anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with either the homozygous (mutant/mutant) or heterozygous (normal/mutant) *MDR1* mutation. To reduce the likelihood of severe toxicity in these dogs (mutant/normal or mutant/mutant), the Veterinary Clinical Pharmacology Laboratory at Washington State University recommends reducing the dose by 25% to 30% and carefully monitoring these patients.[5]

Border collies, unrelated to their *MDR1* status, appear to be more susceptible to developing vincristine-associated myelosuppression.[6]

Do not confuse vinBLAStine with vinCRIStine; writing part of the drug's name using tall man lettering on prescriptions/orders may reduce the risk of errors.

In humans, it is recommended to use 0.9% sodium chloride to dilute vincristine into a flexible sterile container to prevent inadvertent administration by any route other than IV. IV administration should be done over 5 to 10 minutes.

The National Institute for Occupational Safety and Health (NIOSH) classifies vincristine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[7]

Adverse Effects

Although structurally related to and having a similar mechanism of action as vinblastine, vincristine has a different adverse effect profile. Vincristine is much less myelosuppressive (causing mild leukopenia) at usual doses but may cause more peripheral neurotoxicity. Neuropathic clinical signs may include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation. In humans, vincristine commonly causes mild sensory impairment and peripheral paresthesias. These additional neurotoxic effects may also occur in animals; additional caution should be exercised in patients with a predisposing neuropathic disorder (ie, degenerative myelopathy). Cats can develop neurotoxicity associated with constipation or paralytic ileus, thereby aggravating anorexia[8]; they may also develop reversible axon swelling and paranodal demyelination.[9]

In addition, in small animals, vincristine may cause vomiting, diarrhea, anorexia, impaired platelet aggregation, increased liver enzyme activity, inappropriate ADH secretion, jaw pain, alopecia, stomatitis, or seizures. Compared with other chemotherapy treatments, GI effects are considered frequent but mild.[10] Many dogs receiving chemotherapy will have minor hair coat changes (eg, shagginess, loss of luster). Breeds with continuously growing hair coats (eg, poodles, terriers, Afghan hounds, old English sheepdogs) are more likely to experience significant alopecia.

A case report of a cat developing pulmonary edema attributed to vincristine administration has been published.[11]

In dogs, vincristine can cause erythrocyte dysplasia, although this effect is deemed clinically insignificant.[12]

Vincristine is a vesicant, and extravasation may cause localized tissue irritation and cellulitis. Administer IV following a single, clean venipuncture attempt through an IV catheter (indwelling or butterfly). If clinical signs of extravasation are noted, discontinue infusion immediately at that site and apply moderate, dry heat to the area to help disperse the drug and promote vascular absorption. Injections of hyaluronidase have also been suggested to help diffuse the drug.

Reproductive/Nursing Safety

For sexually intact patients, verify pregnancy status prior to administration. Vincristine is teratogenic and embryotoxic (including malformations; embryo resorption and death) when given at recommended dosages in laboratory animals.[13] It may also cause aspermia in males.

It is not known whether this drug is excreted in milk. Because of the potential for serious adverse effects in nursing offspring, the use of milk replacer is recommended if the dam requires vincristine.

Overdose/Acute Toxicity

Following IV administration, the LD_{50} in mice and rats is 3 mg/kg and 1 mg/kg, respectively.

In dogs, the maximum tolerated vincristine dose is reported to be 0.06 mg/kg every 7 days for 6 weeks. Animals receiving this dose showed signs of mild anemia, leukopenia, increased liver enzyme activity, and neuronal shrinkage in the peripheral nervous system and CNS. Megaesophagus and hemorrhagic diarrhea occurred in 1 dog following accidental overdose.[14]

If the overdose is acute (≈6 hours), plasmapheresis may be considered.[15] Other treatment considerations include activated charcoal and cholestyramine (which sequesters intestinal secretion of many acidic drugs and increases their rate of elimination). For subsequent GI signs, a metoclopramide CRI and use of other prokinetic agents (eg, cisapride, erythromycin) may be useful to prevent severe ileus. For severe myelosuppression, filgrastim (G-CSF) may be started prophylactically along with broad-spectrum antibiotics.

In humans, multiple products have been used to reduce neurotoxicity, including rescue with folinic acid (leucovorin) 18 mg every 3 hours 16 times and pyridoxine 50 mg IV or PO every 8 hours[16]; glutamic acid (glutamine) 500 mg PO 3 times daily for 1 month was reported to decrease vincristine neurotoxicity with no additional adverse effects.[17]

In cats, the lethal dose of vincristine is reportedly 0.1 mg/kg. Cats receiving toxic doses showed weight loss, seizures, leukopenia, and general debilitation. A cat receiving vincristine 5 mg/m^2 (NOT mg/kg; 10 times the recommended dose) died 72 hours following the overdose despite intensive treatment with calcium folinate.[14]

In humans, cardiovascular and hematologic monitoring are performed after an overdose. Treatment can include anticonvulsants and prevention of ileus. In addition, an attempt should be made to prevent the effects associated with syndrome of inappropriate antidiuretic hormone (SIADH) by using fluid restriction and loop diuretics to maintain serum osmolality.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information

is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vincristine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Asparaginase**: Additive neurotoxicity and myelosuppression may occur; effects are less common when asparaginase is administered after vincristine or when doses are separated by 24 hours.
- **Cholestyramine**: Pretreatment with cholestyramine blocks enterohepatic vincristine reuptake and enhances vincristine fecal excretion in dogs. No data are available regarding its use for treatment of vincristine overdose.
- **Immunosuppressive Drugs** (eg, **azathioprine, corticosteroids, cyclophosphamide**): Use with other immunosuppressant drugs may increase the risk for infection.
- **Mitomycin**: In humans who have previously or simultaneously received mitomycin-C with vinca alkaloids, severe bronchospasm has occurred.
- **Myelosuppressive Agents** (eg, **antineoplastics, iron chelators**): Concurrent use with other bone marrow depressant medications may result in additive myelosuppression; avoid combination when possible.
- **Vaccines** (live and inactivated): Vincristine may diminish vaccine efficacy and enhance adverse effects of vaccines.

Caution is advised if using vincristine with drugs that can inhibit P-glycoprotein, which may increase intracellular vincristine concentration, particularly in those dogs at risk for *MDR1* genetic mutation (eg, collies, Australian shepherds, Shetland sheepdogs, long-haired whippets, "white feet" breeds), unless they are negative (normal/normal) for the mutation. Drugs and drug classes involved include:

- **Amiodarone**
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**)
- **Carvedilol**
- **Cyclosporine**
- **Diltiazem**
- **Macrolide antibiotics** (eg, **erythromycin, clarithromycin** but NOT **azithromycin**)
- **Quinidine**
- **Spironolactone**
- **Tamoxifen**
- **Verapamil**

Laboratory Considerations

- Vincristine may significantly increase both blood and urine concentrations of **uric acid**.

Dosages

NOTES:

1. Because of the potential toxicity of this drug to patients, veterinary staff, and pet owners, and because chemotherapy indications, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[18-22] are strongly recommended.
2. Do NOT confuse mg/kg with mg/m^2 dosages.

DOGS:

Neoplastic diseases (extra-label): Usually used in combination protocols with other drugs; consultation with a veterinary oncologist is encouraged before use; see **NOTES**. Vincristine is usually administered at 0.5 – 0.75 mg/m^2 (NOT mg/kg) IV every 1 to 2 weeks.

Transmissible venereal tumor (extra-label)

a) Vincristine is used as sole therapy, usually at 0.5 mg/m^2 (NOT mg/kg; maximum dose 1 mg) IV once weekly for 4 to 6 weeks.
b) Vincristine 0.025 mg/kg IV weekly. Can be used in combination with intratumoral interferon alpha-2α.[23]
c) Vincristine 0.025 mg/kg IV every other week, alternating with L-asparaginase 5000 units/m^2 (NOT mg/kg) SC every other week for an 8-week treatment period that includes a total of 4 doses of each drug[24]

Adjunctive treatment of immune-mediated thrombocytopenia (extra-label): In a study, dogs received vincristine 0.02 mg/kg IV bolus once. Dogs also received glucocorticoids (usually prednisone 1.5 – 2 mg/kg PO every 12 hours) and doxycycline until results of serologic testing were negative for tick-borne disease. In dogs that did not have an increase in platelet count 7 days after treatment, azathioprine 2 mg/kg PO once daily was added. **NOTE**: At this dose of vincristine, clinically significant myelosuppression has not been described.[2]

CATS:

Neoplastic diseases (extra-label): Consultation with a veterinary oncologist is encouraged before use; see **NOTES**. Vincristine is usually administered at 0.5 – 0.75 mg/m^2 (NOT mg/kg) IV every 1 to 3 weeks. Intraperitoneal (IP) vincristine administration was considered a safe and effective alternative route of administration.[25]

HORSES:

Neoplastic diseases (extra-label): Consultation with a veterinary oncologist is encouraged before use; see **NOTES**. Usual dosages are 0.5 mg/m^2 (NOT mg/kg; usually 2.5 – 3 mg total dose per horse) IV weekly.

Adjunctive therapy for generalized lymphoma as part of the CAP protocol (extra-label): The following are starting dosages; total doses can be increased by 20% to 30% without the expectation of complications. Cytarabine (cytosine arabinoside) at an average dose of 1 – 1.2 g (total dose) SC or IM once every 1 to 2 weeks; cyclophosphamide 1 g (total dose) IV every 2 weeks (alternating with cytarabine); and prednisolone 1 mg/kg PO every other day. Vincristine 2.5 mg (total dose) IV is added on the weeks when cytarabine is administered if there is no response.

- With remission, the starting doses are maintained for 2 to 3 months, then the horse is switched to a maintenance protocol. The first cycle of maintenance therapy increases the treatment interval for each drug by 1 week (except prednisolone, which is kept at the same frequency but with a reducing dose). If the horse is still in remission 2 to 3 months after the first cycle, the second cycle is started by adding an additional week to the treatment intervals of each drug.[26]

FERRETS

Neoplastic disease (extra-label): 0.12 mg/kg IV once weekly for 3 weeks, then every 3 weeks as part of a modified COP protocol[27]

Monitoring

- Verify pregnancy status prior to administration.
- Physical and neurologic examinations
- Baseline and periodic (prior to each treatment) CBC, and serum liver profile
- Adverse effects: development of peripheral motor and/or sensory deficits, fever, constipation, icterus

Client Information

- Vincristine is a chemotherapy (anticancer) drug. The drug can be hazardous to other animals and humans that come into contact with it. On the day your animal receives the drug and then for a minimum of 3 days afterward, all bodily waste (eg, urine, feces), litter, blood, and vomit should only be handled while wearing disposable gloves. Seal the waste in a plastic bag, then place both the bag and gloves in the regular trash. Those who are pregnant, attempting to conceive, or nursing should not clean up the animal's waste.
- In the interest of safety to other animals and humans, do not take your dog to a dog park or allow your animal to urinate and defecate in public places until your veterinarian tells you that it is okay to do so.
- Bone marrow suppression can occur. The greatest effects on bone marrow usually occur within a few weeks after treatment. Your veterinarian will need to do blood tests to watch for this problem. Do not miss these important follow up visits.
- Your veterinarian will need to do periodic examinations and blood tests on your animal after it receives this medication. Do not miss these important follow-up visits.
- Your animal should not receive vaccines containing live (or modified live) viruses while receiving this medication.
- Contact your veterinarian right away if you see bleeding, bruising, or fever (indicating an infection) or if your animal becomes tired easily.
- Contact your veterinarian right away if you notice pain, redness, or swelling in the area where the injection was given.
- Vincristine can cause serious neurologic toxicity that can result in weakness, severe constipation, and loss of appetite.
- Your animal should not participate in animal competitions while on this drug. Exposure to other animals may put your animal at serious risk of infections during chemotherapy treatment. Talk with your veterinarian about when itis safe to return to these events.

Chemistry/Synonyms

Vincristine sulfate, commonly referred to as a vinca alkaloid, is isolated from the plant *Catharanthus roseus* (*Vinca rosea Linn*) and occurs as a white or slightly yellow, hygroscopic, amorphous, or crystalline powder that is freely soluble in water and slightly soluble in alcohol. The commercially available injection has a pH of 3 to 5.5. Vincristine sulfate has pK_as of 5 and 7.4.

Vincristine sulfate may also be known as leurocristine sulfate, VCR, LCR compound 37231, leurocristine sulphate, NSC-67574, 22-oxovincaleukoblastine sulphate, sulfato de vincristina, vincristini sulfas, and *Oncovin*®; many other trade names are available.

Storage/Stability

Intact vials should be stored upright between 2°C to 8°C (36°F-46°F) and protected from light. Diluted solutions are stable for 7 days at refrigerated temperatures or 2 days at room temperature.

Compatibility/Compounding Considerations

Compatible with normal saline or dextrose 5% in water for dilution. Vincristine sulfate is reportedly physically **compatible** with bleomycin sulfate, cytarabine, fluorouracil, and methotrexate sodium and in syringes or at Y-sites with bleomycin sulfate, cisplatin, cyclophosphamide, doxorubicin HCl, droperidol, fluorouracil, heparin sodium, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, and vinblastine sulfate.

Vincristine sulfate is reportedly physically **incompatible** with furosemide.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Vincristine Sulfate Injection: 1 mg/mL in 1 mL, 2 mL, and 5 mL vials; *Vincasar® PFS*, generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Vinorelbine

(vin-***or***-el-been) *Navelbine®*
Antineoplastic

Prescriber Highlights

- ► A semisynthetic vinca alkaloid antineoplastic used to treat a variety of tumors in dogs and cats
- ► Contraindications include pre-existing anemia, thrombocytopenia, or granulocytopenia (unless a result of the disease being treated) or active bacterial infection; reduce dose for patients with hepatic dysfunction.
- ► Adverse effects in dogs include gastroenterocolitis (eg, nausea, vomiting, diarrhea), myelosuppression; peripheral neuropathy appears less likely than with other vinca alkaloids.
- ► Extravasation injury is possible; ensure the IV catheter is well placed and freely flowing.
- ► Adverse effects in cats include anemia, neutropenia, weight loss, and/or vomiting.
- ► Wear gloves and protective clothing when preparing and administering. Vinorelbine is a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Potentially teratogenic

Uses/Indications

Vinorelbine is an antineoplastic drug that has been studied in dogs for the treatment of hemangiosarcoma,[1] locally aggressive or metastatic cutaneous mast cell tumors,[2] bronchoalveolar carcinoma,[3] primary pulmonary carcinoma[4] histiocytic sarcoma,[4] and with piroxicam for urinary bladder carcinoma.[5]

Vinorelbine use in cats appears to be limited; there is 1 phase I study in cats with a variety of tumor types published.[6]

In humans, vinorelbine is indicated for the treatment of non–small cell lung cancers (first-line, locally advanced, or metastatic) and is also used in the treatment of breast cancer; carcinomas of the esophagus and cervix; head, neck, and salivary gland cancer; Hodgkin's lymphoma; mesothelioma; ovarian cancer; and small cell lung cancer.

Pharmacology/Actions

Vinca alkaloids bind tubulin in the mitotic spindle, which prevents microtubule formation, interferes with axonal neurotransmitter movement, and causes microtubule depolymerization, thereby preventing cell division during metaphase. Vinorelbine also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle, and urea formation.

Pharmacokinetics

In dogs receiving vinorelbine IV, a rapid distribution phase was noted. Protein binding was 90%, and the terminal half-life was 34.5 hours.[7]

In humans, ≈85% of circulating vinorelbine is bound to cellular components (≈75% to platelets and other cells, ≈10% to plasma proteins). Vinorelbine is rapidly distributed to tissues, although the drug does not appreciably enter the CNS. It reaches 300-fold greater concentration in lung tissue than in plasma.

Vinorelbine is extensively metabolized in the liver by CYP3A, and at least 2 active metabolites are formed. The drug is primarily excreted in the bile and/or feces (≈45%), with lesser amounts (11% to 18%) of the unchanged drug eliminated in the urine. Terminal halflife is ≈40 hours.

Contraindications/Precautions/Warnings

Vinorelbine is contraindicated in patients with pre-existing leukopenia or granulocytopenia, thrombocytopenia, or active bacterial infections.[8] Severe myelosuppression resulting in serious infection, septic shock, and death can occur. Doses should be delayed or reduced for patients with decreased neutrophil counts. In humans, a dose reduction of 50% is suggested if neutrophil count is 1000 cells/mm^3 to 1499 cells/mm^3, and delaying treatment is advised if neutrophil count is less than 1000 cells/mm^3. Previous fever, sepsis, or delayed treatments warrant a 25% dose reduction.

Doses of vinorelbine should be reduced in patients with hepatic disease. In humans, a 50% dose reduction is recommended if serum bilirubin levels are greater than 2 mg/dL, and a 75% dose reduction is recommended for bilirubin greater than 3 mg/dL.[8] Vinorelbine use should be avoided in patients receiving radiation therapy in fields that include the liver.

Other vinca alkaloids (ie, vinblastine, vincristine) are substrates of P-glycoprotein and should be used with caution in herding breeds (eg, collies) that may have the the *MDR1* mutation (also known as *ABCB1*-1delta) causing nonfunctional proteins, as adverse effects may be more likely. However, vinorelbine does not appear to be a significant substrate for P-glycoprotein, and it is, therefore, unclear whether testing for the *MDR1* mutation (also known as *ABCB1*-1delta) prior to initiating vinorelbine therapy is warranted.[9]

Intrathecal administration of vinca alkaloids must be avoided, as this route of administration may result in ascending paralysis and death.

In humans, vinorelbine can cause severe and fatal paralytic ileus, constipation, intestinal obstruction, necrosis, and perforation.[8] Pulmonary toxicity, including severe bronchospasm, interstitial pneumonitis, and acute respiratory distress syndrome, can also occur.

The National Institute for Occupational Safety and Health (NIOSH) classifies vinorelbine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[10]

Adverse Effects

In 16% to 46% of dogs, vinorelbine can cause gastroenterocolitis (nausea/vomiting and diarrhea),[2–5] which generally lasts less than 24 hours; it is not considered highly emetogenic.

Myelosuppression was noted in 32% to 54% of dogs[2–5] and can occur at usual dosages. Granulocyte nadir is at 7 to 10 days after treatment; recovery is 7 to 14 days later. Myelosuppression may be cumulative.[3,4] Thrombocytopenia (grade 1 or 2) occurred in 7% of dogs in 1 retrospective study.[4] Vinorelbine is considered more myelosuppressive than vincristine.

Hepatic cirrhosis was noted in 1 dog[3] and nonspecific abdominal pain with elevated liver enzymes occurred in another dog,[4] although it was unclear whether those effects were directly attributable to vinorelbine. Vinorelbine may cause peripheral neurotoxic effects (eg, jaw and muscle pain, peripheral neuropathy, loss of deep tendon reflexes). One case of bilateral hind limb ataxia in a dog has been noted.[4]

In a phase I study in 19 cats, the following adverse effects were noted: anemia (32%), neutropenia (21%), weight loss (16%), persistent vomiting (11%), thrombocytopenia (5.2%), and grade 4 acute renal injury (5.2%).[6]

Administration site reactions (eg, phlebitis, erythema) occur more commonly with rapid IV injection or when administered into peripheral veins. Vinorelbine is considered a vesicant, and extravasation can cause significant tissue irritation, cellulitis, and necrosis. If clinical signs of extravasation are noted, discontinue infusion immediately and attempt to aspirate the drug back. Apply moderate heat to the area to help disperse the drug. Injections of hyaluronidase (150 units/mL, 1 to 6 mL through IV site; or 0.2 mL SC or intradermally in 5 sites [1 mL total] at the leading edge of extravasated drug) may help diffuse the drug. Ice is not recommended for vinca alkaloid extravasation as it can significantly worsen skin ulceration.[11] Topical dimethyl sulfoxide (DMSO) can be considered to treat the area involved. Never administer vinorelbine via SC or IM routes.

Reproductive/Nursing Safety

Vinorelbine possesses teratogenic and embryotoxic properties and should only be used in pregnant patients if the potential benefits to the dam outweigh the risk to the developing fetus. Placental transfer in rats was less than 1%.[7] Vinorelbine may also cause aspermia in males.

Concentrations of vinorelbine in rat mammary glands exceeded that of plasma concentration.[7] It is not known whether vinorelbine is excreted in milk, but because of the potential for serious adverse reactions in nursing offspring, the use of milk replacer is recommended if the dam requires vinorelbine.

For sexually intact patients, verify pregnancy status prior to administration.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In humans, death has occurred after a 5-fold overdose. In addition to the exacerbations of the expected adverse effects (eg, ileus, myleosuppression), neurotoxicity similar to those associated with vincristine (eg, loss of reflexes, paresthesias) may also be noted.

In humans, treatment is supportive and can include anti-infectives, hematopoietic drugs, and/or blood transfusions. Additionally, an attempt is made to prevent the effects associated with the syndrome of inappropriate antidiuretic hormone (SIADH) with fluid restriction and close monitoring of fluid and electrolyte status.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Vinorelbine is a CYP3A substrate. The following drug interactions have either been reported or are theoretical in humans or animals receiving vinorelbine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amphotericin B**: May increase the risk for nephrotoxicity, bronchospasm, and hypotension by an undetermined mechanism
- **Antidiuretic Hormone** (eg, **desmopressin, vasopressin**): May increase the risk for water intoxication and/or hyponatremia
- **Azole Antifungals** (eg, **itraconazole, ketoconazole, voriconazole**): May increase serum concentration of vinorelbine; consider reducing the vinorelbine dose.
- **CYP3A Inhibitors** (eg, **amiodarone, fluvoxamine, grapefruit juice**): Concurrent use may increase vinorelbine concentration and risk for toxicity.
- **Heparins** (eg, **dalteparin, enoxaparin, heparin**): Concurrent use may increase the risk for bleeding.

- **Immunosuppressive Drugs** (eg, **azathioprine, cyclophosphamide, corticosteroids**): Use with other immunosuppressant drugs may increase the risk for infection.
- **Macrolide Antibiotics** (except **azithromycin**): Macrolide antibiotics may increase the serum concentration of vinorelbine; consider reducing the vinorelbine dose.
- **Myelosuppressive Agents** (eg, **antineoplastics, immunosuppressants, iron chelators**): Concurrent use with other myelosuppressive medications may result in additive myelosuppression; avoid combination when possible.
- **Neuropathy-inducing Drugs** (eg, **carboplatin, dapsone, isoniazid, metronidazole, nitrofurantoin**): Concurrent use may increase the risk for peripheral neuropathy.
- **Ototoxic Drugs** (eg, **aminoglycosides, cisplatin, carboplatin**): May cause additive risk for ototoxicity
- **Vaccines** (live and inactivated): Vinorelbine may diminish vaccine efficacy and enhance adverse effects of vaccines.

Laboratory Considerations

- Vinorelbine may significantly increase both blood and urine concentrations of **uric acid** (potentially significant for Dalmatians).

Dosages

NOTE: Because of the potential toxicity of this drug to patients, veterinary personnel, and clients, and because chemotherapy indications, treatment protocols, and monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[12–16] are strongly recommended.

DOGS:

Neoplastic disease (extra-label): Initial dosage is usually 15 mg/m^2 (NOT mg/kg) IV into a freely flowing IV catheter over 6 to 10 minutes as a solution diluted to a concentration of 1 – 3 mg/mL; flush IV line after administration. The frequency of administration is typically every 1 to 2 weeks. Dosage escalation to 16 – 18 mg/m^2 (NOT mg/kg) IV can be considered based on tolerability. Dosage may be decreased by 10% to 20% if myelosuppression occurs.[2–5]

CATS:

Neoplastic disease (extra-label): Recommended starting dose is 11.5 mg/m^2 (NOT mg/kg) administered as a 1.5 mg/mL solution IV over 5 minutes every 7 days for up to 4 treatments; continuation with doses every 2 weeks may be considered. Dosage may be decreased by 10% to 25% if myelosuppression occurs.[6]

Monitoring

- Efficacy
- Baseline and periodic (ie, prior to each dose) CBC with platelet count
- Baseline and periodic liver enzymes

Client Information

- Vinorelbine is a chemotherapy (anticancer) medicine. The medicine can be hazardous to other animals and people that come in contact with it. On the day your animal gets the drug and then for a few days afterward, handle all bodily waste (urine, feces, litter), blood, or vomit only while wearing chemotherapy-resistant gloves. Seal the waste in a plastic bag, then place both the bag and gloves in the regular trash.
- Those who are pregnant, attempting to conceive, or nursing should not clean up the animal's waste.
- Do not wash any items soiled with waste, vomit, or saliva from your dog with other laundry. Take precautions in handling the dog's toys, food bowl, and water bowl; wash separately from other items.
- Your veterinarian will need to perform regular monitoring, including blood tests and/or radiographs, to be sure this drug is not causing toxic effects to your animal. Do not miss these important follow up visits.
- Observe your dog for lack of appetite, vomiting, or diarrhea. If these signs are severe, or if you notice difficulty breathing or signs of infection, contact your veterinarian immediately.
- Bone-marrow suppression can occur. The greatest effects on bone marrow usually occur within a week after treatment. Your veterinarian will do blood tests to watch for this, but if you see bleeding, bruising, fever, or other signs of an infection or if your animal becomes tired easily, contact your veterinarian right away.

Chemistry/Synonyms

Vinorelbine is a semisynthetic vinca alkaloid derived from the plant *Catharanthus roseus*. Pharmaceutical formulations contain vinorelbine tartrate; 1 mg of vinorelbine is equivalent to 1.385 mg of vinorelbine tartrate. Vinorelbine tartrate occurs as a white, yellow, or light-brown, hygroscopic, amorphous powder that is freely soluble in water. The commercially available injection has a pH of 3.3 to 3.8.

Vinorelbine may also be known as 5'-nor-anhydrovinblastine and *Bagovir*®, *Vinelbine*®, or *Navelbine*®.

Storage/Stability

Store intact vials between 2°C and 8°C (36°F-46°F) and protect them from light. The commercially available injection is packaged under inert gas. Diluted solutions at concentrations between 0.5 mg/mL and 2 mg/mL are stable for up to 24 hours at 5°C to 30°C (41°F-86°F).[17] Dispose of any unused product or waste materials in accordance with proper procedures for cytotoxic drugs.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Compatible with lactated Ringer's, Ringer's, 0.45% and 0.9% sodium chloride, and 5% dextrose in water or 0.45% sodium chloride.

Vinorelbine is reportedly **syringe** or **Y-site compatible** with amiodarone, bleomycin sulfate, butorphanol, calcium salts, carboplatin, ceftazidime, ciprofloxacin, cyclophosphamide, dexamethasone sodium phosphate, dexmedetomidine, doxorubicin, famotidine, fentanyl, fluconazole, hydromorphone, leucovorin calcium, lidocaine hydrochloride, meropenem, metoclopramide HCl, midazolam, naloxone, pamidronate, potassium salts, and zoledronic acid.

Vinorelbine sulfate **compatibility information conflicts** with heparin sodium (in syringes).

Vinorelbine sulfate is reportedly physically **incompatible** with ampicillin sodium, amphotericin B (all forms), cefazolin, ceftriaxone, diazepam, furosemide, nitroprusside sodium, pantoprazole, phenobarbital, piperacillin-tazobactam, and sodium bicarbonate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Vinorelbine Sulfate Injection: 10 mg/mL in 1 mL and 5 mL vials; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Vitamin A

Vitamin (Retinoid)

Prescriber Highlights

- ► Potentially useful for adjunctive treatment of some types of dermatoses in dogs. Evidence is weak to support its use, but it is usually tolerated well.
- ► Give with food; may require 1 to 2 months before efficacy can be noted
- ► Must be given IM or SC; do not administer parenteral doses by the IV route.
- ► Keratoconjunctivitis or increased liver enzymes possible

Uses/Indications

In dogs, although evidence supporting the use of vitamin A is weak, exogenously administered (nondietary) vitamin A may be useful for treating vitamin A–responsive dermatosis in cocker spaniels (and other breeds), sebaceous adenitis, primary idiopathic seborrhea and other primary keratinization disorders, follicular disorders (eg, color dilution alopecia), and keratoacanthoma. It also can be used to treat hypovitaminosis A in other species, including chelonians and birds.

One retrospective study (n = 24) using oral vitamin A (mean dosage was 1037 units/kg/day) for a minimum of 1 month to treat sebaceous adenitis has been published.[1] All but 2 dogs also received other treatments, including systemic antibiotics, systemic antifungal medications, fatty acid supplementation, or various topical treatments. At follow-up, ≈½ of the owners were satisfied with the overall appearance of their dogs, reporting at least 25% improvement in clinical signs, but almost ⅓ of owners reported no improvement. The authors concluded that no correlations could be made between vitamin A dosage and response to treatment; prognoses could not be made based on clinical and histopathologic findings.

Pharmacology/Actions

Vitamin A (and its derivatives) is necessary for growth, bone and dental development, vision, reproduction, cortisol synthesis, immunity, and the integrity of mucosal and epithelial surfaces. Vitamin A is a cofactor in various biochemical reactions, including mucopolysaccharide synthesis, cholesterol synthesis, and hydroxysteroid metabolism. Retinol combines with opsin to form rhodopsin in rod cells (responsible for motion detection and night vision) and iodopsin in cone cells (responsible for light and color vision). All retinoids have some antiproliferative, anti-inflammatory, and immunomodulatory effects.

Pharmacokinetics

Orally administered vitamin A (except retinoic acid) must be converted to retinol by pancreatic and mucosal hydrolases before it is absorbed in the small intestine and re-esterified in mucosal cells. Absorption may be reduced with impaired hepatic or pancreatic function. These retinyl esters (primarily retinyl palmitate) enter the systemic circulation via the lymphatics after they are bound by chylomicrons and are then cleared from the circulation and stored by the liver. Retinoic acid is directly absorbed unchanged and then transported into systemic circulation via albumin. It is metabolized by glucuronidation pathways.

Contraindications/Precautions/Warnings

Exogenously administered vitamin A is contraindicated in patients that are known to be hypersensitive to it or in patients with hypervitaminosis A. Vitamin A dosages in excess of the recommended daily requirements are contraindicated during pregnancy. Anaphylactic shock and death have occurred in humans after IV administration.

To avoid hypervitaminosis A, consider all sources of vitamin A (eg, dietary, other supplements, topicals) when prescribing vitamin A.

Adverse Effects

Dogs appear to tolerate oral vitamin A well. Potential adverse effects in dogs can include GI effects, erythema, pruritus, and behavioral changes. Long-term oversupplementation can cause hypervitaminosis A, which is exhibited by localized or generalized papules (firm center), poor coat quality, alopecia, scaling, excessive bleeding, liver disease, and, rarely, keratoconjunctivitis sicca. Adverse effects generally resolve after drug discontinuation.

Cats appear to be susceptible to chronic vitamin A toxicity. A case report of hypervitaminosis A in a cat that was fed raw liver and developed hepatic fibrosis and stellate cell lipidosis has been published.[2]

Reproductive/Nursing Safety

Exogenously administered vitamin A is contraindicated in pregnancy.

Safety to nursing offspring is not known, but vitamin A requirements in dams increase while nursing.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Data on acute toxicity from oral vitamin A in dogs or cats were not located. Oral LD_{50} in rats is 2000 mg/kg.[3]

In humans, acute toxic effects can include GI effects (eg, nausea, vomiting), drowsiness, headache, and vertigo. In adults, blurred vision has been reported, and in infants, bulging fontanelles. Toxic (1 time) doses reported are 350,000 units per dose for infants and children less than 6 years old, and greater than 2,000,000 units per dose for adults, or ≈25,000 units/kg. Long-term overdosing appears to hold the greater risk for dogs (and cats); refer to the ***Adverse Effects*** section for more information. Treatment consists of discontinuation of vitamin A and supportive therapy.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vitamin A and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cholestyramine**: May reduce vitamin A absorption; separate dosages by at least 2 hours if using concomitantly
- **Clopidogrel**: High doses of vitamin A may increase the risk for bleeding.
- **Heparin**: High doses of vitamin A may increase the risk for bleeding.
- **Isotretinoin** (eg, other **retinoids**): Increased risk for vitamin A toxicity
- **Mineral Oil**: May reduce the amount of vitamin A absorbed from the gut. Separate dosages by at least 2 hours if using concomitantly.
- **Neomycin**: May reduce vitamin A absorption
- **Tetracyclines** (eg, **doxycycline, minocycline**): Concurrent use may increase the risk for pseudotumor cerebri (benign intracranial hypertension).
- **Warfarin**: High doses of vitamin A may increase the risk for bleeding.

Laboratory Considerations

- Vitamin A may falsely elevate **bilirubin** when determined by Ehrlich's reagent.

Dosages

NOTE: Dosages are not well defined, and little evidence exists to support any dosing regimen.

DOGS:

Adjunctive treatment of canine sebaceous adenitis (extra-label): Initially, 8000 – 10,000 units/dog (NOT units/kg) PO twice a day; can increase to 20,000 – 30,000 units/dog (NOT units/kg) PO twice a day.[4] From a retrospective study (n = 24): doses varied from 380 – 2667 units/kg/day PO (mean dosage was 1037 units/kg per day for a minimum of 1 month).[1]

Vitamin A-responsive dermatosis, primary idiopathic seborrhea, follicular disorders, keratoacanthoma (extra-label): 625 – 800 units/kg PO once a day or 10,000 – 50,000 units/dog (NOT units/kg) PO once a day with a fatty meal. It may take 4 to 8 weeks before any improvement can be seen.[5]

REPTILES:

Adjunctive treatment of hypovitaminosis A in chelonians (extra-label): In addition to adding carrots and cod liver oil to the diet, vitamin A injection at 2000 units/kg IM can be given.[6]

Hypovitaminosis A in geckos (extra-label): 0.01 mL of vitamin A+D for injection (containing 500,000 units/mL vitamin A) SC; repeat in 14 days[7]

Monitoring

- Efficacy
- Schirmer tear test (STT) if using it long term. Recommendation for frequency for rechecking STT varies; every 3 weeks to every 6 to 12 months have been suggested.
- Liver enzymes if using it long term; baseline and every 6 to 12 months
- Other adverse effects as they arise

Client Information

- Give this medicine with food (meals), preferably food that is high in fat.
- This medicine may be taken 1 to 2 months before it causes any improvement in condition.
- Do not give more of this medicine than your veterinarian prescribes. Vitamin A can be toxic, especially if high doses are given for a long time.
- Watch for dry eyes.

Chemistry/Synonyms

Vitamin A may consist of retinol, or its esters formed from edible fatty acids, principally acetic and palmitic acids. In liquid form, vitamin A is a light yellow to red oil that may solidify upon refrigeration. In solid form, it takes on the appearance of any diluent that has been added. Vitamin A can be practically odorless, or it may have a mild fishy odor (but no rancid odor or taste). It is unstable in air and light. In liquid form, vitamin A is insoluble in water or glycerol and soluble in dehydrated alcohol or vegetable oils. In solid form, vitamin A may be dispersible in water.

Sources of vitamin A can be via retinols or provitamins. Retinols include retinol, retinal, and retinoic acid and are found in foods such as milk, meat, or eggs. Provitamins are plant-derived and include alpha-, beta- and gamma-carotene, which are converted to vitamin A in the body. Food processing, such as freezing, may reduce the amount of vitamin A in foods.

Formerly, vitamin A recommended daily allowances (RDA; for humans) were expressed in units, but now units has been replaced by retinol activity equivalents (RAE), where 1 RAE = retinol 1 µg, beta-carotene (from supplements) 0.2 µg, beta-carotene (from food) 12 µg, alpha-carotene 24 µg, or beta-cryptoxanthin 24 µg. (Note that pharmacologic doses continue to be expressed in units.)

Vitamin A may also be known as axerophthol, oleovitamin A, retinol, or retinyl palmitate.

Storage/Stability

Store oral products in tight, light-resistant containers away from heat. Store the injection between 2°C and 8°C (36°F and 46°F); do not freeze. Protect products from air and light.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Vitamin A for injection can be found in combination with the other fat-soluble vitamins (vitamin D and/or E) labeled for use in newborn or adult cattle, sheep, and swine; FDA approval status is uncertain (OTC).

HUMAN-LABELED PRODUCTS:

Vitamin A Oral Capsules: 7500 units, 8000 units, 10,000 units, and 25,000 units; generic; (OTC)

Vitamin A Palmitate (Retinyl Palmitate) for IM Injection: 50,000 units/mL (15 mg retinol/mL); *Aquasol-A®*; (Rx). **NOTE**: IV administration is contraindicated.

Vitamin E ± Selenium

Alpha-tocopherol

(***vye***-ta-min-***ee;*** se-***lee***-nee-um)

Nutritional; Vitamin

Prescriber Highlights

- ► Vitamin E (alone) has been used for various skin-related conditions (immune-mediated, ischemic dermatopathies); as an adjunctive treatment for hepatopathies and feline pansteatitis; and vitamin E deficiency states caused by dietary deficiency, pancreatitis, or genetics.
- ► Vitamin E with selenium is used for the treatment or prophylaxis of selenium-tocopherol deficiency (STD) syndromes in ewes and lambs (white muscle disease); sows, weanling and baby pigs (hepatic necrosis, mulberry heart disease, white muscle disease); calves and breeding cows (white muscle disease); and horses (myositis associated with STD).
- ► Contraindications: vitamin E/selenium products should only be used in the species for which they are FDA-approved.
- ► Adverse effects include anaphylactoid reactions; IM injections may cause transient muscle soreness. Selenium overdoses can cause depression, ataxia, dyspnea, blindness, diarrhea, muscle weakness, and a garlic odor on the breath. Selenium overdoses can be extremely toxic.

Uses/Indications

Vitamin E may be useful as adjunctive treatment of discoid lupus erythematosus, symmetrical lupoid onychodystrophy,[1] pemphigus complex, and demodicosis in dogs. A review article on canine ischemic dermatopathies states: *The mainstay for pharmacologic management of ischemic dermatopathies is pentoxifylline in combination with vitamin E.*[2]

Vitamin E may also be of benefit in the adjunctive treatment of hepatic fibrosis or adjunctive therapy of copper-associated hepatopathy in dogs and pansteatitis in cats. There is some evidence that vitamin E and silymarin have synergistic effects on hepatocytes and a

study in dogs found evidence that silymarin and vitamin E provided some efficacy in preventing gentamicin-induced nephrotoxicity.[3] However, with respect to using vitamin E for canine liver disease, an article reviewing the evidence states: …*vitamin E supplements have been recommended for dermatologic and hepatobiliary diseases (cholestatic and necro-inflammatory hepatopathies) in which antioxidant activity may be of benefit. However, no scientific data support their use for any of these indications.* The results of one study showed a potential clinical benefit of oral vitamin E as adjunctive treatment of canine atopic dermatitis.[4]

Supplemental vitamin E appears useful for treating retinal pigment epithelial dystrophy (RPED) with neuroaxonal degeneration in English cocker spaniels (and presumably other breeds).[5]

A double-blinded and randomized pilot study (n = 8 in treatment group) in a canine experimental osteoarthritis model found some evidence that dogs treated with vitamin E (≈400 units/dog [NOT units/kg] PO per day) showed a reduction in inflammation joint markers and histological expression, as well as a trend to improving signs of pain.[6]

Some dogs and cats with dilated cardiomyopathy have low vitamin E concentrations, but it is unknown if vitamin E supplementation has any clinical effect. Vitamin E supplementation in cats with chronic kidney disease did not improve anemia or measures of oxidative stress.[7]

Depending on the product and target species, vitamin E/selenium is indicated for the treatment or prophylaxis of selenium-tocopherol deficiency (STD) syndromes in ewes and lambs (white muscle disease); sows, weanling and baby pigs (hepatic necrosis, mulberry heart disease, white muscle disease); calves and breeding cows (white muscle disease); and horses (myositis associated with STD). A small, noncontrolled study indicated that vitamin E/selenium may be useful as adjunct therapy to a miticide (ivermectin) for treating canine sarcoptic mange.[8]

Pharmacology/Actions

Both vitamin E and selenium are involved with cellular metabolism of sulfur. Vitamin E has antioxidant and anti-inflammatory properties and with selenium, protects against red blood cell hemolysis and prevents the action of peroxidase on unsaturated bonds in cell membranes.

Pharmacokinetics

After absorption, vitamin E is transported in the circulatory system via beta-lipoproteins. Water-soluble (water-dispersible) oral forms appear to be more bioavailable. Impaired hepatic or pancreatic function may reduce absorption. Vitamin E is distributed to all tissues and stored in adipose tissue. Vitamin E is only marginally transported across the placenta. Vitamin E is metabolized in the liver via glucuronidation and excreted primarily into the bile. Absorption of vitamin E may be impaired in patients with severe cholestatic liver disease or in animals with fat malabsorption syndromes.

Pharmacokinetic parameters for selenium were not located.

Contraindications/Precautions/Warnings

Vitamin E (alone) should be used with caution in patients with coagulation disorders.

Vitamin E/selenium products should only be used in the species for which they are FDA-approved. Because selenium can be extremely toxic, the indiscriminate use of these products can be dangerous. Give slowly when administering IV to horses.

Adverse Effects

Oral administration of vitamin E appears to be well-tolerated, with a wide margin of safety. Anaphylactoid reactions have been reported. IM injections may be associated with transient muscle soreness. Other adverse effects are generally associated with overdoses of selenium (see ***Overdose/Acute Toxicity***).

Reproductive/Nursing Safety

Because safety has not been established in all animal species, this supplement should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Large overdoses of vitamin E can cause coagulopathies.

Selenium is toxic in overdose quantities but has a fairly wide safety margin. Cattle have tolerated chronic doses of 0.6 mg/kg/day with no adverse effects (approximate therapeutic dose is 0.06 mg/kg). Clinical signs of selenium toxicity include depression, ataxia, dyspnea, blindness, diarrhea, muscle weakness, and a garlic odor on the breath. Horses suffering from selenium toxicity may become blind, paralyzed, slough their hooves, and lose hair from the tail and mane. Dogs may exhibit signs of anorexia, vomiting, and diarrhea at high doses.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vitamin E/selenium and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulant Agents** (eg, **heparins, rivaroxaban, warfarin**): Risk for bleeding may be increased.
- **Antiplatelet Agents** (eg, **aspirin, clopidogrel**): Risk for bleeding may be increased.
- **Cholestyramine**: May reduce the absorption of orally administered vitamin E
- **Iron**: Large doses of vitamin E may delay the hematologic response to iron therapy in patients with iron deficiency anemia.
- **Mineral Oil**: May reduce the absorption of orally administered vitamin E
- **Nonsteroidal Anti-Inflammatory Drugs** (eg, **carprofen, flunixin, meloxicam, phenylbutazone**): Risk for bleeding may be increased.
- **Vitamin A**: Absorption, utilization, and storage may be enhanced by vitamin E.

Laboratory Considerations

- None noted

Dosages

The following dosages are for vitamin E as a single agent; for dosages of vitamin E/selenium veterinary-labeled products see ***Dosage Forms/Regulatory Status***. Do not confuse dosages of units/animal with units/kg.

DOGS:

Ischemic dermatopathies (extra-label): 200 units/small-sized dog (NOT units/kg); 400 units/medium-sized dog (NOT units/kg); 600 units/large-sized dog (NOT units/kg) PO every 12 hours. The ideal oral dosage of vitamin E for maximum cutaneous protection has not been elucidated, but it has a wide margin of safety for oral supplementation. Used in combination with pentoxifylline 15 mg/kg PO every 8 hours to 30 mg/kg PO every 12 hours.[2]

Atopic dermatitis (extra-label): 8.1 units/kg PO once daily improved clinical sign scores in dogs with atopic dermatitis.[4]

Adjunctive treatment of immune-mediated skin diseases (eg, discoid lupus erythematosus, canine demodicosis, or derma-

tomyositis) (extra-label): Anecdotally, 200 – 800 units/dog (NOT units/kg) PO twice daily.

Adjunctive treatment of hepatopathies or as an antioxidant hepatoprotective (extra-label): Anecdotally, 50 – 400 units/dog (NOT units/kg) PO once daily. Some recommend water-soluble (water-dispersible) dosage forms as oral bioavailability may be higher.[9]

Tocopherol deficiency associated with exocrine pancreatic disease (extra-label): 100 – 400 units/dog (NOT units/kg) PO once daily for 1 month then every 1 to 2 weeks as needed.[10]

Retinal pigment epithelial dystrophy (RPED) (extra-label): 600 – 900 units/dog (NOT units/kg) PO twice daily.[5]

CATS:

Pansteatitis (extra-label): 10 – 15 units/kg PO once daily. **NOTE**: One study in 4 cats with pansteatitis showed good clinical response in 3 cats (one was lost to follow-up) after treatment with oral vitamin E 50 mg/kg once a day, in combination with prednisolone (2 mg/kg/day for 1 week and then every other day for an additional 1 to 2 weeks) and dietary changes.[11]

HORSES:

Vitamin E deficiency (extra-label): Natural-source water-dispersible forms of vitamin E (*Elevate W.S.®*) 10 units/kg PO (assume per day—*Plumb*) are 5 to 6 times more bioavailable than synthetic vitamin E acetate, and a 5000 units/horse (NOT units/kg) (*assume per day—Plumb*) more than doubles serum vitamin E levels within 12 hours. Foals should receive 5 – 6.6 units/kg/day PO using a liquid formulation. Before implementing supplementation, it is important to measure serum alpha-tocopherol concentrations to determine if there is an underlying deficiency and to monitor the efficacy of supplementation.[12–14] **NOTE**: Donkeys may have a lower selenium requirement than horses.[15]

Equine metabolic syndrome (extra-label): 1000 units/horse (NOT units/kg) PO daily added to diet[16]

Adjunctive treatment of neurologic disease (extra-label): There are many recommendations for using high levels of vitamin E supplementation for horses with neurologic disease, ranging from 1,500 – 23,000 units/500 kg (1102 lb) horse daily. The use of vitamin E for these conditions is empirically based on a belief that it could be neuroprotective in disorders not related to a deficiency of vitamin E. There appears to be no scientific evidence that supplementation with doses of vitamin E above the 2007 National Research Council (NRC) recommended dose will have a therapeutic effect in horses other than those associated with a vitamin E deficiency. Many of these dosage recommendations exceed the NRC upper safety recommendation of 20 units/kg (10,000 units/500 kg horse). Furthermore, many of these studies were performed before the development of natural forms of vitamin E in horses and these amounts might be excessive if natural vitamin E is used therapeutically.[17]

Monitoring

- Clinical efficacy
- Blood selenium concentrations (when using the combination product). Normal values for selenium have been reported as: more than 1.14 µmol/L in calves, more than 0.63 µmol/L in cattle, more than 1.26 µmol/L in sheep, and more than 0.6 µmol/L in pigs. Values indicating deficiency are: less than 0.40 µmol/L in cattle, less than 0.60 µmol/L in sheep, and less than 0.20 µmol/L in pigs. Intermediate values may result in suboptimal production.
- Optionally, glutathione peroxidase activity may be monitored.

Client Information

- Vitamin E is used to treat some skin, liver, and eye conditions and is safe when given as directed.
- Large overdoses can cause bleeding. Contact your veterinarian if your animal develops bleeding from the gums, low energy level, or blood in the urine or feces.
- If using the vitamin E and selenium injection, do not give more than your veterinarian recommends; selenium can be toxic if too much is given.

Chemistry/Synonyms

Vitamin E is a lipid-soluble vitamin that can be found in either liquid or solid forms. The liquid forms occur as clear, yellow to brownish red, viscous oils that are insoluble in water, soluble in alcohol, and miscible with vegetable oils. Solid forms occur as white to tan-white granular powders that disperse in water to form cloudy suspensions. Vitamin E may also be known as alpha tocopherol. In 2000, one unit of vitamin E was redefined to equal the biologic activity of 1 mg all racemic-alpha-tocopheryl acetate, or 0.91 mg (910 µg) all racemic-alpha-tocopheryl. Potencies expressed in International units or USP units are no longer current.

Selenium in commercially available veterinary injections is found as sodium selenite. Each mg of sodium selenite contains ≈460 µg (46%) of selenium.

Storage/Stability

Vitamin E/selenium for injection should be stored at temperatures less than 25°C (77°F); protect from freezing.

Compatibility/Compounding Considerations

No specific information noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Vitamin E Oral Liquid

Many products may be labeled for use in animals and as they are considered supplements and not drugs, they are not necessarily FDA-approved animal drugs. Some products with horse indications and dosages are: *Elevate® W.S* 500 units/mL and *Elevate® Maintenance Powder 1000 units/7 grams*; (OTC).

Vitamin E (Alone) Injection

Vitamin E Injection: 300 units/mL in 250 mL vials; *Emulsivit® E-300*; (Rx). For SC or IM administration.

Vitamin E Injection: 500 units/mL in 250 mL vials; *Vital E®-500*; (OTC). For SC or IM administration.

Vitamin E/Selenium Oral

Equ-SeE®: Each teaspoon (5 cc) contains ≈1 mg selenium and 220 units vitamin E; (OTC).

Other top dress equine products containing vitamin E and selenium include *Elevate® SE* (1500 units vitamin E plus 1 mg selenium per 7 grams); (OTC)

Vitamin E/Selenium Injection

Mu-Se®: Each mL contains: selenium 5 mg (as sodium selenite); vitamin E 68 units; 100 mL vial for injection. FDA-approved for use in weanling calves, nonlactating dairy cattle, and breeding beef cattle. (Rx) Slaughter withdrawal (at label dosages) = 30 days. Dose: For weanling calves: 1 mL/ 90.9 kg (200 lb) body weight IM or SC. For breeding beef cows: 1 mL/90.9 kg (200 lb) body weight during middle third of pregnancy and 30 days before calving IM or SC.

Bo-Se®: Each mL contains selenium 1 mg (as sodium selenite) and vitamin E 68 units; 100 mL vial for injection. FDA-approved for use in calves, swine, and sheep. (Rx) Slaughter withdrawal (at label dosages) = 30 days (calves); 14 days (lambs, ewes, sows, and pigs). Dose: Calves: 2.5 – 3.75 mL/45.5 kg (100 lb) body weight (depending on

severity of condition and geographical area) IM or SC. Lambs (2 weeks of age or older): 1 mL/18.2 kg (40 lb) body weight IM or SC (1 mL minimum). Ewes: 2.5 mL/45.5 kg (100 lb) body weight IM or SC. Sows and weanling pigs: 1mL/18.2 kg (40 lb) body weight IM or SC (1 mL minimum). Do not use on newborn pigs.

E-Se®: Each mL contains selenium 2.5 mg (as sodium selenite) and vitamin E 68 units in 100 mL vials. FDA-approved for use in horses. (Rx) Equine dose: 1 mL/45.5 kg (100 lb) body weight slow IV or deep IM (in 2 or more sites; gluteal or cervical muscles). May be repeated at 5- to 10- day intervals.

Vitamin E for injection is also available in combination with vitamins A and D. Vitamin E may also a component of feed additives, milk replacers and topical products.

HUMAN-LABELED PRODUCTS:

Vitamin E Tablets: 100 units, 200 units, 400 units, generic; (OTC)

Vitamin E Capsules: 200 units, 400 units, and 1000 units; *Vita-Plus E*®, *Alph E*®, *Vita-Plus E*®, generic; (OTC)

Vitamin E Drops: 15 units/0.3 mL in 12 mL and 30 mL; *Aquasol E*®; (OTC)

Vitamin E Liquid: 400 units/15 mL in 30 and 60 mL; *Nutr-E-Sol*®; (OTC)

Topicals are available. There are no FDA-approved vitamin E/selenium products for humans, but there are many products that contain either vitamin E (alone or in combination with other vitamins ± minerals) or selenium (as an injection alone or in combination with other trace elements) available.

Voriconazole

(vor-ih-***koh***-nah-zohl) *Vfend*®

Second-Generation Triazole Antifungal

See also ***Voriconazole Ophthalmic***

Prescriber Highlights

- ► Broad-spectrum oral/parenteral triazole antifungal
- ► Cats appear to be susceptible to adverse effects. Until further pharmacokinetic and safety studies can be done, it should only be used in cats as a last resort.
- ► Like other compounds in this class, there are many potential drug interactions.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies voriconazole as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Voriconazole may be useful to treat a variety of fungal infections in veterinary patients, particularly against *Blastomyces* spp, *Cryptococcus* spp, *Coccidioides* spp,[1,2] and *Aspergillus* spp. It has high oral bioavailability in a variety of species and can cross into the CNS. There is limited clinical experience using voriconazole in veterinary patients. Because of adverse effects in cats, it is generally only recommended as a last resort. There is considerable interest in using voriconazole for treating aspergillosis in pet birds, as their relatively small size may make the drug more affordable; additional research must be performed before dosing regimens are available.

The drug may be used for horses with fungal keratomycosis.[3–5] See also ***Voriconazole Ophthalmic***.

Pharmacology/Actions

Voriconazole is a synthetic derivative of fluconazole, which has broad-spectrum antifungal activity against a variety of organisms, including *Candida* spp, *Aspergillus* spp, *Trichosporon* spp, *Histoplasma* spp, *Cryptococcus* spp, *Blastomyces* spp, and *Fusarium* spp. Like the other azole/triazole antifungals, it inhibits a fungal cytochrome P450-dependent demethylation enzyme that produces ergosterol in the cell membrane. The resultant intracellular accumulation of methylated sterols weakens the cellular membranes of susceptible fungi, increasing membrane permeability, allowing leakage of cellular contents, and impairing uptake of purine and pyrimidine precursors.

Unlike fluconazole, voriconazole also inhibits 24-methylene dehydrolanosterol demethylation in molds such as *Aspergillus* spp, giving it more activity against these fungi.

Pharmacokinetics

In dogs, voriconazole is rapidly and essentially completely absorbed after oral administration. Absorption is decreased when voriconazole is given with food but is not affected by drugs that raise gastric pH. Peak concentrations occur ≈3 hours after oral dosing. Voriconazole is only moderately (51%) bound to canine plasma proteins and the volume of distribution is ≈1.3 L/kg. Concentrations attained in CSF, aqueous humor, and synovial fluid are 43% to 53% that of plasma.[6] It is metabolized in the liver to a variety of metabolites with the N-oxide metabolite being the primary circulating metabolite. This metabolite has only weak antifungal activity (less than 100 times as active as the parent). The elimination pharmacokinetics of voriconazole in dogs is very complex. Both dose-dependent nonlinear elimination and auto-induced metabolism after multiple dosages are seen, complicating any dosage regimen; dosages may need to be increased over time. Autoinduction of metabolism apparently does not occur in humans, rabbits, or guinea pigs. Terminal half-life in one study was 3.3 hours.[6]

In fasted cats receiving single oral doses of 4 – 6 mg/kg, peak concentrations of 2.2 to 2.5 µg/mL occurred within 1.5 hours after administration. Volume of distribution was 1.7 to 2.1 L/kg. All 4 cats that received tablet formulations had trough voriconazole concentrations above 1 µg/mL for at least 72 hours after administration. Oral administration of a loading dose of 25 mg/cat (NOT mg/kg) followed by 12.5 mg/cat (NOT mg/kg) every other day caused voriconazole accumulation over the 2-week study period. Terminal half-life averaged 43 hours.[7]

In horses, voriconazole is well absorbed after oral administration with peak concentrations at ≈1 to 3 hours postdose. Voriconazole has low protein binding (31%); volume of distribution is ≈1.35 to 1.6 L/kg. The drug is distributed into the CSF, tears, and synovial fluid. Elimination half-life is ≈13 hours after oral dosing. Mean half-life in tear film is ≈25 hours. It is not known if voriconazole self-induces hepatic metabolism after multiple doses in a horse.[5,8,9]

After single oral doses to alpacas, voriconazole had a low bioavailability (≈24%), but IV doses of 4 mg/kg yielded plasma concentrations above 0.1 µg/mL for at least 24 hours. Elimination half-life was ≈8 hours.[10]

In Hispaniolan Amazon parrots, oral voriconazole had a short half-life (≈1 hour). The authors concluded that the drug could be safely administered to this species at a dose of 18 mg/kg PO every 8 hours for 11 days, but that further studies were necessary to determine safety and efficacy of long-term treatment.[11]

Contraindications/Precautions/Warnings

Voriconazole is contraindicated in patients that are hypersensitive to it or other azole antifungals, although evidence is lacking regarding cross-reactivity between voriconazole and other azole antifungal agents.

Voriconazole should be used with extreme caution in cats, as they appear to be prone to serious adverse effects. It should be given with

caution to patients with hepatic dysfunction or proarrhythmic conditions. Electrolytes (eg, potassium, magnesium, calcium) should be corrected before starting voriconazole therapy. Infusion reactions are uncommon, but infusion should be stopped immediately if there is development of flushing, fever, sweating, tachycardia, dyspnea, nausea, or pruritis.

The voriconazole IV product contains 3200 mg of sulfobutyl ether beta-cyclodextrin sodium (SBECD) per vial; this compound can accumulate in patients with decreased renal function.

The National Institute for Occupational Safety and Health (NIOSH) classifies voriconazole as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[12]

Adverse Effects

Accurate adverse effect profiles are unknown for veterinary species. Liver enlargement and up to a 2- to 3-fold increase in cytochrome P450 hepatic microsomal enzyme concentrations were noted in dogs orally dosed for 30 days. This may significantly impact the metabolism of other drugs that are hepatically metabolized (see ***Drug Interactions***). Mild to moderate adverse GI effects have been noted in dogs receiving oral voriconazole.[6] A dog treated with an IV infusion of voriconazole developed significant pyrexia and tachypnea after the infusion.[13] In dogs, high serum voriconazole concentration was associated with a reversible neurotoxicosis and increased liver enzymes.[14]

Cats appear to be susceptible to developing adverse effects from voriconazole. Two cats initially treated with 10 mg/kg PO once daily developed significant adverse reactions, including azotemia, inappetence, lethargy, and weight loss.[15] One developed a presumed cutaneous drug reaction, which resolved when voriconazole was discontinued, and the other cat developed ataxia and hind limb paresis. In another published case report, 3 cats receiving voriconazole at doses of 10 – 13 mg/kg PO once daily developed neurologic signs that included ataxia in all subjects, 2 of the 3 cats developed paraplegia, and 2 of the 3 cats had ophthalmic signs (eg, mydriasis, decreased or absent pupillary light responses, reduced menace response).[16] One cat developed an arrhythmia and in another, hypokalemia was noted. In a pharmacokinetic study, severe miosis and ptyalism were noted in cats receiving voriconazole tablets and suspension; ptyalism caused by voriconazole suspension prevented drug absorption in one cat.[7]

In humans, commonly encountered adverse effects include visual disturbances (eg, blurring, spots, wavy lines) usually within 30 minutes of dosing or if higher drug concentrations are attained, and rashes (usually mild to moderate in severity). Less frequent adverse effects include GI effects (eg, nausea, vomiting, diarrhea), hepatotoxicity (eg, jaundice, abnormal liver function tests), hypertension/hypotension, tachycardia, peripheral edema, hypokalemia, and hypomagnesemia. Rarely, eye hemorrhage, exfoliative dermal reactions, anemia, leukopenia, thrombocytopenia, pancytopenia, QT prolongation, torsade de pointes, and nephrotoxicity have been reported. Hallucinations have also been reported.[17]

Reproductive/Nursing Safety

Voriconazole was teratogenic in rats at low doses (10 mg/kg) and embryotoxic in rabbits at higher doses (100 mg/kg).[18] In humans, voriconazole has a high risk for major birth defects and miscarriage. It is unknown if voriconazole enters milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The minimum lethal dose in rats and mice was 300 mg/kg (4 to 7 times maintenance dose). Toxic effects included increased salivation, mydriasis, ataxia, depression, dyspnea, and seizures. Accidental single overdoses of up to 5 times the recommended dose in human pediatric patients caused only brief photophobia. No antidote is known for voriconazole overdoses. GI decontamination should be considered for large oral overdoses, followed by close observation and supportive treatment if required. Hemodialysis may assist in the removal of voriconazole and the sulfobutyl ether beta-cyclodextrin sodium (SBECD) vehicle.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

There are many potential drug interactions involving voriconazole. Voriconazole is a substrate of CYP450 2C and inhibitor of CYP450 3A isoenzymes. The following partial listing includes reported or theoretical interactions in humans receiving voriconazole that may also be of significance in veterinary patients. Because, in dogs, voriconazole induces hepatic microsomal enzymes (in humans it does not), additional interactions and further clarification may be reported, as clinical use increases in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amiodarone**: Potential for serious cardiac arrhythmias such as torsade de pointes; concurrent use is contraindicated in humans
- **Benzodiazepines** (eg, **alprazolam, midazolam**): Voriconazole may increase benzodiazepine concentrations.
- **Bromocriptine**: Voriconazole may increase serum concentrations of bromocriptine.
- **Buspirone**: Voriconazole may increase serum concentrations of buspirone.
- **Calcium Channel Blockers** (eg, **amlodipine, diltiazem, verapamil**): Voriconazole may increase serum concentrations; dosage adjustment may be required.
- **Cisapride**: Voriconazole may increase serum concentrations of cisapride and increase risk for serious cardiac arrhythmias; use is contraindicated.
- **Corticosteroids** (eg, **prednisolone**): Potentially increased AUC for prednisolone
- **Cyclosporine**: Increased cyclosporine concentrations; 50% reduction in cyclosporine dose recommended
- **Doxorubicin**: Voriconazole may increase serum concentrations of doxorubicin; concurrent use is contraindication in humans.
- **Fentanyl, Alfentanil**: Voriconazole may increase plasma concentrations; monitor for toxicity and adjust dosage if necessary.
- **Glipizide, Glyburide**: Voriconazole may increase serum concentrations of these drugs and increase risk for hypoglycemia.
- **Methadone**: Voriconazole may increase plasma concentrations of R-methadone; monitor for methadone toxicity and adjust dosage if necessary.
- **Phenobarbital**: May decrease voriconazole concentrations resulting in therapeutic failure; use together is contraindicated.
- **Procainamide**: Potential for serious cardiac arrhythmias such as torsade de pointes
- **Proton Pump Inhibitors** (**PPIs**; eg, **omeprazole**): Voriconazole may increase omeprazole (and potentially other PPIs) concentrations.
- **Quinidine**: Potential for serious cardiac arrhythmias such as torsade de pointes; concurrent use is contraindicated in humans.
- **Rifampin**: Decreased voriconazole concentrations; use together contraindicated

- **Sildenafil**: Voriconazole may increase plasma concentrations; monitor for toxicity and adjust dosage if necessary.
- **Sotalol**: Potential for serious cardiac arrhythmias such as torsade de pointes
- **Vinca Alkaloids** (eg, **vinblastine, vincristine**): Possible increased Vinca alkaloid concentrations; monitor for toxicity.
- **Warfarin**: Voriconazole may potentiate warfarin's effects.

Laboratory Considerations

- No specific concerns were noted; see ***Monitoring*** for additional information.

Dosages

DOGS:

NOTE: In dogs, voriconazole may induce its own metabolism (see ***Pharmacokinetics***); dosages may need to be increased over time.

Coccidioidomycosis (extra-label): 4 mg/kg PO every 12 hours[1]

Systemic aspergillosis (extra-label): 4 – 5 mg/kg PO every 12 hours[19]

Sinonasal aspergillosis postsurgical debridement of fungal plaques (extra-label): From a case series (n = 3), 2.5 – 3.3 mg/kg PO every 12 hours[14]

CATS:

Aspergillosis (extra-label): From a pharmacokinetic study, a loading dose of 25 mg/cat (NOT mg/kg) PO, followed by 12.5 mg/cat (NOT mg/kg) every 72 hours.[7] **NOTE**: Case reports have documented significant toxicity at 10 mg/kg PO daily.[15,16]

HORSES:

Susceptible, systemic fungal infections (extra-label): Based on pharmacokinetic studies, 3 – 4 mg/kg PO once daily or 3 mg/kg PO twice daily should be sufficient to treat aspergillosis, but higher doses (4 – 5 mg/kg PO once daily) are probably necessary to treat infections with *Fusarium* spp.[8,9,20]

Guttural pouch mycosis (extra-label): 3 mg/kg PO every 12 hours; used in combination with topical 1% enilconazole[21]

Keratomycosis (extra-label): Based on a pharmacokinetic study, 4 mg/kg PO once daily is expected to achieve voriconazole concentration in tear fluid at the AUC:MIC ratio associated with treatment efficacy against *Aspergillus* spp.[5]

BIRDS:

Susceptible, systemic fungal infections (extra-label): Based on a pharmacokinetic study in Hispaniolan Amazon parrots, the authors concluded that the drug could be safely administered to this species at a dose of 18 mg/kg PO every 8 hours for 11 days, but that further studies were necessary to determine safety and efficacy of long-term treatment. [11]

Avian aspergillosis: 12.5 mg/kg PO twice daily for 60 to 90 days or by nebulization as a 1 mg/mL solution for 60 minutes once daily.[22] In a pharmacokinetic study involving racing pigeons, a suggested dosage is 10 mg/kg PO twice daily or 20 mg/kg PO once daily.[23]

REPTILES:

Susceptible, systemic fungal infections (extra-label):

a) **Red-eared sliders**: Based on pharmacokinetic study, 5 mg/kg SC[24]

b) **Chrysosporium anamorph of *Nannizziopsis vriesii* (CANV) in bearded dragons**: 10 mg/kg PO every 24 hours for 4 to 9 weeks[24]

Monitoring

- Efficacy
- Adverse effects
- Baseline and periodic serum liver chemistry panel and electrolytes
- Voriconazole plasma concentration (target range 1 to 4 µg/mL)[25]

Client Information

- Give this medicine to your animal at least 1 hour before or 1 hour after feeding.
- Report any possible side effects to your veterinarian immediately, including itching/rash; yellowing of the whites of the eyes, gums, or skin; reduced appetite; difficulty walking; vision problems.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine especially if you are pregnant or trying to conceive.

Chemistry/Synonyms

A triazole antifungal, voriconazole occurs as a white to light-colored powder with a molecular weight of 349.3. Aqueous solubility is 0.7 mg/mL.

Voriconazole may also be known as UK-109496, voriconazol, voraconazolum, or *Vfend*®.

Storage/Stability

Voriconazole tablets should be stored at 15°C to 30°C (59°F-86°F).

The unreconstituted powder for oral suspension should be stored in the refrigerator (2°C-8°C [36°F-46°F]). Once reconstituted, it should be stored in tightly closed containers at room temperature (15°C-30°C [59°F-86°F]); do not refrigerate or freeze. After reconstitution, the suspension is stable for 14 days. The suspension should be shaken well for 10 seconds prior to each administered dose.

The powder for injection should be stored at room temperature (15°C-30°C [59°F-86°F). After reconstituting with 19 mL of sterile water for injection, the manufacturer recommends using immediately; however, chemical and physical stability remain for up to 24 hours if stored in the refrigerator (2°C-8°C [36°F-46°F]). Discard solution if it is not clear or if particles are visible.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

The injectable solution must be further diluted to a concentration of 5 mg/mL or less for administration over 1 to 2 hours. Suitable diluents for IV infusion include (partial list): 0.9% sodium chloride, lactated Ringer's solution, 5% dextrose in lactated Ringer's solution, and 5% dextrose. Voriconazole is **not compatible** with simultaneous infusion with blood products or concentrated electrolyte solutions.

Voriconazole tablets can be crushed and made into a 2.5 mg/mL oral suspension by mixing a crushed 200 mg tablet with 20 mL water, then adding 60 mL *OraPlus*®. Thoroughly mix the suspension (eg, shaken, vortex mixed) until no particles are visible. Suspension should also be shaken for ≈30 to 60 seconds prior to each use. The suspension will remain stable for 14 days if kept under refrigeration.[11,26] A voriconazole 40 mg/mL suspension can also be compounded using 200 mg tablets and a vehicle comprised of a commercial suspending agent and either water (3:1 v/v) or sweetening (1:1 v/v) agents. To prepare, thoroughly mix a crushed 200 mg tablet with 5 mL of vehicle. The resultant suspension is stable for up to 30 days at room temperature or refrigerated.[27]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Voriconazole Tablets: 50 mg and 200 mg; *Vfend*®, generic; (Rx)

Voriconazole Powder for Oral Suspension: 45 g (40 mg/mL after reconstitution) in 75 mL bottles; *Vfend®*, generic; (Rx)

Voriconazole Powder for Injection, Lyophilized: 200 mg in single-use vials; *Vfend I.V.®*, generic; (Rx). Also contains sulfobutyl ether beta-cyclodextrin sodium (SBECD, a solubilizing agent) 3200 mg/vial. See ***Contraindications/Precautions/Warnings.***

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Warfarin

(***war***-far-in) *Coumadin®*

Anticoagulant

Prescriber Highlights

- ► Coumarin derivative anticoagulant uncommonly used for long-term thromboprophylaxis, primarily in dogs. Requires careful monitoring and dosage adjustment
- ► Use in cats is not recommended.
- ► Full anticoagulant effect requires several days to be achieved; may need additional anticoagulant (eg, heparin) during this time.
- ► Contraindications include pre-existent hemorrhage; pregnancy; patients undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, or surgery of large, open surfaces; active bleeding from the GI, respiratory, or GU tract; aneurysm; acute nephritis; cerebrovascular hemorrhage; blood dyscrasias; uncontrolled or malignant hypertension; hepatic insufficiency; pericardial effusion; and visceral carcinomas.
- ► Adverse effects include dose-related hemorrhage; death is possible.
- ► Many potentially significant drug interactions
- ► Teratogenic. The National Institute for Occupational Safety and Health (NIOSH) classifies warfarin as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

In veterinary medicine, warfarin has been used for the oral, long-term treatment (or prevention of recurrence) of thrombotic conditions, primarily in dogs. Use of warfarin in veterinary species is controversial due to unproven benefit in reducing mortality, increased expense associated with monitoring, and potential for serious effects (bleeding); many clinicians do not recommend its use.[1]

Pharmacology/Actions

Warfarin inhibits vitamin K epoxide reductase (VKORC1), which interferes with the action of vitamin K_1 in the synthesis of the coagulation factors II, VII, IX, and X, as well as the anticoagulant proteins C and S. Warfarin acts indirectly as an anticoagulant (it has no direct anticoagulant effect) to prevent the extension of an existing thrombus and reduce formation of new clots. Sufficient amounts of vitamin K_1 can override this effect. Depletion of existing clotting factors occurs gradually over the first several days of treatment, and additional anticoagulant therapy (eg, heparin) may be required. Warfarin is administered as a racemic mixture of S (+) and R (-) warfarin. The S (+) enantiomer is a significantly more potent vitamin K antagonist than the R (-) enantiomer in species studied.

Pharmacokinetics

Warfarin is rapidly and completely absorbed in humans after oral administration. In cats, warfarin is also rapidly absorbed after oral administration.

After absorption, warfarin is ≈99% bound to plasma proteins in humans. Only free (unbound) warfarin is active. It is reported that there are wide species variations with regard to protein binding; in cats, greater than 96% of the drug is protein bound, and horses have a higher free (unbound) fraction of the drug than do sheep, swine, or rats. Although other coumarin and indanedione anticoagulants are distributed in human milk, warfarin does not enter milk.

Warfarin is principally metabolized in the liver to inactive metabolites that are excreted in urine and bile (and then reabsorbed and excreted in the urine). The plasma half-life of warfarin may be several hours to several days depending on the patient (and possibly species). In cats, the terminal half-life of the S enantiomer is ≈23 to 28 hours and the terminal half-life of R enantiomer is ≈11 to 18 hours.

Contraindications/Precautions/Warnings

Warfarin is contraindicated in patients with pre-existent hemorrhagic tendencies or diseases, as well as patients undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, or surgery of large, open surfaces. It should not be used in patients with active bleeding from the GI, respiratory, or GU tract. Other contraindications include aneurysm, acute nephritis, cerebrovascular hemorrhage, blood dyscrasias, uncontrolled or malignant hypertension, hepatic insufficiency, pericardial effusion, pregnancy, and visceral carcinomas. Warfarin should not be used in patients with heparin-induced thrombocytopenia until platelet counts have stabilized. Anticoagulated patients have experienced hematomas after spinal or epidural anesthesia. Clients must be willing to comply with the frequency and expense of routine monitoring.

Use warfarin with extreme caution in cats. Most clinicians no longer recommend use of warfarin in cats due to an increased mortality rate and a high rate of significant adverse events, including fatal hemorrhage.[1]

Excessive anticoagulation can be managed by withholding one to several doses, with or without administration of vitamin K and/or blood products, with a subsequent dose reduction. Presurgical management may require withholding warfarin for up to several days prior to surgery and use of alternative anticoagulants (eg, heparin), although warfarin may continue uninterrupted if the surgical bleeding risk is low.

The National Institute for Occupational Safety and Health (NIOSH) classifies warfarin as a hazardous drug[2]; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

The principal adverse effect of warfarin use is dose-related hemorrhage, which may manifest with clinical signs of anemia, thrombocytopenia, weakness, hematomas and ecchymoses, epistaxis, hematemesis, hematuria, melena, hematochezia, hemarthrosis, hemothorax, intracranial and/or pericardial hemorrhage, and death. In humans, skin necrosis, calciphylaxis, and cholesterol microemboli have been reported.

Reproductive/Nursing Safety

Warfarin is embryotoxic, can cause congenital malformations, and is considered contraindicated during pregnancy. If anticoagulant therapy is required during pregnancy, most clinicians recommend using unfractionated or low-molecular weight heparin.

Based on limited published data, warfarin has not been detected in the breast milk of humans treated and is generally considered safe to use in nursing patients, but the nursing infant should be monitored for bruising or bleeding.

Overdose/Acute Toxicity

Acute overdoses of warfarin may result in life-threatening hemorrhage. In dogs and cats, single doses of 5 – 50 mg/kg have been associated with toxicity. It must be remembered that a lag time of 2 to 5 days may occur before signs of toxicity occur, and animals must be monitored and treated accordingly. Cumulative toxic doses of war-

farin have been reported as 1 – 5 mg/kg for 5 to 15 days in dogs and 1 mg/kg for 7 days in cats. Common clinical signs associated with overdose may include anorexia, hematuria, lethargy, and vomiting.

If overdose is detected early, prevent absorption from the gut using standard protocols. If clinical signs are noted, they should be treated with blood products and vitamin K_1 (phytonadione). Refer to ***Phytonadione (Vitamin K_1)*** monograph for more information.

For patients that have experienced or are suspected of having experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

Drug interactions with warfarin are perhaps the most important in human medicine. Warfarin is metabolized principally by CYP2C9, but also by many other CYP enzymes. The following drug interactions have either been reported or are theoretical in humans or animals receiving warfarin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

A multitude of drugs have been documented or theorized to interact with warfarin. The following drugs or drug classes may **increase the anticoagulant response** of warfarin (not necessarily a complete list):

- Acetaminophen
- Allopurinol
- Amiodarone
- Anabolic Steroids (eg, **boldenone**)
- Azole Antifungals (eg, **fluconazole, itraconazole, voriconazole**)
- Cephalosporins (eg, **cefazolin, cefpodoxime, cephalexin**)
- Chloramphenicol
- Cisapride
- Clopidogrel
- Danazol
- Fatty Acids, Omega-3
- Fluoroquinolones (eg, **enrofloxacin**)
- Glucosamine
- Heparins (unfractionated and low molecular weight heparins)
- Lactulose
- Macrolide Antibiotics (eg, **azithromycin, clarithromycin, erythromycin**)
- Metronidazole
- Mirtazapine
- Neomycin
- Nonsteroidal Anti-Inflammatory Drugs (**NSAIDs**; eg, **carprofen, meloxicam, phenylbutazone**)
- Penicillins (eg, **amoxicillin, dicloxacillin, penicillin G, piperacillin**)
- Pentoxifylline
- Proton Pump Inhibitors (**PPIs**; eg, **omeprazole, pantoprazole**)
- Quinidine
- Salicylates (eg, **aspirin**[3])
- Selective Serotonin Reuptake Inhibitors (**SSRIs**; eg, **fluoxetine, sertraline**)
- Sulfonamides (including combinations with ormetoprim and trimethoprim)
- Thyroid Medications
- Tramadol
- Vitamin E

The following drugs or drug classes may **decrease the anticoagulant response** of warfarin (not necessarily a complete list):

- Barbiturates (eg, **phenobarbital**)
- Corticosteroids (eg, **dexamethasone**)
- Cyclosporine: Additionally, warfarin may reduce cyclosporine efficacy.
- Estrogens
- Griseofulvin
- Mercaptopurine
- Rifampin
- Phenobarbital
- Spironolactone
- Sucralfate
- Vitamin K

Should concurrent use of any of the above drugs with warfarin be necessary, enhanced monitoring is required.

Laboratory Considerations

- Warfarin may cause falsely decreased **theophylline values** if using the Schack and Waxler ultraviolet method of assay.

Dosages

NOTE: Warfarin is not recommended as an anticoagulant due to an inconsistent anticoagulant effect, the need for close monitoring, and the risk for significant adverse effects including death due to hemorrhage.[1]

DOGS:

Anticoagulant (extra-label):

a) Initial dose of 0.05 – 0.2 mg/kg PO once daily, with dosage adjusted (see ***Monitoring***) to achieve an INR of 2 to 3. The 2 most important principles in adjusting the warfarin dose were to make adjustments to the total weekly dose rather than the total daily dose, and to keep the dose adjustments small (10% to 15% of the total weekly dose).[4–7]

b) Initial (loading) dose of 0.2 mg/kg PO once daily for 2 days, followed by 0.1 mg/kg PO once daily has been suggested.[8]

HORSES:

Anticoagulant (extra-label): Rarely recommended. Anecdotally, for adjunctive treatment of laminitis, 0.0198 mg/kg PO once daily; monitor prothrombin time until prolonged 2 to 4 seconds beyond baseline.[9]

Monitoring

NOTE: The frequency of monitoring is controversial, and dependent on several factors including dose, the patient's condition, and concomitant problems.

- Although prothrombin times (PT) or international normalized ratio (INR; not validated for veterinary patients[1]) are most commonly used to monitor warfarin, proteins induced by vitamin K antagonists (PIVKA) have been suggested as being more sensitive. Prothrombin times during treatment with warfarin are usually recommended to be 1.5 to 2 times normal and INRs to be between 2 and 3.[5,6,10,11] A retrospective study in dogs used INR to adjust dosage. In that study, some dogs required weekly or biweekly dose adjustments based on the INR value for the first 2 to 4 weeks. Based on concurrent disease processes or concomitant drug therapy, it is recommended that dogs have an INR value checked at least every 3 months with chronic treatment.[4]
- Platelet counts and packed cell volume (PCV) should be done periodically.
- Monitor for bleeding, including feces and urine
- Clinical efficacy

Client Information

- Other medications and foods can interact with warfarin and can either increase the risk for bleeding or reduce warfarin's anticoagulant effects. Talk with your veterinarian before changing diets or starting a new medicine (including those sold over the counter and supplements) or stopping medications that your animal is currently taking.
- Do not allow your animal to be in situations where it could be injured or cut, as serious bleeding may occur. If abnormal bleeding is seen, contact your veterinarian immediately.
- To assure the dose is correct, routine blood tests will be needed. Do not miss these important follow-up visits.
- If a dose is missed, it should be taken as soon as possible on the same day. Do not double up doses the next day.

Chemistry/Synonyms

A coumarin derivative, warfarin sodium occurs as a slightly bitter tasting, odorless, white, amorphous or crystalline powder that discolors in light. It is very soluble in water and freely soluble in alcohol. The commercially available products contain a racemic mixture of the two optical isomers.

Warfarin sodium may also be known as sodium warfarin, warfarinum natricum, *Coumadin®, Jantoven®, or Panwarfin®*; there are many other trade names internationally.

Storage/Stability

Warfarin sodium tablets should be stored in tight, light-resistant containers at room temperature 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 5 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Warfarin Sodium Oral Tablets (scored): 1 mg, 2 mg, 2.5 mg, 3 mg, 4 mg, 5 mg, 6 mg, 7.5 mg, and 10 mg; *Coumadin®*, *Jantoven®*, generic; (Rx)

Xylazine

(***zye***-la-zeen) *Rompun®, AnaSed®*

Alpha-2-Adrenergic Agonist

Prescriber Highlights

- ► Used as a sedative and analgesic agent in a variety of species; used as an emetic in cats
- ► Contraindicated in animals receiving epinephrine or having active ventricular arrhythmias. Do **not** give to animals that are exhausted, dehydrated, or with urinary tract obstruction. Avoid intra-arterial injection as it may cause severe seizures and collapse.
- ► Use with extreme caution in patients that have pre-existing cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, pre-existing seizure disorders, or if severely debilitated. Xylazine should generally not be used in the last trimester of pregnancy, particularly in cattle. Horses may kick after a stimulatory event (usually auditory); use caution.
- ► Use xylazine with caution in patients treated for intestinal impactions and in horses during the vasoconstrictive development phase of laminitis.
- ► Adverse effects in dogs include muscle tremors, bradycardia with partial atrioventricular (AV) block, reduced respiratory rate, movement in response to sharp auditory stimuli, emesis, and bloat from aerophagia, which may require decompression.
- ► Adverse effects in cats include emesis, muscle tremors, bradycardia with partial AV block, reduced respiratory rate, movement in response to sharp auditory stimuli, increased urination.
- ► Adverse effects in horses include muscle tremors, bradycardia with partial AV block, reduced respiratory rate, movement in response to sharp auditory stimuli, sweating, increased intracranial pressure, decreased GI motility, and decreased mucociliary clearance.
- ► Adverse effects in cattle include salivation, ruminal atony, bloating, regurgitation, hypothermia, diarrhea, bradycardia, premature parturition, and ataxia.
- ► Yohimbine, tolazoline, and atipamezole may be used alone or in combination to reverse effects or speed recovery times.
- ► Dosages between species can be very different; be certain of product concentration when preparing doses, especially if treating ruminants.

Uses/Indications

Xylazine is FDA-approved for use in dogs, cats, horses, deer, and elk to produce a state of sedation with a shorter period of analgesia and as a preanesthetic agent before local anesthesia. It is also approved as a preanesthetic agent before general anesthesia in dogs, cats, and horses. In horses, xylazine is often used in combination with other agents (eg, opioids, ketamine, guaifenesin) to induce anesthesia or perioperative sedation and analgesia.[1]

Xylazine use in small animal species is somewhat controversial. It is usually reserved for healthy animals because it can cause arrhythmias, reduce cardiac output, and increase the risk for general anesthesia-related death. Newer alpha-2 agonists (eg, dexmedetomidine) are preferred over xylazine, as they have fewer adverse effects in dogs and cats.

In cats, xylazine causes emesis and can be used to induce vomiting after toxin ingestion or drug overdoses.[2–4]

Pharmacology/Actions

Xylazine, a potent alpha-2-adrenergic agonist, is classified as a sed-

ative/analgesic agent with muscle relaxant properties. Xylazine possesses several of the same pharmacologic actions as morphine. However, it does not cause CNS excitation in cats, horses, or cattle but causes sedation and CNS depression. In horses, the visceral analgesia produced has been demonstrated to be superior to that produced by meperidine, butorphanol, or pentazocine.[5]

Xylazine can also have alpha-1 agonist activity and is less selective for alpha-2 receptors than detomidine, romifidine, or dexmedetomidine. The alpha-2: alpha-1 receptor selectivity of xylazine is 160:1 (detomidine = 260:1, romifidine = 340:1, medetomidine and dexmedetomidine = 1620:1).

Emesis is often seen in cats and occasionally in dogs receiving xylazine. Although it is thought to be centrally mediated, neither dopaminergic blockers (eg, phenothiazines) nor alpha-blockers (eg, yohimbine, tolazoline) block the emetic effect. Xylazine does not cause emesis in cattle, sheep, or goats. Xylazine depresses thermoregulatory mechanisms and either hypo- or hyperthermia is a possibility, depending on ambient air temperatures.

Effects on the cardiopulmonary system include an initial increase in peripheral vascular resistance with increased blood pressure followed by a longer period of lowered blood pressures (below baseline). An initial reflex bradycardia may occur in response to alpha-1-mediated vasoconstriction and can be seen with some animals developing a second-degree atrioventricular (AV) block or other arrhythmias. An overall decrease in cardiac output of up to 30% may be seen. Xylazine, with or without concurrent halothane, has been demonstrated to enhance the arrhythmogenic effects of epinephrine in dogs.

Xylazine's effects on respiratory function are usually clinically insignificant; however, at high doses, xylazine can cause respiratory depression with decreased tidal volumes and respiratory rates and an overall decreased minute volume. Xylazine causes skeletal muscle relaxation through inhibition of centrally mediated pathways, which may result in dyspnea in brachycephalic dogs and horses with upper airway disease.

Xylazine can increase blood glucose secondary to decreased pancreatic secretion of insulin. In nondiabetic animals, there appears to be little clinical significance associated with this effect, although an osmotic diuresis may result from transient hyperglycemia, and polyuria may occur due to decreased production of vasopressin (antidiuretic hormone [ADH]).

In dogs, clinical doses decrease tear production in a dose-related manner[6] but do not affect intraocular pressure and pupil size.[7]

In horses, signs of sedation include a lowering of the head with relaxed facial muscles and drooping of the lower lip. The retractor muscle is relaxed in male horses, but unlike with acepromazine, there are no reports of permanent penile paralysis. Although the animal may appear to be thoroughly sedated, auditory stimuli may provoke arousal with kicking and avoidance responses.

Differences are seen with regard to the sensitivity of species to xylazine. Domestic ruminants are extremely sensitive to xylazine when compared with dogs, cats, or horses, and they generally require ≈10% of the dose that is required for horses to exhibit the same effect. Pigs are less sensitive and require higher doses (≈20 times compared with the ruminant's dose). Xylazine, in combination with ketamine or tiletamine/zolazepam, is commonly used in swine for chemical restraint.

Pharmacokinetics

Absorption is rapid following IM injection, but the bioavailability is incomplete and variable. Bioavailability ranges of 40% to 48% in horses, 17% to 73% in sheep, and 52% to 90% in dogs have been reported after IM administration.

In dogs and cats, the onset of action following an IM or SC dose is ≈10 to 15 minutes and 3 to 5 minutes following an IV dose. The analgesic effects may persist for only 15 to 30 minutes, but the sedative actions may last for 1 to 2 hours, depending on the dose given. The serum half-life of xylazine in dogs has been reported as averaging 30 minutes. Complete recovery after dosing may take 2 to 4 hours in dogs and cats.

In horses, the onset of action following IV administration occurs within 1 to 2 minutes, with a maximum effect observed 3 to 10 minutes after injection. The duration of effect is dose dependent but may last for ≈1.5 hours. After a single dose of xylazine, the serum half-life is ≈50 minutes in a horse. Recovery times generally take from 2 to 3 hours. Intraosseous xylazine administration resulted in no significant differences in pharmacokinetic parameters or physiologic response as compared to IV administration.[8] Intra-articular administration resulted in systemic drug absorption (bioavailability = 58%) and occurrence of systemic effects.[9]

Contraindications/Precautions/Warnings

Do not give xylazine to animals that are dehydrated, debilitated, or with urinary tract obstruction. Xylazine is contraindicated in animals receiving epinephrine or having active ventricular arrhythmias. It should be used with extreme caution in animals with pre-existing cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, or pre-existing seizure disorders.

Do not confuse IV and IM dosages. Avoid intracarotid injection as it may cause severe seizures and collapse. Be certain of product concentration when drawing up into the syringe, especially if treating ruminants, as ruminants are extremely sensitive to the sedative effects of alpha-2 agonists.

Large animal species, including horses, may become ataxic following dosing, and caution should be observed. Use with caution in horses after xylazine administration, as they have been known to kick after a stimulatory event (usually auditory) even when horses to be appear sedated. The addition of opioids (eg, butorphanol) may help temper this effect. Because xylazine may inhibit GI motility, use it with caution in patients treated for intestinal impactions. Use cautiously in horses during the development of the vasoconstrictive phase of laminitis, as xylazine has been shown to reduce digital flow of blood for about 8 hours after administration.

Adverse Effects

Emesis is generally seen within 3 to 5 minutes after xylazine administration in cats and occasionally in dogs. To prevent aspiration, do not induce further anesthesia until this time has lapsed. Other adverse effects noted in dogs and cats after xylazine administration include muscle tremors, bradycardia with second-degree atrioventricular (AV) block, reduced respiratory rate, movement in response to sharp auditory stimuli, and increased urination.

Xylazine can reduce tear production and cause diuresis in dogs and cats.[6,10]

Adverse effects for horses include muscle tremors, bradycardia with second-degree AV block, reduced respiratory rate, movement in response to sharp auditory stimuli, and sweating (rarely profuse).[11] Additionally, horses receiving xylazine may develop transient hypertension, increased urine production, decreased gastric emptying, decreased motility of duodenum, jejunum and pelvic flexure, increased intrauterine pressure/contractions, and reduced mucociliary clearance rates. Ataxia occurs in a dose-dependent fashion.[12]

In cattle, adverse reactions associated with xylazine include salivation, ruminal atony, bloating and regurgitation, hypothermia, diarrhea, and bradycardia.

Reproductive/Nursing Safety

Limited information was located on the safety of xylazine in pregnancy. No reports of teratogenicity in animals were located.

Xylazine can have an oxytocin-like effect on the uterus of pregnant cattle and may induce premature parturition. Because it may induce premature parturition, it should generally not be used in the last trimester of pregnancy, particularly in cattle. For horses, one review concludes "…alpha-2 agonists are safe in pregnant animals, but close monitoring is advised."[13] Reduced fetal survival rates have been noted when xylazine is used as a premedication for cesarean deliveries.[14]

Xylazine does not appear to be excreted in detectable quantities in cows' milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In the event of an accidental overdose, emesis, cardiac arrhythmias, hypotension, and profound CNS and respiratory depression may occur. Seizures have also been reported after overdoses. There has been much interest in using alpha-blocking agents as antidotes or reversal agents to xylazine. Yohimbine, atipamezole, and tolazoline have been suggested to be used alone and in combination to reverse the effects of xylazine or speed recovery times. See ***Yohimbine, Tolazoline,*** and ***Atipamezole*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving xylazine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acepromazine**: Concurrent use of acepromazine with xylazine is generally considered safe; however, there is potential for additive hypotensive effects after the first hypertensive phase of xylazine. Manufacturers warn against using xylazine in conjunction with tranquilizers. Thus, this combination should be used cautiously in animals susceptible to hemodynamic complications.
- **Anesthetic Agents** (eg, **alfaxalone, isoflurane, ketamine, propofol**): May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced.
- **Anticholinergic Agents** (eg, **atropine, butylscopolamine, glycopyrrolate**): Use of anticholinergic agents with alpha-2 agonists may significantly increase arterial blood pressure, heart rate, and the incidence of arrhythmia.[15,16] Clinical use of atropine or glycopyrrolate to prevent or treat bradycardia caused by alpha-2 agonists is controversial and use together is discouraged; this may be particularly important when using higher doses of the alpha-2 agonist.
- **Antiemetic Agents** (eg, **maropitant, metoclopramide, ondansetron**): Antiemetics may decrease the emetogenic effects of xylazine.
- **Atipamezole**: Used clinically to reverse to effects of xylazine
- **Benzodiazepines** (eg, **diazepam, midazolam**): May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced.
- **Chloramphenicol**: Prolonged sedation and GI stasis possible[17]
- **CNS Depressant Agents, Other** (eg, **barbiturates, methocarbamol, trazodone**): May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced.
- **Epinephrine**: The use of epinephrine with xylazine, with or without the concurrent use of halothane, may induce ventricular arrhythmias.
- **Opioids** (eg, **buprenorphine, morphine, tramadol**): May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced
- **Reserpine**: A case of a horse developing colic-like clinical signs after reserpine and xylazine has been reported. Until more is known about this potential interaction, the use of these 2 agents together should be avoided.
- **Yohimbine**: May reverse the effects of medetomidine; however, atipamezole is preferred for clinical use to reverse the drug's effects because atipamezole is more selective for the alpha receptors and is unlikely to cause hypotension, which is common following administration of yohimbine.

Laboratory/Diagnostic Interactions

- In horses, xylazine infusion caused overestimation of lithium dilution method for cardiac output (LiDCO) measurements.[18]
- The use of xylazine before abdominal radiography can make test interpretation difficult in animals that develop gaseous distention of the stomach or bloat.

Dosages

NOTE: A reversal agent should always be on hand; reversal of sedative effects also reverses analgesic effects.

DOGS:

NOTE: Most clinicians prefer using newer alpha-2 agonists (eg, dexmedetomidine) that have a greater selectivity for the alpha-2 adrenergic receptor.

Sedation accompanied by a short period of analgesia; pre-anesthetic agent (label dosage; FDA-approved): 1.1 mg/kg IV OR 1.1 – 2.2 mg/kg IM or SC.[19] **NOTE**: The label dosage for dogs is considered by most clinicians to be greater than is necessary for most indications. The labeled indications are provided below, but the use of lower, extra-label dosages should be considered.

Preanesthetic agent (extra-label): 0.2 – 1 mg/kg IV, IM, or SC[20]

Analgesic adjunct (extra-label): 0.05 – 0.5 mg/kg IV, IM, or SC

CATS:

NOTE: Except for its use as an emetic, most clinicians prefer using newer alpha-2 agonists (eg, dexmedetomidine) that have greater selectivity for the alpha-2 adrenergic receptor.

Sedation accompanied by a short period of analgesia; pre-anesthetic agent (label dosage; FDA-approved): 1.1 mg/kg IV OR 2.2 mg/kg IM or SC.[11] **NOTE**: The label dosage for cats is considered by most clinicians to be greater than is necessary for most indications. The labeled indications are provided below, but the use of lower extra-label dosages should be considered.

Emetic (extra-label): 0.4 – 1.1 mg/kg IM or SC; will not work with toxicants that target the CRTZ. After emesis, effects can be reversed with yohimbine 0.1 mg/kg IV, tolazoline 0.5 – 1 mg/kg IV, or atipamezole 0.05 0.2 mg/kg IM can be considered. Tolazoline may be superior to yohimbine to reverse the emetic effects of xylazine in the cat.[3,21,22]

Preanesthetic agent (extra-label dose): 0.2 – 1 mg/kg IV, IM, or SC[20]

Analgesic adjunct (extra-label): 0.05 – 0.5 mg/kg IV, IM, or SC

Anxiolytic agent (extra-label): 0.05 – 0.2 mg/kg IV or IM[23]

HORSES:

Sedation accompanied by a short period of analgesia; pre-anesthetic agent (label dosage; FDA-approved): 1.1 mg/kg IV;

2.2 mg/kg IM.[24] Allow the animal to rest quietly until full effect is reached.

NOTE: FDA-approved dosages usually produce sedation lasting 1 to 2 hours and analgesia lasting for 15 to 30 minutes.

NOTE: More information for extra-label protocols for the use of xylazine as part of drug combinations for injectable sedation, anesthesia/analgesia protocols can be found in other references.[25] The following are some examples of published recommended dosages and protocols:

a) **Standing sedation and analgesia** (extra-label): Full dose is 1 mg/kg IV; for intraoperative use, IV dose is usually lower than the full dose, or an IV CRI can be used. CRI dosages reported range from 0.5 – 1 mg/kg/hour IV.[26] Epidural dosages range from 0.17 – 0.25 mg/kg.[13] Alternately, 0.5 – 1.1 mg/kg IV (onset of peak action in 2 to 5 minutes; duration ≈30 minutes); 1 – 2 mg/kg IM (onset of peak action in 15 minutes; duration ≈30 minutes). For prolonged procedures: 0.5 mg/kg IV, followed by a CRI of 0.65 mg/kg/hour.[27]

b) **Field anesthesia**: (extra-label): Sedate with xylazine 1 mg/kg IV OR 2 mg/kg IM given 5 to 10 minutes (longer for IM route) before induction of anesthesia with ketamine 2 mg/kg IV. The horse must be adequately sedated (chin to the metacarpals) before giving the ketamine (ketamine can cause muscle rigidity).[28]

c) **Part of induction protocols** (extra-label):
Normal healthy patients: 0.44 – 0.66 mg/kg IV. Wait for sedation and muscle relaxation to occur (≈5 minutes) before induction of general anesthesia. Higher doses (up to 2 mg/kg IV) may be needed depending on the horse's level of excitation.
Compromised patients: Use a very modest dose of xylazine 0.22 – 0.44 mg/kg IV, depending on status and demeanor, to minimize its cardiovascular effects in compromised patients. Slow administration of guaifenesin (5% solution) can be used to gradually create the desired level of sedation, followed by a more rapid administration of guaifenesin and ketamine.[29]

d) **IV anesthesia (greater than 30 minutes) using "GKX" or "triple-drip"** (extra-label): Guaifenesin (50 mg/mL), ketamine (1 – 2 mg/mL; 2 mg/mL concentration used for more painful or noxious procedures), and xylazine (0.5 mg/mL). Most practitioners prefer to induce with xylazine/ketamine or xylazine/diazepam/ketamine, and then use GKX for maintenance. Typically, the CRI runs at 1.5 – 2.2 mL/kg/hour IV, depending on the procedure, patient response, and ketamine concentration.

e) **Recovery after inhalant anesthesia** (extra-label): 0.2 – 0.5 mg/kg IV can be administered after inhalant anesthesia to improve recovery.[30,31]

f) **Supplementation of general anesthesia** (extra-label): Xylazine 0.5 – 1 mg/kg/hour IV CRI has been used with ketamine and isoflurane anesthesia.[26,32,33]

g) **Low-dose sedation to facilitate lameness evaluations** (extra-label): 0.3 mg/kg (route not stated, assume IV- *Plumb*) did not mask lameness (measured with body-mounted inertial sensors) or cause ataxia, despite all horses receiving xylazine showing subjective signs of sedation within 5 minutes of administration and reduced chin-to-ground measurement at a 20-minute observation point.[34]

CATTLE:

CAUTION: Cattle are extremely sensitive to xylazine's effects; be certain of dose and dosage form. Use only the 20 mg/mL solution for this species.

NOTE: Xylazine is approved for use in cattle in several countries; withdrawal times vary depending on labeling in each country. In the United States, xylazine is not FDA-approved for use in cattle. Xylazine withdrawal intervals vary based on the dose and route of administration. Withdrawal intervals may be lengthened if xylazine sedation is reversed with tolazoline or yohimbine. Consult FARAD for further information.

Chemical restraint and injectable anesthesia (extra-label): The reader is encouraged to refer to the in-depth review by Abrahamsen[35] where detailed discussions on the use of alpha-2 agonists alone and in combination with other anesthetic adjuncts (eg, ketamine stun) for both standing and recumbent procedures can be found. Examples:

a) **Analgesia and restraint for standing procedures in cattle** (extra-label): Butorphanol 0.01 – 0.025 mg/kg in combination with xylazine 0.02 – 0.05 mg/kg and ketamine 0.04 – 0.1 mg/kg and administered IM or SC, depending on dose route and patient demeanor. The higher end of these dosages is likely to result in the animal becoming recumbent.[35] For a 450 kg (992.1 lb) animal, total doses (NOT mg/kg) of butorphanol 5 mg, xylazine 10 mg, and ketamine 20 mg would constitute the low end of the dosing range. Up to an hour of cooperation was accomplished using this protocol, but more fractious patients may require increased doses. For animals weighing more than 450 kg (992.1 lb), it is suggested to give no more than butorphanol 10 mg (total dose, NOT mg/kg) or xylazine 20 mg (total dose, NOT mg/kg) for the initial dose.[36]

b) **Standing sedation** (extra-label): The following xylazine dosages would be expected to produce standing sedation with a low incidence of recumbency for facilitating short diagnostic or therapeutic procedures. Patients will generally tolerate mildly uncomfortable stimuli, but these dosages should not be counted on to provide significant analgesia. Duration of effect generally lasts about 30 to 40 minutes. **NOTE**: IM administration of doses intended to be given IV reduces the chance for recumbency.[35]

Patient type	IV (mg/kg)	IM (mg/kg)
Quiet dairy breeds	0.0075 – 0.01	0.015 – 0.02
Tractable cattle	0.01 – 0.02	0.02 – 0.04
Anxious cattle	0.02 – 0.03	0.04 – 0.06
Extremely anxious or unruly cattle	0.025 – 0.05	0.05 – 0.1

Sedation/analgesia: 0.1 – 0.3 mg/kg IM; 0.05 – 0.15 mg/kg IV; 0.05 – 0.07 mg/kg epidurally. When xylazine is used IV/IM, analgesia can be short-lived (½ hour).[37]

DEER/ELK:

Sedative/analgesic (label dosage; FDA-approved): **NOTE**: FDA-approved dosages usually produce sedation lasting 1 to 2 hours and analgesia lasting for 15 to 30 minutes.

a) **Fallow deer**: 4.4 – 8.8 mg/kg IM

b) **Mule, sika, or white-tailed deer**: 2.2 – 4.4 mg/kg IM

c) **Elk**: 0.55 – 1.1 mg/kg IM[24]

Sedative/analgesic (extra-label): For chemical immobilization, reconstitute 1 vial of tiletamine/zolazepam using xylazine 400 mg/4 mL; administer 1 mL/45.5 kg (1 mL/100 lb).[38]

SHEEP & GOATS:

NOTE: Use xylazine with extreme caution in these species due to the risk for acute pulmonary edema and hypoxemia, low pulse oximetry readings, and subsequent cyanosis.[39–41] Use only the 20 mg/mL solution. Consult FARAD for xylazine meat and milk withdrawal intervals, which vary based on dose and route of administration. More information using xylazine as part of drug

combinations for injectable sedation, anesthesia/analgesia protocols can be found in other references.[35,42,43]

Light, standing sedation (extra-label): 0.01 mg/kg IV for light standing sedation to 0.2 mg/kg IM for recumbency of an hour's duration. Goats are a bit more sensitive than sheep. Dosage ranges of 0.05 – 0.1 mg/kg IV (goats) and 0.1 – 0.4 mg/kg IV (sheep) have also been recommended. When beginning to use these drugs, it is advisable to start with a conservative dose until one develops a feel for the level of sedation provided.[44,45]

CAMELIDS:

Procedural pain (eg, **castrations) when recumbency (up to 30 minutes) is desired** (extra-label): Alpacas: Xylazine 0.46 mg/kg in combination with butorphanol 0.046 mg/kg and ketamine 4.6 mg/kg and administered IM. Llamas: Xylazine 0.37 mg/kg in combination with butorphanol 0.037 mg/kg and ketamine 3.7 mg/kg and administered IM. May administer 50% of the original dose of xylazine and ketamine during anesthesia to prolong the effect up to 15 minutes. Expect 20 minutes of surgical time; the patient should stand 45 to 60 minutes after injection.[46]

Standing sedation and restraint (extra-label): Xylazine 0.1 mg/kg in combination with ketamine 0.2 mg/kg and *either* morphine 0.1 mg/kg OR butorphanol 0.05 mg/kg and administered IM. This combination provides ≈15 minutes of standing restraint. An additional dose of ketamine 0.01 mg/kg IM will extend the duration for another 5 to 10 minutes.[47]

Sedative/analgesic with tiletamine/zolazepam (extra-label): Xylazine 0.2 or 0.4 mg/kg in combination with tiletamine/zolazepam 2 mg/kg and administered IM produces significant antinociception. Transient hypoxemia was associated with xylazine administration, which is not considered clinically important in healthy llamas.[48] Adding morphine to the combination of xylazine and tiletamine/zolazepam resulted in a longer duration of analgesia.[49]

Sedative/analgesic (extra-label): 0.2 mg/kg IV OR 0.3 mg/kg IM or SC may provide profound sedation for 10 to 20 minutes and an additional 10 to 20 minutes of mild sedation, but overall effects are often unpredictable.[47]

SWINE:

NOTE: Xylazine dosages in swine are higher than those used in other species.

Sedative/analgesic (extra-label):

a) Xylazine 1 – 2.5 mg/kg IM in combination with ketamine 10 – 12 mg/kg IM[50,51] or xylazine 2 mg/kg IM in combination with ketamine 20 mg/kg IM and midazolam 0.25 mg/kg IM[51,52]
b) 0.5 – 4 mg/kg IM, alone or in combination with ketamine[53,54]

Induction of general anesthesia (extra-label): Xylazine 1 – 2 mg/kg in combination with tiletamine/zolazepam 4 – 6 mg/kg IM[51]

Maintenance of anesthesia (extra-label): Triple drip (ie, guaifenesin/ketamine/xylazine [GKX]) -- To 500 or 1000 mL of guaifenesin (50 mg/mL), add xylazine 1 mg (NOT mg/kg) plus ketamine 1 – 2 mg (NOT mg/kg) per mL of guaifenesin. Run solution at 2.2 mL/kg/hour IV CRI for up to 2 hours.[51]

BIRDS:

Sedative/analgesic (extra-label):

a) 1 – 4 mg/kg IM; provides sedation for ketamine anesthesia. Xylazine has been used at dosages of up to 10 mg/kg in small psittacines.[55,56]
b) Xylazine 2 – 6 mg/kg in combination with ketamine 10 – 30 mg/kg and administered IM; birds weighing less than 250 g require a higher dose (on a mg/kg basis) than birds weighing greater than 250 g.[57]

FERRETS:

Sedative/analgesic (extra-label):

a) 0.5 – 2 mg/kg IM or SC. Usually combined with atropine 0.05 mg/kg OR glycopyrrolate 0.01 mg/kg and administered IM
b) Xylazine 2 mg/kg in combination with butorphanol 0.2 mg/kg and administered IM[58,59]
c) Xylazine 1.5 mg/kg in combination with tiletamine/zolazepam 1.5 mg/kg +/- butorphanol 0.2 mg/kg and administered IM

RABBITS, RODENTS, SMALL MAMMALS:

Sedative/analgesic (extra-label)[60]:

a) **Rabbits**:
   i. Xylazine 5 mg/kg in combination with ketamine 35 mg/kg and administered IM; surgical anesthesia for 20 to 30 minutes, good relaxation, sleep time is 60 to 120 minutes, some effects reversible with atipamezole
   ii. Xylazine 5 mg/kg in combination with ketamine 25 mg/kg and butorphanol 0.1 mg/kg and administered IM; surgical anesthesia for 60 to 90 minutes, good relaxation, sleep time is 120 to 180 minutes
   iii. Xylazine 5 mg/kg in combination with ketamine 25 mg/kg and acepromazine 1 mg/kg and administered IM; surgical anesthesia for 45 to 75 minutes, good relaxation, sleep time is 100 to 150 minutes
b) **Gerbils**: Xylazine 2 mg/kg in combination with ketamine 50 mg/kg and administered IP
c) **Guinea pigs**: Xylazine 5 mg/kg in combination with ketamine 40 mg/kg and administered IP
d) **Hamsters**: Xylazine 10 mg/kg in combination with ketamine 200 mg/kg and administered IP
e) **Mice**: Xylazine 10 mg/kg in combination with ketamine 80 mg/kg and administered IP
f) **Rats**: Xylazine 10 mg/kg in combination with ketamine 75 mg/kg and administered IP

Monitoring

- Level of sedation and analgesia
- Heart rate and rhythm, blood pressure, respiratory depth and rate, $ETCO_2$, pulse oximetry (SpO_2), and body temperature should be considered in all patients, and mandatory in higher risk patients.
- Hydration status

Client Information

- Xylazine should only be used by individuals familiar with its use.

Chemistry/Synonyms

Xylazine HCl is an alpha-2-adrenergic agonist that is structurally related to clonidine. It occurs as a colorless, white or almost white crystalline powder that is freely soluble in water. The pH of the commercially prepared injections is ≈5.5. Dosages and bottle concentrations are expressed in terms of the base.

Xylazine HCl may also be known as Bay-Va-1470, *Rompun*®, *AnaSed*®, *Chanazine*®, *Nerfasin*®, *Sedazine*®, *Tranquived*®, *X-Ject E*®, *Xylamax*®, or *Xylamed*®.

Storage/Stability

Do not store above 30°C (86°F). Some manufacturers state to store at 20°C to 25°C (68°F-77°F) and permit excursions up to 40°C (104°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Xylazine is reportedly physically **compatible** in the same syringe with several compounds, including acepromazine, buprenorphine, butorphanol, chloral hydrate, and meperidine. Anecdotally, xylazine

is physically **compatible** when combined in the same vial with ketamine and/or tiletamine/zolazepam, and in IV solution with guaifenesin and ketamine (ie, "triple drip"). However, the stability and potency of these combinations have not been studied and cannot be recommended.

A study evaluated the stability, sterility, pH, particulate formation, and efficacy of compounded ketamine, acepromazine, and xylazine (KAX) in laboratory rodents. The results supported the finding that the drugs are stable and effective for at least 180 days after mixing if stored at room temperature in the dark. Compounded ketamine/xylazine combinations at concentrations intended for laboratory rodents demonstrated 3 months' stability at any temperature when diluted in saline.[61] Undiluted ketamine/xylazine was stable for 3 months only if refrigerated. The ketamine/acepromazine/xylazine combination was only stable for 1 month if refrigerated, and the unrefrigerated combination was not stable at any temperature.[62]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. The use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Xylazine Injection: 20 mg/mL in 20 mL vials or 100 mg/mL in 50 mL vials: *Rompun®*, *AnaSed®*, generic; (Rx). FDA-approved for use (depending on strength and product) in dogs, cats, horses, deer, and elk. Do not use in horses intended for human consumption or in *Cervidae* less than 15 days before or during hunting season.

Xylazine is not FDA-approved for use in cattle in the United States; however, in Canada, at label dosages, it reportedly has been assigned withdrawal times of 3 days for meat and 48 hours for milk. Consult FARAD for meat and milk withdrawal intervals, which vary based on dose and route of administration.

HUMAN-LABELED PRODUCTS: NONE

Yohimbine

(yo-***him***-been) *Yobine®, Antagonil®*
Alpha-2-Adrenergic Antagonist

Prescriber Highlights

- ► Used to reverse xylazine, other alpha-2 agonists, and, potentially, amitraz; may be used prophylactically before amitraz dips
- ► Use with caution in patients that have renal disease or seizure disorders.
- ► Reversal effects may diminish before the agonist's effects dissipate.
- ► Adverse effects include transient apprehension or CNS excitement, muscle tremors, salivation, hypertension, increased cardiac and respiratory rates, and hyperemic mucous membranes; more likely in small animal species and horses.
- ► Many potential drug interactions

Uses/Indications

Yohimbine is indicated to reverse the effects of xylazine in dogs, but it is used clinically to reverse the effects of other alpha-2 agonists and in several other species as well.

Yohimbine may be efficacious in reversing some of the toxic effects associated with other agents (eg, amitraz) and can be used prophylactically before amitraz dips.

Pharmacology/Actions

Yohimbine is an alpha-2-adrenergic antagonist that can competitively antagonize the effects of xylazine and other alpha-2-adrenergic agonists. Alone, yohimbine increases heart rate and can decrease blood pressure (at high doses),[1] causes CNS stimulation and antidiuresis, and has hyperinsulinemic effects. A study in cats found that yohimbine could antagonize xylazine- and medetomidine-induced diuresis in healthy cats.[2] It can increase borborygmi and GI sounds in horses[3] and act as an antiemetic in cats.[4]

A study in horses that received detomidine 0.03 mg/kg IV followed 15 minutes later by yohimbine 0.2 mg/kg IV found that yohimbine rapidly reversed the sedative effects of detomidine, effectively returned heart rate and the percent of atrioventricular conduction disturbances to pre-detomidine values, and effectively reduced detomidine-induced hyperglycemia.[5] Another study in horses after they received sublingual detomidine showed the effects of yohimbine 0.075 mg/kg IV on detomidine-induced changes in the chin-to-ground distance were minimal, and that the effects on detomidine-induced changes in heart rate and rhythm only persisted for 15 to 20 minutes.[6]

By blocking central alpha-2 receptors, yohimbine enhances sympathetic outflow (norepinephrine). Peripheral alpha-2 receptors are also found in the cardiovascular system, genitourinary system, GI tract, platelets, and adipose tissue.

Pharmacokinetics

A study (using 2 compartmental analyses) where yohimbine 0.12 mg/kg IV was administered to horses found a large volume of distribution (mean, 3.2 L/kg), a low clearance (mean, 13.6 mL/kg per minute), and a long elimination half-life (4.4 hours).[7] A separate study from the same group, using IV doses of 0.1, 0.2, and 0.4 mg/kg IV, reported similar results.[8] The main metabolite, hydroxy-yohimbine, can be detected in urine samples for as long as 96 hours post-administration.[7]

A study reported the pharmacokinetics of yohimbine in steers and dogs.[9] The apparent volume of distribution (steady-state) was ≈5 L/kg in steers and 4.5 L/kg in dogs. The total body clearance was ≈70 mL/minute/kg in steers and 30 mL/minute/kg in dogs. The half-life of the drug was ≈0.5 to 1 hour in steers and 1.5 to 2 hours in dogs.

Yohimbine is believed to penetrate the CNS quite readily. When it is used to reverse the effects of xylazine, the onset of action generally occurs within 3 minutes.

The metabolic fate of the drug is not fully understood, but in humans, 90% of the drug is metabolized in the liver primarily by hydroxylation. In horses, at least 2 metabolites were detected in a pharmacokinetic study, both of which appeared to be hydroxylated metabolites.[8] Whether any metabolites have activity is not known, but in humans, there have been reports that the major metabolite, 11-hydroxy yohimbine, may have pharmacologic activity.

Contraindications/Precautions/Warnings

Yohimbine is contraindicated in patients that are hypersensitive to it. In humans, yohimbine is contraindicated in patients with renal disease.

Yohimbine should be used cautiously in patients with seizure disorders. When used to reverse the effects of xylazine, normal pain perception may result. The alpha-2-adrenergic antagonist effects of yohimbine may diminish before the effects of the agonist dissipate.

Prolonged withdrawal periods for horses in athletic events may be necessary.

Adverse Effects

Yohimbine may cause transient apprehension or CNS excitement, muscle tremors, hypertension, tachycardia,[10] salivation, increased respiratory rates, and hyperemic mucous membranes. Adverse effects appear to be more probable in small animal species and horses.

An in vitro study found that yohimbine inhibited collagen-induced aggregation of bovine and equine platelets.[11] Clinical significance is not known.

Reproductive/Nursing Safety

Safe use of yohimbine in pregnant animals or animals intended for breeding has not been established. No information on safety during lactation was located.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Dogs receiving 0.55 mg/kg (5 times the recommended dose) exhibited transient clinical signs of seizures and muscle tremors.

Yohimbine is commonly found in combination with other stimulants in over-the-counter medications. The most common signs are hyperactivity, tachycardia, anxiety, diarrhea, hind limb weakness, hyperthermia, injected sclera, and vocalization.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Little information is available; use yohimbine with caution with **other alpha-2-adrenergic antagonists** or **other drugs that can cause CNS stimulation**.

- **Antihypertensives** (eg, **angiotensin-converting enzyme inhibitors** [**ACEIs**]**, calcium channel blockers** [eg, **amlodipine**]**, hydralazine**): Reduced effectiveness of antihypertensive medications has been noted.
- **Detomidine**: In horses, a study found that giving yohimbine after prior administration of detomidine caused yohimbine clearance and volume of distribution to decrease with resultant increases in yohimbine peak plasma levels. The authors concluded that this increases the potential for untoward effects and warrants further study into the physiologic effects of this combination of drugs.[12]
- **Reserpine**: Concurrent administration of high doses (1 mg/kg IV of each drug) was uniformly fatal to dogs.[1]
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): In humans, yohimbine is not recommended for use with antidepressants or other mood-altering agents; hypertension has been reported with tricyclic antidepressants.

Dosages

DOGS:

Xylazine reversal (label dosage; FDA-approved): 0.11 mg/kg IV slowly[13]

Reversal or prevention of amitraz toxicity (extra-label): If atipamezole is unavailable, yohimbine 0.1 mg/kg IV or 0.25 mg/kg IM[14,15]; some clinicians recommend using yohimbine in combination with atipamezole 50 µg/kg IM.[14,16]

CATS:

Reversal of xylazine-containing anesthetic combinations (extra-label): 0.5 mg/kg IV at the end of the procedure[17]

HORSES:

Alpha-2-adrenergic agonist reversal (extra-label): The less specific alpha-2 agonists—xylazine, detomidine, and romifidine—are typically reversed using yohimbine 0.05 – 0.2 mg/kg administered IM or slowly IV.[18] A study where yohimbine was given at 0.2 mg/kg IV 15 minutes after IV detomidine found that it effectively reversed detomidine-induced sedation, bradycardia, atrioventricular heart block, and hyperglycemia.[19]

CATTLE:

Alpha-2-adrenergic agonist (xylazine) reversal (extra-label): 0.1 – 0.125 mg/kg IM. Consider IV administration in an emergency situation. If ketamine or tiletamine/zolazepam have been used, allow 30 to 45 minutes before reversing xylazine (nonemergency situation) to avoid rough recovery.[20–22]

LLAMAS:

Xylazine reversal (extra-label): 0.125 – 0.25 mg/kg IV or IM[23,24]

SWINE:

Reversal of dexmedetomidine combination with butorphanol and midazolam (extra-label): 0.3 mg/kg IM[25]

Reversal of xylazine, ketamine, tiletamine/zolazepam anesthesia in sows (extra-label): 0.1 mg/kg IM[26,27]

BIRDS:

Reversal agent for alpha-2-adrenergic agonists (eg, xylazine): 0.1 mg/kg IV[28]

RABBITS, RODENTS, SMALL MAMMALS:

Reversing the effects of xylazine and to partially antagonize the effects of ketamine and acepromazine (extra-label):

a) **Rabbits**: 0.2 mg/kg IV as needed[29]

b) **Mice/Rats**: 0.2 mg/kg IP as needed[29]

Monitoring

- CNS status (arousal level)
- Cardiac rate; rhythm (if indicated), blood pressure (if indicated and practical)
- Respiratory rate

Client Information

- This agent should only be used by veterinary professionals.

Chemistry/Synonyms

Yohimbine HCl, a Rauwolfia or indolealkylamine alkaloid, has a molecular weight of 390.9. It is chemically related to reserpine.

Yohimbine may also be known as aphrodine hydrochloride, chlorhydrate de quebrachine, corynine hydrochloride, *Aphrodyne®, Dayto Himbin®, Pluriviron mono®, Prowess Plain®, Urobine®, Virigen®, Yobine®, Yocon®, Yocoral®, Yohimex®, Yohydrol, Yomax®,* or *Zumba®*.

Storage/Stability

Store yohimbine injection at room temperature (15°C-30°C [59°F-86°F]) and protected from light and heat.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Yohimbine Sterile Solution for Injection: 2 mg/mL in 20 mL vials; *Yobine®*; (Rx). FDA-approved for use in dogs. NADA# 140-866.

The United States product label states yohimbine is not for use in food-producing animals.

HUMAN-LABELED PRODUCTS:
No FDA-approved products were located; 2 mg, 5.4 mg, and 6 mg tablets are available in Canada (Rx) but unlikely to be of veterinary benefit.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Zidovudine

(zid-o-***vew***-den) *Retrovir®*
Antiretroviral

Prescriber Highlights
- ► Antiretroviral agent that may be useful for adjunctive treatment of FeLV or FIV in cats
- ► Use with caution in patients with renal, hepatic, or bone marrow dysfunction.
- ► Nonregenerative anemia is the most common adverse effect in cats.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies zidovudine as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
In veterinary medicine, zidovudine may be useful for treating feline immunodeficiency virus (FIV) or feline leukemia virus (FeLV). Although zidovudine can reduce the viral load in infected cats and improve clinical signs, it may not alter the natural course of the disease to a great extent.

A double-blind placebo-controlled trial assessed the efficacy of human interferon-alpha2a 100,000 IU/kg SC every 24 hours, zidovudine 5 mg/kg PO every 12 hours, and a combination of both drugs in cats infected naturally with FeLV. This study reported that although there was a trend for improved clinical status in treated cats, they were unable to demonstrate measurable statistically significant efficacy of either drug alone or together when given for 6 weeks.[1]

As drug resistance can be seen, one source recommends that zidovudine treatment is likely best reserved for those situations where symptomatic/supportive measures are not working.[2] Drug resistance can be seen as early as 6 months after starting treatment.[3]

Pharmacology/Actions
Zidovudine is considered an antiretroviral agent. Although its exact mechanism of action is not fully understood, zidovudine is converted in vivo to an active metabolite (triphosphate) that interferes with viral RNA-directed DNA polymerase (reverse transcriptase). This causes a virustatic effect in retroviruses.

Zidovudine has some activity against gram-negative bacteria and can be cytotoxic as well.

Pharmacokinetics
Zidovudine is well absorbed after oral administration. In cats, oral bioavailability is ≈95%. When zidovudine is administered with food, peak concentrations may be decreased, but the total area under the curve may not be affected; peak concentrations occur ≈1 hour postdosing in cats. The drug is widely distributed, including into the CSF. It is only marginally bound to plasma proteins. Zidovudine is rapidly metabolized and excreted in the urine. Half-life in cats is ≈1.5 hours.[4]

Contraindications/Precautions/Warnings
Zidovudine is contraindicated in patients that have developed life-threatening hypersensitivity reactions to it in the past.[5]

Use zidovudine with caution in patients with bone marrow, renal, or hepatic dysfunction. The European Advisory Board on Cat Diseases (ABCD) guidelines on prevention and management of feline immunodeficiency advise against the use of zidovudine in cats with myelosuppression. Dosage adjustment may be necessary for cats with renal or hepatic dysfunction.

In humans, hematologic toxicity, including neutropenia and severe anemia, has been associated with zidovudine use.[5] Symptomatic myopathy has also occurred with prolonged use. Lactic acidosis and severe hepatomegaly with steatosis have been reported with nucleoside analogues. In humans, rapid infusions or bolus injections should be avoided, and zidovudine should not be given IM.

The National Institute for Occupational Safety and Health (NIOSH) classifies zidovudine as a hazardous drug[6]; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure

Adverse Effects
In cats, reductions in RBCs, PCV, and hemoglobin are the most common adverse effects reported. Anemia may be nonregenerative and is most commonly seen with the higher end of the dose range (10 – 15 mg/kg). If hematocrit drops below 20%, treatment should be discontinued, and anemia then usually resolves within a few days.[3] Diarrhea and weakness have also been reported.

In a controlled trial with a total of 22 cats receiving zidovudine, no notable adverse effects were detected.[1]

Although there are many adverse effects reported in humans, granulocytopenia and GI effects, especially nausea, vomiting, and anorexia, appear to be the most likely to occur.[5] The frequency and severity of adverse effects in humans are greater in patients with more advanced infection at the time of treatment initiation.

Reproductive/Nursing Safety
Zidovudine given to rats in doses up to 7 times the usual adult (human) doses had no effect on conception rates. Fetal toxicity occurred in rats receiving up to 450 mg/kg/day and in rabbits given 500 mg/kg/day.

Zidovudine is excreted in milk. Clinical significance is not clear for nursing offspring. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
Human adults and children have survived oral overdoses of up to 50 g without permanent sequelae.[5] Vomiting and transient hematologic effects are the most consistent adverse effects reported with overdoses.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving zidovudine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.
- **Antifungals, Azole** (eg, **fluconazole, ketoconazole**): May increase zidovudine serum concentration
- **Atovaquone**: May increase zidovudine serum concentration
- **Doxorubicin**: May antagonize each other's effects; avoid use together.
- **Interferon Alfa**: Increased risk for hematologic and hepatic toxicity

- **Methadone**: May increase serum concentration of zidovudine
- **Myelotoxic/Cytotoxic drugs** (eg, chloramphenicol, doxorubicin, flucytosine, vincristine, vinblastine): Administered with zidovudine may increase the risk for hematologic toxicity
- **Probenecid**: May increase zidovudine serum concentration
- **Rifampin**: May decrease serum concentration (AUC) of zidovudine

Laboratory Considerations
- None were noted.

Dosages
CATS:

Adjunctive therapy of feline leukemia virus (FeLV) and feline immunodeficiency virus (FIV) (extra-label): 5 – 10 mg/kg PO or SC every 12 hours.[3,7,8] The higher dose should be used carefully as adverse effects (eg, nonregenerative anemia) can develop. When using the injectable formulation SC, the product should be diluted (see ***Compatibility/Compounding Considerations***) prior to administration to avoid local irritation[3]; dilution to 4 mg/mL is advised.[5]

Monitoring
- Baseline and weekly CBC for the first month during treatment, then monthly if stable[3]
- CD4/CD8 rates, if possible
- Clinical efficacy

Client Information
- For this medication to work properly, give it exactly as your veterinarian has prescribed.
- Side effects can include anemia, diarrhea, and weakness. If your cat seems overly tired or has no energy, contact your veterinarian right away.
- Your veterinarian will need to monitor you cat while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms
Zidovudine, a thymidine analogue, is synthetically produced and occurs as a white to beige-colored, odorless, crystalline solid. ≈20 mg is soluble in 1 mL of water.

Zidovudine may also be known as ZDV, azidodeoxythymidine, 3'-azido-2',3'-dideoxythymidine, azidothymidine, AZT, BW-A509U, BW-509U, compound-S, zidovudinum, and *Retrovir*®; many other trade names are available.

Storage/Stability
Store zidovudine oral tablets, capsules, and solution at room temperature 15°C to 25°C (59°F-77°F). Protect from heat, light, and moisture.

Store zidovudine injection at room temperature (20-25°C [68-77°F]) and protect from light. Once diluted, it is stable for 24 hours at room temperature or 48 hours if refrigerated at 2°C to 8°C (36°F-46°F).

Compatibility/Compounding Considerations
Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Zidovudine for injection is **compatible** with 5% dextrose, 0.9% sodium chloride, 5% dextrose with 0.45% sodium chloride, lactated Ringer's, and 5% dextrose with lactated Ringer's solutions.[9] It is reported as **Y-site compatible** with amikacin, clindamycin phosphate, dexamethasone sodium phosphate, dexmedetomidine, dobutamine, fluconazole, gentamicin sulfate, heparin sodium, hydromorphone, metoclopramide, metronidazole, ondansetron, pantoprazole, potassium chloride, trimethoprim/sulfamethoxazole, and voriconazole.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Zidovudine Oral Tablets: 300 mg; *Retrovir*®, generic; (Rx)

Zidovudine Oral Capsules: 100 mg; *Retrovir*®, generic; (Rx)

Zidovudine Oral Syrup: 50 mg/5 mL (10 mg/mL) in 240 mL; *Retrovir*®, generic; (Rx)

Zidovudine Injection Solution: 10 mg/mL in 20 mL single-use vials; *Retrovir*®; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Zinc (Systemic)
(zeenk)

Nutritional; Trace Element

See also ***Zinc Gluconate (Neutralized), Topical***

Prescriber Highlights
- ► Metal nutritional agent that may be used for zinc deficiency, to reduce copper toxicity in susceptible dog breeds (eg, Bedlington terriers, West Highland white terriers) with hepatic copper toxicosis, and treat hepatic fibrosis in dogs
- ► Contraindications include animals taking penicillamine and those that are hypersensitive to it.
- ► Use caution or avoid use in animals that may have copper deficiency or elevated zinc concentration; consider obtaining copper and zinc serum concentrations before treating.
- ► Adverse effects related to large doses of zinc supplementation may include GI disturbances or hematologic abnormalities (usually hemolysis), particularly if a coexistent copper deficiency exists.
- ► Zinc overdoses (eg, United States pennies minted after 1982) can be serious.

Uses/Indications
Zinc sulfate is used systemically as a nutritional supplement in a variety of species. Oral zinc acetate has been shown to reduce copper toxicity in dog breeds that are susceptible to hepatic copper toxicosis (eg, Bedlington terriers, West Highland white terriers). Zinc therapy may also be of benefit in the treatment of hepatic fibrosis and zinc-responsive dermatosis. In dogs and cats, zinc has been used for adjunctive therapy for superficial necrolytic dermatitis (metabolic epidermal necrosis; hepatocutaneous syndrome).

Pharmacology/Actions
Zinc is a necessary nutritional supplement; it is required by over 200 metalloenzymes for proper function. Enzyme systems that require zinc include DNA polymerase, ALP, alcohol dehydrogenase, carbonic anhydrase, and RNA polymerase. Zinc is also necessary to maintain the structural integrity of cell membranes and nucleic acids. Zinc catalyzes essential biochemical reactions, such as activation of substrates of carbonic anhydrase in erythrocytes. Zinc-dependent physiological processes include sexual maturation and reproduction, cell growth and division, vision, night vision, wound healing, immune response, and taste acuity. In dogs with hepatitis, zinc induces the intestinal copper-binding protein metallothionein, resulting in antifibrotic and hepatoprotective properties.[1]

When administered orally, large doses of zinc can inhibit the intestinal absorption of copper and inhibit the reabsorption of secreted copper (eg, from bile or feces).

Pharmacokinetics

About 20% to 30% of dietary zinc is absorbed, principally from the duodenum and ileum. Bioavailability is dependent on the food in which it is present. Phytates can chelate zinc and form insoluble complexes in an alkaline pH; high concentrations of dietary calcium or phosphorus may also impair absorption. Food may have a similar effect on the bioavailability of zinc supplements. Zinc is stored mostly in red and white blood cells but is also found in the muscle, skin, bone, retina, pancreas, liver, kidney, and prostate gland. Serum zinc is bound to albumin and amino acids. Elimination is primarily via the feces, but some zinc is also excreted by the kidneys and in sweat. Zinc found in feces may be reabsorbed in the colon.

Contraindications/Precautions/Warnings

Zinc supplementation should be avoided or used cautiously in patients with copper deficiency.

Zinc sulfate injection is NOT for direct IV infusion and it is only intended for use in parenteral nutrition solutions. Solutions with an osmolarity of 900 mOsm/L or greater must be infused through a central catheter. Zinc sulfate injection contains aluminum; prolonged administration may lead to aluminum toxicity, particularly in animals with renal insufficiency.

Do not confuse dosages or concentrations of zinc salts with those of elemental zinc.

Adverse Effects

Large doses of zinc may cause GI disturbances; zinc acetate or methionine may be less irritating to the GI than other salts and mixing the contents of the capsule with a small amount of tuna or hamburger may also minimize vomiting. Hematologic abnormalities (usually hemolysis) may occur with large doses or serum concentrations greater than 1000 µg/dL (1 mg/dL), particularly if a coexistent copper deficiency exists.

Reproductive/Nursing Safety

Zinc requirements increase during pregnancy. Although zinc deficiency during pregnancy has been associated with adverse perinatal outcomes, other studies report no such occurrences. In humans, since zinc deficiency is very rare, the routine use of zinc supplementation during pregnancy is not recommended. No evidence of impaired fertility or fetal harm was noted in laboratory animals receiving up to 6 times the recommended human dose.

Zinc is excreted in breast milk; use it with caution in lactating animals.

Overdose/Acute Toxicity

Signs associated with overdoses of zinc in mammals include hemolytic anemia, neutropenia, hypotension, acute pancreatitis, jaundice, vomiting, and pulmonary edema. The most common clinical signs associated with a zinc overdose in dogs and cats include vomiting, diarrhea, polydipsia, and lethargy.

Zinc toxicosis in dogs ingesting topical zinc oxide includes vomiting, diarrhea, and hemolytic anemia.[2]

Zinc intoxication in birds is relatively common, but clinical signs of intoxication in birds are varied and nonspecific. They include lethargy, anorexia, regurgitation, polyuria, polydipsia, hematuria, hematochezia, pallor, dark or bright green diarrhea, foul-smelling feces, paresis, seizures, and sudden death.[3] Treatment involves removing the source of zinc, chelation therapy (edetate calcium disodium, penicillamine,[4] or succimer), and supportive care.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zinc and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Calcium Supplements, Oral**: May potentially inhibit oral zinc absorption
- **Copper**: Large doses of zinc can inhibit copper absorption in the intestine; if this interaction is not desired, separate copper and zinc supplements by at least 2 hours.
- **Fluoroquinolones** (eg, enrofloxacin, ciprofloxacin): Zinc salts may reduce the oral absorption of some fluoroquinolones.
- **Iron Supplements, Oral**: May potentially inhibit oral zinc absorption; zinc salts may reduce the oral absorption of iron.
- **Penicillamine**: May potentially inhibit oral zinc absorption; zinc salts may reduce the oral absorption of penicillamine; the combination is considered contraindicated in dogs with hepatopathy.
- **Tetracyclines**: Zinc salts may chelate oral tetracyclines and reduce their absorption; tetracyclines may reduce zinc absorption; separate doses by at least 2 hours.
- **Ursodiol**: May potentially inhibit oral zinc absorption; the clinical significance is not clear.

Dosages

NOTE: Zinc products may be labeled with concentrations expressed as salt OR as elemental zinc. Assume the labeled concentration per tablet or capsule is elemental zinc unless the labeled ingredients and concentrations state otherwise. Dosages below are for elemental zinc unless otherwise noted.

DOGS:

Adjunctive treatment and prophylaxis of primary copper hepatopathy (extra-label): 8 – 10 mg/kg elemental zinc PO every 12 hours. Separate dose from meals by 1 to 2 hours. Monitor concentrations every 2 to 3 months and adjust the dose as necessary.[5]

Hepatic fibrosis (extra-label): Empirical dosage is 15 mg/kg of elemental zinc per day (or 200 mg elemental zinc per medium-sized dog per day, tapered to 50 – 100 mg/dog (NOT mg/kg) PO per day based on serum zinc concentrations). Zinc should ideally be given on an empty stomach (1 hour before or after a meal); mix with tuna oil if nausea is noted.[1,6]

Prevention of copper accumulation associated with chronic hepatitis (extra-label): 100 mg elemental zinc/dog (NOT mg/kg) PO daily for 3 to 6 months, then reduce to 50 mg elemental zinc/dog (NOT mg/kg) PO per day.

Adjunctive therapy for superficial necrolytic dermatitis or zinc-responsive dermatosis (extra-label): 2 – 3 mg/kg PO once a day of elemental zinc with food either once daily or divided every 12 hours.[7,8] Doses may need to be adjusted based on response to therapy. The addition of low-dose glucocorticoid therapy may benefit cases that do not respond solely to zinc supplementation. In syndrome I patients (fed balanced diets) that do not respond to oral zinc supplementation and low-dose glucocorticoid therapy, slow IV or IM injections with sterile zinc sulfate solutions at 10 – 15 mg/kg weekly (maximum of 600 mg/month) for at least 1 month have been recommended. Syndrome I patients require lifelong therapy. Syndrome II patients (fed diets low in zinc or high in phytates [cereal grains, soy-based or corn-based diets] or with high concentrations of minerals [calcium, iron, or copper] that may bind dietary zinc) can have zinc supplementation discontinued after the diet has been corrected and clinical signs resolve.[8]

CATS:

Adjunctive therapy of severe hepatic lipidosis (extra-label): 7 – 10 mg/kg PO once daily, in B-complex mixture if possible[9]

Primary copper hepatopathy (extra-label): 2 – 4 mg/kg elemental zinc PO every 12 to 24 hours

Superficial necrolytic dermatitis (extra-label): Dosages are not well described; doses used in dogs could possibly be extrapolated for cats.[8]

Monitoring

- Hepatic diseases:
- Plasma zinc concentration: The goal is above 200 µg/dL but less than 800 µg/dL.[10]
- Copper quantification when possible; serum ALT serially when copper quantification is not feasible.
- There is a poor correlation between serum zinc concentrations and zinc-deficient states in dogs, and zinc concentrations may have more value in the detection of potentially toxic intake or corroboration of a clinical diagnosis of toxicity or deficiency.[11]
- Periodically measure CBC to monitor for hemolytic anemia.[12]

Client Information

- Although it is best to give oral zinc on an empty stomach, if vomiting occurs, mix it with hamburger or tuna fish to decrease this side effect.
- Do not give more than prescribed; zinc can be very toxic (especially in dogs).
- While your animal is taking this medication, it is important to return to your veterinarian for blood tests. Do not miss these important follow-up visits.

Chemistry/Synonyms

Zinc acetate occurs as white crystals or granules. It has a faint acetous odor and effloresces slightly. One gram is soluble in 2.5 mL of water or 30 mL of alcohol. Zinc acetate contains 30% elemental zinc (100 mg zinc acetate = 30 mg elemental zinc).

Zinc sulfate occurs as a colorless granular powder, small needles, or transparent prisms. It is odorless but has an astringent metallic taste. 1.67 g are soluble in 1 mL of water. Zinc sulfate is insoluble in alcohol and contains 23% zinc by weight (100 mg zinc sulfate = 23 mg elemental zinc).

Zinc gluconate occurs as a white or practically white powder or granules. It is soluble in water and very slightly soluble in alcohol. Zinc gluconate contains 14.3% zinc (100 mg zinc gluconate = 14.3 mg elemental zinc).

Zinc methionine contains 18% to 21% elemental zinc. For every 5 mg of zinc methionine, there is ≈1 mg of elemental zinc.

Zinc acetate may also be known as E650 or zinci acetas dihydricus.

Zinc sulfate may also be known as zinc sulphate, zinci sulfas, or zincum sulfuricum; many trade names are available.

Storage/Stability

Store zinc acetate crystals in tight containers. Unless otherwise recommended by the manufacturer, store zinc sulfate products in tight containers at room temperature of 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

If using bulk chemical powder: Zinc acetate contains 30% elemental zinc; zinc gluconate contains 14.3% elemental zinc; zinc sulfate contains 23% elemental zinc; zinc methionine contains 18% to 21% elemental zinc. One milligram of elemental zinc is provided by the following: 2.8 mg zinc acetate, 2.09 mg zinc chloride, 7.14 mg zinc gluconate, and 4.4 mg zinc sulfate. Zinc for injection is intended only as an additive to parenteral nutrition; do not administer the undiluted drug.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None as single-ingredient products for systemic use located; several vitamin/mineral supplements contain zinc, however. *NutriVed Chewable Zinpro®* Tablets contain 15 mg elemental zinc and 30 mg methionine; (OTC).

HUMAN-LABELED PRODUCTS:

Zinc Acetate is available from chemical supply houses.

Zinc Capsules: 25 mg and 50 mg elemental zinc (as zinc acetate or zinc sulfate), *Galzin®*, generic; (Rx/OTC)

Zinc Injection: 1 mg/mL (as 2.46 mg sulfate) in 5 mL and 10 mL vials; 5 mg/mL (as 21.95 mg sulfate) in 5 mL vials; 1 mg/mL (as 2.09 mg chloride) in 10 mL vials; and 3 mg/mL (as 7.41 mg sulfate) in 10 mL vials; generic; (Rx)

Zinc Tablets: 10 mg, 15 mg, 25 mg, 30 mg, and 50 mg elemental zinc (usually as zinc gluconate or zinc sulfate); generic; (OTC)

Zinc is also available in topical dermatologic and ophthalmic preparations.

Zoledronate

Zoledronic Acid

(***zoe***-le-***dron***-ik ***as***-id***)*** *Zometa®, Reclast®*

Bisphosphonate

Prescriber Highlights

- ► Used IV for treating hypercalcemia of malignancy and for adjuvant analgesic treatment of malignant osteolytic bone pain most commonly associated with osteosarcoma
- ► Administer as an infusion in saline or dextrose over no less than 15 minutes (shorter than required for pamidronate administration).
- ► Appears well tolerated in veterinary patients with comorbidities including hypercalcemia but may cause electrolyte abnormalities and renal toxicity
- ► Check renal function prior to administration.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies zoledronic acid as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Zoledronate may be useful as an adjunctive analgesic for treating osteolytic bone pain associated with primary and metastatic skeletal malignancies including osteosarcoma in dogs and hypercalcemia associated with malignancy.[1–6] The drug had a chondroprotective effect in dogs with experimentally induced osteoarthritis.[7]

Zoledronate appears to slow tumor growth and reduce pathologic bone turnover in cats with oral squamous cell carcinoma.[8]

Horses with bone fragility disorder treated with zoledronate demonstrated both clinical and scintigraphic improvement.[9]

Pharmacology/Actions

Bisphosphonates, at therapeutic concentrations, inhibit bone resorption and do not inhibit bone mineralization via binding to hydroxyapatite crystals. Bisphosphonates impede osteoclast activity and induce osteoclast apoptosis, an effect that may be seen with monotherapy[10] or in combination with chemotherapy.[11,12] Zoledronate's primary target is the osteoclast enzyme farnesyl pyrophosphate synthase. Urinary calcium and phosphorus excretion is increased,

and hypocalcemia, hypophosphatemia, and hypermagnesemia may result. Markers of bone turnover are reduced in healthy dogs as well as dogs with experimentally induced disease.[13,14] Zoledronate has ≈100 times greater relative antiresorptive potency as compared with pamidronate.[15]

Bisphosphonates in vitro have direct cytotoxic or cytostatic effects on human and canine osteosarcoma cell lines.[16] Additionally, zoledronate demonstrates bone-preserving activities at the primary tumor in a mouse model of canine osteosarcoma.[17] Zoledronate may also have antiangiogenic effects and inhibit cell migration in certain cancers.[8]

Pharmacokinetics

Zoledronate was administered by 15-minute IV infusion to 4 healthy dogs; the volume of distribution was ≈0.3 L/kg, and half-life was 2.2 hours.[18]

In 8 healthy horses receiving 0.057 mg/kg of an experimental zoledronic acid formulation administered by 30-minute IV infusion, the volume of distribution was 1.5 L/kg, and the elimination half-life was 2.2 hours.[19]

In humans, after IV infusion, ≈50% to 75% is incorporated into bone; the balance is largely excreted unchanged in the urine. It is not metabolized and does not alter the metabolism of other drugs. It has a terminal elimination half-life of ≈146 hours. Total drug exposure (area under the curve) is increased with increasing renal impairment. The shorter half-life reported in animals presumably reflects a shorter sampling period.

Contraindications/Precautions/Warnings

Zoledronic acid is contraindicated in patients with hypersensitivity to it and in patients with hypocalcemia or severe renal impairment.[20] Dosage adjustments are not necessary in patients with mild to moderate renal impairment. Zoledronic acid may cause renal injury and should be used with caution in patients that are receiving nephrotoxic drugs or that have moderate renal impairment, electrolyte imbalances, or disorders affecting mineral metabolism. Patients should be adequately hydrated prior to receiving zoledronic acid.

The National Institute for Occupational Safety and Health (NIOSH) classifies zoledronic acid as group 3 (*non-antineoplastic agents that primarily have adverse reproductive effects*).[21]

Do not confuse the trade name *ZOMeta*® (zolendronate) with *ZIMeta*® (dipyrone).

Adverse Effects

Zoledronate administered by 15-minute IV infusions appears to be well tolerated in veterinary patients.[22] One retrospective study reported adverse effects in dogs that included azotemia, vomiting, and diarrhea; however, concurrent medications could not be ruled out as the cause of these effects.[22] Acute kidney injury has also been reported in dogs but this effect appears infrequent and mild to moderate in severity.[23] Hypocalcemia has been noted, and osteonecrosis of the jaw has been reported.[24] Irritation may occur if extravasated.[5]

In humans, nausea, musculoskeletal pain, osteonecrosis of the jaw, atypical fractures, anemia, iritis/uveitis, hypotension, hypermagnesemia, hypophosphatemia, hypocalcemia, hypocalcemia-related cardiac or neurologic adverse effects, thrombocytopenia, and agranulocytosis have been reported.[20] Postinfusion pyrexia, fatigue, myalgia, and arthralgia commonly occur, and analgesic or antipyretic medication may be used to limit these effects. Infusion site reactions (eg, redness, swelling) occur infrequently. Adverse effects can occur days to months after administration.

Reproductive/Nursing Safety

In pregnant rats, administration of zoledronate during gestation at doses greater than 2.4 times the recommended human systemic exposure amount resulted in pre- and postimplantation losses and fetal skeletal, visceral, and external malformations; maternal mortality also increased.[20]

It is unknown if zoledronic acid is excreted in milk.[20] As neonatal exposure could have effects persisting for weeks to months, use with extreme caution in lactating animals; consider milk replacer.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinically significant hypocalcemia, hypophosphatemia, and hypomagnesemia may occur and should be corrected. Severe hypocalcemia has caused tetany and has been associated with atrial fibrillation. In humans, the risk for renal toxicity increases with 5-minute IV infusion times and doses of 8 mg.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zoledronate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: May enhance hypocalcemic effects of zoledronate; monitor.
- **Corticosteroids** (eg, **dexamethasone, fludrocortisone, prednis(ol)one**): Zoledronate must be used carefully (with monitoring) when used in conjunction with other drugs that can affect calcium.
- **Loop Diuretics** (eg, **furosemide**): Loop diuretics promote calcium excretion and may result in additive effects on calcium concentrations.
- **Nephrotoxic Drugs** (eg, **aminoglycosides, amphotericin B, cisplatin**): Use with caution; potential for increased risk for nephrotoxicity
- **nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, flunixin, meloxicam**): Use with caution; potential for increased risk for nephrotoxicity
- **Thiazide Diuretics** (eg, **hydrochlorothiazide**): Thiazide diuretics promote calcium retention and may impair the hypocalcemic effects of zoledronate.

Laboratory Considerations

- None noted

Dosages

NOTE: See ***Compatibility/Compounding Considerations*** prior to administration.

DOGS:

Adjunctive treatment of hypercalcemia of malignancy (extra-label): 4 mg/dog (NOT mg/kg) IV infusion over 15 minutes.[25] Administration of doses ranging from 0.1 – 0.32 mg/kg have been reported.[5,22]

Palliative treatment of bone pain associated with osteosarcoma (extra-label): 0.1 mg/kg IV infusion over 15 minutes on the second of 2 days of ionizing radiation and repeated every 4 weeks[26]

CATS:

Adjunctive treatment of bone-invasive oral squamous cell carcinoma (extra-label): 0.2 mg/kg IV infusion over 15 minutes every 28 days[8]

HORSES:

Bone fragility disorder (extra-label): 0.075 mg/kg IV infusion over 30 minutes. Zoledronic acid solution was compounded immediately before administration using pharmaceutical grade zoledronate, citric acid, and mannitol solution.[9]

Monitoring

- Baseline and periodic serum renal chemistry panel and electrolytes (eg, calcium [total, ionized], phosphorous, potassium, magnesium) and hydration status should be monitored before starting each dose and especially for patients with pre-existing azotemia or for those receiving concurrent nephrotoxic drugs.
- Baseline and periodic CBC
- Baseline and periodic markers of bone turnover (eg, bone-specific ALP, urine N-telopeptide)[1]
- Baseline and periodic urinalysis

Client Information

- Your pet may have an elevated temperature or loss of appetite after receiving this medicine. Some animals may also experience muscle, bone, or joint pain for several days after treatment. Contact your veterinarian if you think your pet is in pain.
- This medicine must be given in your veterinarian's clinic. It cannot be administered at home.
- Your veterinarian will need to monitor your pet while it is being treated with this medicine. Do not miss these important follow-up visits.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling your animals waste (eg, urine, feces, vomit).

Chemistry/Synonyms

Zoledronic acid is an imidazole bisphosphonate acid analogue of pyrophosphate that occurs as a white crystalline powder. It is sparingly soluble in water, and practically insoluble in organic solvents.

Zoledronic acid is also known as zoledronate, CGP-42446, zoledronsyra, *Reclast®*, *Aclasta®*, and *Zometa®*.

Storage/Stability

Store zoledronate at room temperature 25°C (77°F); excursions to 15°C to 30°C (59°F-86°F) are permitted.

Zoledronic acid concentrate (0.8 mg/mL) that has been diluted for infusion should be stored refrigerated at 2°C to 8°C (36°F-46°F). The total time between dilution and completion of administration must not exceed 24 hours.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Do **not** mix zoledronate with any IV fluid containing divalent cations (eg, calcium and magnesium containing fluids such as lactated Ringer's solution [LRS], *Plasmalyte®*, Ringer's). It is recommended to use a 0.9% sodium chloride or 5% dextrose IV solution and a dedicated IV line. Refrigerated solutions should equilibrate to room temperature before administration.

Zoledronate is reportedly **Y-site compatible** with the following drugs (partial list): aminocaproic acid, ampicillin/sulbactam, azithromycin, buprenorphine, butorphanol tartrate, carboplatin, cefazolin, cefotaxime, ceftazidime, cisplatin, clindamycin, cyclophosphamide, cytarabine, dacarbazine, dexamethasone sodium phosphate, dexmedetomidine, dexrazoxane, diphenhydramine, dopamine, dobutamine, doxorubicin HCl (also liposome form), doxycycline, erythromycin lactobionate, famotidine, fentanyl citrate, fluconazole, fluorouracil, gemcitabine, heparin, hydromorphone, hydroxyzine, imipenem-cilastatin, lidocaine HCl, mannitol, metoclopramide, methylprednisolone sodium succinate, midazolam, mitoxantrone, morphine, ondansetron, pantoprazole, piperacillin-tazobactam, potassium chloride, ranitidine, vinblastine, and vincristine.

Zoledronate is reportedly **incompatible** with dantrolene, diazepam, and phenytoin sodium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Zoledronic Acid Injection: 4 mg in 5 mL (0.8 mg/mL) concentrated solution in single-dose vials and 4 mg and 5 mg in 100 mL ready-to-use IV solution; *Reclast®*, *Zometa®*, generic; (Rx).

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Zonisamide

(zoh-***niss***-a-mide) *Zonegran®*

Anticonvulsant

Prescriber Highlights

- ► May be useful as an add-on drug for refractory epilepsy. May also be considered for initial treatment as monotherapy in dogs
- ► Half-life of 15 hours in dogs allows for twice-daily administration, and half-life of 33 hours in cats allows for once-daily administration.
- ► Increase in dose may be needed when used in conjunction with phenobarbital.
- ► Common adverse effects include sedation, ataxia, and inappetence. Rarely, hepatopathy, urinary calculi, and metabolic and acute tubular acidosis have been reported.
- ► Known teratogen in dogs
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies zonisamide as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

In dogs, zonisamide has demonstrated effectiveness as monotherapy[1–3] and as an add-on drug for the treatment of refractory epilepsy.[4] Open-label studies in dogs with zonisamide used as monotherapy or as an add-on drug reported 58% to 81% response rates.[1,3,4] Based on the limited available evidence, zonisamide is recommended as monotherapy or as add-on treatment for canine epilepsy.[5]

Limited use in cats has occurred with anecdotal success in controlling seizures.[6]

Pharmacology/Actions

Although the exact mechanism of action for zonisamide is not known, it is postulated to produce antiseizure activity at sodium and T-type calcium channels, reducing transient inward currents and thereby stabilizing neuronal membranes and suppressing neuronal hypersynchronization.[7,8] Zonisamide may potentiate serotoninergic and dopaminergic neurotransmission but does not appear to potentiate gamma-aminobutyric acid (GABA). It has carbonic anhydrase inhibitory activity and can scavenge for free radicals in the brain.

Zonisamide reduced the number of paroxysmal electroencephalogram (EEG) discharges in cats with familial spontaneous epilepsy.[9]

Pharmacokinetics

In dogs, zonisamide is well absorbed (oral bioavailability ≈68%), with a volume of distribution of ≈0.8 L/kg and an average protein binding of 40%.[10,11] Plasma T_{max} after a single oral dose was reported

to be 0.44 hours, and C_{max} was observed to be 14.4 µg/mL; C_{max} after repeated administration over 8 weeks was 58 µg/mL.[10,12,13] Concentrations of zonisamide are known to be higher in whole blood and RBCs as compared with plasma, so terminal half-life between RBC and plasma varies considerably. Oral plasma terminal half-life after repeated administration for 8 weeks was ≈23 hours,[10] but RBC half-life was reported at ≈37 hours; plasma half-life following a single oral dose was found to be 17.2 hours. Plasma clearance after a single oral dose was reported to be ≈32 mL/hour/kg. Most of the drug is excreted via the kidneys into the urine but ≈20% is metabolized, primarily in the liver. Unlike in humans, zonisamide exhibits linear pharmacokinetics (dose to plasma trough concentrations) in dogs at doses between 5 – 30 mg/kg PO twice daily.[11,14] Zonisamide administered rectally (10 – 30 mg/kg) failed to reach therapeutic concentration.[15,16]

In cats, zonisamide has an onset of action of ≈4 hours and a half-life of ≈33 hours; steady state is likely reached within 7 days.[17,18]

In Hispaniolan parrots, 20 mg/kg PO every 12 hours resulted in plasma concentrations within the known therapeutic range. Elimination half-life was ≈10 hours.[19]

Human metabolism of zonisamide includes acetylation and glucuronidation of an intermediate metabolite.[20] Approximately ⅔ of a dose is eliminated renally as unchanged drug and metabolites.

Contraindications/Precautions/Warnings

In humans, zonisamide is contraindicated in patients that are hypersensitive to it or any sulfonamide drug.[21] Use zonisamide with caution in patients with significant renal impairment; dosage reduction may be required. Although it is unlikely that a sulfa hypersensitivity reaction can be elicited, use caution in animals with keratoconjunctivitis sicca or other previous sulfonamide-related adverse effects.

The National Institute for Occupational Safety and Health (NIOSH) classifies zonisamide as a hazardous drug (nonantineoplastic agent representing an occupational hazard to healthcare workers); personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[22] See ***Controlling Occupational Exposure to Hazardous Drugs*** for more information.

Adverse Effects

A systematic review and meta-analysis of adverse effects of antiepileptic drugs in dogs showed a weak level of evidence for zonisamide safety profile when used as monotherapy and adjunctive therapy.[23] The most common type I adverse effects (ie, dose dependent, predictable) were sedation followed by ataxia, vomiting, and decreased serum ALP activity; less common effects included increased serum ALT and glutamate dehydrogenase (GLDH) activity, aggression, anorexia, emaciation, and decreased T_4 and serum albumin.[23] When zonisamide was used as monotherapy, increased serum ALT and GLDH activity was not reported; however, in a recent review on incidence of hepatopathies in dogs on oral zonisamide, less than 1% of dogs experienced acute, potentially life-threatening hepatopathy associated with oral zonisamide therapy within the first 3 weeks of therapy.[24] Subclinical abnormalities in ALT and ALP activity were also noted in less than 10% of dogs during long-term therapy; clinical signs of liver disease were not observed.

Type II adverse effects (ie, idiosyncratic, nondose dependent, unpredictable) were idiosyncratic hepatotoxicity and mixed acid-base disorder.[23] A reduction in total T_4 was observed in one study, while free T_4 decreased slightly but remained within the reference range.[10] There are case reports of dogs developing zonisamide-associated apparent acute idiopathic hepatic necrosis,[25,26] pseudolymphoma,[27] urinary calculi,[25] hepatopathy,[28] acute tubular acidosis,[29] febrile neutropenia,[30] erythema multiforme,[31,32] and abnormal behavior (eg, sudden aggression, insomnia, restlessness, constant attention-seeking behavior).[33]

In a combined pharmacokinetic and toxicity study in cats, 50% of the cats receiving zonisamide 20 mg/kg per day developed adverse effects including inappetence, diarrhea, vomiting, ataxia, and somnolence; however, weight loss did not occur.[18] Zonisamide-related hypersensitivity syndrome in a cat has been reported.[34] Anorexia necessitated drug discontinuation in a cat.[35] Although a systematic review found that the majority of cats receiving zonisamide did not have adverse effects in reported studies, the efficacy and safety profile of zonisamide in cats was considered weak.[36]

Zonisamide is a sulfonamide-containing compound, but it does **not** contain the arylamine group known for causing a reactive intermediate, which may become a hapten for immunogenicity, ultimately leading to a sulfa allergy. Cross-reactivity between zonisamide and sulfa antibiotics has been demonstrated in vitro but has not been confirmed to be cross-reactive in humans. Based on currently available information, zonisamide is unlikely to cause keratoconjunctivitis sicca or other sulfonamide-related adverse effects in dogs or cats.

In a pharmacokinetic study of 10 birds, zonisamide did not alter appetite, body weight, or hematologic or serum chemistry panel values.[19]

In humans, the most common adverse effects include anorexia, nausea, dizziness, somnolence, agitation, and headache.[21] Rarely, serious dermatologic reactions (eg, Stevens-Johnson syndrome, toxic epidermal necrolysis [TEN]), blood dyscrasias, oligohidrosis, and hyperthermia have been reported in humans. Nephrolithiasis occurs in 4% of humans. Anorexia and weight loss in humans have also been noted.

Reproductive/Nursing Safety

Zonisamide is teratogenic in dogs, mice, and rats.[21] Zonisamide 10 or 30 mg/kg/day (approximate therapeutic doses in dogs) administered to pregnant dogs resulted in ventricular septal defects, cardiomegaly, and various valvular and arterial anomalies at the higher dose.[14] A plasma zonisamide concentration of 25 µg/mL was the threshold level for malformation. Owners of pregnant dogs should be made aware of and accept the significant risks associated with the use of this drug.

Zonisamide enters maternal milk at levels of 40% to 80% that of maternal plasma concentration. Use zonisamide with caution in nursing animals.[37] Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The LD_{50} of zonisamide in dogs is reportedly 1 g/kg. Human patients have survived zonisamide overdoses of ≈7.5 g (total dose) without complications.[38] In humans, overdoses may cause coma, bradycardia, hypotension, and respiratory depression.[21] Clinical signs associated with toxicity in dogs include sedation/lethargy, anxiety, ataxia, and/or vomiting. In cats, toxicity effects (eg, anorexia, vomiting, diarrhea, lethargy, ataxia) were noted in 50% of cats in a study.[18]

Treatment recommendations include GI decontamination, if ingestion was recent, and supportive therapy. Supportive care may be required for several days because of the drug's long half-life.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In humans, zonisamide is a substrate of CYP3A4.[21] It did not alter P-glycoprotein efflux in an experimental model.[39,40] The following drug interactions have either been reported or are theoretical in humans or animals receiving zonisamide and may be of significance in veterinary patients. Unless otherwise noted, use together is not nec-

essarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **CYP3A Inducers** (eg, **dexamethasone, rifampin**): May shorten the half-life of zonisamide and require dose adjustment[8]
- **Carbonic Anhydrase Inhibitors (CAIs;** eg, **acetazolamide)**: Concurrent use with CAIs may increase the risk for metabolic acidosis and kidney stone formation.[41]
- **Phenobarbital**: In dogs, phenobarbital may increase the clearance of zonisamide and decrease the peak concentrations, half-life, and area under the curve (AUC) of zonisamide[12,13,42,43]; this effect persisted up to 10 weeks after phenobarbital discontinuation.[13] Zonisamide dose may need to be increased by up to 50%.[12] In dogs, if zonisamide will be given in conjunction with phenobarbital, it is recommend that zonisamide be given at the high end of the dose range[44–47]; however, one source recommends reducing the phenobarbital dose by 25%.[48]

Laboratory Considerations

- Zonisamide may decrease total T_4 levels.[10]

Dosages

DOGS:

Seizure control (extra-label):

a) For dogs *not* already receiving phenobarbital, begin with 5 mg/kg PO every 12 hours.[1,4,5,49]

b) For dogs already receiving phenobarbital, begin with 7 – 10 mg/kg PO every 12 hours.[5,49] See ***Monitoring***.

CATS:

Monotherapy for seizure control (extra-label): 2.5 – 5 mg/kg PO every 12 hours[9]

Adjunctive seizure control for cats refractory to phenobarbital (extra-label): Anecdotally, 5 mg/kg PO every 12 to 24 hours.[17,35] From a case series, 6 – 17 mg/kg PO once daily.[6] Because of its long half-life in cats, doses of 5 – 10 mg/kg PO once daily are likely to be appropriate.

Monitoring

- Anticonvulsant efficacy
- Adverse effects (eg, inappetence, vomiting)
- Therapeutic drug monitoring may be useful in veterinary patients when seizures are not controlled. Therapeutic concentrations for zonisamide are thought to be 10 – 40 µg/mL.[1,4,5] One recommendation is to monitor trough levels (ie, within 1 hour prior to next scheduled dose) 1 to 2 weeks after initiating therapy or after dose changes and whenever seizure frequency changes.[5] Consider measuring peak zonisamide concentrations (ie, within 3 to 4 hours postdosing) for patients taking phenobarbital concurrently and that have poor seizure control. Samples obtained from whole blood yield higher zonisamide concentration than samples from plasma.[11] Consult with the veterinary diagnostic laboratory measuring drug concentrations to ensure appropriate samples are collected and to gain guidance on dosage adjustments.
- Baseline and periodic (eg, after 1 month of therapy, then every 3 to 6 months if no problems) CBC and serum chemistry panel[5,7] for hepatic enzyme activity (eg, ALT, ALP), BUN, electrolytes (especially bicarbonate), and venous blood–gas analysis.

Client Information

- This medicine may be given with or without food. If your animal vomits or acts sick after getting it on an empty stomach, give the medicine with food or a small treat.
- Do not stop giving this medicine to your animal without discussing with your veterinarian first, as it may cause seizures to occur.
- Keep a seizure diary to help determine how well this medicine is working.
- Contact your veterinarian immediately if your animal stops eating, has a lack of appetite, becomes overly tired or develops a yellowish tint to the eyes, skin, or gums (jaundice).
- This medicine is considered to be hazardous as defined by the National Institute for Occupational Safety and Health because it may affect the reproductive ability of men or women actively trying to conceive, women who are pregnant or may become pregnant, and women who are breastfeeding. It is recommended that you wear gloves when administering this medication to your animal and wash your hands thoroughly afterwards. If you have questions about this medication's hazards, contact your veterinarian or pharmacist.

Chemistry/Synonyms

Zonisamide, a sulfonamide unrelated to other antiseizure drugs, occurs as a white powder with a pK_a of 10.2. It is moderately soluble in water (0.8 mg/mL).

Zonisamide may also be known as AD-810, CI-912, PD-110843, *Excegran*®, or *Zonegran*®.

Storage/Stability

Zonisamide capsules should be stored at 25°C (76°F); excursions are permitted between 15°C to 30°C (59°F-86°F). Store in a dry place and protect from light.

Compatibility/Compounding Considerations

The preparation and stability of extemporaneously compounded (from 100 mg capsules) zonisamide 10 mg/mL suspensions in simple syrup or methylcellulose (0.5%) have been published.[50] The simple-syrup suspension was stable for at least 28 days when stored at room temperature or under refrigeration and the methylcellulose (0.5%) suspension was stable for 28 days when stored under refrigeration and for 7 days when stored at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Zonisamide Capsules: 25 mg, 50 mg, and 100 mg; *Zonegran*®, generic; (Rx)

Ophthalmic Agents, Topical

ALISON CLODE, DVM, DACVO
Port City Veterinary Referral Hospital
InTown Veterinary Group
Portsmouth, New Hampshire

The following section lists the majority of veterinary-labeled ophthalmic topical products and some of the more commonly used human-labeled products in veterinary medicine; written by Alison Clode, DVM, DACVO, based on previous work by Gigi Davidson, DICVP, and Michael Davidson, DVM, DACVO. Section editor: James A. Budde, PharmD, DICVP. Drugs are listed in alphabetical order.

For additional information, an excellent review on veterinary ophthalmic pharmacology and therapeutics can be found in the following textbooks: *Slatter's Fundamentals of Veterinary Ophthalmology*, 6th Edition. Maggs DJ, Miller PE, and Ofri R, Eds. Saunders, 2017 and *Veterinary Ophthalmology*, 5th Edition; Gelatt KN, Gilger BC, Kern TJ, Eds. Wiley-Blackwell, 2013.

Routes of Administration for Ophthalmic Drugs

The route of administration selected to deliver therapy for an ocular condition is critical to successful therapy. The following table lists advantages and disadvantages of each route of administration for ocular medications. **NOTE:** Unless otherwise indicated, **small animals** (dogs and cats) receive 1 drop of solutions per administration, or ¼ – ½ inch of ointments per administration; **horses** receive 1 – 2 drops (administered directly to the eye) or 0.1 mL (administered via subpalpebral lavage (SPL) catheter or squirted directly into the eye) of solutions, or ¼ – ½ inch of ointments per administration.

Route	Target tissues	Dosage forms	Advantages	Disadvantages	Comments
Topical	Conjunctiva, cornea, anterior uvea, lids	**Solutions, suspensions**	▪ General ease of administration ▪ Minimal interference with vision ▪ Low incidence of contact dermatitis ▪ Minimal toxicity to interior of eye in presence of penetrating wound	▪ Imprecise dosing ▪ Potential for contamination ▪ Short contact time with eye ▪ Requires more frequent application than ointment ▪ Diluted by tearing ▪ Systemic absorption ▪ Difficult to administer to horses without SPL catheter placement	▪ Doses greater than 1 drop rarely indicated in small animals (maximum tear capacity is 10 – 20 µ Ls, volume of a drop is 25 – 50 µLs) ▪ Allow 5 minutes between drops ▪ Instill in order of least viscous to most, solutions prior to suspensions, and aqueous base prior to oil base ▪ Owners should be counseled to avoid contact of applicator tip with eye.
		Ointments	▪ Longer contact time ▪ Less frequent administration than drops ▪ Protect cornea from drying ▪ Not diluted by tearing	▪ Contribute to volume of ocular discharge ▪ Temporarily blur vision ▪ More difficult to administer ▪ Contact dermatitis ▪ Should not be applied to penetrating corneal wounds as vehicles cause granulomatous uveitis ▪ Difficult to determine exact dose ▪ Metal tubes may fatigue and split before all medication is used.	▪ Owners should be counseled to avoid contact of application tube with eye. ▪ Observe patient for brief period after application due to temporarily blurred vision ▪ Instill solutions and suspensions prior to ointments
Subconjunctival injection	Cornea, anterior uvea	**Sterile solutions and suspensions**	▪ High local concentrations with smaller total dose minimizes systemic effects ▪ Circumvents poor patient compliance with topical administration	▪ Uncertain drug disposition following administration ▪ May create scar tissue ▪ Drug cannot be removed once applied. ▪ Drug vehicle residues may persist. ▪ Inadvertent globe perforation	▪ Indicated for poorly compliant owners and/or uncooperative patients ▪ Indicated for drugs with poor corneal penetration
Intracameral injection	Anterior segment	**Sterile, non-preserved solutions and suspensions**	▪ Allows very high local drug concentrations	▪ Risk for infection ▪ Risk for hemorrhage, retinal detachment, cataract formation, and retinal degeneration ▪ Risk for intraocular toxicity	▪ Indicated to dissolve fibrin and blood clots in the anterior chamber (eg, tPA) ▪ Indicated for intraocular surgery (local anesthetics, viscoelastic substances) ▪ With caution, indicated for severe intraocular infections

Route	Target tissues	Dosage forms	Advantages	Disadvantages	Comments
Intravitreal injection	Posterior segment	**Sterile, non-preserved solutions and suspensions**	▪ Allows very high local drug concentrations	▪ Risk for infection ▪ Risk for hemorrhage, retinal detachment, cataract formation, and retinal degeneration ▪ Risk for intraocular toxicity	▪ Indicated to manage end-stage glaucoma (gentamicin/steroid) ▪ With caution, indicated for severe intraocular infections ▪ With caution, indicated for intractable uveitis
Retrobulbar and peribulbar injection	Posterior segment, optic nerve	**Sterile solutions and suspensions**	▪ Allows very high local drug concentrations	▪ Risk for infection ▪ Risk for globe perforation, optic nerve trauma, retrobulbar hemorrhage	▪ Indicated prior to enucleation (local anesthetics) ▪ Indicated for intraocular surgery when neuromuscular blockade is not possible
Systemic drugs (oral, SC, IM, IV)	Lids, posterior segment, optic nerve, anterior uvea (occasionally)	**Tablets, capsules, sterile solutions and suspensions**	▪ Allows drug penetration to areas topical therapy will not reach	▪ Systemic effects, including toxicities, occur ▪ Limited penetration into the cornea	▪ See specific monographs for use of systemic agents.

Principles of Compounding Ophthalmic Products

GIGI DAVIDSON, BSPharm, DICVP

Physiochemical Considerations for Compounding Ophthalmic Preparations

The availability of suitable commercially available products for every veterinary ophthalmic indication is highly unlikely. Many agents used in veterinary ophthalmology are no longer or were never commercially available. Examples of agents that are commonly used by veterinarians but are not currently commercially available include acetylcysteine, amphotericin B, chloramphenicol, cidofovir, tacrolimus, and voriconazole ophthalmic solutions and/or ointments. Even if commercially available, products may be of inappropriate concentration to achieve a therapeutic effect in a given patient (eg, cyclosporine) or may have agents and excipients that may have adverse effects in animal patients (eg, polymyxin B in cats). In other cases, no product is commercially available and must be compounded from other nonophthalmic drugs or from bulk chemicals (eg, acetylcysteine ophthalmic solution and disodium edetate ophthalmic solution). For these reasons, pharmacists are frequently called upon to compound products to be used in the animal eye. These products may be administered topically in the form of solutions, suspensions, or ointments or administered by periocular or intraocular injection, by drug-implanted collagen shields, or by drug-impregnated disposable contact lens delivery systems. The quality and sterility of these products are critical, and preparations for injection into the eye must meet endotoxin limits. To ensure adequate stability, uniformity, and sterility, both the American Society of Health-Systems Pharmacists and the United States Pharmacopoeia (USP) Convention have published standards (eg, USP General Chapter <797> *Pharmaceutical Compounding—Sterile Preparations*) for pharmacy-prepared ophthalmic products. These standards address the following areas of concern.

Validation of Formulation

Before compounding any preparation for ophthalmic use, the pharmacist should obtain documentation that substantiates the stability, safety, and benefit of the requested formulation. Pharmacists may call the manufacturer of the drug, refer to primary literature, call regional eye centers, or call professional compounding organizations to obtain such information. If no such documentation is available, the pharmacist must employ professional judgment in determining a suitable formulation for ophthalmic administration and then apply the most conservative beyond-use dates established in USP <797>. Factors to consider when making this judgment include sterility, tonicity, endotoxin burden, pH and buffering, the toxicity of the drug, need for preservatives, solubility, stability in the chosen vehicle, particle size in suspensions, viscosity, packaging, and any precautions necessary to keep drug residues from occurring in any food-producing animals.

Documentation

A readily retrievable document (electronic or written), known as a Master Formulation Record, must be maintained for each ophthalmic preparation compounded. This Master Formulation Record must indicate the name of the preparation, the dosage form, the specifications and source of each ingredient used, the weights and measures of each ingredient used, the equipment required, a complete description of each step in the compounding process with a special notation of aseptic techniques to be utilized and which method of sterilization is employed, beyond-use dating, storage requirements, specific packaging requirements, sample label and auxiliary labeling, quality control testing that must be performed (eg, pH, sterility, endotoxin testing for injections), and references for the formula. The expected visual appearance of the final preparation must also be described in the Master Formulation Record. Compounding Records for each compound prepared must also be made (electronic or written) and must include the date of compounding, lot or batch number assigned, the quantity of each ingredient used to prepare the compound, the manufacturer, lot number, and expiration date of each ingredient used, results of any quality testing, a sign-off provision for compounder and checker, the amount compounded, and the projected beyond-use date for the compounded preparation.

Sterility

Ophthalmic dosage forms must be compounded in aseptic conditions. Sterile compounding standards must be consulted in the United States Pharmacopeia General Chapter <797>. Sterility is the most important consideration for ophthalmic products. Contaminated ophthalmic products can result in eye infections leading to blindness or even loss of the eye, especially if pathogens, such as Pseudomonas,

are present. Eye infections from contamination can also lead to systemic infections requiring hospitalization and may even result in death. All ophthalmics should be compounded in a primary engineering control (PEC; eg, laminar flow hood or compounding aseptic isolator) that maintains an ISO 5 level of air quality. PECs must be certified at least annually for acceptable performance and maintenance of expected environmental quality. The compounding pharmacist must also be appropriately garbed as described in USP <797> and must use impeccable aseptic technique when handling products intended for use in the eye. All products must be rendered sterile after formulation in the laminar flow hood and maintain sterility throughout their labeled beyond-use date.

Sterilization of the final preparation for ophthalmic solutions is most easily achieved through filtration through vehicle-compatible 0.2 µm sterilizing filters, which also remove particulate matter. Note that this method is not suitable for ophthalmic suspensions or ointments. Ophthalmic suspensions and ointments must be sterilized by other means (such as autoclaving, dry heat, or irradiation) to avoid filtering out active drugs. Preservatives may also be added to prevent bacterial growth, especially if the container is intended for multiple uses. FDA has established maximum potency per unit dose thresholds for preservative agents in FDA-approved ophthalmic products, which can be found at https://www.accessdata.fda.gov/scripts/cder/iig/index.cfm, USP <797>, places limits on beyond-use dates for nonpreserved aqueous ophthalmic preparations. The preservative selected must be compatible with the active drug and excipients as well as nontoxic to the eye or to the patient.

Clarity

Drugs prepared as ophthalmic solutions should meet requirements for particle size and quantity as standardized in USP <789> *Particulate Matter in Ophthalmic Solutions*. Drugs prepared as ophthalmic suspensions cannot be filtered but must be of a particle size that does not irritate or scratch the cornea, typically less than 25 µm. A general rule of thumb is that particles that can be felt when rubbing a drop of the preparation between the thumb and forefinger are too large to be used in the eye. The use of an ointment mill is highly recommended to decrease the particle size for ophthalmic ointments.

Tonicity

Ophthalmic products do not need to be isotonic if the contact time with the cornea is only a few minutes. The eye can tolerate a range of 200 to 600 mOsm/L for short periods of time. Some ophthalmic preparations are intentionally hypertonic in order to reduce corneal edema. For ointments, irrigations, and products that will remain in contact with the eye longer than a few minutes, isotonic products should be used. Hypotonic agents may cause corneal edema, and hypertonic agents may dehydrate the cornea and cause pain. Tear fluid and normal saline have identical osmotic pressures, making 0.9% sodium chloride an excellent vehicle for ophthalmic products. For products that are hypotonic, sodium chloride equivalencies can be used to determine how much sodium chloride is necessary to render the product isotonic. An extensive list of sodium chloride equivalents for drugs has been published.[1]

Buffering and pH

Ophthalmic preparations are generally buffered in a range from 4.5 to 11.5. Buffering is necessary to provide maximal stability of the drug or for the comfort and safety of the patient. Alkaloids, such as atropine and pilocarpine, are usually buffered. If the activity and stability of the drug are not pH-dependent, and the pH of the product is not irritating, then buffers may be omitted from the formulation. Commonly used buffers for ophthalmic preparations include Palitzsch buffer, boric acid buffer, boric acid/sodium borate buffer, sodium acetate/boric acid buffer, Sorensen's modified phosphate buffer, Atkins and Pantin buffer solution, Feldman buffer, and Gilford ophthalmic buffer. Formulations for these solutions and ratios required to achieve the desired pH have been published.[2]

Viscosity Enhancers

Because tears and blinking reflexes reduce the total amount of drug available for penetration, an increase in residence time in the eye will increase drug absorption. Increasing the viscosity of the drug is the most common way to prolong contact time. Methylcellulose derivatives (eg, carboxymethylcellulose, hydroxyethylcellulose, and hydroxypropylmethylcellulose) are the most commonly used agents. Polyvinyl alcohol and polyvinylpyrrolidone have also been used. The FDA has established maximum potency per unit dose thresholds for carboxymethylcellulose and for viscosity agents in FDA-approved ophthalmic products, which can be found at https://www.accessdata.fda.gov/scripts/cder/iig/index.cfm.

Quality Control

Finished preparations should be thoroughly inspected visually for clarity and uniformity of suspension. The pH of the final preparation should always be checked, and the value should be recorded on the master formula record for that batch. Most compounded preparations should have a pH of 5 to 7 unless otherwise indicated for stability or penetration of ocular tissue. Sterility testing and endotoxin testing should be performed where required.

Packaging

Ophthalmic preparations should be packaged in sterile dropper bottles (glass or plastic), or individual doses can be placed in sterile syringes with sterile tip caps. Ointments should be packaged in sterile ointment tubes and heat-sealed. Preparations that are sensitive to light and moisture should be packaged in tight, light-resistant containers.

Beyond-Use Dating

Beyond-use dates must be assigned according to the limits specified in the most current official USP Chapter <797>. Limits are assigned based on the risk for contamination according to the method of preparation, use of nonsterile ingredients, and presence or absence of preservatives.

Considerations for the Use of Ophthalmics in Veterinary Patients

Veterinary patients experience many of the same ophthalmic diseases and conditions as humans, and treatments are often based on human therapy. Animals, however, have a variety of species-related characteristics that might cause human-designed therapies to fail or be toxic. Behavioral characteristics, such as grooming, may significantly reduce the contact time of ophthalmic agents with the eye and increase systemic exposure through ingestion. Anatomical differences, such as size and tear capacity volume, must be considered when formulating ophthalmic therapies. Ease of administration must also be considered. Horses and other large animals may simply elevate their eyes out of a caregiver's reach if ophthalmic treatments are objectionable. Specialized delivery devices have been created to treat these patients. Subcutaneous palpebral lavage systems are tunneled under the skin over the animal's brow into the upper eyelid and allow for the passage of medication through long catheters that are easily reachable by caregivers. Food-producing animals require special consideration, as systemic absorption of ophthalmic agents in

animals could result in violative drug residues in food intended for human consumption. Finally, the use of active pharmaceutical ingredient powders (ie, bulk drug substances) to prepare compounds for animals is allowed only under the regulatory discretion provided by CVM FDA's Guidance for Industry #256.

General Principles of Ocular Penetration

GIGI DAVIDSON, BSPharm, DICVP

Corneal penetration

Drugs must generally be administered topically to treat corneal and intraocular conditions. Although the eye would appear to be an easy target for topical administration, the eye has several anatomical barriers to prevent penetration by foreign substances. Instantaneous tear production, strong blinking reflexes, and alternating layers of lipophilic and hydrophilic tissue all work in conjunction to prevent the entry of foreign substances. The clear tissue known as the cornea covers the visible outer surface of the eye between the lids. The cornea must be clear to allow for vision, and nature has accomplished this by omitting blood vessels in the cornea. Because of this lack of vascular tissue, systemically administered drugs rarely penetrate the cornea. Additionally, the cornea is composed of several layers of lipophilic (outer layers) and hydrophilic (inner layer) tissue. For a topically administered drug to fully penetrate the cornea, the drug must be able to exist in ready equilibrium between both ionized and nonionized forms in order to cross these layers (eg, chloramphenicol, atropine, and pilocarpine). Most antibiotics are water-soluble and will not penetrate the lipophilic outer layer of the cornea unless ulcers are present. Small molecular weight (less than 350) and high local concentration of drugs will increase penetration, however, even if the drugs are ionized and hydrophilic. Thus, topical administration is ideal as it allows for very high local concentrations of the drug on the cornea. For a topically administered drug to reach the anterior chamber and bind to intraocular structures (eg, ciliary body, iris, aqueous humor) to exert a clinical effect, the drug must pass through the cornea. Drugs may also reach the anterior chamber to some extent by passive absorption through the conjunctiva.

Key points for corneal penetration of drugs:

- Lipophilic
- Equilibrium between ionized and nonionized forms
- Small molecular weight (less than 350)
- High local concentrations

Intravitreal Penetration

Topically administered drugs reach the vitreous only in very small concentrations. To treat severe conditions of the anterior chamber (uveitis) as well as intravitreal conditions, drugs may be administered by periocular or intraocular injection. The periocular routes include subconjunctival injection and sub-Tenon's membrane injection, while the intraocular routes are intracameral injection (directly into the aqueous humor) or intravitreal injection (directly into the vitreous humor). Periocular injections can be administered under sedation and topical anesthesia. Intraocular injections are usually only performed while the patient is very heavily sedated or under general anesthesia. Both periocular and intraocular routes bypass the outermost chemical and physical ocular defenses and allow for a better concentration of drugs in the vitreous. The volume of administration for these routes is relatively small: periocular injections should not exceed 0.5 to 1 mL in small animals and 2 mL in large animals, and intraocular injections should not exceed 0.1 mL in small animals and 0.25 mL in large animals because of the risk for increased intraocular pressure. Drugs injected into the eye should be free of preservatives and buffers and must be sterile and meet endotoxin limits for injections.

Route of Therapy for Given Ocular Target

Target tissue	Routes of administration
Eyelids	Topical, systemic
Corneal surface	Topical
Anterior segment	Topical if good penetration or mild disease Systemic if poor penetration or severe disease
Posterior segment	Systemic or intraocular injection (rarely)

Questions to Ponder Prior to Compounding Ophthalmic Products

- Where is the target of therapy? (eyelids, corneal surface, cornea, anterior segment, posterior segment)
- What is the character of the drug?
  - Lipophilic? Hydrophilic?
  - What is the molecular weight?
  - What is the inherent toxicity of the drug to the eye (gentamicin)? To the caregiver (chloramphenicol)? To the patient (polymyxin B in cats)?
  - Are there data to support what concentration is necessary for corneal penetration?
  - Is the drug soluble in a vehicle that is not toxic to the eye?
  - If not soluble, will the particle size of the suspension or the ointment scratch the corneal or conjunctiva?
  - What is the pH of the final product? Is this in an acceptable range to avoid irritation (4.5 to 11.5)?
  - What is the tonicity of the final product? Hypertonic? Hypotonic? How long will the product be in contact with the cornea if not isotonic?
  - Will the viscosity need to be enhanced to prolong contact with the eye? Which agent is compatible?
  - What is the duration of therapy? Will the product require preservation if used long-term and/or multiple times? Which preservative is compatible?

Topical Ophthalmic Agents Listed by Class/Indication

Acetylcysteine Ophthalmic

(a-***see***-tuhl-***sis***-teen)

Anticollagenase Agent

Prescriber Highlights

- ► Mucolytic agent with antioxidant and anti-inflammatory effects; used to stop digestion of the cornea by collagenases and proteases
- ► Used to improve tear film stability
- ► Foul odor is usual and does not affect drug activity

Uses/Indications

Acetylcysteine is used topically to prevent corneal melting caused by proteinases and collagenases that are present when bacterial and/or fungal infection of ulcers occurs. Acetylcysteine at concentrations greater than 0.5% reduces such enzymatic activity in vitro.[1,2] Additionally, acetylcysteine is beneficial in stabilizing the tear film in quantitative and qualitative tear film deficiency disorders.[3]

Pharmacology/Actions

Acetylcysteine inhibits collagenase activity by reducing disulfide bonds and chelating the cofactors zinc and calcium. Additionally, acetylcysteine inhibits matrix metalloproteinase-9 (MMP-9) production by corneal epithelial cells.[4] Although MMPs play a role in initial corneal wound healing, down-regulation is necessary to prevent corneal digestion and allow corneal wound healing.

Contraindications/Precautions/Warnings

Acetylcysteine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Acetylcysteine exposure to the pulmonary tree may result in severe bronchospasm, so this medicine should be used with caution in asthmatic patients.

Adverse Effects

Adverse effects reported in humans or animals include irritation, redness, and tearing of the eyes. If inhaled, acetylcysteine can rarely cause bronchoconstriction and tracheal irritation. Concentrations of acetylcysteine greater than 10% are irritating to the eye.

Acetylcysteine may decrease corneal epithelial migration.[4]

Dosages

Corneal ulcers (extra-label): 1 drop to the affected eye(s) every 1 to 2 hours for the first 24 hours, followed by 3 to 4 times daily until clinical improvement occurs

Dry eye (extra-label): 1 drop to the affected eye(s) every 12 to 24 hours as long as clinical improvement is present

Monitoring

- Clinical efficacy as demonstrated by control of corneal melting and subsequent corneal wound healing, or signs of improved tear film quantity and quality

Client Information

- Use this medication as directed by your veterinarian.
- Wait 5 to 10 minutes after applying this medication before applying any other medications to the eye(s).
- Foul, rotten-egg odor is normal with this drug and does not affect how well it works.
- Store solutions in the refrigerator. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store this product in the refrigerator (2°C-8°C [35.6°F-46.4°F]) away from moisture and sunlight; do not freeze. Compounded 5% or 10% solutions of acetylcysteine are reported as stable for 60 days in the refrigerator, protected from light.[5]

Compatibility/Compounding Considerations

Acetylcysteine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Acetylcysteine ophthalmic solution (1% to 5%) must be compounded by a qualified compounding pharmacist.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Acyclovir Ophthalmic

(a-***sye***-klo-veer)

Antiviral

*For systemic use of acyclovir, refer to **Acyclovir***

Prescriber Highlights

- ► Used as an ophthalmic ointment in cats to treat feline herpesvirus-1 (FHV-1) with variable reported efficacy
- ► Requires frequent administration (ie, 5 to 6 times daily)
- ► This medication should NOT be used systemically in cats because of myelotoxicity, poor bioavailability, and poor efficacy against FHV-1.
- ► In the United States, acyclovir is not commercially available as an ophthalmic preparation; it must be compounded.

Uses/Indications

Acyclovir has been used topically as an ophthalmic ointment in cats with feline herpesvirus-1 (FHV-1), although inferior in vitro efficacy against herpesvirus-1 (FHV-1) and requirements for frequent administration limit its clinical usefulness.[1-4]

Pharmacology/Actions

Acyclovir is an acyclic nucleoside analogue that inhibits viral replication through the inhibition of feline herpesvirus-1 (FHV-1) DNA polymerase. In the first of 3 activation steps, acyclovir is selectively phosphorylated by viral thymidine kinase, with the 2 subsequent steps performed by host cell enzymes. Poor efficacy against FHV-1 is due to poor selectivity of viral thymidine kinase for FHV-1.

Contraindications/Precautions/Warnings

Acyclovir is contraindicated in patients that have a history of hypersensitivity to it or drugs like it (valacyclovir) or to any component of the formulation. Systemic use of acyclovir is contraindicated in cats as it could lead to leukopenia, acute anemia, and nephrotoxicity.[5]

Adverse Effects

When acyclovir is used systemically, adverse effects reported in humans or animals include bone marrow suppression, nephrotoxicity, and hepatotoxicity. When acyclovir is applied topically to the eyes, mild stinging and blepharitis may occur after application.

Dosages

Feline herpesvirus-1 (extra-label): ¼ – ½ inch strip to the affected eye(s) 5 times daily[4]; decreased frequency of administration is associated with decreased clinical effect.

Monitoring

- Resolution of clinical signs associated with corneal ulceration, corneal vascularization, conjunctivitis
- Baseline and periodic CBC and serum renal chemistries with prolonged topical therapy

Client Information
- This medicine must be given 5 times daily to be effective.
- Store acyclovir according to package instructions. Discard this medicine if the color changes or if it becomes cloudy.
- Do not allow cats to lick this medicine when grooming.

Storage/Stability
Because this compound must be compounded (in the United States), storage recommendations can vary; follow storage requirements listed on the packaging.

Compatibility/Compounding Considerations
Acyclovir ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Acyclovir is not approved in an ophthalmic dosage form, but sterile ophthalmic ointment may be compounded by qualified compounding pharmacists.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Alcaftadine Ophthalmic
(al-***kaf***-ta-deen) *Lastacaft®*

Antihistamine

Prescriber Highlights
- ► H1 receptor antagonist and mast cell stabilizer
- ► Indicated for allergic conjunctivitis
- ► May cause ocular burning, stinging, and irritation

Uses/Indications
Alcaftadine may be used in animals to alleviate the clinical signs of allergic conjunctivitis. No reports of clinical efficacy or tolerability in animals have been published.

Pharmacology/Actions
Alcaftadine is a histamine-1 (H_1) receptor antagonist and mast cell stabilizer. Inhibition of histamine receptor activation decreases the early-phase response in allergic conjunctivitis. Mast cell stabilization controls the late-phase allergic response in the conjunctiva by inhibiting the release of cytokines and lipid mediators. In humans, itching is prevented within 3 minutes after administration and this effect lasts up to 24 hours.[1]

Contraindications/Precautions/Warnings
Alcaftadine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans include irritation, burning and stinging on application, redness, and pruritus. Evaluation of adverse effects has not been performed in animals. Discontinue use if pruritus worsens. Alcaftadine has demonstrated less cytotoxicity in corneal epithelial cell cultures compared with other topical antiallergic medications.[2]

Dosages
Allergic conjunctivitis (extra-label): 1 drop to the affected eye(s) once daily

Monitoring
- Clinical efficacy: resolution of ocular pruritus

Client Information
- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the solution. Keep the dropper bottle tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight.

Compatibility/Compounding Considerations
Alcaftadine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Alcaftadine 0.25% Ophthalmic Solution (containing alcaftadine 0.25%; benzalkonium chloride 0.005%; edetate disodium; sodium phosphate, monobasic; purified water; NaCl; NaOH and/or HCl to adjust pH to 7, with osmolality of 290 mOsm/kg); 3 mL in sterile ophthalmic dropper bottle; *Lastacaft®*; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Alteplase Ophthalmic
Tissue Plasminogen Activator (tPA)
(***ahl***-teh-plays) *Activase®*

Fibrinolytic

Prescriber Highlights
- ► Used via intracameral (anterior chamber) injection to lyse intraocular fibrinohemorrhagic clots
- ► Does not lead to fibrinolysis when administered topically
- ► Toxic to the corneal endothelium in intracameral doses greater than 50 µg
- ► Not approved for intraocular injection; must be prepared from the injectable form intended for intracatheter administration

Uses/Indications
Alteplase ophthalmic is most commonly injected intracamerally to lyse intraocular fibrin and blood clots. Intraocular fibrin clots, which form as a result of intraocular inflammation and/or bleeding, can induce synechiae formation and obstruct aqueous humor flow and drainage, thus predisposing affected eyes to the development of glaucoma. Intracameral injection of alteplase in humans following cataract surgery dissolves fibrin clots and reduces posterior synechiae without resulting in re-bleeding.[1]

Immediate postoperative intracameral injection of alteplase in dogs undergoing cataract surgery does not significantly impact postoperative development of anterior chamber fibrin or postoperative ocular hypertension.[2] Topical application of alteplase does not lyse intraocular clots.[3] In dogs and cats, intracameral injection of alteplase 25 µg results in fibrinolysis without corneal toxicity, whereas alteplase doses of 50 µg lead to corneal endothelial toxicity.[3,4]

Pharmacology/Actions
Alteplase (tissue plasminogen activator) is an enzyme (serine protease) that binds to fibrin in clots, which converts the plasminogen component of the clot to plasmin, thus inducing local fibrinolysis.

Contraindications/Precautions/Warnings
Tissue plasminogen activator is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. The most frequent adverse reaction associated with thrombolytics in approved indications is bleeding. Caution should be exercised with patients that have thrombocytopenia, other hemostatic defects (including those secondary to severe hepatic or renal disease), or any condition for which bleeding constitutes a significant hazard.[5] Intracameral doses of 50 µg have resulted in toxicity to the corneal epithelium in dogs and cats.[3,4]

Adverse Effects
Adverse effects reported in humans or animals include increased risk for bleeding following administration. Corneal toxicity is likely with intracameral alteplase doses of 50 µg but does not occur with doses of 25 µg.[3,4]

Dosages
Intraocular fibrinolysis (extra-label): Intracameral injection of 0.1 mL of a 0.25 mg/mL sterile solution (25 µg total dose)

Monitoring
- Clinical efficacy
- Resolution of the intraocular clot, which generally occurs within 24 to 48 hours.[6] Observe the patient for signs of re-bleeding.

Client Information
- This medication is not administered outside of veterinary clinics.

Storage/Stability
Refer to individual packaging for storage information; generally, this product is kept under refrigeration (2°C-8°C [36°F-46°F]). Protect the lyophilized material during extended storage from excessive exposure to light. After reconstitution, the drug may be stored between 2°C and 30°C (36°F-86°F) and used within 8 hours. Discard any unused solution after administration is complete. Alteplase contains no preservatives. Store aliquots of reconstituted and further diluted solutions in an ultralow (-80°C [-112°F]) freezer for 45 days unless extended stability and sterility testing has been conducted. Do not re-freeze aliquots once thawed. Discard this product if the color changes, if it becomes cloudy, or if there are particles in the solution.

Compatibility/Compounding Considerations
Alteplase ophthalmic preparations should not be mixed directly (in vitro) with any other ophthalmic medications. It is not available as an ophthalmic injection. For intraocular injection, *Cathflo Activase®* is further diluted with normal saline to a final concentration of 0.25 mg/mL.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Alteplase is not approved for ophthalmic use.

Cathflo Activase® is available (containing alteplase 2.2 mg [which includes a 10% overfill], L-arginine 77 mg, polysorbate-80 0.2 mg, and phosphoric acid for pH adjustment. Each reconstituted vial will deliver 1 mg/mL of alteplase at a pH of ≈7.3). For intraocular injection, this solution is further diluted with normal saline to a final concentration of 0.25 mg/mL.

Activase® is available as 50 and 100 mg lyophilized powder vials with diluent (sterile water for injection) included.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Amikacin Ophthalmic

(am-uh-***kay***-sin)

Aminoglycoside Antibiotic

*For systemic use, see **Amikacin***

Prescriber Highlights
- ► Topical ophthalmic aminoglycoside antibiotic used for susceptible ocular bacterial infections that are resistant to other aminoglycoside antibiotics
- ► Amikacin is not commercially available as an ophthalmic preparation in the United States; it must be compounded.
- ► Cats may be more subject to toxic effects of amikacin than other species.

Uses/Indications
Although an amikacin ophthalmic formulation is not commercially available, it can be compounded for use in ophthalmic infections caused by susceptible strains of *Pseudomonas* spp, *Escherichia coli*, *Proteus* spp, *Klebsiella* spp, and other gram-negative bacteria.[1] Amikacin has activity against penicillinase and nonpenicillinase-producing species of *Staphylococcus* spp, but low activity against other gram-positive organisms. Amikacin is less toxic to the posterior segment compared with other aminoglycoside antibiotics and the injectable dosage form is sometimes used as an intravitreal injection to treat bacterial endophthalmitis.

The World Health Organization (WHO) has designated amikacin as a Critically Important, High Priority antimicrobial for human medicine.[2] The Office International des Epizooties (OIE) has designated amikacin as a Veterinary Critically Important Antimicrobial (VCIA) Agent in equine species.[3]

Pharmacology/Actions
Amikacin sulfate, an aminoglycoside, is actively transported into the bacterial cell. It binds to a specific receptor protein on the 30S subunit of bacterial ribosomes. It consequently interferes with an initiation complex between mRNA (messenger RNA) and the 30S subunit, inhibiting protein synthesis by inducing misreading of the mRNA. Aminoglycosides are bactericidal, whereas most other antibiotics that interfere with protein synthesis are bacteriostatic. Although topical administration does not produce substantial aqueous humor concentrations, subconjunctival injections of amikacin solutions may achieve therapeutic concentrations in the cornea and the aqueous humor.[4]

Contraindications/Precautions/Warnings
Amikacin is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
When amikacin is used systemically, it can cause nephrotoxicity and neurotoxicity (ototoxicity and vestibular toxicity). Cats are more susceptible to the toxic effects of amikacin, and it is recommended that all patients receiving topical amikacin be monitored for systemic toxicity. Although uncommon, topical aminoglycoside preparations have been reported to cause local reactions such as lid itching, swelling, and conjunctival erythema in humans.

Dosages
Susceptible ocular infections (extra-label): Apply 1 drop to the affected eye(s) every 1 to 2 hours for the first 24 hours, followed by every 4 to 6 hours, pending clinical improvement

Monitoring
- Clinical efficacy: cytology and culture to evaluate for the presence of bacteria. Clinical resolution of signs of ocular surface infection
- Adverse effects (eg, signs of vestibular or auditory toxicity or nephrotoxicity)
- Urinalysis with sediment to check for casts in the urine, which may be an early indicator for nephrotoxicity

Client Information
- Give this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when this medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medications to the eye.
- Store this medicine according to the directions on the product label, protected from light. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are visible particles in the solution.

Storage/Stability
Store product as directed on the product label, protected from light.

Compatibility/Compounding Considerations
Amikacin sulfate ophthalmic solution should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Amikacin is not approved in an ophthalmic dosage form, but sterile solutions of amikacin 1% to 5% may be compounded by qualified compounding pharmacists.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Amphotericin B Ophthalmic

(am-foe-***ter***-i-sin ***bee***)

Polyene Antifungal

Prescriber Highlights
- ► Antifungal agent used to treat ocular surface fungal infections
- ► Not commercially available in an ophthalmic dosage form
- ► Solutions made from the formulation for IV injection may be used topically or injected subconjunctivally.

Uses/Indications
Amphotericin B is used primarily in horses to treat fungal keratitis. It is effective against yeast and dimorphic fungal organisms, including *Histoplasma* spp, *Coccidioides* spp, *Candida albicans*, *Blastomyces* spp, *Cryptococcus* spp, *Sporothrix* spp, and *Mucor* spp, with variable activity against filamentous organisms (more efficacy for *Aspergillus* spp than *Fusarium* spp).

Amphotericin B has demonstrated in vitro ability to reduce biofilm formation by *Candida* spp, thus decreasing virulence.[1] Topical administration is minimally effective. There is evidence supporting the beneficial effect of subconjunctival and intrastromal injections in humans.[2,3]

Pharmacology/Actions
Amphotericin B acts by binding fungal sterols in cell membranes, resulting in leakage of intracellular constituents. Amphotericin B is usually fungistatic but can be fungicidal in higher concentrations.

Contraindications/Precautions/Warnings
Amphotericin B is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans or animals include mild burning, stinging, irritation, or redness. Topical application may be toxic to the corneal epithelium,[4] whereas subconjunctival injection of nonliposomal forms may induce ocular irritation.[5]

Dosages
Topical administration (extra-label; 0.15% to 0.5% solution): 1 – 2 drops in the affected eye(s), or 0.1 mL in the subpalpebral lavage (SPL) catheter, every 2 to 6 hours, depending upon severity of infection

Subconjunctival injection (extra-label): Inject 0.3 mL of a 0.5 mg/mL solution under the bulbar conjunctiva every 48 to 96 hours.[2]

Monitoring
- Clinical efficacy and evaluation for clinical signs suggestive of continued infection
- Corneal scraping to determine the resolution of fungal infection

Client Information
- Give this medication to your animal as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication in a refrigerator protected from light.
- Discard this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store the product in the refrigerator (2°C-8°C [35.6°F-46.4°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Amphotericin B should not be mixed with salt-containing solutions and should not be mixed directly (in vitro) with any other drugs. Amphotericin B is not available as an ophthalmic preparation but may be prepared as a topical solution (0.15% to 0.5% in dextrose 5% or sterile water) or as a subconjunctival injection (0.5 mg/mL in sterile water). Historically, only the nonliposomal injection was recommended for compounding topical solutions; however, studies demonstrate that topical liposomal amphotericin B ophthalmic solutions are equally effective and less irritating.[6] Although stability is concentration-dependent, most solutions are chemically stable for 7 days in the refrigerator protected from light. Additionally, recent evidence suggests that ophthalmic solutions prepared from liposomal amphotericin B retain chemical potency for up to 6 months.[7]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

None are available, but amphotericin B may be compounded by reconstituting the injection as a 0.15% to 0.5% solution and used as an ophthalmic solution. See ***Compatibility/Compounding Considerations***.

HUMAN-LABELED PRODUCTS: NONE

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Apraclonidine Ophthalmic

(a-pra-***cloe***-ni-deen) *Iopidine®*

Alpha-Adrenergic Anti-Glaucoma Agent

Prescriber Highlights

- ► Used to manage glaucoma
- ► Uncommonly used in veterinary species
- ► Do not use in cats, as bradycardia and vomiting may occur.
- ► Results in dry nose and mouth, headaches, cardiac arrhythmias, and fatigue in humans
- ► Tachyphylaxis may occur with long-term use.

Uses/Indications

Apraclonidine ophthalmic may be used as a short-term adjunct for patients that are maximally treated with other anti-glaucoma agents but still require additional lowering of intraocular pressure (IOP). Although reports of the use of apraclonidine in veterinary patients are sparse, one report documented control of IOP for ≈8 months in a dog in conjunction with dorzolamide/timolol ophthalmic medications.[1]

Pharmacology/Actions

Apraclonidine is a relatively selective alpha-2-adrenergic agonist. Activation of presynaptic alpha-2 receptors leads to inhibition of norepinephrine release, and activation of postsynaptic alpha-2 receptors on the nonpigmented ciliary body epithelial cells leads to decreased intracellular cyclic adenosine monophosphate (cAMP), both of which decrease aqueous humor production and intraocular pressure (IOP). Additionally, aqueous humor outflow may be increased by a direct effect on uveoscleral outflow, as well as structural alterations to conventional outflow tract that decrease resistance to outflow. Tachyphylaxis (loss of effect) may occur over time, usually in less than 1 month in humans.

Contraindications/Precautions/Warnings

Apraclonidine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Apraclonidine should not be used in patients that are receiving clonidine or monoamine oxidase inhibitors (MAOIs). Do not use apraclonidine in cats, as it can cause bradycardia, hypersalivation, diarrhea, and vomiting.[2] Apraclonidine should be used with caution, if at all, in animals with hepatic or renal insufficiency.

Adverse Effects

Adverse effects reported in humans or animals include conjunctival blanching, eyelid elevation, and mydriasis. Dogs may experience vomiting and diarrhea.[3] Rarely, ophthalmic use of apraclonidine may cause dry mouth, dry eye, tachycardia, hypertension, and tachypnea.

Dosages

Glaucoma (extra-label): 1 drop to the affected eye(s) every 8 to 12 hours

Monitoring

- Clinical efficacy
- Intraocular pressure (IOP)

Client Information

- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication as directed on the product label away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store product in the refrigerator or at controlled room temperature (2°C-25°C [36°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Apraclonidine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Apraclonidine 0.5% Ophthalmic Solution (containing benzalkonium chloride 0.01%, NaCl, sodium acetate, NaOH and/or HCl [pH 4.4 to 7.8], and purified water) in 5 mL and 10 mL sterile ophthalmic dropper bottles; *Iopidine®*; (Rx)

Apraclonidine 1% Ophthalmic Solution (containing benzalkonium chloride 0.01%, NaCl, sodium acetate, NaOH and/or HCl [pH 4.4 to 7.8], and purified water), 0.1 mL in plastic ophthalmic dispensers, packaged 2 per pouch enclosed in foil overwrap; *Iopidine®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Atropine Ophthalmic

(***ah***-troe-peen) *Isopto Atropine®*

Mydriatic/Cycloplegic

For systemic use, refer to ***Atropine***

Prescriber Highlights

- ► Used therapeutically to dilate the pupil, paralyze the ciliary body, and stabilize the blood–aqueous barrier in animals with anterior uveitis
- ► Used to perform cycloplegic refraction; not intended to induce mydriasis for diagnostic evaluation of the posterior segment as mydriasis will persist for days to weeks
- ► Use with caution in affected and unaffected eyes of animals diagnosed with primary glaucoma.

Uses/Indications

Atropine ophthalmic is primarily used to reverse miosis and treat ciliary body spasm associated with anterior uveitis. It stabilizes the blood–aqueous barrier and lessens the occurrence of pupillary adhesions by minimizing intraocular exudation of proteins and cells caused by uveal inflammation.

Pharmacology/Actions

Atropine is a nonselective muscarinic receptor antagonist, leading to parasympatholytic activity. In the eye, anticholinergic activity produces mydriasis and cycloplegia by blocking stimulation of the iris sphincter muscle and the ciliary body accommodative muscle. It induces mydriasis in ≈1 hour, and the effects may persist up to 120 hours in dogs, 144 hours in cats, and days to weeks in horses.[1]

Contraindications/Precautions/Warnings

Atropine ophthalmic is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Atropine ophthalmic should also not be used in patients with primary glaucoma or in dogs that are predisposed to developing glaucoma, as elevation in intraocular pressure (IOP) may result.[2] Atropine ophthalmic may induce colic in horses secondary to systemic absorption, but this is rare.[3] Avoid using the ointment formulation on

penetrating corneal wounds because of the potential for intraocular damage associated with exposure of the ointment's inactive ingredients to the intraocular environment.

Adverse Effects
Adverse effects reported in animals include sensitivity to bright light or sunlight and burning and irritation upon application. Cats and dogs may experience transiently decreased tear production; thus, concurrent administration of topical tear replacers is appropriate. Hypersalivation, which may occur because of drainage of the bitter-tasting solution into the nasopharynx, can be avoided by use of ointment formulations. Atropine ophthalmic causes tachycardia in healthy dogs.[4]

Dosages
Mydriasis and cycloplegia (extra-label): Initially, 1 drop or a ¼ – ½ inch strip to the affected eye(s) 2 to 3 times daily and then once daily or every other day afterward to achieve mydriasis

Monitoring
- Clinical efficacy: confirm continued mydriasis and degree of patient comfort

Client Information
- Wash your hands prior to and after applying this medicine to your animal's eye(s) to prevent human exposure and unintended exposure of your animal's eye.
- Excessive drooling may occur (especially in cats).
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper (or ointment) tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Keep the cap tightly closed when this medicine is not in use.
- This medicine may cause your animal's tear production to decrease. Your veterinarian may also recommend the use of an over-the-counter (OTC) tear replacement solution or ointment for your animal's eye(s) to alleviate this problem.
- Wait for 5 to 10 minutes after applying atropine before applying any other medications to the eye.

Storage/Stability
Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Atropine sulfate ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Atropine Sulfate 1% Ophthalmic Ointment USP (containing atropine sulfate 10 mg; white petrolatum; mineral oil; lanolin oil; purified water) in 3.5 g ophthalmic tubes; generic; (Rx)

Atropine Sulfate 1% Ophthalmic Solution, USP (containing atropine sulfate 20 mg; benzalkonium chloride 0.01%, dibasic sodium phosphate; edetate disodium; hypromellose (2910); monobasic sodium phosphate; NaOH and/or HCl to adjust pH to 3.5 to 6; water for injection), 2 mL, 5 mL, and 15 mL in sterile ophthalmic dropper bottles; *Isopto Atropine*®, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Azelastine Ophthalmic
(a-za-***las***-teen)
Antihistamine

Prescriber Highlights
- ► Used for the treatment of allergic conjunctivitis
- ► Rapid onset of action (3 minutes) and long duration of action (8 hours) in humans

Uses/Indications
Azelastine is used to relieve pruritus caused by allergic conjunctivitis. No studies describing the efficacy and safety of azelastine after topical administration have been performed in veterinary patients.

Pharmacology/Actions
Azelastine is an H_1- and H_2-receptor antagonist, which also inhibits the release of histamine from mast cells and the production of leukotrienes involved in the allergic response.[1] Azelastine has a rapid onset of action (3 minutes) and a long duration of antipruritic action (8 hours) in humans.

Contraindications/Precautions/Warnings
Azelastine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans include transient burning or stinging upon instillation in the eye (greater than experienced with other ophthalmic solutions, possibly related to the moderate pH of 5 to 6.5) and a bitter taste. Asthma, conjunctivitis, dyspnea, eye pain, fatigue, influenza-like symptoms, pharyngitis, pruritus, rhinitis, and temporary blurring are other reported adverse effects (some of these effects were indistinguishable from the disease being treated).[2]

Dosages
Allergic conjunctivitis (extra-label): 1 drop to the affected eye(s) 2 times daily

Monitoring
- Clinical efficacy. Resolution of pruritus and conjunctivitis

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medicine in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use if the color changes, becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store upright between 2°C and 25°C (36°F-77°F) away from moisture and sunlight.

Compatibility/Compounding Considerations
Azelastine ophthalmic preparations should not be mixed directly (in vitro) with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Azelastine HCl 0.05% Ophthalmic Solution (containing 0.5 mg azelastine hydrochloride; disodium edetate dehydrate; hypromellose; sorbitol solution; NaOH; water for injection; benzalkonium chloride

0.125 mg; pH of ≈5 to 6.5; osmolarity of ≈271 – 312 mOsm/kg), 6 mL in a sterile ophthalmic dropper bottle; generic; (Rx)

Azithromycin Ophthalmic

(uh-***zith***-roe-***mye***-sin) *Azasite®*

Macrolide Antibiotic

For systemic use, refer to ***Azithromycin***

Prescriber Highlights

- ► Used to treat ocular surface bacterial infections
- ► May cause reversible phospholipid accumulation in the cornea
- ► Prolonged use of antibiotic preparations may result in overgrowth of nonsusceptible organisms, including fungi.

Uses/Indications

Azithromycin ophthalmic solution is used to treat susceptible strains of *Haemophilus* spp, *Streptococcus* spp, and *Staphylococcus* spp. In vitro efficacy against some *Chlamydia* spp and *Mycoplasma* spp has also been reported.[1] Reports of clinical efficacy and/or toxicity/tolerability of azithromycin ophthalmic in animals are not available.

The World Health Organization (WHO) has designated azithromycin as a Critically Important, Highest Priority antimicrobial for human medicine.[2]

Pharmacology/Actions

Azithromycin is a bacteriostatic macrolide antibiotic that binds to the 50S ribosomal subunit of susceptible microorganisms and interferes with microbial protein synthesis.

Contraindications/Precautions/Warnings

Azithromycin ophthalmic solution is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Azithromycin ophthalmic solution is indicated for topical ophthalmic use only; it should not be administered systemically, injected subconjunctivally, or introduced directly into the anterior chamber of the eye.[1]

Adverse Effects

Adverse effects reported in humans include burning, stinging, and irritation on application. Systemic azithromycin has also caused phospholipidosis (intracellular phospholipid accumulation) in dogs, mice, and rats, and cytoplasmic microvacuolation of the cornea was observed in rabbits following ocular administration, which resolved when the medication was discontinued.[1]

Dosages

Bacterial conjunctivitis (extra-label): 1 drop to the affected eye(s) 2 times daily the first 2 days, followed by once daily for 5 days

Monitoring

- Clinical efficacy: resolution of bacterial conjunctivitis

Client Information

- Give this medicine exactly as your veterinarian has prescribed.
- Wash your hands before applying this medicine to your animal's eye(s).
- Be sure you understand how to give this medicine to your animal to avoid contamination of the medicine, which could worsen the eye condition.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Keep the cap on the medicine tightly closed when it is not in use.
- Store this medicine in the refrigerator. After opening, the medicine can be stored at room temperature. Discard the medicine 14 days after opening or if if the color of the solution changes, if it becomes cloudy, or if there are particles.

Storage/Stability

Store this product in the refrigerator (2°C-8°C [36°F-46°F]) away from moisture and sunlight; do not freeze. Discard this product 14 days after opening.

Compatibility/Compounding Considerations

Azithromycin ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Azithromycin 1% Ophthalmic Solution (containing azithromycin 10 mg [1%]; mannitol; citric acid; sodium chloride; poloxamer 407; polycarbophil; edetate disodium; water for injection; NaOH to adjust pH), 2.5 mL in a sterile ophthalmic dropper bottle; *Azasite®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Benoxinate Ophthalmic
Oxybuprocaine Ophthalmic

(bin-***ak***-sin-ate) *Altafluor®, Fluress®, Flurox®*

Topical Ocular Anesthetic

Prescriber Highlights

- ► Rapid-acting topical anesthetic used for ocular diagnostic procedures
- ► Should never be prescribed for therapeutic administration
- ► Only available in combinations with the vital dye fluorescein sodium
- ► Chronic use results in tear film instability and corneal epithelial and stromal damage, which may progress to vision loss.
- ► Less burning, stinging, and chemosis than tetracaine

Uses/Indications

Like other topical anesthetic agents, benoxinate is indicated for use in ophthalmic diagnostic procedures, including measurement of intraocular pressure (tonometry), ocular ultrasonography, gonioscopy, and corneal and conjunctival sampling for cytology and culture. Benoxinate is also indicated for therapeutic procedures in the hospital, including removing foreign bodies and sutures from the cornea, eyelid and conjunctival surgery, corneal grafting procedures, and cataract extraction. It is only available in ophthalmic solutions combined with the vital dye fluorescein. In dogs, benoxinate causes fewer adverse reactions (burning, stinging, and chemosis) than tetracaine.[1,2] Benoxinate has demonstrated comparable corneal anesthesia to that achieved by topical proparacaine in normal horses and donkeys.[3]

Pharmacology/Actions

Benoxinate induces local anesthesia by inhibiting neuronal depolarization, thus preventing the generation of an action potential. The action occurs due to the binding of the local anesthetic molecule to the intracellular portion of the voltage-gated sodium channel within the neuron, thus inhibiting the intracellular movement of sodium. Variations in the structure of different local anesthetics influence their relative potencies; however, all local anesthetics have decreased efficacy in the acidic environment of inflammation, whereas alkaline environments improve intracellular penetration, thus increasing efficacy. The duration of action is dose- and species-dependent, with a total duration of corneal anesthesia following a single drop of 55

minutes in dogs and 45 minutes in cats.[1,2]

Contraindications/Precautions/Warnings
Benoxinate is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. It should never be prescribed as an ocular analgesic as prolonged use of a topical ocular anesthetic will produce significant corneal epithelial and stromal disease, as well as tear film instability, and may result in loss of vision.[4]

Adverse Effects
Benoxinate is usually well-tolerated, but local irritation (conjunctival redness, lacrimation, or squinting) may occur several hours after administration. These signs occur less frequently with benoxinate than with tetracaine.[3] Although patients that are sensitive to other local anesthetics may be less likely to react to benoxinate, local or systemic sensitivity may still occur and rarely manifest as a pseudoallergic (anaphylactoid) reaction mimicking an IgE-mediated vasodilatory event. Cardiovascular, respiratory, and CNS depressant effects that may result from local anesthetics are extremely rare with appropriate use of topical local anesthetics. However, care should be exercised when administering to small veterinary patients (ie, puppies, kittens, "pocket pets") or those with pathways that may increase absorption (ie, amphibians). Its use as a therapeutic analgesic leads to superficial punctate keratitis, which may advance to diffuse necrotizing keratitis, severe infiltrative keratitis, persistent epithelial defects, or damage to Descemet's membrane.[4]

Dosages
Ophthalmic procedures requiring local anesthesia (extra-label): 1 – 2 drops to the target eye(s) prior to examination or performing procedure. May repeat adding 1 drop every 5 to 10 minutes for 2 to 3 additional times. With further applications, the duration of corneal anesthesia can be extended to 55 minutes in dogs. Additional doses should be avoided in small patients (ie, puppies, kittens, "pocket pets").

Monitoring
- Onset of action as indicated by awake patient, permitting diagnostic procedures to be performed
- Onset of action as indicated by a reduction in anesthetic requirements when administered pre- and intra-operatively
- Damage to corneal epithelium indicated by a positive fluorescein stain test

Client Information
- Animal owners must not administer benoxinate in the home. It is reserved for diagnostic procedures at veterinary clinics.

Storage/Stability
Store the product in the refrigerator (2°C-8°C [36°F-46°F]). Once opened, the medication can be stored at room temperature for up to 1 month.[5] Keep this product away from moisture and sunlight; do not freeze.

Discard this medication if the color of the solution changes, if it becomes cloudy, or if it develops particles.

Compatibility/Compounding Considerations
Benoxinate ophthalmic preparations should not be mixed directly (in vitro) with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Benoxinate HCl 0.4% and Fluorescein Sodium 0.25% (containing fluorescein sodium 2.5 mg; benoxinate hydrochloride 4 mg; boric acid; povidone; purified water; HCl to adjust pH to 4.3 to 5.3; chlorobutanol 1%); 5 mL in sterile ophthalmic dropper bottles; *Altaflu-or*®, *Fluress*®, *Flurox*®; (Rx). No benoxinate ophthalmic products have been approved by the US FDA.

For the complete list of references, see **wiley.com/go/budde/plumb**

Bepotastine Ophthalmic
(be-po-***tas***-teen) *Bepreve*®

Antihistamine

Prescriber Highlights
- ► H_1 receptor antagonist used in the management of allergic conjunctivitis

Uses/Indications
Bepotastine is used to relieve pruritus caused by allergic conjunctivitis. The efficacy and safety of topical bepotastine has not been evaluated in veterinary species.

Pharmacology/Actions
Bepotastine is a direct histamine-1 (H_1) antagonist and mast cell stabilizer, with inhibitory effects on other inflammatory mediators, such as leukotrienes and eosinophils. The onset of action (control of itching) in humans is 15 minutes following instillation, with a duration of effect up to 8 hours.[1]

Contraindications/Precautions/Warnings
Bepotastine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Use it with caution in pregnant or nursing patients.[2]

Adverse Effects
Adverse effects reported in humans include transient burning or stinging upon instillation in the eye, nasal irritation, and a bad taste in the mouth.[1]

Dosages
Allergic conjunctivitis (extra-label): 1 drop to the affected eye(s) 2 times daily

Monitoring
- Clinical efficacy: resolution of pruritus and conjunctivitis

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Bepotastine ophthalmic preparations should not be mixed directly (in vitro) with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Bepotastine Besilate 1.5% Ophthalmic solution (containing bepotastine besilate 15 mg; benzalkonium chloride 0.005%; monobasic so-

dium phosphate dehydrate; NaCl; NaOH to adjust pH to 6.8; water for injection, USP, with an osmolality of 290 mOsm/kg), 5 mL and 10 mL in sterile ophthalmic dropper bottles; *Bepreve*®; generic (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Besifloxacin Ophthalmic

(be-si-***flocks***-a sin) *Besivance*®

Fourth-Generation Fluoroquinolone Antibiotic

Prescriber Highlights

- ► Available in ophthalmic formulation only
- ► Used to treat bacterial conjunctivitis or keratitis
- ► Physically incompatible with many drugs; therefore, should not be directly mixed with other ophthalmic medications
- ► As with other topical antibiotics, prolonged use may result in overgrowth of nonsusceptible organisms.

Uses/Indications

Besifloxacin ophthalmic is used to treat bacterial conjunctivitis and keratitis. It is generally effective against gram-negative, gram-positive, and anaerobic organisms, particularly *Staphylococcus* spp, *Streptococcus* spp, *Haemophilus* spp, and *Pseudomonas aeruginosa*.

Pharmacology/Actions

Besifloxacin is a fourth-generation fluoroquinolone antibiotic that acts, via inhibition of both topoisomerase II (DNA gyrase) and topoisomerase IV, to impair bacterial DNA synthesis. Inhibition of both enzymes decreases the development of resistance to this class of fluoroquinolones in general, and organisms have demonstrated even lower resistance to besifloxacin due to this balanced inhibition.[1] Besifloxacin achieves superior aqueous humor concentrations in normal dogs relative to gatifloxacin and moxifloxacin (other fourth-generation fluoroquinolones)[2]; however, other studies have demonstrated effective ocular surface concentrations of besifloxacin following topical administration, with lesser aqueous humor concentrations.[1] The currently available formulation of besifloxacin is formulated with a mucoadhesive polymer that increases contact time with the ocular surface, which is favorable for concentration-dependent fluoroquinolone antibiotics.[1,3]

Contraindications/Precautions/Warnings

Besifloxacin is contraindicated in patients with a history of hypersensitivity to besifloxacin, other fluoroquinolones, or any component of the formulation. For topical ophthalmic use only, not for injection subconjunctivally or into the anterior chamber of the eye.[3] Fluoroquinolone-induced retinal toxicity in domestic cats has not been demonstrated with this product.

Adverse Effects

Adverse effects reported in humans or animals include blurred vision, tearing, eye pain, conjunctival redness, itching, and a bad taste in the mouth. Temporary punctate keratitis, which resolves with discontinuation of medication, has also been reported rarely in humans.[4]

Dosages

Conjunctivitis (extra-label): 1 drop to the affected eye(s) 3 times daily

Keratitis (extra-label): 1 drop to the affected eye every 2 to 8 hours

Monitoring

- Clinical efficacy. Corneal cytology with culture and susceptibility testing to evaluate for the persistence of bacteria, and evaluation for clinical signs suggestive of continued infection

Client Information

- Give this medicine to your animal as directed by your veterinarian. Be sure you understand how to safely give to your animal.
- Invert the bottle and shake once before use. Do not give your animal this medicine if the color changes, if it becomes cloudy, or if particles are seen in the solution.
- Crystals may develop on the surface of the eye during treatment but will not cause harm.
- Do not mix this medicine with other eye medications.
- If you are giving your animal other eye medications, wait 5 minutes after applying this medicine before applying any other medications to the eye.
- Do not freeze this medicine. Store this medicine at room temperature, away from light and moisture.

Storage/Stability

Store this product at controlled room temperature 20°C to 25°C (68°F-77°F) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Fluoroquinolone antibiotics interact with many other drugs, including those containing cations (eg, iron, aluminum, magnesium, calcium). Besifloxacin should not be mixed with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Besifloxacin 0.6% (6 mg/mL) Ophthalmic Suspension (containing besifloxacin 0.6%; benzalkonium chloride 0.01%; polycarbophil; mannitol; poloxamer 407; NaCl; edetate disodium dehydrate; NaOH; water for injection, with an osmolality of ≈290 mOsm/kg), 5 mL in a sterile ophthalmic dropper bottle; *Besivance*®; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Betaxolol Ophthalmic

(be-***tax***-uh-lol) *Betoptic*®, *Betoptic S*®

Beta-1-Selective Beta-Adrenergic Blocker

Prescriber Highlights

- ► Beta-blocker that decreases intraocular pressure (IOP) as a treatment for glaucoma
- ► More effective reduction in IOP using 0.5% solution relative to 0.25% solutions in veterinary patients; however, increased risk for adverse effects exists when using the higher concentration
- ► Delays onset of glaucoma in the normal eye of dogs with unilateral glaucoma
- ► Use with caution in asthmatic patients because of the potential to induce bronchospasm.

Uses/Indications

Betaxolol is a beta-1-selective beta-blocker used to reduce intraocular pressure (IOP) in primary glaucoma and as prophylaxis to prevent glaucoma in the normal eye of animals with unilateral glaucoma.[1] In combination with tafluprost, betaxolol leads to a greater reduction of IOP in normal dogs compared to timolol.[2]

Pharmacology/Actions

Betaxolol works through the blockade of the beta-receptors in the ciliary body epithelium to reduce intraocular pressure (IOP) by decreasing aqueous humor production. Several mechanisms have been postulated for this effect, including beta-blockade, particularly beta-2 receptors, reducing norepinephrine-induced tonic sympathetic stimulation, leading to decreased activation of cAMP in the

ciliary body; inhibition of Na+K+ATPase activity; or vasoactive mechanisms on the iris and ciliary body. Betaxolol also inhibits glutamine-induced increases in intracellular calcium and sodium, thereby providing a potential protective effect against ischemic insult to the retina.[3] Because of betaxolol's beta-1-selective activity, its hypotensive effect may be less than that of nonselective beta-blockers, as beta-2 blockade is of greater importance to aqueous humor production.

Contraindications/Precautions/Warnings

Betaxolol is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Betaxolol should be used carefully in patients with heart block, bradycardia, heart failure, asthma, chronic bronchitis, or other cardiopulmonary conditions, although systemic cardiopulmonary adverse effects are not likely with ocular use of betaxolol. Beta-blockers should be used with caution in patients with diabetes mellitus, as these drugs may mask signs of acute hypoglycemia. Beta-blockers should be used with caution in patients with hyperthyroidism, as these drugs may mask indications of this condition. Abrupt discontinuation of beta blockers should be avoided.

Adverse Effects

Adverse effects reported in humans or animals include transient burning, stinging, and irritation upon application to the eye, as well as keratitis, anisocoria, and photophobia. Bradycardia, heart block, congestive heart failure, pulmonary distress, insomnia, dizziness, headaches, lethargy, and depression have been reported in humans. Other topically applied beta-blockers produce significant reductions in heart rate in healthy cats.[4]

Dosages

Glaucoma (extra-label): 1 drop to the affected eye(s) twice daily

Monitoring

- Clinical efficacy
- Monitor intraocular pressure (IOP)
- Observe asthmatic and diabetic patients for respiratory difficulty or acute hypoglycemia, respectively.

Client Information

- Use this medication as directed by your veterinarian.
- Suspension formulations must be shaken well before using.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store this product in the refrigerator (2°C-8°C [36°F-46°F]) or at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Betaxolol ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Betaxolol HCl 0.5% Ophthalmic Solution (containing 5.6 mg betaxolol HCl equivalent to 5 mg betaxolol; benzalkonium chloride 0.01%; edetate disodium; NaCl, HCl, and/or NaOH to adjust pH; purified water) in 2.5 mL, 5 mL, 10 mL, and 15 mL sterile ophthalmic dropper bottles; *Betoptic®*, generic; (Rx)

Betaxolol HCl 0.25% ophthalmic solution (containing betaxolol HCl 2.8 mg equivalent to 2.5 mg betaxolol; benzalkonium chloride 0.01%; mannitol; poly (styrene-divinyl benzene); edetate disodium; NaOH and/or HCl to adjust pH; purified water) in sterile 10 mL and 15 mL ophthalmic dropper bottles; *Betoptic®-S*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Bimatoprost Ophthalmic

(bi-***mat***-oh-prost) *Lumigan®, Latisse®, Durysta®*

Prostaglandin Analogue Anti-Glaucoma Agent

Prescriber Highlights

- ► Used to decrease intraocular pressure (IOP) in patients with primary glaucoma or ocular hypertension
- ► Not effective for feline glaucoma, and unlikely to be effective for equine glaucoma
- ► Do not use if intraocular inflammation is present, as the drug may worsen the inflammation or lead to pupillary block glaucoma
- ► Twice-daily dosing results in less fluctuation of IOP.
- ► Lower concentration of benzalkonium chloride than latanoprost or travoprost; therefore, bimatoprost causes less ocular discomfort on administration
- ► May increase brown pigment, resulting in discoloration of light-colored irises and increased eyelash growth

Uses/Indications

Bimatoprost is used to lower intraocular pressure (IOP) in the management of glaucoma in dogs. It is indicated as a treatment for primary glaucoma; however, secondary glaucomas (caused by uveitis, lens luxation, or intraocular tumor) are not appropriately treated with bimatoprost. Due to differences in intraocular receptors, bimatoprost is ineffective in lowering the IOP in cats, although it does produce miosis.[1,2] Although once-daily administration is indicated in humans, twice-daily administration has been demonstrated to more consistently lower IOP in dogs.[3] Significant miosis also occurs following administration.[3] An intracameral sustained-release bimatoprost implant has demonstrated increased IOP-lowering efficacy in comparison with topical administration of varied concentrations of bimatoprost in normotensive dogs.[4]

Pharmacology/Actions

Bimatoprost, a prostaglandin analogue, is a synthetic structural analogue of prostaglandin derived from a fatty acid precursor, anandamide. It selectively mimics the effects of naturally occurring prostamides. Bimatoprost is believed to lower intraocular pressure (IOP) by increasing the outflow of aqueous humor through both the trabecular meshwork and uveoscleral routes.[5] In humans, the onset of action is in 4 hours, with a total duration of 8 to 12 hours.

Contraindications/Precautions/Warnings

Bimatoprost is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Bimatoprost should be used with caution in the presence of anterior uveitis and secondary glaucoma, particularly in cases already exhibiting significant miosis, as this treatment may exacerbate miosis, promote synechiae formation, and worsen glaucoma. Bimatoprost should also be used with caution in dogs with primary anterior lens luxation, as the miosis that results may trap the lens and/or vitreous within the

pupillary aperture, thus creating pupillary block glaucoma. Bimatoprost is not contraindicated in dogs with secondary posterior lens luxation, as the miosis may (favorably) trap the lens in the posterior segment.

Adverse Effects
Adverse effects reported in humans or animals include stinging, burning, erythema (conjunctival hyperemia), and irritation on administration. Macular edema has been reported in humans using bimatoprost. Bimatoprost may cause increased eyelash growth, may worsen intraocular inflammation through prostaglandin-mediated mechanism, and/or cause darkening of the iris through direct stimulation of iris melanocytes.

Dosages
Glaucoma (extra-label):

a. Solution: Initially, 1 drop to the affected eye(s) once daily in the evening; increase to twice daily as glaucoma progresses. Twice-daily administration of bimatoprost may be more effective in dogs.
b. Sustained-release implant: Intracameral injection of the sustained-release implant is performed using the associated ophthalmic drug delivery system. Repeat implantation should not be performed in an eye that has received a prior implant.

Monitoring
- Clinical efficacy measured through sustained reduction of intraocular pressure (IOP)

Client Information
- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store solution in the refrigerator or at controlled room temperature (2°C-25°C [36°F-77°F]) away from moisture and sunlight; do not freeze.

Store implant in the refrigerator (2°C-8°C [36°F-46°F]).

Compatibility/Compounding Considerations
Bimatoprost ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Bimatoprost 0.01% Ophthalmic Solution (containing bimatoprost 0.1 mg/mL; benzalkonium chloride 0.02%; NaCl; sodium phosphate, dibasic; citric acid; purified water; NaOH and/or HCl to adjust pH to 6.8 to 7.8, with an osmolality of 290 mOsm/kg) in sterile 2.5 mL, 5 mL, and 7.5 mL ophthalmic dropper bottles; *Lumigan®*, generic; (Rx)

Bimatoprost 0.03% Ophthalmic Solution (containing bimatoprost 0.3 mg; benzalkonium chloride 0.005%; NaCl; sodium phosphate, dibasic; citric acid; purified water; NaOH and/or HCl to adjust pH to 6.8 to 7.8, with an osmolality of 290 mOsm/kg) in sterile 2.5 mL, 5 mL, and 7.5 mL ophthalmic dropper bottles; *Latisse®*, generic; (Rx). **NOTE:** *Latisse®* is approved for topical use only for inducing eyelash growth and should not be used in the eye.

Bimatoprost 10 µg Ophthalmic Implant (containing 10 µg bimatoprost in a single-use applicator that is packaged in a sealed foil pouch containing desiccant, NDC 0023-9652-01); *Durysta®* (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Brimonidine Ophthalmic

(bri-***moe***-ni-deen) *Alphagan P®, Combigan®, Qoliana®, Simbrinza®*

Alpha-Adrenergic Agonist; Anti-Glaucoma Agent

Prescriber Highlights
- ► Used to decrease intraocular pressure (IOP) in patients with glaucoma
- ► Produces less severe adverse effects than apraclonidine, but it is not a first-line anti-glaucoma agent in veterinary species
- ► Greenish-yellow color of the solution is a characteristic and not a sign of degradation or contamination

Uses/Indications
Brimonidine may be used to treat elevated intraocular pressure (IOP) in patients with glaucoma or ocular hypertension. Its use in glaucomatous beagles 2 to 3 times daily has demonstrated no consistent clinical effect.[1] Administration of brimonidine to normotensive horses, with or without timolol, has not shown any clinically significant effect.[2]

Pharmacology/Actions
Brimonidine is a relatively selective alpha-2-adrenergic agonist. Activation of presynaptic alpha-2 receptors inhibits norepinephrine release, and activation of postsynaptic alpha-2 receptors on the nonpigmented ciliary body epithelial cells decreases intracellular cAMP, both of which result in decreased aqueous humor production and decreased intraocular pressure (IOP). Additionally, aqueous humor outflow may be increased by a direct effect on uveoscleral outflow, as well as structural alterations to the conventional outflow tract that decrease resistance to outflow.

Contraindications/Precautions/Warnings
Brimonidine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Brimonidine should be used cautiously, if at all, in patients with vascular insufficiency syndromes (eg, laminitis, cerebral, or coronary vascular insufficiency). Concomitant use of monoamine oxidase inhibitors (MAOIs; eg, amitraz, selegiline) may potentiate the risk for systemic hypotension. Instruct pet owners to keep it out of reach of household animals, as ingestion of brimonidine ophthalmic solution has caused serious cardiovascular toxicities.[3] Overdoses of brimonidine can be treated with atipamezole, yohimbine, and other alpha-2 antagonists. Caution should be exercised if brimonidine is used in conjunction with beta-blockers (ophthalmic and systemic), antihypertensives, and/or cardiac glycosides. When brimonidine is used in humans, the clinical effect diminishes over time and requires careful monitoring.

Adverse Effects
Adverse effects reported in humans or animals are numerous and include (but are not limited to) oral dryness, allergic conjunctivitis, conjunctival hyperemia, ocular pruritus, burning, stinging, foreign body sensation, irritation, eyelid and conjunctival edema, dizziness, muscular pain, and hypertension. Use of brimonidine in dogs is associated with miosis and bradycardia.[4] Administration of brimonidine in cats consistently results in vomiting, which may be ameliorated by premedication with oral maripotant.[5] Brimonidine in cats also produces dose-dependent sedation, bradycardia, and hypotension.[6]

Dosages
Glaucoma (extra-label): 1 drop to the affected eye(s) 2 to 3 times daily

Monitoring
- Clinical efficacy measured through continued control of intraocular pressure (IOP)
- Baseline and periodic heart rate and blood pressure, particularly in dogs and cats

Client Information
- Use this medicine as directed by your veterinarian.
- Keep this medicine out of reach of household animals and children, as ingestion of brimonidine ophthalmic solution can cause serious heart problems.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Brimonidine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Brimonidine Tartrate 0.1% Ophthalmic Solution (containing brimonidine tartrate 0.1%; boric acid; calcium chloride; magnesium chloride; potassium chloride; purified water; PURITE® 0.005% as preservative; sodium borate; sodium carboxymethylcellulose; NaCl; HCl and/or NaOH to adjust pH to 7.7), 5 mL, 10 mL, or 15 mL in sterile ophthalmic dropper bottles; *Alphagan-P®*; (Rx)

Brimonidine Tartrate 0.15% Ophthalmic Solution (containing brimonidine tartrate 0.15%; boric acid; calcium chloride; magnesium chloride; potassium chloride; purified water; PURITE® 0.005% as preservative; sodium borate; sodium carboxymethylcellulose; NaCl; HCl and/or NaOH to adjust pH to 7.7), 5 mL, 10 mL, or 15 mL in sterile ophthalmic dropper bottles; *Alphagan-P®*; (Rx)

Brimonidine Tartrate 0.15% Ophthalmic Solution (containing brimonidine tartrate 1.5 mg/mL; POLYQUAD® (polyquaternium-1) 0.01 mg/mL; povidone; boric acid; sodium borate; calcium chloride; magnesium chloride; potassium chloride; mannitol; sodium chloride; purified water; HCl and/or NaOH to adjust pH), 5 mL, 10 mL, or 15 mL in sterile ophthalmic dropper bottles; *Qoliana®*; (Rx)

Brimonidine Tartrate 0.2% Ophthalmic Solution (containing brimonidine tartrate 0.2%; benzalkonium chloride 0.005%; polyvinyl alcohol; NaCl; citric acid; purified water; HCl and/or NaOH to adjust pH to 5.6 to 6.6, with an osmolality of 280 – 330 mOsm/kg) in a 5 mL, 10 mL, and 15 mL dropper bottle; generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:
Brimonidine Tartrate 0.2% and Timolol Maleate 0.5% Ophthalmic Solution (containing brimonidine tartrate 0.2%; timolol 0.5%; benzalkonium chloride 0.005%; purified water; sodium phosphate, dibasic; sodium phosphate, monobasic; HCl and/or NaOH to adjust pH to 6.5 to 7.3, with an osmolality of 280 – 330 mOsm/kg), 5 mL, 10 mL, or 15 mL in sterile ophthalmic dropper bottles; *Combigan®*, generic; (Rx)

Brimonidine Tartrate 0.2% and Brinzolamide 1% Ophthalmic Suspension (containing brinzolamide 10 mg; brimonidine tartrate 2 mg, equivalent to 1.32 mg free base; benzalkonium chloride 0.03 mg; propylene glycol; carbomer 974P; boric acid; mannitol; NaCl; tyloxapol; purified water; HCl and/or NaOH to adjust pH), 8 mL in sterile ophthalmic dropper bottle; *Simbrinza®*; (Rx)

Brinzolamide Ophthalmic

(bryn-***zoe***-la-mide) *Azopt®, Simbrinza®*

Carbonic Anhydrase Inhibitor Anti-Glaucoma Agent

Prescriber Highlights
- ► Decreases intraocular pressure (IOP) by reducing the production of aqueous humor
- ► May be better tolerated than dorzolamide because of less acidic pH
- ► Sulfonamide derivative; caregivers with sulfa allergies should avoid direct contact with the medicine.

Uses/Indications
Brinzolamide is used to decrease intraocular pressure (IOP) in glaucoma and ocular hypertension. It may be used in cases of primary glaucoma or secondary glaucoma (caused by uveitis, lens luxation, or intraocular tumors) in dogs, cats, and horses. Brinzolamide effectively lowers the IOP in normal horses but does not decrease the IOP in normal cats.[1,2] Efficacy of prophylactic brinzolamide administration for preventing manifestation of primary glaucoma in unaffected eyes of dogs with contralateral primary glaucoma has not been demonstrated.[3]

Pharmacology/Actions
Carbonic anhydrase (CA) is an enzyme found in many body tissues, including the eye. CA inhibitors reduce the formation of hydrogen and bicarbonate ions from carbon dioxide and water by noncompetitive, reversible inhibition of the enzyme CA, thereby reducing the availability of these ions for active transport into secretions. In humans, CA exists as a number of isoenzymes, with CA-II being the most relevant to glaucoma management. Inhibition of CA in the ciliary processes of the eye decreases aqueous humor secretion, presumably by slowing the formation of bicarbonate ions with subsequent reduction in sodium and fluid transport, which results in a reduction in intraocular pressure (IOP).[4] Brinzolamide is more lipophilic than dorzolamide, resulting in increased intraocular concentrations following topical administration.[5]

Contraindications/Precautions/Warnings
Brinzolamide is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation or drugs like it, such as sulfonamides. Caregivers with sulfonamide allergies should use caution when applying brinzolamide.

Adverse Effects
Adverse effects reported in humans or animals include stinging, burning, and irritation upon application. Corneal edema may occur in patients with low corneal endothelial cell counts. Humans experience headaches and a bitter taste in the mouth after brinzolamide administration. It is possible that animals experience these adverse effects. Carbonic anhydrase (CA) inhibitors, including brinzolamide, have been implicated in the development of significant ulcerative and nonulcerative keratitis following long-term administration.[6]

Dosages
Glaucoma (extra-label): 1 drop to the affected eye(s) 2 to 3 times daily

Monitoring
- Clinical efficacy
- Confirm maintenance of intraocular pressure (IOP) within the normal range for the species being treated
- Monitor for corneal edema

Client Information
- Use this medication as directed by your veterinarian.
- Shake this medication well before using.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes.

Storage/Stability
Store this product in the refrigerator or at controlled room temperature (4°C-30°C [39°F-86°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Brinzolamide ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Brinzolamide 1% Ophthalmic Suspension (containing brinzolamide 10 mg; benzalkonium chloride 0.01%; mannitol; carbomer 974P; tyloxapol; edetate disodium; NaCl; purified water; HCl and/or NaOH to adjust pH to 7.5; osmolality of 300 mOsm/kg), 10 mL or 15 mL in sterile ophthalmic dropper bottles; *Azopt®*; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:
Brinzolamide 1% and Brimonidine Tartrate 0.2% Ophthalmic Suspension (containing brinzolamide 10 mg; brimonidine tartrate 2 mg, equivalent to 1.32 mg as brimonidine free base; benzalkonium chloride 0.03 mg; propylene glycol; carbomer 974P; boric acid; mannitol; sodium chloride; tyloxapol; purified water; HCl and/or NaOH to adjust pH), 8 mL in sterile 10 mL ophthalmic dropper bottle; *Simbrinza®*; (Rx)

Bromfenac Ophthalmic

(***brome***-fen-ak) *Bromsite®, Prolensa®*

Nonsteroidal Anti-Inflammatory Drug (NSAID)

Prescriber Highlights
- ► Used to control anterior segment inflammation
- ► Longer duration of action than diclofenac
- ► May delay ocular wound healing and increase risk for intraocular bleeding

Uses/Indications
Bromfenac is indicated for controlling anterior segment inflammation (eg, conjunctivitis, keratitis, anterior uveitis) and for providing analgesia following surgical removal of cataracts. In a prospective study evaluating inflammation, postoperative ocular hypertension, and posterior capsular opacification (PCO) in dogs following cataract surgery, the effectiveness of prednisolone acetate was compared with artificial lens implants that were impregnated with celecoxib (NSAID) or topically applied bromfenac. Over the long-term follow-up period of 56 weeks, bromfenac was comparable to prednisolone acetate in controlling inflammation and did not lead to an increased incidence of ocular hypertension, and it effectively managed PCO.[1] In contrast, bromfenac was associated with an increased incidence of elevated intraocular pressure (IOP) relative to flurbiprofen in dogs 6 weeks following surgical cataract removal.[2]

Pharmacology/Actions
Bromfenac is an NSAID that blocks prostaglandin synthesis by inhibiting cyclooxygenase 1 and 2. Prostaglandins mediate many adverse effects that occur because of intraocular inflammation, including disruption of the blood-aqueous humor barrier, vasodilation, increased vascular permeability, leukocytosis, and increased intraocular pressure (IOP).[3] Blocking prostaglandin production, therefore, minimizes the adverse short- and long-term effects of intraocular inflammation.

Contraindications/Precautions/Warnings
Bromfenac is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. The potential for cross-sensitivity to acetylsalicylic acid, phenylacetic acid derivatives, and other NSAIDs exists. Topical NSAIDs may result in corneal epithelial breakdown and corneal thinning, erosion, or ulceration.[3] Topical NSAIDs may slow or delay corneal wound healing. As topical corticosteroids are also known to slow or delay healing, concomitant use of topical NSAIDs and topical steroids may increase the potential for healing problems. Because of interference with thrombocyte aggregation, ophthalmic NSAIDs may cause increased bleeding of ocular tissues (including hyphema) in conjunction with ocular surgery. It is recommended that bromfenac ophthalmic solution be used with caution in patients with known bleeding tendencies or those receiving other medications that may prolong bleeding times.[3]

Adverse Effects
Adverse effects associated with bromfenac that have been reported in humans or animals include burning, stinging, and irritation upon application; conjunctival hyperemia; risk for ocular bleeding; and delayed corneal wound healing.

Dosages
Anterior segment inflammation (extra-label): 1 drop to the affected eye(s) every 8 hours initially, then reduced to lowest effective dose

Postoperative ocular analgesia (extra-label): 1 drop to the affected eye(s) every 6 to 8 hours as needed to control pain

Monitoring
- Clinical efficacy through evidence of efficacious analgesia and control of intraocular inflammation

Client Information
- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication at room temperature away from moisture and sunlight; do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

- Discard compounded gels by the discard date indicated by the compounding pharmacist.

Storage/Stability
Store this product at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Bromfenac ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Bromfenac 0.09% Ophthalmic Solution (containing bromfenac sodium sesquihydrate 0.1035% equivalent to 0.09% bromfenac-free acid; benzalkonium chloride 0.05 mg/mL; boric acid; polysorbate 80; povidone; sodium borate; sodium sulfite anhydrous; NaOH to adjust pH; water for injection), in sterile 2.5 mL and 5 mL ophthalmic dropper bottle; generic; (Rx)

Bromfenac 0.07% Ophthalmic Solution (containing bromfenac sodium hydrate 0.805 mg; benzalkonium chloride 0.005%; boric acid; edetate disodium; povidone; sodium borate; sodium sulfite; tyloxapol; NaOH to adjust pH; water for injection), in sterile 1.6 mL or 3 mL ophthalmic dropper bottle; *Prolensa®*; (Rx)

Bromfenac 0.075% Ophthalmic Solution (containing bromfenac sodium sesquihydrate 0.81 mg equivalent to bromfenac-free acid 0.76 mg; boric acid; sodium borate; citric acid; sodium citrate; poloxamer 407; polycarbophil; NaCl; edetate disodium; water for injection; NaOH to adjust pH; benzalkonium chloride 0.05 mg/0.005%), in sterile 5 mL ophthalmic dropper bottle; *Bromsite®*; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Carteolol Ophthalmic
(kar-***tay***-uh-lol)
Nonselective Beta-Blocker

Prescriber Highlights
- ► Nonselective (beta-1 and beta-2) beta-blocker that decreases aqueous humor production to decrease intraocular pressure (IOP) as a treatment for glaucoma
- ► May delay onset of glaucoma in the normal eye of dogs with unilateral glaucoma
- ► Use with caution in asthmatic patients due to the potential to induce bronchospasm

Uses/Indications
Carteolol may be used to reduce intraocular pressure (IOP) in primary glaucoma and as prophylaxis to prevent glaucoma in the normal eye of animals with unilateral glaucoma. The evaluation of its efficacy in animals has not been performed.

Pharmacology/Actions
Carteolol is a nonselective beta-adrenergic blocking agent with associated intrinsic sympathomimetic activity and without significant membrane-stabilizing activity.[1] Blockade of ciliary body beta-receptors (particularly beta-2-receptors) reduces intraocular pressure (IOP) by decreasing aqueous humor production. Several mechanisms of action have been postulated for this effect, including beta-blockade (particularly beta-2-receptors) reducing norepinephrine-induced tonic sympathetic stimulation, which then leads to decreased activation of cAMP in the ciliary body; inhibition of Na+K+ATPase activity; or vasoactive mechanisms on the iris and ciliary body. Topically administered beta-blockers also inhibit glutamine-induced increases in intracellular calcium and sodium, thereby providing a potential protective effect against ischemic insult to the retina.[2]

Contraindications/Precautions/Warnings
Carteolol is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Carteolol should be used carefully in patients with heart block, bradycardia, heart failure, asthma, chronic bronchitis, or other cardiopulmonary conditions, although systemic cardiopulmonary adverse effects are not likely with ocular use of carteolol.

Beta-blockers should be used with caution in patients with diabetes mellitus, as these drugs may mask signs of acute hypoglycemia. Beta-blockers should also be used with caution in patients with hyperthyroidism, as these drugs may mask indications of this condition. Abrupt discontinuation of beta-blockers should be avoided.

Adverse Effects
Adverse effects reported in humans or animals include transient burning, stinging, and irritation upon application to the eye. Although not specifically evaluated, it is possible that carteolol could lead to reduction in heart rate following topical administration in veterinary species.[3]

Dosages
Glaucoma (extra-label): 1 drop to the affected eye(s) 2 times daily

Monitoring
- Clinical efficacy
- Monitor intraocular pressure (IOP)
- Observe asthmatic and diabetic patients for respiratory difficulty or acute hypoglycemia, respectively

Client Information
- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Carteolol ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Carteolol HCl 1% Ophthalmic Solution (containing carteolol HCl 10 mg; benzalkonium chloride 0.05 mg; NaCl; monobasic and dibasic sodium phosphate; NaOH and/or HCl to adjust pH to 6 to 8; purified water), in a 5 mL, 10 mL, and 15 mL dropper bottle; generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Chloramphenicol Ophthalmic

(klor-am-***fen***-uh-kol)

Broad-Spectrum Antibiotic

For systemic use, refer to ***Chloramphenicol***

Prescriber Highlights

- ► Used to provide antibacterial coverage in the presence of corneal ulcerations or therapeutic antibacterial coverage for susceptible ocular surface infections, particularly feline *Mycoplasma* spp or *Chlamydia* spp infections
- ► Chloramphenicol has caused acute toxicity and death in humans; instruct caregiver to wear gloves and avoid contact with this drug.
- ► Chloramphenicol ophthalmic preparations are no longer commercially available but may be compounded by a qualified compounding pharmacist.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies chloramphenicol as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Chloramphenicol is used for the treatment of surface ocular infections involving the conjunctiva and/or cornea caused by chloramphenicol-susceptible organisms.[1]

The World Health Organization (WHO) has designated chloramphenicol as a Highly Important antimicrobial for human medicine.[2] The Office International des Epizooties (OIE) has designated amphenicol as a Veterinary Critically Important Antimicrobial (VCIA) Agent in veterinary species.[3]

Pharmacology/Actions

Chloramphenicol is a broad-spectrum, bacteriostatic antibiotic that inhibits protein synthesis by interfering with the transfer of activated amino acids from soluble RNA to ribosomes, thus preventing protein elongation. It generally has good activity against gram-positive, gram-negative, and intracellular organisms, common to the ocular surface; the activity against *Pseudomonas* spp is consistently poor. Development of resistance to chloramphenicol is uncommon for *Staphylococcus* spp and *Streptococcus* spp.[4–7]

Chloramphenicol is found in measurable amounts in the aqueous humor following topical application to the eye.

Contraindications/Precautions/Warnings

Chloramphenicol is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Chloramphenicol may induce dose-dependent bone marrow suppression or idiosyncratic aplastic anemia, both of which have a low risk of occurring following topical ophthalmic administration.[8,9] Caregivers should be instructed to wear gloves and wash hands after handling this drug. Chloramphenicol is banned for use in food-producing animals.

The National Institute for Occupational Safety and Health (NIOSH) classifies chloramphenicol as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Adverse effects reported in animals include occasional burning or stinging on application. Bone marrow suppression and blood dyscrasias have been reported following the use of systemic chloramphenicol.

Dosages

Bacterial conjunctivitis (extra-label): ¼ – ½ inch strip or 1 drop in the affected eye(s) every 6 to 8 hours

Monitoring

- Cytology and culture to evaluate for the presence of bacteria
- Clinical resolution of signs related to ocular surface infection
- Baseline and periodic CBC to monitor for bone marrow suppression

Client Information

- Humans should avoid direct contact with this medicine. Wear gloves during administration and wash hands after handling this medicine.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper (or ointment) tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Keep cap tightly closed when not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Do not use if the color changes, becomes cloudy, or if there are particles in the solution.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Storage/Stability

Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Chloramphenicol should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Chloramphenicol was formerly available as a 0.5% ophthalmic solution or a 1% ointment but is no longer commercially available. A qualified compounding pharmacist may prepare it if needed.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Cidofovir Ophthalmic

(sye-***doe***-fo-veer)

Antiviral

Prescriber Highlights

- ► Used as an ophthalmic antiviral agent in cats with feline herpesvirus-1 (FHV-1)
- ► Less frequent administration and shorter treatment duration when compared to other ophthalmic antiviral agents
- ► Cidofovir has caused hypospermia and birth defects in humans and should not be used in animals intended for breeding.
- ► Not commercially available in an ophthalmic dosage form but can be compounded as a 0.5% ophthalmic solution
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies cidofovir as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Cidofovir is compounded into a 0.5% ophthalmic solution for the topical treatment of feline herpesvirus-1 (FHV-1) keratitis in cats. In vitro efficacy of cidofovir against FHV-1 is consistently high.[1,2]

Because cidofovir is effective when administered twice daily for 10 days,[3] it has a significant therapeutic advantage over other antiviral ophthalmic agents (eg, trifluridine, vidarabine, and idoxuridine) which must be administered 4 to 6 times daily for 2 to 3 weeks.

Cidofovir decreases viral shedding in dogs experimentally infected with ocular canine herpesvirus-1 infections; however, it causes local irritation and toxicity.[3] Although the efficacy of cidofovir has not been evaluated in horses for treatment of keratitis associated with equine herpesvirus-2, it has demonstrated mild in vitro efficacy versus other equine alpha-herpesviruses.

Pharmacology/Actions

Cidofovir suppresses viral replication by inhibiting the synthesis of viral DNA. Cidofovir diphosphate, the active intracellular metabolite, demonstrates much greater selectivity for viral, rather than human, DNA. Because cidofovir is incorporated into the growing DNA chain, it reduces the rate of viral DNA synthesis, thereby having a virustatic effect.

Contraindications/Precautions/Warnings

Cidofovir is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Do not use cidofovir in animals intended for breeding, as cidofovir has been shown to cause hypospermia and is mutagenic and teratogenic in humans. Following IV administration, cidofovir has caused death by irreversible nephrotoxicity[4]; do not use in animals with pre-existing renal impairment or concurrently with nephrotoxic drugs. Direct intraocular injection is contraindicated.[4]

The National Institute for Occupational Safety and Health (NIOSH) classifies cidofovir as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Adverse effects reported in humans or animals following topical administration include burning or stinging on application and nasolacrimal occlusion in rabbits and humans following prolonged (weeks) treatment. Severe adverse effects reported in humans following IV administration include nephrotoxicity (after even a single IV dose), neutropenia, metabolic acidosis, and uveitis/ocular hypotony. Although these reactions reported with IV administration have not been reported following ocular administration, nephrotoxicity is theoretically possible. Topical ocular administration of cidofovir to dogs has led to signs of irritation (eg, conjunctival pigmentation, blepharitis).[3]

Dosages

Feline herpesvirus-1 keratitis (extra-label): 1 drop to the affected eye(s) 2 times daily for 10 days[5]

Canine herpesvirus-1 ocular infections (extra-label): 1 drop to the affected eye(s) twice daily for 14 days[3]

Monitoring

- Clinical resolution of signs related to herpesvirus ocular infections (eg, corneal ulceration, corneal vascularization, conjunctivitis)
- Consider baseline and periodic renal chemistry panels

Client Information

- Humans should avoid direct contact with this drug. Wear gloves during administration and wash hands after each treatment is done.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper (or ointment) tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Keep cap tightly closed when this medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medications to the eye.
- Do not use if the color changes or becomes cloudy or if there are particles in the solution.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Storage/Stability

Store in the refrigerator (2°C-8°C [35.6°F-46.4°F]) away from moisture and sunlight; do not freeze.

The reported chemical stability of this solution is 180 days when stored in glass at 4°C (39.2°F), -20°C (-4°F), and -80°C (-112°F).[6] Storage times should be determined by the results of individual extended stability and sterility testing or compendial standards.

Compatibility/Compounding Considerations

Cidofovir should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Cidofovir is not approved for use as an ophthalmic dosage form, but a cidofovir 0.5% ophthalmic solution can be prepared by a qualified compounding pharmacist.

Ciprofloxacin Ophthalmic

(sip-roe-***flox***-a sin) *Ciloxan®*

Fluoroquinolone Antibiotic

For systemic use, refer to ***Ciprofloxacin***

Prescriber Highlights

- ► Used to treat bacterial conjunctivitis or keratitis
- ► Physically incompatible with many drugs; therefore, should not be directly mixed with other ophthalmic medications
- ► Crystalline drug precipitates may be noted in the superficial portion of corneal defects during use.

Uses/Indications

In veterinary patients, ciprofloxacin ophthalmic may be used for the treatment of bacterial conjunctivitis or keratitis caused by susceptible strains of *Staphylococcus* spp, *Streptococcus* spp, *Pseudomonas aeruginosa*, *Chlamydia* spp, and *Haemophilus* spp.[1]

The World Health Organization (WHO) has designated ciprofloxacin as a Critically Important, Highest Priority antimicrobial in human medicine.[2]

Pharmacology/Actions

Ciprofloxacin is a bactericidal and concentration-dependent antibiotic, with susceptible bacteria cell death occurring within 20 to 30 minutes of exposure. Ciprofloxacin has demonstrated a significant postantibiotic effect in both gram-negative and gram-positive bacteria and is active in both the stationary and growth phases of bacterial replication. Its mechanism of action is not thoroughly understood, but it is believed to act by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), thereby preventing DNA supercoiling and DNA synthesis.

Although ciprofloxacin is considered to have greater efficacy against gram-negative organisms as compared with gram-positive, studies involving ocular isolates obtained from dogs and horses with

bacterial keratitis indicate good efficacy with minimal resistance against *Streptococcus* spp, *Staphylococcus* spp, and *Pseudomonas aeruginosa*.[3–6] However, more recent reports involving isolates from humans with ocular infections indicate lower susceptibility of *Staphylococcus* spp to ciprofloxacin.

Contraindications/Precautions/Warnings

Ciprofloxacin is contraindicated in patients that have a history of hypersensitivity to it, other fluoroquinolones, or any component of the formulation. Ophthalmic preparations are for topical ophthalmic use only. They are not for injection subconjunctivally or into the anterior chamber of the eye. Fluoroquinolone-induced retinal toxicity in domestic cats has not been demonstrated with a topical formulation of ciprofloxacin.

Adverse Effects

Adverse effects reported in humans or animals include blurred vision, tearing, eye pain, redness, itching, and a bad taste in the mouth.[7] Crystalline drug precipitates may be observed in the superficial portion of corneal defects during use; however, this effect did not adversely affect clinical and visual outcomes in human clinical studies.[7] The arthropathy that occurs in immature animals associated with oral administration of quinolones has not been noted following topical ophthalmic administration.

Dosages

Conjunctivitis (extra-label): 1 drop or ¼ – ½ inch strip to the affected eye(s) every 2 to 8 hours

Keratitis (extra-label): 1 drop or ¼ – ½ inch strip to the affected eye every 2 to 8 hours

Monitoring

- Corneal cytology and culture to evaluate for the persistence of bacteria
- Evaluation for clinical signs suggestive of persistent infection

Client Information

- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Wait 5 minutes after applying this medicine before applying any other medicine to your animal's eye(s).
- Crystals may appear on the surface of your animal's eye during treatment. This change is not harmful and will go away once treatment is complete.
- Keep cap tightly closed when not in use. Store this medication in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store this product in the refrigerator (2°C-8°C [35.6°F-46.4°F]) or at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Fluoroquinolone antibiotics interact with many other drugs, including those containing cations (eg, iron, aluminum, magnesium, or calcium). Ciprofloxacin should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Ciprofloxacin 0.3% Ophthalmic Solution (containing ciprofloxacin HCl 3.5 mg equivalent to 3 mg base; benzalkonium chloride 0.006%; sodium acetate; acetic acid; mannitol; edetate disodium; HCl and/or NaOH may be used to adjust pH to 4.5; purified water; osmolality is 300 mOsm/kg), 2.5 mL, 5 mL, or 10 mL in sterile ophthalmic dropper bottles; *Ciloxan*®, generic; (Rx)

Ciprofloxacin 0.3% Ophthalmic Ointment (containing ciprofloxacin HCl 3.33 mg equivalent to 3 mg base; mineral oil; white petrolatum), in 3.5 g sterile ophthalmic ointment tubes; *Ciloxan*®; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Cromolyn Ophthalmic

(***kroh***-mah-lin)

Mast Cell Stabilizer

Prescriber Highlights

- ► Used for seasonal allergic conjunctivitis or atopic conjunctivitis
- ► Administer 2 to 6 times daily
- ► Mild transient stinging and burning may occur upon application

Uses/Indications

Mast cell-stabilizing ophthalmic agents are used to control the clinical signs of allergic and atopic conjunctivitis. Response to therapy (eg, decreased itching, tearing, redness, and discharge) is usually evident within a few days, but longer treatment for up to 6 weeks may be required. Once improvement has been established, therapy should be continued for as long as needed to sustain improvement.[1] If required, corticosteroids may be used concomitantly with cromolyn ophthalmic solution. Efficacy of cromolyn as treatment for conjunctivitis in veterinary species has not been established.

Pharmacology/Actions

Cromolyn inhibits the degranulation of sensitized mast cells and blocks the release of histamine and slow-releasing substance of anaphylaxis from mast cells following antigen recognition. Cromolyn does not have intrinsic vasoconstrictor, antihistaminic, cyclooxygenase inhibition, or other anti-inflammatory properties. Cromolyn is poorly absorbed when applied topically.

Contraindications/Precautions/Warnings

Cromolyn is contraindicated in patients that have a history of hypersensitivity to cromolyn or any component of the formulation.

Adverse Effects

Adverse effects reported in humans or animals include a transient mild stinging and burning upon application.

Dosages

Allergic conjunctivitis (extra-label): 1 drop to each eye 2 to 6 times daily

Monitoring

- Clinical efficacy: resolution of clinical signs associated with allergic conjunctivitis

Client Information

- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.

- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use the medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product at room temperature (15°C-30°C [59°F-86°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Cromolyn ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Cromolyn Sodium 4% Ophthalmic Solution (containing cromolyn sodium 40 mg; benzalkonium chloride 0.01%; edetate disodium 0.1%; purified water; HCl and/or NaOH to adjust pH to 4 to 7), 10 mL in sterile ophthalmic dropper bottle; generic; (Rx)

Cyclopentolate Ophthalmic
(sye-kloe-***pen***-toe-late) *Cyclogyl® Cyclomydril®, Akpentolate®, Pentolair®*

Anticholinergic Cycloplegic/Mydriatic Agent

Prescriber Highlights
- ► Primarily used as a diagnostic agent to facilitate mydriasis and cycloplegia
- ► Rapid and intense onset of mydriasis and cycloplegia in 15 to 60 minutes; heavily pigmented irises may require an increased frequency of administration or stronger concentrations. May increase intraocular pressure (IOP); therefore, use cautiously in patients with glaucoma
- ► Higher concentrations (*at least 1%*) cause stinging on application.
- ► Available as a combination product with phenylephrine (*Cyclomydril®*) to facilitate mydriasis with less cycloplegia

Uses/Indications
Cyclopentolate is primarily used to induce rapid mydriasis and cycloplegia to enable funduscopic examination and cycloplegic refraction to be performed. It is also available as a combination with phenylephrine to accomplish greater mydriasis with lesser cycloplegia.

Pharmacology/Actions
Cyclopentolate blocks the responses of the sphincter muscle of the iris and the accommodative muscle of the ciliary body to cholinergic stimulation, resulting in pupillary dilation (mydriasis) and paralysis of accommodation (cycloplegia).[1] Cyclopentolate acts rapidly, producing maximal dilation in less than 1 hour in dogs[2] and cats,[3] and within 12 hours in horses,[4,5] with a total duration of mydriasis from 2 to 4 days. Complete recovery of accommodation usually takes 6 to 24 hours. Heavily pigmented irises may require an increased frequency of administration or stronger concentrations than lightly pigmented irises.[1] When cyclopentolate is combined with phenylephrine (an adrenergic drug), synergistic mydriasis occurs, with less accompanying cycloplegia due to the lower concentration of cyclopentolate in the combination product.

Contraindications/Precautions/Warnings
Cyclopentolate is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Although a single drop of cyclopentolate did not elevate intraocular pressure (IOP) in normal dogs,[2] cyclopentolate may cause an increase in IOP and therefore should be used cautiously in patients with glaucoma. Administration to normal cats[3] and horses[4] has been associated with increased IOP in studies; however, another study documented no effect on IOP in normal horses.[5] Reduction in STT has been reported in cats.[3]

Adverse Effects
Adverse effects reported in humans or animals include burning and stinging on application.[1] Increased intraocular pressure (IOP), photophobia, blurred vision, irritation, hyperemia, conjunctivitis, blepharoconjunctivitis, punctate keratitis, and synechiae have also been reported.[1] Burning and stinging are usually associated with higher concentrations (*at least 1%*). CNS and cardiovascular disturbances are often noted in human pediatric patients and may occur when used in smaller animals.

Dosages
Mydriasis and cycloplegia (extra-label): 1 drop to the desired eye(s) followed by a second drop 5 minutes later if necessary. **NOTE**: Use of a single drop may avoid adverse systemic effects in smaller animals. Administer this medicine 40 to 50 minutes prior to a diagnostic procedure to ensure full effects.

Monitoring
- Clinical efficacy: desired mydriasis and cycloplegia achieved; full recovery in 24 hours

Client Information
- This medicine is rarely used at home.
- This medicine may make your animal sensitive to light for ≈24 hours after administration. Keep your animal out of bright sunlight until pupils return to normal size.
- Wash your hands after use to prevent accidental contact with eyes (causes pupil dilation).
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Cyclopentolate ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Cyclopentolate HCl Ophthalmic Solution 0.5% (containing cyclopentolate HCl 0.5%; benzalkonium chloride 0.01%; boric acid; edetate disodium; sodium carbonate and/or HCl to adjust pH to between 3 and 5.5; purified water), 15 mL in sterile ophthalmic dropper bottles; *Cyclogyl®*, generic; (Rx)

Cyclopentolate HCl Ophthalmic Solution 1% (containing cyclopentolate HCl 1%; benzalkonium chloride 0.01%; boric acid; edetate disodium; sodium carbonate and/or HCl to adjust pH to between 3

and 5.5; purified water), 2 mL, 5 mL, or 15 mL in sterile ophthalmic dropper bottles; *Cyclogyl®*, *Pentolair®*, *Akpentolate®*; (Rx)

Cyclopentolate HCl Ophthalmic Solution 2% (containing cyclopentolate HCl 2%; benzalkonium chloride 0.01%; boric acid; edetate disodium; sodium carbonate and/or HCl to adjust pH to between 3 and 5.5; purified water), 2 mL, 5 mL, or 15 mL in sterile ophthalmic dropper bottles; *Cyclogyl®*; (Rx)

Human-Labeled Combination Products:

Cyclopentolate HCl 0.2% and Phenylephrine HCl 1% Ophthalmic Solution (containing cyclopentolate HCl 0.2%; phenylephrine HCl 1%; benzalkonium chloride 0.01%; edetate disodium; boric acid; HCl and/or sodium carbonate to adjust pH; purified water), 2 mL or 5 mL in sterile ophthalmic dropper bottles; *Cyclomydril®*; (Rx)

Cyclosporine Ophthalmic

(***sye***-klo-***spore***-in) *Cequa®, Ciclosporin, Cyclosporin A, Optimmune®, Restasis®*

Immunosuppressive Agent

See also ***Cyclosporine (Systemic)***

Prescriber Highlights

- ► Approved as an ophthalmic ointment for the treatment of keratoconjunctivitis sicca (KCS) in dogs and for other ocular surface inflammatory diseases in other species
- ► Poor intraocular penetration requires alternate routes of administration to manage intraocular inflammatory diseases
- ► Animals that do not respond to the approved (0.2%) ophthalmic ointment may benefit from higher concentrations (1% to 2%) of cyclosporine ophthalmic solution, which must be compounded.
- ► Weeks of therapy may be required to cause an increase of tear production; however, discontinuation of therapy can quickly (within days) result in loss of normal tear production.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies cyclosporine as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Topical ophthalmic cyclosporine is approved for the treatment of keratoconjunctivitis (KCS) in dogs; it may also be used to treat other ocular surface inflammatory conditions, such as chronic superficial keratitis (CSK; pannus), immune-mediated keratitis (IMMK), eosinophilic keratitis, pigmentary keratitis, and postoperative keratitis in dogs and other species.[1,2] Topical cyclosporine 1.5% has demonstrated efficacy for the management of eosinophilic keratitis in cats.[3] Sustained-released cyclosporine implants have been developed for suprachoroidal and episcleral implantation; the former is for the treatment of equine recurrent uveitis (ERU), and the latter for IMMK in horses and KCS in dogs.[4-9]

Pharmacology/Actions

Cyclosporine, a calcineurin inhibitor, is an immunosuppressive agent that focuses on cell-mediated immune responses, with some humoral immunosuppressive action. Cyclosporine binds to T-cell cyclophilin and blocks calcineurin-mediated T-cell activation. T-helper lymphocytes are the primary target, but T-suppressor cells are also affected. Cyclosporine can also inhibit cytokine production and release (including IL-2 and interferon-gamma in dogs[10-12] and IL-3, IL-4, and tissue necrosis factor-alpha in humans), thereby affecting the function of eosinophils, mast cells, granulocytes, and macrophages.

The immunosuppressive effects make cyclosporine useful when it is administered locally in animals with ocular diseases that are suspected to be immune-mediated, such as keratoconjunctivitis (KCS) and chronic superficial keratitis (CSK). Cyclosporine increases lymphocyte apoptosis and decreases corneal epithelial apoptosis in dogs with KCS,[13] thus protecting the ocular surface. However, other mechanisms likely improve tear production, as tear production is increased by topical administration of cyclosporin in dogs without KCS. For this reason, cyclosporine is thought to have direct stimulatory effects on the lacrimal gland, possibly by altering neurotransmitter release.[14] After initiation of cyclosporine therapy, effective tear production takes several weeks; however, cessation of therapy results in the return of clinical signs in a matter of days.[1] Clinical improvement in cases of KCS is not necessarily dependent on an increase in aqueous tear production as measured by the Schirmer tear test (STT) because other components of the tear film that are not assessed by the STT may also improve with topical cyclosporine administration.[15]

Because of the frequent need for the chronic daily administration of topical cyclosporine, the sustained-release cyclosporine devices are surgically placed in the episcleral space in horses with immune-mediated keratitis (IMMK). The duration of drug release is ≈18 months.[4] Due to limited penetration to the intraocular environment, the sustained-release cyclosporine disc devices are surgically implanted suprachoroidally in horses with equine recurrent uveitis (ERU). The duration of drug release is ≈2 to 3 years.[7]

Contraindications/Precautions/Warnings

Cyclosporine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Use in the presence of ocular viral or fungal infections should be undertaken with caution. Cyclosporine is available as an ophthalmic solution for humans (0.05% to 0.09%); however, these formulations are not effective in controlling keratoconjunctivitis (KCS) in dogs. More concentrated solutions of cyclosporine ophthalmic (1% to 2%) may be prepared (compounded) by qualified compounding pharmacists. It is not recommended to administer cyclosporine ophthalmic ointment or solutions compounded in oil via subpalpebral lavage catheter because of the likely irreversible obstruction of the catheter, necessitating replacement.

The National Institute for Occupational Safety and Health (NIOSH) classifies cyclosporine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Adverse effects reported in humans or animals include local irritation, periocular erythema, lid spasm, rubbing of the eye, alopecia, and epiphora. Many adverse effects are believed to be induced by the vehicle preparation used in compounded formulations rather than by cyclosporine itself. In dogs with herpesvirus keratitis, the administration of topical ophthalmic cyclosporine has not been shown to induce recrudescence of clinical signs.

Dosages

Keratoconjunctivitis sicca and chronic superficial keratitis in dogs (label dosage; FDA-approved): ¼ inch strip to the affected eye(s) every 12 hours[17]

Inflammatory ocular surface diseases (extra-label):

a. Ointment: ¼ – ½ inch strip to the affected eye(s) every 12 hours
b. Cyclosporine solutions (1% to 2%): 1 drop to the affected eye(s) every 12 hours

Immune-mediated keratitis (extra-label): Surgical implantation of a sustained-release device created for episcleral implantation should be

performed by a board-certified veterinary ophthalmologist. The implant contains cyclosporine for continued release over ≈12 to 18 months.

Equine recurrent uveitis (ERU) (extra-label): Surgical implantation of a sustained-release device created for suprachoroidal implantation should be performed by a board-certified veterinary ophthalmologist. The implant contains cyclosporine for continued release over ≈2 to 3 years.

Monitoring

- Clinical effect for keratoconjunctivitis (KCS). Evaluate Schirmer tear test, as well as a reduction in mucoid ocular discharge and conjunctival hyperemia.
- Clinical effect for ocular surface inflammatory conditions (topical administration; episcleral device). Evaluate for lack of progression (and possibly regression) of chronic inflammatory changes, such as corneal pigmentation, vascularization, and fibrosis.
- Clinical effect for equine recurrent uveitis (ERU; suprachoroidal device): Evaluate markers of intraocular inflammation (eg, flare, hypopyon, ocular hypotony, miosis, vitreal debris) and frequency of recurrence.

Client Information

- Make sure you understand how to give this medication to your animal. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 to 10 minutes after applying this medicine before applying any other medicines to the eye.
- Store cyclosporine ointment in the refrigerator or at room temperature away from moisture and sunlight. Handle and squeeze the tube gently so the metal will not crack and leak.
- Store cyclosporine solutions at room temperature (do not refrigerate or freeze).
- Do not use this medicine if the color of the solution changes, if it becomes cloudy, or if there are particles in the solution.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Storage/Stability

Store the commercially available ophthalmic ointment in the refrigerator (2°C-8°C [35.6°F-46.4°F]) or at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight. Do not refrigerate or freeze compounded cyclosporine solutions.

The long-term stability of a 1% solution in corn oil determined by USP is 180 days. Storage times should be determined by the results of individual extended stability and sterility testing or compendial standards.

Compatibility/Compounding Considerations

Cyclosporine should not be mixed directly (in vitro) with any other drugs.

Do not administer cyclosporine ophthalmic ointment or solutions compounded in oil in a subpalpebral lavage catheter, because of the likely irreversible obstruction of the catheter.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Cyclosporine 0.2% Ophthalmic Ointment (containing cyclosporine 2 mg/g, USP; petrolatum, USP; corn oil, NF; petrolatum and lanolin alcohol), in a 3.5 g ophthalmic ointment tube; *Optimmune*®; (Rx). Approved for use in dogs.

Cyclosporine 1% to 2% Ophthalmic Solutions in fixed oils may be compounded by qualified compounding pharmacists.

HUMAN-LABELED PRODUCTS:

Cyclosporine 0.05% Ophthalmic Emulsion (containing cyclosporine 0.05%; glycerin; castor oil; polysorbate 80; carbomer copolymer type A; purified water; NaOH to adjust pH), 30 or 60 sterile, single-use LDPE vials (0.4 mL each), or 5.5 mL sterile multi-dose ophthalmic dropper; *Restasis*®; (Rx). **NOTE:** This solution is not effective in controlling keratoconjunctivitis (KCS) in dogs.

Cyclosporine 0.09% Ophthalmic Solution (containing cyclosporine 0.09%; polyoxyl 40 hydrogenated castor oil; octoxynol-40; sodium phosphate, monobasic, dihydrate; sodium phosphate, dibasic, anhydrous; sodium chloride; povidone K90; hydrochloric acid; sodium hydroxide; water), in 6 pouches with 10 single-use vials (0.25 mL each) per pouch; *Cequa*®; (Rx). **NOTE:** This solution is not effective in controlling KCS in dogs.

Demecarium Ophthalmic

(deh-meh-***kar***-ee-um)

Anticholinesterase Ocular Antihypertensive

Prescriber Highlights

- ► Used primarily for preventive management of glaucoma in the unaffected eye of canine patients diagnosed with primary glaucoma in the fellow eye
- ► Product must be compounded as it is no longer commercially available.
- ► Used 1 to 2 times daily

Uses/Indications

Demecarium ophthalmic is used for preventive management of glaucoma in the contralateral eye of canine patients diagnosed with primary glaucoma in the fellow eye.[1,2] Demecarium's therapeutic efficacy for managing active glaucoma is minimal relative to other commercially available medications.

Pharmacology/Actions

Demecarium is an anticholinesterase that prolongs the effect of acetylcholine by inactivating the cholinesterases that break down acetylcholine, which has been released at the neuroeffector junction of parasympathetic postganglionic nerves. Demecarium inactivates both pseudocholinesterase and acetylcholinesterase. It causes constriction of the iris sphincter muscle (miosis) and the ciliary body muscle. These actions facilitate the outflow of aqueous humor, leading to a reduction in intraocular pressure (IOP). Demecarium is an organophosphate and may cause severe and even fatal dose-related toxicity associated with a decrease in systemic acetylcholinesterase levels, especially in cats.[3] See ***Adverse Effects.***

Contraindications/Precautions/Warnings

Demecarium is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Demecarium is contraindicated in pregnant animals; caregivers that are pregnant or intend to become pregnant should be warned to avoid contact with this medication.

Adverse Effects

Adverse effects reported in humans or animals include stinging, burning, and ocular irritation. Demecarium can cause severe and even fatal dose-related systemic toxicity, especially in cats.[3] Signs of systemic toxicity include vomiting, anorexia, diarrhea, lethargy, and weakness. Short-term (8 days) induction of aqueous humor flare occurs following the administration of demecarium in normal dogs.[4]

Dosages
Prophylaxis of glaucoma in the normal eye (extra-label): 1 drop to the nonglaucomatous eye 1 to 2 times daily

Monitoring
- Clinical efficacy; maintenance of normal intraocular pressure (IOP) in the contralateral eye of dogs with unilateral glaucoma
- Monitor for signs of systemic toxicity (vomiting, anorexia, diarrhea, lethargy, and weakness)

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this product as directed on the product labeling, away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product as directed on the product labeling away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Demecarium ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Demecarium bromide is no longer commercially available but may be prepared (compounded) as a 0.125% or 0.25% ophthalmic solution by qualified compounding pharmacists.

For the complete list of references, see **wiley.com/go/budde/plumb**

Dexamethasone Ophthalmic

(decks-uh-***meth***-uh-sown) *Maxidex®, Dexasporin®, Maxitrol®, Tobradex®*

Corticosteroid

*For systemic use, refer to **Dexamethasone***

Prescriber Highlights
- ► Topical corticosteroid used to treat ocular surface and intraocular inflammatory conditions
- ► May be combined with antibiotics (eg, neomycin, polymyxin B)
- ► Contraindications include a hypersensitivity to dexamethasone; an existing or suspected bacterial, viral, or fungal ocular infection; and in the presence of a corneal abrasion or ulceration.

Uses/Indications
Dexamethasone ophthalmic can be used to treat inflammation following ocular injury or cataract surgery or to treat generalized inflammatory conditions of the anterior segment (eg, conjunctivitis, keratitis, anterior uveitis). Evaluation of relative efficacy of dexamethasone ophthalmic in veterinary patients has not been performed.

Dexamethasone is available in many combinations with antimicrobial agents for topical ophthalmic use.

Pharmacology/Actions
Corticosteroids have broad immunomodulatory and anti-inflammatory actions, which are mediated via direct effects on gene expression, as well as by nongenomic effects on cell membranes and receptors. Ultimately, corticosteroids decrease pro-inflammatory gene transcription, production of pro-inflammatory prostaglandins and leukotrienes, B- and T-cell number and function, cell-mediated immunity, and humoral immunity.[1] Specific mechanisms involved in controlling ocular inflammatory conditions are not definitively known. Dexamethasone is a potent base steroid (relative glucocorticoid potency of 30 versus 4 for prednisolone and 1 for hydrocortisone). Greater intraocular penetration, and therefore potential clinical efficacy in cases of anterior uveitis, is achieved with dexamethasone alcohol formulations relative to sodium phosphate formulations; however, intraocular penetration of dexamethasone alcohol and sodium phosphate preparations is less than that of prednisolone acetate suspensions.

Following the topical administration of dexamethasone sodium phosphate, measurable concentrations of dexamethasone are present in the anterior segment of normal cat and dog eyes.[2, 3]

Contraindications/Precautions/Warnings
Dexamethasone is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Due to inhibition of epithelial wound healing and potentiation of infection, dexamethasone ophthalmic is also contraindicated when corneal ulceration is suspected or present or in the presence of corneal infection (bacterial, fungal, or viral).[4] Topical administration of glucocorticoids may produce systemic effects. For more, refer to ***Glucocorticoid Agents, General Information***. Use dexamethasone ophthalmic with caution in patients with endocrine diseases (eg, diabetes mellitus, acromegaly), infectious diseases, chronic kidney disease, congestive heart failure, systemic hypertension, or gastric ulceration. When use of dexamethasone ophthalmic is necessary to treat a patient with these conditions, the minimal effective dose should be administered for the shortest possible time.

Adverse Effects
Adverse effects reported in humans include development of cataracts (via altered glucose or lenticular metabolic effects), increased intraocular pressure (IOP; via activation of glucocorticoid receptors in the trabecular meshwork), infection (via immunosuppression), decreased wound healing (via increased collagenolytic activity), mydriasis, and calcific keratopathy. In some animals, IOP may increase with chronic use; however, most reports suggest the change is reversible when the treatment is discontinued.[5, 6] Cats with glaucoma have demonstrated a potentially clinically significant increase in IOP with administration of topical dexamethasone.[7] Systemic effects with topical ophthalmic administration are rare but include hepatopathy, suppression of endogenous glucocorticoid production, and focal alopecia. Concurrent use of systemic steroids increases the risk for these adverse effects.

Dosages
Conjunctivitis, keratitis, anterior uveitis (extra-label): 1 drop or ¼ inch strip to the affected eye(s) as frequently as every 2 hours until clinical improvement occurs, then gradually (over days to weeks) decrease the frequency of administration, provided clinical improvement is maintained.

Post-cataract removal (extra-label): 1 drop to the affected eye(s) every 8 to 12 hours

Monitoring
- Clinical efficacy
- Resolution or development of signs of inflammation
- Intraocular pressure (IOP; especially in cats) and ocular surface

integrity (eg, fluorescein stain) as needed based on clinical presentation
- Blood or urine glucose changes based on development of clinical signs (eg, polyuria, polydipsia) in diabetic animals

Client Information
- This medicine can be given for various lengths of time. Be sure you understand how often and for how long your animal should be given this medicine.
- Shake suspensions well before using.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Contact your veterinarian as soon as possible if your animal's eye condition worsens or does not improve while using this medicine.
- Your veterinarian will need to monitor your animal's eye condition while taking this medicine. Do not miss these important follow-up visits.
- Store this medicine as directed on the product label. Do not freeze.
- Do not use this medicine if the color changes, becomes cloudy, or if there are visible particles in the solution.

Storage/Stability
Storage recommendations can vary; follow storage requirements listed on packaging. Most commonly, this product is recommended to be stored at controlled room temperature 68°F to 77°F [20°C-25°C]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Dexamethasone ophthalmic solutions should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Dexamethasone Sodium Phosphate 0.1% Ophthalmic Suspension (containing dexamethasone 0.1%; benzalkonium chloride 0.01%; hypromellose 0.5%; NaCl; dibasic sodium phosphate; polysorbate 80; edetate disodium; citric acid and/or NaOH to adjust pH; purified water), 5 mL or 15 mL in sterile ophthalmic dropper bottle; *Maxidex*®; generic; (Rx)

Dexamethasone Sodium Phosphate 0.1% Ophthalmic Solution (containing dexamethasone 0.1%; benzalkonium chloride 0.01%; hypromellose 0.5%; NaCl; dibasic sodium phosphate; polysorbate 80; edetate disodium; citric acid and/or NaOH to adjust pH; purified water), 5 mL or 15 mL sterile ophthalmic dropper bottle; generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:

Neomycin and Polymyxin B Sulfates and Dexamethasone Ophthalmic Suspension (containing neomycin sulfate equivalent to neomycin 3.5 mg, polymyxin B sulfate 10,000 units, dexamethasone 0.1%, benzalkonium chloride 0.004%, hypromellose 2910 0.5%, sodium chloride, polysorbate 20, HCl and/or NaOH to adjust pH, purified water), in a 5 mL sterile ophthalmic dropper bottle; *Maxitrol*®, *Dexasporin*®; (Rx)

Neomycin and Polymyxin B Sulfates and Dexamethasone Ophthalmic ointment (containing neomycin sulfate equivalent to neomycin 3.5 mg, polymyxin B sulfate 10,000 units, dexamethasone 0.1%, methylparaben 0.05%, propylparaben 0.01%, white petrolatum, anhydrous liquid lanolin), in a sterile 3.5 g tube; *Maxitrol*®, generic; (Rx)

Tobramycin and Dexamethasone Ophthalmic Ointment (containing tobramycin 0.3%, dexamethasone 0.1%, chlorobutanol 0.5% , mineral oil, white petrolatum), in a sterile 3.5 g tube; *Tobradex*®; (Rx)

Tobramycin and Dexamethasone Ophthalmic Suspension (containing tobramycin 0.3%, dexamethasone 0.1%, benzalkonium chloride 0.01%, tyloxapol, edetate disodium, NaCl, hydroxyethyl cellulose, sodium sulfate, sulfuric acid and/or NaOH to adjust pH, purified water), in a sterile 2.5 mL ophthalmic dropper; *Tobradex*®, generic; (Rx)

Tobramycin and Dexamethasone Ophthalmic Suspension (containing tobramycin 0.3%, dexamethasone 0.05%, xanthan gum, tyloxapol, disodium edetate, NaCl, propylene glycol, sodium sulfate, benzalkonium chloride 0.01%, NaOH and/or HCl to adjust pH, purified water), in a sterile 5 mL ophthalmic dropper; *Tobradex*®; (Rx)

References

Diclofenac Ophthalmic
(dye-***kloe***-fen-ak) *Voltaren*®

Nonsteroidal Anti-inflammatory Drug (NSAID)

For topical cream, refer to ***Diclofenac, Topical***

Prescriber Highlights
- ► Used to control anterior segment inflammation
- ► May delay ocular wound healing and increase risk for intraocular bleeding
- ► Sulfite preservatives in diclofenac may trigger asthma attacks in susceptible patients.

Uses/Indications
Diclofenac ophthalmic is indicated for controlling anterior segment inflammation (eg, conjunctivitis, keratitis, anterior uveitis), inducing mydriasis during cataract-removal surgery, and for providing analgesia following surgical removal of cataracts. In dogs and cats, diclofenac significantly reduces clinical signs associated with experimentally induced intraocular inflammation[1,2]; however, it has not demonstrated reliable reduction in corneal sensitivity in normal dogs.[3,4]

Pharmacology/Actions
Diclofenac is an NSAID that blocks prostaglandin synthesis by inhibiting cyclooxygenase 1 and 2. Prostaglandins mediate many of the adverse effects of intraocular inflammation, including disruption of the blood-aqueous barrier, vasodilation, increased vascular permeability, leukocytosis, and increased intraocular pressure (IOP). Blocking prostaglandin production therefore minimizes the adverse short- and long-term effects of intraocular inflammation. Prostaglandins also appear to play a role in the miotic response produced during ocular surgery by constricting the iris sphincter independently of cholinergic mechanisms. Thus, diclofenac inhibits miosis induced during cataract surgery.[4]

Contraindications/Precautions/Warnings
Diclofenac is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. The potential for cross-sensitivity to acetylsalicylic acid, phenylacetic acid derivatives, and other NSAIDs exists.[5] Topical NSAIDs may result in corneal epithelial breakdown and corneal thinning, erosion, or ulceration, which could cause delayed corneal wound healing; concurrent use of topical NSAIDs and topical corticosteroids may further delay healing and increase the potential for development of adverse effects.[5] Due to interference with thrombocyte aggregation, ophthalmic NSAIDs may cause increased bleeding of ocular tissues (eg, hyphema) in conjunction with ocular surgery. It is recommended

that diclofenac ophthalmic solution be used with caution in patients with known bleeding tendencies (eg, severe liver disease) or in those receiving anticoagulant medications (eg, heparins, rivaroxaban), which may prolong bleeding time.[5]

Adverse Effects

Adverse effects reported in humans or animals include transient ocular burning or stinging on administration.[5] Superficial punctate keratitis has been reported with long-term use. NSAIDs may also cause direct cellular damage, causing delayed healing and/or deterioration of existing corneal wounds. Although unlikely, systemic adverse effects may occur with the use of topical NSAIDs, including increased risk for gastric ulceration, decreased platelet aggregation, worsening of asthma and cardiac disease, and renal toxicity. Concurrent use of systemic NSAIDs and corticosteroids increases the risk for systemic adverse effects. The increased bleeding tendency of ocular tissues in conjunction with ocular surgery has also been reported. A comparison of the anti-inflammatory effects of topically administered diclofenac and prednisolone acetate in dogs with cataracts and well-regulated diabetes did not detect differences in measured parameters indicative of diabetes control (eg, fructosamine, body weight), although the authors concluded more research is warranted.[6] Although diclofenac administration was not associated with an elevation in intraocular pressure (IOP) in dogs with normal eyes,[7] it did result in increased IOP in dogs with experimentally induced uveitis.[8]

Dosages

Postoperative cataract surgery (extra-label): 1 drop to the affected eye(s) every 6 hours throughout the first 2 weeks of the postoperative period

Anterior segment inflammation (extra-label): 1 drop to the affected eye(s) every 6 to 12 hours

Monitoring

- Clinical efficacy (eg, decreased or absent anterior segment inflammation)
- Adverse effects (eg, delayed wound healing)

Client Information

- Use this medicine as directed by your veterinarian.
- Do not use this medicine if the color changes, if the solution becomes cloudy, or if there are particles in the solution.
- Diclofenac ophthalmic may cause burning or stinging on administration. It may also increase the risk for bleeding and may slow down healing in the eye.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed on the medicine when it is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medications to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.

Storage/Stability

Store this product at controlled room temperature (68°F to 77°F [20°C-25°C]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Diclofenac ophthalmic solutions should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Diclofenac Sodium 0.1% Ophthalmic Solution (containing 1 mg diclofenac sodium; polyoxyl 35 castor oil; boric acid; tromethamine; sorbic acid (2 mg/mL); edetate disodium (1 mg/mL); purified water), in a 5 mL ophthalmic dropper bottle; *Voltaren®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Difluprednate Ophthalmic

(dye-floo-***pred***-nate) *Durezol®*

Corticosteroid

Prescriber Highlights

- ► Used for treatment of anterior segment inflammatory conditions
- ► Exerts clinical effect equal to that of prednisolone acetate
- ► Do not use in patients with an existing or suspected bacterial, viral, or fungal ocular infection or in the presence of corneal ulceration

Uses/Indications

Difluprednate ophthalmic can be used to treat inflammation following ocular injury or cataract surgery or to treat generalized inflammatory conditions of the anterior segment (eg, conjunctivitis, keratitis, anterior uveitis). It has been shown to exert comparable efficacy to prednisolone acetate in humans[1] and in dogs with experimentally induced anterior chamber inflammation.[2]

Pharmacology/Actions

Corticosteroids have broad immunomodulatory and anti-inflammatory actions, which are mediated via direct effects on gene expression, as well as by nongenomic effects on cell membranes and receptors. Ultimately, corticosteroids decrease proinflammatory gene transcription, production of proinflammatory prostaglandins and leukotrienes, B- and T-cell number and function, cell-mediated immunity, and humoral immunity.[3] Specific mechanisms involved in regulating ocular inflammation are not known.

Contraindications/Precautions/Warnings

Difluprednate is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Due to inhibition of epithelial wound healing and potentiation of infection, difluprednate ophthalmic is contraindicated when corneal ulceration is suspected or present or in the presence of corneal infection (bacterial, fungal, or viral),[4] infectious diseases, chronic renal failure, congestive heart failure, systemic hypertension, or gastric ulceration. When use of difluprednate is necessary in these conditions, the minimal effective dose should be administered for the shortest possible time.

Adverse Effects

Adverse effects reported in humans include development of cataracts (via altered glucose or lenticular metabolic effects), increased intraocular pressure (IOP; via activation of glucocorticoid receptors in the trabecular meshwork), infection (via immunosuppression), decreased wound healing (via increased collagenolytic activity), mydriasis, and calcific keratopathy. Increased IOP may occur in some animals with long-term use of difluprednate; however, most reports suggest the change is reversible.[5,6] Systemic effects are rare but include hepatopathy, suppression of endogenous glucocorticoid production, and focal alopecia. Concurrent use of systemic steroids increases the risk for these adverse effects.

Dosages

Conjunctivitis (extra-label): 1 drop in affected eye(s) every 4 to 8 hours, then gradually decrease the dose over days to weeks, provided

clinical improvement is maintained

Keratitis (extra-label): 1 drop in affected eye(s) every 4 to 8 hours, then gradually decrease the dose over days to weeks, provided clinical improvement is maintained

Anterior uveitis (extra-label): 1 drop in affected eye(s) 4 times daily for 14 days, then gradually decrease the dose over days to weeks, provided clinical improvement is maintained

Post-cataract removal (extra-label): 1 drop in the surgical eye 4 times daily, beginning 24 hours after surgery and continuing 2 weeks postoperative, then decrease to 2 times daily for 1 week, then continue to taper dosage based on clinical response

Monitoring

- Clinical efficacy
- Resolution or development of signs of inflammation
- Intraocular pressure (IOP; especially in cats) and ocular surface integrity (eg, fluorescein stain) as needed based on clinical presentation
- Blood or urine glucose changes based on development of clinical signs (eg, polyuria, polydipsia) in diabetic animals

Client Information

- This medicine can be given for various lengths of time. Be sure you understand how often and for how long your animal should be given this medicine.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Contact your veterinarian as soon as possible if your animal's eye condition worsens or does not improve while using this medicine.
- Your veterinarian will need to monitor your animal's eye condition while taking this medicine. Do not miss these important follow-up visits.
- Store this medicine as directed on the product label. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are visible particles in the solution.

Storage/Stability

Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Difluprednate ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Difluprednate 0.05% Ophthalmic Emulsion (containing difluprednate 0.05%; sorbic acid 0.1%; boric acid; castor oil; glycerin; polysorbate 80; water for injection; sodium acetate; sodium EDTA; NaOH to adjust the pH to 5.2 to 5.8, with tonicity of 304 – 411 mOsm/kg), in 5 mL ophthalmic dropper bottle; *Durezol*®; (Rx)

Dorzolamide Ophthalmic

(dor-***zoe***-la-mide) *Trusopt®, Cosopt®, Cosopt® PF*

Carbonic Anhydrase Inhibitor Anti-Glaucoma Agent

Prescriber Highlights

- ► Decreases intraocular pressure (IOP) by reducing the production of aqueous humor
- ► Three-times-daily dosing recommended over twice-daily dosing
- ► More stinging on application compared with brinzolamide, due to more acidic pH of dorzolamide
- ► Sulfonamide derivative; caregivers with sulfa allergies should avoid direct contact with the medicine.
- ► Available as a single agent or in combination with timolol maleate

Uses/Indications

Dorzolamide ophthalmic (alone or in combination with timolol) is used to decrease intraocular pressure (IOP) in patients with glaucoma and ocular hypertension. In dogs with and without glaucoma, dorzolamide leads to a significant IOP reduction, which is more consistent when it is dosed 3 times daily versus 2 times daily.[1,2] When dorzolamide ophthalmic is administered in combination with a beta-blocker, the IOP-lowering effects are additive.[3,4] Reduced IOP also occurs in normal cats and horses,[5] and similar to dogs, improved efficacy may result when dorzolamide is administered in combination with timolol in horses.[6,7] Efficacy of prophylactic dorzolamide administration for preventing manifestation of primary glaucoma in unaffected eyes of dogs with contralateral primary glaucoma has not been demonstrated.[8]

Pharmacology/Actions

Carbonic anhydrase (CA) is an enzyme found in many body tissues, including the eye. CA inhibitors reduce the formation of hydrogen and bicarbonate ions from carbon dioxide and water by noncompetitive, reversible inhibition of the enzyme CA, thereby reducing the availability of these ions for active transport into secretions.[9] In humans, CA exists as multiple isoenzymes, with CA-II being the most relevant to glaucoma management. Inhibition of CA in the ciliary processes of the eye decreases aqueous humor secretion, presumably by slowing the formation of bicarbonate ions with subsequent reduction in sodium and fluid transport, which results in a decrease in intraocular pressure (IOP).[9] Dorzolamide equilibrates between acidic and basic forms, allowing for both lipid and water solubility and greater corneal and scleral penetration.

Contraindications/Precautions/Warnings

Dorzolamide is contraindicated in patients that have a history of hypersensitivity to it or sulfonamides or any component of the formulation.

Adverse Effects

Adverse effects reported in humans or animals include burning and stinging upon application (due to low pH), superficial punctate keratitis, local hypersensitivity reactions, and corneal edema. Systemic adverse effects are not usually observed with the topical application; however, renal tubular acidosis and hypokalemia have been reported in a cat due to topical carbonic anhydrase inhibitor (CAI) administration.[10] CAIs, including dorzolamide, have been implicated in the development of significant ulcerative and nonulcerative keratitis following long-term administration.[11]

Dosages

Glaucoma (extra-label): 1 drop in the affected eye(s) or 0.1 mL in the subpalpebral lavage (SPL) catheter every 8 to 12 hours

Monitoring
- Clinical efficacy
- Confirm maintenance of intraocular pressure (IOP) within the normal range for the species being treated
- Monitor for corneal edema

Client Information
- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes.

Storage/Stability
Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight.

Compatibility/Compounding Considerations
Dorzolamide ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Dorzolamide HCl 2% Ophthalmic Solution (containing dorzolamide HCl 22.3 mg equivalent to 20 mg dorzolamide; benzalkonium chloride 0.0075%; hydroxyethyl cellulose; mannitol; sodium citrate dehydrate; NaOH to adjust pH; water for injection), in 5 mL and 10 mL ophthalmic dropper bottles; *Trusopt®*, generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:
Dorzolamide HCl 2% and Timolol maleate 0.5% Ophthalmic Solution (containing dorzolamide HCl equivalent to 20 mg dorzolamide; timolol maleate 6.8 mg equivalent to 5 mg timolol; benzalkonium chloride 0.0075%; sodium citrate; hydroxyethyl cellulose; NaOH; mannitol; water for injection, with a pH of 5.65 and an osmolality of 242 – 323 mOsm/kg), in sterile 10 mL ophthalmic dispenser bottles. *Cosopt®*, generic; (Rx)

Dorzolamide HCl 2% and Timolol maleate 0.5% Ophthalmic Solution, preservative-free (containing 22.3 mg dorzolamide HCl equivalent to 20 mg dorzolamide; 6.8 mg timolol maleate equivalent to 5 mg timolol; hydroxyethyl cellulose; mannitol; sodium citrate; NaOH to adjust pH; water for injection), in 15 sterile single-use containers, 0.2 mL per container; *Cosopt® PF*; (Rx)

Edetate Disodium Ophthalmic
Sodium EDTA
(ed-uh-***tayt*** dye-***so***-dee-um)
Chelating Agent

Prescriber Highlights
- ► Used for dissolution of corneal calcium deposits
- ► Also used to decrease corneal digestion due to collagenase activity in infected ulcers
- ► Do not mix with calcium-containing drugs
- ► No longer commercially available; must be compounded

Uses/Indications
Edetate disodium is used topically to remove calcific corneal deposits that occur in the superficial cornea, which may cause pain or impair vision. Corneal calcium deposits may form in association with chronic keratitis, chronic uveitis, or hypercalcemia. These deposits may be dissolved from the conjunctiva, corneal epithelium, and anterior stroma following EDTA administration. Calcium deposits in the deep stroma are not affected, as edetate disodium is lipid-insoluble and does not penetrate the corneal epithelium. Topical administration of EDTA also decreases collagenase activity in infected corneal ulcers, thus helping to control corneal melting.[1,2] Edetate disodium has been used as an emergency treatment to decontaminate the eye after injury by zinc chloride, and for emergency management and follow-up treatment of calcium hydroxide burns in the eye.

Pharmacology/Actions
Edetate disodium forms a soluble complex with calcium ions and other divalent and trivalent metals, which leads to the dissolution of calcium deposits from the ocular surface. As calcium (and other) ions serve as cofactors for enzymes responsible for collagenolysis, binding the ions makes them unavailable to the enzymes, thus decreasing enzymatic activity.[1]

Contraindications/Precautions/Warnings
Edetate disodium ophthalmic should not be used in patients that are hypersensitive to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans or animals include swelling of the stroma (usually following application of concentrations greater than 1%), stinging on application, and swelling of the eyelids. Toxic effects have been demonstrated in vitro to corneal epithelial cells.[3]

Dosages
Calcium chelation for corneal deposits and/or collagenolysis (extra-label): 1 drop of the solution (0.35% to 1.85%, but most commonly 1%) to the affected eye(s) initially 4 to 6 times daily and then 3 to 4 times daily as indicated

Zinc chloride injury (extra-label): Topical, to the cornea, as a 1.7% (0.046 M) solution as irrigation for 15 minutes; more likely to be effective if started within 2 minutes of exposure

Monitoring
- Clinical efficacy
- Monitor mineral deposits in the cornea
- Monitor corneal digestion (melting)

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medicine as directed on the product label. Do not freeze.
- Do not use this product if the color changes, if it becomes cloudy, or if there are particles in the solution.
- Discard this product by the date indicated on the label.

Storage/Stability
Store this product as directed on the product labeling; do not freeze.

Compatibility/Compounding Considerations
Edetate disodium ophthalmic preparations should not be mixed directly with any other ophthalmic medications, especially those containing calcium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Edetate disodium ophthalmic solution must be prepared (compounded) by a qualified compounding pharmacist. It is usually prepared as a 1% solution in an artificial tear solution not containing calcium.

Epinastine Ophthalmic

(ep-i-***nas***-teen) *Elestat®*

Antihistamine

Prescriber Highlights

- ► H_1-selective antihistamine with H_2-blocking and mast cell stabilizing activity
- ► Used to relieve signs of allergic conjunctivitis (particularly pruritus)
- ► Duration of action allows for twice-daily dosing

Uses/Indications

Epinastine is used to treat and prevent pruritus associated with allergic conjunctivitis.

Pharmacology/Actions

Epinastine is a topically active, direct histamine-1 (H_1) receptor antagonist and an inhibitor of histamine release from the mast cell. Epinastine is selective for the H_1 receptor and has an affinity for the histamine-2 (H_2) receptor. Epinastine also possesses an affinity for the alpha-1, alpha-2, and 5-HT_2 receptors.[1] No evaluation of its use as a topical ophthalmic agent has been performed in veterinary species.

Contraindications/Precautions/Warnings

Epinastine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects

Adverse effects reported in humans include burning sensation in the eye, folliculitis, hyperemia, pruritus, and epiphora.[1] The most frequently reported nonocular adverse reactions include cold symptoms and upper respiratory infections, headache, rhinitis, sinusitis, increased cough, and pharyngitis. Some of these adverse effects may be related to the underlying disease being treated.

Dosages

Allergic conjunctivitis (extra-label): 1 drop in the affected eye(s) every 12 hours

Monitoring

- Clinical efficacy: resolution of signs related to allergic conjunctivitis (eg, pruritus, tearing, squinting)

Client Information

- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in solution.

Storage/Stability

Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Epinastine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Epinastine HCl 0.05% Ophthalmic Solution (containing epinastine 0.05%; benzalkonium chloride 0.01%; edetate disodium; purified water; NaCl; sodium phosphate, monobasic; NaOH and/or HCl to adjust pH to 7; osmolality range of 250 – 310 mOsm/kg), in a 5 mL sterile ophthalmic dropper bottle; *Elestat®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Erythromycin Ophthalmic

(eh-***rith***-rowe-***mye***-sin)

Macrolide Antibiotic

*For systemic use, refer to **Erythromycin***

Prescriber Highlights

- ► Used to treat susceptible ocular surface infections (eg, *Mycoplasma* spp and *Chlamydia* spp in cats)
- ► Only available as an ophthalmic ointment
- ► Used up to 6 times daily
- ► Use with caution in pocket pets that may ingest the drug via grooming.

Uses/Indications

Erythromycin ophthalmic ointment is used for the treatment of superficial ocular infections involving the conjunctiva and/or cornea caused by organisms that are susceptible to erythromycin. See ***Pharmacology/Actions***. Administration of topical erythromycin to normal cat eyes did not induce significant changes in normal ocular surface microflora.[1]

The World Health Organization (WHO) has designated erythromycin as a Critically Important, Highest Priority antimicrobial for human medicine.[2] The Office International des Epizooties (OIE) has designated macrolides as Veterinary Critically Important Antimicrobial (VCIA) Agents in avian, bovine, caprine, equine, lagomorphs, ovine, and swine species.[3]

Pharmacology/Actions

Erythromycin inhibits protein synthesis by binding the 50S subunit of the bacterial ribosome, thus inhibiting the formation of peptide bonds between amino acids by a variety of specific mechanisms. Erythromycin is usually active against *Streptococcus* spp, *Staphylococcus* spp, *Mycoplasma* spp, and *Chlamydia* spp.[4]

Erythromycin is considered ineffective against *Pseudomonas aeruginosa*.[5]

Contraindications/Precautions/Warnings

Erythromycin is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Topical macrolides should be used carefully, if at all, in pocket pets (eg, hamsters, chinchillas) and rabbits, as these animals may ingest macrolides while grooming, which increases the potential for GI adverse effects.

Adverse Effects

Adverse effects reported in humans or animals include mild **ocular** stinging, burning, irritation, and redness. Pocket pets ingesting macrolides may suffer from acute and potentially fatal diarrhea.

Dosages
Susceptible ocular infections (extra-label): ¼ – ½ inch strip in the affected eye(s) up to 6 times daily depending on the severity of infection

Monitoring
- Corneal cytology and culture to evaluate for the presence of bacteria
- Clinical efficacy: improvement and resolution of clinical signs associated with bacterial infection
- GI clinical signs; discontinue administration if diarrhea occurs following use on pocket pets.

Client Information
- Use this medicine as directed by your veterinarian
- Do not give this medicine to pocket pets (eg, hamsters, chinchillas) or rabbits without frequent examinations by your veterinarian.
- To prevent contamination, do not touch the dropper tip or allow it to touch your animal's eye or any other surface. Keep the cap tightly closed on the medication when it is not in use.
- If you are administering more than 1 eye medication to your animal, wait 5 minutes between each medication before giving the next. Use eye drops before eye ointments to allow the drops to absorb into the eye.
- Your veterinarian will need to monitor your animal while it is receiving this medicine. Do not miss these important follow-up visits.
- Store this medicine at room temperature; do not freeze. Do not use the medicine if the color or consistency changes.

Storage/Stability
Store erythromycin ophthalmic formulations at controlled room temperature (20°C-25°C [68°F-77°F]); do not freeze.

Compatibility/Compounding Considerations
Erythromycin should not be mixed directly (in vitro) with any other drugs. Erythromycin is not available as an ophthalmic solution.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Erythromycin 0.5% Ophthalmic Ointment (containing erythromycin 5 mg/g in a sterile ophthalmic base of mineral oil and white petrolatum), in a 3.5 g ointment tube; generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Fluorescein Stain Ophthalmic
(***flur***-e-seen)
Ocular Diagnostic Agent

Prescriber Highlights
- ► Used clinically to delineate full-thickness loss of corneal epithelium (corneal ulcer), to evaluate tear film breakup time, and to determine patency of nasolacrimal outflow system (Jones test)
- ► Yellow-green dye binds to corneal stroma but not to the corneal epithelium or Descemet membrane
- ► Available in combination with topical anesthetic (oxybuprocaine) to minimize discomfort on application and to facilitate additional diagnostic tests
- ► IV injection of its approved formulations is used diagnostically during fluorescein angiography.
- ► Fluorescein should **not** be used during intraocular surgery.

Uses/Indications
Topical application of fluorescein solutions to the ocular surface enables identification of corneal ulcers, evaluation of tear film breakup time (an indicator of tear film quality), and determination of patency of the nasolacrimal system (Jones test). Manufactured solutions of fluorescein, with or without topical anesthetics, are available for use, whereas dilution of individually wrapped fluorescein strips with eyewash is an alternative method that also decreases the risk for contamination between patients. Visualization of fluorescein retention by the cornea or conjunctiva, with either white or cobalt blue light, indicates epithelial loss (ulceration). The rapid appearance of breaks in fluorescein within the tear film suggests tear film quality disturbances. The appearance of fluorescein at the nostril following application to the ocular surface indicates functional patency of the nasolacrimal duct system (positive Jones test). IV injection of fluorescein solutions is used to evaluate blood flow patterns within the eye in the diagnostic procedure fluorescein angiography.

Pharmacology/Actions
Fluorescein is a water-soluble dye that is not retained by normal cornea because it does not pass through the hydrophobic epithelium. If the epithelium is absent, fluorescein penetrates the hydrophilic corneal stroma and stains it bright yellow-green. The green color is best visualized utilizing blue light from a cobalt filter attached to a penlight transilluminator, or a Wood's lamp. It may also be visible with ambient white light. Defects in the corneal stroma that extend to the deepest layer (Descemet membrane) will not retain fluorescein in the deepest aspect, as Descemet membrane is hydrophobic. In fluorescein angiography, vessels in the active areas of inflammation and neovascularization demonstrate leakage of fluorescein associated with increased vascular permeability. Fluorescein fluoresces in light with a wavelength between 485 and 500 nm, with maximal emission between 520 and 530 nm.

Contraindications/Precautions/Warnings
Fluorescein is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Fluorescein should not be used during intraocular surgery.

Adverse Effects
Adverse effects reported in humans or animals following the application of the strips include local hypersensitivity reactions and transient discomfort. Temporary staining of the skin and fur may result after use. Adverse effects following IV administration can be severe and include nausea, vomiting, GI distress, headache, syncope, hypotension, and signs of hypersensitivity. In humans, cardiac arrest, basilar artery ischemia, severe shock, convulsions, thrombophlebitis at the injection site, and, in rare cases, death have been reported. Extravasation of the solution at the injection site causes intense pain at the site and dull aching pain in the injected limb.[1]

Dosages
Determination of corneal injury: Wet fluorescein strip with 1 to 2 drops of normal saline solution. Apply moistened tip to conjunctiva or fornix. Allow patient to blink several times after application. Wait 60 seconds, rinse with sterile irrigating solution, and examine with the use of a light source; a cobalt filter may be attached to the light surface for better visualization. Defects in the corneal epithelium illuminate the stroma bright green. In deep corneal lesions, the lesion's center may fail to take up the stain and appears black, indicating that a descemetocele is present.

Tear film breakup time: Wet fluorescein strip with 1 to 2 drops of normal saline solution. Apply moistened tip to conjunctiva or fornix. Allow patient to blink once, and then hold lids open and monitor tear film for breaks, which appear as dark lines within the green.

Normal values are greater than 20 seconds in dogs, with shorter times indicating qualitative tear film deficiency.

Nasolacrimal outflow patency (Jones test): Wet fluorescein strip with 1 to 2 drops of normal saline solution. Apply moistened tip to conjunctiva or fornix. It is recommended that the patient's nose be tipped downward to facilitate drainage of fluorescein-laden tears through the nasolacrimal system, at which point fluorescein will be visible at the nares; a cobalt filter may be attached to a light surface for better visualization. Normal times are 2 to 5 minutes in dogs and up to 10 minutes in cats.

Fluorescein angiography: Rapid IV injection (≈1 mL/second) of 2 to 5 mL of fluorescein 100 mg/mL in the antecubital vein is followed by ocular vasculature visualization, using a cobalt filter light source and appropriate magnification. Time to filling and pattern of filling of vasculature within the anterior and posterior segments are noted and correlated with normal versus disease states. (This procedure is performed by board-certified veterinary ophthalmologists.)

Monitoring
- Diagnostic product; no monitoring is required

Client Information
- Do not use fluorescein strips at home.

Storage/Stability
Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Fluorescein ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Although IV fluorescein solutions have been approved by the US FDA, no topical ophthalmic fluorescein products have been approved.

Fluorescein Sodium 10% Injection (containing fluorescein 100 mg/mL and sterile water for injection; NaOH and/or HCl to adjust pH), in 5 mL single-use glass vials; *Fluorescite®*; (Rx)

Fluorescein Sodium 10% Injection (containing fluorescein 100 mg/mL and sterile water for injection; NaOH and/or HCl to adjust pH), in 5 mL single-dose glass vials; *AK-FLUOR 10%®*; (Rx)

Fluorescein Sodium 25% Injection (containing fluorescein 250 mg/mL and sterile water for injection; NaOH and/or HCl to adjust pH), in 2 mL single-dose glass vials; *AK-FLUOR 25%*; (Rx)

Fluorescein Sodium Ophthalmic Strips USP 1 mg per strip; individually wrapped strips in cartons of 50, 100, or 300; *Dry Eye Test®*, *Ful-Glo®*, *Bioglo®*, *Glostrips®*; (Rx)

COMBINATION PRODUCTS APPROVED FOR USE IN HUMANS:
Fluorescein Sodium and Benoxinate Hydrochloride Ophthalmic Solution 0.25%/0.4% (containing fluorescein sodium 2.5 mg; benoxinate hydrochloride 4 mg; povidone; hydrochloric acid; boric acid; sodium hydroxide; water for injection; hydrochloric acid and/or sodium hydroxide to adjust pH to 4.3 to 5.3), in sterile 5 mL ophthalmic dropper bottle; *Altafluor Benox®*, generic; (Rx)

Fluorescein Sodium and Benoxinate Hydrochloride Ophthalmic Solution 0.25%/0.4% (containing fluorescein sodium 2.5 mg; benoxinate hydrochloride 4 mg; chlorobutanol 10 mg; boric acid; povidone; sodium hydroxide and/or hydrochloric acid may be added to adjust pH to 4.3 to 5.3; purified water), in sterile 5 mL ophthalmic dropper bottle; *Fluress®*, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Fluorometholone Ophthalmic
(flew-roe-***meth***-oh-lone) *Flarex®, FML®, FML Forte®*
Corticosteroid

Prescriber Highlights
- ► Used to treat anterior segment inflammatory conditions
- ► Contraindications include the presence of corneal ulceration and existing or suspected bacterial, viral, or fungal ocular infection.
- ► Use with caution in avian species, as systemic adrenal suppression may result.
- ► Shake suspension well before using.

Uses/Indications
Fluorometholone ophthalmic can be used to treat inflammation following ocular injury or cataract surgery or to treat generalized inflammatory conditions of the anterior segment (eg, conjunctivitis, keratitis, anterior uveitis). Evaluation of relative efficacy of fluorometholone ophthalmic in veterinary patients has not been performed.

Pharmacology/Actions
Corticosteroids have broad immunomodulatory and anti-inflammatory actions, mediated via direct effects on gene expression, as well as by nongenomic effects on cell membranes and receptors. Ultimately, corticosteroids decrease pro-inflammatory gene transcription, production of pro-inflammatory prostaglandins and leukotrienes, B- and T-cell number and function, cell-mediated immunity, and humoral immunity.[1] The specific mechanisms involved in regulating ocular inflammation are not known. Fluorometholone alcohol preparations are most effective for ocular surface inflammation, rather than intraocular inflammation, due to comparatively poor transcorneal penetration relative to the acetate preparations.

Contraindications/Precautions/Warnings
Fluorometholone is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Ocular corticosteroids should not be used in animals with bacterial, fungal, or viral ocular infections, or if corneal ulceration is present, as they may potentiate infection and decrease epithelial wound healing.

Adverse Effects
Adverse effects reported in humans include development of cataracts (via altered glucose or lenticular metabolic effects), increased intraocular pressure (IOP; via activation of glucocorticoid receptors in the trabecular meshwork), infection (via immunosuppression), decreased wound healing (via increased collagenolytic activity), mydriasis, and calcific keratopathy. Some animals may develop increased IOP with chronic use; however, most reports suggest the change is reversible.[2,3] Additionally, fluorometholone is associated with less risk of IOP elevation compared with other topical corticosteroids. Systemic effects are rare but include hepatopathy, suppression of endogenous glucocorticoid production, and focal alopecia. Concurrent use of systemic steroids increases the risk for these adverse effects.

Dosages
Conjunctivitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) as frequently as every 4 hours until clinical improvement occurs, then gradually (over days to weeks) decrease the dosage, provided clinical improvement is maintained

Keratitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) as frequently as every 4 hours until clinical improvement occurs, then

gradually (over days to weeks) decrease the dosage, provided clinical improvement is maintained

Anterior uveitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) as frequently as every 4 hours until clinical improvement occurs, then gradually (over days to weeks) decrease the dosage, provided clinical improvement is maintained

Monitoring
- Clinical efficacy through resolution of signs of inflammation
- Monitor intraocular pressure (IOP) and ocular surface integrity
- Blood or urine glucose changes based on development of clinical signs (eg, polyuria, polydipsia) in diabetic animals

Client Information
- Use this medicine as directed by your veterinarian.
- It is important to shake the suspension well before giving this medicine to your animal.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 to 10 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes or if there are particles in the suspension.

Storage/Stability
Store this product in the refrigerator or at controlled room temperature (2°C-25°C [36°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Fluorometholone ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Fluorometholone 0.1% Ophthalmic Suspension (containing fluorometholone 1 mg/mL; benzalkonium chloride 0.01%; sodium chloride; monobasic sodium phosphate; edetate disodium; hydroxyethyl cellulose; tyloxapol; HCl and/or NaOH to adjust pH; purified water), 5 mL or 10 mL in sterile ophthalmic dropper bottles; *FML®*, *Flarex®*; (Rx)

Fluorometholone 0.25% Ophthalmic Suspension (containing fluorometholone 2.5 mg/mL; benzalkonium chloride 0.005%; edetate disodium; polysorbate 80; polyvinyl alcohol 1.4%; purified water; NaCl; sodium phosphate, dibasic; sodium phosphate, monobasic; NaOH to adjust the pH from 6.2 to 7.5), 5 mL or 10 mL in sterile ophthalmic dropper bottles; *FML Forte®*; (Rx)

Fluorometholone 0.1% Ophthalmic Ointment (containing fluorometholone 1 mg/mL; phenylmercuric acetate (0.0008%); mineral oil; petrolatum (and) lanolin alcohol; white petrolatum), in 3.5 g ophthalmic ointment tubes; *FML®*; (Rx)

Fluorouracil Ophthalmic

(flewr-oh-***your***-uh-sil)

Antineoplastic Agent

*For systemic use, see **Fluorouracil***

Prescriber Highlights
- ► Antifibrotic agent used adjunctively in periocular surgeries (most commonly in glaucoma implant procedures)
- ► Antineoplastic used for susceptible cutaneous tumors
- ► **Do NOT use in cats** or in patients with myelosuppression or serious infections.
- ► Adverse effects include dose-dependent myelosuppression, GI toxicity, and neurotoxicity.
- ► Known teratogen
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies fluorouracil as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
Fluorouracil ophthalmic is used as an adjunct in ocular surgeries, particularly in those that treat glaucoma through placement of drainage shunts or alteration of the natural aqueous humor outflow tracts, because of fluorouracil's ability to reduce fibroblastic proliferation and prevent subsequent scarring.[1] Fluorouracil ophthalmic is also used to treat ocular surface neoplastic conditions, such as squamous cell carcinoma and sarcoids.

Pharmacology/Actions
Fluorouracil is a pyrimidine analogue that is converted through intracellular mechanisms into multiple active metabolites which interfere with DNA and RNA synthesis, inhibit cell growth, and promote cell death.[2]

Contraindications/Precautions/Warnings
Fluorouracil is contraindicated in patients that are hypersensitive to it or any component of the formulation. Fluorouracil is absolutely contraindicated in cats by any route of administration, including ophthalmic administration, as cats develop a severe, potentially fatal neurotoxicity when they are exposed to fluorouracil by any route. Do not use fluorouracil in patients that are pregnant or in those that are myelosuppressed or have concurrent serious infections. Although systemic adverse effects are less likely after topical application of fluorouracil in other species, they can occur.

The National Institute for Occupational Safety and Health (NIOSH) classifies fluorouracil as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects
Although less likely after topical administration, adverse effects reported in humans or animals include myelosuppression, GI toxicity (eg, diarrhea, GI ulceration, sloughing, stomatitis), and neurotoxicity (seizures). The most frequent adverse reactions with ophthalmic fluorouracil administration occur locally and are often related to an extension of the pharmacological activity of the drug.[3] These effects include burning, crusting, allergic contact dermatitis, erosions, erythema, hyperpigmentation, irritation, pain, periorbital alopecia, photosensitivity, pruritus, scarring, rash, soreness, and ulceration.

Dosages
NOTE: Multiple protocols exist for use during surgical procedures for correction of glaucoma; these protocols vary with the type of procedure and other patient parameters. As these procedures should be performed by board-certified veterinary ophthalmologists, the protocols are not detailed here.

Ocular surface neoplasia (extra-label): Fluorouracil 1% ophthalmic solution (compounded), 1 drop in affected eye(s) 4 times daily for 1 week; may be repeated in regular cycles.[4,5] Use of a *topical* 1% fluorouracil ointment applied 4 times daily also has been described.[6,7]

Monitoring
- Clinical efficacy
- Maintenance of patency of the glaucoma implant, which leads to control of intraocular pressure
- Cell or tissue samples for evaluation to confirm remission of neoplasia

Client Information
- This is a chemotherapy (anticancer) drug. The drug and its by-products can be hazardous to other animals and humans. Pregnant women and sick or immunocompromised individuals should avoid contact.
- Wear protective gloves and a mask when administering this medicine. After administration, seal these gloves, mask, and other waste products in a plastic bag, and then place in the regular trash. Wash your hands immediately after each application.
- Loss of hair around the eyes may occur after use.
- Wait for 5 to 10 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine according to instructions on the bottle or prescription label.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solutions.

Storage/Stability
Store this product as directed on the product label.

Compatibility/Compounding Considerations
Fluorouracil ophthalmic preparations should not be mixed directly with any other ophthalmic medications. Fluorouracil ophthalmic preparations are not commercially available but may be prepared by qualified compounding pharmacists by utilizing the 50 mg/mL injectable solution. Fluorouracil 1% ophthalmic solution prepared this way is reported to be stable for 3 weeks.[8]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Fluorouracil ophthalmic formulations must be prepared (compounded) by a qualified compounding pharmacist. See ***Compounding: How to Find a Quality Assured Pharmacy.***

For the complete list of references, see **wiley.com/go/budde/plumb**

Flurbiprofen Ophthalmic

(flur-bi-***proe***-fin) *Ocufen®*

Nonsteroidal Anti-inflammatory Drug (NSAID)

Prescriber Highlights
- ► Used to control anterior segment inflammation
- ► May cause transient increases in intraocular pressure (IOP)
- ► May delay ocular wound healing and increase risk for intraocular bleeding

Uses/Indications
Flurbiprofen ophthalmic is indicated for controlling anterior segment inflammation (eg, conjunctivitis, keratitis, anterior uveitis), inducing mydriasis during cataract-removal surgery, and for providing analgesia following surgical removal of cataracts. In dogs, flurbiprofen significantly reduced clinical signs associated with experimentally induced intraocular inflammation,[1] whereas it demonstrated poor efficacy in cats.[2] Flurbiprofen did not decrease corneal sensitivity in normal dogs, suggesting its use as an ophthalmic analgesic may be limited[3]; however, analgesic effects may improve in the presence of ocular pain.

Pharmacology/Actions
Flurbiprofen is an NSAID that blocks prostaglandin synthesis by inhibiting cyclooxygenase 1 and 2. Prostaglandins mediate many of the adverse effects of intraocular inflammation, including disruption of the blood–aqueous barrier, vasodilation, increased vascular permeability, leukocytosis, and increased intraocular pressure (IOP). Blocking prostaglandin production therefore minimizes the adverse short- and long-term effects of intraocular inflammation. Prostaglandins also appear to play a role in the miotic response produced during ocular surgery by constricting the iris sphincter independently of cholinergic mechanisms. Thus, flurbiprofen inhibits miosis induced during cataract surgery.[4]

Contraindications/Precautions/Warnings
Flurbiprofen is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. The potential for cross-sensitivity to acetylsalicylic acid, phenylacetic acid derivatives, and other NSAIDs exists.[4] Topical NSAIDs may result in corneal epithelial breakdown and corneal thinning, erosion, or ulceration, which could cause delayed corneal wound healing; concurrent use of topical NSAIDs and topical corticosteroids may further delay healing and increase the potential for development of adverse effects.[4] Due to interference with thrombocyte aggregation, ophthalmic NSAIDs may cause increased bleeding of ocular tissues (eg, hyphema) in conjunction with ocular surgery. It is recommended that flurbiprofen ophthalmic solution be used with caution in patients with known bleeding tendencies (eg, severe liver disease) or in those receiving anticoagulant medications (eg, heparins, rivaroxaban), which may prolong bleeding time.[4]

Adverse Effects
Adverse effects reported in humans or animals include transient ocular burning or stinging on administration.[4] Additional adverse reactions reported with the use of flurbiprofen ophthalmic include fibrosis, miosis, and mydriasis. NSAIDs may also cause direct cellular damage, causing delayed healing and/or deterioration of existing corneal wounds. Although unlikely, systemic adverse effects may occur with the use of topical NSAIDs, including increased risk for gastric ulceration, decreased platelet aggregation, worsening of asthma and cardiac disease, and renal toxicity. Concurrent use of systemic NSAIDs and corticosteroids increases the risk for systemic adverse effects. The increased bleeding tendency of ocular tissues in conjunction with ocular surgery has also been reported. Flurbiprofen has been documented to elevate intraocular pressure (IOP) in dogs,[5,6] and decrease the IOP-lowering effect of latanoprost in normal canine eyes6 and canine eyes following surgical cataract removal.[7] Flurbiprofen increased corneal sensitivity when it was administered to normal canine eyes; therefore, it is suspected to be associated with an ocular irritant effect.[8]

Dosages
Preoperative for cataract surgery (extra-label): 1 drop every 30 minutes for 4 applications beginning 2 hours prior to surgery

Anterior segment inflammation (extra-label): 1 drop in affected eye(s) every 8 hours; frequency may be reduced to once daily after resolution of initial inflammation

Monitoring
- Clinical efficacy (eg, decreased or absent anterior segment inflammation)
- Adverse effects (eg, delayed wound healing)

Client Information
- Use this medicine as directed by your veterinarian.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.
- Flurbiprofen ophthalmic may cause burning or stinging on administration. It may also increase the risk for bleeding and may slow down healing in the eye.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed on the medicine when it is not in use.
- Wait for 5 minutes after applying this medicine is before applying any other medications to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.

Storage/Stability
Store as directed on package labeling (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Flurbiprofen ophthalmic solutions should not be mixed directly with any other drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Flurbiprofen sodium 0.03% Ophthalmic Solution (containing flurbiprofen 0.3 mg/mL; thimerosal 0.005%; citric acid; edetate disodium; polyvinyl alcohol 1.4%; potassium chloride; purified water; NaCl; sodium citrate; HCl and/or NaOH to adjust pH to 6 to 7; osmolality of 260 – 330 mOsm/kg), in 2.5 mL ophthalmic dropper bottles; *Ocufen®*, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Ganciclovir Ophthalmic

(gan-***sye***-kloe-veer) *Zirgan®*

Antiviral Agent

Prescriber Highlights
- ► Used as an ophthalmic antiviral in cats with feline herpesvirus-1 (FHV-1) and dogs with canine herpesvirus-1 (CHV-1)
- ► May cause myelosuppression and nephrotoxicity in cats if ingested
- ► In vitro efficacy versus FHV-1 is 2 to 10 times greater than similar antivirals.

Uses/Indications
In veterinary patients, ganciclovir may be used to treat feline herpesvirus-1 (FHV-1)-induced ocular surface disease in cats. In vitro efficacy of ganciclovir versus FHV-1 has been demonstrated at various concentrations1 and is 2 times greater than cidofovir and penciclovir and 10 times greater than acyclovir.[2,3] When ganciclovir was administered to cats with healthy eyes 3 times daily, no signs of ocular irritation developed.[1]

Evaluation of ganciclovir in experimentally induced canine herpesvirus-1 infections (CHV-1) indicated good efficacy without signs of ocular toxicity.[4] In vitro evaluation of ganciclovir suggests efficacy against equine alpha-herpesviruses[5,6] ; however, evaluation of ganciclovir's use in vivo has not been performed.

Pharmacology/Actions
Ganciclovir is a guanosine derivative that, upon phosphorylation, inhibits DNA replication of herpes simplex viruses (HSV). Ganciclovir is transformed by viral and cellular thymidine kinases (TK) to ganciclovir triphosphate, which works as an antiviral agent by competitive inhibition of viral DNA-polymerase and prevents DNA elongation.

Contraindications/Precautions/Warnings
Ganciclovir is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Myelosuppression and nephrotoxicity may occur in cats after systemic treatment. Ganciclovir has been shown to be embryotoxic in rabbits and mice and teratogenic in rabbits following IV administration.[7] Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring. Do not allow cats to ingest the topical formulation; an e-collar may be required to avoid unintentional ingestion during grooming.

Adverse Effects
Adverse effects reported in humans or animals include blurred vision, eye irritation, punctate keratitis, chemosis, and conjunctival hyperemia and discharge.[1,7] Myelosuppression and nephrotoxicity are possible in cats after ingestion by grooming.

Dosages
Herpes keratitis (extra-label): 1 drop in affected eye(s) up to 5 times daily until the corneal ulcer has healed, then 3 times daily for 7 days

Monitoring
- Clinical efficacy: resolution of clinical signs associated with herpes keratitis (eg, corneal ulceration, corneal vascularization, conjunctivitis)
- Baseline and periodic CBC and chemistry panel for cats to detect myelosuppression and nephrotoxicity

Client Information
- Wipe the cat's face after applying. Do not let cats lick this medication, as it can be toxic when ingested.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this product at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the gel.

Storage/Stability
Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight.

Compatibility/Compounding Considerations
Ganciclovir should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Ganciclovir 0.15% Ophthalmic Gel (containing ganciclovir 1.5 mg/mL; carbopol; water for injection; NaOH (to adjust the pH to 7.4); mannitol; benzalkonium chloride 0.075 mg), in a 5 g ophthalmic gel tube; *Zirgan®*; (Rx)

Gatifloxacin Ophthalmic

(gat-i-***flocks***-a sin) *Zymaxid®, Zymar®*

Fourth-Generation Fluoroquinolone Antibiotic

Prescriber Highlights

- ► Fluoroquinolone antimicrobial available in ophthalmic formulation only; used to treat bacterial conjunctivitis or keratitis
- ► Appropriately used as a therapeutic antibiotic in cases with known ocular surface infection; not appropriate for prophylactic use
- ► Physically incompatible with many drugs; therefore, it should not be directly mixed with other ophthalmic medications
- ► Crystalline drug precipitates may be noted in the superficial portion of corneal defects during use.

Uses/Indications

Gatifloxacin ophthalmic may be useful for treating bacterial conjunctivitis or keratitis caused by susceptible strains of *Staphylococcus* spp, *Streptococcus* spp, *Pseudomonas aeruginosa*, *Chlamydophila* spp, and *Haemophilus* spp. Gatifloxacin has demonstrated good in vitro activity versus *Pseudomonas* spp organisms cultured from dogs with ulcerative keratitis,[1] particularly in relation to the second-generation fluoroquinolone ciprofloxacin.[2] In comparison to moxifloxacin and besifloxacin, gatifloxacin demonstrated lower corneal and aqueous humor concentrations when administered to dogs with normal eyes.[3] Gatifloxacin should be used to treat, rather than prevent, bacterial ocular infections.

Pharmacology/Actions

Gatifloxacin is a fluoroquinolone antibiotic that acts via inhibition of both topoisomerase II (DNA gyrase) and topoisomerase IV to impair bacterial DNA synthesis. Inhibition of these 2 enzymes decreases the development of resistance to this class of fluoroquinolones. In comparison with besifloxacin, gatifloxacin is reported to have slightly greater in vitro efficacy versus gram-negative organisms, with slightly lesser in vitro efficacy versus gram-positive organisms.[4]

Contraindications/Precautions/Warnings

Gatifloxacin is contraindicated in patients that have a history of hypersensitivity to it, other fluoroquinolones, or any component of the formulation. This drug should only be used as a topical ophthalmic. Do not inject gatifloxacin subconjunctivally or into the anterior chamber of the eye. Fluoroquinolone-induced retinal toxicity in domestic cats has not been demonstrated with this product.

Adverse Effects

Adverse effects reported in humans or animals include blurred vision, tearing, eye pain, redness, itching, and a bad taste in the mouth. Crystalline drug precipitates may be noted in the superficial portion of corneal defects during use.

Dosages

Conjunctivitis (extra-label): 1 drop in affected eye(s) every 2 to 8 hours
Keratitis (extra-label): 1 drop in the affected eye every 2 to 8 hours

Monitoring

- Clinical efficacy. Corneal cytology and culture to evaluate for persistence of bacteria, and evaluation for clinical signs suggestive of continued infection

Client Information

- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Crystals may appear on the ocular surface after initiation of treatment.
- This medicine may precipitate when mixed with other ophthalmic medicines. Therefore, when giving this medicine to your horse through a subpalpebral lavage catheter, it is important to flush the catheter well with air between medications.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.

Storage/Stability

Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Gatifloxacin ophthalmic preparations should not be mixed directly with any other ophthalmic medications and is considered physically incompatible with many drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Gatifloxacin 0.3% Ophthalmic Solution (containing gatifloxacin 3 mg/mL; benzalkonium chloride 0.005%; edetate disodium; purified water and NaCl; HCl and/or NaOH to adjust pH to ≈6; osmolality of 260 to 330 mOsm/kg) in 5 mL ophthalmic dropper bottles; *Zymar®*, generic; (Rx)

Gatifloxacin 0.5% Ophthalmic Solution (containing gatifloxacin 5 mg/mL; benzalkonium chloride 0.005%; edetate disodium; purified water and NaCl; HCl and/or NaOH to adjust pH to ≈6; osmolality of 260 to 330 mOsm/kg), 2.5 mL in a sterile ophthalmic dropper bottle; *Zymaxid®*, generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Gentamicin Ophthalmic

(***jen***-ta-mye-sin ***sul***-fate) *Genoptic®, Gentocin®, Gentak®*

Aminoglycoside Antibiotic

*For systemic use, see **Gentamicin***

Prescriber Highlights

- ► Topical ophthalmic aminoglycoside antibiotic used as a treatment for susceptible ocular surface bacterial infections
- ► Do not use if a full-thickness corneal wound is present, as gentamicin is toxic to the eye's interior.
- ► Fortified solutions of gentamicin sulfate up to 13.6 mg/mL may be compounded for use in susceptible infections of equine bacterial keratitis.

Uses/Indications

Gentamicin ophthalmic is primarily used for patients with ocular infections caused by gram-negative aerobes, such as *Pseudomonas aeruginosa*.[1,2] Gentamicin does not demonstrate consistent efficacy against versus *Staphylococcus* spp or *Streptococcus* spp isolates.[1,3] As the spectrum of gentamicin is weighted toward gram-negative organisms, and as it is more toxic to the corneal epithelium, gentamicin should not be considered a first-line prophylactic antibiotic in veterinary ophthalmology.[4,5]

In horses with end-stage glaucoma, intravitreal injection of gentamicin at higher doses is used to chemically ablate the ciliary body, thus reducing the production of aqueous humor and lowering intraocular pressure (IOP)[6]; lower doses may be used to manage equine recurrent uveitis (ERU).[7,8] See ***Gentamicin***.

The World Health Organization (WHO) has designated gentamicin as a Critically Important, High Priority antimicrobial for human medicine.[9] The Office International des Epizooties (OIE) has desig-

nated gentamicin as a Veterinary Critically Important Antimicrobial (VCIA) Agent in equine species.[10]

Pharmacology/Actions

Gentamicin sulfate, an aminoglycoside, is actively transported into the bacterial cell. It binds to a specific receptor protein on the 30S subunit of bacterial ribosomes. It consequently interferes with an initiation complex between mRNA (messenger RNA) and the 30S subunit, inhibiting protein synthesis by inducing misreading of the mRNA. Aminoglycosides are bactericidal, whereas most other antibiotics that interfere with protein synthesis are bacteriostatic.

Contraindications/Precautions/Warnings

Gentamicin is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Gentamicin should not be used if a full-thickness corneal wound is present, as gentamicin is toxic to the eye's interior.

Adverse Effects

Adverse effects reported in humans or animals include ocular burning and irritation upon drug instillation, nonspecific conjunctivitis, conjunctival epithelial defects, and conjunctival hyperemia. Other adverse reactions that have rarely been reported include allergic reactions, thrombocytopenic purpura, and hallucinations (humans).[11] In dogs and cats, although causation has not been proven, intravitreal gentamicin injections for ciliary body ablation may be linked to the development of intraocular tumors.[12,13] In horses, cataract formation and diffuse retinal degeneration have been reported following the intravitreal injection of low-dosage gentamicin for equine recurrent uveitis (ERU) management.[8]

When gentamicin is used systemically, it can cause nephrotoxicity and neurotoxicity (ototoxicity and vestibular toxicity). Cats are more susceptible to the toxic effects of gentamicin, and it is recommended that all patients receiving topical gentamicin be monitored for systemic toxicity.

Dosages

Susceptible ocular infections (extra-label): 1 drop of the solution or ¼ – ½ inch strip in the affected eye(s) 4 to 6 times daily. The frequency may be increased to every 30 to 60 minutes for a few hours if needed.

Monitoring

- Clinical efficacy: cytology and culture to evaluate for presence of bacteria; clinical resolution of signs of ocular surface infection and or recurrent inflammation
- Intraocular pressure (IOP) when used as adjunctive treatment for equine glaucoma or recurrent uveitis
- Urinalysis with sediment to check for casts in the urine, which may be an early indicator for renal toxicity

Client Information

- Give this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep cap tightly closed when not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medicine according to the directions on the product label, protected from light. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store this product as directed on the product label, protected from light; do not freeze.

Compatibility/Compounding Considerations

Gentamicin sulfate should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Gentamicin Sulfate 0.3% Ophthalmic solution (containing gentamicin sulfate equivalent to 3 mg gentamicin base; disodium phosphate; monosodium phosphate; NaCl; benzalkonium chloride; aqueous solution with pH 6.8 to 7.3), in sterile 5 mL dropper bottle; generic; (Rx)

VETERINARY-LABELED COMBINATION PRODUCTS:

Gentamicin Sulfate 0.3% and Betamethasone Ophthalmic solution (containing gentamicin sulfate equivalent to 3 mg gentamicin base; 1 mg betamethasone acetate equivalent to 0.89 mg betamethasone alcohol; polyoxyol 40 stearate; polyethoxy 35 castor oil; edetate disodium; 0.1 mg benzalkonium chloride as a preservative; water for injection), supplied in a sterile 5 mL dropper bottle; *Gentocin® Durafilm®*; (Rx)

HUMAN-LABELED PRODUCTS:

Gentamicin 0.3% Ophthalmic Solution (containing gentamicin sulfate equivalent to 3 mg/mL gentamicin base; benzalkonium chloride; edetate disodium; polyvinyl alcohol 1.4%; purified water; NaCl; sodium phosphate, dibasic; HCl and/or NaOH to adjust the pH in an aqueous, buffered solution with a pH of 6.5 to 7.5), in 5 mL ophthalmic dropper bottles; *Genoptic®*, *Gentak®*; (Rx)

Gentamicin 0.3% Ophthalmic Ointment (containing gentamicin sulfate equivalent to 3 mg/mL of gentamicin in a base of white petrolatum and mineral oil, with methylparaben and propylparaben as preservatives), in a 3.5 g ophthalmic ointment tube; generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:

Gentamicin and Prednisolone Acetate Ophthalmic Ointment 0.3%/0.6% (containing gentamicin sulfate equivalent to 0.3% gentamicin base; prednisolone acetate 0.6%; chlorobutanol (chloral derivative) 0.5%; mineral oil; petrolatum (and) lanolin alcohol; purified water; white petrolatum), in a sterile 3.5 g ophthalmic tube; *Pred-G®*; (Rx)

Gentamicin and Prednisolone Acetate Ophthalmic Suspension 0.3%/1% (containing gentamicin sulfate equivalent to 0.3% gentamicin base; prednisolone acetate (microfine suspension) 1%; benzalkonium chloride 0.005%; edetate disodium; hypromellose; polyvinyl alcohol 1.4%; polysorbate 80; purified water; sodium chloride; sodium citrate dehydrate; NaOH and/or HCl to adjust pH (5.4 to 6.6), in a sterile 5 mL ophthalmic dropper bottle; *Pred-G®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Hydrocortisone Ophthalmic

(hye-droe-***kor***-ti-zone)

Corticosteroid Anti-inflammatory Agent

Prescriber Highlights

- ► Ophthalmic corticosteroid used to treat ocular surface inflammation
- ► Only commercially available formulation is in combination with neomycin/polymyxin B +/-bacitracin
- ► NOT effective for deep corneal or intraocular inflammation (uveitis)
- ► Contraindications include a hypersensitivity to dexamethasone; an existing or suspected bacterial, viral, or fungal ocular infection; and in the presence of a corneal abrasion or ulceration.
- ► Use with caution in avian species due to risk for systemic corticosteroid effects.

Uses/Indications
Hydrocortisone is used in combination with topical antibiotics (eg, neomycin, polymyxin, ± bacitracin) for inflammatory conjunctivitis.

Pharmacology/Actions
Hydrocortisone is a naturally occurring corticosteroid that is produced by the adrenal glands. Corticosteroids have broad immunomodulatory and anti-inflammatory actions, which are mediated via direct effects on gene expression, as well as by non-genomic effects on cell membranes and receptors. Ultimately, corticosteroids decrease pro-inflammatory gene transcription, production of pro-inflammatory prostaglandins and leukotrienes, B- and T-cell number and function, cell-mediated immunity, and humoral immunity.[1] Specific mechanisms involved in controlling ocular inflammatory conditions are not definitively known. Hydrocortisone has a relative glucocorticoid potency of 1 (versus 4 for prednisolone and 30 for dexamethasone and betamethasone), which correlates with weak clinical efficacy.

Hydrocortisone is a weak base steroid with poor intraocular penetration; therefore, it is ineffective for treating intraocular inflammation (uveitis).

Contraindications/Precautions/Warnings
Hydrocortisone is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Due to inhibition of epithelial wound healing and potentiation of infection, hydrocortisone ophthalmic is also contraindicated when corneal ulceration is suspected or present, or in the presence of corneal infection (bacterial, fungal, or viral).[2,3] Topical administration of glucocorticoids may produce systemic effects. For more information, refer to ***Glucocorticoid Agents, General Information***. Use hydrocortisone ophthalmic with caution in patients with endocrine diseases (eg, diabetes mellitus, acromegaly), infectious diseases, chronic kidney disease, congestive heart failure, systemic hypertension, or gastric ulceration. When use of hydrocortisone ophthalmic is necessary to treat a patient with these conditions, the minimal effective dose should be administered for the shortest possible time. Ophthalmic steroids should be used with extreme caution in avian species due to increased risk for systemic adverse effects.

Adverse Effects
Adverse effects reported in humans or animals include burning, stinging, and irritation upon application to the eye.[3] Systemic absorption may result in suppression of the hypothalamus-pituitary-adrenal axis. The use of corticosteroids may result in posterior subcapsular cataract formation, glaucoma, and secondary ocular infections due to bacteria, fungi, or viruses.[4] With the chronic use of hydrocortisone, intraocular pressure (IOP) may increase in some animals; however, most reports suggest the change is reversible.[5–7]

Dosages
Inflammatory conjunctivitis (extra-label): ¼ – ½ inch strip in the affected eye(s) up to 4 times daily

Monitoring
- Clinical efficacy
- Resolution of signs of inflammation
- Intraocular pressure (IOP; especially in cats) and ocular surface integrity (eg, fluorescein stain)
- Blood or urine glucose changes based on clinical signs (eg, polyuria, polydipsia) in diabetic animals

Client Information
- Available only as an ointment form, in combination with antibiotics.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medicine as directed on the product label. Do not freeze.
- Discard this medicine if the color change occurs.

Storage/Stability
Store at controlled room temperature (68°F-77°F [20°C-25°C]), away from moisture and sunlight.

Compatibility/Compounding Considerations
Hydrocortisone ophthalmic should not be mixed directly (in vitro) with any other drugs. Instruct caregivers to wait for 5 minutes after applying this medication before applying any other medications to the eye.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

No ophthalmic products containing only hydrocortisone are available; available commercially in combination with antimicrobial agents.

Neomycin/Bacitracin/Polymyxin/Hydrocortisone Ophthalmic Ointment (containing neomycin sulfate equivalent to 3.5 mg neomycin base, polymyxin B sulfate equivalent to 10,000 polymyxin B units, bacitracin zinc equivalent to 400 bacitracin units, hydrocortisone 10 mg/g, and white petrolatum), in a 3.5 g ophthalmic ointment tube; *Vetropolycin HC*®, (Rx)

HUMAN-LABELED PRODUCTS:

Neomycin/Bacitracin/Polymyxin/Hydrocortisone Ophthalmic Ointment (containing neomycin sulfate equivalent to 3.5 mg neomycin base, polymyxin B sulfate equivalent to 10,000 polymyxin B units, bacitracin zinc equivalent to 400 bacitracin units, hydrocortisone 10 mg/g, and white petrolatum), in a 3.5 g ophthalmic ointment tube; generic, (Rx)

Neomycin/Polymyxin/Hydrocortisone Ophthalmic Ointment (containing neomycin sulfate equivalent to 3.5 mg neomycin base, polymyxin B sulfate equivalent to 10,000 polymyxin B units, hydrocortisone 10 mg/g, and white petrolatum), in a 3.5 g ophthalmic ointment tube; generic, (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Idoxuridine Ophthalmic
(eye-docks-***yoor***-uh-deen)

Antiviral (Nucleoside Analogue)

Prescriber Highlights
- ► Topical antiviral agent used in cats with feline herpesvirus-1 (FHV-1)
- ► Must be used 4 to 5 times daily
- ► In vitro efficacy is less than trifluridine and comparable to or greater than other antivirals.
- ► No longer commercially available; must be compounded as an ointment, solution, or suspension

Uses/Indications
Idoxuridine is used topically in cats to treat conjunctivitis and keratitis associated with feline herpesvirus-1 (FHV-1) infections. Idoxuridine has also demonstrated efficacy in the treatment of canine herpesvirus-1 (CHV-1) keratitis.[1] Although relative efficacy versus other antiviral agents is not known and direct causation of clinical effect is difficult to determine, idoxuridine was associated with improvement in keratoconjunctivitis caused by equine herpesvirus-2 (EHV-2) in foals.[2]

Pharmacology/Actions
Idoxuridine is chemically similar to thymidine, and its substitution into viral DNA causes misreading of the viral genetic code, thereby inhibiting viral replication. Because idoxuridine is a nonspecific inhibitor of DNA synthesis, it affects any cellular function requiring thymidine and is not suitable for systemic use. Even with topical therapy, corneal toxicity can occur. Idoxuridine is virustatic. Idoxuridine's in vitro efficacy is less than trifluridine, comparable to ganciclovir, greater than cidofovir, and much greater than acyclovir.[3,4]

Contraindications/Precautions/Warnings
Idoxuridine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans or animals include acute ocular irritation, including burning, corneal stippling, vascularization, and clouding. Following prolonged use of idoxuridine, ocular irritation characterized by follicular conjunctivitis, blepharitis with punctal swelling, bulbar conjunctival hyperemia, and corneal epithelial staining has also been reported. Treatment with idoxuridine should be discontinued if adverse effects occur.

Dosages
Keratitis caused by feline herpesvirus-1 (FHV-1), canine herpesvirus-1 (CHV-1), or equine herpesvirus-2 (EHV-2) (extra-label): 1 drop in affected eye(s) every 2 to 3 hours for 48 hours, then 4 to 5 times daily for a week beyond the resolution of clinical signs

Monitoring
- Resolution of clinical signs of herpetic keratitis (eg, corneal ulceration, corneal vascularization, conjunctivitis)

Client Information
- Give this medicine to your animal as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication as directed on the product label. Do not freeze and protect from light.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in solutions.

Storage/Stability
Because this compound must be compounded (in the United States), storage recommendations can vary; follow storage requirements listed on the packaging. Do not freeze.

Compatibility/Compounding Considerations
Idoxuridine should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

No ophthalmic dosage form of idoxuridine is approved for use; however, Idoxuridine may be compounded as a 0.1% to 0.5% solution, suspension, and/or ointment by a qualified compounding pharmacist.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Irrigating Solutions, Ophthalmic
BSS®, Collyrium®

Ocular Irrigant

Prescriber Highlights
- ► Available for either intraocular or extraocular use
- ► Extraocular (eyewashes) products should NOT be used intraocularly.

Uses/Indications
Extraocular eyewash preparations are used to irrigate the nasolacrimal duct system, remove debris from the eye, and remove the excess stain after diagnostic staining (eg, fluorescein) of the cornea.

Intraocular irrigation solutions are used during intraocular surgery (eg, cataract removal, vitreal surgery) to maintain the shape of the anterior chamber, cool phacoemulsification handpieces, and lavage emulsified lens and surgical byproducts from the eye.

Pharmacology/Actions
OTC extraocular eyewash preparations are sterile isotonic solutions that contain preservatives and are intended to be used for general external ophthalmic use only.

Intraocular sterile irrigating solutions are sterile, preservative-free, physiologically balanced salt solutions that mimic the composition of the aqueous humor in terms of physiologic pH, osmolality, and ion composition; they contain electrolytes required for normal cellular metabolic functions. Some intraocular irrigating solutions also contain glutathione, which is responsible for stabilizing endothelial cell junctions and intraocular pumping functions.

Contraindications/Precautions/Warnings
Extraocular eyewash preparations are contraindicated for intraocular use, as preservative components are toxic to the corneal endothelium. They are also contraindicated if the patient is hypersensitive to any component of the formulation. Adding drugs or other fluids to intraocular irrigating solutions may damage intraocular tissue.

In humans with diabetic mellitus who are undergoing vitrectomy, caution is recommended with the use of intraocular irrigating solutions, as intraoperative lens changes have been noted in some patients; the same recommendation may apply to diabetic animals. Caution should be used in diabetic animals undergoing vitrectomy for other causes (eg, trauma, neoplasia, endophthalmitis).

Adverse Effects
Intraocular irrigation solutions have caused corneal clouding and edema in some patients due to endothelial damage. In humans, lens changes have been noted in some diabetic patients who are undergoing vitrectomy. A study evaluating cooled versus room temperature irrigating solutions demonstrated no significant adverse effects between the 2 temperatures.[1]

Dosages
Extraocular eyewash (extra-label): Flush affected eye(s) as needed; control rate of flow by exerting pressure on the bottle

Intraocular use during surgery (extra-label): Use a sterile, preservative-free balanced salt solution (NOT an OTC eyewash) according to the established practices for each surgical procedure.

Monitoring
- When intraocular solutions are used, monitor for development or worsening of corneal clouding or edema or opacification of the lens.
- In diabetic patients, monitor for lens changes post-vitrectomy.

Client Information
- If you are using an over-the-counter eyewash solution, use proper administration techniques to avoid eye injury or contamination

of the product. Keep the cap tightly closed when the medication is not in use.
- Wait 5 minutes after using the eyewash before applying any medications to the eye.
- Store this product at room temperature away from moisture and sunlight. Do not freeze.
- Discard this product if the color changes or the solution becomes cloudy.

Storage/Stability
Store OTC eyewash products as labeled, usually at controlled room temperature away from moisture and sunlight; do not freeze.

Store solutions for intraocular use at 8°C to 30°C (46°F-86°F); avoid excessive heat, and do not freeze. Discard solution after 6 hours. Store *BSS Plus®* solutions at 2°C to 25°C (36°F-77°F); do not freeze. Discard prepared solution after 6 hours. Do not use unfinished solutions on a different patient.

Compatibility/Compounding Considerations
It is not recommended to add any other solutions or drugs to intraocular or extraocular irrigating solutions; however, extra-label additives in some protocols have included heparin, epinephrine, antibiotics, or local anesthetics.

For reconstituting *BSS Plus®* solutions: Reconstitute solution just prior to use in surgery. Follow the same strict aseptic reconstitution procedures used for IV solution additives. Remove the blue flip-off seal from the part 1 (480 mL) bottle. Remove the blue flip-off seal from the part 2 (20 mL) vial. Clean and disinfect the rubber stoppers on both containers by using sterile alcohol wipes. Transfer the contents of the part 2 vial to the part 1 bottle using the vacuum transfer device (provided). An alternative method of solution transfer may be accomplished by using a syringe to remove precisely 20 mL of the part 2 solution and transfer to the part 1 container through the outer target area of the rubber stopper. **NOTE:** An excess volume of the part 2 solution is provided in each vial; discard unused solution. Gently agitate the contents to mix the solutions. Place a sterile cap on the bottle if the solution is not going to be used immediately. Remove the tear-off portion of the label. Record the time and date of reconstitution and the patient's name on the bottle label.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Several products are marketed as eye washes or rinses for animal patients, including *Clear Eyes®*, *Conquer Hy-Optic®*, *Nutri-Vet® Dog Eye Rinse*, and *Vetericyn® Plus Eye Wash*. Ingredients vary significantly, and some are labeled only as tear stain removers. None of these products appear to be FDA-approved, and they should NOT be used for intraocular procedures.

HUMAN-LABELED PRODUCTS:

Irrigating Solutions, Intraocular

Balanced Salt Solution Irrigating Solution in 15 mL, 18 mL, 30 mL, 250 mL, or 500 mL; preservative-free containing 0.64% NaCl, 0.075% KCl, 0.03% magnesium chloride, 0.048% calcium chloride, 0.39% sodium acetate, 0.17% sodium citrate, and NaOH or HCl; *BSS®*, generic; (Rx)

Balanced Salt Solution Plus; in 2 parts in 10 mL (part 1) and 240 mL (part 2) in a 250 mL bottle; preservative-free containing 0.0154% calcium chloride, 0.714% sodium chloride, 0.038% potassium chloride, 0.02% magnesium chloride, 0.42% sodium phosphate, 0.2% sodium bicarbonate, 0.092% dextrose, 0.0184% glutathione disulfide; *BSS Plus®*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Itraconazole Ophthalmic
(it-ruh-***kon***-uh-zohl) *Sporanox®*

Azole Antifungal Agent

Prescriber Highlights
- ► Used as a treatment for ocular surface fungal infections
- ► Not commercially available as an ophthalmic preparation; must be compounded
- ► Compounded forms contain 10% to 30% DMSO, which may be irritating when administered.
- ► Warn caregivers to wear nitrile gloves when applying this medication to protect them from DMSO exposure.

Uses/Indications
Itraconazole ophthalmic preparations are primarily used to treat fungal keratitis in horses[1,2]; however, they have successfully been used in dogs with fungal keratitis.[3]

Pharmacology/Actions
Itraconazole interacts with 14 alpha-sterol demethylase, a cytochrome P-450 enzyme involved in the conversion of lanosterol to ergosterol. Ergosterol is an essential component of the fungal cell membrane, and preventing its synthesis may increase cellular permeability and cause leakage of cellular contents. Other possible effects of itraconazole include inhibition of endogenous respiration, purine uptake and yeast to mycelial transformation, and impairment of triglyceride and phospholipid biosynthesis. Targeted oxidative enzymes of fungal species, rather than mammalian cells, increase efficacy and decrease host toxicity. Itraconazole is usually effective against *Aspergillus* spp, with variable efficacy versus *Candida* spp and consistently lower efficacy against *Fusarium* spp.[1,2] Identification of fungal species prior to treatment is critical to the success of treatment.[4]

Contraindications/Precautions/Warnings
Itraconazole is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Compounded itraconazole 1% in DMSO 30% may cause irritation to the cornea. A solution of DMSO 1% is commonly used as a control for corneal irritation in ophthalmic drug studies.[5]

Adverse Effects
Adverse effects reported in humans or animals include stinging and irritation from the DMSO component. Although systemic absorption of topically applied ointments is unlikely, systemic exposure to itraconazole has resulted in hepatotoxicity and hearing loss in humans. Compared with miconazole and natamycin, itraconazole demonstrates lower toxic effects on corneal epithelial cells in vitro.[6]

Dosages
Fungal keratitis (extra-label): 1 – 2 drops, ½ inch strip, or 0.1 mL in the subpalpebral lavage (SPL) catheter to the affected eye(s) every 2 to 3 hours initially, followed by tapering of frequency based on clinical response

Monitoring
- Clinical efficacy: corneal scrapings with cytology and cultures to determine the clearing of fungal organisms
- Resolution of clinical signs of infection
- Toxicity: monitor for ocular irritation (eg, corneal edema, chemosis, blepharospasm) from DMSO

Client Information
- Use this medicine as directed by your veterinarian.
- A garlic-like odor is normal (from the DMSO solvent).
- Wear nitrile gloves when applying to prevent absorption of DMSO solvent found in the medicine.

- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store as directed on package labeling away from moisture and sunlight Do not freeze. Discard if the color or consistency changes.

Storage/Stability
Store this product as directed on the label from the compounding pharmacy. Keep this product away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Itraconazole ophthalmic preparations should not be mixed directly with any other ophthalmic medications. Itraconazole ophthalmic preparations are not commercially available, but a compounded preparation containing 30% DMSO has been described.[7,8]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Itraconazole ophthalmic products are not commercially available and must be prepared (compounded) by a qualified compounding pharmacist. Itraconazole has been compounded into a 1% ophthalmic ointment in a base containing 10% to 30% DMSO or into a 1% ophthalmic solution containing 30% DMSO.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Ketorolac Ophthalmic

(kee-***toe***-role-ak) *Acular®, Acular LS®, Acuvail®*

Nonsteroidal Anti-inflammatory Drug (NSAID)

Prescriber Highlights

- ► Used to control anterior segment inflammation, particularly in association with seasonal allergic conjunctivitis
- ► May cause transient increases in intraocular pressure (IOP)
- ► May delay ocular wound healing and increase risk for intraocular bleeding

Uses/Indications
Ketorolac ophthalmic is indicated for controlling anterior segment inflammation (eg, conjunctivitis, keratitis, anterior uveitis), inducing mydriasis during cataract-removal surgery, and for providing analgesia following surgical removal of cataracts. In diabetic patients, ketorolac may be useful to avoid the systemic effects of topically applied corticosteroids. Ketorolac is also indicated to alleviate the signs of allergic conjunctivitis. Ketorolac did not decrease corneal sensitivity in the eyes of normal dogs,[1] suggesting that its use as an ophthalmic analgesic may be limited; however, analgesic effects might improve in the presence of ocular pain.

Pharmacology/Actions
Ketorolac is an NSAID that blocks prostaglandin synthesis by inhibiting cyclooxygenase 1 and 2. Prostaglandins mediate many of the adverse effects of intraocular inflammation, including disruption of the blood-aqueous humor barrier, vasodilation, increased vascular permeability, leukocytosis, and increased intraocular pressure. Blocking prostaglandin production, therefore, minimizes the adverse short- and long-term effects of intraocular inflammation. Prostaglandins also appear to play a role in the miotic response produced during ocular surgery by constricting the iris sphincter independently of cholinergic mechanisms.

Contraindications/Precautions/Warnings
Ketorolac is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. The potential for cross-sensitivity to acetylsalicylic acid, phenylacetic acid derivatives, and other NSAIDs exists.[2] In humans that have either a known hypersensitivity to aspirin or NSAIDs or a past medical history of asthma, there have been reports of bronchospasm or exacerbation of asthma associated with the use of ketorolac tromethamine ophthalmic solution. Therefore, caution should be used when treating individuals that have previously exhibited sensitivities to these drugs. Topical NSAIDs may result in corneal epithelial breakdown, delayed corneal wound healing, and corneal thinning, erosion, or ulceration. As such, ketorolac ophthalmic should be used with caution in patients with complicated or repeated ocular surgeries, corneal denervation, corneal epithelial defects, diabetes mellitus, and corneal surface diseases (eg, KCS).[2] As topical corticosteroids are also known delay healing, concomitant use with topical NSAIDs may increase the potential for delayed or impaired healing. Due to interference with thrombocyte aggregation, ophthalmic NSAIDs may cause increased bleeding of ocular tissues (eg, hyphema) in conjunction with ocular surgery. It is recommended that ketorolac ophthalmic solution be used with caution in patients with known bleeding tendencies (eg, severe liver disease) or in those receiving anticoagulant medications (eg, heparins, rivaroxaban), which may prolong bleeding time.[1]

Adverse Effects
Adverse effects reported in humans or animals include transient stinging and burning on instillation, corneal edema, iritis, ocular inflammation, ocular irritation, superficial keratitis, and superficial ocular infections.[1] Ocular bleeding may occur because of interference with thrombocyte aggregation. Other adverse effects that have rarely occurred in humans include corneal infiltrates, corneal ulcers, eye dryness, headaches, and visual disturbance (blurry vision).

Although unlikely, systemic adverse effects may occur with the use of topical NSAIDs, including increased risk for gastric ulceration, decreased platelet aggregation, worsening of asthma and cardiac disease, and renal toxicity. Concurrent use of systemic NSAIDs and corticosteroids increases the risk for systemic adverse effects.

Dosages
Allergic conjunctivitis: 1 drop to the affected eye(s) 2 to 4 times daily

Anterior segment inflammation (extra-label): 1 drop to the affected eye(s) 2 to 4 times daily

Postoperative analgesia: 1 drop to the surgical eye 2 to 4 times daily, beginning one day prior to surgery and continuing for 2 weeks postoperative

Monitoring
- Clinical efficacy (eg, decreased or absent anterior segment inflammation)
- Adverse effects (eg, delayed wound healing)

Client Information
- Use this medicine as directed by your veterinarian.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in solutions.
- Ketorolac ophthalmic may cause burning or stinging on administration. It may also increase the risk for bleeding and may slow down healing in the eye.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.

- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medicine in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.

Storage/Stability
Store as directed on package labeling (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Ketorolac should not be mixed directly with any other drugs. Ketorolac is not available as an ophthalmic ointment.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Ketorolac Tromethamine 0.5% Ophthalmic Solution (containing ketorolac tromethamine 5 mg/mL; benzalkonium chloride 0.01%; edetate disodium 0.1%; octoxynol 40; purified water; NaCl; HCl and/or NaOH to adjust the pH to 7.4 and osmolality of 290 mOsm/kg), in a 5 mL ophthalmic dropper bottle; *Acular®*, generic; (Rx)

Ketorolac Tromethamine 0.4% Ophthalmic Solution (containing ketorolac tromethamine 0.4%; benzalkonium chloride 0.006%; edetate disodium 0.015%; octoxynol 40; purified water; NaOH; HCl and/or NaOH to adjust pH to ≈7.4), 5 mL in a 10 mL sterile ophthalmic dropper bottle; *Acular LS®*, generic; (Rx)

Ketorolac Tromethamine 0.45% Ophthalmic Solution (containing ketorolac tromethamine 0.45%; carboxymethylcellulose; NaCl; sodium citrate dehydrate; purified water; NaOH and/or HCl to adjust pH), in 30 single-use vials of 0.4 mL each; *Acuvail®*; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Ketotifen Ophthalmic
(kee-toe-***tye***-fin) *Alaway®, Zaditor®*
Antihistamine Agent

Prescriber Highlights
► Relatively selective H_1 blocker used to treat allergic conjunctivitis
► Use up to 2 times daily

Uses/Indications
In veterinary patients, ketotifen is used to provide temporary relief of the clinical signs associated with allergic conjunctivitis.

Pharmacology/Actions
Ketotifen is a relatively selective, noncompetitive histamine antagonist (H_1 receptor) and mast cell stabilizer. Ketotifen inhibits the release of mediators (eg, histamine, leukotrienes C4 and D4 [SRS-A], platelet-activating factor) from mast cells, during hypersensitivity reactions; ketotifen also decreases chemotaxis and activation of eosinophils. Evaluation of the effectiveness of the topical ocular application of ketotifen in veterinary species has not been performed.

Contraindications/Precautions/Warnings
Ketotifen is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans include conjunctival injection, rhinitis, ocular allergic reactions, burning or stinging of the eye, conjunctivitis, eye discharge, dry eye, eye pain, eyelid disorder, itching eye, keratitis, lacrimation disorder, mydriasis, photophobia, rash, and pharyngitis.

Dosages
Allergic conjunctivitis (extra-label): 1 drop in the affected eye(s) twice daily

Monitoring
- Clinical efficacy
- Resolution or relief of signs of allergic conjunctivitis (pruritus, tearing, squinting, erythema)

Client Information
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 to 10 minutes after applying this medication before applying any other medications to the eye.
- Store this medication in the refrigerator or at room temperature away from moisture and sunlight; do not freeze. Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in solutions.

Storage/Stability
Store this medication in the refrigerator or at controlled room temperature away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Ketotifen should not be mixed directly (in vitro) with any other drugs. Ketotifen is not available as an ophthalmic ointment.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Ketotifen Fumarate 0.025% Ophthalmic Solution (containing: ketotifen fumarate equivalent to 0.25 mg ketotifen per milliliter; benzalkonium chloride 0.01%; glycerol; NaOH/HCl to adjust pH to 4.4 to 5.8; water for injection; with an osmolality of 210 to 300 mOsm/kg), in a 5 mL ophthalmic dropper bottle; *Alaway®*, *Zaditor®*, generic; (OTC)

Ketotifen Fumarate 0.035% Ophthalmic Solution (containing: ketotifen fumarate equivalent to 0.25 mg ketotifen per milliliter; benzalkonium chloride 0.01%; glycerol; NaOH/ HCl to adjust pH to 4.4 to 5.8; water for injection; with an osmolality of 210 – 300 mOsm/kg), in a 5 mL ophthalmic dropper bottle; *Alaway®*, generic; (OTC)

Latanoprost Ophthalmic
(la-***ta***-noe-prost) *Rocklatan®, Vyzulta®, Xalatan®, Xelpros®*
Prostaglandin Analogue

Prescriber Highlights
► Used to decrease intraocular pressure (IOP) in patients with primary glaucoma or ocular hypertension
► Not effective for most cases of feline or equine glaucoma
► Do not use if IOP inflammation is present, as it may worsen inflammation or lead to pupillary block glaucoma.
► Twice-daily dosing results in less fluctuation of IOP.
► Preservatives may cause ocular irritation.

Uses/Indications
In dogs, latanoprost is used to reduce intraocular pressure (IOP) to manage primary glaucoma. Up to 60% reduction in IOP can be achieved with either once-daily[1] or twice-daily administration in dogs, with twice-daily administration resulting in lower and less

variable IOP.[2] When it is administered in combination with a topical NSAID to normotensive canine eyes, latanoprost's ocular hypotensive effects are lessened,[3] whereas administration with a topical corticosteroid to normotensive canine eyes does not adversely impact the ocular hypotensive effects.[4]

Latanoprost is generally not indicated for use in cats with glaucoma, as it does not lower IOP in normal feline eyes,[1] and glaucoma in cats is frequently secondary to uveitis (latanoprost is contraindicated in the presence of uveitis). Although encountered uncommonly in clinical practice, primary congenital glaucoma in cats may be effectively managed with latanoprost, with an IOP reduction of up to 60% initially and efficacy decreasing over 3 weeks of treatment.[5]

Use in horses is generally not indicated due to relatively poor IOP-lowering effect and an association with a high incidence of adverse effects (eg, ocular discomfort)[6]; however, concurrent administration of topical latanoprost and diclofenac to normal equine eyes has demonstrated IOP reduction and reduced signs of discomfort.[7]

Pharmacology/Actions

Prostaglandin analogues are chemically modified versions of prostaglandin F2-alpha, an endogenous inflammatory molecule that mediates ocular hypotensive effects by increasing outflow of aqueous humor through both the trabecular meshwork and uveoscleral outflow routes. In addition to reducing intraocular pressure (IOP), latanoprost leads to miosis.

Contraindications/Precautions/Warnings

Latanoprost is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Latanoprost should be used with caution in the presence of anterior uveitis and secondary glaucoma, particularly in cases already exhibiting significant miosis, as this treatment may exacerbate miosis, promote synechiae formation, and worsen glaucoma. Latanoprost should also be used with caution in dogs with primary anterior lens luxation, as the miosis that results may trap the lens and/or vitreous within the pupillary aperture, thus creating pupillary block glaucoma. Latanoprost is not contraindicated in dogs with secondary posterior lens luxation, as the miosis may (favorably) trap the lens in the posterior segment.

Adverse Effects

Adverse effects reported in humans or animals include blurred vision, burning and stinging, conjunctival hyperemia, foreign body sensation, itching, increased pigmentation of the iris, and punctate epithelial keratopathy. Latanoprost may worsen intraocular inflammation. Latanoprost may cause darkening of the iris through direct stimulation of iris melanocytes, and it may also cause eyelash changes (eg, increased length, thickness, pigmentation, and the number of lashes) and eyelid skin darkening. Macular edema, including cystoid macular edema, has been reported after the use of latanoprost in humans. Horses develop conjunctival hyperemia, epiphora, and blepharospasm with latanoprost's administration.[8]

Dosages

Glaucoma (extra-label): 1 drop in the affected eye(s) once to twice daily

Monitoring

- Confirm maintenance of intraocular pressure (IOP) within the normal range for the species being treated

Client Information

- Use this medicine as indicated by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store unopened bottle(s) under refrigeration. Do not freeze. Once a bottle is opened for use, it may be stored at room temperature (up to 25°C [77°F]), protected from light, for up to for 6 weeks.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in solutions.

Storage/Stability

Protect this product from light. Store unopened bottle(s) under refrigeration at 2°C to 8°C (36°F-46°F)[9]; do not freeze. During shipment to the owner, the bottle may be maintained at temperatures up to 40°C (104°F) for a period not exceeding 8 days. Once a bottle is opened for use, it may be stored at room temperature up to 25°C (77°F) for 6 weeks.

Compatibility/Compounding Considerations

Latanoprost ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Latanoprost 0.005% Ophthalmic Solution (containing 50 µg of latanoprost per milliliter; benzalkonium chloride 0.02%; NaCl; sodium dihydrogen phosphate monohydrate; disodium hydrogen phosphate anhydrous; water for injection, with a pH of ≈6.7 and an osmolality of ≈267 mOsm/kg), in 2.5 mL ophthalmic dropper bottles; *Xalatan®*, generic; (Rx)

Latanoprost 0.005% Ophthalmic Solution (containing 50 µg of latanoprost; potassium sorbate 4.7 mg; castor oil; sodium borate; boric acid; propylene glycol; edetate disodium; polyoxyl 15 hydroxystearate; sodium hydroxide; hydrochloric acid; water for injection), in 2.5 mL ophthalmic dropper bottles; *Xelpros®* (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:

Netardusil 0.02% and latanoprost 0.005% Ophthalmic Solution (containing netarsudil 0.285 mg; latanoprost 0.050 mg; benzalkonium chloride 0.20 mg; mannitol; boric acid; sodium hydroxide to adjust pH; water for injection), in 2.5 mL ophthalmic dropper bottles; *Rocklatan®* (Rx)

References

Levobunolol Ophthalmic

(lee-voe-***byoon***-uh-lol) *Akbeta®, Betagan®*

Nonselective Beta-Adrenergic Blocker

Prescriber Highlights

- ► Decreases aqueous humor production to lower intraocular pressure (IOP) as a treatment for glaucoma
- ► May delay onset of glaucoma in the normal eye of dogs with unilateral glaucoma
- ► Use with caution in asthmatic patients due to the potential to induce bronchospasm.

Uses/Indications

Levobunolol is used to reduce intraocular pressure (IOP) in primary glaucoma and as prophylaxis to prevent glaucoma in the normal eye of animals with unilateral glaucoma. In dogs, the magnitude of reduction in IOP is less with levobunolol alone as compared with the combination of levobunolol and dorzolamide,[1] and timolol and dorzolamide.[2]

Pharmacology/Actions

Levobunolol is a nonselective beta-adrenergic blocking agent with associated intrinsic sympathomimetic activity but without signifi-

cant membrane-stabilizing activity; the significance of which is not fully understood in ophthalmic use. Blockade of ciliary body beta receptors, particularly beta-2 receptors, reduces intraocular pressure (IOP) by decreasing aqueous humor production. The exact mechanism of the ocular hypotensive effect of beta-blockers is not clear. Several mechanisms have been postulated for this effect, including beta-blockade of norepinephrine-induced tonic sympathetic stimulation, leading to decreased activation of cAMP in the ciliary body, inhibition of Na+K+ATPase activity, or vasoactive mechanisms on the iris and ciliary body. Topically administered beta-blockers also inhibit glutamine-induced increases in intracellular calcium and sodium, thereby providing a potential protective effect against ischemic insult to the retina.[3]

Contraindications/Precautions/Warnings

Levobunolol is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Levobunolol should be used cautiously, if at all, in patients with heart block, bradycardia, heart failure, asthma, chronic bronchitis, or other cardiopulmonary conditions.[1]

Adverse Effects

Adverse effects reported in humans or animals include transient burning, stinging, and irritation upon application to the eye. Topically applied levobunolol led to a significant reduction in heart rate in healthy dogs, thus supporting its limited use in dogs with cardiopulmonary conditions.

Dosages

Glaucoma (extra-label): 1 drop in the affected eye(s) twice daily

Monitoring

- Clinical efficacy
- Confirm maintenance of intraocular pressure (IOP) within the normal range for the species being treated
- Observe asthmatic and diabetic patients for respiratory difficulty or acute hypoglycemia, respectively.
- Heart rate

Client Information

- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 to 10 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in solutions.

Storage/Stability

Store this product at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Levobunolol ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Levobunolol 0.25% Ophthalmic Solution (containing levobunolol HCl 0.5%; benzalkonium chloride 0.004%; polyvinyl alcohol 1.4%; edetate disodium; sodium metabisulfite; sodium phosphate, dibasic; potassium phosphate, monobasic; NaCl; HCl or NaOH to adjust the pH; purified water), in 5, 10, and 15 mL ophthalmic dropper bottles; *Akbeta®*, *Betagan®*; (Rx)

Levobunolol 0.5% Ophthalmic Solution (containing benzalkonium chloride 0.004%; polyvinyl alcohol 1.4%; edetate disodium; sodium metabisulfite; sodium phosphate, dibasic; potassium phosphate, monobasic; NaCl; HCl or NaOH to adjust the pH; purified water), in 5, 10, and 15 mL ophthalmic dropper bottles; *Akbeta®*, *Betagan®*, generic; (Rx)

Levofloxacin Ophthalmic

(lev-oh-***flocks***-a sin)

Third-Generation Fluoroquinolone Antibiotic

Prescriber Highlights

- ► Used to treat confirmed bacterial conjunctivitis or keratitis based on culture and susceptibility; prophylactic use is not recommended.
- ► Physically incompatible with many drugs; therefore, it should not be directly mixed with other ophthalmic medications.
- ► Crystalline drug precipitates may be noted in the superficial portion of corneal defects when levofloxacin is used on the eye.

Uses/Indications

Levofloxacin ophthalmic may be used to treat bacterial conjunctivitis or keratitis caused by susceptible strains of *Staphylococcus* spp, *Streptococcus* spp, *Pseudomonas aeruginosa*, *Chlamydophila* spp, and *Haemophilus* spp.[1] Levofloxacin is effective against other gram-positive and gram-negative organisms; however, its potency is not considered significantly greater than that of second-generation fluoroquinolones (eg, ciprofloxacin), particularly versus *Staphylococcus* spp.[1,2] The increased clinical efficacy of levofloxacin may be afforded by increased penetration to ocular tissues.[3]

The World Health Organization (WHO) has designated levofloxacin as a Critically Important, Highest Priority antimicrobial in human medicine.[2]

Pharmacology/Actions

Levofloxacin is a third-generation fluoroquinolone antibiotic that acts via the inhibition of bacterial topoisomerase II (DNA gyrase), leading to impaired DNA replication and repair.

Contraindications/Precautions/Warnings

Levofloxacin should not be used prophylactically and is contraindicated in patients that have a history of hypersensitivity to it, other fluoroquinolones, or any component of the formulation. It should only be used as a topical ophthalmic. It should not be injected subconjunctivally or into the anterior chamber of the eye. Fluoroquinolone-induced retinal toxicity in domestic cats has not been demonstrated with this product.

Adverse Effects

Adverse effects reported in humans or animals include blurred vision, tearing, eye pain, redness, itching, and a bad taste in the mouth. Crystalline drug precipitates may be noted in the superficial portion of corneal defects when levofloxacin is used.[4]

Dosages

Conjunctivitis (extra-label): 1 drop in affected eye(s) every 2 to 8 hours

Keratitis (extra-label): 1 drop in affected eye(s) every 2 to 8 hours, or 0.1 mL in the subpalpebral lavage (SPL) catheter every 2 to 8 hours. May precipitate when mixed with other ophthalmic medications; therefore, it is important to flush SPL catheter well with air between medications.

Monitoring
- Corneal cytology and culture to evaluate for the presence of bacteria
- Clinical efficacy: improvement and resolution of clinical signs associated with bacterial infection
- If blepharospasm, uveitis, worsening of ulceration, or no improvement in infection occur within 7 days, reassess microbial susceptibility.

Client Information
- Use this medication as directed by your veterinarian.
- Crystals may appear on the surface of the eye during treatment with levofloxacin ophthalmic.
- Do not mix this medicine with other eye medications.
- Wait 5 minutes after applying this medicine before applying any other medications to the eye.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Your veterinarian will need to monitor your animal while it is receiving this medicine. Do not miss these important follow-up visits.
- Store this medication in the refrigerator or at room temperature. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solutions.

Storage/Stability
Store this product in the at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Fluoroquinolone antibiotics interact with many other drugs, including those containing cations (eg, iron, aluminum, magnesium, calcium). Levofloxacin should not be mixed directly (in vitro) with any other drugs. Levofloxacin is not available as an ophthalmic ointment.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Levofloxacin 0.5% ophthalmic solution (containing levofloxacin 5 mg/mL, benzalkonium chloride 0.005%, NaCl, and water. May also contain HCl and/or NaOH to adjust pH to 6.5 with an osmolality of ≈300 mOsm/kg), in a 5 mL ophthalmic dropper bottle; generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Lidocaine Ophthalmic

(***lye***-doe-kane)

Topical Ocular Anesthetic

*For other uses of lidocaine, see **Lidocaine, Systemic; Lidocaine, Local Anesthetic; Lidocaine, Topical***

Prescriber Highlights
- ► Injectable local anesthetic that may be used for analgesia for ocular diagnostic and therapeutic procedures
- ► Should never be prescribed for at-home administration
- ► Dose- and species-dependent duration, with maximal effect generally between 1 and 5 minutes in dogs, cats, and horses

Uses/Indications
Lidocaine is a local anesthetic available as an injectable solution or an ophthalmic topical gel that can be administered topically to facilitate ophthalmic diagnostic and therapeutic procedures, including measurement of intraocular pressure (tonometry), corneal and conjunctival sampling for cytology and culture, ocular ultrasonography, and gonioscopy. Lidocaine is indicated as an adjunctive anesthetic for performing therapeutic procedures in the hospital, including removal of foreign bodies and sutures from the cornea, eyelid and conjunctival surgeries, corneal grafting procedures, and cataract extraction. Lidocaine demonstrates maximal effect generally between 1 and 5 minutes, lasting around 20 to 25 minutes in dogs[1,2] and ≈45 to 55 minutes in horses.[3–5] The degree of anesthesia in normal canine eyes was comparable to that of topically applied bupivacaine and ropivacaine.[6] Due to the likelihood of developing ocular surface toxicities with prolonged or repeated use, it should never be prescribed for use as an ocular analgesic.

Pharmacology/Actions
Lidocaine induces local anesthesia by inhibiting neuronal depolarization, thus preventing the generation of an action potential. This action occurs due to the binding of the local anesthetic molecule to the intracellular portion of the voltage-gated sodium channel within the neuron, thus inhibiting the intracellular movement of sodium. Variations in the structure of different local anesthetics influence their relative potencies. All local anesthetics have increased efficacy in alkaline environments due to improved intracellular penetration; efficacy is decreased in the acidic environment of inflammation.

Contraindications/Precautions/Warnings
Lidocaine is contraindicated in patients with a history of hypersensitivity to it or any component of the formulation. Prolonged use of a topical ocular anesthetic will likely produce significant corneal epithelial and stromal disease, as well as tear film instability, and may result in loss of vision.[7]

Adverse Effects
Instillation of lidocaine may result in local irritation (eg, blepharospasm, conjunctival hyperemia) several hours after administration. Patients sensitive to other local anesthetics may be less likely to react to proparacaine; however, local or systemic sensitivity may still occur and manifest as a pseudo-allergic (anaphylactoid) reaction mimicking an IgE-mediated vasodilatory event. Cardiovascular, respiratory, and CNS depressant effects that may result from other local anesthetics are extremely rare with the appropriate use of topical anesthetics. Care should be exercised, however, when administering to small veterinary patients (ie, puppies, kittens, "pocket pets", amphibians) that may be more susceptible to the effects of systemically absorbed drug. Use as a therapeutic analgesic leads to superficial punctate keratitis, which may progress to diffuse necrotizing keratitis, severe infiltrative keratitis, persistent epithelial defects, or damage to Descemet's membrane. Application of the topical ophthalmic and nonophthalmic gels in normal dog[1,2] and horse[3] eyes induced conjunctival hyperemia and punctate epithelial damage.

Dosages
Ophthalmic procedures requiring local anesthesia in small animal species (extra-label): 1 – 2 drops in the target eye(s) prior to examination or procedure. May repeat 1 drop every 5 to 10 minutes for 2 to 3 additional times. **Additional doses should be avoided in small patients (puppies, kittens, "pocket pets", amphibians)**.

Ophthalmic procedures requiring local anesthesia in horses (extra-label): Using an ophthalmic topical gel, 0.2 mL in the target eye(s) prior to examination or procedure.[3,5,8] Onset of analgesia is within 1 to 5 minutes and duration is ≈45 to 55 minutes.

Monitoring
- Clinical effect. The onset of action indicated by an awake patient that is permitting diagnostic procedures to be performed and by a reduction in anesthetic requirements when administered preoperatively

Client Information
- Animal owners must **not** administer lidocaine in the home. Its use is limited to diagnostic procedures performed in the veterinary clinical setting.

Storage/Stability
Store at controlled room temperature 15°C to 25°C (59°F-77°F) and protected from sunlight; do not freeze. Discard single-use containers after use.

Compatibility/Compounding Considerations
Lidocaine should not be mixed directly with any other ophthalmic drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Lidocaine HCl 3.5% ophthalmic gel (containing 35 mg lidocaine HCl per mL; hypromellose; NaCl; purified water; HCl, and/or NaOH to adjust pH), in 1 mL tubes and 5 mL in a 10 mL round plastic dropper bottle; *Akten*® (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Lissamine Green Ophthalmic
(***lis***-ah-meen) *Green Glo*®
Ocular Diagnostic Agent

Prescriber Highlights
- ► Vital dye that demonstrates corneal and conjunctival epithelial cell damage, as well as deficiency in ocular surface mucins
- ► Less stinging on administration than is associated with rose bengal
- ► Requires broader interpretive experience than fluorescein staining
- ► Unapproved drug with periodic market shortages

Uses/Indications
Lissamine green is used as a diagnostic agent when superficial corneal or conjunctival epithelial damage is suspected. Lissamine green does not sting on application like rose bengal, but interpretation of the results requires broader evaluative experience than that for rose bengal and fluorescein. A grading scale that implements slit-lamp biomicroscopy to evaluate the regions of uptake is used in humans, and lissamine green has recently been demonstrated to be an effective adjunctive diagnostic test for the evaluation of qualitative and quantitative tear film deficiencies in dogs.[1,2]

Pharmacology/Actions
Lissamine green stains the cornea and conjunctiva blue upon instillation, resulting in speckling of the cornea and conjunctiva if ulcerations or dry patches from muco-deficient or damaged epithelial cells are present.

Contraindications/Precautions/Warnings
Lissamine green is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Lissamine green has demonstrated antimicrobial activity against gram-positive and gram-negative organisms; thus, samples for bacterial culture should be collected before administration of lissamine green.[3]

Adverse Effects
Adverse effects of lissamine green reported in humans or animals include stinging on instillation.

Dosages
Detection of corneal change: Wet the surface of the lissamine green strip with 1 to 2 drops of normal saline solution. Apply moistened tip to the conjunctiva or fornix as required. Allow the patient to blink several times after application to disperse the dye across the surface of the eye. Wait 60 seconds, then read with a white light source. Blue speckling will be evident for areas of the damaged or muco-deficient cornea.

Monitoring
- Lissamine green ophthalmic is a diagnostic agent. Monitoring is not required.

Client Information
- Lissamine green is not used at home by animal caregivers.

Storage/Stability
Store this product in a well-ventilated place protected from moisture and light; do not freeze.[4]

Compatibility/Compounding Considerations
Lissamine green ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Lissamine Green 1.5 mg Strips (containing 1.5 mg of lissamine green per strip), in individually wrapped strips in containers of 100 strips; *Green Glo*®; (Rx). There are no FDA-approved forms of lissamine green strips.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Lodoxamide Ophthalmic
(loe-***doks***-a-mide) *Alomide*®
Mast Cell Stabilizer

Prescriber Highlights
- ► Topical mast cell stabilizer used to treat seasonal conjunctivitis

Uses/Indications
Lodoxamide may be used to treat allergic conjunctivitis. No studies describing the efficacy and safety of lodoxamide after topical administration have been performed in veterinary patients.

Pharmacology/Actions
Lodoxamide is a mast cell stabilizer with efficacy in treatment of type I hypersensitivity reactions (IgE-mediated). Mast cell inhibition decreases vascular permeability, thus diminishing the signs associated with conjunctivitis. It does not possess vasoconstrictor, antihistaminic, cyclooxygenase inhibition, or other anti-inflammatory activity.

Contraindications/Precautions/Warnings
Lodoxamide is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.[1]

Adverse Effects
Adverse effects reported in humans include transient burning, stinging, or discomfort on instillation.[1] Additional adverse effects that were infrequently reported include ocular itching, blurred vision, dry eye, tearing, discharge, hyperemic, crystalline deposits, foreign body sensation, corneal erosion/ulcer, lid/lash scales, eye pain, ocular edema/swelling, ocular warming sensation, ocular fatigue, chemosis, anterior chamber cells, keratopathy/keratitis, blepharitis, allergy, stick sensation, and epitheliopathy. Nonocular adverse events that were infrequently reported include headache, heat sensation, dizziness, somnolence, nausea, stomach discomfort, sneezing, dry nose, and rash.

Dosages
Conjunctivitis (extra-label): 1 drop in the affected eye(s) 4 times daily for up to 3 months

Monitoring
- Clinical efficacy: resolution of conjunctival redness, itching, and discomfort

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes or if there are particles in the solution.

Storage/Stability
Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight.

Compatibility/Compounding Considerations
Lodoxamide ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Lodoxamide Tromethamine Ophthalmic Solution 0.1% (containing lodoxamide tromethamine 1.78 mg, equivalent to 1 mg lodoxamide; benzalkonium chloride 0.007%; mannitol; hypromellose 2910; sodium citrate; tyloxapol; citric acid; edetate disodium; NaOH and/or HCl to adjust pH; purified water), in sterile 10 mL ophthalmic dropper bottle; *Alomide®*; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Loteprednol Ophthalmic
(lote-uh-***pred***-nole) *Lotemax®, Alrex®, Zylet®, Eysuvis®, Inveltys®*
Corticosteroid Anti-Inflammatory Agent

Prescriber Highlights
- ► A topical corticosteroid used to treat ocular surface and anterior segment inflammatory conditions
- ► Do not use in bacterial, fungal, or viral keratitis or if corneal abrasion or ulceration are suspected.
- ► Use with caution in avian species due to risk for systemic corticosteroid effects.

Uses/Indications
Loteprednol ophthalmic is used to treat inflammatory conditions of the palpebral and bulbar conjunctiva, cornea, and anterior segment of the globe (eg, blepharitis, conjunctivitis, keratitis, anterior uveitis). In humans with dry eye syndrome, loteprednol has demonstrated benefit in the initial management of the condition before initiation or in conjunction with topically administered cyclosporine.[1,2] No studies describing the efficacy and safety of loteprednol after topical administration have been performed in veterinary patients.

Pharmacology/Actions
Corticosteroids have broad immunomodulatory and anti-inflammatory actions, which are mediated via direct effects on gene expression, as well as by nongenomic effects on cell membranes and receptors. Ultimately, corticosteroids decrease pro-inflammatory gene transcription, production of pro-inflammatory prostaglandins and leukotrienes, B- and T-cell number and function, cell-mediated immunity, and humoral immunity.[3] The specific mechanisms involved in regulating ocular inflammation are not known. Loteprednol is a "soft" steroid (a metabolically labile moiety that undergoes hydrolysis to its active form within the cornea, thus allowing local anti-inflammatory effects to predominate relative to harmful adverse effects).

Contraindications/Precautions/Warnings
Loteprednol is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Topical corticosteroids are contraindicated in known or suspected corneal ulceration or corneal infection (eg, bacterial, fungal, or viral). Use loteprednol with caution in patients with diabetes mellitus or other endocrine diseases, infectious diseases, chronic renal failure, congestive heart failure, systemic hypertension, or gastric ulceration. When use of loteprednol is necessary in these conditions, the minimal effective dose should be administered for the shortest possible time.

Adverse Effects
Adverse effects reported in humans include development of cataracts (via altered glucose or lenticular metabolic effects), increased intraocular pressure (IOP; via activation of glucocorticoid receptors in the trabecular meshwork), infection (via immunosuppression), decreased wound healing (via increased collagenolytic activity), mydriasis, and calcific keratopathy. Increased IOP and development of cataracts are minimized with loteprednol relative to other topically administered corticosteroids.[4–6] Systemic effects are rare but include hepatopathy, suppression of endogenous glucocorticoid production, and focal alopecia. Concurrent use of systemic steroids increases the risk for these adverse effects.

Dosages
Conjunctivitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) every 4 to 8 hours, then gradually decrease the dosage, provided clinical improvement is maintained

Keratitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) every 4 to 8 hours, then gradually decrease the dosage, provided clinical improvement is maintained

Keratoconjunctivitis sicca (extra-label): 1 drop in the affected eye(s) 4 times daily for 2 weeks

Anterior uveitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) every 4 to 8 hours, then gradually decrease the dosage, provided clinical improvement is maintained

Perioperative cataract removal (extra-label): 1 drop in the surgical eye(s) 4 times daily, beginning 24 hours after surgery, continuing for 2 weeks

Monitoring
- Clinical efficacy: resolution of inflammation
- Monitor intraocular pressure (IOP) and observe for signs of infection or delayed wound healing
- Monitor for blood and/or urine glucose changes in diabetic animals

Client Information
- Use this medicine as directed by your veterinarian.
- Shake suspensions well before using.
- Use proper administration techniques to avoid contamination of the medicine.
- Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.

- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes or if there are particles in the solutions.

Storage/Stability
Store this product at room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight.

Compatibility/Compounding Considerations
Loteprednol ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Loteprednol Etabonate 0.2% Ophthalmic Suspension (containing loteprednol etabonate 2 mg, edetate disodium, glycerin, povidone, purified water, tyloxapol, HCl and/or NaOH may be added to adjust the pH, and benzalkonium chloride 0.10%, as an isotonic suspension of 250 – 310 mOsm/kg), in 10 mL sterile ophthalmic dropper bottle; *Alrex*®; (Rx)

Loteprednol Etabonate 0.25% Ophthalmic Suspension (containing loteprednol etabonate 2.5 mg, glycerin, sodium citrate dihydrate, sodium chloride, poloxamer 407, edetate disodium dihydrate, citric acid, water for injection, and benzalkonium chloride 0.01%), in 10 mL sterile ophthalmic dropper bottle; *Eysuvis*®; (Rx)

Loteprednol Etabonate 0.38% Ophthalmic Gel (containing loteprednol etabonate 3.8 mg, boric acid, edetate disodium dihydrate, glycerin, hypromellose, poloxamer, polycarbophil, propylene glycol, sodium chloride, water for injection, sodium hydroxide to adjust pH, and benzalkonium chloride 0.003%), in 10 mL ophthalmic dropper bottle; *Lotemax SM*®; (Rx)

Loteprednol Etabonate 0.5% Ophthalmic Gel (containing loteprednol etabonate 5 mg, boric acid, edetate disodium dehydrate, glycerin, polycarbophil, propylene glycol, NaCl, tyloxapol, water for injection, NaOH to adjust pH to 6 to 7, and benzalkonium chloride 0.003%), in sterile 5 g ophthalmic tube; *Lotemax*®; (Rx)

Loteprednol Etabonate Ophthalmic Ointment 0.5% (containing loteprednol etabonate 5 mg, white petrolatum, and mineral oil), in a sterile 3.5 g ophthalmic tube; *Lotemax*®; (Rx)

Loteprednol Etabonate 0.5% Ophthalmic Suspension (containing loteprednol etabonate 5 mg, edetate disodium, glycerin, povidone, purified water, tyloxapol, HCl and/or NaOH to adjust the pH, and benzalkonium chloride 0.01%, as an isotonic suspension of 250 – 310 mOsm/kg), in 5 mL, 10 mL, and 15 mL ophthalmic dropper bottles; *Lotemax*®, generic; (Rx)

Loteprednol Etabonate 1% Ophthalmic Suspension (containing loteprednol etabonate 10 mg, glycerin, sodium citrate dihydrate, poloxamer 407, sodium chloride, edetate disodium dihydrate, citric acid, water for injection, and benzalkonium chloride 0.01%), in 2.8 mL sterile ophthalmic dropper bottle; *Inveltys*®; (Rx)

Loteprednol Etabonate 0.5% and Tobramycin 0.3% Ophthalmic Suspension (containing loteprednol etabonate 5 mg, tobramycin 3 mg, edetate disodium, glycerin, povidone, purified water, tyloxapol, sulfuric acid and/or NaOH to adjust the pH, and benzalkonium chloride, as an isotonic suspension of 260 – 320 mOsmol/kg), in sterile 5 mL and 10 mL ophthalmic dropper bottles; *Zylet*®; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Miconazole Ophthalmic
(mye-***kon***-uh-zohl)
Azole Antifungal Agent

Prescriber Highlights
► Used to treat ocular surface fungal infections
► Not commercially available as an ophthalmic preparation; must be compounded
► Penetrates the cornea more efficiently than natamycin

Uses/Indications
Miconazole ophthalmic solution is primarily used to treat fungal keratitis in horses; however, it has been successfully used to treat keratomycosis in a dog.[1] Miconazole has a broad antifungal spectrum against most fungi and yeasts of veterinary interest. Sensitive organisms include *Blastomyces dermatitidis*, *Paracoccidioides brasiliensis*, *Histoplasma capsulatum*, *Candida* spp, *Coccidioides immitis*, *Cryptococcus neoformans*, and *Aspergillus fumigatus*. Some *Aspergillus* spp and *Fusarium* spp are only marginally sensitive.

Pharmacology/Actions
Miconazole interacts with 14-alpha-sterol demethylase, a cytochrome P-450 enzyme involved in the conversion of lanosterol to ergosterol. Ergosterol is an essential component of the fungal cell membrane; preventing its synthesis increases cellular permeability and causes leakage of cellular contents. Other **antifungal** effects of miconazole include inhibition of endogenous respiration, purine uptake, the transformation of yeasts to mycelial forms, and impairment of triglyceride and phospholipid biosynthesis.

Miconazole has a wide antifungal spectrum against most fungi and yeasts of veterinary interest; however, susceptibility of isolates of normal ocular surface microflora and isolates from horses with fungal keratitis indicates variable efficacy. Thus, culture and susceptibility testing should be performed in horses with cytologically confirmed or suspected fungal keratitis.[1–5]

Contraindications/Precautions/Warnings
Miconazole is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans or animals include transient burning or stinging on application. Miconazole may cause local irritation if it is injected subconjunctivally. Although systemic absorption of topically applied solutions is unlikely, systemic exposure to miconazole has resulted in hepatotoxicity and hearing loss in humans. Miconazole had more cytotoxic effects on cultured corneal epithelial cells than itraconazole, but miconazole had less cytotoxic effects than natamycin.[6]

Dosages
Equine fungal keratitis (extra-label): 1 – 2 drops to the affected eye(s) or 0.1 mL in the subpalpebral lavage (SPL) catheter every 2 to 3 hours initially, then taper the frequency based on clinical response

Monitoring
- Clinical efficacy: improvement and resolution of clinical signs associated with the fungal infection
- Corneal scrapings with cytology and cultures to determine the clearing of fungal organisms

Client Information
- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.

- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Your veterinarian will need to monitor your animal while it is receiving this medicine. Do not miss these important follow-up visits.
- Store this medication as directed on the product label. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in solutions.

Storage/Stability
Store this product in the refrigerator (2°C-8°C [36°F-46°F]) or at controlled room temperature (20°C- 25°C [68°F-77°F]); check individual labels for details, as recommendations vary by product. Do not freeze. Keep product away from moisture and sunlight.

Compatibility/Compounding Considerations
Miconazole should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Miconazole has been compounded into a 1% ophthalmic solution that mimics the formerly commercially available *Monistat IV®*. Miconazole topical creams and ointments for dermatological use should **NOT** be used in the eye.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Mitomycin Ophthalmic
(***mye***-toe-***mye***-sin) *Mitosol®, Mitomycin C*

Cytotoxic Agent

Prescriber Highlights
- ► Antifibrotic agent used adjunctively in periocular surgeries (most commonly used in glaucoma implant procedures)
- ► Antineoplastic agent used for susceptible periocular and ocular surface tumors
- ► Product is normally blue in color.
- ► May cause periocular alopecia following treatment
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies mitomycin as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
Because of its ability to reduce fibroblastic proliferation and prevent subsequent scarring, mitomycin is used adjunctively in ocular surgeries, particularly to treat glaucoma by placement of drainage shunts or alternation of the natural aqueous humor outflow tracts; however, efficacy is unknown.[1–3] Mitomycin is also used as an adjunct to surgical removal for treatment of cutaneous and ocular surface neoplastic conditions (eg, squamous cell carcinoma, hemangiosarcoma) to prevent recurrence.[4–8]

Pharmacology/Actions
Mitomycin binds DNA, which leads to cross-linking of DNA and subsequent inhibition of DNA synthesis and function. Evidence suggests that at high concentrations of the drug, cellular RNA and protein synthesis are also suppressed.

Contraindications/Precautions/Warnings
Mitomycin is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Mitomycin is contraindicated in patients with thrombocytopenia, coagulation disorder, or an increase in bleeding tendency due to other causes. Pregnant women or women attempting to become pregnant should avoid contact with this drug.

The National Institute for Occupational Safety and Health (NIOSH) classifies mitomycin as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure. Refer to the Occupational Safety and Health Association (OSHA) website for more information.

Adverse Effects
Adverse effects reported in humans or animals include burning and stinging on application, corneal irritation, and edema formation.[4] Periocular alopecia has been reported in horses after topical application.[5] Topical administration in the presence of corneal epithelial defects has been associated with stromal ulceration and bullous keratopathy.[5] The systemic use of mitomycin has been associated with myelosuppression, particularly thrombocytopenia and leukopenia, nephrotoxicity, and pulmonary toxicity, although these effects are unlikely with topical therapy.

Dosages
Equine periocular squamous cell carcinoma (extra-label): ½ inch strip of a 0.04% ointment to the affected site 3 times daily for 21 days in a cycle of 7 days of drug application, followed by a 7-day drug vacation.[5,6] If using a subpalpebral lavage (SPL) system, instill 0.1 mL of a 0.04% solution 3 times daily for 21 days in a cycle of 7 days of drug application, followed by a 7-day drug vacation; maintain catheter patency by flushing the line with air after each dose.

Adjunctive antifibrotic agent for glaucoma implant surgery (extra-label): A single, 5-minute intraoperative application of 0.5 mg/mL solution at the filtration site following surgical placement of the shunt.[1] **NOTE:** Multiple protocols exist for use during surgical procedures for correcting glaucoma, varying with the type of procedure and other patient parameters. As these procedures should be performed by board-certified veterinary ophthalmologists, the protocols are not detailed here.

Monitoring
- Clinical efficacy depending on indication:
  - Maintenance of patency of the glaucoma implant, leading to control of intraocular pressure (IOP)
  - Cell or tissue samples for evaluation to confirm remission of neoplasia

Client Information
- This medicine is a chemotherapy drug. Pregnant women and sick or immunocompromised individuals should avoid contact with this medicine.
- Personal protective equipment (eg, gloves, mask) should be worn when giving this medicine to your animal. Dispose of any waste in a doubled plastic bag, then place the bag in a secure disposal location that children and animals cannot access.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine in the refrigerator. Do not freeze.
- Do not use this medicine if the color changes (it is normally blue), if it becomes cloudy, or if there are particles in the solution.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Storage/Stability
Store this product in the refrigerator (2°C-8°C [36°F-46°F]), away from moisture and sunlight. Store compounded products as stated on product label.

Compatibility/Compounding Considerations
Mitomycin ophthalmic preparations should not be mixed directly with any other ophthalmic medications. Mitomycin ophthalmic solution is not commercially available, but mitomycin lyophilized powder for injection can be compounded into appropriate ophthalmic solutions as follows:

- If using the 5 mg vial, reconstitute vial with 12.5 mL sterile 0.9% sodium chloride injection to make a 0.4 mg/mL (0.04%) solution.
- If using the 20 mg vial, reconstitute with 50 mL sterile 0.9% sodium chloride injection to make a 0.4 mg/mL (0.04%) solution.

NOTE: Commercially available mitomycin 20 mg vials may not contain 50 mL volume. Use caution when reconstituting, and when volume restrictions require, aseptically transfer contents into a 50 mL empty sterile vial.

Mitomycin ophthalmic ointments are not commercially available but may be prepared by qualified compounding pharmacists.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Mitomycin ophthalmic topical solution for multi-use is not commercially available, but mitomycin lyophilized powder for injection (5 mg or 20 mg vial) can be compounded into a suitable ophthalmic. A commercially available kit for mitomycin ophthalmic topical (single use) as an adjunct to ab externo glaucoma surgery is available; *Mitosol*®, generic; (Rx).

For the complete list of references, see **wiley.com/go/budde/plumb**

Morphine Ophthalmic
(***mor***-feen)
Opioid

Prescriber Highlights
- ► Opioid analgesic that may be beneficial in the treatment of ocular pain
- ► Must be compounded by a qualified compounding pharmacist, as no ophthalmic dosage forms are commercially available
- ► Do not use in animals receiving naloxone, nalbuphine, or nalorphine, as these drugs have opioid antagonist properties.
- ► DEA Schedule II (C-II) controlled substance

Uses/Indications
Morphine ophthalmic solution may be used to manage ocular pain. Dogs with experimentally induced corneal ulcers that received morphine solution 3 times daily experienced a reduction in signs of ocular pain without prolonged healing times[1]; however, in a clinical trial of dogs and cats with naturally occurring corneal ulcers, a single drop of morphine solution did not improve clinical signs of pain.[2] Combined topical administration and subconjunctival injection did not appear to provide ocular pain relief (as evaluated by changes in blepharospasm, conjunctival hyperemia, blinking rates, tearing) in dogs following phacoemulsification surgery.[3] Topical morphine did not affect corneal sensitivity when it was administered to normal equine eyes.[4,5]

Pharmacology/Actions
Morphine is primarily an opioid mu receptor agonist that interacts with mu binding sites located in the brain, as well as within the spinal cord and on peripheral sensory nerves. They are present in the cornea in smaller numbers than delta receptors in the canine cornea.[1] The analgesic effects on the cornea can be variable. It is possible that receptor specificity and localization, frequency of administration, and location of pain stimulus relative to drug penetration all impact clinical efficacy. Topical ocular morphine administration to eyes of normal horses results in measurable intraocular and systemic morphine concentrations, without local or systemic adverse effects.[4]

Contraindications/Precautions/Warnings
Morphine ophthalmic is contraindicated in patients with a history of hypersensitivity to it or any component of the formulation. Adverse effects may occur following concomitant use with monoamine oxidase inhibitors (eg, amitraz, linezolid, selegiline) or within 14 days of such treatment. Because of potential systemic absorption, morphine ophthalmic should be used with caution in patients with respiratory insufficiency or depression; severe CNS depression; bronchoconstrictive disorders (eg, asthma); heart failure secondary to pulmonary hypertension; arrhythmias; increased intracranial or cerebrospinal pressure (eg, head injury, brain tumor); or seizures.

Adverse Effects
Adverse effects reported in humans or animals include stinging and burning on application. Although systemic adverse effects are unlikely with topical administration, they could occur. See ***Morphine***.

Dosages
Corneal ulcers: 1 drop of a morphine 1% solution in the affected eye(s) every 8 hours

Monitoring
- Clinical efficacy: control of signs of ocular discomfort (eg, blepharospasm, conjunctival hyperemia, tearing)

Client Information
- Use this medicine as directed by your veterinarian.
- This medicine is a controlled substance and may not be refilled without a new prescription.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine as directed on package label. Keep product away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product as directed on the package labeling away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Morphine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE
Morphine sulfate ophthalmic solution is not commercially available; it must be compounded. Preservative-free morphine sulfate injection may be aseptically diluted with sterile 0.9% sodium chloride injection to achieve a 1% (10 mg/mL) aseptic ophthalmic solution.

For the complete list of references, see **wiley.com/go/budde/plumb**

Moxifloxacin Ophthalmic

(mox-ih-***flox***-uh-sin) *Vigamox®, Moxeza®*

Fourth-Generation Fluoroquinolone Antimicrobial

Prescriber Highlights

- ► Used to treat confirmed bacterial conjunctivitis or keratitis based on culture and susceptibility; prophylactic use is not recommended
- ► Physically incompatible with many drugs; therefore, it should not be directly mixed with other ophthalmic medications
- ► Crystalline drug precipitates may be noted in the superficial portion of corneal defects when moxifloxacin is used on the eye.

Uses/Indications

Moxifloxacin ophthalmic may be used to treat bacterial conjunctivitis or keratitis caused by susceptible strains of *Staphylococcus* spp, *Streptococcus* spp, *Pseudomonas aeruginosa*, *Chlamydophila* spp, and *Haemophilus* spp. Moxifloxacin is effective against other gram-positive and gram-negative organisms. *Pseudomonas aeruginosa* isolates from dogs with bacterial keratitis showed slightly greater resistance in vitro to moxifloxacin than to other fluoroquinolones,[1] whereas *Staphylococcus pseudintermedius* isolates from dogs with bacterial keratitis demonstrated lower rates of resistance in vitro to moxifloxacin than to other fluoroquinolones.[2] Penetration of topical ophthalmic moxifloxacin into the tears, cornea, and aqueous humor of horses with normal eyes was significantly greater than with the second-generation fluoroquinolone ciprofloxacin.[3,4]

The World Health Organization (WHO) has designated moxifloxacin as a Critically Important, Highest Priority antimicrobial in human medicine.[2]

Pharmacology/Actions

Moxifloxacin is a fourth-generation fluoroquinolone antibiotic that acts via inhibition of bacterial topoisomerase II (DNA gyrase) and topoisomerase IV, leading to impaired DNA replication and repair. The inhibition of both enzymes decreases the rates of resistance as compared to earlier generations of fluoroquinolones.

Contraindications/Precautions/Warnings

Moxifloxacin is contraindicated in patients that have a history of hypersensitivity to moxifloxacin, to other fluoroquinolones, or to any of the components of this medication. This medication should only be used as a topical ophthalmic; it should not be injected subconjunctivally or into the anterior chamber of the eye. Moxifloxacin should not be used prophylactically. Fluoroquinolone-induced retinal toxicity in domestic cats has not been demonstrated with this product.

Adverse Effects

Adverse effects reported in humans or animals include blurred vision, tearing, eye pain, redness, itching, and a bad taste in the mouth. Crystalline drug precipitates may be noted in the superficial portion of corneal defects when moxifloxacin is used.

Dosages

Conjunctivitis (extra-label): 1 drop in the affected eye(s) every 2 to 8 hours

Keratitis (extra-label): 1 drop in the affected eye(s), or 0.1 mL in the subpalpebral lavage (SPL) catheter, every 2 to 8 hours. May precipitate when mixed with other ophthalmic medications; therefore, it is important to flush SPL catheter well with air between medications

Monitoring

- Corneal cytology and culture to evaluate for the persistence of bacteria
- Clinical efficacy: improvement and resolution of clinical signs associated with bacterial infection
- If blepharospasm, uveitis, worsening of ulceration, or no improvement in infection occur within 7 days, reassess microbial susceptibility.

Client Information

- Use this medication as directed by your veterinarian.
- Crystals may appear on the surface of the eye during treatment with moxifloxacin ophthalmic.
- Do not mix this medicine with other eye medications.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Your veterinarian will need to monitor your animal while it is receiving this medicine. Do not miss these important follow-up visits.
- Store this medication in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in solutions.
- Dispose of unused medication in regular trash; do not put it into the sewer system.

Storage/Stability

Store this product in the refrigerator (2°C-8°C [36°F-46°F]) or at controlled room temperature (20°C-25°C [68°F-77°F]); check individual labels for details as recommendations vary by product. Do not freeze. Keep product away from moisture and sunlight.

Compatibility/Compounding Considerations

Fluoroquinolone antibiotics interact with many other drugs, including those containing cations (eg, iron, aluminum, magnesium, or calcium). Moxifloxacin should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Moxifloxacin 0.5% Ophthalmic Solution (containing moxifloxacin HCl 5.45 mg, boric acid, NaCl, purified water, and HCl and/or NaOH to adjust pH), 3 mL in sterile ophthalmic dropper bottle; *Vigamox®*, generic; (Rx)

Moxifloxacin 0.5% Ophthalmic Solution (containing NaCl, xanthan gum, boric acid, sorbitol, tyloxapol, purified water, and HCl and/or NaOH to adjust pH), 3 mL in sterile ophthalmic dropper bottle; *Moxeza®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Nalbuphine Ophthalmic

(***nal***-byoo-feen) *Nubain®*

Opioid Agonist/Antagonist Analgesic Agent

Prescriber Highlights

- ► Used to provide ocular analgesia in patients
- ► Do not use in combination with other opioid ocular analgesics (eg, morphine sulfate).

Uses/Indications

Nalbuphine may be compounded as an ophthalmic preparation to provide ocular surface analgesia. In dogs, nalbuphine 1% administered 3 times daily after the creation of a corneal epithelial wound

was not effective as an analgesic,[1] whereas nalbuphine 0.8% administered 3 times daily following phacoemulsification reduced corneal sensitivity and signs of ocular discomfort.[2] Corneal sensitivity was not decreased in normal horses following a single administration of 1.2% nalbuphine.[3] Additionally, 1.2% nalbuphine did not decrease corneal sensation in rabbits.[4]

Pharmacology/Actions

Nalbuphine is a synthetic opioid agonist/antagonist analgesic of the phenanthrene series. Nalbuphine's analgesic potency is essentially equivalent to that of morphine on a milligram basis. The opioid antagonist activity of nalbuphine is one-fourth as potent as nalorphine and 10 times as potent as pentazocine. Nalbuphine, by itself, has potent opioid antagonist activity at doses equal to or lower than its analgesic dose. When nalbuphine is administered following or concurrently with mu-agonist opioid analgesics (eg, morphine, oxymorphone, fentanyl), it may partially reverse or block opioid-induced respiratory depression from the mu-agonist analgesic.[5]

Contraindications/Precautions/Warnings

Nalbuphine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Nalbuphine is a partial opioid antagonist and should not be used in patients receiving other opioid agents as analgesia may be reversed by nalbuphine. When nalbuphine is used systemically, it has potential to depress respiratory and cardiac systems; however, these effects are unlikely when the drug is used topically.

Adverse Effects

Adverse effects reported in humans or animals include burning, stinging, and irritation on application. Systemic adverse effects, although unlikely following topical use, include respiratory and cardiovascular depression, somnolence, and ataxia.

Dosages

Corneal analgesia (extra-label): 1 drop in the affected eye(s) every 8 hours

Monitoring

- Clinical efficacy as demonstrated by adequate ocular analgesia

Client Information

- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wear gloves when administering the medicine to avoid inadvertent contact with it.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine as directed on the package labeling, away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solutions.

Storage/Stability

Because this medication must be compounded, storage recommendations can vary; follow storage requirements listed on the packaging, away from moisture and sunlight. Do not freeze.

Compatibility/Compounding Considerations

Nalbuphine ophthalmic preparations should not be mixed directly with any other ophthalmic medications. Nalbuphine is not commercially available and must be compounded by a qualified compounding pharmacist.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Nalbuphine is not commercially available as an ophthalmic preparation but may be compounded by qualified compounding pharmacists into 0.8% to 1.2% ophthalmic solution.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Natamycin Ophthalmic

(nat-uh-***mye***-sin) *Natacyn®*

Polyene Antifungal

Prescriber Highlights

- ► Commercially available ophthalmic suspension used to treat fungal keratitis, primarily associated with *Fusarium* spp
- ► Poorly soluble and does not efficiently penetrate corneal epithelium following topical administration
- ► Well tolerated following topical administration
- ► Natamycin suspensions may block subpalpebral lavage (SPL) catheters; therefore, ensure catheter patency by flushing the line with air after each dose.
- ► Expensive

Uses/Indications

Natamycin is primarily used to treat equine fungal keratitis caused by *Fusarium* spp. As natamycin is not as effective for deep stromal lesions, efficacy may be enhanced by creation of superficial ulceration (ie, therapeutic penetrating keratoplasty) to increase transcorneal penetration.[1]

Pharmacology/Actions

Natamycin is a tetraene polyene antibiotic derived from *Streptomyces natalensis*. It possesses in vitro activity against various yeasts and filamentous fungi, including *Candida* spp, *Aspergillus* spp, *Cephalosporium* spp, *Fusarium* spp, and *Penicillium* spp; culture and susceptibility testing is recommended to ensure appropriate therapy.[2–4] The mechanism of action appears to be through binding to the sterol moiety of the fungal cell membrane, thus altering membrane permeability and allowing leakage of essential fungal intracellular constituents. Although the activity against fungi is dose-related, natamycin is predominantly fungicidal.

Contraindications/Precautions/Warnings

Natamycin is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.[5]

Adverse Effects

Adverse effects reported in humans or animals include corneal opacity, eye discomfort, eye edema, eye hyperemia, foreign body sensation, paresthesia, and tearing.[5] Allergic reactions, dyspnea, and chest pain have been reported in humans that were administered natamycin.

Dosages

Equine fungal keratitis (extra-label): 0.1 mL to the affected eye(s) every 2 to 6 hours, depending upon the severity of infection (can be used more frequently initially). If administering via subpalpebral lavage (SPL) catheter, maintain catheter patency by flushing the line with air after each dose.

Monitoring

- Corneal scrapings with cytology and culture and susceptibility testing to determine the clearance of fungal organisms
- Resolution of clinical signs of infection

Client Information

- Give this medicine to your animal as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.

- Shake the medication well before using.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication at room temperature away from moisture and sunlight; do not freeze.
- Avoid exposure to light and excessive heat.
- Do not use this medication if the color changes.

Storage/Stability
Store this medication at 2°C to 24°C (36°F-75°F) away from moisture and sunlight (dispensed in a brown bottle to minimize exposure to light); do not freeze.[5]

Compatibility/Compounding Considerations
Natamycin should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Natamycin 5% Ophthalmic Suspension (containing natamycin 50 mg/mL, benzalkonium chloride 0.02%, NaOH and/or HCl to adjust the pH to 5 to 7.5, and purified water), in a 15 mL amber glass dropper bottle; *Natacyn®*; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Nedocromil Ophthalmic
(ne-doe-***krow***-mill) *Alocril®*
Mast Cell Stabilizing Ophthalmic Agent

Prescriber Highlights
► Topical mast cell stabilizer used to treat allergic conjunctivitis

Uses/Indications
Nedocromil may be used for the treatment of ocular itching associated with allergic conjunctivitis. The efficacy of nedocromil in animals following topical ocular administration has not been evaluated.

Pharmacology/Actions
Nedocromil is a mast cell stabilizer and inhibits histamine release from mast cells. Decreased chemotaxis and decreased activation of eosinophils (anti-inflammatory effects) have also been demonstrated following administration of nedocromil.[1]

Contraindications/Precautions/Warnings
Nedocromil is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans include ocular burning, irritation and stinging, unpleasant taste, and nasal congestion. Approximately 40% of humans report headaches and a bad taste in their mouths after use.[2] Other less common adverse effects associated with nedocromil administration include asthma, conjunctivitis, eye redness, photophobia, and rhinitis.

Dosages
Allergic conjunctivitis (extra-label): 1 drop in the affected eye(s) twice daily. Treatment should be continued throughout exposure (ie, until exposure to the offending allergen is terminated), even when clinical signs are absent.

Monitoring
- Clinical efficacy: resolution of signs of allergic conjunctivitis

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product in the refrigerator (2°C-8°C [35.6°F-46.4°F]) or at controlled room temperature (20°C-25°C [68°F-77°F])[2] away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Nedocromil ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Nedocromil 2% Ophthalmic Solution (containing nedocromil 20 mg/mL; benzalkonium chloride 0.01%; edetate disodium 0.05%; purified water; NaCl 0.5%, buffered to a pH of 4 to 5.54 with an osmolality range of 270 – 330 mOsm/kg), in a 5 mL ophthalmic dropper bottle; *Alocril®*, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Nepafenac Ophthalmic
(ne-***paf***-en-ak) *Nevanac®, Ilevro®*
Nonsteroidal Anti-Inflammatory Drug (NSAID)

Prescriber Highlights
► Used to control anterior segment inflammation, particularly in association with surgical removal of cataracts
► Prodrug to amfenac, which is bioavailable to the posterior segment
► May increase risk for intraocular bleeding, inhibit corneal wound healing, and promote corneal melting

Uses/Indications
Nepafenac is used to decrease inflammation following cataract surgery. It may also be used to control other anterior segment inflammatory conditions (eg, conjunctivitis, keratitis, anterior uveitis).[1] Studies evaluating efficacy in veterinary patients have not been performed.

Pharmacology/Actions
Nepafenac is an NSAID and analgesic prodrug. After topical ocular dosing, nepafenac penetrates the cornea, where it is converted by ocular tissue hydrolases to amfenac, which inhibits the action of prostaglandin H synthase (cyclooxygenase), an enzyme required for prostaglandin production. Prostaglandins mediate many of the adverse effects of intraocular inflammation, including disruption of the blood-aqueous humor barrier, vasodilation, increased vascular permeability, leukocytosis, and alterations in intraocular pressure (IOP). Blocking prostaglandin production, therefore, minimizes the adverse short- and long-term effects of intraocular inflammation.

Contraindications/Precautions/Warnings
Nepafenac is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation or other NSAIDs. Caution should be employed when using nepafenac in patients that have previously exhibited sensitivity to other NSAID drugs, as there

is potential for cross-sensitivity. Nepafenac has been associated with increased bleeding of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay epithelial wound healing. Concomitant use with topical steroidal agents may increase the potential for delayed healing. Nepafenac should be used cautiously in patients receiving systemic anticoagulants (eg, aspirin, clopidogrel, warfarin, and heparin), as concomitant use may increase the risk for intraocular bleeding. Use of topical NSAIDs may result in keratitis due to epithelial breakdown, corneal thinning, corneal erosion, corneal ulceration, or corneal perforation. It should be discontinued immediately in patients exhibiting evidence of corneal epithelial breakdown.

Postmarketing experience with topical NSAIDs suggests that use more than 24 hours before surgery or beyond 14 days after surgery may increase patient risk for the occurrence of corneal adverse effects.[2]

Adverse Effects

Adverse effects reported in humans or animals include capsular opacity, decreased visual acuity, foreign body sensation, increased intraocular pressure (IOP), and sticky sensation.[2] Other ocular adverse effects include conjunctival edema, corneal edema, dry eye, lid margin crusting, ocular discomfort, ocular hyperemia, ocular pain, ocular pruritus, photophobia, tearing, and vitreous detachment. Some of these effects may be the consequence of the cataract surgical procedure.[3] Nonocular adverse effects reported by humans include headache, hypertension, nausea, vomiting, and sinusitis.[2] Increased bleeding time, delayed corneal wound healing, keratitis, and corneal weakening have also been reported.

Although unlikely, systemic adverse effects may occur with the use of topical NSAIDs, including increased risk for gastric ulceration, decreased platelet aggregation, worsening of asthma and cardiac disease, and renal toxicity. Concurrent use of systemic NSAIDs and corticosteroids increases the risk for systemic adverse effects.

Dosages

Perioperative for cataract surgery (extra-label): 1 drop in the affected eye(s) 1 to 3 times daily for up to 2 weeks following cataract surgery

Anterior segment inflammation (extra-label): 1 drop in the affected eye(s) every 8 hours

Monitoring

- Clinical efficacy: decreased or absent inflammation. Monitor for delayed wound healing

Client Information

- Use this medicine as directed by your veterinarian.
- Shake this medicine well before using.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes.

Storage/Stability

Store in the refrigerator (2°C-8°C [35.6°F-46.4°F]) or controlled room temperature (20°C-25°C [68°F-77°F])[2] away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Nepafenac ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Nepafenac 0.1% Ophthalmic Solution (containing nepafenac 1 mg/mL; mannitol; carbomer 974P; NaCl; tyloxapol; edetate disodium; benzalkonium chloride 0.005%; NaOH and/or HCl to adjust pH to 7.4; purified water, USP, with an osmolality of 305 mOsm/kg), 3 mL in a sterile 4 mL ophthalmic dropper bottle; *Nevanac®*; (Rx)

Nepafenac 0.3% Ophthalmic Suspension (containing nepafenac 0.3%; boric acid, propylene glycol; carbomer 974P; NaCl; guar gum; carboxymethylcellulose sodium; edetate disodium; benzalkonium chloride 0.005%; NaOH and/or HCl to adjust pH; purified water, USP), 1.7 mL in a sterile 4 mL ophthalmic dropper bottle, or 3 mL in a sterile 4 mL ophthalmic dropper bottle; *Ilevro®*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Ocular Lubricants

Tear Replacement and Ocular Lubricating Agents

Prescriber Highlights

- ► Used in the temporary enhancement of the quality and quantity of precorneal tear film
- ► Hyaluronate/hyaluronic acid-containing preparations may exert a beneficial effect on corneal ulcer healing.
- ► Most artificial tears and ocular lubricants are labeled for humans and are available OTC.
- ► Preservative-free solutions are less likely to cause stinging or corneal damage with long-term use.
- ► Petroleum-based ocular products should not be used in procedures where combustion may occur (eg, electrocautery, laser) or when contact with the intraocular environment is possible (eg, penetrating corneal wound).
- ► Basic components of an artificial tear/ocular lubricant include demulcent (soothing agent), emollient (a fat-based agent that softens and protects tissues), inactive ingredients (impact viscosity, tonicity, and pH), and preservatives (to prevent bacterial growth).

Uses/Indications

Artificial tear solutions and ocular lubricants are used when there is a decrease in tear production, an increase in tear loss through evaporation, and a decrease in the tear film's break up time, such as in the presence of qualitative and quantitative keratoconjunctivitis sicca (KCS)[1], buphthalmos (enlarged globe that adversely affects the ability to blink), or lagophthalmos (inability to blink due to the conformational or functional abnormality of the eyelid). Ocular lubricants are also beneficial during sedation and anesthesia to prevent corneal desiccation[2] and as a vehicle for compounding water-soluble medications for ocular application. Although the evidence is variable, preparations containing hyaluronic acid/sodium hyaluronate may accelerate the healing of corneal ulcers.[3,4]

Pharmacology/Actions

Improving the quality (eg, viscosity, osmolarity, retention time) of the precorneal tear film results in improvement in comfort for patients with tear film deficiencies, as well as reduction in ocular surface inflammation and damage. Preparations include a demulcent that acts as a soothing and anti-inflammatory agent, an emollient to protect tissues and prevent drying, inactive ingredients to stabilize the preparation for ocular administration, and preservatives to prevent contamination.[5]

Demulcents may include polyethylene glycol (PEG), propylene glycol (PG), glycerin, cellulose derivatives, hydroxymethylcellulose (HMC), hydroxypropylcellulose (HPC), hydroxypropylmethylcellulose (HPMC), and polyvinyl alcohol (PVA). Although each demul-

cent varies slightly in a specific function, broadly, they are all responsible for increasing viscosity of the preparation, decreasing viscosity and osmolarity of the tear film, protecting mucous membranes, relieving inflammation, and improving the stability of the tear film.[6]

Emollients may include lanolin, mineral oil, petrolatum, paraffin, and wax. Although each emollient varies slightly in a specific function, broadly, they are all responsible for lubrication and soothing, stabilizing the lipid layer of the tear film, and sealing in moisture.[6]

Inactive ingredients may include sorbitol, hyaluronic acid (HA), sodium hyaluronate, L-carnitine and erythritol, hydroxypropyl guar, polyacrylic acid, tyloxapol, and tromethamine. Although each inactive ingredient varies slightly in a specific function, they are responsible for lowering the osmolarity of the tear film, stabilizing the viscosity of the tear film, prolonging contact time of active ingredients, promoting appropriate corneal epithelial metabolism, and maintaining hydration.[6]

Preservatives may include benzalkonium chloride, polyquad, sodium perborate, stabilized oxychloro complex, edetate disodium, and chlorobutanol. Although each preservative varies in a specific function, broadly, they are responsible for decreasing bacterial contamination of the preparation, increasing drug penetration, and increasing shelf life.[6] Some preservatives (eg, benzalkonium chloride) are known ocular irritants and cause destabilization of the tear film, which is beneficial in some conditions to allow for improved penetration of active ingredients. Although this action may be beneficial for some ocular conditions (eg, glaucoma), the resulting epithelial cell damage can be harmful in ocular surface diseases (eg, corneal ulceration). Thus, preservatives have been developed that are stable in solution but degrade upon contact to minimize ocular surface damage.

The combination of demulcent and emollient, as well as other inactive ingredients and preservatives, decreases friction on the ocular surface and increases tear retention and tear film moisture while minimally impacting ocular clarity.

Contraindications/Precautions/Warnings

Artificial tear solutions are contraindicated in patients that have a history of hypersensitivity to any component of the formulation. Interactions between topical ocular lubricants and other ocular preparations may occur, leading to alterations in viscosity of the lubricant, decreased efficacy in stabilizing the precorneal tear film, precipitate formation, or patient irritation or discomfort.

Adverse Effects

Adverse effects reported in animals include eye pain, burning or stinging on instillation, and redness. Preservative-free solutions may decrease these adverse effects. Blurred vision is commonly reported in humans after the application of ocular ointments; thus, many OTC preparations are formulated as solutions with varied demulcent and emollient proportions. Sticky eyelashes and increased sensitivity to light are commonly reported by humans using solutions containing hydroxypropyl cellulose.

Dosages

Tear replacement (extra-label): 1 drop or a ¼ – ½ inch strip to the affected eye(s) every 2 to 3 hours or as often as possible

Ocular lubrication during anesthetic procedures (extra-label): ½ – 1 inch strip to each eye every 90 minutes. Do not use in procedures where the combustion of petroleum-based ocular lubricants or contact of the lubricant with the intraocular environment may occur.

Monitoring

- Clinical efficacy
- Monitor corneal surface for signs of damage, as chronic use of preserved solutions may cause corneal damage.

Client Information

- Place these drops in your animal's eye(s) as often as possible during the day. Administer longer-acting ointments at bedtime.
- If you notice any increase in squinting, eye discharge, or ocular redness, discontinue use and contact your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. To prevent contamination, do not touch the dropper tip (or ointment) or allow it to touch your animal's eye or any other surface.
- Keep the cap tightly closed when the medicine is not in use.
- If applying multiple medications to your animal's eye(s), apply lubricating medications last, at least 5 minutes following administration of other eye medications.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if the solution becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight.

Compatibility/Compounding Considerations

Artificial tears and ocular lubricants are often used as vehicles when compounding topical ocular medications. Check to ensure compatibility of all ingredients and preservatives before compounding.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
None are FDA-approved.

sterile water; sorbitol; carbomer; hyaluron; sodium hydroxide; disodium EDTA; cetrimide	OTC; 0.7 oz tube	*OptixCare® Eye Lube Plus*
water; 0.4% Hyasent–S (modified, cross-linked HA); sodium chloride; disodium; phosphate; potassium chloride; potassium phosphate	Rx; 10 mL in a sterile ophthalmic dropper bottle	*Remend® Eye Lubricating Drops* **NOTE**: There is also a 0.75% gel that is marketed as a corneal repair gel for superficial corneal ulcers: *Remend®* Corneal Repair Gel.

HUMAN-LABELED PRODUCTS:
There are many products marketed, and this list is not comprehensive:

Polyvinyl Alcohol-Containing Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
polyvinyl alcohol 1%; polyethylene glycol 400 1%; benzalkonium chloride 0.1 mg/mL; dextrose; edetate disodium; purified water; HCl and/or NaOH to adjust pH	OTC; 15 mL in a sterile ophthalmic dropper bottle	*HypoTears®*
polyvinyl alcohol 0.5%; povidone 0.6%; benzalkonium chloride; dextrose; edetate disodium; potassium chloride; purified water; sodium bicarbonate; sodium chloride; sodium citrate; sodium phosphate (mono- and dibasic)	OTC; 15 mL in a sterile ophthalmic dropper bottle	*Murine Tears®*

Polyvinylpyrrolidone-Containing Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
polyvinyl pyrrolidone 2%; polyvinyl alcohol 2.7%; boric acid; disodium edetate dihydrate; ethanol; glycerin; lecithin; polixetonium; polysorbate-80; potassium chloride; purified water; sodium chloride	OTC; 15 mL in a sterile ophthalmic dropper bottle	*Freshkote®*

Carboxymethylcellulose-Containing Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
sodium carboxymethylcellulose 1%; borate buffers; calcium chloride; magnesium chloride; potassium chloride; purified water; sodium bicarbonate; NaCl; sodium phosphate	OTC; 0.6 mL single-use vials	*TheraTears® Liquid Gel*
sodium carboxymethylcellulose 0.25%; borate buffers; calcium chloride; *Dequest®*; potassium chloride; purified water; sodium bicarbonate; sodium borate; sodium chloride; magnesium chloride; sodium perborate; sodium phosphate; trehalose	OTC; 15 mL in a sterile ophthalmic dropper bottle	*TheraTears® Lubricant Eye Drops*

Hydroxypropyl Methylcellulose-Containing Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
dextran 70 0.1%; hydroxypropyl methylcellulose 2910 0.3%; calcium chloride; magnesium chloride; potassium chloride; purified water; sodium bicarbonate; NaCl; zinc chloride; HCl and/or NaOH and/or carbon dioxide to adjust pH	OTC; 0.4 mL single-use containers in cartons of 28	*Bion Tears®*
dextran 70 0.1%; glycerin 0.2%; hypromellose 0.3%; boric acid; calcium chloride; glycine; HCl and/or NaOH to adjust pH; magnesium chloride; POLYQUAD (polyquaternium-1) 0.002% preservative; polysorbate 80; potassium chloride; purified water; sodium chloride; zinc chloride	OTC; 15 mL in a sterile ophthalmic dropper bottle	*Genteal® Moderate Lubricating Liquid* **NOTE**: Many other *Genteal®* formulations exist.
glycerin 0.2%; hydroxypropyl methylcellulose 0.2%; polyethylene glycol 400 1%; ascorbic acid; benzalkonium chloride; boric acid; dextrose; disodium phosphate; glycine; magnesium chloride; potassium chloride; purified water; sodium borate; sodium chloride; sodium citrate; sodium lactate	OTC; in a sterile 15 mL or 30 mL ophthalmic dropper bottle	*Visine Tears® Dry Eye Relief* **NOTE**: Many other *Visine®* formulations exist.

Hydroxypropyl Guar-Containing Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
hydroxypropyl methylcellulose 0.3%; carbopol 980; phosphonic acid; purified water; sodium perborate; sorbitol	OTC; 10 g in sterile ophthalmic dropper bottles	*Systane®Lubricant Eye Gel* **NOTE**: Many other *Systane®* formulations exist.

Polyethylene Glycol/Hyaluronate-Containing Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
polyethylene glycol 400 0.25%; boric acid; calcium chloride; magnesium chloride; potassium chloride; purified water; sodium borate; sodium chloride; sodium chlorite (*Ocupure®* brand); sodium hyaluronate	OTC; 15 mL in a sterile ophthalmic dropper bottle	*Blink® Gel Tears* **NOTE**: Many other *Blink®* formulations exist.

Petroleum-Based Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
mineral oil 15%; white petrolatum 85%	OTC; 3.5 g ophthalmic ointment tube	*Genteal® Night-Time Ointment*
light mineral oil 1%; mineral oil 4.5%	OTC; 15 mL ophthalmic dropper bottle	*Soothe XP®*
mineral oil 20%; white petrolatum 80%	OTC; 3.5 g ophthalmic ointment tube	*Tears Again®*

For the complete list of references, see **wiley.com/go/budde/plumb**

Ofloxacin Ophthalmic

(o-***flocks***-uh-sin) *Ocuflox®*

Second-Generation Fluoroquinolone Antimicrobial

Prescriber Highlights

- ► Used to treat bacterial conjunctivitis or keratitis
- ► Physically incompatible with many drugs; therefore, it should not be directly mixed with other ophthalmic medications.
- ► Crystalline drug precipitates may be noted in the superficial portion of corneal defects during use.

Uses/Indications

Ofloxacin ophthalmic may be used for the treatment of bacterial conjunctivitis or keratitis caused by susceptible strains of *Staphylococcus* spp, *Streptococcus* spp, *Pseudomonas aeruginosa*, *Chlamydophila* spp, and *Haemophilus* spp.[1] Ofloxacin achieves greater aqueous humor concentrations than ciprofloxacin following topical administration to dogs.[2] In the UK, horses with bacterial keratitis did not demonstrate increased resistance to ofloxacin.[3]

The World Health Organization (WHO) has designated fluoroquinolones as a Critically Important, Highest Priority antimicrobial in human medicine.[4]

Pharmacology/Actions

Ofloxacin is a bactericidal and concentration-dependent fluoroquinolone antibiotic that is believed to act by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), thereby preventing DNA supercoiling and DNA synthesis. The activity of ofloxacin is greater against gram-negative organisms than gram-positive organisms. *Staphylococcus* spp demonstrates lower susceptibility to second-generation fluoroquinolones than most other gram-positive agents.[1]

Contraindications/Precautions/Warnings

Ofloxacin is contraindicated in patients that have a history of hypersensitivity to ofloxacin, to other fluoroquinolones, or to any of the components of this medication. Ofloxacin should only be used as a topical ophthalmic. Do not inject ofloxacin subconjunctivally or into the anterior chamber of the eye. Fluoroquinolone-induced retinal toxicity in domestic cats has not been demonstrated with this product.

Adverse Effects

Adverse effects reported in humans or animals include blurred vision, tearing, eye pain, redness, and itching.[5] Crystalline drug precipitates may be noted in the superficial portion of corneal defects during use. The arthropathy that occurs in immature animals associated with oral administration of quinolones has not been noted following topical ophthalmic administration.[5] Alterations in ocular surface microflora, with the increased population of resistant organisms, have been documented in dogs during 6 weeks of topical ofloxacin therapy following cataract surgery.[6]

Dosages

Conjunctivitis (extra-label): 1 drop in the affected eye(s) every 2 to 8 hours

Keratitis (extra-label): 1 drop in the affected eye(s), or 0.1 mL in the subpalpebral lavage (SPL) catheter, every 2 to 8 hours. It may precipitate when mixed with other ophthalmic medications; therefore, it is important to flush the SPL catheter well with air between medications.

Monitoring

- Corneal cytology and culture to evaluate for the persistence of bacteria
- Evaluation for clinical signs suggestive of continued infection

Client Information

- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Crystals may appear on the ocular surface after initiation of treatment with ofloxacin.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Keep the cap tightly closed when the medication is not in use. Store this medication in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store this medication in the refrigerator (2°C-8°C [35.6°F-46.4°F]) or at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.[5]

Compatibility/Compounding Considerations

Fluoroquinolone antibiotics interact with many other drugs, including those containing cations (eg, iron, aluminum, magnesium, or calcium). Ofloxacin should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Ofloxacin 0.3% Ophthalmic Solution (containing ofloxacin 3 mg/mL; benzalkonium chloride 0.005%; NaCl; HCl and/or NaOH to adjust pH to a range of 6 to 6.8; purified water; with an osmolality of 300 mOsm/kg), in a 5 mL and 10 mL ophthalmic dropper bottle; *Ocuflox®*, generic; (Rx)

Olopatadine Ophthalmic

(o-la-***pat***-a-deen) *Pataday®, Patanol®, Pazeo®*

H_1 and H_2 Receptor Antagonist Antihistamine Agent

Prescriber Highlights

► Used to relieve pruritus caused by allergic conjunctivitis
► Longer duration of action allows once- to twice-daily dosing

Uses/Indications

Olopatadine ophthalmic is used to relieve pruritus caused by allergic conjunctivitis. Evaluation of olopatadine's clinical efficacy in veterinary species has not been performed.

Pharmacology/Actions

Olopatadine is a selective, noncompetitive H_1 and H_2 receptor antagonist and a mast cell stabilizer. It is also an inhibitor of proinflammatory mediators such as leukotrienes and thromboxane.[1]

Contraindications/Precautions/Warnings

Olopatadine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects

Adverse effects reported in humans include transient burning or stinging on instillation in the eye, although instillation was more comfortable compared with other ophthalmic antihistamines.[1]

Dosages

Allergic conjunctivitis (extra-label): 1 drop in the affected eye(s) once daily (*Pataday®*, *Pazeo®*) or twice daily (*Pataday®*, *Patanol®*)

Monitoring

- Clinical efficacy: resolution of pruritus and conjunctivitis

Client Information

- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine in refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solutions.

Storage/Stability

Store this product in the refrigerator (2°C-8°C [35.6°F-46.4°F]) or at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Olopatadine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Olopatadine 0.1% Ophthalmic Solution (containing 1.11 mg olopatadine HCl equivalent to 1 mg olopatadine per mL; povidone; dibasic sodium phosphate; NaCl; edentate disodium; benzalkonium chloride 0.01%; HCl/NaOH to adjust pH to ≈7; purified water, with an osmolality of ≈300 mOsm/kg), in 2.5 mL ophthalmic dropper bottles; *Pataday®*, *Patanol®*; generic; (Rx)

Olopatadine 0.2% Ophthalmic Solution (containing 2.22 mg olopatadine HCl equivalent to 2 mg olopatadine per mL; povidone; dibasic sodium phosphate; NaCl; edentate disodium; benzalkonium chloride 0.01%; HCl/NaOH to adjust pH to ≈7; purified water, with an osmolality of ≈300 mOsm/kg), in 2.5 mL ophthalmic dropper bottles; *Pataday®*; generic; (Rx)

Olopatadine 0.7% Ophthalmic Solution (containing 7.76 mg olopatadine HCl equivalent to 7 mg olopatadine per mL; povidone; hydroxypropyl-gamma-cyclodextrin; polyethylene glycol 400; hydroxypropyl methylcellulose; boric acid; mannitol; benzalkonium chloride 0.015%; HCl/NaOH to adjust pH; purified water), in 2.5 mL ophthalmic dropper bottles; *Pataday®*, *Pazeo®*; generic; (Rx)

Oxytetracycline/Polymyxin B Ophthalmic

(ocks-ih-***tet***-rih-sye-kleen/pol-lee-***mix***-in) *Terramycin®*

Combination Antibiotic

*For information related to systemic use, see **Oxytetracycline** and **Polymyxin B***

Prescriber Highlights

► Used to treat superficial ocular bacterial infections in dogs, cats, horses, cattle, and sheep
► Frequently effective for treating *Chlamydia* spp and *Mycoplasma* spp conjunctivitis in cats
► *Chlamydia* spp infections should be treated for 3 to 4 weeks beyond resolution of clinical signs to disrupt *Chlamydia* spp reproductive cycle.
► Some cats experience local irritation or more severe anaphylactic reactions that necessitate discontinuation of treatment.
► Used to decrease keratomalacia induced by matrix metalloproteinases in response to corneal infections
► May accelerate corneal epithelial wound healing in dogs

Uses/Indications

Oxytetracycline/Polymyxin B is used to prevent or treat superficial ocular infections involving the conjunctiva and/or cornea caused by gram-positive, gram-negative, and intracellular bacteria. It is commonly used to treat known or suspected *Chlamydia* spp and *Mycoplasma* conjunctivitis in cats.

Following a single dose of topical oxytetracycline/polymyxin B administered to normal canine eyes, tear film concentrations surpass MICs for common ocular pathogens.[1] Topical tetracyclines have variable effects on the rate of corneal epithelial wound healing in dogs without bacterial ocular surface infections.[2,3] Topical tetracyclines are useful in decreasing keratomalacia occurring due to bacte-

rial infections of corneal ulcers[4]; however, the twice-daily dosing advised by the manufacturer may not be sufficient to achieve sustained collagenolytic activity within the tear film of normal canine eyes.[1]

Pharmacology/Actions

The reversible binding of tetracyclines to the 30S ribosomal subunits of susceptible organisms inhibits the binding of the tRNA and its associated amino acid to the mRNA-ribosome complex, which disrupts protein synthesis. Tetracyclines demonstrate good activity against *Rickettsia* spp, *Borrelia* spp, *Chlamydia* spp, *Mycoplasma* spp, *Moraxella* spp, and *Brucella* spp, with variable activity against *Staphylococcus* spp and *Streptococcus* spp. Tetracyclines are not effective against *Pseudomonas* spp.

The increased healing rate of uninfected corneal ulcers in dogs treated with topical tetracyclines is thought to be due to upregulation of transforming growth factor-beta.[2] Oxytetracycline is also a potent inhibitor of matrix metalloproteinase-9 and a moderate inhibitor of matrix metalloproteinase-2. The reduction of keratomalacia occurring in infected corneal ulcers is due to inhibition of matrix metalloproteinases (MMP), which is induced by tetracyclines binding calcium and zinc (cofactors necessary for MMP activity).[5]

Polymyxin B sulfate, one of a group of related antibiotics derived from *Bacillus polymyxa*, is rapidly bactericidal. This action is exclusively effective against gram-negative organisms, particularly *Pseudomonas aeruginosa*.[6] Polymyxin B sulfate interacts with the lipopolysaccharide of the cytoplasmic outer membrane of gram-negative bacteria, altering membrane permeability and causing cell death; it does not need to enter the cell. Polymyxin B sulfate has a bactericidal action against almost all gram-negative bacilli except the Proteus group. It is ineffective against gram-positive bacteria, gram-negative cocci, or obligate anaerobes. It lacks activity against viral, fungal, or parasitic pathogens. Pus and cellular debris reduce effectiveness.

Contraindications/Precautions/Warnings

Oxytetracycline and polymyxin are contraindicated in patients that have a history of hypersensitivity to either drug, drugs in the same class, or any component of the formulation.

Adverse Effects

Adverse effects reported in humans or animals are rare. Oxytetracycline with polymyxin B sulfate is well tolerated by the epithelial membranes and other tissues of the eye. Allergic or inflammatory reactions due to individual hypersensitivity are rare; however, some cats may have an anaphylactic reaction to the polymyxin B component.[6,7]

Dosages

Conjunctivitis, keratitis (label dosage; FDA approved): ¼ inch strip in the affected eye(s) 2 to 4 times daily[6]

Monitoring

- Clinical efficacy
- Resolution of conjunctivitis or keratitis

Client Information

- Use this medication as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Wait 5 minutes after applying this medicine before applying any other medicine to your animal's eye(s).
- Crystals may appear on the surface of your animal's eye during treatment. This change is not harmful and will go away once treatment is complete.
- Keep the cap tightly closed when the medication is not in use. Store this medication at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes.

Storage/Stability

Store at controlled room temperature (20°C-25°C [68°F-77°F]), with excursions between 15°C to 30°C (59°F-86°F), away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Oxytetracycline should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oxytetracycline HCl and Polymyxin B Ophthalmic Ointment (containing oxytetracycline 5 mg/g; polymyxin B sulfate 10,000 units/g; white petrolatum; liquid petrolatum), in 3.5 g ointment tubes; *Terramycin*®; (Rx)

HUMAN-LABELED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Phenylephrine Ophthalmic

(fen-il-***ef***-rin) *Cyclomydril*®

Alpha Agonist Vasoconstrictor

For systemic use, refer to ***Phenylephrine***

Prescriber Highlights

- ► Direct-acting sympathomimetic agent (alpha-1 agonist)
- ► Used to augment mydriasis, most commonly during intraocular surgical procedures and to limit bleeding during minor ocular surface procedures
- ► Not an effective mydriatic in cats or horses when used alone but may increase mydriatic effect when combined with atropine
- ► Used to differentiate second- from third-order Horner syndrome
- ► Local discomfort may occur after application.
- ► Cardiovascular adverse effects are more likely in small dogs and cats and following use of 10% concentrations.

Uses/Indications

Phenylephrine is most commonly used to induce mydriasis prior to phacoemulsification for cataract removal. It is also used prior to minor ocular surface procedures (eg, conjunctival biopsy) to limit bleeding. Phenylephrine is also used to distinguish second- from third-order lesions in Horner syndrome because of the phenomenon of denervation hypersensitivity. In dogs, maximal pupillary dilation occurs in 55 minutes[1]; however, phenylephrine alone does not lead to mydriasis in cats[2] and horses.[3]

Pharmacology/Actions

Phenylephrine is a direct alpha-1-adrenergic receptor agonist with potent local vasoconstrictor effects. Mydriatic effects are variable and are achieved through direct stimulation of the radial iris dilator muscle.

Contraindications/Precautions/Warnings

Phenylephrine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Phenylephrine should be used cautiously in patients with thyrotoxicosis or hypertension, as adverse cardiovascular effects may occur.

Adverse Effects

Adverse effects reported in humans or animals include eye pain and stinging on instillation, temporary blurred vision and photophobia, and conjunctival sensitization. Cardiovascular effects following topical administration have been reported in dogs[3] and cats[4] due to

systemic absorption, which may result in adverse cardiovascular effects (eg, marked increase in blood pressure, syncope, myocardial infarction, bradycardia, and ventricular and supraventricular arrhythmias) that could require therapeutic intervention.[4–6] The systemic effects can be severe and may require intervention. The effects of phenylephrine will be increased when it is administered after topical local anesthetic agents because of epithelial damage induced by topical local anesthetic agents. In normal dogs, phenylephrine leads to a statistically (but not necessarily clinically) significant increase in intraocular pressure (IOP) following topical administration.[1]

Dosages

Diagnosis of Horner syndrome (extra-label): 1 drop of phenylephrine 0.25% solution in each eye. Patients suffering from third-order Horner syndrome will experience mydriasis from this low concentration, whereas healthy patients will not. If there is no response in 20 to 30 minutes, apply 1 drop of a 2.5% solution to each eye. If mydriasis occurs, second-order Horner syndrome is likely.

Preoperative cataract removal (extra-label): 1 drop of phenylephrine 2.5% or 10% in the affected eye(s) as a single dose or every 15 minutes for 2 hours. Severe cardiovascular adverse effects are more likely with small dogs and cats and following use of the 10% solution, thus caution should be exercised both with the concentration and the frequency of administration. Effects are augmented when it is administered following topical anesthetic agents.

Monitoring

- Clinical efficacy
- Monitor degree of pupillary dilation
- Monitor bleeding after minor ocular surface surgical procedures
- Monitor heart rate and blood pressure

Client Information

- This medicine is rarely (if ever) indicated for administration to animals at home.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine as directed on package labeling away from moisture and sunlight; do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability

Store this product as directed on package labeling either in the refrigerator (2°C-8°C [35.6°F-46.4°F]) for 10% concentration or at controlled room temperature (20°C-25°C [68°F-77°F]) for 2.5% concentration; do not freeze.

Compatibility/Compounding Considerations

Phenylephrine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Phenylephrine HCl 2.5% Ophthalmic Solution (containing phenylephrine hydrochloride 25 mg (2.5%); sodium phosphate monobasic; sodium phosphate dibasic; boric acid; water for injection; hydrochloric acid and/or sodium hydroxide (to adjust pH); benzalkonium chloride), in a sterile 15 mL ophthalmic dropper bottle; generic; (Rx)

Phenylephrine HCl 10% Ophthalmic Solution (containing phenylephrine hydrochloride 100 mg (10%); sodium phosphate monobasic; sodium phosphate dibasic; boric acid; water for injection; hydrochloric acid and/or sodium hydroxide (to adjust pH); benzalkonium chloride), in a sterile 10 mL ophthalmic dropper bottle; generic; (Rx)

Phenylephrine HCL 1% and Cyclopentolate HCl 0.2% Ophthalmic Solution (containing cyclopentolate hydrochloride 0.2%; phenylephrine hydrochloride 1%; benzalkonium chloride 0.01%; edetate disodium; boric acid; hydrochloric acid and/or sodium carbonate (to adjust pH); purified water), in sterile 5 mL ophthalmic dropper bottle; *Cyclomydril*®; (Rx)

References

Pilocarpine Ophthalmic

(***pye***-loe-***kar***-peen) *Isopto Carpine*®

Cholinergic Miotic Agent

Prescriber Highlights

- ► Primarily used to treat neurogenic keratoconjunctivitis sicca (KCS). It may also be used to treat primary glaucoma in dogs but has largely been replaced by other treatments.
- ► Contraindicated in cases of secondary glaucoma (eg, caused by uveitis or lens luxation) because of the risk for pupillary block
- ► Ophthalmic solution may be administered to the affected eye or be given orally on food as a treatment for neurogenic KCS.
- ► Monitor for ocular and systemic toxicity.

Uses/Indications

The primary use of pilocarpine in veterinary patients is for the treatment of neurogenic keratoconjunctivitis sicca (KCS), which is caused by interrupted neurologic signaling to the otherwise normal lacrimal glands. In dogs with coinciding xeromycteria (dryness of the nasal mucous membranes), pilocarpine also increases nasal secretions. Oral administration and topical ocular administration, alone or in combination, increases tear production in dogs.[1–3] Pilocarpine, administered topically to the eye, may also be used to diagnose parasympathetic denervation of the iris sphincter caused by lesions of or trauma to the oculomotor nerve (cranial nerve III). Pilocarpine may also be used topically to treat primary glaucoma in dogs,[4] but it has largely been replaced by beta-blockers, carbonic anhydrase inhibitors, and prostaglandin agents. Pilocarpine does not reduce intraocular pressure (IOP) in horses and is therefore not used to treat equine glaucoma.[5]

Pharmacology/Actions

Pilocarpine mimics acetylcholine and acts as a direct-acting cholinergic agonist at the neuromuscular junctions. In the eye, this cholinergic stimulation leads to lacrimal secretion, and can therefore be used to treat neurogenic keratoconjunctivitis sicca (KCS; ie, lacrimal gland tissue is normal, but innervation is interrupted). Cholinergic stimulation also leads to ciliary body muscle contraction, which places posteriorly directed tension on the base of the iris to mechanically pull open the iridocorneal angle, increasing aqueous humor outflow in dogs with elevated intraocular pressure (IOP).

Contraindications/Precautions/Warnings

Pilocarpine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Avoid its use in dogs with glaucoma secondary to uveitis or lens luxation, as the induction of miosis may lead to blockage of aqueous humor flow through the pupil, thus worsening glaucoma (pupillary block glaucoma).

Adverse Effects

Adverse effects reported in humans or animals include significant

irritation (due to the low pH) upon application, which may result in inflammation of the uveal tract.[1,6] Local irritation has been reported in dogs within the first 2 days of treatment, but it appears to improve and cause minimal problems thereafter.[7] Long-term use may result in irreversible miosis due to dilator muscle atrophy and sphincter muscle fibrosis. Systemic absorption of pilocarpine, which occurs when the medication is administered orally, may result in vomiting, diarrhea, increased salivation, increased urination, bronchiolar spasm, and pulmonary edema.

Dosages

Diagnosis of ocular parasympathetic denervation (oculomotor nerve [cranial nerve III]) lesions (extra-label): 1 drop of diluted pilocarpine (0.1-0.2%) solution in the affected eye(s)[8]

Neurogenic keratoconjunctivitis sicca (KCS; extra-label): 1 drop of pilocarpine 0.25% solution in the affected eye(s) 4 times daily, alone or in combination with 2 drops/9.1 kg (20 lb) of a pilocarpine 2% solution in food to be consumed orally twice daily.[9] The dose is increased weekly until signs of toxicity occur or until clinical signs are controlled. If signs of toxicity develop, the dose must be decreased.

Primary glaucoma (extra-label): 1 drop of pilocarpine 1% or 2% solution in the affected eye(s) 3 times daily. **NOTE**: Topical pilocarpine is not recommended for first-line or chronic therapy.

Monitoring

- Clinical efficacy (neurogenic keratoconjunctivitis sicca [KCS]): improved tear production as assessed by Schirmer tear test, patient comfort, and decreased ocular redness and irritation
- Clinical efficacy (primary glaucoma): decrease in/control of intraocular pressure (IOP)
- Observe for signs of systemic toxicosis, including vomiting, diarrhea, increased salivation, increased urination, bronchiolar spasm (coughing), and pulmonary edema, which may occur with both oral and topical administration.
- Monitor for signs of ocular irritation (eg, redness, squinting, cloudiness) when the drug is administered topically.

Client Information

- Give this medication as directed by your veterinarian.
- Observe your animal for signs of toxicity, including vomiting, diarrhea, increased salivation, increased urination, and coughing. Contact your veterinarian if any of these signs occur.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solutions.

Storage/Stability

Store this medication at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Pilocarpine should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Pilocarpine HCl 1%, 2%, or 4% Ophthalmic Solution (containing pilocarpine 10 mg/mL, 20 mg/mL, or 40 mg/mL, respectively; benzalkonium chloride 0.01%; monobasic sodium phosphate; hypromellose; edetate disodium; dibasic sodium phosphate, purified water; NaOH and/or HCl may be added to adjust pH to 3.5 to 5.5), in a 15 mL ophthalmic dropper bottle; *Isopto Carpine*®, generic; (Rx).

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pimecrolimus Ophthalmic

(pi-mek-***kroe***-li-mus)

T-cell Immunosuppressive Lacromimetic Agent

Prescriber Highlights

- ► Used to treat dogs with keratoconjunctivitis sicca (KCS), chronic superficial keratitis (CSK), and other immune-mediated ocular surface inflammatory conditions
- ► Useful for cyclosporine-resistant cases of KCS
- ► Not commercially available, must be compounded. *Elidel*® topical (skin) pimecrolimus ointment should NOT be used in the eye.
- ► Advise caregivers to wear gloves when handling pimecrolimus.

Uses/Indications

Pimecrolimus is used to stimulate tear production in dogs with keratoconjunctivitis sicca (KCS) that do not respond to topical cyclosporine. Pimecrolimus 1% administered 3 times daily to patients with KCS and chronic superficial keratitis (CSK) produced favorable improvement in clinical signs.[1] A prospective study in dogs comparing pimecrolimus 1% with cyclosporine 0.2% over an 8-week period found significantly greater improvement in clinical signs that were treated with pimecrolimus rather than cyclosporine.[2] Topical ophthalmic pimecrolimus has not been evaluated in cats or horses.

Pharmacology/Actions

Pimecrolimus is a calcineurin inhibitor (like cyclosporine) that reversibly inhibits T-cell proliferation and prevents the release of pro-inflammatory cytokines. Pimecrolimus binds to intracellular macrophilin, forming a complex that subsequently binds to and inhibits calcineurin. In blocking calcineurin, translocation of the cytoplasmic component of the nuclear factor of activated T cells to the nucleus is prevented. This prevention of translocation impairs transcription of the genes encoding IL-2 and other cytokines, thereby suppressing T-cell proliferation and normal immune function.

Contraindications/Precautions/Warnings

Pimecrolimus is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Caregivers should be advised to avoid contact with pimecrolimus, as skin contact with pimecrolimus has been associated with the development of cancer in humans.

Adverse Effects

Adverse effects to ocular use of pimecrolimus are rare but include orbital alopecia, which may be related to oil vehicles used to compound pimecrolimus solutions.

Dosages

Keratoconjunctivitis sicca (KCS) (extra-label): 1 drop of a pimecrolimus 1% solution in affected eye(s) 2 to 3 times daily

Chronic superficial keratitis (CSK) (extra-label): 1 drop of a pimecrolimus 1% solution in affected eye(s) 2 to 3 times daily

Monitoring

- Baseline and periodic Schirmer tear test, as well as reduction in mucoid ocular discharge and conjunctival hyperemia. Evaluate for lack

of progression (and possibly regression) of chronic inflammatory changes, such as corneal pigmentation, vascularization, and fibrosis

Client Information

- Use this medicine as directed by your veterinarian.
- This is a lifelong medicine and must be given daily. Missed doses may cause return of keratoconjunctivitis sicca (KCS) or chronic superficial keratitis (CSK).
- Wear gloves when handling pimecrolimus. Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine as directed on the package labeling away from moisture and sunlight; do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if particles are seen in solutions.

Storage/Stability

Store this product as directed on the package labeling away from moisture and sunlight.

Compatibility/Compounding Considerations

Pimecrolimus ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Pimecrolimus ophthalmic preparations are not commercially available but have been prepared (compounded) by qualified compounding pharmacists in 1% solutions in oil vehicles including olive oil, corn oil, and medium-chain triglyceride oil.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Povidone-Iodine Ophthalmic

(***poe***-veh-done ***eye***-oh-dyne) *Betadine®*

Ocular Disinfectant

Prescriber Highlights

- ► Primarily used as a component of preoperative periocular surface preparation
- ► An inexpensive alternative to traditional antifungal, antibacterial, or antiviral ophthalmic agents
- ► May be used to debride nonvital corneal epithelium from indolent ulcers
- ► Solutions greater than 1% must be thoroughly lavaged from the eye within 5 minutes of administration to avoid corneal toxicity.
- ► Topical administration causes discomfort.

Uses/Indications

Povidone-iodine ophthalmic solutions (1% to 5%) are used as a component of periocular surface preparation for all surgical procedures. Additionally, they may be used to chemically debride loose epithelium associated with superficial chronic corneal epithelial defects (SCCED; also called indolent ulcer), or as treatment for bacterial, fungal, and viral infections of the ocular surface. Contrary to what may be expected, lower concentrations (less than 1%) of povidone-iodine demonstrate greater bactericidal activity than higher (10%) concentrations.[1] Povidone-iodine 1.25% led to comparable clinical improvement relative to topical neomycin/polymyxin B/gramicidin and ciprofloxacin in human patients with bacterial keratitis caused by various organisms.[2]

Pharmacology/Actions

Povidone-iodine is an iodophor that damages bacterial cell walls and organelle membranes through interactions with fatty acid double bonds. Additionally, povidone-iodine induces oxidative damage to amino acids and nucleotides. These actions lead to formation of pores in membranes, producing bactericidal and virucidal, and, potentially, fungicidal and sporicidal activity, depending on organism and contact time.

Contraindications/Precautions/Warnings

Povidone-iodine is contraindicated in patients with a history of hypersensitivity to it or any component of the formulation.

Adverse Effects

Adverse effects reported in humans or animals include local burning and stinging on application, as well as chemosis and conjunctival hyperemia; however, concentrations less than 1% are better tolerated than more concentrated preparations. Some patients may experience a local hypersensitivity reaction. Solutions of 0.25% to 10% demonstrate varying degrees of toxicity to ocular surface cells in vitro.[3]

Dosages

Periocular preoperative preparation (extra-label): Saturate sterile swabs or ocular gauze with povidone-iodine solution and apply to surgical area as disinfectant component of presurgical preparation; irrigate the ocular surface with sterile saline solution, leaving it in contact with the surgical area for 2 minutes. Residual solution should be removed via irrigation with sterile saline solution.

Fungal, bacterial, or herpesvirus keratitis (extra-label): 1 drop of a 5% solution to the affected eye(s) once every 24 hours. Treated eye(s) must be thoroughly lavaged with sterile saline solution not more than 5 minutes after administration to avoid corneal damage.

Debridement of nonvital epithelium in superficial chronic corneal epithelial defects (SCCED) ulcers (extra-label): 1 – 2 drops of a 5% solution to the affected eye(s) once. Irrigate thoroughly with sterile saline solution to remove all povidone-iodine not more than 5 minutes after application to avoid damage to the healthy corneal epithelium.

Monitoring

- Clinical efficacy

Client Information

- Use this medicine as recommended by your veterinarian.
- Rinse the animal's eyes thoroughly with sterile eyewash solution within 5 minutes of application.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Store at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if particles are seen in the solution.

Storage/Stability

Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Povidone-iodine preparations should not be mixed directly with any other medications. Sterile povidone-iodine ophthalmic preparation is available as a 5% solution intended for application to the eyes, but solutions of 0.5% to 1% may be prepared by diluting this solution with sterile normal saline. Nonsterile povidone-iodine solutions should not be administered to the eye.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Povidone-Iodine 5% Ophthalmic Prep (containing povidone-iodine 5%, with 0.5% available iodine; purified water; citric acid; glycerin; nonoxynol-9; NaCl; NaOH; and dibasic sodium phosphate) in a sterile 30 mL bottle; *Betadine Sterile Ophthalmic Prep®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Prednisolone Ophthalmic

(pred-***niss***-oh-lone) *Pred Forte®, Omnipred®, Blephamide®, Pred G®*

Corticosteroid

For systemic use, refer to ***Prednisolone/Prednisone***

Prescriber Highlights

- ► Topical corticosteroid used to treat ocular surface and intraocular inflammatory conditions
- ► Superior penetration into the anterior segment compared with other topical corticosteroids, particularly in acetate formulation (versus phosphate)
- ► Use cautiously in small diabetic patients to avoid blood glucose dysregulation.
- ► Contraindications include a hypersensitivity to prednis(ol)one; an existing or suspected bacterial, viral, or fungal ocular infection; and the presence of a corneal abrasion or ulceration.

Uses/Indications

Prednisolone ophthalmic is used to treat inflammatory conditions of the palpebral and bulbar conjunctiva, the cornea, and the anterior segment of the globe (eg, blepharitis, conjunctivitis, keratitis, anterior uveitis). Greater intraocular penetration (and therefore potential clinical efficacy) is achieved with acetate formulations relative to phosphate. Administration of prednisolone acetate to the eyes of cats reduced experimentally induced uveitis more significantly than dexamethasone, flurbiprofen, and diclofenac.[1]

Prednisolone is available in combination with antimicrobial agents for topical ophthalmic use.

Pharmacology/Actions

Corticosteroids have broad immunomodulatory and anti-inflammatory actions, which are mediated via direct effects on gene expression, as well as by nongenomic effects on cell membranes and receptors. Ultimately, corticosteroids decrease pro-inflammatory gene transcription, production of pro-inflammatory prostaglandins and leukotrienes, B- and T-cell number and function, cell-mediated immunity, and humoral immunity.[2] Specific mechanisms involved in controlling ocular inflammatory conditions are not known. Prednisolone has a relative glucocorticoid potency of 4 (versus 1 for hydrocortisone and 25 for dexamethasone); however, its superior intraocular penetration when in the acetate formulation leads to increased clinical efficacy relative to dexamethasone ophthalmic formulations.

Contraindications/Precautions/Warnings

Prednisolone is contraindicated in patients with a history of hypersensitivity to it or any component of the formulation. Due to inhibition of epithelial wound healing and potentiation of infection, prednisolone ophthalmic is contraindicated when corneal ulceration is suspected or present or in the presence of corneal infection (bacterial, fungal, or viral),[3] infectious diseases, chronic renal failure, congestive heart failure, systemic hypertension, or gastric ulceration. When use of prednisolone is necessary in these conditions, the minimal effective dose should be administered for the shortest possible time.

Adverse Effects

Adverse effects reported in humans include development of cataracts (via altered glucose or lenticular metabolic effects), increased intraocular pressure (IOP; via activation of glucocorticoid receptors in the trabecular meshwork), infection (via immunosuppression), decreased wound healing (via increased collagenolytic activity), mydriasis, and calcific keratopathy. Increased IOP may occur in some animals with long-term use of prednisolone; however, most reports suggest the change is reversible.[4,5] Systemic effects are rare but include hepatopathy, suppression of endogenous glucocorticoid production, and focal alopecia. Concurrent use of systemic steroids increases risk for these adverse effects.

Dosages

Conjunctivitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) every 6 hours until clinical improvement occurs, then gradually decrease, provided clinical improvement is maintained

Keratitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) every 6 hours until clinical improvement occurs, then gradually decrease, provided clinical improvement is maintained

Anterior uveitis (extra-label): 1 drop or ¼ inch strip in the affected eye(s) every 6 hours until clinical improvement occurs, then gradually decrease, provided clinical improvement is maintained

Post-cataract removal (extra-label): 1 drop in the affected eye(s) every 6 hours

Monitoring

- Clinical efficacy
- Resolution or development of signs of inflammation
- Intraocular pressure (IOP; especially in cats) and ocular surface integrity (eg, fluorescein stain) as needed based on clinical presentation
- Blood or urine glucose changes based on development of clinical signs (eg, polyuria, polydipsia) in diabetic animals

Client Information

- This medicine can be given for various lengths of time. Be sure you understand how often and for how long your animal should be given this medicine.
- Shake suspensions well before using.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Contact your veterinarian as soon as possible if your animal's eye condition worsens or does not improve while using this medicine.
- Your veterinarian will need to monitor your animal's eye condition while taking this medicine. Do not miss these important follow-up visits.
- Store this medicine as directed on the product label. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are visible particles in the solution.

Storage/Stability

Storage recommendations can vary; follow storage requirements listed on packaging. Most commonly, this product is recommended to be stored at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations

Prednisolone ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Prednisolone Acetate 0.12% Ophthalmic Suspension (containing

prednisolone acetate [microfine suspension] 0.12%, benzalkonium chloride, boric acid, edetate disodium, hypromellose, polysorbate 80, purified water, sodium bisulfite, sodium chloride, and sodium citrate) in 10 mL sterile ophthalmic dropper bottle; *Pred Mild*®; (Rx)

Prednisolone Acetate 1% Ophthalmic Suspension (containing prednisolone acetate [microfine suspension] 1%; benzalkonium chloride; boric acid; edetate disodium; hypromellose; polysorbate 80; purified water; sodium bisulfite; NaCl; and sodium citrate, with a pH of 5 to 6) in 5 mL and 10 mL ophthalmic dropper bottles; *Pred Forte* 1%, *Omnipred*® generic; (Rx)

Prednisolone Sodium Phosphate 1% Ophthalmic Solution (containing prednisolone sodium phosphate 10 mg/mL [equivalent to 9.1 mg/mL prednisolone phosphate] in a buffered isotonic solution; hypromellose; monobasic and dibasic sodium phosphate; NaCl, edetate disodium and purified water; NaOH and/or HCl may be added to adjust the pH to 6.2 to 8.2) in 5 mL and 10 mL ophthalmic dropper bottles; generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:

Gentamicin and Prednisolone Acetate Ophthalmic Ointment 0.3%/0.6% (containing gentamicin sulfate equivalent to 0.3% gentamicin base, prednisolone acetate 0.6%, chlorobutanol [chloral derivative] 0.5%, mineral oil, petrolatum [and] lanolin alcohol, purified water, and white petrolatum) in a sterile 3.5 g ophthalmic tube; *Pred-G*®; (Rx)

Gentamicin and Prednisolone Acetate Ophthalmic Suspension 0.3%/1% (containing gentamicin sulfate equivalent to 0.3% gentamicin base, prednisolone acetate [microfine suspension] 1%, benzalkonium chloride 0.005%, edetate disodium, hypromellose, polyvinyl alcohol 1.4%, polysorbate 80, purified water, sodium chloride, sodium citrate dehydrate, NaOH and/or HCl to adjust pH [5.4 to 6.6]) in a sterile 5 mL ophthalmic dropper bottle; *Pred-G*®; (Rx)

Sulfacetamide Sodium and Prednisolone Acetate Ophthalmic Ointment (10%/0.2%) (containing sulfacetamide sodium 10%, prednisolone acetate 0.2%, phenylmercuric acetate 0.0008%, white petrolatum, mineral oil, and petrolatum and lanolin alcohol) in a sterile 3.5 g ophthalmic tube; *Blephamide S.O.P.*®; (Rx)

Sulfacetamide Sodium and Prednisolone Acetate Ophthalmic Suspension (10%/0.2%) (containing sulfacetamide sodium 10%, prednisolone acetate 0.2%, benzalkonium chloride 0.004%, edetate disodium, polysorbate 80, polyvinyl alcohol 1.4%, potassium phosphate monobasic, purified water, sodium phosphate dibasic, sodium thiosulfate, and HCl and/or NaOH to adjust the pH [6.6 to 7.2]); *Blephamide*®; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Proparacaine Ophthalmic

(proe-***pare***-a-kane) *Alcaine*®, *Flucaine*®

Topical Ocular Anesthetic

Prescriber Highlights

- ► Rapid-acting topical anesthetic used for ocular diagnostic procedures
- ► Should never be prescribed for therapeutic administration
- ► Dose- and species-dependent duration, with maximal effect generally between 5 and 15 minutes in dogs, cats, and horses
- ► Long-term use results in tear film instability and globe-threatening corneal epithelial and stromal damage.
- ► Some products must be stored in the refrigerator; consult product label.

Uses/Indications

Proparacaine is indicated for use in ophthalmic diagnostic procedures, including measurement of intraocular pressure (tonometry), corneal and conjunctival sampling for cytology and culture, ocular ultrasonography, and gonioscopy. Proparacaine is indicated as an adjunctive anesthetic for performing therapeutic procedures in the hospital, including removal of foreign bodies and sutures from the cornea; eyelid and conjunctival surgeries; corneal grafting procedures; and cataract extraction. Proparacaine has dose- and species-dependent duration of action, with maximal effect between ≈5 and 15 minutes in dogs, cats, and horses, and duration of effect lasting around 30 minutes.[1–5] The degree of maximal effect of proparacaine is less than that of viscous tetracaine in dogs.[2] Favorably, administration of topical proparacaine has not been associated with decreased positive bacterial or fungal cultures in dogs, cats, or horses.[6,7] Because of the likelihood of developing ocular surface toxicities with prolonged or repeated use, proparacaine should never be prescribed for use as an ocular analgesic.

Pharmacology/Actions

Proparacaine induces local anesthesia by inhibiting neuronal depolarization, which prevents generation of an action potential. This action occurs due to binding of the local anesthetic molecule to the intracellular portion of the voltage-gated sodium channel within the neuron, thus inhibiting intracellular movement of sodium. Variations in the structure of different local anesthetics influence their relative potencies. All local anesthetics have increased efficacy in alkaline environments due to improved intracellular penetration; efficacy of local anesthetics is decreased in acidic environments, such as when there is inflammation.

Contraindications/Precautions/Warnings

Proparacaine is contraindicated in patients with a history of hypersensitivity to it or any component of the formulation. Prolonged use of a topical ocular anesthetic will likely produce significant corneal epithelial and stromal disease, as well as tear film instability, and may result in loss of vision.[8]

Adverse Effects

Instillation of proparacaine may result in local irritation several hours after administration. Although patients that are sensitive to other local anesthetics may be less likely to react to proparacaine, local or systemic sensitivity may manifest as a pseudo-allergic (anaphylactoid) reaction mimicking an IgE-mediated vasodilatory event. Cardiovascular, respiratory, and CNS depressant effects that may result from other local anesthetics are extremely rare with appropriate use of topical anesthetics. Care should be exercised, however, when proparacaine is administered to small veterinary patients (ie, puppies, kittens, "pocket pets"), or those more susceptible to systemic absorption (ie, amphibians). Use of proparacaine as a therapeutic analgesic leads to superficial punctate keratitis, which may progress to diffuse necrotizing keratitis, severe infiltrative keratitis, persistent epithelial defects, or damage to the Descemet membrane.

Dosages

Ophthalmic procedures requiring local anesthesia (extra-label): 1 – 2 drops in the target eye(s) prior to examination or procedure. May repeat 1 drop every 5 to 10 minutes 2 to 3 additional times. With additional applications, the duration of corneal anesthesia can be extended to 55 minutes in dogs. Additional doses should be avoided in small patients (ie, puppies, kittens, "pocket pets").

Monitoring

- Clinical effect: Onset of action is indicated by awake patient permitting diagnostic procedures to be performed, and by a reduction in anesthetic requirements when administered preoperatively.

Client Information

- Proparacaine is **not** administered by pet owners in the home. It is reserved for diagnostic procedures in the veterinary practice.

Storage/Stability
Store this product in a refrigerator or at controlled room temperature (depending on the product label) away from moisture and sunlight; do not freeze.[9]

Discard this product if the solution changes color, if it becomes cloudy, or if it develops particles.

Compatibility/Compounding Considerations
Proparacaine should not be mixed directly (in vitro) with any other drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Proparacaine HCl 0.5% ophthalmic solution (containing 5 mg/mL proparacaine; benzalkonium chloride 0.01%; glycerin; HCl and/or NaOH to adjust pH; purified water) in 15 mL ophthalmic dropper bottles; *Alcaine®*, generic; (Rx)

Proparacaine HCl 0.5% with Fluorescein Sodium Ophthalmic Solution (containing proparacaine 5 mg/mL; fluorescein sodium 2.5 mg/mL; povidone; boric acid; water for injection; NaOH and/or HCl to adjust pH; methylparaben), 5 mL, in sterile plastic or glass ophthalmic dropper bottles; *Flucaine®*, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Rose Bengal Stain, Ophthalmic
(rose ***ben***-gall) *Glostrips®*
Ocular Diagnostic Agent

Prescriber Highlights
- ► Vital dye that demonstrates corneal and conjunctival epithelial cell damage, as well as deficiency in ocular surface mucins
- ► Full-thickness loss of corneal epithelium is not necessary to cause rose bengal uptake by epithelial cells (in contrast to fluorescein).
- ► Very toxic to cornea; irrigate eye(s) well after use
- ► Stings upon application

Uses/Indications
Rose bengal stain is used to detect epithelial cell damage prior to full-thickness epithelial cell loss (ulceration), as most commonly occurs with viral infections. Rose bengal staining may also be used as an adjunctive diagnostic procedure for nonulcerative epithelial and subepithelial keratomycosis in horses.[1] Rose bengal uptake also occurs in patients with qualitative (mucin) tear deficiency syndromes. Rose bengal stain has recently been demonstrated to be an effective adjunctive diagnostic test for evaluation of quantitative tear film deficiencies in dogs.[2]

Pharmacology/Actions
Rose bengal stains both the nuclei and cell walls of dead or degenerated epithelial cells of the cornea and conjunctiva. In contrast to fluorescein stain, rose bengal does not require full-thickness loss of corneal epithelium to indicate damage to the cornea. Rose bengal uptake is decreased in cells that are covered appropriately by mucin, a component of the tear film.

Contraindications/Precautions/Warnings
Rose bengal is contraindicated in patients with a history of hypersensitivity to it or any component of the formulation. Topical anesthetic agents may be indicated to prevent stinging on application. Rose bengal is very toxic to the cornea, and treated eye(s) should be thoroughly irrigated after exposure. Rose bengal is virucidal and may confound results of diagnostic tests for viral keratitis; therefore, culture samples should be obtained prior to application of the stain.

Adverse Effects
Adverse effects reported in humans or animals include burning and stinging upon application.

Dosages
Detection of corneal and conjunctival cell damage (extra-label; NOT FDA-approved): Wet the surface of the rose bengal strip with 1 – 2 drops of normal saline solution. Apply moistened tip of strip or instill 1 drop of rose bengal 1% solution to conjunctival fornix. Examine the eye with white light or with a red-free absorption filter. Degenerated or dead epithelial cells will appear red in color. Flush eye(s) after exposure.

Monitoring
- Evaluate corneas for signs of toxicity (eg, ulceration)

Client Information
- Rose bengal strips should not be used by pet owners at home.

Storage/Stability
Store this product in the refrigerator or at controlled room temperature (below 30°C) away from moisture and sunlight as directed on packaging or by compounding pharmacist; do not freeze. Unpreserved solutions of rose bengal carry a high risk of contamination with bacteria. Store this product as directed and observe all assigned beyond-use dates.

Compatibility/Compounding Considerations
Rose bengal ophthalmic preparations should not be mixed directly with any other ophthalmic medications. Rose bengal solution is no longer commercially available but may be compounded as a 1% solution either with or without preservatives; however, preservation systems are strongly recommended to prevent microbial and fungal contamination.[3]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Rose Bengal 0.13% Strips (containing rose bengal 1.3 mg/strip) as individually wrapped strips in containers of 100 sterile strips; *Glostrips®*, generic; (Rx). No FDA-approved dosage forms of rose bengal are currently available.

Rose bengal may be prepared (compounded) by qualified compounding pharmacists into a 1% sterile solution in sterile water for injection.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Silver Sulfadiazine (SSD) Ophthalmic
(***sil***-ver sul-fa-***dye***-ahy-zeen) *Silvadene®, SSD®, Thermazene®*
Broad-Spectrum Antibacterial; Antifungal Agent

Prescriber Highlights
- ► Antibacterial and antifungal dermatologic topical cream used as treatment for fungal keratitis in horses
- ► Long-term use may result in discoloration of the sclera due to argyrism.
- ► Do not use this medication in subpalpebral lavage (SPL) catheters, as occlusion will result.
- ► Best dispensed in 1 mL sterile tuberculin syringes with sterile tip caps for administration to the ocular surface
- ► Warn caregivers with sulfonamide allergies to avoid contact with this medication.

Uses/Indications
Silver sulfadiazine is used as a broad-spectrum antibacterial and antifungal ophthalmic agent. It is used most commonly as a less expensive alternative to conventional therapy for fungal keratitis in horses. Silver sulfadiazine was found to be superior to natamycin in sensitivity testing for fungal isolates in horses with fungal keratitis.[1]

Pharmacology/Actions
A specific mechanism of action has not been determined for silver sulfadiazine's antibacterial and antifungal activity; however, its effectiveness may be from either synergistic interactions between the silver and sulfadiazine components, or actions of each component individually. Silver is a biocide that binds to a broad range of targets, thus exerting a variety of effects, such as enzyme inhibition, protein denaturation, or membrane leakage, depending upon the target bound. Sulfadiazine interferes with microbial folic acid synthesis via competitive inhibition of bacterial dihydropteroate synthetase.

Contraindications/Precautions/Warnings
Silver sulfadiazine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. It should not be administered through subpalpebral lavage (SPL) catheters as occlusion will result. The package labeling of the topical cream clearly states that it is **NOT** for use in the eye. As such, it is recommended to obtain informed consent from owners before prescribing.

Adverse Effects
Adverse effects reported in humans or animals include argyrism (bluish discoloration of the skin and sclera due to silver accumulation), pain, burning, and itching. Although rare, systemic effects that may occur in association with the sulfonamide component include transient leukopenia, skin rashes and inflammation, blood dyscrasias, GI reactions, hepatitis, and toxic nephrosis.

Dosages
NOTE: All dosages are extra-label, and the package insert of the topical cream clearly states that it is **NOT** for use in the eye. As such, it is recommended to obtain informed consent from owners before prescribing.

Bacterial or fungal keratitis: ¼ – ½ inch strip or 0.1 – 0.2 mL in the conjunctival sac of the affected eye(s) every 1 to 2 hours initially, then tapered to every 4 hours and then per clinical response. Avoid long-term use.

Monitoring
- Clinical efficacy: resolution of keratitis as evidenced by cytology and cultures
- Sclera: discontinue use if sclera becomes blue or gray in color (argyrism)

Client Information
- Use this medicine as directed by your veterinarian.
- Do not use this medicine in subpalpebral lavage (SPL) catheters.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this product at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes.

Storage/Stability
Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Silver sulfadiazine should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Silver sulfadiazine is **NOT** approved for ophthalmic use. The package insert of all brands of silver sulfadiazine topical creams warns against use in the eye. As such, it is recommended to obtain informed consent from owners before prescribing. It is available as a topical cream, silver sulfadiazine 10 mg/g in a water miscible base in 20 g, 50 g, 400 g, and 1000 g containers. It is optimally dispensed in sterile, single-use tuberculin syringes tipped with a sterile tip cap (needle removed) for administration in the conjunctival sac.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Sodium Chloride (Hypertonic) Ophthalmic

(soe-dee-um ***klor***-ide [hye-per-ton-ik]) *Muro 128®, Altachlore®, Sochlor®*

Hyperosmotic Agent

Prescriber Highlights
- ► Used for temporary reduction of corneal edema
- ► Ointment forms have longer contact time and are preferred relative to solution forms.
- ► Available without prescription
- ► Compromise of the corneal surface (eg, corneal ulcer) may diminish the benefits of hypertonic sodium chloride due to loss of a functional epithelial barrier.

Uses/Indications
Hypertonic sodium chloride ophthalmic is used for the temporary reduction of corneal edema and associated bullous keratopathy, superficial corneal erosions, and chronic corneal edema that develop due to endothelial dysfunction induced by a variety of causes. Reduction of edema is short-lived; however, the reduction may be sufficient to favorably impact corneal clarity. Topical administration of 5% sodium chloride ophthalmic ointment to normal canine corneas resulted in decreased corneal thickness.[1] Although topical hypertonic saline has been administered to dogs with spontaneous chronic corneal epithelial defects (SCCEDs) undergoing various debridement techniques,[2] use of 5% sodium chloride ophthalmic did not significantly change the rate of corneal healing, and even prolonged healing time in some cases.[3]

Pharmacology/Actions
Tear film and aqueous humor are continuously absorbed by the hydrophilic corneal stroma; fluid balance is controlled by a normally functioning corneal epithelium and endothelium. When this balance is disrupted because of endothelial dysfunction, fluid accumulates in the corneal stroma and migrates to the surface of the cornea, causing opacification, bullae formation, ulceration, and visual impairment. The use of topical hypertonic saline may reduce the fluid accumulation in the corneal stroma.

Contraindications/Precautions/Warnings
Hypertonic sodium chloride is contraindicated in patients with a history of hypersensitivity to any component of the formulation. It may have lesser efficacy in the presence of corneal ulceration, as intact corneal epithelium is required to create the concentration gradient by which fluid is drawn from the bullae. Application of hypertonic sodium chloride may further increase discomfort associated with ulcerative keratitis.

Adverse Effects
Adverse effects reported in humans or animals include temporary burning and stinging upon application. Short-term application of hypertonic sodium chloride to normal canine eyes did not induce signs of toxicity.[1]

Dosages
Corneal Edema (extra-label): 1 – 2 drops or a ¼ – ½ inch strip in the affected eye(s) every 3 to 4 hours

Monitoring
- Clinical efficacy
- Observe for resolution of corneal edema. Treatment should be discontinued if discomfort or corneal ulceration develop.

Client Information
- Use this medication as directed by your veterinarian.
- This medication is available without a prescription. Only use products recommended by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait 5 to 10 minutes after applying this medication before applying any other medications to the eye.
- Store this medication as directed on the product label. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are visible particles in the solution.

Storage/Stability
Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze. Discard this medication if the color changes, if it becomes cloudy, or if particles are observed in the solution.

Compatibility/Compounding Considerations
Hypertonic sodium chloride should not be mixed directly (in vitro) with any other drugs to avoid dilution of the active ingredient.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Sodium Chloride 5% Ophthalmic Ointment (containing sodium chloride 50 mg/mL, lanolin oil, mineral oil, water for injection and white petrolatum) in a 3.5 g ophthalmic ointment tube; *Muro 128®*, *Altachlore®*, *Sochlor®*; (OTC)

Sodium Chloride 2% or 5% Ophthalmic Solution (containing sodium chloride 20 mg/mL or 50 mg/mL, methylparaben 0.023%, propylparaben 0.01% boric acid, hypromellose, propylene glycol, purified water, sodium borate, NaOH and/or HCl to adjust pH) in a 15 mL ophthalmic dropper bottle; *Muro 128®*, *Altachlore®*, *Sochlor®*; (OTC)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Sulfacetamide Ophthalmic
(sul-fa-***seet***-uh-mide) *Bleph-10®, Blephamide®*
Sulfonamide Antimicrobial Agent

Prescriber Highlights
- ► Topical antimicrobial used to treat ocular surface bacterial infections
- ► Warn caregivers with sulfonamide allergies to avoid contact with this medication.
- ► Some sulfacetamide ophthalmic products are combined with prednisolone; do not use these formulations in patients with bacterial, viral, or fungal keratitis.

Uses/Indications
Sulfacetamide is used to treat conjunctivitis and other superficial ocular infections due to susceptible microorganisms. Sulfacetamide is considered active against *Escherichia coli*, *Staphylococcus aureus*, *Streptococcus pneumoniae* and *Streptococcus viridans*, *Haemophilus*, *Klebsiella*, and *Enterobacter*. Sulfacetamide has no activity when it is applied topically for *Neisseria* spp, *Serratia marcescens*, or *Pseudomonas aeruginosa*. A significant percentage of staphylococcal isolates are completely resistant to sulfa drugs. Sulfacetamide is also found in combination products with prednisolone (eg, *Blephamide®*).

Pharmacology/Actions
All sulfonamides are bacteriostatic agents with a similar spectrum of activity. Sulfonamides inhibit bacterial synthesis of dihydrofolic acid via competitive inhibition of dihydropteroate synthetase. Resistant strains have altered dihydropteroate synthetase with reduced affinity for sulfonamides or produce increased quantities of aminobenzoic acid.[1]

Contraindications/Precautions/Warnings
Sulfacetamide is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Sulfacetamide may induce serious allergic reactions and blood dyscrasias, but this is rare following topical ophthalmic administration.[1] Patients with corneal infections due to bacterial, viral, or fungal organisms should not receive corticosteroid-containing sulfacetamide products.

Adverse Effects
Adverse effects reported in humans or animals following ocular administration include local irritation, stinging, and burning.[1] Although rare, systemic effects that may occur in association with the sulfonamide component include transient leukopenia, skin rashes and inflammation, toxic epidermal necrolysis, blood dyscrasias, GI reactions, fulminant hepatic necrosis, and toxic nephrosis.

In dogs, systemic sulfonamides are known to cause keratoconjunctivitis sicca (KCS) due to a direct toxicity to the lacrimal acinar cells; however, there have been no reports of topical sulfacetamide causing KCS. This toxic effect to the lacrimal acinar cells is caused by the nitrogen-containing pyridine and pyrimidine rings in sulfonamides and is dose-related. The estimated incidence of KCS is 15% to 25% in dogs treated with sulfonamides and may be latent in onset.[2] Dogs exhibiting blepharospasm or excess mucus ocular discharge should be evaluated for KCS. This condition may be reversible if sulfonamide use is discontinued in time. See ***Monitoring***.

Dosages
Susceptible bacterial conjunctivitis and ocular infections (extra-label): 1 drop or ¼ – ½ inch strip on the affected eye(s) every 2 to 3 hours initially and then tapered according to clinical response. Duration of therapy is usually 7 to 10 days.

Monitoring
- Clinical efficacy: resolution of bacterial conjunctivitis as evidenced by cytology and cultures
- Baseline and periodic Schirmer tear testing, especially in predisposed breeds. Dogs should be observed for signs of developing KCS (eg, mucus ocular discharge, blepharospasm).

Client Information
- Use this medicine as directed by your veterinarian.
- Caregivers with sulfa allergies should avoid contact with this medicine.
- Observe dogs for signs of dry eye (eg, squinting, excessive mucus eye discharge, redness of the whites of the eyes) and consult your veterinarian if this occurs.
- Use proper administration techniques to avoid contamination of

the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if it becomes cloudy, or if particles are seen in the solutions. Sulfacetamide solutions will darken over time. The medicine should be thrown away if this occurs.

Storage/Stability
Store this product at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Sulfacetamide ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Sulfacetamide Sodium 10% Ophthalmic Solution (containing sulfacetamide sodium 10%; benzalkonium chloride 0.005%; edetate disodium; polysorbate 80; polyvinyl alcohol 1.4%; purified water; sodium phosphate dibasic; sodium phosphate monobasic; sodium thiosulfate; and HCl and/or NaOH to adjust pH to 6.8 to 7.5), 5 mL in sterile 10 mL ophthalmic dropper bottles; *Bleph-10®*, generic; (Rx)

Sulfacetamide Sodium 10% Ophthalmic Ointment (containing sulfacetamide sodium USP 100 mg; white petrolatum; mineral oil) in 3.5 g tubes; generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:
Sulfacetamide Sodium 10% and Prednisolone Acetate 0.2% Ophthalmic Suspension (containing sulfacetamide sodium 10%; prednisolone acetate 0.2%; benzalkonium chloride 0.004%; edetate disodium; polysorbate 80; polyvinyl alcohol 1.4%; potassium phosphate monobasic; purified water; sodium phosphate dibasic; sodium thiosulfate; and HCl and/or NaOH to adjust the pH to 6.6. to 7.2), 5 mL in 10 mL bottle, and 10 mL in 15 mL bottle; *Blephamide®*; (Rx)

Sulfacetamide Sodium 10% and Prednisolone Sodium Phosphate 0.23% Ophthalmic Suspension (containing sulfacetamide sodium 100 mg; prednisolone sodium phosphate 2.5 mg, equivalent to prednisolone phosphate 2.3 mg; poloxamer 407; boric acid; edetate disodium; purified water; NaOH and/or HCl to adjust pH to 6.5 to 7.5) in 5 mL and 10 mL; generic; (Rx)

Sulfacetamide Sodium 10% and Prednisolone Acetate 0.2% Ophthalmic Ointment (containing sulfacetamide sodium 10%, prednisolone acetate 0.2%, phenylmercuric acetate 0.0008%, white petrolatum, mineral oil, petrolatum (and) lanolin alcohol) in sterile 3.5 g ophthalmic tube; *Blephamide®*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Tacrolimus Ophthalmic
(ta-***kroe***-li-mus)
T-cell Inhibitor Immunosuppressive Agent

Prescriber Highlights
- ► Used to treat dogs with keratoconjunctivitis sicca (KCS), chronic superficial keratitis (CSK), and other immune-mediated ocular surface inflammatory conditions
- ► Useful for cyclosporine-resistant cases of KCS
- ► It is not commercially available; it must be compounded (*Protopic®* topical dermal tacrolimus ointment should **NOT** be used in the eye).
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies tacrolimus as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
Tacrolimus is used to stimulate tear production in dogs with quantitative and qualitative keratoconjunctivitis sicca (KCS). Tacrolimus 0.03% has been demonstrated to be equally efficacious as cyclosporine 2% for canine KCS.1 Concentrations of 0.01% to 0.03% have been reported to be successful in controlling canine KCS.[1–4] Tacrolimus can also manage other ocular surface inflammatory conditions, such as chronic superficial keratitis (CSK). Tacrolimus topical ophthalmic use has not been evaluated in cats or horses.

Pharmacology/Actions
Tacrolimus is a macrolide antibiotic that has a T-cell suppressant activity similar to that of cyclosporine, but the potency is ≈100 times that of cyclosporine. Reversible T-cell suppression results from inhibition of calcineurin by tacrolimus. Within T cells, the binding of tacrolimus with the intracellular protein (FK-506) forms a complex that subsequently binds to and inhibits intracellular calcineurin. Inhibition of calcineurin prevents transcription of pro-inflammatory cytokines and T-cell signal transduction, resulting in immunosuppressive effects.

Contraindications/Precautions/Warnings
Tacrolimus is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. The degree of systemic absorption from ophthalmic preparations is not known; use with caution in small-sized animals.

The National Institute for Occupational Safety and Health (NIOSH) classifies tacrolimus as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects
Adverse effects associated with the ocular use of tacrolimus are rare but include orbital alopecia, which may be related to oil vehicles used to compound tacrolimus solutions.

Dosages
Keratoconjunctivitis sicca (KCS) (extra-label): 1 drop in each eye 2 times daily

Chronic superficial keratitis (CSK) (extra-label): 1 drop in each eye 2 times daily

Monitoring
- Clinical efficacy: baseline and periodic Schirmer tear test, reduction in mucoid ocular discharge and conjunctival hyperemia, and lack of progression (and possibly regression) of chronic inflammatory changes, such as corneal pigmentation, vascularization, and fibrosis

Client Information
- Use this medicine as directed by your veterinarian.

- This is a lifelong medication and must be given daily to be effective. Missed doses may cause rapid (within days) return of keratoconjunctivitis sicca (KCS).
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 minutes after applying this medication before applying other medications to the eye.
- Store this medicine as directed on the package labeling away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solutions.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Storage/Stability
Store this product as directed on the package labeling away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Tacrolimus ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

It is not commercially available and must be prepared (compounded) by a qualified compounding pharmacist.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Tacrolimus ophthalmic preparations are not commercially available but may be compounded by qualified compounding pharmacists in concentrations varying from 0.01% to 0.03% in oil vehicles including olive oil, corn oil, and medium-chain triglyceride oil.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Tafluprost Ophthalmic
(***ta***-floo-prost) *Zioptan®*

Prostaglandin Analogue

Prescriber Highlights
- ► Used as a treatment for primary glaucoma in dogs
- ► Unlikely to be effective for feline or equine glaucoma
- ► Twice-daily dosing of tafluprost may result in less fluctuation of intraocular pressure (IOP).
- ► Preservative-free and may be better tolerated than preservative-containing prostaglandin analogues
- ► May worsen intraocular inflammation through prostaglandin-mediated mechanisms

Uses/Indications
Tafluprost is indicated to reduce intraocular pressure (IOP) in canine glaucoma. It has not been evaluated as a treatment for feline or equine glaucoma; however, other prostaglandin analogues are minimally effective in those species.

Pharmacology/Actions
Prostaglandin analogues are chemically modified versions of prostaglandin F2-alpha. Prostaglandin F2-alpha, an endogenous inflammatory mediator, mediates ocular hypotensive effects, presumably by increasing the outflow of aqueous humor through the trabecular meshwork and uveoscleral routes. In addition to lowering intraocular pressure (IOP), tafluprost induces miosis by activating prostaglandin receptors. In normal canine eyes, tafluprost significantly decreased IOP and induced miosis following a single administration.[1] When combined with betaxolol or timolol, a single administration of tafluprost to normal canine eyes produced a greater IOP reduction than tafluprost alone.[2]

Contraindications/Precautions/Warnings
Tafluprost is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Tafluprost should be used with caution in the presence of anterior uveitis and secondary glaucoma, particularly in cases already exhibiting significant miosis, as this treatment may exacerbate miosis, promote synechiae formation, and worsen glaucoma. Also, in dogs with primary anterior lens luxation, tafluprost should be used with caution, as the resulting miosis may trap the lens and/or vitreous within the pupillary aperture, thus creating pupillary block glaucoma. Tafluprost is not contraindicated in dogs with secondary posterior lens luxation, as the miosis may (favorably) trap the lens in the posterior segment.

Adverse Effects
Adverse effects associated with tafluprost reported in humans or animals include blurred vision, burning and stinging, conjunctival hyperemia, foreign body sensation, itching, increased pigmentation of the iris, and punctate epithelial keratopathy. Tafluprost may cause darkening of the iris through direct stimulation of iris melanocytes, and it may cause increased eyelash growth. Tafluprost may worsen intraocular inflammation. Macular edema, including cystoid macular edema, has also been reported after the use of tafluprost in humans.

Dosages
Glaucoma (extra-label): 1 drop in the affected eye(s) 1 to 2 times daily

Monitoring
- Clinical efficacy: maintenance of normal intraocular pressure (IOP)

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- The solution from one individual unit is to be used immediately in one or both eyes. Because sterility cannot be maintained after the individual unit is opened, the remaining contents should be discarded immediately after administration.
- Store this medicine in the original pouch in the refrigerator. After opening the pouch, the unopened single-use containers may be stored in the opened foil pouch for up to 28 days at room temperature. Protect this medicine from light and moisture. Discard any unused containers 28 days after first opening the pouch.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solutions.

Storage/Stability
Store this product in the original pouch in the refrigerator (2°C-8°C [36°F-46°F]). After opening the pouch, the unopened single-use containers may be stored in the opened foil pouch for up to 28 days at room temperature (20°C-25°C [68°F-77°F]). Protect this product from light and moisture. Discard any unused containers 28 days after first opening the pouch.

Compatibility/Compounding Considerations
Tafluprost ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Tafluprost 0.0015% Ophthalmic Solution (containing tafluprost 0.015 mg/mL; glycerol; sodium dihydrogen phosphate dihydrate; disodium edetate; polysorbate 80; water for injection; HCl and/or NaOH to adjust pH to 5.5 to 6.75 and an osmolality of 260 – 300 mOsm/kg), in 0.3 mL single-use containers in boxes of 30 or 90 pouches; *Zioptan®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Tetracaine Ophthalmic

(***teh***-trah-kane) *Altacaine®, Tetravisc®*

Topical Ocular Anesthetic

Prescriber Highlights

- ► Rapid-acting topical anesthetic for ocular diagnostic procedures; it should not be prescribed for therapeutic administration, as it will cause ocular surface toxicity
- ► Anesthetic duration of the solution is 20 to 30 minutes; viscous forms have a longer duration of action.
- ► Comparable efficacy to oxybuprocaine, as evaluated in dogs; increased efficacy relative to proparacaine, as evaluated in horses
- ► Increased ocular surface irritation as compared with proparacaine and oxybuprocaine
- ► Long-term use results in tear film instability and corneal epithelial and stromal damage, and it may progress to vision loss.

Uses/Indications

Tetracaine is indicated for use in ophthalmic diagnostic procedures, including measurement of intraocular pressure (tonometry), corneal and conjunctival sampling for cytology and culture, ocular ultrasonography, and gonioscopy. Tetracaine is indicated as an adjunctive anesthetic for therapeutic procedures in the hospital, including removal of foreign bodies and sutures from the cornea; eyelid and conjunctival surgeries; corneal grafting procedures; and cataract extraction. In veterinary patients, tetracaine may produce a more rapid and deeper plane of local anesthesia relative to proparacaine.[1] A single application of 1% solution in dogs induces anesthesia for a duration of 30 minutes,[2] whereas viscous tetracaine has a significantly longer duration of action than proparacaine solution and lidocaine gel.[3] With a single application of 0.5% in horses, the anesthesia is 20 to 30 minutes long; additional applications of 1% solution prolongs anesthesia up to 1 hour.[4] A formulation of viscous tetracaine decreases corneal sensitivity and has a longer duration of action (1 hour) in horses compared with proparacaine or nonviscous tetracaine.[1]

Because of the likelihood of developing ocular surface toxicities with prolonged, repeated use, tetracaine should never be prescribed for use as an ocular analgesic. See ***Adverse Effects***.

Pharmacology/Actions

Tetracaine induces local anesthesia by inhibiting neuronal depolarization, which prevents the generation of an action potential. This action occurs due to the binding of tetracaine to the intracellular portion of the voltage-gated sodium channel within the neuron, thus inhibiting the intracellular movement of sodium. Variations in the structure of different local anesthetics influence their relative potencies; however, all local anesthetics have increased efficacy in alkaline environments due to improved intracellular penetration (efficacy is decreased in the acidic environment of inflammation).

Contraindications/Precautions/Warnings

Tetracaine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Prolonged use of a topical ocular anesthetic leads to significant corneal epithelial and stromal disease, as well as tear film instability, and may result in loss of vision.[5]

Adverse Effects

Upon initial administration, instillation of tetracaine in the eye, at recommended concentration and dosage, may produce mild irritation, conjunctival redness, lacrimation, or squinting; however, some local irritation may occur several hours after the instillation, and this irritation may be greater than that seen with proparacaine.[2] Tetracaine appears safe for use in patients that are sensitive to other local anesthetics, but local or systemic sensitivity occasionally occurs and rarely may manifest as a pseudo-allergic (anaphylactoid) reaction mimicking an IgE-mediated vasodilatory event. Cardiovascular, respiratory, and CNS depressant effects that may result from other local anesthetics are rare with the appropriate use of topical anesthetics. Care should be exercised when administering tetracaine to small patients (ie, puppies, kittens, "pocket pets") or animals known to have increased absorption of the drug (ie, amphibians). The use of tetracaine as a therapeutic analgesic leads to superficial punctate keratitis, which may progress to diffuse necrotizing keratitis, severe infiltrative keratitis, persistent epithelial defects, or damage to the Descemet membrane. In horses, reduction in the tear film breakup time has been reported, which is indicative of decreased stability of the precorneal tear film.[6]

Dosages

Ophthalmic procedures requiring local anesthesia (extra-label): 1 – 2 drops in the target eye(s) before examination or procedure. May repeat 1 drop every 5 to 10 minutes for 2 to 3 additional times. With a single application of tetracaine 0.5% in horses, the duration of anesthesia is 20 to 30 minutes; additional applications, application of 1% solution, or application of viscous formulation may prolong anesthesia for as long as 1 hour in horses. Additional doses should be avoided in small patients (ie, puppies, kittens, and "pocket pets").

Monitoring

- Clinical effect. The onset of action is indicated by awake patients permitting diagnostic procedures to be performed and by a reduction in anesthetic requirements when tetracaine is administered preoperatively.

Client Information

- This medicine is only given in the veterinary clinic for use on your animal's eye to allow for examination.

Storage/Stability

Storage recommendations can vary; follow storage requirements listed on packaging. Most commonly, this product is recommended to be stored at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze. Discard the medication if the solution changes color, if it becomes cloudy, or if it develops particles.

Compatibility/Compounding Considerations

Tetracaine ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Tetracaine HCl 0.5% Viscous Ophthalmic Solution (containing tetracaine HCl 0.5%; benzalkonium chloride; boric acid; edetate disodium; hypromellose; potassium chloride; sodium borate; NaCl; water

for injection) in 0.6 mL single unit dose plastic containers and 5 mL ophthalmic dropper bottles; *Tetravisc®*; (Rx) (not US FDA-approved)

Tetracaine HCl 0.5% Ophthalmic Solution (containing tetracaine HCl 5 mg; boric acid; potassium chloride; edetate disodium; purified water; NaOH and/or HCl to adjust pH to 3.7 to 6; chlorobutanol 0.4%) in 15 mL ophthalmic dropper bottles; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Timolol Ophthalmic

(***tim***-oh-lol) *Timoptic®, Betimol®, Istalol®, Combigan®, Cosopt®*

Nonselective Beta-Blocker

Prescriber Highlights

- ► Beta-blocker that decreases aqueous humor production to decrease intraocular pressure (IOP) in patients with glaucoma
- ► Although less effective than 0.5% concentrations, 0.25% concentrations of timolol are associated with fewer systemic adverse effects.
- ► Delays onset of glaucoma in the normal eye of dogs with unilateral glaucoma
- ► Use with caution in asthmatic patients due to the potential to induce bronchospasm.

Uses/Indications

Timolol is used to reduce intraocular pressure (IOP) in primary glaucoma and to prevent glaucoma in the normal eye of animals with unilateral glaucoma. The 0.25% concentration has minimal ocular hypotensive effects in animals and the 0.5% concentration is preferentially employed; however, the potential for systemic adverse effects is greater with the 0.5% solution.[1,2] The maximal IOP-lowering effect is ≈20% to 25% in normotensive dogs[3,4] and horses,[5] and 10% in cats.[6] Gel-forming 0.5% solutions of timolol (meant to increase ocular surface residence time by utilizing the interaction of xanthum gum with tears) reduce IOP by a mean of 5.3 mm Hg in dogs.[7] However, IOP reduction in glaucomatous cats is less consistent.[8] Reduction of IOP following the administration of timolol 0.5% in combination with dorzolamide 2% twice daily in normal eyes of horses is variable but has been reported to be as high as 17%.[5,9,10] Although timolol may also be combined with alpha-adrenergic agonists (eg, brimonidine) to potentiate ocular hypotensive effects through the increased outflow of aqueous humor and decreased aqueous humor production, the adverse effects of brimonidine decrease its utility in small animal patients. This combination does not produce a clinically significant IOP reduction in normal horses.[11]

Pharmacology/Actions

Timolol is a nonselective beta-adrenergic receptor blocking agent with intrinsic sympathomimetic activity, but it lacks membrane-stabilizing activity. Blockade of ciliary body beta-receptors, particularly beta-2 receptors, reduces intraocular pressure (IOP) by decreasing aqueous humor production. The exact mechanism of the ocular hypotensive effect of beta-blockers has not been definitively demonstrated; however, several mechanisms have been postulated for this effect including beta blockade of norepinephrine-induced tonic sympathetic stimulation, leading to decreased cAMP activation in the ciliary body, inhibition of Na+K+ATPase activity, or vasoactive activity on the iris and ciliary body. Topically administered beta-blockers also inhibit glutamine-induced increases in intracellular calcium and sodium thereby providing a potential protective effect against ischemic insult to the retina.[12]

Contraindications/Precautions/Warnings

Timolol is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Timolol should be used cautiously, if at all, in patients with atrioventricular block, bradycardia, heart failure, asthma, chronic bronchitis, or other cardiopulmonary conditions. Use this product cautiously in diabetic patients, as timolol can mask clinical signs associated with hypoglycemia.

Adverse Effects

Adverse effects reported in humans or animals include transient burning, stinging, and irritation upon application to the eye. In dogs, cats, and horses, the administration of timolol may cause slight miosis. It may trigger attacks in cats with asthma. Timolol produces significant reductions in heart rate in healthy cats, thus supporting its limited use in patients with known cardiopulmonary disease.[1]

Dosages

Glaucoma or prophylaxis in the normal eye of unilateral glaucoma (extra-label): 1 drop in the affected eye(s) twice daily

Monitoring

- Clinical efficacy
- Intraocular pressure (IOP) and disease progression
- Respiratory rate in asthmatic patients; blood glucose in diabetic patients; heart rate and resting respiratory rate in cardiac patients (especially cats)

Client Information

- Use this medicine as directed by your veterinarian.
- This medication may delay the onset of glaucoma in the normal eye of dogs with glaucoma in their other eye.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Tell your veterinarian about any conditions or diseases your animal may have now or has had in the past, especially asthma or diabetes.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper (or ointment) tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Keep the cap tightly closed when the medication is not in use.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in solutions.
- Your veterinarian will need to monitor your animal's eye condition while taking this medicine. Do not miss these important follow-up visits.

Storage/Stability

Store this medication at controlled room temperature (15°C-25°C [59°F-77°F]) away from moisture and sunlight; do not freeze. Discard this medication if the solution color change, if it becomes cloudy, or if there are particles in the solution.

Compatibility/Compounding Considerations

Timolol maleate ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Timolol 0.25% Ophthalmic Solution (containing 2.56 mg timolol hemihydrate equivalent to 2.5 mg timolol; monosodium and disodium phosphate dehydrate to adjust pH; water for injection; benzalkonium chloride 0.01%), in 5 mL, 10 mL, and 15 mL sterile ophthalmic dropper bottles; *Betimol®*; (Rx)

Timolol 0.5% Ophthalmic Solution (containing 5.12 mg timolol hemihydrate equivalent to 5 mg timolol; monosodium and disodium

phosphate dehydrate to adjust pH; water for injection; benzalkonium chloride 0.01%), in 5 mL, 10 mL, and 15 mL sterile ophthalmic dropper bottles; *Betimol®*, *Istalol®*; (Rx)

Timolol 0.25% Ophthalmic Solution (containing 3.4 mg timolol maleate equivalent to 2.5 mg timolol; monobasic and dibasic sodium phosphate; NaOH to adjust pH; purified water; benzalkonium chloride 0.01%), in sterile 5 mL and 10 mL ophthalmic dropper bottles; *Timoptic®*, generic; (Rx)

Timolol 0.5% Ophthalmic Solution (containing 6.8 mg timolol maleate equivalent to 5 mg timolol; monobasic and dibasic sodium phosphate; NaOH to adjust pH; purified water; benzalkonium chloride 0.01%), in sterile 5 mL and 10 mL ophthalmic dropper bottles; *Timoptic®*, generic; (Rx).

Timolol 0.25% Gel-Forming Solution (containing 3.4 mg of timolol maleate equivalent to 2.5 mg timolol; gellan gum; tromethamine; mannitol; water for injection; benzododecinium bromide 0.012%), in sterile 5 mL ophthalmic dropper bottles; *Timoptic-XE®*, generic; (Rx)

Timolol 0.5% Gel-Forming Solution (containing 6.8 mg of timolol maleate equivalent to 5 mg timolol; gellan gum; tromethamine; mannitol; water for injection; benzododecinium bromide 0.012%), in sterile 5 mL ophthalmic dropper bottles; *Timoptic-XE®*, generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:

Timolol 0.5% and Dorzolamide 2% Ophthalmic Solution (containing 20 mg/mL dorzolamide (22.26 mg of dorzolamide HCl) and 5 mg/mL timolol (6.83 mg timolol maleate); benzalkonium chloride 0.0075%; sodium citrate; hydroxyethyl cellulose; NaOH; mannitol; water for injection, with a pH of ≈5.65 and an osmolarity of 242 – 323 mOsm/kg), in 10 mL ophthalmic dropper bottles; *Cosopt®*; (Rx)

Timolol 0.5% and Dorzolamide 2% Ophthalmic Solution (containing 20 mg/mL dorzolamide (22.3 mg of dorzolamide HCl) and 5 mg/mL timolol (6.8 mg timolol maleate); hydroxyethyl cellulose; mannitol; sodium citrate; NaOH (to adjust pH); water for injection), supplied in a foil pouch containing 15 low-density polyethylene 0.2 mL single-use containers; *Cosopt PF®*; (Rx)

Brimonidine Tartrate 0.2% and Timolol Maleate 0.5% Ophthalmic Solution (containing brimonidine tartrate 0.2%; timolol maleate 0.5%; benzalkonium chloride 0.005%; citric acid; polyvinyl alcohol; NaCl; sodium citrate; purified water; HCl and/or NaOH added to adjust pH to 5.6 to 6.6, with an osmolality of 280 – 330 mOsm/kg), in a 10 mL dropper bottle; *Combigan®*, generic; (Rx)

Tobramycin Ophthalmic

(tobe-ra-***mye***-sin) *Tobrex®, AkTob®, Tobradex®, Tobradex ST®, Zylet®*

Aminoglycoside Antimicrobial Agent

For systemic use, see ***Tobramycin***

Prescriber Highlights

- ► Used as a treatment for susceptible bacterial infections of the ocular surface
- ► Do not confuse pure tobramycin ophthalmic preparations with preparations containing glucocorticoids.
- ► Fortified solutions of tobramycin greater than 13.5 mg/mL may be compounded for use in susceptible infections where commercially available products are not concentrated enough to achieve inhibitory concentrations.

Uses/Indications

Tobramycin ophthalmic is primarily used to treat ocular surface infections caused by *Pseudomonas aeruginosa*; however, susceptibility of *Pseudomonas* spp isolates may be decreasing.[1] Preparations of tobramycin in combination with a glucocorticoid are used primarily in the management of inflammatory conditions of the conjunctiva that are associated with or at risk for developing a superficial bacterial infection[2]; it may also be used postoperatively following ocular surface or intraocular surgical procedures.

The World Health Organization (WHO) has designated tobramycin as a Critically Important, High Priority antimicrobial for human medicine.[3] The Office International des Epizooties (OIE) has designated tobramycin as a Veterinary Critically Important Antimicrobial (VCIA) Agent in equine species.[4]

Pharmacology/Actions

Tobramycin is actively transported into bacteria and binds to a specific aminoglycoside receptor on the 30S subunit of bacterial ribosomes and interferes with an initiation complex between mRNA and the 30S subunit to inhibit protein synthesis. Aminoglycosides are bactericidal, whereas most other antibiotics that interfere with protein synthesis are bacteriostatic. Tobramycin's spectrum of activity includes coverage against many aerobic gram-negative bacteria, including most species of *Escherichia coli*, *Klebsiella* spp, *Proteus* spp, *Pseudomonas* spp, *Salmonella* spp, *Enterobacter* spp, *Serratia* spp, and *Shigella* spp. Efficacy against *Staphylococcus* spp is limited, and efficacy against *Streptococcus* spp is negligible.[5,6]

The antimicrobial activity of the aminoglycosides is enhanced in an alkaline environment; the acidic nature of pus or cellular debris can reduce efficacy.

The aminoglycoside antibiotics are inactive against fungi, viruses, and anaerobic bacteria.

Contraindications/Precautions/Warnings

Tobramycin is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Cross sensitivity of tobramycin with other aminoglycosides has been known to occur.[7]

Commercially available tobramycin solutions and ointments may not achieve inhibitory concentrations in the eye and may be either compounded in fortified concentrations (greater than or equal to 13.5 mg/mL) or injected subconjunctivally.[8,9]

Adverse Effects

Adverse effects associated with tobramycin reported in humans or animals include ocular burning and irritation upon drug instillation, nonspecific conjunctivitis, conjunctival epithelial defects, and conjunctival hyperemia.

When tobramycin is used systemically, it can cause nephrotoxicity and neurotoxicity (ototoxicity and vestibular toxicity).[7] Because cats are more susceptible to these toxic effects of aminoglycosides, it is recommended that all cats receiving topical tobramycin be monitored for systemic toxicity.

Dosages

Susceptible ocular surface infections (extra-label): 1 drop or ¼ – ½ inch strip in the affected eye(s) 4 to 6 times daily. The frequency may be increased to every 30 to 60 minutes for treating significant infections.

Management of inflammatory conditions of the conjunctiva associated with or at risk for developing a superficial bacterial infection | Postoperative ocular surface or intraocular procedures (extra-label): Using a tobramycin/glucocorticoid combination preparation, 1 drop or ¼ – ½ inch strip in the affected eye(s) 3 to 4 times daily. The frequency is decreased following control of ocular surface inflammation, with a corresponding reduced risk for infection.

Monitoring
- Clinical efficacy: corneal cytology with culture and susceptibility testing to evaluate for the persistence of bacteria. Evaluate clinical signs suggestive of continued infection.
- Baseline and periodic urinalysis with sediment evaluation to check for casts, which may be an early indicator for renal toxicity

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine in the refrigerator or at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product in the refrigerator or at controlled room temperature (2°C-25°C [46°F-77°F]) as directed in product labeling, away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Tobramycin ophthalmic preparations should not be mixed directly with any other ophthalmic medications. Tobramycin may be compounded into a fortified ophthalmic solution in concentrations of greater than or equal to 13.5 mg/mL by aseptically adding tobramycin injection in appropriate amounts to commercially available tobramycin ophthalmic solution.[8]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Tobramycin 0.3% Ophthalmic Solution; *Tobrex*®; *Aktob*®; generic; (Rx)

Tobramycin 0.3% Ophthalmic Ointment; *Tobrex*®; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:
Tobramycin and Dexamethasone Ophthalmic Ointment (containing tobramycin 0.3% (3 mg), dexamethasone 0.1% (1 mg), chlorobutanol 0.5% (5 mg), mineral oil, white petrolatum), in a sterile 3.5 g tube; *Tobradex*®; (Rx)

Tobramycin and Dexamethasone Ophthalmic Suspension (containing tobramycin 0.3% (3 mg), dexamethasone 0.1% (1 mg), benzalkonium chloride 0.01%, tyloxapol, edetate disodium, NaCl, hydroxyethyl cellulose, sodium sulfate, sulfuric acid and/or NaOH to adjust pH, purified water), in a sterile 2.5 mL ophthalmic dropper; *Tobradex*®, generic; (Rx)

Tobramycin and Dexamethasone Ophthalmic Suspension (containing tobramycin 0.3% (3 mg), dexamethasone 0.05% (0.5 mg), xanthan gum, tyloxapol, disodium edetate, NaCl, propylene glycol, sodium sulfate, benzalkonium chloride 0.01%, NaOH and/or HCl to adjust pH, purified water), in a sterile 5 mL ophthalmic dropper; *Tobradex ST*®; (Rx)

Tobramycin 0.3% and Loteprednol 0.5% Ophthalmic Suspension in 5 mL and 10 mL; *Zylet*®; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Travoprost Ophthalmic

(***trav***-oh-prost) *Travatan Z*®

Prostaglandin Analogue

Prescriber Highlights
- ► Used to decrease intraocular pressure (IOP) in dogs with primary glaucoma or ocular hypertension
- ► Based on receptor differences, it is not effective in feline glaucoma and unlikely to be effective in equine glaucoma.
- ► Do not use it if intraocular inflammation is present, as it may worsen inflammation or lead to pupillary block glaucoma.
- ► Twice-daily dosing of travoprost results in less fluctuation of IOP.
- ► Preservative systems may cause ocular irritation and discomfort.

Uses/Indications
Travoprost is used in dogs to reduce intraocular pressure (IOP) to manage primary glaucoma. It has not been evaluated for efficacy in either cats or horses. In normotensive canine eyes, once-daily administration of travoprost reduced IOP comparably to latanoprost. It also resulted in miosis and conjunctival hyperemia.[1] In glaucomatous canine eyes, once- and twice-daily administration of travoprost 0.004% significantly reduced IOP,[2] whereas concentrations above 0.0001% were necessary to mediate ocular hypotension and miosis in a dose-response study.[3]

Pharmacology/Actions
Prostaglandin analogues are chemically modified versions of prostaglandin F2-alpha, an endogenous inflammatory mediator that mediates ocular hypotensive effects by increasing outflow of aqueous humor through both the trabecular meshwork and uveoscleral routes. In addition to reducing intraocular pressure (IOP), travoprost leads to miosis.

Contraindications/Precautions/Warnings
Travoprost is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. Travoprost should be used with caution in the presence of anterior uveitis and secondary glaucoma, particularly in cases already exhibiting significant miosis, as this treatment may exacerbate miosis, promote synechiae formation, and worsen glaucoma. In addition, in dogs with primary anterior lens luxation, travoprost should be used with caution, as the resulting miosis may trap the lens and/or vitreous within the pupillary aperture, thus creating pupillary block glaucoma. Travoprost is not contraindicated in dogs with secondary posterior lens luxation, as the miosis may (favorably) trap the lens in the posterior segment.

Adverse Effects
Adverse effects associated with travoprost reported in humans or animals include blurred vision, burning and stinging, conjunctival hyperemia, foreign body sensation, itching, increased pigmentation of the iris, increased eyelash growth, and punctate epithelial keratopathy. Travoprost may cause darkening of the iris through direct stimulation of iris melanocytes, and it may worsen intraocular inflammation. Macular edema, including cystoid macular edema, has been reported after the use of travoprost in humans.

Dosages
Glaucoma (extra-label): 1 drop in the affected eye(s) once to twice daily

Monitoring
- Clinical efficacy: sustained reduction of intraocular pressure (IOP)

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait 5 minutes after applying this medicine before applying any other medicines to the eye.
- Store this medicine in the refrigerator or at room temperature. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solution.

Storage/Stability
Store this product in the in the refrigerator or at room temperature (2°C-25°C [36°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Travoprost preparations should not be mixed directly with any other medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Travoprost 0.004% Ophthalmic Solution (containing travoprost 0.04 mg; benzalkonium chloride 0.015%; polyoxyl 40 hydrogenated castor oil; tromethamine; boric acid; mannitol; edetate disodium; NaOH and/or HCl to adjust pH; water for injection), in sterile 2.5 mL and 5 mL ophthalmic dropper bottles; generic; (Rx)

Travoprost 0.004% Ophthalmic Solution (containing travoprost 0.04 mg; polyoxyl 40 hydrogenated castor oil; sofzia® [boric acid, propylene glycol; sorbitol; zinc chloride]; NaOH and/or HCl to adjust pH; purified water), in a sterile 2.5 mL ophthalmic dropper bottle; *Travatan Z®*; (Rx)

Trifluridine Ophthalmic
Trifluorothymidine (TFT)
(try-***floor***-ih-deen) *Viroptic®*
Antiviral (Nucleoside Analogue)

Prescriber Highlights
- ► Topical antiviral agent used in cats with feline herpesvirus-1 (FHV-1)
- ► Effective as treatment of dogs with experimentally induced canine herpesvirus-1 (CHV-1) infection
- ► Must be used 4 to 5 times daily
- ► In vitro efficacy of trifluridine is greater than that of acyclovir and idoxuridine.
- ► May cause more irritation and pain upon administration as compared with other topical antiviral agents
- ► Trifluridine is a corneal toxin and should not be used for more than 3 weeks at a time.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies trifluridine ophthalmic as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
Trifluridine is used for topical treatment of feline herpesvirus-1 (FHV-1) keratitis. It may also be used for canine herpesvirus-1 (CHV-1) keratitis.[1,2] Evaluation of trifluridine's efficacy for equine herpesvirus-2 (EHV-2) keratitis has not been performed.

Pharmacology/Actions
Trifluridine interferes with DNA synthesis; however, its antiviral mechanism of action is not completely known. It is believed that trifluridine incorporates into viral DNA, as well as reversibly inhibits thymidylate synthetase, an essential enzyme in DNA synthesis. Trifluridine's in vitro efficacy is consistently greater than that of acyclovir and idoxuridine.[3,4] Trifluridine is virustatic.

Contraindications/Precautions/Warnings
Trifluridine is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

The National Institute for Occupational Safety and Health (NIOSH) classifies trifluridine ophthalmic as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects
Adverse effects reported in humans or animals include acute ocular irritation, including burning, corneal stippling, vascularization, and clouding. The irritation associated with administration of trifluridine may be more intense than the inflammation caused by FHV-1. Following prolonged use of trifluridine, ocular irritation characterized by follicular conjunctivitis, blepharitis with punctal swelling, bulbar conjunctival hyperemia, and corneal epithelial staining have also been reported. In any of these cases, the drug should be discontinued.

Dosages
Keratitis caused by feline herpesvirus-1 (FHV-1) or canine herpesvirus-1 (CHV-1) (extra-label): 1 drop in the affected eye(s) every 2 to 3 hours for 48 hours and then 4 to 5 times daily for a week beyond the resolution of clinical signs. Trifluridine is a corneal toxin and should not be used for greater than 3 weeks at a time.

Monitoring
- Clinical efficacy: resolution of clinical signs (eg, corneal ulceration, corneal vascularization, conjunctivitis)

Client Information
- Give this medicine to your animal as directed by your veterinarian.
- Do not use this medication for more than 3 consecutive weeks.
- Trifluridine may cause stinging upon administration.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait for 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication in the refrigerator away from moisture and sunlight. Do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solutions.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Storage/Stability
Store in the refrigerator (2°C-8°C [36°F-46°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Trifluridine should not be mixed directly with any other ophthalmic medications. Trifluridine is not available as an ophthalmic ointment.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Trifluridine aqueous 1% Ophthalmic Solution (containing trifluri-

dine 10 mg in an aqueous solution with glacial acetic acid and sodium acetate (buffers); NaCl; thimerosal 0.001%), in a 7.5 mL ophthalmic dropper bottle; *Viroptic*®; generic; (Rx)

Triple Antibiotic Ophthalmic (Neomycin/Polymyxin B/Bacitracin; Neomycin/Polymyxin B/Gramicidin) Double Antibiotic Ophthalmic (Bacitracin/Polymyxin B)

Broad-Spectrum Antimicrobial Combination Agent

Prescriber Highlights

- ► First choice for prophylactic antimicrobial coverage in dogs and horses with ocular surface inflammatory conditions, including ulcerative keratitis
- ► First choice for therapeutic antimicrobial coverage in dogs and horses with ulcerative keratitis until culture and sensitivity results are available
- ► Available as an ointment (neomycin/polymyxin B/bacitracin; polymyxin B/bacitracin) or solution (neomycin/polymyxin B/gramicidin)
- ► Some animals, particularly cats, may be hypersensitive to neomycin or polymyxin components in ointments.
- ► Do not confuse hydrocortisone-containing triple antibiotic ophthalmic ointment with those that lack corticosteroids.
- ► Prolonged use of antibiotic preparations may result in overgrowth of nonsusceptible organisms, including fungi.

Uses/Indications

Triple antibiotic ophthalmic products are used for topical treatment of superficial infections of the external eye and its adnexa caused by susceptible bacteria. Triple antibiotic ophthalmic is often used as prophylactic antimicrobial treatment prior to and following ophthalmic surgery. Triple antibiotic ophthalmic is also used for antimicrobial prophylaxis of corneal injuries and wounds. Triple antibiotic ophthalmic ointments may also contain a corticosteroid; thus, it is important to ensure that the appropriate formulation is selected. Specifically, corticosteroid-containing preparations should not be administered in patients with ulcerative keratitis. Triple antibiotic ophthalmic solutions substitute gramicidin for bacitracin. Double antibiotic ophthalmic preparations do not contain neomycin.

Pharmacology/Actions

Neomycin sulfate, an aminoglycoside, is actively transported into the bacterial cell and binds a specific receptor protein on the 30S subunit of bacterial ribosomes. It consequently interferes with the initiation complex between messenger RNA (mRNA) and the 30S subunit, inhibiting protein synthesis by inducing misreading of the mRNA. Aminoglycosides are bactericidal, whereas most other antibiotics that interfere with protein synthesis are bacteriostatic. Aminoglycosides are used primarily in infections involving aerobic, gram-negative bacteria, such as *Pseudomonas* spp, *Acinetobacter* spp, and *Enterobacter* spp. Infections caused by gram-positive bacteria, such as *Staphylococcus* spp and *Streptococcus* spp, are significantly less susceptible to neomycin.[1–4] Aminoglycosides are mostly ineffective against anaerobic bacteria, fungi, and viruses.

Polymyxin B increases the permeability of the bacterial cell membrane by interacting with the phospholipid components of the membrane for a variety of gram-negative organisms, with lesser efficacy versus gram-positive organisms such as *Streptococcus* spp.[1–4] It is bactericidal.

Bacitracin, a polypeptide antibiotic, inhibits bacterial cell wall synthesis by preventing transfer of mucopeptides into the growing cell wall. It has bactericidal activity in vitro against a variety of gram-positive organisms and a few gram-negative organisms. In practice however, topical bacitracin is most useful for gram-positive bacillus infections. Importantly, bacitracin is effective against beta-hemolytic *Streptococcus equi* ocular infections, whereas efficacy against *Pseudomonas aeruginosa* is negligible.[2–4] Bacitracin poorly penetrates the cornea and therefore is of limited value in deep corneal or intraocular infections.

In combination, neomycin sulfate, polymyxin B sulfate, and bacitracin zinc are considered active against *Staphylococcus aureus*; streptococci, including *Streptococcus pneumoniae*; *Escherichia coli*; *Haemophilus influenzae*; *Klebsiella* spp; *Enterobacter* spp; *Neisseria* spp; and *Pseudomonas aeruginosa*.

Gramicidin has activity against gram-positive organisms (not gram-positive bacilli) and some gram-negative organisms. Its mechanism of action is to bacterial cell wall permeability to inorganic cations.

Contraindications/Precautions/Warnings

Triple antibiotic combinations are contraindicated in patients that have a history of hypersensitivity to any component of the formulation. Some cats are hypersensitive to the neomycin or polymyxin component of triple antibiotic ointments.[5] This hypersensitivity has not been associated with steroid-containing triple antibiotic products. Although there is concern that prolonged use of antibiotic preparations may result in overgrowth of nonsusceptible organisms, including fungi, minimal impact on the ocular surface microbiome of dogs or horses was noted after 7 days of administration to normal eyes.[6,7]

Adverse Effects

Adverse effects reported in humans or animals include irritation and swelling upon instillation. Ophthalmic antibiotics, especially those containing neomycin sulfate and polymyxin B, may cause cutaneous sensitization and anaphylaxis, particularly in cats.[5] Clinical signs associated with sensitization to topical antibiotics can include itching, reddening, and edema of the conjunctiva and eyelid but may progress to anaphylaxis. Clinical signs usually subside quickly on withdrawing the medication, and death has been rarely reported.[8]

Dosages

Ulcerative conjunctivitis or keratitis: 1 drop of solution or ¼ inch strip of ointment in the affected eye(s) 3 to 4 times daily until resolution of ulceration and infection or until microbial susceptibilities necessitate a change to another antimicrobial agent

Nonulcerative conjunctivitis or keratitis: 1 drop of solution or ¼ inch strip of ointment in the affected eye(s) 3 to 4 times daily until resolution of infection and inflammation

Monitoring

- Clinical efficacy. Resolution of conjunctivitis or keratitis as evidenced by cytology, cultures, or remission of clinical signs

Client Information

- Use this medication as directed by your veterinarian.
- Cats may have a severe allergic reaction to one of the components of this medication. Contact your veterinarian immediately if your cat has difficulty breathing or has facial swelling after receiving this medication.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper/ointment tip or allow it to touch animal's eye or any other surface to prevent contamination.

- Wait for 5 to 10 minutes after applying any other medicine to your animal's eye.
- Keep the cap tightly closed when the medication is not in use. Store this medicine at room temperature away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes or becomes cloudy.

Storage/Stability
Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Triple antibiotic ophthalmic preparations should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Neomycin/Polymyxin B/Bacitracin Ophthalmic Ointment (containing neomycin sulfate equivalent to 3.5 mg neomycin base, polymyxin B sulfate equivalent to 10,000 polymyxin B units, bacitracin zinc equivalent to 400 bacitracin units, and white petrolatum and mineral oil, q.s.), in a 3.5 g ophthalmic ointment tube; *Vetropolycin®*; (Rx)

Neomycin/Polymyxin B/Bacitracin with Hydrocortisone Ophthalmic Ointment; each gram contains bacitracin zinc USP 400 units, neomycin sulfate 0.5% (equivalent to 3.5 mg neomycin base), polymyxin B sulfate USP 10,000 units, and hydrocortisone acetate USP 1% in a base of white petrolatum and mineral oil; *Vetropolycin HC®*; (Rx)

HUMAN-LABELED PRODUCTS:

Neomycin/Polymyxin B/Bacitracin Ointment (containing neomycin sulfate equivalent to 3.5 mg neomycin base, polymyxin B sulfate equivalent to 5,000 or 10,000 polymyxin B units, bacitracin zinc equivalent to 400 bacitracin units, and white petrolatum, q.s.), in a 3.5 g ophthalmic ointment tube; *Neosporin®*, *Lumi-Sporyn®*, generic; (Rx)

Neomycin/Polymyxin B/Gramicidin Ophthalmic Solution (containing polymyxin B equivalent to 1.75 mg polymyxin B base, polymyxin B sulfate equivalent to 10,000 polymyxin B units, gramicidin 0.025 mg/mL, alcohol 0.5%, thimerosal 0.001%, propylene glycol, polyoxyethylene polyoxypropylene compound, NaCl, and water for injection), in a 10 mL ophthalmic dropper bottle; *Neosporin®*, generic; (Rx)

Bacitracin and Polymyxin B Sulfate Ophthalmic Ointment (containing polymyxin B sulfate equivalent to 10,000 polymyxin B units, bacitracin zinc equivalent to 500 bacitracin units, and white petrolatum, q.s.), *AK-Poly-Bac®*, generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:

Neomycin and Polymyxin B Sulfates and Dexamethasone Ophthalmic Suspension (containing neomycin sulfate equivalent to neomycin 3.5 mg, polymyxin B sulfate 10,000 units, dexamethasone 0.1%, benzalkonium chloride 0.004%, hypromellose 2910 0.5%, sodium chloride, polysorbate 20, HCl and/or NaOH to adjust pH, and purified water), in a 5 mL sterile ophthalmic dropper bottle; *Maxitrol®*, *Dexasporin®*; (Rx)

Neomycin and Polymyxin B Sulfates and Dexamethasone Ophthalmic ointment (containing neomycin sulfate equivalent to neomycin 3.5 mg, polymyxin B sulfate 10,000 units, dexamethasone 0.1%, methylparaben 0.05%, propylparaben 0.01%, white petrolatum, and anhydrous liquid lanolin), in a sterile 3.5 g tube; *Maxitrol®*, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Tropicamide Ophthalmic
(troe-***pik***-uh-myde) *Mydriacyl®, Paremyd®, Tropicacyl®*

Anticholinergic Mydriatic; Cycloplegic Agent

Prescriber Highlights
- ► Mydriatic agent with mild cycloplegic action
- ► Used to produce short-term dilation for funduscopic examination or to prevent synechiae formation following cataract surgery
- ► More rapid onset and shorter duration of mydriasis compared with atropine
- ► Poor cycloplegic ability compared with atropine, resulting in minimal control of ciliary body muscle spasm
- ► Good corneal penetration due to lack of ionization at physiological pH
- ► May increase intraocular pressure (IOP); use with caution in patients with glaucoma

Uses/Indications
Tropicamide is used to produce rapid- and short-acting mydriasis for funduscopic evaluation. Tropicamide has also been used to break down synechiae in uveitis and to prevent synechiae formation following cataract surgery. It is not as effective as atropine in inducing cycloplegia and is consequently a poor choice for controlling ocular pain caused by ciliary spasm. Tropicamide has been demonstrated to overcome the miosis induced by topical ophthalmic latanoprost[1] and parenteral butorphanol[2] administration in dogs with normal eyes, without leading to elevated intraocular pressure, and thus can be used to facilitate posterior segment examination.

Pharmacology/Actions
Tropicamide causes anticholinergic effects by blocking the muscarinic receptors of the sphincter muscle of the iris and the ciliary body muscle, which produces pupillary dilation (mydriasis) and, to a lesser degree, paralysis of accommodation (cycloplegia). Tropicamide induces mydriasis in about 15 to 30 minutes, and the pupil returns to normal in 6 to 12 hours.

Contraindications/Precautions/Warnings
Tropicamide is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation. It should not be used in patients with primary glaucoma as it can induce increases in intraocular pressure (IOP).[3]

Adverse Effects
Adverse effects reported in humans include sensitivity to bright light, burning and irritation upon application, and superficial punctate keratitis. Dry mouth, tachycardia, headache, nausea, vomiting, pallor, psychotic reactions, CNS disturbances, muscle rigidity, behavioral disturbance, and vasomotor and cardiorespiratory collapse have also been reported. Hypersalivation has been reported in cats and dogs due to bitter taste. Tear production may be decreased for several hours after application of tropicamide ophthalmic in cats and horses,[4,5] and intraocular pressure (IOP) may increase in cats and dogs.[3,6]

Dosages
Mydriasis (extra-label): 1 to 2 drops repeated in 5 minutes in the eye to be examined to achieve pupillary dilation[7]

Mydriasis post-cataract removal surgery (extra-label): 1 to 2 drops into the affected eye(s) once to twice daily postoperatively to facilitate pupil mobility

Monitoring
- Clinical efficacy
- Confirm continued pupillary dilation
- Intraocular pressure (IOP)

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medication. Do not touch the dropper (or ointment) tip or allow it to touch your animal's eye or any other surface to prevent contamination.
- Dogs and cats may drool excessively after administration of this medication due to the bitter taste.
- Wash your hands after application to prevent accidentally getting the medicine into your eyes, which can cause pupil dilation.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Keep the cap tightly closed when the medication is not in use. Store this medicine at room temperature away from moisture and sunlight; do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in solutions.
- Your veterinarian will need to monitor your animal's eye condition while taking this medicine. Do not miss these important follow-up visits.

Storage/Stability
Store at controlled room temperature (20°C-25°C [68°F-77°F]) away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Tropicamide should not be mixed directly with any other ophthalmic medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Tropicamide 0.5% Ophthalmic Solution, USP (containing tropicamide 5 mg/mL; benzalkonium chloride 0.01%; NaCl; edetate disodium; purified water; HCl and/or NaOH to adjust pH to 4 to 5.8), in 3 mL and 15 mL dropper bottles; *Tropicacyl*®, generic; (Rx)

Tropicamide 1% Ophthalmic Solution, USP (containing tropicamide 10 mg/mL; benzalkonium chloride 0.01%; NaCl; edetate disodium; purified water; HCl and/or NaOH to adjust pH to 4 to 5.8), in 3 mL and 15 mL dropper bottles; *Mydriacyl*®, generic; (Rx)

HUMAN-LABELED COMBINATION PRODUCTS:

Hydroxyamphetamine hydrobromide 1% and Tropicamide 0.25% Ophthalmic Solution (containing hydroxyamphetamine 1%; tropicamide 0.25%; benzalkonium chloride 0.005%; edetate disodium 0.015%; NaCl; HCl and/or NaOH to adjust pH to 4.2 to 5.8; purified water), in sterile 15 mL ophthalmic dropper bottle; *Paremyd*®; (Rx)

Vancomycin Ophthalmic

(***van***-kohe-***mye***-sin)

Glycopeptide Antimicrobial Agent

For systemic use, refer to ***Vancomycin***

Prescriber Highlights
- ► Topical use reserved for treatment of ocular surface and intraocular infections caused by methicillin-resistant gram-positive organisms
- ► Not effective against gram-negative bacteria
- ► Not approved in an ophthalmic dosage form in the United States, although ocular dosage forms are approved in other countries

Uses/Indications
Vancomycin can be used for treating ocular surface infections caused by methicillin-resistant microorganisms, such as methicillin-resistant *Staphylococcus aureus* (MRSA) or *Staphylococcus pseudintermedius* (MRSP). Vancomycin compounded into 0.3% to 1% ophthalmic ointment has been shown to be effective in treating methicillin-resistant *Staphylococcus aureus* keratitis in a dog,[1] rabbits,[2] and humans; however, it has also been demonstrated that vancomycin is not necessary for all MRSA ocular infections, as chloramphenicol, rifampicin, and tetracyclines, among others, show varied in vitro efficacy.[3,4] Vancomycin can also be administered intravitreally for severe cases of methicillin-resistant endophthalmitis. Intracameral injection of vancomycin nanoparticles has also demonstrated good prophylactic activity against MRSA in rabbits with minimal adverse effects.[5]

The World Health Organization (WHO) has designated vancomycin as a Critically Important, Highest Priority antimicrobial for human medicine.[6]

Pharmacology/Actions
The bactericidal action of vancomycin results from inhibition of cell wall biosynthesis, which is induced by binding of the antibiotic to cell wall precursor molecules. Vancomycin is not active in vitro against gram-negative bacteria (due to different mechanisms for cell wall formation), mycobacteria, or fungi.

Contraindications/Precautions/Warnings
Vancomycin is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

Adverse Effects
Adverse effects reported in humans or animals include burning or stinging on application, ocular discharge, regional pruritus, and conjunctival hyperemia. Nephrotoxicity, ototoxicity, dermal toxicities, vasculitis, and severe gram-negative colitis have been associated with systemic use of vancomycin; however, these adverse effects are not likely to occur following ophthalmic use.

Dosages
Methicillin-resistant bacterial conjunctivitis or keratitis (extra-label): 1 drop of solution or ¼ inch strip of ointment applied to the affected eye(s) 4 to 5 times daily

Monitoring
- Clinical efficacy: corneal cytology and culture to evaluate for bacteria. Evaluate clinical signs suggestive of progressive infection.

Client Information
- Use this medicine as directed by your veterinarian.
- Use proper administration techniques to avoid contamination of the medicine. Keep the cap tightly closed when the medicine is not in use.
- Wait for 5 to 10 minutes after applying this medicine before applying any other medications to the eye.
- Store this product as directed on the package labeling away from moisture and sunlight. Do not freeze.
- Do not use this medicine if the color changes, if it becomes cloudy, or if there are particles in the solutions.

Storage/Stability
Store this product as directed on package labeling away from moisture and sunlight; do not freeze.

Compatibility/Compounding Considerations
Vancomycin preparations should not be mixed directly with any other medications.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Vancomycin ophthalmic preparations are not commercially available in the United States, but vancomycin ointments and ophthalmic solutions (0.3% to 1%) have been prepared (compounded) by qualified compounding pharmacists.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Voriconazole Ophthalmic

(vohr-uh-***kon***-uh-zohl) *VFend®*

Azole Antifungal Agent

Prescriber Highlights

- ► Used as a treatment for ocular surface fungal infections
- ► Although this medication is not commercially available as an ophthalmic preparation, the commercially available IV form may be administered topically to the eye.
- ► Penetrates cornea efficiently and achieves effective concentrations in the aqueous humor
- ► Considerably more effective against filamentous fungal organisms than polyene or other azole antifungal agents
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies voriconazole ophthalmic as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Ocular administration of voriconazole is primarily used to treat fungal keratitis, most commonly in horses but also in other species.[1,2] Voriconazole 1% solution for IV injection, prepared according to the package instructions, achieves effective antifungal concentrations in the aqueous humor while causing minimal to no irritation when it is administered to normal eyes of horses.[3] The same or higher concentrations have been associated with treatment success following intracorneal and subconjunctival injection in horses.[4–6] Voriconazole was associated with successful control of keratomycosis due to both filamentous and yeast organisms in dogs[2,7,8] and filamentous organisms in a cat.[1,9] Intravitreal administration is used in humans as treatment for fungal endophthalmitis.[10]

Pharmacology/Actions

Voriconazole interacts with 14-alpha-sterol demethylase, a cytochrome P-450 enzyme involved in the conversion of lanosterol to ergosterol. Ergosterol is an essential component of the fungal cell membrane and preventing its synthesis may increase cellular permeability and cause leakage of cellular contents. Other possible effects of voriconazole include inhibition of endogenous respiration, purine uptake and the transformation of yeasts to mycelial forms, and impairment of triglyceride and phospholipid biosynthesis. Because voriconazole specifically targets oxidative enzymes of fungal species, it has higher efficacy and lower host toxicity. Voriconazole has a broad antifungal spectrum against most fungi and yeasts of veterinary interest. Sensitive organisms include *Aspergillus* spp, *Candida* spp, *Fusarium* spp, and *Aspergillus* spp.[11–13]

Contraindications/Precautions/Warnings

Voriconazole is contraindicated in patients that have a history of hypersensitivity to it or any component of the formulation.

The National Institute for Occupational Safety and Health (NIOSH) classifies voriconazole ophthalmic as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Adverse effects reported in humans or animals include transient burning or stinging on application. Although not reported following topical administration, neurologic signs have resulted in cats following oral administration of voriconazole.[14]

Dosages

Fungal keratitis (extra-label): 1 drop to the affected eye(s) or 0.1 mL in the subpalpebral lavage (SPL) catheter, every 2 to 3 hours initially, followed by tapering of frequency based on clinical response. Voriconazole may be administered through a SPL catheter; however, its use with constant-rate infusion pumps in conjunction with a SPL catheter is not advised due to crystallization of voriconazole within the unit.[4]

Monitoring

- Clinical efficacy: corneal scrapings with cytology and cultures to determine to clear fungal organisms; resolution of clinical signs of infection

Client Information

- Use this medication up to 10 to 12 times daily initially, with a reduction in frequency occurring as the infection resolves.
- Use proper administration techniques to avoid contamination of the medication. Keep the cap tightly closed when the medication is not in use.
- Wait 5 minutes after applying this medication before applying any other medications to the eye.
- Store this medication in the refrigerator; do not freeze.
- Do not use this medication if the color changes, if it becomes cloudy, or if there are particles in the solutions.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Storage/Stability

Store this medication in the refrigerator (2°C-8°C [35.6°F-46.4°F]); do not freeze. Reconstituted solutions (see ***Compatibilty/Compounding Considerations***) are stable for 14 days (in the absence of sterility testing) when refrigerated.[15]

Compatibility/Compounding Considerations

Voriconazole ophthalmic preparations should not be mixed directly with any other ophthalmic medications. Voriconazole is not approved in an ophthalmic dosage form. A 1% ophthalmic solution can be created by aseptically reconstituting the powder in a 200 mg vial for injection with 19 mL of sterile water for injection or normal saline, according to the package instructions.[16]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Voriconazole is available as a 200 mg lyophilized powder (*VFend®*, generic) for reconstitution to a 1% solution following the addition of 19 mL water for injection. This reconstituted solution can be safely used for topical ophthalmic administration. Voriconazole may be compounded to a 1% ointment by a qualified, licensed compounding pharmacist.

Dermatologic Agents, Topical

SANDRA KOCH, DVM, MS, DACVD
University of Minnesota, St. Paul, MN

The following section lists many of the active ingredients and examples of corresponding preparations used topically for their local action in veterinary medicine. The list includes both veterinary-labeled products and some useful human-labeled dermatologic products. In the marketplace, the drug sponsor, availability, and formulation of these products tend to change rapidly, so this listing should be used as a basic guide; always refer to the specific product label. Active ingredients are listed by therapeutic class. Products that are applied topically but are absorbed systemically and used primarily for their systemic effects are found in the systemic monograph section.

Portions of this section are adapted from Koch SN, Torres SMF, Plumb, DC. *Canine and Feline Dermatology Drug Handbook*. John Wiley & Sons, 2012. This reference provides additional detail on these and other compounds and products.

Anti-Inflammatory/Anti-Pruritic Agents, Topical

Corticosteroid Agents, Topical

NOTE: There are at least 20 chemical entities (plus a variety of salts) used in humans for topical corticosteroid therapy. The following section includes many veterinary topical products and some human products that may be of use in veterinary medicine. See also ***Otic Agents*** for more products.

Betamethasone, Topical

(bet-ah-***meth***-ah-zone)
For systemic use, refer to ***Betamethasone****.*
For otic use, refer to ***Corticosteroid/Antimicrobial Agents, Otic****.*

Indications/Actions

Betamethasone is considered a high-potency topical corticosteroid. It may be beneficial for adjunctive treatment of localized pruritic or inflammatory conditions. Because risks associated with betamethasone (eg, HPA axis suppression, systemic corticosteroid effects, skin atrophy) are higher than with hydrocortisone, betamethasone products are generally reserved for severe localized pruritic conditions or conditions for which hydrocortisone is not efficacious. Most veterinary-labeled topical betamethasone products also contain gentamicin, and labeled indications are for treating infected superficial lesions caused by bacteria sensitive to gentamicin. Additional otic products that contain an antimicrobial (eg, gentamicin) and an antifungal (eg, clotrimazole) are available. See ***Corticosteroid/Antimicrobial Agents, Otic***. These products can be used extra-label for treating localized mixed bacterial and yeast infections when potent anti-inflammatory activity is also desired. Topical dosage forms containing betamethasone as a sole ingredient are only available in products labeled for humans.

Glucocorticoids are nonspecific anti-inflammatory agents. They likely act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (eg, histamine, prostaglandins, kinins). Glucocorticoids also mitigate DNA synthesis via an antimitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area, thereby reducing erythema, pruritus, and edema.

Ointments are the most potent vehicle, as they are the most occlusive, whereas creams tend to be less potent than ointments of the same medication/strength, followed by lotions and gels.[1]

Suggested Dosages/Uses

Betamethasone formulations are best suited for focal (eg, pedal) or multifocal lesions for relatively short durations (ie, less than 2 months). See ***Precautions/Adverse Effects***. Initially, topical glucocorticoids are used sparingly 1 to 4 times per day, and then the frequency is tapered when control is achieved. Long-term, frequent use can cause HPA axis suppression; risk can be reduced by treating for only as long as necessary on as small an area as possible. Refer to the individual product label for specific dosing recommendations.

Precautions/Adverse Effects

Several veterinary topical products list pregnancy as a contraindication. Systemic glucocorticoids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus the potential benefits. Owners should wash their hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow the animal to lick or chew at affected sites for at least 20 to 30 minutes after application. Occlusive dressings increase glucocorticoid penetration and can increase the risk for systemic side effects.

- Reactions to allergen **intradermal skin tests** may be suppressed by glucocorticoids.[2,3] A 2-week (14-day) withdrawal time before intradermal skin testing is recommended for dogs and cats[4,5]; no withdrawal time is required before serum IgE testing to identify sensitizing allergens in cats.[5]

Use care when treating large areas or when using on small-sized patients. Higher potency, increased concentration, or long duration of use increases risks for HPA axis suppression, immune suppression, systemic glucocorticoid effects (eg, PU/PD, polyphagia, vomiting, diarrhea), and complications caused by skin atrophy (eg, skin fragility, alopecia, localized pyoderma, comedones, weakened barrier function). Betamethasone may delay wound healing, primarily if used longer than 7 days. Vomiting and diarrhea have been reported after ingestion of topical products containing betamethasone. Local skin reactions (eg, burning, itching, redness) are possible but uncommon.

Veterinary-Labeled Products

NOTE: There are no veterinary-labeled topical products in the United States that contain betamethasone as a single active ingredient.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Gentamicin 0.57 mg/mL, betamethasone valerate 0.284 mg/mL (spray) Other ingredients: propylene glycol, isopropyl alcohol, parabens	Labeled for dogs	Rx; depending on the product: 60 mL, 72 mL, 120 mL, and 240 mL	*Gentocin*®; *GentaCalm*®; *GentaSpray*®; *Betagen*®; *Gentamicin*®; *Gentaved*®; *GentaSoothe*®; *GenOne*®; *Relifor*®

Human-Labeled Products

NOTE: This is a partial listing. Do not confuse products containing *augmented* betamethasone dipropionate (eg, *Diprolene*®) with betamethasone dipropionate. Augmented betamethasone dipropionate is more potent than betamethasone dipropionate. For more information on human-labeled betamethasone products, refer to a comprehensive human drug reference or contact a pharmacist.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Betamethasone dipropionate 0.05% (ointment)	Rx; 15 g, 45 g	generic
Betamethasone dipropionate 0.05% (cream)	Rx; 15 g, 45 g	generic
Betamethasone dipropionate 0.05% (lotion)	Rx; 60 mL	generic
Betamethasone valerate 0.1% (ointment)	Rx; 30 g, 45 g	generic
Betamethasone valerate 0.1% (cream)	Rx; 15 g	generic
Betamethasone valerate 0.1% (lotion)	Rx; 60 mL	generic
Betamethasone valerate 0.12% (foam)	Rx; 300 g	*Luxic*®; generic
Clotrimazole 1%, betamethasone dipropionate 0.05% (lotion)	Rx; 30 mL	generic
Clotrimazole 1%, betamethasone dipropionate 0.05% (cream)	Rx; 15 g, 45 g	*Lotrisone*®

For the complete list of references, see **wiley.com/go/budde/plumb**

Hydrocortisone, Topical

(hye-droe-***kor***-ti-zone)

Indications/Actions

Hydrocortisone is a topical corticosteroid that may be useful for adjunctive treatment of localized pruritic and/or inflammatory conditions. Due to its low potency, hydrocortisone is a reasonable first choice for larger focal areas or for small-sized patients. Some products contain additional ingredients (eg, Burow's solution [aluminum acetate], pramoxine) that may have additional antipruritic effects.

Topical glucocorticoids are nonspecific anti-inflammatory agents. They are thought to act by inducing phospholipase A_2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (eg, histamine, prostaglandins, kinins). Glucocorticoids also reduce DNA synthesis via an antimitotic effect on epidermal cells. Topically applied glucocorticoids also inhibit the migration of leukocytes and macrophages to the area, reducing erythema, pruritus, and edema.

Suggested Dosages/Uses

Hydrocortisone formulations are best suited for focal (eg, pedal) or multifocal lesions for relatively short durations (ie, less than 2 months; see ***Precautions/Adverse Effects***).

Initially, topical glucocorticoid creams and ointments are applied 1 to 4 times daily, and then the frequency is tapered after control is achieved. In contrast to some more potent topical corticosteroids, hydrocortisone can be applied more frequently and over a greater surface area, with less risk for local or systemic adverse effects; however, long-term frequent use can still cause HPA axis suppression. Risk can be reduced by treating patients for only as long as necessary on the smallest area possible.

Shampoos containing hydrocortisone are generally used from once a week up to once a day. They typically should remain in contact with the skin for at least 10 minutes before rinsing.

Precautions/Adverse Effects

Several veterinary topical products list pregnancy as a contraindication. Owners should wash their hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow the animal to lick or chew at affected sites for at least 20 to 30 minutes after application. Occlusive dressings increase glucocorticoid penetration and can increase the risk for systemic adverse effects. The risks associated with hydrocortisone are significantly less when compared with higher potency corticosteroids (eg, betamethasone).

Local skin reactions are possible but uncommon. Atrophy associated with skin fragility, superficial follicular cysts (milia), and comedones may be seen with long-term frequent use, but these conditions occur more commonly when using more potent topical corticosteroids (eg, betamethasone). Although systemic absorption is rare with hydrocortisone, long-term use may lead to HPA axis suppression. Accidental ingestion may cause GI signs such as nausea, vomiting, or diarrhea.[1]

Reactions to allergen intradermal skin tests may be suppressed by glucocorticoids.[2,3] A 2-week (14-day) withdrawal time before intradermal skin testing is recommended for dogs and cats[4,5]; no withdrawal time is required before serum IgE testing to identify sensitizing allergens in cats.[5]

Veterinary-Labeled Products

Refer to the individual product labeling for specific dosing recommendations and inactive ingredients.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Hydrocortisone 0.5% (lotion)	Labeled for dogs	OTC; 4 oz	*Dogswell®*
Hydrocortisone 1% (lotion)	Labeled for dogs, cats, and horses	OTC; 8 oz	*Vetergen Hydrocortisone; AtopiCream HC*
Hydrocortisone 0.5% (cream)	Labeled for dogs and cats	OTC; 1 oz	*Zymox®*
Hydrocortisone 1% (cream)	Labeled for dogs and cats	OTC; 1 oz	*Zymox®*
Hydrocortisone 0.5% (spray)	Labeled for dogs	OTC; 5 oz	*Hartz®*
Hydrocortisone 1% (spray)	Labeled for dogs and cats	OTC; 2 oz	*Zymox®*
Hydrocortisone 1%, chlorhexidine 4%, (spray)	Labeled for dogs, cats, and horses	OTC; 8 oz	*TrizCHLOR® 4HC*
Hydrocortisone 1%, pramoxine 1% (spray)	Labeled for dogs and cats	OTC; 4 oz, 8 oz	*Comfort HC®; Vetraseb®* HC
Hydrocortisone 1%, acetic acid 1%, boric acid 2%, ketoconazole 0.15% (spray)	Labeled for dogs, cats, and horses	OTC; 8 oz	*MalAcetic® ULTRA*
Hydrocortisone 1%, Burow's solution 2% (solution)	Labeled for dogs and/or cats	OTC or Rx; 1 oz, 2 oz, and 16 oz bottle	*Cort/Astrin®; Corti-Derm®; Bur-O-Cort 2:1®; Hydro-B 1020®; Hydro-Plus®*
Hydrocortisone 0.5%, chlorhexidine 2%, ketoconazole 1% (salve)	Labeled for dogs, cats, and horses	OTC; 4 oz	*EquiShield® CK HC*
Hydrocortisone 1%, chlorhexidine 4% (shampoo)	Labeled for dogs, cats, and/or horses	OTC; 8 oz, 16 oz	*TrizCHLOR 4HC; Chlorhexidine 4% HC*
Hydrocortisone 1%, chlorhexidine 2%, ketoconazole 1% (shampoo)	Labeled for dogs, cats, and horses	OTC; 12 oz	*EquiShield® CK HC*
Hydrocortisone 1%, acetic acid 1%, boric acid 2%, ketoconazole 0.15% (shampoo)	Labeled for dogs and cats	OTC; 8 oz	*MalAcetic® ULTRA*
Hydrocortisone 1%, acetic acid 1%, boric acid 1% (wipes)	Labeled for dogs and cats	OTC; 25 count jar	*MalAcetic® HC*

Human-Labeled Products

NOTE: Partial listing; there are many branded products available with hydrocortisone. For more information on human-labeled hydrocortisone products, refer to a comprehensive human drug reference (eg, *Facts and Comparisons*) or contact a pharmacist.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Hydrocortisone 0.5%, hydrocortisone 1% (ointment)	OTC/Rx; 25 g, 28 g, 28.35 g, 28.4 g, 30 g, 56 g, 110 g, 430 g, and 454 g	Status determined by labeling
Hydrocortisone 2.5% (ointment)	Rx; 20 g, 28.35 g, 435.6 g, and 454 g	
Hydrocortisone 0.5%, hydrocortisone 1% (cream)	OTC/Rx; 1 g, 1.5 g packets, 14 g, 14.2 g, 15 g, 20 g, 26 g, 28 g, 28.3 g, 28.35 g, 28.4 g, 30 g, 42 g, 56 g, 120 g, and 454 g	Status determined by labeling
Hydrocortisone 2.5% (cream)	Rx; 15 g, 20 g, 28 g, 28.35 g, 30 g, and 454 g	
Hydrocortisone 1% (lotion)	OTC/Rx; 30 mL, 59 mL, 60 mL, 88.7 mL, 99 mL, 113 mL, 114 mL, 118 mL, and 120 mL	Status determined by labeling
Hydrocortisone 2%, hydrocortisone 2.5% (lotion)	Rx; 29.6 mL (2% only), 59 mL and 118 mL (2.5% only)	*Ala Scalp®; Scalacort®;* generic
Hydrocortisone 1% (gel)	OTC; 28 g, 30 g, 42.53 g, and 56 g	
Hydrocortisone 2.5% (gel)	Rx; 43 g	
Hydrocortisone 10% (gel compounding kit)	Rx; 60 g jar	*First-Hydrocortisone®*
Hydrocortisone 1%, hydrocortisone 2.5% (solution)	OTC/Rx; 30 mL, 44 mL, 59 mL, and 120 mL	
Hydrocortisone 1% (foam)	OTC; 88.7 mL	*Itch-X®*
Hydrocortisone 1% (applicator)	OTC; 36 mL	*Cortizone-10 Easy Relief®*

Isoflupredone Combinations, Topical

(eye-soe-***floo***-preh-dohn)

Indications/Actions

Isoflupredone is a high-potency topical corticosteroid. In combination with neomycin and tetracaine, isoflupredone is indicated in dogs as a dressing for minor cuts and abrasions, as a postsurgical therapy, and for treating anal gland infections and moist dermatitis.[1] It is indicated in cats and horses as a dressing for minor cuts and abrasions and as postsurgical therapy.[1,2]

Because risks associated with isoflupredone (eg, HPA axis suppression, systemic corticosteroid effects, skin atrophy) are higher than with hydrocortisone, these products are generally reserved for severe localized pruritic conditions or for conditions when hydrocortisone is not efficacious.

Corticosteroids are nonspecific anti-inflammatory agents. They are thought to act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (eg, histamine, prostaglandins, kinins). Corticosteroids also mitigate DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area, reducing erythema, pruritus, and edema.

Suggested Dosages/Uses

Clean the affected area prior to application of isoflupredone. Apply a small amount of ointment or powder 1 to 3 times daily as needed and continue based on clinical response.[1,2]

Precautions/Adverse Effects

Topical corticosteroids are often considered contraindicated in patients that are pregnant or have tuberculosis of the skin. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If isoflupredone is being considered for use during pregnancy, weigh the risks for treating versus the potential benefits.

Residual activity may affect intradermal or allergy serum tests; it is recommended to discontinue use of isoflupredone 2 weeks before allergy testing.[3] Isoflupredone may delay wound healing, particularly when used longer than 7 days.

Isoflupredone products may be harmful if swallowed; prevent treated animals from licking or chewing at affected sites for at least 20 to 30 minutes after application. Powdered formulations may cause allergy or asthma symptoms if inhaled.[2]

Wear gloves or wash hands after application. Avoid contact with eyes.

Use isoflupredone cautiously on large treatment areas and on small-sized patients. Treat the smallest area possible for the minimum duration. The prolonged use of corticosteroid products increases the risk for HPA axis suppression, systemic corticosteroid effects (eg, polydipsia, polyuria, iatrogenic hyperadrenocorticism, skin atrophy). Local skin reactions (eg, burning, itching, redness) or hypersensitivity reactions are possible.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Isoflupredone acetate 0.1%, neomycin sulfate 0.5%, tetracaine HCl 0.5% (ointment)	Labeled for dogs, cats, and horses	Rx; 10 g tube	*Neo-Predef® with Tetracaine; Tritop®*
Isoflupredone acetate 0.1%, neomycin sulfate 0.5%, tetracaine HCl 0.5% (powder)	Labeled for dogs, cats, and horses	Rx; 15 g insufflator bottle	*Neo-Predef® with Tetracaine* Store in a dry place. Do not allow the tip of the bottle to contact moisture.

Human-Labeled Products

None

Mometasone, Topical

(moe-***met***-a-zone)

For otic use, see ***Corticosteroid/Antimicrobial Agents, Otic****.*

Indications

Mometasone is a high-potency topical corticosteroid. It may be beneficial for adjunctive treatment of pruritic and inflammatory conditions. Mometasone products are generally reserved for severe pruritic conditions or for hydrocortisone treatment failures, as the risks associated with mometasone (eg, HPA axis suppression, skin atrophy) are higher than with hydrocortisone.

Mometasone is found in several veterinary-labeled otic suspensions in combination with antibiotics and antifungals. These otic combination products have been used topically extra-label for yeast and bacterial skin infections when a potent anti-inflammatory effect is needed but should only be used when there is evidence of bacterial or yeast infections.

Corticosteroids are non-specific anti-inflammatory agents. They are thought to induce phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (eg, histamine, prostaglandins, kinins). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area, reducing erythema, pruritus, and edema.

Suggested Dosages/Uses

Mometasone should be applied sparingly, initially 1 to 2 times daily then less frequent as clinical signs improve. Mometasone formulations

are best suited for focal (eg, pedal) or multifocal lesions that require relatively short treatment durations (ie, less than 2 months). Frequency of application and duration of treatment should be based on the severity of clinical signs. For veterinary-labeled products, refer to the specific product label for additional usage information.

Precautions/Adverse Effects

Safe use of mometasone during pregnancy is not established; it should only be used when the benefits outweigh the risks. Use cautiously on large treatment areas or in small-sized patients due to risk for systemic absorption. Treat only for as long as necessary on as small of an area as possible to reduce the risk for toxicities such as HPA axis suppression, systemic corticosteroid effects (eg, polydipsia, polyuria, iatrogenic Cushing's, adverse GI effects), and cutaneous atrophy associated with skin fragility. Other potential adverse effects that occur with increases in product concentrations and prolonged duration of use include alopecia, localized pyoderma, superficial follicular cysts (milia), and comedones. Local skin reactions (eg, burning, pruritus, erythema) are possible but unlikely. Mometasone may delay wound healing, particularly if used longer than 7 days. Do not let treated animals lick or chew at affected areas for at least 20 to 30 minutes after application; ingestion may result in GI upset. Occlusive dressings increase steroid penetration and can increase the risk for systemic adverse effects.

Reactions to allergen intradermal skin tests may be suppressed by glucocorticoids. A 2-week (14-day) withdrawal time before intradermal skin testing is recommended for dogs and cats[1]; no withdrawal time is required before serum IgE testing to identify sensitizing allergens in cats.[2]

Wash hands after handling or wear gloves during application. Avoid contact with eyes.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Mometasone 1 mg/g, gentamicin 3 mg/g, clotrimazole 10 mg/g (suspension)	Labeled for otic use in dogs	Rx; 7.5 g, 15 g, 30 g, and 215 g tubes	*Mometamax®; Malmetazone®; Mometavet®; Maxi-Otic®; MotaZol®* Topical use is extra-label.
Mometasone 1 mg/g, orbifloxacin 10 mg/g, posaconazole 1 mg/g (suspension)	Labeled for otic use in dogs	Rx; 7.5 g, 15 g, and 30 g tubes	*Posatex®* Topical use is extra-label.

Human-Labeled Products

NOTES:

1. Mometasone furoate is the salt generally used in pharmaceutical products.
2. Many commercial products exist. Below is a representative list of available products. For more information on human-labeled mometasone products, refer to a comprehensive human drug reference or contact a pharmacist.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Mometasone furoate 0.1% (cream)	Rx; 15 g and 45 g	generic
Mometasone furoate 0.1% (ointment)	Rx; 15 g and 45 g	generic
Mometasone furoate 0.1% (lotion)	Rx; 30 mL and 60 mL	*Elocon®*; generic
Mometasone furoate 0.1% (solution)	Rx; 30 mL and 60 mL	generic
Mometasone furoate 50 µg/100 mg (nasal spray)	OTC; 10 mL and 17 mL bottle	*Nasonex®* Extra-label when used topically

Triamcinolone, Topical

(trye-am-***sin***-oh-lone)

For systemic use, see ***Triamcinolone.***

For otic use, see ***Corticosteroid/Antimicrobial Agents, Otic****.*

Indications/Actions

Triamcinolone is generally considered a medium potency corticosteroid at concentrations less than 0.5%. It may be beneficial for adjunctive treatment of pruritic or inflammatory conditions. Triamcinolone products are typically reserved for severe pruritic conditions or for conditions when hydrocortisone is not efficacious, as the risk for HPA axis suppression and skin atrophy are higher than with hydrocortisone.

Triamcinolone can be found as a sole agent in some veterinary creams or sprays, although most of these contain an antibiotic and/or antifungal agent. These products can be used for treating localized mixed bacterial and yeast infections when potent anti-inflammatory activity is also desired. Additional otic products that contain an antibiotic and an antifungal are available. See ***Corticosteroid/Antimicrobial Agents, Otic***.

Corticosteroids are non-specific anti-inflammatory agents. They are thought to induce phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (eg, histamine, prostaglandins, kinins). Corticosteroids also mitigate DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area, reducing erythema, pruritus, and edema.

Suggested Dosages/Uses

Topical triamcinolone is best suited for focal (eg, pedal) or multifocal lesions for relatively short durations (ie, less than 2 months). Triamcinolone ointment should be applied sparingly, initially 1 to 4 times daily and then tapered when control is achieved. Triamcinolone spray is labeled for use twice daily for 7 days, then once daily for 7 days, then every other day for 14 days. For veterinary products, refer to the specific product label for dosing recommendations.

Precautions/Adverse Effects

Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the risks of treating versus potential benefits. Wear gloves when applying and wash hands after application. Spray should be applied in a well-ventilated area. Avoid contact with eyes. Do not allow animals to lick or chew at affected sites for at least 20 to 30 minutes after application; oral ingestion may result in GI upset.

Reactions to allergen intradermal skin tests may be suppressed by glucocorticoids. A 2-week (14-day) withdrawal time before intradermal skin testing is recommended for dogs and cats[1]; no withdrawal time is required before serum IgE testing to identify sensitizing allergens in cats.[2]

Long-term, frequent use can cause HPA axis suppression. Treat for only as long as necessary on as small of an area as possible using the lowest effective concentration to reduce the risk for HPA axis suppression, cutaneous effects (eg, skin atrophy, skin fragility, alopecia, localized pyoderma, comedones), and other systemic corticosteroid effects (eg, polydipsia, polyuria, iatrogenic Cushing's, GI effects). Use with caution when treating small-sized patients or large areas. Triamcinolone may delay wound healing, mainly if used longer than 7 days. Local skin reactions (eg, burning, itching, redness) are also possible.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Triamcinolone acetonide 0.015% (spray)	Labeled for dogs	Rx; 8 oz, 16 oz bottle	*Genesis*®
Triamcinolone acetonide 0.1% (cream)	Labeled for dogs	Rx; 7.5 g, 15 g	*Medalone*®; *Vetalog*® Although these products are still listed in the FDA Green Book of approved animal drugs, they may no longer be commercially available.
Triamcinolone acetonide 1 mg/g, neomycin 2.5 mg/g, thiostrepton 2500 units/g, nystatin 100,000 units/g (cream)	Labeled for dogs and cats	Rx; 7.5 g, 15 g tube	*Animax*®; *Derma-Vet*®; *Panalog*® Although these products are still listed in the FDA Green Book of approved animal drugs, they may no longer be commercially available.
Triamcinolone acetonide 1 mg/mL, neomycin 2.5 mg/mL, thiostrepton 2500 units/mL, nystatin 100,000 units/mL, (ointment)	Labeled for dogs and cats	Rx; 7.5 mL, 15 mL, 30 mL, and 240 mL	*Animax*®; *Derma-Vet*®; *Dermalog*®; *Dermalone*®; *EnteDerm*®; *Quadritop*®; *Quadruple*®; *Resortin*®; *VetaDerm Tetrafect*®

Human-Labeled Products

NOTE: For more information on human-labeled triamcinolone products, refer to a comprehensive human drug reference or contact a pharmacist.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Triamcinolone acetonide 0.025% (ointment)	Rx; 15 g, 80 g, 454 g	generic
Triamcinolone acetonide 0.05% (ointment)	Rx; 430 g	*Trianex*®; generic
Triamcinolone acetonide 0.1% (ointment)	Rx; 15 g, 80 g, 454 g	generic
Triamcinolone acetonide 0.5% (ointment)	Rx; 15 g	generic
Triamcinolone acetonide 0.025% (cream)	Rx; 15 g, 85.2 g, 454 g	*Triderm*®; generic
Triamcinolone acetonide 0.1% (cream)	Rx; 28.4 g, 85.2 g	*Triderm*®; generic
Triamcinolone acetonide 0.5% (cream)	Rx; 15 g, 454 g	*Triderm*®; generic
Triamcinolone acetonide 0.025% (lotion)	Rx; 60 mL	generic
Triamcinolone acetonide 0.1% (lotion)	Rx; 60 mL	generic
Triamcinolone acetonide 0.147 mg/g (spray)	Rx; 63 g, 100 g	*Kenalog*®; generic 10.3% alcohol
Triamcinolone acetonide 0.1%, nystatin 100,000 units/g (cream)	Rx; 15 g, 30 g, 60 g	generic
Triamcinolone acetonide 0.1%, nystatin 100,000 units/g (ointment)	Rx; 15 g, 30 g, 60 g	generic

Non-Corticosteroid Agents, Topical

Aluminum Acetate Solution, Topical
Burow's Solution

(ah-***loo***-mi-num ***ass***-ih-tate)

Astringent

For otic use, see ***Corticosteroid Agents, Otic.***

Indications/Actions

Aluminum acetate solution (Burow's solution, modified Burow's solution) is an astringent antipruritic agent that can be used for adjunctive treatment of minor skin irritations, such as insect bites and localized inflamed and exudative skin conditions (eg, acute moist dermatitis, fold dermatitis [intertrigo], contact dermatitis). This solution can also be used to reduce inflammation associated with otitis externa (see ***Corticosteroid Agents, Otic***). In addition to astringent and antipruritic actions, aluminum acetate solution also has acidifying effects and it is mildly antiseptic. The exact mechanisms of action for each of these effects is not fully understood; it was shown to have an antibacterial effect against Staphylococcus aureus and Pseudomonas aeruginosa through alterations and damage to the cell wall and bacteriolysis.[1]

Suggested Dosages/Uses

Topical use of aluminum acetate as a single agent is usually via a wet compress, dressing, or soak. Application for 15 to 30 minutes is generally recommended, and the affected area is air-dried between applications. Use can be as often as necessary, but every 4 to 6 hours is often employed. As aluminum acetate solution products come in various dosage forms (powder or tablets for dissolving, liquid), refer to package directions for proper dilutions; dilutions of 1:40, 1:20, or 1:10 are commonly used. Various generic products exist. **NOTE**: The commercially prepared, veterinary-labeled products that also contain hydrocortisone may be directly applied without dilution. See ***Hydrocortisone, Topical***.

Precautions/Adverse Effects

Do not cover application site with plastic or occlusive dressing to try to prevent product evaporation. Use cool or warm[2] water for dissolving powder/tablets. Avoid contact with eyes. Pet owners should wash their hands after application. Aluminum acetate solution may cause dry skin or skin irritation in some patients. For products containing hydrocortisone, prolonged use should be avoided or limited to 1 to 2 weeks at a time to prevent potential skin atrophy and systemic absorption. A minimum of a 2-week withdrawal period is recommended for these products before intradermal or allergy serum testing. See ***Hydrocortisone, Topical***.

Veterinary-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Aluminum acetate 2%, hydrocortisone 1% (solution) Other ingredients: water, propylene glycol	OTC; 1 oz, 2 oz, 16 oz	*Cort/Astrin®; Corti-Derm®; Hydro-B 1020*

Human-Labeled Products

NOTE: In some products, aluminum acetate solution may be listed as aluminum sulfate and calcium acetate combined in water.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Aluminum sulfate tetradecahydrate, 1347 mg; calcium acetate monohydrate, 952 mg (powder)	OTC; packets of various concentrations (12/box)	*Domeboro®* Dilute as directed. When combined with water, the active ingredient (aluminum acetate) is formed.
Aluminum acetate 0.5% (gel)	OTC; 3 oz	*Domeboro®*
Aluminum acetate 0.2% (gel) Other ingredients: dehydroacetic acid, ethylhexylglycerin, glycine, hexylene glycol, malic acid	OTC; 2 oz	*TriCalm®*

For the complete list of references, see **wiley.com/go/budde/plumb**

Camphor/Menthol/Phenol, Topical

(***kam***-for; ***men***-thol; ***fee***-nol)

Indications/Actions

When used in low concentrations, camphor/menthol/phenol products can be used as counterirritants; they may be added to proprietary or compounded products, primarily as antipruritics. Camphor and phenol may also have some antiseptic properties. Camphor and menthol act by stimulating and desensitizing nociceptors.[1] Camphor produces a warming sensation, whereas menthol produces a cooling effect.[2]

Precautions/Adverse Effects

These compounds may cause local irritation and should not be used around or in the eyes. Products containing phenol should NOT be used on cats.

Veterinary-Labeled Products

NOTE: There are also several over-the-counter (OTC) products containing menthol, phenol, or camphor; these products are not listed below and are used primarily on equine patients for overexertion, soreness, or stiffness. These include a variety of liniments (eg, white liniment, Choate's liniment) or gels (eg, *Cool Gel*®, *Ice-O-Gel*®, *Shin-O-Gel*®).

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Menthol 7.5 mg/mL, oil of camphor 7.5 mg/mL, oil of eucalyptus 7.5 mg/mL, oil of pine 7.5 mg/mL, oil of thyme 2.8 mg/mL, Peru balsam 1.5 mg/mL, phenol 7.5 mg/mL, biebrich scarlet red 100 ppm (spray)	Labeled for superficial cuts, wounds, and burns for horses and mules	OTC; 500 mL	Many trade names Shake well

For the complete list of references, see **wiley.com/go/budde/plumb**

Colloidal Oatmeal, Topical

(ko-***loyd***-al ***ote***-meel)

Indications/Actions

Colloidal oatmeal is made from oat grains (*Avena sativa*) and is used topically as an anti-inflammatory, antipruritic, and emollient agent. It ameliorates and provides soothing effects in pruritic, inflamed, and dry and/or scaly skin disorders, such as atopic dermatitis and irritant skin reactions. Although colloidal oatmeal's mechanism of action is not completely understood, avenanthramides, one of its antioxidant phenolic compounds, have been shown to exert anti-inflammatory effects in the skin by inhibiting activities of pro-inflammatory cytokines in human epidermal keratinocytes.[1] Avenanthramides were also shown to inhibit histamine release, prostaglandin biosynthesis, and cleavage of arachidonic acid from phospholipids in keratinocytes. In animal models, avenanthramides also reduced scratching and inflammatory cytokines implicated in pruritus; the antipruritic effect appears to increase as the oatmeal concentration increases. Colloidal oatmeal also forms a hydrophilic film that retains and replenishes moisture in the stratum corneum, and it also helps to normalize the skin's pH. Moreover, colloidal oatmeal was found to improve the epidermal skin barrier by inducing and upregulating the expression of important skin barrier markers in human equivalent keratinocytes.

Suggested Dosages/Uses

Spray formulations can be used 2 to 3 times per day or as needed for itching or pain. Shampoo or conditioner is usually used once a day to once a week. Shampoo should be in contact with the skin for at least 5 to 10 minutes and then rinsed well. Refer to each product's label for further details.

Precautions/Adverse Effects

Colloidal oatmeal has been known to be very safe. In humans, there are some reports of contact dermatitis associated with its use; however, most data indicate a low potential for oatmeal-containing products to cause irritation or allergic sensitization. Some animals might develop sensitivity (eg, pruritus, erythema) to some of these topical agents, in which case the product should be discontinued. Because colloidal oatmeal has a potential antihistamine effect, a minimum of a 2-week withdrawal period is recommended before intradermal testing.

Veterinary-Labeled Products

NOTE: Products listed are representative of those containing only colloidal oatmeal as the principal active ingredient.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Colloidal oatmeal (leave-on spray) Other ingredients: ceramides, safflower oil	Labeled for dogs, cats, and horses	OTC; 8 oz, 12 oz, and 1 gallon	*Dermallay*®

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Colloidal oatmeal 1% (cream rinse) Other ingredients: lactic acid, propylene glycol	Labeled for dogs, cats, and horses	OTC; 8 oz, 16 oz, and 1 gallon	*Epi-Soothe®*
Colloidal oatmeal (conditioner); other ingredients vary	Labeled for dogs and cats	OTC; 16 oz, 17 oz, 1 gallon	*Aloe & Oatmeal Skin and Coat; Aloe & Oatmeal®*
Colloidal oatmeal (shampoo); other ingredients vary	Labeled for dogs and cats; some products labeled for horses	OTC; 4 oz, 8 oz, 12 oz, 16 oz, 17 oz, 1 gallon	*Aloe & Oatmeal®; Dermallay®*(soap free); *Epi-Soothe®; Vet Solutions Aloe & Oatmeal®; Simply Pure®; Aloe and Oatmeal* (soap and alcohol-free); *Aloe Oatmeal* (soap-free)

Human-Labeled Products

NOTE: There are several human products available containing colloidal oatmeal, including creams, lotions, and products, to be added to the bath. Common trade names include *Aveeno®*, *Geri Silk®*, and *Actibath®*.

Diphenhydramine, Topical

(dye-fen-***hye***-dra-meen) *Benadryl®*

For systemic use, see ***Diphenhydramine.***

Indications/Actions

Diphenhydramine is a first-generation antihistamine that has some local anesthetic activity. This activity is probably its primary antipruritic mechanism of action. Diphenhydramine may be absorbed in small amounts transdermally but is unlikely to cause systemic adverse effects with typical use.

Suggested Dosages/Uses

Topical creams, ointments, gels, lotions, or sprays are usually applied 1 to 3 times a day as needed. The shampoos and conditioners are generally used once a week to once a day after bathing, respectively. Shampoos should remain in contact with the skin for at least 10 minutes before being rinsed. Check product label for specific instructions.

Precautions/Adverse Effects

Avoid contact with eyes or mucous membranes. Do not apply to blistered or oozing areas of the skin. Fatalities have rarely been reported in children after excessive exposure (ie, application to a large percentage of body surface area with open sores); veterinary significance is uncertain. Pet owners should wash their hands after application or wear gloves when applying.

Prolonged use could potentially cause local irritation and/or hypersensitization. Residual activity may affect intradermal or allergy serum tests. It has been suggested to stop using this product 2 weeks before allergy intradermal testing.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Diphenhydramine 1%, pramoxine 1%, (conditioner spray)	Labeled for dogs and cats	OTC; 8 oz	*Benasoothe®* Other ingredients: ceramides, phytosphingosine, safflower oil, *Aloe barbadensis*, glycerin, lanolin cholesterol, glycerin, lanolin

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Diphenhydramine 2% (spray), diphenhydramine 2% (gel), diphenhydramine 1% (cream), diphenhydramine 2% (cream), diphenhydramine 2% (ointment), diphenhydramine 2% (stick), diphenhydramine 12.5 mg (strip)	OTC; various sizes available	*Benadryl®; Banophen®*; *CareOne®*; *Allergy Relief®* Other ingredients may include calamine, zinc oxide, acetate, pyrilamine, tripelennamine, menthol, camphor.

Fatty Acids (Omega), Topical

*For systemic use, see **Fatty Acids, Omega-3***

Indications/Actions

Essential fatty acids are polyunsaturated fatty acids that are not synthesized by the body and must be obtained from external sources. The 2 main types of essential fatty acids are omega-3 and omega-6 fatty acids. Essential fatty acids are indicated primarily for pruritic and inflammatory conditions (eg, atopic dermatitis, sebaceous adenitis) and keratinization disorders (eg, seborrhea). They may also be used to improve coat quality and dry skin. Some products may contain other active ingredients and natural oils, and therefore, may have additional indications.

The exact mechanism of action of essential fatty acids is not well understood; however, essential fatty acids affect the arachidonic acid concentrations in plasma lipids and platelet membranes. They decrease the production of inflammatory prostaglandins in the body, thereby reducing inflammation and pruritus. Essential fatty acids may also play a role in restoring the skin barrier.

Suggested Uses/Dosages

Sprays, wipes, and mousses are typically applied up to 2 to 3 times daily as needed. Spot-on treatments vary from weekly to every 2 weeks. Shampoos and crème rinses can be applied daily to weekly. Shampoos should generally be left in contact with the skin for 5 to 10 minutes before rinsing.

Precautions/Adverse Effects

No specific precautions or adverse effects are described for topical essential fatty acids; however, sensitivity reactions are possible. If signs such as pruritus or erythema occur, discontinue use.

Veterinary-Labeled Products

Below is a representative sample of the products available. **NOTE:** Refer to specific product labels for details on inactive ingredients and instructions for use.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Essential fatty acids from safflower oil (shampoo)	Labeled for dogs and cats; some products labeled for horses	OTC; 4 oz, 12 oz, 16 oz, 1 gallon	*HyLyt®; DermaLyte®; EFA Essential Fatty Acid®* Soap-free
Essential fatty acids from safflower oil with oatmeal (shampoo)	Labeled for dogs, cats, and horses	OTC; 12 oz, 1 gallon	*DermAllay®* Soap-free
Essential fatty acids from safflower oil (creme rinse)	Labeled for dogs and cats; some products labeled for horses	OTC; 8 oz, 1 gallon	*HyLyt®;* generic
Essential fatty acids from hemp seed oil (spot-on)	Labeled for dogs, cats, horses, and small mammals	OTC; boxes of 4 pipettes in the following sizes: Dogs: Under 10 kg (22 lb): 0.6 mL 10 - 20.5 kg (22-45 lb): 1.2 mL 20.5 - 40.9 kg (45-90 lb): 2.4 mL Cats: 0.4 mL Small mammals: 0.6 mL Horses: 30 mL bottles	*Essential 6®* Directions: Initially, 1 dose weekly for 2 months, then 1 dose every 2 weeks for maintenance. Do not bathe within 2 days before and 2 days after application. Brush application site 24 hours after applying to remove product residue.
Essential fatty acids from hemp seed oil and tamanu oil (spot-on)	Labeled for dogs	OTC; boxes of 4 pipettes in the following sizes: **Dogs:** under 10 kg (22 lb): 0.6 mL Dogs 10 - 20.4 kg (22-45 lb): 1.2 mL 20.4 - 40.8 kg (45-90 lb): 2.4 mL	*PYOspot®* Directions: 1 pipette weekly Do not bathe during 2 days before and 2 days after application. Brush application site 24 hours after applying to remove product residue.
Essential fatty acids from hemp seed oil (mousse)	Labeled for dogs, cats, and small mammals	OTC; 150 mL	*Essential 6®* Soap-free and rinse-free. Shake before use.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Essential fatty acids from soybean oil (balm)	Labeled for dogs	OTC; 1.67 oz jar	*BIO BALM®* Occlusive and water-resistant
Essential fatty acids from hemp seed oil (wipes)	Labeled for dogs and cats	OTC; pack of 20 wipes	*PYOClean®* Soap-free and alcohol-free
Essential fatty acids from safflower oil (spray)	Labeled for dogs, cats, and horses	OTC; 8 oz, 12 oz, and 1 gallon	*Dermallay®* Soap-free, oatmeal spray conditioner

Human-Labeled Products

NOTE: Several human over-the-counter products are available in the United States but may contain additional ingredients and generally are not used in dogs and cats.

Lidocaine/Lidocaine Combinations, Topical

(***lye***-doe-kane)

For systemic use of lidocaine, please refer to ***Lidocaine (Intravenous; Systemic)****. For local anesthetic use, please refer to* ***Lidocaine, Local Anesthetic****.*

Indications/Actions

Lidocaine is used topically as a dermal anesthetic or antipruritic. It is included in several products used for acute moist dermatitis, pruritic lesions, and painful skin conditions. When combined with prilocaine, it may provide dermal anesthesia before painful or invasive procedures such as catheter placements.

Lidocaine exerts its anesthetic properties by altering sodium ion permeability across the cell membrane, thereby inhibiting conduction from sensory nerves.

Suggested Dosages/Uses

Lidocaine can be applied in a thin layer every 3 to 4 hours as needed. For veterinary-labeled products, refer to the specific product label for details on use.

Precautions/Adverse Effects

Although topical lidocaine may be absorbed systemically, systemic toxicity is unlikely. Applying to a significant percentage of body area, using for prolonged times, using high concentrations, applying to irritated or broken skin, or covering the application site may increase the risk for systemic absorption and subsequent toxicity. Use with caution in patients receiving Class-I antiarrhythmics such as systemic lidocaine or mexiletine. Patches can cause serious adverse effects if chewed.[1]

Possible adverse effects include hypersensitivity reactions or skin irritation such as burning or tenderness. Products containing prilocaine may be more likely to cause methemoglobinemia or systemic toxicity; however, these effects occur rarely.[2] Some products may also contain antiseptics, such as chlorhexidine and povidone-iodine.

Wear gloves when applying and wash hands after handling. Avoid contact with eyes. Do not use in ears unless the product is explicitly labeled for otic use.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Lidocaine 2.4% (spray)	Labeled for dogs and horses	OTC; 2 oz	*Silver L®; BioCalm®*
Lidocaine 2.4%, benzalkonium chloride 0.1% (spray)	Labeled for dogs	OTC; 4 oz	*Allercaine® with Bittran® II*
Lidocaine 2.46%, benzalkonium chloride 0.2% (spray)	Labeled for dogs, cats, and horses	OTC; 4 oz	*Hexa-Caine®*
Lidocaine 0.5%, chlorhexidine 0.2% (solution)	Labeled for dogs, cats, and horses	OTC; 4 oz	*Dermachlor Flush Plus®* These products may no longer be commercially available.
Lidocaine 2%, povidone-iodine 2% (solution)	Labeled for dogs, cats, and horses	OTC; 16 oz	*Barrier® II*

Human-Labeled Products

Phytosphingosine, Topical

(fye-tos-***fin***-goh-seen)

Indications/Actions

Phytosphingosine products are indicated for localized and generalized inflammatory conditions of the skin associated with pruritus and dryness, including allergic diseases such as atopic dermatitis. Some products are also indicated for use as a liquid wound dressing for localized inflammation and after surgery (could be sprayed on sutures). Some products are marketed for seborrheic conditions. There is some evidence supporting the role of phytosphingosine on skin barrier restoration in dogs.[1]

Phytosphingosine acts as a ceramide precursor, and it is a salient molecule in the natural defense mechanism of the skin. Ceramides comprise 40% to 50% of the main lipids responsible for maintaining the cohesion of the stratum corneum. Therefore, ceramides are essential for restoring the skin lipid barrier, controlling local flora, and maintaining the correct moisture balance. Phytosphingosine is also anti-inflammatory; it has anti-IL-1 activity, impairing the production of PGE2, and it inhibits kinase protein C.

Suggested Dosages/Uses

Phytosphingosine spray should be applied every 3 days for 2 to 3 weeks.[2] Gel should be applied once daily as needed for itching relief.[3] Mousse should be applied to dry hair and should be used every 3 days for 2 to 3 weeks.[4] Shampoo should be used 2 to 3 times weekly for 1 to 2 weeks.[5] Leave the shampoo in contact with the skin for at least 5 to 10 minutes before rinsing well. Shake products well before use. Refer to specific product label for details on use.

Precautions/Adverse Effects

Discontinue use if skin redness or irritation occurs. Avoid contact with the eyes.

Veterinary-Labeled Products

NOTE: *Be aware when selecting products that different combinations of active ingredients may be marketed under similar trade names. For products containing other active ingredients, including* ***Chlorhexidine, Topical*** *and* ***Pramoxine, Topical****, please refer to their respective monographs.*

For the complete list of references, see **wiley.com/go/budde/plumb**

Pramoxine, Topical

(pra-***moks***-een)

Indications/Actions

Pramoxine is a topical anesthetic that is often combined with other topical medications to temporarily reduce pain and itching.

Pramoxine affects peripheral nerves and has been shown to antagonize histamine-mediated pruritus; however, the mechanism of action is unknown. Pramoxine is not structurally related to procaine-type anesthetics. Peak local anesthetic effects occur within 3 to 5 minutes of application.

Suggested Dosages/Uses

Pramoxine sprays are typically labeled for daily use as needed. Shampoos are typically labeled for use up to 2 to 3 times weekly and may be used as often as once daily. Allow shampoo to remain in contact with the skin for at least 5 to 10 minutes before rinsing well. Mousse products are labeled for use every 3 days and should be applied to dry hair, massaged in, and left to air dry. Rinses may be applied daily to once weekly, separately or after baths. Ointment is labeled for use every other day. Labeled doses may differ based on active ingredient combinations; refer to specific product labels for detailed use instructions.

Precautions/Adverse Effects

Avoid contact with eyes; pramoxine is too irritating for ophthalmic use. Wear gloves when applying or wash hands after application. Adverse effects are uncommon; however, localized dermatitis is possible. Discontinue use if redness, irritation, swelling, or pain occurs or increases with use.

Pramoxine shows an antagonizing impact on histamine-mediated pruritus. Therefore, at least a 2-week withdrawal period before intradermal testing is recommended.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information

Pramoxine HCl 1% (wipes)	OTC; 30 count	generic

Zinc Gluconate (Neutralized), Topical

*For otic use, see **Cleaning/Drying Otic Agents**.*

Indications/Actions

Zinc gluconate can be used as a sole agent for mild pruritus or as an adjunct treatment for moderate to severe pruritic conditions, mild bacterial infections, or dry skin. It can also be used for minor skin irritations, such as insect bite reactions, acute moist dermatitis, acral lick dermatitis, fold dermatitis (intertrigo), feline acne, and postsurgical wounds.

The exact mechanism of action of topical zinc is unknown. Zinc plays a role in extracellular matrix remodeling, wound healing, connective tissue repair, inflammation, and cell proliferation. Zinc also has antiseptic and astringent properties.

Suggested Dosages/Uses

Zinc gluconate may be applied to affected areas as needed up to twice daily to relieve itching and soothe the skin. For veterinary products, refer to specific product label for details on use. Do not let animals lick or chew at affected areas for at least 20 to 30 minutes after application.

Precautions/Adverse Effects

Avoid contact with eyes and mucous membranes.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Zinc gluconate (spray)	Labeled for dogs, cats, horses, and some exotic pets	OTC; 2 oz, 4 oz	*Maxi/Guard® Zn7 Derm*
Zinc gluconate (gel)	Labeled for dogs, cats, horses, and some exotic pets	OTC; 1 oz, 2 oz	*Maxi/Guard® Zn7 Derm*

Human-Labeled Products

There are a variety of human-labeled OTC zinc gluconate products, some in combination with other active ingredients.

Antimicrobial Agents, Topical

Antibacterial Agents, Topical

See also:
Sulfur, Precipitated, Topical (Keratolytic Agents)

Bacitracin, Topical

(bass-ih-***trase***-in)

Antibiotic

For ophthalmic use, see ***Triple Antibiotic Ophthalmic***.

Indications/Actions

Bacitracin is used topically to treat and prevent infection after dermal lacerations, scrapes, minor burns, and surgical procedures. Bacitracin acts by inhibiting cell wall synthesis of susceptible bacteria by preventing the formation of peptidoglycan chains. It is either bactericidal or bacteriostatic, depending on drug concentration and bacterial susceptibility. Bacitracin is primarily active against gram-positive bacteria, but *Staphylococcus* spp are becoming increasingly resistant; therefore, bacitracin ideally should be used only after confirmation of bacterial skin infections in dogs and cats. Bacitracin activity is not impaired by blood, pus, necrotic tissue, or large inocula.

Suggested Dosages/Uses

Bacitracin may be applied up to 3 times daily and be covered by a suitable dressing. Administration of bacitracin is usually not recommended to continue for more than 1 week.

Precautions/Adverse Effects

Bacitracin topical ointment should not be used in or around the eyes, for the treatment of ulcerated lesions, chronic canine dermatoses, or in patients that are known to be hypersensitive to it. There have been reports of cats developing fatal anaphylactic reactions after administration of triple-antibiotic ophthalmic ointment containing bacitracin.[1] Bacitracin is also well documented as causing allergic contact dermatitis after topical administration in humans with the potential for anaphylaxis.[2] Deep puncture wounds, animal bites, or deep cutaneous infections may require systemic antibiotic therapy. Although topical administration generally results in negligible systemic levels, if bacitracin is used over large areas of the body or on serious burns or puncture wounds, measurable absorption and potential toxicity may occur. Do not let animal lick or chew at affected areas for at least 20 to 30 minutes after application. Pet owners should wash their hands after application.

Veterinary-Labeled Products

None

Human-Labeled Products

Bacitracin ointment is available alone as 500 units/g in various tube sizes. There are many OTC human products available with various combinations of antibiotics. Some products may also contain pramoxine hydrochloride for soothing and pain relief.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Bacitracin zinc 500 units/g (ointment) Other ingredients (depending on the manufacturer): white petrolatum, mineral oil	OTC; 14 g, 14.2 g, 28 g, 28.4 g, and 120 g tubes; 454 g jar	generic
Bacitracin zinc 500 units/g, polymyxin B sulfate 10,000 units/g (ointment)	OTC; 28.3g tube	*Polysporin*®
Bacitracin zinc 400 units/g, neomycin 3.5 mg/g, polymyxin B sulfate 5000 units/g (ointment)	OTC; 14.2g, 28.3g tube	*Neosporin*®; generic

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Benzoyl Peroxide, Topical

(ben-***zoyl*** per-***oks***-ide)

Antibacterial

Indications/Actions

Benzoyl peroxide products are available as gels, shampoos, or cream rinses for topical use. Shampoos are generally used for oily dermatoses (eg, seborrhea oleosa), superficial and deep pyodermas, and furunculosis. Benzoyl peroxide shampoos can also be used as adjunctive therapy for generalized demodicosis and schnauzer comedo syndrome. Gels may be useful for treating localized superficial and deep pyodermas, chin acne, fold pyodermas, and localized lesions caused by *Demodex* spp.

Benzoyl peroxide is an antibacterial agent with comedolytic ("follicular flushing"), keratolytic,[1] and antiseborrheic actions. It also has some mild antipruritic activity and wound healing effects. Benzoyl peroxide is lipophilic and penetrates into the stratum corneum, where it

is converted to benzoic acid. The antibacterial activity of benzoyl peroxide is due to free radical formation that oxidizes bacterial proteins.[2]

Suggested Dosages/Uses

Gels are commonly administered once to twice daily; shampoos may be used anywhere from once daily to once weekly. Shampoos should remain in contact with the skin for 5 to 10 minutes before rinsing well. For veterinary products, refer to the product label for details on use.

Precautions/Adverse Effects

Avoid contact with the eyes or mucous membranes. Benzoyl peroxide will bleach colored fabrics, jewelry, clothing, or carpets and might bleach the animal's haircoat. Owners should be advised to keep treated animals away from fabrics during treatment. Do not let the animal lick or chew at treated areas for a few minutes after application.

In some animals, benzoyl peroxide can be drying or irritating. Adverse effects can include erythema, pruritus, or pain at the treated site, particularly when higher concentrations (greater than 5%) are used. Reducing the frequency of use, applying emollients after bathing, or using shampoos with moisturizing microvesicles may alleviate or prevent these effects. Benzoyl peroxide causes photosensitivity in humans.[3] Limit sun exposure for dogs with light or thin coats. **NOTE:** Benzoyl peroxide shampoos do not lather well.

Veterinary-Labeled Products

CREAM RINSE

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Benzoyl peroxide 2.5%	Labeled for dogs and cats	OTC; 12 oz	generic

GEL

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Benzoyl peroxide 5% Other ingredients: propylene glycol, docusate sodium, DMDM hydantoin	Labeled for dogs and cats	OTC; 30 g bottle	*Micro BP*

SHAMPOOS

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Benzoyl peroxide 2.5% Other ingredients: *Novasome*® microvesicles	Labeled for dogs and cats	OTC; 12 oz, 1 gallon	*Micro-Pearls Advantage Benzoyl-Plus*®
Benzoyl peroxide 2.5%	Labeled for dogs and cats	OTC; 12 oz, 1 gallon	generic
Benzoyl peroxide 2.5% Other ingredients: glycolic acid 1%	Labeled for dogs and cats	OTC; 8 oz	*GlycoBenz*®
Benzoyl peroxide 2.5%, salicylic acid 1%, sulfur 1% (shampoo)	Labeled for dogs and cats	OTC; 12 oz	*Sulfur Benz*®
Benzoyl peroxide 2.5%, sulfur 2%	Labeled for dogs and cats	OTC; 16 oz	generic
Benzoyl peroxide 3%	Labeled for dogs and cats	OTC; 16 oz, 1 gallon	*BPO-3*®
Benzoyl peroxide 3%, salicylic acid 2%, sulfur 2%	Labeled for dogs and cats	OTC; 8 oz, 12 oz, and 16 oz	*Oxibenz-3*®*; Peroxiderm*®*;* generic

Human-Labeled Products

There are many human products available that contain benzoyl peroxide (2.5% to 10%); however, with the possible exception of the 5% gel products, the veterinary formulations would be more suitable for dogs or cats. Benzoyl peroxide 5% gel can be labeled as either Rx or OTC, depending on the product, and are available as generics or with the following trade names: *Benzac*®, *Desquam-X*®, or *PanOxyl*®.

For the complete list of references, see **wiley.com/go/budde/plumb**

Clindamycin, Topical

(klin-da-***mye***-sin) *Cleocin*®, *ClinzGard*®

For systemic use, see ***Clindamycin****.*

Indications/Actions

Topical clindamycin may be used for treating feline acne or other localized skin infections caused by bacteria susceptible to it. It has been recommended by some veterinary dermatologists that topical clindamycin only be used when other topical antibiotics, such as gentamicin,

have failed. Ideally, treatment should be based on culture and susceptibility results. Clindamycin is a lincosamide antibiotic and inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. Its primary activity is against anaerobic and gram-positive aerobic bacteria. For more information on clindamycin pharmacology, see ***Clindamycin***.

Suggested Dosages/Uses

When used for feline acne, topical clindamycin is generally applied in a thin film once to twice daily. *ClinzGard®* is used as a single dose application in bite and puncture wounds, surgical incisions, and anal sacs after cleaning and debridement (when applicable).

Precautions/Adverse Effects

In patients with a history of hypersensitivity to clindamycin or lincomycin, topical clindamycin should not be used. Avoid contact with eyes. Clients should wash their hands after application or wear gloves when applying. Contact reactions (pain, burning, erythema, itching, drying, peeling) are possible. Clindamycin lotions and gels may cause less burning than topical solutions or foams. Because clindamycin can be absorbed through the skin, systemic adverse effects are possible. Although clindamycin-related diarrhea and colitis are rare in animals, severe diarrhea, bloody diarrhea, and severe colitis have been reported in humans with topical use.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Clindamycin hydrochloride 1% (gel)	Labeled for dogs and cats	Rx; sterile 1 or 2 mL single-dose syringes (box with 4 units)	*ClinzGard®* Indicated for anal sac disease, tissue abscesses, bites, puncture wounds, and surgical incisions. Single-dose with a sustained release over 7 to 10 days. Must be applied to clean and debrided (if necessary) surfaces

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Clindamycin phosphate 1% (lotion)	Rx; 60 mL	*Clindamax®; Cleocin T®*; generic
Clindamycin phosphate 1% (gel)	Rx; 30 g, 60 g, 40 mL, and 75 mL	*Clindagel®; Clindamax®; Cleocin T®*; generic
Clindamycin phosphate 1% (solution)	Rx; 30 mL, 60 mL	*Cleocin T®*; generic
Clindamycin phosphate 1% (aerosol foam) Other ingredients: cetyl alcohol, ethanol 58%, stearyl alcohol, propylene glycol	Rx; 50 g, 100 g	*Evoclin®* Dispense into cap or onto a cool surface, then use fingertips to apply small amounts. Dispensing directly onto hands or affected area(s) will cause the foam to melt on contact. If the foam seems runny or warm, run canister under cold water.
Clindamycin phosphate 1% (pledgets) Other ingredients: isopropyl alcohol, propylene glycol	Rx; 60 per box/jar	*Cleocin T®; Clindacin®; Clindacin®-P; Clindets®*; generic

Gentamicin, Topical

(jen-ta-***mye***-sin)
For systemic use, see ***Gentamicin.***
For otic use, see ***Corticosteroid/Antimicrobial Agents, Otic.***

Indications/Actions

Topical gentamicin can be useful for treating both primary and secondary superficial bacterial skin infections caused by susceptible bacteria. Some products indicate prophylactic use after lacerations, abrasions, or after minor surgery; however, dermatologists recommend using topical gentamicin only to treat confirmed bacterial skin infections, as resistance may occur. Therefore, the use of gentamicin solely for the treatment of yeast and/or inflammation without evidence of bacterial infection should also be avoided. In small animal medicine, topical gentamicin is frequently used in combination with a corticosteroid (typically betamethasone or mometasone) to treat superficial lesions, including "hot spots" (acute moist dermatitis and pruritic lesions).

Some products containing betamethasone or mometasone and clotrimazole are labeled for otic use but can also be used extra-label for bacterial and yeast skin infections that are sensitive to gentamicin and clotrimazole when an anti-inflammatory effect is also desired. Formulations containing a corticosteroid are best suited for focal (eg, pedal) or multifocal lesions for relatively short durations (ie, less than 2 months). Initially, topical gentamicin/corticosteroid products are used 1 to 4 times daily until control is achieved, and then the frequency is tapered. Sole ingredient gentamicin sulfate topical forms are available with human labeling.

Gentamicin is an aminoglycoside antibiotic. It binds to the bacterial 30S ribosomal unit and inhibits protein synthesis. It has minimal activity against *Streptococcus* spp, variable activity against *Staphylococcus* spp, and good activity against gram-negative bacteria, including

Klebsiella spp, *Escherichia coli*, and some strains of *Pseudomonas* spp. Gentamicin-resistant strains of *Pseudomonas* spp are an ongoing issue.

Suggested Dosages/Uses

Topical gentamicin creams, ointments, or suspensions are generally applied to affected areas up to 4 times daily. Topical gentamicin/corticosteroid sprays are labeled for use 1 to 4 times daily for up to 7 days. Creams are typically used for infections associated with greasy skin, whereas ointments are typically used for infections associated with dry skin.

Precautions/Adverse Effects

Topical gentamicin may be systemically absorbed if it is used on ulcerated, burned, or denuded skin. Creams are more likely to be absorbed than are ointments; however, systemic toxicity is unlikely to occur unless gentamicin is applied to a significant percentage of body surface area or is used for prolonged times. Do not let the animal lick or chew at treated areas for at least 20 to 30 minutes after application.

Products that contain corticosteroids can cause HPA axis suppression with long-term or frequent use, cutaneous atrophy that can be associated with skin fragility, superficial follicular cysts (milia), reduced or lack of hair regrowth, and comedones. Risk can be reduced by only treating for as long as necessary on the smallest area possible. Mometasone is considered a "soft steroid", delivering its potent anti-inflammatory effect close to its site of action while reducing the degree of systemic exposure and thus limiting the associated systemic and local adverse effects. Nevertheless, care should be taken to avoid excessive or prolonged use. Residual activity may affect intradermal or serum allergy tests, and it has been suggested to discontinue use of corticosteroid-containing products 2 weeks before allergy testing.[1]

Avoid contact with eyes. Clients should wash their hands after application or wear gloves when applying.

Veterinary-Labeled Products

Refer to the individual product labeling for specific dosing recommendations and inactive ingredients.

NOTE: There are no topical gentamicin-only labeled veterinary products in the United States.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Gentamicin 3 mg/g, clotrimazole 10 mg/g, mometasone 1 mg/g (suspension)	Approved for otic use in dogs	Rx; 7.5 g, 15 g, 30 g, and 215 g tubes	*Mometamax®; Mometavet®* Extra-label when used topically in dogs and cats
Gentamicin 3 mg/mL, betamethasone 1 mg/mL (solution)	Approved for otic use in dogs and cats	Rx; 7.5 mL, 15 mL, 240 mL	*Vet Beta-gen®* Extra-label when used topically
Gentamicin 0.57 mg/mL, betamethasone 0.284 mg/mL (spray)	Approved for use in dogs	Rx; 15 g, 30 g, 60 mL, 72 mL, 120 mL, and 240 mL	*Betagen®; Gentacalm®; GentaSoothe®; GentaSpray®; GentaVed®; Gentocin®*
Gentamicin 3 mg/g, clotrimazole 10 mg/g, betamethasone 1 mg/g (ointment)	Approved for otic use in dogs	Rx; 7.5 g, 10 g, 15 g, 20 g, 25 g, 30 g, and 210 g bottles or tubes	*MalOtic®; Otomax®; Tri-Otic®; Vetromax®* Extra-label when used topically in dogs and cats

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Gentamicin 0.1% (cream and ointment)	Rx; 15g, 30 g tubes	generic

For the complete list of references, see **wiley.com/go/budde/plumb**

Honey, Topical

Topical Antibacterial Agent *HoneyCure®, Medihoney®*

Indications/Actions

Honey is a natural product that is generally made from flower nectar by honey bees. Honey is composed of over 200 biologically active compounds, including sugars, proteins, vitamins, minerals, phenols, and plant- and bee-derived enzymes. Medical-grade honey is honey that has been filtered to a higher level than food-grade honey and has been sterilized to kill, remove, or inactivate bacteria, fungi, protozoa, and spores. Medical-grade Manuka honey is commonly used for medicinal purposes and is produced by honey bees foraging only from flowers of the Manuka tree (*Leptospermum scoparium*) from Australia and New Zealand. Other monofloral (eg, honeydew, Scottish Heather) or regionally derived (eg, Saudi, Italian, Portugese) honeys have also been studied for potential medicinal purposes. Medical-grade honey can be used as an alternative or adjunctive therapy for many dermatologic conditions (eg, traumatic wounds, burn wounds) in animals.

Honey is considered to be an effective broad-spectrum topical antibacterial agent, and unlike traditional antibiotics, resistance to its killing

effects has not been reported.[1] Honey's antimicrobial properties have been attributed to its osmotic action and low pH (3.4 to 6.1) as well as to the presence of hydrogen peroxide. Additionally, Manuka honey also has nonperoxide bacteriostatic properties due to the presence of methylglyoxal (MGO), which may inhibit bacterial protein synthesis.[1–3] In vitro studies have shown honey to have potent antimicrobial effects against important skin microbes, including *Staphylococcus aureus*, *Staphylococcus pseudintermedius*, *Acinetobacter baumannii, and Escherichia coli,* in addition to antibiotic-resistant strains of bacteria such as methicillin-resistant *Staphylococcus aureus* (MRSA) and *Pseudomonas aeruginosa.*[3–8] It has also been demonstrated to be effective against fungal organisms such as *Malassezia pachydermatis and Candida albicans* and viruses.[7,9]

Suggested Dosages/Uses

NOTE: Ensure that enough honey is in full contact with the wound bed and that honey dressings extend to cover any areas of inflammation surrounding the wound. If a nonadherent dressing is used between the honey dressing and the wound bed, it must be sufficiently porous to allow the honey to diffuse through.

Honey gels, ointments, or creams: Clean and dry wound. Apply product directly to the affected skin, beyond wound edges, as a thin layer once daily or more often according to the severity of the treated wounds or lesions. Cover with bandage if needed.

Honey dressings: Commercially available honey-impregnated dressings facilitate the application of honey to wounds, especially those that need to be maintained in place or protected longer. Alternatively, honey dressings may be prepared in the clinic by applying medical-grade honey to a clean, dry dressing (eg, sterile gauze pad, adhesive bandage); apply the dressing to the skin, then apply a suitable secondary dressing, such as a semi-occlusive dressing, to prevent leakage of honey. Replace the dressing when drainage from the wound saturates the dressing. Change the dressings frequently enough to prevent the honey from being washed away or excessively diluted by wound exudate. The frequency of dressing change will vary but the typical interval is every 2 to 3 days. As the wound heals, the dressing changes will likely be less frequent. When using honey to debride hard eschar, softening the eschar by soaking with saline will allow better penetration of the honey. Owners may be instructed on how to replace the dressings so that it can be done at home.

Precautions/Adverse Effects

Honey is safe when applied to healthy skin and wounds. Although it is safe if ingested, if applying honey without a bandage, do not let the animal lick or chew affected areas for at least 20 to 30 minutes to prevent removing the honey from the treated area(s). An Elizabethan collar may be helpful. Do not use honey to control heavy bleeding, in third-degree burns, and in patients with known sensitivity to honey. Honey may crystalize, making it difficult to use. If crystalized, gently warm the honey, mix it well, and allow it to cool before use. Honey applied directly to the skin (instead of the bandage) may be "messy" (eg, ooze or leak from or around application site).

Veterinary-Labeled Products

Many different brands of medical-grade honey or medical-grade Manuka honey exist. Listed below are representative examples of products available. Refer to specific product labels for further details.

Active ingredients	Label status/sizes	Trade names; other information
Manuka honey	OTC; labeled for use on dogs; 1 oz and 2 oz tubes; 2 oz, 4 oz, 16 oz, 32 oz jars	*HoneyCure®*
Manuka honey 10%, *MicroSilver BG®* 0.1% (spray gel)	OTC; labeled for use on all animals; 8 oz bottle	*Silver Honey® Hot Spot and Wound Repair*; *Silver Honey® Rapid Wound Repair*
Manuka honey 11%, *MicroSilver BG®* 0.2% (ointment)	OTC; labeled for use on all animals; 2 oz tube	*Silver Honey® Hot Spot and Wound Repair*; *Silver Honey® Rapid Wound Repair*
Manuka honey 40% (gel)	OTC; labeled for use on large and small animals; 1.75 oz tube	*L-Mesitran®*
Untreated raw honey (cream)	OTC; labeled for use on horses; 190 mL jar	*HoneyHeel®*

Human-Labeled Products

Many different brands of medical-grade honey or medical-grade Manuka honey exist. Listed below are representative examples of products available. Refer to specific product label for further details.

Active ingredients	Label status/sizes	Trade names; other information
Manuka honey 30% (cream)	OTC; 0.5 oz tube	*First Honey®*
Manuka honey 63% impregnated hydrogel colloidal sheet (nonadhesive dressing)	OTC; 2.4" x 2.4" and 8" x 12" sheets of 1/pack, 10/pack	*MediHoney® HCS*
Manuka honey 80% (gel)	OTC; 1.5 oz tube	*MediHoney®*
Manuka honey 100% (adhesive dressing)	OTC; 1" x 3.25" adhesive dressings of 12/box, 3" x 4" adhesive dressings of 6/box	*FirstHoney®*
Manuka honey 100% (gel)	OTC; 0.5 oz and 1.5 tubes. Single-use, 10/box or individual tube	*TheraHoney®*

Active ingredients	Label status/sizes	Trade names; other information
Manuka honey 100% (hydrocolloid paste)	OTC; 0.5 oz, 1.5 oz, and 3.5 oz tubes. 1/pack, 4/pack, 10/pack, 12/pack	*MediHoney®*
Manuka honey 100% (ointment)	OTC; 0.5 oz tube	*First Honey®*
Manuka honey 100% (impregnated in calcium alginate pads)	OTC; single-use sheets: 2" x 2", 4" x 5", and ¾" x 12" sheets of 1/pack, 5/pack, 10/pack, and 100/case	*MediHoney® Calcium Alginate Dressing* Calcium alginate provides wound fluid absorption capabilities.
Manuka honey 100% (impregnated in sheets [nonadhesive dressing])	OTC; single-use sheets; can be cut to fit within the wound edges. 2" x 2", 4" x 5" sheets of 10/box; rope: 1" x 12"; 4" x 4" flexible foams of 10/box	*TheraHoney®; TheraHoney® HD; TheraHoney® Foam Flex*

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Mupirocin, Topical

Pseudomonic Acid A

(myoo-***pye***-roe-sin)

Indications/Actions

Mupirocin is FDA-approved for the treatment of bacterial skin infections in dogs caused by susceptible strains of *Staphylococcus aureus* or *Staphylococcus pseudintermedius,* including beta-lactamase producing and methicillin-resistant strains. Mupirocin can be used to treat superficial pyoderma, fold pyoderma, interdigital cysts, draining tracts, acne, and pressure point pyodermas. It may also be used in other species for conditions such as feline acne or equine pyoderma.

Mupirocin also has activity against other gram-positive pathogens, including strains of *Corynebacterium* spp, *Clostridium* spp, *Proteus* spp, and *Actinomyces* spp., Although it has activity against some gram-negative bacteria, it is not used clinically for gram-negative infections. *Pseudomonas* spp is particularly resistant to mupirocin. Mupirocin has anecdotally been reported to have some effect against Malassezia spp in dogs and cats.

Mupirocin is an antibiotic isolated from the bacterium *Pseudomonas fluorescens*. It is unique in that it belongs to the monocarboxylic acid class and is structurally related to other commercially available antibiotics. Pseudomonic acid A represents 90% to 95% of the mixture and is the main compound of mupirocin. It acts by inhibiting bacterial protein synthesis by binding and inhibiting bacterial isoleucyl transfer-RNA synthetase. It is bacteriostatic at low concentrations or bactericidal at high concentrations. While bacterial resistance is rare in animals, resistant strains of *Staphylococcus* spp have been identified. Resistance transference is thought to be plasmid-mediated and thought to occur more frequently when mupirocin is used on large areas of the skin for prolonged durations. Therefore, mupirocin may be best suited for short-term treatment on small, localized areas. Cross-resistance with other antimicrobials has not been identified. Because this antibiotic is a salient treatment used in humans with resistant infections, its use should be limited to select or resistant cases in veterinary patients.

Mupirocin is not significantly absorbed through the skin into the systemic circulation but does penetrate well into granulomatous and deep pyoderma lesions. It is not suitable for application to burns.

Suggested Dosages/Uses

After cleansing the lesion, mupirocin should be applied to completely cover the affected area. It is labeled for twice daily application on dogs. It requires 10 minutes of contact time to be active. The maximum duration of treatment is 30 days.[1]

In cats with chin acne, once- to twice-daily applications have been shown to be effective for treating secondary infections.[2]

Precautions/Adverse Effects

Mupirocin is contraindicated in patients with a history of hypersensitive reactions to it or other ointments containing polyethylene glycol. Use veterinary labeled products with caution on extensive deep lesions due to risk for nephrotoxicity from absorption of large quantities of polyethylene glycol.[1] Do not let animals lick or chew treated areas for at least 20 to 30 minutes after application. Avoid contact with eyes; not for ophthalmic use.

Mupirocin is typically well tolerated. Contact reactions such as pain, erythema, and itching are possible. Overgrowth of non-susceptible organisms (superinfection) is also possible with prolonged use.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Mupirocin 2% (ointment)	Labeled for use on dogs	Rx; 15 g, 22 g	*Muricin®;* generic

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Mupirocin 2% (ointment)	Rx; 1 g, 15 g, 22 g, and 30 g	*Bactroban®; Centany®;* generic
Mupirocin 2% (cream)	Rx; 15 g, 30 g	*Bactroban®;* generic

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Nitrofurazone, Topical

(nye-troe-***fur***-ah-zone) *Furazone®*

Indications/Actions

Nitrofurazone is FDA-approved for prevention or treatment of surface bacterial infections of wounds, burns, and cutaneous ulcers in dogs and horses; some products are also approved for cats.[1] It is a synthetic nitrofuran with a broad-antibacterial spectrum. Nitrofurazone is bactericidal against many bacteria involved in surface infections, including gram-positive (eg, *Staphylococcus aureus*, *Streptococcus* spp) and gram-negative (eg, *Escherichia coli*) bacteria; however, evidence supporting clinical efficacy is unavailable. Nitrofurazone has also anecdotally been used for the adjunctive treatment of myiasis.

The mechanism of action of nitrofurazone is thought to be associated with inhibiting bacterial enzymes that primarily degrade glucose and pyruvate.

Suggested Dosages/Uses

Nitrofurazone ointment should be applied directly to the affected area with a spatula or placed on gauze that is then applied to the lesion.[1] Dressing may be changed several times a day or left in place for longer periods of time, but the ointment should remain in contact with the lesion for at least 24 hours. Nitrofurazone powder should be applied to the affected areas daily to several times per day.[2] Refer to specific product labels for details on use.

Precautions/Adverse Effects

Nitrofurazone has been shown to cause mammary tumors when fed in high doses to rats and ovarian tumors in mice. **Federal law prohibits the use of nitrofurazone products in or on food animals, including horses intended to be used for food**. Wear gloves and wash hands after applying.

Ointments may contain polyethylene glycols. If used on large areas of denuded skin, significant amounts of polyethylene glycol could be absorbed, which can cause nephrotoxicity.[3] Avoid contact with eyes and mucous membranes. Do not allow animals to lick or chew treated areas for at least 30 minutes. Avoid exposing products to sunlight, strong fluorescent lighting, excessive heat, or alkaline materials.

Topical nitrofurazone is typically well tolerated. Hypersensitivity reactions and skin reactions, including pain, erythema, and itching, are possible but uncommon. Discontinue use of this product if redness, irritation, or swelling persists or increases. Overgrowth of nonsusceptible organisms (superinfection) is also possible with the prolonged use of nitrofurazone.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Nitrofurazone 0.2% (ointment)	Labeled for dogs, cats, and horses	OTC; 1 lb jars	*Fura-Septin®; NFZ® Wound Dressing;* generic
Nitrofurazone 0.2% (ointment)	Labeled for horses	OTC; 1 lb jars	*Fura-Zone®*
Nitrofurazone 0.2% (powder)	Labeled for dogs, cats, and horses	OTC; 45 g	*NFZ® Puffer;* generic Shake or rotate to loosen powder. Restricted drug in California

Human-Labeled Products

None. Nitrofurazone products are no longer available for humans in the United States.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Silver Sulfadiazine, Topical

(***sil***-ver sul-fa-***dye***-ah-zeen)

Indications/Actions

Silver sulfadiazine (SSD) is used in veterinary medicine to treat localized bacterial skin infections, particularly those caused by *Pseudomonas* spp. In humans, topical SSD is labeled for prophylaxis and treatment of second- and third-degree burns.

SSD has extensive antimicrobial activity. It is bactericidal against many gram-positive and gram-negative bacteria and is also effective against yeasts. SSD disrupts microbial cell membranes and cell walls; this differs from the antibacterial actions of silver nitrate or sodium sulfadiazine. It can enhance epithelization but can impair granulation.

Suggested Dosages/Uses

For burns, silver sulfadiazine (SSD) is applied once to twice daily at a thickness of ≈1/16th of an inch (1 to 2 mm). Dressings may be applied over the cream. For localized bacterial infections, once- to twice-daily application is recommended. Apply to affected area(s) and massage the cream into the skin.

Precautions/Adverse Effects

Use with caution in patients that are hypersensitive to sulfonamides, as they may also react to silver sulfadiazine (SSD). Patients with significant hepatic or renal dysfunction have increased risk for drug accumulation, particularly when used over large areas. Because SSD can impair

granulation, avoid use in non-granulated wounds. Avoid contact with eyes. Wear gloves or wash hands after applying. Do not let animals lick or chew at affected areas for at least 20 to 30 minutes after application.

Adverse effects of systemic sulfonamides are possible, such as blood dyscrasias and keratoconjunctivitis sicca (KCS). Use over large areas or use for extended durations can increase the risk for systemic adverse effects. Refer to ***Sulfa-/Trimethoprim*** for more information. In humans, transient leukopenia has been reported with SSD treatment. However, leukocyte normalization occurs even with continuation of therapy. Other uncommon adverse effects in humans include skin necrosis, erythema multiforme, skin discoloration, rashes, and interstitial nephritis.

Veterinary-Labeled Products

There are no topical SSD products labeled for veterinary patients. An otic preparation (*Baytril® Otic*) contains silver sulfadiazine (SSD). See ***Antibacterials, Otic*** for more information.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Silver sulfadiazine 1%, enrofloxacin 0.5% (emulsion)	Labeled for otic use in dogs	Rx; 15 mL, 30 mL	*Baytril®* Extra-label when used topically

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Silver sulfadiazine 1% (cream)	Rx; 20 g, 25 g, 50 g, 85 g, 400 g, and 1000 g	*Silvadene®; SSD®; Thermazene®*

Antifungal Agents, Topical

Clotrimazole, Topical

(kloe-***trye***-ma-zole) *Lotrimin®*

For otic products containing clotrimazole, see ***Corticosteroid/Antimicrobial Agents, Otic.***

Indications/Actions

Topical clotrimazole has activity against dermatophytes and yeasts; it may be useful for localized lesions associated with *Malassezia* spp. There is limited information regarding its efficacy for the treatment of dermatophytosis in cats and dogs. Most veterinary clotrimazole products also contain gentamicin and a glucocorticoid and are labeled for otic use; these products may be used in an extra-label manner for bacterial and yeast skin infections with concurrent inflamed, pruritic skin.

Intranasal instillation of clotrimazole via sinus trephination or direct frontal sinuscopy may also be used for the treatment of sinonasal aspergillosis in dogs, with or without systemic antifungal therapy.[1–3]

Clotrimazole is an imidazole antifungal that inhibits the biosynthesis of ergosterol, a component of fungal cell membranes, leading to increased membrane permeability and probable disruption of membrane enzyme systems.

Suggested Dosages/Uses

If sprays are prescribed, twice-daily applications are usually recommended. Ointments are generally applied to affected areas up to 4 times daily. For veterinary products, refer to the product label for details on individual use.

Precautions/Adverse Effects

Avoid contact with eyes and mucous membranes. Clients should wash their hands after application or wear gloves when applying. Skin irritation is possible but unlikely to occur with products containing only clotrimazole. Avoid contact with eyes. Do not allow the animal to lick or chew at affected sites for at least 20 to 30 minutes after application.

Cribriform plate damage has historically been suggested as a contraindication for topical antifungal treatment for sinonasal aspergillosis; however, small retrospective reviews of dogs with cribriform plate lysis cases found no neurologic adverse effects following infusion of clotrimazole 1% into the frontal sinuses.[4,5]

Products containing clotrimazole in combination with a glucocorticoid (eg, betamethasone):

Several veterinary topical products list pregnancy as a contraindication. Systemic glucocorticoids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash their hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow the animal to lick or chew at affected sites for at least 20 to 30 minutes after application. Residual activity from glucocorticoids may affect intradermal or serum allergy tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Use care when treating large areas or when using on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. When higher concentrations of glucocorticoids are used or with longer durations of therapy (ie, longer than 7 days), there is an increased risk for HPA axis suppression, systemic glucocorticoid effects (eg, polydipsia, polyuria, polyphagia), skin changes (eg, atrophy, skin fragility, alopecia, localized pyoderma, comedones), and delayed wound healing. Vomiting and diarrhea have been reported with the use of products containing betamethasone. Local skin reactions (burning, itching, redness) are possible but unlikely to occur.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Clotrimazole 1% (ointment) Other ingredients: bentonite, jojoba oil, magnesium oxide, peppermint oil, silver oxide, tea tree oil, white wax, zinc oxide	Not specified	OTC, not FDA approved; 100 g	*Aardora*®
Clotrimazole 1% (solution)	Labeled for dogs and cats	OTC, not FDA approved or Rx; 30 mL	*ClotrimaTop*®
Clotrimazole 1% (spray or dropper) Other ingredients: propylene glycol, SD alcohol 40, benzoyl alcohol, chloroxylenol	Labeled for dogs and cats	OTC, not FDA approved; 1 oz dropper, 2 oz spray	*Clotrimazole Antifungal*®

Human-Labeled Products

Enilconazole, Topical

(ee-nil-***kon***-a-zole) *Imaverol*®

Indications/Actions

Although no dosage forms are currently commercially available for topical use in the United States, compounded enilconazole is used topically for treating dermatophytosis in small animals and horses. In other countries, a commercially available topical rinse is available for canine, equine, and bovine species. The use of topical enilconazole on cats with dermatophytosis is somewhat controversial as no products are labeled for feline use; however, there are reports of successful use of enilconazole as a sole therapy or in combination with oral itraconazole for cats with dermatophytosis.

Intranasal instillation of enilconazole after plaque debridement has also been shown useful in treating nasal aspergillosis in small animal species.[1]

A poultry environmental disinfectant product (*Clinafarm EC*®) is available in the United States and has been used extra-label to treat dermatophytosis; however, as this product is regulated by the EPA, it is illegal to use it in a manner inconsistent with its labeling.

Enilconazole, like other azoles, inhibits the biosynthesis of ergosterol, an essential component of fungal cell membranes, leading to increased membrane permeability and allowing leakage of intracellular components.

Suggested Dosages/Uses

The commercial product should be diluted by adding 1 part of concentrated solution to 50 parts warm water, which yields a 2 mg/mL emulsion. Remove crusts with a hard brush that has been soaked in the diluted emulsion. It is highly recommended that the animal be sprayed entirely at the first treatment to reach subclinical lesions as well.

Dogs: Clip longhaired dogs prior to treatment, and wash with the diluted emulsion 4 times at 3 to 4 day intervals.[2] During application, the hair should be brushed thoroughly in the opposite direction of hair growth to make sure that the skin is thoroughly wet. Alternatively, dogs may be dipped in a bath of the diluted emulsion.[3]

Horses: The lesions and surrounding skin are to be washed with the diluted emulsion 4 times at 3 to 4 day intervals.[2]

Cattle: Wash with diluted emulsion or apply with a sprayer or high-pressure cleaning unit 3 to 4 times at 3-day intervals.[3]

Dispose of all unused diluted solutions. Refer to the product label for details on use.

Precautions/Adverse Effects

Avoid contact with eyes. Clients should wear gloves and eye protection when applying.

When enilconazole is used topically in cats, hypersalivation, vomiting, anorexia, weight loss, muscle weakness, and a slight increase in serum ALT levels have been reported.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Enilconazole 10% (concentrate)	Labeled for dogs and horses; also labeled for cattle in some countries	50 mL, 100 mL, 1 L	*Imaverol*®*; Austrazole*® Not available in the United States. Refer to specific product labels for withdrawal periods.

Human-Labeled Products
None

Ketoconazole, Topical

(kee-toe-***kah***-na-zole) *Nizoral®, KetoChlor®*
For systemic use, see ***Ketoconazole.***
For otic use, see ***Corticosteroid/Antimicrobial Agents, Otic.***

Indications/Actions
Topical ketoconazole has activity against dermatophytes and yeasts, and ketoconazole shampoos can be an effective treatment for *Malassezia* spp dermatitis and dermatophytosis; however, topical ketoconazole shampoos are generally ineffective or minimally effective when used alone for dermatophytosis. Patients with severe, generalized infections may require additional systemic therapy.

Ketoconazole, like other azoles, inhibits the biosynthesis of ergosterol, an essential component of fungal cell membranes, leading to increased membrane permeability and allowing leakage of intracellular components.

Suggested Dosages/Uses
Sprays and wipes should be applied 1 to 2 times daily. Shampoos and conditioners can be used daily to weekly. Shampoo should typically be left in contact with the skin for at least 10 minutes prior to rinsing; see specific product label for details.

Precautions/Adverse Effects
Avoid contact with eyes; skin irritation is possible. Clients should wash their hands after application or wear gloves when applying. Do not allow animals to chew or lick application site for at least 20 to 30 minutes after application.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Ketoconazole 1%, chlorhexidine 2%, TrisEDTA (spray)	Labeled for dogs and cats	OTC; 8 oz	*Mal-A-Ket® Plus*

Ketoconazole 2% (gel)	Rx; 45 g	*Xolegel®*

Lime Sulfur, Topical

(***lyme sul***-fur)

Indications/Actions

Lime sulfur is used as a generalized topical treatment for dermatophytosis. It is considered one of the most effective agents against *Microsporum canis.* In addition, it is efficacious for treatment of demodicosis in cats.[1] Lime sulfur can also be useful as an adjunctive treatment of *Malassezia* spp dermatitis, cheyletiellosis, chiggers, sarcoptic and notoedric mange, fur mites, lice, canine demodicosis, and sarcoptic mange, in addition to chorioptic mange in horses.

Lime sulfur has antibacterial and antifungal properties secondary to the formation of pentathionic acid and hydrogen sulfide after application. Lime sulfur may also have keratolytic, keratoplastic, antiparasitic, and antipruritic effects.

Suggested Dosages/Uses

Concentrated dips should be shaken well prior to use and must be diluted. Typically, 4 oz of concentrate should be diluted in 1 gallon of water, mixed well, and carefully applied to affected areas.[2] For chronic or resistant cases, 8 oz of concentrate may be diluted per gallon of water. Treatment may be repeated every 5 to 7 days. See specific product label for detailed dilution and application instructions. Do not rinse or blow-dry animals after application. Do not allow animals to ingest lime sulfur; apply a protective collar until dry if necessary to prevent ingestion.

When used for dermatophytosis, twice-weekly treatments have been recommended if tolerated.[3] Continue treatment until 2 consecutive negative cultures at weekly intervals are obtained.

For confirmed cases of feline surface demodicosis, applications are recommended every 5 to 7 days for a total of 6 treatments. For surface demodicosis treatment trials, 3 applications should be performed; if a significant improvement in clinical signs is noted, 3 more applications should be performed to complete treatment. If no significant improvement is seen after 3 applications, demodicosis should be ruled out and other diagnoses should be considered.

Precautions/Adverse Effects

Use caution when handling lime sulfur as adverse effects may occur after accidental dermal exposure, oral ingestion, or inhalation. Wear gloves and wash hands after handling. Avoid contact with eyes and mucous membranes; safety glasses are recommended.[2] Lime sulfur can stain porous surfaces such as concrete and porcelain and can permanently discolor jewelry. Lime sulfur should only be used in a well-ventilated area, or a respirator should be worn during application.

Lime sulfur is safe to use on pregnant and nursing animals and kittens/puppies over 2 to 3 weeks of age.

Lime sulfur may cause skin irritation or drying. Lime sulfur can temporarily stain light-colored fur and can rarely cause hair loss on the pinnae in cats. The odor of lime sulfur may persist on treated animals after application but is generally tolerable after drying. Oral ingestion can rarely cause nausea and oral ulcers, particularly in cats; an Elizabethan collar can help prevent ingestion from licking and grooming. Systemic toxicosis secondary to dermal exposure of lime sulfur has been reported after improper dilution of the concentrate.[4] Therefore, detailed dilution instructions are important for owners when recommending this therapy.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Lime sulfur 97.8% (dip)	Labeled for dogs, puppies, kittens, and cats; some products also labeled for horses	OTC; 4 oz, 16 oz, 1 gallon	*LimePlus®;* generic Shake well and dilute before use.

Miconazole, Topical

(mye-***kah***-nah-zole)

For ophthalmic use, see ***Miconazole Ophthalmic***

For otic use, see ***Antifungal Agents, Otic*** *and* ***Corticosteroid/Antimicrobial Agents, Otic***

Indications/Actions

Topical miconazole is used for the treatment of *Malassezia* spp dermatitis and infections caused by *Microsporum canis, Microsporum gypseum, and Trichophyton mentagrophytes*.[1] Lotions, sprays, and creams are generally used for localized lesions; patients with severe, generalized infections may require systemic antifungal therapy. Topical miconazole products are typically only minimally effective for dermatophytosis when used as a single agent; adjunctive systemic treatment is commonly required.

Miconazole is an imidazole antifungal with activity against dermatophytes and yeast. Its actions are a result of altering the permeability of fungal cellular membranes and interfering with peroxisomal and mitochondrial enzymes, leading to intracellular necrosis. Miconazole products are fungicidal with repeated application. Miconazole has been shown to be active against a series of gram-positive bacteria and to help repair the skin barrier function and mitigate some inflammatory cell reactions.[2]

Suggested Dosages/Uses

Sprays, creams, lotions, or wipes should be applied 1 to 2 times daily. Shampoos and conditioners may be used daily to weekly. Typically, shampoo should be left in contact with the skin for at least 10 minutes prior to rinsing. For veterinary products, refer to the specific product label for details on use.

Precautions/Adverse Effects

Avoid contact with eyes. Wash hands thoroughly after application to prevent the spread of fungal infections.[1] Do not allow treated animals to lick or chew at affected areas for at least 20 to 30 minutes after application.

Skin irritation is uncommon but possible. Wipes and sprays that contain alcohol may be severely irritating to inflamed, eroded, or ulcerated skin.

Veterinary-Labeled Products

NOTE: Miconazole nitrate is the salt generally used in pharmaceutical products. Some products express concentration as base, others express concentrations of the salt.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Miconazole 1% (spray)	Labeled for dogs and cats	Rx; 60 mL, 120 mL, 240 mL	*MicaVed®; Micazole®; Priconazole®; Conzol®*
Miconazole nitrate 2% (spray)	Labeled for dogs, cats, and horses	OTC; 4 oz, 16 oz	generic
Miconazole nitrate 2%, chlorhexidine 2% (spray)	Labeled for dogs, cats, and horses	Rx; 8 oz	*Malaseb®*
Miconazole nitrate 2%, chlorhexidine 2%, TrisEDTA (spray)	Labeled for dogs, cats, and horses	OTC; 8 oz, 12 oz, 32 oz	*MiconaHex+Triz®*
Miconazole nitrate 0.2%, chlorhexidine 0.2% (flush)	Labeled for dogs, cats, and horses	Rx; 4 oz, 12 oz	*Malaseb®*
Miconazole 0.1% (flush)	Labeled for dogs and cats	OTC; 4 oz, 16 oz	*BioTris®*

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information

Nystatin/Nystatin Combinations, Topical

(nye-***sta***-tin)

*For systemic use, see **Nystatin.***

Indications/Actions

Nystatin is typically used in combination with antibiotics and glucocorticoids in small animal medicine; it is generally not used as a single agent due to limited dosage forms and alternative antifungal agents. Combination products containing neomycin, thiostrepton, and triamcinolone are FDA-approved in dogs and cats for treatment of inflammatory dermatologic disorders, particularly associated with bacterial or *Candida albicans* infections.[1] Use for topical yeast infections without a bacterial component should be avoided to prevent antibiotic resistance.

Nystatin is active against many yeasts and yeast-like fungi, such as *Malassezia spp* and *Candida* spp. Nystatin binds to sterols in fungal cell membranes, thereby increasing membrane permeability and allowing leakage of intracellular components. Nystatin does not have activity against bacteria and is ineffective against other fungi.

Suggested Dosages/Uses

Although nystatin is rarely used as a single topical agent, human products can be used if needed. In humans, creams are preferred to ointments in intertriginous areas; topical powders are used for moist lesions.

After cleaning affected areas, nystatin combination products should be applied sparingly in a thin film. Frequency of application is based on severity of infection and may range from once daily to once weekly for mild infections and up to 2 to 3 times daily for severe infections.[1] Frequency can be decreased as infection improves. Products that contain triamcinolone are best suited for focal (eg, pedal) or multifocal

lesions that require relatively short treatment durations (eg, less than 2 months).

Precautions/Adverse Effects

Avoid empiric use of combination products or use in the absence of concurrent bacterial infection to help prevent bacterial resistance.

Avoid contact with eyes. Wear gloves or wash hands after application. Do not let the animal lick or chew at the treated area(s) for at least 20 to 30 minutes after application.

Topical nystatin is considered nontoxic and is generally well-tolerated, although hypersensitivity reactions are possible.[2] Potential adverse effects reported in humans include burning, itching, rash, and eczema.[3] The combination veterinary products are usually well-tolerated when used on the skin; however, neomycin can cause localized sensitivity, and glucocorticoids can potentially cause cutaneous atrophy or HPA-axis suppression.[1] At least a 2-week withdrawal period is recommended prior to intradermal or allergy serum testing for products containing corticosteroids, such as triamcinolone.[4]

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Nystatin 100,000 units/g, neomycin sulfate 2.5 mg/g, thiostrepton 2500 units/g, triamcinolone acetate 1 mg/g (cream)	Labeled for dogs and cats	Rx; 7.5 g, 15 g	*Animax®*
Nystatin 100,000 units/g, neomycin sulfate 2.5 mg/g, thiostrepton 2500 units/g, triamcinolone acetonide 1 mg/g (ointment)	Labeled for dogs and cats	Rx; 7.5 mL, 15 mL, 30 mL, and 240 mL	*Animax®; Quadritop®; Derma-Vet®; Dermalog®; Dermalone®; EnteDerm®*

Nystatin 100,000 units/g, triamcinolone acetate 1 mg/g (cream)	Rx; 15 g, 30 g, and 60 g	generic

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Selenium Sulfide, Topical

(si-***leen***-ee-um ***sul***-fide)

Indications/Actions

Selenium sulfide may be useful in dogs for treating seborrheic disorders (mainly for seborrhea oleosa) and for the adjunctive treatment of *Malassezia* dermatitis, particularly in dogs exhibiting signs of waxy, greasy, or scaly (seborrheic) dermatitis.

Selenium sulfide possesses antifungal and sporicidal activity, keratolytic, keratoplastic, and degreasing properties. It alters epidermal turnover in cells of the epidermis and follicular epithelium and interferes with hydrogen bond formation of keratin, thereby reducing corneocyte production. The antifungal mechanism of action of selenium sulfide is not well understood.

Suggested Dosages/Uses

Selenium sulfide shampooing frequency is patient dependent. In general, medicated shampoos should remain in contact with the skin for 10 minutes. Alternatively, allow 3 to 5 minutes of contact time, rinse thoroughly, and then repeat the procedure. Thoroughly rinse off the shampoo to prevent skin irritation and excessive drying.

Precautions/Adverse Effects

Selenium sulfide products should not be used on cats. Avoid contact with eyes and mucous membranes. Selenium sulfide can damage or discolor jewelry. Clients should wear gloves when using these products.

Selenium sulfide can be irritating, especially to the scrotal area. It can also cause excessive drying and hair-coat staining or discoloration. Do not use these products on broken or inflamed skin. After discontinuation, rebound seborrhea can occur and can be more severe than pretreatment presentation.

GI effects such as nausea, vomiting, or diarrhea may occur if selenium sulfide is ingested orally. Neurologic signs are possible if large quantities are ingested. In case of substantial oral ingestion, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Veterinary-Labeled Products

There are no veterinary labeled products containing selenium sulfide currently available in the United States; products may be available in

other countries.

Human-Labeled Products

Terbinafine, Topical

(ter-***bin***-a-feen)

For systemic use, see ***Terbinafine.***

For otic use, see ***Corticosteroid/Antimicrobial Agents, Otic.***

Indications/Actions

Terbinafine is an allylamine antifungal agent that may be useful for localized lesions associated with *Malassezia* infections. In an in vitro study, topical 1% terbinafine was shown to have good efficacy as adjuvant focal therapy against *Microsporum canis* with good residual activity.[1]

Terbinafine inhibits the biosynthesis of ergosterol by inhibiting the fungal squalene epoxidase enzyme. The resultant depletion of ergosterol within the fungal cell membrane and the intracellular accumulation of squalene are believed to be responsible for the fungicidal effect of terbinafine. It is fungicidal against dermatophytes but may only be fungistatic against yeast organisms.

Suggested Dosages/Uses

Topical terbinafine may be applied to skin areas affected with *Malassezia* once to twice a day. Based on in vitro data, less frequent application (ie, once daily to every other day) may be sufficient for adjuvant therapy of *M canis* skin infections due to the demonstrated residual activity of terbinafine.[1]

Precautions/Adverse Effects

Avoid contact with eyes and mucous membranes. Wash hands after application. Do not allow animals to lick or chew at the treated area(s) for at least 30 minutes after application.

Local irritation is possible, including burning, pruritis, or rash.

Veterinary-Labeled Products

None labeled for use on skin.

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Terbinafine hydrochloride 1% (cream)	OTC; 12 g, 15 g, 24 g, 30 g, 42 g	*Lamisil AT®;* generic
Terbinafine hydrochloride 1% (spray)	OTC; 125 mL	*Lamisil AT®*

Antiseptic Agents, Topical

Acetic Acid/Boric Acid, Topical

(ah-***see***-tik ***ass***-id; ***bor***-ik ***assi***-id)

For otic products, refer to ***Antiseptic Agents, Otic***

Indications/Actions

Acetic and boric acids are indicated for the topical treatment of skin infections caused by bacteria, including *Staphylococcus* spp,[1] *Pseudomonas* spp,[2,3] and yeast, such as *Malassezia* spp. They are also indicated for fold dermatitis, acute moist dermatitis, pododermatitis, and seborrhea oleosa.

Acetic and boric acids are potent antibacterial and antifungal agents with a rapid killing effect. They also possess ceruminolytic, keratolytic, keratoplastic, and astringent properties.

Some products also contain other antimicrobials, such as chlorhexidine and ketoconazole, or anti-inflammatory agents, such as hydrocortisone for anti-pruritic effects.

Suggested Uses/Dosages

Sprays and wipes may be applied up to 2 to 3 times a day. Shampoos and conditioners can be used daily to weekly, during or after routine

bathing. Leave shampoos in contact with the skin for at least 10 minutes prior to rinsing. Refer to the product label for specific instructions.

Acetic acid and boric acid topical products have concentrations ranging from 1% to 2% for each acid. One study found that acetic acid and boric acid concentrations as low as 0.5% have bactericidal effects against *Staphylococcus pseudintermedius* in vitro.[1]

Precautions/Adverse Effects

Skin redness and irritation may occur. Do not let the animal lick or chew at affected areas for at least 20 to 30 minutes after application. For products that also contain hydrocortisone, caution should be used to avoid excessive or frequent use due to its potential cutaneous and systemic adverse effects.

Veterinary-Labeled Products

SHAMPOOS

Acetic acid 2%, boric acid 2%	Labeled for dogs, cats, and horses	OTC; 12 oz, 16 oz, and 1 gallon	*MalAcetic®*
Ketoconazole 0.15%, hydrocortisone 1%, acetic acid 1%, boric acid 2% Other ingredients: ceramide complex	Labeled for dogs, cats, and horses	OTC; 8 oz	*MalAcetic® ULTRA*
Ketoconazole 1%, acetic acid 2%, chlorhexidine 2%	Labeled for dogs, cats, and horses	OTC; 8 oz and 1 gallon	*Mal-A-Ket®*
Ketoconazole 1%, acetic acid 2%, chlorhexidine 2%		OTC; 12 oz	*HexaChlor-K®*

SPRAYS

Chlorhexidine, Topical

(klor-***heks***-ih-deen) *Nolvasan®*

Indications/Actions

Chlorhexidine is a synthetic phenol-related bisbiguanide that exists as acetate, gluconate, and hydrochloride salts. It is a topical antiseptic that has activity against many bacteria and fungi. It appears to have greater efficacy for bacterial infections, particularly *Staphylococcus* spp, than for yeast or dermatophyte infections. Chlorhexidine prevents the outgrowth of bacterial spores but does not prevent germination and is not sporicidal. It can be bacteriostatic or bactericidal depending on concentration.[1] Chlorhexidine is a membrane-active agent that acts by damaging bacterial cytoplasmic membranes. Antifungal activity can be obtained with chlorhexidine concentrations of 2% or higher.

Because chlorhexidine causes less drying and is usually less irritating than benzoyl peroxide, it is sometimes used in patients that cannot tolerate benzoyl peroxide. However, it does not have the keratolytic, comedolytic, or degreasing effects of benzoyl peroxide. Chlorhexidine possesses some residual effects and can remain active on the skin after rinsing.

In one study comparing in vitro efficacy of shampoos, chlorhexidine was shown to be the most effective biocide against *Pseudomonas* spp, methicillin-susceptible and methicillin-resistant *Staphylococcus* spp, and *Malassezia* spp.[2] Another controlled clinical study showed that bathing twice weekly with a 4% chlorhexidine-based shampoo for 4 weeks was as effective as systemic therapy with amoxicillin/clavulanic acid for the treatment of canine superficial pyoderma associated with susceptible and methicillin-resistant *Staphylococcus pseudintermedius*.

Another study found chlorhexidine 2% solution with alcohol had similar efficacy as povidone-iodine 7.5% in reducing total skin bacteria load and preventing surgical site infections in dogs.[3]

Chlorhexidine products may also contain other ingredients, such as antifungals (eg, ketoconazole, miconazole, climbazole), which provide superior antifungal activity as compared with chlorhexidine alone, salicylic acid, phytosphingosine, and hydrocortisone.

Suggested Dosages/Uses

For wound irrigation or foot soaking, diluting the chlorhexidine solution with water to 0.05% to 0.1% is recommended. Sprays, mousses, and wipes/pads are typically applied 1 to 2 times daily. Shampoos and conditioners are typically used daily to weekly. Shampoos should be left in contact with the skin for at least 10 minutes prior to rinsing. For veterinary products, refer to the product label for details and specific instructions.

A nosocomial outbreak of chlorhexidine-resistant *Serratia marcescens* has been linked to improper disinfectant procedures in one veterinary hospital.[4]

Precautions/Adverse Effects

Keep chlorhexidine products away from the eyes. Chlorhexidine is safely used on cats, although irritation and corneal ulcers have been reported. Chlorhexidine may impair wound healing; it is not recommended for long-term use, particularly on granulating lesions.

Hypersensitivity and local skin irritant reactions are possible. Clients should wash their hands after application or wear gloves when applying. The likelihood of irritation increases with increased concentrations. Do not let the animal lick or chew treated areas for at least 20 to 30 minutes after application. Advise clients that blue chlorhexidine solutions can stain furniture, carpets, and the animal.

Veterinary-Labeled Products

Several teat dip and udder wash products, a lubricant, and oral rinses are also available. Several trade names are used for chlorhexidine products, including *Nolvasan®*, *Chlorhexiderm®*, *Dermachlor®*, *Chlorasan®*, *Chloradine®*, *Privasan®*, and *Chlorhex®*.

OINTMENTS

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chlorhexidine 1%		OTC; 7 oz, 16 oz	*Chlorhex®; Nolvasan®*
Chlorhexidine 2%	Labeled for dogs, cats, and horses	OTC; 7 oz, 16 oz	
Chlorhexidine 4%	Labeled for dogs, cats, and horses	OTC; 1 lb	*Vetasan®*

SPRAYS

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chlorhexidine (various concentrations)	Labeled for dogs, cats, and horses	OTC; various sizes	Some products contain aloe.
Chlorhexidine 4%, TrizEDTA	Labeled for dogs, cats, and horses	OTC; 8 oz, 16 oz	*TrizChlor 4®*
Hydrocortisone 1%, chlorhexidine 4%, TrizEDTA	Labeled for dogs, cats, and horses	OTC; 8 oz	*TrizChlor 4HC®* Avoid excessive or prolonged use due to product's steroid content.
Ketoconazole 1%, chlorhexidine 2%, TrizEDTA	Labeled for dogs and cats	OTC; 8 oz	*Mal-A-Ket® Plus*
Miconazole 2%, chlorhexidine 2%, TrizEDTA Other ingredients: ceramide complex	Labeled for dogs, cats, and horses	OTC; 8 oz, 16 oz, and 32 oz	*MiconaHex®*
Ketoconazole 1%, chlorhexidine 2%, phytosphingosine 0.02% Other ingredients: aloe barbadenis, lactic acid	Labeled for dogs and cats	OTC; 8 oz	*VetraSeb CK*
Chlorhexidine 3%, phytosphingosine 0.05%	Labeled for dogs and cats	OTC; 6.8 oz	*DOUXO®*
Chlorhexidine 4% Other ingredients: isopropyl alcohol 4%	Labeled for dogs and cats	OTC; 8 oz	*Chlorhex®*

SHAMPOOS

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chlorhexidine 4%	Labeled for dogs, cats, and horses	OTC; 8 oz, 12 oz, 16 oz, 1 gallon	*ChlorhexiDerm®; Chlorhex®; Max Chlorhexidine®*
Chlorhexidine 4%, TrizEDTA	Labeled for dogs, cats, and horses	OTC; 8 oz, 1 gallon	*TrizCHLOR®*
Hydrocortisone 1%, chlorhexidine 4%, TrizEDTA	Labeled for dogs, cats, and horses	OTC; 8 oz	*TrizCHLOR®4HC* Avoid excessive or prolonged use due to its steroid content.
Chlorhexidine 4% Other ingredients: ceramide III, microsilver	Labeled for dogs and cats	OTC; 8 oz, 16 oz, and 1 gallon	*Hexaderm®* Soap-free
Chlorhexidine 2%		OTC; 8 oz, 16 oz, and 1 gallon	
Chlorhexidine 3%, ophytrium 0.5%	Labeled for dogs and cats	OTC; 200 mL, 500 mL	*DOUXO S3® PYO*
Ketoconazole 1%, chlorhexidine 2%, phytosphingosine salicyloyl 0.05%	Labeled for dogs and cats	OTC; 6.8 oz	*Vetraseb CK®*
Ketoconazole 1%, hydrocortisone 1%, chlorhexidine 2% Other ingredients: vitamin-rich emollients	Labeled for dogs, cats, and horses	OTC; 16 oz	*EquiShield®*
Ketoconazole 1%, acetic acid 2%, chlorhexidine 2%	Labeled for dogs, cats, and horses	OTC; 8 oz, 1 gallon	*Mal-A-Ket®*
Miconazole 2%, chlorhexidine 2%, TrizEDTA Other ingredients: ceramide complex	Labeled for dogs, cats, and horses	OTC; 8 oz, 16 oz, and 1 gallon	*MiconaHex®*
Ketoconazole 1%, chlorhexidine 2% Other ingredients: gylcerin, isopropyl alcohol	Labeled for dogs and cats	OTC; 8 oz, 16 oz, and 1 gallon	*KetoHex®*
Ketoconazole 1%, chlorhexidine 2.3% Other ingredients: alkyl polyglucoside (polysaccharide); chitosanide; D-mannose, D-galactose, L-rhamnose (monosaccharides); *Spherulite®* microcapsules	Labeled for dogs and cats	OTC; 8 oz, 16 oz, and 1 gallon	*KetoChlor®*
Miconazole nitrate 2%, chlorhexidine 2%	Labeled for dogs, cats, and horses	OTC; 8 oz, 12 oz, 16 oz, and 0.5 gallon	*Malaseb®*
Miconazole nitrate 2%, chlorhexidine 2% Other ingredients: ceramide III, microsilver	Labeled for dogs and cats	OTC; 8 oz, 16 oz, and 1 gallon	*BioHex®* Soap-free

SOLUTIONS, FLUSHES, AND SCRUBS

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chlorhexidine 2% (solution)	May be labeled for use on dogs, horses, cattle, and swine	OTC; 16 oz, 1 gallon	
Chlorhexidine 20% (solution)		OTC	*Chlorhexidine®* For 1%: Dilute 6 oz into 1 gallon of water or shampoo. For 2%: Dilute 12 oz into 1 gallon of water or shampoo.
Chlorhexidine (flush)		OTC; 4 oz, 12 oz	
Chlorhexidine 0.2% (flush) Other ingredients: glycerin, isopropyl alcohol	Labeled for dogs and cats	OTC; 4 oz	*Chlorhexis®*
Chlorhexidine 0.15%, TrizEDTA (flush)	Labeled for dogs and cats	OTC; 4 oz	*TrizChlor®*
Ketoconazole 0.15%, chlorhexidine 0.15%, TrizEDTA (flush)	Labeled for dogs and cats	OTC; 4 oz, 12 oz	*Mal-A-Ket®* A multi-cleanse flush to aid in the treatment of bacterial and fungal (dermatophytosis and *Malassezia* spp) infections
Chlorhexidine 0.2%, lidocaine 0.5% (flush) Other ingredients: benzoic acid, glycerin, malic acid, propylene glycol, salicylic acid		OTC; 4 oz	*Dermachlor®*
Miconazole 2%, chlorhexidine 2% (flush)	Labeled for dogs, cats, and horses	OTC; 4 oz, 12 oz	*Malaseb®*
Chlorhexidine 2% (flush)		OTC; 4 oz, 8 oz, and 16 oz	
Ketoconazole 1%, chlorhexidine 2%, phytosphingosine 0.02% (flush)	Labeled for dogs and cats	OTC; 4 oz, 16 oz	*Ketoseb®*
Ketoconazole 1%, chlorhexidine 2%, phytosphingosine salicyloyl 0.05% (flush)	Labeled for dogs and cats	OTC; 6.8 oz	*Vetraseb CK®*
Chlorhexidine 2%, chlorhexidine 4% (scrub)		OTC; 1 gallon	

WIPES

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chlorhexidine 3%, ophytrium 0.5%	Labeled for dogs and cats	OTC; 30 count jar	*DOUXO S3® PYO* Alcohol-free
Ketoconazole 17 mg, chlorhexidine 20 mg, phytosphingosine 0.4 mg	Labeled for dogs and cats (*Ketoseb+PS®*) and horses (*PhytoVet CK®*)	OTC; 50 count jar	*Ketoseb+PS®; PhytoVet CK®*
Ketoconazole 1%, chlorhexidine 2%, phytosphingosine salicyloyl 0.04% Other ingredients: glycerin, lactic acid, propylene glycol	Labeled for dogs and cats	OTC; 60 count jar	*Vetraseb CK®*
Ketoconazole 17 mg, chlorhexidine 20 mg	Labeled for dogs, cats, and horses	OTC; 50 count jar	*KetoHex®*

Ketoconazole 1%, acetic acid 2%, chlorhexidine 2%	Labeled for dogs and cats	OTC; 50 count jar	*Mal-A-Ket®*
Miconazole 2%, chlorhexidine 2%, TrizEDTA Other ingredients: ceramide complex	Labeled for dogs, cats, and horses	OTC; 50 count jar	*MiconaHex®*
Chlorhexidine 4%, TrizEDTA	Labeled for dogs and cats	OTC; 50 count jar	*TrizChlor®*
Climbazole, chlorhexidine 2% Other ingredients: ceramide III, microsilver	Labeled for dogs and cats	OTC; 50 count jar	*BioHex®*

MOUSSES

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chlorhexidine 3%, ophytrium 0.5%	Labeled for dogs and cats	OTC; 5 oz	*DOUXO S3® PYO* Water-based. Leave-on. To be used between bathing or when bathing is not practical
Miconazole 2%, chlorhexidine 2%	Labeled for dogs and cats	OTC; 6.8 oz	*Ketoseb®* Water-based. Leave-on. To be used between bathing or when bathing is not practical
Chlorhexidine 4%, TrizEDTA	Labeled for dogs, cats, and horses	OTC; 7.1 oz	*TrizChlor 4®*
Miconazole 2%, chlorhexidine 2%, TrizEDTA Other ingredients: ceramide complex	Labeled for dogs, cats, and horses	OTC; 7.1 oz	*Miconahex+Triz®*
Climbazole 0.5%, ceramides III 0.05%, chlorhexidine 3%, microsilver 1%	Labeled for dogs and cats	OTC; 6.8 oz	*BioHex®* Leave-on. To be used between bathing or when bathing is not practical

ORAL RINSES

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chlorhexidine 0.12%	Labeled for dogs and cats	OTC; 8 oz	*Dentahex®* For daily use after each meal. Avoid touching tip of bottle to gums.
Chlorhexidine 0.13%	Labeled for dogs and cats	OTC; 8 oz	*Clenz-a-dent®* Orange flavored

Human-Labeled Products

There are several topical skin cleansers available in the 2% to 4% range. Trade names include *Hibiclens®*, *Hibistat®*, *Betasept®*, *Exidine®*, *Dyna-Hex®*, and *BactoShield®*.

Chloroxylenol, Topical

PCMX

(kloro-***zye***-len-ol)

*For otic use, see **Cleaning/Drying Agents, Otic** and **Antiseptic Agents, Otic.***

Indications/Actions

Chloroxylenol is an antiseptic with demonstrated efficacy against gram-negative and gram-positive bacteria, in addition to a wide variety of fungal organisms, and against RNA and DNA viruses. It is slower acting than other antiseptic agents[1] and has minimal residual effects.[2] It can be used in presurgical preparation of the skin; in cleaning wounds; and in the treatment of bacterial, fungal, and yeast skin infections. An in vitro study comparing the efficacy of antimicrobial shampoos showed that a shampoo containing chloroxylenol 2% was not effective against *Pseudomonas* spp and methicillin-susceptible and methicillin-resistant *Staphylococcus* spp; however, it was effective against *Malassezia* spp.[3] Another in vitro study found that chloroxylenol was inferior to chlorhexidine against MRSA biofilms.[4]

Chloroxylenol, also known as PCMX, is a chlorinated phenolic antiseptic. Its antibacterial action is thought to be due to the disruption of bacterial membranes.

Suggested Uses/Dosages

Shampoos should be left in contact with the skin for at least 10 minutes prior to rinsing. Refer to product label for details on individual use. Sprays and wipes/pads can be applied 1 to 3 times daily according to the patient's needs. Do not let the animal lick or chew at treated areas for at least 20 to 30 minutes after application.

Precautions/Adverse Effects

Chloroxylenol may cause skin irritation.

Veterinary-Labeled Products

This list represents only products where chloroxylenol is one of the main active ingredients.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Chloroxylenol 2% (scrub) Other ingredients: deionized water, hydroxyethylcellulose, polysorbate-20, polyquaternium-7, propylene glycol, sodium laureth sulfate, sodium lauryl sulfate		OTC; 16 oz, 1 gallon	Used for surgical scrub and preoperative skin preparation. Do not dilute.
Chloroxylenol 2%, salicylic acid 2%, sodium thiosulfate 2% (shampoo) Other ingredients: citric acid, propylene glycol	Labeled for dogs and cats	OTC; 16 oz, 1 gallon	Has antiseborrheic effect
Miconazole nitrate 2%, chloroxylenol 1% (shampoo) Other ingredients: propylene glycol, salicylic acid	Labeled for dogs, cats, and horses	OTC; 8 oz, 16 oz, and 1 gallon	*Sebozole*® Has antibacterial, antifungal, and antiseborrheic activity. Shake well.
Ketoconazole 1%, chloroxylenol 2% (shampoo)	Labeled for dogs, cats, and horses	OTC; 8 oz, 16 oz, and 1 gallon	*Pharmaseb*®
Ketoconazole 0.3%, chloroxylenol 0.3% (wipes)	Labeled for dogs, cats, and horses	OTC; 60 count	*Pharmaseb*® Water-based
Ketoconazole 0.3%, chloroxylenol 0.3% (flush) Other ingredients: benzyl alcohol, propylene glycol	Labeled for dogs, cats, and horses	OTC; 4 oz, 8 oz	*Pharmaseb*® Water-based. Can be used as a cleansing agent for the skin and ears
Ketoconazole 0.33%, chloroxylenol 0.33% (flush) Other ingredients: benzyl alcohol, propylene glycol, sodium borate decahydrate	Labeled for dogs, cats, and horses	OTC; 8 oz	*Ketomax*® Contains sodium borate decahydrate to obtain pH of 8.5
Ketoconazole 0.3%, chloroxylenol 0.3% (spray) Other ingredients: benzyl alcohol, propylene glycol	Labeled for dogs, cats, and horses	OTC; 4 oz, 8 oz	*Pharmaseb*® Water-based

Human-Labeled Products

There are several topical products available containing chloroxylenol that are usually combined with other ingredients, such as hydrocortisone, menthol, pramoxine, and benzocaine. They are presented in different forms (creams, ointments, lotions, and shampoos) but are not commonly used in dogs and cats. Trade names include *Aurinol*®, *Calamycin*®, *Cortamox*®, *Cortane-B*®, *Dermacoat*®, and *Foille*®.

Enzymes, Topical (Lactoperoxidase, Lysozyme, Lactoferrin)

*For otic use, see **Cleaning/Drying Agents, Otic.***

Indications/Actions

Lactoperoxidase, lysozyme, and lactoferrin are topical enzymes that work synergistically when combined and are reported to be effective against bacterial, fungal, and viral microorganisms. They are listed by the manufacturer to be effective against *Staphylococcus* spp, *Pseudomonas* spp, *Malassezia* spp, *Candida albicans*, and *Microsporum* spp. Lactoperoxidase combined with hydrogen peroxide, thiocyanate, and/or iodide produces hypothiocyanite or hypoiodite ions that are bactericidal by oxidizing components of bacterial cell walls. Hypoiodite also is fungicidal. Lactoferrin acts as a bacteriostatic agent against many bacteria by depriving them of iron.

They can be used alone but are often used in combination with hydrocortisone for mild itching or as an adjunctive treatment for more severe itching, such as atopic dermatitis.

Suggested Uses/Dosages

Sprays and creams are labeled for use 1 to 2 times a day. Shampoos and conditioners should be used daily to weekly. Shampoo should be in contact with the skin for 3 to 5 minutes prior to rinsing well. Products are labeled as worry-free if licked, but animals should be prevented from licking or chewing treated areas for at least 20 to 30 minutes after application if possible. Refer to product label for details on individual product use.

Precautions/Adverse Effects

Overall, these products appear to be safe. There are no reported adverse effects, but skin irritation is possible. Caution should be used to avoid excessive or long-term use of products containing glucocorticoids due to potential adverse effects such as cutaneous atrophy and systemic absorption.

Veterinary-Labeled Products

Refer to each product label for details on use, inactive ingredients, and any precautions.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Lactoferrin, lactoperoxidase, lysozyme (spray)	Labeled for all pets of all ages	OTC; 2 oz	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme, hydrocortisone 0.5% (spray)	Labeled for all pets of all ages	OTC; 2 oz	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme, hydrocortisone 1% (spray)	Labeled for all pets of all ages	OTC; 2 oz	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme (cream)	Labeled for companion animals	OTC; 1 oz	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme, hydrocortisone 0.5% (cream)	Labeled for companion animals	OTC; 1 oz	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme, hydrocortisone 1% (cream)	Labeled for companion animals	OTC; 1 oz	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme (shampoo)	Labeled for all pets of all ages	OTC; 12 oz, 1 gallon	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme (leave-on conditioner)	Labeled for all pets of all ages	OTC; 12 oz, 1 gallon	*Zymox®*
Lactoferrin, lactoperoxidase, lysozyme (shampoo)	Labeled for horses	OTC; 12 oz, 1 gallon	*Zymox®Equine Defense*
Lactoferrin, lactoperoxidase, lysozyme (conditioner)	Labeled for horses	OTC; 12 oz, 1 gallon	*Zymox® Equine Defense*
Lactoferrin, lactoperoxidase, lysozyme (spray)	Labeled for horses	OTC; 8 oz	*Zymox® Equine Defense*
Lactoferrin, lactoperoxidase, lysozyme (cream)	Labeled for horses	OTC; 2.5 oz	*Zymox® Equine Defense*

Human-Labeled Products

None

Hypochlorous Acid, Topical

(hye-poe-***klor***-us ***ass***-id)

*For ophthalmic use, see **Irrigating Solutions, Ophthalmic**.*

*For otic use, see **Antiseptic Agents, Otic** and **Cleaning/Drying Agents, Otic**.*

Indications/Actions

Topical hypochlorous acid is used for the management of wounds, abscesses, cuts, abrasions, skin irritations, ulcers, postsurgical incision sites, burns, wound odors, and to accelerate healing. It may be used for the prevention or treatment of bacterial skin infections, including methicillin-resistant *Staphylococcus* spp and *Pseudomonas* spp; however, one small, controlled study investigating the efficacy of hypochlorous acid 0.011% applied to the skin twice daily for 4 weeks for the treatment of canine superficial pyoderma showed no statistically significant difference as compared with placebo. Hypochlorous acid also has antifungal and antiviral properties and is reported to reduce inflammation, pain, and itching.

Hypochlorous acid products act rapidly against gram-positive and gram-negative bacteria and fungal/yeast organisms. Some products contain oxychlorine (bleach-like) compounds; many products have a neutral pH.

The mechanism of action of hypochlorous acid is to disrupt the cellular membrane of single-cell organisms. Because the mechanism of action is primarily chemical in nature, resistance appears unlikely.

Suggested Dosages/Uses

Clip hair if necessary and apply to affected areas up to 3 times daily; may be used with dressing applications on wounds or in combination with a cleanser. These products are generally safe to use around the eyes, nose, and mouth, and no rinsing is typically required; refer to specific product labels for details on use.

Precautions/Adverse Effects

No precautions or adverse effects have been reported. Hypochlorous acid products are generally non-toxic and safe if licked or ingested. Although they do not sting or irritate the skin, the treated area may redden secondary to increased blood flow. Clients should be warned about possible bleaching/staining of carpets, clothing, and jewelry.

Veterinary-Labeled Products

Below is a representative sample of the products available.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Hypochlorous acid 0.009% (liquid)	Labeled for cats	OTC; 2 oz	*Vetericyn Plus® Feline Facial Therapy*
Hypochlorous acid 0.012% (spray)	Labeled for all animals	OTC; 3 oz, 4 oz, 8 oz, and 16 oz	*Vetericyn Plus® Reptile Wound and Skin Care; Vetericyn Plus® Poultry Care; Vetericyn Plus® All Animal Wound and Skin Care; Vetericyn Plus® Equine Wound and Skin Care*
Hypochlorous acid 0.012% (spray gel)	Labeled for all animals	OTC; 4 oz, 8 oz, and 16 oz	*Vetericyn Plus® Hydrogel; Vetericyn Plus® Feline Hydrogel*
Hypochlorous acid 0.015% (spray)	Labeled for all animals	OTC; 16 oz	*Vetericyn® Pink Eye Spray*

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Hypochlorous acid 0.008%, sodium hypochlorite 0.002% (spray/gel/solution)	Depending on the labeling: OTC/Rx; 1.5 oz to 990 mL	*Microcyn®*
Hypochlorous acid 0.00025%, sodium hypochlorite 0.0036% (spray)	OTC; 2 oz	*Myclyns®* pH: 6.2 to 7.8.

Povidone Iodine, Topical

(***poe***-vi-done ***eye***-oh-dine) *Betadine®*

Indications/Actions

Povidone iodine is used as a topical first-aid agent and a presurgical skin antiseptic. It may be used for superficial pyoderma and *Malassezia* spp dermatitis; however, it is infrequently used in small animal dermatology due to its drying, irritating, and staining effects.

Povidone iodine, an iodophor antiseptic, is rapidly bactericidal at low concentrations against both gram-positive and gram-negative bacteria. It is also fungicidal and sporicidal as a 1% aqueous solution. Povidone acts by slowly releasing iodine to tissues. It has prolonged activity (4-6 hours) but is not as long acting as chlorhexidine. Povidone iodine also has mild degreasing and debriding activity.

Suggested Dosages/Uses

Thoroughly wet affected area(s) to ensure complete coverage. For veterinary products, refer to the specific product label for details on use.

Precautions/Adverse Effects

Povidone may be drying and irritating to skin and can be extremely irritating to the scrotal skin and external ears. Use with emollients may alleviate the drying effects. It may also stain skin, hair, and fabrics. Avoid contact with eyes.

Wear gloves or wash hands after application. Use with caution on deep or puncture wounds or on serious burns. Systemic absorption can result in renal and thyroid dysfunction.

Veterinary-Labeled Products

NOTES:

1. The following products are only representative and not meant to be all-inclusive. There are many available povidone iodine products, including hoof dressings, teat dips, boluses (to prepare a solution), and udder washes. Povidone iodine products are also available in combination with lidocaine and as a combination of povidone and potassium iodine.
2. 10% povidone iodine yields 1% titratable iodine; labels may be confusing. Povidone iodine may also be listed as polyvinylpyrrolidone iodine. Products below are listed as povidone iodine.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Povidone iodine 5% (shampoo)	OTC; Depending on the manufacturer: 8 oz, 16 oz, 32 oz, 1 gallon	*Aloedine®*, generic
Povidone iodine 5% (spray)	OTC; 16 oz	generic
Povidone iodine 7.5% (scrub)	OTC; 32 oz, 1 gallon	*Vetadine®; Pivodine®; Povidine®; Poviderm®*
Povidone iodine 10% (gel)	OTC; 20 oz	*Biozide®*
Povidone iodine 10% (solution)	OTC; 32 oz, 1 gallon	*Poviderm®; Prodine®; Vetadine®*

Human-Labeled Products

NOTE: There are a large number of povidone iodine products available. In addition to those listed, vaginal gels, swabs, sponges, and foaming skin cleansers are also available.

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Povidone iodine 5% (powder spray)	OTC; 2 oz	*Betadine®*
Povidone iodine 5% (spray)	OTC; 3 oz	*Betadine®*
Povidone iodine 7.5% (scrub)	OTC; 4 oz, 16 oz, 32 oz, 1 gallon	*Betadine®*; generic
Povidone iodine 10% (ointment)	OTC; 1 g (packet), 28.4 g	generic
Povidone iodine 10% (solution)	OTC; 0.5 oz, 4 oz, 8 oz, 16 oz, 32 oz, 1 gallon	*Betadine®*; generic

Antiparasitic Agents, Topical

For topical agents that are administered topically but absorbed systemically through the skin to treat ecto- and endoparasites (eg, ***Eprinomectin, Fluralaner, Ivermectin, Moxidectin, Selamectin),*** refer to the respective monographs in the systemic section.

Amitraz Collar, Topical

(a-mi-***traz***) *Preventic®*

Indications/Actions

A water-resistant amitraz collar is available for dogs 12 weeks of age and older that is labeled to kill and detach ticks for up to 3 months[1]; the collar does not control fleas. It starts working within 24 hours of placement. **Do NOT apply the amitraz collar to cats or rabbits as it will cause toxicity**.

Topical amitraz dip was FDA-approved for the treatment of generalized demodicosis in dogs; however, this product is no longer marketed. It was also used to treat canine sarcoptic mange, cheyletiellosis, and feline surface (*Demodex gatoi)* or follicular demodicosis (*Demodex cati)*, and as a general insecticidal/miticidal agent in several other species.

Amitraz is thought to act through agonism of octopamine receptors in ectoparasites. Octopamine receptors are considered the invertebrate equivalent to adrenergic receptors in vertebrates. The overstimulation of octopamine receptors leads to overexcitation, paralysis, and death.[2,3]

Suggested Dosages/Uses

DOGS:

Kill and detach ticks (label dosage; EPA-approved): Apply collar based on dog's body weight. Dogs up to 27.3 kg (60 lb): 18-inch adjustable collar; dogs over 27.3 kg (60 lb): 25-inch adjustable collar. The collar must be worn tightly enough to make contact with the skin. Replace collar every 90 days.

Precautions/Adverse Effects/Drug Interactions

Do not reuse the collar or container; wrap it in a newspaper and throw it in the trash. Do not use the collar on puppies under 12 weeks of age.

Amitraz can be toxic to cats and rabbits and should not be used in these species.

Amitraz collars may cause toxicity if swallowed (by either animals or humans). Treatment should consist of emesis, retrieval of the collar using endoscopy if possible, and administration of activated charcoal and a cathartic to remove any remaining collar fragments. Yohimbine 0.11 – 0.2 mg/kg IV (start with low dosage) may be of benefit to treat adverse effects associated with the overdose. Because yohimbine has a short half-life, it may need to be repeated, particularly if the animal has ingested an amitraz-containing collar that could has not been retrieved from the GI tract. See ***Yohimbine***. Atipamezole has also been used to treat amitraz toxicity; see ***Atipamezole.*** For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Amitraz 9% (collar)	Labeled only for dogs 12 weeks of age and older	OTC (EPA); 18 inches (for dogs less than 27.2 kg [60 lb]), 25 inches (for dogs more than 27.2 kg [60 lb])	*Preventic*® Adjustable (cut off excess). Effective for 3 months

Crotamiton, Topical

(***kroe***-ta-mye-ton)

Indications/Actions

Crotamiton is a topical miticide/scabicide used primarily for adjunctive treatment (with ivermectin) of mite infections (eg, *Knemidocoptes* spp) in birds. Crotamiton has both miticidal and antipruritic actions. Its miticidal mechanism of action is unknown; however, its antipruritic effect is reported to be due to its inhibition of the transient receptor potential vanilloid 4 (TRPV4) channel that is expressed on the skin peripheral neurons and keratinocytes.[1]

Suggested Dosages/Uses

Once- to twice-daily application is usually recommended. Shake well before use.

Precautions/Adverse Effects

Do not apply around the eyes or mouth. Little is known of the compound's safety profile. Irritation or hypersensitivity reactions are possible; do not use on patients with a known hypersensitivity to it.[2] Discontinue if irritation or sensitization develops. Do not apply to acutely inflamed skin or raw, weeping skin.

Prevent grooming or preening after application, as oral ingestion can cause irritation of the buccal, esophageal, and gastric mucosa; nausea; vomiting; and abdominal pain.

Adverse effects in humans include dermatitis, pruritis, and rash.[2]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers. See ***Appendix***.

Crotamiton 10% (lotion) Other ingredients: cetyl alcohol, emollient base	Rx; 60 g, 227 g, 454 g	*Crotan*®, *Eurax*®

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Deltamethrin/Deltamethrin Combination Products, Topical

(del-ta-***meeth***-rin)

Indications/Actions

In the United States, deltamethrin-impregnated collars are labeled for killing fleas (ie, *Ctenocephalides* spp) and ticks[1] (ie, *Amblyomma americanum, Rhipicephalus sanguineus, Dermacentor variabilis, Ixodes scapularis, I pacificus*) and repelling mosquitoes on dogs for up to 6 months.[2] Treatment with deltamethrin has been shown to be an effective strategy to reduce the incidence of leishmaniasis by repelling and

killing mosquitos and phlebotomine sandflies, which are important vectors.[3] The mosquito repellent activity may also help reduce the incidence of heartworm infection[4]; further research is needed.

Deltamethrin is a synthetic pyrethroid insecticide and acts by disrupting the sodium channel conduction in arthropod nerve cell membranes, resulting in paralysis and death. Some collars are combined with pyriproxyfen, an insect growth regulator.

Suggested Dosages/Uses

Collars should be worn continuously and be replaced every 6 months.[1,2] Maximum effect may not occur until 2 to 3 weeks after collar placement; therefore, it is recommended to apply the collar before the start of flea/tick season.[5] Wipe the collar with a damp paper towel prior to application to remove dust. The collar is placed so that 2 to 3 fingers can easily fit between the collar and neck. The collar does not need to be removed for bathing or swimming. Follow specific product label for use instructions.

Precautions/Adverse Effects

Do not use deltamethrin on cats. Collars containing deltamethrin should not be used on dogs younger than 12 weeks.[1,2] Collars may cause irritation if placed too tightly. Skin reactions (erythema, localized dermatitis, pruritis) and hair loss at the application site are possible.[6] In extremely rare cases, neurologic signs such as tremor or lethargy have been reported.[6] Use with caution in debilitated, pregnant, nursing, geriatric, or medicated animals.[1,2]

If a collar is ingested, uncoordinated movements, tremor, drooling, vomiting, or rigidity are possible. Treatment is supportive, and clinical signs usually subside within 48 hours.[6] For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Avoid contact with eyes, skin, or clothing. Wash hands after handling. Mammalian exposure to deltamethrin is classified as safe; however, deltamethrin is highly toxic to aquatic animals (especially fish) and should be used very carefully around water sources.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Deltamethrin 4% (collar)	Labeled for dogs 12 weeks of age or older **Do NOT use on cats.**	OTC (EPA)	*Activyl®; Adams®; PetArmor®; Proact®; Sentry®; Zodiac®* Adjustable (one size fits all). Water-resistant

Dinotefuran/Pyriproxyfen Combinations, Topical

(die-noh-te-***fyoor***-an, pye-ri-***proks***-i-fen)

Indications/Actions

Dinotefuran/pyriproxyfen combinations are used in dogs and cats for the treatment and control of external parasites. The combination of dinotefuran and pyriproxyfen controls adult fleas and all immature flea stages, including eggs, larvae, and pupae. Some canine combination products also contain permethrin, which broadens the spectrum to also repel and kill ticks, mosquitos, lice, mites (excluding mange), biting flies, and sand flies. Some feline combination products contain fipronil, providing rapid speed of kill and added protection against ticks and chewing lice.

Dinotefuran is a nitroguanidine, neonicotinoid insecticide with a structure similar to acetylcholine. It permanently binds to the same insect receptor sites as acetylcholine and activates the nerve impulse at the synapse, which cause stimulation that results in tremors, incoordination, and insect death. Dinotefuran does not bind to mammalian acetylcholine receptor sites.

Pyriproxyfen is a second-generation insect growth regulator that mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, which causes nonviable eggs to be produced. When dinotefuran is combined with an adulticide (eg, permethrin, fipronil), all stages of the parasite are killed, and re-infestation is less likely. It is more resistant to UV light than is methoprene.

Suggested Dosages/Uses

Dinotefuran/pyriproxyfen combination products are recommended once monthly for dogs and cats. Refer to the package labeling for specific dosages and application instructions.

Apparently, bathing or swimming does not interfere with efficacy of canine products; however, the authors do not recommend bathing

the pet until 2 days after application. Cats should be completely dry before the *Catego*® product is applied and they should remain dry for 24 hours after application.[1]

Precautions/Adverse Effects

The dog product containing permethrin (*Vectra 3D*®) **must not be used on cats or on dogs that cohabitate with cats**. The manufacturer recommends not using *Vectra 3D*® or *Vectra*® on debilitated, aged, medicated, pregnant, or nursing animals or on animals known to be sensitive to pesticide products. Mild transitory skin erythema may occur at the application site. Avoid eye and oral contact since dinotefuran can cause substantial but temporary eye irritation. *Vectra 3D*® was reported to be associated with the development of pemphigus foliaceus-like disease occurring at the site of application and at distant sites in 3 dogs.[1]

Veterinary-Labeled Products

Fipronil/Fipronil Combinations, Topical

(***fip***-roe-nil) *Frontline*®

See also ***Permethrin/Permethrin Combinations, Topical; Pyriproxyfen/Pyriproxyfen Combinations, Topical***

Indications/Actions

In the United States, fipronil is indicated for the treatment of fleas, ticks, and chewing lice infestations in dogs and cats. It has also been used successfully for *Trombicula autumnalis* (chigger) infestation, sarcoptic mange, cheyletiellosis, and otoacariasis.

Fipronil is a phenylpyrazole antiparasitic agent that interferes with the passage of chloride ions in GABA-regulated chloride channels in invertebrates, thereby disrupting CNS activity and causing death of the parasite. Fipronil collects in the oils of the skin and hair follicles and continues to be released over a period of time, which results in a long residual activity. When topically applied, the drug spreads over the body in ≈24 hours via translocation.

When fipronil is combined with the insect growth regulator (S)-methoprene, flea eggs and flea larvae are also killed. (S)-methoprene mimics flea juvenile growth hormone, which halts development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing nonviable eggs to be produced. Additional combination products with permethrin, etofenprox, cyphenothrin, and pyriproxyfen (synthetic pyrethroids) or amitraz are available.

Suggested Dosages/Uses

Spot-on solutions are generally applied in one or more spots on the back of the neck or between the shoulder blades. The hair should be parted so the solution can be applied directly to the skin.

When applying spray, use one gloved hand to ruffle the coat while spraying sides, back, legs, abdomen, shoulders, and neck. To apply this product to the head and eye area, spray a gloved hand and gently rub into the coat. Alternatively, a towel soaked with fipronil may be used to treat the face. Apply this product until coat is thoroughly wet.[1]

Fleas, ticks, or chewing lice: Monthly treatments are generally recommended when fipronil is used for treatment and prevention of fleas, ticks, or chewing lice. See product labels for specific directions on administration and recommendations on bathing and swimming after administration. In some cases, for better efficacy, the interval between applications needs to be shortened to every 14 days.

***Trombicula autumnalis* infestation:** Monthly application of fipronil *spray* (0.25%) has been successful in dogs. Apply the *spray* to the entire

body, thoroughly wetting the coat, with particular emphasis on the areas typically affected (eg, feet, ears, face, perineum, and tail). Monthly applications should be administered throughout the trombiculid season at the dose of 3 – 6 mL/kg. In some cases, application every 14 days may be required. Fipronil seemed to have a shorter duration of effect in cats, with reinfestation seen after 7 to 10 days.[2]

Sarcoptic mange: Fipronil *spray* (0.25%) is recommended for confirmed cases using 2 protocols:

a) Apply once weekly for 4 weeks[3]
b) Apply every 2 to 3 weeks for 3 treatments[4]

Dosages ranging from 3 mL/kg to 39 mL/kg were used in these reports. Thoroughly wet the coat, paying special attention to the areas typically affected by the disease (eg, ears, face, ventrum, and extremities). A decrease in pruritus may be noticed as early as 7 days after the first application. Fipronil use is not recommended in treatment trials (ie, high clinical suspicion of mite infestation but mites not found on skin scrapings) because of anecdotal reports of treatment failures with this product.

Cheyletiellosis: Fipronil *spray* (0.25%) has been successfully used at a dose of 3 mL/kg to ensure complete and thorough body coverage, along with environmental permethrin treatment. Repeat fipronil treatment after 30 days.[5] Fipronil use is only recommended for confirmed cases and is not recommended in treatment trials (ie, high clinical suspicion of mite infestation but mites not found on skin scrapings) because of anecdotal reports of treatment failures.

Otoacariasis: Instill 1 drop of fipronil solution inside each ear canal and apply the rest of the dosing tube between the shoulder blades.[6] Fipronil needs to be applied in the ear canals to be effective. Resolution of clinical signs can be seen as early as 7 days posttreatment. Additional applications may be needed.

Precautions/Adverse Effects

Do not use fipronil on puppies or kittens less than 8 weeks of age. Fipronil compounds are reported to be contraindicated in rabbits, as toxicity deaths have occurred with the spray. Do not apply fipronil to or spray in or near the eyes. Temporary irritation may occur at the site of administration. Hypersensitivity has rarely been reported; animals that have demonstrated hypersensitivity reactions to fipronil should not be retreated. Use fipronil with caution on debilitated, elderly, or medicated patients.

Dispose of containers properly to avoid contamination of food or water sources. Avoid human contact with skin, eyes, or clothing. Wash well with soap and water if skin contact occurs. Wear gloves when applying fipronil and wash hands thoroughly after handling. Use sprays only in a well-ventilated area. Avoid contact with treated animals until coat is dry.

Most products are labeled as remaining effective after bathing, water immersion, or exposure to sunlight; however, avoid shampooing within 48 hours of application. Spotted areas may appear wet or oily for up to 24 hours after application.

Veterinary-Labeled Products

NOTE: This is not an all-inclusive list but is representative of the types of products available.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Fipronil 0.29% (spray)	Labeled for use on dogs, cats, puppies, and kittens 8 weeks of age or older	OTC (EPA); 8.5 oz, 17 oz	*Frontline®*
Fipronil 0.29%, (S)-methoprene 0.27% (spray)	Labeled for use on dogs, cats, puppies, or kittens 8 weeks of age or older	OTC (EPA); 8 oz, 16 oz	*Martin's FLEE® Plus*
Fipronil 9.7% (spot-on solution)	Labeled for use on dogs, cats, puppies, and kittens 8 weeks of age or older	OTC (EPA); various formulations and packages depending on each product	*Hartz® First Defense®; Pronyl OTC®; Sentry Fiproguard®; Spectra Sure®* The indication may differ among these products.
Fipronil 9.7% (spot-on solution)	Labeled for use on cats and kittens 8 weeks of age or older and over 0.7 kg (1.5 lb)	OTC (EPA); single-dose applicators 0.5 mL in packages of 3 and 6	*Adams Fortress®; Hartz® First Defense®; Sentry Fiproguard®*
Fipronil 9.8%, (S)-methoprene 11.8% (spot-on solution)	Labeled for use on cats or kittens 8 weeks of age or older and over 0.7 kg (1.5 lb)	OTC (EPA); single-dose applicators 0.5 mL in packages of 3 and 6	*Frontline®* Plus*; Martin's FLEE® Plus;* PetAction® *Plus*; *PetArmor® Plus; Pronyl OTC Plus®*; *Sentry Fibroguard®; Spectra Sure® Plus*

Imidacloprid/Imidacloprid Combinations, Topical

(eye-mi-da-***kloe***-prid) *Advantage®*, Seresto®

*For systemic use, see **Imidacloprid, Systemic and Moxidectin/Moxidectin Combination Products***

Indications/Actions
Imidacloprid topical solution is indicated for the prevention and treatment of flea infestations in cats and flea and lice infestations in dogs. Imidacloprid is effective against both adult fleas and flea larvae.[1] The combination of imidacloprid and pyriproxyfen is indicated for the prevention and treatment of all flea stages in dogs and cats and lice infestations in dogs. The combination of imidacloprid, pyriproxyfen, and permethrin is indicated in dogs only for the prevention and treatment of fleas, ticks, mosquitoes, biting flies, and lice.

The combination of imidacloprid and flumethrin impregnated into a slow-release collar is indicated for the prevention and treatment of ticks, fleas, and lice in dogs and prevention and treatment of ticks and fleas in cats. It has also been shown to prevent babesiosis[2] and leishmaniosis[3] in dogs and is indicated for the prevention of leishmaniosis in some countries.

Imidacloprid's mechanism of action as an insecticide is to act on nicotinic acetylcholine receptors on the postsynaptic membrane, causing CNS impairment and death of the ectoparasite. Certain insect species are more sensitive to these agents than are mammalian receptors. This is a different mechanism of action than other insecticidal agents (organophosphates, pyrethrins, carbamates, insect growth regulators [IGRs], and insect development inhibitors [IDIs]). Imidacloprid is reported to be nonteratogenic, nonhypersensitizing, nonmutagenic, nonallergenic, noncarcinogenic, and nonphotosensitizing. When applied topically, imidocloprid is not absorbed into the bloodstream or internal organs. Permethrin and flumethrin, found in some imidacloprid products, are neurotoxins that slow the movement of sodium ions through sodium channels in neuron membranes of the ectoparasite. Pyriproxyfen may also be found in some imidacloprid products; it mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced.

Suggested Dosages/Uses
Refer to the package information for product-specific application instructions. Imidacloprid products are generally administered once monthly; however, extra-label dosages, such as once weekly or every other week, have been used. Although swimming, bathing, and rain do not significantly affect the duration of action, animals that have been shampooed repeatedly may require additional treatment(s) before the next monthly dosing interval, not to exceed once weekly administration.

Precautions/Adverse Effects
When used as directed, imidacloprid topical solutions are usually well tolerated and adverse effects are minimal. Dermal irritation has been reported at the site of application.

Imidacloprid and pyriproxyfen combinations are contraindicated in puppies younger than 7 weeks, dogs weighing less than 3 lbs, and kittens younger than 7 or 8 weeks (depending on product). Use with caution in debilitated, older, pregnant, or nursing animals.

Combination products that contain permethrin must not be used on cats. They should be used with caution in households with cats, particularly if cats are in close contact with or will groom treated dogs.

Avoid contact with the eyes and mouth; oral contact may cause excessive salivation. If eye contact occurs in humans or animals, flush well with an ophthalmic irrigation solution or water. Wearing gloves is not required during administration but is recommended to avoid contact with human skin. Wash hands with soap and water after handling. Keep out of reach of children. Store products away from food sources to avoid the possibility of contamination. Carefully dispose of products in the trash.

Most toxicities are seen following oral dosing of topical products. In cats, clinical signs may include hypersalivation, vomiting, lethargy, and hiding; oral ulcers have also been rarely reported in cats. In dogs, reported clinical signs include vomiting, hypersalivation, and trembling.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Imidacloprid 9.1% (spot-on solution)	Dogs and puppies 7 weeks of age and older; cats and kittens 8 weeks of age and older	OTC (EPA); packages of 4 or 6 applicators: Cats 4.1 kg (9 lb) and under: 0.4 mL Cats over 4.1 kg (9 lb): 0.8 mL Dogs under 4.5 kg (10 lb): 0.4 mL Dogs 5 - 9.1 kg (11-20 lb): 1 mL Dogs 9.5 - 25 kg (21-55 lb): 2.5 mL Dogs over 25 kg (55 lb): 4 mL	*Advantage®* (product no longer available in the United States)

Isopropyl Myristate, Topical
(eye-so-***proe***-pil ***meer***-is-tate) *Resultix®*

Indications/Actions
Isopropyl myristate is a noninsecticidal product labeled for the removal and killing of attached and crawling ticks on dogs and cats. It acts by dissolving the outer wax layer covering the hard shell (cuticle) of the tick, resulting in uncontrollable water loss and death. Ticks generally die and fall off within 3 hours.

Suggested Dosages/Uses
Spray tick until it is covered with solution, ≈2 sprays. Tick should be dead within 3 hours and will either fall off the animal or will be immobile when it is removed. If the tick has not fallen off after 3 hours, carefully remove it with gloves or tweezers. Dispose of the tick by placing it in a sealable plastic bag. Wash hands after handling product, and after any accidental exposure to ticks.

Isopropyl myristate can be used as often as needed.[1]

Precautions/Adverse Effects
Do not use near the eyes or on irritated skin. Discontinue use if skin irritation or skin infection develops.

Isopropyl myristate is toxic to invertebrates and fish.[1] Never dispose of product down any drain; do not discharge into lakes, streams, ponds, estuaries, oceans, or other waters where aquatic invertebrates or fish may be found.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Isopropyl myristate 50% (spray)	Labeled for dogs and cats	OTC (EPA); 20 mL	*Resultix®*

Methoprene/Methoprene Combinations, Topical

(meth-oh-***preen***)

Indications/Actions

Methoprene is an insect growth regulator that prevents the maturation of flea and mosquito eggs and larva. Methoprene mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, resulting in the production of nonviable eggs.

Methoprene is typically combined with an adulticide to kill all stages of the parasites and prevent reinfestation. Fipronil and pyrethroids (eg, cyphenothrin, etofenprox, permethrin) are commonly used in combination with methoprene. These agents also provide coverage against additional parasites; see specific product labels for details on parasite activity.

Suggested Dosages/Uses

For use and dosage recommendations, refer to the specific product insert.

Precautions/Adverse Effects

Methoprene is commonly found in products containing **pyrethroids that are toxic to cats**, especially small kittens. **Only use products on cats that are specifically labeled for use on cats**. Use pyrethroid-containing products cautiously on dogs that cohabitate with cats.

Hypersensitivity reactions and skin irritation are possible with methoprene-containing products. Avoid eyes and mucous membranes during application. When used as a single agent, methoprene has low toxicity in mammals.

Additional precautions and adverse effects vary based on other active ingredients; refer to specific product insert.

Methoprene products should be protected from light as methoprene is broken down by UV light.

Veterinary-Labeled Products

NOTES:

1. Methoprene is available in a variety of combinations. Use caution selecting products labeled for different species as different combinations of active ingredients may be marketed under the same trade name.
2. There is an extensive number of products marketed, including collars, topical sprays, foggers, and spot-on solutions; the following products are only representative.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Methoprene 2.9% (spot-on solution)	Labeled for cats and kittens 12 weeks of age and older	OTC (EPA); single-dose 1 mL applicators in packages of 3	*Hartz® UltraGuard® OneSpot®*
Methoprene 3%, permethrin 45% (spot-on solution)	Labeled for dogs 6 months of age and older **Do NOT use on cats.**	OTC (EPA); single-dose applicators per weight in packages of 4	*Zodiac® Spot On® for Dogs*
Methoprene 3.6%, etofenprox 40% (spot-on solution)	Labeled for kittens 12 weeks of age and older	OTC (EPA); single-dose 1.8 mL applicators in packages of 3 for cats 2.3 kg (5 lb) and over	*Hartz® UltraGuard Plus® for Cats; Hartz® UltraGuard Pro® for Cats*
Methoprene 4.05%, etofenprox 46%	Labeled for cats and kittens 12 weeks of age and older	OTC (EPA); single-dose applicators per weight in packages of 3	*Adams® Plus for Cats*
Methoprene 8.8%, fipronil 9.8% (spot-on solution)	Labeled for dogs or puppies 8 weeks of age and older	OTC (EPA); single-dose applicators per weight in packages of 3 and 6	*Frontline® Plus for Dogs; Onguard® Plus for Dogs; PetArmor® Plus for Dogs; Sentry® Fiproguard Plus for Dogs*
Methoprene 8.8%, fipronil 9.8%, cyphenothrin 5.2% (spot-on solution)	Labeled for use on dogs 12 weeks of age and older **Do NOT use on cats.**	OTC (EPA); single-dose applicators per weight in packages of 3	*Frontline® Tritak® for Dogs*
Methoprene 11.8%, fipronil 9.8% (spot-on solution)	Labeled for use on cats or kittens 8 weeks of age and older	OTC (EPA); single-dose applicators of 0.5 mL in packages of 3 and 6	*Frontline® Plus for Cats; Onguard® Plus for Cats; PetArmor® Plus for Cats; Sentry® Fiproguard Plus for Cats*
Methoprene 11.8%, fipronil 9.8%, etofenprox 15% (spot-on solution)	Labeled for use on cats or kittens 12 weeks of age or older	OTC (EPA); single-dose applicators of 0.5 mL in packages of 3	*Frontline® Tritak® for Cats*

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Methoprene 8.8%, fipronil 9.8%, pyriproxyfen 0.25% (spot-on solution)	Labeled for dogs and puppies 8 weeks of age and older	OTC (EPA); single-dose applicators of 0.5 mL in packages of 3 and 6 per weight	*Frontline® Gold for Dogs*
Methoprene 11.8%, fipronil 9.8%, pyriproxyfen 0.25% (spot-on solution)	Labeled for cats and kittens 8 weeks of age and older	OTC (EPA); single-dose applicators of 0.5 mL in packages of 3 and 6 for cats 0.7 kg (1.5 lb) or greater	*Frontline® Gold for Cats*
Methoprene 0.27%, piperonyl butoxide 0.37%, pyrethrins 0.2% (spray)	Labeled for use on dogs, cats, puppies, kittens, horses, and ponies **NOT for puppies or kittens less than 12 weeks old**	OTC (EPA); 16 oz, 24 oz, 1 gallon	*Vet-Kem Ovitrol Plus®; Bio-Spot®*
Methoprene 0.27%, fipronil 0.29% (spray)	Labeled for use on cats or kittens 8 weeks of age or older	OTC (EPA); 6.5 oz (aerosol spray), 8 oz (trigger spray)	*Martin's FLEE®*
Methoprene 1.1%, piperonyl butoxide 1.05%, pyrethrins 0.15% (shampoo)	**NOT for puppies or kittens less than 12 weeks old**	OTC (EPA); 12 oz	*Vet-Kem®*
Methoprene 1.02%, tetrachlorvinphos 14.55% (collar)	Labeled for dogs and cats	OTC (EPA); sizing based on neck circumference and varies based on manufacturer	*Hartz® UltraGuard Plus®; Hartz® UltraGuard Pro®; PetArmor® for Cats*; *Adams® Plus*
Methoprene 1.02%, deltamethrin 4% (collar)	Labeled for dogs 12 weeks and older	OTC (EPA); one size, fits dogs with necks up to 26"	*Hartz® InControl®; Hartz® UltraGuard ProMAX*

Human-Labeled Products
None

Permethrin/Permethrin Combinations, Topical
(per-***meth***-rin)

Indications/Actions
Permethrin is a synthetic pyrethroid insecticide that acts as an adulticide and miticide. It has knockdown activity against fleas, ticks, lice, and some mites, including *Cheyletiella* spp and *Sarcoptes scabiei*. Permethrin also has repellant activity against flies, gnats, and mosquitoes.

In dogs, permethrin is primarily used to prevent fleas and ticks. In large animal and food animal species, it is primarily used for flies, lice, mites, mosquitoes, ticks, and keds.

Permethrin acts by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death.

Suggested Dosages/Uses
Permethrin products can typically be applied every 2 weeks or every 4 weeks; refer to specific product label for details on use.

Precautions/Adverse Effects
Permethrin and other synthetic pyrethroids are toxic to cats, especially small kittens. Do not use permethrin-containing products on cats and avoid use on dogs that cohabitate with cats.

Permethrin may cause hypersensitivity reactions. Do not use permethrin near the eyes or mucous membranes. Adverse effects are uncommon but can include pruritus or mild skin irritation at the application site.

Wear gloves and wash hands after application. In case of skin contact, wash off with water.

Permethrin is extremely toxic to aquatic organisms and bees. Apply and dispose of products with caution as not to contaminate the environment.

Veterinary-Labeled Products
NOTES:
1. This is not an inclusive list; there are an extensive number of products marketed, including shampoos, pour-ons, sprays, foggers, and dusts. Use caution selecting products, as different combinations of active ingredients may be marketed under the same trade name.
2. **Permethrin products must NOT be used on cats** and should not be used on dogs that cohabitate with cats.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information

Permethrin 0.1%, 2-[1 methyl-2-(4-phenoxyphenoxy) ethoxy] pyridine 0.125%, N-octyl bicycloheptene dicarboximide 0.479%, pyrethrins 0.112% (spray)	Labeled for dogs over 6 months of age	OTC (EPA); 8 oz bottle	*Veterinary Formula Clinical Care®*
Permethrin 0.1%, piperonyl butoxide 0.5%, pyrethrins 0.05% (spray)	Labeled for dogs over 3 months of age	OTC (EPA); 32 oz bottle	*Flea Halt®*

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Permethrin 1% (creme rinse)	OTC; 59 mL	*Nix®;* generic Labeled for treatment of head lice in humans
Permethrin 5% (cream)	Rx; 60 g	*Acticin®; Elimite®;* generic Labeled for treatment of scabies in humans

Pyrethrin/Pyrethrin Combinations, Topical

(pye-***ree***-thrin)

For otic use, see ***Antiparasitic Agents, Otic.***

Indications/Actions

Pyrethrins are natural insecticides derived from the pyrethrum flower that have knockdown activity against fleas, lice, ticks, and *Cheyletiella* spp. In small animal medicine, pyrethrins are used primarily to treat fleas and ticks on dogs and cats. In large animal and food animal medicine, there are many products available for pour-on, dusting, and spray use.

The natural pyrethrins are made up of 6 compounds. They act by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death. Pyrethrins are often found in combination with insect growth regulators, such as methoprene or pyriproxyfen, or with synergistic agents such as piperonyl butoxide. Insect growth regulators add activity against egg and larval growth stages. Piperonyl butoxide inhibits insect metabolic enzymes (P450 system), which prevents the breakdown of primary insecticides and allows for a lower dose to be used.

Suggested Dosages/Uses

For dosage recommendations, refer to the specific product label.

Precautions/Adverse Effects

Pyrethrins are generally considered to be some of the safest insecticidal products. Avoid contact with the eyes and mucous membranes. Do not apply over wounds or irritated skin. Wear gloves when applying or wash hands after handling.

Cats are more susceptible to pyrethrin toxicity than other species. **Only use products on cats that are specifically labeled for cats.** Use pyrethrin products with caution in dogs that cohabitate with cats, and do not allow cats to groom application areas before dry. Avoid applying to hypothermic patients or applying when ambient temperatures are low. Pyrethrin products are toxic to fish and aquatic animals; do not allow products to enter drains or other water sources during application or disposal.

Adverse effects are uncommon but may include pruritus or mild skin irritation at the application site. Hypersensitivity reactions can also occur.

Veterinary-Labeled Products

There are a wide variety of available products, including shampoos, pour-ons, sprays, dusts, and ointments. The following is not an all-inclusive list.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Pyrethrins 0.2%, piperonyl butoxide 0.37%, (S)-methoprene 0.27% (spray) Other ingredients: N-octyl bicycloheptene dicarboximide 0.62%	Labeled for use on dogs, cats over 3 pounds and 12 weeks of age; horses; and ponies.	OTC (EPA); 16 oz, 1 gallon	*Vet-Kem Ovitrol Plus®*
Pyrethrins 0.05%, permethrin 0.1%, piperonyl butoxide 0.5% (spray)	Labeled for dogs older than 3 months of age. **Do NOT use on cats or on dogs that cohabit with a cat.**	OTC (EPA); 8 oz, 32 oz, 40 oz	*Flea Halt®*
Pyrethrins 0.18%, 2-[1-Methyl-2-(4-phenoxyphenoxy) ethoxy] pyridine 0.125%, N-octyl bicycloheptene dicarboximide 0.957% (spray)	Labeled for dogs over 6 months of age or cats over 7 months of age	OTC (EPA); 8 oz, 15 oz	*Advantage®*
Pyrethrins 0.18%, N-octyl bicycloheptene dicarboximide 0.479%, piperonyl butoxide 0.3% (spray)	Labeled for dogs and puppies over 6 months of age	OTC (EPA); 8 oz, 15 oz	*Advantage®*
Pyrethrins 0.05%, piperonyl butoxide 0.5% (shampoo)	Labeled for dogs and cats over 12 weeks of age	OTC (EPA); 12 oz	*Zodiac®*
Pyrethrins 0.15%, piperonyl butoxide 1.88%, (S)-methoprene 0.1% (shampoo)	Labeled for dogs and cats over 12 weeks of age	OTC (EPA); 12 oz	*Adams® Plus*
Pyrethrins 0.15%, piperonyl butoxide 1.88%, (S)-methoprene 0.1% (shampoo)	Labeled for dogs and cats over 12 weeks of age	OTC (EPA); 12 oz	*Vet-Kem® Ovitrol Plus*
Pyrethrins 0.15%, N-oxyl bicycloheptene dicarboximide 0.5%, piperonyl butoxide 0.3% (shampoo)	Labeled for dogs and cats over 12 weeks of age	OTC; 12 oz, 1 gallon	*Davis®*
Pyrethrins 0.15%, N-octyl bicycloheptene dicarboxamide 0.479%, piperonyl butoxide 0.3% (shampoo)	Labeled for dogs, cats, ferrets, and horses over 12 weeks of age	OTC (EPA); 16 oz, 1 gallon	*Veterinary Formula®*

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Pyrethrins 0.97%, di-n-propyl isocinchomerate 1.94%, N-octyl bicycloheptene dicarboxamide 5.7%, piperonyl butoxide 3.74% (dip)	Labeled for dogs and cats over 12 weeks of age	OTC (EPA); 4 oz	*Adams Plus®*
Pyrethrins 0.3%, piperonyl butoxide 3% (dip)	Labeled for dogs and cats over 12 weeks of age	OTC (EPA); 8 oz, 1 gallon	*Bio-Groom®*

Human-Labeled Products

Active ingredients (formulation)	Label status; size(s)	Trade names/additional information
Pyrethrins 0.33%, piperonyl butoxide 4% (shampoo)	OTC; 2 oz, 4 oz, 8 oz	*Rid®*; generic Indicated for treatment of lice in humans

Pyriproxyfen/Pyriproxyfen Combinations, Topical

(pye-ri-***proks***-i-fen)

See also ***Deltamethrin, Dinotefuran/Pyriproxyfen Combinations, Fipronil/Fipronil Combinations, Imidacloprid/Imidacloprid Combinations, Methoprene/Methoprene Combinations, Permethrin/Permethrin Combinations,*** *and* ***Pyrethrin/Pyrethrin Combinations***

Indications/Actions

Pyriproxyfen is a second-generation insect growth regulator and is added to topical and environmental products to extend the insecticidal spectrum to include eggs and larva.

Pyriproxyfen mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced. Pyriproxyfen is combined with adulticides such as permethrin or fipronil to kill all stages of targeted parasites, making re-infestation less likely.

Suggested Dosages/Uses

For dosage recommendations, refer to the specific product label.

Precautions/Adverse Effects

Pyriproxyfen can be found in products that contain **permethrin, which is toxic to cats**, particularly small kittens. **Only use products containing pyrethroids that are specifically labeled for use on cats**. Pyriproxyfen has low toxicity in mammals, but skin irritation and hypersensitivity reactions are possible.

Wear gloves when applying products containing insecticides and wash hands after handling. Pyriproxyfen is more resistant to UV light than is methoprene.

Veterinary-Labeled Products

Spinetoram, Topical
(***spin***-et-oh-ram)

Indications/Actions
Spinetoram is an insecticide used for the prevention and treatment of flea infestations in cats.

Spinetoram is a semi-synthetic, second-generation derivative of the natural insecticide spinosad. It acts on both GABA and nicotinic acetylcholine receptors in the CNS of insects, leading to CNS hyperexcitation, followed by paralysis and death. Spinetoram begins to act within 30 minutes after application.[1]

Suggested Dosages/Uses
To treat and prevent flea infestations, spinetoram should be applied once monthly to the skin at the base of the head. For detailed application instructions, refer to the specific product label.

Precautions/Adverse Effects
Spinetoram should not be used on kittens less than 8 weeks of age. Do not allow cats to ingest product. Only a single dose should be applied at one time, regardless of the weight of the cat (ie, large cats do not require additional doses). Use spinetoram with caution on debilitated, aged, pregnant, or nursing animals, or any animal known to be sensitive to pesticides. Avoid contact with the eyes or mouth. Spinetoram should not be used in dogs, as they are more sensitive to the toxic effects of spinetoram than mice, rats, or cats.[2]

The primary adverse effects are application site reactions, including hair loss, hair changes (eg, greasing, clumping, matting), redness, inflammation, and itching. Other reported adverse effects include inactivity, vomiting, and inappetence.[3] Do not allow cats to groom after application in order to prevent ingestion. Application at the base of the head, rather than the shoulder blades, decreases the risk for direct ingestion.

Spinetoram has been shown to produce reproductive adverse effects in female rats including treatment-related depletion of primordial

ovarian follicles, growing ovarian follicles, dystocia and other parturition abnormalities, late resorptions or retained fetuses, and increased postimplantation loss. However, no adverse effects were observed on the offspring at dose levels that produced parental toxicity. The developmental toxicity and reproduction studies indicated no evidence of increased susceptibility of the offspring with pre- and/or postnatal exposures.[2]

Sulfur, Precipitated, Topical (Keratolytic Agents)

Immunomodulator Agents, Topical

Imiquimod, Topical
(ih-***mi***-kwih-mod) *Aldara®, Zyclara®*

Indications/Actions
Imiquimod is an immune response modifier that may be useful in the treatment of a variety of topical conditions in animals. In dogs and cats, it may be beneficial in treating actinic keratosis, squamous cell carcinoma, pigmented epidermal plaques, cutaneous viral papillomatosis, localized solar dermatitis, and solar carcinoma in situ. It may also be useful for feline herpesvirus dermatitis, feline Bowen's disease, and canine melanocytomas. Many of these indications are based on anecdotal evidence, as there are very few studies published for veterinary use. In horses, imiquimod has been anecdotally used for treating equine sarcoids, aural plaques, and epitrichial sweat gland ductal carcinoma. In humans, it is labeled as a treatment for genital or perianal warts, superficial basal cell carcinomas, and actinic keratoses of the face and scalp.

Imiquimod is an imidazoquinoline compound that binds to toll-like receptor 7 and stimulates the immune system to release various cytokines, including interferon-alpha and interleukin-12. These locally generated cytokines induce a Th1 immune response with the generation of cytotoxic effectors. Imiquimod itself does not have in vitro activity against wart viruses but stimulates monocytes and macrophages to release cytokines that induce regression in viral protein production.

Suggested Dosages/Uses
Use of imiquimod in animals is limited and further studies are needed. Doses and treatment regimens vary depending on the disease treated and tolerance to the drug. Doses range from applying a thin film once daily to applying every other week. Exudate and crusts should be gently cleaned prior to application of imiquimod. Treatment duration and frequency may be adjusted depending on patient response and adverse reactions.

Precautions/Adverse Effects
Wear gloves when applying imiquimod. Avoid exposing the eyes and mucous membranes to imiquimod; however, dogs with oral mucosal papilloma and horses with corneal squamous cell carcinomas have been treated without significant problems. Although systemic absorption is unlikely, do not allow treated animals to lick or groom the application site.

Local skin reactions are common and expected with imiquimod therapy, including erythema, burning, tenderness, pain, irritation, oozing/exudate, and erosion. Treatment duration and frequency may require adjustment depending on irritant reactions. Depigmentation and hair loss may occur at application sites as posttreatment sequelae.

Increased liver enzymes, neutropenia, partial anorexia, and vomiting were reported in cats in one small study, possibly associated with ingestion postcutaneous application.[1] Consider a baseline hepatic profile with periodic monitoring. Do not cover application site with occlusive dressings. It is thought that imiquimod may increase risk for sunburn; avoid exposing application site to sunlight.

Pimecrolimus, Topical

(pim-e-***kroe***-li-mus)

Indications/Actions

Topical pimecrolimus may be beneficial for the adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease or other cutaneous vasculopathies, alopecia areata, vitiligo, perianal fistulas (concurrent therapy or as maintenance treatment after cyclosporine therapy), and for feline proliferative and necrotizing otitis externa. Unlike topical corticosteroids, pimecrolimus does not have atrophogenic or metabolic effects associated with long-term use or large treatment areas.

Pimecrolimus is a calcineurin inhibitor that acts similarly to cyclosporine and tacrolimus. It inhibits T-lymphocyte activation primarily by inhibiting the phosphatase activity of calcineurin. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils. The mechanism of pimecrolimus may not be identical to tacrolimus, as pimecrolimus did not impair the primary immune response (as did tacrolimus) in mice after a contact sensitizer was applied. Both drugs did impair the secondary response, however. Any clinical significance associated with this difference is not yet clear.

Suggested Dosages/Uses

There is limited experience with pimecrolimus in veterinary patients. It is typically recommended to use twice daily until signs are controlled, then decrease to the least frequent application that controls clinical signs.

Precautions/Adverse Effects

Although a causal relationship has not been established, skin malignancy and lymphoma have rarely been reported in humans using topical pimecrolimus. Therefore, long-term use is not recommended in humans, and pimecrolimus application should be limited to only the affected area(s). The long-term adverse effects of topical pimecrolimus in veterinary patients are currently unknown. Close monitoring is recommended for patients using this medication on a continuous maintenance basis. When long-term treatment is required, the ultimate goal should be to achieve the lowest possible dose that controls clinical signs. Pimecrolimus should not be used in patients that are receiving systemic immunosuppressant therapy or are otherwise immunocompromised.

Wear gloves or use an applicator (eg, cotton swab) when applying the cream and wash hands after handling. Do not allow animals to lick or chew at the treated area(s) for at least 20 to 30 minutes after application to avoid ingestion and allow the medication to work.

Although topical pimecrolimus appears well tolerated in dogs, localized irritation and pruritus have been reported in both humans and dogs. Pimecrolimus has been anecdotally reported to be less irritating than tacrolimus in dogs; however, it may also be less effective. Pimecrolimus may be cost prohibitive.

Pimecrolimus 1% (cream)	Rx; 30 g, 60 g, and 100 g	*Elidel®;* generic

Tacrolimus, Topical

(ta-***kroe***-li-mus)

Indications/Actions

Tacrolimus ointment may be beneficial in veterinary patients as a sole or adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease, alopecia areata, vitiligo, dermal arteritis of the nasal philtrum, perianal fistulas (adjunctive or maintenance treatment after cyclosporin therapy), sterile canine panniculitis, and feline proliferative and necrotizing otitis externa. Unlike topical corticosteroids, tacrolimus does not have atrophogenic or metabolic effects associated with long-term use or large treatment areas.

Tacrolimus is a calcineurin inhibitor that inhibits T-lymphocyte activation. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils.

Suggested Dosages/Uses

There is limited experience with topical tacrolimus in veterinary patients. Twice-daily application is typically recommended until signs are controlled. Application can then be reduced to the minimum frequency needed to control clinical signs.

Precautions/Adverse Effects

Although a causal relationship has not been established, skin malignancy and lymphoma have rarely been reported in humans using topical tacrolimus. Therefore, long-term use is not recommended in humans, and tacrolimus application should be limited to only the affected area(s). The long-term adverse effects of topical tacrolimus in veterinary patients are currently unknown, and thus close monitoring is recommended for patients using this medication on a continuous maintenance basis. When long-term treatment is required, the ultimate goal should be to achieve the lowest possible dose that controls clinical signs. Tacrolimus should not be used in patients that are receiving systemic immunosuppressant therapy or are otherwise immunocompromised. Do not use this ointment on premalignant or malignant skin conditions.

Wear gloves or use an applicator (eg, cotton swab) when applying the ointment and wash hands after handling. Do not allow animals to lick or chew at the treated area(s) for at least 20 to 30 minutes after application to avoid ingestion and allow the medication to work.

The commercially available ointment should not be used as (or compounded into) an ophthalmic preparation for treating KCS in dogs, as it contains propylene carbonate, a known ocular toxin.

Although topical tacrolimus appears well tolerated in dogs, localized irritation and pruritus have been reported in both humans and dogs. Pimecrolimus has been anecdotally reported as less irritating than tacrolimus in dogs; however, it may also be less effective. The cost of topical tacrolimus may be prohibitive.

The National Institute for Occupational Safety and Health (NIOSH) classifies tacrolimus as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Selenium Sulfide, Topical (Antimicrobial Agents, Topical; Antifungal Agents)

Coal Tar/Coal Tar Combinations, Topical

(kole tar)

Indications/Actions

The use of coal tar containing shampoos in veterinary medicine is somewhat controversial, particularly since almost all veterinary-labeled products have been withdrawn from the market. However, coal tar shampoos have been used for many years to treat greasy dermatoses (seborrhea oleosa) in dogs.

Coal tar possesses keratoplastic, keratolytic, vasoconstrictive, antipruritic, and degreasing actions. Coal tar's mechanism of keratoplastic (keratoregulating) action is probably secondary to decreasing mitosis and DNA synthesis of basal epidermal cells.[1]

Suggested Dosages/Uses

The frequency of shampooing will vary according to the patient's needs. When using a medicated shampoo, allow 10 minutes of contact time. Another acceptable regimen is to allow the shampoo to act for 3 to 5 minutes, rinse it thoroughly, then repeat the procedure. Refer to specific product labels for directions, as contact time recommendations may vary. Completely rinse to prevent skin irritation and/or excessive drying.

Precautions/Adverse Effects

The carcinogenic risks associated with coal tar products are debated. At present, most (including the FDA) believe that coal tar products with concentrations of 5% or less are safe for human use. However, should they be used on animals, clients should wear gloves when applying and wash off any product that contacts their skin. Carcinogenic risk assessment for dogs using coal tar products was not located. **Coal tar products should not be used on cats**, patients that have prior sensitivity reactions to tar products, or patients that have dry scaling dermatoses.

Be careful comparing coal tar concentrations on labels. Coal tar solution contains ≈20% coal tar extract or refined tar. For example, a 10% coal tar solution contains ≈2% coal tar (refined).

Photosensitization, skin drying, and skin irritation are possible with coal tar therapy. Adverse effects are more likely with coal tar concentrations greater than 3%. Residual odor is often bothersome to clients. Tar may stain fabrics or haircoats and discolor jewelry.

Veterinary-Labeled Products

Salicylic Acid, Topical

(sal-i-***sil***-ic ***ass***-id)

Indications/Actions

Salicylic acid is used to treat seborrheic disorders with mild to moderate scaling and mild waxy or keratinous debris, including seborrhea sicca and oleosa. Salicylic acid is often combined with sulfur or benzoyl peroxide. In higher concentrations, salicylic acid can be used to remove localized excessive tissues associated with hyperkeratotic disorders, such as calluses and idiopathic thickening of the planum nasale and footpads. Salicylic acid is also used in some wound cleansers.

Salicylic acid has mild antipruritic, antibacterial (bacteriostatic), keratoplastic, and keratolytic actions. Lower concentrations are primarily keratoplastic, and higher concentrations are keratolytic. Salicylic acid lowers skin pH, increases corneocyte hydration, and dissolves the intercellular binder between corneocytes. Salicylic acid and sulfur are thought to be synergistic in their keratolytic actions.

Suggested Dosages/Uses

Salicylic acid shampoos are typically labeled for use 2 to 3 times weekly; however, the frequency will vary according to the patient's needs. Allow medicated shampoos to remain in contact with the skin for 5 to 10 minutes before rinsing well. Alternatively, allow for 3 to 5 minutes of contact time, rinse thoroughly, then repeat the procedure. Ensure shampoo is rinsed completely to prevent skin irritation and excessive drying. Refer to specific product labels for complete directions.

Precautions/Adverse Effects

Salicylic acid products that are combined with coal tar must not be used on cats.

Avoid contact with eyes and mucous membranes. Do not allow animals to lick during bathing in order to avoid ingestion. Avoid using on broken skin unless product is specifically labeled for wounds. Wash hands after application, as skin irritation is possible. Salicylic acid products may bleach colored fabrics.

Possible adverse effects include burning, itching, pain, erythema, and swelling at the application site, particularly when used in concentrations greater than 2%. A rebound seborrheic effect can occur.

Veterinary-Labeled Products

Salicylic acid 6% (gel)	Rx; 40 g, 100 g	*Keralyt®;* generic

Sulfur, Precipitated, Topical

(***sul***-fer)

Indications/Actions

Sulfur-containing shampoos are often used to treat patients with seborrheic disorders exhibiting mild to moderate scaling, with mild waxiness and keratinous debris. Sulfur is often found in combination with salicylic acid.

Sulfur has keratoplastic and keratolytic actions. Lower concentrations of sulfur are primarily keratoplastic secondary to assisting the conversion of cysteine to cystine, which is thought to be an important factor in the maturation of corneocytes. Like salicylic acid, the keratolytic effects of sulfur increase with concentration. Salicylic acid and sulfur are believed to be synergistic in their keratolytic actions. Sulfur also has mild degreasing effects and can be mildly antipruritic. Sulfur has antibacterial, antifungal, and antiparasitic effects secondary to sulfur conversion to hydrogen sulfide and pentathionic acid by bacteria and keratocytes.

Suggested Dosages/Uses

Sulfur shampoo label directions range from once daily to once weekly; the frequency of use will vary depending on the patient. Allow medicated shampoos to remain in contact with the skin for 5 to 10 minutes before rinsing well. Alternatively, allow for 3 to 5 minutes of contact time, rinse thoroughly, then repeat the procedure. Ensure shampoo is rinsed completely to prevent skin irritation and excessive drying. Refer to the specific product label for complete instructions.

Precautions/Adverse Effects

Avoid contact with eyes, mucous membranes, and open cuts or sores. Wear gloves when applying and wash hands after application. Residual odor can be bothersome, and sulfur may stain fabrics and hair.

Sulfur can be irritating or drying and can cause pruritus. A rebound seborrheic effect can occur with sulfur-containing products.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Sulfur 2% (shampoo)	Labeled for dogs **Do NOT use on cats.**	OTC; 12 oz	*Sulfodene®*
Sodium thiosulfate 2%, chloroxylenol 2%, salicylic acid 2% (shampoo)	Labeled for dogs, cats, and horses	OTC; 16 oz, 1 gallon	*Universal Medicated Shampoo®* Sodium thiosulfate serves as source of soluble sulfur.
Sulfur 2%, salicylic acid 2%, selenium sulfide 1% (shampoo)	Labeled for dogs, cats, and horses	OTC; 16 oz	*Siccaderm®*
Sulfur 1%, benzoyl peroxide 2.5%, salicylic acid 1% (shampoo)	Labeled for dogs and cats	OTC; 12 oz, 1 gallon	*Sulfur Benz®*
Sulfur 2%, coal tar solution 1%, salicylic acid 0.22%, zinc oxide 0.22% (shampoo)	Labeled for dogs **Do NOT use on cats.**	OTC; 12 oz, 1 gallon	*Sulfur & Tar®*
Sulfur 2%, salicylic acid 2% (shampoo)	Labeled for dogs and cats	OTC; 4 oz, 8 oz, 16 oz	*Exfolux®*

Human-Labeled Products

NOTE: There are several topical products containing sulfur labeled for human use, including creams, lotions, shampoos, and soaps that are typically labeled for acne or dandruff. For more information on these products, refer to a comprehensive human drug reference or contact a pharmacist.

Retinoid Agents, Topical

Tretinoin, Topical

All-Trans Retinoic Acid; Vitamin A Acid

(***tret***-in-oyn)

Indications/Actions

Topical tretinoin has been used anecdotally for treating localized follicular or hyperkeratotic disorders, such as idiopathic nasal and footpad hyperkeratosis, Schnauzer comedo syndrome, callous pyodermas, and chin acne.

The exact mechanism of action of tretinoin is not well understood, but it stimulates cellular mitotic activity, increases cell turnover, and decreases the cohesiveness of follicular epithelial cells. Similar to other retinoids, tretinoin is derived from vitamin A. It **may have anti-inflammatory and immunomodulatory effects by stimulating cytotoxic T-cells and natural killer cells, inhibiting polymorphonuclear cells and suppressing lymphocyte proliferation. Retinoids also have antineoplastic effects by maintaining epithelial cell differentiation and inhibiting tumor cell proliferation.**

Suggested Dosages/Uses

In small animal species, topical tretinoin is often used initially at a concentration of 0.05% and is applied once daily. Treatment is continued until clinical signs are controlled or until treatment is no longer tolerated. Once clinical signs are controlled, tretinoin frequency is then reduced to only as needed. In animals that are unable to tolerate therapy, a lower concentration of 0.025% to 0.01% may be tried to minimize adverse effects.

Precautions/Adverse Effects

Avoid excessive sun exposure during treatment with tretinoin. Avoid contact with eyes, nostrils, inner ears, and mouth. Wear gloves when applying and wash hands after handling. **Do not use this product in pregnant or nursing animals. Do not let animals lick or chew at the treated area(s) for at least 20 to 30 minutes after application. Some gel products contain soluble fish proteins and should be used with caution in patients with fish allergies.**

Adverse effects can include hypersensitivity reactions and local irritation (eg, erythema, dryness, peeling, pruritus).

The National Institute for Occupational Safety and Health (NIOSH) classifies tretinoin as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Tretinoin 0.1% (gel microspheres)	Rx; 20 g, 45 g, 50 g	*Retin-A Micro®;* generic
Tretinoin 0.05% (lotion)	Rx; 20 g, 45 g, 50 g	*Altreno®*

Otic Agents, Topical

Although this is not a complete list, the following examples are representative of the types of topical otic preparations that are available to veterinarians. Included are both veterinary-labeled and human-labeled products that may be of use in veterinary medicine. Portions of this section are adapted from Koch SN, Torres SMF, Plumb, DC. *Canine and Feline Dermatology Drug Handbook.* John Wiley & Sons, 2012. This reference provides additional detail on these and other compounds and products.

Antibacterial Agents, Otic

See also ***Corticosteroid/Antimicrobial Agents, Otic***

Indications/Actions

Antibacterial ear preparations are commonly used to treat infections caused by various bacteria, such as *Staphylococcus* spp or *Pseudomonas* spp. Ear cytology should be performed to confirm a bacterial infection prior to prescription of topical antibiotics, mainly to prevent antibiotic overuse and bacterial resistance. In long-term cases and when rods are seen on cytology, culture and susceptibility may be recommended to identify multidrug-resistant organisms, such as *Pseudomonas* spp. Very few otic products that contain solely an antibiotic are commercially available to treat bacterial otitis; therefore, ophthalmic products, compounded products, or injectable products applied topically into the ear canals are sometimes used to treat these infections, mainly when steroids and antifungals are not needed. Listed below are the commercial products containing an antibiotic agent exclusively.

Suggested Dosages/Uses

These products should be used 2 to 3 times daily in adequate amounts to coat the entire ear canal. When using acidifying ear cleansers with an aminoglycoside- or fluoroquinolone-containing agent, it is recommended to use these products about 1 hour apart since low pH can decrease the activity of aminoglycosides and fluoroquinolones. Advise the client to discontinue the medication and contact the veterinarian if the animal's ears become redder or more inflamed at any time during treatment.

Patients should be rechecked before discontinuing treatment, and treatment must be continued until 1 week after negative cytology is obtained.

Precautions/Adverse Effects

There is little information available regarding ototoxicity from topical antibiotics use in dogs and cats; therefore, caution should be used when prescribing various topical otic medications in patients with ruptured tympanic membranes due to potential ototoxicity. Ototoxicity has been reported with aminoglycosides in dogs and cats, and cats may be more sensitive to their potential ototoxicity; however, this concern may be overstated. One study showed no vestibulotoxic or ototoxic effects from 21 days of otic gentamicin applied every 12 hours to ears with ruptured tympanic membranes. Another study showed that instillation of aqueous solutions of tris-EDTA combined with marbofloxacin or gentamicin into the middle ear of dogs with otitis media either did not change or improved the brainstem auditory-evoked responses (BAER); however, tobramycin solution impaired the BAER. Based on this study, the concern for ototoxicity is higher with tobramycin compared with marbofloxacin and gentamicin.[1]

Veterinary- and Human-Labeled Products

Refer to each product's label for inactive ingredients and precautions or contraindications.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Enrofloxacin 0.5%, silver sulfadiazine (SSD) 1%	Labeled for dogs	Rx; 15 mL, 30 mL	*Baytril®*
Gentamicin sulfate 0.3% (solution, ointment)	Labeled for dogs and cats	Rx; 5 mL (solution), 3.5 g (ointment)	*Gentocin®* Extra-label use in the ears. Many human ophthalmic products are also available.
Oxytetracycline hydrochloride 5 mg/g, polymixin B 10,000 units/g (ointment)	Labeled for dogs, cats, and horses	3.5 g tube	*Terramycin®* Extra-label use in the ears
Ciprofloxacin hydrochloride 0.3% (solution, ointment)	Human-labeled product	Rx; 5 mL, 10 mL (solution), 3.5 g (ointment)	*Ciloxan®;* generic Extra-label use in the ears
Ciprofloxacin hydrochloride 0.2% (solution)	Human-labeled product	Rx; 0.25 mL single use	*Cetraxal®;* generic
Ofloxacin 0.3% (solution)	Human-labeled product	Rx; 5 mL, 10 mL	*Floxin®*; generic
Tobramycin 0.3% (solution, ointment)	Human-labeled product	Rx; 5 mL	*Tobrex®;* generic Extra-label use in the ears

Antibiotic-Potentiating Agents, Otic

Tromethamine-ethylenediaminetetraacetic acid (tris-EDTA) has antimicrobial and antibiotic potentiating activity. Cell surfaces of gram-negative bacteria are damaged when exposed to EDTA. Tromethamine (tris) enhances the effects of EDTA, and the tris-EDTA combination is bacteriostatic.[1] Exposure to tris-EDTA results in increased permeability to extracellular solutes and leakage of intracellular solutes. Cell surfaces of gram-positive bacteria are more resistant to tris-EDTA than gram-negative bacteria.[2] Tris-EDTA has also shown synergistic effects with various antibiotics, such as aminoglycosides and fluoroquinolones in vitro.[1–4] Tris-EDTA also has antibiofilm activity through inhibition of bacterial adhesion.[5]

Tris-EDTA is non-ototoxic and safe to use in the middle ear. Tris-EDTA–containing products are most effective when applied 15 to 30 minutes before the topical antibiotic. Products containing tris-EDTA are available as a sole ingredient or combined with chlorhexidine or ketoconazole. When recommending ear flushing as part of the treatment regimen, it is important to demonstrate the cleaning technique in the examination room and advise the client to discontinue application and contact the veterinarian if the ears become redder or more inflamed at any time during the course of cleaning. The frequency of cleaning varies according to the needs of the individual patient. ***Refer to each product's label for inactive ingredients and precautions or contraindications.***

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Tris-EDTA (flush)	Labeled for dogs, cats, and horses	4 oz, 16 oz	*TrizEDTA®*
Tris-EDTA (crystals flush)	Labeled for dogs and cats	4 oz, 16 oz	*TrizEDTA crystals®*
Tris-EDTA, chlorhexidine 0.15% (flush)	Labeled for dogs and cats	4 oz	*TrizCHLOR®*
Tris-EDTA, ketoconazole 0.15% (flush)	Labeled for dogs, cats, and horses	4 oz, 12 oz	*TrizULTRA + Keto®*
Tris-EDTA, chlorhexidine 0.15%, ketoconazole 0.15% (flush)	Labeled for dogs and cats	4 oz, 12 oz	*Mal-A-Ket Plus TrizEDTA®*

Antifungal Agents, Otic

See also ***Corticosteroid/Antimicrobial Agents, Otic***

Indications/Actions

Antifungal ear preparations are usually used to treat otitis caused by *Malassezia* spp and rarely other otic fungal diseases, such as aspergillosis and candidiasis. Most commercially available products also contain an antibiotic and/or a glucocorticoid. Therefore, ear cytology should

be performed to confirm a fungal/yeast infection prior to prescription of topical antifungals, particularly if an antimicrobial and antibiotic combination is being considered.

Topical azole antifungals, such as miconazole and clotrimazole, have been shown to possess in vitro activity against *Staphylococcus* spp. Listed in the ***Veterinary-Labeled Products*** section are exclusively the products without antibiotic or glucocorticoid agents. These products are not labeled as otic medications but have commonly been used in veterinary patients.

Suggested Dosages/Uses

Most products are labeled to be used 1 to 2 times daily in adequate amounts to coat the patient's entire ear canal.

Precautions/Adverse Effects

Advise owners to discontinue the medication and contact their veterinarian if their animal's ears become redder or more inflamed at any time during treatment. There is little information available regarding ototoxicity from topical antifungal use in dogs and cats; therefore, caution should be used when prescribing various topical otic medications in animals with ruptured tympanic membranes. In one study in dogs, administration of clotrimazole (15 g tube [2% cream] mixed 50:50 with sterile water) did not change the BAER score, and vestibular signs were not reported.[1] No other safety studies in dogs or cats with otic antifungals are available. Patients should be rechecked before discontinuing treatment, and treatment should be continued until 1 week after negative cytology is obtained.

Refer to each product's label for inactive ingredients and precautions or contraindications. Some inactive ingredients, including alcohol or alcohol-based solvents such as propylene glycol, can be irritating and cause inflammation, particularly in sensitive, eroded, or ulcerated ears, and these ingredients should be avoided in ears with ruptured tympanum.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Clotrimazole 1% (solution)	Labeled for dogs and cats	Rx; 10 mL, 30 mL, and 60 mL	*ClotrimaTop®; Clotrimazole®*
Miconazole nitrate 1.15% (equivalent to 1% miconazole base by weight) (lotion)	Labeled for dogs and cats	Rx; 60 mL, 120 mL	*Conzol®; MicaVed®; Miconosol®*

Antiparasitic Agents, Otic

NOTE: This monograph includes only preparations labeled to be applied directly into the ear canals for the treatment of otoacariosis; however, parasiticides with systemic or more generalized effect are preferred because *Otodectes cynotis* mites are known to also live outside ear canals and can re-infest the ears. See also ***Afoxolaner; Fipronil/Fipronil Combinations, Topical; Fluralaner; Sarolaner; Selamectin***. Refer to specific product labels for complete instructions regarding use, inactive ingredients, precautions, and contraindications.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Piperonyl butoxide 0.5%, pyrethrins 0.05%	Labeled for dogs and cats 12 weeks of age or older	OTC; 3 mL, 9 mL, 0.5 oz, 1 oz	*Adams®; Happy Jack Mitex®; Hartz UltraGuard®* Clean ears. Apply daily for 7 to 10 days. Repeat in 2 weeks if necessary
Piperonyl butoxide 0.6%, pyrethrins 0.06%	For use on dogs and cats 12 weeks of age or older	OTC; 1 oz, 3 oz, 4 oz	*No-Bite®; PetArmor; Sentry HC EARMITE free®; Sergeant's Vetscription MITEaway®* Clean ears. Apply twice daily until ticks/mites are eliminated
Piperonyl butoxide 1%, pyrethrins 0.15%	Labeled for dogs; some products labeled for cats and horses NOT for use on puppies or kittens under 12 weeks old OR for use on horses/foals intended for slaughter	OTC; 4 oz, 6 oz	*Ear-Rite®* (dogs); *Ear Mite®* (dogs, cats, horses) Clean ears. Apply daily for 7 to 10 days. Do not repeat treatment for 3 to 5 days if used as a repellent. Horses are treated daily for 2 to 3 days, then every 3 to 5 days as needed for controlling ectoparasites (eg, ticks, gnats).
Piperonyl butoxide 1.05%, pyrethrins 0.1%	For use on dogs 12 weeks of age or older	OTC; 0.75 oz	*Ear Mite Remedy* Clean ears. Apply once. If needed, repeat every other day until the infestation is resolved.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Piperonyl butoxide 1.5%, pyrethrins 0.15%	Species depends on product No products available for use on dogs, cats, or rabbits under 12 weeks of age	OTC; 0.5 oz, 1 oz	*Ear-Rite*® (cats and kittens); *Eradimite*® (dogs and cats); *Otomite*® *Plus* (dogs, cats, puppies, kittens) Clean ear. Apply as a single dose. May repeat every 2 days until the condition has cleared up or repeat in 7 days depending on product directions. As a preventative treatment, apply every 15 days
Piperonyl butoxide 1%, pyrethrins 0.15% (lotion)	For use on dogs and cats at least 12 weeks old	OTC; 6 oz	*Performer*® Clean ears. Apply for 7 to 10 days
Piperonyl butoxide 1.5%, pyrethrins 0.15% (lotion)	For use on dogs and cats over 12 weeks of age	OTC; 12 mL, 22 mL	*Mita-Clear*® Clean ear; instill enough to wet ear canal and massage. Do not reapply for 7 days
Milbemycin oxime 0.1% (solution)	For use on cats or kittens 4 weeks of age or older	Rx; box of 10 pouches of 2 tubes of 0.25 mL each	*MilbeMite*® Clean ear. Apply entire contents of tube in the external ear canal; one tube per ear. Repeat in 30 days, if recommended by the veterinarian Safe use in cats used for breeding purposes, pregnant, or lactating has not been evaluated.
Ivermectin 0.01% (suspension)	For use in cats and kittens 4 weeks of age or older	Rx; box of 12 foil pouches of 2 ampules of 0.5mL each	*Acarexx*® Apply 0.5 mL in each ear. Repeat 1 time if necessary based on ear mite life cycle and response to treatment
Neomycin sulfate 0.25%, thiabendazole 4%, dexamethasone 0.1%	Labeled for otoacariasis and bacterial and fungal otitis in dogs and cats for a maximum of 1 week duration	OTC; 7.5 mL, 15 mL	*Tresaderm*® Clean ears. Apply twice daily until the infestation is resolved

Antiseptic Cleaning Agents, Otic

See also ***Cleaning/Drying Agents, Otic***

Indications/Actions

Topical antiseptic ear flushes include acetic acid, salicylic acid, boric acid, chlorhexidine, ketoconazole, miconazole, hypochlorous acid, and microsilver-containing products. These products are typically used as adjunctive therapy for ear infections (eg, bacterial and/or yeast) but can also be used as sole treatment in mild, first-time infections and for maintenance in some cases. Acetic and boric acids work as an acidifying, drying, and antimicrobial agent. Chlorhexidine has activity against gram-positive and gram-negative bacteria and fungi. Chloroxylenol is mostly active against bacteria. Ketoconazole and miconazole are fungistatic antifungals, although miconazole has been shown to be fungicidal against *Candida* spp. Hypochlorous acid is a broad-spectrum antimicrobial with rapid activity against gram-positive and gram-negative bacteria and fungal/yeast organisms. Its mode of action against micro-organisms mimics that of neutrophils in the body. The main route of attack against microorganisms is disruption of the cellular membrane. Microsilver has both antibiofilm and antibacterial properties, generating silver ions that kill gram-positive and gram-negative bacteria, such as *Pseudomonas aeruginosa*, *Staphylococcus* spp, *Streptococcus* spp, including multidrug-resistant organisms, in addition to *Malassezia* spp.

Suggested Dosages/Uses

When recommending ear flushing as part of the treatment regimen, it is important to demonstrate the cleaning technique in the examination room and advise the client to discontinue application and contact the veterinarian if the ears become redder or more inflamed at any time during the course of cleaning.

The frequency of cleaning varies according to the needs of the individual patient. Some of these products may also be used as antiseptics for the skin. Refer to each product label for inactive ingredients, details on use, and any precautions.

Precautions/Adverse Effects

There is little information regarding the ototoxicity of ear cleaners in dogs and cats. Agents that are believed to be safe in dogs and cats for

ear flushing in the presence of ruptured tympanic membrane include sterile water, sterile saline, tris-EDTA, and possibly chlorhexidine at a concentration of less than 0.05%. More concentrated chlorhexidine-containing products should be used cautiously in ear canals with ruptured tympanic membranes because of the potential for ototoxicity, particularly in cats.

Alcohol-containing products should be avoided if the status of the tympanic membrane cannot be determined or if it is ruptured. Avoid products containing alcohol for eroded, ulcerative, and/or painful and sensitive ears as that alcohol can be irritant.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Acetic acid 2%, boric acid 2% (cleanser)	Labeled for dogs and cats	OTC; 4 oz, 8 oz, and 16 oz	*MalAcetic®* Other ingredients: water, glycerin, polysorbate 20, fragrance, sodium hydroxide
Acetic acid 2% (solution)	Labeled for dogs and cats	OTC; 4 oz, 16 oz	*OtoCetic®* Other ingredients: water, witch hazel, benzyl alcohol, polysorbate 80, DMDM hydantoin (as preservative), fragrance
Acetic acid 1%, ketoconazole 0.15%, hydrocortisone 1% (cleanser)	Labeled for dogs, cats, and horses	OTC; 2 oz, 8 oz	*MalAcetic® Ultra* Other ingredients: ceramide complex
Acetic acid 1%, boric acid 2%, hydrocortisone 1%, keto-conazole 0.15% (flush)	Labeled for dogs and cats	OTC; 8 oz	*Oticetic®* Other ingredients: propylene glycol, ceramides, glycerin, polysorbate, triethanolamine, fragrance
Chlorhexidine 0.15%, keto-conazole 0.15%, tris-EDTA (flush)	Labeled for dogs and cats	OTC; 4 oz, 12 oz	*Mal-A-Ket Plus TrizEDTA®* Other ingredients: decolorized aloe vera, glycerine, glycolic acid, methylisothiazolinone, nonoxynol-9, tris-EDTA, water
Chloroxylenol 0.2%, ketoconazole 0.2% (flush)	Labeled for dogs, cats, and horses	OTC; 4 oz, 8oz	*Pharmaseb®*
Chloroxylenol 0.33%, ketoconazole 0.33% (flush)	Labeled for dogs, cats, and horses	OTC; 8 oz	*Ketomax®* Other ingredients: benzyl alcohol, fragrance, propylene glycol, purified water, sodium borate decahydrate
Hypochlorous acid (HOCl) 0.009% (rinse)	Safe for use on all animals	OTC; 3 oz	*Vetericyn Plus® Antimicrobial Ear Rinse* Other ingredients: electrolyzed water (H_2O), sodium chloride (NaCl), sodium hypochlorite (NaOCl)
Ketoconazole 0.1% (flush)	Labeled for dogs and cats	OTC; 12 oz	*Curaseb®* Other ingredients: purified water, SDA-40, nonoxynol-9, benzyl alcohol, disodium EDTA, tromethamine technical grade, fragrance
Ketoconazole 0.1%, phyto-sphingosine HCl 0.01% (flush)	Labeled for dogs and cats	OTC; 4 oz, 16 oz	*VetraSeb® TRIS* Other ingredients: water, SDA 40B 190 proof, nonoxynol-9, tromethamine, disodium EDTA, methylisothiazolinone
Miconazole 0.1% (flush)	Labeled for dogs and cats	OTC; 4 oz, 16 oz	*BioTris®* Other ingredients: disodium EDTA, methylchloroisothiazolinone, methylisothiazolinone, N-octadecanoylphytosphingosine (ceramide Ill), PEG-40 hydrogenated castor oil, propylene glycol, purified water, tromethamine (Tris USP)
Microsilver 0.5%. climbazole 0.5% (concentrate)	Labeled for dogs and cats	OTC; 6 mL	*UltraOtic® Concentrate* Other ingredients: avicel RC-591, benzyl alcohol, glycerin, N-octadecanoylphytosphingosine (ceramide Ill), phenoxyethanol, polysorbate 80, purified water, sodium benzoate, titanium dioxide, triton x100/OP10, xanthan gum

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Microsilver 0.2%, lactic acid 1% (rinse)	Labeled for dogs and cats	OTC; 4 oz	*UltraOtic®* Antiseptic/antibiofilm activity. May be used prior to *UltraOtic® Concentrate* for additional benefit Other ingredients: carboxymethyl cellulose, fragrance, glycerin, magnesium aluminum silicate, methylchloroisothiazolinone, methylisothiazolinone, octoxynol-10, purified water
Salicylic acid 0.15%, ketoconazole 0.1% (ear rinse)	Labeled for dogs and cats	OTC; 4 oz	*PetArmor® Medicated Ear Rinse* Other ingredients: glycerin, potassium sorbate, propyelene glycol, purified water, sodium benzoate

Cerumenolytic Agents, Otic

Indications/Actions

Cerumenolytic agents soften hardened cerumen and make it easier to remove. Cerumenolytic agents can be classified as water-based agents, oil-based agents, or agents that are neither water nor oil based. Docusate sodium (DSS) and triethanolamine polypeptide oleate are water-based agents that act as surfactants to emulsify and disperse cerumen. Oil-based agents, such as propylene glycol, squalane, and various oils, soften and loosen cerumen without disintegrating it.[1] Squalane is the most potent of these agents. Some agents are neither water nor oil based, such as carbamide peroxide (urea-hydrogen peroxide) and glycerin. Carbamide peroxide is a foaming agent that releases oxygen to help break up debris. Glycerin acts by softening and loosening cerumen, similar to oil-based agents.

Docusate sodium, calcium sulfosuccinate (docusate calcium), and carbamide peroxide are considered potent cerumenolytic agents. Squalane and triethanolamine polypeptide oleate are less potent agents. Propylene glycol, glycerin, and oils are considered very mild cerumenolytic agents.

Evidence in humans suggests that no cerumenolytic agent is superior to any other, but any type of cerumenolytic agent tends to be superior to no treatment.[2]

Suggested Dosages/Use

These agents work best when they are applied 10 to 15 minutes prior to cleaning an area with an astringent or drying cleaner. Demonstrate proper cleaning technique in the examination room if cerumenolytic products will be administered at home by an owner. Advise owners to discontinue product application and contact their veterinarian if their animals' ears become redder or more inflamed at any time during the course of cleaning.

Precautions/Adverse Effects

Cerumenolytic agents should not be used with ruptured tympanic membranes (especially in cats) because of the potential for ototoxicity, with the exception of squalane.[3] If cerumenolytic agents are needed during in-hospital ear-flushing procedures, use of these products should be followed by multiple flushes with warm sterile isotonic saline. Alcohol-containing products should be avoided if the status of the tympanic membrane cannot be determined, or if the tympanic membrane is ruptured. Avoid products containing alcohol for eroded, ulcerative, and/or painful and sensitive ears, as the alcohol can be an irritant. The frequency of cleaning varies according to the needs of the individual animal. Some of these products may also be used as antiseptics for the skin. Refer to each product label for details on use and any precautions.

Veterinary-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Squalane 25% in isopropyl myristate and light mineral oil	Labeled for dogs and cats	OTC; 4 oz	*Cerumene®*
Phytosphingosine 0.2% in alcohol, water, and propylene glycol	Labeled for dogs and cats	OTC; 4.2 oz, 8.4 oz	*Douxo® Micellar*
Carbamide peroxide 6.5%, glycerin base	Labeled for dogs and cats	OTC; 4 oz	*Earoxide®*
Propylene glycol, salicylic acid, glycerin	Labeled for dogs and cats	OTC; 8 oz, 12 oz	*EpiKlean®*
Squalane 22%, isopropyl myristate, white mineral oil	Labeled for dogs and cats	OTC; 4 oz	*KlearOtic®*
Methylchloroisothiazolinone, methylisothiazolinone, micellar solution (cetrimonium bromide, disodium EDTA, PEG-6 caprylic/capric glycerides, polysorbate 80, water), N-octadecanoyl-phytosphingosine (ceramide III)	Labeled for dogs and cats	OTC; 8 oz	*Milytic®*

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Calendula, capryloyl glycine (*Lipacide*® C8G), glycerin, isopropyl alcohol, labrasol, lemon synthetic perfume, polysorbate 80, transcutol V, tromethamine, undecylenoyl glycine (*Lipacide*® UG), water	Labeled for dogs and cats	OTC; 4 oz	*pH•notix*®
Phytosphingosine hydrochloride 0.01%, salicylic acid 0.15%	Labeled for dogs and cats	OTC; 8 oz	*SkinGuard*® *Cleanse*
Denatured alcohol 10%, lactic acid 1.76%, propylene glycol, docusate sodium, salicylic acid	Labeled for dogs and cats	OTC; 4 oz, 8 oz, and 16 oz	*Vet Solutions*®

Cleaning/Drying Agents, Otic

Indications/Actions

Cleaning and drying agents are typically used after debris or exudate has been removed from the ear canals with a cerumenolytic agent; however, they may also be used as a sole ear cleanser. The primary ingredients are astringents, such as isopropyl alcohol or aluminum acetate, and acids, such as boric acid or salicylic acid. Some cleaning and drying agents may have antimicrobial effects, and some may also be used as antiseptics for the skin.

Suggested Dosages/Use

The frequency of cleaning varies according to the needs of the individual patient. Cleaning and drying ear solutions can be used on a maintenance regimen to help prevent ear infections and after bathing or swimming to keep the external ear canals dry. It is important to demonstrate the cleaning technique in the examination room.

Precautions/Adverse Effects

Advise the client to discontinue the application and contact the veterinarian if the ears become redder or more inflamed at any time during the course of cleaning.

There is little information regarding the ototoxicity of ear cleaners in dogs and cats. Agents that are believed to be safe in dogs and cats for ear flushing in the presence of ruptured tympanic membrane include sterile water, sterile saline, tris-EDTA, and possibly chlorhexidine at a concentration of less than 0.05%. Propylene glycol- and alcohol-containing products should be avoided if the status of the tympanic membrane cannot be determined or if it is ruptured. Avoid products containing alcohol for eroded, ulcerative, and/or painful and sensitive ears as that alcohol can be irritant.

Veterinary-Labeled Products

Refer to each product label for specific details on use, inactive ingredients, and any precautions.

There is an overwhelming number of these products marketed, and the following are representative; they do not appear to be FDA-approved products. Many products also contain cerumenolytic ingredients. See also ***Cerumenolytic Otic Agents***.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Isopropyl alcohol, glycerin (lotion)	Labeled for dogs and cats	OTC; 4 oz, 6 oz, 8 oz, 12 oz, 32 oz, 1 gallon	*ADL*® *Ear Flushing Drying Lotion*
Dioctyl sodium sulfosuccinate, glycerin, lactic acid, salicylic acid, SD alcohol (solution)	Labeled for dogs and cats	OTC; 4 oz, 8 oz, 1 gallon	*Aloe vera otic cleanser (formerly AloeClens®); Aurocin®; Clean Ear® with Aloe Vera; Conquer® Hy-Otic*
Lactic acid 1.76%, salicylic acid 0.1%, SD alcohol 10% (solution)	Labeled for dogs and cats	OTC; 4 oz, 8 oz, 16 oz, and 1 gallon	*Ear Cleansing Solution*
Acetic acid, boric acid, ethanol (flush)	Labeled for dogs and cats	OTC; 12 oz, 1 gallon	*EarMed*® *Boracetic*®
Ethanol (solution)	Labeled for dogs and cats	OTC; 12 oz, 1 gallon	*EarMed*® *Cleansing Solution and Wash*
Ethanol (wipes)	Labeled for dogs and cats	OTC; 40 wipes 5 x 6, 50 wipes 5 x 8.5, and 160 wipes 6 x 7	*EarMed*®
Propylene glycol 3%, salicylic acid 0.05%, SD alcohol (cleanser)	Labeled for dogs and cats	OTC; 8 oz, 12 oz, 32 oz	*EpiKlean*®
Dioctyl sodium sulfosuccinate, chloroxylenol 0.1%, EDTA 0.5%, salicylic acid 0.2% (solution)	Labeled for dogs and cats	OTC; 4 oz, 8 oz	*Epi-Otic*® *Advanced*
Eucalyptus oil, malic acid, salicylic acid (solution)	Labeled for dogs and cats	OTC; 4 oz, 16 oz	*Eucalyptus Oil (formerly Euclens®)*

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Acetic acid 2%, boric acid 2% (cleanser)	Labeled for dogs and cats	OTC; 4 oz, 8 oz, and 16 oz	*MalAcetic®*
Acetic acid 1%, hydrocortisone 1%, ketoconazole 0.15% (cleanser)	Labeled for dogs, cats, and horses	OTC; 2 oz, 8 oz	*MalAcetic ULTRA®*
Boric acid, zinc gluconate (liquid)	Recommended for dogs, cats, and exotics	OTC; 2 oz, 4 oz	*Maxi/Guard® zn 4.5*
Isopropyl alcohol (solution)	Labeled for dogs and cats	OTC; 4 oz, 16 oz	*Nolvasan®*
Malic acid, salicylic acid (solution)	Labeled for dogs and cats	OTC; 4 oz	*Oti-Clens®*
Dioctyl sodium sulfosuccinate, lactic acid, propylene glycol, salicylic acid, SD alcohol (solution)	Labeled for dogs and cats	OTC; 8 oz	*Otiderm®*
Boric acid 2%, glycolic acid 2% (solution)	Labeled for dogs and cats	OTC; 16 oz	*Otiderm® Advanced*
Glycerin, dioctyl sodium sulfosuccinate, lactic acid, salicylic acid (solution)	Labeled for dogs and cats	OTC; 8 oz	*OtiRinse®*
Acetic acid, alcohol (cleanser)	Labeled for dogs and cats	OTC; 4 oz	*Sulfodene®*
Chloroxylenol, SD alcohol (gel)	Labeled for dogs	OTC; 4 oz	*Swimmer's Ear Astringent*
Glycerin, lactic acid 1%, microsilver 0.2% (rinse)	Labeled for dogs and cats	OTC; 4 oz	*UltraOtic®*
Hypochlorous acid (HOCI) 0.009% (rinse)	Safe for all animals	OTC; 3 oz	*Vetericyn Plus®*
Glycerin, lactic acid 2.7%, salicylic acid 0.15%, sodium dioctyl sulfosuccinate, SD alcohol (solution)	Labeled for dogs and cats	OTC; 8 oz, 16 oz	*VetOtic®*
Coco-glucoside, glucose oxidase, glycerin, lactoferrin, lactoperoxidase, lysozyme, zinc gluconate (cleanser)	Labeled for dogs and cats	OTC; 4 oz, 1 gallon	*Zymox®* Ear Cleanser

Corticosteroid Agents, Otic

See also ***Corticosteroid/Antimicrobial Agents, Otic***

Indications/Actions

Corticosteroid-containing ear medications are used in cases of acute or chronic otitis with the goal of reducing inflammation, edema, tissue hyperplasia, pain, and pruritus. In addition, they are helpful in decreasing secretions from sebaceous and apocrine glands, thereby reducing the buildup of debris in ear canals. Otic solutions that contain glucocorticoids without an antibiotic can be used as maintenance therapy, if needed, in cases of allergic otitis.

Suggested Dosages/Uses

The frequency of applications should be according to the patients' needs, usually 1 to 4 times daily.

Precautions/Adverse Effects

When using corticosteroid preparations as maintenance therapy, use the least potent glucocorticoid at the lowest possible frequency to balance efficacy and prevent undesirable adverse effects, including skin atrophy, alopecia, and adrenocortical suppression effects from systemic absorption. Some glucocorticoids, such as dexamethasone and fluocinolone, are believed to be safe for use in the middle ear; however, the combination of fluocinolone and dimethyl sulfoxide (DMSO; *Synotic®*) may not be safe for administration in the ear if the tympanic membrane is ruptured as DMSO may cause ototoxicity.[1]

Veterinary-Labeled Products

Refer to each product's label for inactive ingredients and precautions or contraindications. Some inactive ingredients, including alcohol or alcohol-based solvents such as propylene glycol, can be irritating and cause inflammation, particularly in sensitive, eroded, or ulcerated ears, and should be avoided in ears with ruptured tympanum.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Fluocinolone 0.01%, DMSO 60% (solution)	Labeled for dogs	Rx; 8 mL, 60 mL	*Synotic®*

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Hydrocortisone 0.5% (solution)	Labeled for dogs and cats	OTC; 1.25 oz	*Zymox®*
Hydrocortisone 1% (solution)	Labeled for dogs and cats	OTC; 1.25 oz	*Zymox®*, *Zymox® Plus*
Hydrocortisone 1%, Burow's solution 2% (solution)	Labeled for dogs	OTC; 1 oz, 16 oz	*Cort/Astrin®*

Human-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Fluocinolone acetonide 0.01% (oil)	Labeled for humans	Rx; 20 mL	*DermOtic®;* generic

Corticosteroid/Antimicrobial Agents, Otic

See also ***Corticosteroid Agents, Otic***

Indications/Actions

Most otic antimicrobial preparations for veterinary use that are commercially available combine an antifungal, an antibiotic, and a glucocorticoid agent. These medications should be used when anti-inflammatory and/or anti-pruritic effects are needed in the presence of concurrent bacteria and yeast infections. Ear cytology should be performed to confirm an infection prior to prescription of ear medications containing antimicrobials, particularly antibiotics, to help prevent antibiotic overuse and bacterial resistance. In chronic cases or when rods are seen on cytology, culture and susceptibility may be recommended to identify multidrug-resistant organisms, such as *Pseudomonas* spp. If only bacteria or yeast are present, more targeted otic antimicrobials, with or without glucocorticoids, may be considered.

Suggested Dosages/Uses

Most of these products should be used 2 to 3 times daily in adequate amounts to coat the entire ear canal. Refer to each product's label for detailed usage instructions. Patients should be rechecked before discontinuing treatment, and treatment must be continued until 1 week after negative cytology is obtained.

Precautions/Adverse Effects

Advise the client to discontinue the medication and contact the veterinarian if the ears become redder or more inflamed at any time during treatment and to avoid contact with the animal's mouth and eyes.

Use with caution when prescribing various topical otic medications in patients with ruptured tympanic membranes due to potential ototoxicity. Cats may be more sensitive to irritation and ototoxicity from topical otic agents.[1] Use of aminoglycosides in the presence of a ruptured tympanic membrane is controversial. One study showed no vestibulotoxic or ototoxic effects from 21 days of otic gentamicin applied every 12 hours to ears with ruptured tympanic membranes. Another study measured brainstem auditory-evoked responses (BAER) and found that although tobramycin significantly impaired hearing, gentamicin did not[2]; however, ototoxicity from topical aminoglycoside administration has been shown in many chinchilla and guinea pig studies.[3–6] In dogs, administration of clotrimazole 2% cream mixed 50:50 with sterile water did not change the BAER score, and vestibular signs were not reported. Some glucocorticoids, such as dexamethasone and fluocinolone, are believed to be safe for use in the middle ear. One dog developed pemphigus vulgaris after 1 week of otic polymyxin B application.[7]

Veterinarians and owners must use caution when handling these medications to prevent potential accidental human exposure, especially direct skin and eye contact. *Claro®* and *Osurnia®* contain specific warnings regarding ocular injuries in humans, including corneal ulcers.[8,9] Eye protection is recommended during administration, and dogs should be restrained to minimize postapplication head shaking.

Veterinary- and Human-Labeled Products

Refer to each product's label for inactive ingredients and precautions or contraindications. Some inactive ingredients, including alcohol or alcohol-based solvents, such as propylene glycol, can be irritating and cause inflammation, particularly in sensitive, eroded, or ulcerated ears, and should be avoided in ears with ruptured tympanum.

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Florfenicol 16.6 mg/mL, terbinafine 14.8 mg/mL, mometasone furoate 2.2 mg/mL (solution)	Labeled for dogs	Rx; 1 mL single-dose dropperette	*Claro®* 1 tube per ear; 30-day duration of effect. Shake before use. To be administered in the clinic.
Gentamicin sulfate 0.3%, clotrimazole 1%, betamethasone valerate 0.1% (ointment)	Labeled for dogs	Rx; 7.5 g, 10 g, 15 g, 25 g, 30 g, and 215 g	*Gentizol®*, *MalOtic®*, *Otibiotic®*, *Otomax®*

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Gentamicin sulfate 1.5 mg/mL, miconazole nitrate 17.4 mg/mL, hydrocortisone aceponate 1.11 mg/mL, (suspension)	Labeled for dogs	Rx; 10 mL (10 doses)	*Easotic®* Oily suspension; shake well before use. Labeled for once-daily dosage for 5 days. Prime pump before first use.
Gentamicin sulfate 3 mg/mL, betamethasone valerate 1 mg/mL (solution)	Labeled for dogs and cats	Rx; 7.5 mL, 15 mL, and 240 mL	*GenOne®, GentaOtic®, GentaVed®, Vet Beta-Gen®*
Ketoconazole 0.15%, hydrocortisone 1% (thermally activated gel)	Labeled for dogs and cats	OTC; 2 oz	*KC-Oto Pack®*
Gentamicin 3 mg/g, clotrimazole 10 mg/g, mometasone 1 mg/g (suspension)	Labeled for dogs	Rx; 7.5 g, 15 g, 30 g, and 215 g	*LoZatom®, Malmetazone®, Maxi-Otic®, Mometamax®, Mometavet®, MotaZol®* Once-daily dosing. Shake well before use.
Neomycin sulfate 0.25%, thiostrepton 2500 units/mL, nystatin 100,000 units/mL, triamcinolone acetonide 0.1% (ointment)	Labeled for dogs and cats	Rx; 7.5 mL, 15 mL, 30 mL, and 240 mL	*Animax®, Dermalone®, Derma-Vet®, EnteDerm®, Quadritop®*
Florfenicol 10 mg/mL, terbinafine 10 mg/mL, betamethasone acetate 1 mg/mL (gel)	Labeled for dogs	Rx; single-dose 1 mL tube	*Osurnia®* 1 tube per ear; repeat in 7 days. To be administered in the clinic. Do not clean ear canal for 45 days after initial treatment.
Orbifloxacin 10 mg/g, posaconazole 1 mg/g, mometasone furoate 1 mg/g (suspension)	Labeled for dogs	Rx; 7.5 g, 15 g, and 30 g	*Posatex®* Once-daily dosing. Shake well before use.
Polymyxin B 0.5293 mg/mL, miconazole 23 mg/mL, prednisolone acetate 5 mg/mL (suspension)	Labeled for dogs	Rx; 15 mL, 30 mL	*Surolan®* Shake well before use.
Neomycin 3.2 mg/mL, thiabendazole 40 mg/mL, dexamethasone 1 mg/mL (solution)	Labeled for dogs and cats	Rx; 7.5 mL, 15 mL	*Tresaderm®*
Neomycin sulfate 0.5%, isoflupredone acetate 0.1%, tetracaine hydrochloride 0.5% (ointment)	Labeled for dogs, cats, and horses	Rx; 10 g	*Tritop®*

Human-Labeled Products

Active ingredients (formulation)	Species	Label status; size(s)	Trade names/additional information
Ciprofloxacin 0.3%, dexamethasone 0.1% (suspension)	Human-labeled product	Rx; 7.5 mL	*Ciprodex®* Shake before use.
Ciprofloxacin 0.2%, hydrocortisone 1% (suspension)	Human-labeled product	Rx; 10 mL	*Cipro® HC* Shake well before use.
Colistin 3 mg/mL, neomycin 3.3 mg/mL, thonzonium bromide 0.5 mg/mL, hydrocortisone 10 mg/mL (suspension)	Human-labeled product	Rx; 10 mL	*Coly-Mycin S®, Cortisporin-TC®* Shake well before use.
Neomycin 3.5 mg/mL, polymyxin B 10,000 units/mL, hydrocortisone 10 mg/mL (solution)	Human-labeled product	Rx; 7.5 mL and 10 mL	generic
Tobramycin 0.3%, dexamethasone 0.05% (suspension)	Human-labeled product	Rx; 2.5 mL and 5 mL	*TobraDex® ST* Extra-label use in the ear.
Tobramycin 0.3%, dexamethasone 0.1% (suspension)	Human-labeled product	Rx; 2.5 mL, 5 mL, and 10 mL	*TobraDex®* Extra-label use in the ear.

Appendix

Veterinarian's Guide to Writing Prescriptions

A growing number of pet owners opt to have prescriptions filled at community or online pharmacies to obtain medications for their animals. In accordance with this trend, at least 40 states require veterinarians to provide pet owners with written prescriptions upon request.[1] Additionally, these pharmacies may be needed to fill prescriptions for medications that are compounded or not stocked in the veterinarians' clinic. Legally, animal prescriptions are treated the same as human prescriptions and must meet the same requirements in order to be filled. The following best practices will assist veterinarians to write legally compliant prescriptions while also minimizing the risk for medication errors and reduce potential harm to animal patients.

Prescription Requirements

Prescriptions are legal documents, and the information required on prescriptions, veterinary or otherwise, varies by state. Check with your state's Pharmacy and Veterinary boards to ensure all legal requirements are met.

LEGAL PRESCRIPTION REQUIREMENTS

- Patient name and species
- Pet owner's name and address
- Date prescription was written
  - Do not postdate; however, it may be acceptable to write "Do not fill until ___" to prevent early filling.
- Drug Information
  - Drug name
  - Strength
  - Dosage form (eg, tablet, capsule, suspension)
  - Quantity
  - Instructions for use ("sig"): dose, route, and frequency of administration
- Number of refills. The use of "PRN" generally authorizes refills for 1 year from written date.
- DEA # for controlled substance prescriptions
- Prescriber's name, address, and phone number
- Prescriber signature
- Withdrawal time (if applicable)

HELPFUL ITEMS THAT MAY NOT BE LEGALLY REQUIRED

Think of the pharmacist as the last safety check before the medication reaches the patient. The more information provided on the prescription, the more the safety of patients and their owners can be assured.

- Client phone number
- Patient's breed
- Patient's current body weight
- Indication for use
- Duration of use
- Patient date of birth
- Usage (ie, companion versus food/fiber animal)

Controlled Substances

Controlled substances are drugs that have the potential for abuse or dependence and are classified into 5 schedules according to their medical use, as well as relative abuse potential and dependence liability. Controlled substances are regulated both by individual states as well as by the Federal government. In order to prescribe controlled substances, practitioners must be authorized in the jurisdiction where they are licensed to practice and also be registered with the Drug Enforcement Agency (DEA). As controlled substance requirements vary between states, consult your state's controlled substance act to ensure compliance.

- **All controlled substances prescriptions must include the prescriber's DEA registration number.**
- **Schedule II (C-II) prescriptions** (eg, hydrocodone combinations)
  - Must be a physical (written or printed) prescription with original, manual signature (cannot be called in or faxed). Note that electronic prescribing of C-II prescriptions is permitted by DEA, but current veterinary practice management systems often do not meet DEA requirements.
  - Refills are not permitted – a new prescription must be generated each time
  - States may specify a time limit (eg, 30 or 60 days) within which C-II prescriptions must be filled; unfilled prescriptions become void after this time limit has passed.
  - Quantity limits (eg, 30-day maximum supply) may be mandated by the state
- **Schedule III-IV (CIII-IV) prescriptions** (eg, benzodiazepines, phenobarbital, tramadol)
  - Fax and verbal (ie, telephone) transmission is allowed
  - For chronic medications, a new prescription is required every 6 months
  - Refills are permitted, up to a maximum of 5 refills in 6 months
  - Quantity limits (eg, 90-day maximum supply) may be mandated by the state

Best Practices for Prescription Writing

- Manually written prescriptions should be in blue or black ink.
- Write the quantity to be dispensed both numerically and alphabetically for clarity and to avoid potential diversion (eg, #30 [thirty] tablets).
- When a patient requires a specific brand or manufacturer of a product (eg, *Novolin® N*), write the prescription for the required product name or manufacturer, and notate on the prescription for the pharmacist to "dispense as written."
- Do not pre-sign blank prescriptions.
- Prescribers are not obligated to provide their DEA number for noncontrolled prescriptions and may instead provide a state-issued license number.
  - The National Provider Identifier (NPI) is used for human insurance billing purposes and as such is not intended to be held by veterinarians.

Medication Errors and Patient Safety

The human health care system has given considerable attention to reducing medical errors, including those involving medications. Although prescription abbreviations are used throughout many references and are generally well recognized, they increase the potential for errors to occur. The Institute for Safe Medication Practices (ISMP) and the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) focus on medication safety and have identified certain abbreviations and dose expressions that should be avoided due to the documented increased risk for medication errors. When writing a prescription, writing out the directions in plain English and avoiding the use of error-prone abbreviations help to ensure patient safety.

Style to avoid	Example	Potential problem	Use instead
Naked decimals	.5 mg	Read as 5 mg (10x overdose)	0.5 mg
Trailing zeros	5.0 mg	Read as 50 mg (10x overdose)	5 mg
Examples of error-prone abbreviations (not a complete list)	SID*	Read as BID, QID, 5/day	Write out "daily" or "every 24 hours"
	QD, q.d., q1d	Read as QID	Write out "daily" or "every 24 hours"
	QOD, EOD	Read as QD or other frequency	Write out "every other day" or "every 48 hours"
	QID	Read as QD or other frequency	Write out "four times daily" or "every 6 hours"
	IU or u	Read as "IV" or 10; read as 0	Write out "units"
	ng	Read as mg	Write out "nanogram"
	Gr	Read as "gram" instead of "grain"	Write out "grain" or use metric system (eg, mg equivalent)
	AD, AS, AU	Read as "OD", "OS", or "OU"	Write out "right ear", "left ear", or "both ears"
	hs, qhs	Read as "half strength"	Write out "at bedtime"
	SQ, sq, or sub q	Read as "SL" or "5 every"	SUBQ or write out "subcutaneously"
Drug name shorthand	MgSO4	Read as morphine sulfate	Write out magnesium sulfate
	Bute	Read as butorphanol	Write out "phenylbutazone"

*SID is an abbreviation that is virtually unknown to health professionals outside of veterinary medicine, and most pharmacists do not recognize it. SID should be eliminated from usage and replaced with "daily" or "once daily." The additional time taken to write out "once daily" could prevent a potentially serious, avoidable error.

Commonly Used Abbreviations

Listed below are some commonly used abbreviations; however, the use of any abbreviation can increase the potential for errors to occur.

Abbreviation	Meaning
ac	before meals
amp	ampule
c̄ , c	with
cap	capsule
disp	dispense
g or gm	gram
gtt(s)	drop(s)
h, hr	hour
IA	intra-articular
ID	Intradermal
IM	intramuscular
IO	intraosseous
IP	intraperitoneal
IV	intravenous
kg	kilogram
lb	pound
m^2	meter squared
mg	milligram

Abbreviation	Meaning
mL	milliliter (ensure L is capitalized)
OD	right eye
OS	left eye
OU	both eyes
pc	after meals
PO	by mouth
prn	as needed
q	every
q4h	every 4 hours
qs; qs ad	quantity sufficient; quantity sufficient to make
Sig	directions to patient
SL	sublingual
stat	immediately
susp	suspension
tab	tablet
Tbsp, T	tablespoon (15 mL)
tsp, t	teaspoon (5 mL)
UD, ut dict	as directed

Pharmacist's Quick Guide to Veterinary Prescriptions: A Whole Different Animal

Dogs are not furry versions of people, and cats are not small dogs

Veterinarians may prescribe approved animal and human drugs in an extra-label (off-label) manner for therapeutic purposes to their patients as long as there is no threat to public health and certain other criteria are met, including a valid veterinarian–client–patient relationship (VCPR). Because often there are significant differences in the use of medications in animals versus humans, pharmacists must understand that information applicable to human patients may not be valid for veterinary patients. The following points are essential to consider.

Pharmacokinetics/Pharmacodynamics

The pharmacokinetics/pharmacodynamics can differ significantly for many drugs used in veterinary versus human patients. Some key species-specific examples follow.

DOGS

Dogs have nearly 30% more blood/kg than humans do, which can affect drug concentrations in the blood.

Dogs have a faster glomerular filtration rate, so renal elimination of drugs may be more rapid.

CATS

Cats are deficient or limited in several metabolic pathways, including hepatic glucuronidation, hydroxylation, and demethylation.

As compared to humans, animals—especially cats—may use different hepatic CYP isoenzymes to metabolize drugs.

For example, cats may not adequately convert prednisone to prednisolone.

OF NOTE

Doses and dose frequency can differ radically between humans and animals.

Thyroid supplementation: Levothyroxine doses for hypothyroid dogs can be 10 times (or more) the doses used in hypothyroid humans and may be given twice daily (q12h).

Seizure control: Doses for seizure medications can be much higher than those prescribed for human patients.

Antibiotics: Some antibiotic doses are very large (eg, ciprofloxacin dose for dogs) as compared to doses needed for human patients.

Different breeds of a species may have varying pharmacokinetics for a given drug.

Toxicities/Adverse Effects

Compounds that are considered relatively nontoxic for human patients can cause serious toxicity or adverse effects in veterinary patients. Key examples follow.

DOGS

Over-the-counter (OTC) NSAIDs (eg, aspirin, ibuprofen, naproxen): Relatively low doses can cause serious GI bleeding and/or renal toxicity.

Xylitol (common sweetener, sugar alcohol) can cause life-threatening hypoglycemia and acute hepatic failure in dogs.

Phenobarbital can cause hepatotoxicity in dogs.

CATS

Acetaminophen in cats: As little as 10 mg/kg can cause fatal methemoglobinemia.[1]

Cats can develop serious renal toxicity from the use of NSAIDs.

Dry-pilling doxycycline in cats can cause esophageal erosions and strictures.

Permethrin-containing products are toxic to cats.

OF NOTE

Be wary of pet owners' requests to give food with their pet's oral medications (to increase patient acceptance) without seeking a veterinarian's guidance. Many common foods (eg, chocolate, grapes/raisins) can be toxic to animals.

Understanding the Prescription

Veterinarians use different terminology and abbreviations than physicians and often prescribe drugs differently than pharmacists are accustomed to seeing.

OF NOTE

Pet owners may be referred to as "clients." The pet is the patient.

Veterinarians are taught to use the abbreviation SID (derived from the Latin *semel in die*, meaning once a day) in dosing instructions. Do not confuse this abbreviation with other abbreviations.

Veterinarians will rarely prescribe oral liquids as per 5 mL. Example: Amoxicillin 250 mg/5 mL suspension may be prescribed as 50 mg/mL.

KEY INFORMATION

A few key reminders may help pharmacists avoid medication errors and ensure animal health in partnership with the veterinarian and animal's owner.

KEY REMINDERS

What applies to human patients may not be relevant or valid for veterinary patients.

Refer to a trusted veterinary drug reference or contact the prescribing veterinarian if there are any questions or concerns about a prescription as written.

Do not assume that take-home information intended for human patients, including patient information sheets, is appropriate for animal patients.

Some drugs are used exclusively in animal patients (eg, enrofloxacin).

Veterinary-only drugs may interact with human-labeled drugs being concurrently administered extra-label.

All insulin products require a prescription when used in animals.

OTC drugs labeled for humans (eg, diphenhydramine) require a veterinary prescription to be used in animals, as veterinary use of these drugs is extra-label.

KEY DO NOTS

Do not substitute drug products (especially insulins) or dose forms without first contacting the veterinarian. 10% of veterinarians responding to recent polls indicated that some patients had been harmed when outside pharmacies made unauthorized substitutions.[2]

Do not recommend use of human OTC products or supplements in animal patients without seeking guidance from the animal's veterinarian, as some OTC products may contain combinations of drugs that could be toxic to animals (eg, phenylephrine).

Do not ask veterinarians for their NPI number—it is illegal for veterinarians to have one. A DEA number is not an appropriate substitution.

FOR MORE INFORMATION:

Use of prescription drugs in veterinary medicine. American Veterinary Medical Association: avma.org/resources-tools/avma-policies/use-prescription-drugs-veterinary-medicine.

Veterinary Pharmacy Education (Resolution No: 110-5-14). National Association of Boards of Pharmacy: nabp.pharmacy/news/news-releases/veterinary-pharmacy-education-resolution-110-5-14/. Passed May 30, 2014. NABP 110th Annual Meeting, Phoenix, AZ.

Important Contact Information

Poison Control Centers

In the US:

There are many regional poison centers that may be of assistance with animal poisonings; refer to your local poison control center for more information. The following are known 24-hour poison control centers in the US that specialize in providing information specific for veterinary patients.

- **Arizona Poison and Drug Information Center:**
  - 800-222-1222
  - expertise with management of snake bite envenomation
  - azpoison.com
- **ASPCA Animal Poison Control Center:**
  - 888-426-4435
  - consultation fee applies
  - aspca.org/pet-care/animal-poison-control
- **Pet Poison Helpline:**
  - 855-764-7661
  - consultation fee applies
  - petpoisonhelpline.com

In the UK:

- **Veterinary Poisons Information Center**:
  - +44 20 7305 5055 (for veterinarians)
  - +44 12 0250 9000 (pet owners)
  - subscription service
  - vpisglobal.com

In Australia:

- **Australian Animal Poisons Centre:**
  - +61 1300 869 738
  - animalpoisons.com.au

Governmental Veterinary Drug-Related Websites

In the US:

- **Center for Disease Control and Prevention, National Institute for Occupational Safety and Health (NIOSH):**
  - Useful document: List of Hazardous Drugs (cdc.gov/niosh/docs/2016-161/default.html)
  - cdc.gov/niosh/index.htm
- **Drug Enforcement Administration (DEA):**
  - 800-882-9539 (toll-free number for registration information)
  - deadiversion.usdoj.gov
- **Food and Drug Administration Center for Veterinary Medicine (FDA-CVM):**
  - General questions: email askCVM@fda.hhs.gov
  - Report an adverse event for a pharmaceutical:
    - For FDA-approved or indexed products, contact the drug company directly to report the adverse drug event.
    - Alternatively, file a report by downloading and completing the 1932a electronic form from fda.gov/animal-veterinary/report-problem/how-report-animal-drug-and-device-side-effects-and-product-problems#report See *How Do I Report A Problem (Adverse Events for Animal Drugs and Devices)?*
  - Call 888-332-8387 (888-FDA-VETS)
  - Emergency: 866-300-4374 or 301-796-8240
  - For after hours, call and leave a recorded message
  - Importation of veterinary products: The burden of importation appears to rest upon the exporter in completing necessary Customs and Border Patrol (CBP) documents that will allow the drugs to clear US Customs upon entry into the United States. It is important to note that drug shipments may still be seized by US Customs and returned to the exporter despite efforts to provide necessary documentation.
    - For more information: fda.gov/media/71776/download
    - Questions regarding importation of unapproved animal drugs should be emailed to the FDA Center for Veterinary Medicine, Office of Surveillance and Compliance, Division of Compliance at CVMImportRequests@fda.hhs.gov.
- **Food Animal Residue Avoidance & Depletion Program (FARAD):**
  - 1-888-USFARAD (1-888-873-2723)
  - farad.org
- **US Department of Agriculture (USDA) Animal and Plant Health Inspection Service (APHIS):**
  - Report an adverse event for an immunobiological agent (eg, vaccines, bacterins) or diagnostic kits:
    - For USDA-approved products, contact the manufacturer directly to report the adverse event.
    - Alternatively, call the USDA at 800-752-6255 or file a report by downloading and completing the USDA Adverse Event Reporting form from www.aphis.usda.gov/aphis/ourfocus/animalhealth/veterinary-biologics/adverse-event-reporting/CT_Vb_adverse_event
- **US Environmental Protection Agency (EPA):**
  - Most of the products used topically for the control of ectoparasites and insects on animals are regulated by the Environmental Protection Agency (EPA) under the *Federal Insecticide Fungicide and Rodenticide Act*. The National Pesticide Information Center (NPIC) is a collaboration between Oregon State University and the EPA.
  - Report an adverse event related to topical pesticides:
    - For EPA-approved products, contact the manufacturer directly to report the adverse event.
    - Alternatively, call NPIC at 800-858-7378 or report the adverse on the NPIC web portal located at npic.orst.edu/vet

In Australia:

- Australian Pesticides and Veterinary Medicines Authority (APVMA Website):

Drug Shortage Websites

- The Food and Drug Administration (FDA) maintains a drug shortage website:
  - email notification service is available
  - fda.gov/drugs/drug-safety-and-availability/drug-shortages
  - download the app for Android and iOS: FDA Drug Shortages
- The American Society of Health-System Pharmacists (ASHP) has a website for drug shortages related to human drugs:
  - ashp.org/drug-shortages/current-shortages

Drug Store Toxins in Small Animal Species

Products or compounds may be found in retail settings, pharmacies, or in human drugs that may be potentially toxic to dogs, cats, or other pets. Below is a partial list only. This list is not meant to be inclusive of all potentially toxic items. In addition, there are many human prescription drugs with significant toxic potential for small animal species; refer to the respective systemic monograph section. If the drug is not listed, consult with an animal poison control center for more information. The following known 24-hour poison control centers specialize in providing information specific for veterinary patients. Consultation fees apply.

- **ASPCA Animal Poison Control Center:** 888-426-4435; aspca.org/pet-care/animal-poison-control
- **Pet Poison Helpline (US):** 855-764-7661; petpoisonhelpline.com
- **Veterinary Poisons Information Service (UK):** 0207 305 5055; vpisglobal.com (membership required)
- **Australian Animal Poisons Centre (AU/NZ):** 1300 869 738 (AU) or 0800 869 738 (NZ); animalpoisons.com.au

Over-the-Counter (OTC) Medications

- **5-Hydroxytryptophan** (5-HTP, *Griffonia* seed extract): Human dietary supplement; serotonin precursor. Toxic to dogs and cats, as it induces serotonin syndrome. Clinical signs include sedation at low doses. High doses cause agitation, tremors, seizures, hyperthermia, GI upset, ataxia, abdominal pain, hyperesthesia, and transient blindness. The minimum oral toxic dose for dogs is 24 mg/kg; the minimum oral lethal dose for dogs is 128 mg/kg.[1]
- **Acetaminophen** (eg, *Tylenol®*; also known as APAP, paracetamol): Human analgesic and antipyretic. Contraindicated in cats at any dose and not recommended for ferrets. In cats, this medication can cause methemoglobinemia, hepatic necrosis, and death. Clinical signs include shock, brown mucous membranes, respiratory distress, cyanosis, lethargy, depression, coma, and edema of the face and paws. In dogs, hepatotoxicity and methemoglobinemia can also occur; doses above 100 mg/kg are considered toxic. Clinical signs include anorexia, nausea, vomiting, lethargy, abdominal pain, icterus, hepatic encephalopathy, and coma.[2]
- **Alpha lipoic acid** (thioctic acid, ALA): Dietary supplement used to manage diabetes mellitus. Dose-dependent toxicity in dogs and cats; cats are more sensitive. Clinical signs develop in 30 minutes to several hours, with acute hypoglycemia as the primary concern. Other clinical signs include hypersalivation, vomiting, ataxia, tremors, and seizures. Anecdotal therapeutic dose in cats is 1 – 5 mg/kg daily; the minimum toxic dose is 13 mg/kg. ALA is considered 10 times more toxic to cats than dogs.[3] In dogs, the experimental maximum tolerated dose is 126 mg/kg,[4] but suspicious deaths have been reported at 100 mg/kg.
- **Aspirin** (ASA): NSAID and antiplatelet agent. Toxicity is dose dependent—see the ***Aspirin*** monograph for more information. This medication is used therapeutically in dogs and cats but at very different doses. Cats are very sensitive to salicylates, which have half-lives of 38 to 45 hours at 25 mg/kg in this species. Severe intoxication occurs at more than 80 mg/kg in cats and 100 to 500 mg/kg in dogs. Clinical signs include vomiting, GI ulceration, hematemesis, melena, Heinz body anemia (cats), metabolic acidosis, hyperthermia, and renal and liver damage.
- **Caffeine** (eg, *No-Doze®*, also found in analgesics, coffee, energy drinks, gels and gums, foods such as chocolate): Toxic to dogs and cats. Clinical signs include vomiting, diarrhea, polyuria, polydipsia, hyperactivity, ataxia, tachycardia, tachypnea, hypertension, weakness, cardiac arrhythmias, tremors, seizures, and coma. Death can result from cardiac arrhythmia or respiratory failure. Clinical signs begin at 15 mg/kg. The oral LD_{50} in dogs is 140 mg/kg and 80 – 150 mg/kg in cats.[5]
- **Dextromethorphan** (eg, *Delsym®*, *Robitussin-DM®*): Human cough suppressant—see the ***Dextromethorphan*** monograph for more information. Toxicity is dose dependent. Dextromethorphan has been used anecdotally in dogs at 2 mg/kg PO twice daily to treat cough and repetitive behavioral disorders. Clinical signs of toxicity include agitation, hallucination, nervousness, mydriasis, shaking, facial edema (dogs), vomiting, and diarrhea. Some clinical signs may be similar to serotonin syndrome, such as tremors, seizures, hyperesthesia, hyperthermia, hypersalivation, and death.[5]
- **Ibuprofen** (eg, *Advil®*, *Motrin®*): Human NSAID. Toxic to dogs, cats, and ferrets; not recommended for veterinary use. GI ulceration may occur, as evidenced by hematemesis, diarrhea, melena, weakness, pale mucous membranes, abdominal pain, lethargy, and inappetence. With larger ingestions, acute renal failure, liver failure, and neurologic signs such as tremors or seizures can develop. In ferrets, toxicity affects GI, renal, and central nervous systems.[6]
- **Imidazolines** (eg, oxymetazoline [*Afrin®*], tetrahydrozoline [*Visine®*], naphazoline, tolazoline): Toxic to all pets. Not recommended for veterinary use. Poisoning occurs most commonly after pets chew open product vials. Clinical signs of intoxication may include vomiting, bradycardia, cardiac arrhythmias, poor capillary refill time, hypotension or hypertension, panting, depression, weakness, nervousness, hyperactivity, or shaking. These signs appear within 30 minutes to 4 hours postexposure. In general, imidazoline decongestant exposure may affect the GI, cardiopulmonary, and nervous systems. Veterinary alpha-2-adrenergic antagonists such as atipamezole (*Antisedan®*) or yohimbine may be antidotal.
- **Iron** (Fe): Found in OTC iron supplements (see the ***Ferrous Sulfate*** monograph), multivitamins, prenatal vitamins, fertilizers, pesticides, single-use hand warmers or heating pads such as *ThermaCare®*, and oxygen absorber sachets in food packaging (eg, beef jerky). Toxicity in dogs has been observed at doses greater than 20 mg/kg of elemental iron. Clinical signs include vomiting, bloody diarrhea, lethargy, abdominal pain, and GI ulcerations. More severe signs such as metabolic acidosis, shock, hypotension, hypovolemia, tachycardia, coagulation deficits, hepatic necrosis,

tremors, seizures, and coma can occur. The amount of elemental iron ingested should be determined to assess toxicity. Oxygen absorbers used in food packaging are commonly mistaken for silica gel packets, which are nontoxic.[7]

- **Naproxen** (eg, *Aleve*®): Human NSAID. Highly toxic to dogs, cats, and ferrets. This medication is not recommended for veterinary use in small animal species. In dogs, doses of 5 mg/kg may result in GI irritation or ulceration, and doses greater than 10 – 20 mg/kg may result in acute renal failure. Stomach ulcers, bloody vomiting, diarrhea, melena, weakness, pale gums, abdominal pain, lethargy, and inappetence may occur.
- **Permethrin:** Topical insecticide. Toxic to cats in concentrated formulas (typically greater than 5% to 7%). OTC lice treatment products typically contain 1% permethrin or pyrethrins/piperonyl butoxide and are not usually of concern. Cats are highly sensitive to pyrethrins and pyrethroids; application of concentrated products could be fatal. The most common clinical signs observed are nervous system effects such as hyperesthesia, generalized tremors, muscle fasciculation, hyperthermia, and seizures. Clinical signs can develop within hours or may be delayed up to 72 hours and generally last 2 to 3 days.[8]
- **Phenazopyridine** (eg, *Pyridium*®; PAP): Human urinary analgesic. This medication is not recommended for veterinary use, as it is metabolized to acetaminophen. Cyanosis, methemoglobinemia, rhabdomyolysis, and hepatotoxicity are possible.[9]
- **Phenylephrine** (eg, *Sudafed-PE*®): Human oral decongestant. May be toxic to dogs and cats at high doses. Ingestion can result in hyperactivity, agitation, vomiting, mydriasis, tachycardia, hypertension, hyperthermia, cyanosis, arrhythmias, tremors, and seizures. Pet owners purchasing antihistamines for their pets may unwittingly select a combination product that also contains decongestants like phenylephrine.[5]
- **Pseudoephedrine** (eg, *Sudafed*®): Human oral decongestant with sympathomimetic properties. Pseudoephedrine can be highly toxic to dogs and cats. In dogs, 5 – 6 mg/kg results in moderate to severe clinical signs, with death possible at 10 –12 mg/kg. Ingestion can result in hyperactivity, agitation, vomiting, mydriasis, tachycardia, hypertension, hyperthermia, cyanosis, arrhythmias, tremors, and seizures. Pet owners purchasing antihistamines for their pets may unwittingly select a combination product that also contains decongestants such as pseudoephedrine. See the ***Pseudoephedrine*** monograph for additional information.[5]
- **Vitamin D** (ergocalciferol [D_2], cholecalciferol [D_3]): Found in rodenticides, as a single-agent vitamin, and in multivitamin products. Ingestion of cholecalciferol-rodenticides and single-agent vitamins carries a greater risk for toxicosis than ingestion of multivitamins. Intoxication results from hypercalcemia and hyperphosphatemia followed by metastatic mineralization, typically presenting as acute renal failure. Clinical signs are observed within the first 48 hours of overdose and can include vomiting, lethargy, muscle weakness, bloody diarrhea, depression, polyuria, and polydipsia. With high doses, death from acute renal failure can result.[10]

Medicinal Oils, Solvents, or Excipients

- **Benzyl alcohol**: Preservative. Commonly found in injectable drug products. Cats may be very susceptible to toxic effects. Clinical signs include ataxia, hyperesthesia, muscle fasciculation, depression, coma, respiratory failure, and death.[11]
- **Peppermint oil** (menthol): Toxic to cats. Ingested peppermint oil may cause GI upset, CNS depression, and hepatotoxicity. Inhalation may cause aspiration pneumonia.
- **Propylene glycol**: Commonly found in automotive antifreeze as an alternative to ethylene glycol (also known as pet-safe antifreeze, RV antifreeze), as well as hair dyes, disinfectants, paints, and varnishes; occasionally used in injectable drug products. The canine oral LD_{50} is 9 mL/kg of undiluted propylene glycol. Initial clinical signs can include depression, weakness, ataxia, polyuria, and polydipsia. Lactic acidosis occurs later. Heinz body anemia occurs in cats with chronic ingestion. Hypotension, cardiovascular collapse, and seizures can occur.[12]
- **Tea tree oil** (melaleuca oil): Topical antibacterial agent. Toxicosis is common following exposure to 100% oil (oral or dermal exposure). As little as 7 drops of oil have caused poisoning in pets. Cats are more susceptible to toxicosis than dogs. Clinical signs observed include ataxia, hypothermia, dehydration, muscle tremors, and coma. Tea tree oil may be hepatotoxic to cats.[13] Toxicosis in birds has also been reported.[14]
- **Xylitol**: Natural sweetener with a low glycemic index. Commonly found in many sugar-free foods (eg, peanut butter) and chewing gum, breath mints, nicotine gum, baked goods, oral care products, nasal sprays, chewable vitamins, and some prescription medications, including gabapentin oral liquid, and some oral dispersing tablet (ODT) formulations. It can be toxic to dogs; clinical signs may be delayed up to 12 hours after ingestion and include hypoglycemia, lethargy, vomiting, ataxia, and collapse, and seizures can occur. Acute liver failure is possible. Dogs ingesting greater than 0.1 g/kg of xylitol are considered at risk for developing hypoglycemia; doses greater than 0.5 g/kg may be hepatotoxic. Decontamination is suggested for dogs with exposure greater than 50 mg/kg.[15]

Foods

- ***Allium*-containing foods** (eg, garlic, onion, leeks, chives): May be toxic to dogs and cats. Oral consumption can lead to toxicosis. Clinical signs result from hemolytic anemia and often include depression, hemoglobinuria, icterus, tachypnea, tachycardia, weakness, and exercise intolerance. Inappetence, abdominal pain, and diarrhea may also occur. Development of clinical signs is delayed; they may not be observed until several days after ingestion.[16]
- **Bread/Yeast dough:** Dough containing yeast continues to rise after ingestion, releasing gas that may result in bloating and torsion.[17] Ethanol also can be produced, resulting in ethanol toxicosis. Clinical signs include vomiting, ataxia, lethargy, blindness, abdominal distension, and coma.
- **Chocolate**: Toxic to dogs and cats. Chocolate contains methylxanthines, including caffeine, although the primary toxic component is theobromine, which varies in concentration between brands and types of chocolate products. Clinical signs occur 6 to 12 hours after ingestion. Dogs that ingest 20 mg/kg of methylxanthine content generally display mild GI signs, but cardiotoxic and neurotoxic effects may be seen after ingestion of 40 to 50 mg/kg and more than 60 mg/kg, respectively. Initial signs include polydipsia, vomiting, diarrhea, and restlessness, followed by hyperactivity, polyuria, ataxia, tremors, and seizures. Other effects include tachycardia, premature ventricular contractions, tachypnea, cyanosis, hypertension, hyperthermia, and coma. Pancreatitis can occur 24 to 72 hours after ingestion, due to the high-fat content in chocolate. Death can result from cardiac arrhythmias or respiratory failure. Dogs can easily ingest a toxic dose of chocolate.[18]
- **Grapes, raisins, currants, tamarinds**: These foods are toxic to dogs, as they contain tartaric acid, which dogs are highly sensitive to.[19] Clinical signs can appear within hours and include vomiting, diarrhea, lethargy, and polydipsia. Acute kidney injury may develop within 24 hours to several days after exposure. A toxic dose can be difficult to clinically ascertain, as fruits contain varying amounts of tartaric acid. As such, all exposures are concerning.
- **Macadamia nuts:** Toxic to dogs. Common clinical signs of mac-

adamia nut ingestion include weakness, depression, vomiting, ataxia, tremors, joint pain, lameness, hind limb weakness, hyperthermia, recumbency, and abdominal pain. Clinical signs are typically seen at doses greater than 2 g/kg. Clinical signs have been reported at doses as low as 0.7 mg/kg.[20]

- **Xylitol:** See ***Medicinal Oils, Solvents, or Excipients***

Household Products/Solvents

- **Acids** (eg, drain/toilet bowl cleaners, hair wave neutralizers, metal cleaners, rust removers, vinegar): Tissue damage is related to pH and concentration. Products with a pH of 2 to 4 can cause mild to moderate tissue irritation. Products with a pH less than 2 are corrosive; some examples include acetic acid (concentrations more than 50%), aluminum sulfate (concentrations more than 20%), hydrochloric acid (concentrations more than 10%), and sulfuric acid (concentrations more than 10%). Clinical signs include oral/dermal/GI ulcerations, dysphagia, vomiting, hematemesis, abdominal pain, stridor, and coughing. Induction of emesis is not recommended.[5]
- **Alkalis/Bases** (eg, drain cleaners, dry cell batteries, hair relaxers, lye, nonchlorine bleach, oven cleaners): Tissue damage is related to pH and concentration. Products with a pH of 10 to 11 can cause mild tissue irritation. Products with a pH of 11 to 12 may cause corrosive tissue injury; examples include sodium hypochlorite (concentrations more than 10%), sodium carbonate (concentrations more than 15%), sodium hydroxide (concentrations more than 2%), and sodium silicate (concentrations more than 20%). Clinical signs include ulcerations, dysphagia, vomiting, hematemesis, abdominal pain, stridor, and coughing. Induction of emesis is not recommended.[5]
- **Rodenticides, anticoagulants**: Toxic to all mammals and birds; dogs are more sensitive than cats. Active ingredients (eg, brodifacoum, bromadiolone, chlorophacinone, difethialone, diphacinone, warfarin) antagonize vitamin K epoxidase. Clinical signs typically develop 3 to 5 days after ingestion. Most common clinical signs following ingestion can include dyspnea, coughing, lethargy, exercise intolerance, and hemoptysis. Nonspecific signs can include lethargy, anorexia, or lameness. Signs of bleeding can occur such as hematuria, hematemesis, melena, hyphema, and epistaxis. Vitamin K_1 (phytonadione) is the antidote for these toxicities. See the ***Phytonadione Vitamin K$_1$*** monograph for more information. **NOTE**: As of April 2015, retail stores in the United States are no longer allowed to carry rodenticide products that contain brodifacoum, bromadiolone, or difethialone for residential use.
- **Rodenticides, bromethalin**: Toxic to all species; however, cats are more sensitive than dogs. Intoxication is due to cerebral edema (white matter vacuolization). No antidote is available, although IV lipid emulsion may be effective to reverse the clinical signs associated with bromethalin.[21–23] The minimum lethal dose in dogs is 2.5 mg/kg active ingredient, and in cats it is 0.3 mg/kg. Dogs may exhibit ataxia, weakness, paralysis, tremors, seizures, and coma. Cats are more prone to paralytic signs.[24]
- **DEET** (eg, *Off*®; N,N-diethyl-meta-toluamide): Found in insect repellants. Neurologic signs (eg, tremors, hyperexcitation, ataxia, and seizures), skin irritation, hypersalivation, and vomiting can result. Up to 13% of DEET is absorbed through the skin in dogs.
- **Ethanol** (alcohol, *Purell*® and other hand sanitizers): Ingesting large amounts of ethanol may cause hypoglycemia, hypothermia, and hypotension. Clinical signs include weakness, lethargy, vomiting, collapse, hypothermia, weak respirations, and coma. The minimum oral lethal dose in dogs is 5.55 g/kg. See the ***Ethanol*** monograph for additional information.
- **Ethylene glycol** (found in automotive antifreeze): The minimum lethal dose of undiluted ethylene glycol antifreeze is 4.2 to 6.6 mL/kg in dogs and 1.5 mL/kg in cats. Toxicity typically occurs in 3 stages. The first stage occurs within 30 minutes to 12 hours and clinical signs include nausea, vomiting, polyuria, polydipsia, ataxia, and metabolic acidosis. The second stage occurs 12 to 24 hours after ingestion, and is characterized by dehydration, tachypnea, and tachycardia. The third stage occurs 12 to 24 hours after ingestion in cats and 36 to 72 hours in dogs. Clinical signs include renal failure, anorexia, depression, lethargy, oral ulcers, hypersalivation, coma, and seizures. Products such as wall paint and printer ink that contain less than 5% ethylene glycol rarely cause problems. See the ***Fomepizole*** and ***Ethanol*** monographs for additional information.[25]
- **Ice melts containing calcium chloride:** Exposure may cause severe skin and GI tract irritation, and electrolyte imbalance. Clinical signs associated with exposure include salivation, depression, disorientation, polydipsia, diarrhea, vomiting, and anorexia.[26]
- **Metaldehyde** (found in some snail/slug baits): Concentrations of active ingredient range from 3.25% to 4%, which are toxic to pets. Clinical signs are similar in dogs and cats and may appear minutes to hours after ingestion. Typical signs include anxiety, tachycardia, nystagmus, mydriasis, hyperpnea, panting, hypersalivation, and ataxia. Vomiting, diarrhea, tremors, hyperesthesia, continuous seizures, metabolic acidosis, rigidity, opisthotonos, and severe hyperthermia may also be seen. Delayed signs that may develop are depression, coma, and liver failure. Death from respiratory failure can occur within a few hours of exposure.[27]
- **Methanol** (organic solvent found in windshield washer fluid, paint thinners, household cleaning products): Toxic to dogs and cats. The canine oral LD_{50} of undiluted methanol is 5 to 11.25 mL/kg. Clinical signs in dogs and cats are similar to ethanol intoxication and include ataxia, depression, lethargy, sedation, hypothermia, and metabolic acidosis. It does not cause blindness in dogs and cats as it does in humans.[5]
- **Mothballs** (naphthalene or paradichlorobenzene [PDB]): Toxic to all species via ingestion, inhalation, or dermal contact. Ingestion may cause severe GI upset, neurologic stimulation followed by depression (PDB), hemolytic anemia (naphthalene), and liver and kidney damage. Dogs that ingested 1.5 g/kg of naphthalene mothballs developed hemolytic anemia. PDB is ≈50% less toxic than naphthalene. Mothballs typically weigh 2.7 g to 4 g each.[28]
- **Polyurethane glues** (eg, *Gorilla*®, *Elmer's*® *ProBond*®): Expanding adhesive glues that contain isocyanates. Although not poisonous, the glue expands significantly once ingested to create a firm, foam-like foreign body that can cause gastric or esophageal obstructions.[28] Clinical signs can be seen 15 minutes to 20 hours after ingestion and include vomiting, abdominal distension, stomach pain, inappetence, and lethargy. Surgical removal is almost always necessary. Inducing emesis is not often recommended.

Miscellaneous Items

- **Glow-in-the-dark jewelry and toys** (liquid-filled plastic necklaces, earrings, plastic wands, safety sticks): Mildly toxic to dogs and cats. These products contain dibutyl phthalate, a chemical that has a bitter taste and is capable of causing immediate eye, skin, and mucous membrane irritation. Most commonly, cats are exposed after piercing jewelry with their teeth. Significant but self-limiting hypersalivation results but is of little toxicologic concern.
- **Lily plants** (*Lilium* spp, *Hemerocallis* spp): Highly toxic to cats. *Lilium* spp (eg, Easter lily, stargazer lily, tiger lily, Asiatic hybrids) are frequently sold as cut flowers in retail settings, as they are inexpensive, fragrant, and long lasting. *Hemerocallis* spp (day lilies) are more often sold in pots for outdoor planting. Small ingestions of leaves, petals, pollen, or vase water can cause kidney injury in cats within 1 to 2 days. If untreated, the prognosis is grave.

- **Liquid potpourri** (simmer pot potpourri): Cats are more susceptible to toxicosis than dogs. Products may contain cationic detergents and essential oils. Ingestion of cationic detergents can result in ulceration or severe inflammation of the mouth and upper GI tract. Essential oils are absorbed across the skin and mucous membranes and result in tissue irritation, GI upset, CNS depression, and dermal hypersensitivity. Inducing emesis is not recommended.[29]
- **Lithium-ion disc batteries:** Ingestion can be toxic to dogs and cats. Tissue necrosis is caused by electric current flow in the GI tract. The greatest concern is for esophageal necrosis followed by perforation, potential aortic fistula, and fatal hemorrhage. Clinical signs include ulceration of the gums, teeth discoloration, hypersalivation, food/water refusal, abdominal pain, shock and pallor, and abdominal distension.[5]
- **Pennies from the United States**: Pennies minted after 1982 are toxic to dogs and cats due to high (97%) zinc content. Ingestion can cause acute GI distress and oxidative damage to red blood cells that results in hemolytic anemia. Additionally, damage to the kidneys, liver, GI tract, pancreas, and red blood cells can occur.[30]

Overdose and Toxin Exposure Decontamination Guidelines

Contacting a poison control center to manage overdose and toxin exposures is strongly encouraged. The following known 24-hour poison control centers specialize in providing information specific for veterinary patients:

- **ASPCA Animal Poison Control Center**: 888-426-4435; aspca.org/pet-care/animal-poison-control
- **Pet Poison Helpline (US):** 855-764-7661; petpoisonhelpline.com
- **Veterinary Poisons Information Service (UK):** 0207 305 5055; vpisglobal.com
- **Australian Animal Poisons Centre:** 1300 869 738 (AU) or 0800 869 738 (NZ); animalpoisons.com.au

All patients should be stabilized prior to attempts at decontamination to prevent or limit systemic absorption of toxicants. The choice of decontamination method(s) to be administered is guided by the species being treated and the circumstances related to the exposure (eg, duration since exposure, drug or toxin properties). When a patient has ingested a potentially toxic dose of a substance, the clinician has many options for GI decontamination including, but not limited to, dilution, induction of emesis, gastric lavage, the use of adsorbents or cathartics, and administration of enemas. In many cases, the best treatment plan will include more than one of these methods.

Dilution using a small amount of milk or water is recommended in cases where irritant or corrosive materials have been ingested. A dose of 2 – 6 mL/kg is suggested (ie, ≈1 to 2 teaspoons/cat [NOT teaspoons/kg]).[1,2] Administration of the diluent in small volumes is important because giving excessive amounts may lead to emesis and cause the esophagus to be re-exposed to the damaging material.[3] Fruits and vegetables with high water content can be fed to accomplish dilution in some patients, especially birds and reptiles. Dilution methods should not be used for patients with an increased risk for aspiration (eg, actively seizing, obtunded).[3] Dilution with milk, yogurt, or cottage cheese may be useful for patients with oral irritation after ingesting oxalate-containing plants (eg, *Philodendron* spp).[4]

Emetics are often most effective when administered within 2 to 3 hours postingestion.[3] Induction of emesis beyond 3 hours may still be effective for some ingested substances, such as those that coalesce to form a bezoar in the stomach (eg, chewable medications, chocolate[5]) or those that delay gastric emptying. In general, administration of an emetic will empty ≈40% to 60% of the stomach contents when emesis is induced within an hour of toxin ingestion[2,6,7]; however, the amount of vomitus produced will diminish as time passes.[7] If the patient has not recently eaten, emetic efficacy (ie, productive emesis) may be increased by feeding a small meal prior to administration.

Emetics can be administered to dogs, cats, potbelly pigs, and ferrets; however, they should not be administered to horses, ruminants, birds, rabbits, or rodents. Horses and rodents are physically unable to vomit, and induction of emesis may put them at risk for gastric rupture.

Emesis may not be warranted for patients that have already vomited. Patients that are exhibiting clinical signs such as coma, seizures, or recumbency should not be given an emetic. Additionally, if the patient has ingested a CNS stimulant and is already agitated, the additional stimulation of vomiting could lead to seizures.[3] Do not induce emesis (ie, emesis is **contraindicated**) in patients that have ingested corrosive agents (eg, alkalis, acids) because the lining of the esophagus may become ulcerated when the product is swallowed. Re-exposure of the esophageal lining to the corrosive agent during emesis will increase the risk for esophageal ulceration, perforation, and scarring.[6] Emesis is also not recommended after petroleum distillate ingestion due to the risk for aspiration.

Caution is advised when inducing emesis in patients with underlying conditions (eg, severe cardiac disease, seizures) that may impact the patient's ability to safely vomit; carefully consider the risk versus benefit to induing emesis in these patients.

Apomorphine, Dexmedetomidine, Hydrogen Peroxide 3%, Hydromorphone, Ropinirole, and ***Xylazine*** are emetics that are commonly used in veterinary medicine. Emesis was successful in 95% of dogs that received ropinirole[8] and in over 90% of dogs that received either apomorphine or hydrogen peroxide[9]; however, hydrogen peroxide has fallen out of favor due to its associated adverse effects (eg, protracted emesis, esophageal irritation/injury) and should only be used when no other option is available (eg, patient is too far away from veterinary care). Apomorphine is ineffective as an emetic in cats; dexmedetomidine and hydromorphone are a preferred emetics in this species.[10,11]

Historically, other agents such as table salt, dishwashing liquid, syrup of ipecac, and powdered mustard have been used to induce vomiting; however, they are no longer recommended due to the increased risk for adverse effects.[3,6]

Gastric lavage may be considered for patients when emesis is contraindicated, not possible, or has been unsuccessful (eg, presence of bezoars in the stomach); however, it should also not be used to remove caustic materials or volatile hydrocarbons for the same reasons emesis is contraindicated in such cases.[3] The efficacy of gastric lavage is limited by the substance ingested and the diameter of the stomach tube that can be passed. Lavage is not a routinely chosen decontamination method, as it is unlikely to be as effective as emesis[6] and is associated with significant potential risks (eg, aspiration, general anesthesia).[3]

General anesthesia with endotracheal intubation is required to perform gastric lavage to minimize the risk for aspiration. Rodents with cheek pouches should have these spaces gently emptied with a finger or swab prior to the lavage. Risks associated with gastric lavage include damage to or perforation of the esophagus and/or stomach, electrolyte abnormalities (eg, hypo-/hypernatremia depending on lavage solution used), hypothermia, and unintentional placement of the stomach tube into the trachea with subsequent instillation of fluid into the patient's lungs.[3]

Adsorbents bind to chemicals/toxicants in the GI tract to prevent further systemic absorption of a toxicant; they may be used as a single agent or in addition to administration of an emetic or performing gastric lavage. Activated charcoal (AC) is the most commonly used adsorbent. See also ***Charcoal, Activated*** for more information. Many AC products also contain sorbitol, a cathartic to aid in the elimination of the toxicant. See ***Cathartics*** below. When administering these products, it is important to note which product is being administered to avoid adverse effects caused by overuse of the cathartic.

AC is composed of large porous particles that have a large binding surface area to trap organic compounds within the GI tract, including any orally administered medications given concurrently at the time of decontamination. Over-the-counter charcoal tablets and capsules labeled to control flatulence and bloating are not recommended, as the amount of charcoal is often low, and the binding area is much smaller when compared to the AC products specifically intended for GI decontamination.[12]

Repeated doses of AC can be considered in some instances where toxicants are known to undergo enterohepatic recirculation. Examples of toxicants known to undergo this type of recycling include bromethalin, cholecalciferol, ivermectin, and some NSAIDs. If medications are excreted in the bile, AC can be beneficial regardless of the route the medication was administered.

AC does not bind to all compounds equally. Efficiency of adsorption increases with the molecular size of the toxin, and poorly water-soluble organic substances are better adsorbed than small, polar, water-soluble organic compounds. Chemicals that are not effectively bound include ethanol, methanol, fertilizer, fluoride, petroleum distillates, heavy metals, iodides, nitrates, nitrites, sodium chloride, and chlorate. Animals that have ingested caustic substances should not receive AC, as AC is unlikely to bind these products. Additionally, AC may compound the mucosal surface irritation caused by the caustic substance and complicate the identification of oral and esophageal burns.[12]

Animals with no clinical signs may freely consume the charcoal suspension if administered via syringe. A small amount of food may be added to enhance palatability.[4] In animals exhibiting clinical signs, administration of activated charcoal suspensions may be done via a nasogastric tube, as it may be better accepted (especially in cats) and offer a greater margin of safety. Always ensure adequate airway protection, as AC administration carries a risk for aspiration, which carries a poor prognosis.

Cholestyramine may also be used to treat toxicoses of enterohepatically recirculated agents[13] (eg, cholecalciferol,[14,15] amiodarone, digoxin, NSAIDs,[16] vincristine).[17] Cholestyramine is an anion exchange resin that binds with bile acids in the intestine to prevent their reabsorption; toxins that require binding to bile acids for reabsorption (eg, cholecalciferol, piroxicam, indomethacin) will be excreted in the feces. See ***Cholestyramine*** for more information.

Cathartics promote elimination of substances, including the therapeutically administered AC, from the GI tract. When used in combination with AC, the cathartic is given immediately following or mixed with the charcoal.

Cathartics are contraindicated when corrosive substances were ingested or if the animal is dehydrated or hypotensive or has ileus, diarrhea, intestinal obstruction or perforation, history of recent abdominal trauma, or significant electrolyte imbalance.[7] Saline cathartics should also not be used in birds or reptiles and in patients with renal insufficiency.

Osmotic cathartics cause free water to enter the GI tract; the resulting increase of the lumen volume stimulates GI motility and expulsion of the feces. ***Sorbitol*** and ***Saline Cathartics*** are most commonly used for decontamination procedures and may be combined with AC in commercially prepared products.

Other cathartics are classified as bulk and lubricant cathartics. The most commonly used bulk cathartic is ***Psyllium***; in dogs and cats, unspiced canned pumpkin or squash also can be fed. In birds and reptiles, diluted peanut butter, fruit, or vegetables can also be used as bulking agents. Timothy hay can be used in rabbits. Historically, mineral oil was the most commonly used lubricant cathartic, especially in horses; however, mineral oil is no longer recommended in dogs and cats due to the aspiration risk and limited efficacy. Because all cathartics alter the water balance in the GI tract, hydration needs to be maintained.

Enemas using warm water may be indicated when elimination of toxicants (eg, extended-release or controlled-release drugs) from the lower GI tract is desired.[6,18] Commercially prepared phosphate enema solutions should be avoided due to the risk for electrolyte and acid-base disturbances.[6]

Multidrug Sensitivity (*MDR1* Mutation) in Dogs and Cats

KATRINA L. MEALEY, DVM, PHD, DACVIM, DACVCP
College of Veterinary Medicine, Washington State University

Editor's Note: The following information is adapted, with permission, from Washington State University, College of Veterinary Medicine Program in Individualized Medicine (PrIMe) website: prime.vetmed.wsu.edu/.

Introduction

P-glycoprotein, encoded by the multidrug sensitivity gene (*MDR1* gene, also known as *ABCB1* gene), is a drug transport pump that plays an important role in limiting drug distribution to the brain, as well as pumping many drugs into the bile for excretion from the body. Both canine-specific and feline-specific mutations in the respective *MDR1* genes have been identified such that affected animals have either no P-glycoprotein function, in the case of homozygous animals, or decreased P-glycoprotein function, in the case of heterozygous animals.[1,2] Affected dogs and cats have a decreased ability to limit brain distribution of P-glycoprotein substrate drugs and biliary excretion of those same drugs, which may lead to serious toxicity.

Distribution of Canine and Feline Breeds Affected by the *MDR1* Gene Mutation

Dogs: The canine *MDR1* mutation (also known as *ABCB1*-1delta) is most commonly found in the dog breeds listed in the table below; however, it is important to note that the mutation can occur in any breed, and clinicians should not rely solely on breed predispositions. Genetic testing is the only definitive way to know which dogs are affected.

Breed	Allele frequency (approximate)
Australian shepherd	50%
Australian shepherd, mini	50%
Border collie	Less than 5%
Chinook	25%

Breed	Allele frequency (approximate)
Collie	70%
English shepherd	15%
German shepherd	10%
Herding breed cross	10%
Long-haired whippet	50%
McNab	30%

Old English sheepdog	5%
Shetland sheepdog	15%
Silken windhound	30%

Cats: Current data do not suggest a breed predilection for the feline *MDR1* mutation.

Problem Drugs

P-glycoprotein function can be reduced by drugs that are P-glycoprotein substrates (eg, ketoconazole) and not solely by the *MDR1* mutation itself.[3]

The following drugs have been documented to cause problems in dogs and cats with the *MDR1* mutation. These are general recommendations and are intended to be a starting point; clinical conditions (eg, *MDR1* genotype, health status) and concurrently administered drugs or supplements must be factored in when deciding how to proceed with the use of these drugs in a particular patient. It is recommended to consult a veterinary clinical pharmacologist for details related to a specific patient.

- **Acepromazine**: In dogs with the MDR1 mutation, acepromazine tends to cause more profound and prolonged sedation.4 It is recommended to reduce the dose by 25% in dogs heterozygous for the MDR1 mutation (mutant/normal) and by 30% to 50% in dogs homozygous for the MDR1 mutation (mutant/mutant).
- **Apomorphine**: Apomorphine can cause CNS depression in dogs homozygous for the *MDR1* mutation at standard doses.[5]
- **Butorphanol**: Anecdotally, butorphanol tends to cause more profound and prolonged sedation in dogs with the *MDR1* mutation. It is recommended to reduce the dose by 25% in dogs heterozygous for the *MDR1* mutation (mutant/normal) and by 30% to 50% in dogs homozygous for the *MDR1* mutation (mutant/mutant).
- **Cyclosporine**: Excessive immunosuppression (T-cell suppression) occurred in a dog heterozygous for the *MDR1* mutation (mutant/normal) receiving a relatively low (6.6 mg/kg/day) cyclosporine dose.[6]
- **Doxorubicin**: Dogs with the *MDR1* mutation are more sensitive to adverse effects to these antineoplastic drugs. Myelosuppression (eg, decreased blood cell counts, particularly neutrophils) and GI toxicity (eg, anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with the *MDR1* mutation.[7–10] To reduce the likelihood of severe toxicity in these dogs, *MDR1* mutant/normal dogs should have their initial dose reduced by 25%, whereas *MDR1* mutant/mutant dogs should have their initial dose reduced by 50%; subsequent doses can be increased by 10% if the initial dose is well tolerated. It has been suggested that these dosage reductions may reduce clinical efficacy,[9] but there are no clinical data to support this. These patients should be closely monitored for adverse effects.
- **Emodepside**: Use of emodepside in dogs and cats with the *MDR1* mutation has resulted in neurologic toxicity.[1,11]
- **Eprinomectin**: Eprinomectin used at label dosages in cats with the *MDR1* mutation has resulted in neurologic toxicity.[12]
- **Grapiprant**: Self-limited vomiting occurred in one collie dog homozygous for the *MDR1* mutation. It is recommended to reduce the dose by 25% in dogs heterozygous for the *MDR1* mutation (mutant/normal) and by 30% to 50% in dogs homozygous for the *MDR1* mutation (mutant/mutant).[13]
- **Ivermectin**: Although the dose of ivermectin used to prevent heartworm infection (6 µg/kg) is safe in dogs with the mutation, higher doses, such as those used for treating mange (300 – 600 µg/kg), will cause neurologic toxicity in dogs that are homozygous for the *MDR1* mutation (mutant/mutant) and can cause less severe neurologic toxicity in dogs that are heterozygous for the mutation (mutant/normal).[1,2,14]
- **Loperamide**: At doses used to treat diarrhea, this drug will cause neurologic toxicity in dogs with the *MDR1* mutation. This drug should be avoided in all dogs with the *MDR1* mutation.[15,16]
- **Maropitant**: Maropitant has been noted to cause mild to moderate CNS depression in dogs with the *MDR1* mutation.[17]
- **Milbemycin**: Like ivermectin, milbemycin is safe in dogs with the mutation when it is used for heartworm prevention at the labeled dosages; however, higher doses have been documented to cause neurologic toxicity in dogs with the *MDR1* mutation.[18]
- **Moxidectin**: Similar to ivermectin, moxidectin is safe for use in dogs and cats with the mutation when it is used for heartworm prevention at the labeled dosages. Higher doses (generally 10 to 20 times higher than the heartworm prevention dose) and oral ingestion of topical products have been documented to cause neurologic toxicity in dogs with the *MDR1* mutation.
- **Selamectin**: Like ivermectin, selamectin is safe in dogs and cats with the mutation when it is used for heartworm prevention at the labeled dosages; however, higher doses and oral ingestion of topical products have been documented to cause neurologic toxicity in pets with the *MDR1* mutation.[1,19,20]
- **Vinca alkaloids** (eg, **vinblastine, vincristine, vinorelbine**): Dogs with the *MDR1* mutation are more sensitive to adverse effects to these antineoplastic drugs.[7,8] Myelosuppression (eg, decreased blood cell counts, particularly neutrophils) and GI toxicity (eg, anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with the *MDR1* mutation.[7–10] To reduce the likelihood of severe toxicity in these dogs, *MDR1* mutant/normal dogs should have their initial dose reduced by 25%, whereas *MDR1* mutant/mutant dogs should have their initial dose reduced by 50%; subsequent doses can be increased by 10% if the initial dose was well tolerated. It has been suggested that these dosage reductions may reduce clinical efficacy,[9] but there are no clinical data to support this. These patients should be closely monitored for adverse effects.

The following drugs have been reported to be pumped by P-glycoprotein in humans, but there are currently no data stating whether they are canine or feline P-glycoprotein substrates and should be used with caution until more data are available.

- Domperidone
- Etoposide
- Ondansetron

There are many additional drugs that are P-glycoprotein substrates in humans and data continue to emerge regarding their effects in dogs and cats with the *MDR1* mutation.

Testing

Only genetic diagnostic testing can identify animals with normal

P-glycoprotein function (*MDR1* normal/normal), heterozygote animals (*MDR1* mutant/normal), or homozygote mutant animals (*MDR1* mutant/mutant). Washington State University College of Veterinary Medicine offers *MDR1* genotyping for dogs and cats as well as counseling for dosing patients tested through Washington State University: https://prime.vetmed.wsu.edu/

How to Find a Quality-Assured Compounding Pharmacy

GIGI DAVIDSON, RPH, DICVP, FSVHP (HONORARY), FACVP
VetPharm Consulting and College of Veterinary Medicine, North Carolina State University

Compounded medications are often required in veterinary medicine to provide for the specialized needs of a patient that cannot be met with commercially available dosage forms. However, choosing a "quality" compounding pharmacy among the many available can be challenging. The following guidelines can help the clinician narrow their choices to best provide for their patients. —Donald Plumb, PharmD

1. When choosing a compounding pharmacy, look for the designation "ACHC Accredited Compounding Pharmacy" (www.achc.org).

Accreditation by the Accreditation Commission for Healthcare (ACHC, formerly Pharmacy Compounding Accreditation Board or ACHC) means the pharmacy has independent, external validation that it meets nationally accepted quality assurance, quality control, and quality improvement standards. ACHC's national standards are based on the consensus of industry experts on those elements that should exist in a pharmacy that adheres to high-quality standards. While all pharmacies must be licensed, ACHC accredited pharmacies have gone the "extra mile" to assure quality.

Only when a pharmacy has met ACHC's rigorous standards is accreditation issued. In order to demonstrate compliance with ACHC standards and earn ACHC accreditation, pharmacies voluntarily participate in an off-site and on-site evaluation process that includes:

- Verification by ACHC that the pharmacy is not on probation for issues related to compounding quality, public safety, or controlled substances.
- Verification that the pharmacy is properly licensed in each state in which it does business.
- An extensive on-site evaluation by an ACHC surveyor, all of whom are compounding pharmacists trained in evaluating compliance with ACHC's quality standards. For example, this evaluation includes:
  - An assessment of the pharmacy's system for assuring and maintaining compliance with all of the United States Pharmacopeia (USP) Standards for Compounding. (eg, Chapters <795>, <797>, and <800>.)
  - An assessment of the pharmacy's system for assuring and maintaining staff competency.
  - A review of facilities and equipment.
  - Review of records and procedures required to prepare quality compounded medications.
  - Verification that the pharmacy uses ingredients manufactured in FDA-registered facilities.
  - Review of the pharmacy's program for the quality testing of compounded preparations.

2. In addition to accreditation by ACHC or other compounding accreditation organizations (eg, NABP or the Joint Commission), inquire about specialized training and expertise in compounding dosage forms for delivery to veterinary patients.

- Many active and inactive ingredients (eg, sweeteners, flavors, preservatives, solvents, vehicles, dyes) used to compound preparations for humans can be toxic in nonhuman species. It is critical that pharmacists preparing compounds for animals are aware of these toxicities.
- Specialized administration devices (eg, subpalpebral lavage catheters, tom cat catheters for rectal administration of antiepileptic medications, and enteral feeding tubes) are also used in veterinary patients. Qualified compounding pharmacists preparing medications for administration through these devices must be aware of compound components and qualities (eg, viscosity, causticity, absorbency) that could obstruct or otherwise damage these administration devices.
- Quality veterinary compounding pharmacies maintain a variety of species-specific and species-appropriate flavoring agents and can customize compounded therapies to individual veterinary patients as indicated.

3. Request evidence for assigned beyond-use dates (expiration dates for compounded preparations).

Chemical and physical stability, as well as sterility storage times for compounded preparations, should be supported by scientific evidence or national quality standards, such as the United States Pharmacopeia (USP) Chapters <795> (nonsterile compounds) and <797> (sterile compounds). USP beyond use dating limits for compounds can be found in the current official versions of those General Chapters at www.usp.org and also in USP's Compounding Compendium on USP's website. If a pharmacy assigns longer beyond-use dates (BUDs) than the limits stated in the current official versions of those chapters, a request should be made to the compounding pharmacy to provide supporting scientific evidence.

Glucocorticoid Agents, General Information

Glucocorticoid Comparison Table

Drug	Equivalent anti-inflammatory dose (mg)	Relative anti-inflammatory potency	Relative mineral-corticoid activity	Plasma half-life dogs (minutes) [humans]	Duration of action after oral/IV	Ester form: solubility/release durations (IM)
Hydrocortisone (Cortisol)	20	1	1-2	52-57 [90]	Less than 12 hours (8-12 hours)	Sodium succinate: very/minutes
Betamethasone	0.6	25	0	* [300+]	More than 36 hours (36-54 hours)	Sodium succinate or phosphate: very/minutes
Dexamethasone	0.75	30	0	119-136 [200-300+]	More than 36 hours (36-54 hours)	Sodium succinate or sodium phosphate: very/minutes Phenylpropionate or isonicotinate: moderate/days to weeks
Flumethasone	1.5	15-30	*	*	*	Very/minutes
Isoflupredone	*	17	*	*	*	Acetate: duration of action up to 48 hours
Methylprednisolone	4	5	0	91 [200]	12-36 hours	Sodium succinate: very/minutes Acetate: moderate/days to weeks
Prednisolone	5	4	1	69-197 [112-212]	12-36 hours	Sodium succinate: very/minutes Acetate: moderate/days to weeks
Prednisone	5	4	1	*[60]		*
Triamcinolone	4	5	0	[200+]	24-48 hours	Acetonide: poorly/weeks

*Data not available

Uses/Indications

Although glucocorticoids have been used to treat many conditions in humans and animals, dexamethasone has 5 primary uses with accompanying dosage ranges: 1) as a diagnostic agent to test for hyperadrenocorticism, 2) as a replacement or supplementation (eg, relative adrenal insufficiency associated with septic shock) for glucocorticoid deficiency secondary to hypoadrenocorticism, 3) as an anti-inflammatory agent, 4) for immunosuppression, and 5) as an antineoplastic agent.[1,2]

Glucocorticoids are used in the treatment of endocrine conditions (eg, adrenal insufficiency), autoimmune and immune-mediated diseases (eg, rheumatoid arthritis, systemic lupus, masticatory myositis[3]), severe allergic conditions, anaphylaxis, envenomation, respiratory diseases (eg, asthma), dermatologic diseases (eg, pemphigus, allergic dermatoses), hematologic disorders (eg, thrombocytopenia, autoimmune hemolytic anemia), neoplasias, nervous system disorders (eg, increased CSF pressure), GI diseases (eg, ulcerative colitis exacerbations, inflammatory bowel disease), renal diseases (eg, nephrotic syndrome), and induction of fetal maturation. Some glucocorticoids are used topically on the eye and skin or are injected intra-articularly or intralesionally. This list is not exhaustive. High-dose glucocorticoid use in the treatment of hemorrhagic or hypovolemic shock, head trauma, spinal cord trauma, and/or sepsis is not supported.[4]

In general, when administering glucocorticoids, the following principles should be followed:

- A specific diagnosis is needed before glucocorticoids are administered, as they can mask disease.
- A course of treatment should be determined prior to treatment.
- A therapeutic endpoint should be determined prior to treatment.
- The least potent glucocorticoid should be used at the lowest dose for the shortest amount of time.
- It is important to understand when glucocorticoid use is inappropriate (eg, acute infection, diabetes).[5]

Pharmacology/Actions

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows:

- **Cardiovascular system**: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction, and a clinically insignificant positive inotropic effect can occur after glucocorticoid administration.
- **Cells**: Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes and the cellular response to mediators of inflammation; they can also stabilize lysosomal membranes.
- **CNS/autonomic nervous system**: Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite, and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.
- **Endocrine system**: When an animal is not stressed, glucocorticoids suppress the release of corticotropin (adrenocorticotropic hormone [ACTH]) from the anterior pituitary, which reduces or prevents the release of endogenous corticosteroids. Stress factors (eg, renal disease, liver disease, diabetes) may occasionally nullify the suppressing aspects of exogenously administered steroids. The release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone may be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T4) to triiodothyronine (T3) may be reduced by glucocorticoids, and plasma levels of parathyroid hormone may be increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (antidiuretic hormone [ADH]) activity is reduced at the renal tubules, and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin receptors and the post-receptor effects of insulin.
- **Fluid and electrolytes balance**: Glucocorticoids can increase renal potassium and calcium excretion, sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia rarely occur. Diuresis may develop following glucocorticoid administration.
- **GI tract and hepatic system**: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. Glucocorticoids alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of ALT, and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum ALP levels. Glucocorticoids can cause minor increases in bromosulfophthalein (BSP) retention time.
- **Hematopoietic system**: Glucocorticoids can increase the number of circulating platelets, neutrophils, and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes, and eosinophils can be seen, as glucocorticoids can sequester these cells in the lungs and spleen and can decrease the release from bone marrow; removal of old red blood cells becomes diminished. Glucocorticoids can cause involution of lymphoid tissue.
- **Immune system** (also see Cells and Hematopoietic system): Glucocorticoids can decrease circulating levels of T lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis, chemotaxis, and antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high doses and different species have different responses.
- **Metabolic effects**: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (eg, abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues, and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (except the liver).
- **Musculoskeletal**: Glucocorticoids may cause muscular weakness, atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion, and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.
- **Ophthalmic**: Prolonged glucocorticoid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.
- **Skin**: Thinning of dermal tissue and skin atrophy can be seen with chronic glucocorticoid therapy. Hair follicles can become distended, and alopecia may occur.

Contraindications/Precautions/Warnings

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy for treatment of hypoadrenocorticism), when administered IM in patients with idiopathic thrombocytopenia, and in patients that are hypersensitive to a particular glucocorticoid. Concurrent use of sustained-release injectable glucocorticoids is contraindicated for chronic corticosteroid therapy of systemic diseases. Corticosteroid use may be contraindicated in horses predisposed to laminitis or exhibiting endocrinopathies.

Patients that have received systemic glucocorticoids for more than 2 weeks should be slowly tapered off the drug to allow return of endogenous ACTH and corticosteroid function. If the animal undergoes a stressful event (eg, surgery, trauma, illness) during the tapering process and/or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Adverse Effects

Adverse effects are associated with long-term administration of these drugs, especially if the drugs are administered at high doses or not on an alternate-day regimen. Effects typically manifest as clinical signs of hyperadrenocorticism. Glucocorticoids can delay growth when administered to young, growing animals. See ***Pharmacology***.

In dogs, polyuria (PU), polydipsia (PD), and polyphagia (PP) may occur during short-term burst therapy and on days when the drug is administered during alternate-day maintenance therapy. Adverse effects in dogs can include dull/dry coat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes (ALP more than ALT), vacuolar hepatopathy, GI ulceration/perforation (especially with high parenteral or oral doses), hypercoagulability, hyperlipidemia, activation or worsening of diabetes mellitus, muscle wasting, and behavior changes (eg, depression, lethargy, aggression).[6] Glucocorticoids have been known to delay growth in young animals. Discontinuation of the drug may be necessary; changing to an alternative glucocorticoid may also alleviate adverse effects. Adverse effects associated with anti-inflammatory therapy are relatively uncommon, with the exception of PU, PD, and PP. Adverse effects (eg, secondary infections) associated with immunosuppressive doses are more common and potentially more severe.

Cats generally require higher dosages than dogs for clinical effect, but typically develop fewer adverse effects. Glucocorticoids appear to have a greater hyperglycemic effect in cats than in other species. Occasionally, PU, PD, PP with weight gain, diarrhea, or depression can be seen. Long-term, high-dose therapy can lead to Cushingoid effects.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses, **but this is thought to only occur rarely. In a study of healthy adult horses, hyperglycemia**

and hyperinsulinemia returned to baseline values within 2 to 3 days of discontinuing dexamethasone, but recovery of insulin secretion was delayed by ≈2 weeks.[7]

Reproductive/Nursing Safety

Glucocorticoids are necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreatic, and mammary development. Excessive doses early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy.

Glucocorticoids are present in human breast milk.[8] High doses or prolonged administration to dams may potentially inhibit the growth of nursing newborns. In humans, several studies suggest that amounts excreted in human breast milk are negligible with prednisone or prednisolone doses of 20 mg/day or less, or methylprednisolone doses of less than or equal to 8 mg/day. Large doses for short periods of time may not harm the infant. Waiting 3 to 4 hours after administration before allowing offspring to nurse and using prednisolone rather than prednisone may result in a lower corticosteroid exposure for the offspring.

Overdosage/Acute Toxicity

When given short-term, glucocorticoids are unlikely to cause harmful effects, even in massive doses. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, supportive treatment should be implemented if necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glucocorticoids and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed, and additional monitoring performed when appropriate.

- **Amphotericin B**: When administered concomitantly with glucocorticoids, may cause hypokalemia
- **Anticholinesterase Agents** (eg, **neostigmine, pyridostigmine**): In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **Aspirin (salicylates)**: Glucocorticoids may reduce salicylate blood levels.
- **Cyclophosphamide**: Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **Cyclosporine**: Concomitant administration may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear.
- **Digoxin**: Secondary to hypokalemia, increased risk for arrhythmias
- **Diuretics, potassium-depleting** (eg, **furosemide, thiazides**): When administered concomitantly with glucocorticoids, may cause hypokalemia
- **Ephedrine:** May increase metabolism
- **Estrogens**: The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens.
- **Insulin**: Requirements may increase in patients receiving glucocorticoids.
- **Ketoconazole**: May decrease metabolism
- **Mitotane**: May alter the metabolism of glucocorticoids; higher than usual doses of glucocorticoids may be necessary to treat mitotane-induced adrenal insufficiency.
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam**): Administration of other ulcerogenic drugs with glucocorticoids may increase ulceration risk.
- **Phenobarbital**: May increase the metabolism of glucocorticoids
- **Rifampin**: May increase the metabolism of glucocorticoids
- **Vaccines**: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines, as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids.

Laboratory Considerations

- Glucocorticoids may increase serum **cholesterol** and **urine glucose** levels.
- Glucocorticoids may decrease serum **potassium**.
- Glucocorticoids may induce **ALP activity** in dogs.
- Certain glucocorticoids (eg, prednisone, prednisolone, hydrocortisone) will interfere with **cortisol assays** (**ACTH stimulation testing**). **NOTE:** Dexamethasone does not interfere.
- Glucocorticoids can suppress the release of thyroid-stimulating hormone (TSH) and reduce $\mathbf{T_3}$ and $\mathbf{T_4}$ values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of $\mathbf{I^{131}}$ by the thyroid may be decreased by glucocorticoids.
- Reactions to allergen **intradermal skin tests** may be suppressed by glucocorticoids.[9,10] A 2-week (14-day) withdrawal time before intradermal skin testing is recommended for dogs and cats[11,12]; no withdrawal time is required before serum IgE testing to identify sensitizing allergens in cats.[12]
- False negative results of the **nitroblue tetrazolium test for systemic bacterial infections** may be induced by glucocorticoids.

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, and/or signs of fluid retention
- Serum and/or urine electrolytes
- Total plasma proteins and albumin
- Blood glucose
- Urine culture
- Growth and development in young animals
- ACTH stimulation test to rule out iatrogenic hyperadrenocorticism

Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects progress or become severe.

For the complete list of references, see **wiley.com/go/budde/plumb**

Insulin, General Information

Insulin preparations are used for the treatment of diabetic ketoacidosis (DKA) and uncomplicated diabetes mellitus and as adjunctive therapy in treating hyperkalemia. Veterinary use of insulin has primarily been in dogs and cats, and there are 2 insulin products with FDA approval for use in these species: lente (*vetsulin®*) and recombinant human protamine zinc (*ProZinc®*) insulin. Insulin administration has also been reported for use in other species including, but not limited to, horses, cattle, camelids, birds, ferrets, and guinea pigs. (Information on the individual species and insulins with their exact application can be found in the relevant monographs.)

Goals of insulin therapy in diabetic patients include resolution of clinical signs associated with diabetes mellitus and minimizing the risk for complications such as hypoglycemia or ketosis. Often, hypoglycemia occurring secondary to insulin treatment can be more life-threatening than the hyperglycemia being treated. Diabetic dogs are typically permanently insulin-dependent (similar to a type 1 diabetes in humans) with an inability to produce insulin and require lifelong exogenous insulin. However, diabetic cats tend to develop an early insulin resistance (more consistent with type 2 diabetes in humans), which results in a combination of impaired insulin action (ie, resistance, beta cell dysfunction/failure) and culminates in insulin dependence. Achieving diabetic remission in cats should be considered as a possible treatment goal in newly diagnosed diabetic cats.[1] Increasing the chances for successful remission in cats is often accomplished by instituting more rigorous diabetic management interventions to achieve glycemic control as early as possible after the initial diagnosis.

Treatment of diabetes mellitus is complex. In sick diabetic patients (ie, those with DKA), insulin is only one component of therapy and treatment may require fluid and electrolyte replacement, management of acid/base disturbances, dietary adjustments, and antimicrobial therapy. These patients are typically stabilized with short-acting insulins before transitioning to long-acting insulin therapy; however, in cats, the use of a long-acting insulin (ie, glargine) has been found to be an effective and safe alternative treatment for the management of DKA.[2] Adequate monitoring is mandatory for all patients.

When treating uncomplicated diabetic patients, insulin choice is generally based on efficacy and duration of action in the species being treated. Recommended first-choice insulin products are porcine lente, recombinant human protamine zinc insulin (rPZI), or NPH insulin in dogs and protamine zinc insulin (rPZI) or glargine insulin in cats.[3]

Uses/Indications

Rapid or short-acting insulin:

Rapid or short-acting insulin is commonly used for stabilization of the sick diabetic patient, and as adjunctive therapy for the treatment of hyperkalemia. It is administered by IM and SC injection or by IV infusion. IV insulin administration is recommended in patients with poor tissue perfusion, in shock or cardiovascular collapse, or in those that require adjunct therapy for hyperkalemia.

Regular insulin (or R insulin) is the most commonly used short-acting insulin for diabetic emergencies. If regular insulin is not available or is cost prohibitive, other short-acting insulin preparations include insulin lispro or aspart. All short-acting insulin preparations are human products in U100 (100 units insulin/mL) concentration; higher concentrations may be available for some products, but their use has not been studied in veterinary species.

Regular insulin (*Humulin® R*, *Novolin® R*)

Lispro insulin (*HumaLOG®*, *Admelog®*, or *Lyumjev®*)

Aspart insulin (*NovoLog®*, *Fiasp®*)

Intermediate-acting insulin:

Intermediate-acting insulin preparations can be used for initial and long-term management of diabetes, especially in dogs.

Porcine lente insulin (*vetsulin®*) is a U40 (40 units insulin/mL) insulin and is FDA-approved for use in dogs and cats.

Recombinant human neutral protamine hagedorn (NPH) insulin (*Humulin® N*, or *Novolin® N*) is a U100 insulin approved for use in humans. *Novolin® N* and *Humulin® N* are essentially interchangeable; however, veterinary endocrinologists often recommend using only one brand after therapy is initiated. This insulin is not recommended for use in cats due to its short duration of action in this species.[3]

Long-acting insulin:

Although these insulins are categorized as long-acting, twice-daily therapy is often required. Long-acting insulin preparations can be considered when intermediate-acting insulin preparations are too short in duration of action. Long-acting insulin preparations are often used as first-line insulin choices in diabetic cats.

Glargine insulin is available in U100 concentration (*Lantus®*, *Basaglar®*, *Rezvoglar®, Semglee®*); a U300 (300 units insulin/mL) concentration (*Toujeo®*) is available. Glargine insulin also can be considered as an alternative to regular insulin CRI for the management of DKA.[4]

Protamine zinc insulin (*ProZinc®*) is a U40 insulin and is FDA-approved for use in dogs and cats.

Detemir insulin (*Levemir®*) is a U100 insulin. Use this product cautiously in dogs, as they exhibit a strong hypoglycemic response to detemir.

Degludec insulin (*Tresiba®*) is a U100 insulin that is ultra-long-acting in humans. There are insufficient data and experience in veterinary clinical patients to make a dosing recommendation for this insulin type at this time.

Pharmacology/Actions

Insulin is a hormone secreted by beta cells in the pancreatic islets of Langerhans. Eliciting multiple biologic responses, insulin initiates its actions by binding to cell-surface receptors, which are present in varying numbers in virtually all mammalian cells. This binding results in a cascade of intracellular events that can be studied in detail by consulting a physiology text.

Insulin is the primary hormone responsible for controlling the uptake, utilization, and storage of cellular nutrients. Insulin primarily affects liver, muscle, and adipose tissues but also exerts potent regulatory effects on other cell types. Insulin stimulates carbohydrate metabolism in cardiac, skeletal, and adipose tissue by facilitating glucose uptake into the cells. Other tissues, such as brain, nerve, intestinal, liver, and kidney tubules, do not require insulin for glucose transport. Insulin is involved in hepatic conversion of glucose to glycogen (for storage), and the hypothalamus requires insulin for glucose entry into the satiety center.

Insulin secretion is a tightly regulated process designed to provide stable concentrations of glucose in blood during fasting and feeding. This regulation is achieved by the coordinated interplay of nutrients, GI and pancreatic hormones, and autonomic neurotransmitters. The primary stimulus for secretion of endogenous insulin is glucose. Insulin also has direct effects on fat and protein metabolism. The hormone stimulates lipogenesis, increases protein synthesis, and inhibits lipolysis and free fatty acid release from adipose tissues. Insulin promotes an intracellular shift of potassium and magnesium. Exogenous insulin elicits all the pharmacologic responses usually produced by endogenous insulin.

Contraindications/Precautions/Warnings

There are no alternatives for insulin used for diabetic indications;

thus, there are no absolute contraindications to its use except during episodes of hypoglycemia. The likelihood that significant amounts of insulin antibodies will form is directly related to how divergent the administered insulin molecule is from the species being treated. Porcine insulin is identical to canine insulin and is considered the insulin source of choice for diabetic dogs. Cats have been shown to develop anti-insulin antibodies when given human, beef, and beef/pork insulins[5]; dogs have developed anti-insulin antibodies when given beef and pork insulins.[6] The presence of insulin antibodies may increase, decrease, or have no effect on glycemic control.[5,7] Anti-insulin antibodies should be investigated only after other etiologies for poor control (eg, expired insulin, concurrent disease, medication interference) are ruled out. In dogs with significant (ie, greater than 40%) anti-insulin antibodies and poor glycemic control, consider switching to a porcine or recombinant human insulin source or an insulin preparation devoid of protamine. It is unknown if veterinary patients produce antibodies to insulin analogues (eg, glargine, detemir).

Patients presented with severe ketoacidosis, anorexia, lethargy, and/or vomiting should be treated with short-acting insulin (eg, regular) and appropriate supportive therapy until their condition is stabilized. Alternatively, glargine administration was determined to be an effective and safe alternative to the standard regular insulin IV CRI protocol for the management of diabetic ketoacidosis (DKA) in cats.[4]

For obese patients, dose calculations should be based on the individual patient's ideal body weight to avoid inadvertent insulin overdose.

Long-term repeated SC/IM injections of insulin at the same site may cause lipodystrophic reactions, which could interfere with insulin absorption.

Insulin syringes are designed for use with a specific strength of insulin, with the needle covers color-coded according to strength (U40 syringes have a red top, whereas U100 syringes have an orange top). When dosing from a vial, caution must be used to ensure the correct syringes are being used for the insulin strength (eg, U40 syringes for U40 insulin) and that they are not mismatched (eg, U40 syringes for U100 insulin). U40 syringes contain 0.5 mL and have 20 unit marks. One unit mark in a U40 syringe will contain 1 unit of U40 insulin. U100 syringes are available in 0.3 mL, 0.5 mL, and 1 mL size. One unit mark in a U100 syringe will contain 1 unit of U100 insulin. Some brands of 0.3 mL syringes include half unit markings.

Tuberculin (TB) syringes can also be used but are not generally recommended because the potential for dose calculation confusion is substantial.

Using syringe sizes that do not match the insulin type is not recommended due to the increased risk for (potentially catastrophic) dosing errors; however, if the appropriate syringe is not available, conversions can be carefully calculated. Always double-check the conversion before administering to the patient. **NOTE**: Inadvertently using a U40 syringe for U100 insulin will result in a 2.5 times overdose of insulin; similarly, using U100 syringes with U40 insulin will result in a 2.5 times underdose of insulin.

- **If using U100 syringes to measure U40 insulin doses:**
  - Determine the required dose of U40 insulin.
  - Multiply the required units of U40 insulin by 2.5. Example: If the required U40 insulin dose is 10 units, then 10 units × 2.5 = 25 units of U40 insulin when using U100 syringes to administer.
- **If using TB syringes to measure U40 insulin doses:**
  - Determine the required dose of U40 insulin.
  - Multiply the required units of U40 insulin × 0.025. Example: If the required U40 insulin dose is 10 units, then 10 units × 0.025 = 0.25 mL of U40 insulin when using TB syringes to administer.
- **Be sure to double-check all calculations before administering to patient.**

When using pen devices, ensure the needles being used are designed specifically for the product being given.

When writing prescriptions, do not abbreviate units as "U," as it has been shown to increase the rate of transcription and dosage errors. In human medicine, insulin is considered a "high alert" medication (ie, medication that requires special safeguards to reduce the risk for errors). Consider instituting practices such as redundant drug dosage and volume checking, and special alert labels.

Adverse Effects

Adverse effects of insulin therapy may include hypoglycemia (see ***Overdose/Acute Toxicity***), hypokalemia, hypophosphatemia (diabetic ketoacidosis [DKA] only), and injection site reactions to the "foreign" proteins. In cases of hypoglycemia caused by excessive insulin, rebound hyperglycemia may follow (ie, Somogyi effect) due to release of counter-regulatory hormones in response to hypoglycemia or rapid rates of glucose decline following insulin administration. It is important to recognize this phenomenon when making insulin adjustments to avoid complications caused by inadvertent increases in insulin doses when in fact the dose needs to be decreased.

Reproductive/Nursing Safety

The safe use of veterinary-labeled insulins (ie, *vetsulin*®, *ProZinc*®) in breeding or pregnant animals has not been studied. Refer to specific insulin monographs for further information.

In humans, insulin is considered a treatment of choice for gestational diabetes[8]; insulin is compatible with nursing.

Overdose/Acute Toxicity

Insulin overdose leads to hypoglycemia. Signs may include weakness, shaking, head tilt, lethargy, ataxia, seizures, blindness, unusual behavior, and coma. Other signs may include restlessness, hunger, and muscle fasciculations. Electrolyte disturbances, including hypokalemia, may occur. Prolonged hypoglycemia can result in permanent brain damage or death.

Mild hypoglycemia can be treated by offering the animal its usual food. More serious signs (eg, seizures) should be treated with oral dextrose solutions (eg, *Karo*® syrup) applied to the buccal mucosa or by IV injections of 50% dextrose solutions (small amounts: usually 2 – 15 mL [0.5 – 1 mL/kg], diluted and slowly administered[9]; see ***Dextrose 50% injection***). For in-clinic management, glucagon may also be considered on an as-needed basis for an insulin overdose. See ***Glucagon*** for more information. If the animal is seizing, fingers should not be placed in the animal's mouth. Once the animal's hypoglycemia is alleviated (response usually occurs within 1 to 2 minutes), the animal should be closely monitored (both by physical observation and serial blood glucose concentrations) to prevent a recurrence of hypoglycemia (especially with the slower-absorbed/longer-acting products) and to prevent hyperglycemia from developing. Future insulin dosages or feeding habits should be evaluated or adjusted based on consultation with the clinician to prevent further occurrences of hypoglycemia.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving insulin and may be of importance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and

perform additional monitoring when appropriate.

- **Beta-Adrenergic Antagonists** (eg, **atenolol, propranolol**): Can have variable effects on glycemic control and can mask the signs associated with hypoglycemia
- **Clonidine**: Can mask the signs associated with hypoglycemia
- **Digoxin**: Because insulin can reduce serum potassium concentrations, patients receiving concomitant digoxin therapy—particularly patients receiving concurrent diuretic therapy—should be closely monitored.
- **Diuretics** (eg, **furosemide, hydrochlorothiazide**): Insulin shifts extracellular potassium into the intracellular space; serum potassium concentration should be closely monitored in patients receiving concomitant diuretic therapy. Diuretics may also *decrease* the hypoglycemic activity of insulin (ie, increase insulin requirements).
- **Reserpine**: Can mask the signs associated with hypoglycemia

The following drugs or drug classes may potentiate the hypoglycemic activity of insulin (ie, decrease insulin requirements):

- **Alcohol**
- **Anabolic Steroids** (eg, **boldenone, stanozolol, testosterone)**
- **Angiotensin II Receptor Blockers** (**ARBs;** eg, **telmisartan**)
- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs;** eg, **benazepril, enalapril**)
- **Disopyramide**
- **Fenofibrate**
- **Fluoroquinolones** (**eg, ciprofloxacin, enrofloxacin**)
- **Fluoxetine**
- **Hypoglycemic Agents, Oral** (eg, **acarbose, glipizide, metformin)**
- **Monoamine Oxidase Inhibitors** (**MAOIs;** eg, **amitraz, linezolid, selegiline**)
- **Pentoxifylline**
- **Salicylates** (eg, **aspirin, bismuth subsalicylate**)
- **Somatostatin Derivatives** (eg, **octreotide**)
- **Sulfonamides** (eg, **sulfadimethoxine, sulfamethoxazole**)

The following drugs or drug classes may decrease the hypoglycemic activity of insulin (ie, increase insulin requirements):

- **Alpha-2-Adrenergic Agonists** (eg, **dexmedetomidine, medetomidine, xylazine): May cause hyperglycemia and temporarily interfere with glycemic control**
- **Beta-Adrenergic Agonists** (eg, **albuterol, terbutaline**)
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**)
- **Danazol**
- **Diazoxide**
- **Estrogens** (eg, **diethylstilbestrol** [**DES**], **estriol**)
- **Isoniazid**
- **Niacin**
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**)
- **Progestins** (eg, **megestrol**)
- **Thyroid Hormones:** Can elevate blood glucose concentrations in diabetic patients when thyroid hormone therapy is first initiated

Monitoring

Diabetic patients should be closely monitored, especially during the first month of insulin therapy. Each patient requires an individualized treatment plan, frequent reassessment, and adjustments of the plan based on the response of the patient. It is encouraged to review a veterinary endocrinology reference text or consult with a veterinary emergency and critical care and/or endocrinology specialist for further information related to regulating diabetic patients and insulin adjustments. The overarching goal when monitoring diabetic patients is control of clinical signs related to hyperglycemia (eg, polyuria, polydipsia) while avoiding hypoglycemia.[3] Interpret all monitoring strategies based on clinical signs. Results from the monitoring options below may conflict in regards to achieving good glycemic and clinical control.

- Patient status and control of clinical signs: body weight, appetite, fluid intake, urine output
- Glucose (blood or interstitial). Experience with continuous interstitial glucose monitoring in dogs and cats indicates that these devices are easy to apply, user friendly, and provide useful information surrounding glycemic control while the patient is in the clinic or home environment.[10–14] A blood glucose curve should be considered at the following times[3]:
  a) At the discretion of the supervising veterinarian, after the first dose of a new insulin type, blood glucose can be checked regularly after administration. The goal for monitoring following the first dose of insulin would be solely to identify hypoglycemia. The insulin dose should NOT be increased based on the first-day blood glucose evaluation. If blood glucose falls below 150 mg/dL during the glucose curve, frequency of monitoring should increase to hourly until the blood glucose is greater than 150 mg/dL.[3] Although the insulin dose should never be increased on the first day of therapy, the dose should be decreased by 10% to 50% in dogs and 0.5 units in cats if blood glucose is less than 150 mg/dL at any time during the day.[3] Repeat glucose curves on subsequent days (and decrease insulin dose if necessary) until nadir is greater than 150 mg/dL.
  b) 7 to 14 days after starting insulin or an insulin dose change
  c) At least every 3 months, even in animals with well-controlled diabetes
  d) Any time clinical signs recur in an animal with previously well-controlled diabetes
  e) When hypoglycemia is suspected. **NOTE**: For patients that have experienced or are suspected to have experienced repeated or unexplained hypoglycemia, it is strongly encouraged to consult with a veterinary emergency and critical care and/or endocrinology specialist or reference text that specializes in providing information specific for treatment of hypoglycemia.
- Urine glucose monitoring is typically only helpful for documenting prolonged hypoglycemia (eg, persistently negative urine glucose testing when monitoring for diabetic remission in cats). As most diabetic patients spend time above the renal threshold for urinary glucose spillage, even patients with well-controlled diabetes may be intermittently glucosuric throughout the day.
- Fructosamine or glycosylated hemoglobin can be measured if available and warranted.
- Additional monitoring for patients with diabetic ketoacidosis (DKA)[15]:
  - Glucose measurement every 1 to 2 hours initially; adjust insulin therapy and begin dextrose infusion when blood glucose decreases below 250 mg/dL (14 mmol/L). See ***Dosages*** section of specific insulin type being administered.
  - Hydration status, respiration, pulse every 2 to 4 hours
  - Serum electrolytes (eg, magnesium, phosphorous, potassium), plasma ketones, and total venous CO_2 concentrations every 4 to 8 hours
  - Urine output, glycosuria urine ketones every 4 to 8 hours
  - Body weight, packed cell volume, temperature, and blood pressure every 6 to 8 hours
  - Additional monitoring as applicable to address concurrent disease

Client Information

- **NOTES for veterinarian**:
  1. Correct injection techniques should be taught and practiced with the client before the animal's discharge.

2. Emphasis should be placed on matching the appropriate syringe and insulin concentration (eg, do not interchange U40 insulin and syringes with U100 insulin and syringes) and correct needles with pens/devices.
3. Both veterinary-approved insulins have owner information sheets, client-friendly handouts, and websites to provide client support on administration and use of insulin.

- For this medication to work safely, give the insulin *exactly* as your veterinarian has prescribed. Your veterinarian will teach you correct injection techniques before your animal is discharged. Only use the syringes provided by your veterinarian.
- Always double-check the dose in the syringe before you inject your animal. Overdoses may be fatal.
- Do not give this medicine if your animal is not eating.
- The insulin bottle should be visually inspected prior to use. Some insulins will be clear and colorless, whereas others may appear as a uniform milky suspension. There should never be clumps or unexpected particles. Your veterinarian will show you what the vial contents should look like.
- Some insulins require gentle rolling or shaking of the vial prior to withdrawing a dose.
- Unused insulin is stored in the refrigerator. After the vial or pen/device is first used, the insulin will need to be either kept at room temperature or refrigerated depending on the type of insulin. After measuring the dose from a refrigerated insulin into a syringe, allow the contents to come to room temperature before injection.
- The injection site should be frequently changed, with the main sites being the back of the neck, side of the animal, or shoulder area.
- Place the used needles and syringes in a sharps disposal container immediately after use, making sure you do not attempt to disconnect the needle from the syringe or recap the needle. Your veterinarian or pharmacist will help you obtain these containers. Do not reuse needles or syringes.
- Signs of low blood sugar (*hypoglycemia*) include weakness, depression, lack of energy, sluggishness, staggering gait (ie, stumbling) when walking, behavior changes, muscle twitching, seizures (convulsions), or coma. **If your animal is unconscious or having a seizure, this is a medical emergency.** Take your animal to the veterinarian immediately. **If your animal is conscious and able to swallow**, rub ≈1 tablespoon of corn syrup (*Karo*®) or honey on your animal's gums until it is alert enough to eat. Feed the usual meal and contact your veterinarian for recommendations. Some animals may not show any obvious physical signs of low blood sugar. If your animal is not acting normally, contact your veterinarian to make sure your animal's blood sugar concentrations are in a safe range.
- Contact your veterinarian at your earliest convenience if you notice excessive thirst, increased frequency of urination, or increased appetite in your animal, as these signs may indicate the insulin dose needs to be adjusted.
- Keep insulin products out of temperature extremes. When traveling, insulin should not be left in carry-on luggage that will pass through airport surveillance equipment. Generally, insulin stability is not affected by a single pass-through surveillance equipment; however, longer than normal exposure or repeated passes through surveillance equipment may alter insulin potency.
- Do not stop giving this medication to your animal unless instructed to do so by your veterinarian.
- Your veterinarian will need to closely monitor your animal during treatment. Do not miss these important follow-up visits.
- **Keep insulin out of the reach of children. Avoid contact with eyes. In case of contact, immediately flush eyes with running water for at least 15 minutes. Accidental injection may cause hypoglycemia. In case of accidental injection, seek medical attention immediately.**

Chemistry/Synonyms

The endocrine component of the pancreas is organized as discrete islets (islets of Langerhans) that contain 4 cell types, each of which produces a different hormone. Insulin is produced in the beta cells, which comprise 60% to 80% of the islet. Insulin is a protein consisting of 2 chains, designated A and B, with 21 and 30 amino acids, respectively, that are connected by 2 disulfide bonds. Human insulin has a molecular weight of 5808.

The amino acid composition of insulin has been determined in various animal species. The insulin of dogs and pigs is identical in structure. Dogs, horses, cattle, sheep, and goats differ only in positions 8, 9, and 10 of the A chain. Porcine insulin differs from human insulin by 1 amino acid (alanine instead of threonine at the carboxy terminal of the B chain [ie, in position B 30]), and bovine insulin differs by 2 additional alterations in the A chain (threonine and isoleucine in positions A8 and A10 are replaced by alanine and valine, respectively). Of the domestic species, feline insulin is most similar to bovine insulin, differing by only 1 amino acid (at position 18 of the A chain). Human insulin differs from rabbit insulin by a single amino acid. There is a single insulin gene and a single protein product in most mammalian species (multiple insulins appear to occur frequently among fish). Recombinant DNA technology is used to manufacture most insulins, in which the insertion of the insulin gene into the DNA of nonpathogenic bacteria or yeast allows the organisms to produce the insulin protein.

For therapeutic purposes, doses and concentrations of insulin are expressed in units. This is sometimes abbreviated as "U," but this practice is discouraged to reduce the chance for transcription and dosing errors. One unit of insulin is equal to the amount required to reduce the concentration of blood glucose in a fasting rabbit to 45 mg/dL. All commercial preparations of human-labeled insulin currently manufactured in the United States are supplied in solution or suspension at a concentration of 100 units/mL, which is ≈3.6 mg/mL of insulin (one notable exception is detemir, which contains 14.2 mg/mL of insulin). Likewise, one unit of insulin equals ≈35 µg of insulin, and 1 mg insulin is ≈28.8 units.[16]

All human and purified pork insulin products have a neutral pH of ≈7 to 7.8, except for insulin glargine, which has an acidic pH of ≈4.

Storage/Stability

All insulin manufacturers state that unopened insulin products should be stored in the refrigerator and protected from temperature extremes and direct sunlight. Freezing (less than 2°C [36°F]) may alter the protein structure and decrease potency. Particle aggregation and crystal damage may not be visible to the naked eye. Higher temperature extremes (greater than 30°C [86°F]) and direct exposure to sunlight may produce insulin transformation products and fibril formation. Manufacturers allow room-temperature storage of most in-use vials, but recommendations for duration of use and storage vary by manufacturer and product.

Although manufacturers recommend discarding opened bottles of insulin after 4 to 6 weeks (or expiration date, whichever comes first), studies support that insulin potency and stability is maintained for longer durations.[17,18] Veterinary internal medicine specialists indicate that the vial may be used for 3 to 6 months after opening and possibly beyond the listed expiration date as long as it is handled carefully, stored in the refrigerator, and the solution does not develop discoloration, flocculent precipitates, or changes in consistency. If a lack of diabetes regulation is noted when using the product beyond the expiration date (3 to 6 months after starting therapy), it may be prudent to replace with new insulin prior to adjusting insulin therapy.[3]

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult a pharmacist or specialized references for more specific information.

Diluting insulin: Not all insulin solutions can or should be diluted. Refer to specific insulin monographs for detailed information.

Dosage Forms

Insulin preparations are available for injection from a vial or as an insulin pen. For some pet owners, insulin pens may provide more accuracy with dosing, especially when administering low or half doses of insulin. See specific insulin monographs for details related to available dosage forms.

For humans, insulins are FDA-licensed (approved) biological products. Some insulin types have biosimilar or interchangeable biosimilar products available. Please refer to the FDA's Purple Book for more information about FDA-approved biologics, including biosimilar and interchangeable products.

Opioids, General Information

Receptors for opioid analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues, such as the GI tract, urinary tract, and in other smooth muscles.

Opioid receptors are further broken down into 3 main subgroups:

1. *Mu (MOP)* receptors are found primarily in the pain-regulating areas of the brain. They are responsible for analgesia but also many of the associated adverse effects, including euphoria, respiratory depression, sedation, physical dependence, miosis, decreased GI motility, nausea, vomiting, and hypothermic actions of opioids.
2. *Kappa (KOP)* receptors are located primarily in the deep layers of the cerebral cortex and spinal cord. They are thought to contribute to analgesia, nociception, diuresis, sedation, and miosis.
3. *Delta (DOP)* receptors are located in the limbic areas of the CNS, such as the neocortex and amygdala. They are thought to contribute to analgesia, decreased GI motility, and inhibition of dopamine release.

The nociceptin orphanin peptide receptor [NOP, also known as orphan receptor L1, ORL1]) has a structure that is very similar to the other opioid receptors; however, it does not respond in a classic fashion to opioid antagonists, and its classification as an opioid receptor remains controversial. Previously, several other opioid receptor subtypes (including sigma and epsilon) were proposed but have been reclassified as nonopioid receptors as they have little to no affinity for opioids and morphine-like compounds.[1–4]

All opioids in clinical practice act primarily at the MOP receptor with varying degrees of activity on the KOP and DOP receptors. Opioids can be classified according to origin: naturally occurring (eg, morphine, codeine), semisynthetic (eg, oxycodone, buprenorphine), and synthetic (eg, methadone, fentanyl). Additionally, they can be classified according to their effect on the receptors: agonist (eg, morphine, fentanyl), partial agonist (eg, buprenorphine), and antagonist (eg, naloxone, naltrexone).

The primary pharmacologic effects of opioids include analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation, defecation).

Secondary pharmacologic effects include:

- CNS: Euphoria, excitement
- Cardiovascular: Bradycardia, peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition, which may result in orthostatic hypotension and syncope
- Urinary: Diuresis, increased bladder sphincter tone can induce urinary retention

Various species may exhibit paradoxical effects from these agents. For example, in contrast to the expected effects of sedation and constipation after morphine administration, horses, cattle, swine, and cats may develop excitement while dogs may defecate. Dogs and humans may develop miosis, while other species (especially cats) may develop mydriasis. For more information, see the individual monographs for each agent.

Penicillins, General Information

Uses/Indications

Penicillins are beta-lactam antimicrobials that are used for a wide range of infections in various species. FDA-approved indications/species, as well as non-FDA-approved uses, are listed in the ***Uses/Indications*** and ***Dosages*** section for each drug.

Pharmacology/Actions

Penicillins are beta-lactam antimicrobials that disrupt bacterial cell wall synthesis by binding penicillin-binding proteins (PBPs) within the bacterial cell wall, which inhibits peptidoglycan synthesis. This results in a defective barrier and an osmotically unstable spheroplast. The number and type of PBPs vary between different bacteria, as do the different affinities for various beta-lactams. This helps explain the differences in spectrums of activity the drugs have, which are not explained by the influence of beta-lactamases. Penicillins are time-dependent antimicrobials, usually bactericidal, and like other beta-lactam antibiotics, they are generally considered more effective against actively growing bacteria. The penicillins have no activity against rickettsia, mycobacteria, *Mycoplasma* spp, fungi and viruses. There are several classes of penicillins with various spectrums of activity.

Natural penicillins: penicillin G and V

In general, the natural penicillins are susceptible to the effects of beta-lactamases and are unable to penetrate the cell membrane of gram-negative bacteria. Therefore, their spectrum of activity is mainly aerobic gram-positive cocci, including streptococci and non–penicillinase-producing staphylococci. They also have activity against some aerobic and anaerobic gram-positive bacilli, such as *Bacillus anthracis*, *Clostridium* spp, *Fusobacterium* spp, and *Actinomyces* spp. In addition, they have activity against some nonpenicillinase-producing gram-negative aerobic cocci and against most spirochetes. The natural penicillins are inactive against most aerobic and anaerobic gram-negative bacilli. The natural penicillins are available as sodium, potassium, procaine, or benzathine salt forms. Procaine and benzathine salts slow absorption, leading to a longer duration of action. However, the slow absorption of benzathine penicillin G can result in inadequate penicillin concentration.

Penicillinase-resistant penicillins: nafcillin, cloxacillin, dicloxacillin, oxacillin

The penicillinase-resistant penicillins have a narrower spectrum of activity than the natural penicillins but are resistant to degradation by penicillinases. Their antimicrobial efficacy is aimed directly against penicillinase-producing strains of gram-positive cocci, particularly staphylococcal species. Their spectrum of activity is mainly methicillin-susceptible staphylococci and streptococci; they are inactive against methicillinresistant staphylococci and extended-spectrum beta-lactamase-producing Enterobacteriaceae. In general, this class is more hepatically excreted than other classes of penicillins and is less likely to require dose adjustments for patients with renal insufficiency.

Aminopenicillins: ampicillin, amoxicillin

The aminopenicillins (sometimes referred to as broad-spectrum or ampicillin penicillins) have increased activity against many strains of gram-negative aerobes, including *Escherichia coli*, *Klebsiella* spp, *Proteus mirabilis,* and *Haemophilus* spp. Like the natural penicillins, they are susceptible to inactivation by beta-lactamases. They also have some activity against many anaerobic bacteria, including clostridial organisms. They are inactive against *Pseudomonas aeruginosa*, *Serratia* spp, indole-positive *Proteus* spp (*Proteus vulgaris*), *Citrobacter* spp, and *Acinetobacter* spp.

Extended-spectrum penicillins (anti-pseudomonal penicillins): piperacillin

The extended-spectrum penicillins have increased activity against gram-negative aerobes and are sometimes called anti-pseudomonal penicillins. These agents have similar spectrums of activity as the aminopenicillins but with additional activity against several gramnegative organisms of the family Enterobacteriaceae, as well as many strains of *Pseudomonas aeruginosa*. Like the aminopenicillins, these agents are susceptible to inactivation by beta-lactamases. The primary agent in this class (ie, piperacillin) is only available as a piperacillin/tazobactam combination.

Potentiated penicillins: amoxicillin/clavulanic acid, ampicillin/sulbactam, piperacillin/tazobactam

In order to reduce the inactivation of penicillins by beta-lactamases, beta-lactamase inhibitors, such as clavulanic acid, sulbactam, and tazobactam, have been developed to inactivate these enzymes. These compounds have little to no inherent antimicrobial activity but can inactivate beta-lactamases, rendering beta-lactamase-producing bacteria susceptible to the penicillin component of the combination. This is an effective approach against many resistant bacteria, particularly staphylococci and Enterobacteriaceae. The effect of these betalactamase inhibitors depends on the type of beta-lactamase that is being produced. Extended-spectrum beta-lactamases (ESBLs), an increasing problem in human and veterinary medicine, are variably susceptible to beta-lactamase inhibitors.

Resistance mechanisms:

In addition to the production of beta-lactamases, other resistance mechanisms against penicillins exist. Some bacteria, such as *Staphylococcus aureus* (MRSA), *Enterococcus* spp, and *Streptococcus pneumonia,* have PBP mutations or alterations that have decreased affinity for penicillins.[1] Resistance may also occur through decreased entry through membrane porins or removal of the drug via efflux pumps.

Pharmacokinetics (General)

The oral absorption characteristics of the penicillins are dependent upon their class. Penicillin G is the only available oral penicillin that is substantially affected by gastric pH and can be completely inactivated at a pH of less than 2. The other orally available penicillins are resistant to acid degradation. Effects of food vary between the penicillins. Of the orally administered penicillins, penicillin V and amoxicillin tend to have the greatest bioavailability in their respective classes.

Penicillins are generally distributed widely throughout the body. Most drugs attain therapeutic concentrations in the kidneys, liver, heart, skin, lungs, intestines, bile, bone, and peritoneal, pleural, and synovial fluids. Penetration into the CSF and eye only occur with inflammation and may not reach therapeutic concentrations. Penetration into the prostate is poor.[2] Penicillins are bound in varying degrees to plasma proteins and cross the placenta.

Most penicillins are rapidly excreted largely unchanged by the kidneys into the urine via glomerular filtration and tubular secretion and, therefore, achieve high concentrations in the urine. Probenecid can prolong half-lives and increase serum concentrations by blocking the tubular secretion of penicillins. Except for the penicillinase-resistant penicillins, hepatic inactivation and biliary secretion are minor routes of excretion.

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients that are documented hypersensitive to other beta-lactam antibiotics (eg, cephalosporins, cephamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses, as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral (preferably IV) routes should be used for these cases. Certain species (eg, snakes, birds, turtles, guinea pigs, and chinchillas) are reportedly sensitive to procaine penicillin G.

Do not use oral penicillins in hindgut fermenting species, such as horses and rabbits, as they can cause a fatal GI disease.

High doses of penicillin G sodium or potassium, particularly in small animals with a pre-existing electrolyte abnormality, renal disease, or congestive heart failure, may cause electrolyte imbalances, including hypokalemia. Other injectable penicillins, such as ampicillin, have significant quantities of sodium per gram and may cause electrolyte imbalances when used in large dosages in susceptible patients.

Adverse Effects

Penicillins are typically well tolerated. When given orally, penicillins may cause GI effects (eg, anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur.

Hypersensitivity reactions, unrelated to dose, can occur with these agents and manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins.[3] The incidence of cross-reactivity in veterinary patients is unknown.

Neurotoxicity (eg, ataxia in dogs) has been associated with very high doses or prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Some penicillins (ticarcillin, piperacillin, and nafcillin) have been implicated in causing bleeding problems in humans. These drugs are infrequently used systemically in veterinary species, so the ramifications of this effect are unclear.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta. Safe use during pregnancy has not been firmly established, but no teratogenic reports have been documented either.

Penicillins are excreted in maternal milk in low concentrations; use potentially could cause diarrhea, candidiasis, or allergic response in the nursing offspring.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral penicillin overdoses are most likely to cause GI distress, but other effects are possible (see ***Adverse Effects***). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and

toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillins and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins. Penicillins and aminoglycosides should not be administered in the same syringe because of the potential for inactivation.
- **Bacteriostatic antibiotics** (eg, **chloramphenicol, erythromycin, tetracyclines**): Use with penicillins is generally not recommended, particularly in acute infections where the organism is rapidly proliferating as penicillins tend to perform better on actively growing bacteria.
- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives

Laboratory Considerations

- Penicillins may cause false-positive **urine glucose** determinations when using cupric-sulfate solution (Benedict's solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by penicillin.
- In humans, clavulanic acid and high dosages of piperacillin have caused a false-positive direct **Coombs test**.
- Penicillins may cause false-positive **urine protein** determinations and falsely elevated **urine, serum,** or **CSF protein** in a variety of testing methods.

Monitoring

- Clinical signs of efficacy
- Culture and susceptibility as indicated for clinical condition being treated
- CBC and electrolytes may be indicated in some cases.
- Adverse effects including hypersensitivity reactions and GI disturbances (ie, vomiting, diarrhea, inappetence)
- Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Gastrointestinal side effects are most common.
- Compliance with the therapeutic regimen should be stressed. It is important to complete the full course of therapy, even after clinical signs improve.

Antimicrobials in Human and Veterinary Medicine: A Global Classification

ERICA EARNHARDT WASSACK, PHARMD, DICVP, FSVHP, FACVP
College of Veterinary Medicine, Mississippi State University

Antimicrobial agents used in human and veterinary medicine are drugs used to kill or inhibit the growth of microorganisms such as bacteria and fungi. These drugs are essential for human and animal health and welfare. Human and veterinary antimicrobial use has created a global health concern regarding antimicrobial resistance.[1,2]

The World Health Organization (WHO), in collaboration with the Food and Agriculture Organization of the United Nations (FAO) and the World Organization for Animal Health (OIE), addressed the public health consequences of using antimicrobial agents in food producing animals and concluded that:

1. Antimicrobial resistance was a global public and animal health concern that has been impacted by the use of antimicrobial agents in all sectors.
2. Evidence existed of human health consequences as a product of nonhuman use of antimicrobials resulting in resistant microorganisms.
3. The volume and pattern of nonhuman antimicrobial use have affected the human exposure to resistant bacteria.
4. The consequences of antimicrobial resistance were severe in pathogens resistant to antimicrobials critically important in humans.

As a result, WHO appointed an expert committee to develop a list of antimicrobial agents considered critically important in human medicine [Critically Important Antimicrobials for Human Medicine[1]]. WHO also recommended that OIE develop a list of critically important antimicrobial agents in veterinary medicine [OIE List of Antimicrobial Agents of Veterinary Importance[2]]. These lists should be used to ensure that all antimicrobials, especially critically important antimicrobials, are used prudently in both human and veterinary medicine to minimize the risk for antimicrobial resistance.

Additionally, antimicrobials listed as critically important (eg, fluoroquinolones, third- and fourth-generation cephalosporins, and colistin) in the WHO and OIE veterinary guidelines should be used with the following antimicrobial stewardship recommendations:

- Antimicrobials are not to be used as preventive treatment applied via feed or water in the absence of clinical signs in animal(s) to be treated.
- Antimicrobials are not to be used as a first-line treatment unless justified. When antimicrobials are used as second-line treatment, their use should ideally be based on results of bacteriological tests.
- Extra-label use should be limited and reserved for instances where no alternatives are available.
- Antimicrobials should be phased out for use as growth promotors.

WHO Critically Important Antimicrobials for Human Medicine

The WHO list of Critically Important Antimicrobials for Human Medicine is a reference to help public health authorities as well as practitioners formulate and prioritize risk assessment and management strategies to preserve antimicrobial effectiveness and minimize risk for transmission of resistance to the human population.[1] The list takes into account pathogens likely to transfer from animals, food products, or the environment to humans.

The ranking of antimicrobial agents helps identify which veterinary antimicrobials pose a higher risk to humans.

As stated in the Critically Important Antimicrobials for Human Medicine document,[1] categorization of medically important antimicrobial classes is determined by two criteria:

Criterion 1: Antimicrobial class is the sole, or one of limited available therapies, to treat serious bacterial infections in humans.
Criterion 2: Antimicrobial class is used to treat infections in humans caused by either:

1. Bacteria that may be transmitted to humans from nonhuman sources, or
2. Bacteria that may acquire resistance genes from nonhuman sources.

Based on the above criteria, antimicrobial agents are placed into three categories:

- **Critically Important**: Antimicrobial class meets *both* criterion 1 and criterion 2
- **Highly Important**: Antimicrobial class meets *either* criterion 1 or criterion 2
- **Important**: Antimicrobial class does not meet *either* criterion

Antimicrobial agents within the Critically Important category are further prioritized to determine which agents need the most resources allocated to provide risk management strategies. Antimicrobial classes in this group that also meet all three of the following criteria are considered the Critically Important, *Highest* Priority; those that meet only one or two of these additional criteria are considered Critically Important, *High* Priority.

1. Antimicrobial class used to treat a large number or proportion of humans being treated for serious infections for which there are limited antimicrobial choices available.
2. Antimicrobial class has high frequency of use for any indication in human medicine, or high proportion of use for serious infection in healthcare settings; use in these situations may increase microbial resistance.
3. Antimicrobial class used to treat infections in people with existing evidence that animal sources transmit *resistant bacteria* (eg, nontyphoidal *Salmonella* spp and *Campylobacter* spp) or *resistance genes* (eg, *Escherichia coli* and *Enterococcus* spp).

OIE Antimicrobial Agents of Veterinary Importance

The development of the OIE List of Antimicrobial Agents of Veterinary Importance took into consideration any antimicrobial agent authorized for use in veterinary medicine according to the criteria of quality, safety, and efficacy defined by the *Terrestrial Animal Health Code*.[2] Therefore, all antimicrobial agents used in food-producing animals (avian, bee, bovine, caprine, camel, equine, rabbit, ovine, fish, swine) were divided into three categories: critically important, highly important, and important. **NOTE**: The OIE list of antimicrobials was compiled for antimicrobial importance in *food-producing* animals only and differs from the WHO classification listed above.

The criteria to define veterinary important antimicrobial agents took into account the vast number of species treated in veterinary medicine.

Categorization of important antimicrobial classes used in veterinary medicine is determined by two criteria.

Criterion 1: Majority (greater than 50%) of OIE Member Country contributions response to questionnaire identified the importance of antimicrobial class.

Criterion 2: Compounds within the antimicrobial class were identified as essential against specific infections and sufficient therapeutic alternatives were lacking.

Categorization of antimicrobials of veterinary importance is similar to the WHO guidelines:

Veterinary Critically Important Antimicrobial Agents (VCIA): Antimicrobial class meets *both* criterion 1 and criterion 2

Veterinary Highly Important Antimicrobial Agents (VHIA): Antimicrobial class meets *either* criterion 1 or criterion 2

Veterinary Important Antimicrobial Agents (VIA): Antimicrobial class meets *neither* criterion 1 nor criterion 2

Summary of the Current WHO and OIE Antimicrobial Classifications

WHO Abbreviations

CI-Highest: Critically Important, Highest Priority
CI-High: Critically Important, High Priority
Highly: Highly Important
Important: Important
NC: Not classified

OIE Abbreviations

VCIA: Veterinary Critically Important Antimicrobial Agents
VHIA: Veterinary Highly Important Antimicrobial Agents
VIA: Veterinary Important Antimicrobial Agents
NC: Not classified

*Veterinary-approved drug only

Antimicrobial class	Example of antimicrobials(s)	WHO	OIE
Amdinopenicillins	Mecillinam, Pivmecillinam	Highly	VCIA
Aminocoumarin	Novobiocin	NC	VIA
Aminocyclitols	Spectinomycin	Important	VCIA
Aminoglycosides	Amikacin, Arbekacin, Apramycin*, Bekanamycin, Dibekacin, Dihydrostreptomycin, Framycetin, Gentamicin, Isepamicin, Kanamycin, Neomycin, Netilmicin, Ribostamycin, Streptomycin, Tobramycin	CI-High	VCIA
Amphenicols	Chloramphenicol, Florfenicol*, Thiamphenicol	Highly	VCIA
Ansamycins	Rifabutin, Rifampicin, Rifaximin, Rifapentine, Rifamycin	CI-High	VHIA
Arsenical	Nitarsone, Roxarsone	NC	VIA
Bicyclomycin	Bicozamycin	NC	VIA
Carbapenems and other penems	Biapenem, Doripenem, Ertapenem, Faropenem, Imipenem, Meropenem, Panipenem	CI-High	NC
Cephalosporins, first generation	Cefacetrile, Cefadroxil, Cefaloridine, Cefalexin, Cefalonium*, Cefalotin, Cefaparin, Cefatrizine, Cefazedone, Cefazolin, Cefradine, Cefroxadine, Ceftezole	Highly	VHIA

Antimicrobial class	Example of antimicrobials(s)	WHO	OIE
Cephalosporins, second generation	Cefaclor, Cefamandole, Cefbuperazone, Cefmetazole, Cefminox, Cefonicid, Ceforanide, Cefotetan, Cefotiam, Cefoxitin, Cefprozil, Cefuroxime	Highly	VHIA
Cephalosporins, third generation	Cefcapene, Cefdinir, Cefditoren, Cefetamet, Cefixime, Cefmenoxime, Cefodizime, Cefoperazone, Cefoperazone/Sulbactam, Cefotaxime, Cefpiramide, Cefpodoxime, Cefovecin*, Cefsulodin, Ceftazidime, Ceftazidime/Avibactam, Ceftibuten, Ceftiofur*, Ceftizoxime, Ceftriaxone, Ceftriazone/sulbactam, Latamoxef, Tazobactam	CI-Highest	VCIA
Cephalosporins, fourth generation	Cefepime, Cefoselis, Cefozopran, Cefpirome, Cefquinome*	CI-Highest	VCIA
Cephalosporins, fifth generation	Ceftaroline fosamil, Ceftobiprole, Ceftolozane	CI-Highest	NC
Cephamycins	Flomoxef, Loracarbef	Highly	NC
Cyclic polypeptides	Bacitracin, Enramycin, Gramicidin	Important	VHIA
Drugs used solely to treat tuberculosis and mycobacterial diseases	Bedaquiline, Calcium aminosalicylate, Capreomycin, Cycloserine, Delamanid, Ethambutol, Ethionamide, Isoniazid, Morinamide, Para-aminosalicylic acid, Protionamide, Pyrazinamide, Sodium aminosalicylate, Terizidone, Tiocarlide	CI-High	NC
Fluoroquinolones	Besifoxacin, Cinoxacin, Ciprofloxacin, Danofloxacin*, Delafloxacin, Difloxacin*, Enoxacin, Enrofloxacin*, Fleroxacin, Garenoxacin, Gatifloxacin, Gemifloxacin, Grepafloxacin, Bafloxacin*, Levofloxacin, Lomefloxacin, Marbofloxacin*, Moxifloxacin, Nadifloxacin, Norfloxacin, Ofloxacin, Orbifloxacin*, Pazufloxacin, Pefloxacin, Pipemidic acid, Piromidic acid, Pradofloxacin*, Prulifloxacin, Rosoxacin, Rufloxacin, Sitafloxacin, Sparfloxacin, Temafloxacin	CI-Highest	VCIA
Fusidic acid	Fusidic acid	NC	VIA
Glycopeptides and lipoglycopeptides	Avoparcin*, Dalbavancin, Oritavancin, Teicoplanin, Telavancin, Vancomycin	CI-Highest	NC
Glycylcyclines	Tigecycline	CI-High	NC
Ionophores	Lasalocid, Maduramycin, Monensin, Narasin, Salinomycin, Semduramicin	NC	VHIA
Lincosamides	Clindamycin, Lincomycin, Pirlimycin*	Highly	VHIA
Lipopeptides	Daptomycin	CI-High	NC
Macrolides and ketolides	Azithromycin, Cethromycin, Clarithromycin, Dirithromycin, Erythromycin, Fidaxomicin, Flurithromycin, Gamithromycin*, Josamycin, Kitasamycin*, Midecamycin, Miocamycin, Oleandomycin, Ramoplanin, Rokitamycin, Roxithromycin, Solithromycin, Spiramycin, Telithromycin, Tildipirosin*, Tilmicosin*, Troleandomycin, Tulathromycin*, Tylosin*, Tylvalosin*	CI-Highest	VCIA
Monobactams	Aztreonam, Carumonam	CI-High	NC
Nitrofurantoins	Furaltadone*, Furazolidone, Nifurtoinol, Nitrofural, Nitrofurantoin	Important	NC
Nitroimidazoles	Metronidazole, Ornidazole, Tinidazole	Important	NC
Orthosomycins	Avilamycin	NC	VIA
Oxazolidinones	Cadazolid, Linezolid, Radezolid, Tedizolid	CI-High	NC
Penicillins (anti-staphylococcal)	Cloxacillin, Dicloxacillin, Flucloxacillin, Oxacillin, Nafcillin	Highly	VCIA
Penicillins (natural, aminopenicillins, antipseudomonal)	Amoxicillin, Amoxicillin/Clavulanate, Ampicillin, Ampicillin/Sulbactam, Aspoxicillin*, Azidocillin, Azlocillin, Bacampicillin, Carbenicillin, Carindacillin, Clometocillin, Epicillin, Hetacillin, Metampicillin, Meticillin, Mezlocillin, Panamecillin, Penethamate hydriodide*, Penicillin G (benzylpenicillin), Penicillin V (phenoxymethylpenicillin), Pheneticillin, Piperacillin, Piperacillin/Tazobactam, Pivampicillin, Propicillin, Sulbenicillin, Sultamicillin, Talampicillin, Temocillin, Ticarcillin, Ticarcillin/Clavulanate	CI-High	VCIA
Phosphoglycolipids	Bambermycin (Lavomycin)	NC	NC
Phosphonic acid	Fosfomycin	CI-High	VHIA
Pleuromutilins	Retapamulin, Tiamulin*, Valnemulin*	Important	VHIA

Antimicrobial class	Example of antimicrobials(s)	WHO	OIE
Polymyxins	Colistin, Polymyxin B	CI-Highest	VHIA
Pseudomonic acids	Mupirocin	Highly	NC
Quinolones, first generation	Flumequine, Miloxacin, Nalidixic acid, Oxolinic acid	CI-Highest	VHIA
Quinoxalines	Carbadox, Olaquindox	NC	VIA
Riminofenazines	Clofazimine	Highly	NC
Steroid antibacterials	Fusidic acid	Highly	VIA
Streptogramins	Quinupristin/Dalfopristin, Pristinamycin, Virginiamycin*	Highly	VIA
Sulfonamides, dihydrofolate reductase inhibitors, and combinations	Brodimoprim, Formosulfathiazole*, Iclaprim, Phthalylsulfathiazole*, Pyrimethamine, Sulfadiazine, Sulfadimethoxine, Sulfadimidine, Sulfafurazole, Sulfaisodimidine, Sulfalene, Sulfamazone, Sulfamerazine, Sulamethizole, Sulfamethoxazole, Sulfamethoxypyridazine, Sulfametomidine, Sulfametoxydiazine, Sulfametrole, Sulfamoxole, Sulfanilamide, Sulfaperin, Sulfaphenazole, Sulfapyridine, Sulfathiazole, Sulfathiourea, Tetroxoprim, Trimethoprim	Highly	VCIA
Sulfones	Aldesulfone, Dapsone	Highly	NC
Tetracyclines	Chlortetracycline, Clomocycline, Demeclocycline, Doxycycline, Lymecycline, Metacycline, Minocycline, Omadacycline, Oxytetracycline, Penimepicycline, Rolitetracycline, Tetracycline	Highly	VCIA
Thiostrepton	Nosiheptide	NC	VIA

ARCI UCGFS Classifications

The Association of Racing Commissioners International (ARCI), Inc. is a not-for-profit corporation that *exists to assist in the coordination of the collective efforts of its members who are responsible for ensuring compliance with government laws and regulations designed to protect the general public and racing industry participants, including the equine and canine athletes.*

The organization's website has the most current information on the *Uniform Classification Guidelines for Foreign Substances (UCGFS) and Recommended Penalties Model Rule*. It can be accessed at: https://www.arci.com/wp-content/uploads/2020/12/Uniform-Classification-Guidelines-Version-14.4.pdf

Extra-Label Drug Use

JAMES A. BUDDE, PHARMD, FSVHP, DICVP
VetMedux

The following information is adapted from the FDA website: https://www.fda.gov/AnimalVeterinary/GuidanceComplianceEnforcement/ActsRulesRegulations/ucm085377.htm

The Animal Medicinal Drug Use Clarification Act of 1994 (AMDUCA) permits veterinarians to prescribe extra-label use of certain approved new animal drugs and approved human drugs for animals under certain conditions. *Extra-label use* refers to the use of an approved drug in a manner that is not in accordance with the approved label directions. This includes, but is not limited to, use in species not listed in the labeling, use for indications (disease or other conditions) not listed in the labeling, use at dosage levels, frequencies, or routes of administration other than those stated in the labeling, and deviation from the labeled withdrawal time based on these different uses. Under AMDUCA and its implementing regulations published at Title 21, Code of Federal Regulations, Part 530 (21 CFR 530), any extra-label use of an approved new animal or human drug must be by or on the lawful order of a veterinarian within the context of a veterinarian-client-patient relationship (VCPR).

There are additional specific conditions that must be met for extra-label use of approved animal and approved human drugs in food-producing animals. The following conditions appear in 21 CFR 530.20:

- There is no approved animal drug that is labeled for such use and that contains the same active ingredient in the required dosage form and concentration, except where a veterinarian finds, within the context of a valid VCPR, that the approved animal drug is clinically ineffective for its intended use.
- Before prescribing or dispensing an approved animal drug or approved human drug for extra-label use in food animals, the veterinarian must:
  1. make a careful diagnosis and evaluation of the conditions for which the drug is to be used;
  2. establish a substantially extended withdrawal period prior to marketing of milk, meat, eggs, or other edible products supported by appropriate scientific information, if applicable;
  3. institute procedures to assure that the identity of the treated animal or animals is carefully maintained; and
  4. take appropriate measures to assure that assigned time frames for withdrawal are met and no illegal drug residues occur in any food-producing animal subjected to extra-label treatment.

The following additional conditions must be met for a permitted extra-label use, in food-producing animals, of an approved human drug, or of an animal drug approved only for use in animals not intended for human consumption:

- Such use must be accomplished in accordance with an appropriate medical rationale.
- If scientific information on the human food safety aspect of the use of the drug in food-producing animals is not available, the veterinarian must take appropriate measures to assure that the animal and its food products will not enter the human food supply.
- Extra-label use of an approved human drug in a food-producing animal is not permitted if an animal drug approved for use in food-producing animals can be used in an extra-label manner for the particular use.

Any drug prescribed and dispensed for extra-label use by a veterinarian or dispensed by a pharmacist on the order of a veterinarian must bear or be accompanied by labeling information adequate to assure the safe and proper use of the drug.(21 CFR 530.12) At a minimum, such information shall include the following:

- the name and address of the prescribing veterinarian. If the drug is dispensed by a pharmacy on the order of a veterinarian, the labeling shall include the name of the prescribing veterinarian and the name and address of the dispensing pharmacy, and may include the address of the prescribing veterinarian
- the established name of the drug (active ingredient), or, if formulated from more than one active ingredient, the established name of each ingredient
- any directions for use specified by the veterinarian (including class/species or identification of the animal(s) being treated; dosage, frequency, and route of administration; and the duration of therapy)
- any cautionary statements
- the veterinarian's specified withdrawal, withholding, or discard time(s) for meat, milk, eggs, or any food which might be derived from the treated animal(s).

AMDUCA provides specific conditions under which extra-label use from compounding of approved animal drugs or approved human drugs is permitted. The compounding must be in compliance with all relevant provisions of 21 CFR 530. The extra-label drug use regulation does not permit animal drug compounding from active pharmaceutical ingredients (bulk drugs). FDA/CVM issued the final compounding drug guidance for veterinarians and pharmacists in 2022. For more information, consult guidance document #256 Compounding Animal Drugs from Bulk Drug Substances; CVM GFI #256 - Compounding Animal Drugs from Bulk Drug Substances | FDA

Under the AMDUCA provisions, FDA has the right to prohibit extra-label uses of certain drugs in animals.

FDA may prohibit the extra-label use of an approved animal drug or approved human drug or class of drugs in food-producing animals if FDA determines that:

- An acceptable analytical method needs to be established and such method has not been established or cannot be established.
- The extra-label use of the drug or class of drugs presents a risk to the public health.
- A prohibition may be a general ban on the extra-label use of the drug or class of drugs or may be limited to a specific species, indication, dosage form, route of administration, or combination of factors. FDA may prohibit the extra-label use of an animal or human drug in nonfood-producing animals if FDA determines that such extra-label use presents a risk to the public health.

The following drugs, families of drugs, and substances are prohibited for extra-label animal and human drug uses in food-producing animals (21CFR 530.41 Drugs prohibited for extra-label use in animals)**:**

- Chloramphenicol
- Clenbuterol
- Diethylstilbestrol (DES)
- Dimetridazole
- Ipronidazole
- Other nitroimidazoles
- Furazolidone
- Nitrofurazone
- Sulfonamide drugs in lactating dairy cattle (except approved use of sulfadimethoxine, sulfabromomethazine, and sulfaethoxypyridazine)
- Fluoroquinolones
- Glycopeptides
- Phenylbutazone in female dairy cattle 20 months of age or older
- Cephalosporins (not including cephapirin) in cattle, swine, chickens, or turkeys:
  (i) for disease prevention purposes;
  (ii) at unapproved doses, frequencies, durations, or routes of administration; or
  (iii) if the drug is not approved for that species and production class.

The following drugs, or classes of drugs, that are approved for treating or preventing influenza A, are prohibited from extra-label use in chickens, turkeys, and ducks:

- Adamantanes
- Neuraminidase inhibitors

To clarify extra-label use of cephalosporins, a cephalosporin may be used for an extra-label indication to treat cattle, swine, chickens, or turkeys provided the cephalosporin product being administered is approved for use in that species for another indication, and the dosage used adheres to the labeled dose, route of administration, frequency and duration of use for that species. The following examples of extra-label drug use are prohibited:

- Use of cefpodoxime tablets in a pig because cefpodoxime is not labeled for use in that species
- Administration of ceftiour sodium (*Naxcel*®) 5 mg/kg SC in a cow, because only the labeled dose of 1.1 – 2.2 mg/kg may be used
- Administration of ceftiour sodium (*Naxcel*®) to healthy cattle prior to shipment to prevent shipping fever, as cephalosporins may not be used for disease prevention
- Administration of ceftiofur crystalline free acid (*Excede*®) to cattle intramuscularly because it is only labeled for subcutaneous use
- administration of ceftiofur crystalline free acid (*Excede*®) to cattle subcutaneously but at a site other than the posterior aspect of the ear, because it is only labeled to be administered in the posterior aspect of the ear

Veterinary Feed Directive

JAMES A. BUDDE, PHARMD, DICVP
VetMedux

Per the Federal Register, *In 1996, Congress enacted the Animal Drug Availability Act (ADAA) to facilitate the approval and marketing of new animal drugs and medicated feeds. In passing the ADAA, Congress created a new regulatory category for certain animal drugs used in or on animal food (animal feed) called veterinary feed directive drugs (or VFD drugs).*[1] Per the FDA, *This category was created to provide veterinary supervision without invoking state pharmacy laws for prescription drugs that were unworkable for the distribution of medicated feed.*[2] VFD drugs are not prescription drugs. In 2015, the Food and Drug Administration (FDA) amended the new animal drug reg-

ulations to implement the VFD drugs section of the ADAA, with full implementation beginning in December 2016. The VFD requirements apply to all VFD drugs for use in major or minor species.

The FDA approves drugs that require veterinary supervision and oversight for their use. These drugs are classified into 2 separate regulatory categories. When the drug being approved is not for use in or on animal feed, the drug is approved as a prescription drug. When the drug being approved is for use in or on animal feed (a medicated feed), the FDA approves these drugs as a VFD drug.

Per the FDA: *A veterinary feed directive (VFD) is a written (nonverbal) statement issued by a licensed veterinarian in the course of the veterinarian's professional practice that authorizes the use of a VFD drug or combination VFD drug in or on an animal feed. This written statement authorizes the client (the owner of the animal or animals or other caretaker) to obtain and use animal feed bearing or containing a VFD drug or combination VFD drug to treat the client's animals only in accordance with the conditions for use approved, conditionally approved, or indexed by the FDA. A VFD is also referred to as a VFD order.*[2]

To issue a VFD, a veterinarian must meet all the following requirements*:

- Be licensed to practice veterinary medicine
- Be operating in the course of the veterinarian's professional practice and in compliance with all applicable veterinary licensing and practice requirements
- Write VFD orders in the context of a valid client–patient relationship
- Issue a VFD compliant with the conditions for use approved, conditionally approved, or indexed for the VFD drug or combination VFD drug (ie, **Extra-label use of VFD is NOT permitted**.)
- Prepare and sign a written VFD providing all required information
- Enter additional discretionary information to more specifically identify the animals to be treated/fed the VFD feed (See ***Optional information on the VFD*** below for more information)
- Include required information when a VFD drug is authorized for use in a drug combination that includes more than 1 VFD drug
- Restrict or allow the use of the VFD drug in combination with 1 or more OTC drug(s)
- Provide the feed distributor with a copy of the VFD via hardcopy, facsimile (fax), or other electronic means
- Provide the client with a copy of the VFD
- Retain the original VFD in its original form (electronic or hardcopy) for 2 years
- Provide VFD orders for inspection and copying by FDA on request.

**This list was adapted from US FDA. Veterinary Feed Directive Requirements for Veterinarians. https://www.fda.gov/animal-veterinary/development-approval-process/veterinary-feed-directive-requirements-veterinarians.*

Use of medicated feed is authorized by a VFD, not by a prescription (Rx). A lawful VFD must be complete. The following information is required on a lawful VFD*:

- Veterinarian's name, address, and telephone number
- Client's name, business or home address, and telephone number
- Premises at which the animals specified in the VFD are located
- Date of VFD issuance
- Expiration date of the VFD (the expiration date specifies the last day the VFD feed can be fed)
- Name of the VFD drug(s) (**NOTE**: By default, the VFD feed manufacturer may use an approved substitute, but the VFD may specify that a substitution is not allowed)
- Species and production class of animals to be fed the VFD feed
- Approximate number of animals to be fed the VFD feed by the expiration date of the VFD
- Indication for which the VFD is issued
- Level of VFD drug in the feed and duration of use (Duration of use determines the length of time [established as part of the approval, conditional approval, or index listing process] that the animal feed containing the VFD drug is allowed to be fed to the animals.)
- Withdrawal time, special instructions, and cautionary statements necessary for use of the drug in conformance with the approval
- Number of reorders (refills) authorized, if permitted by the drug approval, conditional approval, or index listing (refills may not be authorized if a drug approval is silent on refills)
- Statement: *Use of feed containing this veterinary feed directive (VFD) drug in a manner other than as directed on the labeling (extra-label use), is not permitted.*[1]
- An affirmation of intent for combination VFD drugs as described in 21 CFR 558.6(b)(6)
- Veterinarian's electronic or written signature

**This list was adapted from US FDA. Veterinary Feed Directive Requirements for Veterinarians. https://www.fda.gov/animal-veterinary/development-approval-process/veterinary-feed-directive-requirements-veterinarians.*

Optional information on the VFD*:

- A more specific description of the location of the animals (eg, by site, pen, barn, stall, tank, or other descriptor the veterinarian deems appropriate)
- Approximate age range of the animals
- Approximate weight range of the animals
- Any other information the veterinarian deems appropriate to identify the animals at issue

**This list was adapted from US FDA. Veterinary Feed Directive Requirements for Veterinarians. https://www.fda.gov/animal-veterinary/development-approval-process/veterinary-feed-directive-requirements-veterinarians.*

The following definitions may be useful*:

- VFD drug: a drug intended for use in or on animal feed, which is limited to use under the professional supervision of a licensed veterinarian.
- Combination VFD drug: an approved combination of new animal drugs intended for use in or on animal feed under the professional supervision of a licensed veterinarian, and at least 1 of the new animal drugs in the combination is a VFD drug.
- Category I drugs: drugs that do not require a withdrawal period at the lowest use level in each species for which they are approved.
- Category II drugs: drugs that require a withdrawal period at the lowest use level for at least 1 species for which they are approved or are regulated on a "no-residue" basis or with a zero tolerance because of a carcinogenic concern, regardless of whether a withdrawal period is required.
- Type A medicated articles are the most concentrated form of the new animal drug and are used in the manufacture of another Type A medicated article, or a Type B or C medicated feed. (**NOTE**: To reduce the potential to create unsafe drug residues, the manufacturing of medicated feeds with Category II Type A medicated articles is restricted to licensed feed mills.)
- Type B medicated feed is intended solely for the manufacture of other Type B or Type C medicated feeds and contains a substantial quantity of nutrients with the new animal drug.
- Type C medicated feed is intended as the complete feed for the an-

imal, or may be added on top of a usual ration, or may be offered as a supplement with other animal feed. A Type C medicated feed has the lowest concentration of the new animal drug.

**This list was adapted from US FDA. Veterinary Feed Directive Requirements for Veterinarians. https://www.fda.gov/animal-veterinary/development-approval-process/veterinary-feed-directive-requirements-veterinarians*

Conversion of Conventional Chemistry Units to SI Units

The Système Internationale d'Unites (SI), or the International System of Units, was recommended for use in the health professions by the World Health Assembly in 1977. It is slowly being adopted in the United States and many journals now require its use. The following is an abbreviated table of conversion values for some of the more commonly encountered tests that may now be reported in SI units.

Chemistry analyte	Conventional unit	Conversion factor	SI unit
Albumin	g/dL	x 10	= g/L
Ammonia	µg/dL	x 0.5872	= µmol/L
Bilirubin	mg/dL	x 17.10	= µmol/L
Calcium	mg/dL	x 0.2495	= mmol/L
Cholesterol	mg/dL	x 0.0259	= mmol/L
CO_2 pressure, pCO_2	mm Hg	x 0.1333	= kPa
Creatinine	mg/dL	x 88.4	= µmol/L
Glucose	mg/dL	x 0.0555	= mmol/L
Lactate	mg/dL	x 0.1110	= mmol/L
Magnesium	mg/dL	x 0.4114	= mmol/L
O_2 pressure, pO_2	mm Hg	x 0.1333	= kPa
Phosphorus	mg/dL	x 0.3229	= mmol/L
Protein	g/dL	x 10	= g/L
Urea nitrogen	mg/dL	x 0.3570	= mmol/L
Amylase	IU/L	x 1	= units/L
AST (SGOT)	IU/L	x 1	= units/L
ALT (SGPT)	IU/L	x 1	= units/L
Lipase	IU/L	x 1	= units/L
ALP	IU/L	x 1	= units/L
SDH (Sorbitol)	IU/L	x 1	= units/L
Bicarbonate	mEq/L	x 1	= mmol/L
Chloride	mEq/L	x 1	= mmol/L
Potassium	mEq/L	x 1	= mmol/L
Sodium	mEq/L	x 1	= mmol/L
CO_2 (total)	mEq/L	x 1	= mmol/L

Conversion: Weights; Temperature; Liquids

WEIGHTS:

1 ounce (oz) = 28.4 grams
1 pound (lb) = 0.454 kilogram = 454 grams = 16 ounces (oz)
1 kilogram (kg) = 2.2 pounds = 1000 grams
1 gram (g) = 1000 milligrams = 15.43 grains

1 milligram (mg) = 1000 micrograms (µg or mcg)
1 microgram (mcg or µg) = 1000 nanograms (ng)
1 grain (gr) = 64.8 mg (often rounded to 60 mg or 65 mg)

TEMPERATURES:

°F = (°C + 1.8) + 32
°C = (°F – 32) ´ 0.56

LIQUIDS:

1 gallon (gal) = 4 quarts = 8 pints = 128 fluid ounces = 3.785 liters = 3785 mL
1 quart (qt) = 2 pints = 32 fluid ounces = 946 mL
1 pint = 2 cups = 16 fluid ounces = 473 mL
1 cup = 8 fluid ounces = 237 mL = 16 tablespoons
1 fluid ounce = 30 mL
1 tablespoon = 15 mL = 3 teaspoons
1 teaspoon = 5 mL
4 liters = 1.06 gallons
1 liter (L) = 1000 mL = 10 deciliters
1 deciliter (dL) = 100 mL
1 milliliter (mL) = 1 cubic centimeter (cc) = 1000 microliters (µL; mcL)

Milliequivalents and Molecular Weights

The term milliequivalent (mEq) is typically used to express the quantities of electrolytes administered to patients. A mEq is 1/1000 of an equivalent (Eq). For pharmaceutical purposes, an equivalent may be thought of as equal to the equivalent weight of a given substance. In practical terms, an equivalent is the molecular weight of the substance divided by the valence or the radical. Examples:

How many milligrams equal 1 mEq of potassium chloride (KCl)?
Equivalent weight = molecular weight ÷ valence
[Molecular weight of KCl = 74.5 (K^+ = **39.1** + Cl^-= **35.4**) grams; Valence = 1 (K^+; Cl)]
Equivalent weight = 74.5 ÷ 1 = 74.5 grams ÷ 1000 = 0.0745 grams
Milliequivalent weight of KCl = 0.0745 grams × 1000 mg/1 gram = 74.5 mg = 1 mEq KCl

How many milligrams equal 1 mEq of anhydrous calcium chloride ($CaCl_2$)?
Equivalent weight = molecular weight ÷ valence
[Molecular weight of anhydrous $CaCl_2$ = 111 (Ca^{2+} = **40** + Cl^-= 35.4 × 2 = **71**) grams; Valence = 2 (Ca^{2+}; 2-Cl^-)]
Equivalent weight = 111 ÷ 2 = 55.5 grams ÷ 1000 = 0.0555 grams
Milliequivalent weight of anhydrous $CaCl_2$ = 0.0555 grams × 1000 mg/1 gram = 55.5 mg = 1 mEq anhydrous $CaCl_2$

Listed below are some commonly used electrolytes with their molecular weights and valences in parentheses:

Electrolyte	Molecular weight (valence)
Sodium chloride	58.44 (1)
Sodium bicarbonate	84 (1)
Sodium acetate, anhydrous	82 (1)
Sodium acetate, trihydrate	136 (1)
Sodium lactate	112 (1)
Potassium chloride	74.55 (1)
Potassium gluconate	234.25 (1)
Calcium gluconate	430.4 (2)
Calcium lactate, anhydrous	218.22 (2)
Calcium chloride, anhydrous	111 (2)
Calcium chloride, dihydrate	147 (2)

Electrolyte	Molecular weight (valence)
Magnesium sulfate, heptahydrate	246.5 (2)
Magnesium sulfate, anhydrous	120.4 (2)
Magnesium chloride, anhydrous	95.21 (2)
Magnesium chloride, hexahydrate	203.3 (2)

Solubility Definitions

The following definitions are used throughout the book in the chemistry section for each agent:

Descriptive term	Parts of solvent for 1 part of solute
Very soluble	Less than 1
Freely soluble	From 1 to 10
Soluble	From 10 to 30
Sparingly soluble	From 30 to 100
Slightly soluble	From 100 to 1000
Very slightly soluble	From 1000 to 10,000
Practically insoluble or insoluble	More than 10,000

Parenteral Fluids

(Not a complete listing; includes both human- and veterinary-approved products)

Sodium chloride solutions	Sodium (mEq/L)	Chloride (mEq/L)	Osmolality (mOsm/L)	Volumes available (mL)
Sodium chloride 0.45% (half-normal saline)	77	77	155	3, 5, 500, 1000
Sodium chloride 0.9% (normal saline)	154	154	308	1, 2, 2.5, 3, 4, 5, 10, 20, 25, 30, 50, 100, 130, 150, 250, 500, 1000
Sodium chloride 3%	513	513	1027	500
Sodium chloride 5%	855	855	1710	500

Normal Vital Signs

Species	Temperature °C (°F)*	Resting heart rate/minute	Resting respiratory rate/minute
Dog, young	37.5-39.2 (99.5-102.5)	110-120	15-30
Dog, adult medium breed	37.5-39.2 (99.5-102.5)	–	–
Dog, adult large breed	37.5-39.2 (99.5-102.5)	60-90	15-30
Cat, young	37.8-39.5 (100-102.5)	130-140	20-30
Cat, senior	37.8-39.5 (100-102.5)	100-120	20-30
Cattle, up to 1 year old	38.6-39.4 (101.5-103.5)	100-120	15-40
Cattle, over 1 year old	37.8-39.2 (100-102.5)	55-80	10-30
Chicken	40.5-43 (105-109.4)	250-300	–
Chinchilla	37-38 (98.6-100.4)	100-150	–
Ferret	37.8-39.2 (100-102.5)	200-400	33-36
Gerbil	38.2 (100.8)	260-600	85-160
Goat	38.5-40.2 (101.3-104.5)	70-120	10-30
Guinea pig	–	200-300	–
Hamster	37.6 (99.7)	300-600	38-110
Hedgehog, African	35.5-37 (95.7-98.6)	180–280	25-50
Horse, foal	37.5-39.3 (99.5-102.7)	64-128	10-14
Horse, 3 to 24 months	37.5-39.3 (99.5-102.7)	40-80	10-14
Horse, adult	37.2-38.5 (99-101.3)	28-40	10-14
Mouse	37.1 (98.8)	450-750	90-210
Rat	37.7 (99.9)	250-400	71-146
Rabbit	38.5-39.3 (100.4-105)	150-350	50-60
Sheep	38.5-40 (101.3-104)	66-115	10-30
Swine, piglet	38.9-40 (102-104)	100-130	24-36
Swine, adult	37.8-38.9 (100-102)	60-90	8-18
Sugar glider	36.3 (97.3)	200-300	16-40

*__Temperature (Rectal):__ Temperatures will normally fluctuate over the course of the day. The following things may increase body temperature: time of day (evening), food intake, muscular activity, approaching estrus, during gestation, and high external temperatures. The following conditions may decrease body temperature: intake of large quantities of cool fluids, time of day (morning), and low atmospheric temperature. Small-breed dogs tend to have higher normal temperatures than large-breed dogs.

Reference Laboratory Ranges

NOTE: The following reference ranges are as a general reference only. For clinical use, refer to the designated normal values published by the specific laboratory used. Values were originally published by **Marshfield Clinic Laboratories, Veterinary Diagnostic Service**.

Ferret values were adapted from ***Biology and Diseases of the Ferret,* 3rd Edition**. Fox, JG and Marini, RP, Eds; Wiley-Blackwell, 2014.

Rabbit values were adapted from ***Animal Models in Toxicology*, 3rd Edition**. Gad, SC, Ed; CRC Press, 2013.

Rat hematology values were adapted from ***Schalm's Veterinary Hematology*, 3rd Edition**. Weiss, DJ and Wardrop, KJ, Eds; Wiley-Blackwell, 2010.

Cerebral Spinal Fluid: Canine, Feline

Values were originally published by Marshfield Clinic Laboratories, Veterinary Diagnostic Service.

Test	Units	Canine	Feline
Pressure	mm H_20	Less than 170	Less than 100
Specific gravity	–	1.005-1.007	1.005-1.007
Lymphocytes/µL	–	Less than 5	Less than 5
Pandy test	–	Negative–trace	Negative
Protein	mg/dL	Less than 25	Less than 25
Creatine kinase (CK)	units/L	9-28	**
Potassium	mEq/L	3.5-6	**
Chloride	mEq/L	96-106	**
Triglycerides	mg/dL	30-180	**
Gamma glutamyl transferase (GGT)	units/L	0-10	**

**No normal range established in this laboratory

Estrus and Gestation Periods: Dogs and Cats

	Dog	Cat
Appearance of first estrus at the age of:	7-9 months	4-12 months
Estrous cycle in animals not served:	Mean = 7 months Range = every 5-8 months	Every 4-30 days (14-19 day model) if constant photoperiod
Duration of estrus period:	7-42 days (proestrus plus estrus)	2-19 days
First occurrences after parturition:	Pregnancy does not alter interval	7-9 days
Gestation period	Mean = 63 days; Range 58-71 days	Mean = 63 days; Range 58-70 days
Number of young	8-12 large breeds 6-10 medium breeds 2-4 small breeds	4-6
Suckling period	3-6 weeks	3-6 weeks

Systemic Drugs Sorted by Therapeutic Class or Major Indication

This appendix lists systemic drugs or combination drug products by their therapeutic class or major indication. Classifications are based on the American Society of Health-System Pharmacists (ASHP) drug classification system. As some drugs have multiple indications, there may not be a specific dosage listed for a specific indication for every species. As such, the following species codes are used in parentheses after the drug name to indicate for which species a dosage is presented:

A = Avian
B = Bovine, Cattle
C = Cat, Feline
D = Dog, Canine
Fer = Ferret
Fi = Fish
H = Horse, Equine
Hb = Honey Bees
L = Llama, Alpacas, New World Camelids, Camels
Po = Pocket Pets, Rabbits, Small Mammals
R = Reptiles/Amphibians
Ru = Ruminants
Sh = Sheep/Goats; Ovine/Caprine; Small Ruminants
Sw = Swine, Pigs
Z = Wildlife/Zoo Animals

Antihistamines

Cetirizine (D, C, H)
Chlorpheniramine (D, C, H, A, Fer)
Clemastine (D, C)
Cyproheptadine (D, C, H)
Diphenhydramine (D, C, H, B, A, Fer, Po)
Doxepin (D, C, H, A)
Fexofenadine (D, C)
Hydroxyzine (D, C, H, A, Fer, Po)
Loratadine (D, C)
Meclizine (D, C, Po)
Promethazine (D, C, H)
Pyrilamine (H)
Trimeprazine/Prednisolone (D, C)
Tripelennamine (H, B)

Central Nervous System Drugs

(including anti-inflammatories, analgesics, muscle relaxants)

CNS/Respiratory Stimulants

Caffeine (D, H)
Doxapram (D, C, H, B, Sw, A, Fer, Po, R)

Analgesics, Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

Aspirin (D, C, H, B, Fer, Po)
Carprofen (D, C, H, B, Sh, A, Fer, Po, R)
Deracoxib (D)
Diclofenac, Topical (H)
Dimethyl Sulfoxide (DMSO) (D, H)
Dipyrone (D, C, H)
Etodolac (D, H)
Firocoxib (D, H)
Flunixin (B, H, Sh, Sw, Fer, Po)
Grapiprant (D)
Ketoprofen (D, C, H, B, Sh, Sw, A, Fer, Po)
Ketorolac (D, Po)
Mavacoxib (D)
Meloxicam (D, C, H, B, Sh, L, Sw, A, Fer, Po, R)
Phenylbutazone (D, H, Ru)
Piroxicam (D, C, H, Po)
Robenacoxib (D, C)
Tolfenamic Acid (D, C, B, Sw)

Analgesics, Opioid Agonists

Alfentanil (D, C)
Codeine (D, C, Po)
Fentanyl Injection (D, C, H, Sh, Fer, Po)
Fentanyl Transdermal Patch (D, C, H, Sh, L, Sw, A, Po)
Hydrocodone Combinations (D)
Hydromorphone (D, C, H, Fer, Po, R)
Meperidine (D, C, H, B, Fer, Po)
Methadone (D, C, H, Sh)
Morphine (D, C, H, Sh, L, Po)
Oxymorphone (D, C, H, Sh, A, Fer, Po)
Remifentanil (D, C, H)
Sufentanil (D, C)
Tramadol (D, C, H, B, A, Po, R)

Analgesics, Opioid Agonist/Antagonists

Buprenorphine (D, C, H, Sh, Sw, Fer, Po)
Butorphanol (D, C, H, B, Sh, L, A, Fer, Po)
Nalbuphine (D, C, B, Po)

Analgesics, Other

Acetaminophen (D, H, Po)
Amantadine (D, C)
Clonidine (D, C, B)
Frunevetmab (C)
Gabapentin (D, C, A)
Ketamine (D, C, H, B, Ru, L, Sw, A, Fer, Po, R)
Lidocaine (Intravenous; Systemic) (D, C, H, Sh, Po)
Medetomidine/Vatinoxan (D)
Pregabalin (D, C, H)

Antipyretics

Acetaminophen (D, H)
Aspirin (D, C)
Dipyrone (H)
Flunixin (B, Sw)
Ketoprofen (B, Sh, Sw)

Behavior-Modifying Agents

Alprazolam (D, C, H)
Amitriptyline (D, C, A)
Buspirone (D, C)
Clomipramine (D, C, A)
Clonazepam (D, C)
Clorazepate (D, C)
Diazepam (D, H, Sh, A)
Doxepin (D, C, H, A)
Fluoxetine (D, C, H)
Fluvoxamine (D, C)
Gabapentin (D, C)
Imepitoin (D, C)
Imipramine (D)
L-Theanine (D, C)
Lorazepam (D, C)
Methylphenidate (D)
Oxazepam (D, C)
Paroxetine (D, C, A)
Pheromones (D, C, H)
Pregabalin (C)
Sertraline (D, C)
Trazodone (D, C, H)

Cannabinoids

Cannabidiol (CBD) (D)

Tranquilizers/Sedatives

Acepromazine (D, C, H, B, Sh, Sw, Fer, Po)
Alfaxalone (D, C, B, Po)
Alprazolam (D, C, H)
Chlorpromazine (D, C, B, Sh, Sw)
Detomidine (D, C, H, B, Sh, L, A)
Dexmedetomidine (D, C, H, Po)
Diazepam (D, C, H, Sh, L, A, Fer, Po)
Ketamine (D, C, H, B, Ru, L, Sw, A, Fer, Po, R)
Lorazepam (D, C)
Medetomidine (D, C, H, B, Sh, L, A, Fer, Po, R)
Medetomidine/Vatinoxan (D)
Midazolam (D, C, H, Ru, A, Po)
Pentobarbital (H)
Reserpine (H)
Romifidine (D, C, H, B)
Tiletamine/Zolazepam (D, C, H, Ru, L, Sw, Fer, Po, R)
Xylazine (D, C, H, B, Sh, L, Sw, A, Fer, Po, Z)

Anesthetic Agents, Barbiturates

Pentobarbital (D, C, H, Po)
Thiopental (D, C, H, B, Sh, Sw, Po)

Anesthetic Agents, Inhalants

Desflurane (D, C, H, L, Po)
Isoflurane (D, C, H, Sh, A, Fer, Po, R)
Sevoflurane (D, C, H, Sh, L, A, Po, R)

Anesthetic Agents, Local

Bupivacaine (D, C, H, B, Sh, Po, R)
Bupivacaine Liposomal (D, C)
Lidocaine, Local Anesthetic (D, C, H, B, Sh, L, Po, R)

Mepivacaine (D, C, H, B, Sh, Sw)
Ropivacaine (D, C, H, B, Sh, Sw)

Anesthetic Agents, Miscellaneous
Alfaxalone (D, C, H, B, Sh, Fer, Po)
Alfentanil (D, C)
Etomidate (D, C, Fer, Po)
Fentanyl Injection (D, C, H, Sh, Fer, Po)
Ketamine (D, C, H, B, Ru, L, Sw, A, Fer, Po, R)
Propofol (D, C, H, Sh, L, Po, R)
Remifentanil (D, C, H)
Sufentanil (D, C)
Tiletamine/Zolazepam (D, C, H, Ru, L, Sw, Fer, Po, R)

Reversal Agents
Atipamezole (D, C, H, B, Sh, L, A, Po, R)
Flumazenil (D, C, H, A, R)
Naloxone (D, C, H, Po, R)
Naltrexone (D, C)
Neostigmine (D, C, H)
Tolazoline (D, C, H, Ru, L, Sw, A, Z)
Yohimbine (D, C, H, B, L, Sw, A, Po)

Anticonvulsants
Bromides (D)
Clonazepam (D, C)
Clorazepate (D, C)
Diazepam (D, H)
Felbamate (D)
Gabapentin (D, C, A)
Imepitoin (D, C)
Levetiracetam (D, C, H)
Lorazepam (D, C)
Phenobarbital (D, C, H, Fer)
Pregabalin (D, C, H)
Topiramate (D, C)
Zonisamide (D, C)

Neuromuscular Blockers
Atracurium (D, C, H, Sh, L, Po)
Rocuronium (D, C, H)
Succinylcholine (D, C, H, Ru, R)
Vecuronium (D, C)

Muscle Relaxants, Skeletal
Dantrolene (D, H)
Diazepam (D)
Guaifenesin, Intravenous (H, Sh, L)
Methocarbamol (D, C, H)

Euthanasia Agents
Euthanasia Agents with Pentobarbital (D, C, Large Animals)
Potassium (-Acetate, -Chloride, -Gluconate) (H, Ru)

Cardiovascular Agents
Inotropic Agents
Digoxin (D, C, Fer)
Dobutamine (D, C, H, A)
Pimobendan (D, C)

Antiarrhythmic Drugs
Amiodarone (D, H)
Digoxin (D, C, H, B)
Diltiazem (D, C, H, Fer, Po)
Lidocaine (Intravenous; Systemic) (D, C, H, Po)
Mexiletine (D, C)
Procainamide (D, C, H)
Quinidine (D, H) Verapamil (D, C, H, Po)
See also, Beta-Blockers

Anticholinergics (Parasympatholytics)
Atropine (D, C, H, B, Sh, L, Sw, A, Fer, Po, R)
Butylscopolamine (H)
Glycopyrrolate (D, C, H, Ru, Fer, Po, R)
Hyoscyamine (D)

Angiotensin Converting Enzyme Inhibitors (ACEIs)
Benazepril (D, C, H)
Enalapril (D, C, A, Fer)
Imidapril (D)
Lisinopril (D, C)
Ramipril (D, C)

Calcium Channel Blocking Agents
Amlodipine (D, C, A)
Diltiazem (D, C, H, Fer, Po)
Verapamil (D, C, H, Po)

Vasodilating Agents
Hydralazine (D, C, H)
Isoxsuprine (H, A)
Nitroglycerin, Transdermal (D, C, Fer)
Nitroprusside (D, C)
Pimobendan (D, C)
Sildenafil (D, C)
Tadalafil (D)

Agents Used to Treat Hypotension and Shock
Dobutamine (D, C, H, A)
Dopamine (D, C)
Ephedrine (D, C, H)
Epinephrine (D, C, H, Ru, Sw, A, Po, R)
Isoproterenol (D, C)
Norepinephrine (D, C, H, Sh, L)
Phenylephrine (D, C, H, Sh)
Vasopressin (D, C, H)

Alpha-Adrenergic Blocking Agents
Phenoxybenzamine (D, C, H)
Prazosin (D, C)

Beta-Adrenergic Blocking Agents
Atenolol (D, C, Fer)
Carvedilol (D)
Esmolol (D, C)
Metoprolol (D, C)
Propranolol (D, C, H, Fer)
Sotalol (D, C, H)

Angiotensin Receptor Blockers (ARBs)
Irbesartan (D, C)
Losartan (D)
Telmisartan (D, C)

Antihypertensive Agents, Miscellaneous
Fenoldopam (D, C, H)
Nitroprusside (D, C)

Other Cardiovascular Agents
Carnitine (D, C)
Taurine (D, C)

Respiratory Drugs
Sympathomimetics
Albuterol (D, C, H, B)
Clenbuterol (H, B)
Ephedrine (D, C, H)
Epinephrine (D, C, H, Ru, Sw)
Isoproterenol (D, C)
Pseudoephedrine (C)
Terbutaline (C, A, R)

Xanthines
Aminophylline (D, C, H, B)
Caffeine (D, H)
Theophylline (D, C)

Antitussives
Butorphanol (D)
Codeine (D)
Diphenoxylate/Atropine (D)
Hydrocodone Combinations (D)

Mucolytics
Acetylcysteine (D, C, H)

Other Respiratory Agents
Ciclesonide (H)
Cromolyn (H)
Fluticasone (D, C, H)
Ipratropium (H, Po)
Montelukast (C)

Renal and Urinary Tract Agents
Diuretics, Carbonic Anhydrase Inhibitors
Acetazolamide (D, C, H)
Dichlorphenamide (D, C)
Methazolamide (D, C)

Diuretics, Thiazides
Chlorothiazide (D, C)
Hydrochlorothiazide (D, C, H, A)

Diuretics, Loop
Furosemide (D, C, H, B, A, Fer, Po, R, Fi)
Torsemide (D, C)

Diuretics, Potassium Sparing
Spironolactone (D, C)
Triamterene (D)

Diuretics, Osmotic
Glycerin, Oral (D, C)
Mannitol (D, C, H, B, Sh, Sw, Fer, Po)

Agents for Urinary Incontinence or Retention
Bethanechol (D, C, H)
Dantrolene (D, C, Po)
Diazepam (D)
Diethylstilbestrol (DES) (D)
Ephedrine (D)
Estriol (D)
Imipramine (D, C)
Oxybutynin (D, C)
Phenoxybenzamine (D, C, H)
Phenylpropanolamine (D, C)
Prazosin (D, C)
Pseudoephedrine (D)
Tamsulosin (D, C)

Urinary Alkalinizers
Citrate, Potassium (D, C)
Sodium Bicarbonate (D, C, H, Ru, A)

Urinary Acidifiers
Ammonium Chloride (D, C, H, Sh)
Methionine (D, C, Sh)

Agents for Urolithiasis
Allopurinol (D, A, R)
Ammonium Chloride (D, C, H, Sh)
Citrate, Potassium (D, C)
Methionine (D, C, Sh)
Tiopronin (D)

Renal/Urinary Agents, Miscellaneous
Amitriptyline (D, C, A)
Colchicine (D, A)
Probenecid (R)

Gastrointestinal (GI) Agents

Antiemetic Agents
Acepromazine (D, C)
Chlorpromazine (D, C)
Dimenhydrinate (D, C)
Diphenhydramine (D, C)
Dolasetron (D, C)
Granisetron (D, C)
Maropitant (D, C)
Meclizine (D, C, Po)
Metoclopramide (D, C)
Mirtazapine (D, C)
Ondansetron (D, C)
Prochlorperazine (D, C)
Promethazine (D, C)

Antacids, Oral
Aluminum Hydroxide (D, C, H, B, Po, R)
Calcium Acetate (D, C)
Calcium, Oral (-Carbonate, -Gluconate, -Lactate) (D, C)
Magnesium Hydroxide (D, C, B, Sh)
Sodium Bicarbonate (D, C, H, Ru, A)

Histamine-2 Antagonists
Cimetidine (D, C, H, Fer, Po)
Famotidine (D, C, H, B, Fer, Po)
Nizatidine (D, C)
Ranitidine (D, C, H, Fer, Po)

Gastromucosal Protectants
Sucralfate (D, C, H, A, Fer, R)

Prostaglandin E Analogues
Misoprostol (D, C, H, B, Sh)

Proton Pump Inhibitors
Esomeprazole (D, C, H)
Omeprazole (D, C, H, Sw, Fer)
Pantoprazole (D, C, H, L)

Appetite Stimulants
Capromorelin (D, C)
Cyproheptadine (D, C)
Mirtazapine (D, C)
Oxazepam (C)

GI Antispasmodics-Anticholinergics
Hyoscyamine (D)
Butylscopolamine (H)
Propantheline (D, C, H)

GI Stimulants/Prokinetic
Cisapride (D, C, H, Po)
Erythromycin (D, C, H, B)
Lidocaine (Intravenous; Systemic) (H)
Metoclopramide (D, C, H, Po)
Neostigmine (H, B, Sh, Sw)
Nizatidine (D, C)
Ranitidine (D, C, Po)

Digestive Enzymes
Pancrelipase (D, C, A, Po)

Laxatives
Bisacodyl (D, C)
Docusate (D, C, H, Sh)
Lactulose (D, C, A, R)
Magnesium Hydroxide (D, C, B, Sh)
Mineral Oil (D, C, H, B, Sh, Sw, A, Po)
Polyethylene Glycol 3350 (PEG 3350) (D, C)
Psyllium (D, C, H)
Saline Cathartics (D, C, H, Ru)
Sorbitol (D, C, H)

Antidiarrheals
Bismuth Subsalicylate (D, C, H, B, Sw, Fer)
Cholestyramine (D, Po)
Clonidine (D, C)
Crofelemer (D)
Diphenoxylate/Atropine (D, C)
Kaolin/Pectin (D, C, H, B, Sh, Sw, A, Fer, Po)
Loperamide (D, C, Po)

Emetics
Apomorphine (D, Fer)
Hydrogen Peroxide 3% (D, Sw, Fer)
Hydromorphone (D, C)
Ropinirole (D)
Xylazine (C)
Tranexamic Acid (D)

GI Drugs, Miscellaneous
Bismuth Subsalicylate (D, C, H, B, Sw, Fer)
Budesonide (D, C)
Colchicine (D, A)
Olsalazine (D)
Phenobarbital (D)
S-Adenosyl Methionine ± Silybin (D, C)
Sulfasalazine (D, C, H, Fer)
Ursodiol (D, C, H, A)

Hormones/Endocrine/Reproductive Agents

Sex Hormones, Estrogens
Diethylstilbestrol (DES) (D)
Estradiol (H)
Estriol (D)

Sex Hormones, Progestins
Altrenogest (D, H, Sw)
Medroxyprogesterone (D, C, H)
Megestrol (D, C)

Sex Hormones, Androgens
Testosterone (D, B)

Anabolic Steroids
Stanozolol (D, C, H, A, Fer, Po, R)

Posterior Pituitary Hormones
Desmopressin (D, C, H, A)
Vasopressin (D, C, H)

Oxytocics
Oxytocin (D, C, H, B, Sh, L, Sw, A, Po, R)

Adrenal Cortical Steroids
Corticotropin (ACTH) (D, H, A)
Cortisone (D)
Cosyntropin (D, C, H)

Mineralocorticoids
Desoxycorticosterone Pivalate (DOCP) (D, C)
Fludrocortisone (D, C, Fer)

Glucocorticoids
Betamethasone (D, H)
Budesonide (D, C, H)
Ciclesonide (H)
Dexamethasone (D, C, H, B, Sw, Po)
Flumethasone (D, C, H)
Fluticasone (D, C, H)
Hydrocortisone (D, C)
Isoflupredone (H, B, Sw)
Methylprednisolone (D, C, H)

Prednisolone/Prednisone (D, C, H, B, L, A, Po, R)
Triamcinolone (D, C, H)

Adrenal Steroid Inhibitors
Metyrapone (C)
Mitotane (D, Fer)
Selegiline (D)
Trilostane (D, C, H, Po)

Antidiabetic Agents
Acarbose (D, C)
Exenatide (C)
Glipizide (C)
Glyburide (C)
Insulin, Aspart (D, C, B)
Insulin, Detemir (D, C)
Insulin, Glargine (D, C, H, Fer, Po)
Insulin, Lente (D, C)
Insulin, Lispro (D, C)
Insulin, NPH (D, H, L, A, Fer, Po)
Insulin, Protamine Zinc (PZI) (D, C, H, B, L)
Insulin, Regular (Crystalline Zinc) (D, C, H, L, A)
Metformin (C, H)

Glucose Elevating Agents
Diazoxide (D, Fer, Po)
Glucagon (D, C, B, Fer)
Octreotide (D, H, Fer)

Thyroid Hormones
Levothyroxine (D, C, H, A, R)
Liothyronine (D, C)
Thyrotropin (TSH) (D, C, A, Fer, Po)

Antithyroid Drugs
Carbimazole (C)
Methimazole (C, Po)

Prostaglandins
Cloprostenol (D, C, H, B, Sh, L, Sw)
Dinoprost (D, C, H, B, Sh, Sw)

Endocrine/Reproductive Drugs, Miscellaneous
Aglepristone (D, C, Sh, Po)
Bromocriptine (D, C, H)
Cabergoline (D, C, A)
Calcitriol (D, C)
Chorionic Gonadotropin (HCG) (D, C, H, B, Sh, Sw, A, Fi)
Clenbuterol (H, B)
Cyproheptadine (H)
Deslorelin (D, H, Fer)
Finasteride (D, Fer)
Gonadorelin (D, C, B)
Imipramine (H)
Leuprolide (A, Fer, Po)
Melatonin (D, C, H, Sh, Fer, Z)
Metergoline (D, C)
Misoprostol (D, C, H, B, Sh)
Osaterone (D)
Pergolide (H)
Somatotropin (D, B)
Terbutaline (D, C)
Thyrotropin (TSH) (D, C, H, A, Fe, Po)
Thyrotropin-Releasing Hormone (TRH) (D, C, H)

Anti-infective Drugs

Antiparasitics, Ectoparasiticides
Afoxolaner (D, C, Sw, A)
Doramectin (D, C, H, B, L, Sw, Po)
Eprinomectin (C, H, B, Sh, L)
Fluralaner (D, C, Po)
Imidacloprid, Systemic (D)
Ivermectin (D, C, H, B, Sh, L, Sw, A, Fer, Po, R, Z)
Ivermectin/Clorsulon (B)
Lotilaner (D, C)
Lufenuron (D, C, Po)
Milbemycin Oxime (D, C)
Moxidectin (D, C, H, B, Sh, L, Fer)
Nitenpyram (D, C, R)
Sarolaner (D, C)
Selamectin (D, C, Fer, Po)
Selamectin/Sarolaner (C)
Spinosad (D, C)

Antiparasitics, Endoparasiticides
Albendazole (B, Sh, L, Po)
Allopurinol (D, C, A, R)
Amprolium (D, C, B, Sh, L, Sw, A, Fer, Po)
Atovaquone (D, C)
Decoquinate (D, B, Sh, L, A)
Diclazuril (D, C, H, B, Sh, A, Po)
Diminazene (D, H, B, Sh, Po)
Doramectin (D, C, H, B, L, Sw, Po)
Emodepside/Praziquantel (D, C, R)
Eprinomectin (C, H, B, Sh, L)
Eprinomectin/Praziquantel (C)
Epsiprantel (D, C)
Febantel (D, C)
Fenbendazole (D, C, H, B, Sh, L, Sw, A, Fer, Po, R, Z)
Furazolidone (C)
Imidocarb (D, C, H, B)
Ivermectin (D, C, H, B, Sh, L, Sw, A, Fer, Po, R, Z)
Ivermectin/Clorsulon (B)
Levamisole (D, H, B, Sh, Sw, R)
Meglumine Antimoniate (D)
Melarsomine (D)
Metronidazole (D, C, A, Po, R)
Milbemycin Oxime (D, C)
Miltefosine (D, Fer)
Morantel (B, Sh)
Moxidectin (D, C, H, B, Sh, L, Fer)
Nitazoxanide (D, C, H)
Oxfendazole (H, B, Sh, Sw)
Oxibendazole (H, Po)
Paromomycin (D, C, Sh, L, R)
Piperazine (D, C, Sw, A, Po, R)
Ponazuril (D, C, H, Sh, L, A, Po, R)
Praziquantel/Praziquantel Combination Products (D, C, H, Sh, L, A, Po, R)
Primaquine (C)
Pyrantel (D, C, H, L, A, Po)
Pyrimethamine (D, C, H, A)
Pyrimethamine/Sulfadiazine (H)
Quinacrine (D, C, R)
Ronidazole (D, C)
Selamectin (D, C, Fer, Po)
Selamectin/Sarolaner (C)
Sodium Stibogluconate (D)
Sulfadiazine (H)
Sulfamethoxazole (D, C, Fer, A, Po, R)
Sulfadimethoxine (D, C, B, L, Fer, Po, R)
Tinidazole (D, C)
Toltrazuril (D, C, B, Sh, L, Sw, A, Po, R)

Antibiotics, Aminoglycosides, and Aminocyclitols
Amikacin (D, C, H, L, A, Fer, Po, R, Fi)
Apramycin (B, Sw, A, Po)
Gentamicin (D, C, H, Sw, A, Fer, Po, R)
Neomycin (D, C, B, Sh, Sw, A, Fer)
Spectinomycin (Sw, A, Po)
Tobramycin (D, C, H, L, A, R)

Antibiotics, Carbapenems
Ertapenem (D, C)
Imipenem/Cilastatin (D, C, H)
Meropenem (D, C, H)

Antibiotics, Cephalosporins
Cefaclor (D, C)
Cefadroxil (D, C, Fer)
Cefazolin (D, C, H, R)
Cefepime (D, C, H)
Cefixime (D, C)
Cefotaxime (D, C, H, A, R)
Cefotetan (D, C)
Cefovecin (D, C)
Cefoxitin (D, C, H)
Cefpodoxime (D, C, H)
Cefquinome (H, B)
Ceftazidime (D, C, H, R)
Ceftiofur Crystalline Free Acid (H, B, Sh, Sw, Po)
Ceftiofur HCl (B, Sw)
Ceftiofur Sodium (D, C, H, B, Sh, Sw, A, R)
Ceftriaxone (D, C, H)
Cefuroxime (D, C, Sh)
Cephalexin (D, C, A, Fer, Po, R)
Cephapirin (B)

Antibiotics, Macrolides
Azithromycin (D, C, H, B, A, Po)
Clarithromycin (D, C, H, Fer)
Erythromycin (D, C, H, B, A, Fer)
Gamithromycin (H, B, Sh, Sw)
Tildipirosin (B, Sw)
Tilmicosin (B, Sh, Sw, Po)
Tulathromycin (B, Sh, Sw, Z)
Tylosin (D, C, B, Sw, A, Fer, Po, Hb)

Antibiotics, Penicillins
Amoxicillin (D, C, B, A, Fer, Po, R)
Amoxicillin/Clavulanate (D, C, A, Fer)
Ampicillin (D, C, H, B, Fer, Po, R)
Ampicillin/Sulbactam (D, C)
Cloxacillin (B)
Dicloxacillin (D, C)
Oxacillin (D, C, H)
Penicillin G (D, C, H, B, Ru, Sw, A, Fer, Po)
Penicillin V (D, C)
Piperacillin/Tazobactam (D, C, A, R)

Antibiotics, Tetracyclines
Chlortetracycline (C, A, Po)
Doxycycline (D, C, H, A, Po, R)
Minocycline (D, C, H)
Oxytetracycline (D, C, H, B, Sh, Sw, A, R, Z)
Tetracycline (D, C, B, Sh, Sw, A, Fer, Po)

Antibiotics, Lincosamides
Clindamycin (D, C, A, Fer, R)
Lincomycin (D, C, Sw, A, Fer)
Pirlimycin (B)

Antibiotics, Quinolones
Ciprofloxacin (D, C, H, A, Fer, Po)
Danofloxacin (B, R)
Enrofloxacin (D, C, H, B, L, Sw, A, Fer, Po, R)
Marbofloxacin (D, C, A, Po, R)
Orbifloxacin (D, C, H, A, Po)
Pradofloxacin (D, C, A)

Antibiotics, Sulfonamides
Sulfa-/Trimethoprim (D, C, H, A, Fer, Po, R)
Sulfadiazine/Pyrimethamine (H)
Sulfadimethoxine (D, C, H, B, L, Fer, Po, R)
Sulfadimethoxine/Ormetoprim (D)

Antibiotics, Antibacterials, Miscellaneous
Chloramphenicol (D, C, H, A, Fer, Po, R)
Clofazimine (D, C, A)
Dapsone (D, H)
Ethambutol (D, C, A)
Florfenicol (B, Sh, L, Sw)
Fosfomycin (D)
Isoniazid (INH) (D, C, B, Ru)
Linezolid (D, C)
Methenamine (D, C)
Metronidazole (D, C, H, A, Fer, Po, R)
Nitrofurantoin (D, C, H)
Novobiocin (B)
Polymyxin B (C, H, Sh)
Rifampin (D, C, H)
Rifaximin (D)
Ronidazole (D, C)
Tiamulin (Sw, A)
Tinidazole (D, C)
Vancomycin (D, C, H)

Antifungal Agents
Amphotericin B (D, C, H, L, A, Po, R)
Caspofungin (D, C)
Fluconazole (D, C, H, A, Po, R)
Flucytosine (D, C)
Griseofulvin (D, H, Po)
Iodide (Potassium-, Sodium-) (D, C, H, B, Sh)
Itraconazole (D, C, H, A, Po, R)
Ketoconazole (D, C, H, A, Po, R)
Nystatin (D, C, H, A, R)
Posaconazole (D, C)
Terbinafine (D, C, A, Po, R)
Voriconazole (D, C, H, A, R)

Antiviral Agents
Acyclovir (D, H, A)
Amantadine (D, C)
Famciclovir (C)
Interferon Alfa, Human Recombinant (D, C)
Interferon Omega, Feline Origin (D, C)
Lysine (C)
Oseltamivir (D, H)
Valacyclovir (H)
Zidovudine (C)

Blood Modifying Agents

Anticoagulants/Antithrombotics
Aspirin (D, C, H, Po)
Clopidogrel (D, C, H)
Cobalamin (Po)
Dalteparin (D, C, H)
Enoxaparin (D, C, H)
Heparin (D, C, H)
Rivaroxaban (D, C)
Warfarin (D, H)

Erythropoietic Agents
Cobalamin | Vitamin B_{12} (D, C, H, B, Sw, Po)
Darbepoetin Alfa (D, C)
Epoetin Alfa (D, C, Fer, Po)
Ferrous Sulfate (D, C)
Folic Acid | Vitamin B_9 (D, C, H, Po)
Iron Dextran (D, C, Sw, A, Fer)
Leucovorin (D, C H)

Blood Modifying Agents, Miscellaneous
Aminocaproic Acid (D, H)
Fenofibrate (D)
Filgrastim (D, C, H, L)
Gemfibrozil (D, C)
Hemoglobin Glutamer-200 (Bovine) (D, C)
Pentoxifylline (D, C, H)
Tranexamic Acid (D, C)
Vitamin K_1 | Phytonadione (D, C, H, B, Sh, Sw, A, Po)

Fluid and Electrolyte Modifiers
Albumin, Human (D, C)
Aluminum Hydroxide (D, C, Po, R)
Calcitonin (D, R)
Calcitriol (D, C)
Calcium Acetate (D, C)
Calcium, Oral (-Carbonate, -Gluconate, -Lactate) (D, C)
Calcium, IV (-Borogluconate, -Chloride, -Gluconate) (D, C, H, B, Sh, Sw, A, R)
Dextran 70 (D, C, B)
Dextrose 50% Injection (D, C, H, B, Sh, Sw)
Ergocalciferol (D, C)
Hydroxyethyl Starch (HES) Colloids (D, C, H, L, A)
Hypertonic Saline (7% – 7.5%) (D, C, H, B, A)
Lanthanum (D, C)
Magnesium Hydroxide (D, C, B, Sh)
Magnesium, IV (D, C, H, B, Sh, Sw)
Phosphate, (Potassium-, Sodium-) IV (D, C)
Potassium (-Acetate, -Chloride, -Gluconate) (D, C, H, Ru)
Sevelamer (D, C)

Antineoplastics

Antineoplastics, Alkylating Agents
Carboplatin (D, C)
Chlorambucil (D, C, H, Fer)
Cisplatin (D, H)
Cyclophosphamide (D, C, H, Fer, Po)
Dacarbazine (DTIC) (D)
Ifosfamide (D, C)
Lomustine (D, C)
Mechlorethamine (D, C)
Melphalan (D, C)
Procarbazine (D, C)

Antineoplastics, Antimetabolites
Cytarabine (D, C, H)
Fluorouracil (D, H)
Methotrexate (D, C, H)
Rabacfosadine (D)

Antineoplastics, Antibiotics
Bleomycin (D, C)
Dactinomycin (D, C)
Doxorubicin (D, C, H, Fer)
Epirubicin (D, C)
Streptozocin (D)

Antineoplastics, Mitotic Inhibitors
Vinblastine (D, C)
Vincristine (D, C, H, Fer)
Vinorelbine (D, C)

Antineoplastics, Miscellaneous
Asparaginase (D, C)
Gemcitabine (D, C)
Hydroxyurea (D, C)

Interferon Alfa, Human Recombinant (D)
Mitoxantrone (D, C)
Mitotane (D)
Piroxicam (D, C, H)
Tigilanol Tiglate (D, H)
Toceranib (D, C)
Verdinexor (D)

Immunomodulators

Immunosuppressive Drugs

Azathioprine (D, H, Fer)
Cyclosporine (D, C)
Dexamethasone (D, C, H, B, Sw, Po)
Flumethasone (D, C, H)
Hydroxychloroquine (D)
Immune Globulin, Intravenous (IVIG) (D)
Leflunomide (D, C)
Methotrexate (D, C, H)
Methylprednisolone (D, C, H)
Mycophenolate (D, C)
Niacinamide (D)
Oclacitinib (D, C)
Prednisolone/Prednisone (D, C, H, B, L, A, Po, R)
Triamcinolone (D, C, H)

Gold Compounds

Auranofin (D, C)

Immunostimulants

Mycobacterial Cell Wall Fraction Immunomodulator (D, H, B)
Parapox Ovis Virus Immunomodulator (H)
Propionibacterium acnes Injection (D, C, H)
Staphylococcal Phage Lysate (D)

Antidotes/Antivenoms/Reversal Agents

Acetylcysteine (D, C)
Antivenom, Black Widow Spider (D, C)
Antivenom, Crotalidae (D, C, H)
Antivenom, North American Coral Snake (D, C, H)
Atipamezole (D, C, H, B, Sh, L, A, Po, R)
Atropine (D, C, H, B, Sh, L, Sw, A, Fer, Po, R)
Charcoal, Activated (D, C, H, Ru, Fer)
Cobalamin (D)
Deferoxamine (D, C, H)
Dexrazoxane (D)
Dimercaprol (BAL) (D, C, H, Ru)
Domperidone (D, H)
Edetate Calcium Disodium (CaEDTA) (D, C, H, Food Animals, L, A, Po)
Ethanol (D, C, H)
Flumazenil (D, C, H, A, R)
Glycopyrrolate (D, C, H)
Fomepizole (D, C)
Leucovorin (D, C, H)
Lipid Emulsion, Intravenous (ILE) (D, C, H, Sh, Po, R)
Methylene Blue (D, C, H, Ru)
Molybdates (D, Food Animals, Sh)
Naloxone (D, C, H, Po, R)
Penicillamine (D, C, Ru, A)
Phenobarbital (B)
Physostigmine (D, H, B)
Polymyxin B (C, H, Sh)
Pralidoxime (2-PAM) (D, C, H, Ru, L, A)
Pyridoxine (Vitamin B_6) (D, C)
S-Adenosyl Methionine (SAMe) ± Silybin (D, C)
Sodium Thiosulfate (D, C, H, Ru)
Succimer (D, C, H, A)
Trientine (D)
Vitamin K_1 | Phytonadione (D, C, H, B, Sh, Sw, A, Po)
Zinc, Systemic (D, C)

Bone/Joint Agents

Alendronate (D, C)
Allopurinol (A, R)
Clodronate (H)
Glucosamine/Chondroitin (D, C, H)
Hyaluronate (D, H)
Pamidronate (D, C, H)
Pentosan Polysulfate (D, C, H)
Polysulfated Glycosaminoglycan (D, C, H, Po)
Tiludronate (H)
Zoledronic Acid (D, C, H)

Dermatologic Agents (Systemic)

Amitriptyline (D, C, A)
Interferon Omega, Feline Origin (D, C)
Isotretinoin (D, C)
Lokivetmab (Canine Atopic Dermatitis Immunotherapeutic, CADI) (D)
Pentoxifylline (D, C, H)
Terbutaline (H)
Topiramate (C)

Vitamins and Minerals/Nutrients

Ascorbic Acid | Vitamin C (D, C, H, B, Po)
Calcitriol (D, C)
Calcium, IV (-Borogluconate, -Chloride, -Gluconate) (D, C, H, B, Sh, Sw, A, R)
Calcium, Oral (-Carbonate, -Gluconate, -Lactate) (D, C)
Carnitine (D, C)
Cobalamin (D, C, H, B, Sh, Sw, Po)
Ergocalciferol | Vitamin D_2 (D, C)
Fatty Acids, Omega-3 (D, C, H)
Ferrous Sulfate (D, C)
Folic Acid | Vitamin B_9 (D, C, H, Po)
Iron Dextran (D, C, Sw, A, Fer)
Leucovorin (D, C H)
Lipid Emulsion, Intravenous (ILE) (small, large animal species)
Lysine (C)
Magnesium, IV (D, C, H, B, Sh, Sw)
Medium Chain Triglycerides (MCT Oil) (D)
Melatonin (D, C, H, Sh, Fer, Z)
Methionine (D, C, Sh)
Niacinamide (D)
Phosphate, (Potassium-, Sodium-) IV (D, C)
Potassium (-Acetate, -Chloride, -Gluconate) (D, C, H, Ru)
Pyridoxine | Vitamin B_6 (D, C)
Taurine (D, C)
Thiamine | Vitamin B_1 (D, C, H, B, Sh, L, Sw)
Vitamin A (D, R)
Vitamin E ± Selenium (D, C, H)
Vitamin K_1 | Phytonadione (D, C, H, B, Sh, Sw, A, Po)
Zinc, Systemic (D, C)

Cholinergic Muscle Stimulants

Edrophonium (D, C, H)
Pyridostigmine (D, C, Fer)

Systemic Acidifiers

Acetazolamide (D, C, H)
Acetic Acid (H, B, Ru)

Systemic Alkalinizers

Citrate, Potassium (D, C)
Sodium Bicarbonate (D, C, H, Ru, A)

Unclassified

Iohexol (D, C, H, A, Po, R)

Plumb's® 10th Edition Veterinary Drug Handbook (VDH) Errata

Below is a listing of the errata found in the first printing of the 10th edition of *Plumb's® Veterinary Drug Handbook*. Please make note of these changes in your book.

Systemic Monographs	Page #	CHANGE
Afoxolaner	17	In the ***Client Information*** section, the sixth bullet incorrectly lists the drug name as "Sarolaner." The drug name should be listed as "Afoxolaner."
Albuterol	26	In the ***Dosages*** section, under Horses for the indication of **Recovery of BAL fluid**, the dosage should read "1 puff/100 kg (1 µg/kg) as a single dose..."
Buprenorphine	150	In the ***Uses/Indications*** section, the first sentence of the third paragraph incorrectly states the duration as 72 hours. The sentence should read "In cats, one product (*Simbadol®*) is a high concentration (1.8 mg/mL), long duration (24 hours) form of buprenorphine..." In the ***Pharmacology*** section, the last sentence of the first paragraph incorrectly states the duration as 72 hours. The sentence should read "The high-concentration, long-duration buprenorphine product lasts 24 hours when given SC to cats."
Butorphanol	162	In the ***Dosages*** section, under Horse indications (Horses-->Analgesic-->c)-->iv), the units in bold were incorrectly listed as µg/kg/hour; units for butorphanol portion of the IV CRI should read mg/kg/hour as listed here: Butorphanol 0.02 mg/kg combined with dexmedetomidine 3.5 µg/kg and given as an initial IV bolus followed by butorphanol 0.024 **mg**/kg/hour with dexmedetomidine 3.5 µg/kg/hour IV CRI provided clinically sufficient sedation for 30 minutes.
Calcium, IV (-Borogluconate, -Chloride, -Gluconate)	177	In the ***Dosage Forms/Regulatory Status*** section, under Veterinary-Labeled Products, the equivalent mg elemental calcium per mL was incorrectly listed as 21.4 mg for the calcium gluconate 23% solution. The sentence should read "Calcium Gluconate 23% (230 mg/mL; equivalent to 21.4 mg [1.07 mEq] elemental calcium per mL), in 500 mL bottles; (OTC).
Cefpodoxime	215	In the ***Pharmacokinetics*** section, in the third sentence of the first paragraph, "...peak concentration is ≈16 **mg**/mL" should be replaced with "...peak concentration is ≈16 **µg**/mL."
Clopidogrel	298	In the ***Drug Interactions*** section, the description for CYCLOSPORINE should be replaced with "A study in dogs showed that cyclosporine can increase clopidogrel peak concentration, but drug exposure was the same as compared with clopidogrel alone."<citation does not change>
Frunevetmab	562	In the ***Monitoring*** section, "(eg, Feline Grimace Scale)" should be removed from the second bullet. Corrected bullet should read "Pain scale or rating system."

Insulin Detemir	657	In the ***Client Information*** section, the third bullet (Both veterinary-approved insulins have owner information sheets, client-friendly handouts, and websites to provide client support on administration and use of insulin) was listed incorrectly and should be removed.
Medetomidine/ Vatinoxan	813	In the ***Drug Interactions*** section, the second bullet (ANALGESICS, SEDATIVES, TRANQUILIZERS, AND/OR ANESTHETIC AGENTS, OTHER) incorrectly states "increase" instead of "decrease." This bullet should read "Vatinoxan blocked the decrease in alfaxalone clearance caused by medetomidine."
Melatonin	824	In the ***Dosages*** section, under Dogs for the indication of Stressful situations, Pre-appointment calming (Dogs-->Stressful situations>Pre-appointment calming>table), remove "(lb)" from the "Body weight in kg(lb)" table header so it reads "Body weight in kg"; add "mg/dog" to the "Amount of melatonin to administer/dog (NOT mg/kg)" table header so that it reads "Amount of melatonin to administer (mg/dog [NOT mg/kg])."
Oxfendazole	966	In the ***Pharmacokinetics*** section, the last sentence in the first paragraph should state: "Absorbed oxfendazole is metabolized to oxfendazole sulfone (inactive)."
Oxytocin	978	In the ***Dosages*** section for Dogs/Cats, under the indication of **Uterine inertia**, bullet 1, the maximum dose for dogs should read "20 Units per bitch [NOT Units/kg])", not "20 Units/kg."
Sulfa-/Trimethoprim	1195	In the ***Dosages*** section, under Dogs for the indication of Coccidiosis (Dogs-- >Parasitic diseases>Coccidiosis> a and b), the weight in lbs should be listed as 8.8 lb: “a) Body weight less than 4 kg (8.8 lb)”... and “b) Body weight greater than 4 kg (8.8 lb)...”
