NOTE: Ammonium molybdate or ammonium tetrathiomolybdate (TTM) can be obtained from various chemical supply houses. There are no FDA-approved products, but the FDA has historically used discretion in enforcement when molybdate is used for copper toxicosis in animals. It is recommended to contact the FDA Center for Veterinary Medicine (CVM) before treating for guidance.

In food animals, FARAD recommends a minimum 10-day preslaughter withdrawal time and a minimum 5-day milk withholding interval.[18]

Montelukast

(mon-teh-***loo***-kast) *Singulair*®

Leukotriene Antagonist

Prescriber Highlights

- ► Potentially useful in cats for feline asthma, IBD, upper respiratory disease, and heartworm-associated respiratory disease syndrome; however, there is limited evidence to support use in this species and limited clinical experience in veterinary species
- ► No significant adverse effects reported in cats

Uses/Indications

In veterinary medicine, montelukast has been used primarily in cats. Potential indications include feline asthma, atopy, upper respiratory disease, inflammatory bowel disease, and heartworm disease. Its use in treating feline asthma has been disappointing, and few clinicians recommend it for this purpose. At the time of writing, there was only anecdotal evidence for efficacy of this class of drugs in cats. A small trial in horses with recurrent airway obstruction (RAO) did not show efficacy.[1]

In humans, montelukast is FDA-approved for allergic rhinitis and asthma. It is used off-label in humans for atopic dermatitis, urticaria (chronic and NSAID-induced), and eosinophilic esophagitis.

Pharmacology/Actions

Montelukast is a leukotriene antagonist that inhibits at the cysteinyl leukotriene (CysLT1) receptor. The cysteinyl leukotrienes (ie, LTC4, LTD4, LTE4) are proinflammatory products of arachidonic acid metabolism released from certain cells, including mast cells and eosinophils.

Pharmacokinetics

No pharmacokinetic information for montelukast in cats was located.

In humans, oral bioavailability is 64% and peak concentrations occur 3 to 4 hours after dosing.[2] The presence of food does not affect bioavailability. Montelukast is highly bound (99%+) to human plasma proteins. It is extensively metabolized in the liver via cytochrome P450 isoenzymes CYP3A4, CYP2A6, and CYP2C9. Based on in vitro studies in human liver microsomes, therapeutic plasma concentrations of montelukast do not inhibit CYP450 isoenzymes 3A4, 2C9, 1A2, 2A6, 2C19, or 2D6. Metabolites are excreted primarily in the bile and eliminated in the feces. In healthy young adults, plasma half-life is ≈4 hours.

Contraindications/Precautions/Warnings

Montelukast is contraindicated in patients that are hypersensitive to it. Humans are warned not to use it to attempt to reverse acute bronchospasm.[2]

Adverse Effects

No adverse effects were noted for montelukast in cats, but the drug has not been extensively studied or used in cats.

In humans, the drug is usually well tolerated with minimal adverse effects reported. Rarely, behavioral effects (eg, aggression, suicidal thoughts), palpitations, cholestatic hepatitis, and allergic granulomatous angiitis have been reported.[2]

Reproductive/Nursing Safety

Montelukast appears safe to use during pregnancy. No teratogenicity was observed in rats at oral dosages up to 100 times the recommended human dose, or in rabbits at 110 times the recommended human dose.[2]

Although studies in rats have shown that montelukast is excreted in milk, data from breastfeeding women suggest the drug is safe to use during nursing.[2]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Montelukast is relatively safe in overdose situations. Rats and mice survived oral doses of ≈230 times and 335 times the recommended human adult dose, respectively. Cases of human adults and children receiving doses as high as 1000 mg have been reported and the majority of overdoses had no adverse effects. The most frequent adverse effects observed in humans are headache, vomiting, psychomotor hyperactivity, thirst, somnolence, mydriasis, hyperkinesia, and abdominal pain. Treatment is supportive.

For patients that have experienced or are suspected to have expe-

rienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans receiving montelukast and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **CYP450 Enzyme Inducers** (eg, **phenobarbital, rifampin**): May reduce the montelukast plasma concentrations and efficacy
- **Gemfibrozil**: May increase montelukast concentration

Laboratory Considerations

- None were noted.

Dosages

CATS:

Adjunctive treatment of feline asthma, allergic rhinitis, mild cases of IBD, atopy, or feline heartworm (extra-label): There is no clear evidence that montelukast is effective for any of these indications. Anecdotal dosages are 0.25 – 1 mg/kg PO once daily. Practically, this would be ⅛ to ¼ of a 10 mg tablet per cat PO once daily.

Monitoring

- Clinical efficacy

Client Information

- This medicine may be given with or without food. Food may help if the animal vomits or acts sick after getting the drug. If vomiting continues, contact your veterinarian.
- Montelukast does not reverse an active asthma attack and it is not useful for immediate treatment of asthma.
- No significant side effects were reported when montelukast was used in cats, but the drug has not been used in many cats. Contact your veterinarian if any new problems or side effects occur after starting this medication.

Chemistry/Synonyms

Montelukast is a cyclopropaneacetic acid derivative leukotriene inhibitor. It is freely soluble in ethanol, methanol, and water.

Montelukast may also be known as MK-476, L-706631, or montelukastum.

Storage/Stability

Store tablets or granules at room temperature; excursions are permitted between 15°C and 30°C (59°F-86°F). Protect from moisture and light.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) Uniform Classification Guidelines for Foreign Substances (UCGFS) Class 4 Drug. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Montelukast Sodium Oral Tablets: 4 mg (chewable), 5 mg (chewable), and 10 mg; *Singulair*®, generic; (Rx)

Montelukast Sodium Oral Granules: 4 mg/packet; *Singulair*®, generic; (Rx)

Morantel

(mor-***an***-tel) *Rumatel*®

Antiparasitic Agent

Prescriber Highlights

- ► Infrequently used anthelmintic that is available as a medicated feed for cattle and goats
- ► Use with caution in severely debilitated animals.
- ► Adverse effects are uncommon.
- ► Clinical signs of overdose include increased respiratory rate, profuse sweating, ataxia, or other cholinergic effects.

Uses/Indications

Morantel is an FDA-approved Type A medicated feed that is labeled for the removal and control of mature forms of *Haemonchus* spp, *Ostertagia* spp, *Trichostrongylus* spp, *Nematodirus* spp, *Cooperia* spp, and *Oesophagostomum radiatum* in cattle. In goats, it is indicated for the removal and control of mature *Haemonchus contortus, Ostertagia (Teladorsagia) circumcincta,* and *Trichostrongylus axei*.

Pharmacology/Actions

Morantel is a depolarizing neuromuscular blocking agent that paralyzes susceptible parasites, similar to pyrantel. It possesses nicotine-like properties and acts similarly to acetylcholine. Morantel also inhibits fumarate reductase in *Haemonchus* spp.

Morantel has a slower onset of action than pyrantel but is ≈100 times as potent.

Pharmacokinetics

After oral administration, morantel is absorbed rapidly from the upper abomasum and small intestine. Peak concentrations occur ≈4 to 6 hours after dosing. The drug is promptly metabolized in the liver. Within 96 hours of administration, 17% of the drug is excreted in the urine, with the remainder in the feces.

Contraindications/Precautions/Warnings

There are no absolute contraindications for use.

Morantel should be used with caution in severely debilitated animals.[1] Do not underdose morantel, as underdosing can result in ineffective treatment and lead to development of parasite resistance.

Adverse Effects

At recommended dosages, adverse effects are uncommon.

Reproductive/Nursing Safety

Morantel is generally considered safe to use during pregnancy.

Overdose/Acute Toxicity

Morantel tartrate has a large safety margin. In cattle, doses of up to 200 mg/kg (20 times the recommended dose) resulted in no toxic reactions. The LD_{50} in mice is 5 g/kg. Clinical signs of toxicity that might possibly be seen include increased respiratory rates, profuse sweating (in species with sweat glands), ataxia, or other cholinergic effects.

Chronic toxicity studies have been conducted in cattle and sheep. Four times the recommended dose of morantel was given to sheep with no detectable deleterious effects. Cattle receiving 2.5 times the recommended dose for 2 weeks showed no toxic signs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information

is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in animals receiving morantel and may be of significance. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Bentonite**: Do not add morantel to feeds containing bentonite.
- **Levamisole, Pyrantel**: Because of similar mechanisms of action (and toxicity), morantel is not recommended for use concurrently with pyrantel or levamisole.
- **Organophosphates, Diethylcarbamazine**: Increased risk for adverse effects; additional monitoring may be required
- **Piperazine**: Piperazine and morantel have antagonistic mechanisms of action; do not use together.

Dosages

CATTLE:

Susceptible parasites (label dosage; FDA-approved): Feed at a rate of morantel tartrate 0.44 g/45.36 kg (100 lb) of body weight as a single treatment, which results in a 10 mg/kg morantel dose.[1] Medicated feed should be consumed within 6 hours of mixing. It can be fed as the sole ration, mixed with 1 to 2 parts of complete feed, or used as a top dress. When used as a top dress, the medication (as well as the underlying feed) should be evenly distributed. Animals should be grouped by size for optimum efficacy. Fresh water should be available at all times. Resume normal feeding once all medicated feed is consumed. Conditions of constant parasite exposure may require repeat treatment within 2 to 4 weeks.

GOATS:

Susceptible parasites (label dosage; FDA-approved): Feed at a rate of morantel tartrate 0.44 g/45.36 kg (100 lb) of body weight as a single treatment, which results in a 10 mg/kg morantel dose. Medicated feed should be consumed within 6 hours of mixing. Fresh water should be available at all times. Conditions of constant parasite exposure may require retreatment in 2 to 4 weeks.[1]

SHEEP:

Susceptible parasites (extra-label): Feed at a rate of morantel tartrate 0.44 g/45.36 kg (100 lb) of body weight as a single treatment, which results in a 10 mg/kg morantel dose. Medicated feed should be consumed within 6 hours of mixing. Fresh water should be available at all times. Conditions of constant parasite exposure may require retreatment in 2 to 4 weeks.[2]

Client Information

- Follow all label directions and withdrawal times.
- Contact your veterinarian before using this medicine in sick animals.

Chemistry/Synonyms

A tetrahydropyrimidine anthelmintic, morantel tartrate occurs as a practically odorless, off-white to pale-yellow crystalline solid that is soluble in water. It has a melting range of 167°C to 171°C (332.6°F-339.8°F). The tartrate salt is equivalent to 59.5% of base activity.

Morantel tartrate may also be known as CP-12009-18, moranteli hydrogenotartras, UK-2964-18, *Goat Care-2X*®, or *Rumatel*®.

Storage/Stability

Morantel tartrate products should be stored at or below 25°C (77°F) and protected from light unless otherwise instructed by the manufacturer. Excursions are permitted up to 40°C (104°F).

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Morantel Tartrate Medicated Pellets: 0.194% (880 mg/lb) in 3 lb bags (treats 12 to 50 lb goats) and 10 lb bags (treats 40 to 50 lb goats). *Goat Care-2X*®; (OTC, Type C medicated feed); 30-day slaughter withdrawal. Do not mix this product in feeds containing bentonite.

Morantel Tartrate Medicated Premix: 19.4% (morantel tartrate 88 g/lb) in 25 lb bags. *Rumatel*®*-88*; (OTC, Type A medicated article). FDA-approved for use in beef or dairy cattle and goats. Do not mix this product in feeds containing bentonite. No milk withdrawal at label dosages; 14-day meat withdrawal in cattle and 30-day meat withdrawal in goats at label dosages

HUMAN-LABELED PRODUCTS: NONE

Morphine

(***mor***-feen)

Opioid Agonist

Prescriber Highlights

- ► Classic opioid analgesic that can be reversed with naloxone
- ► Response varies by species
- ► Contraindications include hypersensitivity to morphine; recent treatment with monoamine oxidase inhibitors; diarrhea caused by a toxic ingestion; ileus or GI obstruction; and scorpion or coral snake envenomation.
- ► Use with extreme caution in patients with severe respiratory disease or acute respiratory dysfunction, or with head injuries or increased intracranial pressure (particularly in cases of impaired consciousness or coma); ventilatory monitoring and support are warranted in these cases.
- ► Use with caution in patients with hypothyroidism, severe renal insufficiency (acute azotemia), severe hepatic disease, or adrenocortical insufficiency; severely hypotensive or hypovolemic patients; geriatric or severely debilitated patients; brachycephalic patients; and patients with acute abdominal conditions (eg, colic). Morphine may obscure clinical signs of acute abdominal conditions during diagnosis.
- ► Adverse effects include histamine release/vasodilation (with rapid IV injection), CNS system depression or excitation (varies by species), hyperthermia (cats, horses, cattle, goats, and camelids), hypothermia, GI effects (may include nausea, vomiting, and decreased intestinal peristalsis), defecation or micturition, respiratory depression, and bronchoconstriction.
- ► Dogs can develop physical dependence with chronic use; dose needs to be tapered to minimize clinical signs associated with withdrawal.
- ► DEA Schedule II (C-II) controlled substance

Uses/Indications

Morphine is used to treat acute pain in dogs, cats, horses, swine, sheep, and goats. Morphine is used as a preanesthetic in several species. For sedation and analgesia in critically ill small animals, a combination of a sedative agent (eg, midazolam) and a mu-opioid (eg, morphine, hydromorphone) is often preferred because of its minimal effect on cardiac output, systemic blood pressure, and oxygen delivery. Additionally, sedative effects from opioids can be reversed with naloxone if necessary.

Morphine is typically administered by parenteral (ie, IV, IM, SC) routes. Oral morphine is not recommended in dogs because of poor oral bioavailability.[1] Epidural administration is used to provide analgesia primarily in the hindlimbs and, to a lesser extent, in the forelimbs and perineal region in small and large animals species. Intra-articular morphine administration as part of a balanced analgesic protocol may be beneficial in horses for synovitis or after joint surgery.[2,3] Morphine has been used for IV limb perfusion in standing sedated horses.[4]

Pharmacology/Actions

The morphine-like agonists (eg, morphine, meperidine, hydromorphone) have primary activity at mu-opioid receptors, with some activity at delta- and kappa-opioid receptors. The primary pharmacologic effects of these agents are species-specific but can include analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (defecation followed by constipation). Secondary pharmacologic effects include CNS (euphoria, sedation, and confusion), cardiovascular (bradycardia due to central vagal stimulation, depressed alpha-adrenergic receptors resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition [orthostatic hypotension and syncope may occur]), and urinary (increased bladder sphincter tone can induce urinary retention).

When morphine was administered intra-articularly (0.05 mg/kg) in horses with experimentally induced synovitis, it demonstrated anti-inflammatory effects such as reducing swelling, synovial total protein, serum amyloid, and white blood cell counts.[3] In a study where morphine (120 mg) was injected into the talocrural joint of horses 1 hour after inducing synovitis, significant decreases were found in synovial white blood cell count, prostaglandin E_2, and bradykinin levels, and there was improvement in clinical lameness of kinematic and behavioral parameters as compared with placebo.[2]

Morphine's CNS effects are irregular and are species-specific. Generally, cats, horses, cattle, sheep, goats, and swine may exhibit stimulatory effects after morphine injection. Dogs, humans, and other primates exhibit CNS depression. Dogs and cats are sensitive to the emetic effects of morphine. Significantly higher morphine doses are required in cats before vomiting occurs from direct stimulation of the chemoreceptor trigger zone (CRTZ). Other species (horses, ruminants, and swine) do not respond to the emetic effects of morphine.

Morphine is an effective centrally acting antitussive in dogs. Morphine can cause miosis in humans and rabbits. A study in healthy dogs following IV morphine (dose not specified) showed no significant effect on pupil size or intraocular pressure.[5]

Morphine is a respiratory depressant. In dogs, morphine can cause alterations to the thermoregulatory center, leading to an initial increase in respiratory rate with a decrease in tidal volume (panting). The overall effect on minute ventilation is minimal. As CNS depression progresses, respirations may become depressed. Morphine at moderate to high doses can also cause bronchoconstriction in dogs.

The cardiovascular effects of morphine in dogs are minimal when recommended doses are used and if slow IV administration is performed. Like meperidine, morphine can affect the release of histamine from mast cells. When administered at 0.5 – 1 mg/kg IV or 0.3 – 0.6 mg/kg followed by 0.17 – 0.34 mg/kg/hour IV CRI, histamine release is present with no cardiovascular effects at the lower doses and minimal cardiovascular depression at the higher doses.[6,7] In contrast, when high doses (3 mg/kg IV) of morphine were used in dogs that were anesthetized with pentobarbital, profound hypotension was noted.[8] However, when the same dose is used in awake dogs, minimal system effects on hemodynamics were observed.[9]

The effects of morphine on the GI tract consist primarily of decreased motility and secretions. Horses that received morphine doses as low as 0.05 mg/kg IM had decreased GI motility 1 to 2 hours later.[10] Dogs may defecate following morphine injection then exhibit signs of decreased intestinal motility and can cause constipation. Biliary, pancreatic, and gastric secretions (including hydrochloric acid) are reduced following morphine administration.[11]

Initially, morphine can induce micturition. Higher morphine doses (greater than 2.4 mg/kg IV) may substantially reduce urine production by an increase in antidiuretic hormone (ADH) release. Morphine may cause bladder hypertonia, which can lead to increased urinary difficulties.[3]

Refer to ***Appendix: Pharmacology of Narcotic (Opioid) Agonist Analgesics*** for more information.

Pharmacokinetics

Morphine is absorbed after IM, SC, buccal (oral transmucosal, OTM), and rectal administration. Although absorbed after PO administration, bioavailability is reduced, likely from the high first-pass effect. Morphine's very low oral bioavailability (less than 20%) and erratic absorption of the oral extended-release formulation limit oral usefulness in canines.[12–14] Morphine concentrates in the kidneys, liver, and lungs; lower concentrations are found in the CNS. Most free morphine is found in skeletal muscle, with lower concentrations found in parenchymatous tissue.

The majority of morphine is eliminated via hepatic metabolism, primarily by glucuronidation. Cats are deficient in this metabolic pathway and morphine's half-life in cats is prolonged compared with other species (reported to be ≈3 hours). The glucuronidated metabolite M6G (active) is renally excreted.

After administration of morphine 0.5 mg/kg IV in dogs, morphine had a half-life of 1.2 hours, a volume of distribution of ≈4.6 L/kg, and a clearance of ≈62.5 mL/minute/kg.[14]

In horses, morphine's serum half-life is reported to be 1.5 hours after a dose of 0.1 mg/kg IV or IM.[15] At this dose, morphine was detectable in serum for 48 hours and urine for 6 days. Epidurally administered morphine in horses caused rapid, short-lasting serum concentrations and delayed, long-lasting CSF concentrations (elimination half-life ≈8 hours). Isoflurane anesthesia did not significantly alter values.[16]

Contraindications/Precautions/Warnings

Morphine is contraindicated in patients that are hypersensitive to narcotic analgesics, are receiving or are within 14 days of receiving monoamine oxidase inhibitors (MAOIs), have diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract, or have GI tract obstruction or paralytic ileus. Avoid morphine in envenomation situations, as clinical signs associated with histamine release can be confused with anaphylaxis. Respiratory depressants, including morphine, should not be used in coral snake envenomation in dogs or cats.[17] Opioid analgesics are contraindicated in patients that are stung by scorpions (eg, *Centruroides* spp), as they may potentiate venom effects.[18]

Use extreme caution with morphine in patients with brain tumors, head injuries, or increased intracerebral pressure and avoid use in patients with impaired consciousness or coma as morphine may increase intracerebral pressure secondary to cerebral vasodilation caused by increased $PaCO_2$ stemming from respiratory depression. Also use extreme caution in patients that are suffering from severe respiratory disease or acute respiratory dysfunction (eg, pulmonary edema secondary to smoke inhalation). Ventilatory monitoring and support are warranted in these cases.

Use opioids with caution in patients with hypothyroidism, hypoadrenocorticism, severe hypotension or hypovolemia, or in severely debilitated patients.[19] Caution is warranted in acute abdominal conditions (eg, colic), as morphine may obscure the diagnosis or clinical course of these conditions. Because of the drug's effects

on vasopressin (ADH), morphine should be used cautiously in patients that are suffering from acute azotemia or severe renal insufficiency. Urine flow is reported to decrease as much as 90% in dogs following large morphine doses. If administering the drug IV, give morphine slowly or significant hypotension can result. Hypotension may result in decreased cardiac output and blood pressure. Biliary tract impairment may be worsened, and caution is recommended. Morphine may constrict the sphincter of Oddi, decreasing pancreatic and biliary secretions. Patients with severe hepatic disease may have prolonged duration of action of the drug.

Neonatal, debilitated, or geriatric patients may be more susceptible to the effects of morphine and require lower dosages. Anecdotally, some clinicians have suggested that animals with brachycephalic airway syndrome are potentially sensitive to morphine's adverse effects, but no scientific documentation for this was located.

Intrathecal administration is contraindicated in patients with upper airway obstruction. Intrathecal and epidural administration are both contraindicated by presence of infection at injection site, anticoagulant therapy, or uncontrolled bleeding.

Some dosage forms may contain benzyl alcohol as a preservative. In human newborns, benzyl alcohol and its derivatives can potentially displace bilirubin from protein-binding sites and caution for use in human neonates is advised. Some dosage forms may contain sulfites, which could cause allergic reactions in susceptible patients. The significance of these cautions for veterinary patients is unclear.

Morphine has significant potential for drug abuse and drug diversion in humans; caution is advised when prescribing this drug.

Sedative drugs such as morphine should only be used in situations in which sufficient monitoring and patient-support capabilities (eg, intubation, ventilation) are available.

Adverse Effects

At recommended dosages, opioids have limited respiratory depressant effects in veterinary species compared to humans. Decreased tidal volume, depressed cough reflex, and drying of respiratory secretions may have a detrimental effect on susceptible patients (eg, patients with brachycephalic airway syndrome, aspiration, or pneumonia). Bronchoconstriction following IV morphine doses may be noted in dogs[20]; significant hypotension results if morphine is administered rapidly IV. Panting and bradycardia may be seen in dogs after morphine administration.[21]

GI effects may include nausea, vomiting, and decreased intestinal peristalsis. Maropitant can significantly decrease the incidence of morphine-induced vomiting in dogs[22,23] and cats.[24] Dogs may defecate after an initial dose of morphine, but this is uncommon when used postoperatively. Horses exhibiting signs of mild colic may have their clinical signs masked by narcotic analgesics. Horses may be prone to developing colic, constipation, and ileus, particularly when an opioid-alpha-2 agonist combination is used.[20] In ferrets, morphine can induce nausea and vomiting and is often avoided in this species.[25]

CNS excitation is typically only seen after rapid IV administration, or with doses that are higher than those used clinically. Dose-related excitatory changes appear more likely in cats, horses, ruminants, and camelids, and may include dysphoria, vocalization, thrashing, increased locomotor activity (eg, pacing), restlessness, ataxia, and convulsions at very high doses. Morphine-induced CNS depression may hinder the abilities of working animals. Long-term administration may lead to physical dependence in dogs.[26,27]

Morphine initially may induce micturition which may be followed by substantially reduced urine production and/or urethral sphincter hypertonia, which can lead to urine retention.[19]

Body temperature changes, including hypothermia, may be seen. Panting is often seen in dogs after morphine administration and contributes to the development of hypothermia. Cats, horses, cattle, and goats may develop hyperthermia.

Sheep may exhibit drooling, bruxism, facial tremors, vocalization, and mydriasis.[28]

In one case report of a Holstein calf epidural of morphine 0.1 mg/kg with a fentanyl patch, adverse effects included altered consciousness, mydriasis, nystagmus, increased locomotion, vocalization, tail myoclonus, hyper-responsiveness, hyperthermia, tachycardia, and tachypnea.[29]

Reproductive/Nursing Safety

Placental transfer of opioids is rapid, but morphine appears safe to use during pregnancy when given at recommended dosages. Administration during late stages of pregnancy may result in respiratory depression of the offspring.[30]

Morphine appears in maternal milk, but the effects on offspring may not be significant when used for short periods.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals. Parenteral doses greater than 100 mg/kg are thought to be fatal in dogs. Other toxic effects can include cardiovascular collapse, hypothermia/hyperthermia, and skeletal muscle hypotonia. Some species such as cats, horses, cattle, and swine may demonstrate CNS excitability (hyperreflexia, tremors) and seizures at high doses of morphine, or if it is administered rapidly IV.

Naloxone is the reversal agent for morphine. In cases of massive overdoses, naloxone doses may be repeated. Observe animals closely as naloxone's effects might diminish before attaining subtoxic morphine levels. Consider mechanical respiratory support in cases of severe respiratory depression.

Pentobarbital has been suggested as a treatment for CNS excitement and seizures in cats. Extreme caution should be used in administering this treatment, as barbiturates and narcotics can have additive effects on respiratory depression.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving morphine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate, oxybutynin**): Medications with anticholinergic properties may increase the risk for urinary retention and constipation when combined with opioids.
- **Clopidogrel**: Morphine may diminish clopidogrel's antiplatelet effect and serum concentration.
- **Blood Pressure Lowering Agents** (eg, **amlodipine, enalapril, telmisartan**): Agents that lower blood pressure may have additive hypotensive effects when used with morphine.
- **CNS Depressants, Other** (eg, **anesthetic agents, antihistamines, barbiturates, phenothiazines**): May cause increased CNS or respiratory depression when used with morphine
- **Desmopressin**: Opioids may increase the risk for water intoxi-

cation or hyponatremia when combined with desmopressin.

- **Diuretics**: Opioids may decrease diuretic efficacy in congestive heart failure patients.
- **Esmolol**: Serum concentrations of esmolol may be increased with concomitant morphine use.
- **GI Prokinetic Agents** (eg, **cisapride, metoclopramide**): Opioids may decrease the effectiveness of GI prokinetic agents.
- **Magnesium Sulfate**: The CNS depressant effects of morphine may be increased, more likely with higher magnesium doses or IV magnesium therapy.
- **Minocycline**: IV minocycline therapy may enhance the CNS depressant effects of morphine.
- **Mixed Opioid Agonist/Antagonist** (eg, **butorphanol**, **nalbuphine**): Combined use with morphine could antagonize opioid effects.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid**, **selegiline**): Morphine may enhance the serotonergic effect of MAOIs and lead to possible serotonin syndrome; avoid concurrent use or use of morphine within 14 days of stopping MAOIs.
- **Muscle Relaxants, Skeletal** (eg, **atracurium**): Morphine may enhance neuromuscular blockade.
- **Naloxone**: Antagonizes opioid effects. **NOTE**: This action is an expected outcome when naloxone is used as a reversal agent.
- **P-Glycoprotein Modulators** (eg, **ketoconazole**): Medication that induces, inhibits, or is a substrate of P-glycoproteins may affect morphine bioavailability and serum concentration.
- **Rifampin**: May induce morphine metabolism and decrease morphine serum concentration
- **Serotonin Modulators** (eg, **SSRIs, linezolid, methylene blue, metoclopramide**): Serotonin levels may be enhanced when serotonin modulators are given concomitantly with morphine. Monitor for serotonin syndrome.
- **Succinylcholine**: Opioids combined with succinylcholine may enhance the bradycardic effects of opioids.
- **Tricyclic Antidepressants** (eg, **clomipramine, amitriptyline**): Morphine may exacerbate the effects of tricyclic antidepressants.
- **Warfarin**: Opioids may potentiate anticoagulant activity.

Laboratory Considerations

- Opioids may increase biliary tract pressure, resulting in increased plasma **amylase** and **lipase** values up to 24 hours following their administration.
- Quinolones may cause false positive results on urine screening tests for morphine.

Dosages

NOTES:

1. Preservative-free morphine formulations should be used for epidural administration.
2. Do not confuse CRI dosages listed as mg/kg/hour with those listed as µg/kg/minute.
3. For additional dosages/protocols for using morphine in combination with other drugs (eg, ketamine, lidocaine, dexmedetomidine) for pain/sedation in dogs or cats, see the dosages and their accompanying references in the ***Dexmedetomidine***, ***Ketamine***, and ***Lidocaine*** monographs.

DOGS:

Analgesia (extra-label):

a) **Intermittent dosing**: 0.5 – 1 mg/kg IM, SC, or IV (slowly). Lower doses may be necessary in severely debilitated animals, and higher doses may be required for treatment of extreme pain. Duration of effect can vary, and re-dosing is often needed after 2 hours.

b) **CRI dosing**: Initial loading dose of 0.3 – 0.5 mg/kg IM, IV (slowly), followed by 0.1 – 1 mg/kg/*hour* IV CRI.[31,32] Adjust dosage based on clinical analgesic response and/or adverse effects, which may be pronounced at higher infusion rates or with prolonged duration of use.

c) **Epidural**: Using preservative-free morphine, 0.1 mg/kg diluted with saline to a volume of 0.3 mL/kg (maximum 6 mL). Opioids provide analgesia without loss of hindlimb function or muscle tone. Extended analgesia can be maintained with an epidural catheter (although catheter placement and maintenance may be difficult). One advantage of epidural morphine is that analgesia will migrate cranially and be effective up to 18 hours.[33]

In combination as a preanesthetic agent or perioperative sedative analgesic (extra-label): Many combinations can be used. Morphine is usually dosed between 0.1 – 0.5 mg/kg IM in combination with drugs such as acepromazine, midazolam, dexmedetomidine, and/or ketamine. Lower morphine doses (eg, 0.05 mg/kg) may be necessary in debilitated or critically ill animals.

Morphine/Lidocaine/Ketamine (MLK) low-dose CRI: Morphine 3.3 **µg**/kg/*minute* in combination with lidocaine 50 **µg**/kg/*minute* and ketamine 10 **µg**/kg/*minute* IV CRI decreases isoflurane minimum alveolar concentration (MAC) in dogs and is not associated with adverse hemodynamic effects.[34,35]

Dexmedetomidine/morphine/lidocaine/ketamine (DMLK): Dexmedetomidine 0.5 µg/kg/*hour* in combination with morphine 0.2 mg/kg/*hour*, lidocaine 3 mg/kg/*hour*, and ketamine 0.6 mg/kg per *hour* admixed in IV fluids and administered IV as CRI.[36]

CATS:

Analgesia (extra-label):

a) **Intermittent dosing**: 0.1 – 0.25 mg/kg IV, IM, or SC every 2 to 4 hours as needed.[31] Duration of effect can vary, and often re-dosing is needed after 3 hours.

b) **CRI dosing**: 0.05 – 0.1 mg/kg/*hour* IV CRI[31]

c) **Epidural analgesia** (extra-label): In one study, using preservative-free morphine 0.1 mg/kg diluted with saline to a volume of 0.22 mL/kg was administered over 1 minute.[37] Morphine provided analgesia for 12 hours postadministration. In another study of 24 cats undergoing ovariohysterectomy, morphine 0.1 mg/kg with 2% lidocaine 4 mg/kg was administered as an epidural and provided adequate analgesia for the procedure.[38]

HORSES:

NOTE: Some clinicians recommend pretreatment with acepromazine, detomidine, or xylazine to reduce drug-induced behavioral changes caused by morphine.

Analgesia (extra-label):

a) **Intermittent dosing**:

i. 0.1 mg/kg IM every 4 hours; this dose reduces morphine's impact on GI motility.[39]

ii. 0.012 – 0.66 mg/kg IV in combination with alpha-2 agonists[40]

b) **CRI dosing**: Initial loading dose of 0.12 – 0.15 mg/kg IV (slowly) or IM, followed by 0.05 – 0.1 mg/kg/hour IV CRI[41,42]

c) **Epidural analgesia**: **NOTE**: Use preservative-free morphine for epidural administration.

i. In one study, 6 hours after inducing carpal synovitis in ponies, morphine 0.1 mg/kg (diluted in a 0.9% saline solution to a final volume of 0.15 mL/kg) was administered epidurally at a rate of 1 mL per 10 seconds.[43] The authors conclud-

ed that epidural morphine produced analgesia that lasted more than 12 hours without adverse effects and would be an analgesic option to alleviate joint pain in ponies' forelimbs.[43]

ii. Morphine 0.1 – 0.2 mg/kg diluted in 10 to 20 mL of 0.9% saline solution (total volume of 0.04 mL/kg body weight) epidurally alone or in combination with detomidine 0.015 – 0.03 mg/kg epidurally to provide effective analgesia of the caudal half of the body.[40,44,45] Analgesic effects are seen within 20 to 30 minutes and may last 8 to 24 hours without adverse effects on motor function.

iii. Adult horses: Preservative-free morphine 0.1 – 0.2 mg/kg; dilute with saline to a total volume of 0.04 mL/kg or 20 mL/450 kg (992 lb) and administer epidurally[31]

iv. Foals: Preservative-free morphine 0.1 mg/kg epidurally. Use of preservative-containing morphine is not recommended, but if unavoidable then dilute to a volume of 0.2 mL/kg.

d) **Intraregional limb perfusion**: Morphine 0.1 mg/kg IV has been used for IV limb perfusion in standing sedated horses. Measurable levels were detected in the synovial fluid and this technique did not cause adverse effects.[4]

e) **Intra-articular injection for acute inflammatory joint pain** (extra-label): Two single-dose experimental studies suggest that intra-articular morphine has anti-inflammatory effects for acute synovitis. One study used morphine 0.05 mg/kg IA (radiocarpal joint) and another used 120 mg diluted in 20 mL saline (talocrural joint).[2,3]

CAMELIDS:

Epidural (extra-label): 0.1 – 0.3 mg/kg of preservative-free morphine diluted to 12 mL and administered epidurally[46]

SHEEP:

Sedation (extra-label):

a) In a study of 6 Santa Inês sheep, dexmedetomidine 0.005 mg/kg combined with morphine 0.5 mg/kg and given IV resulted in similar sedation scores and cardiopulmonary effects compared with dexmedetomidine alone.[47]

b) In another study of 6 Santa Inês sheep administered xylazine 0.1 mg/kg combined with morphine 0.5 mg/kg and given IV, the combination produced superior sedation for 30 minutes compared with xylazine alone.[28]

RABBITS, RODENTS, SMALL MAMMALS:

Analgesic/sedative (extra-label):
Rats: 2.5 mg/kg SC every 4 hours
Mice: 2.5 mg/kg SC every 2 to 4 hours
Guinea pigs: 2 – 5 mg/kg SC or IM every 4 hours[48]
Rabbits: 2 – 5 mg/kg IM or SC every 2 to 4 hours; epidurally at 0.1 mg/kg[49]

Monitoring

- Respiratory rate and depth; $ETCO_2$; pulse oximetry (SpO_2)
- Heart rate
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Analgesic efficacy
- Body temperature

Client Information

- Morphine is a pain reliever for dogs or cats that is not suitable for use at home.
- Use of morphine may lead to nausea, vomiting, and constipation. Contact your veterinarian if these effects do not resolve within a few days.

Chemistry/Synonyms

The sulfate salt of a naturally occurring (derived from opium) opioid analgesic, morphine sulfate occurs as white, odorless crystals. One gram of morphine is soluble in 16 mL of water (62.5 mg/mL) or 570 mL of alcohol (1.75 mg/mL). Morphine is insoluble in chloroform or ether. Morphine sulfate injection pH ranges from 2.5 to 6.

Morphine sulfate may also be known as morphini sulfas, *Astramorph PF®*, *Avinza®*, *DepoDur®*, *Infumorph®*, *Kadian®*, *MSIR®*, *MS Contin®*, *Oramorph SR*, *RMS®*, and *Roxanol®*.

Storage/Stability

Morphine is a DEA schedule II (C-II) controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Morphine injection should be stored at room temperature (20°C-25°F [68°F-77°F]), protected from light; do not freeze.[19] Morphine gradually darkens in color when exposed to light. Morphine does not appear to adsorb to plastic or polyvinyl chloride (PVC) syringes, tubing, or bags.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Morphine sulfate has been shown to be physically **compatible** at a concentration of 16.2 mg/L with the following IV fluids: dextrose 2.5%, 5%, and 10% in water; Ringer's injection and lactated Ringer's injection; and sodium chloride 0.45% and 0.9% for injection.[50] Morphine sulfate has been demonstrated to be generally physically **compatible** when mixed at Y-sites with a wide variety of agents.

The following drugs have been shown to be physically **incompatible** when mixed at Y-sites with morphine sulfate: amphotericin B, azathioprine, cloxacillin, dantrolene, diazoxide, doxorubicin, folic acid, inamrinone, pentobarbital sodium, and phenytoin sodium.

The following drugs have been shown to have **variable** compatibility and should be used cautiously when mixed at Y-sites with morphine sulfate: acyclovir, ampicillin ± sulbactam, azithromycin, cefepime, cefoperazone, cisplatin, diazepam, furosemide, gallium nitrate, hydralazine, regular insulin, levofloxacin, minocycline, nutrient admixtures, pantoprazole, propofol, sulfamethoxazole-trimethoprim, and thiopental sodium.

Morphine sulfate has been shown to physically **incompatible** when admixed with the following: aminophylline, chlorothiazide sodium, fluorouracil, heparin sodium, meperidine HCl, phenobarbital sodium, phenytoin sodium, sodium bicarbonate, and thiopental sodium.

Morphine sulfate has been shown to have **variable** compatibility and should be used cautiously when admixed with alteplase.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 1 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

NOTE: Accurate record keeping is required regarding use and disposition of stock. Report dispensing to state monitoring programs where required.

Morphine Sulfate for Injection: 1 mg/mL, 2 mg/mL, 4 mg/mL, 5 mg/mL, 8 mg/mL, 10 mg/mL, and 50 mg/mL in ampules, vials, sy-

ringes, and prefilled IV bags in sizes that range from 1 mL to 250 mL depending on manufacturer and concentration; generic; (Rx; C-II)

Morphine Sulfate for Injection (preservative-free): 0.5 mg/mL: 10 mL ampules; 1 mg/mL: 10 mL ampules and vials, 30 mL vials and syringes; 2 mg/mL: 1 mL syringes; 4 mg/mL: 1 mL syringes and vials; 5 mg/mL: 30 mL vials; 8 mg/mL: 1 mL syringes and vials; 10 mg/mL: 1 mL syringes and vials, 20 mL ampules; 25 mg/mL: 20 mL ampules and vials; *Duramorph®*, *Infumorph®*, *Astramorph PF®*, generic; (Rx, C-II)

Moxidectin/Moxidectin Combination Products

(mox-i-***dek***-tin) *Cydectin®, ProHeart®, Quest®; Advantage Multi®, Bravecto® Plus, Simparica Trio®*

Macrocyclic Lactone Antiparasitic

Prescriber Highlights

- ► Milbemycin-class antiparasitic that is FDA-approved for use in cattle, dogs, cats, ferrets, sheep, and horses
- ► Contraindications include hypersensitivity to the drug, or in female dairy cattle of breeding age, veal calves, and horses intended for food purposes or foals younger than 4 months of age. Use with extreme caution in sick, debilitated, or underweight animals.
- ► Adverse effects with oral and topical formulations in dogs potentially include lethargy, vomiting, ataxia, anorexia, diarrhea, nervousness, weakness, increased thirst, and itching. Adverse effects are minimal in cattle and appear to be minimal in horses at labeled doses. Adverse effects with the injection formulation include swelling and slight edema at the injection site.
- ► Current data indicate moxidectin at labeled doses is safe to use in dogs with the *MDR1* mutation (also known as *ABCB1*-1delta); higher doses may cause neurotoxicity in these dogs.

Uses/Indications

For dogs, an extended-release injectable moxidectin product is FDA-approved for the prevention of heartworm disease caused by *D immitis* and for the treatment of existing larval and adult hookworm (*A caninum, U stenocephala*) infections. A 6-month injectable product (*ProHeart® 6*)[1] is approved for dogs aged 6 months and older, and a 12-month injectable product (*ProHeart® 12*)[2] is approved for dogs aged 12 months and older.

Moxidectin/fluralaner topical solution (*Bravecto® Plus*) is labeled for the prevention of heartworm disease caused by *D immitis*, treatment of intestinal roundworms (*T cati*) and hookworms (*A tubaeforme*), treatment and prevention of flea infestations (*C felis*), and treatment and control of tick infestations (*Ixodes scapularis* [black-legged tick] and *Dermacentor variabilis* [American dog tick]) for 2 months duration in cats 6 months of age and older and weighing 1.2 kg (2.6 lb) or more.[3] In infected cats, a single dose of topical moxidectin/fluralaner was 100% effective at eliminating *Capillaria* spp, hookworm, and *Toxascaris* spp ova and was 99% effective in clearing *T cati* infection.[4]

In dogs and cats, moxidectin/imidacloprid (*Advantage Multi®*)[5,6] is labeled for use as a once-monthly topical solution for the prevention of heartworm disease caused by *D immitis*, as a flea (*Ctenocephalides felis*) adulticide, and for the treatment and control of hookworms (*A caninum*, *U stenocephala)* and roundworms (*T cati, Toxascaris leonina*). In cats, this combination drug is also approved for the treatment of ear mites. In dogs, it is also approved for the treatment of whipworms (*T vulpis*), sarcoptic mange (*Sarcoptes scabiei* var *canis*), and circulating heartworm microfilariae, as well as having been shown to be effective for extra-label treatment of fox lungworm (*Crenosoma vulpis*) in dogs after a single treatment.[7] The moxidectin/imidacloprid combined product is approved for use in cats and kittens 9 weeks of age and older and that weigh at least 2 lb and in dogs and puppies 7 weeks of age and older and weighing 3 to 9 lb.

In ferrets, moxidectin/imidacloprid (*Advantage Multi® for Cats*) is labeled for the treatment and control of adult fleas and flea infestations (*Ctenocephalides felis*) and the prevention of heartworm disease caused by *D immitis*.[5]

Moxidectin/pyrantel/sarolaner (*Simparica Trio®*) is labeled as a monthly oral treatment for the prevention of heartworm disease caused by *D immitis*; treatment and prevention of flea infestations (*C felis*); treatment and control of tick infestations with *A americanum* (lone star tick), *A maculatum* (Gulf Coast tick), *D variabilis* (American dog tick), *I scapularis* (black-legged tick), and *Rhipicephalus sanguineus* (brown dog tick); and treatment and control of roundworms (*T canis, T leonina*) and hookworms (*A caninum, U stenocephala*) in dogs 8 weeks of age and older and weighing 1.3 kg (2.8 lb) or more.[8]

The use of moxidectin in slow-kill protocols for treatment of heartworm infection is no longer recommended and is considered a salvage procedure only for dogs in which melarsomine therapy is not possible or is contraindicated.[9] An accelerated dosage protocol that combined oral doxycycline for 7 to 14 days with topical moxidectin/imidacloprid every 10 to 15 days for 50 to 90 days, followed by monthly administration, was found to eradicate microfilariae and adult heartworms within 3 and 7 months, respectively.[10] Similar results have been noted with monthly topical moxidectin/imidacloprid administration when combined with doxycycline at 10 mg/kg every 12 hours for the first 30 days.[11,12]

Generalized demodicosis in dogs has been treated with extra-label oral moxidectin and increased frequency of administration of the canine topical product. In a systematic review of published clinical trials, the optimal determined treatments for demodicosis were daily oral milbemycin and weekly[13,14] or monthly[15–17] topical moxidectin (± imidacloprid); however, isoxazolines (eg, fluralaner, sarolaner) are as effective as the moxidectin/imidacloprid combination, and have supplanted macrocyclic lactones for the treatment of demodicosis.[14–16,18]

In horses and ponies 6 months of age and older, moxidectin is indicated for the treatment and control of the following stages of GI parasites:

Large strongyles: *Strongylus vulgaris* (adults and L4, L5 arterial stages), *S edentatus* (adults and tissue stages), *Triodontophorus brevicauda* (adults), *T serratus* (adults)

Small strongyles (adults and undifferentiated luminal larvae): *Cyathostomum* spp; *Cylicocyclus* spp; *Cylicostephanus* spp; *Coronocyclus* spp, *Gyalocephalus capitatus* (adults); *Petrovinema poculatus* (adults); undifferentiated lumenal larvae

Encysted cyathostomes: Late L3 and L4 mucosal cyathostome larvae

Ascarids: *Parascaris equorum* (adults and L4 larval stages)

Pin worms: *Oxyuris equi* (adults and L4 larval stages)

Hair worms: *T axei* (adults)

Large-mouth stomach worms: *Habronema muscae* (adults)

Horse stomach bots: *Gasterophilus intestinalis* (second and third instars) and *G nasalis* (third instars)

Resistance to antiparasitic agents is an ongoing problem in horses. Moxidectin has demonstrated efficacy against fenbendazole-resistant adult and encysted cyathostomins and continues to be a founda-

tion for control of strongyle parasites.[19,20] Strongyle egg production is suppressed for 84 days after a single labeled dose of moxidectin. When moxidectin is combined with praziquantel (*Quest® Plus*), additional coverage against *Anoplocephala* spp occurs.

In cattle, moxidectin (topical and injection) is indicated for the treatment and control of the following internal (ie, adult and fourth stage larvae [L4]) and external parasites:

GI roundworms: *Ostertagia ostertagi* (adult and L4, including inhibited larvae), *Haemonchus placei* (adult), *Trichostrongylus axei* (adult and L4), *Trichostrongylus colubriformis* (adult and L4), *Cooperia oncophora* (adult), *C pectinata* (adult), *C punctata* (adult and L4), *C spatulata* (adult), *C surnabada* (adult and L4), *Bunostomum phlebotomum* (adult), *Oesophagostomum radiatum* (adult and L4), *Nematodirus helvetianus* (adult), *Trichuris* spp (adult)

Lungworm: *Dictyocaulus viviparus* (adult and L4)

Cattle grubs: *Hypoderma bovis*, *H lineatum*

Mites: *Chorioptes bovis*, *Psoroptes ovis* (*Psoroptes communis* var *bovis*)

Lice: *Linognathus vituli*, *Haematopinus eurysternus*, *Solenopotes capillatus*, *Bovicola (Damalinia) bovis*

Horn flies: *Haematobia irritans*

Moxidectin for injection (or pour-on, as indicated) is also used to control infections and protect from reinfection of *Haemonchus placei* for 35 days (14 days for pour-on) after treatment, 42 days (28 days for pour-on) after treatment for *Oesophagostomum radiatum*, 14 days (28 days for pour-on) after treatment for *Ostertagia ostertagi*, 14 days after injectable treatment for *Trichostrongylus axei*, and 42 days after treatment for *Dictyocaulus viviparous*. Moxidectin demonstrated efficacy in the treatment of feedlot cattle that were infected with ivermectin-resistant GI nematodes.[21]

In sheep, oral moxidectin is indicated for the treatment and control of adult and L4 stages of *Haemonchus contortus*; *Teladorsagia circumcincta* and *T trifurcate*; *Trichostrongylus colubriformis*, *T axei*, and *T vitrinius*; *Cooperia curticei* and *C oncophora*; *Oesophagostomum columbianum* and *O venolosum*; and *Nematodirus battus, N filicollis,* and *N spathiger*.

Pharmacology/Actions

The primary mode of action of milbemycin drugs is to affect chloride ion channel activity in the nervous system of nematodes and arthropods. The drug binds to receptors that increase membrane permeability to chloride ions, inhibiting the electrical activity of nerve cells in nematodes and muscle cells in arthropods and causing paralysis and death of the parasites.

Milbemycins also enhance the release of gamma-aminobutyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks postsynaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods.

Milbemycins are generally not toxic to mammals, as they do not have glutamate-gated chloride channels and because these compounds do not readily cross the blood–brain barrier in which mammalian GABA receptors occur.

Pharmacokinetics

Moxidectin's metabolism is unknown in small animal species.

Peak moxidectin blood concentrations occur ≈7 to 14 days after administration of either the 6- month or 12-month injection.[1,2] The half-life is 50 days; residual drug concentrations are negligible at the end of the treatment intervals (ie, 6 months for *ProHeart® 6* and 12 months for *ProHeart® 12*).

After topical application in cats, peak moxidectin concentration occurred between 1 to 5 days after administration, and elimination half-life was 20 to 30 days.

In large animal species, moxidectin is metabolized by the liver and excreted in the bile.

In horses, moxidectin may have a duration of action of up to 12 weeks.

In cattle, the drug apparently has a long duration (ie, 14 to 15 days) of plasma residence. A pharmacokinetic study of SC administration in feedlot calves showed a time to peak concentration (T_{max}) of 9.6 hours and elimination half-life of 11 days.[21]

In sheep, elimination half-life is ≈18 days and mean residence time is ≈27 days; pregnancy reduced these values to ≈12 and ≈21 days, respectively.[22]

In alpacas, elimination half-life was ≈12 days after SC administration. Oral bioavailability was 11% relative to SC administration.[23]

In swine, V_d was 89.6 L/kg after IV administration, elimination half-life was ≈10 days after IV administration and 6.2 days after pour-on administration. T_{max} was 1.7 days after pour-on administration.[24]

Because moxidectin is lipophilic (100 times that of ivermectin), the volume of distribution (V_d) is likely to be very high. Animals with very low body fat (eg, neonates, cachectic animals) could potentially have serum concentrations much higher than patients with normal body condition.

Contraindications/Precautions/Warnings

Do not use moxidectin in animals hypersensitive to it, or in sick, debilitated, or underweight animals. Animals with poor body condition (eg, neonates, cachectic animals) may be more prone to adverse effects.

DOGS:

Labeled heartworm preventive doses for the oral (up to 3 µg/kg per month) and topical (2500 µg/kg/month) formulations are safe for all dogs with the *MDR1* mutation (also known as *ABCB1*-1delta; see ***Appendix***).[25] High-dose treatment can be neurotoxic in all dogs, particularly dogs with the *MDR1* mutation.

Moxidectin as a sole agent:

Injectable products (*ProHeart® 6, ProHeart® 12*): Use with caution in dogs with pre-existing allergic disease, including food allergy, atopy, and flea allergy dermatitis. Use with caution when administering the drug concurrently with vaccinations; adverse effects, including anaphylaxis, have been reported following concomitant use of *ProHeart® 6* and vaccinations.[1] Dogs should be tested for existing heartworm infections before this drug is administered; caution should be used if it is administered to heartworm positive dogs. The safety and effectiveness of *ProHeart® 6* have not been evaluated in dogs younger than 6 months of age. *ProHeart® 12* is approved for use in dogs 12 months of age and older.[2] Do not provide an overdose to growing puppies in anticipation of their expected adult weight.

Combination products:

Moxidectin/imidacloprid (*Advantage Multi®*): For the first 30 minutes after application, ensure that dogs cannot lick the product from application sites on themselves or other treated dogs, and separate all treated dogs and other household pets to reduce the risk for accidental ingestion. Ingestion of this product by dogs may cause serious adverse effects, including depression, salivation, dilated pupils, incoordination, panting, and generalized muscle tremors. In dogs sensitive to milbemycin, signs may be more severe and can include coma and death. **Do not use canine products on cats.**[6]

Moxidectin/pyrantel/sarolaner (*Simparica Trio®*): This product contains sarolaner, which is an isoxazoline. This class of drugs has been associated with neurologic adverse effects (eg, muscle tremors, ataxia, seizures), even in dogs with no known history of neurologic problems. Use with caution in dogs with a history of seizures

or neurologic disorder. Dogs should test negative for heartworm infection before being treated with this product, which is not effective against adult *D immitis* infection. This combination product should not be used in dogs younger than 8 weeks of age or weighing less than 1.3 kg (2.8 lb).[8]

CATS:

Moxidectin/imidacloprid (*Advantage Multi® for Cats*): Not indicated for use in cats weighing less than 0.91 kg (2 lb) or in kittens younger than 9 weeks of age. **Do not use canine products on cats**.[5]

Moxidectin/fluralaner (*Bravecto® Plus*): Not indicated for use in kittens younger than 6 months of age and/or weighing less than 1.2 kg (2.6 lb)[3]

FERRETS:

Moxidectin/imidacloprid (*Advantage Multi® for Cats*): Not indicated for use in ferrets weighing less than 0.91 kg (2 lb)[5]

HORSES:

Moxidectin is not for use in horses intended for food purposes and is not labeled for use in foals younger than 6 months of age.[26,27] Extreme caution should be used when administering this product to foals and young and miniature horses, as overdose may result in serious adverse effects.

CATTLE:

Moxidectin injection is not for use in female dairy cattle of breeding age or in calves younger than 8 weeks of age.[28]

SHEEP:

The sheep product should not be used in other animal species, as severe adverse effects, including fatalities in dogs, may result.[29]

Adverse Effects

DOGS:

Moxidectin as a sole agent:

Injectable products (*ProHeart® 6, ProHeart® 12*): Previously, the injectable product (*ProHeart® 6*) was implicated in serious adverse effects. In 2004, at the request of the FDA, the manufacturer instituted a voluntary recall of *ProHeart® 6* after reports of serious adverse effects (including anaphylaxis, liver disease, autoimmune hemolytic disease, convulsions, and death) were discovered to have been caused by contamination from residual solvent. The product reentered the market in 2013 after data analysis and label revision. In 2019, the 12-month injectable product (*ProHeart® 12*) was approved with a restricted distribution program that allows only clinicians to order and administer the product after the clinician and pet owner complete a Risk Mitigation Action Plan (RiskMAP) program. Anaphylaxis, vomiting, diarrhea, listlessness, weight loss, seizures, injection site reactions, and elevated body temperature have been reported. Coughing and dyspnea may occur in heartworm-positive dogs. Elevated BUN, elevated creatinine, elevated liver enzymes, hypoproteinemia, hyperbilirubinemia, and hepatopathy were reported as rare adverse effects; for this reason, the drug should be used cautiously in dogs with renal or hepatic dysfunction.[1,2]

Combination products:

Moxidectin/imidacloprid (*Advantage Multi®*): In heartworm-negative dogs, field studies report pruritus, mild erythema, and a dry residue at the site of application.[6] Some dogs had GI signs (eg, vomiting, diarrhea, anorexia), lethargy, coughing, nasal discharge, or ocular discharge; these signs were postulated to have been caused by drug administration or underlying worm burdens.

Moxidectin/pyrantel/sarolaner (*Simparica Trio®*): This product contains sarolaner, which is an isoxazoline. This class of drug has been associated with neurologic adverse effects (eg, muscle tremors, ataxia, seizures), even in dogs with no known history of neurologic problems. Use with caution in dogs with a history of seizures or neurologic disorder. Adverse effects reported in field safety studies in dogs receiving this oral combination product include vomiting (14.3%), diarrhea (13.2%), and lethargy (8.5%).[8]

CATS:

Moxidectin/imidacloprid (*Advantage Multi® for Cats*): In field studies, behavioral changes (eg, agitation, excessive grooming, hiding, pacing, spinning), discomfort (eg, scratching, rubbing, headshaking), lethargy, hypersalivation, polydipsia, and coughing or gagging were noted. Cats may experience hypersalivation, tremors, vomiting, and decreased appetite if the topical solution is ingested. Postapproval adverse effect reports include pyrexia, tachypnea, hypersalivation, depression/lethargy, application site reactions (eg, alopecia, pruritus, lesions, erythema), decreased appetite, vomiting, bloody stool, hyperactivity, ataxia, trembling, and behavior changes.[5]

Moxidectin/fluralaner (*Bravecto® Plus*): Fluralaner, an isooxazoline, has been associated with neurologic adverse effects (eg, muscle tremors, ataxia, seizures), even in cats with no known history of neurologic problems. Use this product with caution in cats with a history of neurologic disease.[3]

FERRETS:

Moxidectin/imidacloprid (*Advantage Multi® for Cats*): Ferrets may experience lethargy, pruritus/scratching, scabbing, redness, wounds, and/or inflammation at the treatment site, and they may emit a chemical odor.[5]

HORSES:

Adverse effects appear to be nonexistent or minimal in horses given a label-recommended dose of moxidectin.[26,27] A case report in which 4 foals developed CNS depression and coma after receiving high doses has been reported.[30]

CATTLE:

Adverse effects appear to be nonexistent or minimal in cattle given a label-recommended dose of moxidectin.[28,31]

Reproductive/Nursing Safety

DOGS/CATS/FERRETS:

Reproductive studies have demonstrated no evidence of adverse effects on fertility, reproductive performance, or offspring of dogs given moxidectin as a single agent.[1,2]

Safe use of moxidectin combination products has not been evaluated in dogs, cats, and ferrets used for breeding and those that are pregnant or lactating.[3,5,6,8]

CATTLE/HORSES:

Reproductive studies have not demonstrated evidence of adverse effects on fertility, reproductive performance, or offspring in male or female cattle or horses.[26–28,31] After SC injection, ≈5% of a dose given to the cow can be passed to suckling calves. Calves as young as 8 weeks of age showed no signs of toxicity when treated with up to 3 times the recommended dose while nursing from cows being concurrently treated with the label-recommended injection dose of moxidectin.[28]

Overdose/Acute Toxicity

DOGS:

Moxidectin as a sole agent:

Injectable products (*ProHeart® 6, ProHeart® 12*): In safety studies, no clinical signs of moxidectin toxicity were observed in dogs receiving 3 or 5 times the recommended dose.[1,2]

Combination products:

Moxidectin/imidacloprid (*Advantage Multi®*): In safety studies, loose stools, diarrhea, reduced appetite, and vomiting were noted in puppies 7 weeks of age given up to 5 times the labeled dose every 2

weeks. After oral administration of the topical solution, vomiting, nervousness, and neurologic signs (eg, circling, ataxia, tremors) were noted.[6] Topical exposure of up to 5 times the labeled dose did not cause clinical abnormalities in ivermectin-sensitive collies, but neurologic signs (eg, depression, ataxia, mydriasis, salivation) occurred after oral administration of 40% of the label-recommended dose.

Moxidectin/pyrantel/sarolaner (*Simparica Trio*®): Puppies 8 weeks of age receiving 5 times the maximum recommended dose did not have clinically relevant adverse effects.[8] Collies with the *MDR1* mutation (also known as *ABCB1*-1delta) demonstrated signs of avermectin sensitivity (eg, ataxia, muscle fasciculations, mydriasis) after receiving 5 times the label-recommended dose.

CATS:

Combination products:

Moxidectin/imidacloprid (*Advantage Multi*® *for Cats*): Topical overdoses as low as 3 times the label-recommended dose caused lethargy, ataxia, and disorientation in a healthy 9-week-old kitten. Oral ingestion of the topical solution (at the maximum labeled dose) caused vomiting, inappetence, tremor, cough, and/or hypersalivation.[5]

Moxidectin/fluralaner (*Bravecto*® *Plus*): No clinically relevant effects were noted in kittens after topical administration of up to 5 times the labeled dose. Oral administration of the topical solution to kittens and adult cats at the labeled dose caused hypersalivation, vomiting, and transient reduction in food consumption; coughing after administration was also noted in adult cats.

HORSES:

In one report, 5 horses (4 of which were foals) showed clinical signs (eg, coma, dyspnea, depression, ataxia, tremors, seizures, weakness) after receiving an oral moxidectin overdose greater than 1.7 mg/kg (≈4 times the label-recommended dose). Four other horses received an oral overdose of 0.9 – 1.7 mg/kg and did not show clinical signs.[30]

CATTLE:

In studies on cattle, application of the pour-on moxidectin solution at 5 times the label-recommended dose for 5 consecutive days, 10 times for 2 consecutive days, and 25 times for 1 day did not produce any significant adverse clinical or pathological effects.[31] No signs of toxicity were seen in growing cattle that were given up to 5 times the labeled dose of moxidectin injection or in calves as young as 8 weeks of age given 3 times the recommended dose. Mild, transient ataxia occurred in growing cattle given 10 times the recommended injection dose.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

Use caution when administering injectable moxidectin (*ProHeart*® *6 or ProHeart*® *12*) in conjunction with vaccinations, as there is an increased potential for anaphylaxis and other immune-mediated reactions.[1,2]

Although no other specific drug interactions for moxidectin have been reported, the following drug interactions have either been reported or are theoretical in humans or animals receiving ivermectin (a related compound) and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Benzodiazepines**: Effects may be potentiated by moxidectin; use together not advised in humans
- **P-Glycoprotein Inhibitors**: Caution is advised if using moxidectin with other p-glycoprotein inhibitors. Those dogs at risk for the *MDR1* mutation (also known as *ABCB1*-1delta; eg, collies, Australian shepherds, shelties, long-haired whippets, "white feet" breeds) should probably not be given moxidectin with the following drugs (unless determined to be unaffected):
  - Amiodarone
  - Carvedilol
  - Clarithromycin
  - Cyclosporine
  - Diltiazem
  - Erythromycin
  - Itraconazole
  - Ketoconazole
  - Quinidine
  - Spinosad
  - Spironolactone
  - Tamoxifen
  - Verapamil

Laboratory Considerations

- When performing a **fecal egg count reduction (FECR) test** in horses, it is preferable to wait at least 12 weeks after the previous moxidectin administration before collecting another pretreatment sample.[32]

Dosages

DOGS:

Moxidectin 10% (*ProHeart*® *6 or ProHeart*® *12*) labeled indications (label dosage; FDA-approved): 0.05 mL of the constituted suspension/kg SC (delivers moxidectin at 0.17 mg/kg for *ProHeart*® *6* and 0.5 mg/kg for *ProHeart*® *12*).[1,2] Alternate injection sites (either right or left of the dorsum of the neck cranial to the scapula) with subsequent administrations. Calculate the dose based on the dog's weight at the time of treatment; a dose chart in the package insert can be used as a guide. **NOTE**: Clinicians must complete the RiskMAP training and certification program before administering *ProHeart*®. Dogs should be monitored for 30 minutes after injection. Educational materials should be provided to the owners, and the dog should be carefully observed at home for 24 hours following administration.

Frequency of treatment: *ProHeart*® *6* and *ProHeart*® *12* prevent infection by *Dirofilaria immitis* for 6 months and 12 months, respectively.[1,2] *ProHeart*® should be administered within 1 month of the dog's first exposure to mosquitoes. Follow-up treatments can be given every 6 months for *ProHeart*® *6* or 12 months for *ProHeart*® *12* if the dog has continued exposure to mosquitoes and continues to be healthy without weight loss. When switching from a different heartworm preventive product, *ProHeart*® should be given within 1 month of the last dose of the former medication.[1]

Moxidectin 2.5%/imidacloprid 10% (*Advantage Multi*®) label indications (label dosage; FDA-approved): The recommended minimum dose is imidacloprid 10 mg/kg with moxidectin 2.5 mg/kg once a month by topical administration (**NOTE**: See package insert for specific instructions on application and safety).[6] For dogs 1.4 to 4 kg (3 to 9 lb) = 0.4 mL, 4.1 to 9 kg (9.1 to 20 lb) = 1 mL, 9.1 to 24.9 kg (20.1 to 55 lb) = 2.5 mL, 25 to 39.9 kg (55.1 to 88 lb) = 4 mL, 40 to 49.9 kg (88.1 to 110 lb) = 5 mL; dogs weighing more than 49.9 kg (110 lb) should be treated with an appropriate combination for their weight. For prevention of heartworm disease, moxidectin should be administered at 1-month intervals. For treatment and control of intestinal nematode infections, moxidectin should be administered once.

Moxidectin/pyrantel/sarolaner (*Simparica Trio*®) (label dosage; FDA-approved): Chewable tablets are available in sizes for dogs weighing 1.3 to 59.9 kg (2.8 to 132 lb). Each tablet size is formulated to provide minimum dosages of moxidectin 24 µg/kg (0.011 mg/lb), sarolaner 1.2 mg/kg (0.54 mg/lb), and pyrantel pamoate 5 mg/kg (2.27 mg/lb) PO with or without food once monthly.[8]

Canine demodicosis (extra-label): **NOTE**: Isoxazolines (eg, fluralaner, sarolaner) have supplanted avermectins for ectoparasite management.

1. Moxidectin 0.2 – 0.5 mg/kg PO daily (oral dosage forms not available in the US).[33] **WARNING**: Because these doses can cause serious neurotoxicity in dogs with the *MDR1* mutation (also known as *ABCB1*-1delta), it is highly recommended that this mutation be tested for before milbemycins (eg, moxidectin) are used to treat demodicosis in dogs. Because a negative *MDR1* test (normal/normal) does not ensure tolerance to this medication, it is recommended to begin with a test dose of moxidectin 50 µg/kg PO on the first day with gradual daily dose increases of 50 µg/kg until the desired dose is achieved without adverse effects.[34]
2. **Moxidectin 2.5 %/imidacloprid 10% (*Advantage Multi*® *for Dogs*)**: Apply product based on body weight recommendations found on product label once weekly for dogs with juvenile-onset and mild cases of demodicosis.[35] If clinical improvement is not seen in the first few weeks, other therapy (eg, isoxazolines[15]) should be considered.

Ocular *Thelazia callipaeda* (eyeworm) (extra-label): moxidectin 2.5%/imidacloprid 10% (*Advantage Multi*®) applied topically according to product weight-range dose recommendations for label indications; repeat dose 28 days after initial treatment[36]

CATS:

Moxidectin 1%/imidacloprid 10% (*Advantage Multi*® *for Cats*) label indications (label dosage; FDA-approved): The recommended minimum dose is imidacloprid 10 mg/kg with moxidectin 1 mg/kg once a month by topical administration (**NOTE**: See package insert for specific instructions on application and safety).[5] For cats 0.9 to 2.2 kg (2 to 5 lb) = 0.23 mL; 2.3 to 4 kg (5.1 to 9 lb) = 0.4 mL; 4.1 to 8.2 kg (9.1 to 18 lb) = 0.8 mL; cats weighing more than 8.2 kg (18 lb) should be treated with an appropriate combination for their weight. For prevention of heartworm disease, moxidectin should be administered at 1-month intervals. For the treatment and control of intestinal nematode infections, moxidectin should be administered once.

Moxidectin/fluralaner (*Bravecto*® *Plus*) labeled indications (label dosage; FDA-approved): Based on body weight, each applicator contains moxidectin 2 mg/kg and fluralaner 40 mg/kg applied topically as a single dose every 2 months. For cats 1.2 to 2.8 kg (2.6 to 6.2 lb) = 0.4 mL; more than 2.8 to 6.3 kg (6.2 to 13.8 lb) = 0.9 mL; more than 6.3 to 12.5 kg (13.8 to 27.5 lb) = 1.8 mL.[3] Cats weighing more than 12.5 kg (27.5 lb) should be administered the appropriate combination of tubes for their weight. The drug may be administered year-round or, at a minimum, should be administered at 2-month intervals beginning with the cat's first seasonal exposure to mosquitoes.

Feline aelurostrongylosis (*Aelurostrongylus abstrusus*) (extra-label): 1 to 3 topical applications of moxidectin 1% with imidacloprid 10% (*Advantage Multi*® *for Cats*) according to product weight range and applied every two weeks appeared to be effective in the treatment of cats infected with *A abstrusus*.[37,38] Monthly applications also appear to be effective.[39]

Notoedric mange (feline scabies) (extra-label): Moxidectin 1% / imidacloprid 10% (*Advantage Multi*® *for Cats*) according to product label-recommended dosing according to body weight[40]

FERRETS:

Moxidectin 1%/imidacloprid 10% (*Advantage Multi*® *for Cats*) labeled indications (label dosage; FDA-approved): The recommended minimum dose is imidacloprid 20 mg/kg (9 mg/lb) and moxidectin 2 mg/kg (0.9 mg/lb) once a month by topical administration.[5] Only the 0.4 mL applicator tube volume should be used on ferrets; the 0.23 mL applicator tube volume can result in an underdose, and the 0.8 mL size can result in an overdose.

HORSES:

Combination oral gel with or without praziquantel (*Quest*®, *Quest*® *Plus*) label indications (label dosage; FDA-approved): Moxidectin 0.4 mg/kg PO.[26,27] Dial in the weight of the animal on the syringe. Administer gel by inserting the syringe applicator into the animal's mouth through the interdental space and depositing the gel in the back of the mouth near the base of the tongue. After the syringe is removed, the animal's head should be raised to ensure proper swallowing of the gel. Horses weighing more than 680 kg (1500 lb) require additional gel from a second syringe.

CATTLE:

Pour-on label indications (label dosage; FDA-approved): Moxidectin 1 mL (5 mg)/10 kg (22 lb) body weight applied slowly in a narrow strip directly to the hair and skin along the top of the back from the withers to the base of the tail.[31] Application should be made to healthy skin and avoiding mange scabs, skin lesions, or extraneous foreign matter. Varying weather conditions do not affect pour-on efficacy.

Injection label indications (label dosage; FDA-approved): Moxidectin 0.2 mg/kg (1 mL for each 50 kg [110 lb] of body weight) SC under the loose skin in front of or behind the shoulder.[28] Needles ½ to ¾ inch in length and 16 to 18 gauge are recommended. Do not give this product by any other route.

Injection (extra-label): Moxidectin 1 mg/kg SC was more effective against helminths than the labeled dose in feedlot calves, but the authors expressed caution regarding the potential for moxidectin resistance with this dose.[41]

SHEEP/GOATS:

Label indications for sheep (label dosage; FDA-approved): Moxidectin 0.2 mg/kg (1 mL per 5 kg [11 lb] body weight) PO (drench)[42]

Goats (extra-label): Moxidectin dosing in goats should be used at 2 times the oral dose for sheep.[43] In countries in which the injection is licensed for use in sheep, 1.5 times the injectable sheep dose can be given to goats.[44]

NEW WORLD CAMELIDS:

Antiparasitic agent (extra-label): Moxidectin 0.2 mg/kg PO for GI helminths[45]

Monitoring

- Efficacy based on clinical signs and diagnostic testing (eg, FECR testing, fecal flotation, heartworm antigen testing, external parasite elimination)
- For demodicosis, clinical signs and monthly skin scrapings; continue treatment for 4 weeks beyond 2 negative monthly skin scrapings[33]
- Adverse effects
- Fecal egg count reduction testing (FECR testing) for horses and ruminants[49]

Client Information

- If your animal is receiving *ProHeart®* injection, your veterinarian will provide guidance according to the FDA-required RiskMAP program.
- Do not apply topical products to irritated skin.
- Children should not come into contact with the topical small animal products for 30 minutes (*Advantage® Multi for Cats)* to 2 hours (*Bravecto® Plus, Advantage® Multi for Dogs*) after application. For the first 30 minutes after application of *Advantage® Multi* products, ensure that dogs and cats cannot lick the product from application sites on themselves or other treated pets, and separate all treated animals and other pets to reduce the risk for accidental ingestion. Ingestion of this product by dogs or cats may cause serious side effects, including depression, salivation, dilated pupils, incoordination, panting, and generalized muscle tremors. In dogs and cats sensitive to milbemycins, the side effects may be more severe and can include coma and death.
- When using topical products on dogs, cats, and ferrets, part the animal's hair and apply the product directly to the skin at the base of the head (cats and ferrets) or between the shoulder blades (dogs). For dogs weighing more than 9.1 kg (20 lb), apply the solution in 3 or 4 spots that cannot be licked. Do not apply to irritated skin. Pink skin, damp hair, or a powdery residue may be seen temporarily.
- Wash your hands well after application. Contact a physician if any skin irritation occurs in humans.
- Treated cattle can be easily identified by a characteristic purple color of the topical pour-on, which remains for a short period after application. To avoid inadvertent residue, untreated animals should be housed separately from treated animals for the duration of the withdrawal period.
- In horses, oral gels are safe to use when used as directed.
- Moxidectin is toxic to aquatic organisms, including fish. Do not contaminate water by direct application or improper disposal of drug containers. Dispose of containers in an approved landfill site.
- The topical products are flammable; keep away from open flames, heat, sparks, or other sources of ignition.

Chemistry/Synonyms

Moxidectin, a milbemycin-class antiparasitic agent, is a semisynthetic, methoxime derivative of nemadectin. Moxidectin is a white or pale-yellow, amorphous powder that is practically insoluble in water and very soluble in alcohol.

Moxidectin may also be known as CL-301423, *Advantage® Multi*, *Advocate®*, *Barrier®*, *Bravecto® Plus, ComboCare®*, *Coraxis®*, *Cydectin®*, *Imoxi®*, *Midamox®*, *Parasedge® Multi, Quest®*, or *Simparica Trio®*.

Storage/Stability

Store the unconstituted sustained-release injection product at or below 25°C (77°F). Do not expose to light for extended periods of time. After constitution, *ProHeart® 6* is stable for 4 weeks when refrigerated at 2°C to 8°C (36°F-46°F).[1] *ProHeart® 12* is stable for 8 weeks when refrigerated at 2°C to 8°C (36°F-46°F).[2]

The topical solution for small animal species should be stored between 4°C and 25°C (39°F-77°F); avoid excess heat or cold.[5,6] Only open the outer pouch immediately before administration.

The oral gel for horses should be stored at or near room temperature (15°C-30°C [59°F-86°F]); avoid freezing.[26,27] If the product freezes, thaw completely before using. Partially used syringes should have the cap tightly secured.

The topical solution for cattle should be stored at or below room temperature.[31] Do not allow prolonged exposure to temperatures above 25°C (77°F). If the product becomes frozen, thaw completely and shake well before using.

The commercially available injection and the oral drench for sheep should be stored at or below 25°C (77°F) and protected from light.[28,42] The moxidectin solution for injection for sheep should be used within 12 months of first puncture.

Compatibility/Compounding Considerations

When constituting the sustained-release injectable product (*ProHeart®6* or *ProHeart® 12*), the provided diluent must be used and there are very specific directions for proper preparation. Refer to the package insert for more information.[1,2]

Do not mix moxidectin oral drench for sheep with any other product.[42]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Single Agent Products:

Moxidectin 2.5% Topical Solution; *Coraxis®*; (Rx). FDA-approved for use in dogs NADA# 141-417. While this product is still listed in FDA's Green Book of approved animal drugs, it may no longer be commercially available in the United States.

Moxidectin 10% Sustained-Release (microspheres) Injectable: 598 mg/vial with 17 mL diluent vial; *ProHeart® 6*; (Rx).[1] FDA-approved for use in dogs 6 months of age or older. NADA# 141-189

Moxidectin 10% Sustained-Release (microspheres) Injectable: 889 mg/vial with 8 mL diluent vial, and 4444 mg/vial with 40 mL diluent vial; *ProHeart® 12*; (Rx). FDA-approved for use in dogs 12 months of age or older. NADA# 141-519

Moxidectin 0.5% (5 mg/mL) Pour-On for Cattle in 500 mL and 1 L squeeze-measure pour bottles, and 2.5 L, 5 L, and 10 L containers for use with commercial applicators; *Cydectin®*; (OTC). FDA-approved for use in cattle; not to be used in veal calves. No meat or milk withdrawal times required, but the FDA has established tolerances of 50 ppb and 200 ppb for parent moxidectin in muscle and liver, respectively, in cattle. NADA# 141-099

Moxidectin 10 mg/mL Injectable Solution in 200 mL and 500 mL; *Cydectin® Injectable Solution*; (OTC). FDA-approved for use in cattle. Not to be used in female dairy cattle 20 months of age or older, veal calves, or calves younger than 8 weeks of age. Meat withdrawal is 21 days. NADA# 141-220

Moxidectin 1 mg/mL Oral Drench Solution in 1 L and 4 L; *Cydectin® Oral Drench for Sheep*; (OTC).[29] FDA-approved for use in sheep. Not to be used in female sheep providing milk for human consumption. Meat withdrawal is 7 days. NADA# 141-247

Moxidectin Oral Gel containing 20 mg/mL in 14.4 g syringes (sufficient to treat one 680 kg [1500 lb] horse); *Quest®*; (OTC).[26] FDA-approved for use in horses or ponies 6 months of age and older and not intended for food purposes. NADA# 141-087

Combination Products:

Moxidectin 1.4% (14 mg/mL) and Fluralaner 28% (280 mg/mL) Topical Solution in 0.4 mL, 0.9 mL, and 1.8 mL tubes; *Bravecto® Plus*; (Rx).[3] FDA-approved for use in cats and kittens 6 months of age and older. NADA# 141-518

Moxidectin 1% (10 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in three 0.23 mL tubes, six 0.4 mL tubes, and six 0.8 mL tubes; *Advantage Multi® for Cats*, generic; (Rx).[46] FDA-approved for use in cats 9 weeks of age or older and weighing 0.9 kg (2 lb) or more. FDA-approved (0.4 mL only) for ferrets weighing 0.9 kg (2 lb) or more. NADA# 141-254

Moxidectin 2.5% (25 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in six 0.4 mL tubes, six 1 mL tubes, six 2.5 mL tubes, six 4 mL tubes, and six 5 mL tubes; *Advantage Multi® for Dogs*; ge-

neric; (Rx).[47] FDA-approved for use on dogs 7 weeks of age or older and weighing more than 1.4 kg (3 lb). This product may be known as *Advocate®* in some countries. Do not use canine product on cats. NADA# 141-251

Moxidectin 20 mg/mL and Praziquantel 125 mg/mL Oral Gel in 14 g syringes (sufficient to treat one 680 kg [1500 lb] horse); *Quest Plus®*; (OTC). FDA-approved for use in horses or ponies 6 months of age and older and not intended for food purposes. NADA# 141-216

Moxidectin with Pyrantel Pamoate and Sarolaner Chewable (flavored) Tablets for dogs: 1.3 to 2.4 kg (2.8 to 5.5 lb): moxidectin 0.06 mg, pyrantel pamoate 12.5 mg, and sarolaner 3 mg; 2.5 to 4.9 kg (5.6 to 11 lb): moxidectin 0.12 mg, pyrantel pamoate 25 mg, and sarolaner 6 mg; 5 to 9.9 kg (11.1 to 22 lb): moxidectin 0.24 mg, pyrantel pamoate 50 mg, and sarolaner 12 mg; 10 to 19.9 kg (22.1 to 44 lb): moxidectin 0.48 mg, pyrantel pamoate 100 mg, and sarolaner 24 mg; 20 to 39.9 kg (44.1 to 88 lb): moxidectin 0.96 mg, pyrantel pamoate 200 mg, and sarolaner 48 mg; 40 to 60 kg (88.1 to 132 lb): moxidectin 1.44 mg, pyrantel pamoate 300 mg, and sarolaner 72 mg; *Simparica Trio®* (Rx). FDA-approved for use in dogs 8 weeks of age and older and weighing 1.3 kg (2.8 lb) or more. NADA# 141-521

In the United Kingdom and other countries, moxidectin is available in combination with triclabendazole (*Cydectin® TriclaMox*) as topical pour-on solutions for use in sheep and cattle.

HUMAN-LABELED PRODUCTS: NONE

Mycobacterial Cell Wall Fraction Immunomodulator

(my-koe-bak-***tear***-ee-al)
Immunostimulant

Prescriber Highlights

- ► Biologic agent labeled for treatment of mixed mammary tumors and mammary adenocarcinomas in dogs, treatment of sarcoids, equine respiratory disease complex (ERDC), or endometritis in horses, and the reduction of mortality and clinical signs associated with scours in calves.
- ► Contraindications include hypersensitivity and mycobacterial infection.
- ► Use with caution in patients with hyperimmune disease and discontinue use if clinical signs such as urticaria, lymphadenitis, cellulitis, or abscessation develop.
- ► Patients receiving corticosteroids or immunosuppressants may not respond to therapy.
- ► Adverse effects include transient fever, depression, decreased appetite, and localized pain. Hypersensitivity and systemic inflammatory reactions are also possible.

Uses/Indications

Mycobacterial cell wall fraction (MCWF) immunomodulator is USDA-approved for use in dogs, horses, and cattle for a variety of indications. The canine product is approved for the treatment of mixed mammary tumors and mammary adenocarcinomas.[1]

There are multiple equine products with different indications, including treatment of sarcoids, equine respiratory disease complex (ERDC), and treatment of equine endometritis caused by *Streptococcus zooepidemicus*.[2]

Although these are not labeled indications, *Equimune®* has also been used anecdotally in horses as an adjuvant immunostimulant for equine protozoal myeloencephalitis (EPM) treatment and as an adjuvant for herpesvirus vaccines when injected IM at a separate site from the vaccine.

The bovine product is labeled for treatment of neonatal calves 1 to 5 days of age to reduce mortality and clinical signs associated with calf scours caused by enterotoxigenic *Escherichia coli* K99.[3]

Pharmacology/Actions

Mycobacteriaceae have been known for many years to have antitumor activity. Mycobacterial cell wall fractionated compounds are an emulsion of mycobacterial cell wall fractions derived from *Mycobacterium phlei* that have been modified to reduce their toxic and allergic effects but retain their antitumor activity.[1]

Mycobacterial cell wall fractionated compounds require a functional immune system for efficacy.[1] They stimulate the activation of macrophages and thymic lymphocytes which indirectly kill tumor cells through antitumor cytokines. Interleukin-1 release from macrophages is thought to be the primary mediator for their actions.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

Mycobacterial fractionated compounds should not be used in patients with prior hypersensitivity to them or those with mycobacterial infections. They should be used with caution in animals with a history of hyperimmune diseases. Discontinue use of mycobacterial fractionated compounds in animals that develop clinical signs such as urticaria, lymphadenitis, cellulitis, or abscessation.[1–4]

The inflammatory response can occasionally be severe after initial treatment, leading to edema and malaise. Discontinue treatment until clinical signs have resolved.[1]

Patients receiving corticosteroids or immunosuppressants may not respond to treatment.[1,2,4]

Adverse Effects

Adverse effects may occur for 1 to 2 days following and can include fever, drowsiness, and decreased appetite. Local inflammation commonly occurs and can cause pain and tenderness at the injection site. Necrosis and draining may occur in regressing tumors, which can last for several weeks. Anaphylaxis or hypersensitivity reactions are possible[1–4]; severe respiratory inflammatory reactions have also been reported in horses.

Reproductive/Nursing Safety

Some equine products are safe to use in pregnant mares[2,4]; refer to specific labels for detailed information prior to administration. No other information was located. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in animals receiving mycobacterial cell wall fraction (MCWF) immunomodulator and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- ■ **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May reduce the effectiveness of MCWF immunostimulants

- **Corticotropin (ACTH), Cosyntropin**: May reduce the effectiveness of MCWF immunostimulants
- **Immunosuppressive Drugs** (eg, **cyclosporine**): May reduce the effectiveness of MCWF immunostimulants

Laboratory Considerations

- None identified

Dosages

DOGS:

Immunotherapy for mixed mammary tumor and mammary adenocarcinoma (label dosage; USDA-approved): Administer by intratumoral injection only. Using no larger than a 20-gauge needle, infiltrate entire tumor and a small region of adjacent and underlying tissue. Dose varies with tumor size, but 1 mL should be considered a minimum dose. Administer as a single dose 2 to 4 weeks prior to surgery or repeat treatment every 1 to 3 weeks as an alternative to surgery. Discontinue therapy if there is no response after 4 treatments.[1] Mix the emulsion thoroughly prior to administration; inject shortly after mixing, as the emulsion can separate rapidly. As pain may occur from injection, additional anesthetics or analgesics may be used.

HORSES:

NOTE: Various equine products exist. Ensure the correct product is being used for the intended indication via the labeled route. See ***Dosage Forms/Regulatory Status***.

Immunotherapy for sarcoids (label-dosage; USDA-approved): Administer by intratumoral injection only. Using no larger than a 20-gauge needle, infiltrate entire tumor and a small region of adjacent and underlying tissue. Dose varies with tumor size, but 1 mL should be considered a minimum dose. Repeat treatment every 1 to 3 weeks. Discontinue therapy if no response after 4 treatments.[4] Mix the emulsion thoroughly prior to administration; inject shortly after mixing, as the emulsion can separate rapidly. Large pedunculated sarcoids should be debulked by partial excision prior to treatment. As pain may occur from injection, additional anesthetics or analgesics may be used.

Immunotherapeutic agent for the treatment of equine respiratory disease complex (ERDC) (label dosage; USDA-approved): 1.5 mL IV into the jugular vein; may repeat dose in 1 to 3 weeks[2]

Treatment of equine metritis caused by *Streptococcus zooepidemicus* (label dosage; USDA-approved):

a) IV administration: 1.5 mL IV into the jugular vein during the early estrus period[5]

b) Intrauterine instillation: 1.5 mL mL diluted in sterile LRS, 0.9% sodium chloride, water for injection, or semen extender to a total volume of 25 – 50 mL and aseptically instilled into the uterus using a sterile catheter[5]

CATTLE:

Immunotherapeutic treatment for calves 1 to 5 days of age to reduce mortality and clinical signs associated with calf scours caused by enterotoxigenic *Escherichia coli* K99 (label dosage; USDA-approved): 1 mL IV once[3]

Monitoring

- Clinical efficacy: tumor size, metritis improvement, or respiratory infection improvement
- Adverse effects: fever, local reactions, anaphylaxis, appetite suppression

Client Information

- Your animal may be painful around the tumor injection site. As the medicine begins to work, tumors may ooze and drain. If this occurs and is bothersome, contact your veterinarian for further instructions on management.
- Treated animals may have a low-energy level, develop fever, or have a reduced appetite for a few days after treatment. If these signs persist, or are severe, contact your veterinarian.

Chemistry/Synonyms

Mycobacterial cell wall fraction (MCWF) compounds are oil-in-water emulsions containing purified cell wall fractions obtained from *Mycobacterium phlei* that are modified to reduce their toxic and allergic effect.[1] MCWF may also be known as mycobacterial cell wall extract; bacillus Calmette-Guerin, or BCG; *Amplimune®*; *Equimune®; Immunocidin®*; *Immunocidin® Equine;* and *Settle®*.

Storage/Stability

These products should be stored refrigerated (2°C-8°C [36°F-46°F]). Do not freeze. Unused product from vials not labeled for multi-dose use should be discarded after use. The emulsion breaks upon standing and the product must be re-emulsified prior to administration. To re-emulsify to a milky appearance, shake vial or roll syringe between hands.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: These products are USDA-licensed biologics, not FDA-approved products.

Mycobacterial Cell Wall Fraction (MCWF) Immunomodulator products:

Immunocidin®: **Intratumoral injection** for mixed mammary tumors and adenocarcinomas in **dogs**; 1 mg/mL of MCWF in a 2.5 mL vial. Contains gentamicin as a preservative

Immunocidin® Equine: **Intratumoral injection** for sarcoid tumors in **horses**; 5 mL vial. Contains gentamicin as a preservative. Do not administer within 21 days of slaughter.

Equimune®: **IV administration** for Equine Respiratory Disease Complex (ERDC) in **horses**; 1.5 mL single-dose vial. Contains gentamicin as a preservative. Do not administer within 21 days of slaughter.

Settle®: **IV or intrauterine administration** for endometritis in **horses**; 1.5 mL single-dose vial. Contains gentamicin as a preservative. Do not administer within 21 days of slaughter.

Amplimune®: **IV administration** for scours in **calves** 1 to 5 days of age; 5 mL, 20 mL, and 100 mL vials. Contains gentamicin as a preservative. Do not administer within 21 days of slaughter.

HUMAN-LABELED PRODUCTS: NONE

Mycophenolate

Mycophenolate Mofetil (MMF)

(mye-koe-***fen***-oh-late) *Cellcept®*

Immunosuppressant

Prescriber Highlights

- Immunosuppressive drug that may be useful for treating dogs with IMHA, IMTP, glomerulonephritis, myasthenia gravis, or meningoencephalomyelitis of unknown etiology in dogs; potentially useful in cats, but there is little information available on safety or efficacy.
- Limited experience in veterinary medicine, especially in cats or with long-term use
- Adverse effects include GI signs (eg, diarrhea, vomiting, anorexia) most commonly are dose-limiting and can be severe.
- Can be administered PO or IV. Compounding into appropriate oral dosage forms may be needed.
- Teratogenic in humans
- The National Institute for Occupational Safety and Health (NIOSH) classifies mycophenolate as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Although clinical experience using mycophenolate in veterinary medicine has been limited and no large well-controlled studies were located, mycophenolate appears useful in the treatment of a variety of autoimmune diseases, including immune-mediated hemolytic anemia (IMHA),[1-4] immune-mediated thrombocytopenia (IMTP),[5,6] myasthenia gravis,[7,8] meningoencephalomyelitis,[9,10] glomerulonephritis,[11] and pemphigus foliaceous.[12] Mycophenolate has been suggested for use in treating inflammatory bowel disease in dogs; however, the drug's primary adverse effects in dogs are gastritis, diarrhea, and intestinal inflammation. Mycophenolate is also used in anti-rejection protocols for organ transplants in animals. Mycophenolate is often used as part of a combination immunosuppressive therapy protocol in a patient, although it has also been used alone as monotherapy. The drug was ineffective for the treatment of sudden acquired retinal degeneration syndrome (SARDS) in dogs.[13]

In humans, although this drug is used off-label for a variety of autoimmune disease indications, it is labeled only for use in preventing transplant rejection.

Pharmacology/Actions

Mycophenolate mofetil (MMF) is a prodrug that must be hydrolyzed in vivo to mycophenolic acid (MPA) to be pharmacologically active. Mycophenolic acid noncompetitively, but reversibly, inhibits inosine monophosphate dehydrogenase (IMPDH). Two distinct forms of IMPDH exist in the body, including type 1 found in most cells and type 2 existing in activated lymphocytes. Mycophenolic acid has a 5-fold greater affinity for the type 2 IMPDH isoform. Inosine monophosphate dehydrogenase is the rate-limiting enzyme in de novo synthesis of guanosine nucleotides. As T cells and B cells are dependent on de novo synthesis of purines (eg, guanosine) and, unlike other cells, cannot use salvage pathways, proliferative responses of T cells and B cells are inhibited, and suppression of B cell antibody formation occurs, thus inhibiting both cell-mediated and humoral immune responses. These effects enable MPA to inhibit leukocyte recruitment to inflammatory sites and allotransplant tissues.

In a study in juvenile dachshunds, MMF administration did not inhibit proliferating CD5+ T lymphocytes at any time point.[14] In healthy cats, MMF administration resulted in little change in peripheral blood mononuclear cell counts or CD4+/CD8+:T-cell ratios.[15]

Pharmacokinetics

Mycophenolate mofetil is absorbed after oral administration, but limited bioavailability studies in dogs have shown both a wide interpatient and interdose variation. A study performed in a single dog showed bioavailabilities of 54%, 65%, and 87% after administration of 10, 15, and 20 mg/kg of MMF, respectively.[16]

A study in dogs compared the pharmacokinetic parameters of mycophenolic acid (MPA) with its pharmacodynamic effects on inosine monophosphate dehydrogenase (IMPDH) activity in lymphocytes[17]; volume of distribution at steady-state was ≈5 L/kg, but inter-patient variability (±4.5) was wide. Elimination half-life for MPA was ≈8 hours (±4 hours). In a study performed in juvenile dachshunds receiving 13 mg/kg PO, peak MPA concentration occurred within 1 hour of administration, and half-life was 5.5 minutes.[14] Mycophenolic acid is primarily excreted in the urine, both unchanged (≈5%) and as the glucuronide metabolite (≈90%). In this study, the authors concluded that the pharmacokinetic/pharmacodynamic profile of MMF in dogs suggests that an every 8-hour dosing schedule would be required for optimization of immunosuppressive efficacy. However, dosing every 8 hours can be clinically challenging because of the severity of adverse effects, and thus has not entered common clinical usage (see ***Adverse Effects***).

In a study in healthy cats, administration of 20 mg/kg MMF IV as a CRI over 2 hours resulted in all cats forming the active MPA metabolite. Disposition of plasma MPA was highly variable and unpredictable. The major metabolite was a glucoside product, and a glucuronide product was found in only 3 of 6 cats.[18] An in vitro study similarly demonstrated a relative deficiency of MPA glucuronidation in cats.[19]

In humans, oral bioavailability averages 94%; food reduces peak MPA concentrations by 40%.[20] After absorption, MMF is rapidly and completely hydrolyzed to mycophenolic acid. Peak blood concentrations are seen ≈1 to 2 hours after oral administration. Mycophenolic acid 97% protein (albumin) bound and undergoes extensive hepatic metabolism, primarily via glucuronidation. Mycophenolic acid undergoes extensive enterohepatic recirculation, and reactivation to MPA within the gut may result in a second peak blood concentration 4 to 12 hours after administration. Elimination half-life of MPA is ≈17 hours. Metabolites are eliminated primarily via the kidneys.

Contraindications/Precautions/Warnings

Do not use mycophenolate in patients with documented hypersensitivity reactions to mycophenolate. Patients with severe renal dysfunction may require dosage adjustment. Because MMF can cause diarrhea, use with caution in patients with inflammatory bowel disease.

IV mycophenolate must be administered over at least 2 hours; do not give it as an IV bolus or via rapid IV infusion.

In humans, the active metabolite, MPA, is primarily excreted as the MPA-glucuronide metabolite. Mycophenolate should be used with caution in cats because of deficient MPA glucuronidation in this species.

For humans, mycophenolate has a black box warning regarding potential increased risk for lymphoma and serious infection associated with its use. Severe neutropenia has occurred in human transplant patients receiving mycophenolate.

The National Institute for Occupational Safety and Health (NIOSH) classifies mycophenolate as a group II hazardous drug (non-antineoplastic agent representing an occupational hazard to healthcare workers); personal protective equipment (PPE) should be used accordingly to minimize the risk of exposure.[21]

Do not confuse mycophenolate mofetil with mycophenolic acid. A study comparing adverse effects in dogs with MMF capsules and mycophenolate sodium (the sodium salt of mycophenolic acid) enteric-coated tablets demonstrated significantly greater occurrences

and severity of diarrhea, weight loss, and decreased activity in dogs that received the sodium salt enteric-coated tablets.[22]

Adverse Effects

Because of limited experience with mycophenolate in veterinary patients, the adverse effect profile is not well established. At usual doses (10 mg/kg PO twice daily), mycophenolate is usually well tolerated in dogs. Dose-dependent diarrhea appears to be the most common adverse effect, but vomiting, anorexia, lethargy/reduced activity, lymphopenia, papillomatosis, and increased rates of dermal infections can be seen. In a study evaluating MMF in dogs for the treatment of IMHA at a dosage of 10 to 15 mg/kg PO every 8 hours, the authors concluded that the level of GI toxicity observed could not justify the use of MMF with this dosing regimen, despite the fact that 4 of 5 dogs achieved disease remission.[1] Ulcerative colitis may develop.[4] Mild hypersensitivity reactions after IV administration are possible. Because of the drug's immunosuppressive actions, increased systemic infection and malignancy rates are possible, especially with long-term use.

Diarrhea was the most common adverse effect in healthy cats enrolled in mycophenolate pharmacokinetic studies. Diarrhea was less frequent after IV administration and appeared dose related with oral use. Hyporexia was noted in 1 cat. Decreases in PCV and platelet counts have been noted, but the reduced values remained within the reference range.[15,18,23] Hepatopathy and pancreatitis were reported in one cat after receiving MMF for treatment of IMHA.[24]

In humans, the most common adverse effects include constipation, diarrhea, nausea, vomiting, and headache. Hypertension and peripheral edema occur in ≈30% of patients. Leukopenia has been reported in 25% to 45% of patients taking the medication. Other effects that occur more rarely include GI bleeding, severe neutropenia, cough, confusion, tremor, fatal neurologic disease, infection, and malignant lymphoma (0.4% to 1%).

Reproductive/Nursing Safety

Mycophenolate should be avoided, if at all possible, during pregnancy. Mycophenolate is a known teratogen in humans, causing congenital malformations and first trimester pregnancy loss. At doses significantly lower than those used in humans, increased resorptions and malformations were noted in rabbits and rats.

Mycophenolic acid is distributed in rat milk. It is unknown if mycophenolate is safe to use during nursing and it should be considered contraindicated.[25]

Overdose/Acute Toxicity

In acute toxicity studies performed in mice and monkeys, no deaths occurred in oral doses of mycophenolate up to 4000 mg/kg and 1000 mg/kg, respectively. In small animals, acute GI disturbances or neutropenia are possible. Treat supportively, if required. Cholestyramine may increase mycophenolate excretion.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mycophenolate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acyclovir and Valacyclovir**: Increased serum concentrations of acyclovir and the phenolic glucuronide of mycophenolic acid
- **Aminoglycosides** (eg, **amikacin, gentamicin**): In rats, use together induced greater nephrotoxicity.
- **Antacids, Oral (Aluminum-, Calcium-, or Magnesium-Containing)**: Decreased absorption of mycophenolate; separate dosing by at least 2 hours.
- **Azathioprine**: Increased risk for myelosuppression; concurrent use is not recommended.
- **Cholestyramine**: May inhibit enterohepatic recycling of mycophenolate, reducing serum concentrations
- **Immunosuppressive Agents** (eg, **corticosteroids** [eg, **dexamethasone, predniso(lo)ne**], **leflunomide**): Additive immunosuppressant effects could occur
- **Iron (oral)**: Decreased absorption of mycophenolate; separate dosing by at least 2 hours.
- **Lanthanum Carbonate**: May decrease mycophenolate plasma concentrations
- **Probenecid**: Potentially increased serum concentrations of mycophenolic acid and the phenolic glucuronide of mycophenolic acid
- **Proton Pump Inhibitors (PPIs;** eg, **omeprazole, pantoprazole)**: May reduce mycophenolate absorption, decreasing MPA exposure (AUC)
- **Salicylates** (eg, **aspirin, bismuth subsalicylate**): Potentially increased concentrations of free mycophenolic acid
- **Sevelamer**: Decreased absorption of mycophenolate; administer MMF at least 2 hours prior to sevelamer.
- **Telmisartan**: May decrease mycophenolate exposure (AUC)
- **Vaccines, Modified Live**: Vaccines may be less effective; administer vaccines prior to initiating mycophenolate therapy and avoid concurrent use.

The following drugs or drug classes may reduce MPA exposure by inhibiting the enterohepatic recycling of the mycophenolate glucuronide metabolite:

- **Cephalosporins** (eg, **cephalexin, cefpodoxime**)
- **Clindamycin**
- **Cyclosporine**: additive immunosuppressant effects also possible
- **Fluoroquinolones** (eg, **ciprofloxacin, enrofloxacin**)
- **Metronidazole**
- **Rifampin**
- **Penicillins** (eg, **amoxicillin/clavulanate**)
- **Sulfonamides, Potentiated** (eg, **sulfa-/trimethoprim**)

Laboratory Considerations

- No issues noted

Dosages

DOGS:

Immune-mediated hemolytic anemia (extra-label): 8 – 12 mg/kg PO or IV every 12 hours in combination with predniso(lo)ne 2 – 3 mg/kg/day PO (50 – 60 mg/m2/day [NOT mg/kg/day] for dogs greater than 25 kg)[2,4]

Immune-mediated thrombocytopenia (IMTP) (extra-label): 7 – 9 mg/kg PO every 12 hours in combination with predniso(lo)ne (≈2 mg/kg/day)[5,6]

Meningoencephalomyelitis of unknown etiology (extra-label): 10 – 20 mg/kg PO or IV every 12 hours in conjunction with corticosteroids.[9,10] One study described administering MMF IV over 20 minutes using a syringe pump.[10]

Adjunctive immunosuppressive treatment of glomerular disease based on established pathology (extra-label): The International Renal Interest Society (IRIS) consensus statement recom-

mends mycophenolate alone or in combination with prednisolone for peracute and/or rapidly progressive glomerular disease: mycophenolate 10 mg/kg PO every 12 hours. For stable or slowly progressive glomerular diseases, IRIS recommends mycophenolate alone. In the absence of overt adverse effects, therapy should continue for at least 8 weeks before altering or discontinuing the drug. Therapy should be continued in dogs demonstrating a complete or partial response to initial treatment for a minimum of 12 to 16 weeks. Thereafter, consideration should be given to tapering the treatment to a dose/schedule that maintains the response without worsening the proteinuria, azotemia, or clinical signs.[11]

Myasthenia gravis (extra-label): 15 – 20 mg/kg diluted and given IV over 2 to 4 hours every 24 hours until able to swallow, then 10 – 20 mg/kg PO every 12 hours.[7] One retrospective study found that when compared to using pyridostigmine alone, MMF with pyridostigmine did not significantly affect remission rate, time to remission, or survival time.[8]

Aplastic anemia (extra-label): From a case report in a single dog: mycophenolate 10 mg/kg PO every 12 hours. The first effects (improvements in hematocrit) were observed 2 weeks later, and complete remission of all blood cell counts were obtained in ≈3 weeks.[26]

Immune-mediated skin disease (extra-label): Dosages varied, but 10 – 20 mg/kg PO twice daily was typical. Adverse GI effects were noted with higher dosages.[12,27] In one study, dogs that achieved remission still required glucocorticoids.[12]

CATS:

Adjunctive treatment of IMHA (extra-label): From a case report of 2 cats: mycophenolate 10 mg/kg PO every 12 hours.[28] Use for immune-mediated disorders in cats is not recommended by some based on pharmacokinetic and pharmacodynamic data.[15]

Monitoring

- Efficacy
- Baseline and periodic CBCs every 2 to 3 weeks for the first month, then every 2 to 3 months during treatment.[4]
- Baseline and periodic serum chemistry profile, urinalysis, and urine culture
- Signs associated with infection (eg, fever, malaise, inappetence)
- GI effects (eg, inappetence, vomiting, diarrhea)

Client Information

- Preferably give on an empty stomach; if vomiting or lack of appetite occurs, try giving with food.
- Limited experience in veterinary medicine, especially in cats or for long-term use
- Diarrhea, vomiting, and anorexia are the most likely adverse effects and can be severe. If any of these signs persist or are severe, contact your veterinarian.
- Because of concerns that this drug can suppress the immune system and cause birth defects, pregnant women should wear gloves when handling this drug and avoid inhaling dust from capsules or split or crushed tablets. The manufacturer recommends that tablets or capsules not be crushed, split, or opened.
- This medicine is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH) because it may affect the reproductive ability of males or females actively trying to conceive, women who are pregnant or may become pregnant, and women who are breastfeeding. It is recommended to wear gloves when administering this medication to your animal, and wash hands thoroughly afterwards. If you have any concerns about the risks associated with exposure to this medicine, speak with your veterinarian or health care provider.

Chemistry/Synonyms

Mycophenolate mofetil occurs as a white or almost white, crystalline powder. It is sparingly soluble in alcohol and practically insoluble in water at neutral pH; aqueous solubility increases as pH decreases. The pH of mycophenolate for injection after reconstitution is 2.2 to 4.1.

Mycophenolic acid is derived from *Penicillium stoloniferum*.

Mycophenolate mofetil may also be known as RS-61443 or MMF. International trade names include *CellCept®*, *Cellmune®*, *Imuxgen®*, *Munotras®*, *Mycept®*, *Myfortic®*, and *Refrat®*.

Storage/Compatibility

Mycophenolate mofetil tablets and capsules should be stored between 20°C and 25°C (68°F-77°F) and protected from light.

Mycophenolate mofetil powder for oral suspension should be stored between 15°C and 30°C (59°F-86°F), preferably at 25°C (77°F). Once reconstituted with 94 mL of water, the solution may be stored at room temperature or in the refrigerator; do not freeze. The unused drug should be discarded after 60 days. Refer to the product label of generic formulations for specific reconstitution recommendations.

The injectable product should be stored between 15°C and 30°C (59°F-86°F); preferably at 25°C (77°F). Each vial should be reconstituted with 14 mL of 5% dextrose injection; the final volume is ≈15 mL. Gently agitate to dissolve the powder. Mycophenolate injection should not be mixed or given with any other medication or diluent. Administer mycophenolate within 6 hours of dilution. The drug must be administered over at least 2 hours and is not to be given as an IV bolus or via rapid IV infusion. For human use, the manufacturer recommends further diluting with dextrose 5% to a concentration of 6 mg/mL for IV administration. Mycophenolate diluted in dextrose 5% to a final concentration between 1 – 10 mg/mL in PVC bags was stable for seven days when stored under refrigeration or at room temperature.[29]

Compatibility/Compounding Considerations

The manufacturer states that mycophenolate injection should not be mixed or given with any other medication or diluent. The drug appears **Y-site compatible** with buprenorphine, butorphanol, calcium chloride, dexmedetomidine, dobutamine, dopamine, hydromorphone, magnesium sulfate, metoclopramide, metronidazole, ondansetron, potassium chloride, and ranitidine. The drug appears **Y-site incompatible** with amphotericin B, calcium gluconate, cefazolin, dexamethasone sodium phosphate, furosemide, heparin, meropenem, pantoprazole, phenobarbital, and sodium bicarbonate.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Mycophenolate Mofetil Oral Capsules: 250 mg; *CellCept®*, generic; (Rx)

Mycophenolate Mofetil Oral Tablets: 500 mg; *CellCept®*, generic; (Rx)

Mycophenolate Mofetil Powder for Oral Suspension: 200 mg/mL (reconstituted) in 225 mL bottles; *CellCept®*; (Rx)

Mycophenolate Mofetil Lyophilized Powder for Injection: 500 mg in 20 mL vials; *CellCept®*; (Rx)

Mycophenolate is also available as the sodium salt of mycophenolic acid in oral, delayed-release tablets; however, this dosage form cannot be used interchangeably with mycophenolate mofetils.[22]

For the complete list of references, see **wiley.com/go/budde/plumb**

Nalbuphine

(***nal***-byoo-feen) *Nubain®*

Opioid Partial Agonist

See also ***Nalbuphine Ophthalmic***

Prescriber Highlights

- ► Injectable opioid mixed agonist/antagonist used in combination as a premedication prior to general anesthesia in small animal species
- ► May also be used for mild-to-moderate pain relief or to reverse effects of full mu-opioid agonists without complete elimination of analgesic effects
- ► Has a relatively short duration of action in dogs and cats
- ► Use cautiously in patients with hepatic or renal impairment, bradyarrhythmias, or head trauma.
- ► Limited information about its use in veterinary medicine, but appears to be relatively safe and effective in small animal species
- ► Not a controlled substance in the United States

Uses/Indications

Nalbuphine may be used as premedication prior to general anesthesia. It could theoretically be used for analgesia, but it is only effective for relief of mild-to-moderate pain and has a relatively short duration of effect. Nalbuphine may be used to reverse the adverse effects (eg, respiratory depression) of mu-agonists (eg, morphine) while retaining some analgesic effects.

Nalbuphine has been used in dogs epidurally to decrease the MAC of isoflurane and to provide postoperative analgesia for ovariohysterectomy.[1] In calves undergoing surgical castration, nalbuphine reduces some pain-related behaviors but does not eliminate physiological signs of distress.[2]

When compared with other mixed agonist/antagonists (eg, butorphanol, buprenorphine), the potential benefit of nalbuphine is that it is not a controlled substance in the United States; however, there is considerably less clinical experience and published information about its use in animals.

Pharmacology/Actions

Nalbuphine is a synthetic opioid-receptor agonist-antagonist of the phenanthrene series. Nalbuphine binds to kappa-, mu-, and delta-opioid receptors. Its primary analgesic pharmacologic activity is due to its agonist activity at kappa receptors. Nalbuphine can cause respiratory depression, but above a certain dose (30 mg in adult humans), further respiratory depression does not occur.[3]

Nalbuphine does not increase plasma histamine in dogs.[4]

Pharmacokinetics

Nalbuphine has a similar pharmacokinetic profile as morphine.[5] Nalbuphine must be administered parenterally as it has very low oral bioavailability secondary to GI mucosal metabolism and a high first-pass effect. In humans, the onset of action is usually within 3 minutes after IV administration and 15 minutes after SC or IM doses. In humans, plasma half-life is ≈5 hours. Analgesic effects usually last from 3 to 6 hours after a dose. Analgesic duration of action in dogs and cats has anecdotally been reported as significantly shorter than in humans.

In calves, after 0.4 mg/kg IV, half-life, volume of distribution, and clearance were 0.68 hours, 6.8 L/kg, and 114 mL/minute/kg, respectively. Plasma concentrations were only detectable 3 hours after the injection.[2]

In Hispaniolan Amazon parrots, IM dosages of nalbuphine HCl had complete bioavailability. After IV administration, the measured volume of distribution was 2 L/kg and clearance was ≈70 mL per minute/kg. Terminal half-life was ≈20 minutes for both IV and IM doses.[6] A follow-up study using a sustained-release IM form (nalbuphine decanoate 37.5 mg/kg IM) showed a mean terminal half-life of 20.4 hours. Plasma concentrations that could be associated with antinociception (20 ng/mL) were maintained for 24 hours after injection.[7]

Contraindications/Precautions/Warnings

Nalbuphine is contraindicated in patients hypersensitive to it. Severe pain should be treated with other analgesics (eg, mu-opioid agonists). Use nalbuphine cautiously in patients with hepatic or renal impairment, bradyarrhythmias, or head trauma.

When used alone, nalbuphine rarely causes clinically significant respiratory depression, but it should be used with caution in patients with impaired respiratory function or when used concomitantly with other CNS- or respiratory-depressant agents; respiratory depression can be severe in these patients—adequate monitoring is required. Naloxone can reverse nalbuphine-induced respiratory depression.

In humans, nalbuphine is contraindicated in patients with significant respiratory depression, acute or severe asthma, and known or suspected GI obstruction.[3]

Nalbuphine can precipitate withdrawal signs in patients that are physically dependent on opioid drugs. While the potential for abuse of nalbuphine by humans is less than with other opioids (especially mu-receptor agonist agents), there have been reports of diversion, abuse, and dependence. Although there are no special recordkeeping or storage requirements, veterinarians should be alert to this potential.

Adverse Effects

Respiratory depression is unlikely but can occur. Other adverse effects that can be seen with nalbuphine include excitement (high doses), dysphoria, vomiting, and bradycardia.

Reproductive/Nursing Safety

Safe use of nalbuphine during pregnancy has not been established.

Very little drug is excreted into milk, and nalbuphine is considered relatively safe in humans to use while nursing; however, offspring exposed to nalbuphine should be monitored for excess sedation or respiratory depression.[3]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of nalbuphine are rarely serious, particularly when used on an inpatient basis and with adequate monitoring when used with other CNS and respiratory depressant drugs. Respiratory depression can be reversed with naloxone.[3] In humans, single doses of nalbuphine 72 mg SC administered to healthy subjects caused sedation, sleepiness, and mild dysphoria. Oral ingestions are not serious as the drug has low oral bioavailability.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nalbuphine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cimetidine**: Increased nalbuphine effects possible
- **CNS or Respiratory Depressants**: Additive CNS and/or respiratory depression can occur.

- **Mu-Opioid Agonists** (eg, **fentanyl**, **morphine**): Administration of nalbuphine with or following a mu agonist may result in a reduced analgesic effect.

Laboratory Considerations

- Opioid **screening tests.** Nalbuphine may interfere with enzymatic tests.

Dosages

DOGS/CATS:

In combination as a preanesthetic adjunct (extra-label): 0.2 – 0.4 mg/kg IV, IM, or SC in combination with other preanesthetic agents (eg, midazolam, acepromazine, alpha-2 agonists)

Sole agent for mild-to-moderate pain (extra-label): 0.25 – 1 mg/kg IV, IM, or SC.[8] Up to 2 mg/kg IV or IM has been suggested for use in dogs.

CALVES:

Pain relief after surgical castration (extra-label): 0.4 mg/kg IV reduced some pain-related behaviors but did not significantly eliminate signs of distress in calves.[2]

SMALL MAMMALS:

Analgesic (extra-label):
Rabbits, Ferrets: 0.5 – 1.5 mg/kg IV, IM every 4 hours
Guinea Pigs: 1 – 4 mg/kg IM, SC every 3 hours
Gerbils, Mice, Rats, Hamsters: 1 – 2 mg/kg IM, SC every 2 to 4 hours (dosages have been recommended up to 8 mg/kg IM)

Monitoring

- Level of sedation and analgesia
- Respiratory depth and rate especially when used in combination with other respiratory depressant drugs

Client Information

- Nalbuphine is only used in an inpatient setting.

Chemistry/Synonyms

Nalbuphine HCl is a synthetic opioid agonist/antagonist in the phenanthrene series and is structurally related to both naloxone (opioid antagonist) and oxymorphone (opioid agonist). Nalbuphine HCl is soluble in water and ethanol; insoluble in chloroform and ether.

The commercially available injection in 10 mL vials also contains sodium citrate hydrous 0.94%, citric acid anhydrous 1.26%, methyl- and propylparabens 0.2%, and hydrochloric acid to adjust pH to 3.5 to 3.7.

Nalbuphine HCl may also be known as EN-2234A, Nubian (street name), and *Nubain®*.

Storage/Stability

Store intact vials and ampules at 15°C to 30°C (59°F-86°F) and protect from light.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Nalbuphine HCl injection has been found **compatible** with the following IV solutions: dextrose 5% in sodium chloride 0.9%; dextrose 10%; lactated Ringer's solution (LRS); sodium chloride 0.9%.[9]

At usual concentrations, nalbuphine has been found **compatible** with the following drugs (partial listing) when mixed in syringes: atropine sulfate, diphenhydramine, glycopyrrolate, hydroxyzine, lidocaine, midazolam, and ranitidine. Diazepam, ketorolac, and pentobarbital are **incompatible**. Propofol is **compatible** at a 1:1 ratio at Y-site.[9] There are anecdotal reports of syringe mixtures successfully combining nalbuphine with acepromazine, dexmedetomidine, or medetomidine, although published stability data were not located.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Nalbuphine HCl Injectable Solution: 10 mg/mL and 20 mg/mL in 1 mL ampules and 10 mL multi-dose vials; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Naloxone

(nal-***ox***-one) *Narcan®*
Antidote; Opioid Antagonist

Prescriber Highlights

- ► Most effective at reversing pure mu-opioid receptor agonists (eg, fentanyl, morphine); less effective reversal agent for partial opioid agonists (eg, buprenorphine)
- ► Use with caution in animals with pre-existing cardiac abnormalities or patients that are opioid dependent. At reversal dosages, can negate opioid analgesic effects.
- ► Reversal effect may last for a shorter time than opioid effect; monitor and re-dose as needed.

Uses/Indications

Naloxone is used almost exclusively for its opioid reversal effects, but the drug has been investigated for treating other conditions (eg, septic, hypovolemic, or cardiogenic shock). Frequent administration of low-dose naloxone is advocated by some to reverse opioid effects while minimizing consequences of opioid withdrawal. Some have found low-dose naloxone useful in treating postanesthetic dysphoria associated with perioperative opioids,[1] but this practice is somewhat controversial due to the difficulty in distinguishing pain from dysphoria in animal patients. Naloxone has been employed as a test drug to see if endogenous opioid blockade will result in diminished tail chasing or other self-mutilating behaviors.[2]

Pharmacology/Actions

Naloxone is considered a pure opioid antagonist and has no analgesic activity at usual dosages. The drug acts as a competitive antagonist by binding to the mu, kappa, and delta opioid receptor sites, and has its highest affinity for the mu receptor. It also has some GABA antagonistic effects, which can elicit convulsions, although this is usually not clinically relevant.

Naloxone reverses the majority of effects associated with high-dose opioid administration (eg, respiratory and CNS depression). In dogs, naloxone does not reverse the emetic or hypotensive actions of apomorphine.[3]

At higher doses, naloxone has other pharmacologic activity including effects on dopaminergic mechanisms (increases dopamine levels) and GABA antagonism.

Pharmacokinetics

Naloxone is only minimally absorbed when given orally due to an extensive first-pass metabolism. Much higher doses are required if using this route of administration for any pharmacologic effect. When given IV, naloxone has a rapid onset of action (usually 1 to 2 minutes). If given IM, the drug generally has an onset of action within 5 minutes of administration. The duration of action usually persists from 45 to 90 minutes but may have an effect for up to 3 hours.

Naloxone is distributed rapidly throughout the body with high concentrations found in the brain, kidneys, spleen, skeletal muscle, lung, and heart. Naloxone is metabolized in the liver, principally via glucuronidative conjugation, with metabolites excreted into the urine. In humans, the serum half-life is ≈60 minutes, but ≈3 hours in neonates.[4]

Contraindications/Precautions/Warnings

Naloxone is contraindicated in patients hypersensitive to it.[4] It should be used cautiously in animals that have preexisting cardiac abnormalities or that may be opioid dependent. Excessive naloxone doses or abrupt reversal following surgery may result in vomiting, tachycardia, blood pressure changes, ventricular arrhythmias, pulmonary edema, and seizures.[4] The drug should be used cautiously (and in smaller doses) in animals who have received exceedingly large doses of narcotics as it may produce an acute withdrawal syndrome.

Naloxone is reportedly not effective for reversing meperidine-induced seizures. In a case of a dog that received an overdose of meperidine at ten times the labeled dosage, naloxone administration elicited CNS excitement. The authors recommend that naloxone (and butorphanol) should be avoided when normeperidine (active metabolite of meperidine) excitotoxicity is suspected, unless severe respiratory depression is present without a method of ventilatory support available.[5]

Naloxone has not been shown to be an effective therapy to reverse apnea of newborns and its routine use is not recommended. However, if the dam received opioids during parturition, it may reverse opioid-induced respiratory depression.

Large doses of naloxone may be required to reverse the effects of buprenorphine because buprenorphine has a long duration of action due to its slow rate of binding and subsequent slow dissociation from the opioid receptor.[4] Doses 100 times the label dosage have been required to reverse buprenorphine effects in a normal dog.

When used to reduce postoperative dysphoria associated with perioperative opioids, naloxone dose and administration rate must be carefully titrated or hyperalgesia can occur.

Do not confuse nalOXone with nalTREXone.

Adverse Effects

At recommended dosages, naloxone is relatively free of adverse effects in non-opioid dependent patients; however, when used to reverse opioid effects, it can also reverse any analgesic effects of the opioid (see ***Contraindications/Precautions/Warnings***). Because the duration of action of naloxone may be shorter than that of the narcotic being reversed, animals that are being treated for opioid intoxication or with clinical signs of respiratory depression should be closely monitored, as additional doses of naloxone and/or ventilatory support may be required.

Rare cases of noncardiogenic pulmonary edema have been reported following IV administration of naloxone at standard dosages in dogs and humans.[4,6]

Reproductive/Nursing Safety

Naloxone readily crosses the placenta.[4] No embryotoxic or teratogenic effects were observed in mice and rats treated with naloxone hydrochloride during the period of organogenesis. Opioid withdrawal may occur in the fetuses of dams that have received opioids during the course of pregnancy or in those that are or may be opioid-dependent.

It is not known whether the drug is excreted in maternal milk. Although oral absorption of naloxone by the offspring would be unlikely, use with caution when administering to nursing patients. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Naloxone is considered a safe agent with a wide margin of safety, but very high doses have initiated seizures (possibly secondary to GABA antagonism) in a few patients. Abdominal distress (eg, rapid-onset diarrhea, abdominal checking), restlessness, tachycardia and tachypnea, and diaphoresis were noted in horses given naloxone 0.75 mg/kg IV.[7]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving naloxone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Apomorphine**: Emetic effect may be prolonged.[8] Naloxone can reverse the respiratory depressant effects but not the emetic or cardiovascular effects of apomorphine.
- **Clonidine**: Naloxone may reduce the hypotensive and bradycardic effects of clonidine; potentially useful for clonidine overdoses.
- **Meperidine** (overdose): Naloxone may contribute to CNS excitatory effects of normeperidine (meperidine metabolite). In cases where normeperidine excitotoxicity is suspected, avoid use of naloxone (or butorphanol), unless severe respiratory depression is present without a method of ventilatory support.[5]
- **Opioid Agonist-Antagonists** (eg, **butorphanol**, **pentazocine**, **nalbuphine**): Naloxone may also antagonize the effects of these agents (respiratory depression, analgesia).
- **Opioid Partial-Agonists** (eg, **buprenorphine**): Naloxone may also antagonize the effects of these agents (respiratory depression, analgesia), although higher naloxone doses maybe needed. It should not be relied upon to treat respiratory depression caused by buprenorphine.
- **Yohimbine**: Naloxone may increase the CNS effects of yohimbine (eg, anxiety, tremors, nausea, palpitations) and increase plasma cortisol levels.

Laboratory Considerations

None noted

Dosages

DOGS & CATS:

Opioid reversal (extra-label):

a) 0.001 – 0.04 mg/kg IV, IM, SC; the IO route has also been used.[9,10] Dosages up to 0.1 – 0.2 mg/kg have been suggested depending on severity of the patient.[11] IV doses may be repeated every 2 to 3 minutes as necessary for re-narcotization. If given IM or SC, effects may be delayed up to 5 minutes.

b) **As a constant rate infusion (CRI):** 0.001 – 0.004 mg/kg per minute (1 – 4 µg/kg/minute) IV CRI[12]

c) **Respiratory depression in newborns when opioids given to dam:**

i. 0.1 mg/kg IV, SC, or IM; repeat as necessary[13]

ii. **Transmucosal**: Using the 0.4 mg/mL injection, 1 – 2 drops given under tongue or intranasally (approximately 0.2 mg/kg)[14]; repeat as necessary.

d) **During CPR in cases of opioid toxicity or if recent opioids were administered:** 0.04 mg/kg IV; IO may be considered[15]

e) **Postoperative dysphoria**: If the patient is clearly dysphoric or returns to a whining state shortly after opioid administration or if suspicion exists related to the use of high doses of opioid during surgery, a slow titration of IV naloxone can be given to effect. Depending on the size of the patient, either dilute 0.1 mL of the 0.4 mg/mL injection (0.04 mg; 40 µg) into 5 mL sterile saline (to make an 8 µg/mL solution) OR 0.25 mL of the 0.4 mg/mL injection (0.1 mg; 100 µg) into 10 mL sterile saline

(to make a 10 µg/mL). Give 1 mL of the diluted solution IV over 30 to 60 seconds at the Y-site injection port nearest to the patient. Observe patient carefully during infusion. Infusion can be stopped once patient calms or sleeps. Most patients do not require the full 1 mL. Overdosing can induce hyperalgesia. If dysphoria recurs, may need to repeat.[16,17]

f) **Postepidural urinary retention**: 0.01 - 0.04 mg/kg IV can be used to reverse urinary retention that follows epidural morphine.[10]

g) **Adjunctive treatment of postanesthesia hyperthermia in cats** (extra-label): Postanesthesia hyperthermia (ie, exceeding 41.1°C [106°F]) has been treated with naloxone at 0.01 – 0.02 mg/kg IV, IM or SC. Temperatures have returned to normal under 30 minutes.[18]

HORSES:

Opioid reversal (extra-label): 0.01 – 0.05 mg/kg IV; low end of dosing range can limit opioid-induced locomotor activity; upper end may stimulate colonic propulsion. Duration of effect can be very short (under 30 minutes).

RABBITS, RODENTS, SMALL MAMMALS:

Opioid reversal (extra-label): Wide range of anecdotal dosages noted naloxone 0.005 – 0.1 mg/kg; consider an initial dose of 0.01 – 0.02 mg/kg IV, IM, SC, or IP; repeat as necessary.

REPTILES:

Opioid reversal (extra-label): for significant respiratory depression, 0.04 – 0.2 mg/kg SC[19]

Monitoring

- Because the duration of action of naloxone may be shorter than that of the narcotic being reversed, animals that are being treated for opioid intoxication or that have clinical signs of respiratory depression should be closely monitored for re-narcotization, as additional doses of naloxone and/or ventilatory support may be required.
- Respiratory rate/depth
- CNS function
- Pain associated with opioid reversal

Client Information

- Should be used with direct veterinary professional supervision only

Chemistry/Synonyms

An opioid antagonist, naloxone HCl is structurally related to oxymorphone. It occurs as a white to slightly off-white powder with a pK_a of 7.94. Naloxone is soluble in water and slightly soluble in alcohol. The pH ranges of commercially available injectable solutions are from 3 to 4.5.

Naloxone HCl may also be known as N-allylnoroxymorphone, naloxona, EN-15304, naloxoni and by the trade name, *Narcan*®.

Storage/Stability

Naloxone HCl for injection should be stored at room temperature (15 to 30°C) and protected from light.

When given as an IV infusion, dilute naloxone in either dextrose 5% or sodium chloride 0.9%.[4] Sterile water for injection may be used to dilute naloxone injection prior to SC, IM or bolus IV injection.

Compatibility/Compounding Considerations

Naloxone HCl injection **should not** be mixed with solutions containing sulfites, bisulfites, long-chain or high molecular weight anions or any solutions at alkaline pH. Naloxone HCl is reportedly **Y-site compatible** with the following IV solutions and drugs (partial list): D_5W, 0.9% NaCl, lactated Ringer's solution, acetylcysteine, aminocaproic acid, amiodarone HCl, atropine sulfate, calcium salts, dexamethasone sodium phosphate, dexmedetomidine, dobutamine HCl, epinephrine HCl, esmolol, famotidine, heparin sodium, hydrocortisone sodium succinate, lidocaine HCl, mannitol, methylprednisolone sodium succinate, midazolam HCl, ondansetron, potassium chloride, propofol, and sodium bicarbonate.

Naloxone HCl is reportedly **incompatible** or compatibility varies with the following: cefazolin, diazepam, magnesium sulfate, and pantoprazole sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

There were approved products in the past, but these have been discontinued. The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Naloxone HCl Injection: 0.4 mg/mL (400 µg/mL) and 1 mg/mL; generic; (Rx)

Naloxone HCl Auto-Injector: 0.4 mg/0.4 mL and 2 mg/0.4 mL; *Evzio*®; (Rx)

Naloxone Nasal Spray: 2 mg and 4 mg in 0.1 mL single-dose applicators; *Narcan*®; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Naltrexone

(nal-trex-ohne) *ReVia*®

Opioid Antagonist

Prescriber Highlights

- ► Oral opioid antagonist that may be useful in determining if adverse behaviors have a significant endorphin component and for short-term treatment of adverse behaviors. Compounded injection may be an alternative to naloxone for reversing opioid effects.
- ► Contraindications include patients that are physically dependent on opioid drugs, are in hepatic failure, or have acute hepatitis.
- ► Use with caution in patients with hepatic dysfunction or patients with a history of allergic reaction to naltrexone or naloxone.
- ► Relatively free of adverse effects. Potential adverse effects include abdominal cramping, nausea, vomiting, nervousness, joint or muscle pain, skin rashes, and pruritus. Dose-dependent hepatotoxicity is also possible.
- ► May cause clinical signs of withdrawal in physically dependent patients
- ► Oral treatment can be expensive.

Uses/Indications

Naltrexone may be useful in determining if adverse behaviors (eg, self-mutilating or tail-chasing) in dogs or cats have a significant endorphin component. Naltrexone has largely been supplanted for treatment of behavior disorders by other more accepted treatments. Compounded injectable naltrexone may be an acceptable replace-

ment for reversing opioids when commercial naloxone injection is not available. A study in cats found that hourly naltrexone 600 µg/kg IV antagonized the dysphoric and antinociceptive effects of high doses of remifentanil.[1]

Adjunctive use of low-dose oral naltrexone in female dogs with surgically resected mammary carcinoma reduced the incidence of chemotherapy-related adverse effects and improved quality of life.[2]

Due to its long duration of action (approximately twice that of naloxone), naltrexone is preferred in wildlife and zoo animals when potent opioids, such as etorphine and thiafentanil, are used. These potent opioids are long-acting, and the use of naltrexone minimizes the potential of renarcotization, especially when redosing of antagonists is not possible for personnel safety reasons.

Pharmacology/Actions

Naltrexone is an orally available narcotic antagonist. It competitively binds to opioid receptors in the CNS, thereby preventing both endogenous opioids (eg, endorphins) and exogenously administered opioid agonists or agonist/antagonists from occupying the site. Naltrexone may be more effective in blocking the euphoric aspects of the opioids and less effective at blocking the respiratory depressive or miotic effects.

Naltrexone may also increase plasma concentrations of luteinizing hormone (LH), cortisol, and ACTH. In dogs with experimentally induced hypovolemic shock, naltrexone (like naloxone) given IV in high doses increased mean arterial pressure, cardiac output, stroke volume, and left ventricular contractility.[3]

Pharmacokinetics

In humans, naltrexone is rapidly and nearly completely absorbed, but it undergoes a significant first-pass effect as only 5% to 12% of a dose reaches systemic circulation. Naltrexone circulates throughout the body and CSF concentrations are ≈30% of those found in plasma. Approximately 20% to 30% is bound to plasma proteins. Naltrexone is metabolized in the liver primarily to 6-beta-naltrexol, which has some opioid-blocking activity. The metabolites are eliminated primarily via the kidney. In humans, the serum half-life of naltrexone is ≈4 hours and ≈13 hours for 6-beta-naltrexol.[4]

Contraindications/Precautions/Warnings

Naltrexone is contraindicated in patients physically dependent on opioid drugs, in hepatic failure, or acute hepatitis. The benefits of the drug versus its risks should be weighed in patients with hepatic dysfunction or with a history of allergic reaction to naltrexone or naloxone.

Do not confuse NALTREXone with NALOXone.

Adverse Effects

At recommended dosages, naltrexone is relatively free of adverse effects in non-opioid–dependent patients.[4] Some human patients have developed abdominal cramping, nausea and vomiting, nervousness, insomnia, joint or muscle pain, skin rashes, and pruritus. Dose-dependent hepatotoxicity has been described in humans on occasion.[4]

Naltrexone will block the analgesic, antidiarrheal, and antitussive effects of opioid agonist or agonist/antagonist agents. Withdrawal clinical signs may be precipitated in physically dependent patients.

Reproductive/Nursing Safety

In humans, naltrexone crosses the placenta.[4] It is unknown whether it enters human milk; however, animal studies have shown that naltrexone and its metabolite, 6-beta-naltrexol are excreted in the milk of rats dosed orally with naltrexone. Very high doses (5 times the recommended label dose based on body surface area) have caused increased embryotoxicity in some laboratory animals.[4]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Naltrexone appears to be relatively safe even after very large doses. The LD_{50} in dogs after SC injection has been reported to be 200 mg/kg. Oral LD_{50} in species tested ranged from 1.1 g/kg in mice to 3 g/kg in monkeys (dogs and cats not tested). Deaths at these doses were a result of respiratory depression and/or tonic-clonic seizures. Massive overdoses should be treated using GI decontamination protocols when warranted and supportive treatment.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving naltrexone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Opiods** (eg, **etorphine**, **fentanyl, thiafentanil**): May result in decreased opioid effectiveness; naltrexone can be used clinically to reverse adverse opioid effects (eg, CNS or respiratory depression).
- **Yohimbine**: Naltrexone may increase the CNS effects of yohimbine (anxiety, tremors, nausea, palpitations) and increase plasma cortisol concentrations.

Laboratory Considerations

Naltrexone reportedly does not interfere with TLC, GLC, or HPLC methods of determining **urinary opioids** or **quinine**, but can interfere with some enzymatic assays.

Dosages

DOGS:

Adjunctive therapy in behavior disorders (eg, stereotypy); (extra-label): 1.1 – 2.2 mg/kg PO every 8 to 12 hours. Dosage recommendations vary but naltrexone 2 – 5 mg/kg PO once daily[5] or divided every 12 hours have been noted. If using commercially available tablets (50 mg), dose is typically rounded to nearest 25 mg. Tablets can be bitter. **NOTE**: Limited evidence to support use

Adjunctive treatment of surgically resected canine mammary carcinoma (extra-label): 0.1 mg/kg PO every 24 hours for 24 weeks, in addition to chemotherapy with carboplatin[2]

CATS:

Adjunctive therapy in behavior disorders (eg, stereotypy); (extra-label): 25 – 50 mg/cat (NOT mg/kg) PO every 24 hours[6]

Monitoring

- Efficacy
- Liver enzymes if using high doses with prolonged therapy

Client Information

Give this medicine as directed by your veterinarian.

Additional behavior modification techniques may be required to improve undesired behavior and clinical signs. Follow your veterinarian's recommendations.

Chemistry/Synonyms

A synthetic opioid antagonist, naltrexone HCl occurs as white crystals having a bitter taste. 100 mg are soluble in 1 mL of water.

Naltrexone may also be known as EN-1639A, *ReVia*®, and *Vivitrol*®.

Storage/Stability

Naltrexone tablets should be stored at controlled room temperature (15°C-30°C [59°F-86°F]) in well-closed containers.

Compatibility/Compounding Considerations

No specific information noted

Neomycin

(nee-o-***mye***-sin) *Biosol®, Neomix®*

Aminoglycoside Antibiotic

NOTE: *For topical formulations of neomycin, refer to* ***Neomycin Ophthalmic, Triple Antibiotic Ophthalmic, Corticosteroid/Antimicrobial Otic Preparations***

Prescriber Highlights

- ► Orally administered aminoglycoside antibiotic used to treat enteric infections; it is also used for adjunctive treatment of hepatic encephalopathy.
- ► Contraindications include hypersensitivity to aminoglycosides, intestinal obstruction, and use in hindgut fermenters (eg, rabbits, horses).
- ► Adverse effects include ototoxicity, nephrotoxicity, severe diarrhea, and intestinal malabsorption. Long-term use can lead to GI superinfections.
- ► Minimal amounts absorbed via GI tract

Uses/Indications

Orally administered neomycin is indicated to treat enteric infections in cattle, sheep, goats, and swine; it may also be administered orally or as an enema to reduce ammonia-producing bacteria as adjunctive treatment of hepatic encephalopathy. In humans, neomycin is no longer considered a first-line choice for the treatment of hepatic encephalopathy due to lack of evidentiary support and increased risk for nephrotoxicity and ototoxicity compared with other treatment options.[1] Unlike other aminoglycoside antibiotics (eg, amikacin, gentamicin), neomycin is not used for treatment of systemic infections because of poor oral absorption and adverse effect profile.

The World Health Organization (WHO) has designated aminoglycosides as Critically Important (High Priority) antimicrobials for human medicine.[2] The Office International des Epizooties (OIE) has designated aminoglycosides as Veterinary Critically Important Antimicrobial Agents (VCIA) in bee, avian, bovine, caprine, equine, lagomorph, ovine, and swine species.[3]

Pharmacology/Actions

Neomycin has a mechanism of action and spectrum of activity (primarily gram-negative aerobes) similar to the other aminoglycosides, but in comparison with either gentamicin or amikacin, it is significantly less effective against several species of gram-negative organisms, including strains of *Klebsiella* spp, *Escherichia coli*, and *Pseudomonas* spp. Neomycin-resistant bacteria often remain susceptible to amikacin.

More detailed information on the aminoglycoside mechanism of action and spectrum of activity is outlined in the ***Amikacin*** monograph. Neomycin has been shown to decrease the production of ammonia and reduce glutamine activity.[4]

Pharmacokinetics

Approximately 3% of a dose of neomycin is absorbed after oral or rectal (retention enema) administration, but this can be increased if gut motility is slowed or if the bowel wall is damaged. Therapeutic levels are not attained in systemic circulation after oral administration. In humans, growth of gut bacteria is rapidly suppressed following oral administration and persists for 48 to 72 hours. Orally administered neomycin is nearly all excreted unchanged in the feces.

After IM administration, therapeutic levels can be attained with peak levels occurring within 1 hour of dosing. Neomycin apparently distributes to tissues and is eliminated like the other aminoglycosides (see ***Amikacin***). It is minimally protein bound.

Contraindications/Precautions/Warnings

Oral neomycin is contraindicated in the presence of intestinal obstruction or if the patient is hypersensitive to aminoglycosides.

In neonates, orally administered neomycin can yield high systemic levels and corresponding toxic effects; it should be avoided in neonatal patients.

Aminoglycosides are generally considered contraindicated in rabbits and hares, as this class of drugs adversely affects the GI microbiota in these animals. Oral neomycin has been associated with antibiotic-associated diarrhea (enterocolitis) in horses and should not be used in this species.

Long-term use of oral aminoglycosides may result in bacterial or fungal superinfections.

The human product contains a black box warning stating that neurotoxicity, irreversible ototoxicity, and nephrotoxicity can occur after oral administration. The risk for these toxicities is increased with higher neomycin doses and in patients with decreased renal function, advanced age, and dehydration. Neomycin should be avoided in patients that are azotemic or who have any evidence of intestinal bleeding or ulcerations. See package insert for the full warning.[5]

Adverse Effects

Antibiotic-associated diarrhea can occur, and some species may be more susceptible, particularly hindgut fermenters (eg, rabbits, horses). Rarely, oral neomycin may cause ototoxicity, nephrotoxicity, severe diarrhea, and intestinal malabsorption.

Reproductive/Nursing Safety

Aminoglycosides cross the placenta and have very rarely been associated with congenital deafness in humans.[5] The safety of neomycin has not been established in pregnant animals.

Neomycin is excreted in cow's milk following a single IM injection.[5] If used orally, neomycin may negatively alter gut flora and cause diarrhea in nursing offspring; the risk for more serious adverse effects (eg, otoxicity) is unknown.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

An acute overdose of oral neomycin is not expected to result in significant systemic toxicity due to poor oral absorption.[5] Ototoxicity, nephrotoxicity, and severe diarrhea are possible, particularly with prolonged exposure or in patients with underlying renal impairment, advanced age, or dehydration.

For patients that have or are suspected of having experienced an overdose, consultation with a 24-hour poison center specializing in

providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral neomycin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cephalosporins** (eg, **ceftiofur, cephalexin**): Concurrent use may enhance the nephrotoxic effect of neomycin.
- **Cyclosporine**: Neomycin may increase the nephrotoxic potential of cyclosporine.
- **Digoxin**: Oral neomycin may decrease oral digoxin absorption. Separating the doses of the 2 medications may not alleviate this effect. Some human patients (less than 10%) metabolize digoxin in the GI tract, and neomycin may increase serum digoxin levels in these patients. It is recommended that therapeutic drug monitoring be performed if oral neomycin is added or withdrawn from the drug regimen of a patient stabilized on a digitalis glycoside.
- **Mannitol**: Concurrent use should be avoided as it may enhance the nephrotoxic effect of neomycin.
- **Methotrexate**: Absorption may be reduced by oral neomycin but is increased by oral kanamycin (another aminoglycoside).
- **Neuromuscular-Blocking Agents** (eg, **atracurium, pancuronium**): Concomitant use with neuromuscular-blocking agents could potentiate neuromuscular blockade.[6]
- **Ototoxic, Nephrotoxic Drugs**: Although only minimal amounts of neomycin are absorbed after oral or rectal administration, the concurrent use of other ototoxic or nephrotoxic drugs with neomycin should be done with caution. Topical use for the treatment of otitis should be avoided if an intact tympanic membrane has not been confirmed.
- **Penicillin V Potassium** (**oral**): Oral neomycin should not be given concurrently with oral penicillin V potassium, as malabsorption of the penicillin may occur.
- **Vancomycin**: May enhance the nephrotoxic effect of neomycin
- **Vitamin K Antagonists** (eg, **warfarin**): Oral neomycin may decrease the amount of vitamin K absorbed from the gut; this may have ramifications for patients receiving oral anticoagulants.

Laboratory Considerations

- No specific concerns were noted.

Dosages

DOGS/CATS:

Adjunctive treatment of hepatic encephalopathy (extra-label): 20 mg/kg PO every 8 to 12 hours[7]

CATTLE:

Oral administration to treat and control colibacillosis (bacterial enteritis) caused by *Escherichia coli* (label dosage; FDA-approved): 22 mg/kg PO daily[8]; administer to individual animals as a drench in divided doses or mix in drinking water that will be consumed in 12 to 24 hours. Treat for a maximum of 14 days. **NOTE**: One reference states, *Published studies do not support the oral administration of potentiated sulfonamides, tetracyclines or neomycin in the treatment of calf scours.*[9]

SHEEP & GOATS:

Oral administration to treat and control colibacillosis (bacterial enteritis) caused by *E coli* (label dosage; FDA-approved): 22 mg/kg PO daily[8]; administer to individual animals as a drench in divided doses or mix in drinking water that will be consumed in 12 to 24 hours. Treat for a maximum of 14 days.

SWINE:

Oral administration to treat and control colibacillosis (bacterial enteritis) caused by *E coli* (label dosage; FDA-approved): 22 mg/kg PO daily[8]; administer to individual animals as a drench in divided doses or mix in drinking water that will be consumed in 12 to 24 hours. Treat for a maximum of 14 days.

FERRETS:

Susceptible enteric infections (extra-label): 10 – 20 mg/kg PO 2 to 4 times daily[10]

TURKEYS:

Oral administration for control of mortality associated with *E coli* (label dosage; FDA-approved): 22 mg/kg PO daily for 5 days[8]; administer to individual animals as a drench in divided doses or mix in drinking water that will be consumed in 12 to 24 hours.

Monitoring

- Clinical efficacy
- Systemic and GI adverse effects with prolonged use

Client Information

- This medication should **not** be given to horses, hamsters, or rabbits.
- This medicine may be given by mouth with or without food. If your animal vomits or acts sick after receiving the medicine on an empty stomach, give with food or a small treat to see if this helps. If vomiting continues, contact your veterinarian.
- When neomycin is given by mouth for short periods, it is usually tolerated well. Contact your veterinarian if your animal develops diarrhea while taking this medicine.
- Rarely, this medicine can cause hearing loss and damage to the kidneys and nerves when used for long periods of time. Contact your veterinarian if your animal develops hearing loss, a head tilt, weakness, changes in appetite, or with drinking and urination habits.

Chemistry/Synonyms

An aminoglycoside antibiotic obtained from *Streptomyces fradiae*, neomycin is a complex of 3 separate compounds: neomycin A (neamine; inactive), neomycin C, and neomycin B (framycetin). The commercially available product almost entirely consists of the sulfate salt of neomycin B. It occurs as an odorless or almost odorless, white to slightly yellow, hygroscopic powder or cryodessicated solid. It is freely soluble in water and very slightly soluble in alcohol. One mg of pure neomycin sulfate is equivalent to not less than 650 units.

Neomycin sulfate may also be known as fradiomycin sulfate, neomycin sulphate, or neomycini sulfas, *Neo-325®*, *Neo-fradin®*, *Neo-Sol 50®*, *Neomix® 325*, and *Neovet®*.

Storage/Stability

Neomycin sulfate oral solution should be stored at room temperature (15°C-30°C [59°F-86°F]) in airtight, light-resistant containers. Unless otherwise instructed by the manufacturer, oral tablets/boluses should be stored in airtight containers at room temperature.

In the dry state, neomycin is stable for at least 2 years at room temperature.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Neomycin Sulfate; Oral Liquid: 200 mg/mL (140 mg neomycin base/mL); generic. Depending on labeling, FDA-approved for use in cattle, swine, sheep, goats, turkeys, laying hens, and broilers.

Neomycin Sulfate Soluble Powder: 325 g/lb: *Neo-325® Soluble Powder*, *Neovet® 325/100,* and *NeoVet® 325 AG Grade* (includes turkey

label), *Neo-Sol 50*®; (Rx). FDA-approved for use in cattle (not veal calves), swine, sheep, goats, and turkeys (some products).

Check labels for slaughter withdrawals; may vary with product. General withdrawal times (when used as labeled): Cattle = 1 day; sheep = 2 days; and swine and goats = 3 days. Withdrawal period has not been established in pre-ruminating calves. Do not use in calves to be processed for veal. A milk discard period has not been established in lactating dairy cattle. Do not use in female dairy cattle 20 months of age or older.

HUMAN-LABELED PRODUCTS:
Neomycin Sulfate Tablets: 500 mg; generic; (Rx)

Neostigmine

(nee-oh-***stig***-meen) *Bloxiverz*®
Parasympathomimetic (Cholinergic)

Prescriber Highlights

- ► Parasympathomimetic used to initiate peristalsis, empty the bladder, and stimulate skeletal muscle contractions. Also used for diagnosis and treatment of myasthenia gravis and to reverse or treat overdoses of nondepolarizing neuromuscular blocking agents (eg, curare-type).
- ► Contraindications include peritonitis, mechanical intestinal or urinary tract obstructions, late stages of pregnancy, hypersensitivity to this class of compounds, or treatment with other cholinesterase inhibitors.
- ► Adverse effects are cholinergic in nature and dose related and include nausea, vomiting, diarrhea, excessive salivation and drooling, sweating, miosis, lacrimation, increased bronchial secretions, bradycardia or tachycardia, cardiac arrhythmias, bronchospasm, hypotension, muscle cramps, extreme weakness, agitation, restlessness, or paralysis.
- ► Do not confuse cholinergic crisis with myasthenic crisis.
- ► Use may be cost-prohibitive due to significant expense.

Uses/Indications

Neostigmine is labeled for treatment of rumen atony, initiating peristalsis, urinary bladder emptying, and skeletal muscle contraction stimulation in horses, cattle, sheep, and swine.[1] It has also been used in dogs for the diagnosis and treatment of myasthenia gravis and to reverse or treat overdoses of nondepolarizing neuromuscular blocking agents (eg, curare-type).[2] Under experimental conditions in beagles, edrophonium demonstrated better reversal of neuromuscular blocking agents and thus may be preferred over neostigmine for this use[3]; however, the lack of commercial availability of edrophonium may limit its use.

Pharmacology/Actions

Neostigmine competes with acetylcholine for binding of acetylcholinesterase, which forms a carbamyl-ester complex. The neostigmine-acetylcholinesterase complex is hydrolyzed at a slower rate than that of an acetylcholine-acetylcholinesterase complex, resulting in acetylcholine accumulation with a resultant exaggeration and prolongation of its effects. These effects can include increased tone of intestinal and skeletal musculature, stimulation of salivary and sweat glands, bronchoconstriction, ureter constriction, miosis, and bradycardia. Of note, the effects of the neostigmine-acetylcholinesterase complex last longer compared to edrophonium. Neostigmine also has a direct cholinomimetic effect on skeletal muscle. Neostigmine effects may be diminished in patients with metabolic acidosis.[4]

In horses, it has been reported that neostigmine decreases jejunal activity and delays gastric emptying; however, a study in horses given neostigmine 0.008 mg/kg/hour IV CRI reported increased fecal production and urination frequency and no decrease in gastric emptying.[5] The study also found that neostigmine stimulated contractile activity of jejunum and pelvic flexure smooth muscle strips in vitro. Neostigmine's use for treating colon impactions and postoperative ileus is controversial and more studies are necessary to determine its clinical usefulness for these indications in horses.

Pharmacokinetics

After IV administration in dogs, neostigmine is rapidly removed from the circulation. The apparent volume of distribution and clearance are ≈150 mL/kg and ≈6.9 mL/minute/kg, respectively.[6]

In humans, neostigmine effects on peristaltic activity begin within 10 to 30 minutes after parenteral administration and can persist for up to 4 hours. It is ≈15% to 25% bound to plasma proteins, and the half-life is ≈1 hour. Neostigmine is metabolized in the liver and hydrolyzed by cholinesterases to 3-OH PTM, which is weakly active. When administered parenterally, ≈80% of the drug is excreted in the urine within 24 hours, with 50% excreted unchanged.

Contraindications/Precautions/Warnings

Neostigmine is contraindicated in patients with peritonitis, with mechanical obstruction of the intestinal or urinary tract, in animals hypersensitive to this class of compounds, or in animals treated with other cholinesterase inhibitors. Neostigmine is contraindicated in lactating animals.[1]

Use with extreme caution in patients with recent urinary bladder or intestinal surgery. Use with caution in patients with epilepsy, peptic ulcer disease, bronchial asthma, cardiac arrhythmias, hyperthyroidism, vagotonia, or megacolon. In humans, neostigmine has been associated with bradycardia.[7]

Adverse Effects

Adverse effects of neostigmine are dose-related and cholinergic in nature. Postoperative diarrhea may occur in humans that have had neuromuscular blockade reversal.[8] A case report of a dog developing a cholinergic crisis after receiving a dose of neostigmine 0.05 mg/kg SC has been published.[9] For more information on cholinergic signs, see ***Overdose/Acute Toxicity***. Rapid administration to horses increases likelihood of bradycardia and hypotension.[4]

In humans, common adverse effects include hypotension, nausea, and vomiting.[7]

Reproductive/Nursing Safety

No adverse effects on organogenesis were noted in rats or rabbits. In humans, acetylcholinesterase inhibitors given IV to pregnant patients near term may lead to premature labor.[7]

Neostigmine has not been detected in human milk and would not be expected to cross the placenta when given at recommended doses due to its ionization at physiologic pH; however, it is not labeled for use in lactating animals due to risk of milk contamination.[1]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of neostigmine can induce a cholinergic crisis. Clinical signs may include nausea, vomiting, diarrhea, excessive salivation and drooling, sweating (in animals with sweat glands), miosis, lacrimation, increased bronchial secretions, bradycardia or tachycardia, cardiac arrhythmias, bronchospasm, hypotension, muscle cramps and extreme weakness, agitation, restlessness, or paralysis. Death may occur secondary to respiratory paralysis. In patients with myasthenia gravis, it may be difficult to distinguish between a cholinergic crisis and myasthenic crisis.

Treat a cholinergic crisis by temporarily ceasing neostigmine therapy and instituting treatment with atropine. Maintain adequate ventilation using mechanical assistance if necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving neostigmine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Atropine**: Atropine will antagonize the muscarinic effects of neostigmine and some clinicians routinely use the two together, but concurrent use should be done cautiously as atropine can mask the early clinical signs of a cholinergic crisis.
- **Beta-Blockers** (eg, **atenolol, propranolol**): May increase risk for bradycardia or hypotension caused by beta-blockers. Beta-blockers may worsen clinical signs of myasthenia gravis and reduce efficacy of neostigmine.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May decrease the anticholinesterase activity of neostigmine; after stopping corticosteroid therapy, neostigmine may cause increased anticholinesterase activity
- **Dexpanthenol**: Theoretically, dexpanthenol may have additive effects when used with neostigmine.
- **Magnesium**: Anticholinesterase therapy may be antagonized by administration of parenteral magnesium therapy, as it can have a direct depressant effect on skeletal muscle.
- **Muscle Relaxants**: Neostigmine may prolong the Phase I block of depolarizing muscle relaxants (eg, **succinylcholine, decamethonium**) and neostigmine antagonizes the actions of nondepolarizing neuromuscular blocking agents (eg, **pancuronium, tubocurarine, gallamine, vecuronium, atracurium**). Effect may be seen with certain antibiotics that also possess mild nondepolarizing blocking effects (eg, **aminoglycosides, clindamycin**).
- **Tetracyclines, Lincomycin, and Clindamycin**: These drugs can enhance the blockade of neuromuscular blocking agents. This blockade is difficult to reverse with neostigmine in the presence of these antibiotics.[10]

Laboratory Considerations

- No specific concerns noted

Dosages

DOGS/CATS:

Diagnosis of myasthenia gravis (extra-label): From a retrospective study, 0.01 – 0.05 mg/kg SC, IM, IV[2]; IV administration should be over 1 minute. Some pretreat with atropine, but this must be done with caution as it can mask the early signs associated with a cholinergic crisis. If clinical improvement occurs in 15 to 30 minutes, it is suggestive of a diagnosis.

Treatment of myasthenia gravis when administration of oral pyridostigmine is not possible (extra-label): If pyridostigmine is not available or oral medication cannot be given in actively regurgitating animals: neostigmine 0.04 mg/kg IM, SC every 6 hours.[2] (**NOTE**: Currently available human products are only labeled for IV use, to be given over 1 minute.)

Adjuvant epidural analgesia for orthopedic surgery in dogs (extra-label): neostigmine 5 µg/kg epidurally with morphine 0.1 mg/kg administered at the end of surgery resulted in improved pain scores and fewer doses of rescue analgesia.[11]

Reversal agent for neuromuscular blockade in dogs (extra-label): **NOTE**: use for this indication should be limited to individuals familiar with neuromuscular blockade and Train of Four (TOF) monitoring.

a) Neostigmine 0.01 – 0.1 mg/kg IV (over 1 minute) in combination with atropine 0.02 mg/kg IV or glycopyrrolate 0.01 mg/kg IV[4]

b) Neostigmine 0.02 – 0.07 mg/kg IV in combination with atropine 0.03 mg/kg IV. Reversal time was 5 to 10 minutes and was faster when higher doses of neostigmine were used.[12]

HORSES:

Initiating peristalsis to cause evacuation of the bowel; emptying the urinary bladder; and stimulating skeletal muscle contractions (label dosage; FDA-approved): 1 mg/45.3 kg (100 lb) of body weight SC; repeat as indicated[1]

Reversal agent for neuromuscular blockade (extra-label): 0.007 mg/kg IV over 1 to 2 minutes is recommended. Reversal should not be attempted until some degree of spontaneous recovery has been established and ECG monitoring is in use; atropine should be readily available.[4,13-15] Edrophonium is preferred to neostigmine due to its shorter duration of action and milder muscarinic effect, which may reduce the need for administration of anticholinergic drugs; however, the lack of commercially available edrophonium may limit its use.

Decrease clinical signs associated with botulism A toxin (extra-label): From a case report, neostigmine 0.025 mg/kg SC 3 times daily improved palpebral reflexes and tongue and tail tone. Although the horse regained limited ability to stand and defecate, neostigmine did not restore chewing and swallowing function.[16]

Adjuvant for epidural injection (extra-label): 1 µg/kg combined with 2% lidocaine 0.2 mg/kg epidurally provided analgesia for ≈2.5 hours with moderate ataxia.[17,18]

CATTLE:

Rumen atony; initiating peristalsis to cause evacuation of the bowel; emptying the urinary bladder; and stimulating skeletal muscle contractions (label dosage; FDA-approved): 1 mg/45.3 kg (100 lb) of body weight SC; repeat as indicated[1]

SWINE:

Initiating peristalsis to cause evacuation of the bowel; emptying the urinary bladder; and stimulating skeletal muscle contractions (label dosage; FDA-approved): 2 – 3 mg/45.3 kg (100 lb) of body weight IM; repeat as indicated[1]

SHEEP:

Rumen atony; initiating peristalsis that causes evacuation of the bowel; emptying the urinary bladder; and stimulating skeletal muscle contractions (label dosage; FDA-approved): 1 – 1.5 mg/45.3 kg (100 lb) of body weight SC; repeat as indicated[1]

Monitoring

Dependent on reason for use:

- Adverse effects
- Clinical efficacy

Client Information

- Neostigmine should only be administered by a veterinary professional under close monitoring.

Chemistry/Synonyms

Synthetic quaternary ammonium parasympathomimetic agents, neostigmine bromide and neostigmine methylsulfate both occur

as odorless, bitter, white, crystalline powders that are very soluble in water and soluble in alcohol. The melting point of neostigmine methylsulfate is 144°C-149°C (291.2°F-300.2°F). The pH of the commercially available neostigmine methylsulfate injection is from 5 to 6.5.

Neostigmine methylsulfate may also be known as neostigmine metilsulfate, neostigmine methylsulphate, neostigmini metilsulfas, proserinum, *Bloxiverz®*, *Prostigmin®*, *Prostigmina®, or Stiglyn®*.

Storage/Stability

Neostigmine methylsulfate injection should be stored at room temperature (20°C-25°C; 68°F-77°F) with excursions permitted between 15°C and 30°C (59°F-86°F). Protect from light; avoid freezing.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Neostigmine methylsulfate injection is reportedly physically **Y-site compatible** with the following IV replacement solutions and drugs: 0.9% sodium chloride, heparin sodium, hydrocortisone sodium succinate, and potassium chloride.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

Historically, there was an approved injectable product (*Stiglyn®* 1:500), but although still listed in FDA's Green Book, it does not appear to be marketed.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Neostigmine Methylsulfate Injection: 0.5 mg/mL and 1 mg/mL in 10 mL vials; *Bloxiverz®*, *Prostigmin®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Niacinamide

Nicotinamide

(nye-a-***sin***-a-mide)

Immunomodulator; Nutritional; Vitamin

Prescriber Highlights

- ► Used in combination with a tetracycline for a variety of sterile inflammatory and autoimmune conditions in dogs
- ► Possible contraindications include seizures, liver disease, active peptic ulcers, or hypersensitivity to the drug.
- ► Adverse effects include anorexia, vomiting, and lethargy; rarely increases in liver enzymes.
- ► Clinical response may be gradual and take at least 6 to 8 weeks.
- ► Nicacinamide is inexpensive, but 3 times daily dosing may be problematic for some owners.

Uses/Indications

Niacinamide is used in conjunction with a tetracycline antibiotic (eg, tetracycline, doxycycline) in controlling a variety of sterile inflammatory or autoimmune conditions in dogs. Some examples of indications include localized and generalized discoid lupus erythematosus (DLE),[1,2] cutaneous vesicular lupus erythematosus,[3] sterile granulomatous/pyogranulomatous syndrome, sterile nodular panniculitis,[4] cutaneous reactive histiocytosis,[5] pemphigus complex,[6] mucous membrane pemphigoid,[7,8] idiopathic symmetrical (lupoid) onychodystrophy/onychitis,[9] metatarsal fistulae, vasculitis, arteritis of the nasal philtrum,[10] sebaceous adenitis, dermatomyositis,[11] nodular granulomatous conjunctivitis,[12] and chronic ulcerative paradental stomatitis (CUPS).[13]

Controlled prospective studies demonstrating clear efficacy are lacking, but niacinamide appears effective in some patients, including 70% of dogs treated for DLE in one study.[2] It is often used in conjunction with other immunomodulating drugs such as glucocorticoids[1] or omega-3 fatty acids, especially in the initial treatment phase. Niacinamide may be particularly efficacious for milder disease forms or as a steroid-sparing agent. It may take 6 to 8 weeks of using niacinamide (with a tetracycline) before efficacy is noted.

Pharmacology/Actions

Niacinamide is an essential nutrient in humans; it is necessary for lipid metabolism, tissue respiration, and glycogenolysis. Its primary pharmacologic use (in combination with a tetracycline) for autoimmune disorders in dogs is secondary to its ability to block IgE-induced histamine release and degranulation of mast cells. When niacinamide is used with a tetracycline, it may suppress leukocyte chemotaxis secondary to complement activation by antibody-antigen complexes. It also inhibits phosphodiesterases and decreases the release of proteases.

Niacinamide is a product of niacin metabolism. Although niacinamide and niacin act identically as vitamins, at higher (pharmacologic) doses, they exert different effects. For example, niacinamide does not affect blood lipid levels or the cardiovascular system.

Pharmacokinetics

Niacinamide is absorbed well after oral administration and widely distributed to body tissues. Niacinamide is metabolized in the liver to several metabolites that are excreted into the urine. At physiologic doses, only a small amount of niacinamide is excreted into the urine unchanged, but as dosages increase, larger quantities are excreted unchanged.

Contraindications/Precautions/Warnings

In humans, niacinamide therapy is contraindicated in patients with liver disease, active peptic ulcers, or hypersensitivity to the drug.

Use niacinamide/tetracycline drug combination with caution, or avoid use, in dogs with a seizure history.

Do not confuse niacinamide with niacin (see ***Pharmacology/Actions***).

Adverse Effects

Adverse effects of niacinamide in dogs are uncommon, but may include anorexia, vomiting, diarrhea, and lethargy. Administration of niacinamide with food may help alleviate adverse GI effects. Occasionally, increases in liver enzymes may be noted; loss of glycemic control is possible in diabetic patients, although documentation of this adverse effect was not located. There have been some anecdotal reports of increased seizure frequencies in dogs.[5] Because niacinamide is used clinically in combination with a tetracycline, adverse effects noted may be due to niacinamide and/or the tetracycline.

Reproductive/Nursing Safety

Although niacinamide alone should be safe to use in pregnant and lactating animals, its use in combination with a tetracycline may not be safe.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Niacinamide overdoses are unlikely to cause adverse effects other than acute GI distress.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Niacinamide and tetracycline treatment does not interfere with antibody production associated with routine vaccinations in dogs.[14] Also see ***Tetracycline, Doxycycline,*** *or* ***Minocycline*** monographs for additional drug interactions if using combination therapy.

The following drug interactions have either been reported or are theoretical in humans or animals receiving niacinamide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- Insulin/Oral Antidiabetic Agents (eg, **glipizide, metformin**): In diabetic humans, dosage increases for insulin or oral antidiabetic agents have sometimes been necessary after initiating niacinamide therapy; significance in veterinary patients is unknown.

Laboratory Considerations

- Potentially could interfere with intradermal or serum **allergy testing**; withdraw the drug 1 to 2 weeks before testing.

Dosages

DOGS:

Adjunctive treatment of sterile inflammatory or autoimmune diseases (extra-label): Niacinamide is typically used in combination with a tetracycline. Recommended dosages are empirical and vary.

- **Dogs 10 kg (22 lb) or less:** Niacinamide 250 mg/dog (NOT mg/kg) PO 3 times daily in combination with tetracycline 250 mg/dog (NOT mg/kg) PO 3 times daily[5]
- **Dogs more than 10 kg (22 lb):** Niacinamide 500 mg/dog (NOT mg/kg) PO 3 times daily in combination with tetracycline 500 mg/dog (NOT mg/kg) PO 3 times daily[5]

NOTES:

1. If efficacious, may reduce niacinamide dose to twice-daily administration and then taper further over time when possible.
2. Tetracycline may be replaced with doxycycline 5 – 10 mg/kg PO every 12 hours OR minocycline 5 – 10 mg/kg PO every 12 hours.[15]
3. Some clinicians have used 15 kg (33.1 lb) as the weight cutoff (ie, dogs 15 kg [33.1 lb] or less receive 250 mg/dog [NOT mg/kg]; dogs more than 15 kg [33.1 lb] receive 500 mg/dog [NOT mg/kg]).[9] Other clinicians have suggested niacinamide 45 mg/kg PO every 8 hours in combination with tetracycline 45 mg/kg PO every 8 hours.[1]

Monitoring

- Efficacy: Clinical response may be gradual and take up to 6 to 8 weeks.
- Adverse effects (baseline and occasional monitoring of liver enzymes is suggested), particularly when combined with other drugs that may increase liver enzymes such as doxycycline or minocycline

Client Information

- Niacinamide is used in dogs in combination with a tetracycline for treatment of a variety of serious skin conditions and other autoimmune diseases.
- Give as directed to your animal; usually 3 times daily at first. Improvement may be gradual and may take up to 6 to 8 weeks.
- Side effects from niacinamide are rare. Vomiting, diarrhea, and reduced appetite (eating less than normal) are the most common side effects. When niacinamide is used in combination with a tetracycline, the risk for side effects is greater and includes lethargy (tiredness or lack of energy) and, rarely, liver problems.
- Be careful to purchase the correct product; niacinamide is not the same as niacin (which is more readily available).
- Your veterinarian will need to monitor your animal with recheck examinations while it is receiving this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

Niacinamide, also commonly known as nicotinamide, occurs as a white crystalline powder. It is odorless or nearly odorless and has a bitter taste. It is freely soluble in water or alcohol.

Niacinamide may also be known as nicotinamide, nicotinamidum, nicotinic acid amide, nicotylamide, vitamin B (3), or vitamin PP.

Storage/Stability

Store niacinamide tablets in tight containers at room temperature unless otherwise labeled. Niacinamide is **incompatible** with alkalis or strong acids.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Niacinamide Tablets and Capsules: 100 and 500 mg; generic; (OTC)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Nitazoxanide

(nye-tah-***zox***-ah-nide)

Antiparasitic Agent

Prescriber Highlights

- ► Drug that has activity against a variety of protozoa, nematodes, bacteria, and trematodes, including *Sarcocystis neurona*, *Giardia* spp, *Cryptosporidia* spp, and *Helicobacter pylori*
- ► Historically approved for use in horses for equine protozoal myeloencephalitis (EPM), but veterinary paste no longer marketed
- ► Interest in using in other companion animals (eg, dogs, cats), but data are lacking to support use
- ► Adverse effects in dogs include GI (eg, hypersalivation, vomiting, diarrhea), which may be therapy limiting.

Uses/Indications

Nitazoxanide may be useful as an alternative treatment for cryptosporidiosis in cats. A single nitazoxanide dose reduces shedding of *Giardia* spp cysts and *Cryptosporidium* spp oocysts in dogs.[1] Because of the drug's spectrum of activity and apparent safety, there is potential for using it in a variety of companion animal species, but data are lacking for specific indications and dosages.

Nitazoxanide oral paste was approved for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*, but the product is no longer marketed in the United States.

In humans, nitazoxanide is FDA-approved to treat diarrhea caused by *Cryptosporidium parvum* and *Giardia lamblia.*

Pharmacology

Although the precise mechanism of action of nitazoxanide is unknown, its active metabolites (tizoxanide and tizoxanide glucuronide) are thought to inhibit the pyruvate ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reactions essential to anaerobic energy metabolism. Nitazoxanide has activity against a variety of protozoa, nematodes, bacteria, and trematodes, including *Sarcocystis neurona, Giardia* spp, *Cryptosporidia* spp, and *Helicobacter pylori*.

Pharmacokinetics

Following oral administration in horses, nitazoxanide is absorbed and rapidly converted to its active metabolite (tizoxanide [desacetyl-nitazoxanide]). Peak concentrations of tizoxanide are attained between 2 to 3 hours and are not detectable by 24 hours postadministration. In humans, nitazoxanide is not detectable in plasma, but peak concentrations of tizoxanide and tizoxanide glucuronide occur ≈3 to 4 hours postadministration. More than 99% of tizoxanide is bound to plasma proteins. Tizoxanide is excreted in the urine, bile, and feces; the glucuronide metabolite is secreted in the urine and bile.

Contraindications/Precautions/Warnings

Nitazoxanide is contraindicated in patients that are hypersensitive to it. Safety for use in animals with compromised renal or hepatic function has not been established; use with caution.

Do not confuse niTAZOXanide with niZATidine.

Adverse Effects

In cats, GI irritation can occur.

In a study using nitazoxanide in 9 dogs with naturally occurring *Giardia* spp infections, 5 of the dogs developed excessive salivation, vomiting, or diarrhea that resulted in removal from the study.[2]

In humans, nitazoxanide appears to be well tolerated and adverse effect rates are similar to placebo. Rarely, sclera may turn yellow secondary to drug disposition (not jaundice) but return to normal after drug discontinuation.

Reproductive/Nursing Safety

Reproduction studies have been performed using dosages of up to 3200 mg/kg/day PO in rats (≈48 times the clinical dose adjusted for body surface area) and 100 mg/kg/day PO in rabbits (≈3 times the clinical dose adjusted for body surface area) and have revealed no evidence of impaired fertility or harm to the fetus due to nitazoxanide.[3] It is unknown if nitazoxanide is excreted into milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

There is limited information available on the acute toxicity of nitazoxanide. It has been reported that overdoses of 2.5 times in horses have been associated with fatalities. The oral LD_{50} for dogs and cats is greater than 10 g/kg. Repeated doses of 450 mg/kg in rats caused intense salivation and increased liver and spleen weights. In a study of horses given ≈5 times the label-recommended dose, all of the horses developed anorexia, diarrhea, and lethargy, and testing was halted after 4 days of study. Human volunteers have taken doses of up to 4 g without significant adverse effects occurring.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nitazoxanide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Highly Protein Bound Drugs** (eg, **NSAIDs [eg, meloxicam], salicylates, sulfonamides** [eg, **sulfadimethoxine**], **warfarin**): Because nitazoxanide is highly protein bound, it could theoretically displace other highly bound drugs, causing a transient increase in serum concentrations of each drug. These interactions are unlikely to be of clinical concern because increased free drug concentrations will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.

Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

Dosages

DOGS:

***Giardia* spp associated diarrhea** (extra-label): 75 – 150 mg/kg PO once[1]

***Cryptosporidia* spp associated diarrhea** (extra-label): 75 – 150 mg/kg PO once[1]

CATS:

***Cryptosporidia* spp associated diarrhea** (extra-label): 10 – 25 mg/kg PO every 12 to 24 hours for up to 28 days[4,5]

HORSES:

Equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*: For a 28-day course of therapy, 25 mg/kg PO once daily on days 1 through 5 followed by 50 mg/kg PO once daily on days 6 through 28[6]

Monitoring

- Clinical efficacy
- Weekly body weight
- Adverse effects

Client Information

- This medicine has not been commonly used in dogs or cats, and adverse effects such as excessive salivation, vomiting, or diarrhea may occur.

Chemistry/Synonyms

A nitrothiazolyl-salicylamide derivative antiparasitic agent, nitazoxanide occurs as a light-yellow powder. It is slightly soluble in ethanol and practically insoluble in water.

Nitazoxanide may also be known as PH-5776, *Alinia*®, *Daxon*®, *Heliton*®, and *Navigator*®.

Storage/Stability

The human-approved powder for oral suspension should be stored at 25°C (77°F); excursions permitted to 15°C to 30°C (59°F-86°F). Once suspended with tap water, the oral suspension should be kept in tightly closed containers at room temperature and discarded after 7 days.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

Nitazoxanide oral paste (32%) *Navigator*® was FDA-approved in the United States for use in horses. Although this product is still listed in FDA's Green Book of approved animal drugs, it is no longer commercially available in the United States.

HUMAN-LABELED PRODUCTS:

Nitazoxanide Oral Tablets: 500 mg; *Alinia*®, generic; (Rx)

Nitazoxanide Powder for Oral Suspension: 20 mg/mL in 60 mL; *Alinia*®; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Nitenpyram

(nye-ten-***pye***-rum) *Capstar*®

Oral Insecticide

Prescriber Highlights

- ► Oral insecticide used primarily as a flea (*Ctenocephalides felis*) adulticide in dogs and cats; may also be used for the treatment of myiasis
- ► Fast onset of action: fleas begin to die within 30 minutes of administration
- ► Not effective for killing flea eggs or other immature forms when used as a single agent
- ► Safe and well tolerated, including in pregnant and lactating dogs and cats
- ► Available over the counter (OTC)

Uses/Indications

Nitenpyram is indicated as a flea (*Ctenocephalides felis*) adulticide in dogs and cats that are at least 0.9 kg (2 lb) in weight and 4 weeks old.[1] It does not repel fleas or ticks and does not reliably kill ticks or fleas in other life stages (ie, eggs, larvae, or immature fleas). Nitenpyram tablets begin working within 30 minutes of administration and kill 90% of fleas within 4 hours in dogs and 6 hours in cats.[1,2] It has been anecdotally reported that rectal administration is effective when PO administration is not possible.

Nitenpyram is also effective for treating myiasis (ie, fly larvae/maggot infestation) in dogs due to various species, including *Cochliomyia hominivorax* and *Chrysomya bezziana*.[3,4]

Pharmacology/Actions

Nitenpyram is in the class of neonicotinoid insecticides. It enters the systemic circulation of the adult flea after consuming a blood meal from a treated animal. It binds to nicotinic acetylcholine receptors in the postsynaptic membranes and blocks acetylcholine-mediated neuronal transmission, causing paralysis and death of the flea. Nitenpyram is 3500 times more selective for insect alpha-4 beta-2 nicotinic receptors than vertebrate receptors. It does not inhibit acetylcholinesterase. Efficacy appears to be greater than 98% (kill rate) in dogs or cats within 6 hours of treatment.[2] When combined with an insect growth regulator (eg, lufenuron), immature stages of fleas may also be controlled.

Pharmacokinetics

Nitenpyram is rapidly and almost completely absorbed after oral administration. Tablets begin working within 30 minutes, with peak levels occurring ≈80 minutes after dosing in dogs and ≈40 minutes in cats.[1] Elimination half-life is ≈3 hours in dogs and 8 hours in cats. Nitenpyram is excreted primarily as conjugated metabolites in the urine, and excretion is complete within 48 hours of dosing. In dogs and cats, ≈3% and ≈5% of doses are excreted in the feces, respectively.

Contraindications/Precautions/Warnings

Nitenpyram is not to be used in animals under 0.9 kg (2 lb) of body weight or 4 weeks of age. Use it with caution in animals under 8 weeks old.

Adverse Effects

Nitenpyram is usually well tolerated.[5]

Based on postapproval adverse drug experience reporting, the following adverse effects (listed in decreasing order of frequency) have been reported:

Cats: Hyperactivity, panting, lethargy, itching, vocalization, vomiting, fever, decreased appetite, nervousness, diarrhea, difficulty breathing, salivation, incoordination, seizures, pupil dilation, increased heart rate, and trembling[1]

Dogs: Lethargy/depression, vomiting, itching, decreased appetite, diarrhea, hyperactivity, incoordination, trembling, seizures, panting, allergic reactions including hives, vocalization, salivation, fever, and nervousness[1]

Reported clinical signs are generally associated with flea die-off and are not related to the medication. Clinical signs are usually self-limiting and resolve without any treatment.

The frequency of severe signs, including neurologic signs and death, was higher in animals under 0.9 kg (2 lb) of body weight, less than 8 weeks of age, and/or reported to be in poor body condition.[1]

Reproductive/Nursing Safety

Nitenpyram is considered safe to use in pregnant or lactating dogs and cats.[1] In some instances, birth defects and fetal/neonatal loss were reported after treatment of pregnant and/or lactating animals.

Because safety has not been established in animals, this drug should only be used in breeding animals when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Nitenpyram is relatively safe in high doses to mammals. The oral LD_{50} in rats is ≈1.6 g/kg.[5] Adult dogs and cats were dosed up to 10 times a therapeutic dose daily for 14 days without adverse effects.[2] Cats receiving 125 mg/kg (125 times the therapeutic dose) exhibited hypersalivation, lethargy, vomiting, and tachypnea.[6] These clinical signs typically occurred within 2 hours of treatment and resolved within 24 hours.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information on overdose and toxin exposures, as well as for poison control centers' contact information, refer to ***Appendix.***

Drug Interactions

- ■ No specific drug interactions were located. Nitenpyram has reportedly been used safely with a variety of other medications and other flea products.

Laboratory Considerations

- ■ No specific laboratory interactions or considerations were noted.

Dosages

DOGS/CATS:

Flea infestations (label dosage; FDA-approved): Appropriate dose is given orally based on body weight according to the table below. If reinfestation occurs, the dose may be safely repeated as often as once daily. Tablets may be administered with or without food.

Recommended Dosing Schedule[1]

Species	Body weight (kg [lb])	Dose	Nitenpyram per tablet
Dog or Cat	0.9 -11.4 (2-25)	1 tablet	11.4 mg
Dog	11.4-56.8 (25.1-125)	1 tablet	57 mg

Canine screwworm myiasis (extra-label): Using the label dosage for fleas, administer one dose by mouth once, or one dose followed by a second dose 6 hours later.[3,4] Medication targets the screwworm larvae. Spontaneous expulsion of larvae combined with mechanical removal of dead larvae resulted in 100% efficacy within 18 hours.[7]

REPTILES:

Myiasis (extra-label): Crush one 11.4 mg tablet into powder and administer once orally, as an enema, or on the wound.[8]

Monitoring

- Efficacy (ie, reduction in number of adult fleas)

Client Information

- This medicine is used primarily to kill adult fleas on dogs and cats.
- When used alone, this medicine does not kill flea eggs or other immature forms. Your veterinarian will discuss any additional treatments needed to control the flea problem. All animals in the household must be treated.
- Give this medicine as directed by your veterinarian.
- This medicine is usually tolerated well in dogs and cats. Serious side effects are rare and occur most often in animals that weigh less than 0.9 kg (2 lb), are less than 8 weeks old, or are in poor health.
- Keep this medicine out of reach of children.

Chemistry/Synonyms

Nitenpyram, a neonicotinoid insecticide, occurs as a pale-yellow crystalline powder and is very soluble in water (840 mg/mL).

Nitenpyram may also be known as TI-304, (E)-Nitenpyram, *Bestguard®*, and *Capstar®*.

Storage/Stability

Store commercially available nitenpyram tablets at room temperature (15°C to 25°C [59°F-77°F]).

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Nitenpyram Oral Tablets: 11.4 mg and 57 mg in boxes containing blister packs of 6 tablets; *Capstar®*, generic; (OTC); FDA-approved for use in dogs and cats

Combination products:

Nitenpyram with Lufenuron [*Program® Flavor Tabs* and *Capstar® Flea Management System for Dogs* and P*rogram® Flavor Tabs* (OTC); *Capstar® Flea Management System for Cats* (OTC)]. Refer to the ***Lufenuron*** monograph for details. Although this combination product is listed in the FDA Green Book, it does not appear to be commercially available.

Nitenpyram with milbemycin and lufenuron (*Sentinel® Flavor Tabs* and *Capstar® Flea Management System for Dogs* [Rx]). Refer to ***Lufenuron*** and ***Milbemycin*** monographs for details. Although this combination product is listed in the FDA Green Book, it does not appear to be commercially available

HUMAN-LABELED PRODUCTS: NONE

Nitrofurantoin

(nye-troe-fyoor-***an***-toyn) *Macrodantin®, Macrobid®*

Urinary Antimicrobial

Prescriber Highlights

- ► Antibacterial that is useful for the treatment of some cases of bacterial cystitis that are resistant to first-line drugs
- ► Only achieves therapeutic concentrations in urine, so this drug should only be used for bacterial cystitis (not pyelonephritis or other infections)
- ► Contraindications include food-producing species, renal impairment, and hypersensitivity to nitrofurantoin.
- ► Adverse effects include GI disturbances, peripheral neuropathy, and hepatopathy.

Uses/Indications

Nitrofurantoin is used primarily in small animal species as a potential treatment for bacterial cystitis in cases where resistance to first-line antibiotics (eg, amoxicillin ± clavunate, sulfa-/trimethoprim) is present.[1–4] It is recommended as a second-line option for sporadic bacterial cystitis.[3] Because nitrofurantoin only reaches therapeutic concentrations in urine, it is not an appropriate choice for the treatment of infections that require tissue drug concentrations (eg, pyelonephritis).

The World Health Organization (WHO) has designated nitrofurantoin as an Important antimicrobial in human medicine.[5]

Pharmacology/Actions

Nitrofurantoin usually acts as a bacteriostatic antimicrobial, but it may be bactericidal depending on the concentration of the drug and the susceptibility of the organism. Although the exact mechanism of action of nitrofurantoin has not been fully elucidated, the drug apparently inhibits various bacterial enzyme systems, including synthesis of DNA, RNA, and proteins, acetyl coenzyme A, as well as energy metabolism and cell wall synthesis. Nitrofurantoin has greater antibacterial activity in acidic environments. Bacterial resistance to nitrofurantoin has remained inconsequential.

Nitrofurantoin has activity against several gram-negative and some gram-positive organisms, including many strains of *Escherichia coli, Klebsiella* spp, *Enterobacter* spp, *Enterococcus* spp, *Streptococcus* spp, *Staphylococcus* spp, *Enterobacter* spp, *Citrobacter* spp, *Salmonella* spp, *Shigella* spp, and *Corynebacterium* spp. It has little or no activity against most strains of *Proteus* spp, *Serratia* spp, or *Acinetobacter* spp and has no activity against *Pseudomonas* and *Corynebacterium* spp.

Pharmacokinetics

There are 3 commercial (human label) oral forms of nitrofurantoin (regular nitrofurantoin in an oral suspension, macrocrystalline capsules, and monohydrate/macrocrystals capsules). No pharmacokinetic studies comparing these different forms in dogs or cats were located. In humans, nitrofurantoin is rapidly absorbed from the GI tract; the presence of food may enhance the absorption of the drug. Macrocrystalline (eg, *Macrodantin®*) capsules are more slowly absorbed, but they are still dosed 3 to 4 times daily for treating UTIs in humans. Monohydrate/macrocrystalline forms of the drug (eg, *Macrobid®*) are absorbed even more slowly, with less GI upset. Because of the monohydrate/macrocrystalline form's slower absorption, urine concentrations of the drug may be prolonged with the monohydrate macrocrystalline form and so it is dosed twice daily in humans.

In dogs, absorption was widely variable (38% to 120%) following oral administration, although absorption half-lives were higher with solid dosage forms versus suspension.[6] Elimination half-lives after

oral administration ranged from 19 to 87 minutes.

Therapeutic concentrations in the systemic circulation are not maintained because of the rapid elimination of the drug. Approximately 20% to 60% of the drug is bound to serum proteins. Administration of the macrocrystalline form results in therapeutic peak urine concentrations occurring within 30 minutes of dosing.

Approximately 40% to 50% of the drug is eliminated into the urine unchanged. Some of the drug is metabolized, primarily in the liver. The elimination half-lives in humans with normal renal function average 20 minutes.

Contraindications/Precautions/Warnings

Nitrofurantoin is contraindicated in patients that have renal impairment as the drug is much less efficacious, and the development of neurotoxicity is much more likely. The drug is also contraindicated in patients that are hypersensitive to it.

Use nitrofurantoin with caution in patients with pre-existing hepatic dysfunction. Although rare, significant hepatic reactions (eg, jaundice, hepatitis, hepatitis necrosis) have been documented in humans with its use.

In humans, pulmonary reactions have also been reported rarely in patients receiving treatment for greater than 6 months. Treatment should be immediately discontinued in the event of pulmonary toxicity.

Rats can develop neurotoxicity when they are given nitrofurantoin; avoid using the drug in this species.

Adverse Effects

In dogs and cats, GI disturbances (primarily vomiting and diarrhea), peripheral neuropathies (reversible), pulmonary hypersensitivity reactions, and hepatopathy can occur. Chronic active hepatitis, hemolytic anemia, and pneumonitis have been described in humans. These effects are believed to occur very rarely in animals with nitrofurantoin's use.

Reproductive/Nursing Safety

Nitrofurantoin crosses the placenta. In humans, nitrofurantoin is contraindicated in pregnant patients at term and neonates, as hemolytic anemia can occur secondary to immature enzyme systems. Safe use of the drug during earlier stages of pregnancy has not been determined in animals. Nitrofurantoin has been implicated in decreasing spermatogenesis in rats and humans, as well as in causing infertility in male dogs.

Nitrofurantoin is excreted into maternal milk in very low concentrations. Safety for use in the nursing mother or offspring has not been established. In humans, nitrofurantoin is considered compatible with breastfeeding in healthy, full-term infants over 1 month old.[7,8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located. Because the drug is rapidly absorbed and excreted, patients with normal renal function should require little therapy when mild overdoses occur. A high fluid intake should be maintained to promote urinary excretion of the drug. Nitrofurantoin is dialyzable. If the ingestion was relatively recent, massive overdoses should be handled with standard GI decontamination protocols; the patient should then be monitored for adverse effects (see ***Adverse Effects***).

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nitrofurantoin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Drugs** (eg, **atropine, glycopyrrolate**): May increase the oral bioavailability of nitrofurantoin
- **Fluconazole**: Increased risk for hepatic and pulmonary toxicity.
- **Fluoroquinolones** (eg, **ciprofloxacin, enrofloxacin**): Nitrofurantoin may antagonize the antimicrobial activity of the fluoroquinolones. Concomitant use is best avoided.
- **Local Anesthetics** (eg, **bupivacaine**, **lidocaine)**: In humans, nitrofurantoin may increase the risk for methemoglobinemia when used with local anesthetics. The significance in veterinary medicine is unknown.
- **Probenecid**: May inhibit the renal excretion of nitrofurantoin, potentially increasing its toxicity and reducing its effectiveness in UTIs
- **Psyllium**: Psyllium may bind and reduce nitrofurantoin absorption if given at the same time; if possible, separate doses by 3 or more hours.
- **Spironolactone**: Nitrofurantoin may increase hyperkalemic effects.

Laboratory Considerations

- Nitrofurantoin may cause false-positive **urine glucose** determinations if using cupric-sulfate solutions (Benedict's reagent, *Clinitest®*). Tests using glucose oxidase methods (*Tes-Tape®, Clinistix®*) are not affected by nitrofurantoin.
- Nitrofurantoin may cause decreases in **blood glucose** and increases in **serum creatinine**, **bilirubin,** and **ALP**.

Dosages

DOGS/CATS:

NOTE: Neither reference below states which form is being used (macrocrystalline [eg, *Macrodantin®*] or monohydrate/macrocrystals [eg, *Macrobid®*]).

As a second-line antimicrobial for sporadic bacterial cystitis, particularly when multidrug-resistant pathogens are involved (extra-label): 4.4 – 5 mg/kg PO every 8 hours for 5 days.[3] Longer treatment courses (eg, 7 to 14 days may be reasonable for persistent, recurrent, or relapsing infections). Amoxicillin (+/- clavulanic acid) and sulfa-/trimethoprim are considered first-line agents.

HORSES:

Sporadic bacterial cystitis, particularly when multidrug-resistant pathogens are involved (extra-label): 4.5 mg/kg PO for the first dose, then 2.25 mg/kg PO every 8 hours for 7 days

Monitoring

- Clinical efficacy
- Adverse effects
- Culture and susceptibility for recurrent or persistent infections[3]
- Baseline and periodic hepatic enzymes should be considered with chronic therapy

Client Information

- Give this medicine with food.
- Your animal may develop brownish-colored urine while taking this medicine.
- Stomach upset (acting sick) and vomiting are the most common side effects, but muscle weakness may indicate nerve toxicity (se-

rious). Contact your veterinarian if any of these signs occur.
- Be sure your animal always has access to fresh water while receiving this medication.

Chemistry/Synonyms
Nitrofurantoin is a synthetic and nitrofuran antibacterial, which occurs as a bitter-tasting, lemon-yellow, crystalline powder with a pK_a of 7.2. It is very slightly soluble in water or alcohol.

Nitrofurantoin may also be known as furadoninum or nitrofurantoinum, *Furadantin*®, *Macrobid*®, and *Macrodantin*®.

Storage/Stability
Nitrofurantoin preparations should be stored in tight containers at room temperature and protected from light. The oral suspension should not be frozen. Nitrofurantoin will decompose if it comes into contact with metals other than aluminum or stainless steel.

Compatibility/Compounding Considerations
No specific information was noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE
Nitrofurantoin use in food-producing animals is strictly prohibited.

HUMAN-LABELED PRODUCTS:
Nitrofurantoin Macrocrystalline Oral Capsules: 25 mg, 50 mg, and 100 mg; *Macrodantin*®, generic; (Rx)

Nitrofurantoin Monohydrate/Macrocrystals Oral Capsules: 100 mg; *Macrobid*®, generic; (Rx)

Nitrofurantoin Oral Suspension: 5 mg/mL (25 mg/5 mL) in 230 mL and 240 mL bottles; *Furadantin*®, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Nitroglycerin, Transdermal
(nye-troe-***gli***-ser-in) *NTG, Nitro-bid*®
Venodilator; Afterload Reducer

Prescriber Highlights
- ► Transdermal, oral, and injectable venodilator; occasionally used topically in veterinary medicine for congestive heart failure (CHF) or hypertension
- ► Continuous use results in tolerance after 48 to 72 hours.
- ► Contraindications include severe anemia and hypersensitivity.
- ► Use cautiously (if at all) in patients with cerebral hemorrhage, head trauma, diuretic-induced hypovolemia, or other hypotensive conditions.
- ► Adverse effects include rashes at the application sites; hypotension is possible. Transient headaches (common in humans); may be a problem for some animals.
- ► Rotate application sites.
- ► Wear gloves when applying; avoid human skin contact.

Uses/Indications
Transdermal nitroglycerin (NTG) in small animal medicine is used primarily as an adjunctive vasodilator in heart failure and cardiogenic edema. Because of questionable efficacy and rapid development of tolerance, topical nitroglycerin is not commonly used in veterinary medicine today. In humans, NTG is also used as an anti-anginal agent, antihypertensive (acute), and topically to treat Raynaud's disease.

For horses, topical nitroglycerin is ineffective in increasing digital blood flow in laminitis.[1,2]

Pharmacology/Actions
Nitroglycerin relaxes vascular smooth muscle primarily on the venous side, but a dose-related effect on arterioles is possible. Preload (left end-diastolic pressure) is reduced from the peripheral pooling of blood and decreased venous return to the heart. Because of its arteriolar effects, depending on the dose, afterload may also be reduced. Myocardial oxygen demand and workload are reduced, and coronary circulation can be improved.

Pharmacokinetics
Nitroglycerin transdermal ointment is absorbed through the skin, with an onset of action usually within 1 hour and duration of action of 2 to 12 hours. It is generally dosed in dogs and cats every 6 to 8 hours (3 to 4 times a day). The transdermal patches have a wide inter-patient bioavailability. Reportedly, the topical paste can be absorbed when rubbed on the gums of dogs and cats. Nitroglycerin has a very short half-life (1 to 4 minutes in humans) and is metabolized in the liver. At least 2 metabolites have some vasodilator activity and have longer half-lives than NTG.

Contraindications/Precautions/Warnings
Nitrates are contraindicated in patients with severe anemia or those hypersensitive to them. They should be used with caution (if at all) in patients with cerebral hemorrhage, head trauma, diuretic-induced hypovolemia, or other hypotensive conditions.

Continuous use (48 to 72 hours) of nitroglycerin results in the rapid development of tolerance to the effects of the drug.

Do not confuse nitroGLYCERIN with nitroPRUSSIDE or nitrofurantoin.

Adverse Effects
Most common adverse effect seen is a rash at the application site. If hypotension is a problem, reduce dosage. Transient headaches are a common adverse effect seen in humans and may be a problem for some animals.

Reproductive/Nursing Safety
No toxic effects were observed in pregnant rats or rabbits receiving doses up to 80 mg/kg/day and 240 mg/kg/day, respectively.[3] It is not known whether nitrates are excreted in maternal milk; use with caution in nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
If severe hypotension results after topical administration, wash the site of application to prevent any more absorption of ointment. Fluids may be administered if necessary. Epinephrine is contraindicated as it is ineffective and may complicate the animal's condition.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving nitroglycerin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.
- **Acetylcysteine**: Concurrent use may result in enhanced hypotension.
- **Antihypertensive Drugs, Other** (eg, **amlodipine**, **enalapril**, **telmisartan**): Use of nitroglycerin with other antihypertensive drugs may cause additive hypotensive effects.
- **Aspirin**: Concurrent use may result in increased nitroglycerin

concentrations and additive platelet function depression.
- **Phenothiazines** (eg, **acepromazine**): May increase hypotensive effects
- **Sildenafil** (and other **PDE inhibitors**): May profoundly increase risk for hypotension. Concurrent use is contraindicated in humans.

Dosages

NOTE: Transdermal nitroglycerin is not used alone for the treatment of acute heart failure. It must be used with a loop diuretic (eg, furosemide). There is very limited evidence of efficacy of topical nitroglycerin in dogs and cats, but it is unlikely to cause harm.

DOGS/CATS:

Adjunctive treatment of acute heart failure using the transdermal ointment (*Nitro-bid*®) (extra-label): Dosed semi-quantitatively based on animal size. Cats: 1/8 – 1/4 inch; small dogs: 1/4 – 1/2 inch; medium dogs: 1/2 – 1 inch; large dogs: 1 – 2 inches every 6 to 12 hours for first 24 to 48 hours. Applied with a gloved finger to the inner ear pinna, groin, or axilla. Some clinicians have suggested that it can be applied to oral mucous membranes and is absorbed and tolerated well. Alternatively for dogs: 0.5 inch per 10 kg[4]

FERRETS:

Adjunctive therapy for heart failure (extra-label): 1/8 inch strip applied to inside of pinna every 12 hours for the first 24 hours of therapy[5]

Monitoring

- Clinical efficacy
- Sites of application for signs of rash
- Blood pressure, particularly if hypotensive effects are seen

Client Information

- Dosage is measured in inches of ointment; use papers supplied with product to measure appropriate dose.
- Wear gloves (nonpermeable) when applying the medicine.
- Do not pet animal where ointment has been applied.
- Rotate application sites. Recommended application sites include groin, inside the ears, and axilla (arm pits). Rub ointment into skin well. If rash develops, do not use on that site again until it has cleared. Sometimes, veterinarians will have you rub it onto the gums of your animal.
- Contact your veterinarian if rash persists or if your animal's condition deteriorates.
- There is no danger of explosion or fire with the use of this product.
- While your animal is taking this medication, it is important to return to your veterinarian for blood pressure checks. Do not miss these important follow-up visits.

Chemistry/Synonyms

Famous as an explosive, nitroglycerin (NTG) occurs undiluted as a thick, volatile, white-pale yellow flammable, explosive liquid with a sweet, burning taste. The undiluted drug is soluble in alcohol and slightly soluble in water. Because of obvious safety reasons, nitroglycerin is diluted with lactose, dextrose, propylene glycol, and so on when used for pharmaceutical purposes.

Nitroglycerin may also be known as glyceryl trinitrate, glonoine, GTN, nitroglycerol, NTG, trinitrin, or trinitroglycerin, *Nitro-bid*®, and *Nitro-Dur*®.

Storage/Stability

The topical ointment should be stored at room temperature and the cap firmly attached. For storage/stability and compatibility for dosage forms other than the topical ointment, see specialized references or the package inserts for each product.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

NOTE: Many dosage forms of nitroglycerin are available for human use, including sublingual or buccal tablets and powders, lingual spray, extended-release oral capsules and tablets, and parenteral solutions for IV infusion. Because the use of nitroglycerin in small animal medicine has been limited to the use of topical ointment or transdermal patches, those other dosage forms are not listed here.

Nitroglycerin Topical Ointment: 2% in a lanolin-white petrolatum base in 30 gram and 60 gram tubes and 1 gram unit-dose foil packets; *Nitro-bid*®; (Rx)

Nitroglycerin Transdermal Systems (patches): 0.1 mg/hour, 0.2 mg/hour, 0.3 mg/hour, 0.4 mg/hour, 0.6 mg/hour, and 0.8 mg/hour; *Nitro-Dur*®, generic; (Rx) **NOTE**: Various products contain differing quantities of nitroglycerin and patch surface area size, but release rates of drug are identical for a given mg/hr.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Nitroprusside

(nye-troe-***pruss***-ide) *Nitropress*®

Vasodilator

Prescriber Highlights

- ► Vascular, smooth muscle relaxant used for acute/severe hypertension; acute heart failure secondary to mitral regurgitation and in combination with dobutamine for refractory congestive heart failure (CHF). Use only in an ICU setting; monitoring essential, including continuous measurement of direct or, less ideally, indirect arterial blood pressure.
- ► Drug of choice in animals under general anesthesia to treat severe hypertension caused by manipulation of pheochromocytomas.
- ► Contraindications include compensatory hypertension, inadequate cerebral circulation, or during emergency surgery in patients near death. Use caution in geriatric patients, hepatic insufficiency, severe renal impairment, hyponatremia, cobalamin deficiency, or hypothyroidism.
- ► Adverse effects include hypotensive effects; potentially: nausea, retching, restlessness, apprehension, muscle twitching, dizziness.
- ► Solution for infusion (but not the IV tubing) must be protected from light.
- ► Continued use at high dosages may lead to potential thiocyanate and cyanide toxicity.

Uses/Indications

Nitroprusside is used for adjunctive treatment of severe, acute heart failure, and hypertensive crisis when blood pressure must be reduced relatively rapidly. Its use in veterinary medicine is generally reserved for the treatment of critically ill patients only when constant blood

pressure monitoring can be performed. In patients with dilated cardiomyopathy, administering dobutamine first to improve contractility and increase cardiac output can offset the hypotensive effects of sodium nitroprusside.[1] Due to its potency, rapid onset, and duration of action, it is considered the drug of choice in anesthetized animals undergoing adrenalectomy to treat acute and severe hypertension due to manipulation of pheochromocytomas.[2]

Pharmacology/Actions

Sodium nitroprusside provides intracellular nitric oxide, which activates guanylate cyclase. This effect produces an increase in intracellular cyclic-GMP, which inhibits vascular smooth muscle contraction. Nitroprusside is an immediate acting IV hypotensive agent that directly causes peripheral vasodilation (arterial and venous) independent of autonomic innervation. It produces a lowering of blood pressure, an increase in heart rate, a mild decrease in cardiac output, and a significant reduction in total peripheral resistance. Preload, afterload, and left ventricular end-diastolic pressures are reduced. Unlike the organic nitrates, tolerance does not develop to nitroprusside.

Pharmacokinetics

After starting an IV infusion of nitroprusside, reduction in blood pressure and other pharmacologic effects begin almost immediately. Blood pressure will return to pretreatment concentrations within 1 to 10 minutes following cessation of therapy.

Nitroprusside is metabolized nonenzymatically in the blood and tissues to cyanogen (cyanide radical). Cyanogen is converted in the liver to thiocyanate, then eliminated in the urine, feces, and exhaled air. The half-life of cyanogen is 2.7 to 7 days if renal function is normal, but prolonged in patients with impaired renal function or with hyponatremia.

Contraindications/Precautions/Warnings

Nitroprusside is contraindicated in patients with compensatory hypertension (eg, arteriovenous shunts or coarctation of the aorta; Cushing's reflex), inadequate cerebral circulation, or during emergency surgery in patients near death.

Nitroprusside must be used with caution in patients with hepatic insufficiency, severe renal impairment, hyponatremia, cobalamin deficiency, or hypothyroidism. When nitroprusside is used for controlled hypotension during surgery, patients may have less tolerance to hypovolemia, anemia, or blood loss. Geriatric patients may be more sensitive to the hypotensive effects of nitroprusside.

Do **NOT** flush IV line or severe hypotension can result secondary to acute overdose.

The FDA label (human use)[3] includes a black box warning that includes the following: *Nitroprusside is not suitable for direct injection. The solution must be further diluted in dextrose 5% injection before infusion. Nitroprusside can cause precipitous decreases in blood pressure. In patients not properly monitored, these decreases can lead to irreversible ischemic injuries or death. Use only when available equipment and personnel allow blood pressure to be continuously monitored. Except when used briefly or at low (less than 2 µg/kg/minute) infusion rates, nitroprusside injection gives rise to important quantities of cyanide ion, which can reach toxic and potentially lethal levels. The usual dose rate is 0.5 to 10 µg/kg/minute, but infusion at the maximum dose rates should never last more than 10 minutes. If blood pressure has not been adequately controlled after 10 minutes of infusion at the maximum rate, terminate administration immediately. Although acid-base balance and venous oxygen concentration should be monitored and may indicate cyanide toxicity, these laboratory tests provide imperfect guidance.*

Nitroprusside is considered a high alert medication (medications that require special safeguards to reduce the risk of errors). Consider instituting practices such as redundant drug dosage and volume checking, and special alert labels.

Do not confuse nitroPRUSSIDE with nitroGLYCERIN or nitroFURANTOIN.

Adverse Effects

Most adverse reactions from nitroprusside are associated with its hypotensive effects, particularly if blood pressure is reduced too rapidly. Clinical signs such as nausea, retching, restlessness, apprehension, muscle twitching, and dizziness have been reported in humans. These effects disappear when the infusion rate is reduced or stopped. Nitroprusside may be irritating at the infusion site; avoid extravasation.

Continued use may lead to potential thiocyanate and cyanide toxicity (see ***Overdose/Acute Toxicity*** section). Cats may be more susceptible to nitroprusside-induced oxidative damage; use minimum dosage required for efficacy.

Reproductive/Nursing Safety

Nitroprusside crosses the placenta, and fetal cyanide concentration is dose-related to maternal nitroprusside concentration, and lethal cyanide concentrations have been detected in fetal sheep.[3] It is not known whether nitroprusside and its metabolites are excreted in maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute overdoses are characterized by profound hypotension, tachycardia, hyperventilation, metabolic acidosis, and seizures. Treat by reducing or stopping the infusion and giving IV fluids. Monitor blood pressure constantly.

Excessive doses, prolonged therapy, a depleted hepatic thiosulfate (sulfur) supply, or severe hepatic or renal insufficiency may lead to profound hypotension, and cyanogen or thiocyanate toxicity. Acid-base status should be monitored to evaluate therapy and to detect metabolic acidosis (early sign of cyanogen toxicity). Tolerance to therapy is also an early sign of nitroprusside toxicity. Hydroxocobalamin (vitamin B_{12a}) may prevent cyanogen toxicity and sodium thiosulfate may be used to treat cyanogen or thiocyanate toxicity. Thiocyanate toxicity may be exhibited as delirium in dogs. Serum thiocyanate concentration may need to be monitored in patients on prolonged therapy, especially in those patients with concurrent renal dysfunction. Serum thiocyanate concentration greater than 100 µg/mL are considered toxic.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nitroprusside and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, Inhalant** (eg, **isoflurane**): Concurrent use may potentiate hypotensive effects.
- **Dobutamine**: Synergistic effects (increased cardiac output and reduced wedge pressure) may result if dobutamine is used with nitroprusside.
- **Hypotensive Agents, Other** (eg, **amlodipine, enalapril, telmisartan**): Patients receiving other hypotensive agents may be more sensitive to the hypotensive effects of nitroprusside.

- **Negative Inotropic Agents** (eg, **propranolol, verapamil**): Concurrent use may potentiate hypotensive effects.
- **Phenothiazines** (eg, **acepromazine**): May increase hypotensive effects
- **Sildenafil**: Concurrent use may potentiate hypotensive effects. Combination is contraindicated in humans.

Dosages

NOTE: Must be diluted before use. See ***Compatibility/Compounding Considerations*** for information on preparing the infusion and protecting the solution from light.

DOGS/CATS:

Hypertensive crisis (systolic arterial blood pressure greater than 180 mm Hg with accompanying target organ damage) (extra-label): 0.5 – 3.5 µg/kg/minute IV CRI. Begin infusion at 0.5 µg/kg per minute[4] and titrate upwards every 5 minutes until target blood pressure is attained. Reduce blood pressure 25% over 4-hour period.

Adjunctive treatment of acute heart failure (cardiogenic shock; fulminant pulmonary edema; acute treatment for myxomatous mitral valve disease stage C and D) (extra-label): Initially, infuse 0.5 – 1 µg/kg/minute IV CRI. Titrate dosage upwards to effect in 0.5 – 1 µg/kg/minute increments every 10 to 30 minutes. Maximum CRI rate is 10 – 15 µg/kg/minute IV, although most animals are improved at 2 – 3 µg/kg/minute IV CRI. May use for 12 to 48 hours. Dobutamine can be used to treat or prevent hypotension if severe heart failure is confirmed by echocardiogram.[5,6]

Monitoring

- Blood pressure must be constantly monitored. Direct arterial blood pressure monitoring is recommended; however, if an arterial catheter cannot be placed (eg, smaller dogs and cats), continuous indirect blood pressures (eg, Doppler) can be used.
- Respiratory rate
- Acid-base balance and venous oxygen concentration, as acidemia and hypoxemia are early signs of cyanide toxicity
- Electrolytes (especially Na^+)

Client Information

- Must only be used by professionals in a setting where precise IV infusion and constant blood pressure monitoring can be performed.

Chemistry/Synonyms

A vascular smooth muscle relaxant, nitroprusside sodium occurs as practically odorless, reddish-brown crystals or powder. It is freely soluble in water and slightly soluble in alcohol. After reconstitution in D_5W, solution may have a brownish, straw, or light orange color and have a pH of 3.5 to 6.

Nitroprusside sodium may also be known as natrii nitroprussias, sodium nitroferricyanide dihydrate, sodium nitroprusside, SNP, or sodium nitroprussiate, and *Nitropress*®.

Storage/Stability

Nitroprusside sodium for injection should be stored protected from light and moisture and kept at room temperature (15°C-30°C [59°F-86°F)]. Nitroprusside solutions exposed to light will cause a reduction of the ferric ion to the ferrous ion with a resultant loss in potency and a change from a brownish color to a blue color. Degradation is enhanced with nitroprusside solutions in *Viaflex*® (Baxter) plastic bags exposed to fluorescent light. After dilution, protect immediately by covering infusion bag with aluminum foil or other opaque material. Discard solutions that turn to a blue, dark red, or green color. IV infusion tubing does not need to be protected from light while the infusion is running. It is not recommended to use IV infusion solutions other than 5% dextrose or to add any other medications to the infusion solution.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

It is not recommended to use IV infusion solutions other than 5% dextrose or to add any other medications to the prepared infusion solution. However, nitroprusside is considered **compatible at Y-sites** with the following drugs: atracurium, dexmedetomidine, diltiazem, dopamine, enalaprilat, esmolol, furosemide, heparin, lidocaine, midazolam, morphine, norepinephrine, potassium chloride, propofol, and vecuronium. ***Dobutamine Y-site compatibility with nitroprusside is variable*** depending on drug concentration. Nitroprusside solutions with concentrations up to 1.2 mg/mL were compatible with dobutamine 12.5 mg/mL solutions for 48 hours in one study.[7]

Directions for preparation of infusion: Add 2 – 3 mL 5% dextrose to 50 mg vial to dissolve powder. Add dissolved solution to 1000 mL of 5% dextrose and promptly protect solution from light (using aluminum foil or other opaque covering). Resultant solution contains 50 µg/mL of nitroprusside. Different concentrations may be necessary for precise administration and/or restricting IV fluids. The administration set (IV line) does not need to be protected from light. Solution may have a slight brownish tint, but discard solutions that turn to a blue, dark red or green color. Solution is stable for 24 hours after reconstitution. Do not add any other medications to IV running nitroprusside. Avoid extravasation at IV site. Use an accurate flow control device (infusion pump, controller) for administration. If a mini-drip IV set must be used: 60 drops ≈1 mL; 1 drop contains ≈0.83 µg of nitroprusside.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Nitroprusside Sodium for Injection: 25 mg/mL in 2 mL single-dose vials; *Nitropress*®, generic; (Rx)

Nitroprusside Sodium Injection in 0.9% Sodium Chloride: 0.2 mg/mL in 50 mL and 100 mL vials, and 0.5 mg/mL in 100 mL vials; *Nipride*® *RTU*; (Rx)

Nizatidine

(ni-***za***-ti-dine) *Axid*®

H_2-Receptor Antagonist; Prokinetic

Prescriber Highlights

- ► H_2-receptor antagonist similar to ranitidine; reduces gastric acid and has prokinetic activity
- ► Use with caution in geriatric patients and those with hepatic or renal insufficiency.
- ► Adverse effects are rare.

Uses/Indications

Although nizatidine acts similarly to cimetidine and ranitidine as an H_2 blocker to reduce gastric acid secretion in the stomach,[1,2] in small animal medicine its use has been primarily for its prokinetic effects. It may be useful to treat delayed gastric emptying, pseudo-obstruction of the intestine, and constipation.[3]

Pharmacology/Actions

At the H_2 receptors of the parietal cells, nizatidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, amino acids, penta-

gastrin, histamine, or insulin.

Nizatidine stimulates gastric emptying and intestinal motility by inhibiting acetylcholinesterase (thereby increasing acetylcholine at muscarinic receptors).[1,4–6] It may also have direct agonist effects on M3 muscarinic receptors. Lower esophageal sphincter pressures may be increased by nizatidine. By decreasing the amount of gastric juice produced, nizatidine decreases the amount of pepsin secreted.

Pharmacokinetics

In dogs, oral absorption is rapid and nearly complete with minimal first pass effect.[7] Food can enhance the absorption of nizatidine, but this is not considered clinically important. The drug is only marginally bound to plasma proteins. It is unknown if it enters the CNS. Nizatidine is metabolized in the liver to several metabolites, including at least one that has some activity.[7] Elimination half-life is 1 to 2 hours.[2] In animals with normal renal function over half the drug is excreted in the urine unchanged.

Contraindications/Precautions/Warnings

Nizatidine is contraindicated in patients who are hypersensitive to it. It should be used cautiously and, possibly, at reduced dosage in patients with diminished renal function. Nizatidine has caused increased serum ALT levels in humans receiving high IV doses for longer than 5 days. The manufacturer recommends that with high dose, chronic therapy, serum ALT values be monitored.

Do not confuse niZATidine with niTAZOXanide.

Adverse Effects

Nizatidine was reportedly well tolerated in animal studies.[2]

In humans, nizatidine appears to be well tolerated. Rarely, anemia has been reported. CNS effects have been noted (headache, dizziness) but incidence is similar to those taking placebo. Rash and pruritus have also been reported in a few humans taking nizatidine.

Reproductive/Nursing Safety

Doses of nizatidine up to 275 mg/kg per day in pregnant rabbits did not reveal any teratogenic or fetotoxic effects. Nizatidine is excreted in maternal milk in a concentration of 0.1% of the oral dose in proportion to plasma concentrations.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Single nizatidine doses of 75 mg/kg IV and single or daily (up to 3 months) doses of 800 mg/kg PO were not lethal in dogs.[8] Adverse effects could include cholinergic effects (lacrimation, salivation, emesis, miosis and diarrhea); suggest treating supportively based on clinical presentation.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nizatidine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **atropine, propantheline**): May negate the prokinetic effects of nizatidine
- **Antacids, Aluminum-, Calcium- or Magnesium-Containing** (high doses): May decrease the absorption of nizatidine; give at separate times (2 hours apart) if used concurrently.
- **Antihistamines, First Generation** (eg, **diphenhydramine, meclizine**): Anticholinergic effects may negate the prokinetic effects of nizatidine.
- **Azole Antifungals** (eg, **ketoconazole**, **itraconazole**): By raising gastric pH, nizatidine may decrease the absorption of these agents; if both drugs are required, administer the azole antifungal one hour prior to nizatidine.
- **Cefpodoxime, Cefuroxime**: Nizatidine may decrease the absorption of these cephalosporins; giving with food may alleviate this effect.
- **Iron Salts** (**oral**): Nizatidine may decrease the absorption of oral iron; administer iron at least one hour prior to nizatidine.
- **Phenothiazines** (eg, **acepromazine**): Anticholinergic effects may negate the prokinetic effects of nizatidine.
- **Salicylates** (eg, **aspirin, bismuth subsalicylate**): Nizatidine may increase salicylate concentrations in patients receiving high salicylate doses.
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): Anticholinergic effects may negate the prokinetic effects of nizatidine.

Laboratory Considerations

- False positive tests for **urobilinogen** may occur with patients receiving nizatidine.

Dosages

DOGS/CATS:

Prokinetic agent, reduce gastric acid production (extra-label): 2.5 – 5 mg/kg PO once daily[3,9]

Monitoring

- Clinical efficacy (dependent on reason for use) monitored by decrease in clinical signs, endoscopic examination, and blood in feces.

Client Information

- This medicine is used to treat or prevent stomach ulcers or to stimulate the movement of food through the stomach and intestines.
- If this medicine is given once each day, it works best if given before the first meal of the day.
- Nizatidine is available over the counter (OTC), without a prescription, but only give it to your animal if your veterinarian recommends it.

Chemistry/Synonyms

Nizatidine occurs as an off-white to buff-colored crystalline powder. It has a bitter taste and a slight sulfur-like odor. Nizatidine is sparingly soluble in water.

Nizatidine may also be known as LY-139037, nizatidinum, and *Axid®*.

Storage/Stability

Nizatidine products should be stored in tight, light-resistant containers at room temperature (20°C-25°C [68°F-77°F]); for the oral solution, excursions permitted between 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 5 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance.

See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Norepinephrine
Noradrenaline
(nor-eh-pih-***nef***-rin) *Levophed®*
Alpha- and Beta- Adrenergic Pressor Agent

Prescriber Highlights
- ► Vasopressor agent for persistent, profound shock (after fluid deficits replaced)
- ► Specifically indicated for hypotension associated with septic shock; may also be useful for isoflurane-induced hypotension
- ► Administration requires IV constant rate infusion (CRI) and continuous monitoring.
- ► Extravasation injuries possible
- ► Norepinephrine is considered a high alert medication (medication that requires special safeguards to reduce the risk for errors). Consider instituting practices such as redundant drug dosage and volume checks and special alert labels.

Uses/Indications
Norepinephrine (NE) is a direct-acting sympathomimetic vasopressor and cardiac inotrope used for treatment of profound hypotension in small and large animal species. NE is the first choice vasopressor for septic shock in volume-replete animals, and it can be used to raise blood pressure and as a cardiac stimulant in these patients.[1] In humans, NE is a first-line agent for hypotension associated with post-resuscitation shock[2,3]; these established guidelines have been extrapolated into use for dogs and cats although further research is warranted.[1,4] NE has been shown to correct hypotension secondary to isoflurane anesthesia in a variety of species. In humans, NE may also be useful when administered intragastrically or intraperitoneally for treatment of upper GI bleeding.[5,6]

Pharmacology/Actions
Norepinephrine (NE) is a strong alpha-1- and alpha-2-adrenergic receptor agonist, and a moderate beta-1 agonist.

NE acts as a peripheral vasoconstrictor (alpha-adrenergic), inotropic cardiostimulant, and coronary artery dilator (beta-adrenergic). Total peripheral resistance is increased, resulting in increased systolic and diastolic blood pressure. Perfusion to vital organs, skin, and skeletal muscle can be reduced, especially at higher dosages.

Pharmacokinetics
When administered IV, norepinephrine's (NE) onset of action occurs within 1 to 2 minutes and persists for an additional 1 to 2 minutes. Due to its vasoconstrictive effects, it can cause tissue damage and is poorly absorbed when given SC. After oral administration, NE is destroyed in the GI tract and not absorbed. After uptake by sympathetic nerve endings, it is rapidly metabolized via catechol-*O*-methyltransferase (COMT) and monoamine oxidase (MAO) to inactive metabolites.

Contraindications/Precautions/Warnings
In life-threatening situations, there are no absolute contraindications to norepinephrine (NE) use. Vasopressors are not a substitute for adequate blood, fluid, or electrolyte replacement. NE should not be given to patients that are hypotensive from hypovolemia,[7] except as an emergency measure to maintain coronary and cerebral artery perfusion until volume replacement therapy can be completed. If used in the absence of volume replacement, severe peripheral and visceral vasoconstriction, decreased renal perfusion and urine output, and poor systemic blood flow can occur despite normal blood pressures.[7] NE should not be used if severe peripheral vasoconstriction exists because it may be ineffective and may cause further reductions in blood flow to vital organs. Because it increases myocardial oxygen demand, risks for use during cardiac events (eg, arrhythmias) may outweigh the drug's benefits.

NE is a drug used in the critical care setting. Animals must be observed and infusion rates titrated. See ***Monitoring***. Avoid abrupt withdrawal of the infusion.[7]

In humans, it is recommended that NE be administered through a central venous catheter, if possible, to minimize risks for tissue ischemia from extravasation that can occur with a peripheral catheter. If a peripheral catheter must be used, it should be placed in a large vein[7] with the largest gauge catheter possible, and a slow infusion rate is advised. NE should not be used in patients with pre-existing vascular thrombosis, as this may increase ischemia.[7]

Do **NOT** confuse NOR-EPInephrine with EPInephrine. NE is considered a high alert medication (medication that requires special safeguards to reduce the risk for errors).[8] Consider instituting practices such as redundant drug dosage and volume checking and special alert labels.

Adverse Effects
If used in the absence of blood volume replacement, the following may occur: severe peripheral and visceral vasoconstriction, decreased renal perfusion and urine output, and poor systemic blood flow despite normal blood pressures.[7] Higher doses can cause arrhythmias.[7] Cats may be more susceptible to these adverse effects. In humans, reported adverse effects for norepinephrine (NE) include headache, weakness, dizziness, anxiety, pallor, respiratory difficulty, and pulmonary edema.[7]

The human label has a black box warning regarding extravasation injuries from NE.[7] To prevent sloughing and necrosis in areas where extravasation has taken place, the area should be infiltrated as soon as possible with 10 – 15 mL 0.9% sodium chloride solution containing 5 to 10 mg of phentolamine,[7] an adrenergic-receptor blocking agent (this product may need to be obtained from a human hospital pharmacy). A syringe with a fine hypodermic needle should be used to administer the saline solution, with the solution being infiltrated liberally throughout the area, which is easily identified by its cold, hard, and pallid appearance. Sympathetic blockade with phentolamine causes immediate and conspicuous local hyperemic changes if the area is infiltrated within 12 hours. Therefore, phentolamine should be given as soon as possible after the extravasation is noted.

Reproductive/Nursing Safety
Placental blood flow was diminished in pregnant sheep receiving high dose norepinephrine (NE) (40 µg/minute [NOT µg/kg/minute] IV).[7] It is not known if NE enters maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
Overdose with norepinephrine (NE) can result in severe hypertension, arrhythmias, reflex bradycardia, cardiac ischemia, increase in peripheral resistance with resulting decreased perfusion to vital organs, digital or other satellite tissue necrosis, and decreased cardiac output. If any of these signs occur, discontinue administration of the

drug. Immediate toxic effects from NE should resolve within 1 to 2 minutes, but ischemic lesions may not become evident for hours to days later. Propranolol may be used to treat NE-induced cardiac arrhythmias.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving norepinephrine (NE) and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-2-Adrenergic Agonists** (eg, **detomidine, dexmedetomidine, medetomidine, xylazine**): NE possesses alpha-agonist effects; thus, it should **NOT** be used to treat cardiac effects caused by alpha-2-adrenergic agonists.
- **Alpha-Adrenergic Antagonists** (eg, **phenoxybenzamine**, **phentolamine**, **prazosin**): May reverse the pressor effects of NE due to alpha-1 blockade
- **Antihistamines**: Certain antihistamines (eg, **chlorpheniramine, diphenhydramine**) may potentiate the effects of NE.
- **Atropine**: May block the reflex bradycardia caused by NE and enhance the pressor response
- **Beta-Adrenergic Antagonists** (eg, **atenolol, esmolol, propranolol**): May result in higher blood pressures secondary to antagonizing beta-2 receptors to cause arteriole dilation. Can antagonize cardiac stimulating effects; propranolol may be used to treat NE-induced cardiac arrhythmias.
- **Digoxin**: Increased risk for arrhythmias
- **Diuretics** (eg, **furosemide**): May decrease arterial responsiveness to NE
- **Monoamine Oxidase Inhibitors** (MAOIs; eg, **amitraz, linezolid, selegiline**): Hypertension can result.
- **Nitrates** (eg, **nitroglycerin**): May reverse the pressor effects of NE
- **Oxytocin**: Hypertension may result if NE is used with oxytocic agents.
- **Phenothiazines** (eg, **acepromazine**): May reverse the pressor effects of NE due to alpha-1 blockade
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Hypertension, cardiac arrhythmias, and tachycardia can result.

Laboratory Considerations

None noted

Dosages

NOTE: Dosages and drug concentrations are listed as norepinephrine base; injectable product concentration is labeled as norepinephrine base.

DOGS/CATS:

Persistent, profound hypotension after adequate fluid volume replacement (extra-label): Initial dosage: 0.05 – 0.1 µg/kg per minute IV CRI then titrated up to desired effect[9,10]; most recommend a maximum rate of 1 – 2 µg/kg/minute IV CRI. Can be used in combination with dopamine, dobutamine, or vasopressin.

Isoflurane-induced hypotension (extra-label): In a study comparing 12 healthy beagles, the average effective dose was 0.44 µg/kg/minute IV CRI.[11] Dosages ranged from 0.1 – 2 µg/kg per minute IV CRI.

HORSES:

Hypotension in critically ill foals (extra-label): Initial dosage: 0.1 µg/kg/minute IV CRI then titrated up to desired effect.[10] Upper end of dosage range is ≈1.5 µg/kg/minute IV CRI.[12] Use with dobutamine could be considered.[13]

Isoflurane-induced hypotension (extra-label):

a) **Neonatal foals**: 0.3 – 1 µg/kg/minute IV CRI. Norepinephrine improved cardiac index and O_2 delivery; high dosage significantly increased blood pressure.[14]

b) **Adult horses**: 0.1 – 0.5 µg/kg/minute IV CRI[15]

Acepromazine-induced hypotension (extra-label): The hypotensive effect of acepromazine in the awake horse was treated by a norepinephrine infusion of 1 µg/kg/minute IV CRI for 15 minutes. When these horses received the norepinephrine infusion without prior acepromazine, second degree AV block developed.[16]

ALPACAS:

Isoflurane-induced hypotension (extra-label): 0.3 – 1 µg/kg per minute IV CRI. It is recommended to titrate the dose starting at the lowest dose to avoid excessive vasoconstriction.[17]

SHEEP:

Hypotension after adequate fluid volume replacement during septic shock (extra-label): 0.4 – 1 µg/kg/minute IV CRI has been safely used in experimentally induced sepsis in sheep.[12,18] Norepinephrine in combination with dobutamine may be more effective than norepinephrine alone.[19]

Monitoring

Norepinephrine is a drug used in the intensive care unit (ICU) for critical patients. Animals must be observed, and dosage rates titrated. Avoid abrupt withdrawal of the infusion.

- Blood pressure. Preferably including central venous pressure or pulmonary arterial diastolic pressure; maintain mean arterial pressure at more than 65 mm Hg
- Continuous ECG
- Urine output

Client Information

- Must only be used by veterinary professionals in a hospital critical care setting.

Chemistry/Synonyms

Norepinephrine bitartrate (noradrenaline acid tartrate) occurs as a white or grey-white, odorless, crystalline powder that slowly darkens on exposure to air and light. One part is soluble in 2.5 parts water. Solutions in water have a pH of ≈3.5. The bitartrate injection contains sulfites.

Norepinephrine may also be known as levarterenol, noradrenaline, or L-arterenol. A commonly known trade name is *Levophed*®.

Storage/Stability

Store at room temperature (25°C [77°F]). Excursions are permitted to 15°C to 30°C (59°F-86°F). Protect from light.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

The following drugs are listed as **compatible** with norepinephrine infusions: amikacin sulfate, calcium chloride/gluconate, ciprofloxacin, dimenhydrinate, dobutamine HCl, heparin sodium, hydrocortisone sodium succinate, magnesium sulfate, meropenem, methylprednisolone sodium succinate, multivitamins, potassium chloride, succinylcholine chloride, and verapamil HCl.

Avoid contact with iron salts, alkalis, or oxidizing agents. Norepinephrine is **incompatible** with aminophylline, sodium bicarbonate,

ranitidine, or pantoprazole. Administer whole blood or plasma separately (via a Ytube and individual containers if given simultaneously).

Dilute norepinephrine in dextrose 5% or dextrose 5% with 0.9% sodium chloride. Administration in 0.9% sodium chloride alone is not recommended as significant loss of potency can occur due to oxidation. Dextrose-containing fluids can help prevent oxidation. A 4 mL vial (4 mg) is added to a 250 mL, 500 mL, or 1 L bag of a dextrose 5%-containing IV solution. Each mL of this dilution then contains either 16 µg/mL (250 mL bag), 8 µg/mL (500 mL bag), or 4 µg/mL (1 L bag) of norepinephrine bitartrate base. Do not use if solution color is pinkish, darker than slightly yellow, or if it contains a precipitate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated norepinephrine as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Norepinephrine bitartrate for injection (must be diluted before use): 1 mg/mL in 4 mL vials; *Levophed*®, generic; (Rx). Concentrations are listed as norepinephrine base.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Novobiocin

(noe-ve-***bye***-oh-sin) *Albadry Plus*®

Antibiotic

Prescriber Highlights

- ► Used as an intramammary treatment of subclinical mastitis in dry cows caused by susceptible strains of *Staphylococcus aureus* and *Streptococcus agalactiae*
- ► Primarily effective against some gram-positive cocci but is uncommonly used clinically
- ► Oral formulations no longer available

Uses/Indications

Novobiocin is FDA-approved in combination with penicillin G for use in dry dairy cattle for the treatment of subclinical mastitis caused by susceptible strains of *Staphylococcus aureus* and *Streptococcus agalactiae*.

The Office International des Epizooties (OIE) has designated novobiocin as a Veterinary Important Antimicrobial (VIA) Agent in veterinary species.[1]

Pharmacology/Actions

Novobiocin is believed to act in a bactericidal manner. It inhibits bacterial DNA gyrase, interfering with protein and nucleic acid synthesis, and also interferes with bacterial cell wall synthesis. Activity of the drug is enhanced in an alkaline medium.

The spectrum of activity of novobiocin includes some gram-positive cocci (staphylococci, *Streptococcus pneumoniae*, and some group A streptococci). Novobiocin resistance is not associated with methicillin resistance and some methicillin-resistant staphylococci are susceptible.[2] Activity is variable against other streptococci and weak against the enterococci. Most gram-negative organisms are resistant to the drug, but some *Haemophilus* spp, *Neisseria* spp, and *Proteus* spp may be susceptible.

Pharmacokinetics

After oral administration, novobiocin is well absorbed from the GI tract. Peak concentrations occur within 1 to 4 hours. The presence of food can decrease peak concentrations of the drug.

Novobiocin is only poorly distributed to body fluids with concentrations in synovial, pleural, and ascitic fluids less than those found in plasma. Only minimal quantities of the drug cross the blood-brain barrier, even when meninges are inflamed. Highest concentrations of novobiocin are found in the small intestine and liver. The drug is ≈90% protein bound and is distributed into milk.

Novobiocin is primarily eliminated in the bile and feces. Approximately 3% is excreted into the urine; urine concentrations are usually less than those found in serum.

Contraindications/Precautions/Warnings

Novobiocin is contraindicated in patients hypersensitive to it. Additionally, systemic use of the drug should be undertaken with extreme caution in patients with preexisting hepatic or hematopoietic dysfunction.

Adverse Effects

Adverse effects reported with the systemic use of this drug include fever, GI disturbances (eg, nausea, vomiting, diarrhea), rashes, and blood dyscrasias. In humans, occurrences of hypersensitivity reactions, hepatotoxicity, and blood dyscrasias have significantly limited the use of this drug. A novobiocin degradation product may cause a yellow skin discoloration.

Reproductive/Nursing Safety

Intramammary novobiocin infusions are safe to administer to pregnant cattle when used as a dry cow treatment; however, they are not intended for use in lactating cows.

Overdose/Acute Toxicity

Little information is available regarding overdoses of novobiocin. It is suggested that large oral overdoses be handled by emptying the gut following standard protocols; monitor and treat adverse effects symptomatically if necessary.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving novobiocin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Lactam Antibiotics**: Novobiocin may block the renal tubular transport of drugs (similar to probenecid). Although the clinical significance of this action is unclear, the elimination rates of drugs excreted in this manner (eg, **cephalosporins, penicillins**) could be decreased and half-lives prolonged.

Laboratory Considerations

- Novobiocin can be metabolized into a yellow-colored product that can interfere with **serum bilirubin** determinations.
- Novobiocin may interfere with the determination of **BSP** (bromosulfophthalein, sulfobromophthalein) uptake tests by altering BSP uptake or biliary excretion.

Dosages

CATTLE:

Subclinical mastitis in dry cows (label dosage; FDA-approved): Infuse the entire contents of one syringe into each quarter at the time of drying off, but not less than 30 days prior to calving.[3] Warm to body temperature and shake well before using.

Monitoring
- Clinical efficacy
- Adverse effects

Client Information
- Be sure you understand how to give this medicine to your cow. Shake the medicine tubes well before placing into each quarter.
- Only give this medicine as directed by your veterinarian. Do not give more medicine or treat for longer than is recommended by your veterinarian.

Chemistry/Synonyms
An antibiotic obtained from *Streptomyces niveus* (*S spheroids*), novobiocin sodium occurs as white to light yellow, crystalline powder and is very soluble in water.

Novobiocin or novobiocin sodium may also be known as crystallinic acid, PA-93, streptonivicin, U-6591, novobiocinum natricum, sodium novobiocin, *Albadry Plus*®, *Albamycin*®, *Biodry*®, and *Delta Albaplex*®.

Storage/Stability
Novobiocin should be stored at room temperature, 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations
No specific information noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Novobiocin Combination Products:

Novobiocin sodium 400 mg and Penicillin G Procaine 200,000 units per 10 mL *Plastet*® Syringe; *Albadry Plus*®; (OTC). FDA-approved for use in dry cows only. Do not use 30 days prior to calving. Milk must not be used for food for 72 hours after calving. Slaughter withdrawal at label dosages is 30 days.

Historically, novobiocins have been available as single-agent intramammary infusions for lactating and dry cows, and in combination with tetracycline with or without prednisolone for oral use in dogs. These products are still listed in FDA's Green Book but are no longer marketed in the United States.

HUMAN-LABELED PRODUCTS: NONE

Nystatin
(nye-***stat***-in)

Antifungal

See also ***Nystatin/Nystatin Combinations, Topical***

Prescriber Highlights
- ► Oral antifungal used for treatment of oral and GI *Candida* spp infections
- ► Do not use for treatment of systemic infections, as nystatin is not absorbed systemically after PO administration.
- ► Adverse effects include GI signs at high doses or hypersensitivity.
- ► Dosed in units; calculate doses carefully.

Uses/Indications
Orally administered nystatin is used primarily for the treatment of oral or GI *Candida* spp infections or overgrowth in dogs, cats, and birds. It has been used less commonly in other species for the same indications.

Pharmacology/Actions
Nystatin is a polyene antifungal and has a mechanism of action similar to that of amphotericin B. It binds to sterols in the membrane of the fungal cell, altering the permeability of the membrane and thus allowing intracellular potassium and other cellular constituents to leak out. Nystatin must come into contact with the target organism to be effective.

Nystatin is fungistatic and fungicidal against yeasts and yeast-like fungi, particularly *Candida* spp.[1] It has no activity against bacteria, protozoa, or viruses.

Pharmacokinetics
Nystatin is not measurably absorbed after oral administration and is almost entirely excreted unchanged in the feces. The drug is not used parenterally because it is reportedly extremely toxic to internal tissues.

Contraindications/Precautions/Warnings
Nystatin is contraindicated in patients with known hypersensitivity to it. Do not use for treatment of systemic mycoses.[1]

Do not confuse nystatin with HMG-CoA reductase inhibitors (ie, statin drugs such as simvastatin).

Adverse Effects
Occasionally, high dosages of nystatin may cause oral irritation or GI upset (anorexia, vomiting, diarrhea). Hypersensitivity reactions have rarely been reported in humans.

Reproductive/Nursing Safety
Effects of nystatin on fertility have not been studied. Although the safety of the drug during pregnancy has not been firmly established, the lack of appreciable absorption appears to make it safe to use.

It is not known whether nystatin is excreted in maternal milk; however, milk concentrations are likely insignificant due to its lack of systemic absorption.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
Because the drug is not absorbed after oral administration, acute toxicity after an oral overdose is extremely unlikely, but transient GI distress may result.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
- No significant interactions reported for oral nystatin

Laboratory Considerations
- No significant laboratory considerations noted

Dosages
DOGS/CATS:

Oral candidiasis (extra-label): Dosages are not well established. Anecdotal dosages of nystatin range from 100,000 – 150,000 units/dog or units/cat (NOT units/kg) PO 3 to 4 times daily.

HORSES:

Intrauterine infusion for *Candida* spp overgrowth (extra-label): 250,000 – 1,000,000 units mixed with sterile water; precipitates in saline. Limited evidence is available for a recommended dose, volume infused, frequency, or diluent. Most intrauterine treatments are performed every day or every other day for 3 to 7 days.[2]

BIRDS:

Enteric yeast (*Candida* spp) infections (extra-label):

a) 200,000 – 300,000 units/kg PO every 8 to 12 hours. **NOTE**: Oral lesions may be missed if bird is tubed.[3]

b) **Neonates on antibiotic therapy**: Crush one fluconazole 100 mg tablet and mix with 20 mL of nystatin 100,000 units/mL oral suspension. Then dose the solution at 0.5 mL/kg (2.2 lb) of body weight PO twice daily for duration of antibiotic therapy.[4]

c) **Candidiasis after antibiotic or in conjunction with antibiotics**: Using the nystatin 100,000 units/mL suspension, 1 mL/300 grams (0.66 lb) body weight PO 1 to 3 times daily for 7 to 14 days. If treating mouth lesions, do not give by gavage. Hand-fed baby birds should receive antifungal therapy if being treated with antibiotics.[5]

REPTILES:

Candidiasis (extra-label):

a) **Turtles with enteric yeast infections**: 100,000 units/kg PO once daily for 10 days[6]

b) **All reptiles**: 100,000 units/kg PO once daily[7]

Monitoring

- Clinical efficacy

Client Information

- Shake suspension well before administering

Chemistry/Synonyms

A polyene antifungal antibiotic produced by *Streptomyces noursei*, nystatin occurs as a yellow to light tan, hygroscopic powder having a cereal-like odor. It is very slightly soluble in water and slightly to sparingly soluble in alcohol. One mg of nystatin contains not less than 4400 units of activity. According to the USP, nystatin used in the preparation of oral suspensions should not contain less than 5000 units per mg.

Nystatin may also be known as fungicidin, nistatina, nystatinum, *Mycostatin®*, and *Nilstat®*.

Storage/Stability

Nystatin tablets and oral suspension should be stored at room temperature (15°C-30°C [59°F-86°F]) in airtight, light-resistant containers. Avoid freezing the oral suspension or exposing to temperatures above 40°C (104°F).

Nystatin deteriorates when exposed to heat, light, air, or moisture.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None for oral use

HUMAN-LABELED PRODUCTS:

Nystatin Oral Suspension: 100,000 units/mL in 5 mL, 60 mL, 473 mL, and 480 mL; generic; (Rx)

Nystatin Oral Tablets: 500,000 units; generic; (Rx)

Also available in topical creams, powders, and ointments

Oclacitinib

(***ok***-la-***sit***-ih-nib) *Apoquel®*

Janus Kinase (JAK) Inhibitor, Antipruritic, Anti-Inflammatory

Prescriber Highlights

- ► FDA-approved for treating allergic skin diseases in dogs
- ► Studies have demonstrated short-term effectiveness and safety in cats with feline atopic skin syndrome. Pruritus relief in dogs starts within 4 hours of administration of the first dose, with significant itch relief by 24 hours.
- ► Oclacitinib may increase susceptibility to infections. Avoid use in dogs with serious infection, and use with caution in dogs with history of recurrent infection.
- ► Patients should be monitored for the development of any new (or exacerbations of existing) neoplastic conditions, including cutaneous or subcutaneous masses.
- ► Extra-label use may be considered in cats, but safety data are limited.

Uses/Indications

Oclacitinib is FDA-approved in dogs at least 12 months of age for controlling pruritus associated with allergic dermatitis, including flea allergies and atopic dermatitis.[1] Oclacitinib is suitable for the treatment of both acute flares and long-term management of atopic dermatitis.[2,3] Studies in dogs with atopic dermatitis indicate an efficacy rate comparable to glucocorticoids and cyclosporine except that oclacitinib has a faster onset of action (within 24 hours) for control of pruritus.[4,5] Oclacitinib appears to reduce antimicrobial usage in dogs with allergic dermatitis.[6]

Based on case reports in dogs, oclacitinib has also been shown to be effective for treatment of ischemic dermatopathy,[7–9] hyperkeratotic erythema multiforme,[10] autoimmune subepidermal blistering dermatosis,[11] ear tip ulcerative dermatitis,[12] cutaneous epitheliotropic T-cell lymphoma (partial remission),[13] and as a temporary treatment to relieve pruritus associated with sarcoptic mange.[14] Anecdotal reports also suggest that oclacitinib may be beneficial for the treatment of canine lupus and pemphigus.

Oclacitinib is not approved for use in cats; however, cats with feline atopic skin syndrome (FASS) showed improvement in clinical signs and pruritus when they were treated with oclacitinib.[15–18] Oclacitinib appeared to be as effective as methylprednisolone. Cats that responded to treatment did so within one month. Successful reports for oclacitinib use in cats also exist for cutaneous mastocytosis,[19] asthma,[20] head and neck pruritus,[17,21] idiopathic ulcerative dermatitis,[22] and pemphigus foliaceus.[23] Long-term studies with a larger number of cats are needed to investigate the true efficacy and safety of oclacitinib in cats and identify the proper dose range.

Pharmacology/Actions

Oclacitinib is a nonselective JAK inhibitor. It inhibits cytokines that are dependent on the JAK enzyme, inhibiting mostly JAK1 enzyme activity with some inhibition of JAK2 and JAK3. Specifically, oclacitinib inhibits IL-31, an important pruritogenic cytokine in atopic dogs, as well as pro-inflammatory cytokines such as IL-2, IL-4, IL-6, and IL-13 that also play an important role in canine atopic dermatitis. At the approved regimen, oclacitinib appears to have no effect on hematologic parameters, but at higher extra-label doses or frequencies, inhibition of hematopoiesis might occur in some dogs. Oclacitinib is not an antihistamine or glucocorticoid.[1]

Under experimental conditions, oclacitinib delayed the development of dermatitis at the site of cutaneous antigen exposure in atopic beagles.[24] In a study of client-owned dogs with allergic dermatitis, pruritus scores were reduced by 31% within 4 hours of the first dose and by 67% at 14 days.[4] Anecdotally, a subset of dogs that responded

favorably to oclacitinib every 12 hours experienced partial loss of clinical sign control when administration frequency was reduced to every 24 hours. Chronic administration of the initial dose every 12 hours is extra-label use, as it may increase the risk for immunosuppression and is not recommended.

A study in mice showed a significant rebound phenomenon in pruritus after abrupt withdrawal of oclacitinib, which correlated with increased concentrations of pruritogenic cytokines that cause scratching; this has been reported anecdotally in dogs as well.[25] Further studies in allergic dogs are needed to corroborate these findings.

Pharmacokinetics

After oral administration in dogs, oclacitinib maleate had a bioavailability of 89%, and peak plasma concentrations occurred in less than 1 hour.[1] The feeding state did not affect pharmacokinetics. Oclacitinib was not significantly bound to plasma proteins in dogs (66% to 69%). The apparent volume of distribution (steady-state) was 942 mL/kg, and total body plasma clearance was 5.3 mL/minute/kg. The terminal half-life was 3.5 hours (IV) and 4.1 hours (PO). Oclacitinib was metabolized to several metabolites, with an oxidative form being the major metabolite. Less than 4% of the drug was excreted unchanged in the urine within 24 hours of administration.[26,27]

After oral administration in cats, oclacitinib bioavailability was 87%, T_{max} was 35 minutes, and the elimination half-life was 2.3 hours.[28] Volume of distribution (steady state) was 0.67 L/kg and clearance was calculated as 4.45 mL/minute/kg following IV administration). In cats with feline atopic skin syndrome (FASS), control of clinical signs did not correlate with plasma oclacitinib concentration.[18]

Contraindications/Precautions/Warnings

Oclacitinib should not be used in dogs younger than 12 months, dogs with serious infections, breeding dogs, or pregnant or lactating bitches.[1] At label dosages, there is increased potential for susceptibility to infections, demodicosis, and exacerbation or development of neoplastic conditions.[1] Clinicians should avoid or carefully consider the use of oclacitinib in animals with pre-existing disorders, such as demodicosis, severe infections (eg, pneumonia), and neoplastic diseases. Cats should be screened for FIV or FeLV prior to treatment with oclacitinib.[15]

Adverse Effects

Oclacitinib appears to be well tolerated in dogs, with an incidence of adverse effects similar to placebo. One study in allergic dogs showed that chronic use of oclacitinib for up to 630 days is generally safe.[5] Most commonly, GI effects (eg, vomiting, diarrhea, anorexia) or lethargy have been noted; in most cases these effects are transient and resolve spontaneously.[1,5] Polydipsia, lymphadenopathy, polyphagia, aggression, and weight loss were noted in less than 1.5% of treated dogs.

In dogs, oclacitinib may increase susceptibility to infections (eg, pneumonia, demodicosis, pododermatitis, pyoderma, otitis).[2,5] Proteinuria, hematuria, hyposthenuria, and microalbuminemia have also been reported.[5]

The rate of UTI/cystitis was reported as 11.3% in one long-term study,[5] whereas a small prospective study in healthy dogs without a prior history of UTI concluded that oclacitinib did not increase the risk for bacterial UTI over the average 6-month study.[29] Caution may be warranted when treating dogs with prior history of or predisposing factors for UTI, as the risk of UTI with oclacitinib administration in this population has not been determined.

New (or exacerbations of existing) benign and malignant neoplastic conditions have been observed in dogs treated with oclacitinib.[1] Unspecified benign cutaneous and subcutaneous masses, histiocytomas, and papillomas have also been reported in dogs.[2,5] A retrospective cohort study (660 client-owned dogs followed for a mean of 36 months) indicated that long-term treatment with oclacitinib did not increase the risk for malignancy as compared to an age- and breed-matched control group that was treated with other systemic atopic dermatitis medications (eg, cyclosporine, glucocorticoids).[30] Reductions of leukocyte (neutrophil, eosinophil, monocyte) counts, transient increased lymphocyte counts, and decreased serum globulin have occurred; however, study population mean values remained within normal ranges.[1]

In small, short-term studies of up to 28 days in cats, oclacitinib seems to be well tolerated; adverse effects appear more frequently at higher doses. In a placebo-controlled safety study, healthy cats were administered oclacitinib 1 or 2 mg/kg PO every 12 hours for 28 days.[31] In the 2 mg/kg dose group, adverse GI effects (vomiting, soft stools) were noted. There were no differences in CBC parameters and serum chemistry profiles between the 2 treatment groups and placebo. A different study (oclacitinib 0.7 – 1.2 mg/kg PO every 12 hours) showed that 4 of 14 cats had mild increases in BUN and creatinine.[15] In a study of cats with experimental asthma, no adverse effects were noted when cats were administered oclacitinib 0.5 or 1 mg/kg PO twice daily for 28 days[20]; however, a case report described fatal toxoplasmosis in a feline immunodeficiency virus-positive domestic short hair cat with feline atopic skin syndrome after treatment with oclacitinib for 5 months.[32] Until more studies with a larger number of cats, longer duration of monitoring, and more extensive safety data are available, oclacitinib should only be used in cats when other medications with known safety data in cats cannot be used or are not effective.[33]

Reproductive/Nursing Safety

Safe use of oclacitinib during pregnancy, breeding, or nursing has not been established; it should not be used in breeding dogs or pregnant or lactating bitches.[1]

Overdose/Acute Toxicity

Limited information is available on acute toxicity. In rats, the oral LD_{50} is 310 mg/kg.[34] In preapproval margin of safety studies in beagles receiving 5 times the label dosages (3 mg/kg PO every 12 hours for 6 weeks, then every 24 hours for 20 weeks), clinically observed adverse effects attributable to the drug included vomiting, diarrhea, interdigital furunculosis/dermatitis, papillomas, microscopic evidence of mild interstitial pneumonia, and lymphoid hyperplasia and chronic active inflammation in lymph nodes draining feet affected by interdigital furunculosis. No deaths or serious effects were reported.[1]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

Oclacitinib causes minimal inhibition of canine cytochrome P450, and no significant drug interactions have been reported to date. It has been reported to be safely used in conjunction with other common medications, including **vaccines, NSAIDs, antibiotics, parasiticides, anticonvulsants**, and **allergen immunotherapy**.[4,5,35,36] Oclacitinib at label dosages was shown to be well tolerated when given in combination with **carboplatin** or **doxorubicin** in a small pilot study.[37]

- **Cyclosporine**: Although concurrent administration of oclacitinib and cyclosporine appears safe when administered for up to 3 weeks,[38] the combination of cyclosporine and oclacitinib is relatively contraindicated for long-term use, especially in cases in which infection is present, because of the theoretical increased risk for immunosuppression.[3]
- **Immunosuppressive Agents** (eg, **azathioprine, glucocor-**

ticoids, mycophenolate): The use of oclacitinib in combination with systemic glucocorticoids or other systemic immunosuppressive agents has not been evaluated, especially with long-term administration. Concurrent use may lead to additive immunosuppression and increase risk for infection.

- **Tigilanol Tiglate:** Use of oclacitinib 14 days prior to tigilanol tiglate was prohibited in field studies. Use together cautiously.[39]

Laboratory Considerations

- After 30 days of therapy at the label dose, oclacitinib did not interfere with the reactivity results of **allergy serum** and **intradermal testing.**[40]

Dosages

DOGS:

Control of pruritus associated with allergic and atopic dermatitis (label dosage; FDA-approved): 0.4 – 0.6 mg/kg PO every 12 hours for up to 14 days, then 0.4 – 0.6 mg/kg PO every 24 hours for maintenance therapy.[1] Long-term twice-daily administration is not recommended. Oclacitinib may be administered with or without food. See dosing chart below for the appropriate number and size of tablets based on the dog's body weight.

Body weight (kg)	Body weight (lb)	Number of 3.6 mg tablets	Number of 5.4 mg tablets	Number of 16 mg tablets
3-4.4	6.6-9.9	0.5	–	–
4.5-5.9	10-14.9	–	0.5	–
6-8.9	15-19.9	1	–	–
9-13.4	20-29.9	–	1	–
13.5-19.9	30-44.9	–	–	0.5
20-26.9	45-59.9	–	2	–
27-39.9	60-89.9	–	–	1
40-54.9	90-129.9	–	–	1.5
55-80	130-175.9	–	–	2

Pruritus associated with allergic and atopic dermatitis in dogs that experience recurrence of clinical signs when frequency is reduced to once-daily maintenance therapy (extra-label): 0.4 – 0.6 mg/kg PO every 12 hours.[41] Anecdotally, 0.2 – 0.3 mg/kg PO every 12 hours. The long-term safety of these dosages has not been rigorously studied.

Ischemic dermatopathy (extra-label):

a) From a case series (n = 4), 0.5 – 0.7 mg/kg PO twice daily in conjunction with oral prednisolone 0.5 – 1 mg/kg/day. After decreasing and discontinuing prednisolone, oclacitinib dose reductions to 0.5 – 0.7 mg/kg PO once daily were attempted, but 3 dogs (littermates) required twice-daily dosing to maintain disease control.[7]

b) From a case report: 0.6 mg/kg PO every 12 hours for 60 days, then 0.6 mg/kg PO every 24 hours[8]

Relief of pruritus associated with sarcoptic mange (extra-label): In conjunction with systemic antiparasitic treatment, oclacitinib 0.5 mg/kg PO every 12 hours for 14 days, then 0.5 mg/kg PO every 24 hours for another 14 days[14]

Hyperkeratotic erythema multiforme (extra-label): 0.6 – 0.9 mg/kg PO twice daily.[10] A case report (n = 2) showed rapid improvement in clinical signs, and complete remission was observed in 7 and 12 weeks for each dog.

Ear tip ulcerative dermatitis (extra-label): 0.4 – 0.6 mg/kg PO every 12 hours for up to 14 days, then 0.4 – 0.6 mg/kg PO every 24 hours. Several dogs required prolonged use of every 12-hour dosing.[12]

CATS:

Feline atopic skin syndrome (FASS, formerly nonflea-, nonfood-induced hypersensitivity dermatitis [NFNFIHD]) (extra-label): 1 mg/kg PO once or twice daily for 28 days[15,17,18,33]

Hypersensitivity, dermatitis, or head and neck pruritus (extra-label): 0.4 – 0.8 mg/kg (practically, 2.7 mg/cat [NOT mg/kg] as ½ of a 5.4 mg tablet) PO every 12 hours for 14 days, then 0.4 – 0.8 mg/kg every 24 hours for 14 additional days[17,21]

Asthma (extra-label): 0.5 – 1 mg/kg PO every 12 hours[20]

Monitoring

- Clinical efficacy
- Development of infections (eg demodicosis, interdigital furunculosis, pneumonia, UTI)
- Development of new (or exacerbations of existing) cutaneous or subcutaneous masses or other neoplasms
- There are no data to support mandated bloodwork monitoring; however, according to the individual patient's needs and concurrent medications of unknown drug interaction with oclacitinib, baseline and periodic (eg, every 6 to 12 months) CBC, serum chemistry profile, and urinalysis may be performed.

Client Information

- This medicine is approved for use in dogs only. Not for human use
- Wash your hands immediately after handling the tablets. In case of accidental eye contact, flush the eye immediately with water or saline for at least 15 minutes, then seek medical attention. In case of accidental ingestion, seek medical attention immediately.
- Oclacitinib may be administered with or without food. If your animal vomits or acts sick after a dose, try administering the medicine with some food. If there is no improvement, discontinue the medication and contact your veterinarian.
- This medicine may make it so that your animal gets infections (eg, respiratory, urinary). Contact your veterinarian immediately if you have concerns about whether your animal has an infection.
- If you see abnormal skin changes, new growths, or changes in pre-existing masses on your animal, contact your veterinarian.

Chemistry/Synonyms

Oclacitinib maleate (CAS Registry 1208319-26-9; ATC: QD11AH90) is a synthetic sulfonamide-derivative inhibitor of JAK. Oclacitinib occurs as a white to off-white powder that is insoluble in water but soluble in DMSO.

Oclacitinib may also be known as PF-03394197-11. The trade name is *Apoquel*®.

Storage/Stability

Store tablets at room temperature (20°C-25°C [68°F-77°F]). Excursions are allowed between 15°C-40°C (59°F-104°F).

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oclacitinib Oral Tablets (scored): 3.6 mg, 5.4 mg, and 16 mg; *Apoquel*®; (Rx). Approved for use in dogs. NADA# 141-345

HUMAN-LABELED PRODUCTS: NONE

Octreotide

(ok-***trye***-oh-tide) *Sandostatin®*

Somatostatin Analogue

Prescriber Highlights

- ► Injectable long-acting somatostatin analogue that may be useful for adjunctive treatment of insulinomas and gastrinomas
- ► Limited veterinary experience but appears safe. Reduced appetite or anorexia may occur in dogs. May affect GI fat absorption, thyroid levels, or blood glucose levels
- ► Multiple daily SC injections are required. Only a single case report in a dog describes the information for veterinary use of depot IM form.
- ► Drug cost may be a barrier to treatment.

Uses/Indications

Octreotide may be useful in the treatment of clinical signs associated with gastrinomas in dogs or cats and in the adjunctive treatment of hyperinsulinemia in patients with insulinomas (especially dogs and ferrets). A case report of successful treatment using octreotide in a dog with necrolytic migratory erythema (NME; superficial necrolytic dermatitis) due to metastatic glucagonoma has been published.[1] Octreotide has also been reported successful for amatoxin mushroom poisoning in a small number of dogs.[2]

More research is needed before octreotide can be recommended for use in veterinary patients with acute pancreatitis. Octreotide has not been effective in reducing growth hormone levels or enhancing insulin sensitivity in cats with acromegaly.

Pharmacology/Actions

Octreotide is a synthetic, long-acting analogue of somatostatin. It inhibits the synthesis and secretion of insulin (in both normal and neoplastic beta cells), glucagon, secretin, growth hormone, gastrin, and motilin. In humans, octreotide has an inhibitory effect on bile secretion and gall bladder function. Five somatostatin receptor subtypes exist, which are variably expressed depending on species and tumor type. Octreotide may bind to any one of 5 subtypes of somatostatin receptors found on human neoplastic beta cells, but preferentially binds the somatostatin receptor-2 (SSTR2).[3] Dogs only have one subtype (SSTR2). Canine insulinoma cells receptors can have a high affinity for octreotide. In dogs with insulinomas, increased glycemic effects may be transient and persist for only 3 to 4 hours.

Hypersomatotropic cats overexpress subtypes SSTR1 and SSTR5, and in horses, the SSTR2 dominates on beta cells.[3,4] Cats with acromegaly do not respond to octreotide possibly due to underexpression of SSTR2.[5]

Pharmacokinetics

Treated dogs or ferrets generally require 2 to 3 injections per day to maintain blood glucose.[6]

In humans, after SC administration, octreotide is completely absorbed and distributed rapidly from the injection site. Half-lives in humans average ≈2 hours with duration of effect up to 12 hours.[7] About 32% of a dose is excreted unchanged in the urine, and patients with severe renal or hepatic dysfunction may need dosage adjustment.

Contraindications/Precautions/Warnings

Octreotide is contraindicated in patients that are hypersensitive to it. It should be used with caution in patients with biliary tract disorders. Severe renal or hepatic dysfunction my require dose adjustments.

For insulinomas, duration of effect can be short, and response is variable, presumably dependent on whether the tumor cells have receptors for somatostatin. Dogs with insulinomas can also become refractory to treatment long-term despite a good initial response to therapy.

Adverse Effects

Limited experience in domestic animals suggests octreotide is well tolerated. Anorexia has been reported in some dogs. In healthy human patients, single doses of octreotide were shown to inhibit gall bladder contraction and decrease bile secretion. Bradycardia, hypothyroidism, GI effects (eg, nausea, diarrhea, abdominal discomfort), and biliary tract disorders (including gallstones, biliary sludge, and biliary tract dilatation) are most commonly noted in human patients, particularly those with acromegaly. Hypoglycemia and hyperglycemia are possible. Injection site discomfort and reactions have been noted with SC administration; use smallest possible injection volume and rotate injection sites.

Pancreatitis and decreased vitamin B_{12} levels have been reported in humans.[7]

Reproductive/Nursing Safety

Studies in rats and rabbits of doses up to 16 times the highest labeled human dosage resulted in no evidence of fetal harm.[7] It is not known whether this drug is excreted in maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Serious adverse effects are unlikely with octreotide overdoses. Increased mortality was noted in mice and rats receiving IV bolus injections of 72 mg/kg and 18 mg/kg, respectively; however, human subjects have received up to 120 mg (total dose; ≈1.5 mg/kg) IV over 8 hours with no untoward effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving octreotide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Adrenergic Receptor Antagonists** (eg, **atenolol, propranolol**): Octreotide may cause additive bradycardic effects.
- **Bromocriptine**: Octreotide may increase oral bioavailability.
- **Calcium Channel Blockers**: Octreotide may cause additive bradycardic effects.
- **Cyclosporine**: Octreotide may reduce cyclosporine blood concentrations.
- **Diuretics, Agents that Affect Fluid/Electrolyte Balance** (eg, **furosemide**): Octreotide may enhance fluid/electrolyte imbalances.
- **Drugs That Prolong QT Interval** (eg, **ciprofloxacin, cisapride, clomipramine, domperidone, erythromycin, fluconazole, fluoxetine, ketoconazole, methadone, ondansetron**): May increase risk of QT prolongation; concurrent cisapride and octreotide is contraindicated in humans.
- **Food**: Octreotide may reduce fat absorption.
- **Insulin, Oral Hypoglycemics**: Octreotide may inhibit the actions of insulin.
- **Quinidine**: Octreotide may reduce the quinidine clearance.

Dosages

NOTE: All listed dosages are for the short-acting octreotide injection (not the human depot, long-acting formulation) unless otherwise noted.

DOGS:

Adjunctive medical treatment of insulinoma (beta cell tumor) particularly in patients refractory to or unable to tolerate other medical or surgical therapy (extra-label):

a) Based on limited numbers of dogs, for acute treatment: 20 – 40 µg/kg SC every 8 to 12 hours. For long-term treatment: 2 – 4 µg/kg SC every 8 to 12 hours[8]

b) **Short- and long-term management in dogs**: 10 – 40 µg/dog (NOT µg/kg) SC every 8 to 12 hours[9]

Adjunctive medical treatment of gastrinoma (extra-label): Based on limited numbers of dogs, 1 – 20 µg/kg SC 3 to 4 times daily. One dog with gastrin-secreting neuroendocrine neoplasia that initially responded to 8 µg/kg SC was subsequently administered sustained-release octreotide 0.5 mg/kg IM every 28 days. Measurements of 2 target lesions remained essentially unchanged 1 month after administration and reductions in serum gastrin were seen; however, disease progression was noted despite a dose increase of sustained-release octreotide to 1 mg/kg IM every 28 days. Administration continued for 10 doses, during which time the dog's tumor size and gastrin level increased, weight declined, and clinical condition deteriorated.[10]

Necrolytic migratory erythema (NME) secondary to glucagonoma (extra-label): Based on a single case report, initial dosage of 2 µg/kg SC every 12 hours, with the dose increased over time to attempt to achieve clinical remission, to a dosage as high as 3.7 µg/kg SC every 6 hours.[1]

Amatoxin poisoning (extra-label): 10 – 20 µg/dog (NOT µg/kg) IV followed by a 10 – 20 µg/dog/hour (NOT µg/kg/hour) IV CRI[2]; from a case report of 5 dogs, dose extrapolated from human protocols

CATS:

Medical treatment of chylothorax (extra-label): Beginning 7 days after partial surgical resolution of idiopathic chylothorax, octreotide 10 µg/kg SC 3 times daily was given to 2 cats for 30 days and to 1 cat for ≈6 months; treatment was considered safe and effective.[11]

Adjunct medical management of gastrinoma (extra-label): Based on a single case report, octreotide 2 µg/kg SC every 8 hours for 2 doses, followed by 4 µg/kg SC every 8 hours for 2 doses, and then 10 µg/kg SC every 8 hours long term.[12]

HORSES:

Detection of insulin dysregulation (extra-label): 1 µg/kg IV resulted in an immediate decrease in plasma insulin concentration, causing hyperglycemia. The rate of decreasing blood glucose and magnitude of rebounding insulin concentration may aid in the diagnosis of insulin dysregulation, but an octreotide response test for detecting insulin dysregulation has not been developed.[13]

FERRETS:

Medical treatment of insulinoma, particularly in patients refractory to or unable to tolerate other medical or surgical therapy (extra-label): 1 – 2 µg/kg SC 2 to 3 times a day[14]

Monitoring

- Blood glucose (for insulinoma treatment)
- Thyroid function as indicated
- Heart rate and rhythm
- Clinical efficacy

Client Information

- There is limited experience with this medicine in animals, and therapy must be considered experimental.
- Administration in between meals may reduce adverse GI effects.
- The expense associated with this medication can be considerable.

Chemistry/Synonyms

Octreotide acetate is a synthetic polypeptide related to somatostatin with a molecular weight of 1019 (octreotide). It is commercially available in injectable forms for SC or IV injection, and as an extended-release suspension for IM administration.

Octreotide acetate may also be known as SMS-201-995, *Longastatina®*, *Samilstin®*, *Sandostatin®*, *Sandostatina®*, or *Sandostatine®*.

Storage/Stability

When stored at room temperature and protected from light, octreotide acetate injection remains stable for 14 days while the powder for injection may be kept at room temperature for 30 to 60 minutes. For long-term storage, keep this product refrigerated between 2°C to 8°C (36°F-46°F). If injecting solution that has been in the refrigerator, allow it to come to room temperature in the syringe before injecting. Do not use artificial warming techniques. It is recommended to use multidose vials within 14 days of initial use. Octreotide is stable in 0.9% sodium chloride or 5% dextrose for 24 hours.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Octreotide acetate for injection is reported to be **compatible** with isotonic saline and dextrose IV solutions. In humans, octreotide acetate may be diluted in volumes of 50 mL to 200 mL for infusion over 15 to 30 minutes, or may be administered by IV push over 3 minutes.[7] Octreotide is reportedly **Y-site compatible** with the following drugs (partial list): aminocaproic acid, amiodarone HCl, calcium salts, cefazolin, dexamethasone sodium phosphate, dexmedetomidine, dobutamine HCl, epinephrine HCl, esmolol, heparin sodium, hydrocortisone sodium succinate, lidocaine HCl, mannitol, methylprednisolone sodium succinate, ondansetron, potassium chloride, and sodium bicarbonate.

Octreotide is reported **incompatible,** or compatibility varies with the following: dantrolene sodium, diazepam, and pantoprazole sodium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Octreotide Acetate for Injection: 0.05 mg/mL (50 µg/mL), 0.1 mg/mL (100 µg/mL), 0.2 mg/mL (200 µg/mL), 0.5 mg/mL (500 µg/mL), and 1 mg/mL (1000 µg/mL) in 1 mL amps, single-dose vials or syringes and 5 mL multi-dose vials; *Sandostatin®*, generic; (Rx)

Octreotide Acetate Powder for Injectable Suspension: 10 mg, 20 mg, and 30 mg vials in single-use kits with 2 mL diluent provided; *Sandostatin® LAR Depot*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Olsalazine

(ole-***sal***-a-zeen) *Dipentum®*

Anti-inflammatory, Local GI Tract

Prescriber Highlights

- ► Used for treatment of chronic colitis in dogs that cannot tolerate sulfasalazine; limited experience
- ► Converted to 2 molecules of 5-aminosalicylic acid in colon; results in approximately double the amount of mesalamine compared to sulfasalazine
- ► Adverse effects include transient, watery diarrhea; keratoconjunctivitis sicca (KCS) has been reported in some dogs.

Uses/Indications

Olsalazine can be used for treatment of dogs with chronic colitis that cannot tolerate the adverse effects associated with sulfasalazine. It has been proposed for use in dogs that have failed to respond to sulfasalazine, but since both olsalazine and sulfasalazine have a similar mechanism of action (delivery of 5-aminosalicylic acid [5-ASA] to the colon), it may be more rational to try other treatment modalities in dogs that have failed to respond to another 5-ASA pro-drug. Olsalazine results in approximately double the amount of mesalamine compared to sulfasalazine.[1]

Pharmacology/Actions

Olsalazine is cleaved in the large intestine into 5-aminosalicylic acid (5-ASA; also known as mesalamine) by colonic bacteria. Although its exact mechanism is unknown, mesalamine is thought to have efficacy for chronic colitis secondary to its topical anti-inflammatory activity, including cyclooxygenase and lipoxygenase inhibition. Olsalazine appears to have an inhibitory effect on water and electrolyte absorption in the small intestine, which may contribute to its adverse effect profile.

Pharmacokinetics

In humans (and likely in other species, including horses[2]), olsalazine is poorly absorbed, ≈98% of a dose reaches the colon intact, and what drug is absorbed is rapidly eliminated; 90% of olsalazine that reaches the colon is converted to the active agent mesalamine. Serum half-life is ≈1 hour.[1]

Contraindications/Precautions/Warnings

Olsalazine is contraindicated in patients hypersensitive to it or to salicylates. Use with caution in animals with renal disease as nephritis and tubular damage has developed, though rarely, in human and experimental animal patients.[1]

Adverse Effects

Transient, watery diarrhea is the main adverse effect. In humans, ≈17% of patients developed diarrhea sometime during therapy with olsalazine.[1] This effect appears to be dose-related and transient; however, it may be difficult to distinguish this adverse effect from clinical signs associated with underlying colitis. Keratoconjunctivitis sicca (KCS) has been occasionally reported in dogs receiving olsalazine.

Reproductive/Nursing Safety

Olsalazine had no impact on fertility in rats. In high-dose rat studies, some fetal abnormalities were seen.[1] Oral olsalazine given to lactating rats in doses 5 to 20 times the human dose produced growth delays in their pups. Use with caution in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses in dogs may cause vomiting, diarrhea, and decreased motor activity; treat clinical signs supportively. Doses up to 2 g/kg were not lethal in dogs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving olsalazine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Heparin and Low Molecular Weight Heparins** (eg, **dalteparin, enoxaparin**): Concurrent use may increase risk for bleeding.
- **Mercaptopurine**: Concurrent use may increase risk for myelosuppression.
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)**: Concurrent use may increase risk for GI bleeding.
- **Warfarin**: Olsalazine may increase prothrombin times in patients receiving warfarin.

Laboratory Considerations

- Olsalazine may cause increases in **ALT** or **AST**.

Dosages

DOGS:

Inflammatory bowel disease (extra-label): 5 – 20 mg/kg PO 3 times daily. Not commonly recommended unless dogs cannot tolerate sulfasalazine. If a tolerated dose is effective, attempt to slowly titrate down to the lowest effective dose.

Monitoring

- Clinical efficacy
- Adverse effects
- Baseline and periodic serum renal chemistry panel (eg, BUN, creatinine) and urinalysis

Client Information

- This medicine should be given with food in evenly spaced doses (if possible).
- Contact your veterinarian immediately if side effects such as vomiting, worsening watery diarrhea, and development of eye problems (eg, mucoid discharge, redness, squinting) are seen.

Chemistry/Synonyms

Olsalazine sodium occurs as a yellow crystalline powder that is sparingly soluble in water or alcohol, soluble in dimethyl sulfoxide, and stable under physiologic acidic and alkaline conditions. It is basically 2 molecules of mesalamine (5-ASA) connected at the azo bonding site.

Olsalazine sodium may also be known as azodisal sodium, dimesalamine, CI mordant yellow 5, CI No. 14130, CJ-91B, olsalazinum natricum, sodium azodisalicylate, *Dipentum®* or *Rasal®*.

Storage/Stability

Store capsules at room temperature (20°C-25°C [68°F-77°F]), with excursions permitted from 15°C to 30°C (59°F-86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:
Olsalazine Sodium Oral Capsules: 250 mg; *Dipentum*®, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Omeprazole

(oh-***meh***-prah-zahl) *GastroGard®, Prilosec®, Ulcergard®*
Proton Pump Inhibitor

Prescriber Highlights

- ► Approved for use in horses to prevent and treat GI ulcers and erosions; also commonly used in other species
- ► Administer every 12 hours for optimal efficacy.
- ► Adverse effects in horses are unlikely, although hypersensitivity is possible. Omeprazole appears to be well tolerated in small animal species.
- ► Administration may affect the bioavailability of other drugs in which pH affects absorption.
- ► Capsules and tablets should not be crushed, and patients should not be allowed to chew capsules or tablets.

Uses/Indications

Omeprazole is potentially useful in the treatment of both gastroduodenal ulcer disease and the prevention or treatment of gastric erosions caused by ulcerogenic drugs (eg, aspirin, NSAIDs). Omeprazole was superior to famotidine when used to prevent exerciseinduced gastritis in racing Alaskan sled dogs.[1] In healthy dogs, omeprazole decreased gastric acid[2] and was found to be a more effective acid suppressant than famotidine.[3] One study demonstrated that omeprazole given in the evening and 3 hours before anesthesia in dogs increased gastroesophageal reflux pH and decreased the incidence of strongly acidic reflux.[4] Omeprazole should be administered twice daily for best therapeutic effect.[5] When administered to patients for longer than 4 weeks, omeprazole should be gradually tapered to avoid rebound gastric acid hypersecretion; consider a decrease in the dose by 50% each week, with cessation of the evening dosing during the first week.

Omeprazole is considered a key part of the treatment of moderate to severe reflux esophagitis in dogs and cats. Omeprazole also has been used as part of triple therapy (with clarithromycin and amoxicillin) in the successful treatment of *Helicobacter* spp infections in dogs.[6]

In dogs and rabbits following ventriculo-cisternal or IV administration of omeprazole, a reduction in CSF production has been noted.[7,8] Although this effect could be useful in the treatment of conditions causing intracranial hypertension (eg, hydrocephalus, syringomyelia), this effect has not been confirmed in healthy dogs after oral administration.[9] Omeprazole can also be considered as one of the possible drugs used for medical management of decreasing CSF production in diseases such as hydrocephalus and Chiari-like malformation.[7,10,11]

In healthy cats, twice-daily omeprazole increased gastric pH to a significantly greater extent than did once-daily omeprazole or twice-daily ranitidine.[12] In a feline study, 2 preanesthetic doses of 1.45 mg/kg and 2.2 mg/kg effectively increased gastric and esophageal pH within 24 hours; however, no increase in serum gastrin was noted.[13] In a study in cats with chronic kidney disease, once-daily omeprazole did not markedly increase appetite.[14]

Oral paste products are labeled for use in horses and foals 4 weeks of age and older. The drug effectively treats[15,16] and prevents[17,18] gastric ulcers and is considered the drug of choice for equine gastric ulcer syndrome.[19] Ulcer healing and improvement were much better when omeprazole was used for squamous gastric ulcers than glandular gastric ulcers.[20,21] Omeprazole was more effective than sucralfate in preventing the development of gastric ulcers in horses being administered NSAIDs.[22] Esophageal pH was not significantly altered by omeprazole use under experimental conditions.[23]

Pharmacology/Actions

Omeprazole is a substituted benzimidazole proton pump inhibitor. In an acidic environment, omeprazole is activated to a sulfenamide derivative that binds irreversibly at the secretory surface of parietal cells to the active enzyme H^+/K^+ ATPase, where it inhibits the transport of hydrogen ions into the stomach by 90% to 99%. Omeprazole can reduce acid secretion during both basal and stimulated conditions. A lag time between administration and efficacy may be observed. In dogs, ≈3 to 5 days are required for maximum gastric acid reduction. The drug has no effect on gastric emptying time or secretion of intrinsic factor.[24]

Pharmacokinetics

Omeprazole's effects on acid secretion are independent of its drug concentrations. Omeprazole is rapidly absorbed from the gut; the human commercial product is in an enteric-coated granule form, as the drug is rapidly degraded by acid. The equine paste is not enteric-coated. In humans, peak serum concentrations can occur within 0.5 to 3.5 hours, and the onset of action can occur within an hour. The FDA-approved equine oral paste is ≈10% bioavailable due to a significant first-pass effect. Food reduces omeprazole absorption in horses by as much as 67%.[25] Omeprazole is distributed widely but primarily in gastric parietal cells. In humans, ≈95% is bound to albumin and alpha-1 acid glycoprotein.

Omeprazole is extensively metabolized in the liver to at least 6 different metabolites; these are excreted principally in the urine but also via the bile into feces. Significant hepatic dysfunction reduces the first-pass effect of the drug. In humans and dogs with normal hepatic function, serum half-life averages ≈1 hour, but the duration of therapeutic effect may persist for 24 to 72 hours or more. Effects on acid production in horses can last up to 27 hours, depending on the dose.[25]

After IV administration of 0.5 mg/kg in a study of horses, maximum plasma concentration and elimination half-life were 1.8 µg/mL, and 35.5 minutes, respectively. The enteric coating can increase maximal plasma concentrations in horses from 0.25 to 0.4 µg/mL, and food does not appear to decrease absorption. The elimination half-life of an oral enteric-coated formula is ≈107 minutes in horses.[26] In horses, the pharmacokinetics of enteric-coated omeprazole granules appear similar to those of FDA-approved formulations[26,27]; however, diet and dose might affect the pharmacokinetics and pharmacodynamics of the drug, as peak concentrations and total omeprazole exposure (from paste formulation) as well as time with intragastric pH greater than 5 appeared greater in horses fed a grain diet compared to hay.[28,29] Oral absorption of a commercial paste formulation is reduced by ≈67% when administered in the presence of food.[30]

Contraindications/Precautions/Warnings

Omeprazole is contraindicated in patients hypersensitive to it or other proton pump inhibitors. In patients with hepatic or renal disease, the drug's elimination half-life may be prolonged, and dose adjustment may be necessary if the disease is severe. Discontinue omeprazole administration in patients with interstitial nephritis. Use for the shortest duration of therapy appropriate to the condition being treated.

Do not confuse PriLOSEC® (omeprazole) with PROzac® (fluoxetine) or OMEprazole with ESOMEprazole or FOMEpizole.

Adverse Effects

Omeprazole appears to be well tolerated in both dogs and cats at

effective dosages. GI distress (eg, anorexia, colic, nausea, vomiting, flatulence, diarrhea), hematologic abnormalities (rare in humans), proteinuria, and CNS disturbances can potentially occur. Diarrhea is the most common adverse effect reported in association with proton pump inhibitors in dogs; this adverse effect has not been reported in cats.[5] Chronic high doses in rats have caused enterochromaffin-like cell hyperplasia and gastric carcinoid tumors; effects occurred in a dose-related manner.[24] The clinical significance of these findings for long-term use at clinical dosages is not known; however, in humans, administration for more than 8 weeks is not recommended unless the benefits of therapy outweigh the potential risks. In dogs, omeprazole therapy is believed to be safe for at least 4 weeks. A small study has indicated that a shift in canine pharyngeal flora may occur during omeprazole therapy, but further studies are needed to determine the clinical significance of this finding.[31]

The manufacturer does not note any adverse effects for use in horses at recommended label dosages.[30] In foals, calcium absorption may potentially be reduced; the clinical significance is not clear. There is an anecdotal case report of 1 horse developing urticaria after receiving omeprazole. Treatment of horses for up to 90 days is believed to be safe. No adverse effects were reported in horses treated with 12 mg/kg (3 times the maximum recommended dose) for 90 days.[32] No significant changes to fecal microbiota were noted in research horses given omeprazole 4 mg/kg/day PO for 28 days.[33,34] Omeprazole may increase the rate of intestinal complications (eg, small- or large-intestine obstruction, diarrhea, enterocolitis) when administered concurrently with phenylbutazone to horses with equine glandular gastric disease or equine gastric ulcer syndrome.[35]

In humans, long-term omeprazole use is associated with an increased risk for bone fractures, fundic gland polyps, acute interstitial nephritis, and hypomagnesemia.[24]

Reproductive/Nursing Safety

Omeprazole's safety during pregnancy has not been established, but a study in rats at doses of up to 34 times the recommended dose did not demonstrate any teratogenic effects; however, increased embryo–lethality has been noted in laboratory animals at very high doses. The manufacturer of products labeled in the US for equine use has determined the drug is safe for use in breeding stallions.[25,30]

It is not known whether omeprazole is excreted in maternal milk. In humans, nursing is discouraged if the drug is required. Because safety has not been established, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

LD_{50} in rats after oral administration is reportedly greater than 4 g/kg. Horses and foals older than 2 months of age have tolerated oral doses of 40 mg/kg/day for 3 weeks and 20 mg/kg/day for 3 months without adverse effects.[30] Humans have tolerated oral dosages of 360 mg/day without significant toxicity. If a massive overdose occurs, patients should be treated supportively and based on clinical signs.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In humans, omeprazole is an inhibitor of CYP 2C19 and is a CYP 2C19 and 3A4 substrate. The following drug interactions have either been reported or are theoretical in humans or animals receiving omeprazole and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Benzodiazepines** (eg, **alprazolam**, **diazepam**): Omeprazole may potentially alter benzodiazepine metabolism and prolong CNS effects.
- **Bisphosphonates** (eg, **alendronate, clodronate**): Omeprazole may decrease the effectiveness of bisphosphonate derivatives.
- **Cefpodoxime**: Serum cefpodoxime concentrations may be reduced.
- **Cephalexin**: Omeprazole reduced peak cephalexin concentration and AUC and delayed oral absorption in adult dogs; however, time greater than MIC was not altered.[36]
- **Clarithromycin**: Increased concentrations of omeprazole, clarithromycin, and 14-hydroxyclarithromycin are possible.
- **Clopidogrel**: In healthy dogs, concurrent omeprazole increases the formation of an inactive clopidogrel metabolite but without significant alteration of the antiplatelet effect.[37] Pantoprazole should be considered in place of omeprazole if an interaction with clopidogrel is a concern.
- **Clorazepate**: Concurrent use with omeprazole may result in an increased risk for clorazepate toxicity.
- **Cyanocobalamin** (**oral; vitamin B_{12}**): Omeprazole may decrease the oral absorption of cyanocobalamin.
- **Cyclosporine**: Omeprazole may reduce cyclosporine metabolism and increase serum concentrations of cyclosporine.
- **Digoxin**: Omeprazole may increase digoxin bioavailability, increasing the risk for toxicity.
- **Doxycycline**: Concurrent use may decrease bioavailability of doxycycline.
- **Diuretics** (eg, **furosemide**, **hydrochlorothiazide**): May increase the risk for hypomagnesemia
- **Drugs Requiring Decreased Gastric pH For Optimal Absorption** (eg, **ketoconazole, itraconazole, iron, ampicillin esters**): Omeprazole may decrease drug absorption. If both drugs are used together, the pH-dependent medication should be administered 1 hour before omeprazole.
- **Levothyroxine**: Concurrent use may decrease levothyroxine absorption.
- **Methotrexate**: Concurrent use may increase methotrexate concentrations and risk for toxicity.
- **Mycophenolate**: Mycophenolate peak concentration and total exposure (AUC) may be reduced.[24]
- **Phenobarbital**: Concurrent use may increase the risk for phenobarbital toxicity.
- **Rifampin**: Omeprazole serum concentrations may be decreased.
- **Voriconazole**: Concurrent use may increase voriconazole concentrations.
- **Warfarin**: Omeprazole may increase the anticoagulant effect. Prothrombin time (PT) should be monitored in patients on concurrent warfarin therapy.

Laboratory Considerations

- Omeprazole will increase **serum gastrin** levels early in therapy. A study reported that a 7-day withdrawal from short-term administration of omeprazole is sufficient for serum gastrin to return to the baseline concentration.[38]

Dosages

The dose is dependent on formulation, and equine paste and human oral forms may not be interchangeable. Be wary of compounded formulations; bioequivalence is not assured.

DOGS:

GI ulcer management/prevention (extra-label): 1 mg/kg PO every 12 hours[39]

Severe esophagitis: 1 – 1.5 mg/kg PO every 12 hours, often in combination with a prokinetic (cisapride) and sucralfate.[40] Some have recommended giving omeprazole up to 2 mg/kg every 12 hours.[41]

Prevention of exercise-induced gastritis (extra-label): In a study, racing Alaskan sled dogs were administered omeprazole at ≈0.85 mg/kg (one 20 mg tablet) every 24 hours, 30 minutes before being fed. The administration began ≈48 hours before exercise.[1]

***Helicobacter* spp infection/gastritis** (extra-label): Omeprazole 0.5 – 1 mg/kg PO every 24 hours in combination with amoxicillin 20 mg/kg PO every 12 hours and clarithromycin 7.5 mg/kg PO every 24 hours for 21 days.[6] Diarrhea can be an adverse effect of this treatment protocol.

Decrease CSF production: 0.5 – 1 mg/kg PO every 24 hours.[7,10] In 1 study, omeprazole was evaluated in 12 dogs with hydrocephalus at a dose of 10 mg/kg PO every 24 hours and showed medical improvement in all dogs and reduced ventricular size in most dogs.[11]

CATS:

GI ulcer management/prevention (extra-label): 1.1 – 1.3 mg/kg PO every 12 hours.[12] Enteric-coated tablets may be split.[42]

HORSES:

Gastric ulcers (label dosage; FDA-approved):

a) **Treatment of gastric ulcers**: 4 mg/kg PO every 24 hours for 4 weeks[30]

b) **Prevention of gastric ulcers**:

i. 2 mg/kg PO every 24 hours for at least another 4 weeks[30]

ii. 1 mg/kg minimum dose PO every 24 hours[25]

Treatment of squamous ulceration (extra-label): Dosages as low as 1 mg/kg PO once daily were effective when administered following a brief fast and prior to exercise.[43]

Prevention of gastric ulcers (extra-label): One study found that dosages as low as 0.5 mg/kg PO every 24 hours were as effective as the higher, label dosage.[21]

Treatment or prophylaxis of gastric ulcers in foals (extra-label):

a) **Treatment**: 4 mg/kg PO every 24 hours[44]

b) **Prophylaxis**: 1 – 2 mg/kg PO every 24 hours for prophylaxis[44]

SWINE:

Ulcer management (extra-label): 40 mg PO every 24 hours for 2 days; fasted for 48 hours[45]

FERRETS:

Short-term treatment of gastroenteritis (extra-label): 0.7 mg/kg PO every 24 hours[46]

Monitoring

- Efficacy
- Adverse effects

Client Information

- This medicine is used to treat or prevent stomach ulcers and usually only used short-term.
- This medicine works best if given before the first meal of the day.
- Before giving the oral paste to your horse, set the lock ring so that the side nearest the barrel is at the intended dose. Syringes are marked either for body weight or in precalibrated individual doses. Make sure there is no feed in the horse's mouth then deposit the dose on the back of the tongue or deep in the cheek pouch. Redose if any of the doses are lost or rejected.

Chemistry/Synonyms

Omeprazole, a substituted benzimidazole proton pump inhibitor, has a molecular weight of 345.4 and pK_as of 4 and 8.8. Omeprazole occurs as a white to off-white crystalline powder that is slightly soluble in water and soluble in ethanol. The equine oral paste is in a paraffin-based vehicle.

Omeprazole may also be known as H-168/68, omeprazolum, *GastroGard®*, *Peptizole®*, *Prilosec®*, *UlcerGard®*, and *Zegerid®*.

Storage/Stability

Store omeprazole oral paste between 20°C and 25°C (68°F and 77°F); excursions between 15°C and 30°C (59°F and 86°F) are permitted; discard tube 28 days after first opening.[47] Store omeprazole tablets at room temperature in tight, light-resistant containers. Omeprazole pellets found in the capsules should not be crushed.

Compatibility/Compounding Considerations

Caution should be used when administering compounded omeprazole products; bioequivalence has been an issue with some compounded preparations. Omeprazole capsules or tablets should not be crushed or chewed. A study in cats found that fractionated enteric-coated omeprazole tablets were effective in suppressing gastric acid.[42] If the dose of the commercially available capsules is being reduced, the capsule contents should be reinserted into a gelatin capsule so they cannot be chewed.

Compounded preparation stability: A formula for an omeprazole oral suspension compounded from the commercially available powder packets has been published.[48] Dissolving one (1) omeprazole 20 mg powder packet qs ad to 10 mL of sterile water yields 2 mg/mL omeprazole oral suspension that retains more than 98% potency for 45 days when stored at 4°C (39.2°F); however, the resulting low concentration and strawberry flavoring may not be suitable for administration to veterinary patients. Information on the efficacy of omeprazole 40 mg/mL oral suspension compounded by diluting commercially available equine paste 1:9 with sesame oil for use in dogs has been published.[3] Although the long-term stability of this preparation has not yet been assayed, it meets the default beyonduse date criteria of 180 days for nonaqueous oral suspensions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Omeprazole Oral Paste, 2.28 g per syringe; *GastroGard®*, (Rx); *UlcerGard®*; (OTC). Contains 370 mg omeprazole per gram of paste.

The Association of Racing Commissioners International (ARCI) Uniform Classification Guidelines for Foreign Substances (UCGFS) has designated this drug as a class 5 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Omeprazole Delayed-Release Capsules: 10 mg, 20 mg, and 40 mg; *Prilosec®* (*Losec®* in Canada), generic; (Rx)

Omeprazole Delayed-Release Tablets: 20 mg; *Prilosec® OTC*, generic; (OTC)

Omeprazole Delayed-Release Oral Suspension: 2.5 mg and 10 mg packets; *Prilosec®*; (Rx). Packet contents are reconstituted with water.

Omeprazole Suspension: 2 mg/mL; *First®-Omeprazole, Omeprazole+Syrspend® SF Alka*; (Rx)

Omeprazole/Sodium Bicarbonate Capsules (Immediate Release):

20 mg omeprazole/1100 mg sodium bicarbonate and 40 mg omeprazole/1100 mg sodium bicarbonate; *Zegerid®*, *Zegerid®* OTC; (Rx and OTC)

Omeprazole/Sodium Bicarbonate Powder for Suspension: 20 mg omeprazole/1680 sodium bicarbonate and 40 mg omeprazole/1680 sodium bicarbonate in 30 unit-dose packets; *Zegerid®*; (Rx)

Ondansetron

(on-***dan***-sah-tron) *Zofran®*

5-HT_3 Receptor Antagonist

Prescriber Highlights

- ► Oral and injectable agent used for prevention and treatment of vomiting and nausea
- ► Can be used in combination with other antiemetics
- ► Use with caution when administering it with other drugs that increase serotonin in order to avoid serotonin syndrome.
- ► Appears to be well tolerated

Uses/Indications

Ondansetron is an antiemetic that may be used to treat nausea and vomiting in dogs and cats. Ondansetron, metoclopramide, and maropitant can be equally effective in reducing the frequency of vomiting in dogs with parvoviral enteritis.[1,2] Ondansetron is effective for treating chemotherapy-associated nausea and vomiting[3–5]; in preventing the incidence of emesis and nausea in healthy dogs premedicated with hydromorphone, acepromazine, and glycopyrrolate[6]; and in treating nausea in dogs with vestibular syndrome.[7] As an antiemetic and antinausea agent, ondansetron is as effective or more effective than metoclopramide[1,4,8]; however, maropitant appears to be as effective or more effective than ondansetron.[1–4,8,9] Ondansetron has shown promise in the management of obstructive sleep apnea.[10,11]

A study in cats found that ondansetron 0.22 mg/kg IM administered with dexmedetomidine and buprenorphine (in the same syringe) reduced the incidence (≈33%) and severity of nausea and vomiting as compared with ondansetron given 30 minutes before dexmedetomidine and buprenorphine (67%) or when ondansetron was not given (76%).[12]

In donkeys, IV ondansetron decreased duodenal, jejunal, and cecal contractility, as well as small and large intestinal motility.[13] Six out of 30 donkeys experienced a cardiac arrhythmia that began 30 minutes postinfusion and lasted up to 180 minutes.

In humans, ondansetron is approved for the prevention and treatment of nausea and vomiting due to chemotherapy, radiation, and surgery. It may be used in combination with other antiemetics.[14]

Pharmacology/Actions

Ondansetron is a 5-HT_3 receptor antagonist. 5-HT_3 receptors are found peripherally on vagal nerve terminals and centrally in the chemoreceptor trigger zone (CRTZ). Ondansetron's effects appear to be mediated by the antagonism of these receptors both centrally and peripherally. At typical dosages, ondansetron does not have an effect on GI motility or transit time.

Pharmacokinetics

In cats, ondansetron's oral bioavailability is ≈32%, but bioavailability is 75% when the drug is injected SC. Elimination half-life is ≈2 hours (IV), 1.2 hours (PO), and 3.2 hours (SC).[15] Administration of ondansetron 2 mg SC to geriatric cats and cats with renal and hepatic disease revealed reductions in clearance, which were greatest in cats with hepatic disease.[16] Application of ondansetron in *Lipoderm®* transdermal gel to the inner ear pinnae of healthy cats resulted in no measurable serum ondansetron concentrations.[17]

After a single 8 mg oral dose was given to healthy beagles, peak concentrations were reached at 1.1 hours, and the elimination half-life was ≈1.3 hours.[18]

In humans, ondansetron is well absorbed from the GI tract but exhibits some first-pass hepatic metabolism. Oral bioavailability is ≈50% to 60%; bioavailability is ≈75% after IM administration. Oral dosage forms are bioequivalent. Protein binding is ≈75%. Peak plasma concentrations occur ≈2 hours after oral administration. Ondansetron is extensively metabolized in the liver by several cytochrome P450 enzymes, primarily via CYP3A4. Elimination half-lives are ≈3 to 4 hours but are prolonged in elderly patients and pediatric patients 1 to 4 months of age, whereas half-life is reduced in pediatric patients younger than 4 months.

Contraindications/Precautions/Warnings

Ondansetron is contraindicated in patients hypersensitive to it or other agents in this class. Ondansetron may mask ileus or gastric distention; it should not be used in place of nasogastric suction or appropriate diagnostic assessment. Ondansetron should be used with caution in patients with hepatic dysfunction, as absorption may be increased because of reduced first-pass metabolism and halflife may be prolonged; dosage adjustment may be warranted in severe hepatic impairment.

In humans, ondansetron is pumped by P-glycoprotein (the protein encoded by the *MDR1* gene, also known as *ABCB1*-1delta gene), but there are currently no data stating whether it is pumped by canine P-glycoprotein. It is suggested to use caution when administering ondansetron to dogs with the MDR1 gene mutation.[19]

Dose-related prolongation of the QT interval and cases of torsades de pointes have been reported in humans. Patients that have electrolyte abnormalities, have underlying cardiac conditions, or take other QT-prolonging drugs can be at greater risk. Ondansetron caused QT prolongation in healthy dogs,[20] but QT prolongation in sick dogs was identified by only 1 of the 2 methods used to calculate the QT interval.[21]

Serotonin syndrome has occurred in humans receiving ondansetron.[22]

Adverse Effects

Ondansetron appears to be well tolerated. GI effects (ie, constipation, diarrhea), sedation, extrapyramidal clinical signs (eg, head shaking), increased liver enzymes, arrhythmias, and hypotension can be possible (incidence in humans is less than 10%). Headaches occur in 10% to 25% of humans; relevance for veterinary patients is unknown. Transient vision changes, including blindness, during IV administration, have been reported rarely in humans.

Reproductive/Nursing Safety

Safety in pregnancy is not clearly established, but high-dose studies in rodents did not demonstrate overt fetal toxicity or teratogenicity. A review of ondansetron use in women during pregnancy and the risk for birth defects noted a small increase in the incidence of cardiac abnormalities, and the authors concluded that ondansetron should be avoided during the first trimester if possible.[23]

Ondansetron is excreted in the maternal milk of rats.[22] Caution should be used when 5-HT_3 antagonists are administered to nursing patients.

Overdose/Acute Toxicity

Overdoses of up to 10 times the label dosage did not cause significant morbidity in humans. If an overdose occurs, it should be treated supportively.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consulta-

tion center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions/Laboratory Considerations

In humans, ondansetron is a substrate of P-glycoprotein and CYP 3A4, although other CYP isoenzymes (eg, 2D6, 1A2) are involved in the drug's metabolism to a lesser extent. The following drug interactions have either been reported or are theoretical in humans or animals receiving ondansetron and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Apomorphine**: Ondansetron may reduce the emetic effect of apomorphine. A human patient that received ondansetron and apomorphine developed severe hypotension and loss of consciousness. In humans, use together is contraindicated.
- **Azole Antifungals** (eg, **itraconazole, posaconazole**): May inhibit ondansetron metabolism, and concurrent use may increase prolong QTc interval.
- **Cisplatin**: Plasma cisplatin concentrations may be decreased.
- **Cyclophosphamide**: Plasma cyclophosphamide concentrations may be decreased.
- **Drugs Affecting QTc Interval** (eg, **amiodarone, cisapride, procainamide, quinidine, sotalol**): Theoretically, ondansetron may have additive effects on QTc interval; possible serious arrhythmias may result.[21]
- **Monoamine Oxidase Inhibitors** (**MAOIs;** eg, **amitraz, methylene blue, selegiline**): Increased risk for serotonin syndrome has been reported in humans.
- **Metformin**: Ondansetron may increase the serum concentration of metformin.
- **P-glycoprotein Inhibitors** (eg, **amiodarone, cyclosporine, diltiazem, quinidine**): In humans, these drugs may increase serum concentrations of ondansetron. It is unclear if ondansetron is a P-glycoprotein substrate in veterinary patients.
- **Ropinirole**: Ondansetron may reduce the emetic effect of ropinirole.
- **Serotonergic Drugs** (eg, **clomipramine, fluoxetine, mirtazapine, trazodone**): Increased risk for serotonin syndrome has been reported in humans.
- **Tramadol**: In humans, use together may reduce the efficacy of both drugs. Veterinary significance is not known.

Dosages

NOTE: In humans, it is recommended that IV administration of ondansetron occur over at least 30 seconds, and preferably over 2 to 5 minutes.[24]

DOGS:

Antiemetic (extra-label): 0.5 – 1 mg/kg PO or IV (slowly) every 8 to 12 hours is commonly used, although studies supporting these dosages are limited; however, doses of 0.1 – 0.2 mg/kg IV have been noted and are closer to human pediatric recommendations.

Chemotherapy-induced nausea and vomiting (extra-label): 0.3 – 0.5 mg/kg IV (slowly) 30 minutes before chemotherapy administration[3,5,8,25]; may repeat every 8 to 12 hours

Parvovirus-induced nausea and vomiting (extra-label): 0.5 mg/kg IV (slowly) every 8 hours[1,2]

Obstructive Sleep Apnea (extra-label): 1 – 2 mg/kg PO twice daily[10,11]

Vestibular syndrome-associated nausea (extra-label): 0.5 mg/kg IV (slowly) as a single dose[7]

CATS:

Acute vomiting (extra-label): Dosage recommendations vary somewhat; 0.1 – 1 mg/kg IV (slowly), SC, IM, or PO every 6 to 12 hours. Based on a pharmacokinetic study,[15] oral dosages may need to be toward the high end and given more frequently than IV or SC. If using before chemotherapy, give IV (slowly) 30 minutes before treatment; may repeat every 6 to 12 hours.

Vomiting associated with chronic kidney disease (extra-label):

a) IRIS Stage 1 or 2: 0.1 – 0.2 mg/kg slow IV, SC, PO every 6 to 12 hours[26]

b) IRIS Stage 3: 0.05 – 0.1 mg/kg slow IV, SC, PO every 6 to 12 hours[26]

c) IRIS Stage 4: 0.025 – 0.05 mg/kg slow IV, SC, or PO every 6 to 12 hours[26]

Reducing the incidence and severity of vomiting associated with dexmedetomidine/buprenorphine premedication (extra-label): Ondansetron 0.22 mg/kg IM administered with dexmedetomidine and buprenorphine (in the same syringe)[12]

Monitoring

- Clinical efficacy

Client Information

- This medicine is used to treat or prevent severe vomiting. The oral medication may be given with or without food.
- This medicine is usually tolerated well.
- If using orally disintegrating tablets, protect the tablets from moisture, and be sure hands are dry when handling them. Place the tablet on top of the animal's tongue after removing it from the package.

Chemistry/Synonyms

Ondansetron HCl dihydrate is a selective inhibitor of the 5-HT_3 receptor. It occurs as a white to off-white powder that is sparingly soluble in water and alcohol. Solutions for injections have a pH of 3.3 to 4. The potency of commercial dosage forms is expressed as an ondansetron base; 1 mg ondansetron is equivalent to 1.25 mg ondansetron HCl dihydrate.

Ondansetron HCl may also be known as GR-38032F or ondansetroni hydrochloridum, and *Zofran*®.

Storage/Stability

Unless otherwise labeled, store oral products in tight, light-resistant containers between 20°C and 25°C (68°F-77°F); temperature excursions of 15°C to 30°C (59°F-86°F) are permitted for the oral solution. Store orally disintegrating tablets in the original foil blisters and administer immediately upon opening; discard opened/unused tablets or tablet remnants. Store the injection between 2°C and 25°C (36°F-77°F) and protected from light. Solutions diluted for IV infusion retain potency for 48 hours at room temperature, but the manufacturer recommends discarding them 24 hours after dilution.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist may be consulted for more specific information.

An ondansetron 0.8 mg/mL oral suspension can be compounded by crushing oral tablets to a fine powder, suspending with *Ora-Plus*®, and diluting with an equal amount of *Ora-Sweet*® (regular or sugar-free), *Syrpalta*®, or Cherry syrup USP[27]; the resulting product is stable for 6 weeks when refrigerated. Alternatively, using the suspending vehicle, *SyrSpend*® *SF* pH 4 results in a 90-day beyond-use date when refrigerated or stored at room temperature.[28]

Drugs reported to be **compatible** with ondansetron when combined in a syringe and administered via a Y-site include alfentan-

il, atropine, fentanyl, glycopyrrolate, metoclopramide, midazolam, morphine, naloxone, neostigmine, and propofol. Ondansetron is also reported to be **compatible** with dextrose, saline, and lactated Ringer's solutions, as well as with the following drugs when administered via a **Y-site**: amikacin, aminocaproic acid, amiodarone, azithromycin, bleomycin, butorphanol, carboplatin, carmustine, cefazolin, cefotaxime, cefuroxime, cisplatin, clindamycin, cyclophosphamide, cyclosporine, cytarabine, dacarbazine, dactinomycin, daunorubicin, dexamethasone sodium phosphate, dexmedetomidine, dexrazoxane, digoxin, diphenhydramine, dopamine, doxorubicin HCL (also liposome form), doxycycline, famotidine, filgrastim, fluconazole, gemcitabine, gentamicin, heparin, hydromorphone, hydroxyzine, ifosfamide, lidocaine, mannitol, methotrexate, mitoxantrone, norepinephrine, pamidronate, piperacillin-tazobactam, potassium chloride, procainamide, prochlorperazine, promethazine, ranitidine, vancomycin, vinblastine, vincristine, zidovudine, and zoledronic acid.

A precipitate may form when mixed with alkaline solutions. Ondansetron is reportedly **incompatible** with amphotericin B (conventional and lipid-based forms), ampicillin/sulbactam, furosemide, pantoprazole, and phenobarbital sodium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Ondansetron HCl Tablets: 4 mg and 8 mg; *Zofran®*, generic; (Rx)

Ondansetron Orally Disintegrating Tablets or Oral Film: 4 mg and 8 mg (as base); *Zofran® ODT*, *Zuplenz®*, generic; (Rx)

Ondansetron HCl Oral Solution: 0.8 mg/mL (4 mg/5 mL) in 50 mL; *Zofran®*, generic; (Rx)

Ondansetron HCl Injection: 2 mg/mL in 2 mL single-dose syringes and 20 mL single- or multi-dose vials; *Zofran®*, generic; (Rx)

Orbifloxacin

(or-bi-***flox***-a-sin) *Orbax®*

Fluoroquinolone Antibiotic

Prescriber Highlights

- ► Fluoroquinolone antibiotic labeled for treating skin and soft tissue infections in dogs and cats and for treating bacterial urinary infections in dogs.
- ► Contraindications: Immature dogs during the rapid growth phase; known hypersensitivity to this class of drugs. Caution: Known or suspected CNS disorders
- ► Adverse effects: GI effects most likely
- ► In cats, tablet and suspension formulations are not bioequivalent.
- ► Many potential drug interactions
- ► Federal law prohibits extra-label use in food-producing animals.

Uses/Indications

Orbifloxacin is indicated for treatment of susceptible skin and soft tissue bacterial infections in dogs and cats. In dogs, it is also indicated for treatment of UTIs. It is recommended that orbifloxacin be reserved for documented resistant UTIs, but it is a good first-line choice for pyelonephritis or infections that involve the prostate.[1] In addition, fluoroquinolones are recommended as second-tier drugs for treatment of bacterial folliculitis.[2]

Orbifloxacin may also be of benefit in treating susceptible gram-negative infections in horses, although clinical data are lacking and an equine formulation is not available.

The World Health Organization has designated orbifloxacin as a Critically Important (Highest Priority) antimicrobial for human medicine.[3] The Office International des Epizooties (OIE) has designated quinolones as Veterinary Critically Important Antimicrobial (VCIA) Agents in veterinary species.[4]

Pharmacology/Actions

Orbifloxacin is a concentration-dependent bactericidal agent. It acts by inhibiting bacterial DNA-gyrase (a type II topoisomerase), thereby preventing DNA supercoiling and DNA synthesis. The net result is disruption of bacterial cell replication. Like other fluoroquinolones, orbifloxacin has demonstrated a significant postantibiotic effect for both gram-negative and gram-positive bacteria. Clinical efficacy is associated with achieving a peak orbifloxacin concentration 10 times greater than bacterial MIC,[5,6] resulting in infrequent (once-daily) administration of high doses.

Like other fluoroquinolones, orbifloxacin has excellent activity against many gram-negative bacteria and many gram-positive bacteria. This includes most species and strains of *Klebsiella* spp, *Staphylococcus pseudintermedius* or *S aureus, E coli, Enterobacter* spp, *Campylobacter* spp, *Bartonella* spp, *Shigella* spp, *Proteus* spp, and *Pasteurella* spp. Some strains of *Pseudomonas aeruginosa* and other *Pseudomonas* spp are resistant to orbifloxacin and most *Enterococcus* spp are resistant. Like other fluoroquinolones, orbifloxacin has weak activity against most anaerobes and is not a good choice when treating known or suspected anaerobic infections. Acquired resistance can occur in virtually any bacterial species but is most commonly encountered in Enterobacteriaceae (*E coli* and related species) and staphylococci.

Pharmacokinetics

After oral administration in dogs or cats, orbifloxacin is apparently nearly completely absorbed, although the suspension formulation results in lower and more variable plasma levels in cats as compared with tablets.[7] Dogs receiving 7.5 mg/kg PO had an average peak orbifloxacin concentration of ≈6 μg/mL 2 hours after administration. Cats receiving orbifloxacin tablets 7.5 mg/kg PO had peak plasma level of 6 μg/mL as compared with 3 μg/mL in cats receiving an equivalent dose of orbifloxacin suspension. The drug is distributed well (V_d=1.2 L/kg in dogs; 1.3 L/kg in cats) and only slightly bound to plasma proteins (8% dogs; 15% cats). Orbifloxacin is eliminated primarily via the kidneys. Approximately 50% of the drug is excreted unchanged. Serum half-life after oral dosing is ≈5.5 hours in dogs and 4.5 to 7.5 hours in cats. Urine levels remain well above MICs for susceptible organisms for at least 24 hours after dosing.

In horses, orbifloxacin is well absorbed after oral administration (bioavailability is ≈70%) and distributes in many body fluids and endometrial tissue. Protein binding is relatively low (≈20%). Elimination half-life is ≈3.5 to 9 hours.[8,9]

Rabbits receiving 20 mg/kg PO reached a peak concentration of 3 μg/mL at 2 hours after administration. Volume of distribution was 1.3 L/kg, and terminal half-life was 8.6 hours.[10]

Contraindications/Precautions/Warnings

Some fluoroquinolones can cause arthropathies in immature, growing animals, and the risk posed by orbifloxacin is unclear. Because dogs appear to be more sensitive to this effect, the manufacturer states that the drug is contraindicated in immature dogs during the rapid growth phase (age 2 to 8 months in small- and medium-sized breeds and up to 18 months in large and giant breeds). The drug is also contraindicated in dogs and cats known to be hypersensitive to orbifloxacin or other drugs in its class (quinolones). Orbifloxacin use is contraindicated in patients receiving cyclosporine.

The manufacturer states that orbifloxacin should be used with caution in animals with known or suspected hepatic and CNS disorders (eg, seizure disorders) as, rarely, drugs in this class have been associated with CNS stimulation. Because fluoroquinolones, including orbifloxacin, are known to adversely affect the retina in cats, the manufacturer cautions to not exceed doses of 7.5 mg/kg per day in cats.[7]

Adverse Effects

Although the manufacturer states that no adverse effects were reported during clinical studies (at 2.5 mg/kg dosing) in adult animals, GI effects (eg, anorexia, vomiting, hypersalivation), depression/lethargy, and convulsions have been reported.[7]

Blindness has been reported in cats receiving orbifloxacin.[7]

Induction of *Streptococcus canis* necrotizing fasciitis, which can be seen with enrofloxacin, does not appear to be a problem with orbifloxacin.

Reproductive/Nursing Safety

Safety in breeding or pregnant dogs or cats has not been established. Other fluoroquinolones are known to cross the placenta.

It is not known whether orbifloxacin enters maternal milk. Other fluoroquinolones are known to be excreted in milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

Dogs and cats receiving up to 5 times (37.5 mg/kg) the label dose for 30 days did not exhibit any significant adverse effects. At 75 mg/kg, dogs experienced adverse GI effects, including anorexia, vomiting, diarrhea, and mild weight loss. Glucosuria was also noted. Cats receiving the higher doses exhibited emesis, salivation, lacrimation, soft feces, and decreased food consumption. Ophthalmic changes were apparent in cats receiving 45 and 75 mg/kg/day, including retinal degeneration.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving orbifloxacin or related fluoroquinolones and may be of significance in veterinary patients. Orbifloxacin has been shown to inhibit CYP1A activity in dogs.[11] Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids/Dairy Products** (containing cations Mg^{++}, Al^{+++}, Ca^{++}): May bind to orbifloxacin and prevent its absorption; separate doses of these products by at least 2 hours.
- **Antibiotics, Other** (eg, **aminoglycosides, 3rd-generation cephalosporins, penicillins—extended-spectrum**): Synergism may occur, but is not predictable, against some bacteria (particularly *Pseudomonas aeruginosa*) with these compounds. Although orbifloxacin has minimal activity against anaerobes, in vitro synergy has been reported when the drug is used with **clindamycin** against strains of *Peptostreptococcus* spp, *Lactobacillus* spp, and *Bacteroides fragilis*.
- **Cimetidine**: May impair fluoroquinolone metabolism
- **Cyclosporine**: Fluoroquinolones may exacerbate the nephrotoxicity and reduce the metabolism of systemically administered cyclosporine. The manufacturer states concurrent orbifloxacin use with cyclosporine is contraindicated.
- **Flunixin**: Has been shown in dogs to increase the AUC and elimination half-life of enrofloxacin, and enrofloxacin increases the AUC and elimination half-life of flunixin; it is unknown whether orbifloxacin also causes this effect or other NSAIDs interact with orbifloxacin in dogs.
- **Glyburide**: Severe hypoglycemia possible
- **Iron, Zinc** (**oral**): Decreased orbifloxacin absorption; separate doses by at least 2 hours.
- **Methotrexate**: Increased methotrexate levels possible with resultant toxicity
- **Nitrofurantoin**: May antagonize the antimicrobial activity of the fluoroquinolones, and their concomitant use is not recommended.
- **Phenytoin**: Orbifloxacin may alter phenytoin levels.
- **Probenecid**: Blocks tubular secretion of ciprofloxacin and may also increase the blood level and half-life of orbifloxacin
- **Sucralfate**: May inhibit absorption of orbifloxacin; separate doses of these drugs by at least 2 hours.
- **Theophylline**: Orbifloxacin may increase theophylline blood levels.
- **Warfarin**: Potential for increased warfarin effects

Dosages

DOGS/CATS:

Susceptible infections (label dose; FDA-approved):

Tablets: *Dogs and cats,* **For the treatment of susceptible bacterial infections***:* 2.5– 7.5 mg/kg PO once daily. Treatment duration is 10 days for UTI, and treatment for other infections should continue for 2 to 3 days past resolution of clinical signs to a maximum of 30 days. Do not exceed 7.5 mg/kg/day in cats.[7] **NOTE**: Higher doses may be preferable for any situation because of the concentration-dependent nature of the drug.

Suspension:

Dogs: **For the treatment of UTIs and skin and soft tissue infections** (wounds and abscesses) caused by susceptible bacteria: 2.5 – 7.5 mg/kg PO once daily. Treatment duration is 10 days for UTI; treatment for other infections should continue for 2 to 3 days past resolution of clinical signs to a maximum of 30 days. **NOTE**: Higher doses may be preferable for any situation because of the concentration-dependent nature of the drug.

Cats: **For the treatment of skin infections (wounds and abscesses) caused by susceptible strains of *S aureus, E coli*, and *P multocida***: 7.5 mg/kg PO once daily. Treatment should continue for 2 to 3 days past resolution of clinical signs. Do not exceed 7.5 mg/kg/day in cats.[7]

Sporadic cystitis for which amoxicillin (±clavulanic acid) and trimethoprim-sulfonamide are not appropriate based on culture and susceptibility or patient factors (extra-label): 2.5 – 7.5 mg/kg PO once daily (7.5 mg/kg/day PO in cats treated with oral suspension) for 3 to 5 days.[1]

HORSES:

Susceptible infections (extra-label): Little documentation exists for clinical use of orbifloxacin in horses. Two PK studies suggested 5 mg/kg PO once daily[12] and 7.5 mg/kg PO once daily.[13]

BIRDS:

Japanese Quail (extra-label): From a PK/PD study: Authors concluded that 20 mg/kg PO once daily would be a rational dose to treat susceptible infections in Japanese quail not intended for food; for more susceptible organisms, 15 mg/kg PO may also be effective.[14]

RABBITS:

Susceptible infections (extra-label): 20 mg/kg PO once daily[10]

Monitoring
- Efficacy
- Adverse effects

Client Information
- This drug is best given without food on an empty stomach, but if your animal vomits or acts sick after receiving it, give with small amount of food or a small treat (**no** dairy products, antacids, or anything containing iron). If vomiting continues, contact your veterinarian.
- Do not give at the same time with other drugs or vitamins that contain calcium, iron, or aluminum, as these can reduce the amount of drug absorbed.
- Most common side effects are vomiting, nausea (animal acts sick), or diarrhea. May discolor feces
- The suspension form does not require refrigeration but must be shaken well before use; the oral dosing syringe should be rinsed after use.
- Give the medicine for as long as your veterinarian has prescribed it for, even if your animal appears well.

Chemistry/Synonyms
A 4-fluoroquinolone antibiotic, orbifloxacin occurs as a white to pale yellow, odorless crystalline powder. It is slightly soluble in water at neutral pH. Solubility increases in either an acidic or basic medium.

Orbifloxacin may also be known as marufloxacin, orbifloxacine, orbifloxacinum, or *Orbax®*.

Storage/Stability
The commercially available tablets should be stored between 2°C to 30°C (36°F-86°F) and protected from excessive moisture.

The oral suspension should be stored between 2°C to 25°C (36°F-77°F). It does not require refrigeration. Store upright. Shake well before use.

Compatibility/Compounding Considerations
An orbifloxacin 22.7 mg tablet crushed and mixed with molasses, dark corn syrup, water from canned tuna, Kame fish sauce, *Ora-Plus®*, *Syrplata®*, or simple syrup was relatively stable (greater than 85% expected value) for up to 7 days when stored unrefrigerated but protected from light. Mixing with oral supplements that contain calcium or magnesium (eg, *Lixotinic®*) showed significant inactivation of orbifloxacin after 4 days.[15]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Orbifloxacin Oral Tablets: 22.7 mg (green) and 68 mg (blue) E-Z Break tablets; *Orbax®*[7]; (Rx). FDA-approved for use in dogs and cats. Federal law prohibits the use of the drug in food-producing animals. NADA# 141-081

Orbifloxacin Oral Suspension: 30 mg/mL malt-flavored in 20 mL bottles; *Orbax® Suspension*[16]; (Rx). FDA-approved for use in dogs and cats. Federal law prohibits the use of the drug in food-producing animals. NADA# 141-305

An otic suspension containing orbifloxacin, mometasone furoate monohydrate, and posaconazole is also available; *Posatex® Otic Suspension* (Rx). For otic use in dogs only. See ***Corticosteroid/Antimicrobial Preparations***.

HUMAN-LABELED PRODUCTS: NONE

Osaterone

(oh-***sat***-eh-rone) *Ypozane®*

Antiandrogenic; Progestational

Prescriber Highlights
- ► Approved in other countries for benign prostatic hypertrophy (BPH) in intact male dogs. Not commercially available in the United States
- ► Labeled as a 7-day treatment course; efficacy persists for several months
- ► Contraindications include in female dogs and patients that are hypersensitive to it.
- ► Most common adverse effects include transient appetite stimulation and behavioral changes.
- ► May decrease cortisol levels and affect ACTH stimulation tests
- ► Women of child-bearing age should avoid contact with, or wear disposable gloves when administering, osaterone.

Uses/Indications
Osaterone is used in male dogs to treat benign prostatic hypertrophy (BPH). It is also being investigated as a treatment for alopecia X in dogs.[1]

Osaterone is not available in the United States but is available in other countries.

Pharmacology/Actions
Osaterone acetate is structurally related to progesterone and has anti-androgenic effects. It is thought to act primarily by decreasing testosterone transport into the prostate, inhibiting 5-alpha reductase, competitively inhibiting binding to prostate androgen receptors, and decreasing androgen nuclear receptors.[2] The 15-beta hydroxylated metabolite (PB-4) also has anti-androgenic activity. Although osaterone has weak affinity for glucocorticoid receptors, PB-4 can cause some adrenosuppression. Osaterone has some progestational activity but does not have mineralocorticoid activity.

Pharmacokinetics
In dogs, osaterone is rapidly absorbed after oral administration and peak concentrations occur ≈2 hours after dosing. Plasma protein binding of osaterone is ≈90% and ≈80% for its active metabolite (PB-4). Osaterone is primarily metabolized via hydroxylation to PB-4.[3] Elimination half-life is ≈80 hours. It is eliminated primarily in feces via biliary excretion and, to a lesser extent, in urine. After a single dose, osaterone and its metabolites can be detected in urine and feces for up to 14 days.

Contraindications/Precautions/Warnings
Osaterone is contraindicated in female animals and animals that are hypersensitive to it. Use osaterone cautiously in animals with hepatic dysfunction.

Wash hands after handling osaterone.[4] Women of child-bearing age should avoid contact with, or wear disposable gloves when administering, osaterone.

Adverse Effects
The most common adverse effect reported in dogs is a temporary increase in appetite. Transient behavioral changes are common, including changes in activity level and sociability. Polyuria, polydipsia, mammary gland hyperplasia (rare), hair coat changes (rare), and GI effects (eg, vomiting, diarrhea) have been reported. Decreased cortisol plasma levels occur commonly early in treatment and can persist for several weeks. In dogs with hypoadrenocorticism or that are under physiological stress (eg, postsurgery, posttrauma), consider additional monitoring and glucocorticoid support, if required.

Reproductive/Nursing Safety

Osaterone should not be used in female animals.[4] In laboratory animals, it has caused serious adverse effects on reproductive functions. Women of child-bearing age should wear gloves and avoid handling osaterone when possible.

No adverse effects on semen quality have been reported[4,5]; however, an early study in beagles reported transient abnormalities in semen quality likely secondary to decreased testosterone effects on the epididymis.[6]

Overdose/Acute Toxicity

Limited information is available for clinical overdoses of osaterone. Doses greater than 10 mg/kg may cause ataxia and tremors. Dogs given 1.25 mg/kg (2.5 times the label dose) for 10 days only showed decreased plasma cortisol levels.[4] A single 40 mg dose in human males resulted in sporadic decreases of LH, FSH, and testosterone levels, but no associated clinical signs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

There are no known interactions.[4] Osaterone may be administered concurrently with antimicrobials.

Laboratory Considerations

- Plasma cortisol levels may decrease after starting treatment and persist for several weeks. ACTH stimulation tests may be suppressed.[4]

Dosages

DOGS:

Benign prostatic hypertrophy (BPH) in male dogs (extra-label): 0.25 – 0.5 mg/kg PO once daily for 7 days.[4] Re-evaluate 5 months after treatment or earlier if clinical signs recur. The decision to retreat should be based on examination findings as well as the risks and benefits of treatment.

Monitoring

- Clinical efficacy (reduced prostate size, improvement in constipation, ease of urination)
- Liver enzymes (ALT, ALP) in dogs with a history or signs of hepatic dysfunction
- Monitor for the development of clinical signs related to hypoadrenocorticism

Client Information

- This medicine can be given with or without food.
- Osaterone is usually given for 7 days and then stopped. Improvement is usually seen within 2 weeks and can last for 5 months or more. Your veterinarian will need to evaluate your dog 5 months after treatment or sooner if the effects of the medicine wear off.
- Side effects include increased appetite or changes in activity level and sociability but are usually temporary.
- Wash hands after administration. In the case of accidental human ingestion, seek medical advice immediately and show the product label to the physician. Women of childbearing age should avoid handling this medication when possible, or they should wear disposable gloves when handling.

Chemistry/Synonyms

Osaterone acetate is structurally related to progesterone and is a derivative of chlormadinone. The commercially available tablets also contain pre-gelatinized starch, carmellose calcium, corn (maize) starch, talc, and magnesium stearate as excipients.

Osaterone acetate may also be known as TZP-4238, 17alpha-acetoxy-6-chloro-2-oxa-4, 6-pregnadiene-3, or 20-dione. The trade name is *Ypozane®*.

Storage/Stability

Osaterone tablets should be stored at room temperature (15°C-30°C [59°F-86°F]). Expiration dates of 3 years postmanufacture are assigned.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE IN THE UNITED STATES

Oral Tablets: 1.875 mg, 3.75 mg, 7.5 mg, and 15 mg; *Ypozane®*; (Rx). Approved for use in dogs in countries other than the United States

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Oseltamivir

(oh-sell-***tam***-ih-vir) *Tamiflu®*

Antiviral; Neuraminidase Inhibitor

Prescriber Highlights

- ► Neuraminidase inhibitor that has been suggested as a treatment for canine parvovirus infections or other mixed bacterial/viral infections; evidence supporting its use is lacking
- ► Treatment must begin as early as possible for it to be effective.
- ► Limited information on efficacy and safety in animals
- ► Use in veterinary medicine is controversial due to public health concerns.
- ► Expense may be an issue, especially when treating horses.

Uses/Indications

Oseltamivir has been suggested as a treatment for canine parvovirus infections. In a small, prospective, randomized, blinded, placebo-controlled clinical trial of 35 dogs with parvovirus, 19 were treated with oseltamivir.[1] Although the oseltamivir group showed statistically significant differences in weight gain and maintenance of white blood cell count compared with untreated dogs, no significant decreases in hospitalization time, treatments needed, clinical scores, morbidity, or mortality were seen. Another study in 50 dogs also found no significant reduction in mortality or morbidity.[2]

Oseltamivir may be beneficial for adjunctive treatment of other viral infections, particularly those with associated secondary bacterial components, but evidence and experience are lacking. One small study in horses experimentally infected with equine influenza A (H3N8) documented some efficacy in the attenuation of pyrexia, viral shedding, and secondary bacterial pneumonia.[3] Oseltamivir given to swine prior to H1N2 exposure prevented clinical signs and significantly reduced virus shedding.[4]

Because oseltamivir is the primary antiviral agent proposed for treatment or prophylaxis for influenza in humans, its use in veterinary patients is controversial. Concerns include adequate drug supply for the human population and the potential for the development of viral resistance. Extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys, and ducks is prohibited by the FDA.[5]

Pharmacology/Actions

Oseltamivir phosphate is a prodrug that is hydrolyzed after absorption into its active form, oseltamivir carboxylate. Oseltamivir carboxylate competitively inhibits influenza virus neuraminidase, an enzyme that is required for viral replication, release of virus from in-

fected cells, and the prevention of formation of viral aggregates after release from cells. Resistance to oseltamivir has been induced in the laboratory and from posttreatment isolates from infected humans.

It has been postulated that oseltamivir may limit the ability of canine parvovirus to pass through the intestinal mucosa and infect intestinal crypt cells. There is some evidence that oseltamivir has this effect (increased mucous inactivation) on influenza viruses in the respiratory tract of humans. It may also reduce GI bacteria colonization, translocation, and toxin production.

Pharmacokinetics

No information was located for the pharmacokinetic profiles of oseltamivir in dogs or cats.

The pharmacokinetics of oseltamivir and the active metabolite (oseltamivir carboxylate) were evaluated in horses.[6] After NG administration of a 2 mg/kg dose, the drug was rapidly absorbed with peak concentrations attained between 1 and 2 hours postdose. The elimination half-life was ≈2 hours for oseltamivir and 2.5 hours for oseltamivir carboxylate. At 2 mg/kg, it was concluded that the dosing interval should be less than 10 hours to maintain concentrations above the inhibitory concentrations of equine influenza A viruses.

In humans, oseltamivir phosphate is readily absorbed and converted into the active carboxylate metabolite predominantly via liver esterases. The bioavailability of oseltamivir carboxylate is ≈75%, and it is minimally bound to plasma proteins. Elimination of oseltamivir carboxylate is primarily via renal mechanisms, including both glomerular filtration and tubular secretion. The elimination half-life is ≈6 to 10 hours in patients with normal renal function. Up to 20% of a dose may be eliminated in the feces.

Neither oseltamivir nor oseltamivir carboxylate act as substrates or inhibitors for any CYP-450 isoenzymes.

Contraindications/Precautions/Warnings

Oseltamivir is contraindicated in patients with documented hypersensitivity to it.[7] Treatment must begin as early as possible for it to be effective; delay in treatment beyond 40 hours after the onset of clinical signs in humans with influenza is associated with minimal efficacy. Dosage adjustments may be needed in patients with impaired renal function.

In humans, anaphylaxis and skin reactions have been reported.[7]

Extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys, and ducks is prohibited by the FDA.[5]

Oseltamivir is not recommended for the treatment of canine influenza at this time, as it represents a primary line of defense against a human influenza pandemic.

Adverse Effects

The adverse effect profile in animals is not known. In small canine and equine studies, no major adverse effects were noted in the treatment groups.[1,3]

In humans, the most common adverse effects are nausea and vomiting. GI effects are usually transient and may be alleviated by giving the medication with food. Serious skin reactions (eg, erythema multiforme, toxic epidermal necrolysis) have also been reported.

Reproductive/Nursing Safety

Oseltamivir has not been shown to increase the risk for adverse outcomes during pregnancy. In humans, it is the preferred agent during pregnancy because it has the most evidence to suggest safety and benefit. Oseltamivir and oseltamivir carboxylate have been detected in milk, but adverse events have not been reported in breastfed infants.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Oseltamivir has relatively low toxic potential. In humans, overdoses of up to 1000 mg have caused only nausea and vomiting.

In studies where neonatal rats were administered oseltamivir 1 g/kg, concentrations of the prodrug in the brain were 1500 times greater, and the active metabolite was 3 times higher than those found in adult rats. Potentially, newborn puppies could exhibit similar findings; neurotoxicity is a possibility.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oseltamivir and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Probenecid**: May increase 2-fold the exposure to the active metabolite, oseltamivir carboxylate, by reducing tubular secretion. This could potentially be useful in reducing drug doses or dosing frequency or increasing serum concentrations at the usual dosage; however, supporting data are not readily available.
- **Vaccines, Influenza (live)**: Oseltamivir may potentially reduce the immune response to live influenza virus vaccines. There does not appear to be any effect on inactivated (killed) vaccines.
- **Warfarin**: May increase risk for bleeding

Laboratory Considerations

- None noted

Dosages

DOGS:

Adjunctive treatment of canine parvovirus enteritis (extra-label): 2 mg/kg PO every 12 hours for 5 days was used in one small study but did not significantly reduce morbidity or mortality.[1]

HORSES:

Treatment of equine influenza A (extra-label): 2 mg/kg PO twice daily for 5 days was used in a small experimental study based on human pediatric dosages, not equine pharmacokinetic or pharmacodynamic data.[3]

Prophylaxis of equine influenza A (extra-label): 2 mg/kg PO once daily for 5 days was experimentally studied; however, it was concluded that a different dose or longer administration may provide better prophylaxis.[3]

Monitoring

- Efficacy

Client Information

- This medicine has not been commonly used in animals. It is not known how well this medicine works and how safe it is to use in animals. Contact your veterinarian if your animal has any side effects of concern.

Chemistry/Synonyms

Oseltamivir phosphate occurs as a white crystalline solid that is freely soluble in water, soluble in propylene glycol, and slightly soluble in alcohol.

Oseltamivir phosphate may also be known as GS-4104/002, or Ro-64-0796/002 and *Tamiflu®*.

Storage/Stability

Store oseltamivir capsules at 25°C (77°F), with excursions permitted from 15°C to 30°C (59°F-86°F). Store the oral powder for reconstitution between 15°C and 30°C (59°F-86°F). Once reconstituted with

55 mL of water, it may be stored at room temperature (15°C-30°C [59°F-86°F]) for 10 days or in the refrigerator (2°C-8°C [36°F-46°F]) for 17 days. Protect this product from freezing.

Compatibility/Compounding Considerations

An extemporaneously compounded oral suspension (6 mg/mL) may be made using the commercially available capsules with cherry syrup, simple syrup, or *OraSweet® SF* when the commercially available oral suspension product is in short supply.[7] The compounded suspension is stable for 5 days at room temperature, and for 5 weeks if refrigerated.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

Extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys, and ducks is prohibited by the FDA.[5]

HUMAN-LABELED PRODUCTS:

Oseltamivir Phosphate Oral Capsules: 30 mg, 45 mg, and 75 mg; *Tamiflu®*; (Rx)

Oseltamivir Phosphate Powder for Oral Suspension: 6 mg/mL after reconstitution in 60 mL bottles; *Tamiflu®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Oxacillin

(ox-a-***sill***-in) *Bactocill®*

Anti-Staphylococcal Penicillin

Prescriber Highlights

- ► Penicillinase-resistant penicillin that is rarely used therapeutically; only parenteral dosage forms are available in the United States.
- ► Oxacillin resistance is a marker for methicillin-resistance in staphylococci.
- ► Predominant adverse effects are GI in nature.

Uses/Indications

Oxacillin has been primarily used in veterinary medicine for the treatment of bone, skin, and other soft tissue infections in small animal species when penicillinase-producing *Staphylococcus* spp have been isolated. It is rarely used due to frequency of dosing and lack of oral dosage forms.

Pharmacology/Actions

Oxacillin, cloxacillin, and dicloxacillin are penicillinase-resistant penicillins. They have a nearly identical spectrum of activity and can be considered therapeutically equivalent when comparing in vitro activity. Penicillinase-resistant penicillins have a narrower overall spectrum of activity than the natural penicillins (penicillin G, penicillin V); however, unlike the natural penicillins, they are effective against penicillinase-producing bacteria. Their antimicrobial efficacy is aimed directly against penicillinase-producing strains of gram-positive cocci, particularly staphylococcal species, and they are sometimes referred to as anti-staphylococcal penicillins.

Oxacillin resistance is a marker for methicillin resistance in staphylococci. Although this class of penicillins does have activity against some other gram-positive and gram-negative aerobes and anaerobes, other antibiotics are usually better choices. Oxacillin is inactive against rickettsial organisms, mycobacteria, fungi, *Mycoplasma* spp, and viruses.

Pharmacokinetics

Although oxacillin sodium is resistant to acid inactivation in the gut, it is only partially absorbed after oral administration. The bioavailability after oral administration in humans has been reported to range from 30% to 35%. Both the rate and extent of absorption are decreased when given with food. In humans, oxacillin is rapidly absorbed after IM administration and peak concentrations generally occur within 30 minutes.[1]

Oxacillin is distributed to the lungs, kidneys, bone, bile, pleural fluid, synovial fluid, and ascitic fluid. The volume of distribution is reportedly 0.3 L/kg in dogs and 0.4 L/kg in humans. As with other penicillins, CSF penetration is limited but increased with meningeal inflammation. In humans, ≈89% to 94% of the drug is bound to plasma proteins.[1]

Oxacillin is partially metabolized to both active and inactive metabolites. These metabolites and the parent compound are rapidly excreted in the urine via both glomerular filtration and tubular secretion mechanisms. A small amount of the drug is also excreted in the feces via biliary elimination. The serum half-life in humans with normal renal function ranges from ≈18 to 48 minutes. In dogs, the reported elimination half-life is 20 to 30 minutes.

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because cross-reactivity is possible, use with caution in patients that have documented hypersensitivity to other beta-lactam antibiotics (eg, cephalosporins, carbapenems).

Adverse Effects

Adverse effects of penicillins are generally mild. Hypersensitivity reactions are possible, including rash, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or anaphylaxis. In humans, it is estimated that 1% to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

After oral administration, penicillins may cause GI effects (eg, anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (eg, ataxia in dogs) has been associated with high doses or prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Reproductive/Nursing Safety

Reproduction studies in mice, rats, and rabbits using penicillinase-resistant penicillins have not revealed evidence of impaired fertility or teratogenic effects; however, penicillins have been shown to cross the placenta and safe use during pregnancy has not been firmly established.[1]

Penicillins are excreted in maternal milk in low concentrations; use may cause diarrhea, candidiasis, or allergic response in nursing offspring.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant effects other than GI distress, but other effects are possible (see ***Adverse Effects***). In humans, high doses of parenteral penicillins have resulted in CNS effects, especially in patients with renal disease.[1]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and

toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxacillin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: In vitro evidence of synergism with oxacillin against staphylococci
- **Probenecid**: May increase oxacillin concentrations by competitively inhibiting the tubular secretion of oxacillin
- **Tetracyclines**: Theoretical antagonism; use together typically not recommended
- **Warfarin**: Oxacillin may cause decreased warfarin efficacy.

Laboratory Considerations

Penicillinase-resistant penicillins may interfere with or cause false-positive results in a variety of test methods used to determine urinary or serum proteins.

Dosages

NOTE: Oxacillin is rarely used due to availability of other licensed and/or proven therapies. It is only available commercially in the US as a parenteral injection. Dicloxacillin capsules may be substituted for oxacillin for oral therapy.

DOGS/CATS:

Susceptible infections (extra-label): 22 – 40 mg/kg SC, IM, or IV every 8 hours[2]

HORSES:

Susceptible infections in foals (extra-label): 20 – 30 mg/kg IV every 6 to 8 hours (Dose extrapolated from adult horse data; use lower dose or longer interval in premature foals or those less than 7 days old)[3,4]

Monitoring

- Clinical efficacy
- Adverse effects (eg, GI signs, hypersensitivity reactions)

Client Information

- This medication is only available as an injection. Be sure you understand how to give this medicine to your animal.
- The most common side effects of this medicine are mild in nature but may include a decrease in appetite, vomiting, and diarrhea. Contact your veterinarian if you have any concerns about your animal.

Chemistry/Synonyms

Oxacillin sodium is a semi-synthetic, penicillinase-resistant, isoxazolyl-penicillin. It is available commercially as the monohydrate sodium salt, which occurs as a fine, white, crystalline powder that is odorless or has a slight odor. It is freely soluble in water and has a pK_a of ≈2.8. One milligram of oxacillin sodium contains not less than 815 to 950 µg of oxacillin. Each gram of the commercially available powder for injection contains 2.8 to 3.1 mEq of sodium.

Oxacillin sodium may also be known as sodium oxacillin, methylphenyl isoxazolyl penicillin, (5-methyl-3-phenyl-4-isoxazolyl) penicillin sodium, oxacillinum natricum, oxacillinum natrium, P-12, SQ-16423, or *Bactocill*®.

Storage/Stability

Store oxacillin sodium powder for injection at room temperature (15°C-30°C [59°F-86°F]).

Powder for injection reconstituted with sterile water to 167 mg/mL for IM injection is stable for 3 days at room temperature or 7 days if refrigerated.[1] Quantity of diluent depends on route of administration; stability of IV solutions depends on the diluent used, storage temperature, and final concentration; refer to the package insert for specific instructions.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Oxacillin sodium injection is reportedly physically **compatible** with the following fluids/drugs: 5% and 10% dextrose in water, 5% and 10% dextrose in 0.9% sodium chloride 0.9%, lactated Ringer's injection, cefazolin, chloramphenicol sodium succinate, dopamine HCl, famotidine, metoclopramide, midazolam, and potassium chloride.

Oxacillin sodium injection is reportedly physically **incompatible** with the following fluids/drugs: calcium salts, oxytetracycline HCl, and tetracycline HCl. As penicillins can inactivate aminoglycosides *in vitro*, they should never be mixed together in the same syringe or administration set.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Oxacillin Sodium Powder for Injection: 1 g, 2 g, and 10 g; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Oxazepam

(ox-***a***-ze-pam) *Serax*®

Benzodiazepine

Prescriber Highlights

- ► Benzodiazepine used primarily as an appetite stimulant in cats, but may also be useful to treat behavior problems in dogs and cats
- ► Contraindications include known benzodiazepine hypersensitivity and acute narrow-angle glaucoma.
- ► Use with caution in animals with myasthenia gravis, hepatic dysfunction, or seizure disorders.
- ► Sedation is the primary adverse effect; ataxia is occasionally seen.
- ► DEA Schedule IV (C-IV) controlled substance

Uses/Indications

Oxazepam is used most frequently in small animal medicine as an appetite stimulant in cats. It may also be useful as an oral anxiolytic agent for adjunctive therapy of behavior-related disorders for both dogs and cats. Like lorazepam, it does not have any active metabolites so it may be a good choice for treating geriatric patients and those with liver dysfunction. However, use in feline patients is controversial, as fulminant hepatic failure has been anecdotally reported.

Pharmacology/Actions

Oxazepam is classified as an intermediate acting benzodiazepine. The subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed by oxazepam and other benzodiazepines, thus producing the anxiolytic, sedative, skeletal muscle relaxant and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include antagonism of serotonin, increased release of gamma-aminobutyric acid (GABA) and/or facilitation of GABA activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine-specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors were lacking in the white matter.

Pharmacokinetics

Oxazepam is absorbed from the GI tract, but it is one of the more slowly absorbed oral benzodiazepines. Oxazepam, like other benzodiazepines, is widely distributed and is highly bound to plasma proteins (97% in humans). Although not confirmed, oxazepam may cross the placenta and enter maternal milk. Oxazepam is principally conjugated in the liver via glucuronidation to an inactive metabolite. Serum half-life in humans ranges from 3 to 21 hours.

Contraindications/Precautions/Warnings

Oxazepam is contraindicated in patients that are hypersensitive to it or other benzodiazepines and in those with acute narrow-angle glaucoma. Caution is advised when using oxazepam in animals that have hepatic or renal disease; that are comatose or in shock; that have respiratory depression; or that are debilitated, obese, or geriatric. Although oxazepam is less susceptible to accumulation than many other benzodiazepines in patients with hepatic dysfunction, it should still be used with caution.

Use of oxazepam in feline patients is controversial, as anecdotal fulminant hepatic failure in cats has rarely been reported.

Adverse Effects

The most common adverse effect seen with oxazepam in small animal species is sedation. Ataxia is also seen occasionally. Adverse effects may be transient, and dosage adjustment may be required to alleviate them. Paradoxical effects such as excitability, vocalization, or aggression are possible. When oxazepam is used to treat negative behaviors, a rebound effect can occur, particularly if the drug is not withdrawn slowly.

Reproductive/Nursing Safety

Safe use of oxazepam during pregnancy has not been established; teratogenic effects of similar benzodiazepines have been noted in rabbits and rats. In humans, mild tranquilizers have been associated with increased risk for congenital malformations when used in the first trimester.[1]

Benzodiazepines are excreted in maternal milk. Neonates metabolize benzodiazepines more slowly than adults do, and accumulation of toxic levels of the drug and its metabolites is possible. Long-term diazepam use in nursing mothers has reportedly caused lethargy and weight loss in human infants; avoid the use of benzodiazepines in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

When oxazepam is used alone, overdoses are generally limited to significant CNS depression (eg, confusion, coma, decreased reflexes). Treatment of significant oral oxazepam overdoses consists of standard GI decontamination protocols and supportive therapy based on clinical presentation. CNS stimulants such as caffeine or amphetamines are generally not recommended. Flumazenil could potentially be used in life-threatening overdoses.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxazepam and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **CNS Depressants** (eg, **anesthetics, barbiturates, opioids**): Additive CNS depressant effects may occur.
- **Metoclopramide**: May increase risk for CNS depression
- **Mirtazapine**: May increase risk for somnolence
- **Probenecid**: May impair glucuronide conjugation in dogs and prolong effects
- **Rifampin**: May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines
- **St. John's Wort**: May decrease oxazepam effectiveness
- **Theophylline, Aminophylline**: May decrease oxazepam effectiveness

Laboratory Considerations

- Benzodiazepines may decrease the thyroidal uptake of I^{123} or I^{131}.

Dosages

NOTE: Because 10 mg capsules are the smallest dosage form available, compounded dosage forms may be required for cats and smaller dogs.

DOGS:

Fears and phobias (extra-label): Anecdotally, 0.2 – 1 mg/kg PO every 12 to 24 hours. Dosage recommendations vary and no published evidence supporting one dose over the other was located.

CATS:

Appetite stimulation or behavior-related conditions (extra-label): Anecdotally, 0.2 – 0.5 mg/kg PO every 12 to 24 hours. Dosage recommendations vary and no published evidence supporting one dose over the other was located.

Monitoring

- Efficacy
- Adverse effects
- Consider baseline and period serum liver chemistry panels with long-term administration

Client Information

- When using this medicine for thunderstorm phobias or other triggers (eg, separation anxiety), try to give it about an hour before the event or trigger.
- If you see yellowing of the whites of the eyes, gums, or skin, contact your veterinarian immediately.
- Sleepiness is the most common side effect, but sometimes this medicine can change behavior or cause unexpected excitement.
- This medicine may increase appetite, especially in cats.
- Contact your veterinarian immediately if your animal stops eating or has a low-energy level.
- Oxazepam is classified as a Schedule IV (C-IV) controlled drug by the federal Drug Enforcement Agency (DEA). Use of this medication in animals or humans other than those for whom it is prescribed is illegal.

Chemistry/Synonyms

Oxazepam is a benzodiazepine that occurs as a creamy white to pale-yellow powder. It is practically insoluble in water.

Oxazepam may also be known as oxazepamum, Wy-3498, or *Serax®*.

Storage/Stability

Store oxazepam capsules and tablets at room temperature, 20°C to 25°C (68°F-77°F), in well-closed containers.

Oxazepam is a DEA Schedule IV (C-IV) controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Oxazepam Capsules: 10 mg, 15 mg, and 30 mg; generic; (Rx; C-IV). Report dispensing to state monitoring programs where required.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Oxfendazole

(ox-***fen***-da-zole) *Synanthic®*

Antiparasitic Agent (Anthelmintic)

Prescriber Highlights

- ► Benzimidazole anthelmintic used primarily in cattle
- ► Contraindicated for use in female dairy cattle of breeding age
- ► Use caution in debilitated or sick horses
- ► Adverse effects appear unlikely; hypersensitivity possible

Uses/Indications

Oxfendazole (*Synanthic®*) is indicated in cattle for the removal and control of lungworms, stomach worms, intestinal worms (including inhibited forms of *Ostertagia ostertagi*), and tapeworms. See product label for specific parasite species covered for the indication.

In swine, oxfendazole has demonstrated activity against nematodes (*Ascaris suum, Oesophagostomum* spp, *Trichuris suis, Metastrongylus* spp) and liver flukes (*Fasciola hepatica*).

Oxfendazole, marketed as *Benzelmin®*, was indicated (no longer marketed in the US) for the removal of the following parasites in horses: large roundworms (*Parascaris equorum*), large strongyles (*Strongylus edentatus, Strongylus equinus, Strongylus vulgaris*), small strongyles, and pinworms (*Oxyuris equi*).

Oxfendazole has shown efficacy in sheep and goats[1] and is approved for use in sheep in the UK.[2]

Pharmacology/Actions

Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action is believed to be due to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

Pharmacokinetics

Limited information is available regarding this compound's pharmacokinetics. Unlike most of the other benzimidazole compounds, oxfendazole is absorbed more readily from the GI tract. The elimination half-life has been reported to be ≈7.5 hours in sheep and 5.25 hours in goats. Absorbed oxfendazole is metabolized to oxfendazole sulfone (inactive).

After a single oral dose of 50 mg/kg to dogs, oxfendazole levels peaked at 8 hours. The elimination half-lives for the parent compound and the sulfoxide metabolite (active) were both ≈5.5 hours. In dogs, oxfendazole plasma concentrations were significantly higher and resident times longer than that of either fenbendazole or albendazole following single oral administration at the same dose (50 mg/kg).[3]

Contraindications/Precautions/Warnings

Oxfendazole is not for use in female dairy cattle of breeding age.

There are no contraindications to using this drug in horses, but it is recommended to use oxfendazole cautiously in debilitated or sick horses.

Adverse Effects

When used as labeled, it is unlikely that any adverse effects will be noted. Hypersensitivity reactions secondary to antigen release by dying parasites are theoretically possible, particularly at high dosages.

Reproductive/Nursing Safety

Oxfendazole may be safely used in pregnant mares and foals. It is not labeled for use in female dairy cattle of breeding age.

Overdose/Acute Toxicity

Doses of 10 times the recommended dose elicited no adverse reactions in horses tested. It is unlikely that this compound would cause serious toxicity when given alone.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxfendazole and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Bromsalan Flukicides** (eg, **dibromsalan**, **tribromsalan**): Oxfendazole should not be given concurrently with these agents; abortions in cattle and death in sheep have been reported after using these compounds together.

Dosages

NOTE: Ensure animals receive a complete dose based on a current and accurate estimate of weight. Underdosing may result in ineffective treatment and promote parasite resistance.

HORSES:

Susceptible parasites: 10 mg/kg PO.[4] **NOTE**: No longer marketed

CATTLE:

Removal and control of lungworms, roundworms (including inhibited forms of *Ostertagia ostertagi*), and tapeworms. See product label for the specific parasite species covered for the indication (label dose; FDA-approved): 4.5 mg/kg PO. May repeat in 4 to 6 weeks.[5]

SWINE:

Adult stages of *Ascaris suum, Oesophagostomum* spp, *Trichuris suis, Metastrongylus* spp, and ***Fasciola hepatica*** (extra-label): 30 mg/kg PO once[6,7]

SHEEP/GOATS:

GI nematodes (extra-label): 5 mg/kg PO once [1,2]

Monitoring

- Efficacy, including fecal examination/FECRT

Client Information

- Do not use in horses intended for food purposes.
- Shake suspension well immediately before use.
- Administer oxfendazole oral suspension using an accurate dose syringe.

- Slaughter withdrawal in cattle is 7 days; not FDA-approved for lactating dairy cattle.

Chemistry/Synonyms
Oxfendazole, a benzimidazole anthelmintic, occurs as white or almost white powder possessing a characteristic odor. It is practically insoluble in water. Oxfendazole is the active sulfoxide metabolite of fenbendazole.

Oxfendazole may also be known as RS 8858; there are many international trade names.

Storage/Stability
Store this product at or below 25°C (77°F). Brief excursions up to 30°C (86°F) are permitted. Do not freeze.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Oxfendazole Oral Suspension: 9.06% in 1 L and 4 L; *Synanthic®*; (OTC). FDA-approved for use in beef cattle and female dairy cattle not of breeding age. Because a withdrawal time in milk has not been established, do not use in female dairy cattle of breeding age. At recommended dosages, slaughter withdrawal is 7 days.

Oxfendazole Oral Suspension: 22.5% in 500 mL and 1 L; *Synanthic®*; (OTC). FDA-approved for use in beef cattle and female dairy cattle not of breeding age. Because a withdrawal time in milk has not been established, do not use in female dairy cattle of breeding age. At recommended dosages, slaughter withdrawal is 7 days.

HUMAN-LABELED PRODUCTS: NONE

Oxibendazole
(ox-i-***ben***-da-zole) *Anthelcide EQ®*

Antiparasitic Agent

Prescriber Highlights
- ► Benzimidazole anthelmintic used primarily in horses
- ► Resistance development is an ongoing concern.
- ► Contraindications include severely debilitated horses or horses suffering from colic, toxemia, or infectious disease.
- ► Adverse effects are uncommon; hypersensitivity is possible.

Uses/Indications
Oxibendazole is FDA-approved in horses for the removal and control of large roundworms (*Parascaris equorum*), large strongyles (*Strongylus edentatus, S equinus, S vulgaris*), small strongyles (various genera), threadworms, and pinworms (*Oxyuris equi*). Resistance to antiparasitic agents is an ongoing concern. Fecal egg count reduction testing (FECRT) is recommended for strongyle nematodes. A value of less than 90% in 5 to 10 horses is the suggested cut-off for determining resistance on a given farm.[1] One study in horses found that the combination of oxibendazole and pyrantel pamoate demonstrated additive effects in reducing fecal egg counts compared to either drug alone.[2]

Oxibendazole has also been used in rabbits for adjunctive treatment of *Encephalitozoon cuniculi*.

Pharmacology/Actions
Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action disrupts intracellular microtubular transport systems by binding tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles are also believed to act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

Pharmacokinetics
No information was located.

Contraindications/Precautions/Warnings
Oxibendazole is contraindicated in severely debilitated horses and horses suffering from colic, toxemia, or infectious disease.[3]

Treatment with oxibendazole should be in conjunction with parasite management practices to help prevent parasite resistance.[3] Do not underdose, as underdosing can result in ineffective treatment and encourage development of resistance.

Do not use in horses intended for human consumption.

Adverse Effects
At recommended doses, adverse effects in horses are uncommon. Hypersensitivity reactions are theoretically possible secondary to antigen release by dying parasites, particularly at high doses.

Oxibendazole in combination with diethylcarbamazine (*Filaribits Plus®*) was implicated in causing periportal hepatitis in dogs when it was marketed (1980s).

Myelosuppression has been reported in rabbits.[4]

Reproductive/Nursing Safety
Oxibendazole is considered safe to use in pregnant mares.

Overdose/Acute Toxicity
Doses of 60 times those recommended on the product label elicited no adverse reactions in horses tested. Serious toxicity from overdose of oxibendazole alone is unlikely in horses.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
- No significant interactions have been reported.

Dosages
HORSES:

Removal and control of susceptible parasites other than threadworms (label dosage; FDA-approved): 10 mg/kg PO once.[3] Re-treat in 6 to 8 weeks if reinfection is likely.

Removal and control of *Strongyloides westeri* (threadworms; label dosage; FDA-approved): 15 mg/kg PO once.[3] Re-treat in 6 to 8 weeks if reinfection is likely.

RABBITS:

Adjunctive treatment of *E cuniculi* (extra-label): Published evidence is limited; suggested dosage is 30 mg/kg PO once daily for 7 to 14 days, then 15 mg/kg once daily for 30 to 60 days. For palliative treatment of larval migrans, 60 mg/kg PO once daily indefinitely has been suggested.[5]

Monitoring
- Efficacy (eg, fecal egg count reduction test)
- For rabbits, consider baseline CBC prior to treatment and 14 days later.

Client Information
- Protect suspension from freezing.
- Not for use in horses intended for food.
- Side effects are uncommon.

Chemistry/Synonyms
Oxibendazole is a benzimidazole anthelmintic that occurs as a white powder and is practically insoluble in water.

Oxibendazole may also be known as SKF-30310 and *Anthelcide EQ®* and in the UK by the proprietary names: *Dio®*, *Equidin®*, *Equitac®* or *Loditac®*.

Storage/Stability
Oxibendazole oral paste should be stored at controlled room temperature 15°–30°C (59°–86°F) and protected from freezing.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
Oxibendazole Oral Paste: 227 mg/g (22.7%) in 24-g syringes. *Anthelcide EQ® Paste*; (OTC). FDA-approved for use in horses not intended for food. NADA# 121-042

HUMAN-LABELED PRODUCTS: NONE

Oxybutynin
(ox-i-***byoo***-tin-in) *Ditropan®, Oxytrol®*
Genitourinary Smooth Muscle Relaxant

Prescriber Highlights
- ► Urinary antispasmodic potentially useful in dogs or cats
- ► Use with caution (risk vs benefit) in animals with obstructive GI tract disease, gastric retention or conditions that decrease intestinal motility, gastroesophageal reflux, angle closure glaucoma, hiatal hernia, cardiac disease (particularly associated with mitral stenosis, associated arrhythmias, tachycardia, CHF), myasthenia gravis, hyperthyroidism, prostatic hypertrophy, severe ulcerative colitis, urinary retention, or other obstructive uropathies.
- ► Adverse effects include diarrhea, constipation, urinary retention, dry mouth, hypersalivation, and sedation.

Uses/Indications
Oxybutynin may be useful for the adjunctive therapy of detrusor hyperreflexia in dogs and in cats with FeLV-associated detrusor instability.

Pharmacology/Actions
Considered a urinary antispasmodic, oxybutynin has direct antimuscarinic (atropine-like) and spasmolytic (papaverine-like) effects on smooth muscle. Spasmolytic effects appear to be most predominant on the detrusor muscle of the bladder and small and large intestine. It does not have appreciable effects on vascular smooth muscle. In humans with neurogenic bladders, oxybutynin increases bladder capacity, reduces the frequency of uninhibited contractions of the detrusor muscle, and delays the initial desire to void.[1] Effects were more pronounced in patients with uninhibited neurogenic bladders than in patients with reflex neurogenic bladders. Other effects noted in laboratory animal studies include moderate antihistaminic, local anesthetic, mild analgesic, very low mydriatic, and antisialagogue effects.

Pharmacokinetics
Oxybutynin is rapidly and well absorbed from the GI tract. Studies done in rats show the drug is distributed into the brain, lungs, kidneys, and liver. Although elimination characteristics have not been well documented, oxybutynin apparently is metabolized in the liver and excreted in the urine. In humans, the duration of action is from 6 to 10 hours after a dose.

Contraindications/Precautions/Warnings
Oxybutynin is contraindicated in patients that are hypersensitive to the drug substance or other components of the product.

Because of the drug's pharmacologic actions, oxybutynin should only be used when its benefits outweigh its risks if the following conditions are present: obstructive GI tract disease, gastric retention or conditions that decrease intestinal motility, gastroesophageal reflux, hiatal hernia, severe ulcerative colitis, angle closure glaucoma, cardiac disease (particularly associated with mitral stenosis, associated arrhythmias, tachycardia, CHF), myasthenia gravis, hyperthyroidism, prostatic hypertrophy, or urinary retention or other obstructive uropathies. Use with caution in patients with hepatic impairment.

Adverse Effects
Although use of oxybutynin in small animals is limited, diarrhea, constipation, urinary retention, hypersalivation, and sedation have been reported. Other adverse effects reported in humans, and potentially seen in animals, primarily result from the drug's pharmacologic effects, including dry mouth or eyes, tachycardia, anorexia, vomiting, weakness, or mydriasis.

Reproductive/Nursing Safety
Although safety during pregnancy has not been firmly established, studies in a variety of laboratory animals have demonstrated no teratogenic effect associated with the drug.

It is not known whether this drug is excreted in maternal milk. Although oxybutynin may inhibit lactation, no documented problems associated with its use in nursing offspring have been noted.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
Overdoses may cause CNS effects (eg, restlessness, excitement, seizures), cardiovascular effects (eg, hyper- or hypotension, tachycardia, circulatory failure), fever, nausea, or vomiting. Massive overdoses may lead to paralysis, coma, respiratory failure, and death. Treatment of overdoses should consist of general techniques to limit absorption of the drug from the GI tract and supportive care as required; IV physostigmine may be useful. See the ***Atropine*** monograph (***Overdoses/Acute Toxicity***) for more information on the use of physostigmine. Oxybutynin is highly protein bound; excessive overdose leading to paralysis or coma would require therapeutic plasma exchange to rapidly remove the drug from the patient.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving oxybutynin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.
- **Amantadine**: May increase anticholinergic adverse effects of oxybutynin
- **Anticholinergic Agents** (eg, **atropine, propantheline, scopolamine, isopropamide, glycopyrrolate, hyoscyamine, tricyclic antidepressants, disopyramide, procainamide, antihistamines**): May intensify oxybutynin's anticholinergic effects
- **Azole Antifungals** (eg, **ketoconazole**): May increase oxybutynin concentration
- **Benzodiazepines** (eg, **diazepam, midazolam**): May exacerbate the sedating effects of oxybutynin
- **Beta-Receptor Antagonists** (eg, **atenolol**): Oxybutynin may increase the bioavailability of atenolol.

- **CNS Depressants** (eg, **methocarbamol, trazodone**): Other sedating drugs may exacerbate the sedating effects of oxybutynin.
- **Macrolide Antibiotics** (eg, **erythromycin, clarithromycin**): May increase oxybutynin concentration
- **Opioids** (eg, **buprenorphine, hydrocodone, morphine**): May exacerbate the anticholinergic and sedating effects of oxybutynin

Dosages

NOTE: All dosages are for using regular 5 mg oxybutynin tablets or oral syrup unless otherwise noted. There are also sustained-release tablets for humans and transdermal gels/patches commercially available. No dosages for these products for dogs or cats were found.

DOGS:

Refractory incontinence (detrusor hyperreflexia) (extra-label): 0.2 – 0.3 mg/kg PO every 8 to 12 hours; practically, most dogs are dosed at 1.25 – 5 mg per dog (NOT mg/kg) PO every 8 to 12 hours (¼ to 1 tablet)

CATS:

Refractory incontinence (detrusor hyperreflexia) (extra-label): 0.5 – 1.25 mg per cat (NOT mg/kg) every 8 to 12 hours ≈⅛ to ¼ of a 5 mg tablet)

Monitoring

- Efficacy (eg, frequency of urination)
- Adverse effects (eg, drowsiness/sleepiness, dry mouth, and constipation)

Client Information

- In dogs and cats, oxybutynin is used to help stop bladder spasms that cause leaking of urine.
- Side effects include constipation, urinary retention (ie, trouble urinating), dry mouth, and sedation/drowsiness.
- The most common side effects are drowsiness/sleepiness, dry mouth, and constipation. Diarrhea and hypersalivation are also possible. Be sure your animal has access to fresh water at all times.

Chemistry/Synonyms

Oxybutynin chloride is a synthetic tertiary amine that occurs as white to off-white crystals. It is freely soluble in water.

Oxybutynin chloride may also be known as oxybutinyn HCl, 5058, MJ-4309-1, oxybutynini hydrochloridum, *Ditropan®* and *Oxytrol®*.

Storage/Stability

Tablets and oral solution should be stored in tight, light-resistant containers at room temperature 20°C to 25°C (68°F-77°F); excursions permitted within 15°C to 30°C (59°F-86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Oxybutynin Chloride Oral Tablets: 5 mg; generic; (Rx)

Oxybutynin Chloride Oral Syrup: 1 mg/mL in 473 mL; generic; (Rx)

Oxybutynin extended-release tablets (*Ditropan® XL)*, transdermal system (*Oxytrol®)*, and topical gel (*Gelnique®*) also are available.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Oxymorphone

(ox-ee-***mor***-fone) *Numorphan®*

Opioid Agonist

Prescriber Highlights

- ► Injectable opioid used as a sedative/premedication and analgesic agent
- ► Injectable oxymorphone was discontinued in 2017; ***hydromorphone*** is a commonly used alternative.
- ► DEA Schedule II (C-II) controlled substance

Uses/Indications

Oxymorphone is used in dogs and cats as a sedative and analgesic agent. It is occasionally used in horses as an analgesic and as an induction agent for anesthesia. In swine, oxymorphone is used as an adjunctive analgesic with ketamine and xylazine for anesthesia. Oxymorphone is used in small rodents as an analgesic and anesthetic agent for minor surgical procedures.

Oxymorphone is effective for moderate to severe pain and has minimal effects on the cardiovascular system. Oxymorphone causes less histamine release than morphine.

One study in dogs found that oxymorphone was comparable to hydromorphone in potency and efficacy for pain control and caused less vomiting than hydromorphone.[1]

Pharmacology/Actions

Oxymorphone is a mu-opiate receptor agonist and is ≈10 times more potent than morphine. Opioid receptors are in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. The GI tract, urinary tract, and other smooth muscle tissues also contain opioid receptors.

Oxymorphone primarily has activity at mu-opioid receptors and potentially some activity at delta-receptors. Primary pharmacologic effects include analgesia and sedation. In dogs at usual doses, oxymorphone alone has good sedative qualities. Respiratory depression is another primary effect of oxymorphone. Like morphine, oxymorphone initially increases respiratory rates (eg, panting in dogs); however, actual oxygenation may be decreased, and blood CO_2 levels may increase by 10 mm Hg or more. In dogs, oxymorphone may cause more panting and has less antitussive activity than morphine. GI effects include emesis, constipation, defecation, and decreased gut motility with resultant delayed gastric emptying time.

Oxymorphone has many secondary pharmacologic effects. Central nervous system effects include euphoria, sedation, and confusion. Cardiovascular effects include bradycardia due to central vagal stimulation, peripheral vasodilation due to depressed alpha-adrenergic receptors, decreased peripheral resistance, baroreceptor inhibition, orthostatic hypotension, syncope, and slight decreases in cardiac contractility and/or blood pressure. Urinary effects can also occur, including urinary retention due to increased bladder sphincter tone.

Contradictory effects are possible from mu-opioid agonists, including oxymorphone. Morphine administration in dogs may cause defecation rather than the expected effect of constipation. Dogs and humans may develop miosis, whereas cats and some other species may develop mydriasis. Horses, cattle, swine, and cats may develop excitement after morphine administration rather than sedation. However, unlike morphine or meperidine, oxymorphone does not appear to cause histamine release when administered IV and may cause less excitement.

Pharmacokinetics

Oxymorphone is bioavailable after IM, SC, and rectal administration. In humans, oral, bioavailability is ≈10%. After IV administration, analgesic efficacy usually occurs within 3 to 5 minutes.

After oxymorphone 0.1 mg/kg IM administration to dogs, onset of action is ≈15 minutes and duration of effect is 2 to 4 hours.

In cats, oxymorphone exhibits a moderate steady state volume of distribution (≈2.5 L/kg), clearance of ≈26 mL/minute/kg, and a short elimination half-life of ≈1.6 hours.[2] After buccal administration to cats, bioavailability is ≈17%.[3]

Like morphine, oxymorphone concentrates in the kidneys, liver, and lungs with lower concentrations found in the CNS. Oxymorphone crosses the placenta and narcotized newborns can result if mothers are given the drug before giving birth. Effects can be rapidly reversed with naloxone.

The drug is metabolized in the liver primarily by glucuronidation and is excreted by the kidneys.

Contraindications/Precautions/Warnings

Oxymorphone is contraindicated in patients hypersensitive to narcotic analgesics and patients with diarrhea caused by a toxic ingestion (until the toxin is eliminated from the GI tract). Additionally, oxymorphone is considered contraindicated in humans with GI tract obstruction and paralytic ileus. Patients with severe hepatic disease may have prolonged duration of drug action; moderate to severe hepatic impairment is a contraindication in humans.

Because oxymorphone may cause vomiting, use as a preanesthetic medication is generally considered contraindicated in animals with suspected gastric dilation-volvulus, intestinal obstruction, or increased intracerebral and intraocular pressure. Pretreatment with maropitant may help prevent vomiting in dogs medicated with hydromorphone and presumably oxymorphone.[4–7]

Use extreme caution in patients with head injuries, increased intracranial or intraocular pressure, and acute abdominal conditions (eg, colic) as oxymorphone may obscure the diagnosis or clinical course of these conditions. In horses, opioids can mask behavioral and cardiovascular clinical signs associated with mild colic. Use oxymorphone with extreme caution in patients suffering from respiratory disease or acute respiratory dysfunction (eg, pulmonary edema secondary to smoke inhalation).

Use opioids with caution in patients with hypothyroidism, severe renal insufficiency, and hypoadrenocorticism. Use cautiously in geriatric or severely debilitated patients. Neonatal, debilitated, or geriatric patients may be more susceptible to the effects of oxymorphone, including respiratory depression, and may require lower doses. Use cautiously in patients with seizures as oxymorphone, may induce or aggravate seizures. Hypotension following oxymorphone administration may result in decreased cardiac output and blood pressure. Use with caution in hypotensive patients or those in circulatory shock. Oxymorphone can cause bradycardia and should be used cautiously in patients with pre-existing bradyarrhythmias. Use with caution in patients with biliary tract impairment, including acute pancreatitis, as oxymorphone may cause sphincter of Oddi spasm.

At high doses in cats, concurrent administration with a tranquilizing agent is typically recommended with any mu-opioid agonist, as unpredictable behavioral changes may occur.

Opioid analgesics are contraindicated in patients stung by the scorpion species *Centruroides sculpturatus Ewing* and *C gertschi Stahnke* as oxymorphone may potentiate the effect of the venom.[8]

There is an FDA black box warning to call attention to the risk for abuse, respiratory depression, neonatal withdrawal syndrome, and accidental ingestion in humans.

Adverse Effects

In general, oxymorphone has a similar adverse effect profile to hydromorphone or morphine in dogs and cats. Dose-related respiratory depression is possible and is more likely during general anesthesia. Panting can occur but may be less than with hydromorphone, and cough suppression may occur. Secondary to enhanced vagal tone, oxymorphone can cause bradycardia. Although oxymorphone may cause histamine release, it is significantly less than histamine release from morphine and is usually clinically insignificant; however, it may be significant in critically ill animals. Constipation is possible with chronic oxymorphone dosing.

In dogs, adverse effects include vomiting, sedation, panting, whining/vocalization, and defecation. Vomiting, nausea, and defecation reportedly occurs more frequently after SC administration than IV administration. CNS depression may be greater than desired, particularly when treating moderate to severe pain. In dogs, IV constant rate infusions greater than 0.05 mg/kg/hour administered for more than 12 hours may cause sedation and adverse effects severe enough to require rate reduction.[9]

In cats, high doses of oxymorphone may cause ataxia, hyperesthesia, and behavioral changes such as hyperexcitability or aggression. Behavioral changes can be unpredictable, and concomitant tranquilization is recommended.

In horses, opioids may cause CNS excitement and pretreatment (eg, xylazine) is usually administered to reduce CNS behavioral changes.

Humans have an increased tendency to experience nausea and vomiting with oxymorphone than with morphine.

Reproductive/Nursing Safety

Opioids cross the placenta. In humans, there is a boxed warning that prolonged use of oxymorphone during pregnancy can result in potentially life-threatening neonatal opioid withdrawal syndrome.[10]

Most opioids appear in maternal milk. In humans, withdrawal signs have occurred in breastfeeding infants after stopping maternal administration of an opioid-analgesic.[10]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Massive overdoses of oxymorphone may produce profound respiratory and/or CNS depression. Other effects may include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Naloxone is the agent of choice to treat respiratory depression. Animals should be closely monitored after naloxone administration as effects may diminish before subtoxic concentrations of oxymorphone are attained, and naloxone doses may need to be repeated. Consider mechanical respiratory support in cases of severe respiratory depression.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxymorphone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents**: Medications with anticholinergic properties may increase risk for urinary retention and constipation when combined with opioids.
- **Butorphanol, Buprenorphine, Nalbuphine**: May antagonize opioid effects
- **Clopidogrel**: Opioids may decrease metabolism of clopidogrel to its active metabolite and thus decrease clopidogrel's antiplatelet effect.
- **Central Nervous System (CNS) Depressants** (eg, **anesthetic agents, antihistamines, barbiturates, ethanol, gabapen-**

tin, phenothiazines, tranquilizers): May increase risk for CNS or respiratory depression
- **Desmopressin**: Opioids may increase the risk for water intoxication or hyponatremia when combined with desmopressin**.**
- **Diuretics**: Opioids may decrease efficacy in congestive heart failure patients.
- **Gastrointestinal (GI) Prokinetic Agents** (eg, **cisapride, metoclopramide**): Opioids may decrease the effectiveness of GI prokinetic agents.
- **Magnesium Sulfate**: The CNS depressant effects of oxymorphone may be increased; more likely with higher magnesium doses or IV magnesium therapy.
- **Minocycline**: IV minocycline therapy may enhance the CNS depressant effects of oxymorphone.
- **Opioid Antagonists** (eg, **naloxone, naltrexone**): Combined use negates opioid effects.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid, selegiline**): Use MAOIs with oxymorphone with extreme caution as meperidine (a related opioid) is contraindicated in human patients receiving MAOIs and for at least 14 days after receiving MAOIs. Some human patients have exhibited signs of opioid overdose after receiving therapeutic doses of meperidine while taking MAOIs.
- **Muscle Relaxants, Skeletal**: Oxymorphone may enhance effects.
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**): Some phenothiazines may antagonize analgesic effects and increase risk for hypotension.
- **Rufinamide**: The CNS effects of oxymorphone may be increased when used concurrently, specifically dizziness and sleepiness.
- **Serotonin Modulators** (eg, **linezolid, methylene blue, metoclopramide, SSRIs, trazodone**): Serotonin concentrations may be enhanced when serotonin modulators are given concomitantly with oxymorphone. Monitor for serotonin syndrome.
- **Succinylcholine**: Opioids combined with succinylcholine may enhance the bradycardic effects of opioids.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Oxymorphone may exacerbate the effects of tricyclic antidepressants.
- **Warfarin**: Opioids may potentiate the anticoagulant activity of warfarin.

Laboratory Considerations
- As they may increase biliary tract pressure, opioids can increase plasma **amylase** and **lipase** values up to 24 hours following their administration.
- Quinolones may cause false positive results on urine screening tests for oxymorphone.[11]

Dosages
DOGS/CATS:

Analgesia for acute pain, sedation, premedication agent (extra-label):

a) 0.05 – 0.2 mg/kg IV, IM, or SC every 1 to 6 hours as needed. May be given in combination with a sedative.

b) Epidural administration: 0.05 – 0.1 mg/kg diluted in 0.3 mL/kg of 0.9% sodium chloride.[12] Some recommend a maximum of 6 mL. Use of preservative-free product is recommended.[13]

HORSES:

Analgesia (extra-label): 0.01 – 0.03 mg/kg IV or IM. NOTE: Oxymorphone may cause CNS excitement in horses. Pretreatment with acepromazine or xylazine is recommended to reduce the severity of this effect.

SHEEP:

Premedication (extra-label): 0.05 mg/kg IV once[14]

BIRDS:

Premedication (in most species; extra-label): 0.05 – 0.2 mg/kg IV, IM, or SC once

FERRETS:

Analgesia (extra-label): 0.05 – 0.2 mg/kg IV, IM, or SC every 6 to 12 hours as needed

SMALL MAMMALS:

Analgesia (extra-label):

Rabbits: 0.1 – 0.3 mg/kg IV, IM, or SC every 2 to 4 hours as needed

Hamsters, Gerbils, Mice, Rats, Guinea pigs, Chinchillas: 0.2 – 0.5 mg/kg SC every 6 to 12 hours as needed

Monitoring
- Respiratory rate and depth
- Level of central nervous system depression or excitation
- Blood pressure (especially with IV use)
- Analgesia
- Cardiac rate

Client Information
- This medication is normally given intramuscularly, intravenously, subcutaneously, or rectally. This drug is normally only used in the veterinary clinic or under direct professional supervision.
- Oxymorphone is classified as a schedule II (C-II) controlled drug by the federal Drug Enforcement Agency (DEA) and requires a new written prescription for refills. Use of this medication in animals or humans other than that for which it is prescribed is illegal.

Chemistry/Synonyms
A semi-synthetic phenanthrene narcotic agonist, oxymorphone HCl occurs as odorless white crystals or a white to off-white powder. Oxymorphone will darken with prolonged exposure to light. One gram of oxymorphone HCl is soluble in 4 mL of water and sparingly soluble in alcohol or ether. Commercially available oxymorphone injection has a pH of 2.7 to 4.5.

Oxymorphone HCl may also be known as 7,8-Dihydro-14-hydroxymorphinone hydrochloride, oximorphone hydrochloride, *Numorphan*®, and *Opana*®.

Storage/Stability
Store vials protected from light at room temperature 15°C to 30°C (59°F-86°F) and avoid freezing. Store commercially available suppositories at 2°C to 15°C (35.6°F-59°F). Store commercially available oral products at 25°C (77°F) with excursions permitted from 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations
Oxymorphone is reported to be physically **compatible** when mixed with acepromazine, atropine, glycopyrrolate, and ranitidine.

Oxymorphone is physically **incompatible** when mixed with barbiturates or diazepam.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug a Class 1 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Oxymorphone HCl for Injection: 1 mg/mL in 1 mL ampules; *Opa-*

na®; (Rx, C-II). **NOTE**: manufacturing of the injection was stopped in 2017.

Oxymorphone oral tablets (*Opana*®) and extended-release tablets (*Opana ER*®) are also available.

NOTE: Oxymorphone is a DEA schedule-II (C-II) controlled substance. Report dispensing to state monitoring programs where required.

Oxytetracycline

(ox-ee-tet-ra-***sye***-kleen) *Terramycin®, Pennox®, LA-200®*

Tetracycline Antibiotic

For ophthalmic use, refer to ***Oxytetracycline/Polymyxin B Ophthalmic***

Prescriber Highlights

- ► Although many bacteria are now resistant, oxytetracycline is still used to treat *Mycoplasma* spp, *Rickettsia* spp, spirochetes, and *Chlamydia* spp.
- ► When used in food animals, refer to product labels for indications, restrictions, dosages, and withdrawal times.
- ► Contraindications include hypersensitivity to tetracyclines.
- ► Use with extreme caution in pregnancy due to risk for impaired fetal skeletal development and discoloration of deciduous teeth.
- ► Use with caution in liver or renal insufficiency
- ► Adverse effects include GI distress (diarrhea, alteration of microbiota, ruminoreticular stasis); staining and impaired development of teeth and bones in young, growing animals; superinfections; and photosensitivity. Long-term use may cause uroliths.
- ► Avoid rapid IV administration of undiluted propylene glycol-based products due to risk for intravascular hemolysis and cardiodepressant effects. Local reactions, yellow staining, and necrosis may be seen at IM injection sites.

Uses/Indications

Certain oxytetracycline products are FDA-approved for use in dogs and cats (no known products are currently being marketed), calves, nonlactating dairy cattle, preruminating calves, beef cattle, sheep, swine, fish, honeybees, and poultry.

In dogs and cats, oxytetracycline has been used to treat susceptible infections including for the treatment of infections caused by *Neorickettsia helminthoeca* (salmon poisoning disease)[1] and antibiotic-responsive diarrhea.[2] Oxytetracycline also has been used to address tear staining that may develop near the medial canthus[3] ; however, the use of an antimicrobial for non-antimicrobial effects is under increasing scrutiny.

For cattle, there are several injectable oxytetracycline products, concentrations, and formulations. Depending on the product, they may be indicated for infectious diseases such as bovine respiratory disease (BRD), diphtheria, foot rot, infectious bovine keratoconjunctivitis (pink eye), bacterial enteritis (scours), wooden tongue, leptospirosis, wound infections, and acute metritis. Concentrated formulations (200 mg/mL and 300 mg/mL) have been used for the control of respiratory infections in cattle at high risk for BRD. Historical overuse has limited the efficacy of oxytetracycline for conditions such as BRD in many areas.[4–6]

For swine, oxytetracycline is FDA-approved for the treatment of pneumonia caused by *Pasteurella multocida*, bacterial enteritis caused by *Escherichia coli*, leptospirosis caused by *Leptospira pomona,* and for use in farrowing sows to control bacterial enteritis in suckling piglets caused by *E coli*.

The World Health Organization (WHO) has designated oxytetracycline as a Highly Important antimicrobial for human medicine.[7] The Office International des Epizooties (OIE) has designated tetracyclines as Veterinary Critically Important Antimicrobial (VCIA) Agents in avian, bovine, camelids, caprine, equine, lagomorph, ovine, and swine species.[8]

Pharmacology/Actions

Tetracyclines are time-dependent bacteriostatic antibiotics that inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing aminoacyl transfer-RNA binding to those ribosomes. Tetracyclines are alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can also inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most *Mycoplasma* spp, spirochetes (including *Borrelia burgdorferi*), *Chlamydia* spp, and *Rickettsia* spp. For gram-positive bacteria, tetracyclines have activity against some strains of staphylococci and streptococci, but resistance of these organisms is increasing. Gram-positive bacteria that are usually susceptible to tetracyclines include *Actinomyces* spp, *Bacillus anthracis, Clostridium perfringens, Clostridium tetani*, *Listeria monocytogenes*, and *Nocardia* spp. Tetracyclines usually have in vivo and in vitro activity against some gram-negative bacteria, including *Bordetella* spp, *Brucella* spp, *Bartonella* spp, *Haemophilus* spp, *Pasteurella multocida, Shigella* spp, and *Yersinia pestis*. Many or most strains of *Escherichia coli, Klebsiella* spp, *Bacteroides* spp, *Enterobacter* spp, *Proteus* spp, and *Pseudomonas aeruginosa* are resistant to tetracyclines. Although most strains of *Pseudomonas aeruginosa* show in vitro resistance to tetracyclines, tetracycline and oxytetracycline attain high levels in urine and have been associated with clinical cures in dogs with UTI caused by *P aeruginosa*.

Oxytetracycline and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance. A tetracycline susceptibility disk is usually used for in vitro testing for oxytetracycline susceptibility. Tetracycline susceptibility indicates oxytetracycline susceptibility.

Oxytetracycline appears to have immunomodulatory effects that may contribute to its clinical efficacy. In horses, oxytetracycline appears to be a potent inhibitor of matrix metalloproteinase-9 and a modest inhibitor of matrix metalloproteinase-2[9]; however, the clinical relevance of this is unclear.

Pharmacokinetics

Both oxytetracycline and tetracycline are readily absorbed after oral administration to fasting animals. Bioavailability ranges from ≈60% to 80%. The presence of food, and especially dairy products, can reduce the amount of tetracycline absorbed by as much as 50% or more. After IM administration of oxytetracycline (short-acting), peak levels may occur in 30 minutes to several hours, depending on the volume and site of injection. The long-acting product (*LA-200®)* has significantly slower absorption after IM injection. Pharmacokinetic data for 200 mg/mL single injection oxytetracycline products administered IM as per the label single injection regimen of 20 mg/kg suggest that plasma concentrations are ≈1, 0.2, and 0.1 mg/mL at 48, 72, and 96 hours, respectively.[10]

Tetracyclines are widely distributed in the body, including to the heart, kidney, lungs, muscle, pleural fluid, bronchial secretions, sputum, bile, saliva, urine, synovial fluid, ascitic fluid, and aqueous and vitreous humor. Only small quantities of tetracycline and oxytetracycline are distributed to the CSF and therapeutic levels may not be attainable. Although all tetracyclines distribute to the prostate and eye, doxycycline or minocycline penetrate better into these and most other tissues. Tetracyclines cross the placenta, enter fetal circulation,

and are distributed into milk. The volume of distribution of oxytetracycline is ≈2.1 L/kg in small animals, 1.4 L/kg in horses, and 0.8 L/kg in cattle. The amount of plasma protein binding is ≈10% to 40% for oxytetracycline. Oxytetracycline tissue concentrations are higher in diseased lung than in healthy lung and concentrations in milk are higher than serum when mammary glands are inflamed.

Both oxytetracycline and tetracycline are eliminated unchanged, primarily via glomerular filtration. Patients with impaired renal function can have prolonged elimination half-lives and may accumulate the drug with repeated dosing. These drugs are apparently not metabolized but are excreted into the GI tract via both biliary and nonbiliary routes and may become inactive after chelation with fecal material. The elimination half-life of oxytetracycline is ≈4 to 6 hours in dogs and cats, 4.3 to 9.7 hours in cattle, 10.5 hours in horses, 6.7 hours in swine, and 3.6 hours in sheep.

In broilers, oxytetracycline absorption was significantly slower in chickens that were treated with the long-acting formulation compared with those administered short-acting formulation. However, a therapeutic plasma concentration (greater than 1 μg/mL) was maintained for 72 hours following a single long-acting injection.[11] Oxytetracycline soluble powder is poorly absorbed from the GI tract following oral administration, even in the absence of food and with the use of deionized water. The oxytetracycline injectable products, given SC and IM, are rapidly absorbed to a similar extent, irrespective of the administration route.[12]

Contraindications/Precautions/Warnings

Oxytetracycline is contraindicated in patients that are hypersensitive to it or other tetracyclines. Because tetracyclines can impair fetal skeletal development, discolor deciduous teeth, and lead to enamel hypoplasia, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline and tetracycline are considered more likely to cause these abnormalities than doxycycline or minocycline.

In patients with renal insufficiency or hepatic impairment, oxytetracycline and tetracycline must be used cautiously. In these situations, lower than usual doses are recommended, with enhanced monitoring of renal and hepatic function if an alternative antibiotic is unavailable. Avoid concurrent administration of other nephrotoxic or hepatotoxic drugs with tetracyclines. Monitoring of serum levels should be considered if long-term treatment is required.

Oral administration of tetracycline, chlortetracycline, or oxytetracycline appears safe in mice and rats, but little appears to be absorbed, which limits efficacy. Oral tetracyclines are known to be toxic to guinea pigs, and may be toxic to hamsters, gerbils, and rabbits.[13]

Adverse Effects

Oxytetracycline and tetracycline given to young animals can cause a yellow, brown, or gray discoloration of bones and teeth. High doses or long-term administration may delay bone growth and healing. In humans, tetracyclines in high concentrations have been shown to exert an antianabolic effect, which can cause an increase in BUN and/or hepatotoxicity, particularly in patients with pre-existing renal dysfunction.[14] As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated. Veterinary significance is unclear.

In small animal species, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline well, and may present with GI distress, fever, hair loss, and depression. There are reports that long-term tetracycline use may cause urolith formation in dogs, but this is thought to occur very rarely.

Diarrhea in horses is possible. Acute kidney injury has been observed in foals receiving high-dose oxytetracycline treatment for flexural limb deformities.[15,16]

In ruminants, high oral doses can cause ruminal microflora depression and ruminoreticular stasis. Rapid IV injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Perivascular injection or leakage from an IV injection may cause severe swelling at the injection site. Propylene glycol-based products have also caused cardiodepressant effects when administered to calves. When the drug is administered IM, local reactions, yellow staining, and necrosis may be seen at the injection site. Reports of adverse effects associated with oxytetracycline administration in cattle include injection site swelling; restlessness; ataxia; trembling; swelling of eyelids, ears, muzzle, anus, vulva (or scrotum and sheath in males); respiratory abnormalities (labored breathing); frothing at the mouth; collapse; and death. Some of these reactions may be attributed to anaphylaxis or to cardiovascular collapse of unknown cause.

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of nonsusceptible bacteria or fungi.

Tetracyclines have also been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias.

Reproductive/Nursing Safety

Tetracyclines cross the placenta; they are embryotoxic when used early in pregnancy and can retard fetal skeletal growth and permanently discolor teeth.

Tetracyclines are excreted in maternal milk. Milk to plasma ratios vary between 0.25 and 1.5. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day PO or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). If the patient develops severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants can cause ruminal microflora depression and ruminoreticular stasis. Rapid IV administration of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

Rapid IV injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions and/or the cardiodepressant effects of the propylene glycol vehicle. If the drug must be given rapidly IV (in less than 5 minutes), some clinicians recommend pretreating the animal with IV calcium gluconate.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxytetracycline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Atovaquone**: Tetracyclines have caused decreased atovaquone concentrations.
- **Beta-Lactam** or **Aminoglycoside Antibiotics**: Bacteriostatic drugs, such as the tetracyclines, may interfere with bacte-

ricidal activity of the penicillins, cephalosporins, and aminoglycosides; actual clinical significance of this interaction is in doubt.

- **Cholestyramine**: May decrease oxytetracycline absorption
- **Digoxin**: Tetracyclines may increase the bioavailability of digoxin in a small percentage of human patients and lead to digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.
- **Divalent or Trivalent Cations** (eg, **oral antacids, saline cathartics or other orally administered products containing aluminum** [eg, **sucralfate**]**, bismuth, calcium, iron, magnesium, or zinc cations**): When administered orally, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations. It is recommended that all oral tetracyclines be given at least 1 to 2 hours before or after the cation-containing product.
- **Furosemide**: Increased risk for acute kidney injury and renal failure
- **Lanthanum**: May decrease oxytetracycline absorption
- **Retinoid Acids** (eg, **acitretin, isotretinoin**): May increase the potential for the occurrence of intracranial hypertension. Combination is contraindicated.
- **Warfarin**: Tetracyclines may depress plasma prothrombin activity, and patients on anticoagulant therapy may need dosage adjustment.

Laboratory Considerations

- Tetracyclines (except minocycline) may cause falsely elevated values of **urine catecholamines** when using fluorometric methods of determination.
- Tetracyclines can reportedly cause false positive **urine glucose** results if the cupric sulfate method of determination (Benedict's reagent, *Clinitest®*) is used, but this effect may be the result of ascorbic acid, which is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false negative results in determining urine glucose when the glucose oxidase method (*Clinistix®*, *Tes-Tape®*) is used.

Dosages

DOGS/CATS:

Susceptible systemic infections (extra-label):

a) 10 mg/kg IV every 12 hours

b) 20 mg/kg PO every 8 to 12 hours

Adjunctive treatment of *Neorickettsia helminthoeca* | Salmon poisoning (extra-label): 7 mg/kg IV every 8 hours for 3 to 5 days[1]

HORSES:

Susceptible infections (extra-label): Dosage recommendations can vary considerably. For short-acting oxytetracycline injection, 6.6 – 10 mg/kg IV once daily is commonly used. Some clinicians use oxytetracycline 5 – 6.6 mg/kg IV every 12 hours. The following are representative indications and dosages:

a) **Foals**: 5 – 10 mg/kg IV every 12 hours diluted and given slowly, or 10 – 20 mg/kg IV once daily, diluted and given slowly. Monitor creatinine and UA.[17]

b) **Equine monocytic or granulocytic ehrlichiosis**: 6.6 – 7 mg/kg IV once daily for 5 to 7 days; to safeguard against adverse effects (muscle tremors, agitation, or acute collapse), dilute in a 1:1 ratio (at least) and give IV slowly, or deliver it as an infusion in 500 mL or 1 L of fluids.[17,18]

c) **Lyme disease**: 5 – 6.6 mg/kg every 12 to 24 hours IV for 1 month[19]

d) **Potomac horse fever (*Neorickettsia risticii*) early in the clinical course of the disease**: 6.6 mg/kg IV twice a day. Usually no more than 5 days treatment is necessary.[18]

e) **Proliferative enteropathy (*Lawsonia intracellularis*) in foals**: Oxytetracycline 6.6 mg/kg IV (slowly) once daily; typically administered for 2 to 4 weeks.[20] Alternatively, oxytetracycline 5 – 6.6. mg/kg IV every 12 hours for 3 to 7 days followed by doxycycline 10 mg/kg PO every 12 hours for 7 to 17 days[21]

f) **Intrauterine infusion**: 1 – 5 g/horse (NOT g/kg); use povidone-based products only. There is limited information available for recommending doses, volume infused, frequency, and diluents. Most intrauterine treatments are commonly performed every day or every other day for 3 to 7 days.[22]

Adjunctive treatment of flexural limb deformities in foals: 44 – 70 mg/kg (3 g for a 50 kg [110 lb] foal) diluted in 250 to 500 mL of normal saline and given IV.[23,24] May repeat once daily for 2 to 3 days

CATTLE:

Susceptible infections in beef cattle, dairy cattle, and calves, including preruminating (veal) calves (label dosages; FDA-approved):

a) Using the short-acting (100 mg/mL) product:

Treatment of pneumonia and shipping fever complex associated with *Pasteurella* spp; bacterial enteritis (scours) caused by *Escherichia coli*; foot rot and calf diphtheria caused by *Fusobacterium necrophorum;* wooden tongue caused by *Actinobacillus lignieresi*; wound infections, metritis, and traumatic injury caused by sensitive strains of *Staphylococcus* spp and *Streptococcus* spp: 6.6 – 11 mg/kg (3 – 5 mg/lb) IV (*slowly* over a period of at least 5 minutes) once daily; use of the higher end of the dosage range (11 mg/kg) is recommended for severe forms of indicated diseases. Treatment should continue for 24 to 48 hours following remission of clinical signs related to infection and should not exceed a total of 4 consecutive days.[25]

b) Using the *Liquamycin LA-200®* product: **NOTE**: Do not exceed 10 mL per SC or IM injection site.

Treatment of pneumonia and shipping fever complex caused by *Pasteurella* spp and *Haemophilus* spp and infectious bovine keratoconjunctivitis (pink eye) caused by *Moraxella bovis* in calves and yearlings where re-treatment is impractical because of husbandry conditions, such as cattle on range, or where their repeated restraint is inadvisable or for infectious bovine keratoconjunctivitis (pink eye) caused by *Moraxella bovis*: 20 mg/kg (9 mg/lb) IM or SC once[26]

Treatment of pneumonia and shipping fever complex caused by *Pasteurella* spp and *Haemophilus* spp; foot rot and diphtheria caused by *Fusobacterium;* wooden tongue caused by *Actinobacillus lignieresii;* leptospirosis caused by *Leptospira pomona*; and wound infections and acute metritis caused by sensitive strains of *Staphylococcus* spp and *Streptococcus* spp: 6.6 – 11 mg/kg (3 – 5 mg/lb) IM, SC, or IV (*slowly* over a period of at least 5 minutes) once daily; use of the higher end of the dosage range (11 mg/kg SC or IV slow) is recommended when used to treat severe foot rot and other advanced cases of other indicated diseases.[26] Treatment should continue for 24 to 48 hours following resolution of clinical signs related to infection and should not exceed a total of 4 consecutive days.

c) Using *300 PRO LA®*: **NOTE**: Do not exceed 10 mL per SC or IM injection site.

Control of respiratory disease in cattle at high risk for developing bovine respiratory disease (BRD) associated with *Mannheimia (Pasteurella) haemolytica*: 30 mg/kg (13.6 mg/lb) IM or SC once

Treatment of pneumonia and shipping fever complex caused by *Pasteurella* spp (shipping fever) in calves and yearlings

where re-treatment is impractical due to husbandry conditions, such as cattle on range, or where their repeated restraint is inadvisable; or infectious bovine keratoconjunctivitis (pink eye) caused by *Moraxella bovis*: 20 – 30 mg/kg (9 – 13.6 mg/lb) IM or SC once[27]

Treatment of pneumonia and shipping fever complex caused by *Pasteurella* spp and *Histophilus* spp; foot rot and diphtheria caused by *Fusobacterium necrophorum*; bacterial enteritis (scours) caused by *E coli*; or wooden tongue caused by *Actinobacillus lignieresii;* leptospirosis caused by *Leptospira pomona*; and wound infections and acute metritis caused by sensitive strains of *Staphylococcus* spp and *Streptococcus* spp: 6.6 – 11 mg/kg (3 – 5 mg/lb) IM, SC, or IV (IV *slowly* over a period of at least 5 minutes) once daily[27]; use of the higher end of the dosage range (11 mg/kg SC or IV slow) is recommended when used to treat severe foot rot and other advanced cases of other indicated diseases. Treatment should continue for 24 to 48 hours following resolution of clinical signs related to infection and should not exceed a total of 4 consecutive days.

d) Using the combination product with flunixin (*Hexasol®*): **NOTE**: Do not exceed 10 mL per SC or IM injection site.

Treatment of pneumonia associated with *Pasteurella* spp and for the control of associated pyrexia in beef and nonlactating dairy cattle: oxytetracycline 30 mg/kg (13.6 mg/lb) and flunixin 2 mg/kg (0.9 mg/lb) IM or SC once.[28] Do not administer more than 10 mL per injection site (1 to 2 mL per site in small calves). Recommended where re-treatment of calves and yearlings is impractical because of husbandry conditions, such as cattle on range, or where their repeated restraint is inadvisable.

Listeria monocytogenes (extra-label): 10 mg/kg IV (*slowly* over a period of at least 5 minutes) every 12 hours for at least 5 days.[29]

SHEEP & GOATS:

Enteritis caused by *E coli* and for pneumonia caused by *Pasteurella multocida* (extra-label): oxytetracycline (for use in water) 22 mg/kg PO in water daily for 7 to 14 days[21]

***Chlamydophila abortus* in pregnant ewes** (extra-label): Long-acting oxytetracycline 20 mg/kg IM.[30] In the face of an outbreak, all pregnant ewes should be treated.

***Coxiella burnetii* | Q fever** (extra-label): Aborting ewes or does and other females in late pregnancy were given 2 doses of oxytetracycline 20 mg/kg IM during the last month of gestation; injections were typically separated by 7 to 27 days (mean = 16 days). Treatment does not totally suppress abortions and shedding of *C burnetii* at lambing.[31]

Foot rot in sheep *(Dichelobacter nodosus or Fusobacterium necrophorum)*: 20 mg/kg IM, once[32]

SWINE:

Susceptible infections (label dosages, FDA-approved):

a) Using the *Liquamycin® 100* product[33]:

Treatment of sows as an aid in the control infectious enteritis (baby pig scours, colibacillosis) in suckling piglets caused by *E coli*: 6.6 mg/kg (3 mg/lb) IM once ≈8 hours before farrowing or immediately after completion of farrowing

b) Using the *Liquamycin® LA-200® product:* **NOTE**: Do not exceed 5 mL per SC or IM injection site. For pigs weighing less than 11.3 kg (25 lb), see product label for specific administration instructions.

Treatment of bacterial enteritis (scours, colibacillosis) caused by *E coli*, pneumonia caused by *P multocida*, and leptospirosis caused by *Leptospira pomona* where retreatment is impractical due to husbandry conditions or where repeated restraint is inadvisable: 20 mg/kg (9 mg/lb) IM, once in the neck region[34]

Treatment of bacterial enteritis (scours, colibacillosis) caused by *E coli*, pneumonia caused by *P multocida*, and leptospirosis caused by *Leptospira pomona:* 6.6 – 11 mg/kg (3 – 5 mg/lb) IM daily.[34] Treatment should continue for 24 to 48 hours following resolution of clinical signs related to infection and should not exceed a total of 4 consecutive days.

Treatment of sows as an aid in the control infectious enteritis (baby pig scours, colibacillosis) in suckling piglets caused by *E coli*: 6.6 mg/kg (3 mg/lb) IM once ≈8 hours before farrowing or immediately after completion of farrowing[34]

c) Using the *300 PRO LA®* product: **NOTE**: Do not exceed 5 mL per injection site. For pigs weighing less than 11.3 kg (25 lb), see product label for specific administration instructions.

Treatment of pneumonia caused by *P multocida* where re-treatment is impractical because of husbandry conditions or where repeated restraint is inadvisable: 20 mg/kg (9 mg/lb) IM once[27]

Treatment of bacterial enteritis (scours, colibacillosis) caused by *E coli*; pneumonia caused by *P multocida;* and leptospirosis caused by *Leptospira pomona*: 6.6 – 11 mg/kg (3 – 5 mg/lb) IM once daily.[27] Treatment should be continued for 24 to 48 hours following resolution of clinical signs related in infection and should not exceed a total of 4 consecutive days.

Treatment of sows as an aid in the control of infectious enteritis (baby pig scours, colibacillosis) in suckling piglets caused by *E coli*: 6.6.mg/kg (3 mg/lb) IM once ≈8 hours before farrowing or immediately after completion of farrowing[27]

Susceptible infections (extra-label): 2 - 10 mg/kg IM, SC every 12 to 24 hours[35]

BIRDS:

Chlamydiosis (psittacosis) (extra-label): Using 200 mg/mL product (*Liquamycin® LA-200®):* 50 mg/kg IM once every 3 to 5 days in birds suspected or confirmed of having disease. Using 300 mg/mL product: single dose 20 mg/kg IM in broilers.[11] **NOTE**: IM injections may cause severe local tissue reactions.[36]

REPTILES:

Susceptible infections in turtle and tortoises (extra-label): 10 mg/kg PO once daily for 7 days (useful to treat ulcerative stomatitis caused by *Vibrio* spp)[37]

Monitoring

- Adverse effects (eg, GI distress, staining of teeth, overgrowth (superinfections) of nonsusceptible bacteria or fungi infections)
- Clinical efficacy (ie, improvement in clinical signs of disease being treated)
- Long-term use or in susceptible patients: periodic CBC and serum biochemistry profiles as indicated by clinical condition

Client Information

- When this medicine is given orally, oxytetracycline should be administered on an empty stomach 1 to 2 hours before or after consumption of food, milk, other dairy products, and minerals such as calcium or iron. If your animal vomits or acts sick after receiving the medicine on an empty stomach, give it with a small amount of food to see if this helps. If vomiting continues, contact your veterinarian.
- Oxytetracycline may permanently stain teeth and interfere with developing bones in young animals.

- Darkening of your animal's urine may occur. In some cases, this change may occur shortly after the first dose. Contact your veterinarian if this effect persists, or if you notice blood in the urine.
- This medicine may make your animal's skin more sensitive to sunlight and increase the risk for sunburn on hairless areas such as the nose and around the eyelids and ears. Keep treated animals out of the sun or apply a veterinary-approved sunblock product to protect the skin. Tell your veterinarian if you notice any reddening/sunburn on the skin while your animal is on this medication.
- Administration of injectable forms of this medicine drug may be painful and cause staining of the skin around the injection and result in trim losses. Be sure you understand how to give the medications.

Chemistry/Synonyms

A tetracycline derivative obtained from *Streptomyces rimosus*, oxytetracycline base occurs as a pale yellow to tan crystalline powder that is very slightly soluble in water and sparingly soluble in alcohol. Oxytetracycline HCl occurs as a bitter, hygroscopic, yellow crystalline powder that is freely soluble in water and sparingly soluble in alcohol. Commercially available 50 mg/mL and 100 mg/mL oxytetracycline HCl injections are usually available in either propylene glycol- or povidone-based products.

Oxytetracycline may also be known as glomycin, hydroxytetracycline, oxytetracyclinum, riomitsin, terrafungine, *Agrimycin®*, *Biomycin®*, *Liquamycin®*, *Medamycin®*, *Oxybiotic®*, *Oxytet®*, *Terramycin®*, and *Vetrimycin®*.

Storage/Stability

Unless otherwise directed by the manufacturer, oxytetracycline HCl and oxytetracycline products should be stored in airtight, light-resistant containers at temperatures of less than 40°C (104°F) and preferably at room temperature (15°C-30°C [59°F-86°F]); avoid freezing. Products do not require refrigeration. Because storage requirements and discard specifications vary slightly by manufacturer and by product, refer to product label for specific information.

Some products state to discard vial after a defined number of stopper punctures or days after first use.

Compatibility/Compounding Considerations

The following information pertains to short-acting (not long-acting) forms of oxytetracycline HCl. It is generally considered to be physically **compatible** with most commonly used IV infusion solutions, including D_5W, sodium chloride 0.9%, and lactated Ringer's, but can become relatively unstable in solutions with a pH more than 6, particularly in those containing calcium. This is apparently more of a problem with the veterinary injections that are propylene glycol-based rather than those that are povidone-based. Other drugs that are reported to be physically **compatible** with oxytetracycline for injection include: corticotropin, dimenhydrinate, insulin (regular), isoproterenol HCl, norepinephrine bitartrate, potassium chloride, tetracycline HCl, and vitamin B complex with C.

Drugs that are reportedly physically **incompatible** with oxytetracycline, data conflict, or compatibility is concentration/time dependent include: amikacin sulfate, aminophylline, amphotericin B, calcium chloride/gluconate, chloramphenicol sodium succinate, erythromycin gluceptate, heparin sodium, hydrocortisone sodium succinate, iron dextran, methohexital sodium, oxacillin sodium, penicillin G potassium/sodium, pentobarbital sodium, phenobarbital sodium, and sodium bicarbonate.

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oxytetracycline HCl 100 mg/mL Injection: There are many FDA-approved oxytetracycline products marketed in these concentrations. Some trade names for these products include: *Terramycin®, Liquamycin® 100, Biomycin®*, *Duramycin®, Oxybiotic®*, and *Oxytet®*. Some are labeled for Rx (prescription) use only, whereas some are OTC. Depending on the product, this drug may be FDA-approved for use in cattle, beef cattle, swine, chickens, or turkeys. Products may also be labeled for IV, IM, or SC use. Withdrawal times vary with regard to individual products; when used as labeled, slaughter withdrawal times vary in cattle from 15 to 22 days, swine 20 to 26 days, and 5 days for chickens and turkeys. Refer to the labeled information for the product used for more information.

Oxytetracycline base 200 mg/mL Injection in 100 mL, 250 mL, and 500 mL bottles; *Liquamycin® LA-200®, Vetrimycin®* 200, *Biomycin®-200* generic; (OTC). FDA-approved for use in swine and cattle. When used as labeled, slaughter withdrawal = 28 days for swine and cattle; milk withdrawal = 96 hours.

Oxytetracycline base 300 mg/mL Injection in 100 mL, 250 mL, and 500 mL vials; *Noromycin® 300*-LA (OTC), *300 Pro® LA*; (Rx). FDA-approved for use in beef cattle, nonlactating dairy cattle, calves, including preruminating (veal) calves, and swine. When used as labeled, slaughter withdrawal = 28 days.

Oxytetracycline Oral Tablets (Boluses) 250 mg and 500 mg tablets; *Calf Scour Bolus®*, *Oxy 500 Calf Bolus, Terramycin® Scours Tablets*; (OTC). FDA-approved for use in nonlactating dairy and beef cattle. Withdrawal periods may vary; refer to the product label.

Combination Products:

Oxytetracycline 300 mg/mL and Flunixin (as flunixin meglumine) 20 mg/mL in 100 mL, 250 mL, and 500 mL; *Hexasol®*; (Rx). When used as labeled, slaughter withdrawal = 21 days. Restricted drug in California. Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established for this product in preruminating calves. Do not use in calves to be processed for veal.

Water Soluble, VFD, and Milk Replacer Products:

Water soluble oxytetracycline products transitioned from OTC to Rx status on January 1, 2017. Some trade names include *Pennox 343®*, *Tetroxy® 25*, *Tetroxy 343®*; *Tetroxy HCA®*; (Rx)

Feed additive products transitioned from OTC to VFD status on January 1, 2017. Some trade names for these products include *Neo-Oxy®*, *Neo-Terramycin®*, *NT Concentrate®*, *Pennox®*, *Terramycin®*; (VFD)

Milk replacer products available for use in calves. Some trade names include *Sav-A-Caf®*, *Scour-Ease®* (OTC), *Calf Solutions®* (VFD)

Oxytetracycline is also available as an ophthalmic ointment for use in beef and dairy cattle for the treatment of eye infections; *Terramycin Ophthalmic Ointment®*; (OTC). See ***Oxytetracycline/Polymyxin B Ophthalmic***.

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Oxytocin

(ox-ee-***toe***-sin) *Pitocin®*

Hormone

Prescriber Highlights

- ► Hypothalamic hormone used for induction or enhancement of uterine contractions during parturition, postpartum retained placenta and metritis, uterine involution after manual correction of prolapsed uterus in dogs, and agalactia. It is also used for stimulation of milk letdown in dairy animals.
- ► Contraindications include a known hypersensitivity and dystocia due to abnormal maternal anatomy and/or presentation of fetus(es) unless correction is made. When used prepartum, oxytocin should be used only when the cervix is relaxed naturally or by prior administration of estrogens.
- ► Correct hypocalcemia before using oxytocin.
- ► Adverse effects usually occur only when used at a dosage that is too high.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies oxytocin as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Oxytocin has been used in veterinary medicine for induction or enhancement of uterine contractions at parturition, postpartum evacuation of uterine debris or control of uterine bleeding, uterine involution after manual correction of prolapsed uterus in dogs, and treatment of agalactia.

Pharmacology/Actions

Oxytocin stimulates uterine contractions by increasing the sodium permeability of uterine myofibrils. The threshold for oxytocin-induced uterine contraction is reduced with pregnancy duration, in the presence of high estrogen levels, and in patients already in labor.

Oxytocin can facilitate milk ejection, but it does not have any galactopoietic properties. Oxytocin has weak antidiuretic properties.

Pharmacokinetics

Oxytocin must be administered parenterally because it is destroyed in the GI tract. Uterine response occurs almost immediately after IV administration. Following IM administration, the uterus generally responds within 3 to 5 minutes. The duration of effect in dogs after IV or IM/SC administration has been reported to be 13 minutes and 20 minutes, respectively. Although oxytocin can be administered intranasally, absorption can be erratic. Oxytocin is distributed throughout the extracellular fluid. It is believed that small quantities of the drug cross the placenta and enter the fetal circulation.

In most mammals, the plasma half-life of oxytocin is ≈1 to 6 minutes. In goats, this value has been reported to be ≈22 minutes. Oxytocin is metabolized rapidly in the liver and kidneys; oxytocinase, a circulating enzyme, can also destroy the hormone. Very small amounts of oxytocin are excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Oxytocin is considered contraindicated in animals hypersensitive to it or with obstructive dystocia due to abnormal presentation of fetus(es) unless correction is made. It is also contraindicated when female anatomy does not allow vaginal birth. When used prepartum, oxytocin should be used only when the cervix is fully relaxed, either naturally or by prior administration of estrogens. (**NOTE**: Most clinicians avoid the use of estrogens, as natural relaxation is a better indicator of when to induce contractions.)

Oxytocin is ineffective for treatment of primary uterine inertia (uterine muscles do not contract normally at parturition). Correcting hypocalcemia may improve the effectiveness of oxytocin in stimulating uterine contractions.[1]

In humans, oxytocin is contraindicated in patients with significant cephalopelvic disproportion, with unfavorable fetal positions, in obstetrical emergencies when surgical intervention is warranted, with grand multiparity, with uterine hypertonia or severe toxemia, or in which vaginal delivery is contraindicated. This drug should be used with caution in patients with uterine overdistention, previous major cervical or uterine surgery, or cervical carcinoma. Nasally administered oxytocin is contraindicated in pregnancy.

In human medicine, IV oxytocin is considered to be a high-alert medication (ie, medication that requires special safeguards to reduce the risk for errors). Consider instituting practices such as redundant drug dosages, volume checking, and using special alert labels. The National Institute for Occupational Safety and Health (NIOSH) classifies oxytocin as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk of exposure.[2]

Adverse Effects

Oxytocin used appropriately at reasonable doses rarely causes significant adverse effects. Most adverse effects are a result of the drug being used at dosages that are too high (see ***Overdose/Acute Toxicity***) or in patients that should not receive oxytocin (see ***Contraindications/Precautions/Warnings***); adequate physical examination and monitoring of the patient are essential. Most older (ie, higher) dosage recommendations for dogs and cats are obsolete, as mini-doses have been found to improve the frequency of uterine contractility and are less hazardous to the bitch (ie, uterine rupture) and fetus(es) (ie, placental compromise).[1] Hypersensitivity reactions are a possibility with products derived from animal sources. Repeat bolus injections of oxytocin may cause uterine cramping and discomfort.

The human product lists QT interval prolongation and cardiac arrhythmias as possible adverse effects. Water intoxication can occur if the drug is administered too quickly IV and/or if excessively large volumes of electrolyte-free IV fluids are co-administered.

Overdose/Acute Toxicity

Effects of overdose on the uterus depend on the stage of parturition and position of the fetus(es). Hypertonic or tetanic contractions can occur, leading to tumultuous labor, uterine rupture, and/or fetal injury or death.

Water intoxication can occur if large doses of oxytocin are infused for a long period of time, especially if there is free access to drinking water or large volumes of electrolyte-free IV fluids are concomitantly administered. Clinical signs can range from listlessness and/or depression to coma, seizures, and eventual death. Treatment includes stopping oxytocin therapy and restricting water access until signs are resolved. Severe intoxication may require the use of osmotic diuretics (eg, mannitol, urea, dextrose) with or without furosemide

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Reproductive/Nursing Safety

Oxytocin is contraindicated in humans with significant cephalopelvic disproportion, with unfavorable fetal positions, in obstetrical emergencies in which surgical intervention is warranted, with severe toxemia, or when vaginal delivery is contraindicated. Nasally administered oxytocin is contraindicated in pregnancy.

There are no known indications for use of oxytocin in the first trimester other than in relation to spontaneous or induced abortion. When used as indicated, oxytocin is not expected to present a risk for fetal abnormalities.

Oxytocin may be found in small quantities in maternal milk but

is unlikely to have significant effects. Oxytocin may alter milk flow.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxytocin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Adrenergic Agonists** (eg, **albuterol, clenbuterol**): May reduce effects of oxytocin and delay labor
- **Dinoprost**: May enhance effects of oxytocin
- **Misoprostol**: May enhance effects of oxytocin
- **nonsteroidal anti-inflammatory drugs (NSAIDs**; eg, **flunixin**): Attenuation of oxytocic effects has been demonstrated in postpartum cows.[3]
- **Vasoconstrictors** (eg, **ephedrine, epinephrine**): Concurrent use with sympathomimetic agents or other vasoconstrictors increases the risk for hypertension.

Dosages

NOTE: Unless otherwise indicated, all dosages are extra-label.

DOGS/CATS:

Uterine inertia: In most cases, calcium is given *before* oxytocin to improve contraction strength. See ***Calcium IV (-Borogluconate, -Chloride, -Gluconate)*** for further information.

a) Initial oxytocin doses of 0.1 units/kg IM; repeat doses every 30 to 40 minutes, and increase doses incrementally to a maximum of 2 units/kg (maximum of 20 units/kg).[4]

b) Oxytocin 2 units (total dose, NOT units/kg) IV, repeated in 30 to 60 minutes[5]

c) Oxytocin 0.25 units per bitch or queen (NOT units/kg) SC or IM to a maximum dose of 4 units per bitch or queen (NOT units/kg). The frequency of oxytocin administration is dictated by the labor pattern; oxytocin should generally not be given more frequently than hourly.[6]

Secondary agalactia: Oxytocin 0.25 – 1 unit per bitch or queen (NOT units/kg) SC every 2 hours. Neonates are removed for 30 minutes postinjection and encouraged to suckle, or gentle stripping of the glands is performed. Metoclopramide (dopamine antagonist) 0.1 – 0.2 mg/kg SC every 12 hours can also be given to promote milk production. Therapy is usually rewarding within 24 hours.[7]

Adjunctive treatment of acute metritis: Start broad-spectrum antibiotic therapy with good tissue penetration into the reproductive tract (eg, clindamycin plus gentamicin, ampicillin/sulbactam, amoxicillin/clavulanate, second generation cephalosporin), while waiting for culture and susceptibility results. Institute fluid therapy if the patient is dehydrated or in shock. Oxytocin 0.5 – 5 units per bitch or queen (NOT units/kg) IM may be used if birth has occurred less than 24 hours prior, or dinoprost (prostaglandin [PGF2-alpha] analogue) 0.25 mg/kg SC may be used at any time to promote evacuation of the uterus.[8]

Promotion of uterine involution after uterine prolapse manual reduction:

a) Digital manipulation to replace the uterus can be attempted using general and/or epidural anesthesia. If the tissue is very swollen, hyperosmotic fluids (eg, 50% dextrose, mannitol) may be used to assist in replacement. In some cases, an episiotomy is required to successfully reduce the prolapse. Following reduction, oxytocin 0.5 – 5 units per bitch or queen (NOT units/kg) IM will promote uterine involution.

b) Anesthetize the patient and apply sterile lubricant liberally to the exposed tissue. The uterine horn is flushed with sterile saline under pressure. Mannitol or hypertonic saline can be used to reduce edema, if necessary, before attempting reduction. Once the uterus is replaced, give oxytocin 5 – 10 units per bitch or queen (NOT units/kg) IM to cause uterine involution.

HORSES:

Augmentation or initiation of uterine contractions during parturition in properly evaluated mares: Ideally, colostrum should be present in the udder prior to induction, the cervix should be soft and dilating, and the mare should be as close to her normal due date as possible. The optimal dose and route of administration for induction remains controversial. Three protocols have been suggested: (1) low-dose oxytocin 2.5 – 5 units (total dose; NOT units/kg) IV every 15 to 30 minutes; (2) oxytocin 1 unit (total dose; NOT units/kg)/minute IV CRI; or (3) multiple smaller doses of oxytocin 15 units (total dose; NOT units/kg) IM every 15 to 20 minutes.[9]

Prevention of luteolysis:

a) Oxytocin 60 units (total dose; NOT units/kg) IM once daily can be given from day 7 to day 14 postovulation to prolong corpus luteum lifespan. With this protocol, mares have remained out of heat for up to 45 to 60 days; however, ovulation must be documented (or estimated closely) when oxytocin is used this manner.[10]

b) A similar protocol (ie, oxytocin 60 units IM from days 8 to 17) prolonged luteal maintenance past 30 days in most mares.[11]

Evacuation of uterine fluid: 10 – 20 units (total dose; NOT units/kg) IV or IM every 4 to 8 hours[12]

Assistance in removal of retained fetal membranes: 20 units (total dose; NOT units/kg) IV or IM given every hour beginning 2 to 3 hours after foaling; repeat as needed.[12] Alternatively, 20 units IV or IM every 15 min for one 2-hour block in the morning and one 2-hour block in the evening.[13]

Treatment of esophageal obstruction ("choke"): Butylscopolamine 0.3 mg/kg IV once and oxytocin 0.11 – 0.22 units/kg IV once. Oxytocin use should be avoided in mares, or the dose should be significantly reduced. Do not use in pregnant mares.

CATTLE:

Milk letdown (label dosage; FDA-approved): 10 – 20 units IV; may be repeated as necessary[14]

Obstetrical use in cows (label dosage; FDA-approved): 100 units IV, IM, or SC; may be repeated as necessary.[14] **NOTE**: Many clinicians believe this dosage to be higher than necessary.

Retained fetal membranes: 20 – 30 units (total dose; NOT units/kg) IM immediately following calving, repeated 2 to 4 hours later[15–17]

Mild to moderate cases of acute postpartum metritis: 20 units (total dose; NOT units/kg) IM 3 to 4 times daily for 2 to 3 days[15]

Augmentation of uterine contractions during parturition: 30 units (total dose; NOT units/kg) IM; repeat no sooner than 30 minutes, if necessary[18]

SHEEP/GOATS:

Obstetrical use in ewes (label dosage; FDA-approved): 30 – 50 units (total dose; NOT units/kg) IV, IM, or SC; may be repeated as necessary[14]

Retained placenta in patients with uterine atony: 10 – 20 units (total dose; NOT units/kg) IM; this drug is of limited value 48 hours postpartum, as uterine sensitivity is reduced. Treat with antibiotics if signs of metritis develop.[19]

Mild to moderate cases of acute postpartum metritis: 5 – 10 units (total dose; NOT units/kg) IM 3 to 4 times daily for

2 to 3 days[15]

Control of postextraction cervical and uterine bleeding in goats after internal manipulations (eg, fetotomy): 10 – 20 units (total dose; NOT units/kg) IV; may repeat SC in 2 hours[20]

Nonsurgical embryo recovery: Oxytocin 50 units (total dose; NOT units/kg) IV or intravaginally given 20 minutes before embryo flushing. Cloprostenol 37.5 **µg (total dose, NOT mg/kg)** via latero-vulvar injection and estradiol benzoate 1 mg (total dose, NOT mg/kg) by either IM or intravaginal route were administered 16 hours before embryo flushing.[21,22]

NEW WORLD CAMELIDS:

Retained placenta: 5 – 30 units (total dose; NOT units/kg) IM may be given at 10-minute intervals, with or without gentle traction. Strenuous traction may induce uterine prolapse.[23,24]

Agalactia: 20 units (total dose; NOT units/kg) IM up to every 2 hours[24]

SWINE:

Milk letdown in sows (label dosage): 5 – 20 units (total dose; NOT units/kg) IV; may be repeated as necessary[14]

Augmentation of uterine contractions during parturition:

a) **Obstetrical use in sows** (label dosage; FDA-approved): 30 – 50 units (total dose; NOT units/kg) IV, IM, or SC; may be repeated as necessary[14]

b) 10 units (total dose; NOT units/kg) IM; repeat no sooner than 30 minutes, if necessary[18]

Mild to moderate cases of acute postpartum metritis: 5 units (total dose; NOT units/kg) IM; may need to be repeated, as effect may be as short as 30 minutes[25]

Adjunctive treatment for mastitis, metritis, agalactia (MMA) syndrome: 20 – 50 units (total dose; NOT units/kg) IM or 5 – 10 units IV[26]

Retained placenta in patients with uterine atony: 20 – 30 units (total dose; NOT units/kg) every 2 to 3 hours as necessary in conjunction with antimicrobial therapy [19] 5 – 10 units (total dose; NOT units/kg) around the time of expulsion of first placental part (route not specified, assume IM; editors).[27]

BIRDS:

Egg binding (nonobstructive): 0.2 – 2 units per hen (total dose; NOT unit/kg) IM once. Adequate calcium must be present. In general, prostaglandins are considered superior to oxytocin because they can increase uterine contraction and relax the vaginal sphincter.[28] Oxytocin 0.5 – 10 units/kg have been reported, up to 30 units/bird, often repeated in 30 to 60 minutes. Oxytocin should be used in conjunction with other therapeutics (eg, PGE2, PGF2alpha, calcium gluconate).[24]

RABBITS, RODENTS, SMALL MAMMALS:

Dystocia:

Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 0.2 – 3 units/kg IV, IM, or SC[29]

Rabbits: Calcium glubionate 10%, 5 – 10 mL PO 30 minutes before giving oxytocin 1 – 3 units (total dose; not units/kg) IM[24]

Ferrets: 5 – 10 units per ferret (NOT units/kg) IM[30]

REPTILES:

Egg binding (nonobstructive): Depending on the species, oxytocin 1 – 40 units/kg have been effective, especially in chelonians. A second dose is generally given anywhere from 20 minutes to 12 hours after the first dose has been administered. Keep reptiles near their optimal body temperature, as temperature likely influences the effect of oxytocin on the oviduct. For best results, use with a therapy protocol that includes environmental optimization, rehydration, and calcium supplementation.

Snakes: 5 – 20 units/kg IM[24]

Lizards: 5 – 30 units/kg IM or intracoelomically[24]

Chelonians: Generally, 1 – 3 units/kg IM, IV, or by intraosseous infusion; 50% to 100% of the initial dose can be repeated IV or IM 1 to 12 hours later.[24,31]

Monitoring

- Uterine contractions, status of cervix
- Fetal monitoring if available and indicated

Client Information

- Do not use during obstructed labor, if cervix is not ready/relaxed, or if vaginal birth is not possible or recommended.
- Oxytocin should only be used in animals that can be adequately monitored for its effects.
- Use this medication only in close communication with your veterinarian.
- Oxytocin is administered by injection. Be sure you understand the instructions from your veterinarian about how and when to give this medication.
- Place used needles and syringes in a sharps disposal container immediately after use.
- Contact your veterinarian immediately if the fetus fails to be delivered within the expected timeframe or if your animal develops a fever, vomiting, or seizures.
- Those trying to conceive, and women who are pregnant or breastfeeding, should handle oxytocin carefully.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Oxytocin, a nonapeptide hypothalamic hormone stored in the posterior pituitary (in mammals), occurs as a white powder that is soluble in water. The commercially available preparations are highly purified and have virtually no antidiuretic or vasopressor activity when administered at usual doses. Oxytocin potency is standardized according to its vasopressor activity in chickens and is expressed in USP Posterior Pituitary Units. One unit is equivalent to ≈2 – 2.2 µg of pure hormone.

Commercial preparations of oxytocin injection have the pH adjusted with acetic acid to 2.5 to 4.5, and multidose vials generally contain chlorobutanol 0.5% as a preservative.

Oxytocin may also be known as alpha-hypophamine, oxytocinum, or *Pitocin®*.

Storage/Stability

Oxytocin injection should be stored at temperatures of less than 25°C (77°F) but not frozen. Some manufacturers recommend storing the product under refrigeration (2°C-8°C [36°F-46°F]), but some products have been demonstrated to be stable for up to 5 years when stored at less than 26°C (78.8°F).

Compatibility/Compounding Considerations

Oxytocin is reportedly physically **compatible** with most commonly used IV fluids and amikacin, buprenorphine, butorphanol, calcium salts (eg, chloride, gluconate), cefazolin, clindamycin, dexamethasone sodium phosphate, famotidine, ketamine, lidocaine, metoclopramide, metronidazole, midazolam, ondansetron, penicillin G potassium/sodium, sodium bicarbonate, and verapamil.

Oxytocin is reportedly physically **incompatible** with ampi-

cillin sodium, diazepam, pantoprazole, and sulfamethoxazole/trimethoprim.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oxytocin for Injection: 20 USP units/mL in 100 mL vials; generic; (Rx). Oxytocin products are labeled for several species, including horses, dairy cattle, beef cattle, sheep, swine, cats, and dogs. There are no milk or meat withdrawal times specified for oxytocin. Other strengths may be available in some countries.

HUMAN-LABELED PRODUCTS:

Oxytocin Solution for Injection: 10 units/mL in 1 mL single-dose vials, and 10 mL and 30 mL multiple-dose vials; *Pitocin*®, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pamidronate

(pah-***mih***-dro-nate) *Aredia*®

Bisphosphonate

Prescriber Highlights

- ► IV bisphosphonate used for the treatment of hypercalcemia and for the palliative treatment of bone cancer
- ► Must be given IV in saline over several hours
- ► Use with caution in patients with renal insufficiency as pamidronate can cause renal toxicity.
- ► Adverse effects include electrolyte abnormalities and anemia.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies pamidronate as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

In companion animals, pamidronate has been used to treat refractory idiopathic hypercalcemia, hypercalcemia associated with malignancy, or vitamin D–related toxicosis. Pamidronate is also utilized in the adjunctive treatment of pain associated with osteolytic bone tumors.

Pamidronate administered to horses with osteoarthritis had a beneficial effect on clinical scores and reduced inflammatory biomarkers of disease.[1]

Pharmacology/Actions

Bisphosphonates, at therapeutic concentrations, inhibit bone resorption and do not inhibit bone mineralization via binding to hydroxyapatite crystals. They impede osteoclast activity and induce osteoclast apoptosis. Pamidronate has ≈100 times greater relative antiresorptive potency when compared to etidronate.

Bisphosphonates in vitro have direct cytotoxic or cytostatic effects on human osteosarcoma cell lines. They may also have antiangiogenic effects and inhibit cell migration in certain cancers.

Pharmacokinetics

After IV infusion in rats, 50% to 60% of the dose is rapidly absorbed by bone.[2] Bone uptake is highest in areas of rapid bone turnover. Pamidronate is not metabolized, and the kidneys very slowly eliminate the drug. Terminal half-life is on the order of 300 days in rats. When used for hypercalcemia, pamidronate's onset of action is in 24 to 48 hours, and its duration of effect ranges from 2 to 4 weeks.

Contraindications/Precautions/Warnings

Pamidronate is contraindicated in patients hypersensitive to it or any of the bisphosphonate drugs or mannitol (many commercial pamidronate products also contain mannitol—see ***Dosage Forms/Regulatory Status***). Use with caution in juvenile animals in which skeletal development is still occurring and in those animals healing from a bone fracture.

Pamidronate should be used with caution in patients with impaired renal function as it has been associated with renal toxicity. Pamidronate potentially causes renal toxicity in dogs; infuse over at least 2 hours. In humans, infusions are administered over 2 to 24 hours, and infusions longer than 2 hours may reduce the risk for renal toxicity, particularly in patients with pre-existing renal impairment. In humans, it has not been tested in patients with serum creatinine levels greater than 5 mg/dL.

The National Institute for Occupational Safety and Health (NIOSH) classifies pamidronate as a hazardous drug[3]; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Electrolyte abnormalities (g, calcium, phosphorus, potassium, magnesium) may occur with pamidronate therapy. One case of a dog developing hypomagnesemia and arrhythmias after pamidronate has been reported.[4] In dogs, injection site reactions in association with pamidronate extravasation have been described.[5] In humans, fever, dose-related injection site reactions, ocular inflammation, transient musculoskeletal pain, electrolyte disturbances, osteonecrosis of the jaw, atypical fractures, anemia, thrombocytopenia, and leukopenia have been reported.[2] One case of medication-related osteonecrosis of the jaw (MRONJ) has been reported in a cat that had received long-term pamidronate therapy.[6]

Reproductive/Nursing Safety

Pamidronate has produced both maternal and embryo/fetal toxicity in laboratory animals when given at dosages therapeutically used in humans.[2] If it is used in pregnant veterinary patients, informed consent by the owner accepting the risks to both dam and offspring is recommended. It is unknown if pamidronate is excreted into milk. Use it with caution in nursing mothers. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of pamidronate may cause hypocalcemia, including tetany. If this occurs, treat with short-term IV calcium. For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pamidronate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: May enhance hypocalcemic effects of pamidronate; monitor
- **Corticosteroids** (eg, **dexamethasone, fludrocortisone, prednis(ol)one**): Pamidronate must be used carefully (with monitoring) when used in conjunction with other drugs that can affect calcium.
- **Loop Diuretics** (eg, **furosemide**): Loop diuretics promote calcium excretion and may result in additive effects on calcium concentrations.
- **Nephrotoxic Drugs** (eg, **aminoglycosides, amphotericin B, cisplatin**): Use with caution; potential for increased risk for nephrotoxicity
- **Nonsteroidal Anti-inflammatory Drugs** (**NSAIDs**; eg,

carprofen, flunixin, meloxicam): Use with caution; potential for increased risk for nephrotoxicity

- **Thiazide Diuretics** (eg, **hydrochlorothiazide**): Thiazide diuretics promote calcium retention and may impair the hypocalcemic effects of pamidronate.

Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

Dosages

DOGS/CATS

Refractory hypercalcemia (extra-label): 1.3 – 2.3 mg/kg diluted in 150 to 250 mL of 0.9% sodium chloride and administered IV as a CRI over 2 to 4 hours.[7,8] May be repeated every 21 to 28 days

Treatment of vitamin D (cholecalciferol, calcipotriene, and related compounds) induced hypercalcemia: 1.3 – 2 mg/kg diluted into 250 mL of 0.9% sodium chloride and administered IV as a CRI over 2 hours; may repeat dose after 3 days. In most cases, a single dose will lower calcium levels back to normal. Recommended monitoring calcium levels daily for at least 10 days after they have returned to normal, and some patients may need to be retreated in 5 to 7 days.[9,10]

Palliative adjunctive analgesia for osteosarcoma bone pain (extra-label): 1 – 2 mg/kg; diluted into 250 mL of 0.9% sodium chloride and administered IV as a CRI over 2 hours every 28 days.[11–16] **NOTE**: Some sources anecdotally recommend giving as frequently as once per week.

HORSES:

Osteoarthritis (extra-label): 90 mg (0.4 – 0.8 mg/kg) IV with a second dose repeated 9 days later resulted in improved clinical scores and reduced proinflammatory markers.[1]

Monitoring

- Baseline and periodic (prior to each dose) serum renal chemistry panel
- Hydration status
- Baseline and periodic serum calcium, phosphate, magnesium, potassium
- Baseline and periodic CBC
- Baseline and periodic urinalysis
- Injection site should be checked periodically during infusion

Client Information

- This medicine must only be given at the veterinary hospital.
- Owners should understand the costs for the medication, care, and monitoring associated with its use.

Chemistry/Synonyms

Pamidronate disodium, a bisphosphonate inhibitor of bone resorption, occurs as a white, crystalline powder that is soluble in water and practically insoluble in organic solvents.

Pamidronate may also be known as ADP sodium, AHPrBP sodium, GCP-23339A, *Aminomux®*, *Aredia®*, *Aredronet®*, *Ostepam®*, or *Pamidran®*.

Storage/Stability

Store at room temperature, 20°C to 25°C (68°F-77°F).

Once the lyophilized powder for injection is reconstituted (10 mL) with sterile water for injection, it may be stored in the refrigerator for 24 hours. Be sure drug is completely dissolved before withdrawing into syringe.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors, such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Do **NOT** mix pamidronate with any IV fluid containing calcium (eg, lactated Ringer's solution [LRS]). It is recommended to use a dedicated IV solution (0.45% or 0.9% sodium chloride or 5% dextrose) and line.

Pamidronate disodium is reported **compatible** with dextrose and saline solutions and the following drugs when administered via a **Y-site**: aminocaproic acid, ampicillin/sulbactam, azithromycin, bleomycin, butorphanol, carboplatin, carmustine, cefazolin, cefotaxime, ceftazidime, cisplatin, clindamycin, cyclophosphamide, cytarabine, dacarbazine, daunorubicin (liposomal), dexamethasone sodium phosphate, dexmedetomidine, dexrazoxane, diphenhydramine, dopamine, doxorubicin HCL (also liposome form), doxycycline, erythromycin lactobionate, famotidine, fentanyl citrate, fluconazole, fluorouracil, gemcitabine, heparin, hydromorphone, hydroxyzine, ifosfamide, imipenem-cilastatin, mannitol, mesna, methotrexate, metoclopramide, methylprednisolone sodium succinate, mitoxantrone, morphine, ondansetron, piperacillin-tazobactam, potassium chloride, prochlorperazine, promethazine, ranitidine, vinblastine, and vincristine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Pamidronate Disodium Lyophilized Powder for Injection: 30 mg, 60 mg, and 90 mg vials; generic; (Rx). Also contains mannitol 375 mg, 400 mg, or 470 mg per vial, respectively.

Pamidronate Disodium Injection: 3 mg/mL, 6 mg/mL, and 9 mg/mL (may contain mannitol) in 10 mL vials; generic; (Rx).

Pancrelipase

(pan-kree-***lih***-pase) *Viokase®*

Pancreatic Enzymes

Prescriber Highlights

- ► Used to treat exocrine pancreatic insufficiency
- ► Contraindications include hypersensitivity to pork products.
- ► Adverse effects include GI effects (eg, diarrhea, cramping, nausea), and oral or esophageal irritation are possible.
- ► Most human products are enteric-coated delayed-release formulations; veterinary products are not coated.
- ► Respiratory irritant: avoid inhalation of powder; may cause skin irritation: wash hands after handling

Uses/Indications

Pancrelipase is used to treat patients with exocrine pancreatic enzyme insufficiency (EPI).

Dogs may have EPI and not respond to pancreatic enzyme replacement because a) the enzyme product is poorly effective, b) the diet is too high in fat, and/or c) the dog has concurrent antibiotic responsive enteropathy. About 15% of dogs with EPI simply will not respond to therapy and have a bad prognosis.[1]

Pharmacology/Actions

Pancrelipase is a combination of porcine lipase, proteases, and amylase, which help to digest and absorb fats, proteins, and carbohydrates. It catalyzes the hydrolysis of fats to glycerol and fatty acids, degrades protein into amino acids, and converts starch into dextrin and sugars. In humans, the enteric-coated form is preferred as it is more stable in gastric acid; however, it is not recommended in patients with rapid gastrojejunal transit.[2] This may indicate that non–enteric-coated formulations would be more effective in dogs, and

most GI experts advocate for powdered non–enteric-coated formulations.[3] However, one study revealed a positive treatment response to an enteric-coated pancreatic supplementation product.[4] Another study found no difference between the 2 formulations, although it was too underpowered to determine clinical significance.[5]

Pharmacokinetics

Pancrelipase is inactivated by gastric acid. The enteric coating of delayed-release products prevents destruction and inactivation in gastric acid. In humans, non–enteric-coated products are recommended to be given with proton pump inhibitors to help prevent their breakdown in the stomach.[6] Pancrelipase is not absorbed from the GI tract and is not systemically active.

Contraindications/Precautions/Warnings

Pancrelipase products are contraindicated in animals that are hypersensitive to pork proteins. Use pancrelipase with caution in patients with gout, renal impairment, or hyperuricemia, as pancrelipase has been shown to increase blood uric acid concentrations in humans.[7] Because pancrelipase is a porcine product, human products contain a warning that there is a theoretical risk for transmission of viral diseases.

Do not crush capsule contents of delayed-release capsules or mix with foods with a pH greater than 4, as this disrupts the protective coating.[7] In humans, non–enteric-coated tablets are intended to be swallowed whole and should not be crushed or chewed.[7] One veterinary product specifies that tablets are intended to be administered prior to being fed and they are not intended for being mixed directly with food[8]; other products do not specify. However, crushing tablets should be avoided when possible due to risks associated with the inhalation of powders.

Do not inhale the powder, as it may cause respiratory irritation, including coughing, chest tightness, allergies, or asthma clinical signs.[9] Avoid contact with mucous membranes or skin; wash hands after handling.

Adverse Effects

The most common adverse effects are GI-related (eg, diarrhea, cramping, nausea). Pancreatic enzymes can cause oral or esophageal irritation or ulcers; follow dosing with food or water. Oral bleeding has been reported in dogs after receiving pancrelipase.[10] Dose reduction and moistening the food-pancreatic powder mix may also decrease the incidence of this adverse effect.

Reproductive/Nursing Safety

These enzymes are unlikely to be excreted in maternal milk or pose a risk for offspring.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses may cause diarrhea or other intestinal upset. The effects should be temporary and may be treated by reducing the dose and providing supportive care if diarrhea is severe.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pancrelipase and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids** (magnesium hydroxide, calcium carbonate): May diminish the effectiveness of pancrelipase[11]
- **Cimetidine** (or other H2 Antagonists): May increase the amount of pancrelipase that reaches the duodenum

Laboratory Considerations

None noted

Dosages

DOGS:

Exocrine pancreatic insufficiency (extra-label):

a) Initially, 1 teaspoon/10 kg (22 lb; NOT mg/kg) body weight per meal. Mix with food immediately prior to feeding. When clinical signs have resolved, the amount of pancreatic enzymes given can be gradually decreased to the lowest effective dose, which may vary from patient to patient and from batch to batch of the pancreatic supplement.[12,13]

b) 1 – 2 teaspoons of powder to each of 2 meals of balanced canine ration. Tailor regimen to maintain optimal body weight.[14]

CATS:

Exocrine pancreatic insufficiency (extra-label): **NOTE**: Cats reportedly dislike the taste of the powder but may accept the powder if mixed with fish/tuna oil and then thoroughly mixed with canned food. If using solid dosage forms (enteric-coated tablets or compounded capsules made from powder or crushed tablets), be certain that immediately after dosing, water or food is consumed to reduce the risk for esophageal damage.

a) 1 teaspoon of powder to each of 2 meals of balanced feline ration. Cats that refuse to eat food treated with powder may be dosed with capsules filled with powder. Tailor regimen to maintain optimal body weight.[14]

b) Initially, 1 teaspoon/cat (NOT teaspoon/kg) with each meal. When clinical signs have resolved, the amount of pancreatic enzymes given can be gradually decreased to the lowest effective dose, which may vary from patient to patient and from batch to batch of the pancreatic supplement.[12]

c) 0.5 – 1 teaspoon/cat (NOT teaspoon/kg) with each meal. Mix within the food immediately prior to feeding. Enteric-coated tablets, granules, and capsules are not recommended due to their variable efficacy.[15]

BIRDS:

Exocrine pancreatic insufficiency (extra-label): ⅛ teaspoon/kg mixed with moistened feed or administer by gavage. Incubate with food for 15 minutes prior to gavage.[17] Used in birds that are polyphagic "going light", passing whole seeds, and slow in emptying crops

RABBITS, RODENTS, SMALL MAMMALS:

Gastric trichobezoars in rabbits (extra-label): 1 teaspoon pancrelipase powder plus 3 teaspoons (15 mL) of yogurt; let stand for 15 minutes, then give 2 – 3 mL PO every 12 hours. Questionable efficacy for removing hairballs, but might help dissolve the protein matrix surrounding hair[16]

Monitoring

- Animal's weight
- Stool consistency, frequency

Client Information

- Pancrelipase powder is usually mixed in the food and left to stand for 15 to 20 minutes before feeding. Your veterinarian may instruct you to mix it into food and offer it to your animal without waiting.
- Cats often dislike the taste of the powder and pancrelipase may be more easily given using tablets or specially compounded capsules.

Some cats will eat food mixed with one brand of veterinary powder and refuse another.

- If using capsules or tablets, be certain that your animal gets plenty of water or food right after dosing to reduce the risk for esophageal damage.
- Use caution to avoid inhaling powder, as it can cause lung irritation and asthma. If your skin comes into contact with the powder, wash it off immediately.

Chemistry/Synonyms

Pancrelipase contains pancreatic enzymes, primarily lipase but also amylase and protease, and is obtained from the pancreas of hogs. Each milligram of pancrelipase contains not less than 24 USP units of lipase activity, not less than 100 USP units of protease activity, and not less than 100 USP units of amylase activity. When compared on a per weight basis, pancrelipase has at least 4 times the trypsin and amylase content of pancreatin, and at least 12 times the lipolytic activity of pancreatin.

Pancrelipase may also be known as pancrelipasa, *Epizyme®, Panakare®, Pancrepowder Plus®, Pancreved®, Pancrezyme®,* and *Viokase®*.

Storage/Stability

Unless otherwise recommended by the manufacturer, store this product at room temperature (20°C-25°C [68°F-77°F]) in a dry place in tight containers. When present in quantities greater than trace amounts, acids will inactivate pancrelipase.

Dosage Forms/Regulatory Status

NOTE: There are several dosage forms (both human and veterinary-label) available containing pancrelipase, including oral capsules, oral delayed-release capsules, tablets, and delayed-released tablets. Most small animal practitioners believe the oral powder is most effective in dogs.

VETERINARY-LABELED PRODUCTS: (**NOTE**: NONE OF THE VETERINARY PRODUCTS ARE FDA-APPROVED.)

Pancrelipase Powder containing ≈2.8 g per teaspoonful: 71,400 units lipase; 388,000 units protease; 460,000 units amylase; in 8 oz bottle; *Viokase®-V Powder*, *Pancrezyme® Powder*, *Pancrepowder Plus®*, *Pancreved® Powder*, *Epizyme® Powder*, *Panakare® Plus Powder*; (Rx). Labeled for use in dogs and cats

Pancreatic enzyme concentrate plus fat-soluble vitamins in tablet form: each tablet contains a minimum of 9000 USP units of lipase; 57,000 units of protease; 64,000 USP units of amylase; and is fortified with vitamins A, D_3, and E; *Panakare® Plus Tablets, Pancreplus® Tablets*, *Pancreved®* Tablets. Labeled for use in dogs and cats

HUMAN-LABELED PRODUCTS:

There are capsules, tablets, and powders available containing lipase, protease, and amylase in varying units available for human consumption from many distributors. Most formulations are enteric-coated/delayed-release. Human formulations are not directly interchangeable.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pantoprazole

(pan-***toe***-prah-zohl) *Protonix®, Pantoloc®*

Proton Pump Inhibitor

Prescriber Highlights

- ► Used for the treatment of gastric acid-related pathologies in dogs, cats, foals, camelids, and ruminants; more effective than histamine-2 receptor antagonists (eg, famotidine)
- ► Administer every 12 hours for optimal efficacy; available in IV dosage form
- ► Appears to be well tolerated
- ► Tapering dose after long-term (ie, 3 to 4 weeks) use is recommended.

Uses/Indications

Pantoprazole may be useful in the treatment of gastric acid-related pathologies in dogs, cats, foals, camelids, and ruminants, particularly when the IV route is required.

Based on studies conducted in healthy dogs,[1,2] IV pantoprazole significantly increased gastric pH and the percentage of time gastric pH was greater than 3 or 4.[1,2] Under these experimental conditions, twice-daily esomeprazole IV or omeprazole PO and famotidine CRI were the only treatments that attained intragastric pH goals (ie, pH greater than 3 for 75% of the day, and greater than 4 for 67% of the day) established for treatment of humans with duodenal ulcers and/or gastroesophageal reflux.[1,2] There were no significant differences in intragastric pH in dogs given combination pantoprazole with famotidine as compared with dogs given pantoprazole alone,[3] and combining a histamine-2 receptor antagonist with a proton pump inhibitor is not recommended.[4] If pantoprazole has been used for 3 weeks or longer, it is recommended to taper the dose by decreasing to once-daily administration for 7 days before discontinuing to minimize the risk for developing rebound gastric acid hypersecretion.[4,5]

Pantoprazole use has been described in case reports for ruminant species.[6–8] One retrospective study found that pantoprazole may be a safe adjunct therapy in cattle, sheep, and goats[9]; however, further studies are needed to assess safety and toxicity.

Pantoprazole is used in some *Helicobacter pylori* treatment protocols for humans; however, there is no evidence that acid suppression is indicated for the treatment of *Helicobacter* spp infections in dogs and cats.[4]

Pharmacology/Actions

Pantoprazole is a substituted benzimidazole proton pump inhibitor. At the secretory surface of gastric parietal cells, pantoprazole forms a covalent bond at 2 sites of active H^+/K^+ ATPase (proton pump), inhibiting the transport of hydrogen ions into the stomach. Pantoprazole reduces acid secretion during both basal and stimulated conditions. Inactivation of the proton pump is permanent, which contributes to the durability of pantoprazole's acid suppressing effect.[10] Steady state acid suppression is reached after 2 to 4 days, as some proton pumps are dormant.[11,12]

In alpacas, pantoprazole has been shown to increase the pH of the third compartment.[13]

Pharmacokinetics

No specific information was located for pantoprazole pharmacokinetics in dogs or cats.

In neonatal foals, intragastric (IG) administered pantoprazole bioavailability was 41%, and the drug was detected in plasma within 5 minutes of administration.[14] Gastric pH was significantly increased 2 hours after administration by either IV or IG routes, and mean hourly gastric pH remained elevated for the remainder of the 24-hour study-period.[14]

In neonatal calves given 1 mg/kg IV, plasma clearance was ≈4.5 mL/kg/minute, elimination half-life was ≈2.8 hours, and volume of distribution was ≈0.3 L/kg.[15]

In goats given 1 mg/kg IV, plasma clearance was ≈0.3 mL/kg/minute, elimination half-life was ≈0.7 hours, and volume of distribution was ≈0.9 L/kg.[16]

In alpacas, pantoprazole has a high SC bioavailability (ie, greater than 100% in some animals). A dose of 2 mg/kg SC produced significantly higher area under the curve (AUC) and longer half-life than when given IV, but the half-life remained short (mean, 0.58 hours).[13]

In humans, the drug is rapidly absorbed after oral administration, with an oral bioavailability of 77%. Food can reduce the rate of absorption but does not appear to affect the extent of absorption. On average, 51% of gastric acid secretion is inhibited 2.5 hours after a single dose and 85% is inhibited after 7 days of daily administration. Protein binding is 98%, primarily to albumin. The drug is metabolized in the liver, primarily by CYP2C19 isoenzymes. CYP3A4, 2D6, 2C9, and 1A2 are minor components of pantoprazole biotransformation; pantoprazole does not appear to clinically affect (ie, induce or inhibit) the metabolism of other drugs using these isoenzymes for biotransformation. Metabolites of pantoprazole do not appear to have pharmacologic activity. The elimination half-life for both PO and IV administration is ≈1 hour, but the drug's pharmacologic action can last 24 hours or longer, presumably due to irreversible binding at the receptor site. Approximately 71% of a dose is excreted as metabolites in the urine, with the remainder in the feces as metabolites and unabsorbed drug.

Contraindications/Precautions/Warnings

Pantoprazole is contraindicated in those known to be hypersensitive to it or other proton pump inhibitors.

In humans, pantoprazole is not for SC or IM use due to the pH of the reconstituted solution.[17] Anecdotally, SC dosing in camelids and ruminants appears to be tolerated. When given IV, the reconstituted injection (4 mg/mL) must be administered over at least 2 minutes. Hypomagnesemia has been reported in humans, typically after long-term use.[17]

Adverse Effects

Pantoprazole appears to be well tolerated.

In a retrospective study of 36 cattle receiving pantoprazole, edema was reported in 7 (16%) cattle.[9] Safe duration of use has not been established in ruminants; increasing abomasal pH for extended periods may lead to growth of enteropathogenic bacteria.[6]

In humans, the most commonly reported adverse effects are diarrhea and headache.[17] Hyperglycemia has been reported in ≈1% of patients. Proton pump inhibitors have been associated with an increased risk for developing community-acquired pneumonia in humans. Injection site reactions (eg, thrombophlebitis, abscess) have occurred with IV administration.

Reproductive/Nursing Safety

Daily administration of pantoprazole 20 mg/kg IV to rats and 15mg/kg IV to rabbits during organogenesis had no effects on fertility, and no teratogenic effects were noted; however, daily pantoprazole 5 – 30 mg/kg given to pregnant rats from the sixth gestational day through the twenty-first day of lactation resulted in changes in bone morphology in rat pups.[17]

Pantoprazole and its metabolites are excreted in milk. Use pantoprazole with caution during lactation.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

Limited information is available. A single dose of 266 mg/kg IV or 887 mg/kg PO was lethal in dogs. Acute toxic signs included ataxia, hypoactivity, and tremors. In humans, single overdoses of up to 600 mg (total dose) PO have been reported without adverse effects. In the event of a large overdose, it is recommended to contact an animal poison control center for guidance.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pantoprazole and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Bisphosphonate Derivatives** (eg, **alendronate, etidronate**): Pantoprazole may diminish therapeutic effects.
- **Drugs Requiring Decreased Gastric pH for Optimal Absorption** (eg, **ampicillin esters, iron, itraconazole, ketoconazole**): Pantoprazole may decrease drug absorption.
- **Levothyroxine**: Concurrent use may result in increased TSH concentrations.
- **Mycophenolate mofetil**: May result in decreased exposure to the active metabolite of mycophenolate
- **Sucralfate**: Concurrent use may decrease bioavailability of orally administered pantoprazole.
- **Warfarin**: Pantoprazole may increase the anticoagulant effect.

Laboratory Considerations

- Although not likely to be important for veterinary patients, pantoprazole may cause false-positive results for urine screening tests for THC (tetrahydrocannabinol).[17]

Dosages

DOGS/CATS:

Gastric acid suppression (extra-label): 0.7 – 1 mg/kg IV over 15 minutes every 12 hours[1,3]

HORSES:

Gastric acid suppression in neonatal foals (extra-label): 1.5 mg/kg IV once daily. **NOTE**: From an experimental study evaluating the pharmacokinetics and pharmacodynamics in normal neonatal foals.[14] Further studies are required to investigate the use of this drug in critically ill patients.

CATTLE:

Prevention of abomasal ulceration (extra-label): 1 mg/kg IV once daily, or 2 mg/kg SC once daily[9]

SHEEP/GOATS:

Prevention of abomasal ulceration (extra-label): 1 mg/kg IV once daily, or 2 mg/kg SC once daily[9]

NEW WORLD CAMELIDS:

Gastric acid suppression(extra-label): 1 mg/kg IV or 2 mg/kg SC every 24 hours for 3 days (from a pharmacokinetic and efficacy study in alpacas)[13]

Monitoring

- Efficacy
- Adverse effects (eg, vomiting, diarrhea, injection site reactions)

Client Information

- This medicine is used on a short-term basis to treat stomach or intestinal ulcers.
- This medicine works best if it is given before the first meal of the day.
- Do not break or cut tablets.

Chemistry/Synonyms

Pantoprazole sodium sesquihydrate occurs as a white to off-white crystalline powder and is racemic. It is freely soluble in water and very slightly soluble in phosphate buffer at a pH of 7.4. Stability of aqueous solutions is pH dependent. At room temperature, solutions are stable for ≈3 hours at a pH of 5 and 220 hours at a pH of 7.8.

Pantoprazole may also be known as BY-1023 or SKF-96022. International trade names include *Controloc®, Pantoloc®, Pantop®, Pantozol®, Protium®, Protonix®, Somac-MA®*, and *Zurcal®*.

Storage/Stability

Delayed-release tablets should be stored at between 15°C and 30°C (59°F-86°F).

The powder for injection should be stored protected from light at 20°C to 25°C (68°F-77°F); excursions are permitted between 15°C and 30°C (59°F-86°F).

Reconstituted solutions (10 mL) are stable for up to 6 hours at room temperature prior to further dilution. If the reconstituted solution is further diluted (according to the label 15-minute infusion protocol), the solution is stable at room temperature for up to 24 hours from the time of initial reconstitution.[17] Reconstituted and admixed solutions do not require protection from light. Do not freeze. Do not use any of the IV solutions if discoloration or precipitates are seen; stop infusion immediately if these are observed during the infusion. A study demonstrated that pantoprazole 4 mg/mL was stable (at least 90% of initial concentration) for 3 days when stored in glass vials at 20°C to 25°C (68°F-77°F) or for 28 days when stored in polypropylene syringes at 2°C to 8°C (36°F-46°F).[18] Pantoprazole 0.4 mg/mL diluted in 5% dextrose and stored in PVC mini-bags was stable for 2 days at 20°C to 25°C (68°F-77°F) or for 14 days at 2°C to 8°C (36°F-46°F). At 0.8 mg/mL, pantoprazole in 5% dextrose was stable for 3 days at 20°C to 25°C (68°F-77°F) or 28 days at 2°C to 8°C (36°F-46°F). Pantoprazole diluted to either 0.4 or 0.8 mg/mL in 0.9% sodium chloride and stored in PVC mini-bags was stable for 3 days at 20°C to 25°C (68°F-77°F) or 28 days at 2°C to 8°C (36°F-46°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Precipitation has been reported in cases in which maropitant and pantoprazole are coadministered in the same IV line.

At Y-sites, pantoprazole injection is **incompatible** with dobutamine, esmolol, mannitol, midazolam, and multivitamins and may not be compatible with solutions containing zinc. It is reportedly **compatible** (at Y-sites) with ampicillin, cefazolin, ceftriaxone, dimenhydrinate, dopamine, epinephrine, furosemide, morphine, nitroglycerin, potassium chloride, and vasopressin.

For a 2-minute IV infusion, reconstitute with 10 mL of 0.9% sodium chloride injection. To prepare the injection for a 15-minute IV infusion, reconstitute with 10 mL of 0.9% sodium chloride injection, then dilute further with 100 mL of 5% dextrose, 0.9% sodium chloride, or lactated Ringer's injection to a final concentration of ≈0.4 mg/mL.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 5 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Pantoprazole Sodium Delayed-Release Tablets: 20 mg (as base) and 40 mg (as base); *Protonix®*, generic; (Rx)

Pantoprazole Lyophilized Powder for Injection Solution: 40 mg (as base) in vials; *Protonix I.V.®*, generic; (Rx)

Pantoprazole Sodium Delayed-Release Granules for Suspension: 40 mg; *Protonix®*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Parapox Ovis Virus Immunomodulator

(pair-ah-***poks oh***-vis) *Zylexis®*

Immunostimulant

Prescriber Highlights

- ► Biologic immunostimulant that may be used as an aid in reducing upper respiratory disease caused by equine herpesvirus types 1 and 4 in healthy horses 4 months of age and older
- ► 3-dose regimen; important to give all doses
- ► Limited published information available on safety and clinical efficacy
- ► Contraindicated in patients with prior hypersensitivity to it or in patients that have chronic conditions with unclear causality
- ► Rare adverse effects include hypersensitivity reactions, hyperthermia, general malaise, and musculoskeletal signs.

Uses/Indications

Parapox ovis virus immunomodulator (inactivated *Parapoxvirus ovis*, iPPVO) is labeled as an aid in reducing upper respiratory disease caused by equine herpesvirus types 1 and 4 in healthy horses 4 months of age and older.

There is conflicting evidence regarding the clinical efficacy of iPPVO for reducing the incidence of equine respiratory disease complex (ERDC). A placebo-controlled study in foals 24 to 48 hours old (n = 59) on a farm with endemic *Rhodococcus equi* infections found no significant difference in the pneumonia incidence between foals treated with iPPVO versus placebo.[1] One review concluded that although immunomodulators such as iPPVO provide non-specific stimulation of an innate immune response, they may not provide protection against direct infection or transmission of respiratory pathogens associated with ERDC. They may, however, contribute to the reduction of the disease severity and reduce the frequency of complications, and improve the rate of recovery.[2]

Parapoxvirus products may also be available in other countries for use in small animal species.

Pharmacology/Actions

Parapox ovis virus immunomodulator stimulates non-specific immune mechanisms[3] and is believed to prevent viral infection by infecting host cells with a non-replicating virus, which interferes with pathogenic virus infection. Postulated mechanisms of action include induction of interferons, cytokines and colony-stimulating factors, and activation of natural killer cells.

Parapoxvirus ovis is the DNA virus responsible for orf, a contagious pustular dermatitis in sheep.

Pharmacokinetics

Effects on the immune system are reported to occur 4 to 6 hours after administration and persist for 1 to 2 weeks.

Contraindications/Precautions/Warnings

Parapox ovis virus immunomodulator is contraindicated in patients with prior hypersensitivity to it. If anaphylaxis occurs, administer epinephrine or equivalent. Do not use in animals that have chronic diseases with unclear causality.[3]

The first dose of *Parapox ovis* virus immunomodulator should be administered shortly before or up to the day of crowding or exposure to other stressful conditions to ensure efficacy.[3]

Reproductive/Nursing Safety
No information was located. Because safety has not been established in animals, this biologic agent should only be used when the maternal benefits outweigh the potential risks to offspring.

Adverse Effects
Hypersensitivity or anaphylactic reactions are possible. Hyperthermia, general malaise, and musculoskeletal signs (eg, stiffness, abnormal posture) have rarely been reported.[3]

Overdose/Acute Toxicity
No systemic or local reactions were seen in horses given double the recommended dose.[3]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
- None noted

Laboratory Considerations
- None identified

Dosages
HORSES:

Aid in reducing upper airway disease caused by herpesvirus types 1 and 4 (label dosage): Reconstitute with the provided sterile diluent and administer 2 mL/horse (NOT mL/kg) IM (day 0). Repeat dose on day 2 and day 9. Retreatment is recommended during subsequent disease episodes or prior to stress inducing situations.

Monitoring
- Clinical efficacy (respiratory infection improvement)

Chemistry/Synonyms
Parapox ovis virus immunomodulator is provided commercially as a freeze-dried inactivated (killed) virus component with separate 2 mL vial of sterile diluent.

Parapox ovis virus immunomodulator may also be known as iPPVO, PPOV, PIND-ORF, *Baypamun*®, and *Zylexis*®.

Storage/Stability
Parapox ovis virus immunomodulator should be stored refrigerated (2°C-8°C [36°F-46°F]), but not be frozen. After reconstituting, entire contents of vial should be used.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

NOTE: This product was a USDA-licensed biologic but is no longer listed on the USDA-licensed veterinary biologics product summary and appears to no longer be marketed in the US.

Parapox Ovis Virus Immunomodulator Injection in boxes of 5 single dose vials for reconstitution with 5-2mL vials of sterile diluent; *Zylexis*®. Labeled for use in horses. Refer to specific product label and local regulations for potential withdrawal times.

HUMAN-LABELED PRODUCTS: NONE

Paromomycin
(pair-oh-moe-***my***-sin) *Humatin*®

Oral Aminoglycoside Antiparasitic

Prescriber Highlights
- ► Oral aminoglycoside used primarily as a treatment of cryptosporidiosis in small animal species
- ► Not appreciably absorbed when given orally if the gut is intact
- ► Adverse effects are usually limited to GI effects (nausea, vomiting, diarrhea); cats may be susceptible to renal and ophthalmic toxicity and some clinicians consider it contraindicated in cats because of toxicity.
- ► Use it with caution in patients with intestinal ulceration.

Uses/Indications
Paromomycin may be useful as a treatment for cryptosporidiosis in dogs and cats. Although some clinicians consider paromomycin to be the second-line treatment for dogs and should be avoided in cats, others recommended it as a first choice.[1]

In dogs, paromomycin is also used topically to treat cutaneous leishmaniasis. Subcutaneously administered paromomycin (no dosage forms available in the United States) in combination with meglumine antimoniate is used in some protocols for treating systemic leishmaniasis, but serious adverse effects limit usefulness.[2–4]

Paromomycin has been used successfully to treat cryptosporidiosis in cattle,[5] goats, lambs,[6] and reptiles.[7]

In humans, paromomycin has been used as an alternative oral treatment for intestinal amebiasis and for management of hepatic coma.[8]

The World Health Organization has designated aminoglycosides as Critically Important, High Priority antimicrobial agents for human medicine.[9] The Office International des Epizooties (OIE) has designated paromomycin as a Veterinary Critically Important Antimicrobial (VCIA) Agent in avian, bovine, caprine, ovine, rabbit, and swine species.[10]

Pharmacology/Actions
Like other aminoglycoside antibiotics, paromomycin irreversibly binds bacterial 30S ribosomal subunits, thereby inhibiting protein synthesis. It is considered a bactericidal, concentration-dependent antibiotic. Paromomycin has an antimicrobial spectrum of activity similar to neomycin, including aerobic gram-positive and gram-negative bacteria, but its primary therapeutic uses are for the treatment of intestinal protozoa, including *Leishmania* spp, *Entamoeba histolytica*, and *Cryptosporidium* spp. It also has activity against a variety of tapeworms, but there are better choices available for clinical use.

Pharmacokinetics
Like neomycin, paromomycin is poorly absorbed when given orally. It is excreted unchanged in the feces.

Contraindications/Precautions/Warnings
Paromomycin is contraindicated in patients with known hypersensitivity to the drug or with ileus or intestinal obstruction. Patients should be well-hydrated prior to treatment to minimize risk for nephrotoxicity. The foreign label for paromomycin solution cautions against using it in animals with impaired renal or hepatic function.[11] It should be used with caution in patients with GI ulceration or blood in feces, which increases the likelihood of systemic absorption with resultant toxic effects. Use with caution in newborn animals as paromomycin has increased GI absorption in neonates.[11]

Use with caution in cats; because of potential toxicity, some clinicians consider paromomycin contraindicated in cats due to this risk.

Do not confuse *Humatin*® (paromomycin trade name) with *Humulin*® (insulin trade name).

Adverse Effects

GI effects (eg, nausea, inappetence, vomiting, diarrhea) are the most likely adverse effects to be noted with therapy.[8] Because paromomycin can affect the gut flora, nonsusceptible bacterial or fungal overgrowths are a possibility. In patients with significant gut ulceration or degradation of GI mucosal barriers, paromomycin may be absorbed systemically with resultant nephrotoxicity, ototoxicity, or pancreatitis. Use in cats has been associated with renal dysfunction, ototoxicity, and blindness.

Reproductive/Nursing Safety

Because minimal amounts are absorbed when administered orally, paromomycin should be safe to use during pregnancy.[12] It should not be used parenterally during pregnancy. When used orally, paromomycin should be safe to use during lactation. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Because paromomycin is not appreciably absorbed after oral administration, acute overdose adverse effects should be limited to GI distress in patients with an intact GI system. Chronic overdoses may lead to systemic toxicity.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving paromomycin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- Digoxin: Paromomycin may reduce digoxin absorption.
- Methotrexate: Paromomycin may reduce methotrexate absorption.

Laboratory Considerations

- None were noted.

Dosages

DOGS:

Cryptosporidiosis (extra-label): 125 – 165 mg/kg PO twice daily for 5 days has been suggested[13]; commonly, 150 mg/kg PO once daily for 5 days is recommended.[14]

CATS:

Cryptosporidiosis (extra-label): **NOTE**: Higher doses of paromomycin have caused renal or otic toxicity and/or blindness in some treated cats. Consider using an alternative treatment first (eg, azithromycin) or paromomycin at an initially reduced dose.

a) 150 mg/kg PO every 12 to 24 hours.[15] If the cat is responding to the first 7 days of therapy and toxicity has not been noted, continue treatment for 1 week past clinical resolution of diarrhea.

b) 150 mg/kg PO once daily for 5 days[14]

CATTLE:

Cryptosporidiosis (extra-label): 25 mg/kg PO daily for 5 days[5]

Reduction of diarrhea due to *Cryptosporidium parvum* in pre-ruminating calves (extra-label): 35 mg/kg PO daily for 7 consecutive days[16]

NEW WORLD CAMELIDS:

Cryptosporidiosis in crias (extra-label): 50 mg/kg PO (*dosing interval not specified, assume once per day—Plumb*) for 5 to 10 days[17,18]

Clinical endoparasitism (extra-label): 25 – 100 mg/kg PO every 12 hours[19]; however, this has **not** been studied for safety or efficacy, and extreme caution is recommended.

SHEEP:

***Giardia duodenalis* in lambs** (extra-label): 100 mg/kg PO once daily for 3 days resulted in no cysts shed in feces 6 days after treatment.[20]

***Cryptosporidium parvum* in lambs** (extra-label): 100 mg/kg/day for 3 consecutive days significantly decreased oocyst shedding and improved clinical signs.[6] 200 mg/kg/day for 2 consecutive days did not improve efficacy and appeared to stunt weight gain; further studies are needed to determine the optimal dose and duration of treatment.

Reduction of diarrhea due to *Cryptosporidium parvum* in pre-ruminating lambs (extra-label): 35 mg/kg PO daily for 7 consecutive days[21]

GOATS:

Reduction of diarrhea due to *Cryptosporidium parvum* in pre-ruminating kids (extra-label): 35 mg/kg PO daily for 7 consecutive days[21]

REPTILES:

Cryptosporidiosis (extra-label):

General: 300 – 800 mg/kg PO every 24 to 48 hours for 7 to 14 days or as needed[7]

Bearded dragons: 100 mg/kg once daily for 7 days, then 100 mg/kg twice per week for 6 weeks, then 360 mg/kg every 48 hours for 10 days[22] (*route not specified, assume PO- Plumb*)

Leopard geckos: 100 mg/kg PO once daily for 7 days, then once weekly thereafter. Clinical signs and shedding in stool 6 weeks after drug discontinuation[23]

King cobra: 360 mg/kg PO twice weekly for 6 weeks was successful in 1 case report.[24]

Monitoring

- Serial fecal examinations
- GI adverse effects
- If used in cats, monitor renal function.

Client Information

- Unless otherwise instructed, give this medicine with food.
- When paromomycin is given by mouth for short periods, it is usually tolerated well. Contact your veterinarian if your animal develops diarrhea while taking this medicine.
- Rarely, this medicine can cause hearing loss and damage to the kidneys and nerves when used for long periods of time. Contact your veterinarian if your animal develops hearing loss, a head tilt, weakness, changes in appetite, or with drinking and urination habits.

Chemistry/Synonyms

Paromomycin sulfate, an aminoglycoside antibiotic, occurs as an odorless, creamy white to light yellow, hygroscopic, amorphous powder having a saline taste. Paromomycin is very soluble in water (greater than 1 g/mL).

Paromomycin may also be known as aminosidin sulphate, aminosidine sulphate, catenulin sulphate, crestomycin sulphate, estomycin sulphate, hydroxymycin sulphate, monomycin A sulphate, neomycin E sulphate, paucimycin sulphate, and *Humatin*®.

Storage/Stability

Store paromomycin capsules at room temperature (15°C-30°C [59°F-86°F]) in tight containers protected from moisture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the United States. In some

countries, it is available as:

Paromomycin solution: 140 mg/mL in 125 mL, 250 mL, 500 mL, or 1 L; for use in drinking water, milk, or milk replacer in pre-ruminant cattle (20-day withdrawal) and pigs (3-day withdrawal); *Gabbrovet®*

Paromomycin powder: 70,000 IU/g in a 25 g package; for use in drinking water, milk, or milk replacer in pre-ruminant cattle (20-day withdrawal) and pigs (3-day withdrawal); *Parofor®*

Paromomycin oral solution: 140 mg/mL in 125 mL, 250 mL, 500 mL, or 1 L; for use in pre-ruminating cattle (62-day withdrawal); *Parofor crypto*

Paromomycin oral solution: 140 mg/mL in 125 mL, 250 mL, 500 mL, or 1 L; for use in pre-ruminating lambs and pre-ruminating kids (24-day withdrawal); *Parofor crypto*

HUMAN-LABELED PRODUCTS:

Paromomycin Sulfate Oral Capsules: 250 mg; generic; (Rx).

Paroxetine

(pah-***rox***-a-teen) *Paxil®*

Selective Serotonin Reuptake Inhibitor (SSRI)

Prescriber Highlights

- Selective serotonin reuptake inhibitor (SSRI) used extra-label in dogs and cats to treat a variety of behavior disorders
- Contraindications include patients with known hypersensitivity or receiving monoamine oxidase inhibitors. Caution in patients with severe cardiac, renal, or hepatic disease. Dosages may need to be reduced in patients with severe renal or hepatic impairment.
- If patient is on the drug for an extended period, gradual withdrawal is recommended.
- Potential adverse effects in dogs: anorexia, lethargy, GI effects, anxiety, irritability, insomnia, hyperactivity, panting, or aggression; in cats: behavior changes (anxiety, aggression, sleep disturbances), anorexia, constipation, or changes in elimination patterns
- The National Institute for Occupational Safety and Health (NIOSH) classifies paroxetine as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Paroxetine may be beneficial for the treatment of canine aggression, anxiety, and stereotypic or other obsessive-compulsive behaviors. It has been used occasionally in cats for urine marking, aggression, and feline hyperesthesia syndrome.

Pharmacology/Actions

Paroxetine is a highly selective inhibitor of the reuptake of serotonin (SSRI) in the CNS, thus potentiating the pharmacologic activity of serotonin. Paroxetine has a very weak effect on dopamine and norepinephrine reuptake and little affinity for other neurotransmitter (eg, histamine) receptors; it also has mild anticholinergic effects.[1,2]

Pharmacokinetics

No data for cats or dogs were located.

In Grey parrots, paroxetine HCl dissolved in water given PO was slowly absorbed and had a bioavailability (mean) of 31%, but there was significant interpatient variation.[3] Repeated administration increased bioavailability. Terminal elimination half-life was ≈5 hours.

In humans, paroxetine is slowly and nearly completely absorbed from the GI tract. Because of a relatively high first-pass effect, relatively small amounts reach the systemic circulation unchanged. Food does not impair absorption.

The drug is ≈95% bound to plasma proteins. Paroxetine is extensively metabolized, probably in the liver. Half-life in humans ranges from 7 to 65 hours and averages ≈24 hours.

Contraindications/Precautions/Warnings

Paroxetine is contraindicated in patients with known hypersensitivity to it; it should also not be used in combination with monoamine oxidase inhibitors (MAOIs) or other serotonergic drugs (eg, mirtazapine, ondansetron) due to the risk for developing serotonin syndrome (see ***Drug Interactions***). Use with caution in patients with seizure disorders or severe cardiac, hepatic, or renal disease; dosages may need to be reduced in patients with severe hepatic or renal impairment.

If paroxetine is discontinued and the patient has been receiving the drug for an extended period, a gradual withdrawal over several weeks is recommended to minimize withdrawal reactions (eg, nausea, behavior changes [eg, agitation, anxiety, dysphoria], tremors).

Do not confuse paroxetine with fluoxetine or piroxicam. Do not confuse paroxetine *hydrochloride* with paroxetine *mesylate* (*Brisdelle®*, *Pexeva®*). Do not confuse PAXil with PLAVix or PACLitaxel.

The National Institute for Occupational Safety and Health (NIOSH) classifies paroxetine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[4]

Adverse Effects

In dogs, paroxetine can cause lethargy, salivation, GI effects, anxiety, irritability, insomnia, hyperactivity, or panting. Anorexia is a common adverse effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further use of paroxetine.

There seems to be less incidence of anorexia in paroxetine than in fluoxetine. Aggressive behavior in previously unaggressive dogs has been reported. Selective serotonin reuptake inhibitors (SSRIs) may also cause changes in blood glucose levels and potentially reduce seizure threshold.

Paroxetine in cats can cause behavior changes (eg, anxiety, irritability, sleep disturbances), anorexia, constipation, or changes in elimination patterns.

Paroxetine has mild anticholinergic effects; anticholinergic adverse effects are possible, including constipation, urinary retention, and arrhythmias. Serotonergic effects may reduce platelet aggregation and increase the risk of bleeding. Hyponatremia has been reported in humans.

Reproductive/Nursing Safety

Paroxetine crosses the placenta. Paroxetine's safety during pregnancy in veterinary medicine has not been established. No teratogenic effects were noted in laboratory animals receiving paroxetine during periods of organogenesis, but increased pup deaths were observed in rats given the drug during the third trimester and through lactation.[5] Use of paroxetine during human pregnancies, particularly in the first trimester, is associated with increased risk of congenital malformations, including cardiac defects.

The drug is excreted into milk but at low levels; caution is advised in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Although paroxetine is not as toxic as the tricyclic antidepressants, fatalities and significant morbidity have occurred after paroxetine

overdoses. In one retrospective study in dogs, a median dose of 7.7 mg/kg (range: 0.3 – 25.9 mg/kg; $n = 5$) was associated with clinical signs of overdoses, but no clinical significance could be differentiated from doses that did not cause clinical signs.[6] Another retrospective review in dogs found the following overdoses and associated clinical signs: 1 – 3 mg/kg: vomiting, drooling, and lethargy; greater than 3 mg/kg: agitation and seizures; greater than 4 mg/kg (sustained-release product): sedation, drooling, and vomiting; greater than 4.5 mg/kg (sustained-release product): agitation—no seizures reported from the sustained-release product.[7]

There were 222 single-agent exposures to paroxetine reported to the ASPCA Animal Poison Control Center (APCC) from 2009 to 2013. Of the 194 dogs, 33 showed clinical signs with lethargy (36%) and vomiting (18%) being the most common. Of the 30 cats, 9 showed clinical signs, with 56% having behavior changes and 44% being mydriatic.

When ingestion amounts are associated with significant morbidity or when the ingested amount is unknown, consider GI decontamination (if not contraindicated). Activated charcoal can be very effective in binding paroxetine; induction of emesis is not recommended. Treat supportively based on clinical signs at the time of presentation. For overdoses in patients that are subclinical, the animal should be monitored for the first 12 hours for development of clinical signs.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

Paroxetine is both a substrate and an inhibitor of CYP2D6 in humans. The following drug interactions have either been reported or are theoretical in humans or animals receiving paroxetine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **heparin, rivaroxaban, warfarin**): Paroxetine may increase the risk for bleeding.
- **Antiplatelet Agents** (eg, **aspirin, clopidogrel**): Paroxetine may increase the risk for bleeding.
- **Beta-Adrenergic Blocking Agents** (eg, **atenolol, propranolol, sotalol**): Selective serotonin reuptake inhibitors (SSRIs) may increase serum concentrations of beta-blockers and the combination may increase risk for arrhythmias due to prolongation of the QT interval. Atenolol may be safer to use if paroxetine is required.
- **Buspirone**: Increased risk for serotonin syndrome
- **Codeine**: Paroxetine may reduce codeine's conversion into morphine.
- **Cyproheptadine**: May decrease or reverse the effects of SSRIs
- **Diuretics** (eg, **furosemide, hydrochlorothiazide**): Increased risk for hyponatremia
- **Doxorubicin**: Paroxetine may increase doxorubicin concentration.
- **Insulin**: May alter insulin requirements
- **Isoniazid**: Increased risk for serotonin syndrome
- **MAO Inhibitors** (amitraz, linezolid, selegiline): High risk for serotonin syndrome; use contraindicated; in humans, a 5-week washout period is required after discontinuing paroxetine and a 2-week washout period if first discontinuing the MAO inhibitor.
- **Methylene Blue**: Increased risk for serotonin syndrome; avoid concomitant use.
- **Metoclopramide**: May enhance adverse/toxic effects of SSRIs and increase risk for serotonin syndrome
- **Mexiletine**: SSRIs may decrease the metabolism of mexiletine.
- **Mirtazapine**: Increased risk for serotonin syndrome
- **Nonsteroidal Anti-Inflammatory Drugs** (NSAIDs; eg, aspirin, carprofen, meloxicam): SSRIs may increase the risk for bleeding and GI ulceration.
- **Ondansetron**: Increased risk for serotonin syndrome
- **Opioids** (eg, fentanyl, methadone): Increased risk for serotonin syndrome
- **Pentazocine**: Serotonin syndrome-like adverse effects are possible.
- **Phenobarbital**: May reduce paroxetine concentration and exposure
- **Phenytoin**: Increased plasma levels of phenytoin are possible.
- **St John's Wort**: Increased risk for serotonin syndrome.
- **Tramadol**: SSRIs can inhibit the metabolism of tramadol to its active metabolites, decreasing its efficacy and increasing the risk for toxicity (serotonin syndrome, seizures).
- **Tricyclic antidepressants** (eg, clomipramine, amitriptyline): Paroxetine may increase TCA blood levels and the risk for serotonin syndrome.
- **Trazodone**: Increased plasma levels of trazodone possible. Increased risk for serotonin syndrome

Dosages

DOGS:

Selective serotonin reuptake inhibitor (SSRI)-responsive behavior problems (extra-label): Using regular (not extended-release) tablets: 0.5 – 2 mg/kg PO once daily. Used in conjunction with behavior modification. Usually start at the low end of the dosing range and treat for ≈2 months; evaluate and adjust dosage if necessary.

CATS:

SSRI-responsive behavior problems (extra-label): Using regular (not extended release) tablets: 0.25 – 1 mg/kg once to twice daily; practically, 1.25 – 5 mg (⅛ – ½ of a regular 10 mg tablet) per cat (NOT mg/kg) once or twice daily. Usually start at the low end of the dosing range and treat for ≈2 months; evaluate and adjust dosage if necessary.

BIRDS:

Stress- or anxiety-related behavior disorders (eg, feather picking; extra-label): From a pharmacokinetic study in Grey parrots: Paroxetine HCl dissolved in water (human oral suspension was not consistently absorbed) and given at 4 mg/kg PO twice daily was sufficient to reach plasma concentrations reported to be effective in humans.[3]

Monitoring

- Efficacy
- Adverse effects; including appetite (weight)
- Baseline CBC, serum chemistry profile, urinalysis, and thyroid testing. Repeat yearly during treatment; consider twice-yearly testing in senior animals.

Client Information

- May take up to 6 weeks to determine if the drug is effective.
- Most common side effects are drowsiness, sleepiness, and reduced appetite.
- Rare side effects that can be serious (contact veterinarian immediately) include seizures, aggression (threatening behavior and actions).
- Overdoses can be very serious; keep out of the reach of animals and children.
- If your animal wore a flea and tick collar 2 weeks prior to starting

this drug, let your veterinarian know. Do not use one of these collars on your animal while it's receiving this medicine without first talking to your veterinarian.

- Do not abruptly discontinue this medication without speaking with a veterinarian. A gradual withdrawal is usually recommended if your animal has been on this medication for an extended period.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Paroxetine HCl is a selective serotonin reuptake inhibitor (SSRI) antidepressant that occurs as an off-white, odorless powder. Its solubility in water is 5.4 mg/mL and pK_a is 9.9.

Paroxetine may also be known as BRL-29060, FG-7051, and *Paxil®*.

Storage/Stability

Paroxetine oral tablets should be stored at 15°C to 30°C (59°F-86°F). The oral suspension should be stored below 25°C (77°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. See the ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Paroxetine HCl Oral Tablets: 10 mg, 20 mg, 30 mg, and 40 mg; *Paxil®*, generic; (Rx)

Paroxetine HCl Oral Tablets Controlled-Release: 12.5 mg, 25 mg, and 37.5 mg; *Paxil® CR*, generic; (Rx)

Paroxetine HCl Oral Suspension: 2 mg/mL in 250 mL; *Paxil®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Penicillamine

(pen-i-***sill***-a-meen) *Depen®, Cuprimine®*

Antidote; Chelating Agent

Prescriber Highlights

- ► Chelating agent used primarily for copper-storage hepatopathies in dogs. Can be considered for lead poisoning or cystine urolithiasis, but other therapies are preferred
- ► Contraindications: history of penicillamine-related blood dyscrasias, lead present in GI tract
- ► Potentially teratogenic
- ► Adverse effects: nausea, vomiting, and hyporexia. Can reduce GI dietary mineral absorption (zinc, iron, copper, and calcium) and cause deficiencies; Rarely: fever, lymphadenopathy, skin hypersensitivity reactions, or immune-complex glomerulonephropathy
- ► Pyridoxine deficiency may occur; consider supplementation.
- ► Food significantly reduces oral bioavailability. Give on an empty stomach (if it can be tolerated).

Uses/Indications

Penicillamine is used primarily for its chelating ability in veterinary medicine. It is the drug of choice for copper-associated hepatopathies in dogs[1]; clinical improvement may require weeks to months of treatment. It can also be used for the long-term oral treatment of lead or mercury poisoning or in cystine urolithiasis. It was effective in treating zinc toxicosis in a dog.[2]

Because it has antifibrotic effects,[1] penicillamine may be of benefit in chronic hepatitis, but doses necessary for effective treatment are likely too high to be tolerated.

Pharmacology/Actions

Penicillamine chelates a variety of metals, including copper, lead, iron, and mercury, forming stable water-soluble complexes that are excreted by the kidneys. Urinary copper excretion does not correlate with baseline hepatic copper concentration.[3] Penicillamine combines chemically with cystine to form a stable, soluble complex that can be readily excreted.

Penicillamine has antirheumatic activity; however, the exact mechanisms for this action are not understood. Penicillamine has been shown to improve lymphocyte function, depress T-cell activity, and decrease IgM rheumatoid factor and immune complex formation in serum and synovial fluid.

Penicillamine possesses antifibrotic activity via inhibition of collagen crosslinking, thereby causing collagen to be more susceptible to degradation.

Although penicillamine is a degradation product of penicillins, it has no antimicrobial activity.

Pharmacokinetics

In dogs, giving penicillamine with food reduces bioavailability, peak concentration, and area under the curve (AUC) (24 hours) by ≈70%, as compared with the fasted state.[4]

In humans, penicillamine is 40% to 70% absorbed after oral administration and peak serum concentrations occur ≈1 hour after dosing. It is ≈80% bound to plasma proteins. The drug apparently crosses the placenta, but little information is known about its distribution. Penicillamine that is not complexed with either a metal or cystine is thought to be metabolized by the liver and excreted in the urine and feces.

Contraindications/Precautions/Warnings

Penicillamine is contraindicated in patients with a history of penicillin hypersensitivity or penicillamine-related blood dyscrasias and should be avoided in patients with renal insufficiency. Penicillamine can potentially enhance absorption of lead from the GI tract. If lead is still present in the gut, penicillamine should not be administered.

Adverse Effects

In dogs, the most common adverse effects associated with penicillamine includes nausea, vomiting, and hyporexia. Although penicillamine should be given on an empty stomach (at least 30 minutes before feeding), if the animal develops problems with vomiting or anorexia, consider one or more of the following suggestions:

1) Give the same total daily dose but divide into smaller individual doses and give more frequently.
2) Temporarily reduce the daily dose and gradually increase to recommended dosage.
3) Give a long-acting antiemetic 1 hour before dosing.
4) Give with a small amount of food (eg, small piece of meat[1]) if one of the above does not alleviate vomiting.

Rare adverse effects in dogs include proteinuria, fever, lymphadenopathy, skin hypersensitivity reactions, or immune-complex glomerulonephropathy. A case of hemolytic anemia in a cat has been reported.[5]

In humans, other rare side effects include oral ulcerations, rash-

es, hepatic failure, pancreatitis, and adverse hematologic effects (eg, leukopenia, thrombocytopenia; see ***Contraindications/Precautions/Warnings***).

Penicillamine can reduce GI dietary mineral absorption (zinc, iron, copper, and calcium) and cause deficiencies with long-term use. Pyridoxine-deficient states may occur; supplementation advised. Interference with collagen and elastin production may lead to increased skin friability and impaired wound healing.

Reproductive/Nursing Safety

Penicillamine has been associated with the development of birth defects in offspring of rats given 6 times the recommended dose.[6,7] There are also some reports of human teratogenicity, including skin and collagen defects. Penicillamine is relatively contraindicated during human pregnancy.

The manufacturer warns that mothers taking penicillamine should not nurse offspring.[6,7]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific acute toxic dose has been established for penicillamine and toxic effects generally occur in patients taking the drug chronically. Any relationship of toxicity to dose is unclear; patients on small doses may also develop toxicity.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillamine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **4-aminoquinoline Drugs** (eg, **chloroquine, quinacrine**): Concomitant administration with these agents may increase the risks for severe dermatologic adverse effects.
- **Cations, Oral including Zinc, Iron, Calcium, & Magnesium**: May decrease the effectiveness of penicillamine if given orally together. Long-term use of penicillamine may induce deficient states.
- **Food**: The amount of penicillamine absorbed from the GI tract may be significantly reduced by the concurrent administration of food or antacids.
- **Gold Compounds** (eg, **auranofin**): May increase the risk for hematologic and/or renal adverse reactions
- **Immunosuppressant Drugs** (eg, **cyclophosphamide, azathioprine**, but not corticosteroids): May increase the risk for hematologic and/or renal adverse effects
- **Phenylbutazone**: May increase the risk for hematologic and/or renal adverse effects
- **Pyridoxine**: Penicillamine may induce deficient states. Supplementation is advised in human patients.

Laboratory Considerations

- When using technetium Tc 99m gluceptate to visualize the kidneys, penicillamine may chelate this agent and form a compound that is excreted via the hepatobiliary system resulting in gallbladder visualization that could confuse the results.
- In humans, penicillamine may cause a positive ANA test.

Dosages

DOGS:

Copper-associated hepatopathy (extra-label): The standard recommended dosage is 10 – 15 mg/kg PO twice daily on an empty stomach (at least 20 to 30 minutes before feeding). However, in a pharmacokinetic study, the authors suggest that a lower dosage (7 mg/kg PO twice daily on an empty stomach) might be efficacious and also reduce drug cost and the incidence of vomiting. Alternatively, a long-acting antiemetic could be administered 1 hour before dosing in dogs that have a proclivity to vomit.[4,8]

Copper-associated chronic hepatitis (extra-label): 10 – 15 mg/kg PO every 12 hours, 30 minutes before or 2 hours after a meal. Treatment duration is based on hepatic copper quantification. Some dogs need maintenance with chronic intermittent low-dose (5 – 10 mg/kg PO) administration 2 to 3 times weekly; however, this has not been studied.[1]

Cystine urolithiasis (extra-label): 15 mg/kg PO twice daily with food.[9]

Subclinical hepatitis in Doberman pinschers (extra-label): 6.7 mg/kg PO twice daily 30 minutes prior to feeding for 4 months improved liver appearance on histopathology.[10]

Lead poisoning (extra-label): As an alternative or adjunct to CaEDTA: penicillamine 110 mg/kg/day divided every 6 to 8 hours PO 30 minutes before feeding for 1 to 2 weeks. If vomiting is a problem, may premedicate with dimenhydrinate 2 – 4 mg/kg PO. Alternatively, may give penicillamine 33 – 55 mg/kg/day divided as above. Dissolving medication in juice may facilitate administration.[11,12]

CATS:

Primary copper hepatopathy (extra-label): From a retrospective study where 5 cats received penicillamine: 10 – 15 mg/kg PO every 12 hours. One cat developed hemolytic anemia.[5]

Lead toxicosis (extra-label): 125 mg/cat (NOT mg/kg) PO every 12 hours for 5 days. Do not administer if any lead remains in the GI tract, as it will increase systemic lead absorption.

RUMINANTS:

NOTE: When used in food animals, FARAD recommends a minimum milk withdrawal time of 3 days after the last treatment and a 21-day preslaughter withdrawal.[13]

Copper toxicity in small ruminants (extra-label): 26 – 52 mg/kg PO once daily for 6 days[14,15]

Lead or mercury toxicity (extra-label): 110 mg/kg PO for 1 to 3 weeks. To prevent continued metal absorption, must clear GI tract of toxic metal before treatment.[16]

BIRDS:

Adjunctive treatment of lead poisoning (extra-label): 55 mg/kg PO every 12 hours for 1 to 2 weeks. It has been recommended to combine CaEDTA and penicillamine for several days until clinical signs dissipate, followed by a 3- to 6-week treatment with penicillamine.[17]

Monitoring

- NOTE: The manufacturer cautions that penicillamine can produce severe toxic reactions, and that patients receiving the drug should be continuously monitored for adverse effects.
- Monitoring for efficacy is dependent on the reason for its use (eg, liver copper concentrations, blood lead concentrations)
- CBC (including platelets) and renal function (including urinalysis) should be routinely monitored.
- Adverse effects

Client Information

- Used to remove excess metals (eg, copper, lead, mercury) from the body
- Can cause nausea (acting sick) and vomiting
- Should be given on an empty stomach, at least 30 minutes before feeding
- Does not have any antibiotic activity

Chemistry/Synonyms

A monothiol chelating agent that is a degradation product of penicillins, penicillamine occurs as a white or practically white, crystalline powder with a characteristic odor. Penicillamine is freely soluble in water and slightly soluble in alcohol with pK_a values of 1.83, 8.03, and 10.83.

Penicillamine may also be known as D-Penicillamine; beta,beta-Dimethylcysteine; D-3-Mercaptovaline; penicillaminum; *Depen*®; and *Cuprimine*®.

Storage/Stability

Penicillamine should be stored at room temperature, 20°C to 25°C (68°F-77°F), protected from moisture, and in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Penicillamine Titratable Oral Tablets: 250 mg (scored); *Depen*®; (Rx)

Penicillamine Oral Capsules: 250 mg; *Cuprimine*®; (Rx)

Penicillin G

(pen-i-***sill***-in ***jee***)

Penicillin Antibiotic

Prescriber Highlights

- ► Prototypical penicillin agent used parenterally for treatment of susceptible infections
- ► Contraindications include known hypersensitivity.
- ► Adverse effects may include hypersensitivity. Very high doses or IV injection of procaine-containing products may cause adverse CNS effects.
- ► Label dosages may be too low.
- ► Benzathine penicillin only effective against extremely susceptible agents and has limited clinical use

Uses/Indications

Penicillin G is FDA-approved for systemic use in horses, cattle, and sheep for respiratory infections, and in swine for treatment of erysipelas. Natural penicillins (G and V) remain the drugs of choice for a variety of bacteria, including group A beta-hemolytic streptococci, many gram-positive anaerobes, spirochetes, and some gram-negative aerobic bacilli and cocci. Generally, if bacteria remain susceptible to a natural penicillin, either penicillin G or V is preferred for treating that infection as long as adequate penetration of the drug to the site of the infection occurs and the patient is not hypersensitive to penicillins. The high prevalence of penicillinase production by clinically relevant bacteria has limited the use of natural penicillins.

The World Health Organization (WHO) has designated penicillin G as a Critically Important, High Priority antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) has designated natural penicillins as Veterinary Critically Important Antimicrobial (VCIA) Agents in avian, bovine, camelids, caprine, equine, lagomorph, ovine, and swine species.[2]

Pharmacology/Actions

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall, resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, and endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins [PBPs]) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria. Penicillins are considered time-dependent antibiotics, as efficacy depends on the length of time that plasma (or tissue) concentrations exceed the MIC of pathogens.

The natural penicillins (G and V) have similar spectrums of activity, but penicillin G is slightly more active in vitro on a per weight basis against many organisms. The natural penicillins are narrow in spectrum and have in vitro activity against most spirochetes and gram-positive and gram-negative aerobic cocci, but not penicillinase-producing strains. They have activity against some aerobic and anaerobic gram-positive bacilli such as *Bacillus anthracis*, *Clostridium* spp, *Fusobacterium* spp, and *Arcanobacterium* spp. The natural penicillins are inactive against most gram-negative aerobic and anaerobic bacilli, and all *Rickettsia* spp, mycobacteria, fungi, *Mycoplasma* spp, and viruses. Natural penicillins are consistently inactive against *Pseudomonas* spp, most Enterobacteriaceae, and penicillinase-producing *Staphylococcus* spp.

Pharmacokinetics

Penicillin G potassium is poorly absorbed orally because of rapid acid-catalyzed hydrolysis. When penicillin G is administered on an empty (fasted) stomach, oral bioavailability is ≈15% to 30%. If penicillin G is given with food, absorption rate and extent will be decreased.

Penicillin G potassium and sodium salts are rapidly absorbed after IM injections and yield high peak concentrations usually within 20 minutes of administration. In horses, equivalent doses given either IV or IM demonstrated that IM dosing will provide serum concentrations above 0.5 µg/mL for approximately twice as long as IV administration (≈3 to 4 hours [IV] vs 6 to 7 hours [IM]). Penicillin G potassium administered IM to rabbits yielded peak concentration at 30 minutes, with a half-life of 2 hours.[3]

Penicillin G procaine is slowly hydrolyzed to penicillin G after IM injection. Peak levels are much lower than with parenterally administered aqueous penicillin G sodium or potassium, but serum concentrations are more prolonged.

Penicillin G benzathine is also very slowly absorbed after IM injection after being hydrolyzed to the parent compound. Serum concentrations can be very prolonged, but concentrations attained generally only exceed MICs for the most susceptible streptococci, and the use of penicillin G benzathine should be limited to these infections when other penicillin use is impractical.

After absorption, penicillin G is widely distributed throughout the body with the exception of the CSF, joints, and milk. In lactating dairy cattle, the milk to plasma ratio is ≈0.2. CSF concentrations are generally 10% or less of that found in the serum when meninges are not inflamed. Concentrations in the CSF may be greater in patients with inflamed meninges or if probenecid is given concurrently. Binding to plasma proteins is ≈50% in most species.

Penicillin G is principally excreted unchanged in the urine through renal mechanisms via both glomerular filtration and tubu-

lar secretion. Elimination half-lives are rapid and are usually 1 hour or less in most species (if normal renal function exists).

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them.[4] Because there may be cross-reactivity, use penicillins cautiously in patients documented as hypersensitive to other beta-lactam antibiotics (eg, cephalosporins, cefamycins, carbapenems).

High doses of penicillin G sodium or potassium, particularly in small animal species with a pre-existing electrolyte abnormality, renal disease, or congestive heart failure, may cause electrolyte imbalances.[5] Certain species (eg, snakes, birds, turtles) are reportedly sensitive to penicillin G procaine.

A retrospective observational study in horses found an association between perioperative penicillin G sodium administration and postanesthetic colic.[6] The authors concluded an alternative to penicillin G sodium should be investigated to reduce the incidence of postanesthetic colic.

Accidental IV injection of procaine- or benzathine-containing penicillin products to humans may lead to immediate excitatory CNS toxicity (procaine) or cardiovascular arrest and death (benzathine).[4,7] Injections near major peripheral nerves or blood vessels may lead to tissue damage, necrosis, or permanent neurologic damage.

Adverse Effects

Adverse effects from the penicillins in animals are usually not severe and have a relatively low frequency of occurrence.

Hypersensitivity reactions, unrelated to dose, can occur with these agents and manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemia, lymphadenopathy, or anaphylaxis. In humans, it is estimated that up to 15% of patients that are hypersensitive to cephalosporins will also be hypersensitive to penicillins.[8] The incidence of cross-reactivity in veterinary patients is unknown.

Neurotoxicity (eg, ataxia in dogs) has been associated with very high doses or prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects noted in dogs include tachypnea, dyspnea, edema, and tachycardia.

Procaine toxicity can occur when procaine penicillin is administered at high doses or is inadvertently administered IV. These reactions are poorly characterized in animals but rapid onset behavioral, locomotor, neurologic, and vascular reactions have been reported in multiple animal species.[9–12] Some cases have resulted in death.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but there have not been any documented teratogenic problems associated with these drugs.

Penicillins are excreted in maternal milk in low concentrations; use could potentially cause diarrhea, candidiasis, or allergic responses in nursing offspring. Milk replacer could be considered.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see ***Adverse Effects***). In humans (especially those with renal disease), very high doses of parenteral penicillins have induced CNS effects. Rapid-onset behavioral, locomotor, neurologic, and vascular reactions have been reported in dogs, cats, horses, and sows, particularly when penicillin procaine has been administered IV or at high doses. Some cases have resulted in death.[9–13] Treatment, if required, should be supportive and include anticonvulsants, centrally acting muscle relaxants, and sedation as indicated.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillin G and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides or Cephalosporins**: In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins.
- **Bacteriostatic Antibiotics** (eg, **chloramphenicol, erythromycin, tetracyclines**): Use with penicillins is generally not recommended, particularly in acute infections where the organism is proliferating rapidly as penicillins tend to perform better on actively growing bacteria. However, clinical significance is unknown.
- **Methotrexate**: Penicillins may decrease renal elimination of methotrexate.
- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum concentrations and serum half-lives

Laboratory Considerations

- As penicillins and other beta-lactams can inactivate **aminoglycosides** in vitro (and in vivo in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- Penicillin G can cause falsely elevated **serum uric acid** values if the copper-chelate method is used; phosphotungstate and uricase methods are not affected.
- Penicillins may cause false positive **urine glucose** determinations when using cupric-sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by penicillin.

Dosages

NOTE: Label dosages of penicillin have been unchanged for decades and may result in marked underdosing based on current understanding of antibiotic therapy. Although consideration of the label recommendations is required, present-day recommended dosing regimens should be used.

DOGS/CATS:

Susceptible infections (extra-label):

Penicillin G procaine: 20,000 – 40,000 units/kg IM or SC every 12 to 24 hours

Penicillin G sodium or potassium: 20,000 – 40,000 units/kg IV or IM every 4 to 8 hours

Leptospirosis (extra-label): Penicillin G sodium or potassium 25,000 – 40,000 units/kg IV every 12 hours initially, followed by doxycycline 5 mg/kg PO every 12 hours or 10 mg/kg PO every 24 hours for 2 weeks, starting once the patient can tolerate PO administration[14]

HORSES:

Strangles caused by *Streptococcus equi* (label dosage; FDA-approved): Penicillin G procaine: 3000 units per 0.45 kg (1 lb) of body weight (1 mL per 45.3 kg [100 lb] body weight) IM daily. **NOTE**: According to modern principles of antibiotic therapy the labeled dosage is understood to be too low and the dosing interval too infrequent to effectively treat infections.

Susceptible infections caused by gram-positive aerobes (extra-label):

Penicillin G procaine: 22,000 – 44,000 units/kg IM every 12 hours

Penicillin G potassium or sodium: 20,000 units/kg IV or IM every 6 hours

Serious gram-positive infections (eg, tetanus, clostridial myonecrosis): Penicillin G sodium or potassium: 22,000 – 44,000 units/kg IV every 6 hours[15]

Carriers with *Streptococcus equi* infections of the guttural pouches (extra-label): Administration of both systemic and topical penicillin G may improve treatment success rate. Before topical therapy, remove all visible inflammatory material from guttural pouch. To make a gelatin-penicillin G mix of 50 mL for guttural pouch instillation:

1) Measure 2 g gelatin (Sigma G-6650 or household) and add 40 mL of sterile water.
2) Heat or microwave to dissolve. Cool to 45°C to 50°C (113°F-133°F).
3) Add 10 mL sterile water to a vial of 10 million units penicillin G sodium for injection and mix with the cooled gelatin to a total volume of 50 mL.
4) Dispense into syringes and leave overnight in the refrigerator.
5) Instillation is easiest through a catheter inserted up the nose and endoscopically guided into the pouch opening, with the last inch bent at an angle to aid entry under the pouch flap. Elevate horse's head for 20 minutes after instillation.[16]

Foals (extra-label):

Penicillin G procaine: 22,000 units/kg every 12 hours IM (painful, lower blood concentrations than penicillin G potassium)[17]

Penicillin G potassium: 22,000 units/kg every 6 hours IV or IM[17]

CATTLE (AND OTHER RUMINANTS UNLESS SPECIFIED):

NOTE: When penicillin G procaine is administered in an extra-label manner, the dose, dosage frequency, treatment duration, injection site, and injection route (IM vs SC) can all affect drug residues.[18] Veterinarians seeking information for determination of a withdrawal interval following extra-label drug use should contact the Food Animal Residue Avoidance Databank (FARAD) for assistance.

Susceptible infections in beef cattle (label dosage; FDA-approved): Penicillin G benzathine and Penicillin G procaine: 2 mL per 68 kg (150 lb) body weight, SC only. Repeat in 48 hours. **NOTE**: According to modern principles of antibiotic therapy the labeled dosage is understood to be too low and the dosing interval too infrequent to effectively treat infections.

Bacterial pneumonia (shipping fever) caused by *Pasteurella multocida* in cattle and sheep (label dosage; FDA-approved): Penicillin G procaine: 3000 units per 0.45 kg (1 lb) of body weight (1 mL per 45.3 kg [100 lb] body weight) IM daily. Treatment duration varies by manufacturer; follow the directions found on product label. **NOTE**: According to modern principles of antibiotic therapy the labeled dose is understood to be too low and the dosing interval too infrequent to effectively treat infections.

Susceptible infections (extra-label): Penicillin G procaine: 24,000 – 66,000 units/kg IM once per day[19]

Clostridial abomasitis and enteritis in calves (extra-label): Penicillin G procaine: 22,000 units/kg PO every 24 hours for 3 to 5 days. Oral penicillin is preferred over systemic as oral penicillin is poorly absorbed from the GI tract and will provide activity in the intestinal lumen where the target bacteria reside.[20]

SWINE:

NOTE: When penicillin G procaine is administered in an extra-label manner, the dose, dosage frequency, treatment duration, injection site, and injection route (IM vs SC) can all affect drug residues.[21] Veterinarians seeking information for determination of a withdrawal interval following extra-label drug use should contact the Food Animal Residue Avoidance Databank (FARAD) for assistance.

Erysipelas caused by *Erysipelothrix rhusiopathiae* (label dosage; FDA-approved): Penicillin G procaine: 3000 units per 0.45 kg (1 lb) of body weight (1 mL per 45.3 kg [100 lb] body weight) IM daily. Treatment duration varies by product; consult label for specific information. **NOTE**: According to modern principles of antibiotic therapy the labeled dose is understood to be too low and the dosing interval too infrequent to effectively treat infections.

Susceptible infections (extra-label):

Penicillin G procaine: 40,000 units/kg IM once daily[22]

Penicillin G procaine/penicillin G benzathine combination: 40,000 units/kg IM once[23]

BIRDS:

Susceptible infections in turkeys (extra-label): Penicillin G procaine/penicillin G benzathine combination: 200 mg/kg IM once daily.[24,25] Use cautiously in small birds as it may cause procaine toxicity[26]

FERRETS:

Susceptible infections (extra-label): Penicillin G procaine: 20,000 – 40,000 units/kg IM once or twice daily[27]

RABBITS, RODENTS, SMALL MAMMALS:

Rabbits (extra-label): Penicillin G procaine: 20,000 – 84,000 units/kg SC or IM every 24 hours for 5 to 7 days for venereal spirochetosis.[28] **NOTE**: Parenteral administration of penicillin, unlike the oral route, appears to be tolerated by rabbits and other hindgut fermenters.

Hedgehogs (extra-label): Penicillin G procaine: 40,000 units/kg IM once daily[29]

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum concentrations and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- This medicine is not usually given orally.
- Penicillin G procaine and/or Penicillin G benzathine should not be administered in the vein. Inadvertent administration into a vein (IV) may result in serious toxicity and death. Be sure you understand the proper injection technique.
- Injectable solutions may cause stinging when injected under the skin (subcutaneously).
- Side effects to penicillin G are uncommon. Contact your veterinarian if you have any concerns about your animal's condition.

Chemistry/Synonyms

Penicillin G is a natural penicillin obtained from cultures of *Penicillium chrysogenum* and is available in several different salt forms. Penicillin G potassium (also known as benzylpenicillin potassium, aqueous or crystalline penicillin) occurs as colorless or white crystals, or

white crystalline powder. It is very soluble in water and sparingly soluble in alcohol. The potency of penicillin G potassium is generally expressed in terms of units. One mg of penicillin G potassium is equivalent to 1440 to 1680 USP units (1355 to 1595 USP units for the powder for injection). After reconstitution, penicillin G potassium powder for injection has a pH of 6 to 8.5 and contains 1.7 mEq of potassium per 1 million units.

Penicillin G sodium (also known as benzylpenicillin sodium, aqueous or crystalline penicillin) occurs as colorless or white crystals, or white to slightly yellow, crystalline powder. Approximately 25 mg are soluble in 1 mL of water. The potency of penicillin G sodium is generally expressed in terms of units. One mg of penicillin G sodium is equivalent to 1500 to 1750 USP units (1420 to 1667 USP units for the powder for injection). After reconstitution, penicillin G sodium powder for injection has a pH of 6 to 7.5 and contains 2 mEq of sodium per 1 million units.

Penicillin G procaine (also known as procaine penicillin G, aqueous procaine penicillin G, APPG, benzylpenicillin procaine, procaine benzylpenicillin) is the procaine monohydrate salt of penicillin G. In vivo it is hydrolyzed to penicillin G and acts as a depot or repository form of penicillin G. It occurs as white crystals or a very fine, white crystalline powder. Approximately 4 to 4.5 mg is soluble in 1 mL of water and 3.3 mg is soluble in 1 mL of alcohol. The potency of penicillin G procaine is generally expressed in terms of units. One mg of penicillin G procaine is equivalent to 900 to 1050 USP units. The commercially available suspension for injection is buffered with sodium citrate and has a pH of 5 to 7.5. It is preserved with methylparaben and propylparaben.

Penicillin G benzathine (also known as benzathine benzylpenicillin, benzathine penicillin G, benzylpenicillin benzathine, dibenzylethylenediamine benzylpenicillin) is the benzathine tetrahydrate salt of penicillin G. It is hydrolyzed in vivo to penicillin G and acts as a long-acting form of penicillin G. It occurs as an odorless, white, crystalline powder. Solubility ranges from 0.2 to 0.3 mg/mL in water and 15 mg/mL in alcohol. One mg of penicillin G benzathine is equivalent to 1090 to 1272 USP units. The commercially available suspension for injection is buffered with sodium citrate and has a pH of 5 to 7.5. It is preserved with methylparaben and propylparaben.

Penicillin G may also be known as benzylpenicillin, crystalline penicillin G, pen G, penicillin, *Bicillin C-R®*, and *Pfizerpen®*.

Storage/Stability

Penicillin G procaine should be stored at 2°C to 8°C (36°F-46°F); avoid freezing. Penicillin G benzathine should be stored at 2°C to 8°C (36°F-46°F).

Penicillin G sodium and potassium powder for injection can be stored at room temperature (15°C-30°C [59°F-86°F]). After reconstituting, the injectable solution is stable for 7 days when kept refrigerated (2°C-8°C [36°F-46°F]) and for 24 hours at room temperature.

Compatibility/Compounding Considerations

All commonly used IV fluids (some Dextran products are physically **incompatible**) and the following drugs are reportedly physically **compatible** with penicillin G potassium: ascorbic acid injection, calcium chloride/gluconate, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, corticotropin, dexamethasone sodium phosphate, diphenhydramine HCl, ephedrine sulfate, famotidine, gentamicin, hydrocortisone sodium succinate, ketamine hydrochloride, lidocaine HCl, methicillin sodium, methylprednisolone sodium succinate, metronidazole with sodium bicarbonate, nitroprusside sodium, potassium chloride, prednisolone sodium phosphate, procaine HCl, prochlorperazine edisylate, sodium iodide, and verapamil HCl.

The following drugs/solutions are either physically **incompatible** or the data conflict regarding compatibility with penicillin G potassium injection: amikacin sulfate, aminophylline, chlorpromazine HCl, dopamine HCl, erythromycin lactobionate, heparin sodium, hydroxyzine HCl, metoclopramide HCl, oxytetracycline HCl, pentobarbital sodium, prochlorperazine mesylate, promazine HCl, promethazine HCl, sodium bicarbonate, tetracycline HCl, and vitamin B complex with C.

The following drugs/solutions are reportedly physically **compatible** with penicillin G sodium injection: Dextran 40 10%, dextrose 5% (some degradation may occur if stored for 24 hours), sodium chloride 0.9% (some degradation may occur if stored for 24 hours), calcium chloride/gluconate, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dexamethasone sodium phosphate, diphenhydramine HCl, famotidine, gentamicin sulfate, hydrocortisone sodium succinate, ketamine hydrochloride, prednisolone sodium phosphate, procaine HCl, verapamil HCl, and vitamin B complex with C.

The following drugs/solutions are either physically **incompatible** or the data conflict regarding compatibility with penicillin G sodium injection: amphotericin B, bleomycin sulfate, chlorpromazine HCl, dobutamine hydrochloride, erythromycin lactobionate, heparin sodium, hydroxyzine HCl, methylprednisolone sodium succinate, oxytetracycline HCl, polymyxin B sulfate, potassium chloride, prochlorperazine mesylate, promethazine HCl, and tetracycline HCl.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: Withdrawal times are for labeled dosages only. Contact Food Animal Residue Avoidance Databank (FARAD) when used in an extra-label manner for assistance in determining a withdrawal interval.

Penicillin G Procaine Injection 300,000 units/mL in 100 mL, 250 mL, and 500 mL vials: Variety of trade names available (OTC). Depending on product, FDA-approved for use in horses, cattle, sheep, and swine. Not intended for use in horses used for food. Withdrawal times vary depending on the product and are for the labeled dosage of 6600 units/kg once daily (rarely used today). Milk withdrawal times (at labeled doses) = 48 hours. Slaughter withdrawal: Calves (nonruminating) = 7 days; cattle = 4 to 14 days; sheep = 8 to 9 days; swine = 6 to 7 days; refer to label for more information.

Penicillin G benzathine 150,000 units/mL with Penicillin G procaine Injection 150,000 units/mL for Injection in 100 mL, 250 mL, and 500 mL vials: Variety of trade names available (Rx). FDA-approved (most products) in horses and beef cattle. Not FDA-approved for horses intended for food. Slaughter withdrawal: cattle = 30 days (at labeled doses). Actual species approvals and withdrawal times vary with the product; refer to the product label.

Penicillin G is also available in syringes for intramammary administration and as a powder for use in poultry drinking water systems.

The Association of Racing Commissioners International (ARCI) has designated procaine (including penicillin G procaine) as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Penicillin G (aqueous) sodium powder for injection: 5 million units/vial; generic; (Rx)

Penicillin G (aqueous) premixed injectable solution: 1, 2, or 3 million units/50 mL (Rx)

Penicillin G (aqueous) potassium powder for injection: 5 million, and 20 million units; *Pfizerpen-G®*, generic; (Rx)

Penicillin G procaine injection: 600,000 units/vial in 1 mL *Tubex* and 1.2 million units/vial in 2 mL *Tubex*; generic; (Rx)

Penicillin G benzathine injection: 600,000 units/dose in 1 mL *Tubex*; 1.2 million units/dose in 2 mL; 2.4 million units/dose in 4 mL prefilled syringes; *Bicillin L-A®*; (Rx)

Penicillin G Benzathine 600,000 units/mL with Penicillin G Procaine Injection 600,000 units/mL for Injection: in 2 mL syringes; *Bicillin C-R®;* (Rx)

Penicillin G Benzathine 900,000 units/mL with Penicillin G Procaine Injection 300,000 units/mL for Injection: in 2 mL syringes; *Bicillin CR 900/300®;* (Rx)

Penicillin V

Phenoxymethylpenicillin

(pen-i-***sill***-in ***vee***)

Oral Penicillin Antibiotic

Prescriber Highlights

- ► Requires frequent administration on an empty stomach, which limits its utility in veterinary medicine
- ► Contraindications include known hypersensitivity, and hindgut fermenters.
- ► Adverse effects include anorexia, vomiting, and diarrhea.

Uses/Indications

Penicillin V is a natural penicillin that is active against many streptococci. It is rarely used today in veterinary medicine because it requires frequent administration on an empty stomach and has no significant advantages over other available related drugs.

The World Health Organization (WHO) has designated penicillin V as a Critically Important, High Priority antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) has designated natural penicillins as Veterinary Critically Important Antimicrobial (VCIA) Agents in avian and swine species.[2]

Pharmacology/Actions

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall, resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, and endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins [PBPs]) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria. Penicillin V is considered a time-dependent antibiotic as its efficacy depends on the length of time that plasma (or tissue) concentrations exceed the MIC of pathogens.

The natural penicillins (G and V) have similar spectrums of activity, but penicillin G is slightly more active in vitro on a per weight basis against many organisms. The natural penicillins are narrow in spectrum and have in vitro activity against most spirochetes and gram-positive and gram-negative aerobic cocci, but not penicillinase-producing strains. They have activity against some aerobic and anaerobic gram-positive bacilli such as *Bacillus anthracis*, *Clostridium* spp, *Fusobacterium* spp, and *Arcanobacterium* spp. The natural penicillins are inactive against most gram-negative aerobic and anaerobic bacilli, and all *Rickettsia* spp, mycobacteria, fungi, *Mycoplasma* spp, and viruses. Natural penicillins are consistently inactive against *Pseudomonas* spp, most Enterobacteriaceae, and penicillinase-producing *Staphylococcus* spp. Although penicillin V may be slightly less active than penicillin G against organisms that are susceptible to the natural penicillins, its superior absorptive characteristics after oral administration make it a better choice against mild to moderately severe infections in monogastric animals when oral administration is desired.

Pharmacokinetics

The pharmacokinetics of penicillin V are very similar to penicillin G with the exception of oral bioavailability and the percentage of the drug that is bound to plasma proteins. Penicillin V is significantly more resistant to acid-catalyzed inactivation in the gut and bioavailability after oral administration in humans is ≈60% to 73%. Bioavailability in calves is only 30%, but studies performed in horses and dogs demonstrated that therapeutic serum concentrations can be achieved after oral administration. In dogs, food will decrease the rate and extent of absorption.[3]

Distribution of penicillin V follows that of penicillin G but, in humans, the drug is bound to a larger extent to plasma proteins (≈80% with penicillin V vs 50% with penicillin G).

Like penicillin G, penicillin V is excreted rapidly in the urine via the kidney. Elimination half-lives are generally less than 1 hour in animals with normal renal function. An elimination half-life of 3.7 hours has been reported after oral dosing in horses.[4]

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients documented as hypersensitive to other beta-lactam antibiotics (eg, cephalosporins, cefamycins, carbapenems).[5]

Oral penicillins should be avoided in hindgut fermenters (eg, horses, rabbits, guinea pigs, hamsters, gerbils, chinchillas) because of potential for *Clostridium* spp bacterial overgrowth.

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished.

Adverse Effects

Adverse effects from the penicillins are usually not severe and have a relatively low frequency of occurrence.

Hypersensitivity reactions, unrelated to dose, can occur with these agents and manifest in humans as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemia, or anaphylaxis.[6] In humans, it is estimated that up to 15% of patients that are hypersensitive to cephalosporins will also be hypersensitive to penicillins.[7] The incidence of hypersensitivity and cross-reactivity in veterinary patients is unknown.

When penicillins are given orally, they may cause GI effects (eg, anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and can allow for the proliferation of resistant bacteria in the colon (superinfections).[5]

Neurotoxicity (eg, ataxia in dogs) has been associated with very high doses or prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but there have not been any documented teratogenic problems associated with these drugs. Despite this, use penicillins only when the potential benefits outweigh the risks.

Penicillins are excreted in maternal milk in low concentrations. Use of penicillins in the dam could potentially cause diarrhea, candidiasis, or allergic response in nursing offspring; consider using a milk replacer if treatment is necessary.

Overdose/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see ***Adverse Effects***). In humans (especially in patients with renal disease), very high doses of parenteral penicillins have induced CNS effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillin V and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides or Cephalosporins**: In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins.
- **Bacteriostatic Antibiotics** (eg, **chloramphenicol, erythromycin, tetracyclines**): Use of bacteriostatic antibiotics with penicillins is generally not recommended, particularly in acute infections where the organism is proliferating rapidly, as penicillins tend to perform better on actively growing bacteria. The clinical significance of this interaction is unknown.
- **Methotrexate**: Penicillins may decrease renal elimination of methotrexate.
- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum concentrations and serum half-lives.

Laboratory Considerations

- As penicillins and other beta-lactams can inactivate **aminoglycosides** in vitro (and in vivo in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- Penicillin V can cause falsely elevated **serum uric acid** values if the copper-chelate method is used; phosphotungstate and uricase methods are not affected.
- Penicillins may cause false positive **urine glucose** determinations when using cupric-sulfate solution (Benedict's Solution, *Clinitest®*). Tests utilizing glucose oxidase (*Tes-Tape®*, *Clinistix®*) are not affected by penicillin.

Dosages

DOGS/CATS:

Susceptible infections (extra-label): 10 mg/kg PO every 8 hours for 7 days[8]

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum concentrations and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Penicillin V should not be given to horses, rabbits, guinea pigs, gerbils, hamsters, and chinchillas, as life-threatening diarrhea may occur.
- Penicillin V is best given without food, but if your animal vomits or acts sick after receiving this medicine on an empty stomach, try giving the next dose with food or a small treat. If vomiting continues, contact your veterinarian.
- Liquid forms of this medication must be measured carefully and should be stored in the refrigerator. Your veterinarian or pharmacist can help by providing special measuring spoons or syringes. Liquid forms of this medication should be discarded 14 days after mixing.
- This medication can be given for various lengths of time. Be sure you understand how long your veterinarian wants you to continue giving this medication. Prescription refills may be necessary before the therapy will be complete. Before stopping this medication, talk to your veterinarian, as there may be important reasons to continue its use.
- It is uncommon for side effects to occur in animals treated with penicillin V. The most common side effects are loss of appetite, vomiting, and diarrhea. It is important to contact your veterinarian if you have any concerns.
- Allergic reactions to penicillin V are rare but can be severe with signs including rashes, fever, collapse, or difficulty breathing. In the event of such signs, contact your veterinarian immediately.

Chemistry/Synonyms

A natural penicillin, penicillin V is produced from *Penicillium chrysogenum* and is commercially available as the potassium salt. Penicillin V potassium occurs as an odorless, white, crystalline powder that is very slightly soluble in water and slightly soluble in alcohol. The potency of penicillin V potassium is usually expressed in terms of weight (in mg) of penicillin V, but penicillin V units may also be used. One mg of penicillin V potassium is equivalent to 1380 to 1610 USP units. Manufacturers generally state that 125 mg of penicillin V potassium is ≈200,000 USP units. Each 5 mL of reconstituted penicillin V potassium oral solution (250 mg/5 mL) contains contain 0.85 mEq (32.8 mg) of potassium; each 250 mg tablet contains 0.71 mEq (27.9 mg) of potassium.

Penicillin V may also be known as phenoxymethylpenicillin, fenoximetilpenicilina, penicillin, phenoxymethyl phenomycilline, phenoxymethyl penicillin, phenoxymethylpenicillinum, and *Veetids®*.

Storage/Stability

Penicillin V potassium tablets and powder for oral solution should be stored in tight containers at room temperature (20°C-25°C [68°F-77°F]). Refer to each product label for specific storage temperature recommendations as they may vary by manufacturer. The powder for oral solution should be reconstituted by adding water in 2 portions; the solutions should be shaken vigorously after each addition. After reconstitution, the oral solution should be stored in the refrigerator at 2°C to 8°C (36°F-46°F) and any unused portion discarded after 14 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Penicillin V Potassium Tablets: 250 and 500 mg; generic; (Rx)

Penicillin V Potassium Powder for Oral Solution: 25 mg/mL (labeled as 125 mg/5 mL) and 50 mg/mL (labeled as 250 mg/5 mL) in 100 mL and 200 mL; generic; (Rx)

Pentobarbital

(pen-toe-***bar***-bi-tal) *Nembutal®*

Barbiturate

NOTE: *For information related to pentobarbital and pentobarbital combinations for euthanasia, see* ***Euthanasia Agents***.

Prescriber Highlights

- ► Used therapeutically as a sedative/anesthetic and for treating intractable seizures; also used for euthanasia
- ► Contraindications include in patients with known hypersensitivity and porphyria.
- ► Use with caution in patients with liver dysfunction, renal dysfunction, severe respiratory depression, hypovolemia, anemia, borderline hypoadrenal function, or with cardiac or respiratory disease.
- ► Must have ventilatory support available if using for anesthesia
- ► Adverse effects include respiratory depression, hypothermia, or excitement postanesthesia (dogs).
- ► Extravasation or SC administration can cause local tissue damage or necrosis; do not give intra-arterially.
- ► IV administration must be done slowly; during induction of anesthesia, administer ⅓ to ½ of the calculated dose as a bolus and wait to see effects, then give the rest SLOWLY to effect.
- ► Numerous drug interactions
- ► DEA Schedule II (C-II) controlled substance

Uses/Indications

Pentobarbital is used therapeutically as a sedative/restraining agent in patients being mechanically ventilated and has been used as a sedative and anesthetic agent in horses, cattle, swine, sheep, and goats. It is also commonly used as an anesthetic for rodents in laboratory situations. Although pentobarbital was once the principal agent used for general anesthesia in small animal species, it has been largely supplanted by the use of inhalant and other injectable anesthetic agents.

Pentobarbital can also be used for treating intractable seizures secondary to convulsant agents (eg, strychnine) or secondary to CNS toxins (eg, tetanus). It should not be used to treat seizures caused by lidocaine intoxication. Pentobarbital may be used for refractory status epilepticus that is not controlled with diazepam and phenobarbital; however, propofol or inhalant anesthetics are generally preferred.

Pentobarbital is a major active ingredient in several euthanasia solutions; see ***Euthanasia Agents*.**

Pharmacology/Actions

Although barbiturates are generally considered CNS depressants, they can invoke all levels of CNS mood alteration from paradoxical excitement to deep coma and death. Barbiturates have been shown to inhibit the release of acetylcholine, norepinephrine, and glutamate. They also have effects on GABA receptors; pentobarbital has been shown to be GABA-mimetic. Pentobarbital may have neuroprotective effects via decreasing cerebral metabolic rate and oxygen consumption, scavenging of free radicals, and stabilization of endothelial and glial membranes. At high anesthetic doses, barbiturates have been demonstrated to inhibit the uptake of calcium at nerve endings.

The degree of depression produced by pentobarbital is dependent on the dose, route of administration, and species treated. Additionally, effects may be altered by patient age, physical condition, or concurrent use of other drugs. The barbiturates depress the sensory cortex, lessen motor activity, and produce sedation at low dosages. Barbiturates have no true intrinsic analgesic activity.

Although barbiturates cause dose-dependent respiratory depression in most species, they can also cause slight respiratory stimulation in some species. At lower sedative/hypnotic doses, respiratory depression is similar to that during normal physiologic sleep. As doses increase, the medullary respiratory center is progressively depressed with resultant decreases in rate, depth, and volume. Respiratory arrest may occur at doses 4 times lower than those that cause cardiac arrest.

Cardiovascular effects of pentobarbital in dogs include tachycardia, decreased myocardial contractility and stroke volume, and decreased mean arterial pressure and total peripheral resistance. At high doses, pentobarbital has cardiac arresting effects.

Barbiturates cause reduced tone and motility of the intestinal musculature, likely secondary to its central depressant action. Thiobarbiturates (thiamylal, thiopental) may, after initial depression, cause an increase in both tone and motility of the intestinal musculature; however, these effects do not appear to have much clinical significance. Administration of barbiturates reduces the sensitivity of the motor endplate to acetylcholine, thereby slightly relaxing skeletal muscle. Because the musculature is not completely relaxed, other skeletal muscle relaxants may be necessary for surgical procedures.

Barbiturates have no direct effect on the kidney, but overdoses may cause severe renal impairment secondary to hypotensive effects. Liver function is not directly affected with short-term use, but hepatic microsomal enzyme induction is well documented with extended barbiturate administration, especially pentobarbital. Although barbiturates reduce oxygen consumption of all tissues, no change in metabolic rate is measurable at sedative doses; however, at anesthetic doses, basal metabolic rates may be reduced with resultant decreases in body temperature.

Pharmacokinetics

In humans, pentobarbital is rapidly absorbed from the GI tract after oral and rectal administration.[1] Peak plasma concentrations occur between 30 and 60 minutes after oral dosing. The onset of action usually occurs within 15 to 60 minutes after oral dosing and within 1 minute after IV administration.

Pentobarbital, like all barbiturates, distributes rapidly to all body tissues, with the highest concentrations found in the liver, brain, and kidneys.[1] It is 35% to 45% bound to plasma proteins in humans. Although less lipophilic than the ultra-short-acting barbiturates (eg, thiopental), pentobarbital is highly lipid soluble, and the amount of adipose tissue may alter the distribution of the drug.

Pentobarbital is metabolized in the liver principally by oxidation. Ruminants, especially sheep and goats, metabolize pentobarbital at a rapid rate. Reported elimination half-life in goats is ≈0.9 hours. Conversely, the half-life in dogs is ≈8 hours. In humans, half-life ranges from 15 to 50 hours.[1]

Contraindications/Precautions/Warnings

Barbiturates are contraindicated in patients that have demonstrated previous hypersensitivity reactions to them and in patients with porphyria.[1] Large doses are contraindicated in patients with nephritis or severe respiratory dysfunction. Use of barbiturates for cesarean section is not recommended because of fetal respiratory depression.

Use pentobarbital with caution in patients with renal or hepatic dysfunction; dose reduction is required. Use pentobarbital cautiously in patients that are hypovolemic, anemic, have borderline hypoadrenal function, or cardiac or respiratory disease. Doses should be reduced in geriatric and debilitated patients, as significant excitement and/or depression may occur. Use this medicine with caution in

neonates, as pentobarbital concentrations in the CNS may be substantially higher than in adults; exposure to sedatives or anesthetics may have detrimental effects on fetal/neonatal brain development. Female cats appear to be more susceptible to the effects of pentobarbital than male cats.

If pentobarbital is administered IV too rapidly, respiratory depression, apnea, laryngospasm, or vasodilation and subsequent blood pressure decrease may occur. It is recommended to administer ⅓ to ½ of the calculated dose initially as a bolus, then administer the remainder slowly after the initial effects are ascertained. Concurrent IV fluids are recommended during administration of the bolus to decrease pain on injection. Pentobarbital is highly alkaline and can cause local tissue damage or necrosis if extravasated or administered SC. Do not administer pentobarbital intra-arterially.

Do not confuse PENTObarbital with PHENObarbital. Consider writing orders and prescriptions using tall man letters to reduce the risk of errors.

Adverse Effects

Pentobarbital causes respiratory depression; respiratory activity must be closely monitored, and ventilatory support must be readily available. Hypotension can occur at high doses. Pentobarbital may cause excitement in dogs during recovery from anesthetic doses; this can be confused with seizure activity. Hypothermia may develop in animals receiving pentobarbital if exposed to temperatures below 27°C (80.6°F).

Reproductive/Nursing Safety

All barbiturates cross the placenta and enter milk at concentrations far below those of plasma. In neonates, pentobarbital may cross into the CNS at concentrations up to 6 times those in adult animals.

Barbiturates can cause fetal damage when administered to pregnant patients. Studies have suggested a connection between maternal barbiturate administration and fetal abnormalities.[1]

Exercise caution when administering pentobarbital to nursing mothers, as small amounts are excreted in maternal milk. Drowsiness in nursing offspring has been reported.

Overdose/Acute Toxicity

In dogs, the reported oral LD_{50} is 85 mg/kg and IV LD_{50} is 40 – 60 mg/kg. Fatalities from ingestion of meat from animals euthanized by pentobarbital have been reported in dogs. Treatment of pentobarbital overdose consists of GI decontamination protocols if appropriate and offering ventilatory and cardiovascular support.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with pentobarbital have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed, and additional monitoring performed when appropriate.

- **Acetaminophen**: Increased risk for hepatotoxicity, particularly with large doses or long-term administration of barbiturates
- **Lidocaine**: Fatalities have been reported when dogs suffering from lidocaine-induced seizures were treated with pentobarbital. Until this interaction is further clarified, diazepam is recommended for initial treatment of lidocaine-induced seizures in dogs.
- **Rifampin**: May induce enzymes that increase the metabolism of barbiturates

The following drugs may increase the effect of pentobarbital:

- **Antihistamines**
- **Benzodiazepines**
- **Chloramphenicol**
- **Opioids**
- **Phenothiazines**
- **Valproic Acid**

Pentobarbital (particularly after chronic therapy) may decrease the effect of the following drugs/drug classes by lowering their serum concentrations:

- **Anticoagulants, Oral (Warfarin)**
- **Beta-Blockers**
- **Chloramphenicol**
- **Clarithromycin**
- **Clonazepam**
- **Corticosteroids**
- **Cyclosporine**
- **Doxorubicin**
- **Doxycycline** (may persist for weeks after barbiturate discontinued)
- **Estrogens**
- **Griseofulvin**
- **Methadone**
- **Metronidazole**
- **Paroxetine**
- **Phenothiazines**
- **Progestins**
- **Quinidine**
- **Selegiline**
- **Theophylline**
- **Tricyclic Antidepressants**
- **Verapamil**

Laboratory Considerations

- Barbiturates may cause increased retention of **bromosulfophthalein** (BSP; sulfobromophthalein) and give falsely elevated results. It is recommended that barbiturates not be administered within the 24 hours before BSP retention tests.

Dosages

NOTES:

1. To avoid confusion, doses used for euthanasia are listed separately under the monograph for ***Euthanasia Agents***.
2. Due to the potential lethal nature of this drug, it is highly recommended to review ***Contraindications/Precautions/Warnings*** and ***Adverse Effects*** prior to administration.

DOGS/CATS:

Maintenance of chemical restraint in patients being mechanically ventilated (extra-label): 1 – 3 mg/kg/hour IV CRI. Switching to a shorter-acting agent such as propofol ≈12 hours prior to weaning from the ventilator will allow the pentobarbital concentrations to decrease and will help attenuate any seizure-like activity.[2]

Intractable seizures refractory to benzodiazepine boluses (extra-label): 3 – 15 mg/kg IV slowly to effect; may require several minutes for full therapeutic effect. Once seizures are controlled, consider 0.5 – 5 mg/kg/hour IV CRI. After seizures have been controlled for at least 6 hours, patient may be slowly weaned from the CRI while standard anticonvulsant therapy is initiated. **NOTE**: Patients may require intubation.

HORSES:

NOTE: Pentobarbital is generally not considered an ideal agent

for use in adult horses due to possible development of excitement and injury when the animal is being induced for anesthesia.

Sedative/anesthetic (extra-label): Doses of 3 – 18 mg/kg IV have been noted.

SMALL MAMMALS/RODENTS:

Chemical restraint (extra-label):

a) **Mice**: 30 – 80 mg/kg IP
b) **Rats**: 40 – 60 mg/kg IP
c) **Hamsters/Gerbils**: 70 – 80 mg/kg IP
d) **Guinea pigs**:
   i) 15 – 40 mg/kg IP
   ii) 30 mg/kg IV
e) **Rabbits**: 20 – 60 mg/kg IV[3]

Monitoring

- Levels of consciousness and/or seizure control. EEG monitoring may be helpful in patients with intractable seizures.
- Protect and maintain airway patency.
- Heart and respiratory rate; $ETCO_2$, SpO_2
- Blood pressure
- Body temperature
- Hydration status; body weight

Client Information

- This medicine is used in an inpatient setting with close professional supervision.

Chemistry/Synonyms

Pentobarbital sodium occurs as a white, odorless, slightly bitter, crystalline powder or granules. It is very soluble in water and freely soluble in alcohol. The pK_a of the drug has been reported to range from 7.85 to 8.03 and the pH of the injection is from 9 to 10.5.

Alcohol or propylene glycol may be added to enhance the stability of the injectable product.

Pentobarbital may also be known as aethaminalum, mebubarbital, mebumal, pentobarbitalum, or pentobarbitone.

Storage/Stability

The injectable product should be stored at room temperature. The aqueous solution is not stable and should not be used if it contains a precipitate. Because precipitates may occur, pentobarbital sodium should not be added to acidic solutions.

Pentobarbital is a DEA Schedule II (C-II) controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

The following solutions and drugs have been reported to be physically **compatible** with pentobarbital sodium: dextrose IV solutions, Ringer's injection, lactated Ringer's injection, saline IV solutions, dextrose-saline combinations, dextrose-Ringer's combinations, dextrose-Ringer's lactate combinations, amikacin sulfate, aminophylline, atropine sulfate (for at least 15 minutes, not 24 hours), calcium chloride, cephapirin sodium, chloramphenicol sodium succinate, hyaluronidase, hydromorphone HCl, lidocaine HCl, neostigmine methylsulfate, scopolamine HBr, sodium bicarbonate, sodium iodide, thiopental sodium, and verapamil HCl.

The following drugs have been reported to be physically **incompatible** with pentobarbital sodium: butorphanol tartrate, chlorpromazine HCl, cimetidine HCl, chlorpheniramine maleate, codeine phosphate, diphenhydramine HCl, droperidol, fentanyl citrate, glycopyrrolate, hydrocortisone sodium succinate, hydroxyzine HCl, insulin (regular), meperidine HCl, nalbuphine HCl, norepinephrine bitartrate, oxytetracycline HCl, penicillin G potassium, pentazocine lactate, phenytoin sodium, prochlorperazine edisylate, promazine HCl, and promethazine HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Pentobarbital sodium injection: 64.8 mg/mL; S*omnopentyl*® Injection; (Rx, C-II). Approved for use in dogs, cats, and horses as a general anesthetic; although still listed in FDA's Green Book of approved animal drugs, it is no longer commercially available. NADA # 004-536.

HUMAN-LABELED PRODUCTS:

Pentobarbital Sodium Injection: 50 mg/mL in 2 mL *Tubex*; *Nembutal*®, generic; (Rx, C-II). Report prescribing and/or dispensing to state monitoring programs where required.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pentosan Polysulfate (PPS)

Sodium Pentosan Polysulfate

(***pen***-toe-san) *Cartrophen-Vet®, Elmiron®*

Anti-inflammatory, Osteoarthritis Disease-Modifier

Prescriber Highlights

- ► Injectable pentosan polysulfate (PPS) may be beneficial in treating osteoarthritis in dogs, cats, and horses.
- ► Contraindications include hypersensitivity to PPS, advanced kidney or liver impairment, infection, active bleeding or bleeding disorders, impending surgical procedures, skeletal immaturity, and periparturient animals.
- ► Use with caution when combining with other drugs affecting coagulation.
- ► Adverse effects are uncommon but may include bleeding and GI effects (eg, vomiting, anorexia).

Uses/Indications

Pentosan polysulfate (PPS) may be beneficial for treating osteoarthritis in dogs, cats, and horses. No products are approved for use in animals in the United States; however, an injectable product is licensed in the UK (dogs), Canada (dogs), and Australia (dogs, horses).

Strong evidence of PPS efficacy for the treatment of osteoarthritis in dogs is lacking.[1,2]

It has been suggested that orally, intravesically, and parenterally administered PPS may benefit cats with lower urinary tract disease as an adjunctive treatment; however, studies have shown no significant difference between PPS treatment and placebo.[3,4]

In a small study, horses with experimentally induced osteoarthritis experienced significantly reduced articular cartilage fibrillation and an increase in chondroitin sulfate concentration in the joints of PPS treated horses. The study authors concluded that PPS may be considered a therapeutic option for treatment of osteoarthritis in horses.[5]

Pharmacology/Actions

Pentosan polysufate (PPS) has disease-modifying effects on osteo-

arthritic joints similar to polysulfated glycosoaminoglycans.[6,7] Proposed mechanisms of action include modulation of cytokine action, preservation of proteoglycan content, and stimulation of hyaluronic acid synthesis. PPS has anti-inflammatory, hypolipidemic, anticoagulant (considerably weaker than heparin—1/15th), and fibrinolytic properties. These effects may increase synovial blood flow and reduce joint inflammation. Proposed modes of action for PPS's efficacy include increasing proteoglycan synthesis, reducing matrix metalloproteinase activity, inducing synoviocyte biosynthesis of high molecular weight hyaluronan, and increasing subchondral blood flow via thrombolytic activity.

PPS has a mild analgesic effect when used for interstitial cystitis. The mechanism for its action in treating interstitial cystitis is not known. However, it is postulated that it may adhere to bladder wall mucosal membranes and act as a buffer to prevent irritating compounds in urine from reaching bladder cells.

Pharmacokinetics

In rats, 10% to 20% of the calcium derivative (pentosan polysulfate calcium) is absorbed after oral dosing. In humans, only ≈3% of an oral dose of pentosan polysulfate sodium is absorbed. It distributes primarily to the uroepithelium of the genitourinary tract. Smaller concentrations are found in the liver, spleen, lung skin, bone marrow, and periosteum. About 2/3 of the absorbed drug is desulfated in the liver and spleen within one hour; ≈3.5% of the absorbed drug is excreted into the urine.

In dogs, peak plasma concentrations were reached within 15 minutes following subcutaneous administration. The volume of distribution was 0.43 L, with higher concentrations in the liver, kidneys, and reticuloendothelial system. Low levels were found in the connective tissue and muscle. The elimination half-life was ≈3 hours.

Contraindications/Precautions/Warnings

Contraindications to the use of pentosan polysulfate include septic arthritis, advanced kidney or liver impairment, infection, active bleeding or bleeding disorders, malignancy (especially hemangiosarcoma), peri-operative or peri-parturient animals, skeletally immature animals, and in animals that are hypersensitive to it. Use this drug with caution when combining with other drugs that affect coagulation.

No more than 3 courses of 4 injections should be administered in 12 months.

Adverse Effects

Parenterally administered pentosan polysulfate (PPS) is usually well tolerated, and adverse effects in veterinary species appear mild and transitory. In dogs, vomiting, anorexia, lethargy, or mild depression are possible. Because PPS has some anticoagulant effects, bleeding is possible in any species, perhaps more likely in animals receiving other drugs that affect coagulation (eg, aspirin, anticoagulants) or during stressful exercise. PPS can cause dose-dependent increases in activated partial thromboplastin time (aPTT) up to 24 hours postdose.[8]

When used orally in cats, PPS seems to be well tolerated.

In a small percentage (less than 2%) of humans taking PPS, transient increases in liver enzymes have been reported. There is also some evidence that chronic use of PPS can cause ocular changes in humans[9]; this has not been documented in veterinary species.

Reproductive/Nursing Safety

Safe use of pentosan polysulfate (PPS) in animals intended for breeding or during pregnancy has not been demonstrated. PPS should not be used at the time of parturition due to its anticoagulant effects. Embryotoxic effects resulted when PPS was administered to rabbits at 2.5 times the recommended dose.[8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Information regarding overdoses is not readily available. Potentially, overdoses could cause bleeding, thrombocytopenia, GI distress, and increased liver enzyme (ALT) elevations. At present, treatment recommendations are supportive. If an oral overdose occurs, consider GI decontamination. In healthy dogs receiving repeated daily doses 5 times or more than the recommended dose, increases in aPTT and thrombin time (TT) persisted for over 1 week.[8]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information on overdose and toxin exposures, as well as poison control centers' contact information, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pentosan polysulfate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **rivoroxaban, warfarin**): Concurrent use may increase the risk for bleeding.
- **Antiplatelet Agents** (eg, **aspirin, clopidogrel**): Concurrent use may increase the risk for bleeding.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one, triamcinolone**): Glucocorticoids could mask the clinical signs associated with septic joints.
- **Heparin, Low Molecular Weight Heparins** (eg, **dalteparin, enoxaparin**): Concurrent use may increase the risk for bleeding.
- **NSAIDs** (eg, **carprofen, phenylbutazone**): NSAIDs could mask the clinical signs associated with septic joints and increase the risk for bleeding.

Laboratory Considerations

- No laboratory interactions or considerations were noted.

Dosages

DOGS:

Treatment of lameness and pain of degenerative joint disease/osteoarthritis (noninfectious arthrosis) in the skeletally mature dog (extra-label): 3 mg/kg SC on 4 occasions with an interval of 5 to 7 days between injections.[7,8] **NOTE**: Other products, with an interval of 5 to 7 days between injections, may be labeled in some markets for IM or SC use.

CATS:

Chondroprotective agent for osteoarthritis (extra-label): 3 mg/kg SC or IM once weekly for 4 weeks has been used anecdotally in cats.[10]

HORSES:

Aid in the treatment of noninfectious, inflammatory joint disease (extra-label): Intramuscular administration: 3 mg/kg IM on 4 occasions with an interval of 5 to 7 days between injections.[7] Intra-articular injection: 1 mL (250 mg) IA. It may be repeated at weekly intervals for 3 to 4 treatments.[11] More than one joint may be treated at one time. The horse should be rested for 2 weeks after the final injection, followed by a further 2 weeks of graded walking exercise before returning to work. (**NOTE**: See the label for specific directions on injection technique.)

Monitoring

- Clinical efficacy (eg, decrease in pain and inflammation in arthritic joints, improved mobility)

- Baseline and periodic packed cell volume (PCV), capillary refill time
- Signs of blood loss. When administered into joints, animals should be assessed for intra-articular bleeding.
- Consider coagulation testing before surgical procedures for patients that have recently received this medication.

Client Information

- If giving this medicine to your animal at home, be sure you understand how to give it.
- Monitor for side effects, including vomiting, decreased appetite, low energy level, and bleeding.
- Pentosan polysulfate is typically administered more than once. Follow the treatment recommendations of your veterinarian. Do not miss important follow up visits.

Chemistry/Synonyms

Pentosan polysulfate sodium, a heparin-like compound, is a mixture of linear polymers of beta-1->4-linked xylose, which is usually sulfated at the 2- and 3- positions. The average molecular weight is between 4000 and 6000. It is not derived from animal sources but Beechwood hemicellulose.

Pentosan may also be known as pentosan polysulphate sodium; PPS; PZ-68; sodium pentosan polysulphate; NaPPS; sodium xylanpolysulphate; SP-54, *Arthropen Vet® 250; Cartrophen-Vet®*, *AU-PEN5000®, Zydax®*, and *Elmiron®*.

Storage/Stability

Unless otherwise labeled, store oral pentosan products at controlled room temperature (15°C-30°C [59°F-86°F]) and injectable pentosan products under refrigeration (2°C-8°C [36°F-46°F]) and protected from light.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No products are currently FDA-approved in the United States.

Injectable pentosan polysulfate sodium 100 mg/mL (*Cartrophen-Vet®* Injection) labeled for use in dogs and pentosan polysulfate sodium 250 mg/mL products (eg, *Arthropen Vet® 250*, *Cartrophen-Vet Forte®* Injection) labeled for use in horses are available in several other countries. Be sure to check local regulations for withdrawal times when used in animals intended for human consumption.

HUMAN-LABELED PRODUCTS:

Pentosan Polysulfate Sodium Oral Capsules: 100 mg; *Elmiron®*; (Rx)

Pentoxifylline

(pen-tox-***ih***-fi-leen) *Trental®*

Hemorrheologic, Immunomodulatory Agent

Prescriber Highlights

- ► Increases erythrocyte flexibility, reduces blood viscosity, and reduces inflammation; used for the treatment of numerous immune-mediated, inflammatory, and ischemic conditions, and may be beneficial for other conditions in which improved microcirculation would be helpful
- ► Contraindications include retinal or cerebral hemorrhage and intolerance or hypersensitivity to pentoxifylline or other xanthines (eg, theophylline).
- ► Use with caution in patients that are at risk for hemorrhage and avoid or dose-reduce in patients with severe hepatic or renal impairment.
- ► Adverse effects are infrequent and when present, typically affect the GI tract (eg, vomiting, inappetence); adverse CNS or cardiovascular effects could also occur.

Uses/Indications

Pentoxifylline is used to treat immune-mediated dermatologic conditions, enhance tissue healing, reduce inflammation, and to improve microcirculation in ischemic conditions and vasculitis.

Reported indications in dogs include[1,2] exfoliative cutaneous lupus erythematosus, idiopathic sterile nodular and vaccine-associated panniculitis,[3] sterile nodular pyogranulomatous/granulomatous syndrome, erythema multiforme,[4] interdigital furunculosis, pemphigus foliaceus,[5] symmetrical lupoid onychodystrophy,[6] proliferative arteritis of the nasal philtrum,[7] antivenom-associated serum sickness,[8] cutaneous and renal vasculopathy of greyhounds,[9] and vasculitis.[10] It is also used for ischemic dermatopathies[11] including familial canine dermatomyositis,[12] ischemic reactions to vaccines,[13] ear tip ulcerative dermatitis/necrosis,[14] and thermal necrosis.[15] There is some evidence for efficacy for pentoxifylline in the treatment of IgE-mediated allergic reactions,[16] contact dermatitis,[17] and as an adjunctive treatment for canine atopic dermatitis.[18]

Limited experience exists for use of pentoxifylline in cats with reported indications including inflammatory dermatologic conditions[19] and cutaneous vasculitis[20] similar to dogs. Pentoxifylline has been used in cats to decrease vasculitis associated with FIP but has failed to demonstrate benefit.[21]

In horses, pentoxifylline has been used as adjunctive therapy for cutaneous vasculitis, placentitis,[22] and atopic dermatitis, and has demonstrated benefit in experimental models of endotoxemia.[23,24] Additionally, the results of one study suggested a potential use for pentoxifylline in treating horses with recurrent airway obstruction, as it effectively reduced reactive oxygen and nitrogen species in pulmonary tissues of affected horses.[25]

Pharmacology/Actions

The mechanisms for pentoxifylline's actions to improve microcirculatory blood flow are not fully understood. The drug increases flexibility of newly formed erythrocytes probably by inhibiting erythrocyte phosphodiesterase and altering erythrocyte electrolyte concentrations. It decreases blood viscosity possibly by stimulating prostacyclin synthesis and release, reducing plasma fibrinogen, decreasing collagen synthesis, and increasing fibrinolytic activity. Pentoxifylline increases leukocyte deformability (flexibility), inhibits neutrophil adhesion and activation and inhibits tumor necrosis factor alpha (TNF-alpha),[26] a cytokine implicated in the pathogenesis of many microvascular disease states. Pentoxifylline is postulated to reduce negative endotoxic effects of cytokine mediators via its phosphodiesterase inhibition.

In healthy dogs, pentoxifylline was also shown to inhibit mast cell degranulation and to significantly decrease the total numbers of cutaneous inflammatory cells, especially eosinophils, impairing late phase reactions but not immediate reactions at site of intradermal injection of IgE-specific antibodies.[27] Several weeks of treatment may be required before beneficial effects are realized.

In horses, pentoxifylline appears to be a potent inhibitor of matrix metalloproteinase-9 and a modest inhibitor of matrix metalloproteinase-2.[28]

Pharmacokinetics

In dogs, pentoxifylline reportedly has a bioavailability of ≈50% with peak concentrations occurring ≈1 to 3 hours after dosing.[29] Serum half-life is ≈6 to 7 hours for the parent compound, 36 hours for active metabolite 1, and 8 hours for active metabolite 2.

In horses, after PO administration of crushed, sustained-release tablets, pentoxifylline is rapidly absorbed with a wide interpatient variation of bioavailability that averages around 68%. Bioavailability may decrease with continued administration over several days. The authors concluded that 10 mg/kg every 12 hours PO yields serum concentrations equivalent to those observed after administration of therapeutic doses to humans and horses.[30]

In humans, pentoxifylline absorption from the GI tract is rapid and almost complete but a significant first-pass effect occurs. Food affects the rate, but not the extent, of absorption. Pentoxifylline is metabolized both in the liver and erythrocytes; all identified metabolites appear to be active. Elimination half-life of drug and metabolites is ≈1 to 2 hours. Metabolites are eliminated in the urine.

Contraindications/Precautions/Warnings

Pentoxifylline should be considered contraindicated in patients that have been intolerant to the drug or xanthines (eg, theophylline, caffeine, theobromine) in the past and those with cerebral hemorrhage or retinal hemorrhage.[31] It should be used cautiously in patients with hepatic or renal impairment.[31]

Adverse Effects

Pentoxifylline is generally well-tolerated in dogs. Most commonly reported adverse effects involve the GI tract (eg, vomiting, inappetence, loose stools) or CNS (eg, excitement, nervousness) in dogs[29,32] and cats.

In horses, IV administration may be associated with transient leukocytosis, muscle fasciculations, sweating on shoulders and flanks, and mild increases in heart rate.[30] Oral dosing at 10 mg/kg or less appears to be well tolerated.

There are reports of dizziness and headache occurring in a small percentage of humans receiving the drug. Other adverse effects, primarily GI, CNS, and cardiovascular related, have been reported in humans but are considered to occur rarely; dosage reduction is recommended in such cases, and the drug should be discontinued if the adverse effects persist.[31] Veterinary experience is limited with pentoxifylline, and animal adverse effects may differ.

Reproductive/Nursing Safety

Pentoxifylline may be teratogenic at high doses. In dogs, high concentration of pentoxifylline was shown to induce capacitation and acrosome reaction and improve quality of motility in ejaculated spermatozoa.[33] Pentoxifylline showed no deleterious effect on sperm motility, viability, and capacitation of cryopreserved stallion epididymal sperm.

Studies in rats and rabbits revealed no evidence of fetal malformation but increased resorption was noted in rats receiving 25 times the maximum labeled dose.

In humans, pentoxifylline and its metabolites are excreted in maternal milk. Because of the potential for tumorigenicity (seen in rats), use cautiously in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Humans overdosed with pentoxifylline have demonstrated signs of flushing, seizures, hypotension, unconsciousness, agitation, fever, somnolence, GI distress, and ECG changes. One human patient who ingested 80 mg/kg recovered completely. Symptoms appear dose-related, and typically persist for ≈12 hours. Overdoses should be treated using appropriate GI decontamination and supportive therapies.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pentoxifylline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **rivaroxaban**, **warfarin**): When pentoxifylline is used with anticoagulants, increased risk for bleeding may result; use together with enhanced monitoring and caution.
- **Antihypertensive Drugs** (eg, **amlodipine, enalapril, telmisartan**): Pentoxifylline may increase hypotensive effect.
- **Cimetidine**: May increase pentoxifylline concentration
- **Fluoroquinolones** (eg, **ciprofloxacin**): May increase pentoxifylline concentration
- **Insulin**: May increase risk of hypoglycemia
- **Macrolides** (eg, **clarithromycin, erythromycin** [not azithromycin]): May increase pentoxifylline concentration
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs**; eg, **carprofen, meloxicam, phenylbutazone**): Concurrent use may increase risk for bleeding. In horses, use of NSAIDs with pentoxifylline is controversial. Some sources state that when used for endotoxemia in horses, pentoxifylline's beneficial effects are negated by NSAIDs, but one study showed superior efficacy when flunixin and pentoxifylline were used together, compared with either used alone.
- **Platelet-Aggregation Inhibitors** (eg, **aspirin, clopidogrel**): Increased risk for bleeding
- **Theophylline**: Theophylline serum concentration may be increased when used concurrently with pentoxifylline.

Laboratory Considerations

- Pentoxifylline could potentially alter **intradermal allergen testing** results. It is advised to discontinue treatment at least one week prior to testing.

Dosages

NOTE: The commercially available pentoxifylline product is a 400 mg extended-release tablet. Cutting or crushing the tablets may negate the extended-release characteristics and alter pharmacokinetics but splitting tablets may be necessary to administer or accurately dose. Avoid crushing tablets for small animal use.

DOGS:

Inflammatory/autoimmune dermatologic conditions (extra-label): 10 – 30 mg/kg PO every 8 to 12 hours. Typically, 15 – 20 mg/kg PO every 8 to 12 hours[34]

Symmetric lupoid onychitis (extra-label): 15 – 25 mg/kg PO every 12 hours[35]

Ischemic dermatopathies (extra-label): 15 mg/kg PO every 8 hours to 30 mg/kg PO every 12 hours.[11] One open label study used 25 mg/kg PO every 12 hours.[36]

Vasculitis (extra-label): 10 – 15 mg/kg PO every 12 hours[37]

CATS:

Inflammatory dermatologic conditions (extra-label): 100 mg/cat (NOT mg/kg) PO every 12 hours[19]

Cutaneous vasculitis (extra-label): 10 – 15 mg/kg PO every 12 hours[37]

HORSES:

Cutaneous vasculitis (extra-label): From a pharmacokinetic study, 10 mg/kg PO every 12 hours yields serum concentrations equivalent to those observed after administration of therapeutic doses to humans and horses. Sustained-release tablets may be crushed and mixed with molasses. If efficacy wanes with time, consider increasing the dosage to 15 mg/kg PO twice daily or 10 mg/kg PO 3 times a day. In the experience of the authors, 10 mg/kg PO twice daily for 30 days results in clinical response in horses with cutaneous vasculitis.[38]

Inflammatory/autoimmune dermatologic conditions (extra-label): 8 – 10 mg/kg PO every 8 to 12 hours[39]

Placentitis (extra-label): From a study in pony mares with experimentally induced equine placentitis. Treated group was given trimethoprim/sulfamethoxazole 30 mg/kg PO every 12 hours, pentoxifylline 8.5 mg/kg PO every 12 hours, and altrenogest 0.088 mg/kg PO every 24 hours from the onset of clinical signs to delivery of a live foal or abortion. 83% of treated mares delivered viable foals.[40]

Monitoring

- Efficacy
- Adverse effects (eg, hyporexia, vomiting, diarrhea, hyperexcitability)
- Consider more intensive monitoring for evidence of hemorrhage (eg, PCV) in patients with increased risk of bleeding, such as recent surgery or GI ulceration.

Client Information

- Give this medicine with food.
- Side effects are not common in dogs but may include loss of appetite, vomiting, and nervousness or excitement. This medicine is usually well tolerated in horses.
- This medicine may cause an increased risk for bleeding, particularly in animals that may be predisposed to this problem.
- This medicine can take 1 to 2 weeks (or longer) to see its full effect.
- Extended-release tablets can be split if necessary to give the appropriate dose. Crushing the tablets may increase the risk for side effects and should be avoided when possible.

Chemistry/Synonyms

A synthetic xanthine derivative structurally related to caffeine and theophylline, pentoxifylline occurs as a white, odorless, bitter-tasting, crystalline powder that is soluble in water and sparingly soluble in alcohol.

Pentoxifylline may also be known as BL-191, oxpentifylline, pentoxifyllinum, *Pentoxil®*, PTX, and *Trental®*.

Storage/Stability

The commercially available tablets should be stored in well-closed containers, protected from light at 20°C to 25°C (68°F -77°F).

Compatibility/Compounding Considerations

The commercially available product in the United States is a 400 mg extended-release tablet (labeled for human use). Cutting or crushing tablets may negate the sustained-release characteristics and alter pharmacokinetics[41]; however, splitting tablets may be necessary to administer or accurately dose. Avoid use of crushed tablets in dogs or cats as adverse effects (hyperexcitability, diarrhea) may occur; crushing tablets may be required for horses.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Pentoxifylline Controlled-/Extended-Release Tablets: 400 mg; generic; (Rx). See ***Compatibility/Compounding Considerations***.

Pergolide

(***per***-go-lide) *Prascend®*

Dopamine Agonist

Prescriber Highlights

- ► Used in horses to control clinical signs associated with pituitary pars intermedia dysfunction (PPID)
- ► Contraindications include in patients that are hypersensitive to ergot derivatives.
- ► Well tolerated in horses; anorexia may occur

Uses/Indications

Pergolide is FDA-approved for use in horses for the control of clinical signs associated with pituitary pars intermedia dysfunction (PPID).

Pharmacology/Actions

Pergolide is a potent agonist at dopamine (D_1 and D_2) receptors and is 10 to 1000 times more potent than bromocriptine.[1] It is thought that pituitary pars intermedia dysfunction (PPID) in horses is a degenerative disease associated with loss of dopaminergic control of the melanotropes of the pars intermedia, with a subsequent overproduction of proopiomelanocortin (POMC) and POMC-derived peptides. These POMC-derived peptides are implicated in causing the signs associated with PPID. In horses with PPID, pergolide is believed to exert its therapeutic effect by stimulating dopamine receptors and has been shown to decrease the plasma levels of adrenocorticotropic hormone (ACTH), alpha-melanocyte-stimulating hormone (MSH), and other POMC-derived peptides. Additionally, pergolide inhibits the release of prolactin, which suggests that it may interfere with lactation.

Pharmacokinetics

Pharmacokinetic studies of pergolide in horses are limited and provide varying information. In horses, pergolide is reportedly 90% plasma protein-bound.[2] Pharmacokinetic information in horses is based on a study using single oral doses of 10 µg/kg in 6 healthy mares between 3 and 17 years of age. Pergolide was rapidly absorbed with an average maximum concentration (C_{max}) of ≈4 ng/mL and a median time to maximum concentration (T_{max}) of ≈0.4 hours. The area under the curve (AUC) was ≈14 hours ng/mL. The mean half-life was ≈5.9 hours; mean apparent oral clearance (CL/F) was 1204 mL/kg/hour; and mean apparent volume of distribution (V/F) was ≈3082 mL/kg. Below are summaries of each study.

In horses (6 in the study), pergolide was rapidly absorbed following oral administration (0.01 mg/kg), with plasma concentra-

tions reaching maximum concentrations within 1 hour of dosing.[3] Maximum plasma concentrations ranged from 1.07 to 3.38 ng/mL. Pergolide appears to be rapidly and widely distributed. Elimination half-life averaged 27 hours, but there was high interpatient variation.

In a study evaluating 6 aged (18 to 28 years old) horses with PPID, 2 mg (≈0.004 mg/kg) of pergolide was dissolved in water and immediately given in the feed each day over a period of 6 months.[4] Pharmacokinetic parameters were measured after the last dose. Maximum plasma concentrations were reached on average within 1 hour of dosing at concentrations ranging from 0 to 1.38 ng/mL. The average elimination half-life was determined to be 19.7 hours.

In a study evaluating 8 healthy, young horses, pergolide 0.02 mg/kg IV was given.[5] The mean C_{max} was found to be 15.62 ng/mL, with a mean terminal elimination half-life of 5.64 hours.

In humans, the drug is orally absorbed (estimated 60% bioavailable) and 90% bound to plasma proteins. At least 10 different metabolites have been identified, some of which are active. The principal route of elimination is via the kidneys.

Contraindications/Precautions

Pergolide is contraindicated in patients that are hypersensitive to it or other ergot derivatives. Treatment with pergolide may cause inappetence.[2]

In humans, caution is recommended in patients that are prone to cardiac arrhythmias.[1]

Pergolide should not be handled by anyone who has experienced adverse reactions to ergotamine or ergot derivatives (eg, bromocriptine). Pergolide has been reported to cause eye irritation, an irritating smell, or headache when tablets are split or crushed[2]; therefore, tablets should not be crushed, and care should be taken to minimize exposure when tablets are split. Wear gloves when handling this product if pregnant or nursing.[2]

Adverse Effects

Pergolide appears to be well tolerated in horses. Decreased appetite is seen during the first week of therapy[2]; temporary dose reduction is often beneficial in alleviating this effect. Lethargy, colic, diarrhea, and weight loss have been reported to occur more rarely.

In post-approval reports, additional adverse effects included dermatologic effects such as alopecia, hyperhidrosis, and dermatitis; musculoskeletal effects such as laminitis and muscle stiffness/soreness; and neurologic effects such as ataxia, seizures, and muscle tremors.[2] Behavioral aggression was also reported.

In humans, common adverse effects reported include CNS effects (eg, dyskinesia, hallucinations, somnolence, insomnia), GI effects (eg, nausea, vomiting, diarrhea, constipation), transient hypotension, and rhinitis.[1]

Reproductive/Nursing Safety

In pregnant mice and rabbits given pergolide, no evidence of fetal harm was seen[1]; however, the safety of pergolide in pregnant horses has not been established.[2] It is not known if pergolide enters maternal milk; however, like other ergot-derivative dopamine agonists, it may interfere with lactation.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

There is limited information available on pergolide overdoses. Potential effects include GI disturbances, CNS effects, seizures, and hypotension. One pony that was given a single 110-fold overdose of pergolide demonstrated transient tachycardia, a decreased appetite, and anxiety.[6]

Clinical signs associated with a pergolide overdose in dogs include vomiting, lethargy, and trembling. In cats, hyperthermia, mydriasis, and elevation of the third eyelids may be seen.

Treatment is supportive based on clinical presentation. Activated charcoal may help prevent absorption; phenothiazines may decrease CNS stimulation effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pergolide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Dopamine Antagonists** (eg, **phenothiazines**): May decrease the effects of pergolide
- **Metoclopramide**: May decrease the effects of pergolide

Laboratory Considerations

- None noted

Dosages

HORSES:

Control of clinical signs associated with pituitary pars intermedia dysfunction (PPID; label dosage; FDA approved): Starting dosage of 2 µg/kg PO once daily, then adjust to effect.[2] Dose titration is based on individual response to therapy, including improvement in clinical signs associated with PPID and/or improvement or normalization of endocrine tests. Titrate to achieve the lowest effective dose. Tablets are scored and dose should be rounded to the nearest half-tablet increment, not to exceed 4 µg/kg daily. If signs of dose intolerance develop, decrease the dose by 50% for 3 to 5 days, then titrate back up in 2 µg/kg increments every 2 weeks until the desired effect is achieved.[2] **NOTE**: Although early studies noted maximum daily doses of 10 µg/kg, the currently recommended daily maximum dose is 4 µg/kg. Doses higher than 4 µg/kg should be only used in extenuating circumstances where no effect is achieved with doses between 2 and 4 µg/kg.[5]

Monitoring

- Baseline and periodic endogenous adrenocorticotropic hormone (ACTH). Periodic testing should begin 1 to 3 months after starting treatment or changing the dose. Once clinical signs are controlled, testing can be done every 6 to 12 months.[7] **NOTE**: The results of this testing should take seasonal variation into account. A TRH stimulation test may be necessary for those horses with equivocal ACTH levels.
- Clinical signs (improvements in quality of hair coat, body weight, PU/PD)

Client Information

- Pergolide does not cure your horse's condition. This medicine is intended to help control the signs associated with it. This medicine may take several weeks to months to see positive effects.
- It is important to not crush tablets to avoid exposure to the medicine.
- People who have had adverse reactions to ergotamine or other ergot derivatives should not administer pergolide.
- Pregnant or nursing women should wear gloves when handling this medicine.
- Keep pergolide tablets in a secure location out of reach of children and animals to prevent accidental ingestion or overdose. Animals

may get sick if they eat horse feed mixed with this medicine.
- Decreased appetite is the most common side effect seen with this medicine.
- Watch for unpredictable behavior and colic while your horse is taking this medicine. Contact your veterinarian if you have any concerns.
- Your veterinarian will need to monitor your horse while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

Pergolide is an ergot derivative that occurs as white to off-white powder and is slightly soluble in water, dehydrated alcohol, or chloroform. It is very slightly soluble in acetone, practically insoluble in ether, and sparingly soluble in methyl alcohol.

Pergolide mesylate may also be known as LY-127809, pergolide mesilate, pergolidi mesilas, *Prascend®*, *Celance®*, *Nopar®*, *Parkotil®*, *Parlide®*, or *Pharken®*.

Storage/Stability

Store pergolide tablets in tight containers at room temperature (25°C [77°F]); excursions permitted to 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

FDA-approved products should be the first choice when prescribing pergolide for pituitary pars intermedia dysfunction (PPID). Compounded products are available; however, because of concerns regarding stability, the use of this product is questionable when the approved product is accessible.

A 1 mg/mL oral suspension of pergolide mesylate was prepared using bulk powder obtained from a commercial supplier. 20 mg of pergolide mesylate was added to the plunger of a 35 mL Luer-lock syringe containing 10 mL of *Ora-Plus®* suspending liquid. The 35 mL syringe was connected to an empty 35 mL Luer-lock syringe using a fluid-dispensing connector. Using the plunger of the original 35 mL syringe, the suspension was mixed by depressing the plungers back and forth for a total of 50 depressions (or until uniformly mixed). 10 mL of *OraSweet®* was added to the suspension and mixed in a similar manner for a final suspension volume of 20 mL. The suspension was found to be stable for 30 days when protected from light and stored under refrigeration (2°C-8°C [36°F-46°F]). Formulations that have undergone a color change should be considered unstable and discarded. **NOTE**: The use of a mortar and pestle to prepare this suspension is not recommended, as it has resulted in a loss of suspending vehicle that caused a 20% increase in final concentration. Proper precautions to prevent eye and skin irritation from exposure to free powder should be taken.[8]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Pergolide Mesylate Tablets: 1 mg; *Prascend®*; (Rx) FDA-approved for use in horses. NADA# 141-331. Do not use this product in horses intended for human consumption.

HUMAN-LABELED PRODUCTS: NONE

Because of an increased potential for heart valve damage associated with pergolide use in humans, all dosage forms were withdrawn from the United States market in the spring of 2007.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Phenobarbital

Phenobarbitone

(fee-noe-***bar***-bi-tal)

Barbiturate

Prescriber Highlights

- ► Used primarily as an antiseizure medication
- ► Contraindicated in patients with known hypersensitivity, severe liver disease, severe respiratory distress, or nephritis (with large doses). Phenobarbital should be used with caution in patients with hypovolemia, anemia, borderline hypoadrenal function, or severe cardiac or respiratory disease.
- ► Cats are more sensitive to respiratory depression when receiving phenobarbital at high doses.
- ► Adverse effects in dogs include anxiety/agitation or lethargy (when treatment is initiated); profound depression is possible even at low doses. Sedation, ataxia, polyuria/polydipsia, and polyphagia can be seen at moderate to high serum phenobarbital concentrations. An increase in liver enzymes (ALP more so than ALT) is common; however, overt hepatotoxicity is not. Anemia, thrombocytopenia, and neutropenia are rarely seen.
- ► Adverse effects in cats include ataxia, lethargy, facial pruritus, polyphagia with weight gain, and polyuria/polydipsia. Immunemediated reactions and bone marrow hypoplasia are rare. Hepatotoxicity has not been reported in cats.
- ► Should be given slowly when administered IV; should not be administered SC or perivascularly, as it can cause severe irritation
- ► Drug and drug–laboratory test interactions are possible.
- ► When therapy is discontinued, phenobarbital doses should be tapered over several weeks (see ***Dosages***).
- ► DEA Schedule IV (C-IV) controlled substance

Uses/Indications

Based on its efficacy, relative safety, and reasonable dose frequency (every 12 hours), phenobarbital is considered a first-line treatment for epilepsy in dogs and cats.[1,2] Phenobarbital has a slower onset of action than benzodiazepines, which should be used first to manage status epilepticus. Phenobarbital is generally used for long-term control to prevent seizure recurrence in dogs, cats, and horses. In a study, more dogs receiving phenobarbital were seizure-free as compared with those receiving potassium bromide (85% vs 52%); phenobarbital reduced seizure duration more than potassium bromide.[3]

Phenobarbital may also be useful in controlling excessive drooling (ie, sialadenosis) in horses[4] and dogs.[5–9] Phenobarbital improves clinical signs in dogs with orthostatic tremor; however, most responses were partial rather than complete.[10]

In cattle, it has been suggested that the microsomal–enzyme-stimulating properties of phenobarbital increase the detoxification process of organochlorine (ie, chlorinated hydrocarbon) insecticide poisoning.

Phenobarbital has also been used in the treatment and prevention of neonatal hyperbilirubinemia in human infants. It is unknown if phenobarbital effectively treats hyperbilirubinemia in veterinary patients.

Pharmacology/Actions

Although barbiturates are nonselective CNS depressants, they can invoke all levels of CNS mood alteration, from paradoxical excitement to deep coma and death. The exact mechanisms of the CNS effects caused by barbiturates are unknown. Barbiturates have been shown to inhibit the release of acetylcholine, norepinephrine, and glutamate; they also have effects on gamma-aminobutyric acid

(GABA). At high anesthetic doses, barbiturates have been demonstrated to inhibit the uptake of calcium at nerve endings. The seizure threshold is raised, and the spread of seizures is limited. In humans, selective anticonvulsant activity of phenobarbital is independent of the degree of sedation produced.

The degree of CNS depression produced is dependent on the dose, route of administration, the pharmacokinetics of the drug, and species treated. In addition, patient age, physical condition, and/or concurrent use of other drugs can alter drug effects. Barbiturates may depress the sensory cortex, lessen motor activity, and produce sedation at low doses. In humans, barbiturates have been shown to reduce the rapid eye movement (REM) stage of sleep. Barbiturates have no true intrinsic analgesic activity.

In most species, barbiturates can cause dose-dependent respiratory depression and, in some species, can cause slight respiratory stimulation. At sedative/hypnotic doses, respiratory depression is similar to that during normal physiologic sleep. As doses increase, the medullary respiratory center is progressively depressed, with resultant decreases in rate, depth, and volume. Respiratory arrest can occur at doses 4 times lower than those that can cause cardiac arrest. Barbiturates must be used very cautiously in cats, as cats are particularly sensitive to their respiratory depressant effects.

Barbiturates can cause reduced tone and motility of the intestinal, uterine, ureteral, and bladder musculature, likely secondary to their central depressant action. Barbiturates can reduce the sensitivity of the motor endplate to acetylcholine, thereby slightly relaxing the skeletal muscle.

Liver function is not directly affected when barbiturates are used short-term, but hepatic microsomal enzyme induction is well documented with extended barbiturate administration,[11–14] particularly with phenobarbital, and may persist for up to 4 weeks after discontinuation.[11] Although barbiturates reduce oxygen consumption in all tissue, no change in metabolic rate is measurable when barbiturates are administered at sedative doses; however, basal metabolic rates may be reduced with resultant decreases in body temperature when barbiturates are administered at anesthetic doses.

Pharmacokinetics

Phenobarbital is slowly absorbed from the GI tract. Bioavailability ranges from 70% to 90% in humans and ≈90% in dogs.[15,16] Absorption is practically complete in cats[17] and adult horses.[18] Peak concentrations occur 4 to 8 hours after oral administration in dogs[19] and 8 to 12 hours in humans. One study in cats showed that phenobarbital compounded in PLO gel and applied transdermally to the pinna twice daily achieved steady-state serum concentrations within the therapeutic range in some cats; more individual variation was seen when *Lipoderm ActiveMax*® was used instead of PLO.[20]

Phenobarbital is widely distributed throughout the body, but because of its lower lipid solubility, it does not distribute as rapidly into the CNS as compared with most other barbiturates. In humans, peak drug concentration in the CNS may be delayed up to 15 minutes after IV administration. In humans, the amount of phenobarbital bound to plasma proteins has been reported to be 40% to 60%. The reported apparent volumes of distribution are ≈0.8 to 1 L/kg in horses,[21,22] ≈0.86 L/kg in foals, ≈0.7 L/kg in cats,[23] and ≈0.75 L/kg in dogs.[24]

The drug is metabolized in the liver primarily by hydroxylated oxidation to p-hydroxyphenobarbital; sulfate and glucuronide conjugates are also formed. In humans, elimination half-life ranges from 2 to 6 days compared to 12 to 125 hours (average of ≈2 days) in dogs.[16,19,24] Elimination half-life in dogs fed protein- or fat-restricted diets appears to be shorter (26 and 24 hours, respectively).[25] Because of phenobarbital's ability to induce the hepatic enzymes used to metabolize itself and other drugs, elimination half-life may decrease with time, along with concomitant reductions in serum concentrations. The half-life of phenobarbital may be less than 24 hours in some dogs that may require 3 times daily administration for maximal control.[26] An elimination half-life of 34 to 43 hours has been reported in cats.[23] Elimination half-life in horses is considerably shorter, with reported values of ≈13 hours in foals and 10 to 12 hours in adult horses with chronic administration.[21,22] Approximately 25% of a dose is excreted unchanged by the kidney; alkalinizing urine and/or substantially increasing urine flow increases phenobarbital excretion rates. The remaining 75% of a dose is renally excreted as metabolites. Anuric or oliguric patients may accumulate the unmetabolized drug; dose adjustments may be required.

In dogs, changes in diet, body weight, and body composition may alter the pharmacokinetics of phenobarbital and necessitate dosage adjustment.

In goats given phenobarbital 10 mg/kg IV and PO, bioavailability was ≈25%, and half-life was ≈4 hours for both routes.[27]

Contraindications/Precautions/Warnings

Barbiturates are contraindicated in patients that have severe liver disease, severe respiratory distress, or those that have demonstrated previous hypersensitivity reactions to these drugs.[28] Large doses are contraindicated in patients with nephritis.[29] Barbiturates should be used cautiously in patients with hypovolemia, anemia, borderline hypoadrenal function, and/or cardiac or respiratory disease. Dose reductions may be necessary in patients with significant renal impairment.

The drug should be given slowly (not more than 1 – 2 mg/kg per minute) when administered IV; IV administration that is too rapid can cause respiratory depression. Commercially available injectable preparations are very alkaline and must not be administered SC, intraarterially, or perivascularly, as significant pain, tissue irritation, and possible necrosis can result.[29] Extreme care should be taken to avoid extravasation. Applications of moist heat and local infiltration of 0.5% procaine solution have been recommended to treat extravasation reactions.

In humans, IM injection is limited to a total volume of 5 mL and injected into a large muscle to avoid tissue irritation.[29]

PHENobarbital should not be confused with PENTobarbital.

Adverse Effects

Dogs may exhibit increased clinical signs of anxiety/agitation or lethargy when therapy is initiated. These effects are generally transitory in nature. Occasionally, dogs will exhibit profound depression at lower doses (and plasma concentrations). Decreased physical activity levels have been observed in dogs receiving phenobarbital-containing antiepileptic drug combinations.[30]

Polydipsia, polyuria, and polyphagia are also commonly observed; these signs usually begin 2 to 3 weeks after initiating phenobarbital therapy. Sedation and/or ataxia often become significant concerns as serum phenobarbital concentrations reach the higher ends of the therapeutic range. Anemia, thrombocytopenia, and/or neutropenia occur rarely and are reversible if detected early.[31–33] Increased triglycerides[34] and pancreatic lipase activity[35,36] have been reported in dogs.

Increases in liver enzymes with phenobarbital in dogs are well described[37–39] and are not necessarily indicative of liver dysfunction but should raise concern if serum ALT or ALP is more than 4 to 5 times the upper limit of normal or if any elevation in gamma-glutamyltransferase (GGT) is noted. Of note, in a study, serum ALP was higher in dogs receiving phenobarbital and fed protein- or fat-restricted diets as compared with dogs receiving a maintenance diet.[25] Phenobarbital should generally be discontinued if any increases in serum bilirubin, total serum bile acids, or hypoalbuminemia are detected. If phenobarbital needs to be discontinued yet antiepileptic medication is required, alternative antiepileptic therapy (eg, potassium bromide,

levetiracetam) should be started immediately. Frank hepatic failure is uncommon and is usually associated with higher serum phenobarbital levels (greater than 30 to 40 µg/mL).[39] In a study, hematologic abnormalities occurred within the first 3 months of therapy in 4.2% of dogs treated with standard doses.[40]

In dogs, phenobarbital rarely causes superficial necrolytic dermatitis (SND) associated with changes in hepatocytes (ie, severe parenchymal collapse with glycogen-laden hepatocytes and moderate fibrosis sharply demarcated by nodules of normal hepatic parenchyma)[41] distinct from that seen with phenobarbital hepatotoxicity (ie, chronic hepatic fibrosis with nodular regeneration [cirrhosis]).[39] A presumed case of Stevens-Johnson syndrome in a dog has also been reported.[42]

Phenobarbital may increase the metabolism of cortisol and has been implicated in contributing to relative adrenal insufficiency,[43] including a case of Addisonian crisis in an Irish setter.[44] Pseudolymphoma has been documented or suspected in at least 1 dog[45] and 2 cats.[46,47]

Cats may develop ataxia, persistent sedation and/or lethargy, facial pruritus, polyphagia/weight gain, and/or polydipsia/polyuria. Rarely, immune-mediated reactions and bone marrow hypoplasia (eg, thrombocytopenia, neutropenia) may be seen.[48] A presumed case of phenobarbital-induced fever has been reported in a cat.[49] Phenobarbital-induced anticonvulsant hypersensitivity syndrome has also been reported. In 1 cat, tachypnea, hyperthermia, high serum amyloid A, and abdominal lymph node enlargement were seen 8 days after initiation of phenobarbital.[50] Another cat presented immune-mediated anemia 2 weeks after starting phenobarbital.[51]

Cats, unlike dogs, do not develop increased liver enzymes; increases in liver enzymes in cats on phenobarbital should prompt further investigation. High doses (ie, 10 – 40 mg/kg/day) have caused coagulopathies in cats.[52,53]

Although there is much less information regarding phenobarbital use in horses (and foals in particular), cattle, goats, and ferrets, it would generally be expected for adverse effects to mirror those seen in other species.

In humans, phenobarbital can cause rare, possibly fatal, hypersensitivity reactions, including exfoliative dermatitis and Stevens-Johnson syndrome.[28] It is recommended to discontinue use whenever dermatologic reactions occur.

Reproductive/Nursing Safety

Barbiturates readily cross the placenta.[28,29] Phenobarbital has been associated with rare congenital defects and bleeding problems in newborns but may be safer than other anticonvulsants. Clinical signs related to withdrawal can occur in offspring born to dams receiving phenobarbital.

Caution should be used when administering to a nursing dam, as small amounts are excreted in maternal milk. Drowsiness in nursing offspring has been reported. A foal born to a mare receiving phenobarbital reportedly had a serum phenobarbital concentration of 12.2 µg/mL, and the concentration in the mare's milk was 7.5 µg/mL.[54]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs caused by overdoses of phenobarbital are an extension of its adverse effect profile. Animals may present with ataxia, lethargy/sedation, hypothermia, recumbency, and mydriasis (cats).

Barbiturates have no direct effect on the kidneys, but severe renal impairment can occur secondary to hypotensive effects in overdose situations.

Treatment of phenobarbital overdose consists of GI decontamination, if appropriate, and respiratory and cardiovascular support. Activated charcoal has been shown to be of considerable benefit in enhancing the clearance of phenobarbital even when the drug was administered parenterally. Charcoal acts as a sink for the drug to diffuse from the vasculature back into the gut. Forced alkaline diuresis can also be of substantial benefit in augmenting the elimination of phenobarbital in patients with normal renal function. Peritoneal dialysis or hemodialysis can be helpful in severe intoxications or anuric patients.[55]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

In humans, phenobarbital induces CYP 3A strongly and most other CYP isoenzymes to a lesser degree; it is a substrate of CYP 2C19. The following drug interactions have either been reported or are theoretical in humans or animals receiving phenobarbital and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetaminophen**: Increased risk for hepatotoxicity, particularly when large or chronic doses of barbiturates are administered
- **Alpha-2 Agonists** (eg, **dexmedetomidine, xylazine**): Concurrent use may result in additive respiratory depression.
- **Antihistamines** (eg, **diphenhydramine**): May increase the effects of phenobarbital
- **Benzodiazepines** (eg, **diazepam, midazolam**): Concurrent use may result in additive respiratory depression.
- **Bromides**: Synergistic efficacy and toxicity
- **Carprofen**: There may be an increased risk for hepatotoxicity secondary to carprofen metabolites. One source states that patients should not receive phenobarbital or other hepatic drug-metabolizing enzyme inducers when receiving carprofen.[56]
- **Chloramphenicol**: May increase the effects of phenobarbital
- **Cholestyramine**: May reduce phenobarbital absorption and/or levels. Should be administered separately
- **CNS Depressants** (eg, **methocarbamol**, **mirtazapine**, **trazodone**): Concurrent use may result in additive respiratory and CNS depression.
- **Felbamate**: May increase the effects of phenobarbital
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz**, **selegiline**): May prolong phenobarbital effects
- **Opioids** (eg, **buprenorphine, hydrocodone, morphine, tramadol**): Concurrent use may result in additive respiratory and CNS depression.
- **Phenothiazines** (eg, **acepromazine**): May increase the effects of phenobarbital
- **Rifampin**: May induce enzymes that increase the metabolism of barbiturates
- **Urinary Acidifiers** (eg, **ammonium chloride**): Unchanged phenobarbital elimination in urine may be decreased and cause an increase in serum half-life.[57]

Phenobarbital (particularly after chronic therapy) may decrease the effects of the following drugs/drug classes by lowering their serum concentrations; effects may persist for several weeks after phenobarbital is discontinued[11]; these drugs may require initial or maintenance doses that are at or above the higher end of the dosing range, and doses of these drugs may need to be reduced when phenobarbital is being discontinued:

- **Azole Antifungals** (eg, **itraconazole, ketoconazole, voriconazole**): Phenobarbital levels may be increased, and antifungal levels may be decreased. Concurrent use is contraindicated in humans.
- **Benzimidazoles** (eg, **albendazole, fenbendazole**): May reduce active metabolite concentration
- **Benzodiazepines** (eg, **clorazepate, diazepam**)[58]
- **Buspirone**
- **Chloramphenicol**: Concurrent use also may increase the risk for phenobarbital toxicity.
- **Clarithromycin**
- **Clindamycin**
- **Corticosteroids** (eg, **dexamethasone, methylprednisolone, prednis[ol]one**)
- **Cyclosporine**[59]
- **Digoxin**[60]
- **Doxorubicin**
- **Doxycycline**
- **Estrogens** (eg, **diethylstilbestrol [DES], estriol**)
- **Felbamate**: Phenobarbital concentrations may increase, and felbamate concentrations may decrease.
- **Griseofulvin**
- **Ivermectin**
- **Levetiracetam**: Levetiracetam dosage requirements are increased by phenobarbital. In dogs receiving immediate-release levetiracetam, phenobarbital therapy reduced levetiracetam elimination half-life by ≈35% to 50%.[61] In dogs receiving extended-release levetiracetam, phenobarbital reduced levetiracetam peak concentration and increased clearance, although half-life appeared to be unaffected.[62]
- **Levothyroxine**
- **Methadone**
- **Metoprolol**
- **Metronidazole**
- **Quinidine**
- **Paroxetine**
- **Phenothiazines** (eg, **acepromazine**)
- **Praziquantel**
- **Progestins** (eg, **medroxyprogesterone**)
- **Sulfonamides**[14]
- **Tacrolimus**
- **Theophylline, Aminophylline**
- **Topiramate**
- **Tricyclic Antidepressants**
- **Urinary Alkalinizers** (eg, **potassium citrate**): Unchanged phenobarbital elimination in urine may be increased and cause a decrease in serum half-life.[57]
- **Verapamil**
- **Vincristine**
- **Vitamin D**
- **Warfarin**
- **Zonisamide**[63]

Laboratory Considerations

- Barbiturates may cause increased retention of **bromosulfophthalein** (BSP; sulfobromophthalein) and give falsely elevated results. It is recommended that barbiturates not be administered within the 24 hours before a BSP retention test is performed or, if they must be administered (eg, for seizure control), the results be interpreted accordingly.[64,65]
- Phenobarbital can alter the results of **thyroid** testing. Decreased total and free thyroxine (T_4), normal triiodothyronine (T_3), and either normal or increased thyroid-stimulating hormone (TSH) have been reported. It has been suggested to wait at least 4 weeks after discontinuing phenobarbital to perform thyroid testing.[38,66]
- In some dogs, phenobarbital may cause a false-positive **low dose dexamethasone suppression test** by increasing the clearance of dexamethasone. Phenobarbital apparently has no effect either on adrenocorticotropic hormone (ACTH) stimulation tests or on the hormonal equilibrium of the adrenal axis. Because phenobarbital can potentially increase the metabolism of cortisol, it has been implicated in contributing to relative adrenal insufficiency.

Dosages

DOGS:

Idiopathic epilepsy (extra-label): Initially, 2.5 – 3 mg/kg PO every 12 hours is commonly recommended, although starting dosages may vary. To achieve therapeutic phenobarbital concentrations sooner in phenobarbital-naïve dogs, some clinicians suggest an initial loading dose of 12 – 20 mg/kg (total dose); this dose can be administered as a single, slow (over at least 5 minutes) IV injection but may cause profound sedation and respiratory depression.[67] To minimize these effects, the total dose can be divided into increments of 3 – 4 mg/kg IV every 1 to 4 hours; the degree of sedation and respiratory depression during administration should be monitored, and subsequent doses should be adjusted accordingly. Doses should be adjusted based on phenobarbital concentrations, efficacy, and adverse effects. Administration of 3 – 5.6 mg/kg PO every 8 hours in dogs with a shorter phenobarbital elimination half-life appeared safe and improved seizure management in some patients.[26] Combination with other anticonvulsants is common.

Adjunctive treatment of status epilepticus (extra-label): After use of benzodiazepines (eg, diazepam, midazolam), phenobarbital 4 – 8 mg/kg IV slow (over at least 5 minutes) can be administered. If seizure activity continues, additional increments of phenobarbital can be administered at 4 mg/kg IV every 20 to 30 minutes with a maximum total phenobarbital dose of 20 – 24 mg/kg IV.[67,68] Once seizure activity has diminished and the patient is alert, the patient can be transitioned to oral phenobarbital, as noted above.

Sialadenosis (extra-label): In case reports, 1 mg/kg PO every 12 hours appears to be most common, although dosages up to 2.5 mg/kg PO twice daily have been noted.[69] In one case,[5] 6 mg/kg IM every 12 hours was initially prescribed. In several but not all cases, dogs were slowly weaned off phenobarbital without relapse.[5,6,9,70]

Discontinuing phenobarbital therapy (taper guidelines): Tapering guidelines may vary and are anecdotal. In general, for patients stabilized on another anticonvulsant, a typical tapering schedule involves reducing the phenobarbital dose by 25% every 2 weeks. Smaller dose decreases (eg, 10% to 20%) or longer intervals between reductions (eg, every 3 to 4 weeks) can be considered. Available tablet size may dictate actual dose decrease. Reductions can be made more rapidly (eg, every 7 days) if necessary (eg, fulminant phenobarbital hepatotoxicity); because seizure activity may increase during a rapid taper, concurrently initiating another anticonvulsant is recommended. Doses of other anticonvulsants may need to be reduced as phenobarbital's effects on CYP enzyme induction wane, which may take several weeks after discontinuation.

CATS:

Idiopathic epilepsy (extra-label): Initially, 1 – 3 mg/kg PO every 12 hours is commonly recommended, although starting dosages may vary. Cats receiving phenobarbital 2.5 – 8.6 mg/kg/day PO

had a therapeutic serum phenobarbital concentration between 15 and 45 µg/mL; seizure control can be achieved in most cats in this range regardless of the cause of the seizures.[71] Practically, ½ to one 15 mg tablet/cat (NOT mg/kg) PO every 12 hours is used. To achieve therapeutic phenobarbital concentrations sooner in phenobarbital-naïve cats, some suggest an initial phenobarbital loading dose of 12 – 24 mg/kg IV given in increments of 3 to 4 mg/kg IV every 2 to 6 hours. The dose should be adjusted based on phenobarbital concentrations, efficacy, and adverse effects.

Transdermal phenobarbital compounded in PLO (extra-label): 9 mg/kg applied to the inside of the pinna every 12 hours (18 mg/kg/day). Therapeutic concentrations may be achieved in some cats, and consistent monitoring is recommended.[20,72] Further study is warranted to prove this route effectively controls seizures.

Adjunctive treatment of status epilepticus (extra-label): After use of benzodiazepines (eg, diazepam, midazolam), phenobarbital 3 mg/kg IV can be administered. Phenobarbital can be repeated every 20 minutes up to 24 mg/kg in a 24-hour period or given as loading of 10 mg/kg IV bolus.[67,68,73]

Discontinuing phenobarbital therapy (taper guidelines): In patients stabilized on another anticonvulsant, a typical tapering schedule involves reducing the phenobarbital dose by 25% every 2 weeks. Smaller dose decreases (eg, 10% to 20%) or longer intervals between reductions (eg, every 3 to 4 weeks) can be considered. Available tablet size may dictate actual dose decrease. Reductions can be made more rapidly (eg, every 7 days) if necessary; because seizure activity may increase during a rapid taper, concurrently initiating another anticonvulsant is recommended. Doses of other anticonvulsants may need to be reduced as phenobarbital's effects on CYP enzyme induction wane, which may take several weeks after discontinuation.

HORSES:

Seizure control (extra-label):

a) Adult horses: Loading dose of 16 – 20 mg/kg IV once; maintenance dose of 1 – 5 mg/kg PO every 12 hours

b) Foals: Loading dose of 16 – 20 mg/kg IV once; maintenance dose of 100 – 500 mg/foal (NOT mg/kg) PO every 12 hours[74,75]

CATTLE:

Enzyme induction in organochlorine toxicity (extra-label): 5 g/animal (NOT mg/kg) PO for 3 to 4 weeks, off 3 to 4 weeks, then repeat for 3 to 4 more weeks[76]

FERRETS:

Seizure control (extra-label): Loading dose of 16 – 20 mg/kg IV once; maintenance dose of 1 – 2 mg/kg PO every 8 to 12 hours[74,75]

Monitoring

- Anticonvulsant efficacy
- Adverse effects (eg, CNS related, polyuria/polydipsia, weight gain)
- Serum phenobarbital concentration:
  - After initiation of therapy or dosage change:
    - If a loading dose of phenobarbital was not administered, at least 5 to 6 half-lives (dogs, ≈12 to 14 days; cats, 9 to 10 days) should be allowed to pass before measuring serum phenobarbital concentrations to confirm that therapeutic levels have been reached; on the day of sampling, the time between drug administration sampling does not appear to be significant.[77,78]
    - Re-measure at 6 weeks postinitiation of phenobarbital to determine the patient's steady-state concentration and the extent of autoinduction of phenobarbital metabolism.[2]
  - Once steady-state is achieved and the patient's clinical condition is controlled with a maintenance dose: measure serum phenobarbital concentrations every 6 months in dogs and cats. Rechecking concentration more often should be considered when efficacy is reduced or adverse effects are suspected.
  - Dogs: Serum phenobarbital concentrations of 15 to 35 µg/mL (86 to 150 mmol/L) have been recommended, with the high end of the range reflecting suggested changes to minimize the potential for hepatotoxicity.[2] Approximately ⅓ of dogs receiving phenobarbital with bromides may require lower phenobarbital doses and serum concentrations that are ≈33% less for seizure control.[79]
  - Cats: In a retrospective study of 30 cats, 93% of cats had seizures controlled with serum phenobarbital concentrations between 15 and 45 µg/mL.[71] Optimum therapeutic levels of 23 to 30 µg/mL (100 to 130 mmol/L) have been recommended in cats in an attempt to maximize seizure control with the lowest potential for adverse effects.[80] Cats being treated with a transdermal formulation will require more frequent monitoring.
- If phenobarbital is used long term, routine CBC and comprehensive serum chemistry profile are recommended at least every 6 months.
- If results of routine serum chemistry profile suggest possible hepatotoxicity, bile acids and abdominal ultrasonography should be considered for further evaluation.

Client Information

- This medicine may be given with or without food. If your animal vomits or acts sick after getting it on an empty stomach, give it with food or a small treat. If vomiting continues, contact your veterinarian.
- Do not skip doses. Try to give doses at the same time each day. Do not suddenly stop giving this medicine to your animal.
- Do not change the amount you are giving your animal without first talking with your veterinarian.
- Sleepiness, lack of energy, greater thirst, appetite, and increased need to urinate commonly occur when starting therapy.
- Liver problems can occur in dogs. Contact your veterinarians if your animal has any vomiting, diarrhea, lethargy, loss of appetite, or swollen abdomen. Your veterinarian will need to perform examinations and blood work on your dog while it is taking this medicine. Do not miss these important follow-up visits.
- Phenobarbital is classified as a schedule-IV controlled drug by the federal Drug Enforcement Agency (DEA). The use of this medication in animals or humans other than those for whom they are prescribed is illegal.

Chemistry/Synonyms

Phenobarbital, a barbiturate, occurs as glistening, odorless, small, white crystals or a white crystalline powder with a melting point of 174°C to 178°C (345.2°F-352.4°F) and a pK_a of 7.41. One gram is slightly soluble in ≈1000 mL of water and freely soluble in 10 mL of alcohol. Compared with other barbiturates, it has a low lipid solubility.

Phenobarbital sodium occurs as bitter-tasting, odorless, flaky, white crystals, crystalline granules, or powder. It is very soluble in water, soluble in alcohol, and freely soluble in propylene glycol. The injectable product has a pH of 8.5 to 10.5.

SI units (mmol/L) are multiplied by 0.232 to convert phenobarbital levels to conventional units (µg/mL); conversely, conventional units are multiplied by 4.31 to obtain SI units.

Phenobarbital may also be known as fenobarbital, phenemalum, phenobarbitalum, phenobarbitone, phenylethylbarbituric acid, phenylethylmalonylurea, *Luminal Sodium*®, or *Solfoton*®.

Storage/Stability

Store phenobarbital tablets in tight, light-resistant containers at room temperature 20°C to 25°C (68°F-77°F); protect from moisture.

Store phenobarbital elixir in tight containers at room temperature (15°C-30°C [59°F-86°F]).

Store phenobarbital sodium injection at room temperature (15°C-30°C [59°F-86°F]). Do not add solutions of phenobarbital sodium to acidic solutions or use them if they contain a precipitate or are grossly discolored.

Aqueous solutions of phenobarbital are not very stable. Propylene glycol is often used in injectable products to help stabilize the solution.

Phenobarbital is a DEA Schedule-IV controlled substance (C-IV) that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding the disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

The following solutions and drugs have been reported to be physically **compatible** with phenobarbital sodium: dextrose IV solutions, Ringer's injection, lactated Ringer's injection, sodium chloride IV solutions, dextrose-sodium chloride combinations, dextrose-Ringer's combinations, dextrose-Ringer's lactate combinations, amikacin sulfate, aminophylline, atropine sulfate (stable for at least 15 minutes but not 24 hours), calcium chloride and gluconate, dexmedetomidine, dimenhydrinate, glycopyrrolate, heparin sodium, methylprednisolone sodium succinate, piperacillin-tazobactam, polymyxin B sulfate, ranitidine, sodium bicarbonate, and verapamil.

The following drugs have been reported to be physically **incompatible** with phenobarbital sodium: buprenorphine, chlorpromazine, codeine phosphate, cyclosporine, diazepam, diphenhydramine, dobutamine, ephedrine sulfate, fentanyl citrate, glycopyrrolate, hydralazine, hydrocortisone sodium succinate, hydroxyzine, insulin (regular), ketamine, meperidine, midazolam, morphine sulfate, nalbuphine, norepinephrine bitartrate, oxytetracycline, pentazocine lactate, procaine, prochlorperazine, promazine, and promethazine.

Phenobarbital 10 mg/mL oral suspension can be made by crushing the appropriate number of tablets and suspending in *ORA-Blend*® (regular or sugar-free). In a study, potency was maintained over the 115-day study period when stored at room temperature in amber plastic bottles.[81]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International [ARCI] Uniform Classification Guidelines for Foreign Substances [UCGFS] has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Phenobarbital Tablets: 15 mg, 16.2 mg, 30 mg, 32.4 mg, 60 mg, 64.8 mg, 97.2 mg, and 100 mg; *Solfoton*®, generic; (Rx; C-IV). **NOTE**: Phenobarbital strengths previously were expressed in grains, whose abbreviation ("gr") can easily be confused with gram (g). To prevent medication errors, using grains to express strength should be avoided when prescribing phenobarbital.

Phenobarbital Elixir/Oral Solution: 20 mg/5 mL (4 mg/mL); generic; (Rx, C-IV). Contains 15% ethanol

Phenobarbital Sodium Injection: 65 mg/mL and 130 mg/mL; *Luminal Sodium*®, generic; (Rx; C-IV). Contains benzyl alcohol

Phenoxybenzamine

(fen-ox-ee-***ben***-za-meen) *Dibenzyline*®

Alpha-adrenergic Antagonist (nonselective), Vasodilator

Prescriber Highlights

- ► An alpha-adrenergic antagonist used primarily in small animals for urethral hypertonus and urethral obstruction and to control hypertension in cases of pheochromocytoma
- ► May be contraindicated in patients with hypotension, glaucoma, or diabetes mellitus and in horses with colic
- ► Use with caution in patients with congestive heart failure or other heart disease, renal impairment, or cerebral/coronary arteriosclerosis.
- ► Adverse effects include hypotension, rebound hypertension, miosis, increased intraocular pressure, tachycardia, inhibition of ejaculation, nasal congestion, weakness, ataxia, and GI effects (eg, nausea, vomiting). Constipation may occur in horses.
- ► Availability and cost can be problematic; product may need to be obtained from compounding pharmacy.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies phenoxybenzamine as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Phenoxybenzamine is used primarily for its effect in reducing internal urethral sphincter tone when urethral sphincter hypertonus is present. It can also be used to treat hypertension associated with pheochromocytoma before surgery. It was used in the management of tachycardia resulting from phenylpropanolamine overdose in a dog.[1] In cats with recurrence of urethral obstruction, prazosin appears to be more effective to prevent the incidence of reobstruction as compared with phenoxybenzamine.[2,3]

Phenoxybenzamine has been anecdotally reported to increase acupuncture effectiveness.[4]

In horses, phenoxybenzamine has been used to decrease urethral sphincter tone with bladder paresis. It has also been historically tried for preventing or treating laminitis in early stages[5-7] and treating secretory diarrhea.[8,9]

Pharmacology/Actions

Phenoxybenzamine noncompetitively blocks the alpha-adrenergic response to circulating epinephrine or norepinephrine; it is considered a nonselective alpha-adrenergic antagonist, with greater affinity for alpha-1 receptors than alpha-2 receptors. The effect of phenoxybenzamine has been described as a chemical sympathectomy. Phenoxybenzamine has no effects on beta-adrenergic receptors or on the parasympathetic nervous system.

Phenoxybenzamine increases cutaneous blood flow, but little effect is noted on skeletal muscle or cerebral blood flow.

Phenoxybenzamine can also block pupillary dilation, lid retraction, and nictitating membrane contraction. Prevention of epinephrine inhibitory action on insulin secretion is noted. Both standing and supine systolic blood pressures are decreased when this drug is used in humans.

Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, phenoxybenzamine is variably absorbed from the GI tract and has a bioavailability of 20% to 30%.

Onset of action is slow (several hours) and increases over several days after regular dosing. Effects persist for 3 to 4 days after discontinuation.

Phenoxybenzamine is highly lipid soluble and may accumulate in body fat. The serum half-life is ≈24 hours in humans. It is metabolized (dealkylated) and excreted in both urine and bile.

Contraindications/Precautions/Warnings

Phenoxybenzamine is contraindicated in patients hypersensitive to it, in horses with clinical signs of colic, and in patients in which hypotension would be deleterious (eg, those with renal impairment or shock) unless blood pressure can be adequately monitored and maintained. One source[10] lists glaucoma and diabetes mellitus as contraindications to the use of phenoxybenzamine in dogs.

Phenoxybenzamine should be used with caution in patients with congestive heart failure or other heart disease due to drug-induced tachycardia. It should also be used cautiously in patients with renal impairment or cerebral/coronary arteriosclerosis. Adrenergic blockade may worsen signs of respiratory infections.

Phenoxybenzamine is not recommended for long-term use in humans because it has been shown to be mutagenic and carcinogenic in mice, rats, and humans.

The National Institute for Occupational Safety and Health (NIOSH) classifies phenoxybenzamine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[11]

Adverse Effects

Adverse effects associated with alpha-adrenergic blockade include hypotension, weakness/dizziness, GI effects (eg, nausea, vomiting), miosis, increased intraocular pressure, tachycardia, sodium retention, inhibition of ejaculation, and nasal congestion.

When used in dogs for controlling hypertension before surgery for pheochromocytoma, phenoxybenzamine can cause prolonged postoperative hypotension; volume expansion may be required. Increased preoperative sodium intake has been suggested in human medicine.

Phenoxybenzamine can cause constipation in horses.

Reproductive/Nursing Safety

It is unknown if phenoxybenzamine crosses the placenta. Phenoxybenzamine has been shown to cause abnormalities in the closure of the patent ductus in guinea pigs. Long-term phenoxybenzamine is mutagenic and carcinogenic to humans.

Whether phenoxybenzamine is excreted into milk is also unknown, but this activity could be expected.[12] Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of phenoxybenzamine may yield signs of hypotension (eg, ataxia, syncope), tachycardia, vomiting, lethargy, shock.

Treatment should consist of GI decontamination if the ingestion was recent, and there are no contraindications to those procedures. Hypotension can be treated with fluid support. Epinephrine is contraindicated (see ***Drug Interactions***), and most vasopressor drugs are ineffective in reversing the effects of alpha-blockade. IV norepinephrine (ie, levarterenol) may be beneficial, however, if clinical signs are severe.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenoxybenzamine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antihypertensive Agents** (eg, **amlodipine**): Concurrent use may result in hypotension.
- **Beta-blockers** (eg, **atenolol**): May enhance hypotensive effects
- **Epinephrine**: Use in combination with drugs that have both alpha- and beta-adrenergic effects may result in increased hypotension, vasodilation or tachycardia.
- **Phenylephrine**: Phenoxybenzamine will antagonize the effects of alpha-adrenergic agonists.
- **Reserpine**: Phenoxybenzamine can antagonize the hypothermic effects of reserpine.
- **Sildenafil**: May enhance hypotensive effects

Dosages

DOGS:

Functional urethral obstruction caused by increased sympathetic urethral tone (extra-label): A common dosage recommendation is 0.25 mg/kg PO every 12 hours, or practically 5 – 20 mg/dog (NOT mg/kg) PO every 12 hours.

Hypertension associated with pheochromocytoma (extra-label): Initially 0.25 – 0.5 mg/kg PO every 12 hours. Dosage is gradually increased to a maximum of 2.5 mg/kg PO every 12 hours or until clinical signs of hypotension (eg, lethargy, weakness, syncope), or adverse effects (eg, vomiting) occur. Median dosage in one study was 0.6 mg/kg PO every 12 hours.[6] Continue until surgery; close monitoring during the perioperative period is critical for a successful outcome.

CATS:

Functional urethral obstruction caused by increased sympathetic urethral tone (extra-label): 2 – 4 mg/cat (NOT mg/kg) every 12 hours[2,13] If using in combination with bethanechol, it is recommended that phenoxybenzamine be started 2-3 days prior to bethanechol (1.25 mg – 7.5 mg per cat [NOT mg/kg] PO every 8 to 12 hours).

HORSES:

Decreasing urethral sphincter tone in horses with bladder paresis (extra-label): 0.7 mg/kg PO 4 times a day (in combination with bethanechol at 0.25 – 0.75 mg/kg PO 2 to 4 times a day)[14]

Diarrhea unresponsive to other intervention (extra-label): 1 – 1.5 mg/kg IV infusion with a second dose given 12 to 24 hours later; total cumulative dose is 2 mg/kg[8,9]

Monitoring

- Clinical efficacy (eg, adequate urination, controlled blood pressure)
- Efficacy for urinary problems may take a week or longer, and the drug should be given for several weeks before it is determined to be ineffective.
- Baseline and periodic blood pressure

Client Information

- May be given with or without food
- Efficacy for urinary problems may take a week or longer, and the drug should be given for several weeks before it is determined to be ineffective.
- Can cause GI effects (eg, vomiting and diarrhea in small animals, constipation in horses), rapid heartbeat, small pupils, and runny nose

- If the animal collapses while receiving this medication, contact your veterinarian immediately.

Chemistry/Synonyms

An alpha-adrenergic–blocking agent, phenoxybenzamine HCl is an odorless, white crystalline powder with a melting range of 136°C to 141°C (277°F-304°F) and a pK_a of 4.4. Approximately 40 mg are soluble in 1 mL of water, and 167 mg are soluble in 1 mL of alcohol.

Phenoxybenzamine may also be known as SKF-688A, *Dibenyline®*, *Dibenzyran®*, or *Fenoxene®*.

Storage/Stability

Phenoxybenzamine capsules should be stored at room temperature (20°C-25°C [68°F-77°F]) in well-sealed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated phenoxybenzamine as a class 3 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Phenoxybenzamine HCl capsules: 10 mg; *Dibenzyline®*; generic; (Rx)

Phenylbutazone

(fen-ill-***byoo***-ta-zone) *Butazolidin®, Bute*

Non-Steroidal Anti-inflammatory Drug (NSAID)

Prescriber Highlights

- ► NSAID used primarily in horses
- ► Contraindications include known hypersensitivity, history of or pre-existing hematologic or bone marrow abnormalities, pre-existing GI ulcers; use in horses and dairy cattle intended for food is prohibited.
- ► Use with caution in foals or ponies, and in patients with pre-existing renal disease or CHF.
- ► Adverse effects in horses include oral and GI erosions and ulcers, hypoalbuminemia, diarrhea, anorexia, azotemia, and renal papillary necrosis.
- ► Parenteral injections should be administered only by the IV route.

Uses/Indications

Phenylbutazone is used primarily for treating pain and inflammation in horses. It has been used in other species (eg, dogs, cattle, swine), but generally other NSAIDs are preferred.

Pharmacology/Actions

Phenylbutazone is an NSAID with analgesic, anti-inflammatory, antipyretic, and mild uricosuric properties. The proposed mechanism of action is by the inhibition of cyclooxygenase, thereby reducing prostaglandin synthesis. Additional pharmacologic actions include reduced renal blood flow, decreased glomerular filtration rate, decreased platelet aggregation, and gastric mucosal damage.

Pharmacokinetics

Following oral administration, phenylbutazone is absorbed from both the stomach and small intestine. The drug is distributed throughout the body with highest concentrations attained in the liver, heart, lungs, kidneys, and blood. Plasma protein binding in horses exceeds 99%.

The serum half-life in horses ranges from 3.5 to 6 hours and, like aspirin, it is dose dependent. Therapeutic efficacy, however, may last for more than 24 hours, likely due to the irreversible binding of phenylbutazone to cyclooxygenase. In horses and other species, phenylbutazone is nearly completely metabolized, primarily to oxyphenbutazone (active) and gamma-hydroxyphenylbutazone. Oxyphenbutazone has been detected in horse urine up to 48 hours after a single dose. Phenylbutazone is more rapidly excreted into alkaline than acidic urine. One study suggests equine CYP 3A97 is responsible for in vitro conversion of phenylbutazone to oxyphenbutazone.[1] Another study in 17 horses showed the following pharmacokinetic parameters: volume of distribution at steady state was 0.194 L/kg; systemic clearance was 23.9 mL/hour/kg; terminal half-life following IV administration was 10.9 hours; terminal half-life after PO administration with paste was 13.4 hours; and terminal half-life after PO administration with tablets was 15.1 hours.[2] Complete elimination of phenylbutazone in horses may take 2 months and phenylbutazone can be detected in the urine for at least 7 days following administration.

Serum half-lives reported for other animals are as follows: dogs ≈2 to 6 hours, cattle ≈42 to 55 hours, swine ≈2 to 6 hours, and rabbits ≈2 hours.[3]

Contraindications/Precautions/Warnings

Phenylbutazone is contraindicated in patients that are hypersensitive to it or have a history of or pre-existing hematologic or bone marrow abnormalities. Avoid use of phenylbutazone in horses with known or suspected equine gastric ulcer syndrome (EGUS); single doses of phenylbutazone will likely not result in catastrophic consequences, but repeated doses can exacerbate gastric ulcers.[4] Phenylbutazone may cause decreased renal blood flow and sodium and water retention; use cautiously in animals with pre-existing renal disease or CHF. Use with caution in patients who have a history of drug allergy.

Cautious use in both foals and ponies is recommended because of increased incidences of hypoproteinemia and GI ulceration. Foals with a heavy parasite burden or that are undernourished may be more susceptible to developing adverse effects.

Therapeutic response to phenylbutazone typically occurs within 24 hours.[5,6] Re-evaluate diagnosis and treatment if patient's condition does not improve after 5 days.

Because phenylbutazone may mask clinical signs of lameness in horses for several days following therapy, it may be used to mask lameness prior to soundness examinations.

Parenteral phenylbutazone should only be administered IV; do not administer phenylbutazone IM or SC, as it may cause local tissue swelling, necrosis, and sloughing. Intracarotid injections may cause CNS stimulation and seizures.

Phenylbutazone is labeled for use in horses that are not intended to be used for food. A thorough evaluation of phenylbutazone residues and toxicology in humans and horses concluded that the illegal and erratic presence of trace amount residues of phenylbutazone in horse meat is not a public health issue.[3]

Adverse Effects

Adverse effects that have been reported in horses include oral and GI erosions and ulcers, hypoalbuminemia, diarrhea, right dorsal colitis, anorexia, azotemia, and renal papillary necrosis. Unlike in humans, it does not appear that phenylbutazone causes much sodium and water retention in horses at labeled dosages, but edema has been reported. In dogs, however, phenylbutazone may cause sodium and water retention and diminished renal blood flow. Phenylbutazone-induced blood dyscrasias and hepatotoxicity have also been reported in dogs. Therapy should be halted at first signs of anorexia, oral lesions, depression, reduced plasma proteins, increased serum creatinine or BUN, leukopenia, or anemias.

Although gastric ulceration is frequently observed in adult horses and foals, evidence of an association between this disease and administration of NSAIDs such as phenylbutazone or flunixin at recommended dosages is lacking. On the basis of the current evidence, prophylactic anti-ulcer medications for horses receiving therapeutic doses of NSAIDs are likely unnecessary in patients that are otherwise at low risk for gastric ulceration.[7] Use of sucralfate or H_2 blockers (eg, ranitidine, famotidine) has been suggested to treat the adverse GI effects. Misoprostol, a prostaglandin E analogue, may also be useful in reducing the GI effects of phenylbutazone.

IM or SC injection can cause swelling, necrosis, and sloughing. Intracarotid injections may cause CNS stimulation and seizures.

The primary concerns with phenylbutazone therapy in humans include its bone marrow effects (agranulocytosis, aplastic anemia), renal and cardiovascular effects (fluid retention to acute renal failure), and GI effects (dyspepsia to perforated ulcers). Other serious concerns with phenylbutazone include hypersensitivity reactions, neurologic, dermatologic, and hepatic toxicities.

Reproductive/Nursing Safety

Both phenylbutazone and oxyphenbutazone (active metabolite) cross the placenta and are excreted into milk. Although phenylbutazone has shown no direct teratogenic effects, rodent studies have demonstrated reduced litter sizes, increased neonatal mortality, and increased stillbirth rates. Phenylbutazone should, therefore, be used in pregnancy only when the potential benefits of therapy outweigh the risks associated with it.

The safety of phenylbutazone during nursing has not been determined. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In humans, manifestations of an acute phenylbutazone overdose include a prompt respiratory or metabolic acidosis with compensatory hyperventilation, renal failure (oliguric, with proteinuria and hematuria), liver injury (hepatomegaly and jaundice), bone marrow depression, ulceration (and perforation) of the GI tract, seizures, coma, and acute hypotensive crisis. Other symptoms reported in humans include nausea, vomiting, abdominal pain, diaphoresis, neurologic and psychiatric symptoms, edema, hypertension, respiratory depression, and cyanosis.

The most common clinical signs in dogs with a phenylbutazone toxicity (per unpublished ASPCA Animal Poison Control Center [APCC] data) include tremors, seizures, ataxia, vomiting, tachypnea, and tachycardia. Oral LD_{50} in dogs is 332 mg/kg.[3] In horses, the most common clinical signs (per unpublished APCC data) are colic, anorexia, and ataxia. Horses receiving 30 mg/kg/day PO for up to 2 weeks became anorectic and depressed; reduced neutrophils count, decreasing serum calcium, and increased serum BUN and creatinine were noted.[8] In the same study, all horses given 15 or 30 mg/kg/day IV died within 4 to 7 days. Pathology findings included GI ulcerations, renal papillary necrosis, and vascular thromboses.

Standard overdose procedures should be followed (eg, GI decontamination, IV fluid diuresis). Benzodiazepines IV may be used to help control seizures. Monitor for fluid overload as phenylbutazone may cause fluid retention.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving phenylbutazone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin Converting Enzyme Inhibitors (ACEIs; benazepril, enalapril)**: Combined use with phenylbutazone may increase the risk for renal dysfunction and/or may decrease the efficacy of the ACEI.
- **Anticoagulants** (eg, **enoxaparin, heparin, rivaroxaban, warfarin**): May increase risk for bleeding. Avoid combination
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May increase the risk for GI ulceration or bleeding and risk for hepatotoxicity
- **Cyclosporine**: May increase risk for renal dysfunction
- **Digoxin**: Phenylbutazone may increase serum digoxin concentrations, prolong digoxin half-life, and thus increase the risk for adverse effects related to digoxin toxicity (eg, arrhythmias, GI adverse effects).
- **Diuretics, Loop** (eg, **furosemide, torsemide**): May increase risk for renal toxicity
- **Diuretics, Potassium-Sparing** (eg, **spironolactone**): May decrease diuretic and antihypertensive efficacy; increased risk for hyperkalemia and nephrotoxicity
- **Hepatotoxic Drugs** (eg, **acetaminophen, chlorpromazine, isoniazid**): May increase risk for hepatotoxicity
- **Methotrexate**: May increase risk for methotrexate toxicity, especially with higher methotrexate doses. Avoid combination
- **Misoprostol**: May result in CNS adverse effects (eg, **ataxia**)
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs;** eg, **firocoxib, flunixin**): May increase the potential for GI ulceration and renal toxicity
- **Penicillamine**: May increase the risk for hematologic and/or renal adverse reactions
- **Penicillin G**: Phenylbutazone may increase plasma half-life of penicillin G.
- **Pentoxifylline**: May increase risk for bleeding
- **Phenobarbital**: May result in decreased phenylbutazone half-life and increased risk for hepatotoxicity
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine, paroxetine**): May increase risk for bleeding
- **Sulfonamides** (eg, **sulfa-/trimethoprim, sulfadimethoxine**): Phenylbutazone could potentially displace sulfonamides from plasma proteins, increasing the risk for adverse effects.[9]
- **Tricyclic Antidepressants (TCAs**; eg, **amitriptyline, clomipramine**): May increase risk for bleeding

Laboratory Considerations

- Phenylbutazone and oxyphenbutazone may interfere with thyroid function tests by competing with thyroxine at protein-binding sites or by inhibiting thyroid iodine uptake.

Dosages

DOGS:

Anti-inflammatory for musculoskeletal conditions (label dosage; FDA-approved): 14.7 mg/kg PO 3 times daily initially (maximum of 800 mg/dog [NOT mg/kg] daily regardless of weight); titrate to lowest effective dose.[10] **NOTE**: The lack of suitable tablet sizes and the ready availability of safer NSAIDs precludes use of phenylbutazone in dogs.

HORSES:

Anti-inflammatory for musculoskeletal conditions (label dosage; FDA-approved):

a) 1 – 2 g/454 kg (1000 lb) horse (NOT mg/kg) IV slowly once

daily.[6] Limit IV administration to no more than 5 successive days of therapy. Follow with oral forms if treatment needs to be continued.

b) 2 – 4 g/454 kg (1000 lb) horse (NOT per kg) PO once daily.[5] Do not exceed 4 g/day. Use high end of dose range for the first 48 hours, then titrate to lowest effective dose.

Extra-label dosage: 2 – 4.4 mg/kg PO, IV every 12 to 24 hours[11,12]

RUMINANTS:

NOTE: The FDA has issued an order prohibiting the extra-label use of phenylbutazone in female dairy cattle 20 months of age or older. In the United States, there is zero tolerance for phenylbutazone residues in any edible tissue from any animal and many believe that phenylbutazone use in any food animal should be banned.[13]

Analgesia for surgical pain (extra-label):

a) 5 mg/kg PO every 24 to 48 hours or 10 mg/kg PO every 48 to 72 hours[14]

b) 4 mg/kg IV every 24 hours[11]

Monitoring

- Analgesic/anti-inflammatory/antipyretic effect
- Baseline and periodic CBCs with chronic therapy (especially if used in dogs); consider weekly CBCs early in therapy and every other week with long-term therapy.
- Baseline and periodic urinalysis and renal chemistry profile (including albumin, total protein) with long-term therapy

Client Information

- This medicine works best when given to your animal with food.
- Injections must only be administered in the vein (IV).
- Side effects can include mouth/stomach ulcers, kidney damage, loss of appetite, and swelling of the limbs.

Chemistry/Synonyms

A synthetic pyrazolone derivative related chemically to aminopyrine, phenylbutazone occurs as a white to off-white, odorless crystalline powder that has a pK_a of 4.5. It is very slightly soluble in water and 1 g will dissolve in 28 mL of alcohol. It is tasteless at first but has a slightly bitter aftertaste.

Phenylbutazone may also be known as butadiene, fenilbutazona, bute, phenylbutazonum, or phenylbute.

Storage/Stability

Oral products should be stored at 15°C to 30°C (59°-86°F) in tight, child-resistant containers if possible. The injectable product should be refrigerated 2°C to 8°C (36°F-46°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The extra-label use of phenylbutazone in female dairy cattle 20 months of age or older is prohibited.[15] Not to be used in animals used for food. Some products are listed in the Green Book but appear to no longer be marketed. Except where otherwise noted, the following are labeled for use in horses. Different racing jurisdictions and equine disciplines have different standards regarding the use of phenylbutazone in racing and nonracing performance animals.

Phenylbutazone Tablets: 100 mg, 200 mg, and 1 g; many tradename and generic products available; (Rx). FDA-approved for use in dogs (only 100 mg and 200 mg size) and horses (all strengths).

Phenylbutazone Oral Powder: 1 g in 10 g of powder to be mixed into feed. *generic*; (Rx)

Phenylbutazone Paste Oral Syringes: Contains 6 g, 12 g, or 20 g/syringe; many tradename and generic products available; (Rx)

Phenylbutazone Granules: Contains 8 g of phenylbutazone per package. *Butazolidin*® Granules; (Rx)

Phenylbutazone Injection: 100 mg/mL (approved for use in dogs) and 200 mg/mL in 100 mL vials; many tradename and generic products available; (Rx)

HUMAN APPROVED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Phenylephrine

(fen-ill-***ef***-rin) *Neo-Synephrine*®

Alpha-adrenergic Agonist

For ophthalmic use, see ***Phenylephrine, Ophthalmic***

Prescriber Highlights

- ► Used parenterally to treat hypotension without overt cardiostimulation
- ► Contraindicated in patients with severe hypertension, ventricular tachycardia, or that are hypersensitive to it
- ► Use with extreme caution in geriatric patients, patients with hyperthyroidism, bradycardia, partial heart block, or other heart disease.
- ► Not a replacement for adequate volume therapy in patients with shock
- ► Adverse effects include reflex bradycardia, CNS effects (eg, excitement, restlessness), and rarely, arrhythmias. Hemorrhage is possible in horses.
- ► Blood pressure must be monitored.
- ► Extravasation injuries with phenylephrine can be very serious.

Uses/Indications

Phenylephrine has been used to treat hypotension and shock after adequate volume replacement in dogs, cats, horses, and sheep. Phenylephrine is rarely used in dogs but may be useful when profound vasodilation occurs, such as with septic shock. In cats, it may be useful in patients with pronounced systemic vasodilation (eg, visceral inflammation) or to increase blood pressure when increasing myocardial contractility may be disadvantageous (eg, hypertrophic cardiomyopathy).

Phenylephrine is sometimes recommended to treat hypotension secondary to general anesthesia, drug overdoses, or idiosyncratic hypotensive reactions to drugs such as phenothiazines, adrenergic blocking agents, and ganglionic blockers. Its use to treat hypotension resulting from barbiturate or other CNS depressant agents is controversial.

In horses, phenylephrine has been used as adjunctive treatment of ascending colon displacement[1]; however, one case series found that pretreatment with phenylephrine did not affect efficacy of the rolling technique or surgery for nephrosplenic entrapment of the colon,[2] and a retrospective study found that rolling was more effective than phenylephrine and exercise.[3]

Ophthalmic uses of phenylephrine include diagnostic eye examinations, reducing posterior synechiae formation, and relieving pain associated with complicated uveitis. In horses, it has also been applied intranasally in an attempt to reduce nasal congestion by reducing nasal mucous membrane thickness and upper airway resistance.

In humans, phenylephrine has been used to treat hypotension and prolong the effects of spinal anesthesia.[4,5]

Pharmacology/Actions

Phenylephrine is an alpha-1-adrenergic agonist that has predominantly postsynaptic alpha effects at therapeutic doses. Beta-adrenergic effects are typically negligible but can occur at high doses.

After IV administration, the primary effects of phenylephrine include peripheral vasoconstriction with resultant increases in diastolic and systolic blood pressure, small decreases in cardiac output, and an increase in circulation time. As mean arterial pressure increases, vagal activity also increases which can result in reflex bradycardia. Renal splanchnic, pulmonary, and cutaneous vascular beds are constricted, but coronary blood flow is increased. Its alpha effects can cause contraction of the uterus during pregnancy and constriction of uterine blood vessels.[6]

Pharmacokinetics

In humans, bioavailability after oral administration is ≈1.3%. Phenylephrine is rapidly metabolized in the GI tract, and cardiovascular effects are generally unattainable when administered orally. Following IV administration, pressor effects begin almost immediately and will persist for up to 20 minutes.

Phenylephrine is metabolized by the liver, and the effects of the drug are also terminated by uptake into tissues.

Contraindications/Precautions/Warnings

Phenylephrine is contraindicated in patients with severe hypertension, ventricular tachycardia, or those that are hypersensitive to it. It should be used with extreme caution in geriatric patients (especially horses), patients with hyperthyroidism, bradycardia, partial heart block, or other heart disease. Phenylephrine is not a replacement for adequate volume therapy in patients with shock.

Extravasation injuries with phenylephrine can be serious and result in necrosis and sloughing of surrounding tissue.[6] Monitor infusion site routinely for signs of extravasation. If extravasation occurs, infiltrate ischemic areas with a solution of phentolamine 5 – 10 mg in 10 to 15 mL of normal saline. A syringe with a fine needle should be used to infiltrate the site with many injections.

Some products contain sodium metabisulfite which can cause anaphylactic in humans.[6] Phenylephrine can cause excessive peripheral and visceral vasoconstriction and ischemia to vital organs. In humans, renal function should be monitored during use. Phenylephrine can also exacerbate underlying heart failure and increase pulmonary arterial pressure.

Adverse Effects

At recommended doses, adverse effects reported in humans include reflex bradycardia and CNS effects such as excitement and restlessness; arrhythmias have rarely been reported. Blood pressure must be monitored to prevent hypertension. Hemorrhage is possible in horses, with the highest risk in aged horses.[7]

In humans, arrythmias, decreased cardiac output, hypertensive crisis, ischemia, severe bradycardia, headache, nausea, vomiting, tremors, dyspnea, and increased pulmonary arterial pressure have been reported.[6]

Reproductive/Nursing Safety

In humans, phenylephrine crosses the placenta at term. It is unknown whether phenylephrine is excreted in maternal milk.[6]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of phenylephrine can cause hypertension, seizures, vomiting, paresthesias, ventricular extrasystoles/tachycardia, lethargy, depression, hyperactivity, reflex bradycardia, hypertension, and cerebral hemorrhage; however, the margin of safety with phenylephrine overdose is fairly wide, especially after oral administration. Vomiting is commonly seen with overdoses. Overdose can also cause CNS stimulation including agitation, hyperactivity, and muscle tremors. Cardiovascular changes often respond well to fluids. Beta-blockers or nitroprusside may be indicated when cardiovascular signs are refractory to fluids.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenylephrine systemically and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-Adrenergic Receptor Antagonists** (eg, **phenothiazines, phenoxybenzamine, phentolamine**): Higher doses of phenylephrine may be required to attain a pressor effect if these agents have been used prior to therapy.
- **Anesthetics, General/Halogenated** (eg, **halothane**): Phenylephrine may potentially induce cardiac arrhythmias when used with halothane anesthesia.
- **Anticholinergics** (eg, **atropine**): Block reflex bradycardia caused by phenylephrine and can precipitate cardiac arrhythmias
- **Beta-Adrenergic Receptor Antagonists** (eg, **propranolol**): The cardiostimulatory effects of phenylephrine can be blocked.
- **Digoxin**: Use with phenylephrine may cause increased myocardial sensitization and increase risk for arrhythmias.
- **Insulins** : May decrease blood glucose lowering effect of insulin
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid, methylene blue, selegiline**): MAOIs should not be used with phenylephrine because of a pronounced pressor effect; combination is considered contraindicated in humans.
- **Oxytocin**: When used concurrently with oxytocic agents, pressor effects may be enhanced; severe, persistent hypertension can occur.
- **Pergolide**: May enhance hypertensive effect of phenylephrine
- **Sympathomimetic Agents** (eg, **epinephrine**): Tachycardia and serious arrhythmias are possible.

Laboratory Considerations

None noted

Dosages

DOGS:

Hypotension (extra-label): 1 – 3 µg/kg/minute IV CRI; doses up to 10 µg/kg/minute IV CRI have been used.[8]

CATS:

Hypotension (extra-label): 1 – 2 µg/kg/minute IV CRI. Infusions of 1 µg/kg/minute IV CRI significantly increased mean arterial pressure without a change in cardiac output; however, at 2 µg/kg/minute, cardiac index also was increased with an increase in stroke volume index.[9]

HORSES:

Adjunctive medical treatment of ascending (large) colon displacement (extra-label): 3 **µg**/kg/minute IV CRI for 15 minutes; repeat every 12 hours if horse does not respond.[1]

Decrease postanesthesia intranasal airway obstruction and edema (extra-label): Dilute phenylephrine 15 mg with 0.9% sodium chloride to a final volume of 10 mL, then administer 5 mL into each nostril.[10]

Hypotension during general anesthesia (extra-label): 0.5 – 2 µg/kg/minute IV CRI. Increased blood pressure and sys-

temic vascular resistance are seen at these doses; however, cardiac output and oxygen delivery are decreased. Phenylephrine should not be used routinely, and its use is recommended only when other treatments have failed to reverse hypotension.[11,12]

SHEEP

Hypotension due to sepsis (extra-label): 1 – 2 µg/kg/minute IV CRI resulted in increased mean arterial blood pressure and decreased heart rate in septic sheep with hypotension. Stroke volume increased but cardiac output decreased, and renal blood flow also increased.[13]

Monitoring

- Heart rate and rhythm
- Blood pressure
- Blood gases if possible
- Infusion site

Client Information

- Parenteral phenylephrine should only be used by professionals in a setting where adequate monitoring is possible.

Chemistry/Synonyms

Phenylephrine is an alpha-adrenergic sympathomimetic amine that occurs as bitter, odorless, white to off-white crystals with a melting point of 145°C to 146°C (293°F-294°F). It is freely soluble in water and alcohol. The pH of the commercially available injection is 3 to 6.5.

Phenylephrine may also be known as fenilefrina, phenylephrinum, m-synephrine, or *Neo-Synephrine*®.

Storage/Stability

The injectable product should be stored protected from light. Do not use solutions if they are brown or contain a precipitate. Oxidation of the drug can occur without a color change. To protect against oxidation, the air in commercially available ampules for injection is replaced with nitrogen and a sulfite added.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Phenylephrine is reported to be physically **compatible** with all commonly used IV solutions and the following drugs: chloramphenicol sodium succinate, dobutamine HCl, lidocaine HCl, potassium chloride, and sodium bicarbonate. Although stated to be physically **incompatible** with alkalis, it is stable with sodium bicarbonate solutions. Phenylephrine is reported to be **incompatible** with ferric salts, oxidizing agents, and metals.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Phenylephrine HCl Injection: 1% (10 mg/mL); generic; (Rx)

Phenylephrine is also available in oral tablets (eg, *Sudafed PE*®), oral solutions, ophthalmic solutions, and intranasal dosage forms. It is also available in combination with antihistamines, analgesics, and decongestants for oral administration.

Phenylpropanolamine

(fen-ill-proe-pa-***nole***-a-meen) *Proin*®

Sympathomimetic

Prescriber Highlights

- ► Sympathomimetic used primarily to treat acquired urethral sphincter hypotonus in spayed dogs
- ► Should be used with caution in animals with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, liver disease, hypertension or conditions that predispose to hypertension, or renal insufficiency
- ► Adverse effects include vomiting, hypertension, anorexia, weight loss, proteinuria, restlessness, and irritability.
- ► Those prescribing this drug should be aware of human abuse potential as it is a precursor to methamphetamine.

Uses/Indications

Phenylpropanolamine is FDA-approved for the control of urinary incontinence caused by urethral sphincter hypotonus in dogs.[1]

Pharmacology/Actions

It is believed that phenylpropanolamine indirectly stimulates both alpha- and, to a lesser degree, beta-adrenergic receptors of smooth muscle by causing the release of norepinephrine and inhibition of reuptake at the synaptic junction. Phenylpropanolamine's alpha-adrenergic stimulation increases urethral sphincter tone[2–6] and produces closure of the bladder neck. Prolonged use or excessive dosing frequency can deplete norepinephrine from storage sites and tachyphylaxis can occur, although this has not been documented in dogs or cats when used to treat urethral sphincter hypotonus.

Other pharmacologic effects of phenylpropanolamine include increased vasoconstriction, heart rate (although bradycardia may also occur), coronary blood flow, and blood pressure; mild CNS stimulation; and decreased nasal congestion and appetite.

Pharmacokinetics

In a study of 4 female beagles given phenylpropanolamine chewable tablets, peak concentration was reached 2 hours after administration and elimination half-life was 4 hours.[7] Extended-release phenylpropanolamine tablets result in a lower peak concentration and overall drug exposure as compared with chewable tablets.

Contraindications/Precautions/Warnings

Phenylpropanolamine is contraindicated in animals hypersensitive to it.

Because it is a sympathomimetic agent, phenylpropanolamine should be used with caution in animals with cardiovascular disease. It should also be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, hyperadrenocorticism, liver disease, hypertension or conditions that predispose to hypertension, or renal insufficiency.[1] Phenylpropanolamine does not treat incontinence caused by UTI, anatomical abnormalities, behavioral disorders, or neurologic disease. In female dogs younger than 1 year of age, anatomical abnormalities should be ruled out prior to treatment with phenylpropanolamine.

Animals should have access to plenty of fresh water while receiving phenylpropanolamine, as it can cause increased thirst.[1]

Overdose has been associated with dogs chewing through closed bottles; store bottles securely out of reach.[1]

Human use of phenylpropanolamine has been withdrawn in the United States and Canada due to increased risk for stroke in women; it is not clear if this is applicable to veterinary patients.

Adverse Effects

Most adverse effects are dose related. Typical adverse effects include hypertension, arrhythmias, weight loss, vomiting, proteinuria, an-

orexia, restlessness, anxiety, irritability, increased thirst, urine retention, tachycardia or bradycardia, panting, diarrhea, and mydriasis.[1,8,9] Severe left and mild right ventricular hypertrophy have been reported in a dog receiving phenylpropanolamine long-term.[10] Effects of phenylpropanolamine on blood pressure can be seen within 2 hours of administration.[11] Hypersensitivity has been reported in rare cases.[9]

Reproductive/Nursing Safety

Drug labels in some countries outside of the United States state that phenylpropanolamine is contraindicated during pregnancy.[9] Phenylpropanolamine may cause decreased ovum implantation; however, uncontrolled clinical experience has not demonstrated any untoward effects during pregnancy.

Safe use during lactation has not been studied. Drug labels in other countries state that it should not be administered to pregnant or lactating dogs.[1,9]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs of overdose may consist of an exacerbation of the adverse effects listed above. In the case of a very large overdose, severe cardiovascular effects (ie, hypertension to rebound hypotension, bradycardias to tachycardias, cardiovascular collapse) or CNS effects (ie, stimulation to coma) may occur.

In a case report of a dog ingesting phenylpropanolamine 56 – 69 mg/kg, clinical signs included anxiety, piloerection, mucosal ulceration, mydriasis, hyphema, and retinal detachment.[8] Laboratory findings included elevated creatine kinase (CK) and AST, proteinuria, and pigmenturia; cardiac arrhythmia (eg, ventricular tachycardia) and severe systemic hypertension were also noted. Ventricular tachycardia and hypertension were successfully treated with phenoxybenzamine, sotalol, esmolol, and nitroprusside.

Survival rate in a 2011 retrospective case study of phenylpropanolamine overdose in dogs was 99.4%, with one death out of 170 dogs studied.[12] Adverse effects were dose dependent. Thirty-nine percent of dogs studied experienced no clinical signs, and the median dose ingested for dogs that experienced no clinical signs was 18 mg/kg. Median dose for dogs that experienced adverse effects was 37.3 mg/kg. For the dogs that developed clinical signs, most developed signs within 8 hours of ingestion. Common signs included agitation, vomiting, lethargy, tremor or twitching, adverse cardiac effects, and erythema. Most dogs did well with decontamination and supportive care. The dog that died had ingested multiple medications from the trash; the exact amount of phenylpropanolamine ingested was not known but could have been as much as 145 mg/kg.[12]

If the overdose was within 2 to 3 hours before presentation, the stomach should be emptied using the usual precautions and activated charcoal with a cathartic administered. Clinical signs should be treated supportively as they occur. Propranolol, a nonspecific beta-blocker, should *not* be used to treat hypertension in bradycardic patients, and atropine should *not* be used to treat bradycardia. Use of alpha-adrenergic blockers (eg, acepromazine [low dose such as 0.02 mg/kg IV or IM]) may be appropriate in cases of hypertension caused by a severe overdose.[9] If phenothiazines do not normalize blood pressure, a nitroprusside IV CRI can be considered.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenylpropanolamine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Aspirin**: Phenylpropanolamine may potentiate decreased platelet aggregation.[1]
- **Estriol**: In a study of female dogs receiving estriol, the addition of phenylpropanolamine did not result in further increases of urethral resistance.[13]
- **Isoflurane, Desflurane, and Sevoflurane**: Phenylpropanolamine may increase potential for cardiac arrhythmias; use combination with caution.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid, selegiline**): Phenylpropanolamine should not be given within 2 weeks of a patient receiving MAO inhibitors, as concurrent use may result in severe hypertension. Combination is contraindicated in humans.[1,9] NOTE: In one small study, selegiline and phenylpropanolamine were used together in healthy dogs without noticeable adverse effects.[14]
- **Reserpine**: Phenylpropanolamine may reduce the antihypertensive effect of reserpine.
- **Sympathomimetic Agents, Other** (eg, **ephedrine**): Phenylpropanolamine should not be administered with other sympathomimetic agents, as increased toxicity may result.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Concurrent use increases the risk for hypertension and arrhythmias.

Laboratory Considerations

None noted

Dosages

DOGS:

Control of urinary incontinence due to urethral sphincter hypotonus (label dosage, FDA-approved):

Immediate-release formulation: 2 mg/kg PO twice daily. The dose should be calculated in half-tablet increments.[1]

Extended-release formulation: 2 – 4 mg/kg PO once daily with food.[15] Dogs weighing less than 4.5 kg (10 lb) cannot be safely dosed with available tablet sizes. Dogs weighing more than 56.8 kg (125 lb) should receive the appropriate combination of tablets. Tablets should not be split or crushed.

Control of urinary incontinence due to urethral sphincter hypotonus (extra-label): 1.5 mg/kg twice daily.[16–18] Some dogs may require administration every 8 hours (eg, 0.8 mg/kg PO 3 times daily[9]), and some may respond adequately to once-daily administration[19]

Retrograde ejaculation (extra-label): 3 – 4 mg/kg PO twice daily may be tried.[20]

CATS:

Control of urinary incontinence due to urethral sphincter hypotonus (extra-label): From a case report, 1.5 mg/kg PO once daily.[21] Anecdotally, 1 – 2.2 mg/kg PO 2 to 3 times daily; practically, 12.5 mg/cat (NOT mg/kg) PO 2 to 3 times a daily

Monitoring

- Clinical effectiveness
- Adverse effects
- Baseline blood pressure (BP) and soon after initiating therapy or increasing the dose. BP should be monitored twice a year in animals that are predisposed to hypertension or have comorbid conditions that may be impacted by hypertension.[22]

Client Information

- Improvement in incontinence may not be apparent until several days after beginning treatment.
- If your pet is incontinent at night, give the largest dose at night before sleeping.
- May be given with or without food; however, giving it with food may help if your animal vomits or acts sick after getting the drug on an empty stomach.
- If you miss a dose, give it as soon as you remember. If it is close to the time for the next dose, skip the dose you missed and give it at the next scheduled time. After that, return to the regular dosing schedule. Do not give 2 doses at once or give extra doses.
- May cause increased thirst; provide ample fresh water.
- Tablets are liver flavored, so keep out of reach of animals and children. Instances of dogs chewing through closed bottles and ingesting the contents have been reported. Contact your veterinarian immediately if your dog ingests more than the prescribed dose.

Chemistry/Synonyms

Phenylpropanolamine HCl, a sympathomimetic amine analogue, occurs as a white crystalline powder with a slightly aromatic odor. It has a melting range between 191°C and 194°C (375.8°F-381.2°F) and a pK_a of 9.4. One gram is soluble in ≈1.1 mL of water or 7 mL of alcohol.

Phenylpropanolamine may also be known as (±)-norephedrine, dl-norephedrine, PPA, *Cystolamine®*, *Proin®*, *Propalin®*, *Uricon®*, *Urilin®*, and *Uriflex-PT®*.

Storage/Stability

Store phenylpropanolamine products in light-resistant, tight containers at controlled room temperature (20°C-25°C [68°F-77°F]). Excursions between 15°C and 40°C (59°F-104°F) are permitted. Phenylpropanolamine syrup (available outside the United States) should be discarded 3 months after first use.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Phenylpropanolamine Chewable Tablets: 25 mg, 50 mg, and 75 mg; *Proin®*; (Rx). FDA-approved for use in dogs. NADA# 141-324

Phenylpropanolamine Extended-Release Tablets: 18 mg, 38 mg, 74 mg, and 145 mg; *Proin ER®;* (Rx). FDA-approved for use in dogs. NADA# 141-517

Phenylpropanolamine Oral Liquid: 50 mg/mL; *Propalin®*; (Rx). Approved in Australia, Canada, and the United Kingdom for use in dogs. Not available in the United States

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

In the United States, phenylpropanolamine is classified as a list 1 chemical (drugs that can be used as precursors to manufacture methamphetamine), and in some states, it may be a controlled substance or have other restrictions placed on its sale. Those prescribing this medication should be alert to persons desiring to purchase this medication.

HUMAN-LABELED PRODUCTS:

NOTE: Because of potential adverse effects in humans, phenylpropanolamine has been removed from the United States market for human use.

Pheromones

(***fer***-i-mones) *Feliway®, D.A.P.®, Adaptil®, Comfort Zone®*

Pheromone Behavior Modifier

Prescriber Highlights

- ► May be useful in cats, dogs, and horses for a variety of behavioral concerns
- ► May need adjunctive therapy such as behavior modification or drug therapy for treating unwanted behaviors
- ► Dog and cat products are administered environmentally; the equine product is administered at the base of the nostrils.

Uses/Indications

Pheromones may be useful as adjunct therapy for a variety of behavioral concerns in dogs, cats, and horses. Behavioral modification and/or concomitant drug therapy may be required.

In dogs, pheromone products may be useful for treating behaviors associated with fear or stress (eg, separation anxiety, destruction, excessive barking, house soiling, licking, phobias) or calming animals in new environments or situations.

In cats, feline facial pheromones may be useful for treating urine marking or spraying, vertical scratching, avoidance of social contact, loss of appetite, stressful situations, or inter-cat aggression; it may also be useful for reducing tension or conflict between cats in the same household.

In horses, pheromones may be useful for reducing stress in situations such as transport, shoeing, clipping, new environments, or training.

Pharmacology/Actions

Appeasing pheromones are thought to be produced during nursing by all mammals. They are detected by the Jacobson's organ or vomero-nasal organ (VNO). The VNO is more sensitive in young animals but is believed to continue to function in older animals as well. It is not well understood what neurotransmitters or neurochemical processes are involved for pheromones to exhibit their effects. In most animals, pheromones have a general calming effect. In cats, the F3 facial pheromone is thought to inhibit urine marking, encourage feeding, and enhance exploratory behaviors in unfamiliar situations. The F4 pheromone is an allomarking pheromone that calms and familiarizes the cat with its surroundings.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

Do not touch diffusers with wet hands or metal objects while plugged in. Do not touch diffuser with uncovered hands during or immediately after use. Never use diffusers with extension cords or adaptors.

Do not spray products directly onto animals.[1,2]

Reproductive Safety

No risks are expected following inhalation of pheromone products.

Adverse Effects

No adverse effects have been reported.

Overdose/Acute Toxicity

No specific animal toxicity data were located. Do **not** induce vomiting if ingested.[2,3] Although pheromone products are considered non-toxic, humans that are accidentally exposed and experiencing adverse reactions should report to a physician or poison control center.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and

toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

- Effects may be reduced or negated by concurrent administration of drugs that cause CNS stimulation.

Laboratory Considerations

- No information was located.

Dosages

DOGS:

Provide calming and comfort during stressful situations (label use; not FDA-approved): Using a canine appeasing pheromone product:

a) Diffuser: Plug diffuser into electric outlet in the room where dogs spend the most time.[4] Ensure airflow from the diffuser is not covered or obstructed. Diffuser vial lasts ≈4 weeks and covers 700 sq ft. Effects are not immediate as diffuser may require up to 72 hours to saturate area.

b) Collar: Apply collar with enough room for 2 fingers between the collar and the neck.[5] Collar should be worn continuously and lasts ≈30 days.

Provide comfort during travel (label use; not FDA-approved): Using a canine appeasing pheromone product:

Spray: Spray 8 pumps per treatment area 10 minutes before travel.[1] May spray in car and kennels or on collars, leashes, bandanas, and blankets; wait 10 minutes after application before introducing dogs to treated items or environment. Application lasts ≈4 to 5 hours.

CATS:

Provide calming and comfort to reduce unwanted behaviors (label use; not FDA-approved): Using a feline facial pheromone (F3) product:

Diffuser: Plug diffuser into electric outlet in an area where cats spend the most time or where spraying behavior occurs.[3] Ensure airflow from the diffuser is not covered or obstructed. Diffuser vial lasts ≈4 weeks and covers 700 sq ft. Effects are not immediate as diffuser may require up to 72 hours to saturate the area.

Spray: Spray 5 to 8 pumps per treatment area 15 minutes prior to introducing cat into the treated environment.[2,6] May be applied to bedding, carriers, or areas of the home that are affected by spraying or scratching behaviors. Spray lasts ≈4 to 5 hours and may be re-applied as needed. For urine spraying behaviors, area should be sprayed at least once daily. If cat is observed rubbing its own facial pheromones onto a spot, treatment is no longer necessary at that location.

Reduce tension and conflict between cats (label use; not FDA-approved): Using a feline facial pheromone (F3) product:

Diffuser: Plug diffuser into an electric outlet in an area where cats spend the most time, ensuring airflow from the diffuser is not covered or obstructed.[7] One diffuser covers 700 sq ft and contents last ≈30 days. Diffusers should be replaced after 6 months. Inter-cat aggression problems may also require behavior modification and concomitant drug therapy.

HORSES:

Reduce or prevent situational stress (label use; not FDA-approved): Apply gel from 1 packet to the base of the nostril 30 minutes before anticipated stressful situation.[8] Takes effect in 30 minutes and lasts 2.5 hours; may be re-applied as needed.

Monitoring

- Clinical efficacy

Client Information

- This product may be useful in treating behaviors associated with stress and anxiety.
- Administered to dogs and cats by sprays, diffusers, and collars.
- Administered to horses via gel at the base of the nostrils.
- No known side effects.

Chemistry

Mammalian pheromones are fatty acids. Canine appeasing pheromone is a synthetic derivative of bitch intermammary pheromone. Feline pheromone is a synthetic analog of feline cheek gland secretions (feline facial pheromone; FFP). The commercially available product available in the US is an analog of the F3 fraction of the pheromone. Equine appeasing pheromone (EAP) is derived from maternal pheromones found in the "wax area" close to the mammae of nursing mares.

Storage/Stability

Unless otherwise labeled, store at room temperature and do not mix with other ingredients or substances. Keep products out of reach of children.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: These products have not been evaluated for safety or efficacy by the FDA.

Canine products

Canine Appeasing Pheromone Diffuser: Canine Appeasing Pheromone 2% in 48 mL vials; *Adaptil® Calm Diffuser*; (OTC)

Canine Appeasing Pheromone (DAP) Spray: Canine Appeasing Pheromone 2% in 60 mL bottles; *Adpatil® Travel Spray*; (OTC)

Caine Appeasing Pheromone Collar: Canine Appeasing Pheromone 5% in 3 collar sizes; *Adaptil® Calm Collar*; (OTC)

Feline products

Feline Facial Pheromone (FFP-F3 fraction) Diffuser: FFP 2% in 48 mL vials; *Feliway® Classic Diffuser*; (OTC)

Feline Facial Pheromone (FFP-F3 fraction) Spray: 10% in 60 mL bottles; *Feliway® Classic Spray*; (OTC)

Cat Appeasing Pheromone (CAP) Diffuser: CAP 2% in a 48 mL vial; *Feliway®* MultiCat Diffuser; (OTC)

Phosphate (Potassium-, Sodium-), IV

(***fos***-fayt)

Electrolyte

Prescriber Highlights

- ► Used for treatment or prevention of acute, severe hypophosphatemia
- ► Available as either sodium or potassium salts
- ► Contraindications include hyperphosphatemia, hypocalcemia, oliguric renal failure, and tissue necrosis.
- ► Hyperkalemia is a contraindication for *potassium* phosphate; hypernatremia is a contraindication for *sodium* phosphate.
- ► Use with caution in animals with cardiac (especially if receiving digoxin) or renal disease.
- ► Adverse effects include hyperphosphatemia, hypocalcemia, hypotension, renal failure, or soft tissue mineralization; hyperkalemia or hypernatremia are possible.
- ► Must be diluted prior to administration

Uses/Indications

Parenteral phosphate is used to correct or prevent hypophosphatemia when adequate oral phosphorous intake is not possible. Parenteral phosphate is typically recommended when serum phosphorous is less than 1.5 mg/dL or less than 2 mg/dL if concurrent clinical signs (eg, hemolysis, ileus, rhabdomyolysis, decreased contractility, platelet dysfunction) are present. Acute, severe hypophosphatemia can cause hemolytic anemia, thrombocytopenia, neuromuscular and CNS disorders, bone and joint pain, and decompensation in patients with cirrhotic liver disease.

Pharmacology/Actions

Phosphorous is involved in several functions in the body, including calcium metabolism, acid-base buffering, B-vitamin utilization, bone deposition, and several enzyme systems.

Pharmacokinetics

Phosphate administered IV is eliminated by the kidneys. It is glomerularly filtered, but up to 80% is reabsorbed by the tubules.[1]

Contraindications/Precautions/Warnings

Potassium and sodium phosphates are contraindicated in patients with hyperphosphatemia, hypercalcemia or significant hypocalcemia, oliguric renal failure, and patients with tissue necrosis. Potassium phosphate is contraindicated in patients with hyperkalemia[2]; sodium phosphate is contraindicated in patients with hypernatremia.[3]

Sodium and potassium phosphates should be used with caution in patients with cardiac or renal disease. Use potassium phosphate with extreme caution in patients receiving digoxin, as life-threatening hyperkalemia may result.

In humans, undiluted or rapid IV administration has resulted in seizures, cardiac arrhythmias, cardiac arrest, and death.[2]

Adverse Effects

Oversupplementation with parenteral phosphate can result in hypocalcemia, hypotension, renal failure, or soft tissue mineralization. Either hyperkalemia or hypernatremia may occur in susceptible patients.

Reproductive/Nursing Safety

Safety has not been established in animals; this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Phosphorous intoxication may result in hypocalcemia that manifests as hypocalcemic tetany.[2,3] Stop phosphate infusion in patients that are developing hyperphosphatemia secondary to parenteral phosphate therapy and administer appropriate parenteral calcium therapy to restore serum calcium levels. Monitor serum potassium and treat if required.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phosphate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- ■ **Angiotensin Converting Enzyme Inhibitors (ACEIs;** eg, **benazepril, enalapril**): May result in hyperkalemia when used with potassium phosphate
- ■ **Digoxin**: Potassium phosphate must be used with extreme caution in patients taking digoxin, as life-threatening hyperkalemia can result; do not use in digitalized patients with heart block.
- ■ **Potassium Sparing Diuretics** (eg, **spironolactone**): May result in hyperkalemia when used with potassium phosphate

Dosages

NOTE: Sodium and potassium phosphate injections **must be diluted** before IV administration. Dilute in a calcium-free IV fluid such as 0.9% sodium chloride or 5% dextrose (ie, **NOT** lactated Ringer's solution [LRS]).

DOGS/CATS:

Hypophosphatemia (extra-label): Sodium or potassium phosphate 0.01 – 0.03 mmol/kg/hour IV CRI is typically suggested.[4] For diabetic ketoacidosis (DKA), dosages ranging up to 0.12 mmol/kg/hour have been noted.[5] When treating DKA, it is sometimes recommended to provide ⅓ to ½ of the supplemented phosphate as potassium phosphate due to the concurrent need for potassium supplementation in these patients.[6] **NOTE**: When using this protocol, it is important to account for all sources of potassium being administered to the patient in the overall fluid therapy plan to minimize the risk for hyperkalemia. Monitor serum phosphorous levels every 4 to 6 hours initially and adjust infusion rate to maintain serum phosphorous above 2 mg/dL. Use caution not to induce hyperphosphatemia. Correct the underlying cause for hypophosphatemia if possible. Once patient is stabilized and phosphorous levels are maintained above 2 to 2.5 mg/dL, consider transitioning to oral phosphate if continued supplementation is needed.

Monitoring

- ■ Serum inorganic phosphorous
- ■ Serum electrolytes, including calcium, potassium, and sodium

Chemistry

Potassium phosphate injection is a combination of 224 mg of monobasic potassium phosphate and 236 mg of dibasic potassium phosphate. The pH of the injection is 6.5 to 7.5 and has an osmolarity of ≈7700 mOsm/L.[2]

Sodium phosphate injection is a combination of 276 mg of monobasic sodium phosphate and 142 mg of dibasic sodium phosphate. The pH of the injection is 5.5 and has an osmolarity of ≈7000 mOsm/L.[3]

Because commercial preparations are a combination of monobasic and dibasic forms, dosages are calculated in mmol of phosphate.

Storage/Stability
Potassium and sodium phosphate injections should be stored at room temperature and protected from freezing.

Compatibility/Compounding Considerations
Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Potassium phosphate injection is reportedly physically **compatible** with the following IV solutions and drugs: 4% amino acids/25% dextrose, 2.5% to 10% dextrose injection, 0.45% to 0.9% sodium chloride, magnesium sulfate, metoclopramide HCl, and verapamil HCl.

Phosphates may be physically **incompatible** with metals such as calcium and magnesium.

Potassium phosphate injection is reportedly physically **incompatible** with the following solutions or drugs: 2.5% dextrose in half-strength lactated Ringer's solution (LRS), 5% dextrose in Ringer's, 10% dextrose in 0.9% sodium chloride, Ringer's injection, LRS, and dobutamine HCl.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

There are no FDA-approved parenteral phosphate products for veterinary use and no veterinary phosphate-only injectable products. There are several proprietary phosphate-containing products labeled for large animal species that may also include calcium, magnesium, potassium, and/or dextrose; refer to the individual product labeling for specific dosage information. Trade names for these products include *Magnadex®*, *Norcalciphos®*, *Cal-Dextro® Special* and *#2*, *CMPK®*, and *Cal-Phos® #2*; (Rx)

HUMAN-LABELED PRODUCTS:

Potassium Phosphates (monobasic/dibasic) Injection: Each mL contains monobasic potassium phosphate 175 mg and dibasic potassium phosphate 300 mg and provides phosphorous 3 mmol (93 mg) and potassium 4.7 mEq (184 mg); available in 15 mL vials; generic; (Rx)

Potassium Phosphates (monobasic/dibasic) Injection: Each mL contains monobasic potassium phosphate 224 mg and dibasic potassium phosphate 236 mg and provides phosphorous 3 mmol (93 mg) and potassium 4.4 mEq (172 mg); available in 15 mL vials; generic; (Rx)

Sodium Phosphate Injection: Each mL contains monobasic sodium phosphate monohydrate 276 mg and dibasic sodium phosphate, anhydrous, 142 mg, and provides phosphorous 3 mmol (93 mg) and sodium 4 mEq (92 mg); available in 5 mL, 15 mL, and 50 mL vials; generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Physostigmine
(fye-zoh-***stig***-meen) *Antilirium®*

Cholinesterase Inhibitor

Prescriber Highlights
- ► May be used as a diagnostic aid for ivermectin toxicity in dogs and narcolepsy in dogs and horses. May be useful to improve recovery after isoflurane anesthesia in horses and to treat tall larkspur poisoning in cattle
- ► Enters the CNS and is therefore effective for treating central anticholinergic toxicity; however, it is not recommended for use as an antidote due to availability of safer alternatives
- ► Contraindications include hypersensitivity reactions, asthma, gangrene, diabetes mellitus, cardiovascular disease, mechanical obstruction of the GI or urinary tract, and vagotonic states.
- ► Adverse effects are cholinergic in nature; diarrhea and colic are possible in horses. Cholinergic crisis can occur with high doses; must be administered with direct patient supervision as adverse effects can be serious

Uses/Indications
Physostigmine has been used as a diagnostic aid for ivermectin toxicity in dogs and narcolepsy in dogs[1] and horses.[2,3] It has been used to treat experimentally induced anticholinergic toxicity in dogs[4] and to antagonize CNS depressant effects of benzodiazepines in humans; however, use as an antidote in animals is not recommended due to potential serious adverse effects and availability of safer alternatives, such as neostigmine and pyridostigmine.

One small study in horses demonstrated that physostigmine, but not neostigmine, may be useful for improving recovery and reducing emergence delirium after general anesthesia with isoflurane.[5]

Physostigmine has been used in cattle to treat tall larkspur (*Delphinium barbeyi*) poisoning.[6,7]

Pharmacology/Actions
Physostigmine reversibly inhibits the breakdown of acetylcholine by acetylcholinesterase, thereby prolonging the effect of acetylcholine at receptor sites. Physostigmine is a tertiary amine that crosses the blood–brain barrier and therefore inhibits acetylcholinesterase both centrally and peripherally. This distinguishes physostigmine from quaternary amine cholinesterase inhibitors (eg, neostigmine, pyridostigmine) that cannot cross the blood–brain barrier.

Pharmacologic effects of physostigmine include miosis, bronchial constriction, hypersalivation, muscle weakness, and sweating (in species with sweat glands). At higher doses, a cholinergic crisis can occur. See ***Adverse Effects***.

Pharmacokinetics
Physostigmine is rapidly absorbed from subcutaneous tissue and mucous membranes. After parenteral administration, physostigmine readily crosses the blood–brain barrier into the CNS. Peak effects occur within 5 minutes after IV administration and ≈25 minutes after IM administration. The mean elimination half-life in dogs is ≈30 minutes. The majority of the administered drug is rapidly metabolized via hydrolysis by cholinesterases. Very small amounts can be eliminated unchanged into the urine. The duration of pharmacologic effect can range from 30 minutes to 5 hours with an average duration of 30 to 60 minutes. After administration of 0.1 mg/kg IV to beagles, maximal inhibition of cholinesterase (78%) in plasma occurred at 2 minutes; cholinesterase activity in plasma was still 60% inhibited at 45 minutes.[8]

Contraindications/Precautions/Warnings
Physostigmine is contraindicated in patients with prior hypersensitivity reactions to it or sulfites, bronchoconstrictive disease (asthma),

gangrene, diabetes mellitus, cardiovascular disease, mechanical obstruction of the GI or urinary tract, and patients in vagotonic states.

Use of physostigmine in the absence of anticholinergic toxicity or for treatment of tricyclic or tetracyclic antidepressant overdoses increases risk for a cholinergic crisis. Rapid IV administration increases the potential for bradycardia, hypersalivation, and seizures. In humans, it should be given IV at a slow, controlled rate not exceeding 1 mg/minute in adults or 0.5 mg/minute in children.[9]

Because of the risks for toxicity, atropine should be readily available (see ***Overdose/Acute Toxicity***).

Physostigmine injection contains benzyl alcohol that may be toxic in neonatal animals.

Do not confuse PHYSOstigmine with PYRIDOstigmine or phytosophingosine. Consider writing part of the drug's name in uppercase letters (tall man designations) on prescriptions/orders to reduce the risk of errors.

Adverse Effects

Adverse effects of physostigmine include hypersensitivity and cholinergic effects. Cholinergic effects are dose-related and include miosis, bronchial constriction, hypersalivation, muscle weakness, and sweating (in species with sweat glands). In horses, diarrhea or colic are also possible.[10]

At higher doses, a cholinergic crisis can occur with clinical signs such as seizures, bradycardia, tachycardia, hypotension, asystole, nausea, vomiting, diarrhea, depolarizing neuromuscular block, pulmonary edema, and respiratory paralysis.

In humans, bradycardia and convulsions can occur if IV administration is too rapid.[9]

Reproductive/Nursing Safety

Limited information is available, but physostigmine would be expected to cross the placenta. Behavioral, biochemical, and metabolic teratogenic effects have been observed in mice studies. It is unknown if physostigmine enters milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The IV LD_{50} in cats is 0.66 mg/kg.[11] Overdoses or acute toxicity can result in a cholinergic crisis, which can be life-threatening (see ***Adverse Effects***); however, because of the short duration of effect, supportive care may be sufficient. Treatment of serious acute toxicity includes mechanical ventilation, repeated bronchial aspiration, and administration of IV atropine. See ***Atropine***. Readministration of atropine may be required. Pralidoxime (2-PAM) may be useful to reverse the ganglionic and skeletal muscle effects of physostigmine. See ***Pralidoxime.***

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving physostigmine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergics** (eg, **atropine, glycopyrrolate**): Concurrent use may diminish the effects of physostigmine and the anticholinergic agent.
- **Antidepressants, Tricyclic, Tetracyclic** (eg, **clomipramine, mirtazapine**): Concurrent use may diminish the effects of physostigmine and the anticholinergic agent.
- **Choline Esters** (eg, **bethanechol, carbachol, methacholine**): Concurrent use may cause additive adverse effects; monitor for signs of toxicity.
- **Inhalation Anesthetics**: The efficacy of anticholinesterases in reversing neuromuscular blockade may be impaired by inhalation anesthetics.
- **Organophosphates**: May cause additive adverse effects.
- **Succinylcholine**: May increase succinylcholine concentrations and prolong neuromuscular blockade; avoid concurrent use

Laboratory Considerations

- None noted

Dosages

DOGS:

Temporarily reverse the CNS effects of ivermectin toxicosis to support the diagnosis (extra-label): 1 mg/dog (NOT mg/kg) IV once[12]

Provocative test for narcolepsy/cataplexy (extra-label): 0.025 – 0.1 mg/kg IV increases the chance of cataplexy occurring within 15 minutes for mild cases.[13] Starting at the low end of the range is recommended.

HORSES:

Provocative test to diagnose cataplexy or narcolepsy (extra-label): 0.05 – 0.1 mg/kg IV slowly will precipitate a cataplectic attack within 3 to 10 minutes after administration in affected horses.[10,14] A lack of positive response does not rule out the diagnosis of narcolepsy as the response may be variable, even with repeated doses in the same animal.

Improve recovery after isoflurane anesthesia (extra-label): 0.04 mg/kg IV over 8 to 10 minutes during the anesthetic weaning process prior to moving to the recovery stall[1]

CATTLE:

Reversal of clinical effects caused by tall larkspur (*Delphinium barbeyi*) poisoning (extra-label): 0.04 – 0.08 mg/kg IV reversal lasts ≈2 hours and multiple doses may be necessary.[6,7]

Monitoring

- Adverse effects such as miosis, bronchial constriction, hypersalivation, muscle weakness, and sweating (in species with sweat glands); colic and diarrhea in horses
- Heart rate and rhythm
- Blood pressure

Client Information

- This medication is administered in a hospital setting with close monitoring.

Chemistry/Synonyms

Physostigmine salicylate is made from an extract of *Physostigma venenosum* (Calabar bean) seeds. It occurs as white, shiny, odorless crystals or crystalline powder. Degradation occurs upon exposure to heat, light, air, or exposure to traces of metals for a long period, causing a red tint to develop. Solutions for injection use should not be used if more than slightly discolored. One gram is soluble in 75 mL of water or 16 mL of alcohol. The injection has a pH of 3.5 to 5.

Physostigmine salicylate may also be known as eserine salicylate, physostigmine monosalicylate, and *Anticholium*®.

Storage/Stability

Store the injection (ampules) below 40°C (104°F); preferably between 15°C and 30°C (59°F-86°F). Protect this product from light and freezing.

Compatibility/Compounding Considerations

Physostigmine is administered undiluted in humans. It may be given

IV via a Y-site or stopcock port on IV sets but should **not** be added to IV solutions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Physostigmine Salicylate Injection: 1 mg/mL (contains benzyl alcohol 2% and 0.1% sodium metabisulfite) in 1 mL ampules; generic; (Rx; not FDA-approved)

Phytonadione

Vitamin K_1

(fye-toe-na-***dye***-ohne) *Mephyton®*

Antidote, Fat Soluble Vitamin

Prescriber Highlights

- ► Used for the treatment of anticoagulant rodenticide toxicity, dicumarol toxicity associated with sweet clover ingestion in ruminants, sulfaquinoxaline toxicity, and bleeding disorders associated with faulty formation of vitamin K-dependent coagulation factors
- ► Contraindicated in patients with hypersensitivity; does not correct hypoprothrombinemia due to hepatocellular damage
- ► Adverse effects include severe reactions that resemble hypersensitivity reactions after IV administration; IM use may result in acute bleeding at the injection site during the early stages of treatment. SC injections or PO doses may be slowly or poorly absorbed in hypovolemic animals.
- ► May require 6 to 12 hours for effect. When dosing orally, absorption is significantly enhanced when given with a meal.
- ► Small-gauge needles are recommended for use when injecting SC or IM.

Uses/Indications

The principal use of exogenously administered phytonadione (ie, vitamin K_1) is in the treatment of anticoagulant rodenticide toxicity. Phytonadione is also used for treatment of dicumarol toxicity associated with sweet clover ingestion in ruminants, sulfaquinoxaline toxicity, and bleeding disorders associated with faulty formation of vitamin K-dependent coagulation factors (eg, liver failure). Disorders of fat absorption can lead to decreased vitamin K absorption, including inflammatory bowel disease, exocrine pancreatic insufficiency, and bile duct obstruction. In cases of anticoagulant rodenticide ingestion, GI decontamination within 6 hours of oral ingestion may reduce the need for phytonadione therapy.[1]

Pharmacology/Actions

Vitamin K is a cofactor in hepatic activation of blood coagulation factors II (ie, prothrombin), VII, IX, and X, as well as anticoagulant proteins C and S. Without vitamin K, these coagulation proteins remain inactivated and thus nonfunctional. Intestinal microorganisms produce small amounts of endogenous vitamin K.[2,3] Exogenous phytonadione appears to have a pharmacologic effect only in vitamin K-deficient patients; it appears to have no effect in normal, healthy patients.[4] In humans, vitamin K storage is much less than that of other fat-soluble vitamins, and reserves may be rapidly depleted.[4]

Increases in clotting factors may not occur until 6 to 12 hours after oral administration but may be detected within 1 to 2 hours after parenteral administration.[4,5]

Vitamin K also appears to be necessary for bone mineralization and cell growth regulation[6] and possibly for CNS sphingolipid metabolism.[7]

Pharmacokinetics

Phytonadione is absorbed from the GI tract in monogastric animals via the intestinal lymphatics in the jejunum and ileum, only in the presence of bile salts. Oral absorption of phytonadione may be significantly enhanced by giving the drug with food. The relative oral bioavailability of vitamin K is increased 4 to 5 times when given to dogs with canned food. Phytonadione is readily absorbed after IM administration.[4]

In humans, oral administration may be more rapidly absorbed than SC administration.

Phytonadione may concentrate in the liver for a short period but is not appreciably stored in the liver or other tissue; its elimination is not well understood.

Contraindications/Precautions/Warnings

Phytonadione is labeled as contraindicated in patients hypersensitive to it or any component of its formulation.

After oral phytonadione administration, new clotting factors can take up to 6 to 12 hours to be synthesized; therefore, in an emergency, clotting factors must be provided by giving blood products (ie, whole blood, fresh plasma, fresh frozen plasma).[8,9]

Intravenous use of phytonadione preparations may cause severe reactions that resemble hypersensitivity reactions or anaphylaxis (eg, cardiac arrest, death)[4]; the trigger appears to be excipients (emulsifier of the injection's castor oil solution) versus phytonadione itself.[10,11] In human medicine, IV phytonadione using a slow infusion rate (ie, no faster than 1 mg/minute[4]) is cautiously recommended for severe bleeding associated with prolonged clotting times. In small animals, oral treatment is preferred unless the oral route is contraindicated (eg, vomiting, recently received activated charcoal).

Use caution when giving phytonadione to correct hypoprothrombinemia caused by anticoagulant therapy, as overzealous phytonadione dosing may restore conditions that caused thromboembolic events. It is important to note that phytonadione does not counteract anticoagulant effects of heparin or direct-acting anticoagulants (eg, rivaroxaban) or correct hypoprothrombinemia caused by hepatocellular damage. Absorption after oral or SC administration may be delayed in animals that are hypovolemic, and oral absorption may be impaired in patients with bile acid deficiency (eg, biliary obstruction) and malabsorptive conditions (eg, inflammatory bowel disease, GI neoplasia).

Other forms of vitamin K (eg, vitamin K_3 [ie, menadione]) are not recommended as alternatives for phytonadione.

Adverse Effects

Severe hypersensitivity-like reactions have been reported following IV administration of phytonadione (see ***Contraindications/Precautions/Warnings***) and are also possible when injecting IM and SC.[10] These reactions are due to the emulsifier in phytonadione products and are more common with older formulations.[12] Rarely, venous irritation or phlebitis have been reported in association with IV administration. IM or SC administration may cause injection site reactions, as well as acute bleeding from the injection site during the early stages of treatment. Use small-gauge needles (eg, 25-gauge) when injecting SC or IM and administer into large-muscle groups.

Reproductive/Nursing Safety

Phytonadione crosses the placenta only in small amounts, but its

safety has not been documented in pregnant animals. It has been used without apparent adverse effects in pregnant dogs with anticoagulant rodenticide poisoning.[13] Pregnancy in animals with anticoagulant rodenticide poisoning are high risk; neonates are at risk for hemorrhage even if there are no toxic signs in the dam.[14] Phytonadione is considered compatible with pregnancy in humans.[15]

Vitamin K is excreted in maternal milk but is unlikely to have negative effects in nursing offspring. In humans, phytonadione is considered compatible with breastfeeding.[15]

Overdose/Acute Toxicity

Phytonadione is relatively nontoxic. It is unlikely that toxic clinical signs would result after a single overdose; however, refer to ***Adverse Effects*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

There are many drugs that may prolong or enhance the effects of coumarin anticoagulants (including ingested coumarin rodenticides) and thus impede some of the therapeutic effects of phytonadione. See ***Warfarin*** for more details.

The following drug interactions have either been reported or are theoretical in humans or animals receiving phytonadione and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antibiotics, Oral**: Although chronic antibiotic therapy should have no significant effect on the absorption of phytonadione, these drugs may decrease the numbers of vitamin K-producing bacteria in the colon.
- **Cholestyramine**: May reduce oral absorption of phytonadione
- **Mineral Oil**: Concomitant oral administration of mineral oil may reduce the absorption of oral vitamin K.
- **Warfarin**: Phytonadione antagonizes the anticoagulant effects of coumarin and indanedione agents.

Dosages

DOGS/CATS:

Acute hypoprothrombinemia (with hemorrhage) and nonacute hypoprothrombinemia (label dosage; NOT FDA-approved): 0.25 – 5 mg/kg SC or IM. Use higher end of dosing range for second generation rodenticides.[16]

Adjunctive treatment of anticoagulant rodenticide toxicity (extra-label): **NOTE**: For short-acting anticoagulant rodenticides (eg, warfarin, pindone), the minimum duration of treatment with phytonadione is 14 days, bromadiolone is 21 days, and other second-generation anticoagulant rodenticides (eg, brodifacoum, difethialone, difenacoum) is 28 days. More than 4 weeks of treatment with phytonadione may be necessary if PT remains prolonged due to ingestion of a large anticoagulant dose.

a) **Subclinical patients**: After gastric decontamination (if appropriate) either begin prophylactic phytonadione 1.5 – 2.5 mg/kg PO (with a fatty meal) twice daily without monitoring prothrombin time (PT) OR monitor PT and give phytonadione only if PT becomes elevated.[1] If PT is to be monitored, perform baseline test (to determine if any prior exposure occurred) and repeat the test 48 and 72 hours after exposure.[17] Phytonadione treatment is not needed if PT remains normal after 48 to 72 hours; however, a full course of treatment with phytonadione is needed if any PT prolongation occurs.

b) **Bleeding patients**:

i. 2.5 mg/kg PO twice daily with a fatty meal; duration of treatment depends on type of anticoagulant exposure.

ii. 5 mg/kg once daily, preferably with a meal, PO or slow IV injection, depending on the clinical condition. If IV administration is required, switch to oral administration as soon as practicable. Alternatively, a second injection can be given after 12 to 18 hours if oral treatment is not immediately possible.[16]

iii. Initial dose of 2.5 – 5 mg/kg PO or SC followed by 5 mg/kg per day PO in 2 or 3 divided doses.[18] Most dogs also received fresh whole blood or plasma. Phytonadione treatment continued for 14 days in dogs exposed to warfarin and 21 to 42 days in dogs exposed to second-generation anticoagulants.

Excessive bleeding secondary to hepatic disease (extra-label):

a) Prior to venipuncture, hepatic biopsy, feeding tube placement: 0.5 – 1.5 mg/kg SC every 12 hours for 2 or 3 doses. Initiating treatment early in disease course allows earlier use of invasive procedures. PT normalizes within 1 to 2 days. Weekly doses can be continued if hepatic disease progresses or persists.[19–22]

b) From a case series in 7 cats, phytonadione 3.7 – 5 mg/kg SC or PO initially, then continued at 1 – 2 mg/kg PO twice daily for 31 to 61 days.[23] Five cats received fresh whole blood transfusions on day 0.

Adjunctive treatment of hepatic failure due to blue-green algae (*Microcystis* spp) exposure (extra-label): From a case report in a dog, 5 mg/kg SC initially, then 4 mg/kg SC every 8 hours for 2 days, followed by 4 mg/kg PO every 8 hours for an additional 9 days.[24] Treatment also included whole blood transfusion on the third hospital day.

HORSES:

NOTE: Label dosages and route and rate of administration vary by manufacturer; refer to specific product label.

Acute or nonacute hypoprothrombinemia, anticoagulant rodenticide toxicity, or moldy/spoiled sweet clover ingestion (label dosage; NOT FDA approved): 0.5 – 2.5 mg/kg IM or SC once daily.[16] For acute cases (with hemorrhage) that may require IV administration, recommended administration rates vary from 1 mg/minute up to but not exceeding 10 mg/minute (5 mg/minute in newborn and very young animals). Treatment duration depends on anticoagulant. See ***Dogs/Cats*** for estimated treatment times.

Moldy sweet clover (dicumarol) toxicosis (extra-label): 1.5 mg/kg SC or IM twice daily for up to 3 days

Vitamin K deficiency in foals (extra-label): From a case report of a 4-week-old colt: 2 mg/kg SC every 12 hours for 2 days, then 0.5 mg/kg PO every 12 hours for 17 days normalized clotting factors and terminated spontaneous bleeding.[25]

CATTLE, SHEEP, GOATS, SWINE:

NOTE: Label dosages and route and rate of administration vary by manufacturer; refer to specific product label.

Acute hypoprothrombinemia, anticoagulant rodenticide toxicity, or moldy/spoiled sweet clover ingestion (label dosage; NOT FDA approved): 0.5 – 2.5 mg/kg IM or SC once daily.[16] For acute cases (with hemorrhage) that may require IV administration, recommended administration rates vary from 1 mg/minute[5] up to but not exceeding 10 mg/minute (5 mg/minute in newborn and very young animals).[16] Treatment duration may require several weeks. See ***Dogs/Cats*** for estimated treatment times.

Sweet clover (*Melilotus* spp) or lespedeza (*Lespedeza* spp) toxic-

ity (extra-label): 1 – 1.5 mg/kg SC once daily for several days. Remove the animal from the source and avoid stress and/or injury.[26]

BIRDS:

Anticoagulant rodenticide toxicity (extra-label): 0.2 – 2.2 mg/kg IM every 4 to 8 hours until stable, then daily.[27,28] See ***Dogs/Cats*** for estimated treatment times.

Secondary brodifacoum toxicity (extra-label): From a case report in a red-tailed hawk,[29] 2.5 mg/kg SC every 12 hours for 4 days, followed by 2.5 mg/kg PO in food every 24 hours for 4 weeks

Vitamin K-related hemorrhagic disorders (extra-label): 0.2 – 2.5 mg/kg IM as needed; usually only 1 to 2 injections are required[30]

RABBITS, GUINEA PIGS:

Anticoagulant rodenticide toxicity (extra-label): 3 – 5 mg/kg PO every 12 hours.[31,32] See ***Dogs/Cats*** for estimated treatment times.

Monitoring

- Clinical efficacy (lack of hemorrhage)
- Prothrombin time (PT)
- A study in dogs with GI decontamination performed within 6 hours of anticoagulant rodenticide ingestion1 suggests that phytonadione therapy could be delayed until a follow-up PT check is performed 48 to 72 hours later and found to be prolonged.
- For anticoagulant poisoning treatment regimens, PT should be checked 48 to 72 hours after the last phytonadione dose is administered. If PT is still elevated, continue phytonadione therapy for an additional week, then repeat PT 48 to 72 hours after the last dose was given.[17,33–35]

Client Information

- Oral phytonadione is best given with food that is high in fat content.
- This vitamin is considered very safe when given by mouth for treatment of anticoagulant rodenticide poisoning (ie, mouse/rat poison).
- Do not skip doses, or your animal may start to bleed. If you miss a dose, give it as soon as possible. If it is time for the next dose, give both doses at that time.
- Your animal will need to have clotting times checked at the end of treatment. Do not miss these important follow-up visits.

Chemistry/Synonyms

Phytonadione, a naphthoquinone derivative identical to naturally occurring vitamin K_1, occurs as an odorless, clear, yellow to amber, viscous liquid. It is insoluble in water, slightly soluble in alcohol, and soluble in lipids.

Phytonadione may also be known as methylphytylnaphthochinonum, phylloquinone, phytomenadione, phytomenadionum, vitamin K_1, *Aqua-Mephyton®*, K_1®, *K-Caps®*, *Konakion®*, or *Mephyton®*.

Storage/Stability

Phytonadione is resistant to heat and moisture but is oxygen sensitive and subject to photodegradation; protect from light at all times. If used as an IV infusion, the container should be wrapped with an opaque material. All phytonadione products should be stored protected from light at room temperature between 15°C to 30°C (59°F-86°F). Tablets and capsules should be stored in well-closed containers.

Compatibility/Compounding Considerations

Most sources state that phytonadione is contraindicated for IV use; consult specialized references or a hospital pharmacist for more specific information on compatibility of phytonadione with other agents.

Injectable phytonadione may be administered orally, directly into the mouth.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: The following veterinary products may not be FDA approved, as no phytonadione products were located in the FDA-Approved Animal Drug Products (Green Book).

Phytonadione Oral Capsules: 25 mg and 50 mg; generic; (Rx). Labeled for use in dogs and cats

Phytonadione Oral Tablets, Chewable: 25 mg and 50 mg; *Vitamin K_1 Chewable®*, generic; (Rx). Labeled for use in dogs and cats

Phytonadione Aqueous Colloidal Solution for Injection: 10 mg/mL in 100 mL vials; *Vitamin K_1*, generic; (Rx). May be labeled for use in dogs, cats, cattle, calves, horses, swine, sheep, or goats. Product labels do not list withdrawal times. Food Animal Residue Avoidance Databank (FARAD) currently lists a 0 day milk and slaughter withdrawal interval in all indicated species; it is recommended to check withdrawal times with FARAD prior to administration.

HUMAN-LABELED PRODUCTS:

Phytonadione Oral Tablets: 5 mg; *Mephyton®*; (Rx)

Phytonadione Oral Tablets and Gelcaps: 0.1 mg (100 µg); generic; (OTC)

Phytonadione Injection, Emulsion: 2 mg/mL and 10 mg/mL in 0.5 mL and 1 mL amps; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pimobendan

(pi-moe-***ben***-den) *Vetmedin®*

Inodilator

Prescriber Highlights

- ► Used for treatment of heart disease in dogs (FDA-approved) and cats (extra-label)
- ► Effects of food on drug absorption are unknown; should be given consistently (with or without food)
- ► May increase the risk for arrhythmias

Uses/Indications

Pimobendan is FDA-approved for congestive heart failure (CHF) in dogs secondary to dilated cardiomyopathy (DCM) or chronic myxomatous/degenerative atrioventricular valve insufficiency (AVVI). Two studies reported that, in dogs with AVVI and CHF, administration of pimobendan and furosemide can improve survival times and quality of life when compared with standard treatment (ie, ACE inhibitor and furosemide).[1,2] The QUEST study also concluded that although dogs given pimobendan or benazepril had a similar quality of life during the study, patients treated with pimobendan had increased time before CHF treatment intensified, which resulted in the patient having a smaller heart size and higher body temperature as well as less retention of free water.[3]

In other countries, pimobendan also has a labeled indication to delay the onset of clinical signs of heart failure, to reduce heart size, and to increase survival time in dogs with evidence of increased heart size secondary to asymptomatic (preclinical) AVVI. A large international multicenter trial (known as the EPIC trial) of dogs in stage B2 AVVI (meaning substantial cardiomegaly but no CHF) showed a delay of over 15 months to reach a composite endpoint of CHF, cardiac-related death, or euthanasia in dogs receiving pimobendan as compared with dogs receiving placebo.[4] In the ACVIM consensus guidelines for the diagnosis and treatment of myxoma-

tous mitral valve disease in dogs, the panel recommended incorporation of pimobendan in the treatment of dogs in stage B2 preclinical disease. The guidelines also recommend pimobendan in the acute and chronic treatment of dogs in stage C (current or historical signs of CHF) heart failure.[5] An abstract has suggested administration of pimobendan at an escalated total daily dose for dogs in stage D (end stage, refractory) heart failure.[6]

Some countries have a labeled indication for pimobendan in large breed dogs with DCM to prolong the time to the onset of CHF or sudden death. A study performed in Doberman pinschers concluded that pimobendan should be used as first-line therapy for the treatment of CHF caused by DCM.[7] In addition, the PROTECT trial concluded that administration of pimobendan to Doberman pinschers with preclinical DCM can prolong the onset of clinical signs and extend survival time compared to placebo.[8]

Pimobendan has been suggested as an adjunctive treatment option for dogs with pulmonary arterial hypertension secondary to AAVI.[9]

Pimobendan is not FDA-approved for use in cats. A prospective, double-blind, randomized, non-pivotal, exploratory field study in 83 cats with hypertrophic cardiomyopathy and CHF found no benefit at 180 days for pimobendan as compared to placebo.[10] However, in the cats without obstructive disease, treatment with pimobendan was associated with a tendency toward benefit while cats with dynamic outflow tract obstruction had an increased likelihood of early removal from the study or an increase of furosemide dose if treated with pimobendan.[10] Retrospective studies have previously suggested that pimobendan is tolerated in cats and may have potential benefits.[11–13] A case-control study of cats with hypertrophic cardiomyopathy and CHF suggested that pimobendan prolonged survival time as compared with cats not receiving pimobendan.[14]

Pharmacology/Actions

Pimobendan is an inodilator, with both positive inotropic and vasodilatory effects. Pimobendan typically (indirectly) decreases heart rate (negative chronotrope) in animals with CHF. Pimobendan's inotropic effects occur via inhibition of phosphodiesterase III (PDE-III) and by increasing intracellular calcium sensitivity in the cardiac contractile apparatus. Cardiac contractility is enhanced without an increase in myocardial oxygen consumption, as pimobendan does not increase intracellular calcium levels. Commercially available pimobendan is a 50:50 mixture of *l*- and *d*-isomers. In dogs, the *l*-isomer of pimobendan has ≈1.5 times greater inotropic activity than the *d*-isomer. Pimobendan's vasodilator effects are via vascular PDE-III inhibition, and both arterial and venous dilation occur. In dogs, pimobendan administered at high dosages (0.6 mg/kg PO every 12 hours for 10 days) with furosemide 2 mg/kg PO every 12 hours did not substantially affect the renin–angiotensin–aldosterone system.[15] Pimobendan also possesses some antithrombotic activity, but at clinically used doses pimobendan does not have an effect on platelet function in dogs.[16] Pimobendan is occasionally used as adjunct therapy for pulmonary arterial hypertension, with experimental data suggesting it may have some activity against phosphodiesterase V and may result in an increase in cyclic guanosine monophosphate (cGMP), although this has not been confirmed in vivo.[17]

One study noted that pimobendan administered IV has positive chronotropic and inotropic effects for healthy mature horses when administered at 0.25 mg/kg slowly over 15 minutes. Additional studies are needed to determine clinical applications.[18]

Pharmacokinetics

Peak concentrations of the parent compound and the active metabolite were observed 1 to 4 hours after administration (mean, 2 and 3 hours, respectively) of a single dose of pimobendan 0.25 mg/kg PO to dogs. Food decreased the bioavailability of an aqueous solution of pimobendan, but the effect of food on absorption of pimobendan from chewable tablets is unknown. The steady-state volume of distribution of pimobendan is 2.6 L/kg in dogs. Protein binding of pimobendan and the active metabolite in dog plasma is greater than 90%. Pimobendan is oxidatively demethylated to a pharmacologically active metabolite that is then conjugated with sulfate or glucuronic acid and excreted mainly via feces. Clearance of pimobendan is ≈90 mL/min/kg, and the terminal elimination half-lives of pimobendan and the active metabolite are ≈0.5 hours and 2 hours, respectively. After oral administration, plasma concentrations of pimobendan and the active metabolite were below quantifiable concentrations by 4 and 8 hours, respectively.

In healthy cats, the pharmacokinetics of pimobendan after a single oral dose (≈0.28 mg/kg) were determined; peak concentrations of the parent compound occurred at 0.9 hours, apparent volume of distribution was high, and mean elimination half-life was 1.3 hours.[19] In another study of oral pimobendan pharmacokinetics in cats that evaluated low-dose (0.625 mg per cat; ≈0.14 mg/kg) and high-dose (1.25 mg per cat; ≈0.28 mg/kg) administration, both the compound and the active metabolite (*O*-desmethylpimobendan) rapidly reached peak plasma concentration, with a volume of distribution of ≈3 L/kg, a clearance of 42.9 – 51.1 mL/min/kg, and an elimination half-life of 0.7 to 0.8 hours.[20]

The pharmacokinetics of pimobendan after single PO doses were determined in healthy Hispaniolan Amazon parrots. A suspension prepared using commercially available tablets and stored for no more than 1 hour was administered at 10 mg/kg and reached a C_{max} of 8.26 ng/mL at 3 hours with a half-life of 2.1 hours; when pimobendan was administered with a suspension prepared using bulk pimobendan powder, the C_{max} was 1.28 ng/mL at 12 hours and half-life was 2.3 hours.[21]

Pimobendan is rapidly absorbed in humans with heart failure, with peak concentrations occurring less than 1 hour after an oral dose. The volume of distribution is ≈3.2 L/kg and clearance is ≈25 mL/min/kg. The terminal half-life is slightly less than 3 hours.

Contraindications/Precautions/Warnings

Pimobendan is contraindicated in animals hypersensitive to it and relatively contraindicated in animals with semilunar valve stenosis or any condition in which an augmentation of cardiac output is inappropriate for functional or anatomic reasons. Pimobendan should be used with caution in patients with uncontrolled cardiac arrhythmias.

The label states pimobendan has not been evaluated for use in dogs younger than 6 months; or dogs with congenital heart defects, diabetes mellitus, or other serious metabolic diseases.

Adverse Effects

GI effects (eg, decreased appetite, vomiting, diarrhea) and lethargy are the primary adverse effects noted in dogs.

There is variable evidence that pimobendan may increase the development of arrhythmias. Atrial fibrillation or increased ventricular ectopic beats have been reported in dogs receiving pimobendan, but a causative effect has not been established because the underlying heart disease can cause arrhythmias. A small (n = 8) prospective study in small-breed dogs with AVVI and CHF did not find evidence of increased incidence of cardiac arrhythmias as compared with dogs given a placebo over a 2-week evaluation period.[22] A trial of pimobendan demonstrated an increased patient mortality rate when administered to humans with heart failure. In a US field trial (56 days duration) performed on dogs with heart disease, the adverse effect incidence (at least 1 occurrence reported per dog) included poor appetite (38%), lethargy (33%), diarrhea (30%), dyspnea (29%), azotemia (14%), weakness and ataxia (13%), pleural effusion (10%), syncope (9%), cough (7%), sudden death (6%), ascites (6%), and heart murmur (3%).[23] In the EPIC study of 360 dogs with preclini-

cal AVVI, 12 of 178 dogs (6.7%) receiving pimobendan experienced sudden cardiac death as compared with 5 of 176 dogs (2.8%) receiving a placebo[4]; these rates were not statistically different. The primary endpoint of time to CHF or cardiac death was strongly favorable for the group receiving pimobendan.

In a study comparing the cardiac adverse effects of pimobendan versus benazepril,[24] dogs with mitral valve regurgitation that were given pimobendan had increases in systolic function and developed worsening mitral valve disease and specific mitral valve lesions (eg, acute hemorrhages, endocardial papilliform hyperplasia on the dorsal surfaces of the leaflets, infiltration of chordae tendinae by glycosaminoglycans) not seen in the group receiving benazepril.

A retrospective study concluded that cats (n = 27) with systolic anterior motion of the mitral valve may develop systemic hypotension when treated with pimobendan.[13] However, a prospective crossover study of 13 cats with hypertrophic cardiomyopathy found no increase in left ventricular outflow tract obstruction in cats receiving pimobendan as compared with cats receiving a placebo, whereas pimobendan improved left atrial function.[25] As noted above, in the exploratory field study of pimobendan compared to placebo in cats with CHF those with left ventricular outflow tract obstruction had a tendency to do worse when receiving pimobendan as compared to those cats with no obstruction.[10]

Reproductive/Nursing Safety

The product label states pimobendan has not been evaluated in dogs used for breeding or for pregnant or lactating bitches. Increased fetal resorptions occurred when pimobendan was administered at high doses (300 mg/kg) to pregnant laboratory animals. Rabbits receiving pimobendan 100 mg/kg showed no adverse effects on fetuses.

No information on the safety of pimobendan during nursing was noted.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In nonclinical dogs, prompt decontamination, including emesis induction and administration of activated charcoal (once the patient has stopped vomiting), is advised. For patients exhibiting clinical signs associated with toxicity, supportive care is recommended. Hypotension should be treated as needed with IV fluid therapy and vasopressors; monitoring of heart rate, blood pressure, and an electrocardiogram is advised.[26] In the event of any potential overdose, clinicians are encouraged to contact a poison control center for patient decontamination and management advice.

In a 4-week study of dogs, dose-dependent increases in heart rate were seen after administration of pimobendan 2 and 8 mg/kg IV. In a 6-month toxicity study of dogs, mild heart murmurs developed in one dog at 3 times (1.5 mg/kg) the labeled dosage and in 2 dogs at 5 times (2.5 mg/kg) the labeled dosage; the murmurs were nonclinical.

There were 468 single-agent exposures to pimobendan reported to the ASPCA Animal Poison Control Center (APCC) from 2009 to 2013. Of the 427 reported dogs, 111 showed clinical signs, with tachycardia (48%), vomiting (24%), hypertension (12%), lethargy (12%), and hypotension (9%) being the most common. Of the 41 cats reported, only 6 showed clinical signs, with 33% experiencing vomiting.

A review of the Pet Poison Helpline database from November 2004 to April 2010 identified 98 cases of pimobendan toxicosis.[26] Of those, 7 dogs that ingested between 2.6 to 21.3 mg/kg of pimobendan were selected for further evaluation. Clinical signs of cardiovascular abnormalities, including severe tachycardia in 4 out of 7 dogs, hypotension in 2 of 7 dogs, and hypertension in 2 of 7 dogs, were noted. No clinical signs were seen in 2 dogs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In field studies pimobendan was safely used with furosemide, digoxin, enalapril, atenolol, nitroglycerin, hydralazine, diltiazem, antiparasitic products (including heartworm preventative), antibiotics, famotidine, theophylline, levothyroxine, diphenhydramine, hydrocodone, metoclopramide, and butorphanol.[27] The following drug interactions have either been reported or are theoretical in animals receiving pimobendan and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Adrenergic Blocking Agents** (eg, **propranolol**): The positive inotropic effect of pimobendan may be reduced.[28]
- **Calcium Channel Blockers** (eg, **diltiazem, verapamil**): The positive inotropic effect of pimobendan may be reduced.[28]

Laboratory Considerations

- No laboratory interactions or special considerations were located.

Dosages

DOGS:

Management of the signs of mild, moderate, or severe congestive heart failure due to AV valve insufficiency or dilated cardiomyopathy (label dosage; FDA-approved): 0.5 mg/kg PO total daily dose divided into 2 portions that are not necessarily equal (using whole or half tablets) and should be administered ≈12 hours apart. Calculated dose should be rounded to the nearest half-tablet increment.[27]

Adjunctive treatment of preclinical dilated cardiomyopathy (extra-label): Same as the labeled dosage. In the PROTECT study, all dogs that weighed more than 35.1 kg (77.4 lb) received pimobendan 10 mg PO twice daily.[8] All dogs that weighed less than 35 kg (77 lb) received 5 mg pimobendan PO twice daily.

Adjunctive treatment of stage B2 and stage C atrioventricular valve insufficiency (AVVI) (extra-label): 0.25 – 0.3 mg/kg PO every 12 hours.[5] In the EPIC study, all dogs received 0.4 – 0.6 mg/kg/day divided into 2 doses.[4] It is important to note that dogs were required to have relevant cardiac remodeling, including both radiographic and echocardiographic evidence of cardiomegaly. Administration of pimobendan to dogs with AVVI before CHF is not advised unless criteria for cardiac enlargement, as established by the EPIC study, are met.

Adjunctive treatment of acute or chronic stage D heart failure (extra-label): 0.3 mg/kg PO 3 times (every 8 hours) daily.[5,6]

CATS:

Heart failure with left ventricular systolic dysfunction, pleural effusion, renal insufficiency, or severe refractory pulmonary edema (extra-label): 0.25 mg/kg PO twice daily; practically, one 1.25 mg tablet/cat (NOT per kg) twice daily. Generally used in combination with an ACE inhibitor and furosemide[14]

Monitoring

Cardiovascular parameters used to monitor heart function including:

- Resting respiratory rate
- Heart rate and rhythm (ECG)
- Blood pressure
- Thoracic auscultation and radiographs
- Echocardiography

Client Information

- Give this medicine as directed by your veterinarian. Do not stop giving this medicine to your pet without discussing with your veterinarian.
- This medicine works best when given on an empty stomach.
- Gastrointestinal effects (eg, poor appetite, vomiting, diarrhea) are the most likely side effects. Contact your veterinarian if these signs persist, worsen, or if your pet is having other signs that are of concern.
- Your veterinarian will need to monitor your pet closely while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

Pimobendan, a benzimidazole-derivative phosphodiesterase inhibitor, occurs as a white or slightly yellowish, hygroscopic powder. Pimobendan is practically insoluble in water and slightly soluble in acetone or methyl alcohol. Pimobendan's chemical name is 4,5-Dihydro-6-[2-(p-methyoxyphenyl)-5-benzimidazolyl]-5-methyl-3(2H) pyridazinone. Pimobendan has a molecular weight of 334.4.

Pimobendan may also be known as UDCG-115, *Acardi*®, *Vetmedin*®, or *Zelys*®.

Storage/Stability

Unless otherwise labeled, store pimobendan chewable tablets or capsules at room temperature below 25°C (77°F) in a dry place. Store commercial pimobendan oral solution at 25°C (77°F) and protected from light. Pimobendan injection has no storage requirement; use single-dose vials immediately after opening and discard any unused drug.

Compatibility/Compounding Considerations

Compounded suspensions may not be stable[29]; use should be avoided unless stability data are available.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Pimobendan Chewable Tablets (artificial beef-flavored): 1.25 mg, 2.5 mg, 5 mg, and 10 mg; *Vetmedin*®; (Rx). NADA# 141-273. FDA-approved for use in dogs. Pimobendan capsules and chews may be available in other countries.

Pimobendan 0.75 mg/mL Injectable Solution: 5 mL and 10 mL single dose vials; *Vetmedin*® Injectable Solution for Dogs; (Rx). Approved in some countries (not the United States) for use in dogs

Pimobendan 3.5 mg/mL Oral Solution for Dogs is available in Australia in 21 mL, 42 mL, and 168 mL bottles; *Vetmedin*®; (Rx)

HUMAN-LABELED PRODUCTS: NONE

Piperacillin/Tazobactam

(***pype***-er-ah-sill-in; tay-zoh-***bak***-tam) *Zosyn*®

Extended Spectrum Penicillin/Beta-Lactamase Inhibitor Combination

Prescriber Highlights

- ► Parenteral penicillin and beta-lactamase inhibitor combination
- ► Broad-spectrum agent; covers many gram-positive, gram-negative, and anaerobic pathogens including *Pseudomonas* and *Enterobacter* spp
- ► Limited experience and research in veterinary medicine

Uses/Indications

Although veterinary experience is limited with piperacillin/tazobactam, it has broad-spectrum activity against many bacteria and may be used to treat bacterial infections based on culture and susceptibility data, or for surgical prophylaxis when gram-negative or mixed aerobic/anaerobic infections are concerns.

Pharmacology/Actions

Piperacillin is a bactericidal, extended-action acylaminopenicillin that inhibits septum formation and cell wall synthesis in susceptible bacteria. It has a wide spectrum of activity against many aerobic and anaerobic gram-positive (including some enterococci eg, *E faecalis*) and gram-negative bacteria. It has a similar spectrum of activity as the aminopenicillins, but with additional activity against several gram-negative organisms of the family Enterobacteriaceae, including *Enterobacter* spp and many strains of *Pseudomonas aeruginosa*. *Klebsiella* spp are often resistant. Alone, it is susceptible to inactivation by beta-lactamases; the addition of tazobactam increases piperacillin's spectrum of activity against many strains of bacteria that produce beta-lactamase.

Tazobactam is a beta-lactamase inhibitor that irreversibly binds to beta-lactamases. It has minimal antibacterial activity when used alone, but when combined with piperacillin, it protects the beta-lactam ring of piperacillin from hydrolysis. This extends piperacillin's spectrum of activity to those bacteria that produce beta-lactamases of Richmond-Sykes types II-V that would otherwise render it ineffective. It has slightly more activity than either clavulanate or sulbactam against some Type I beta-lactamases. Unlike clavulanic acid, tazobactam does not induce chromosomal beta-lactamases at the serum concentrations achieved.

Pharmacokinetics

Limited information is available for veterinary species. In mares, piperacillin has an elimination half-life of ≈7 hours.[1] IM bioavailability is 86% and protein binding is ≈19%.

In humans, piperacillin is not appreciably absorbed from the gut so it must be administered parenterally. After IM administration, peak concentrations occur in ≈30 minutes. The drug exhibits low protein binding and has a volume of distribution of 0.1 L/kg. It is widely distributed into many tissues and fluids including lung, gallbladder, intestinal mucosa, uterus, bile, and interstitial fluid. With inflamed meninges, piperacillin concentrations in the CSF are ≈30% those in serum. If meninges are normal, CSF concentrations are only ≈6% of serum concentrations. Piperacillin crosses the placenta and is distributed into milk in low concentrations. Piperacillin is partly metabolized in the liver to a desethyl metabolite that only has minimal antibacterial activity. Piperacillin is primarily (68%) eliminated unchanged in the urine via active tubular secretion and glomerular filtration; it is also excreted in the bile. Elimination half-life in humans is ≈1 hour.

Tazobactam's pharmacokinetics generally mirror that of piperacillin. In dogs, piperacillin reduced the renal clearance of tazobactam, presumably due to competition for tubular secretion.[2]

Contraindications/Precautions/Warnings

Piperacillin/tazobactam should not be used in patients with documented hypersensitivity reactions to penicillins, cepholosporins, or beta-lactamase inhibitors.

Because of the sodium content, high doses of piperacillin/tazobactam may adversely affect patients with cardiac failure or hypernatremic conditions.

Dosage adjustment (ie, reduced dosing frequency) may be required in patients with significantly decreased renal function.

Penicillins, cephalosporins, and macrolides should not be administered to rabbits, guinea pigs, chinchillas, or hamsters as serious enteritis and clostridial enterotoxemia may occur.

Adverse Effects

Piperacillin/tazobactam is generally well tolerated. Hypersensitivity

reactions and GI effects (eg, nausea, vomiting, diarrhea, constipation) are possible. Local effects (eg, thrombophlebitis) associated with IV injection may occur. Alterations in gut microbiota may lead to antibiotic-associated diarrhea.

In humans, bleeding has been reported in patients receiving some beta-lactams, including piperacillin. Very high doses may cause neurotoxicity (seizures). These effects are more likely in patients with diminished renal function. Dermatologic effects have been reported in humans, including rash and pruritus.[3] Superinfections with *Clostridium difficile* have been reported (rare).

Reproductive/Nursing Safety

Piperacillin/tazobactam is relatively safe to use during pregnancy. No teratogenic effects have been attributed to either drug in humans or laboratory animals.

Piperacillin is distributed in milk in low concentrations. It is not known if tazobactam enters milk. This drug combination is likely safe to use during nursing.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

One-time overdoses are unlikely to pose much risk although very large overdoses may cause vomiting, diarrhea, or neurotoxicity. Dogs receiving up to 800 mg/kg/day of piperacillin/tazobactam for 6 months demonstrated no serious toxic effects. Doses of 400 mg/kg/day or more caused some transient effects to the liver (glycogen granules in the cytoplasm and increases in smooth endoplasmic reticulum in hepatocytes) that were mostly reversed after discontinuing the drug for one month.[4] Treatment for overdoses, if required, is supportive.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piperacillin/tazobactam and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin, tobramycin**): In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. However, beta-lactam antibiotics can inactivate aminoglycosides in vitro and in vivo in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.
- **Anticoagulants**: Because piperacillin may rarely affect platelets, increased monitoring of coagulation parameters is suggested for patients on heparin or warfarin.
- **Methotrexate**: Piperacillin may increase methotrexate serum concentrations.
- **Probenecid**: Can reduce the renal tubular secretion of both piperacillin and tazobactam, thereby maintaining higher systemic concentrations for a longer period; this potential beneficial interaction requires further investigation before dosing recommendations can be made for veterinary patients.
- **Vancomycin**: Increased risk for acute kidney injury
- **Vecuronium**: Piperacillin may prolong neuromuscular blockade.

Laboratory Considerations

- Urine glucose determinations when using cupric sulfate solution (Benedict's solution, *Clinitest®*): Piperacillin may cause false positive results. Tests using glucose oxidase (*Tes-Tape®*, *Clinistix®*) are not affected by piperacillin.
- Aminoglycoside serum quantitative analysis: As penicillins and other beta-lactams can inactivate aminoglycosides in vitro (and in vivo in patients in renal failure or when penicillins are used in massive dosages), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- Aspergillus galactomannan antigen assay: False positive results may occur.
- Direct antiglobulin (Coombs) tests: False positive results may occur.
- Urine protein: Piperacillin may produce false positive urine protein results with the sulfosalicylic acid and boiling test, nitric acid test, or the acetic acid test. Strips using bromophenol blue reagent (eg, *Multi-Stix®*) do not appear to be affected by high concentrations of penicillins in the urine.

Dosages

DOGS/CATS:

Bacterial sepsis (extra-label):

a) 40 – 50 mg/kg IV over 30 minutes every 6 hours have been suggested.[5–7]

b) 3 mg/kg IV loading dose, followed by 3.2 mg/kg/hour IV CRI[7]

BIRDS:

Susceptible infections (extra-label): Reconstitute to 200 mg/mL and administer 100 mg/kg IM every 8 to 12 hours; for severe polymicrobic bacteremia: give 100 mg/kg IV every 6 hours; for preoperative orthopedic or coelomic surgery: 100 mg/kg IM every 12 hours[8]

REPTILES:

Susceptible respiratory tract infections (extra-label): 100 – 200 mg/kg IM every 24 hours. 10 mg/mL in saline and nebulized every 4 to 6 hours.[9] **NOTE**: This reference was for using piperacillin alone; if using piperacillin/tazobactam, calculate dose per the piperacillin component.

Monitoring

- Clinical signs of infection
- CBC
- Electrolytes

Client Information

- Piperacillin/tazobactam is an antibiotic that is reserved for serious infections and must be given by infusion into the vein. It should only be used in a setting where adequate patient monitoring is available.

Chemistry/Synonyms

Piperacillin sodium/tazobactam sodium occurs as a white to off-white, cryodessicated powder. Tazobactam is structurally related to sulbactam and a penicillanic acid sulfone derivative. The commercially available piperacillin/tazobactam injection contains 2.79 mEq of sodium and 0.25 mg of EDTA per gram of piperacillin.

Tazobactam may also be known as CL 298741 or YTR 830H. Piperacillin may also be known as piperacillinum, BL-P 1908, Cl 867, CL 227193, T 12220, and TA 058. International trade names for piperacillin/tazobactam include *Tazobac®*, *Tazocin®*, *Zosyn®*, and others.

Storage/Stability

Piperacillin/tazobactam injection vials and *ADD-Vantage* vials should be stored at controlled room temperature (20°C-25°C [68°F-77°F]). Piperacillin/tazobactam pre-mixed solution for injection must be frozen at -20°C (-4°F) and thawed only under refrigeration (2°C-8°C [36°F-46°F]) or at room temperature (20°C to 25°C [68°F-77°F]); never force thawing with a hot water bath or microwave. Thawed solutions are stable at room temperature for 24 hours, or 14 days when refrigerated.

Conventional vials should be reconstituted with 5 mL of diluent per gram of piperacillin. Suitable diluents include 0.9% sodium chloride, sterile water for injection, and bacteriostatic saline or water for injection. Once reconstituted, further dilute for intravenous infusion with 50 to 150 mL of 0.9% sodium chloride, lactated Ringer's solution (reformulated product only; see below) or 5% dextrose. IV infusion should be over at least 30 minutes.

Once reconstituted, vials should be used immediately. It is recommended to discard after 24 hours if kept at room temperature or 48 hours if stored in the refrigerator. The manufacturer recommends not freezing reconstituted vials. IV bags (50 to 150 mL) containing further diluted product are stable for up to 24 hours at room temperature and one week if refrigerated. As no preservatives are used, sterility is not assured in stored reconstituted products.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist can be consulted for more specific information.

Zosyn® (piperacillin/tazobactam) injection underwent a formulation change in 2006. Sodium citrate (buffer) and EDTA (metal chelator) were added, which made it **compatible** with lactated Ringer's injection and via simultaneous Y-site administration at specific concentrations of gentamicin and amikacin (but not tobramycin). This reformulated product has a yellow background behind the *Zosyn*® name on the label. The manufacturer states that other medications should **not** be added to piperacillin/tazobactam solutions, or mixed within the same syringe. Consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Piperacillin Sodium and Tazobactam Injection (powder for solution); 2.25 g (piperacillin 2 g; tazobactam 0.25 g), 3.375 g (piperacillin 3 g; tazobactam 0.375 g), 4.5 g (piperacillin 4 g; tazobactam 0.5 g), and 40.5 g (piperacillin 36 g; tazobactam 4.5 g); *Zosyn*®, generic; (Rx)

Piperacillin Sodium and Tazobactam Injection (solution in D_5W); 2.25 g/50 mL (piperacillin 2 g; tazobactam 0.25 g), 3.375 g/50 mL (piperacillin 3 g; tazobactam 0.375 g), and 4.5 g/100 mL (piperacillin 4 g; tazobactam 0.5 g); *Zosyn*® in Galaxy container; (Rx). Must be kept frozen.

Piperazine

(pi-per-a-***zeen***)

Antiparasitic

Prescriber Highlights

- ► Anthelmintic for ascarids in a variety of species. Limited efficacy. Rarely recommended today
- ► Adverse effects are unlikely, but diarrhea, emesis, or ataxia are possible.

Uses/Indications

Piperazine may be used for the treatment of ascarids, but its use is rarely recommended, as more effective treatments are preferred. Piperazine is considered safe to use in animals with concurrent gastroenteritis.

Pharmacology/Actions

Piperazine is thought to paralyze susceptible nematodes. The neuromuscular blocking effect is believed to be caused by stimulation of GABA-gated chloride ion channels.[1] In ascarids, succinic acid production is also inhibited.

Pharmacokinetics

Piperazine and its salts are reportedly readily absorbed from the proximal sections of the GI tract, and the drug is metabolized and excreted by the kidneys. Absorptive, distribution, and elimination kinetics on individual species were not located.

Contraindications/Precautions/Warnings

Piperazine is contraindicated in patients with chronic liver or kidney disease and with GI hypomotility. Do not use piperazine in puppies or kittens less than 6 weeks old. It should not be used in sick, feverish, underweight, or physically weak animals.[2,3] There is some evidence in humans that high-dose piperazine may provoke seizures in patients with a seizure history or renal disease.

If piperazine is used in horses with heavy infestations of *Parascarus equorum*, rupture or blockage of intestines is possible due to the rapid death and detachment of the parasite.

Adverse Effects

Adverse effects are uncommon at recommended dosages, but diarrhea, emesis, and ataxia may be noted in dogs or cats. Horses and foals generally tolerate the drug quite well, even at high doses, but transient soft stools may be seen.

Reproductive/Nursing Safety

Piperazine is considered safe to use during pregnancy. No information was located on use during nursing, but it appears to be safe to use.

Overdose/Acute Toxicity

Piperazine is considered to have a wide margin of safety; however, acute massive overdoses can lead to paralysis and death. The oral LD_{50} of piperazine adipate in mice is 11.4 g/kg.

In cats, adverse effects occur within 24 hours after a toxic dose is ingested. Emesis; weakness; dyspnea; muscular fasciculations of ears, whiskers, tail, and eyes; rear limb ataxia, hypersalivation, depression, dehydration, head-pressing, positional nystagmus, and slowed pupillary responses have all been described after toxic ingestions. Many of these effects may also be seen in dogs after toxic piperazine ingestions.

Treatment is supportive and based on clinical presentation. If ingestion was recent, use of activated charcoal with a cathartic has been suggested. IV fluid therapy and keeping the animal in a quiet, dark place is recommended. Recovery generally takes place within 3 to 4 days.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piperazine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential

risks and perform additional monitoring when appropriate.

- **Chlorpromazine**: Although data conflict, piperazine and chlorpromazine may precipitate seizures if used concomitantly.
- **Laxatives**: The use of purgatives (laxatives) with piperazine is not recommended, as the drug may be eliminated before its full efficacy is established.
- **Pyrantel/Morantel**: Piperazine and pyrantel/morantel have antagonistic modes of action and should generally not be used together.

Laboratory Considerations

- Piperazine can have an effect on uric acid blood levels, but references conflict with regard to the effect. Both falsely high and low values have been reported; interpret results cautiously.

Dosages

CAUTION: Piperazine is available in several salts that contain varying amounts of piperazine base (see ***Chemistry/Synonyms*** below). Refer to specific label information for the product being used.

DOGS/CATS:

NOTE: Rarely recommended today

Ascarids (label dosage; NOT FDA-approved): 50 – 55 mg/kg (as base) PO once; repeat in 10 days[4,5] then every 30 days to prevent reinfestation[5]

Ascarids (extra-label): 100 – 110 mg/kg PO once; repeat in 21 days[6]

SWINE:

Large roundworms (*Ascaris suum*) and nodular worms (label dosage): 112 mg/kg of piperazine base in sole source drinking water for 24 hours.[2,3] May repeat dosing every 30 days. Refer to specific product label for instructions on how to prepare medicated water.

BIRDS:

***Ascaridia galli* in poultry** (extra-label): 32 mg/kg (as base) (≈0.3 grams for each adult) given in each of 2 successive feedings or for 2 days in drinking water. Citrate or adipate salts are usually used in feed and the hexahydrate in drinking water.[7]

RABBITS, RODENTS, SMALL MAMMALS:

a) **Mice, rats, hamsters, gerbils, and rabbits for pinworms** (extra-label): Piperazine citrate in drinking water at 3 g/liter for 2 weeks[8]

b) **Rabbits for pinworms** (extra-label): Piperazine citrate 100 mg/kg PO once a day for 2 days. Piperazine adipate: Adults: 200 – 500 mg/kg PO once a day for 2 days. **Young rabbits**: 750 mg/kg PO once daily for 2 days. Wash the perianal area[9]

c) **Mice, rats, hamsters, gerbils, guinea pigs, and chinchillas for pinworms/tapeworms** (extra-label): Using piperazine citrate: 2 – 5 mg/mL drinking water for 7 days, off 7 days and repeat[10]

REPTILES:

Nematodes (extra-label): 40 – 60 mg/kg PO. Repeat in 2 weeks, followed by fecal examination 14 days after the second dose. If positive for parasites, a third dose is given, and the cycle continues until the parasites are cleared from the animal.[11]

Monitoring

- Clinical efficacy (eg, serial fecal flotations)
- Adverse effects

Client Information

- This medicine is used to rid your animal of roundworm infections only. It does not work for treatment of many other intestinal parasites.
- Side effects are unlikely, but diarrhea, vomiting, and incoordination/weakness (eg, stumbling, clumsiness) are possible in dogs and cats.

Chemistry/Synonyms

Piperazine occurs as a white, crystalline powder that may have a slight odor. It is soluble in water and alcohol.

Piperazine is available commercially in a variety of salts, including citrate, adipate, phosphate, hexahydrate, monohydrochloride, and dihydrochloride. Each salt contains a variable amount of piperazine (base): adipate (37%), chloride (48%), citrate (35%), dihydrochloride (50% to 53%), hexahydrate (44%), phosphate (42%), and sulfate (46%).

Piperazine may also be known as diethylendiamin, dispermin, hexahydropropyrazin, piperazinum, and *Pipa-Tabs*®.

Storage/Stability

Unless otherwise specified by the manufacturer, piperazine products should be stored at room temperature (15°C-30°C [59°F-86°F]).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

OTC products may be available under a variety of trade names labeled for use in dogs, cats, chickens, turkeys, or swine. Read and carefully follow all label instructions. Meat withdrawal is 14 days for poultry and 21 days for swine.[2,3]

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pirlimycin

(per-li-***mye***-sin) *Pirsue*®

Lincosamide Antibiotic

Prescriber Highlights

- ► For intramammary use in lactating dairy cattle
- ► Repeated infusion with pirlimycin may increase the potential for intramammary infections and subsequent clinical mastitis.
- ► Be sure to observe longer withdrawal times when using extended therapy.

Uses/Indications

Pirlimycin is FDA-approved for the treatment of clinical and subclinical mastitis in lactating dairy cattle associated with *Staphylococcus* spp and *Streptococcus* spp.

The World Health Organization (WHO) has designated pirlimycin as a Highly Important antimicrobial agent for human medicine.[1] The Office International des Epizooties (OIE) Antimicrobial Classification has designated pirlimycin as a Veterinary Highly Important Antimicrobial agent.[2]

Pharmacology/Actions

Like other lincosamides, pirlimycin acts by binding to the 50S ribosomal subunit of susceptible bacterial RNA, thus interfering with bacterial protein synthesis. It is primarily active against gram-positive bacteria, including a variety of *Staphylococcus* spp (eg, *S aureus, S epidermidis, S chromogenes, S hyicus, S xylosus*), *Streptococcus* spp (eg, *S agalactiae, S dysgalactiae, S uberis, S bovis*) and *Enterococcus faecalis*. It is not active against gram-negative bacteria.

Pharmacokinetics

Systemic absorption after intramammary (IMM) administration is ≈50%. Pirlimycin is lipophilic and diffuses readily across tissue membranes. After systemic absorption, it is secreted into the milk of

all four quarters. Tissue pirlimycin concentrations in treated quarters are ≈2-3 times those found in the extracellular fluid. It is eliminated primarily as parent drug when administered via IMM; however, 4% of the dose is oxidized by the liver to pirlimycin sulfoxide.

Contraindications/Precautions/Warnings

Repeated infusion for extended-duration therapy regimens (ie, infusion longer than twice in a 24-hour interval, up to 8 days) can result in elevated somatic cell counts or clinical mastitis, which can be fatal.[3] Failure to thoroughly clean quarters or use aseptic infusion technique may increase this risk. Discontinue use if acute clinical mastitis or other signs of illness develop during extended-duration therapy.

Milk from untreated quarters must be disposed of during withdrawal time as residues may be detected from untreated quarters.

Adverse Effects

Repeated infusion with pirlimycin may increase the potential for intramammary infections and subsequent clinical mastitis (see ***Contraindications/Precautions/Warnings***).[3]

Reproductive/Nursing Safety

No information was noted. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No data were located. For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

- Because erythromycin and clindamycin have shown antagonism in vitro, antagonism may also occur with pirlimycin.

Laboratory Considerations

- The established tolerance of pirlimycin in milk is 0.4 ppm.

Dosages

CATTLE:

Clinical and subclinical mastitis caused by susceptible organisms in lactating dairy cattle (label dosage; FDA-approved): Using proper teat end preparation, sanitation, and intramammary infusion technique, infuse contents of one syringe (50 mg/10 mL) into each affected quarter.[3] Repeat treatment after 24 hours. For extended therapy, treatment may be repeated at 24-hour intervals for up to 8 consecutive days. **NOTE**: US withdrawal times are extended when used daily for longer than 2 consecutive days. See ***Dosage Forms/Regulatory Status***.

Monitoring

- Efficacy: resolution of clinical signs related to mastitis

Client Information

- It is important to follow and understand your veterinarian's recommendations for how to give this medicine to your cow.
- Be sure you understand how long to treat your cow. Repeated infusion during extended duration therapy regimens, even with adequate teat end preparation and sanitation, can result in serious illness, including death of the animal.
- Carefully follow your veterinarian's instructions for appropriate milk and meat withdrawal times.
- Milk from untreated quarters must also be disposed of during withdrawal time as residues may be detected from untreated quarters.

Chemistry/Synonyms

Pirlimycin HCl is a lincosamide antibiotic. It has a molecular weight of 465.4.

Pirlimycin HCl may also be known as U-57930E and *Pirsue*®.

Storage/Stability

Store syringes at or below 25°C (77°F); protect from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Pirlimycin HCl Sterile Solution: pirlimycin base 50 mg in a 10 mL disposable teat syringe; *Pirsue*®; (Rx). FDA-approved for use in lactating dairy cattle. At United States label dosages, milk withdrawal is 36 hours. Meat withdrawal is 9 days if 2 infusions 24 hours apart are used; however, if administering *any* extended duration of therapy (ie, more than 2 daily infusions, up to 8 consecutive days), meat withdrawal is 21 days.

HUMAN-LABELED PRODUCTS: NONE

Piroxicam

(peer-**ox**-i-kam) *Feldene*®

Nonsteroidal Anti-Inflammatory Drug (NSAID), Anti-Tumor

Prescriber Highlights

- ► NSAID primarily used for its antitumor (indirect) activity. Safer FDA approved NSAIDs are available for treatment of pain and inflammation in dogs and cats.
- ► Contraindications include hypersensitivity or animals with allergic-type reactions to aspirin or other NSAIDs.
- ► Extreme caution is advised in animals with active or history of GI ulcer disease or bleeding disorders. Caution should be used in those with severely compromised cardiac function.
- ► Adverse effects include GI ulceration and bleeding, GI distress (eg, vomiting, anorexia, diarrhea), elevated liver enzymes, and, rarely, renal papillary necrosis.

Uses/Indications

In dogs and cats, piroxicam is primarily indicated for adjunctive treatment of bladder transitional cell carcinoma.[1-4] This drug may also be beneficial in the treatment of squamous cell carcinoma,[5,6] inflammatory mammary carcinoma,[7] soft tissue sarcoma,[8] primary lung carcinoma,[9] and transmissible venereal tumor (TVT).[2] Piroxicam may be beneficial in reducing the pain and inflammation associated with degenerative joint disease; however, FDA-approved, safer alternatives are available. When used in combination with oral alkylator therapy, piroxicam also has anti-angiogenic effects, thereby delaying tumor recurrence and/or metastases in dogs.[10]

Piroxicam has shown benefits in treating cats with transitional cell carcinoma[11,12] and cats with oral squamous cell carcinoma.[13-15]

Piroxicam administered after surgical debulking successfully treated transitional cell carcinoma in a horse.[16] Other case reports for adjunctive treatment of squamous cell carcinoma in horses have been published.[17,18]

Pharmacology/Actions

Like other NSAIDs, piroxicam has anti-inflammatory, analgesic, and antipyretic activity. The drug's anti-inflammatory activity is thought to be primarily due to its inhibition of prostaglandin synthesis, but additional mechanisms (eg, superoxide formation inhibition) may also be important. As with other NSAIDs, piroxicam can affect renal function, cause GI mucosal damage, and inhibit platelet aggregation.

Piroxicam's antitumor effects are believed to be due to its action

on the immune system[2] and its antiangiogenic effect[19] rather than direct effects on tumor cells. Piroxicam has been shown to enhance the activity of vinblastine in dogs with transitional cell carcinoma.[20]

Pharmacokinetics

After oral administration, piroxicam is well absorbed from the GI tract. Although the presence of food decreases the rate of absorption, the amount absorbed is not decreased. It is not believed that antacids significantly affect absorption.

In dogs, piroxicam has a high oral bioavailability of 100%, with peak plasma levels reached ≈3 hours after administration. Volume of distribution is ≈0.3 L/kg; total body clearance is 0.066 L/hour, and elimination half-life is ≈40 hours.[21]

In cats given single oral doses, piroxicam is well absorbed with an oral bioavailability of ≈80%. Peak levels occur in ≈3 hours. Elimination half-life after IV or PO administration is ≈12 to 13 hours.[22]

Piroxicam is highly bound to plasma proteins. In humans, synovial levels are ≈40% of those found in plasma. Maternal milk concentrations are only ≈1% of plasma levels.

In humans, piroxicam has a long plasma half-life (ie, ≈50 hours). The drug is principally excreted as metabolites in the urine after hepatic (CYP2C9) biotransformation.

Contraindications/Precautions/Warnings

Piroxicam is contraindicated in patients hypersensitive to it or in those with allergic-type reactions to aspirin or other NSAIDs. This drug should be used only when its potential benefits outweigh the risks in patients with active or history of GI ulcer disease or bleeding disorders. Because peripheral edema has been noted in some human patients, piroxicam should be used with caution in patients with severely compromised cardiac function. Antipyretic effects may mask signs of infection (eg, fever).

Do not confuse PIRoxicam with PARoxetine.

Adverse Effects

Like other NSAIDs used in dogs, piroxicam has the potential for causing significant GI ulceration and bleeding. The therapeutic window for the drug is narrow, as doses as low as 1 mg/kg given daily have caused significant GI ulceration and peritonitis. Other adverse effects reported in humans that are possible in dogs include CNS effects (eg, headache, dizziness), otic effects (eg, tinnitus), elevations in hepatic enzymes, pruritus and rash, reduced renal function, hyperkalemia, heart failure, and peripheral edema. Renal papillary necrosis has been seen in dogs postmortem but, apparently, clinical effects have not been noted with these occurrences.[2,23] In dogs, advanced age increases the likelihood of adverse effects.[24]

Cats may have GI effects (eg, vomiting, anorexia, diarrhea), particularly early in therapy[13]; vomiting is the most common clinical sign, affecting ≈15% to 20% of cats treated with piroxicam. Gastric erosions[25] and elevated liver enzymes[13] have been documented. There are anecdotal reports of piroxicam decreasing hematocrits in cats given a daily regimen for 7 to 14 days. Renal toxicity is possible if used for prolonged periods.

Reproductive/Nursing Safety

Studies in animals have not demonstrated any teratogenic effects associated with piroxicam. Postimplantation losses occurred in rats, but not rabbits, given piroxicam during organogenesis. Premature closure of fetal ductus arteriosus has occurred in human pregnancies, and the drug should be avoided starting at gestational week 30. NSAIDs inhibit prostaglandin synthesis, which may delay parturition and increase the risk for stillbirth.

The drug is excreted into maternal milk in very low concentrations (ie, ≈1% found in maternal plasma). Use with caution in nursing patients.

Overdose/Acute Toxicity

Limited information is available, but dogs may be more sensitive to piroxicam's ulcerative effects than are humans.

Common clinical signs associated with overdose include vomiting and bloody vomitus.

As with any NSAID, overdoses can lead to GI and renal effects. In monogastric animals, acute toxicity can also result in neurologic effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses with expected GI effects, the use of GI protectants is warranted. If renal effects are also expected, fluid diuresis should be considered. Patients with significant overdose should be monitored carefully and treated supportively.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piroxicam and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **ACE Inhibitors** (eg, **benazepril, enalapril**): Concurrent piroxicam use may reduce ACE inhibitor efficacy.
- **Aminoglycosides** (eg, **amikacin, gentamicin**): Increased risk for nephrotoxicity
- **Angiotensin Receptor Blockers (ARB**; eg, **telmisartan**): Concurrent piroxicam use may reduce ACE inhibitor efficacy.
- **Anticoagulants** (eg, **enoxaparin, heparin, rivaroxaban, warfarin**): Increased risk for bleeding is possible.
- **Aspirin**: Increased risk for bleeding. When aspirin is used concurrently with piroxicam, plasma levels of piroxicam could decrease, and there may be an increased likelihood of GI adverse effects (eg, blood loss). Concomitant administration of aspirin with piroxicam is not recommended.
- **Bisphosphonates, Oral** (eg, **alendronate**): May increase the risk for GI ulceration
- **Cisplatin**: Piroxicam may potentiate the renal toxicity of cisplatin when used in combination.
- **Clopidogrel**: Increased risk for bleeding
- **Corticosteroids** (eg, **dexamethasone, predniso(lo)ne**): Concomitant administration with NSAIDs may significantly increase the risk for GI adverse effects.
- **Cyclosporine**: Concurrent use may result in increased risk for cyclosporine nephrotoxicity.
- **Digoxin**: Concurrent use may result in increased serum concentration of digoxin and prolonged digoxin half-life.
- **Diuretics** (eg, **furosemide**): Concurrent use may result in reduced diuretic efficacy and possible nephrotoxicity.
- **Highly Protein Bound Drugs** (eg, oral anticoagulants, other anti-inflammatory agents, phenytoin, salicylates, sulfonamides, sulfonylurea antidiabetic agents [eg, **glipizide, glyburide**]): Because piroxicam is highly bound to plasma proteins (99%), it could theoretically displace other highly bound drugs; a temporary increase serum levels may occur. These interactions have not been shown to be of clinical concern.
- **Methotrexate**: Serious toxicity (eg, bone marrow suppression, nephrotoxicity) has occurred when NSAIDs were used concomitantly with methotrexate; use together with extreme caution.
- **SSRIs** (eg, **fluoxetine, paroxetine, sertraline**): Concurrent use may result in an increased risk for bleeding.

- **Tacrolimus**: Concurrent use may result in acute renal failure.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Concurrent use may result in increased risk for bleeding.

Laboratory Considerations

- Piroxicam may cause falsely elevated **blood glucose** values when using the glucose oxidase and peroxidase method, with ABTS as a chromogen.

Dosages

DOGS:

Adjunctive therapy for neoplastic diseases (extra-label): 0.3 mg/kg PO with food once daily (preferred, if tolerated) or once every other day (every 48 hours).[2] Adding misoprostol may be considered in dogs that do not tolerate GI effects of NSAIDs.

Adjunctive treatment for idiopathic lymphoplasmacytic rhinitis (LPR; extra-label): Piroxicam 0.3 mg/kg PO once a day is recommended. Long-term administration of antibiotics with immunomodulatory effects (eg, doxycycline 3 – 5 mg/kg PO every 12 hours or azithromycin 5 mg/kg PO once a day) combined with NSAIDs can be helpful in some dogs. If clinical improvement is observed within 2 weeks, daily piroxicam therapy should be continued but the frequency of administration of doxycycline should be reduced to once daily or azithromycin to twice weekly. Therapy will likely be required for a minimum of 6 months, if not indefinitely.[26]

CATS:

Adjunctive therapy for transitional cell carcinomas (extra-label): 0.3 mg/kg PO every 48 hours (every other day)[11]

Adjunctive treatment for other neoplasias (eg, oral squamous cell carcinoma (OSCC), solid tumors) (extra-label): 0.13 – 0.41 mg/kg PO daily.[13,14] 0.3 mg/kg PO every 48 hours has also been used in cats with OSCC.[15]

Anti-inflammatory/analgesic (extra-label): 1 mg/cat (NOT mg/kg) PO once a day for a maximum of 7 days[27,28]

Idiopathic chronic rhinosinusitis (extra-label): 0.3 mg/kg PO once daily or every other day may reduce clinical signs in some cats[26]

HORSES:

Neoplastic diseases (extra-label):

a) From a case report treating mucocutaneous squamous cell carcinoma[17]: 80 mg/horse (NOT mg/kg) PO once daily; lip lesion resolved completely over 3 months, but the patient developed signs of colic twice. The dose was eventually reduced to every other day or every third day.

b) From a case report treating a squamous cell carcinoma of the third eyelid after surgical excision[18]: 80 mg/horse (NOT mg/kg) PO once daily

c) From a case report treating bladder TCC after surgical debulking[16]: 0.2 mg/kg PO once daily, started 10 days postoperatively and continued for 4 months, then reduced to 0.1 mg/kg PO once daily

RABBITS, RODENTS, SMALL MAMMALS:

Fracture with associated limb swelling in rabbits (extra-label): 0.1 – 0.2 mg/kg PO every 8 hours for 3 weeks[29]

Monitoring

- Adverse effects (eg, inappetence, vomiting, diarrhea, melena)
- Liver enzymes and renal function tests should be monitored occasionally with chronic use, especially in cats.

Client Information

- This drug is best given with food to reduce the chance for stomach upset.
- Gastrointestinal (stomach) ulcers and bleeding and kidney problems (especially in cats) are possible.

Chemistry/Synonyms

Piroxicam, an oxicam derivative NSAID, occurs as a white crystalline solid. It is sparingly soluble in water. Piroxicam is not structurally related to other NSAIDs.

Piroxicam may also be known as CP-16171, piroxicamum, or PIRO; many trade names are available.

Storage/Stability

Capsules should be stored at temperatures less than 30°C (86°F) in tight, light-resistant containers. When stored as recommended, capsules have an expiration date of 36 months after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Piroxicam Oral Capsules: 10 and 20 mg; *Feldene®*, generic; (Rx)

Polyethylene Glycol 3350 (PEG 3350)

(pah-lee-**eth**-il-een **gly**-kol) *MiraLAX®, CoLyte®, GoLYTELY®*

Laxative, Hyperosmotic

NOTE: Within this monograph, "PEG 3350 with electrolytes" refers to polyethylene glycol 3350 products that also contain electrolytes (eg, GoLYTELY®) while PEG 3350 refers to polyethylene glycol 3350 as a single agent (ie, no electrolytes; eg, *Miralax®*).

Prescriber Highlights

- ► Indications include constipation, bowel cleansing in preparation for colonoscopy, or to increase elimination of GI toxins
- ► For enteral use only.
- ► Contraindicated in patients hypersensitive to it. When used for bowel cleansing, contraindications include patients with GI obstruction, gastric retention, bowel perforation, toxic colitis, or megacolon.
- ► Adverse effects may include cramping and nausea; electrolyte disturbances may occur with repeated use.

Uses/Indications

Polyethylene glycol 3350 (PEG 3350) is an osmotic laxative agent and is used as an adjunct therapy for feline constipation. When balanced electrolytes are added (PEG 3350 with electrolytes; eg, *CoLyte®*, *GoLYTELY®*), it is used as a bowel cleansing solution. It could also be used to reduce intestinal transit time to reduce the absorption of orally ingested toxicants and poisons, but usually sorbitol is chosen for this indication. It is without odor, taste, or texture, allowing it to easily be added to food or fluids.

Pharmacology/Actions

Polyethylene glycol 3350 is a non-absorbable compound that acts as an osmotic laxative agent that does not alter nutrient, glucose, or electrolyte absorption. PEG 3350 with electrolytes is used as a bowel cleansing solution (eg, *CoLyte®*, *GoLYTELY®*), and the additional electrolytes are added to help prevent electrolyte imbalance. Sodium sulfate is the primary sodium source, so sodium absorption is mini-

mized. Other electrolytes (bicarbonate, potassium, chloride) are also added so that no net change occurs with either absorption or secretion of electrolytes or water in the gut.

Pharmacokinetics

PEG 3350 is not absorbed after oral administration. Depending on formulation, dose and additional fluid consumed, PEG 3350 can have a laxative effect within one hour of dosing.

Contraindications/Precautions/Warnings

In humans, all PEG 3350 solutions are contraindicated in patients that are hypersensitive to it. PEG 3350 with electrolytes also is contraindicated in patients with GI obstruction, gastric retention, bowel perforation, toxic colitis, or megacolon. PEG 3350 solutions with electrolytes should be used with caution in patients with inflammatory bowel disease and in patients already receiving laxatives, as fluid or electrolyte imbalances may occur. Patients should have electrolyte imbalances corrected and be adequately hydrated prior to using PEG 3350 with electrolytes. Enteral infusions of large volumes may increase the risk of aspiration.

Do not confuse PEG 3350 without electrolytes (eg, *Miralax*®) with PEG 3350 containing electrolytes (eg, *GoLYTELY*®).

Adverse Effects

Vomiting, nausea, and cramping are possible. Vomiting occurring during acute administration of PEG 3350 with electrolytes may be managed with metoclopramide or by reducing the flow rate by 50% for one hour, then resuming the original rate.[1] Long-term use could potentially cause hyponatremia, dehydration, or hyperkalemia. If PEG 3350 is absorbed systemically, oxidative injury to red blood cells could occur in cats, but this has not been documented to date.

In one small study (n = 6) in cats where PEG 3350 with electrolytes (powder in food and dose titrated to produce soft, but formed stools) was given for 4 weeks, 1 cat sporadically vomited after dosing, mild erythrocytosis was noted in 1 cat, and 3 cats developed mild hyperkalemia. The authors concluded that PEG 3350 was a safe and palatable oral laxative in cats for long-term use; potential side effects include hyperkalemia and subclinical dehydration.[2]

In humans, PEG 3350 has rarely caused hyponatremia secondary to syndrome of inappropriate vasopressin release (SIADH). Contact dermatitis has also been reported in humans. Neither of these adverse effects have been reported in veterinary patients.

Reproductive/Nursing Safety

Minimal amounts are systemically absorbed, and it is therefore likely that these products are safe to use in pregnant or lactating animals at recommended dosages.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

A single oral overdose event could cause diarrhea and fluid or electrolyte abnormalities.

Toxicity may occur when there is aspiration of the PEG 3350 solution or administration through an unintended route. A case report describes the successful use of bronchoscopy to lavage the lungs of a dog that aspirated PEG 3350 solution.[3] The authors recommend early intervention with cases of aspiration due to the rapid progression of the pulmonary edema that occurs.

Another case report describes inadvertent 6 g/kg IV administration of PEG 3350 to a cat which resulted in severe hypernatremia (Na = 203 mmol/L), encephalopathy (initially laterally recumbent with diminished cranial nerve reflexes, with head pressing and vocalization on day 4 of hospitalization), transient hemolysis, and azotemia (Cr = 3.1 mg/dL).[4] Treatment with supportive care (including appropriate IV and oral fluid therapy) allowed for correction of the hypernatremia and azotemia, as well as improved clinical signs. One month after discharge, there was complete resolution of clinical signs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with PEG 3350 (single agent, or with electrolytes) either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring should be performed when appropriate.

- **Anticholinergic Agents** (eg, **atropine**): May decrease GI motility and reduce laxative effect
- **Diuretics** (eg, **furosemide**): May increase risk for dehydration
- **Laxatives, Other** (eg, **bisacodyl, lactulose**): May have additive effects on GI motility and increase risk for adverse effects. Stimulant laxatives may increase the risk for GI mucosal ulceration.
- **Opioids** (eg, **morphine**): May decrease GI motility and reduce laxative effect
- **Other Drugs, Oral**: Reduced absorption of other oral drugs (especially extended-release) could occur if given concomitantly. Administer any necessary oral medications at least 1 hour prior to PEG 3350 administration to ensure adequate absorption.
- **Tricyclic Antidepressants** (**TCA**s, eg, **amitriptyline, clomipramine**): May decrease GI motility and reduce laxative effect

Dosages

DOGS:

Polyethylene Glycol 3350-Electrolyte Solution (eg, *CoLyte*®, *GoLYTELY*®):

Colonic cleansing prior to colonoscopy (extra-label): Several slightly different protocols have been suggested. The following is an example: Keep animal from food for a minimum of 24 to 36 hours. On the evening prior to a morning colonoscopy (or the morning for an afternoon colonoscopy), give 60 mL/kg *GoLYTELY*® via orogastric tube. Repeat in 2 hours. A warm water enema should follow each dose and a third enema given prior to anesthesia.[5–7]

Enterogastric lavage for decontamination (extra-label): 25 mL/kg/hour delivered via NG tube. Do not exceed 175 mL/kg total.[1] Alternatively, 500 mL/hour (NOT mL/kg/hour) via NG tube. Administer until fecal effluent runs clear, which may take several hours.

CATS:

Laxative (extra-label): Using the polyethylene 3350 powder (eg, *MiraLax*®), ⅛ to ¼ teaspoon/cat (NOT teaspoon/kg) twice daily in food.

Polyethylene Glycol 3350-Electrolyte Solution (eg, *CoLyte*®, *GoLYTELY*®):

Adjunctive treatment of obstipation/constipation (extra-label): From an observational study in 9 cats, *CoLyte*® was administered via naso-esophageal tube at rates between 6 – 10 mL/kg/hr. The median total dose given was 80 mL/kg (range 40 – 156 mL/kg). Median time to significant defecation was 8 hours (range 5 to 24 hours). Side effects were limited to vomiting in 1 cat (was vomiting prior to admission).[8]

Colonic cleansing prior to colonoscopy (extra-label): Keep animal from food for 24 to 36 hours. On the evening prior to a morning colonoscopy, give 30 mL/kg *GoLYTELY*® via nasogastric tube. Repeat in 2 hours. A warm water enema should follow each dose and a third enema given prior to anesthesia.[6,7] **NOTE**: An antiemetic may be given before the first *GoLYTELY*® dose is given to reduce vomiting.

Monitoring

- Fluid and electrolyte status; in particular, if using high doses or with long-term use
- Clinical efficacy (eg, production of feces)
- Adverse effects, especially vomiting and aspiration when a large volume is administered

Client Information

- This medicine is used to treat constipation, for bowel cleansing before procedures (eg, colonoscopy), or to help remove toxins from the gastrointestinal tract.
- Polyethylene glycol 3350 (PEG 3350) powders are mixed into canned food or dissolved in liquid before using. Follow your veterinarian's or pharmacist's measuring instructions carefully.
- PEG 3350 is available OTC (over-the-counter; without a prescription). Do not give PEG 3350 (or any other OTC medications) to your animal without first consulting your veterinarian.
- Contact your veterinarian if your animal begins vomiting or develops any new signs after starting this medication.
- While your animal is taking this medication, it is important to return to your veterinarian for periodic examinations and bloodwork monitoring. Do not miss these important follow-up visits.

Chemistry/Synonyms

Polyethylene glycol 3350 is a non-absorbable compound that acts as an osmotic agent. It occurs as white or almost white solid with a waxy appearance and is very soluble in water and very slightly soluble in alcohol. One common trade name is *Miralax*®.

Storage/Stability

Store powder at 25°C (77°F); excursions are permitted from 15°C-30°C (59°F-86°F). Reconstituted PEG 3350 solutions (from powder by the pharmacy, client, clinic) should be kept refrigerated and used within 24 hours.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 5 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Polyethylene Glycol 3350 Powder for solution: *MiraLax*®, *GlycoLax*®, *ClearLax*®, *Gavilax*®, *Dulcolax Balance*®, generic; (OTC). Available in either pre-measured 17 g packets or bulk powder

Polyethylene Glycol 3350 and Electrolyte Solutions (Rx): There are a variety of products available. The following are representative:

CoLyte®; (Rx); 1 gallon of Powder for Oral Solution in bottles: 227.1 g PEG 3350, 5.53 g sodium chloride (NaCl), 6.36 g sodium bicarbonate, 21.5 g sodium sulfate, 2.82 g potassium chloride (KCl); 4 L of solution: 240 g PEG 3350, 22.72 g sodium sulfate, 6.72 g sodium bicarbonate, 5.84 g NaCl, 2.98 g KCl

GoLYTELY®; (Rx); Powder for Oral Solution in jugs: 5.86 g NaCl, 6.74 g sodium bicarbonate, 22.74 g sodium sulfate, 2.97 g KCl, 236 g PEG 3350; Packets: 227.1 g PEG 3350, 21.5 g sodium sulfate, 6.36 g sodium bicarbonate, 5.53 g NaCl, 2.82 g KCl

NuLytely®, *TriLyte*®, (Rx); Powder for Reconstitution in 4 L jugs: 420 g PEG 3350, 5.72 g sodium bicarbonate, 11.2 g NaCl, 1.48 g KCl

MoviPrep®; (Rx); Powder for Reconstitution in pouches (amount per 1 L): 100 g PEG 3350, 7.5 g sodium sulfate, 2.691 g NaCl, 1.015 g KCl

Polymyxin B, Systemic

(***pol***-lee-***mix***-in ***B***)

Polymyxin Antibiotic

For specific information related to topical use of polymyxin B, see ***Corticosteroid/Antimicrobial Preparations, Otic; Oxytetracycline/Polymyxin B Ophthalmic, Triple Antibiotic Ophthalmic.***

Prescriber Highlights

- ► Concentration-dependent polypeptide bactericidal antibiotic effective against most gram-negative bacilli
- ► Primarily used at subantimicrobial dosages to treat endotoxemia in equine patients
- ► Rarely given at antimicrobial doses because of dose-related adverse effects, including nephrotoxicity and neurotoxicity
- ► Thrombophlebitis at the administration site is possible.

Uses/Indications

Polymyxin B is primarily used in equine patients at subantimicrobial dosages to treat endotoxemia. No studies have been performed in naturally occurring cases of endotoxemia. Polymyxin B administration to healthy foals or horses given lipopolysaccharide (LPS) under experimental conditions resulted in dose-dependent decreases in rectal temperature, decreases in respiratory and heart rates, improved attitude, reduced incidence of hypoglycemia, and decreased concentrations of blood lactate, tumor necrosis factor-alpha, thromboxane B_2, and IL-6.[1–5] The beneficial effects of polymyxin B for endotoxemia appear to be both time- and dose-dependent, with early administration of higher doses proving more beneficial than delayed treatment or lower doses. Similar beneficial results for experimentally induced endotoxemia were found in cats,[6,7] sheep,[8] and dwarf goats.[9] IV regional limb perfusions of polymyxin B may be used as an alternative treatment of horses with induced gram-negative bacteria synovial infections.[10]

In humans, polymyxin B is used to treat sepsis, bacteremia, and serious urinary or respiratory tract infections caused by susceptible bacteria, when safer antibiotics cannot be used.

The World Health Organization has designated polymyxin B as a Critically Important, Highest Priority antimicrobial for human medicine.[11]

Pharmacology/Actions

As an antibacterial agent, polymyxin B binds to phospholipids in bacterial cytoplastic membranes, increasing permeability and causing loss of intracellular components and cell death. It has concentration-dependent bactericidal activity against most gram-negative bacilli, including *Escherichia coli*, *Enterobacter* spp, *Klebsiella* spp, *Haemophilus* spp, and *Pseudomonas* spp, but not *Proteus* spp. Polymyxin B may have synergistic antibacterial effects against *Pseudomonas* spp, *Klebsiella* spp, and *Acinetobacter* spp when combined with imipenem, rifampin, and/or azithromycin. Pus and cellular debris reduce effectiveness. Polymyxin B is ineffective against gram-positive bacteria, gram-negative cocci, or obligate anaerobes. It lacks ac-

tivity against viral, fungal, or parasitic pathogens.

When administered at subantimicrobial dosages to equine patients with endotoxemia, polymyxin B binds to and inactivates the lipopolysaccharide (LPS) component of endotoxin. Polymyxin B inhibited TNF-alpha production in an equine ex vivo study.[12]

Pharmacokinetics

In horses receiving 6000 units/kg polymyxin B sulfate as an IV infusion over 15 minutes, elimination half-life averaged ≈3.3 hours. Administration of 6000 units/kg every 8 hours for 5 treatments was determined to maintain an effective anti-lipopolysaccharide (LPS) polymyxin B concentration.[13]

In humans, polymyxin B is not orally bioavailable. After parenteral administration, polymyxin B distributes poorly into tissues and does not cross the blood–brain barrier. Approximately 50% is bound to cell membrane phospholipids. It is renally excreted. Half-life is 6 hours, which may increase to 48 to 72 hours in anuric patients.

Contraindications/Precautions/Warnings

Polymyxin B is contraindicated in patients that are hypersensitive to it or other polymyxins. It should be used with caution in patients with, or at risk for, renal impairment or respiratory paralysis; it should only be used in hospitalized patients being monitored for these conditions. Fluid support should be provided to maintain renal perfusion; dose reduction may be required in patients with significant renal dysfunction. Overgrowth infections caused by fungi or nonsusceptible bacteria, including *Clostridia* spp, may occur during or after treatment with polymyxin B.

Adverse Effects

Few veterinary data are available. One dog developed pemphigus vulgaris after 1 week of otic polymyxin B application.[14] Transient ataxia during administration was observed in healthy horses.[15]

In humans, most adverse effects are dose related. Polymyxin B may cause renal tubule damage, and hyponatremia, hypokalemia, hypochloremia, and hypocalcemia have been noted. Thrombophlebitis is possible at administration sites. Additional adverse effects may include fever, rash and other skin reactions, and eosinophilia. Neurotoxicity (eg, irritability, weakness, lethargy, ataxia) may occur but is rare; patients with renal impairment that receive high-dose polymyxin B therapy are at increased risk. Rapid IV injection or infusion increases the risk for neuromuscular blockade. IM administration is not advised due to significant pain at the injection site.

Reproductive/Nursing Safety

Although polymyxin B does not cross the placenta and is not absorbed orally, safe use in pregnant or lactating women has not been established; thus, the drug should be used with caution in pregnant or nursing veterinary patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdosage/Acute Toxicity

Polymyxin B may cause renal tubule damage, which may reduce its elimination and prolong its half-life. Respiratory paralysis and other signs of neuromuscular blockade are possible.

Dialysis may remove only 5% to 13% of polymyxin B and is considered ineffective. Neither neostigmine nor calcium administration reverse neuromuscular blockade. Supportive treatment is recommended, including mechanical ventilation when required.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving polymyxin B and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin**): Combination may increase risk for nephropathy.[15]
- **Bisphosphonates** (eg, **clodronate, pamidronate, zoledronic acid**): Combination may increase risk for nephropathy.
- **Loop Diuretics** (eg, **furosemide**): Combination may increase risk for nephropathy.
- **Nephrotoxic Drugs, Other** (eg, **amphotericin B, carboplatin, cyclosporine, iohexol**): Combination may increase risk for nephropathy.
- **Neuromuscular Blockers** (eg, **atracurium, pancuronium, succinylcholine**): Combination may enhance or prolong neuromuscular blockade and increase risk for respiratory paralysis.
- **Nonsteroidal Anti-inflammatory Drugs (NSAIDs;** eg, **flunixin, meloxicam**): Combination may increase risk for nephropathy.
- **Polymyxins, Other** (eg, **colistin – polymyxin E**): Combination may increase risk for toxicity.
- **Sodium Citrate**: Combination may increase risk for respiratory depression.

Laboratory Considerations

None noted

Dosages

NOTE: All dosages are for polymyxin B *sulfate* unless otherwise noted.

CATS:

Reduce clinical signs related to endotoxemia (extra-label): 6000 units/kg IV infusion administered over 30 minutes as a single dose under experimental conditions.[7] Further clinical study is warranted to validate the safety and efficacy of this dosage.

HORSES:

Reduce clinical signs related to endotoxemia (extra-label): 6000 units/kg IV bolus every 8 to 12 hours is most commonly recommended, but an effective dosage range of 1000 – 10,000 units/kg has been supported in experimental studies. Polymyxin B doses were typically further diluted with 0.9% NaCl to a total volume of 12 to 50 mL and administered as an IV bolus.[1,3–5] No cases of nephrotoxicity were observed at these doses in the study patients (healthy foals or horses). Administration early in the disease course is believed to improve outcomes.

Synovial infections (extra-label): From a pharmacokinetic study: 250,000 units (NOT units/kg) via IV regional limb perfusion (IVRLP) achieved therapeutic concentration in synovial fluid.[10] Further clinical study is warranted to validate the safety and efficacy of this dosage.

SHEEP/GOATS:

Reduce clinical signs related to endotoxemia (extra-label):

a) In sheep, under experimental conditions: 6000 units/kg IV infusion along with 2.5 L of isotonic fluids at 20 mL/kg/hour[8]

b) In dwarf goats, under experimental conditions: 3 mg/kg IV infusion administered over 30 minutes (0.1 mg/kg/minute).[9] Study methods do not state whether polymyxin B or polymyxin B sulfate was used.

Monitoring

- Resolution of clinical signs related to endotoxemia (eg, vital signs, CBC)

- Baseline and periodic renal chemistry panel with electrolytes, urinalysis (check for proteinuria), and urine output. In humans, decreased urine output and increasing BUN are indications to discontinue treatment.
- Clinical signs related to neurotoxicity (eg, irritability, weakness, lethargy, ataxia) and respiratory depression or paralysis
- Culture and susceptibility testing prior to treatment when this drug is used for its antimicrobial properties (rare); this testing is not indicated when polymyxin B is used to treat endotoxemia.

Client Information

- Polymyxin B is an antibiotic administered only in the clinic to severely ill patients.
- Polymyxin B use may result in antibiotic-related diarrhea, which may persist for up to 2 months after treatment. Inform your veterinarian if diarrhea develops.

Chemistry/Synonyms

Polymyxin B is a polypeptide antibiotic derived from *Bacillus polymyxa* (*B aerosporous*) that contains Polymyxin B_1 and B_2. Parenteral formulations contain polymyxin B sulfate, which occurs as a white or almost-white, hygroscopic powder and is freely soluble in water and slightly soluble in alcohol. Available formulations of polymyxin B sulfate for injection contain no less than 6000 units polymyxin B per 1 mg. 1 mg pure polymyxin B base is equal to 10,000 units polymyxin B.

Storage/Stability

Prior to reconstitution, polymyxin B sulfate should be stored at controlled room temperature (20°C to 25°C [68°F-77°F]) and protected from light. Reconstituted polymyxin B sulfate solution must be refrigerated (2°C to 8°C [36°F-46°F]); the manufacturer recommends discarding any unused portion after 72 hours. Polymyxin B should not be mixed or stored in strongly acidic or alkaline solutions.

Compatibility/Compounding Considerations

Polymyxin B sulfate for injection requires reconstitution with 2 mL sterile water for injection, 0.9% sodium chloride for injection, or 5% dextrose for injection. In humans, further dilution with 5% dextrose to a final concentration of 1000 to 1667 units/mL is recommended. IV infusions should be administered over 30 to 90 minutes. In studies conducted in healthy foals or horses, polymyxin B doses were diluted with 0.9% NaCl to a total volume of 12 to 50 mL and safely administered as an IV bolus.[4,5]

Polymyxin B is reportedly **compatible** with 5% dextrose and 0.9% sodium chloride solutions. Polymyxin B is reportedly **incompatible** with IV solutions containing calcium or magnesium and is **incompatible** with amphotericin B, ampicillin, calcium salts, cefazolin, cefoxitin, chloramphenicol sodium succinate, diazepam, heparin sodium, insulin, magnesium salts, pantoprazole, and piperacillin-tazobactam.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used. Specialized references or a hospital pharmacist should be consulted for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Polymyxin B Sulfate for Injection: Each vial of lyophilized powder contains the equivalent of 500,000 polymyxin B units; generic; (Rx)

Polymyxin B may be found in a multitude of otic, ophthalmic, and topical products.

Polysulfated Glycosaminoglycan

(***pol***-ee-***sulf***-ayte-ed glye-***kose***-a-meen-ohe-***glye***-kan) *Adequan®*

Proteolytic Enzyme Inhibitor; Chondroprotectant

Prescriber Highlights

- ► FDA-approved for the treatment of noninfectious degenerative and/or traumatic arthritis/joint dysfunction in dogs (IM) and horses (IM or IA)
- ► Contraindications include hypersensitivity to polysulfated glycosaminoglycan (PSGAG) or known or suspected bleeding disorders. Should not be used in place of other treatments when infection suspected or present or in place of necessary surgical repair or joint immobilization
- ► Use it with caution in patients that have hepatic or renal impairment.
- ► Adverse effects are unlikely after IM injection. IA use in horses may result in postinjection inflammation; discontinue therapy if inflammation is excessive.

Uses/Indications

Polysulfated glycosaminoglycan (PSGAG) is FDA-approved in dogs for the control of signs associated with noninfectious degenerative and/or traumatic arthritis of synovial joints.[1] PSGAG had a beneficial and steroid-sparing effect in 3 dogs with pemphigus foliaceus.[2]

PSGAG is indicated in horses for the treatment of noninfectious degenerative and/or traumatic joint dysfunction and associated lameness of the carpal and hock joints.[3,4] The intra-articular product is labeled only for use in the carpal joint. PSGAG can be characterized as a disease-modifying agent in horses with osteoarthritis.[5] Additionally, the drug has demonstrated a positive effect on tendon healing under experimental conditions in horses.[6] PSGAG reduced the lameness score in horses with moderate to severe lameness caused by traumatic arthritis.[7]

Pharmacology/Actions

In joint tissue, polysulfated glycosaminoglycan (PSGAG) inhibits catabolic and proteolytic enzymes (eg, serine proteases, elastase, metalloproteases, hyaluronidases) that can degrade proteoglycans (including naturally occurring glycosaminoglycans), collagen, and hyaluronic acid, all of which increase connective tissue flexibility, resistance to compression, and resiliency. PSGAG also inhibits the synthesis of prostaglandin E_2, which is released in response to joint injury and is associated with the loss of proteoglycan from cartilage. By acting as a precursor, PSGAG increases the synthesis of proteoglycans[8] and hyaluronate in the joint to reduce inflammation and restore synovial fluid viscosity.

Pharmacokinetics

After IM injection, polysulfated glycosaminoglycan (PSGAG) is widely distributed throughout the body. Studies in rabbits and dogs showed peak serum concentrations ≈20 to 40 minutes after IM injection,[1] and peak joint concentrations are reached in 48 hours and persist for up to 96 hours. The drug passively diffuses from the synovial fluid into cartilage. PSGAG is deposited in all layers of articular cartilage and is preferentially taken up by osteoarthritic cartilage. When administered IM, articular concentrations will, over time, exceed those found in the serum.

In rabbits, metabolism occurs in the liver, spleen, bone marrow, and possibly the kidneys. The unchanged drug is primarily renally excreted.[1]

Pharmacokinetic information for horses was not located.

In humans, PSGAG was found to be 30% to 40% bound to plasma proteins.

Contraindications/Precautions/Warnings

Polysulfated glycosaminoglycan (PSGAG) is contraindicated in patients hypersensitive to it. Use is contraindicated in dogs with known or suspected bleeding disorders.[1] Use it with caution in patients with hepatic or renal impairment. PSGAG should not be used in place of other therapies in cases where the infection is present or suspected or in place of necessary surgical repair or joint immobilization.

In horses, concomitant use of PSGAG and NSAIDs or steroids may mask the clinical signs associated with joint sepsis.[3]

Products formulated for intramuscular use must not be injected intra-articularly.[1,3,4]

Adverse Effects

In dogs, adverse effects include pain at the injection site, transient diarrhea or vomiting, and abnormal bleeding.[1] Adverse effects are uncommon and are typically self-limiting without requiring treatment modification. Dose-related inhibition of hemostasis has been described.

In horses, intra-articular administration may cause inflammatory joint reactions, including joint pain, effusion, swelling, and associated lameness.[3] Joint reactions may be due to sensitivity or may be secondary to traumatic injection technique, overdose, or the number or frequency of the injections. Treatment consists of anti-inflammatory drugs, cold hydrotherapy, and rest. Discontinue therapy if excessive inflammation develops. Although uncommon, intra-articular administration can result in septic arthritis[3]; strict aseptic technique should be employed to minimize this occurrence. Amikacin 125 mg has been added to polysulfated glycosaminoglycan (PSGAG) solution (extra-label) when the intra-articular route is used in horses.[5] Nonseptic arthritis, hemathrosis, and cellulitis at the injection site have also rarely been reported.[3]

A case series reported fatal coagulopathies in avian species.[9] Another study in chickens found that thrombin-clotting times were significantly prolonged at 5 and 10 mg/kg doses, but at 1 mg/kg, there was no significant difference compared to control.[10] The results suggested that lower doses could potentially be safely used in avian species, but more research is needed to confirm safety and efficacy.

Reproductive/Nursing Safety

Safe use of polysulfated glycosaminoglycan (PSGAG) in animals intended for breeding or during pregnancy has not been demonstrated. It is not known whether glycosaminoglycans are excreted in maternal milk, but because PSGAG is not orally absorbed,[11] this effect is unlikely to be of clinical significance to the nursing offspring.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In dogs, dose-related intramuscular inflammation, hemorrhage, and degeneration have been noted. Dogs that received 3 times the recommended dose for 3 times the recommended duration were found to have increased cholesterol and microscopic lesions in the liver, kidneys, and lymph nodes. Dogs administered 10 times the recommended dose for 3 times the recommended duration also showed increased prothrombin time, reduced platelet count, increased ALT, and 1 large hematoma, which necessitated euthanasia.[1]

Horses that received 5 times (2.5 g) the recommended dose IM twice weekly for 6 weeks exhibited no untoward effects. ≈2% of horses receiving overdoses (up to 1250 mg) intra-articularly showed transient clinical signs associated with joint inflammation; dose-related increased partial thromboplastin time was noted. Hematoma, increased prothrombin time, and reduced platelet count occurred in dogs receiving 50 mg/kg IM twice weekly for 13 weeks (10 times the labeled dose and triple the labeled duration).

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving polysulfated glycosaminoglycan (PSGAG) and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **rivoroxaban, warfarin**): Concurrent use may increase the risk for bleeding.
- **Antiplatelet Agents** (eg, **aspirin, clopidogrel**): Concurrent use may increase the risk for bleeding.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one, triamcinolone**): Glucocorticoids could mask the clinical signs associated with septic joints.
- **Heparin, Low Molecular Weight Heparins** (eg, **dalteparin, enoxaparin**): Concurrent use may increase the risk for bleeding.

Dosages

DOGS:

Noninfectious degenerative and/or traumatic arthritis (label dosage; FDA-approved): 4.4 mg/kg IM twice weekly for up to 4 weeks (maximum of 8 injections)[1]

Noninfectious degenerative and/or traumatic arthritis (extra-label): 4.4 mg/kg SC twice weekly. Only anecdotal evidence supports the use via a nonapproved route and/or for a longer duration of treatment.

Pemphigus foliaceus (extra-label): Only case studies exist, which suggest a dosage of 4.4 – 4.6 mg/kg SC every 4 days for 4 weeks, then once weekly, in addition to standard treatment.[2]

CATS:

Chondroprotectant agent (extra-label): 2 mg/kg IM every 3 to 5 days for 4 treatments; only anecdotal experience in cats.[12] Many protocols exist for administering polysulfated glycosaminoglycan (PSGAG) to cats, such as 5 mg/kg SC twice weekly for 4 weeks, then once weekly for 4 weeks, then once monthly. No long-term data exist for cats.[13]

HORSES:

Noninfectious and/or traumatic joint dysfunction and associated lameness (label dosage; FDA-approved):

IM administration: 500 mg/horse (NOT mg/kg) IM every 4 days for 28 days[4]

IA administration in the carpal joint (IA-labeled product only): 250 mg total dose (NOT mg/kg) intra-articularly once a week for 5 weeks. The joint area must be shaved, cleansed, and sterilized as in a surgical procedure prior to injecting.[3]

RABBITS, RODENTS, SMALL MAMMALS:

Rabbits for arthritis (extra-label): 2.2 mg/kg SC or IM every 3 days for 21 to 28 days, then once every 2 weeks[14]

Monitoring

- Efficacy
- Joint inflammation and/or signs of infection if administered intra-articularly

Client Information

- Only veterinary professionals should administer the intra-articular product. If using the product used for intramuscular injec-

tions, be sure you understand how to give the injections properly.
- This medicine must be given as an injection as it is not effective when given by mouth.
- It may take up to 4 weeks of treatment to see if the medicine is helping.
- Side effects from this medicine are unlikely.

Chemistry/Synonyms
Polysulfated glycosaminoglycan (PSGAG) is chemically similar to natural mucopolysaccharides found in cartilaginous tissues. It contains repeating disaccharide units primarily composed of chondroitin with 3 or 4 sulfate esters per disaccharide unit and has a molecular weight between 3000 and 150,000. Solutions for injection are clear and colorless to slightly yellow. Multidose vials are preserved with benzyl alcohol. PSGAG is reportedly an analog of heparin.

Polysulfated glycosaminoglycan is also known as PSGAG and *Adequan®*.

Storage/Stability
Store polysulfated glycosaminoglycan (PSGAG) products (canine or equine) at 20°C to 25°C (68°F to 77°F). Products intended for IM use may tolerate excursions of 15°C to 30°C (59°F to 86°F). Avoid prolonged exposure to temperatures greater than 40°C (104°F).

Use multidose containers within 28 days of the first puncture and puncture a maximum of 10 times. When using single-dose vials, discard any unused portions.

The manufacturer does not recommend mixing with any other drug or solvent.[1,3,4]

Compatibility/Compounding Considerations
The manufacturer states that polysulfated glycosaminoglycan (PSGAG) should not be mixed with other drugs or solvents,[1,3,4] although amikacin has been added to PSGAG solution (extra-label) for intra-articular administration to horses.[5]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Polysulfated Glycosaminoglycan for IM Injection: 100 mg/mL in 5 mL vials.; *Adequan® Canine*; (Rx). FDA-approved for use in dogs. NADA #141038

Polysulfated Glycosaminoglycan for Intra-Articular Injection: 250 mg/mL in 1 mL single-use vials, boxes of 6; *Adequan® I.A.*; (Rx). FDA-approved for use in horses (not in those intended for food). NADA# 136-383

Polysulfated Glycosaminoglycan for Intramuscular Injection: 100 mg/mL in 5 mL single-dose vials and 50 mL multidose vials; *Adequan® I.M.*; (Rx). FDA-approved for use in horses (not in those intended for food). NADA# 140-901

Ponazuril
Toltrazuril Sulfone
(poe-***naz***-yoor-ill) *Marquis®*

Antiprotozoal

Prescriber Highlights
- ► Triazine approved to treat equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*
- ► May also be used to treat other protozoal infections in various species, including coccidiosis in shelter dogs and cats
- ► Usually well tolerated; in equine field trials, rashes, hives, blisters, and GI signs were noted.

Uses/Indications
Ponazuril is indicated for the treatment of equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*.[1] Clinical improvement was noted in 60% to 75% of horses that were treated with ponazuril.

One study of shelter dogs and cats with coccidiosis reported ≈90% clearance of infection after a 3-day treatment with ponazuril; animals with low oocyst burdens appeared to respond better than those with high counts.[2]

Pharmacology/Actions
Ponazuril (also known as toltrazuril sulfone) is a metabolite of toltrazuril. The triazine class of antiprotozoals is believed to target the plastid body, an organelle found in the members of the Apicomplexa phylum, including *Sarcocystis neurona*.[3] Ponazuril is coccidiocidal; in vitro concentrations required to kill *Sarcocystis neurona* range from 0.1 to 1 µg/mL. Ponazuril also has activity against several genera of the Apicomplexa phylum and may also be useful in treating *Neospora caninum, Toxoplasma* spp, and other protozoal infections (eg, *Isospora* spp, *Cryptosporidium* spp) in other species (eg, dogs, cats, birds, reptiles, ruminants).

Pharmacokinetics
When ponazuril is administered orally to horses in water, it has a bioavailability of ≈30% and elimination half-life of 80 hours.[4] After daily (5 mg/kg) oral administration to horses, ponazuril reaches its peak serum concentrations in ≈18 days and peak CSF concentrations in ≈15 days. Peak CSF concentrations are 1/20th (0.21 µg/mL) of those found in the serum.[5] Because ponazuril has a long terminal half-life, it takes ≈8 days to reach steady state serum/CSF concentrations in horses dosed at 5 mg/kg once daily.[6] Therefore, a single loading dose of 15 mg/kg is recommended to achieve steady state concentrations more quickly, in ≈1 to 2 days. Elimination half-life from serum averages ≈4.5 days.[1]

Ponazuril dissolved in DMSO and administered orally significantly enhanced bioavailability and peak plasma concentration.[7] Ponazuril administered orally with corn oil increased steady state serum and CSF concentrations by ≈30%.[8]

In cattle, oral doses of ponazuril 5 mg/kg are relatively well absorbed and have an approximate elimination half-life of 58 hours.[4]

Piglets receiving a single 5 mg/kg PO dose had peak plasma concentrations of 5.8 µg/mL at 42 hours, and a terminal half-life of 135 hours.[9]

In goats, a single 10 mg/kg oral dose reached peak plasma levels of 9 µg/mL in 36 hours, with an average half-life of 129 hours.[10]

In healthy llamas given a single 20 mg/kg PO dose, a peak serum concentration of 24 µg/mL was reached at 84 hours, and the elimination half-life was 136 hours.[11]

In tortoises, absorption appears to be prolonged and variable compared with mammals. A 20 mg/kg dose failed to reach serum concentrations that are considered therapeutic in mammals.[12]

Contraindications/Precautions/Warnings

No contraindications were noted. Before treating horses for EPM, other conditions that can cause ataxia should be ruled out. Neurologic deficits may worsen early in the treatment period. Successful treatment may not resolve all the clinical signs associated with equine protozoal myeloencephalitis (EPM).[1]

Adverse Effects

Ponazuril appears to be well tolerated in most species. Equine field trials showed some animals developing blisters on the nose and mouth or a rash/hives.[1] Individual horses developed diarrhea, mild colic, or seizures.[1]

Reproductive/Nursing Safety

Safety during pregnancy has not been evaluated in lactating mares, or horses used for breeding purposes. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Daily doses of up to 30 mg/kg (2 times the loading dose and 6 times the maintenance dose) of ponazuril primarily caused loose feces. Moderate edema of the uterine epithelium was also noted on histopathology for female horses at this higher dose.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions/Laboratory Considerations

- None noted

Dosages

NOTE: The commercially available paste (*Marquis®*) is too concentrated to be given to very small animals and should be diluted before being administered. See ***Compatibility/Compounding Considerations.***

DOGS/CATS:

Coccidiosis (extra-label):

a) 20 mg/kg PO once daily for 3 days[13]
b) 50 mg/kg PO once daily for 3 days; extended courses (two 3-day courses) are sometimes necessary for fecal flotation results to become negative in dogs and cats with coccidiosis[2]
c) 30 mg/kg PO given on days 0 and 7 (2 doses total)

Neosporosis or toxoplasmosis (extra-label): 7.5 – 15 mg/kg PO once daily for 28 days. Dosage extrapolated between known dosages for horses and mice.[14]

Canine hepatozoonosis (extra-label): 10 mg/kg PO every 12 hours for 14 days followed by long-term treatment with decoquinate[15,16]

HORSES:

Equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona* (label dosage; FDA-approved): 15 mg/kg PO as a loading dose on the first day of treatment, followed by 5 mg/kg PO once daily for 27 days[11]

EPM caused by *S neurona* or *Neospora hughesi* (extra-label): 5 mg/kg PO once daily for 28 days.[5] Treatment may continue for 6 to 8 weeks (or longer) if clinical signs continue to improve.[17,18]

Prevention of EPM (extra-label): Therapy minimized, but did not eliminate, infection in horses experimentally infected with *S neurona*.[17]

a) 2.5 – 5 mg/kg PO every 24 hours for 30 to 60 days[19]
b) 20 mg/kg PO every 7 days for 28 days

NEW WORLD CAMELIDS:

Eimeria macusaniensis (extra-label): 20 mg/kg PO once daily for 3 days. Because *E macusaniensis* can cause clinical disease or even death before oocysts are present in feces, prophylactic treatment should be considered in camelids that have unexplained weight loss with concurrent hypoproteinemia and without severe anemia.[11,20]

GOATS:

Coccidiosis (extra-label): 10 mg/kg PO once resulted in decreased oocyst counts. Goats receiving amprolium appeared to respond more favorably than goats that received ponazuril.[21]

BIRDS:

***Cryptosporidium* spp respiratory disease in falcons** (extra-label): From a case report of 2 patients, 20 mg/kg PO (as a compounded suspension) once daily for 7 days[22]

SMALL MAMMALS:

Adjunctive treatment of *Eimeria* spp in rabbits (extra-label): 20 mg/kg PO once a day for 7 days[16]

REPTILES:

Coccidiosis in bearded dragons (extra-label): Anecdotal dosage recommendations vary considerably. Daily spot cleaning of the environment with weekly deep cleaning and disinfection is essential to prevent reinfection.

a) 30 mg/kg PO twice 48 hours apart[23]
b) 30 – 45 mg/kg PO once daily for 28 days[24]

Testudine intranuclear coccidiosis (TINC) in tortoises (extra-label): 20 mg/kg PO every other day for 3 months.[25] Long-term subclinical infection may be possible after treatment despite resolution of clinical signs.[26]

Monitoring

- Clinical efficacy (ie, improvement in neurologic signs such as ataxia and muscle weakness)
- Adverse effects (eg, diarrhea, colic, skin rash, and blisters on the nose and mouth)

Client Information

- It is very important to not miss any doses of this medicine or it may not be effective.
- Ponazuril can be given with or without food.
- Contact your veterinarian if your animal develops a rash, hives, blisters, poor appetite, diarrhea, or redness or discharge from the eyes.

Chemistry/Synonyms

Related to other antiprotozoals such as toltrazuril, ponazuril is a triazine antiprotozoal (anticoccidial) agent. The commercially available oral paste is white to off-white in color and odorless; pH is 5.7 to 6. Solubility of ponazuril in DMSO is 250 mg/mL.

Ponazuril may also be known as toltrazolone sulfone, toltrazuril sulfone, ICI-128436, *Marquis®*, and *Ponalrestat®*.

Storage/Stability

Store the paste at room temperature, 20°C to 25°C (68-77°F), with excursions permitted between 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

For use in small animal species, particularly in shelter situations, various dilutions of the equine paste can be made. One recommendation is to dilute the paste to 100 mg/mL by weighing out 40 g of ponazuril paste, adding sufficient distilled water to reach a total *weight* of 60 g, and mixing well. The paste is water-soluble and can be easily syringed into the animal.[11,20]

For practical purposes, 1 g of paste is roughly equivalent to 1 mL of paste and contains ≈150 mg of ponazuril. No specific stability data were located for these dilutions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Ponazuril Oral Paste (15% w/w): 127 g tubes; each gram of paste contains 150 mg of ponazuril; each syringe is enough to treat a 1200-lb horse for 7 days. *Marquis*®; (Rx). Do not use in horses intended for food.

HUMAN-LABELED PRODUCTS: NONE

Posaconazole

(***poe***-sa-***kon***-a-zole) *Noxafil*®
Azole Antifungal

Prescriber Highlights

- ► Second-generation triazole antifungal with a wide spectrum of activity, but little information on clinical efficacy and safety has been published in veterinary medicine
- ► Currently cost-prohibitive for most clients. May be cost-effective in cats and small dogs for itraconazole- or fluconazole-resistant infections
- ► Full adverse effect profile for animals is not known. GI effects and increases in liver enzymes have been reported.
- ► Treatment may be required for months, and infection may not be fully cleared.
- ► Many potential drug interactions

Uses/Indications

Posaconazole has demonstrated efficacy (eg, improved clinical signs, clinical remission) against severe refractory or resistant systemic fungal infections in dogs and cats, including aspergillosis[1–4] and coccidioidomycosis,[5] and may be useful for treating blastomycosis, histoplasmosis, sporotrichosis, and zygomycosis.

In humans, posaconazole is labeled for prophylaxis (in at-risk patients) or treatment of candidiasis or aspergillosis. It is also used in an extra-label manner for the treatment of other fungal infections.

The currently available dosage forms are expensive and may prohibit posaconazole's clinical use for many animals.

Pharmacology/Actions

Posaconazole is structurally related to itraconazole but has a wider spectrum of activity and, at present, significantly less potential for fungal resistance. Like other triazoles, posaconazole inhibits a fungal cytochrome P450-dependent demethylation enzyme that produces ergosterol in the cell membrane. The resultant intracellular accumulation of methylated sterols weakens the cellular membranes of susceptible fungi, increasing membrane permeability, allowing leakage of cellular contents, and impairing uptake of purine and pyrimidine precursors.

Posaconazole's spectrum of activity includes a variety of organisms, including many species of *Blastomyces*, *Coccidioides*, *Cryptococcus*, *Histoplasma*, *Aspergillus*, *Fusarium*, *Candida*, *Mucor*, and zygomycetes. Fungi that are resistant to posaconazole may also be resistant to other azole antifungals (eg, fluconazole, itraconazole).

Pharmacokinetics

In dogs, the oral bioavailability of 2 different posaconazole oral suspension formulations was 43% to 59%; food increased bioavailability (peak concentration and area under the curve) ≈4 times. The terminal half-life was 15 hours (after IV dosing). Multiple-day dosing caused some accumulation of the drug. Based on the kinetics results and minimum fungicidal concentrations for most organisms, the authors concluded that a dosage of 10 mg/kg/day should be effective.[5]

Another study in dogs compared commercially available oral suspension, delayed-release tablet (DRT), and IV formulations. DRTs resulted in markedly greater absorption compared with oral suspension. Peak concentrations of 0.42 µg/mL (oral suspension) and 1.8 µg/mL (DRT) occurred 7.5 to 9.5 hours after administration (with a meal). Terminal half-lives were 24 hours (oral suspension) and 42 hours (DRT).[6]

In cats that received the oral suspension after a small meal, a peak concentration of 1.2 µg/mL was reached roughly 18 hours after administration. The volume of distribution was 1.9 L/kg, with a terminal half-life of 38 hours.[7]

In humans, DRTs result in greater posaconazole bioavailability compared with oral suspension. Therefore, the 2 dosage forms are not interchangeable at equal doses. Peak concentration after oral suspension administration occurs in 3 to 6 hours. Bioavailability is significantly increased if posaconazole is given with food. Maximum concentration and total exposure were 3 times higher when administered with food compared with fasting and 4 times higher than fasting when given with a high-fat meal. It is widely distributed in tissues, and protein binding is greater than 98%. Posaconazole is metabolized primarily via glucuronidation. ≈71% of a dose is eliminated in feces, primarily as an unchanged drug. About 13% of a dose is eliminated in the urine as metabolites. The average elimination half-life is 35 hours.

Contraindications/Precautions/Warnings

Posaconazole is contraindicated in patients with hypersensitivity to the drug or any component in the suspension. In humans, posaconazole use is contraindicated with concomitant use with HMG-CoA reductase inhibitors (eg, atorvastatin, simvastatin), sirolimus, ergot alkaloids, or CYP3A4 substrates that can prolong QT interval (eg, pimozide, quinidine). Dosage adjustment for patients with decreased renal function is not required when using oral formulations of posaconazole; however, the parenteral formulation contains an inactive ingredient that could accumulate in patients with impaired renal function. Additionally, patients with severe renal impairment should be monitored closely for breakthrough infections, as variable exposure was shown in humans with severe renal insufficiency.

No dose adjustment is needed for patients with hepatic impairment, but caution is recommended. Patients experiencing severe vomiting or diarrhea should be closely monitored for breakthrough infections.

Adverse Effects

There is limited information on the adverse effect profile for posaconazole in dogs or cats. The only adverse effect possibly associated with a 16-week posaconazole treatment in a cat with orbital aspergillosis was facial and ear pruritus with erythema. In a retrospective study of cats with sino-nasal and sino-orbital aspergillosis that had received posaconazole, 2 out of 10 cats developed transient 1.1 to 2 times elevations in ALT activity, but it was otherwise well tolerated.[8]

In 10 dogs with disseminated aspergillosis treated with posaconazole for an average of 7.5 months, adverse effects included vomiting, inappetence, diarrhea, polyuria/polydipsia, and mild increases in ALT.[2] One dog experienced mild thrombocytopenia, and 1 experienced leukopenia/neutropenia. No discontinuation or alteration of dosage was required.[2]

The most commonly reported adverse effects in humans are GI-related and include nausea, vomiting, abdominal pain, and diarrhea. Rare but serious adverse effects include liver failure and cholestasis (associated with high dosages), prolonged QT interval/torsade des pointes, and hypokalemia. Other adverse effects reported include skin rash, headache, tremors, hypertension, anorexia, and weakness.

Mild to moderate increases in liver enzymes and bilirubin can be seen but are usually reversible with therapy discontinuation; monitor

for the development of more severe hepatic injury. Consider discontinuing the drug if clinical signs of liver disease occur.

Reproductive/Nursing Safety

Safe use of posaconazole during pregnancy or nursing has not been established. In rats, skeletal malformations were seen in some offspring of mothers given posaconazole while pregnant. Other azole antifungal drugs are associated with teratogenic effects or early embryonic loss and are not recommended for use in pregnancy except in life-threatening maternal diseases without therapeutic alternatives.[9,10]

Posaconazole is excreted into rat milk, and safe use during nursing is not known.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute toxicity due to a posaconazole overdose is unlikely. Humans have tolerated up to 1600 mg/day in clinical studies, and 1 patient that ingested 1200 mg twice daily for 3 days did not develop adverse effects. In dogs, single oral doses of 240 mg/kg (females) and 480 mg/kg (males) were tolerated with no observable adverse effects; the nonlethal oral dose in dogs was 2000 mg/kg. Repeated dose safety studies with 30 mg/kg/day orally in dogs for up to 1 year showed minimal clinical adverse effects but mild histopathologic changes consistent with other azole antifungal drugs.[11]

Hemodialysis does not remove posaconazole.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Posaconazole can inhibit CYP3A4 and can potentially cause increased plasma concentrations of drugs that are metabolized by CYP3A4. Posaconazole is also a substrate of the P-glycoprotein transport system and can potentially interact with other drugs that inhibit or induce this system.

The following drug interactions (partial list) have either been reported or are theoretical in humans or animals receiving posaconazole and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Benzodiazepines** (eg, **alprazolam, midazolam**): Increased benzodiazepine concentration (up to 5-fold) possible
- **Cimetidine**: Decreased concentration of posaconazole possible; avoid use together. No interactions reported with other H2 blockers (eg, **famotidine**)
- **Cisapride**: Possible prolonged QT interval. In humans, the use of cisapride and posaconazole together is contraindicated, but any clinical relevance for animal patients is unknown.
- **Cyclosporine**: Increased cyclosporine concentration possible; in humans, it is recommended to decrease cyclosporine dose by 25% when starting posaconazole in patients that are already receiving cyclosporine.
- **Digoxin**: Possibility for increased digoxin concentration
- **Diltiazem**: May increase diltiazem concentration
- **Metoclopramide**: Decreased absorption of posaconazole oral suspension is possible; there is no effect on the absorption of posaconazole delayed-release tablets (DRTs)
- **Proton Pump Inhibitors** (eg, **omeprazole**): Decreased absorption of posaconazole oral suspension only; there is no effect on the absorption of posaconazole DRTs.
- **Quinidine**: Increased quinidine concentration, possible prolonged QT interval
- **Rifampin**: Decreased posaconazole concentration
- **Vinca Alkaloids** (eg, **vincristine, vinblastine**): Increased risk for vinca alkaloid toxicity possible
- **Warfarin**: Increased bleeding risk

Laboratory Considerations

No laboratory test interactions were noted.

Dosages

NOTES:

1. The dosing regimens for the oral suspension and the delayed-release tablets (DRTs) are different; do not interchange dosage forms on a mg per mg basis.
2. Oral doses should be administered with food, preferably right after a high-fat meal.[9] Several months of treatment may be required.

DOGS:

Susceptible fungal infections (extra-label):

a) **Suspension**: 5 – 10 mg/kg PO every 12 to 24 hours. A preclinical study suggested that a dosage of 10 mg/kg/day PO should be effective.[2,5]

b) **DRTs**: Based on the results of a pharmacokinetic study, a dosage of 5 mg/kg PO every 48 hours may be considered.[6]

CATS:

Susceptible fungal infections (extra-label):

a) 30 mg/kg PO loading dose followed by 15 mg/kg PO every 48 hours or 15 mg/kg PO loading dose followed by 7.5 mg/kg every 24 hours[3,7]

b) 5 – 7.5 mg/kg PO every 24 hours or divided into 2 doses per day[4,12]

Monitoring

- Efficacy and adverse effects
- Liver enzymes and serum electrolytes; baseline and periodically during treatment
- Patients with severe renal impairment should be monitored closely for breakthrough fungal infections.

Client Information

- When using the oral suspension, shake the bottle well before measuring the dose.
- Delayed-release tablets must be swallowed whole and not chewed or crushed.
- Give this medicine after food; a full meal if possible.
- This medicine may be dosed once per day, but if your animal vomits or acts sick after a dose, your veterinarian may have you give ½ of the daily dose twice per day.
- Treatment for many months may be required.
- There is not much experience with this medication in animals, so if you see any side effects, contact your veterinarian.

Chemistry/Synonyms

Posaconazole is a triazole antifungal that occurs as a white powder that is insoluble in water. The commercially available oral suspension is a white, cherry-flavored immediate-release oral suspension that contains polysorbate 80, simethicone, sodium benzoate, sodium citrate dihydrate, citric acid monohydrate, glycerin, xanthan gum, glucose, titanium dioxide, artificial cherry flavor, and purified water.

Posaconazole may also be known as Sch-56592. Trade names include *Noxafil*® and *Spriafil*®.

Storage/Stability

Store the commercially available oral products at room temperature 25°C (77°F), with excursions permitted to 15°C to 30°C (59°F-86°F); do not freeze. Store the formulation for injection refrigerated 2°C to 8°C (36°F-46°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Posaconazole injection must be further diluted to a final concentration between 1 and 2 mg/mL using a saline or saline/dextrose IV solution. The manufacturer cautions to inspect for particulates prior to administration. Posaconazole should be administered over 90 minutes through a central line with an in-line 0.22-micron filter. The manufacturer states posaconazole for injection is **Y-site compatible** with (partial list) amikacin sulfate, ciprofloxacin, dobutamine HCl, famotidine, gentamicin sulfate, hydromorphone HCl, meropenem, morphine sulfate, and potassium chloride. Posaconazole for injection is **incompatible** with lactated Ringer's solution.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: No systemic products are labeled in the United States.

An otic suspension containing posaconazole 0.1%, orbifloxacin 1%, and mometasone 0.1% is available (for use in dogs with otitis externa); *Posatex*®; (Rx). Refer to ***Corticosteroid/Antimicrobial Preparations, Otic***.

HUMAN-LABELED PRODUCTS:

Posaconazole Oral Suspension: 40 mg/mL in 105 mL bottles; *Noxafil*®; (Rx)

Posaconazole Delayed-Release Tablets: 100 mg; *Noxafil*®; generic; (Rx)

Posaconazole Injection: 300 mg in 16.7 mL vials (18 mg/mL); *Noxafil*®; (Rx)

It is also available as a veterinary otic preparation (*Posatex*®) containing orbifloxacin, posaconazole, and mometasone.

Potassium (-Acetate, -Chloride, -Gluconate)

(po-***tass***-ee-um)

Electrolyte

See also ***Bromides; Iodide (Potassium-, Sodium-);*** and ***Citrate, Potassium***

Prescriber Highlights

- Parenteral and oral electrolyte used for treatment or prevention of hypokalemia
- Contraindications include hyperkalemia, renal failure or severe renal impairment, severe hemolysis, untreated hypoadrenocorticism, acute dehydration, and GI motility impairment (solid oral dosage forms).
- Use with caution in patients receiving digoxin.
- Adverse effects include hyperkalemia. Specific adverse effects with oral therapy include GI distress and, with IV therapy, phlebitis.
- ***Rapid IV potassium supplementation can cause cardiac arrest and death; potassium salts must be diluted before administering IV slowly.***
- Serum potassium and acid-base and hydration status must be monitored during therapy.

Uses/Indications

Potassium supplementation is used to prevent or treat potassium deficits associated with a variety of conditions (eg, vomiting, diarrhea, diabetic ketoacidosis, feline hyperaldosteronism, chronic kidney disease[1]). When it is feasible and appropriate, oral or nutritional supplementation is generally preferred over parenteral potassium administration because oral and nutritional routes carry fewer risks for adverse effects such as cardiac arrest.

Potassium chloride injection can be used for euthanasia of unconscious or fully anesthetized animals (ie, a surgical plane of anesthesia is required *before* using), although its use is generally reserved for situations when other euthanasia methods are unavailable, or when predators or scavengers may consume the euthanized remains.[2]

Pharmacology/Actions

Potassium is the principal intracellular cation in the body. It is essential in maintaining cellular tonicity; nerve impulse transmission; smooth, skeletal, and cardiac muscle contraction; and maintenance of normal renal function. Potassium is also used in carbohydrate metabolism and protein synthesis. Magnesium is a cofactor for potassium regulation, and correction of potassium imbalance may also require addressing serum magnesium.

Potassium requirements in mature dogs are ≈3.7 mEq/kg/day and ≈1.5 mEq/kg/day in mature cats. Puppies and kittens have higher dietary potassium requirements than do mature animals.

Pharmacokinetics

Approximately 98% of total body potassium is found in the intracellular fluid space, with only 2% found in the extracellular fluid space. Plasma pH can alter potassium distribution. Acidosis can shift potassium out of the intracellular space and, conversely, alkalosis shifts potassium into the intracellular space. Insulin shifts potassium to the intracellular space; glucose may also accomplish this effect by stimulating insulin release. Potassium is primarily (80% to 90%) excreted via the kidneys, with the majority of the remainder excreted in the feces. Potassium concentration in GI secretions exceeds that of plasma. Small amounts of potassium may be excreted in perspiration (in animals with sweat glands).

Contraindications/Precautions/Warnings

Potassium salts are contraindicated in patients with hyperkalemia.

Potassium supplementation should be administered with extreme caution when administered IV in patients with renal failure or severe renal impairment, severe hemolysis, extensive tissue damage, untreated hypoadrenocorticism, or acute dehydration. IV potassium salts must be diluted and thoroughly mixed before being administered[3] (see ***Overdose/Acute Toxicity***), then given slowly (see ***Dosages***). ***Rapid IV potassium supplementation can cause cardiac arrest and death;*** infusion rate must not exceed 0.5 mEq/kg/hour.

Use oral potassium supplementation with caution in patients with renal failure or severe renal impairment, severe hemolysis, extensive tissue damage, untreated hypoadrenocorticism, GI motility impairment, or acute dehydration.

Potassium salts of any formulation should be used with caution in patients that are receiving digoxin (see ***Drug Interactions***) and in horses with hyperkalemic periodic paralysis (HYPP).

Because potassium is primarily an intracellular electrolyte, serum measurements may not adequately reflect the total body stores of potassium. Acid-base balance may also impact potassium measurements. Patients with systemic acidosis conditions may appear to have hyperkalemia when, in fact, they may be significantly low in total body potassium. Conversely, alkalosis may cause a falsely low serum potassium value. Assess renal and cardiac function prior to potassium therapy and closely monitor serum potassium levels. IV potassium supplementation should generally occur over 3 to 5 days to allow equilibration to occur between extracellular and intracellular fluids. Some clinicians believe that if acidosis is present or a concern, potassium acetate, citrate, gluconate, or sodium bicarbonate should be used. If alkalosis is present, potassium chloride should be used.

Adverse Effects

The biggest risk associated with potassium supplementation is the development of hyperkalemia, which may be more serious than hypokalemia. Clinical signs associated with hyperkalemia can range from muscular weakness and/or GI disturbances to cardiac conduction disturbances and cardiac arrest.[4] In dogs and cats, ECG changes seen in critical patients with hyperkalemia may be affected by concurrent metabolic derangements (eg, metabolic acidosis, hypermagnesemia, hyponatremia, hypocalcemia) and thus may not typify the expected ECG changes (eg, bradyarrhythmias, loss of P wave, wide QRS complexes, peaked T waves) commonly described for hyperkalemia.[5] In humans, treatment for hyperkalemia is recommended when serum potassium is greater than 5.5 mEq/L if there are ECG changes, or when serum potassium is greater than 6 mEq/L, regardless of ECG findings.[6]

Oral potassium therapy can cause GI distress, including ulceration and GI bleeding, and IV therapy may cause phlebitis.

Reproductive/Nursing Safety

Monitored potassium supplementation is unlikely to have negative effects during pregnancy or lactation. Potassium supplementation that results in hyperkalemia in the dam may also have adverse effects on the fetus or lactating offspring.

Overdose/Acute Toxicity

Fatal hyperkalemia may develop if potassium salts are administered too rapidly IV or if potassium renal excretory mechanisms are impaired (eg, urethral obstruction). Clinical signs associated with hyperkalemia are noted in ***Adverse Effects***. Treatment of hyperkalemia is dependent on the cause and/or severity of the condition and can consist of discontinuation of the drug with ECG, acid-base and electrolyte monitoring, dextrose/insulin infusions, sodium bicarbonate, calcium therapy, polystyrene sulfonate resin, and dialysis.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving potassium and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): Potassium retention may occur; increased risk for hyperkalemia
- **Angiotensin-Receptor Blockers** (**ARBs**; eg, **irbesartan, telmisartan**): Potassium retention may occur; increased risk for hyperkalemia
- **Antimuscarinic Agents** (eg, **atropine, opioids**): Delay GI transit, increasing risk for adverse GI effects from tablet or capsule formulations
- **Digoxin**: In patients with severe or complete heart block that are receiving digitalis therapy, potassium salts are generally not recommended.
- **Diuretics, Potassium-Sparing** (eg, **spironolactone**): Potassium retention may occur; increased risk for hyperkalemia. Avoid concomitant use.
- **Nonsteroidal Anti-inflammatory Drugs (NSAIDs;** eg, **carprofen, meloxicam, robenacoxib**): Oral potassium administered with NSAIDs may increase the risk for GI adverse effects.

Dosages

DOGS/CATS:

NOTE: There are no exact formulas for calculating the total body potassium depletion or the requirement for supplementation needed to restore normokalemia. Guidelines should always be modified based on patient response. Patients with hypokalemia and osmotic diuresis will have a much higher requirement for potassium than patients with normal urine output. Hypokalemia associated with diabetic ketoacidosis and postobstructive diuresis requires additional monitoring and treatment; refer to specific references for additional information.

Chronic mild hypokalemia (3.0 – 3.5 mEq/L):

a) **Potassium gluconate** (label dosage; not FDA-approved): 2 mEq/4.5 kg (10 lb) PO with food twice daily; adjust dosage as necessary based on periodic serum potassium measurements.

b) **Potassium chloride** (extra-label): 0.5 – 1 mEq/kg PO mixed in food once or twice daily; adjust dosage as necessary based on periodic serum potassium measurements.

Moderate to severe (less than 3.0 mEq/L) hypokalemia | acute hypokalemia with or without metabolic alkalosis:

a) The rate of IV administration of KCl is more critical than the total amount administered. Under most circumstances, the rate should not exceed 0.5 mEq/kg/hour. Under the most dire circumstances (serum potassium less than 2.0 mEq/L), the rate of potassium administration can be increased to 1.5 mEq/kg per hour along with close, continuous ECG monitoring.[7] **NOTE**: Administering more than 10 mEq/hour of KCl to a small animal (less than 10 kg [22 lb] body weight) can be potentially life-threatening because of the effects of a more concentrated solution on the wall of the right ventricle if the solution is given through a central IV line.[4] Although potassium administration should be determined by how much potassium to administer to the patient (not by how much KCl to add to a

bag of fluid), see table below for suggested guidelines:

Measured serum K+ (mEq/L or mmol/L)	mEq KCl/1000 mL IV fluid*
Less than 2	60 – 80
2 – 2.5	40 – 60
2.5 – 3	30 – 40
3 – 3.5	20 – 30

*Be sure to take into consideration the amount of potassium already present in polyionic crystalloids (eg, LRS contains 4 mEq potassium/1000 mL of fluid) when deciding how much potassium to add to the fluid bag.

b) For patients less than 10 kg that are not able to be hospitalized and require outpatient treatment, isotonic fluids such as lactated Ringer's or 0.9% saline with added 30 – 35 mEq KCL/L can be given at a dose of 150 mL SC every 12 hours.[8]

HORSES:

Hypokalemia (extra-label): To counteract potassium depletion in a completely anorectic adult horse, IV fluids should be supplemented to deliver at least 50 mEq KCl/hour. Hypertonic oral KCl pastes can be administered to horses with diarrhea.[9] **NOTE**: IV administration rate should not exceed 0.5 mEq/kg/hour.

Euthanasia of unconscious or fully anesthetized animals (extra-label): 1 – 2 mEq/kg rapid IV or intracardiac.[2] Animal ***must*** be fully unconscious prior to administration. Administered volume may be quite large (eg, 250 mL – 500 mL of KCl 2 mEq/mL solution for a 500 kg [1102.3 lb] horse).

RUMINANTS:

Severe hypokalemia (less than 2.3 mEq/L) with severe muscle weakness or recumbency (extra-label): Isotonic potassium chloride 11.5 g/1 L of sterile water at a rate of 4 mL/kg/hour IV CRI in combination with large doses of oral potassium salts (ie, KCl 200 g/day).[10]

Hypokalemia (less than 3.5 mEq/L): Potassium chloride 100 – 120 g PO dissolved in water every 12 hours; doses exceeding 0.4 g/kg/day PO are not recommended, except in cattle with profound hypokalemia.[11,12]

Euthanasia of unconscious or fully anesthetized animals (extra-label): 1 – 2 mEq/kg rapid IV or intracardiac.[2] Animal ***must*** be fully unconscious prior to administration. Administered volume may be quite large (eg, 350 to 700 mL of 2 mEq/mL solution for a 700 kg cow).

Monitoring

The degree and frequency of monitoring associated with potassium therapy is dependent on the cause and/or severity of hypokalemia, the route of potassium administration, acid-base abnormalities, renal function, concomitant drugs administered, and disease states and can include:

- Serum potassium; other electrolytes; frequent monitoring of serum potassium is strongly recommended when potassium supplementation ia administered by the IV route
- Acid-base status
- Glucose
- ECG; continuous ECG monitoring is strongly recommended when correcting moderate to severe hypokalemia with aggressive potassium supplementation and/or when other metabolic derangements (eg, metabolic acidosis) are encountered with critical patients.[13]
- CBC
- Urinalysis

Client Information

- Oral potassium is best administered with food to help prevent stomach upset.
- Overdoses (both one time and over a period of time) of potassium can be life-threatening. Contact your veterinarian immediately if you suspect an overdose.

Chemistry/Synonyms

Potassium acetate occurs as a white crystalline powder or as flakes. It is odorless or has a slight acetic odor and is freely soluble in water. The 2 mEq/mL commercial solution has a pH of 6.2 (5.5 to 8). One gram of potassium acetate contains 10 mEq of potassium.

Potassium acetate may also be known as E262, hocura-diureticum, kalii acetas, kaliumacetat, *Onixol®*, and Trikates oral solution.

Potassium chloride occurs as either a white, granular powder or as colorless, elongated, prismatic, or cubical crystals. It is odorless and has a saline taste. One gram is soluble in ≈3 mL of water and is insoluble in alcohol. The pH of the injection ranges from 4 to 8. One gram of potassium chloride contains 13.4 mEq of potassium. A 2 mEq/mL solution has an osmolarity of 4000 mOsm/L.

Potassium chloride may also be known as cloreto de potassio, E508, kalii chloridum, kalium chloratum, *Kaochlor®*, KCl, *K-Dur 20®*, *K-lor®*, *Klorvess®*, *K-lyte®*, potash muriate, and potassium muriate.

Potassium gluconate occurs as a white to yellow-white, crystalline powder or as granules. It is odorless, has a slightly bitter taste, and is freely soluble in water. One gram of potassium gluconate contains 4.3 mEq of potassium.

Potassium gluconate may also be known as E577, *K-G Elixir®*, *Kaon®*, *Kaylixir®*, *Potasoral®*, *Potassiject®*, *Potassium-Rougier®*, *Renakare®*, *Sopa-K®*, *Tumil-K®*, and *Ultra-K®*.

Storage/Stability

Potassium acetate injection should be stored at controlled room temperature (20°C-25°C [68°F-77°F]).

Unless otherwise directed by the manufacturer, potassium chloride products should be stored in tight containers at room temperature (15°C-30°C [59°F-86°F]); protect from freezing.

Potassium gluconate oral products should be stored in tight, light-resistant containers at room temperature (15°C-30°C [59°F-86°F]), unless otherwise instructed by the manufacturer.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Adequate mixing of IV solutions to which potassium has been added must occur prior to administration; multiple inversions of the bag are recommended.[3]

Potassium chloride for injection is reportedly physically **compatible** with the following IV solutions and drugs (as an additive): all commonly used IV replacement fluids (not 10% fat emulsion), aminocaproic acid, aminophylline, amiodarone HCl, ampicillin, calcium gluconate, cefazolin, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, corticotropin (ACTH), cytarabine, diphenhydramine, dopamine HCl, erythromycin gluceptate/lactobionate, famotidine, fentanyl citrate, fluconazole, gentamicin, heparin sodium, hydrocortisone sodium succinate, isoproterenol HCl, lidocaine HCl, magnesium sulfate, metoclopramide HCl, morphine sulfate, norepinephrine bitartrate, oxacillin sodium, oxytetracycline HCl, penicillin G potassium, phenylephrine HCl, ranitidine, tetracycline HCl, vancomycin HCl, verapamil HCl, and vitamin B-complex with C.

Potassium chloride for injection **compatibility information con-**

flicts or is dependent on diluent or concentration factors with the following drugs or solutions: fat emulsion 10%, amikacin sulfate, dobutamine HCl, mannitol, methylprednisolone sodium succinate (**at Y-site**), ondansetron, penicillin G sodium, promethazine HCl (**at Y-site**), and sodium bicarbonate.

Potassium chloride for injection is reportedly physically **incompatible** with the following solutions or drugs: amphotericin B, diazepam **(at Y-site),** and phenytoin sodium **(at Y-site).**

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Parenteral Products: There are several products for parenteral use that contain potassium; refer to ***Appendix*** tables or individual proprietary veterinary products for additional information.

Oral Products: These products are not found in the FDA Green Book; approval status is uncertain.

Potassium Gluconate Tablets: 2 mEq (468 mg); *Tumil-K®*, *Renakare®*, generic; (Rx). Labeled for use in cats and dogs

Potassium Gluconate Oral Powder: Each 0.65 g (¼ teaspoon) contains 2 mEq of potassium in 4 oz containers; *Renakare®*, *Tumil-K®*; (Rx). Labeled for use in dogs and cats

Potassium Gluconate Gel: Each 2.34 g (½ teaspoon) contains 2 mEq of potassium in 5 oz tubes; *Tumil-K® Gel*, *Renakare®*; (Rx). Labeled for use in dogs and cats

HUMAN-LABELED PRODUCTS (NOT A COMPLETE LIST):

Parenteral Products:

Potassium Chloride for Injection Concentrate: 2 mEq/mL in single-dose and multi-dose vials and ***must be diluted before administering***; generic; (Rx)

Potassium Chloride for Injection, Highly Concentrated: 10 mEq and 20 mEq in 50 mL or 100 mL bags, and 40 mEq/100 mL bags; generic; (Rx). Ready-to-use solution for fluid-restricted patients; requires administration through a central line via calibrated infusion device.

There are also premixed IV bags of saline and dextrose (both separately and in various combinations) that contain potassium 10 mEq/L, 20 mEq/L, 30 mEq/L, or 40 mEq/L.

Potassium Acetate for Injection Concentrate: 2 mEq/mL and 4 mEq/mL and ***must be diluted before administering***; (Rx)

Potassium Phosphate for Injection (see ***Phosphate, Intravenous***) is also available.

Oral Products: There are many human-labeled potassium salts for oral use available in several dosage forms; refer to human drug references for more information on these products. Tablets, controlled/sustained release tablets and capsules, effervescent tablets, liquids, and powder in varying strengths available; (OTC, Rx)

Pradofloxacin

(pra-doe-***flox***-a-sin) *Veraflox®*

Fluoroquinolone Antibiotic

Prescriber Highlights

- ► FDA-approved for use in cats; approved for dogs in some countries
- ► Enhanced aerobic gram-positive activity and activity against anaerobes; its gram-negative activity is similar to other fluoroquinolones.
- ► Contraindications include hypersensitivity to fluoroquinolones; do not administer to pregnant or lactating animals, or kittens less than 12 weeks of age, as safety has not been determined.
- ► May produce erosions of cartilage of weight-bearing joints and other signs of arthropathy in immature animals of various species
- ► Use with caution in patients with renal insufficiency, pre-existing CNS disorders (eg, epilepsy), or underlying conditions that predispose to arrhythmias (eg, electrolyte imbalances, cardiac disease); use with caution in immunocompromised cats (ie, infected with feline leukemia and/or feline immunodeficiency virus), as safety has not been determined.
- ► Adverse effects may include GI distress, photosensitivity, myelosuppression, and arrhythmias (dogs only).
- ► Many potential drug interactions
- ► FDA prohibits extra-label use in food animals. Should not be used in humans

Uses/Indications

In cats, pradofloxacin oral suspension is FDA-approved for the treatment of skin infections (wounds and abscesses) caused by susceptible strains of *Pasteurella multocida, Streptococcus canis, Staphylococcus aureus, Staphylococcus felis,* and *Staphylococcus pseudintermedius.* Pradofloxacin has also been used clinically in cats for the treatment of bacterial UTIs, *Bartonella* spp,[1] *Mycoplasma haemofelis* upper respiratory infections, and in combination with other antimycobacterial drugs for feline leprosy syndromes. One study showed pradofloxacin to be equivalent to amoxicillin for treatment of bacterial upper respiratory infections.[2]

Pradofloxacin is not FDA-approved for use in dogs (see ***Contraindications/Precautions/Warnings***). In other countries, pradofloxacin is labeled for the treatment of wound infections, superficial and deep pyoderma caused by susceptible strains of the *S pseudintermedius* group (including *S pseudintermedius*); acute UTIs caused by susceptible strains of *Escherichia coli* and the *S pseudintermedius* group (including *S pseudintermedius*); and as adjunctive treatment to mechanical or surgical periodontal therapy in the treatment of severe infections of the gingiva and periodontal tissues caused by susceptible strains of anaerobic organisms (eg, *Porphyromonas* spp and *Prevotella* spp).

The World Health Organization (WHO) has designated fluoroquinolones as Critically Important (Highest Priority) antimicrobials for human medicine.[3] The Office International des Epizooties (OIE) has designated fluoroquinolones as Veterinary Critically Important Antimicrobial (VCIA) Agents for veterinary species.[4]

Pharmacology/Actions

Pradofloxacin is a broad-spectrum third-generation bactericidal fluoroquinolone antibiotic. The bactericidal activity of pradofloxacin is concentration dependent, so its antibacterial activity is dependent on high peak concentrations. Its antibacterial action is via inhibition of DNA gyrase and topoisomerase IV, thereby preventing DNA supercoiling and DNA synthesis.

Pradofloxacin is unique among veterinary fluoroquinolones in that it has enhanced aerobic gram-positive activity and activity against anaerobes; its gram-negative activity is similar to other fluoroquinolones. This spectrum of activity is similar to the human fluoroquinolone, moxifloxacin. Pradofloxacin, compared with other veterinary fluoroquinolones, also has enhanced activity against *Mycoplasma* spp. It is the only antibiotic shown to date that can eliminate *Mycoplasma haemofelis* from the blood of experimentally inoculated cats.[5] Methicillin-resistant staphylococci (MRSP) isolates are usually resistant to all fluoroquinolones, including pradofloxacin.[6] Proposed ALCS breakpoints during the FDA approval process of less than 1 µg/mL were considered susceptible and breakpoints greater than 2 µg/mL were considered resistant.

Pradofloxacin has weak activity against streptococci and enterococci and is not recommended in the treatment of these infections.

Unlike enrofloxacin, pradofloxacin does not cause retinal toxicity in cats.[7] It has also not been linked to *Streptococcus canis*-associated necrotizing fasciitis.

Pharmacokinetics

In dogs, after oral administration, pradofloxacin is rapidly absorbed with peak plasma concentrations occurring ≈2 hours after a dose.[8] Bioavailability is reported to be high and not affected by tablet size or the dose administered. Repeated doses do not impact pharmacokinetics. Volume of distribution is more than 2 L/kg, and only ≈35% of the drug is bound to plasma proteins. Peak drug concentrations are slightly higher in serum than in interstitial fluid but persist at concentrations higher than in plasma for most of the 24-hour dosing period. Pradofloxacin at 3 mg/kg PO resulted in 5 times as high PK-PD values in leukocytes compared with plasma, with the lowest values in CSF, synovial fluid, and aqueous humor.[9] Highest tissue concentrations were found in cartilage, liver, and kidneys and measured 1 to 1.5 hours after a dose. Clearance was 0.24 L/hour/kg, and plasma elimination half-life was ≈8 hours. Pradofloxacin is primarily metabolized via glucuronidation and sulfation; ≈40% of a dose is excreted in the urine. Approximately 85% of a dose is excreted into the urine within 24 hours—40% is excreted unchanged and the rest is excreted primarily as glucuronide metabolites.[10–13]

In cats, pradofloxacin is rapidly absorbed with peak plasma concentrations occurring within 1 to 2 hours.[8,14] Oral bioavailability is ≈60% with oral suspension and ≈70% with oral tablets. Repeat doses do not significantly alter the pharmacokinetics. A 5 mg/kg PO dose produced a peak concentration of 2.1 µg /mL when given to fasted cats; administration with food reduces peak concentrations by 50% and total absorption by ≈25%. Volume of distribution is relatively high, and only ≈30% of the drug is bound to plasma proteins. Like in dogs, glucuronidation is the major metabolic pathway for cats; 70% of a dose is excreted into the urine within 24 hours, but only ≈10% of it is excreted as unchanged drug. Clearance is 0.27 L/hour/kg, and terminal plasma elimination half-life has been variably reported from 3 to 8 hours.[11,12,15] Clinical efficacy is associated with achieving a peak pradofloxacin concentration 10 times greater than bacterial MIC.[16,17]

Contraindications/Precautions/Warnings

Pradofloxacin is contraindicated in animals that are hypersensitive to it or other quinolones. It should not be used in kittens younger than 12 weeks of age[18] (younger than 6 weeks on United Kingdom label[14]), as safety has not been evaluated. Pradofloxacin has been shown to produce erosions of cartilage of weight-bearing joints and other signs of arthropathy in immature animals of various species.[18] Pradofloxacin should not be used in dogs and cats with pre-existing articular cartilage lesions.[8,14] Additionally, pradofloxacin administration to healthy cats for longer than 7 days resulted in reversible leukopenia, neutropenia, and lymphopenia.[18]

Although pradofloxacin is approved for use in dogs in other countries (eg, United Kingdom, Europe), it is not FDA-approved in the United States due to myelosuppression (thrombocytopenia and leukopenia) observed in canine safety studies at daily oral pradofloxacin doses of 27 mg/kg (6 times the maximum recommended dose) and above, but not at lower, recommended doses.[12,18] Additional contraindications for dogs include use in dogs less than 12 months of age (most breeds), in giant breeds less than 18 months old due to effects on articular cartilage, and with CNS disorders (eg, epilepsy).[19]

Use with caution in animals with impaired renal function or severely impaired hepatic function. It should also be used with caution in dogs predisposed to arrhythmias and in cats with pre-existing CNS disorders[18] (eg, epilepsy, a contraindication on the United Kingdom label[8,14]). The safety of pradofloxacin in immune-compromised cats (eg, cats infected with feline leukemia virus and/or feline immunodeficiency virus) has not been evaluated.[18]

Fluoroquinolones may cause photosensitization, and prolonged exposure of bare (eg, nose) or thinly haired skin to direct sunlight should be avoided.

The artificial beef flavor used in the tablets originates from irradiated (to inactivate any viruses or micro-organisms) pig livers. Dogs that are hypersensitive to pork products could potentially react to these proteins.

Extra-label use of fluoroquinolones is prohibited in food animals.

Adverse Effects

In dogs and cats, pradofloxacin at recommended dosages appears to be well tolerated with diarrhea/loose stools occasionally reported. Articular cartilage abnormalities have been noted in young, rapidly growing animals given fluoroquinolones (see ***Contraindications/Precautions/Warnings***).[8,14,18]

Myelosuppression (thrombocytopenia, neutropenia, lymphopenia) is possible in dogs and cats (when used for longer than 7 days).[18] Therapy should be discontinued if this occurs. See ***Contraindications/Precautions/Warnings***

In dogs, QT interval can be increased and pradofloxacin potentially could have proarrhythmic effects, especially in patients with coexisting risk factors (eg, hypothyroidism, bradycardia, electrolyte disturbances, heart failure, or liver or kidney disease).[20]

Reproductive/Nursing Safety

Pradofloxacin is labeled as contraindicated for use during pregnancy or lactation.[8,14] The drug does not pose additional risk when used in breeding animals.[8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Pradofloxacin appears to be quite safe in acute overdose situations, with vomiting and diarrhea possible. The approximate LD_{50} after a single intraperitoneal application in rats was more than 50 mg/kg, and single oral doses of 100 mg/kg were tolerated well in young cats, and in dogs; however, in one dog there was temporary overloading of renal excretory capacity.[12]

Acute overdoses should be managed supportively. Consider performing baseline white blood cell counts in dogs with overdoses.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions either have been reported or are

theoretical in humans or animals receiving pradofloxacin or other fluoroquinolones and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids, Aluminum-, Calcium- or Magnesium-Containing**: May bind to pradofloxacin and prevent its absorption; separate doses of these products by at least 2 hours.
- **Cimetidine**: Cimetidine has been shown to interfere with the metabolism of quinolones and should be used with care when used concurrently.[18]
- **Corticosteroids** (eg, **dexamethasone, prednisone**): May enhance the toxic effect of quinolones, specifically the risk for tendonitis and tendon rupture
- **Cyclosporine**: Fluoroquinolones may exacerbate the nephrotoxicity and reduce the metabolism of cyclosporine. Concurrent use of pradofloxacin with oral cyclosporine should be avoided.[18]
- **Dairy Products**: May bind to pradofloxacin and prevent its absorption; do not administer pradofloxacin with dairy products.
- **Digoxin**: Concurrent use of pradofloxacin with digoxin should be avoided, as it may increase the oral bioavailability of digoxin.
- **NonSteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **flunixin**): Flunixin has been shown in dogs to increase the AUC and elimination half-life of enrofloxacin, and enrofloxacin increases the AUC and elimination half-life of flunixin; it is unknown if pradofloxacin also causes this effect or if other NSAIDs interact with pradofloxacin in dogs. Fluoroquinolones should not be used in combination with NSAIDs in animals with a history of seizures due to potential pharmacodynamic interactions in the CNS.[8,14]
- **Glyburide**: Severe hypoglycemia is possible with concurrent use of glyburide with pradofloxacin.
- **Iron, Zinc** (oral): Decreased pradofloxacin absorption; separate doses by at least 2 hours.
- **Lanthanum**: May decrease pradofloxacin absorption
- **Methotrexate**: When used concurrently with pradofloxacin, increased methotrexate levels possible with resultant toxicity
- **Nitrofurantoin**: May antagonize the antimicrobial activity of fluoroquinolones, and concomitant use of nitrofurantoin with pradofloxacin is not recommended.
- **Probenecid**: Blocks tubular secretion of ciprofloxacin and may also increase the blood level and half-life of pradofloxacin
- **QT-Prolonging Agents** (eg, **cisapride, sotalol, quinidine, erythromycin, ondansetron**): May enhance the QT-prolonging effect of pradofloxacin
- **Sevelamer**: May decrease pradofloxacin absorption
- **Sucralfate**: May inhibit absorption of pradofloxacin; separate doses of these drugs by at least 2 hours.
- **Theophylline**: Pradofloxacin may increase theophylline blood concentration. The United States label states, The dosage of theophylline should be reduced when used concurrently with quinolones.[18] The United Kingdom labels state, The combination of fluoroquinolones with theophylline could increase the plasma levels of theophylline by altering its metabolism and thus should be avoided.[8,14]

Laboratory Considerations

No specific concerns noted.

Dosages

DOGS:

Wound infections, superficial and deep pyoderma caused by susceptible strains of the *Staphylococcus pseudintermedius* group (including *S pseudintermedius*); acute UTIs caused by susceptible strains of *Escherichia coli* and the *Staphylococcus pseudintermedius* group (including *S pseudintermedius*); and as adjunctive treatment to mechanical or surgical periodontal therapy in the treatment of severe infections of the gingiva and periodontal tissues caused by susceptible strains of anaerobic organisms (extra-label):

3 – 4.5 mg/kg PO once daily.[8] As with other fluoroquinolones, the upper end of the dosing range may be preferable. The duration of the treatment depends on the nature and severity of the infection and on the response to treatment.

CATS:

Skin infections (wounds and abscesses) caused by susceptible strains of *Pasteurella multocida, Streptococcus canis, Staphylococcus aureus, Staphylococcus felis,* and *Staphylococcus pseudintermedius* (label dosage; FDA-approved): 7.5 mg/kg (3.4 mg/lb) PO once daily for 7 consecutive days. If acceptable response to treatment is not observed, or if no improvement is seen within 3 to 4 days, then the diagnosis should be re-evaluated and appropriate alternative therapy considered.[18]

Bartonellosis (extra-label): 5 – 10 mg/kg PO once or twice daily for 28 to 42 days.[1,21] (**NOTE**: larger, once-daily dosages of fluoroquinolones are preferred over twice-daily administration.) Elimination of infection often requires use of more than one class of antibiotic. For cats that are reasonably stable (eg, when treating *Bartonella* spp-linked polyarthritis), one recommendation is to start with one antibiotic (eg, doxycycline 5 mg/kg PO every 12 hours), then add the second antibiotic (eg, pradofloxacin) 5 to 7 days later. Initiation of both antibiotics simultaneously has been associated with a Jarisch-Herxheimer-like reaction, which can be confused with an adverse drug reaction.[1,21]

Mycoplasma haemofelis (extra-label): 5 – 10 mg/kg PO once daily for 14 days[5]

Acute infections of the upper respiratory tract caused by susceptible strains of *Pasteurella multocida*, *E coli,* and the *Staphylococcus intermedius* group (including *S pseudintermedius*) (extra-label): Oral suspension, 5 – 7.5 mg/kg PO once daily[14]; oral tablets, 3 – 4.5 mg/kg PO once daily.[8] The duration of the treatment depends on the nature and severity of the infection and on the response to treatment. For most infections the following treatment courses will be sufficient: wound infections and abscesses, 7 days; acute infections of the upper respiratory tract, 5 days.

BIRDS:

Infections caused by susceptible strains of *Staphylococcus* spp and *Streptococcus* spp species (extra-label): 15 mg/kg PO every 24 hours[22]

Monitoring

- Clinical efficacy, including culture and susceptibility when indicated
- Consider performing baseline and periodic white blood cell counts. Discontinue therapy if an unexplained drop in leukocyte, neutrophil, and/or lymphocyte counts is noted.[18]

Client Information

- This medicine is an antibiotic used to treat bacterial infections. Be sure to give your animal this medicine exactly as prescribed by your veterinarian.
- If using the liquid form, shake the container well before measuring each dose. Use the syringe provided to ensure accurate dosing. Rinse syringe between doses.
- This medicine is best given without food on an empty stomach,

but if your animal vomits or acts sick afterwards, give it with food or a small treat (no dairy products, antacids, or anything containing iron). If vomiting continues, contact your veterinarian.
- Be sure to finish the entire course of treatment even if your animal appears to feel better.
- Pradofloxacin may stunt bone growth or cause joint abnormalities if used in young animals, or during pregnancy or while nursing.
- The most common side effects are vomiting, nausea (acting sick), or diarrhea.
- For animals with thin hair coats, there may be a risk of sun sensitivity within a few hours after receiving this type of antibiotic.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

Pradofloxacin (CAS Registry 0195532-12-8; ATCvet: QJ01MA97, QJ01MA) is an 8-cyano fluoroquinolone antibiotic structurally similar to moxifloxacin. It occurs as a brownish, light yellow to yellow, fine crystalline powder. Pradofloxacin has 4 enantiomeric forms, but secondary to its high antimicrobial potency, the S,S-isomer is used in the pharmaceutical products.

The oral suspension contains 2 mg/mL sorbic acid (E200) as a preservative.

Pradofloxacin may also be known as UNII-6O0T5E048I. Its trade name is *Veraflox*®.

Storage/Stability

The oral suspension should be stored below 30°C (86°F) in the original container and kept tightly closed; after opening, it is stable for 60 days[18] (3 months on United Kingdom label[19]). Oral tablets require no special storage conditions, but once the container is opened, they should be protected from light and moisture.

Compatibility/Compounding Considerations

No information has been located.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Pradofloxacin Oral Suspension: 25 mg/mL in 15 mL and 30 mL bottles; *Veraflox*®; (Rx). Approved for use in cats. NADA 141-344#

Pradofloxacin Oral Tablets: 15 mg, 60 mg, and 120 mg. Approved in United Kingdom and Europe for cats (15 mg only) and dogs (15 mg, 60 mg, 120 mg); POM-V; *Veraflox*®; (Rx)

HUMAN-LABELED PRODUCTS: NONE

Pralidoxime (2-PAM)

(pra-li-***dox***-eem) *Protopam Chloride*®

Antidote; Cholinesterase Reactivator

Prescriber Highlights

- ► Cholinesterase reactivator used for adjunctive treatment of organophosphate poisoning
- ► Contraindications include hypersensitivity; generally not recommended for carbamate poisoning.
- ► Use with caution in animals with renal impairment and patients receiving anticholinesterase agents for the treatment of myasthenia gravis.
- ► Adverse effects appear to be uncommon; rapid IV injection may cause tachycardia, muscle rigidity, transient neuromuscular blockade, or laryngospasm.
- ► Most effective if given within 24 hours of exposure
- ► Available dosage forms and significant cost may be a limiting factor.

Uses/Indications

Pralidoxime is used in the treatment of organophosphate poisoning, in conjunction with atropine and supportive therapy.

Pralidoxime must generally be given within 24 hours of exposure to be effective, but some benefits may occur, particularly in large exposures, if given within 36 to 48 hours.

Pralidoxime has been shown to have vasoconstrictive properties. When pralidoxime is administered during CPR in pig models, it has been shown to increase coronary perfusion pressure leading to higher rates of restoration of spontaneous circulation[1–3]; however, clinical significance is not yet determined.

Pharmacology/Actions

Pralidoxime reactivates cholinesterase that has been inactivated by phosphorylation secondary to certain organophosphates. Via nucleophilic attack, the drug removes and binds the offending phosphoryl group attached to the enzyme, which is then excreted. Pralidoxime may have protective effects on cholinesterase and may directly detoxify some organophosphates. It has greater activity at nicotinic sites. Its effects occur primarily at the neuromuscular junction of respiratory and skeletal muscle. Because it acts in the periphery, atropine is needed to block the effect of accumulated acetylcholine in the respiratory center.

Pharmacokinetics

Pralidoxime is only marginally absorbed after oral dosing, and oral dosage forms are no longer available in the United States. It is rapidly distributed, primarily throughout the extracellular fluid. Because of its quaternary ammonium structure, it has limited CNS penetration.

Pralidoxime is thought to be metabolized by the liver and rapidly excreted as both metabolite(s) and unchanged drug in the urine. Elimination half-life in humans is ≈75 minutes. The half-life in ruminants is ≈2 to 5 hours.[4]

Contraindications/Precautions/Warnings

Pralidoxime is contraindicated in patients that are hypersensitive to it. Pralidoxime is generally not recommended for use in instances of carbamate poisoning because cholinesterase inhibition by carbamates is rapidly reversible, but there is some controversy regarding this issue. One case report has demonstrated efficacy in a dog with carbamate toxicity using a lower, more frequent dosing regimen.[5]

Pralidoxime should be used with caution in patients receiving anticholinesterase agents for the treatment of myasthenia gravis, as it may precipitate a myasthenic crisis. It should also be used cautiously and at a reduced dose in patients with renal impairment. Temporary

worsening of cholinergic signs can occur if pralidoxime is administered IV too rapidly.

Adverse Effects

At usual doses, pralidoxime generally is safe and free of significant adverse effects. Transient increases in liver enzymes and creatine phosphokinase may occur. Rapid IV injection may cause tachycardia, muscle rigidity, transient neuromuscular blockade, and laryngospasm.

In humans, pain at injection site has been reported after IM administration.

Reproductive/Nursing Safety

It is not known whether this drug causes fetal harm or is excreted in maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The acute LD_{50} of pralidoxime in dogs is 190 mg/kg. Signs of overdose may include dizziness, nausea, or increased heart rate; however, it may be difficult to distinguish these signs from effects of the poisoning being treated.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pralidoxime and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Atropine**: Effects of atropine occur more rapidly with concomitant use.
- **Barbiturates**: Anticholinesterases can potentiate the action of barbiturates; use with caution.
- **Benzodiazepines** (eg, **diazepam, midazolam**): Respiratory depressants should be avoided in patients with organophosphate toxicity.
- **Cimetidine**: Use should be avoided in patients with organophosphate toxicity.
- **Reserpine**: Use should be avoided in patients with organophosphate toxicity
- **Opioids** (eg, **morphine**): Respiratory depressants should be avoided in patients with organophosphate toxicity.
- **Succinylcholine**: Use should be avoided in patients with organophosphate toxicity.
- **Theophylline**: Use should be avoided in patients with organophosphate toxicity.

Dosages

NOTES:

1) Usually used in conjunction with ***Atropine***; refer to that monograph and/or the references below for more information.
2) Treatment may vary depending on patient factors such as type of poisoning, amount ingested, and time since ingestion.

DOGS/CATS:

Organophosphate poisoning (extra-label):

a) 25 mg/kg IM; repeat in 1 hour if muscle weakness has not been resolved
b) Cats: 20 – 25 mg/kg IM every 12 hours[6]
c) Initial dose of 20 mg/kg IV, IM, or SC. IV administration is preferred; dilute in saline and administer over at least 5 minutes (see ***Compatibility/Compounding Considerations*** below). Subsequent doses of 20 mg/kg IM, SC, or IV (slowly) every 6 to 12 hours can be administered until nicotinic signs (eg, tachycardia, hypertension, muscle fasciculations, respiratory depression) are present. Discontinue after 3 to 4 treatments if no response or if nicotinic signs are aggravated.
   i. Alternatively, 50 mg/kg/day IV CRI may be used[7]
   ii. Kittens: 50 mg/kg initial dose followed by a 20 mg/kg dose the next day in a kitten[8]
   iii. Dogs: 66 mg/kg given IV over 12 hours in a dog[9]

HORSES:

Organophosphate poisoning (extra-label): 20 mg/kg (may require up to 35 mg/kg) IV and repeat every 4 to 6 hours[10]

RUMINANTS:

Organophosphate poisoning in cattle (extra-label): 30 mg/kg IM every 8 hours[11]

CAMELIDS:

Organophosphate poisoning (extra-label): 20 mg/kg (route not specified)[12]

BIRDS:

Organophosphate poisoning (extra-label):

a) 10 – 20 mg/kg every 8 to 12 hours (route not specified) with atropine 0.2 – 0.5 mg/kg IM every 3 to 4 hours.[13] Use lower dose when given with atropine[14]
b) 10 – 100 mg/kg IM every 24 to 48 hours or repeat once in 6 hours[15]

Monitoring

- Pralidoxime therapy is monitored via improvement in the clinical signs associated with organophosphate poisoning (eg, salivation, lacrimation, urination, defecation/diaphoresis, gastrointestinal upset, emesis [SLUDGE]). For more information, refer to one of the references outlined in the dosage section.

Client Information

- This agent should only be used with close professional supervision.

Chemistry/Synonyms

A quaternary ammonium oxime cholinesterase reactivator, pralidoxime chloride occurs as a white to pale yellow, crystalline powder with a pK_a of 7.8 to 8. It is freely soluble in water. The commercially available injection has a pH of 3.5 to 4.5 after reconstitution.

Pralidoxime chloride may also be known as 2-Formyl-1-methylpyridinium chloride oxime, 2-PAM, 2-PAM chloride, 2-PAMCl, 2-pyridine aldoxime methochloride and *Protopam®*.

Storage/Stability

Unless otherwise instructed by the manufacturer, pralidoxime chloride powder for injection should be stored at room temperature, with excursions permitted to 15° to 30°C (59°F-86°F). After reconstituting with sterile water (preservative-free) for injection, the solution should be used immediately. Do not use sterile water with preservatives to reconstitute the powder for injection.

Compatibility/Compounding Considerations

Reconstitute with 20 mL of sterile water for injection to yield 50 mg/mL. For IV infusion, a concentration of 10 – 20 mg/mL in sodium chloride 0.9% is recommended. For IM injection when IV administration is not feasible, reconstitute each vial with 3.3 mL of sterile water for injection (with no preservatives added) to yield 300 mg/mL.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

NOTE: When used in food animals, FARAD recommends a 28-day meat and a 6-day milk withdrawal time.[16]

HUMAN-LABELED PRODUCTS:
Pralidoxime Chloride Powder for Injection: 1 g in 20 mL single-use vials; *Protopam® Chloride*; (Rx)

Also available in 600 mg/2 mL IM auto-injectors as single agent, or in combination with atropine sulfate 2.1 mg/0.7 mL.

Praziquantel/Praziquantel Combination Products

(pra-zi-***kwon***-tel) *Droncit®, Drontal®, Drontal Plus®*

Anticestodal Antiparasitic

For information on other combination products that contain praziquantel, see ***Emodepside/Praziquantel, Eprinomectin/Praziquantel, Ivermectin, Lufenuron, Milbemycin Oxime, Moxidectin/Moxidectin Combination Products,*** *and* ***Pyrantel.***

Prescriber Highlights

- ► Anthelmintic approved for treatment of cestodes (tapeworms) in dogs and cats. It may also be useful for some trematodes.
- ► Many combination products exist with different anthelmintic spectrums of activity.
- ► Contraindications include puppies younger than 4 weeks, kittens younger than 6 weeks, and hypersensitivity to the drug.
- ► Use with caution in patients with hepatic impairment.
- ► Adverse effects are uncommon after oral use but may include GI upset or lethargy. Adverse effects appear more common after injection and include pain at the injection site, anorexia, salivation, vomiting, lethargy, weakness, or diarrhea.

Uses/Indications

Praziquantel is FDA-approved in dogs for the treatment of *Dipylidium caninum*, *Taenia pisiformis*, *Echinococcus granulosus* and treatment and control of *E multilocularis*. In cats, it is FDA-approved for the treatment of *D caninum* and *T taeniaeformis*. A single dose is usually effective, but measures should be taken to prevent reinfection (eg, flea control), particularly against *D caninum*.

Praziquantel can also be used extra-label to treat trematodes (eg, *Alaria* spp, *Paragonimus kellicoti, Heterobilharzia americana*) and other cestodes (eg, *Diphyllobothrium* spp, *Spirometra* spp) in dogs and cats.

Praziquantel has been used in birds and other animals, including horses and small ruminants; however, use in large animal species (ie, cattle, horses, small ruminants) is usually not economically feasible.

Combination products with praziquantel can control a wide spectrum of internal parasites in a variety of species. The combination products containing pyrantel pamoate have additional activity against hookworms and roundworms; adding febantel broadens the spectrum of activity to include whipworms.

Pharmacology/Actions

The mechanism of action of praziquantel against cestodes is thought to be the result of the drug interacting with phospholipids in the parasite integument, causing ion fluxes of sodium, potassium, and calcium. At low concentrations in vitro, the drug appears to paralyze the worm's sucker function and stimulate worm motility. At higher concentrations in vitro, praziquantel contracts and paralyzes (irreversibly at very high concentrations) the worm's strobilla (ie, chain of proglottids). In addition, praziquantel causes irreversible focal vacuolization, with subsequent cestodal disintegration at specific sites of the cestodal integument. The parasite ultimately becomes susceptible to digestion.

In schistosomes and trematodes, praziquantel directly kills the parasite, possibly by increasing calcium ion flux in the worm. This is followed by focal vacuolization of the integument, and the parasite is phagocytized by the host.

Details related to additional components of combination products can be found in the respective drug monographs. Febantel is an anthelmintic with activity against nematode parasites, including whipworms, and is partially metabolized into the active metabolites fenbendazole and oxibendazole. For more information, refer to ***Fenbendazole*** and ***Oxibendazole***. Pyrantel pamoate is active against hookworms and roundworms. It acts on the cholinergic receptors of the nematode, resulting in spastic paralysis. For more information, refer to ***Pyrantel***.

Pharmacokinetics

Praziquantel is nearly completely absorbed after oral administration, but there is a significant first-pass effect. Peak serum concentrations are achieved between 30 to 120 minutes in dogs.[1] It is distributed throughout the body. It crosses the intestinal wall and blood–brain barrier into the CNS. Protein binding is ≈80%.[1]

Praziquantel is metabolized in the liver via CYP3A enzymes to metabolites of unknown activity. It is excreted primarily in the urine; elimination half-life is 1 hour in cats[2] and ≈3 hours in dogs[1] (a half-life of 7.4 hours has been reported in greyhounds[3]). Elimination half-life after administration of a topical combination product containing praziquantel was 347 hours in dogs and 152 hours in cats.[3] In dogs, orally administered grapefruit juice can increase drug exposure (area under the curve; AUC) by 150% to 200%.[4] Hepatic impairment may result in prolonged, higher praziquantel concentration; elimination half-life was 1.5 to 3 times longer in humans with moderate to severe hepatic impairment.[5]

Praziquantel pharmacokinetics in parasites have not been described, but drug uptake appears to occur readily.

Contraindications/Precautions/Warnings

Praziquantel is contraindicated in patients that have previously shown hypersensitivity to it or any excipients. The manufacturer recommends not using praziquantel in puppies younger than 4 weeks or kittens younger than 6 weeks.

In humans, praziquantel is contraindicated in patients with ocular parasitism and should be used with caution in patients with moderate to severe liver dysfunction or a history of epilepsy.[6]

Adverse Effects

In dogs, oral administration of praziquantel can cause anorexia, vomiting, lethargy, or diarrhea; the incidence of these effects is less than 5%.[7] In cats, salivation and diarrhea were reported after oral administration; in field trials, the incidence of adverse effects was less than 2%.[7]

A greater incidence of adverse effects has been reported after use of the injectable product. In dogs, pain at the injection site was the most frequent adverse effect, with vomiting, drowsiness, and/or a staggering gait also reported.[8] Approximately 9.4% of cats showed clinical signs of diarrhea, weakness, vomiting, salivation, sleepiness, transient anorexia, and/or pain at the injection site.

Reproductive/Nursing Safety

Praziquantel is considered safe for use in pregnant dogs or cats. Praziquantel (up to 300 mg/kg/day) did not impair fertility or reproductive performance in rats and was not harmful to rabbit or rat fetuses.[6] However, the label for the combination product containing praziquantel, pyrantel pamoate, and febantel states to not use in pregnant animals, as doses 3 times the label dosage increased the incidence of abortion and fetal abnormalities in dogs.[9]

Praziquantel appears in maternal milk at a concentration of ≈25% of that in maternal serum but appears safe for use in nursing patients.

Overdose/Acute Toxicity

Praziquantel has a wide margin of safety. In rats and mice, oral LD_{50} is at least 2 g/kg. Praziquantel at 25 – 50 mg/kg IM or SC every 14 days did not cause clinical toxicity in dogs as young as 4 weeks or cats as young as 5.5 weeks. Vomiting, salivation, and depression occurred in dogs given praziquantel at 150 – 200 mg/kg. Parenteral doses of 100 – 200 mg/kg in cats caused vomiting, muscle tremors, transient ataxia, and depression; death occurred in ≈80% of cats. In dogs homozygous for the *ABCB1* (*MDR-1*) gene mutation, tremors, ataxia, salivation, agitation, panting, and seizures followed administration of a topical praziquantel/emodepside combination.[10,11]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Praziquantel is metabolized by the CYP3A enzyme.[12] The following drug interactions have either been reported or are theoretical in humans or animals receiving praziquantel and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Albendazole**: May increase albendazole sulfoxide concentration
- **Cimetidine**: May increase the serum concentration of praziquantel
- **CYP3A4 Inducers** (eg, **dexamethasone, phenobarbital, rifampin**): May decrease praziquantel concentrations.[12,13] In humans, it is recommended to discontinue rifampin 4 weeks before administering praziquantel.
- **Grapefruit Juice**: Can significantly increase praziquantel serum concentrations[4]
- **Itraconazole, Ketoconazole**: May increase praziquantel concentrations

Laboratory Considerations

None noted

Dosages

NOTE: For dosages of other combination products that contain praziquantel, *see* ***Emodepside/Praziquantel, Eprinomectin/Praziquantel, Ivermectin, Lufenuron, Milbemycin Oxime, Moxidectin/Moxidectin Combination Products,*** *and* ***Pyrantel***.

DOGS:

Praziquantel as a single agent:

Removal of tapeworms (eg, *Dipylidium caninum*, *Taenia pisiformis*, *Echinococcus granulosus*) and removal and control of *E multilocularis* (label dosage; FDA-approved): For use in dogs and puppies 4 weeks of age and older

Injectable: IM or SC dose using the 56.8 mg/mL injectable product is determined by body weight. In dogs, IM may be preferred, as it appears less painful than SC administration.

Droncit® Injectable

Body weight	Dose
Up to 2.3 kg (5 lb)	17 mg (0.3 mL)
2.7-4.5 kg (6-10 lb)	28.4 mg (0.5 mL)
5-11.4 kg (11-25 lb)	56.8 mg (1 mL)
Over 11.4 kg (25 lb)	5 mg/kg (0.2 mL per 5 lb); maximum of 3 mL

Oral: Using the 34 mg canine tablet in dogs 4 weeks of age and older[8]:

Droncit® Tablets for Puppies and Adult Dogs

Body weight	Number of tablets
2.3 kg (5 lb) and under	0.5
2.7-4.5 kg (6-10 lb)	1
5-6.8 kg (11-15 lb)	1.5
7.2-13.6 kg (16-30 lb)	2
14.1-20.5 kg (31-45 lb)	3
20.9-27.3 kg (46-60 lb)	4
Over 27.3 kg (60 lb)	5 (maximum)

Praziquantel combination products:

Praziquantel/Febantel/Pyrantel Pamoate (*Drontal® Plus*):

Removal of tapeworms (eg, *Dipylidium caninum*, *Taenia pisiformis*, *Echinococcus granulosus*), hookworms (eg, *Ancylostoma caninum, Uncinaria stenocephala*), ascarids (eg, *Toxocara canis, Toxascaris leonina*), and whipworms (*Trichuris vulpis*) and removal and control of *Echinococcus multilocularis* (label dosage; FDA-approved): Three tablet sizes are available: Puppies and small dogs, 0.9 to 11.3 kg (2 to 25 lb); medium-sized dogs, 11.8 to 27.2 kg (26 to 60 lb); large dogs, more than 20.4 kg (45 lb). See table below to determine the correct tablet size and dose. **NOTE**: Dogs from 45 to 60 lb can be dosed with either 2 medium tablets or 1 large tablet. Ensure correct dose is given for tablet size used. Not for use in puppies younger than 3 weeks of age or dogs weighing less than 0.9 kg (2 lb).[9]

Drontal® Plus Tablets and Taste Tabs® for Puppies and Small Dogs (0.9 to 11.3 kg [2 to 25 lb])

Body weight	Number of tablets
0.9-1.8 kg (2-4 lb)	0.5
2.3-3.2 kg (5-7 lb)	1
3.6-5.5 kg (8-12 lb)	1.5
5.9-8.2 kg (13-18 lb)	2
8.6-11.4 kg (19-25 lb)	2.5

Drontal® Plus Tablets and Taste Tabs® for Medium-Sized Dogs (11.8 to 27.2 kg [26 to 60 lb])

Body weight	Number of tablets
11.8-13.6 kg (26-30 lb)	1
14.1-20 kg (31-44 lb)	1.5
20.5-27.3 kg (45-60 lb)	2

Drontal® Plus Tablets and Taste Tabs® for Large Dogs (20.4 kg [45 lb] and greater)

Body weight	Number of tablets
20.5-27.3 kg (45-60 lb)	1
27.7-40.9 kg (61-90 lb)	1.5
41.4-54.5 kg (91-120 lb)	2

Praziquantel as a single agent (extra-label):

a) ***Taenia* spp, *Echinococcus* spp, *Dipylidium caninum*, *Mesocestoides* spp (adult)**: 5 mg/kg PO or SC[14]
b) ***Diphyllobothrium* spp**: 7.5 mg/kg PO once daily for 2 days.[14] Alternatively, 25 mg/kg PO daily for 2 consecutive days[15]
c) ***Sparganum proliferum* (adult)**: 7.5 mg/kg or 25 mg/kg PO or SC daily for 2 days[14]
d) ***Spirometra mansonoides* or *Diphyllobothrium erinacei***: 7.5 mg/kg PO once daily for 2 days[16]
e) **Paragonimiasis (*Paragonimus kellicotti*)**: 23 – 25 mg/kg PO every 8 hours for 3 days[17,18]
f) **Liver flukes (*Platynosomum* spp or Opisthorchiidae families)**: 20 – 40 mg/kg PO once daily for 3 to 10 days.[19] Alternatively, 20 mg/kg PO as a single dose appeared effective in an infected kennel of huskies.[20]
g) ***Alaria* spp**: 20 mg/kg PO once[21] or once daily for 2 to 10 days[22]
h) **Adjunctive treatment of flukes (*Nanophyetus salmincola*) associated with Salmon poisoning**: 10 – 30 mg/kg PO or SC once[23]
i) ***Heterobilharzia americana***: From a case report, 25 mg/kg PO every 8 hours for 2 days; the dog had previously received 3 courses of fenbendazole[24]
j) **Peritoneal larval cestodiasis:** From a case report, 5 mg/kg SC; the dog was previously treated with a 10-day course of fenbendazole 50 mg/kg PO every 12 hours[25]

Praziquantel combination products (extra-label):

a) **Giardiasis using *Drontal® Plus***: Use the label dosage according to weight-based dosing tables on the product label once daily PO for 3 days[26]
b) **Persistent *Ancylostoma caninum*:** Label dosages according to weight-based dosing tables on the product labels for topical moxidectin combination products or oral praziquantel/febantel/pyrantel pamoate administered once monthly were effective in 8 greyhounds with persistent *Ancylostoma caninum*, as measured by monthly fecal ova testing.[27]

CATS:

Praziquantel as a single agent:

Removal of *Dipylidium caninum* and *Taenia taeniaeformis* (label dosage; FDA-approved): For use in cats 6 weeks of age and older

Injectable: IM or SC dose using the 56.8 mg/mL injectable product as a single dose:

Droncit® Injectable

Body weight	Dose
Less than 2.3 kg (5 lb)	11.4 mg (0.2 mL)
2.3-4.5 kg (5-10 lb)	22.7 mg (0.4 mL)
5 kg (11 lb) and over	34.1 mg (0.6 mL); maximum dose

Oral: Using the 23 mg feline tab as a single dose:[8]

Droncit® Tablets for Cats and Kittens

Body weight	Number of tablets
1.8 kg (4 lb) and under	0.5
2.3-5 kg (5-11 lb)	1
Over 5 kg (11 lb)	1.5

Praziquantel combination products:

Praziquantel/Pyrantel Pamoate (*Drontal®*):

Removal of tapeworms (*Dipylidium caninum*, *Taenia pisiformis*), hookworms (*Ancylostoma tubaeforme*), and ascarids (*Toxocara cati*) (label dosage; FDA-approved): In cats and kittens at least 2 months of age and weighing 0.9 kg (2 lb) or more.[28]

Drontal® Tablets for Cats

Body weight	Number of tablets
0.9-1.4 kg (2-3 lb)	0.5
1.8-3.6 kg (4-8 lb)	1
4.1-5.4 kg (9-12 lb)	1.5
5.9-7.3 (13-16 lb)	2

Praziquantel as a single agent (extra-label):

a) **Paragonimiasis (*Paragonimus kellicotti*)**: 23 – 25 mg/kg PO every 8 hours for 3 days[17,18]
b) ***Diphyllobothrium* spp (adult)**: 25 mg/kg PO daily for 2 consecutive days or 35 mg/kg PO once has been recommended[14,15]
c) ***Sparganum proliferum* (adult)**: 7.5 mg/kg or 25 mg/kg PO or SC daily for 2 days[14]
d) ***Alaria* spp**: 20 mg/kg PO once[21] or once daily for 2 to 10 days[22]
e) ***Taenia* spp, *Echinococcus* spp, *Dipylidium caninum*, *Mesocestoides* spp (adult)**: 5 mg/kg PO or SC once[14]
f) ***Spirometra mansonoides***: 30 – 35 mg/kg PO once[29] or once daily for 2 days[30]
g) ***Platynosomum* spp:** 30 mg/kg PO every 24 hours for 5 to 10 days[31]

Praziquantel combination products (extra-label):

a) ***Aelurostrongylus abstrusus* (adult) using praziquantel/emodepside (*Profender®*):** Emodepside 3 mg/kg and praziquantel 12 mg/kg, applied topically; repeat dose 14 days after initial treatment[32]
b) ***Giardia* spp infections using praziquantel/febantel/pyrantel (*Drontal®* Plus)**: Give 2 small dog tablets (praziquantel, 22.7 mg; febantel, 113.4 mg; pyrantel, 22.7 mg) PO once daily for 5 days[33]

HORSES:

Susceptible parasites (label dosage; FDA-approved): 1 – 2.5 mg/kg PO using combination products containing praziquantel with ivermectin or moxidectin[34,35]

Anoplocephala perfoliata (extra-label): 1.5 – 2 mg/kg PO was 100% effective in treated horses; 1 mg/kg PO was 99.7% effective[36]

NEW WORLD CAMELIDS:

Dicrocoelium dendriticum (extra-label): 50 mg/kg PO once (**NOTE**: concentrated [250 mg/mL] galenic paste formulation[37])

SHEEP, GOATS:

a) ***Moniezia* spp, *Stilesia* spp, or *Avitellina* spp** (extra-label): 10 – 15 mg/kg PO[16]
b) **Cestodes** (extra-label): 10 – 15 mg/kg PO once[38]
c) ***Dicrocoelium dendriticum*** (extra-label): 50 mg/kg PO once was 95.9% effective[39]
d) ***Schistosoma bovis* in goats** (extra-label): 60 mg/kg PO once[40]

BIRDS:

Susceptible parasites (tapeworms) (extra-label):

a) ¼ of one 23 mg tablet/kg PO, repeated after 10 to 14 days. Add to feed or give by gavage. Injectable form is toxic to finches.[41]

b) **Common tapeworms in chickens**: 10 mg/kg PO[16]

c) **Cestodes and some trematodes**: Direct dose: 5 – 10 mg/kg PO or IM once or 12 mg of crushed tablets baked into a 9 × 2-inch cake. Finches should have their regular food withheld and be pre-exposed to a non-medicated cake.[42]

RABBITS, RODENTS, SMALL MAMMALS:

NOTE: All dosages are extra-label.

a) **Chinchillas**: 6 – 10 mg/kg PO[43]

b) **Cestodes in chinchillas, rats, mice, hamsters, gerbils, and guinea pigs**: 6 – 10 mg/kg PO or SC once[44]

c) **Ferrets**: 5 mg/kg PO once[45]; alternatively, 5 – 10 mg/kg PO, repeated after 10 to 14 days[44]

d) **Trematodes in ferrets**: 25 mg/kg PO once daily for 3 days (depending on type of trematode)[45]

e) **Cestodes and trematodes in rabbits**: 5 – 10 mg/kg PO once[46]; may be repeated after 10 days[44]

f) ***Schistosoma bovis* in rabbits**: 40 mg/kg PO

REPTILES/AMPHIBIANS:

NOTE: All dosages are extra-label.

a) **Reptiles**: Cestodes and some trematodes in most species: 7.5 mg/kg PO once, repeated after 2 weeks PO[47]

b) **Removal of common tapeworms in snakes**: 3.5 – 7 mg/kg[16]

c) **Cestodes and trematodes in reptiles and amphibians**: 7 – 8 mg/kg PO, IM, SC[48]

d) **Removal of susceptible cestodes in tortoises**: 8 mg/kg SC, repeated after 14 days[49]

Monitoring

- Clinical efficacy: Confirm presence of parasites with fecal laboratory examination

Client Information

- This medicine can be given with or without food. The tablets may be crushed or mixed with food. Your animal does not need to have food withheld prior to treatment.
- When this medicine is given by mouth, side effects are rare, but this medicine can cause loss of appetite, salivation or drooling (in cats), vomiting, lethargy/tiredness/lack of energy, and/or diarrhea. Persistent vomiting, bloody stool, or profuse/watery diarrhea should be reported to your veterinarian.
- Dead tapeworms are not usually seen in the feces after treatment.
- Praziquantel removes tapeworms but does not prevent re-infestation, which may occur as early as 1 month after treatment. It is important to discuss parasite control with your veterinarian.

Chemistry/Synonyms

Praziquantel, a prazinoisoquinoline derivative anthelmintic, occurs as a white to practically white, hygroscopic, bitter, crystalline powder, either odorless or having a faint odor. It is very slightly soluble in water and freely soluble in alcohol.

Praziquantel may also be known as EMBAY-8440, praziquantelum, *Anthelmin®*, *Biltricide®*, *Bio-Cest®*, *Cazitel®*, *Cercon®*, *Cesol®*, *Cestox®*, *Cisticid®*, *ComboCare®*, *Cysticide®*, *Doplac®*, *Droncit®*, *Dronspot®*, *Drontal®*, *Ehliten®*, *Endogard®*, *Equimax®*, *Eqvalan®*, *Extiser® Q®*, *Mycotricide®*, *Opticide®*, *Praquantel®*, *Prasikon®*, *Prazite®*, *Prozitel®*, *Quest® Plus*, *Sincerck®*, *Teniken®*, *Veloxa®*, *Virbantel®*, *Waycital®*, *Zifartel®*, or *Zimecterin Gold Paste®*.

Storage/Stability

Unless otherwise instructed by the manufacturer, praziquantel tablets should be stored in tight containers at room temperature (25°C [77°F]). Protect from light. Praziquantel injection should be stored at or below 25°C (77°F) and not allowed to freeze. Vials of praziquantel injection should be used within 6 months of first vial puncture and discarded after a maximum number of punctures (10 mL vial, 25 times; 50 mL vial, 90 times).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Praziquantel Tablets: 23 mg (feline); 34 mg (canine); *Droncit® Canine Tablets*, *Droncit® Feline Tablets*, generic; (Rx; OTC). FDA-approved for use in cats and dogs

Praziquantel Injection: 56.8 mg/mL in 10 mL and 50 mL vials; *Droncit® Injection*, generic; (Rx). FDA-approved for use in cats and dogs

Combination Products:

Praziquantel/Emodepside: Praziquantel 7.94% w/w (85.8 mg/mL) and emodepside 1.98% w/w (21.4 mg/mL) topical solution for cats in 0.35 mL (2.2-5.5 lb), 0.7 mL (5.5-11 lb) and 1.12 mL (over 11-17.6 lb) tubes; *Profender®*; (Rx). FDA-approved for use on cats 8 weeks of age and older and weighing at least 1 kg (2.2 lb).

Praziquantel/Eprinomectin: Praziquantel (83 mg/mL) and eprinomectin (4 mg/mL) topical solution for cats in 0.3 mL (1.8-5.5 lb) and 0.9 mL (5.6-16.5 lb); *Centragard®*; (Rx). FDA-approved for use on cats 7 weeks of age and older and weighing at least 1.8 lb.

Praziquantel/Febantel/Pyrantel Oral Tablets and Chewable Tablets: 22.7 mg/113.4 mg/22.7 mg (puppies and small dogs 2-25 lb); 68 mg/340.2 mg/68 mg (Medium-Sized Dogs 26-60 lb); 136 mg/680.4 mg/136 mg (Large Dogs more than 45 lb); *Drontal®* Plus Tablets and *Taste Tabs®*, generic; (Rx). FDA-approved for use in dogs 3 weeks of age and older.

Praziquantel/Ivermectin Oral Paste: 14.03% praziquantel and 1.87% ivermectin in oral syringes (sufficient to treat a 1320 lb horse); *Equimax®*, generic; (OTC). FDA-approved for use in horses or ponies not intended for food purposes.

Praziquantel/Ivermectin Oral Paste: 7.75% praziquantel and 1.55% ivermectin in oral syringes; *Zimecterin Gold®*; (OTC). FDA-approved for use in horses or ponies not intended for food purposes

Praziquantel/Milbemycin Chewable Oral Tablets for Dogs: 22.8 mg/2.3 mg (2-8 lb); 57 mg/5.75 mg (8.1-25 lb); 114 mg/11.5 mg (25.1-50 lb); 228 mg/23 mg (50.1-100 lb); *Interceptor® Plus* (Rx). FDA-approved for use in dogs and puppies 6 weeks of age or older and weighing 0.9 kg (2 lb) or greater

Praziquantel/Milbemycin/Lufenuron Chewable Oral Tablets for dogs: 2.3 mg/46 mg/22.8 mg (2-8 lb); 5.75 mg/115 mg/57 mg (8.1-25 lb); 11.5 mg/230 mg/114 mg (25.1-50 lb); 23 mg/460 mg/228 mg (50.1-100 lb); *Sentinel® Spectrum®* (Rx). FDA-approved for use in dogs and puppies 6 weeks of age or older

Praziquantel/Moxidectin: Praziquantel 125 mg/mL and moxidectin 20 mg/mL oral gel in 11.6 g syringes (sufficient to treat one 1250 lb horse); *Quest Plus®*; (OTC). FDA-approved for use in horses or ponies 6 months of age and older and not intended for food purposes

Praziquantel/Pyrantel Tablets: Praziquantel 18.2 mg/pyrantel base 72.6 mg (as pamoate); *Drontal® Tablets*; (OTC). FDA-approved for use in cats and kittens that are 2 months of age or older and weighing 0.9 kg (2 lb) or greater

Praziquantel/Pyrantel Chewable Tablets: Praziquantel 30 mg/pyrantel pamoate 30 mg; Praziquantel 114 mg/pyrantel pamoate 114 mg chewable tablets; *Virbantel®* Flavored *Chewables*, generic; (OTC). FDA-approved for use in dogs

Praziquantel/Pyrantel/Ivermectin Chewable Tablets: 28.5 mg/28.5 mg/34 µg (6-12 lb), 57 mg/57 mg/68 µg (12.1-25 lb); 114 mg/114 mg/136 µg (25.1-50 lb); 228 mg/228 mg/272 µg (50.1-100 lb); *Iverhart®Max, Quadriguard®*; (Rx). FDA-approved for use in dogs 8 weeks of age and older

HUMAN-LABELED PRODUCTS:
Praziquantel Oral Tablets (film-coated): 600 mg; *Biltricide®*; (Rx)

Prazosin

(pra-zoe-***sin***) *Minipress®*
Alpha-1-Adrenergic Blocker

Prescriber Highlights

- ► Alpha-1-adrenergic blocker that may be useful to treat functional urethral obstruction in dogs and cats
- ► May also be used as adjunctive treatment for congestive heart failure (CHF) or systemic hypertension in dogs; however, prazosin is not considered a first-line choice
- ► Should be used with caution in patients that have chronic kidney disease (CKD) or pre-existing hypotensive conditions
- ► Adverse effects include hypotension and CNS (lethargy, dizziness) and GI effects.

Uses/Indications

Prazosin may be useful in the treatment of functional urethral obstruction (eg, vesicourethral reflex dyssynergia [VURD]) in dogs. It has been successfully used to manage dysuria in dogs with prostatic carcinoma.[1] Its usefulness for this purpose in male cats is somewhat controversial,[2] and its efficacy is unknown. In a study of cats with recurrent urethral obstruction, prazosin appeared to be more effective in preventing reobstruction as compared with phenoxybenzamine[3]; however, subsequent placebo-controlled studies have demonstrated that prazosin does not lessen the severity or prevent the recurrence of urethral obstruction in male cats[4,5] and may increase the likelihood of recurrent urethral obstruction.[6]

Prazosin could be considered for adjunctive treatment of CHF, but its use for this indication has fallen out of favor as other medications are more effective. Prazosin may also be used for the treatment of systemic hypertension in dogs but is not typically a first-line drug for this indication.[7]

Pharmacology/Actions

Prazosin's effects are a result of its selective, competitive inhibition of postsynaptic alpha-1-adrenergic receptors. It directly relaxes vascular smooth muscle, which reduces blood pressure and peripheral vascular resistance. Prazosin has dilatory effects on the arterial and venous side.

Prazosin reduces systemic arterial and venous blood pressure and right atrial pressure in patients with CHF, resulting in increased cardiac output and reduced pulmonary and systemic vascular resistance. Heart rates can be moderately decreased or unchanged. Glomerular filtration rate and renal blood flow are unchanged or may be increased. Unlike hydralazine, prazosin does not seem to increase renin release.

Prazosin has not been shown to antagonize medetomidine-[8] or xylazine-induced[9] diuresis in cats.

Laminar microcirculation has not been shown to change in healthy horses given IV prazosin.[10]

Pharmacokinetics

The pharmacokinetic parameters for this agent were not located for veterinary species.

In humans, prazosin is variably absorbed after oral administration. Peak concentrations occur 2 to 3 hours after administration. Prazosin is widely distributed throughout the body and is ≈97% bound to plasma proteins. Prazosin is metabolized in the liver, and some metabolites have activity. Elimination half-life is ≈3 hours. Metabolites, some of which are active, and some unchanged drug (5%-10%) are primarily eliminated in feces via bile.

Contraindications/Precautions/Warnings

Prazosin is contraindicated in patients hypersensitive to it or other quinazolines (eg, tamsulosin). The drug should be used with caution in patients with CKD or pre-existing hypotensive conditions.

There are some anecdotal reports that dogs with the multidrug sensitivity gene (*MDR1* gene, also known as *ABCB1* gene) mutation may be overly sensitive to the effects of prazosin; it should be used with caution in breeds known to be susceptible to this mutation. Alternative drugs should be considered for dogs that have tested positive for the *MDR1* mutation until more information becomes available; if this is not possible, reducing the dose and increased monitoring, particularly blood pressure, should be considered.

Adverse Effects

In an experimental study of dogs receiving prazosin, 0.025 mg/kg IV caused significant decreases in systolic, diastolic, and mean arterial blood pressures.[11] Whether this is a clinical concern when using prazosin orally to decrease urethral resistance is unclear. Other reported adverse effects include CNS effects (lethargy, dizziness [usually transient]), GI effects (nausea, vomiting, diarrhea, constipation), and nictitans elevation. Drug tolerance has been reported in humans, but dose adjustment, temporarily withdrawing the drug, and/or adding an aldosterone antagonist (eg, spironolactone) usually corrects this effect.

Syncope secondary to orthostatic hypotension has been reported in humans after the first dose of the drug. This effect may persist if the dose is too high for the patient.

Reproductive/Nursing Safety

In a study, testicular atrophy and necrosis occurred in dogs and rats receiving 25 mg/kg daily for one year, and decreased fertility was noted in male rats receiving 75 mg/kg/day.[12] Decreased litter size occurred in rats receiving very high dosages, but no fetal abnormalities were observed in rats or rabbits.[12]

Prazosin is excreted into maternal milk in small amounts.[12]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs associated with a prazosin overdose in dogs include ataxia, lethargy, trembling; hypotension is the most common clinical finding in cats.

GI decontamination with activated charcoal using standard precautionary measures should be considered if the ingestion was recent, the animal is conscious with control of its airway, and the animal is hemodynamically stable. Heart rate and blood pressure should be monitored. Shock should be treated using volume expanders and, if necessary, pressor agents. Renal function should be monitored and supported. Prazosin is not removed by dialysis.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving prazosin and may be of significance in veterinary patients. Unless otherwise noted, use together

is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Angiotensin-Converting Enzyme Inhibitors (ACEIs;** eg, benazepril, enalapril): May increase risk for hypotension
- **Amlodipine**: May increase risk for hypotension
- **Beta-Blocking Agents** (eg, propranolol): May enhance the postural hypotensive effects seen after the first dose of prazosin
- **Clonidine**: May decrease prazosin antihypertensive effects
- **Pentoxifylline**: May increase risk for hypotension
- **Phosphodiesterase Inhibitors** (eg, sildenafil): May increase risk for hypotension
- **Telmisartan**: May increase risk for hypotension
- **Vasopressors** (eg, dopamine, norepinephrine): Prazosin may reduce dopamine pressor effect.
- **Verapamil**: May cause synergistic hypotensive effects when used concomitantly with prazosin

Laboratory Considerations

None noted

Dosages

DOGS:

Decrease urethral resistance in idiopathic vesico-urethral reflex dyssynergia (VURD; extra-label):

a) 0.5 mg/kg PO twice daily. If adverse effects develop, decrease the dose by 50%. Moderate to good effect was noted in 60% of the dogs treated.[13]

b) Anecdotally, 1 mg/15 kg (33 lb) PO 2 to 3 times daily

Dysuria in patients with prostatic carcinoma (extra-label): From a case report, 0.1 – 0.4 mg/kg PO daily was helpful in managing dysuria associated with prostatic carcinoma.[1]

Systemic hypertension (extra-label):

a) Weight-based dosage: 0.5 – 2 mg/kg PO every 8 to 12 hours[7]

b) Dosage per dog: 0.5 – 2 mg/dog (NOT mg/kg) PO every 8 to 12 hours[14,15]

Adjunctive treatment of heart failure (extra-label): 1 mg/dog (NOT mg/kg) PO 3 times daily for dogs weighing less than 15 kg (33 lb); 2 mg/dog (NOT mg/kg) 3 times daily PO for dogs weighing more than 15 kg (33 lb)[16,17]

CATS:

Decreasing urethral resistance with functional urethral obstruction (extra-label): Use is controversial, and efficacy has been questioned.[2,6] Several dosages have been suggested, but most commonly 0.25 – 1 mg/cat (NOT mg/kg) PO every 12 hours for 1 to 2 weeks[4–6]

Hypertension (extra-label): 0.25 – 0.5 mg/cat (NOT mg/kg) PO once daily[7]

Monitoring

- Clinical efficacy
- Baseline and periodic blood pressure
- Mucous membrane color, capillary refill time (CRT), pulse oximetry

Client Information

- This medicine may be given with or without food. If your animal vomits, stops eating, or acts sick after getting prazosin on an empty stomach, give the medicine with food or a small treat to see if this helps. If vomiting continues, contact your veterinarian.
- The most common side effect with this medicine is lethargy (tiredness/lack of energy).

Chemistry/Synonyms

Prazosin HCl, a quinazoline-derivative postsynaptic alpha-1-adrenergic blocker, occurs as a white to tan powder. It is slightly soluble in water and very slightly soluble in alcohol. Dosage forms contain prazosin HCl, but potency and dosage are expressed (and calculated) as prazosin base.

Prazosin may also be known as CP-12299-1, furazosin hydrochloride, prazosini hydrochloridum; many trade names are available.

Storage/Stability

Prazosin capsules should be stored in well-closed containers and protected from light and moisture at room temperature (20°C-25°C [68°F-77°F]).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Prazosin Capsules: 1 mg, 2 mg, and 5 mg (as base); *Minipress®*, generic; (Rx)

PrednisoLONE/Prednisone/ PrednisoLONE Sodium Succinate

(pred-***niss***-oh-lone; ***pred***-ni-zone)

Glucocorticoid

*For more information, see **Glucocorticoid Agents, General Information** and **Trimeprazine/Prednisolone***

NOTE: *Prednisone and prednisoLONE are distinct drugs. This monograph uses TALL man letters to differentiate prednisoLONE from prednisone. They are often considered bioequivalent as most species rapidly convert prednisone to its active form, prednisolone, in the liver; however, horses, cats, and animals that have severe hepatic failure may not efficiently absorb or convert prednisone to prednisoLONE. PrednisoLONE or an alternative glucocorticoid should be used for these animals when possible.*

Prescriber Highlights

► Used to treat many conditions in a variety of species.
► Prednisone's anti-inflammatory activity is 4 times more potent than hydrocortisone and it has some mineralocorticoid activity.
► Contraindications (relative) include systemic fungal infections. Increased risk of GI ulceration when used concurrently with NSAIDS or aspirin.
► Caution is advised for use in animals with an active bacterial infection, corneal ulcer, hyperadrenocorticism, diabetes mellitus, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, congestive heart failure, and renal insufficiency.
► Goal of therapy should be to use the lowest dose possible for the least amount of time to treat and control patient's condition.
► PrednisoLONE is recommended for use in cats and horses because of the poor bioavailability of prednisone.
► Primary adverse effects are related to iatrogenic hyperadrenocorticism with sustained use.
► Many potential drug and laboratory interactions

Uses/Indications

Although glucocorticoids have been used to treat many conditions in humans and animals, prednisoLONE and prednisone have 4 primary uses with accompanying dosage ranges: 1) replacement or supplementation (eg, relative adrenal insufficiency associated with septic shock) for glucocorticoid deficiency secondary to hypoadrenocorticism, 2) anti-inflammatory agent, 3) immunosuppression, and 4) antineoplastic agent.

Glucocorticoids are used in the treatment of endocrine conditions (eg, adrenal insufficiency), autoimmune and immune-mediated diseases (eg, rheumatoid arthritis, systemic lupus, masticatory myositis), severe allergic conditions, anaphylaxis, envenomation, respiratory diseases (eg, asthma), dermatologic diseases (eg, pemphigus, allergic dermatoses), hematologic disorders (eg, thrombocytopenia, autoimmune hemolytic anemia), neoplasias, nervous system disorders (eg, increased CSF pressure), GI diseases (eg, ulcerative colitis exacerbations, inflammatory bowel disease), renal diseases (eg, nephrotic syndrome), and induction of fetal maturation. Some glucocorticoids are used topically on the eye and skin or are injected intra-articularly or intralesionally. This list is not exhaustive. High-dose use is not supported for hemorrhagic or hypovolemic shock, head trauma, spinal cord trauma,[1] or sepsis.

In general, when administering glucocorticoids, the following principles should be followed:

- A specific diagnosis is ideally obtained before glucocorticoids are administered as they can mask disease.
- A course of treatment should be determined prior to treatment.
- A therapeutic endpoint should be determined prior to treatment.
- The least potent glucocorticoid should be used at the lowest dose for a minimal amount of time.
- It is important to understand when glucocorticoid use is inappropriate (eg, acute infection, diabetes).[2]

Pharmacology/Actions

PrednisoLONE and prednisone are intermediate-acting corticosteroids with biologic half-lives of 12 to 36 hours. Glucocorticoids have effects on almost every cell type and system in mammals.

Cardiovascular system: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A clinically insignificant positive inotropic effect can occur after glucocorticoid administration. This drug's vasoconstrictive properties and increased blood volume can result in increased blood pressure.

Cells: Glucocorticoids can inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes, and the cellular response to mediators of inflammation; they can also stabilize lysosomal membranes.

CNS/autonomic nervous system: Glucocorticoids can lower the seizure threshold, alter mood and behavior, diminish response to pyrogens, stimulate appetite, and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

Endocrine system: When an animal is not stressed, glucocorticoids suppress the release of corticotropin (adrenocorticotropic hormone [ACTH]) from the anterior pituitary, which reduces or prevents the release of endogenous corticosteroids. Stress factors (eg, renal disease, liver disease, diabetes) may occasionally nullify the suppressing aspects of exogenously administered steroids. The release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone may be reduced when glucocorticoids are administered at pharmacologic doses. Conversion of thyroxine (T_4) to triiodothyronine (T_3) may be reduced by glucocorticoids, and plasma levels of parathyroid hormone may be increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (antidiuretic hormone [ADH]) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

Fluid and electrolyte balance: Glucocorticoids can increase renal potassium and calcium excretion, sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia rarely occur. Diuresis may develop following glucocorticoid administration.

GI tract and hepatic system: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased, whereas fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits in hepatocytes and increased serum levels of ALT and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum ALP levels. Glucocorticoids can cause minor increases in bromosulfophthalein (BSP) retention time.

Hematopoietic system: Glucocorticoids can increase the number of circulating platelets, neutrophils, and RBCs, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes, and eosinophils are seen because glucocorticoids can sequester these cells into the lungs and spleen and can prompt decreased release from bone marrow; removal of old RBCs becomes diminished. Glucocorticoids can cause involution of lymphoid tissue.

Immune system (also see ***Cells*** and ***Hematopoietic system***): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; and inhibit phagocytosis, chemotaxis, antigen processing, and intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high doses and species have different responses.

Metabolic effects: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (eg, abdomen), and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

Musculoskeletal: Glucocorticoids may cause muscular weakness, atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion, and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

Ophthalmic: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

Skin: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

Pharmacokinetics

Prednisone is a prodrug and requires hepatic bioactivation.

In cats, prednisoLONE has a higher bioavailability when administered orally as compared with prednisone.[3] Reported bioavailabilities (of active prednisoLONE) are 100% and 21%, respectively. Although it is not clear if this is due to decreased GI absorption or decreased hepatic conversion of prednisone to prednisoLONE, oral prednisoLONE is the superior choice in cats.[3,4] In a study, overconditioned cats had significantly higher plasma prednisoLONE concentrations (2 times) as compared with normal-conditioned cats.[5]

In horses, oral prednisone has been shown to have poor oral bioavailability and minimal conversion to prednisoLONE, and therefore prednisoLONE is recommended over prednisone in horses.[6]

In humans, prednisoLONE is hepatically conjugated and metabolites are primarily excreted in the urine. Plasma half-life is not meaningful from a therapy standpoint when evaluating systemic corticosteroids. PrednisoLONE and prednisone are intermediate-acting corticosteroids with biologic half-lives of 12 to 36 hours in humans.

Contraindications/Precautions/Warnings

Systemic use of glucocorticoids is considered contraindicated in systemic fungal infections (unless it is being used as replacement therapy for Addison's disease), when administered IM in animals with idiopathic thrombocytopenia and in those hypersensitive to a particular compound. Sustained-released injectable glucocorticoids are considered contraindicated for chronic corticosteroid therapy for systemic diseases.

The veterinary injectable product label states: C*ontraindicated in animals with tuberculosis, Cushingoid syndrome, and peptic ulcer. Existence of congestive heart failure, diabetes, chronic nephritis, and osteoporosis are relative contraindications. In the presence of infection, appropriate antibacterial agents should also be administered and should be continued for at least 3 days after discontinuance of the glucocorticoid and disappearance of all signs of infection. Do not use in viral infections.*[7]

Caution is advised when using predis(ol)one in animals with concomitant renal disease, as they may be at increased risk for adverse GI effects. Animals with hepatic dysfunction may have impaired ability to metabolize prednisone to prednisoLONE.

Systemic glucocorticoids can suppress adrenal function. Animals that have received these drugs chronically should be tapered off slowly, as endogenous ACTH release and corticosteroid function may return slowly. Additional glucocorticoids should be administered if the animal undergoes a stressor (eg, surgery, trauma, illness) during the tapering process or until normal adrenal and pituitary functions resume.

Animals, particularly cats, at risk for diabetes mellitus should be administered glucocorticoids with caution because of the potent hyperglycemic effects of these agents. Patients with cardiovascular disease should be monitored closely, as glucocorticoids can cause fluid retention, which may cause the patient's condition to decompensate. Glucocorticoids are immunosuppressive at higher doses (greater than or equal to 2 mg/kg/day) and may increase the risk for infection. In humans, long-term glucocorticoids may increase intraocular pressure and may increase the risk for cataracts and/or osteoporosis.

Do not confuse prednisoLONE with predniSONE, particularly in cats and horses.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if the drugs are administered at high doses or not on an alternate-day regimen. Effects typically manifest as clinical signs of hyperadrenocorticism. Glucocorticoids can delay growth when administered to young, growing animals. A listing of potential effects are outlined in ***Glucocorticoid Agents, General Information***.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may occur during short-term burst therapy and on days when the drug is administered during alternate-day maintenance therapy. Adverse effects in dogs can include dull/dry coat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, GI ulceration (especially with high parenteral or oral doses); hypercoagulability; hyperlipidemia, activation or worsening of diabetes mellitus, muscle wasting, and/or behavior changes (eg, depression, lethargy, aggression). Glucocorticoids have been known to delay growth in young animals. Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate adverse effects. Adverse effects associated with anti-inflammatory therapy are relatively uncommon, with the exception of PU, PD, and PP. Adverse effects associated with immunosuppressive dosages are more common and potentially more severe. In healthy dogs, immunosuppressive dosages of prednis(ol) one 2 – 4 mg/kg/day PO for 1 to 3 weeks did not enhance platelet function or coagulation[8] or produce clinical or histologic evidence of pancreatitis.[9] PrednisoLONE reduced gallbladder emptying in healthy beagles.[10] Bone mineral density, as assessed by quantitative CT, was reduced ≈15% from baseline after a 9-week tapered prednisoLONE dose, which recovered to near baseline 30 months after prednisoLONE was discontinued.[11]

Cats generally require higher doses than dogs for clinical effects but typically develop fewer adverse effects. Glucocorticoids appear to have a greater hyperglycemic effect in cats than other species. Occasionally, PU, PD, and PP with weight gain, diarrhea, and/or depression will be present. Long-term, high-dose therapy can lead to Cushingoid effects. Systemic steroid administration may increase the chance for development of acute bullous keratopathy.[12]

Reproductive/Nursing Safety

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy. The veterinary label states: *Clinical and experimental data have demonstrated that corticosteroids administered orally or by injection to animals may induce the first stage or parturition is used during the last trimester of pregnancy and may precipitate premature parturition followed by dystocia, fetal death, retained placenta, and metritis. Additionally, corticosteroids administered to dogs, rabbits, and rodents during pregnancy have resulted in cleft palate in offspring. Corticosteroids administered to dogs during pregnancy have also resulted in other congenital anomalies, including deformed forelegs, phocomelia, and anasarca.* Multiple midline defects were noted in a litter of golden retriever puppies with gestation exposure to doxycycline and prednisone.[13] In humans, maternal glucocorticoid use may lead to hypoadrenalism in newborns.[12]

Caution is advised when using in nursing dams; glucocorticoids unbound to plasma proteins can enter milk. High doses or prolonged administration to nursing dams may potentially inhibit growth, interfere with endogenous corticosteroid production, or cause other unwanted effects in nursing offspring. In humans, several studies suggest that amounts excreted in milk are negligible when the prednisone or prednisoLONE dose given to the mother is less than or equal to 20 mg/day or when the methylprednisoLONE dose is less than or equal to 8 mg/day. Larger doses given for short periods may not harm the infant.

Overdose/Acute Toxicity

Overdoses of glucocorticoids used alone are unlikely to cause harmful effects, but GI effects that are sometimes severe can be seen in dogs. Supportive treatment may be required if clinical signs occur. Other clinical signs associated with an overdose in dogs include polyuria and polydipsia.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral prednisoLONE/prednisone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Amphotericin B**: May cause hypokalemia when administered concomitantly with glucocorticoids
- **Anticholinesterase Agents** (eg, **neostigmine, pyridostigmine**): In animals with myasthenia gravis, concomitant glucocorticoid use with these agents may lead to profound muscle weakness. If possible, anticholinesterase medication should be discontinued at least 24 hours before corticosteroid administration.
- **Aspirin** (salicylates): Glucocorticoids may reduce salicylate blood levels. Combination may increase the risk for GI ulcers or erosions. In dogs, prednisone given with ultra-low–dose aspirin (0.5 mg/kg/day is often used in the treatment of immune-mediated hemolytic anemia (IMHA) does not increase the severity of GI lesions as compared with prednisone alone but may increase incidence of diarrhea.[14]
- **Barbiturates**: May increase the metabolism of glucocorticoids
- **Cholestyramine**: May reduce prednis(ol)one absorption
- **Cyclophosphamide**: Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **Cyclosporine**: Concomitant administration with glucocorticoids may increase the blood levels of each by mutually inhibiting the hepatic metabolism of the other; clinical significance of this interaction is not clear.
- **Digoxin**: Secondary to hypokalemia, increased risk for arrhythmias
- **Diuretics, Potassium-Depleting** (eg, **furosemide, thiazides**): May cause hypokalemia when administered concomitantly with glucocorticoids
- **Ephedrine**: May increase metabolism of glucocorticoids
- **Estrogens**: Effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens.
- **Fluoroquinolones**: Concurrent use may increase risk for tendinitis and tendon rupture.
- **Insulin**: Insulin requirements may increase in animals receiving glucocorticoids.
- **Ketoconazole**: May decrease the metabolism of glucocorticoids
- **Macrolide Antibiotics** (eg, **clarithromycin, erythromycin**): May decrease the metabolism of glucocorticoids
- **Mitotane**: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency.
- **Mycophenolate**: PrednisoLONE increased the in vitro unbound (active) fraction of mycophenolic acid in dogs but not in cats.[15]
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam, phenylbutazone, robenacoxib**): Administration of other ulcerogenic drugs with glucocorticoids may increase risk for GI ulceration.
- **Phenobarbital, Primidone**: May increase the metabolism of glucocorticoids
- **Rifampin**: May increase the metabolism of glucocorticoids
- **Vaccines**: Animals receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines, as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in animals receiving glucocorticoids.
- **Warfarin**: Glucocorticoids may affect clotting times; monitoring is advised.

Laboratory Considerations

- Glucocorticoids may increase serum cholesterol and urine glucose levels.
- Glucocorticoids may decrease serum potassium.
- In cats, increases in ALP are not attributable to glucocorticoid administration due to lack of a steroid-induced ALP isoenzyme.
- Glucocorticoids can suppress the release of TSH and reduce T_3 and T_4 values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I^{131} by the thyroid may be decreased by glucocorticoids.
- Reactions to allergen intradermal skin tests may be suppressed by glucocorticoids.[16,17] A 2-week (14-day) withdrawal time before intradermal skin testing is recommended for dogs and cats[18,19]; no withdrawal time is required before serum IgE testing to identify sensitizing allergens in cats.[19]
- False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids.
- High-dose prednisone increases serum cystatin C in dogs.[20]
- Bovine urinary prednisoLONE:cortisol ratio of greater than or equal to 0.26 may discriminate between endogenous and exogenous prednisoLONE.[21]

Dosages

NOTE: Currently, there are no injectable prednisone/prednisoLONE products available for use in animals in the United States.

Unless cited by a veterinary-approved product, all dosages should be considered extra-label.

DOGS/CATS:

NOTES:

1. PrednisoLONE should be used in place of prednisone in cats whenever possible, as cats do not absorb or convert prednisone to prednisoLONE as well as dogs.[3]
2. If given daily, therapy for longer than 1 to 2 weeks will suppress the hypothalamic-pituitary-adrenal (HPA) axis and recovery will take longer than 1 week. Therefore, if corticosteroids are used for longer than a few days, dosage must be tapered off using alternate-day therapy. Many glucocorticoid responsive diseases can be managed with chronic alternate-day therapy. If possible, it is suggested to avoid giving doses greater than 1 mg/kg (prednisoLONE equivalent) every other day; larger doses saturate a dog's ability to fully metabolize the last dose before the next dose is given and can negate the benefits of alternate-day therapy. However, to induce remission of clinical signs or manage their recurrence initially requires daily therapy at an appropriate dose to control clinical signs, then tapering the drug to reach a minimum daily dose that will control clinical signs, followed by alternate-day therapy to manage the disease. Animals vary greatly in their response to the therapeutic and adverse effects of glucocorticoids, and there may be qualitative differences between the effects of different glucocorticoids in the same animal.[22]

Anti-inflammatory agent:

Dogs: 0.5 – 1 mg/kg PO once daily; not to exceed 40 mg/dog (NOT mg/kg) in large breed dogs.[23] Dose can be given once daily, or the total dose can be divided and given twice daily.[4,24]

Cats: prednisoLONE 1 – 2 mg/kg PO once daily[4,24]

Immunosuppressive agent:

Dogs: Initial dose of 2 – 4 mg/kg PO once daily.[4,24] 50 – 60 mg/m^2 once daily for dogs over 25 kg (55 lb) can be considered an initial dosage to provide immunosuppression and minimize adverse ef-

fects in larger dogs.[25] Many suggest beginning with 2 mg/kg PO once daily and dividing the total dose and giving it twice daily. Administration of a dose at the upper end of the range may not provide additional immune suppression but may cause more pronounced adverse effects. Many internists believe that the prednisone total daily dose should not exceed 60 – 80 mg, regardless of a dog's weight.[23] A sample prednisone immunosuppressive protocol for dogs is (dosages should be tailored to the ongoing requirements of the individual animal): 2.2 mg/kg daily (daily dose not to exceed 60 – 80 total) for 3 weeks, then 1 mg/kg daily for 3 weeks, then 0.5 mg/kg daily for 3 weeks, then 0.5 mg/kg every other day, provided disease remission is maintained.

Cats: Initial dose of prednisolone 2 – 8 mg/kg PO once daily.[4,24,26] Many start with 4 mg/kg PO daily then dividing the total dose and giving it twice daily.[4]

Antineoplastic/cytotoxic agent: When prednis(ol)one is used as an antineoplastic agent, alone or in a multidrug chemotherapy protocol, the following dosages should be used only as a general guide. Consultations with a veterinary oncologist and referral to current veterinary oncology references are strongly recommended.

Dogs: 2 mg/kg PO daily. Omission of prednisone from the L-CHOP protocol did not improve progression-free survival in dogs with peripheral nodal lymphoma.[27]

Cats: PrednisoLONE should be used. Cats are relatively steroid resistant and require higher doses than dogs. Doses can typically be safely doubled as compared with dogs. See above note for additional information.[22] **NOTE**: When used with other cytotoxic agents in chemotherapy protocols, prednisoLONE doses may be reduced.

Adjunctive treatment for hypoadrenocorticism:

Acute treatment using prednisoLONE sodium succinate: 1 – 2 mg/kg IV after second blood draw for cortisol measurement (ACTH stimulation test).[28] Injectable glucocorticoid therapy (eg, prednisoLONE sodium succinate 0.5 mg/kg IV every 6 hours) should be continued until the animal can be safely switched to oral glucocorticoid therapy.[29] Alternatively, injectable dexamethasone sodium phosphate can be used in the acute management of hypoadrenocorticism.

Oral glucocorticoid replacement (ongoing, with a mineralocorticoid): Oral glucocorticoid therapy can begin after a confirmed diagnosis of hypoadrenocorticism has been made and parenteral therapy has achieved a positive clinical response. Prednisone can be given initially at 0.1 – 0.22 mg/kg PO once daily, then tapered to the lowest dose to control clinical signs.[28] An increase in dose is often needed in times of stress (eg, surgery, illness). It is common for dogs to require no more than 0.1 mg/kg once per day of prednis(ol)one and less may be sufficient to prevent recurrence of signs of glucocorticoid insufficiency. When using fludrocortisone for mineralocorticoid replacement therapy, up to 50% of dogs will not require any additional prednisone, as there is enough glucocorticoid activity in fludrocortisone for those dogs. One study reported 11 out of 13 dogs receiving fludrocortisone 0.022 mg/kg PO daily required a mean prednisoLONE dosage of 0.06 mg/kg daily and suggested that most dogs receiving fludrocortisone may benefit from the addition of a small prednisoLONE dose.[30] All dogs receiving desoxycorticosterone pivalate (DOCP) will also require prednis(ol)one, as it only has mineralocorticoid activity.[4] In one study, dogs receiving DOCP initially received prednisoLONE 0.22 mg/kg PO daily, but it was possible to reduce the dosage to 0.13 mg/kg PO daily.[31]

HORSES:

NOTE: Prednisone does not appear to be absorbed well after oral administration; prednisoLONE or another oral steroid should be used.

Glucocorticoid effects (label dosage; FDA-approved): prednisoLONE sodium succinate 50 – 100 mg/horse (NOT mg/kg) as an initial dose, IV or IM over a period of 30 seconds to 1 minute. Dose may be repeated in inflammatory, allergic, or other stress conditions at intervals of 12, 24, or 48 hours based on the size of the animal, the severity of the condition, and the response to treatment.[7]

Adjunctive therapy of severe equine asthma (SEA):

a) **Short-term treatment with environmental control**: In the study, dexamethasone sodium phosphate was given 0.1 mg/kg IM once daily for 4 days, 0.075 mg/kg IM once daily for 4 days, and 0.05 mg/kg IM for 4 days or oral prednisoLONE was given 1 mg/kg PO for 4 days, 0.75 mg/kg for 4 days, and 0.5 mg/kg PO for 4 days. Except for bronchoalveolar lavage cytology, PO prednisoLONE was as effective as IM dexamethasone.[32]

b) In horses under continuous antigen exposure, dexamethasone was given 0.05 mg/kg PO once daily for 7 days or prednisoLONE was given 2 mg/kg PO once daily for 7 days. Although both were effective, dexamethasone was more so.[33]

Pruritus: Topical therapy is preferred, but for more severe cases, oral prednisoLONE can be considered. Induction dose of 2 mg/kg PO once daily for 3 to 10 days. Dose can be tapered to 0.5 mg/kg PO every 48 hours once pruritus is controlled.[34]

Adjunctive therapy of neoplasia responsive to glucocorticoid therapy: Typical dose is prednisoLONE 1 mg/kg PO every other day.[35]

CATTLE:

Glucocorticoid activity: PrednisoLONE sodium succinate 0.2 – 1 mg/kg IV or IM[36]

NEW WORLD CAMELIDS:

Steroid-responsive pruritic dermatoses secondary to allergic origins: 0.5 – 1 mg/kg PO initially; can be gradually reduced to lowest effective dose given every 48 hours.[37]

BIRDS:

Anti-inflammatory: 0.2 mg/30 g (1 oz) body weight, or one 5-mg tablet can be dissolved in 2.5 mL of water and 2 drops administered orally, twice daily. Administration schedule should be tapered if using long-term.[38]

Shock: PrednisoLONE sodium succinate (10 mg/mL) 0.1 – 0.2 mL/100 g (3.5 oz) body weight repeated every 15 minutes to effect. Dose may be decreased by half in large birds.[38]

RABBITS/RODENTS/SMALL MAMMALS:

Rabbits: Rarely indicated. As an anti-inflammatory agent: 0.5 – 2 mg/kg PO

Mice, rats, gerbils, hamsters, guinea pigs, chinchillas: 0.5 – 2.2 mg/kg IM or SC

REPTILES:

Shock in most species: PrednisoLONE sodium succinate 5 – 10 mg/kg IV[39,40]

Monitoring

Monitoring of glucocorticoid therapy is dependent on reason for use, dosage, agent used (amount of mineralocorticoid activity), dose schedule (daily vs alternate-day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; clinical assessment and judgment should be used if adverse effects are noted.

- Response to therapy
- Weight, appetite, and/or signs of fluid retention
- Serum and/or urine electrolytes
- Total plasma proteins and albumin
- Blood glucose
- Urine culture
- Growth and development in young animals

Client Information

- Follow your veterinarian's instructions on how to give this medicine. Give this medicine with food.
- The goal of treatment is to find the lowest dose possible and use it for the shortest period of time. Do not change the amount of medicine you give your animal without talking to your veterinarian first.
- Many side effects are possible, especially when used long-term or when given in higher doses. The most common side effects are increased appetite, thirst, and need to urinate.
- In dogs, stomach or intestinal ulcers, perforation, or bleeding can occur while taking this medicine. Contact your veterinarian right away if your animal stops eating or if you notice a high fever, black tarry stools, or bloody vomit (looks like coffee grounds).
- Do not suddenly stop giving this medicine to your animal without talking to your veterinarian first, as serious side effects could occur.
- Be sure to tell your veterinarian what other medications (including vitamins, supplements, or herbal therapies) you give your animal.

Chemistry/Synonyms

PrednisoLONE and prednisone are synthetic glucocorticoids. PrednisoLONE and prednisoLONE acetate occur as odorless, white to practically white crystalline powders. PrednisoLONE is very slightly soluble in water and slightly soluble in alcohol. The acetate ester is practically insoluble in water and slightly soluble in alcohol. The sodium succinate ester is highly water-soluble. The sodium phosphate ester occurs as a slightly yellow or white powder or as granules, is odorless or may have a slight odor, and is freely soluble in water and soluble in methanol.

Prednisone occurs as an odorless, white to practically white crystalline powder. Prednisone is very slightly soluble in water and slightly soluble in alcohol.

PrednisoLONE is also known as deltahydrocortisone or metacortandralone.

Prednisone may also be known as delta(1)-cortisone, 1,2-dehydrocortisone, deltacortisone, deltadehydrocortisone, metacortandracin, NSC-10023, prednisonum; many trade names are available.

Storage/Stability

Store prednisoLONE and prednisone tablets in tightly closed containers below 40°C (104°F), ideally between 15°C to 30°C (59°F-86°F). PrednisoLONE oral solution storage requirements vary by product and manufacturer; refer to product label for specific information. Avoid freezing all liquid prednisoLONE products. Do not autoclave. Store oral liquid preparations of prednisone in tightly closed containers.

PrednisoLONE sodium succinate should be stored at room temperature and protected from light (stored in a carton). After reconstitution, the product is recommended for immediate use and should not be stored for later use. If the solution becomes cloudy after reconstituting, it should not be used IV.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Few data appear to be available regarding the compatibility of prednisoLONE sodium succinate injection (*Solu-Delta Cortef®*) with other products. A related compound, prednisoLONE sodium phosphate is reportedly physically **compatible** with the following drugs/solutions: ascorbic acid injection, cytarabine, erythromycin lactobionate, fluorouracil, heparin sodium, penicillin G potassium/sodium, tetracycline HCl, and vitamin B-complex with C. It is reportedly physically **incompatible** with calcium gluconate/gluceptate, dimenhydrinate, metaraminol bitartrate, methotrexate sodium, prochlorperazine edisylate, polymyxin B sulfate, promazine HCl, and promethazine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

A zero-tolerance residue in milk for these compounds has been established for dairy cattle. All of these agents require a prescription (Rx). Known FDA-approved veterinary products for systemic use are indicated below; not all products may be marketed.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

PrednisoLONE Tablets: 5 mg and 20 mg: *Prednis-Tab®* (various), generic; (Rx). FDA-approved for use in dogs

PrednisoLONE Acetate Injection: 25 mg/mL; *Meticortelone Acetate®*; (Rx). FDA-approved for use in dogs, cats, and horses

PrednisoLONE Sodium Succinate for Injection *act-o-vial®* System 100 mg (equivalent to 10 mg prednisoLONE) and 500 mg (equivalent to 50 mg prednisoLONE) per 10-mL vial; *Solu-Delta-Cortef®*; (Rx). FDA-approved for use in dogs, cats, and horses. May be unavailable in some countries.

PrednisoLONE Sodium Succinate Powder for Injection: 10 mg/mL, 20 mg/mL, and 50 mg/mL of prednisoLONE; *Solu-Delta Cortef®* Sterile Powder; (Rx). FDA-approved for use in dogs, cats, and horses. May be unavailable in some countries.

PrednisoLONE Tertiary Butylacetate Injection: 20 mg/mL; *Hydeltrone-TBA® Suspension*; (Rx). FDA-approved for use in cats, dogs, and horses

Prednisone Injection: 10 mg/mL and 40 mg/mL; *Meticorten®*; (Rx). FDA-approved for use in dogs, cats, and horses

PrednisoLONE and Trimeprazine Tartrate Tablets: Each tablet contains trimeprazine 5 mg and prednisoLONE 2 mg; *Temaril-P®*; (Rx). FDA-approved for use in dogs

HUMAN-LABELED PRODUCTS:

PrednisoLONE Oral Tablets: 5 mg; *Millipred®*, generic; (Rx).

PrednisoLONE Sodium Phosphate Orally Disintegrating Tablets: 10 mg, 15 mg, and 30 mg (as base); *Orapred ODT®*; (Rx)

PrednisoLONE Syrup/Oral Liquid or Solution: 5 mg/5 mL (1 mg/mL), 10 mg/5 mL (2 mg/mL), 15 mg/5 mL (3 mg/mL), 20 mg/5 mL (4 mg/mL), and 25 mg/5 mL (5 mg/mL); *Pediapred®*, *Millipred®*, *Orapred®*, *Flo-Pred®*, *Veripred®* 20, generic; (Rx)

Prednisone Tablets: 1 mg, 2.5 mg, 5 mg, 10 mg, 20 mg, and 50 mg; *Deltasone®*, generic; (Rx)

Prednisone Oral Tablet (Delayed Release): 1 mg, 2 mg, and 5 mg; *Rayos®*; (Rx)

Prednisone Oral Solution/Syrup: 5 mg/5 mL (1 mg/mL); *Prednisone* and *Prednisone Intensol® Concentrate*; (Rx)

Ophthalmic solutions/suspensions are available.

Pregabalin

(pre-***gab***-ah-lin) *Lyrica®*

Anticonvulsant; Neuropathic Pain Agent

Prescriber Highlights

- ► Similar to gabapentin; may be useful as an anticonvulsant or to treat tremors and neuropathic pain
- ► Little information is available on safety and efficacy in dogs or cats.
- ► The most common adverse effects are sedation and ataxia.
- ► May be cost prohibitive
- ► DEA Schedule V (C-V) controlled substance

Uses/Indications

Like gabapentin, pregabalin may be useful as adjunctive therapy for refractory or complex partial seizures,[1] and treating chronic pain, particularly neuropathic pain in small animal species. In an open-label, noncomparative study in epileptic dogs that were not controlled with phenobarbital and/or bromides, pregabalin reduced seizures by ≈60% in 7 out of 9 dogs.[1] When pregabalin is administered pre- and postoperatively in combination with opioids after surgical treatment of intervertebral disc herniation in dogs, it reduces pain more than opioids alone.[2] Pregabalin has been successfully used to reduce clinical signs related to central neuropathic pain associated with syringomyelia in dogs.[3,4] Other potential uses include treatment of orthostatic tremors in dogs[5] and as a pre-transportation anxiolytic for cats.[6]

In humans, pregabalin is used to treat pain associated with diabetic peripheral neuropathy, partial-onset seizures, postherpetic neuralgia, and fibromyalgia. Extra-label uses include treatment of generalized anxiety, possible reduction of opioid demand for postsurgical analgesia, and to decrease postoperative nausea and vomiting.

Pharmacology/Actions

Pregabalin has antiepileptic, analgesic, and anxiolytic activity. Like gabapentin, pregabalin is a structural analogue of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA). The mechanism of action of pregabalin, for either its anticonvulsant or analgesic actions, is not fully understood, but it appears to bind to CaVa2-d (alpha2-delta subunit of the voltage-gated calcium channels). By decreasing calcium influx, release of excitatory neurotransmitters (eg, substance P, glutamate, norepinephrine) is inhibited. It is ≈5 times as potent as gabapentin.[7,8]

Pharmacokinetics

After a single oral pregabalin dose of 4 mg/kg in 6 dogs, median parameters included the following: T_{max} = 1.5 hours; C_{max} = 7.15 µg /mL; elimination half-life = 6.9 hours.[9]

In 6 cats receiving a single oral dose (4 mg/kg using pregabalin capsules), pregabalin median parameters included the following: T_{max} = 2.9 hours; C_{max} = 8.3 µg /mL; elimination half-life = 10.4 hours.[10]

After a single dose of 4 mg/kg administered via nasogastric tube in 5 horses, pregabalin median parameters included the following: T_{max} = 1 hour; C_{max} = 5 µg/mL; and elimination half-life = 8 hours.[11] After IV administration of 4 mg/kg the initial concentration was 22.2 µg/mL and elimination half-life was 7.74 hours. Bioavailability was 97.7%. Signs of mild, transient colic and behavioral abnormalities were observed after IV administration.

In humans, oral bioavailability is ≈90%.[12] Presence of food can delay the rate, but not the amount absorbed, and it can be administered regardless of feeding status. Pregabalin is not bound to plasma proteins, and it has an apparent volume of distribution of ≈500 mL/kg. Hepatic metabolism is negligible, and it does not appear to affect hepatic enzymes. The drug is almost exclusively cleared unchanged by renal routes with a renal clearance of 67 to 81 mL/minute in young, healthy subjects. Elimination half-life is ≈6 hours. Dosage adjustment may be required in patients with diminished renal function.

Contraindications/Precautions/Warnings

Pregabalin is contraindicated in patients that are hypersensitive to it. Use with caution in patients with renal insufficiency; if required, dosage adjustment should be considered. In humans, pregabalin doses are adjusted based on creatinine clearance. Pregabalin is used with caution in human patients with heart failure or underlying respiratory impairment.

In humans, abrupt discontinuation may lead to increased seizure frequency, diarrhea, headache, insomnia, or nausea.[12]

Adverse Effects

The most common adverse effects reported include sedation and ataxia. Because use to date is limited in animals, the adverse effect profile may evolve with additional clinical experience. Superficial dermatitis lesions on the face were reported in 1 cat that was receiving pregabalin.[13] Transient sedation, ataxia, tremor, and salivation were observed in cats receiving a single oral dose.[6,10]

In humans, the most commonly reported adverse effects include somnolence, dizziness, ataxia, difficulty with concentration/attention/memory, blurred vision, dry mouth, peripheral edema, constipation, and weight gain.[12] Syncope and congestive heart failure have been reported less frequently. Rarely, renal failure (reversible) and rhabdomyolysis have been reported.

Hypersensitivity reactions have included angioedema, rash, blisters, and wheezing. Pregabalin therapy has been associated with decreased platelet production or increased creatine kinase levels in some human patients.[12]

Reproductive/Nursing Safety

Very high doses of pregabalin have caused skeletal malformations in offspring when administered to pregnant rats and rabbits.[12] Pregabalin is excreted into milk, and safety during nursing has not been established.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs most commonly seen in dogs and cats with a pregabalin overdose include ataxia and lethargy. There is no specific antidote for overdose with pregabalin. Standard GI decontamination protocols with supportive care based on clinical presentation can be employed if indicated.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving pregabalin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin-Converting Enzyme Inhibitors** (eg, **benazepril, enalapril**): In humans, co-administration with pregabalin may increase risks for edema and hives.
- **Benzodiazepines** (eg, **alprazolam, diazepam, midazolam**):

Pregabalin may cause additive CNS and respiratory depression.

- **Central Nervous System (CNS) Depressants** (eg, **acepromazine, dexmedetomidine, phenobarbital**): Pregabalin may cause additive CNS and respiratory depression.
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)**: In humans, ketorolac and naproxen have been cited as possibly reducing anticonvulsant effectiveness. Substantive evidence is weak, however.
- **Opioids** (eg, **morphine**): Pregabalin may cause additive CNS and respiratory depression.

Laboratory Considerations

- None noted

Dosages

DOGS:

Seizure disorders (extra-label): 3 – 4 mg/kg PO every 8 hours.[1] Generally used when seizure control cannot be obtained with a combination of phenobarbital and bromides. In a small single-dose pharmacokinetic study, the authors concluded that 4 mg/kg PO twice daily would produce plasma concentrations within the therapeutic range extrapolated from humans[9]; further studies evaluating its safety and efficacy for the treatment of seizures in dogs are warranted. To reduce sedation, consider starting at 2 mg/kg PO every 12 hours and titrating dosage upwards in 1 mg/kg increments per week to 3 – 4 mg/kg PO every 8 to 12 hours.

Neuropathic pain (extra-label): 2 – 5 mg/kg PO every 8 to 12 hours.[4,14] In another study in King Charles Cavalier spaniels, 150 mg/dog (NOT mg/kg) PO once daily for 2 days, then 150 mg/dog (NOT mg/kg) PO twice daily was used.[3] This latter dosage equated to ≈13 – 19 mg/kg PO twice daily.

Control of perioperative pain (extra-label): 4 mg/kg PO 1 hour before anesthesia, followed by postoperative treatment of 4 mg/kg PO 3 times daily for 5 days[2]

Orthostatic tremor (extra-label): 3.5 mg/kg PO every 8 to 12 hours[5]

CATS:

Seizure disorders (extra-label): Anecdotally, 1 – 2 mg/kg PO every 12 hours is most commonly mentioned.[15] Based on their single-dose pharmacokinetic study in 6 cats, the authors theorize that a dose of 1 – 2 mg/kg PO twice daily would be a reasonable starting dosage. Further clinical trials are warranted based on a favorable pharmacokinetic profile.[16]

Neuropathic pain (extra-label):

a) 1 mg/kg PO every 8 to 12 hours[15,17]

b) 3 mg/kg PO every 12 hours from a case report[18]

Anxiolytic for carrier transportation (extra-label): 5 – 10 mg/kg PO 90 minutes prior to transportation.[6] The study used pregabalin oral solution; anxiolysis in association with veterinary visits was not assessed.

HORSES:

Neuropathic pain, seizures (extra-label): 4 mg/kg PO every 8 hours; based on single-dose pharmacokinetic study.[11] Efficacy and safety of this dosage requires validation.

Monitoring

- Efficacy/adverse effects
- At present, pregabalin plasma concentrations are not routinely monitored in human medicine. In humans, plasma pregabalin concentrations greater than 2.8 mg/mL have been suggested as being therapeutic.

Client Information

- This medicine may be given with or without food. If your animal vomits or acts sick after getting it on an empty stomach, try giving the medicine with food or a small treat to see if this helps. If vomiting continues, contact your veterinarian.
- Sleepiness and loss of coordination (eg, stumbling) and weakness are the most likely side effects. Pregabalin is a controlled drug in the US. It is against federal law to use, give away, or sell this medication to others than for whom it was prescribed.
- When it is used for seizure control, do not suddenly stop giving this medicine.

Chemistry/Synonyms

Pregabalin is (S)-3-(aminomethyl)-5-methylhexanoic acid. It is freely soluble in water and in both basic and acidic aqueous solutions.

Pregabalin may also be known as CI-1008, PD-144723, pregabalina, prégabaline, or pregabalinum. A common trade name is *Lyrica*®.

Storage/Stability

Store capsules and oral solution at room temperature (25°C [77°F]); excursions permitted between 15°C to 30°C (59°F-86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Pregabalin Oral Capsules: 25 mg, 50 mg, 75 mg, 100 mg, 150 mg, 200 mg, 225 mg, and 300 mg; *Lyrica*®, generic; (Rx; C-V controlled substance)

Pregabalin Oral Solution: 20 mg/mL; *Lyrica*®, generic; (Rx; C-V controlled substance)

References

Primaquine

(***prim***-ah-kwin)

Antiprotozoal Agent

Prescriber Highlights

- ► Considered the drug of choice for treating *Babesia felis* in cats. May not eliminate infection, and repeated courses of therapy may be necessary.
- ► Most common adverse effect in cats is vomiting; give with food.
- ► Very narrow therapeutic index; use extreme caution when determining a dose, particularly considering the large difference between primaquine base and salt (phosphate) doses. In cats, doses of primaquine phosphate greater than 1 mg/kg can be lethal.
- ► Compounded formulations may be necessary for accurate dosing.
- ► Monitor CBC weekly during treatment

Uses/Indications

Primaquine is considered the drug of choice for treating *Babesia felis* in cats. Primaquine typically resolves anemia and clinical signs of disease; however, it often does not eliminate the infection and repeated courses of therapy may be necessary.[1,2] Relapse rates of 20% to 80% have been reported but these are lower than other therapy protocols.[1] Primaquine may be useful in treating *Hepatazoon* spp infection in dogs and cats, or *Plasmodium* spp in birds.

In humans, primaquine is used in the treatment and prophylaxis for malaria and treating *Pneumocystis* spp pneumonia.[3]

Pharmacology/Actions

The antiprotozoal mechanism of primaquine is not well understood; it may be related to the drug binding and altering protozoal DNA. When used for *Babesia felis* in cats, decreased parasitemia and improvement in clinical signs is usually seen within 1-3 days.

Pharmacokinetics

No pharmacokinetic information was located for small animal species.

In humans, primaquine is rapidly absorbed with ≈96% systemic bioavailability.[4] It is extensively distributed and rapidly metabolized in the liver to carboxyprimaquine. Antiprotozoal activity of the metabolite is unknown. Elimination half-life is ≈6 hours for primaquine and ≈24 hours for carboxyprimaquine.

Contraindications/Precautions/Warnings

Primaquine is contraindicated in patients with known hypersensitivity to it. In humans, it is contraindicated in patients receiving other myelosuppressive medications or patients susceptible to granulocytopenia (eg, lupus, rheumatoid arthritis). Primaquine is also contraindicated in humans with glucose-6-phosphate dehydrogenase (G6PD) deficiency, as there is increased risk for hemolytic anemia when exposed to drugs that cause oxidative stress, such as primaquine.[5]

Safety margin is particularly narrow with this drug in cats (see ***Overdose/Acute Toxicity***).

Adverse Effects

The most common adverse effect associated with primaquine in cats is vomiting[1,2]; administration with food may decrease GI upset. Other potential adverse effects include myelosuppression, methemoglobinemia, and hemolysis.

Reproductive/Nursing Safety

In humans, primaquine is considered contraindicated during pregnancy as it can cause hemolytic anemia in G6PD deficient fetuses. Chloroquine should be used instead. Primaquine may be used during lactation if infants have normal G6PD activity.[3] Although significance for veterinary patients is unclear, primaquine should be avoided during pregnancy and lactation.

Overdose/Acute Toxicity

In cats, the lethal dose of primaquine phosphate has been reported as greater than 1 mg/kg.[2] Overdoses should initially be handled aggressively using standardized GI decontamination protocols.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving primaquine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- Grapefruit Juice: May increase primaquine concentrations
- Hemolysis-Inducing Drugs (eg, **acetohydroxamic acid, quinidine, sulfonamides, sulfonylureas**): Use with primaquine may cause increased risk for toxicity.
- Myelosuppressive Drugs (eg, **amphotericin B, antineoplastic drugs, azathioprine, chloramphenicol**): Use with primaquine may cause increased risk for myelotoxicity.
- Quinacrine: May potentiate the toxicity of one another; use of primaquine within 3 months of quinacrine is not recommended.
- QT Prolonging Agents (eg, **cisapride, domperidone, erythromycin, sotalol**): Concurrent use may increase the risk for QT prolongation and should be avoided.[5]
- Rabies Vaccine: In humans, primaquine can decrease the immune response to rabies vaccine.[6] Significance to veterinary patients is unknown.

Laboratory Considerations

- No specific concerns noted

Dosages

CATS:

NOTES:

1. Primaquine has an extremely narrow therapeutic index in cats.
2. Primaquine dosing for humans is typically described in terms of primaquine ***base***; however, dosages for cats may not distinguish between primaquine base or phosphate. ***Primaquine phosphate 26.3 mg tablets contain 15 mg of primaquine base***. Due to the large difference between doses of phosphate and base and the narrow therapeutic index, it is important to have a clear understanding of the desired amount of primaquine to be given per dose.
3. The strength of the commercially available tablet is typically too high to be accurately dosed in cats; compounded formulations may be required. See ***Compounding: How to Find a Quality-Assured Pharmacy***.

Babesia felis (extra-label):

a) Primaquine ***base*** 0.5 – 1 mg/kg (as base) PO once or administered daily on 3 consecutive days. Duration of therapy should be based on hematologic variables and clinical signs rather than parasitemia. Do not exceed dosages of 1 mg/kg/day as fatalities have occurred.[2]

b) Primaquine ***phosphate*** 1 mg/cat (NOT mg/kg) PO every 36 hours for 4 doses followed by 1 mg/cat (NOT mg/kg) every 7 days for 4 additional doses[7,8]

Monitoring

- Baseline and weekly CBC during treatment
- Improvement of clinical signs (increased appetite and body weight, improvement in anemia)

Client Information

- This medicine can be very toxic to cats if they are given too much. Be sure to follow your veterinarian's instructions closely.
- In case of a missed dose, do not double-up the next dose.
- Give with food to decrease vomiting and upset stomach.
- Your veterinarian will need to monitor your cat closely while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

Primaquine phosphate is an 8-amino-quinoline compound that occurs as an orange-red, odorless, bitter-tasting, crystalline powder. It is soluble (1 gram in 15 mL) in water and practically insoluble in alcohol. 1 mg of primaquine phosphate contains 0.57 mg of primaquine base.

Primaquine may also be known as primachina, primachinum, primaquina or SN 13272.

Storage/Stability

Primaquine phosphate tablets should be stored in a tight, light resistant container below 40°C (104°F), preferably between 15 and 30°C (59 to 86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Primaquine Phosphate Oral Tablets: 26.3 mg (equivalent to 15 mg primaquine base); generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Probenecid
(proh-***ben***-eh-sid)
Uricosuric; Renal Tubular Secretion Inhibitor

Prescriber Highlights
- ► Uricosuric and renal tubular secretion inhibitor that may be useful for treating gout (particularly in reptiles)
- ► Probenecid is associated with many drug interactions as it inhibits the renal tubular secretion of numerous drugs, including several beta-lactam antibiotics; some interactions may be beneficial, whereas others may increase potential for toxicity.
- ► Little experience using this drug in mammals other than humans

Uses/Indications
Although there has been limited clinical use or research on probenecid in veterinary medicine, it may be useful in treating gout (hyperuricemia), particularly in reptiles.

Probenecid's effect in inhibiting renal tubular secretion of certain beta-lactam antibiotics and other weak organic acids is of interest for increasing serum concentrations or reducing doses and dosing frequency of these drugs. This effect may allow greater efficacy and reduce the cost or dosing frequency of expensive human drugs. Probenecid has a significantly long elimination half-life in dogs (≈18 hours), which may make it particularly useful in this species; however, at present there is little research supporting this in veterinary patients.

Pharmacology/Actions
Probenecid reduces serum uric acid concentrations by enhancing uric acid excretion into the urine by competitively inhibiting urate reabsorption at the proximal renal tubules.

Probenecid competitively inhibits tubular secretion of weak organic acids (eg, penicillins, some cephalosporins, sulbactam, tazobactam, oseltamivir).

Pharmacokinetics
There is limited information available for veterinary species. In dogs, after IV administration of probenecid, the distribution half-life was 2.3 hours and apparent volume of distribution at steady state was 0.46 L/kg.[1] Probenecid exhibits biphasic concentration-dependent plasma protein binding characteristics; probenecid plasma protein binding appeared to be less than that occurring in humans. Plasma clearance was 0.343 mL/minute/kg and elimination half-life was 17.7 hours, which is considerably longer than in humans (6.5 hours) or sheep (1.55 hours).[1]

After administration to mares (10 mg/kg), probenecid had an oral bioavailability of ≈90%.[2] The drug was highly bound (99.9%) to equine plasma proteins. Elimination half-life was ≈90 to 120 minutes.

In humans, absorption after oral administration is rapid and complete. The drug is converted in the liver to glucuronidated, carboxylated, and hydroxylated compounds that have uricosuric and renal tubular secretion inhibition activity. Elimination half-life is dose dependent and large doses (greater than 500 mg) have longer half-lives.

Contraindications/Precautions/Warnings
Probenecid is contraindicated in patients with a history of hypersensitivity to it, and should not be used in patients with, or that are susceptible to, uric acid renal or bladder calculus formation or urate nephropathy (eg, receiving chemotherapy with rapidly cytolytic agents). Probenecid requires sufficient renal function to be effective; efficacy decreases with increasing renal function impairment. The drug may not be effective in human patients with a creatinine clearance of less than 30 mL/minute.[3]

Probenecid is not usually recommended for treating gout in birds, as it can exacerbate the condition.

Adverse Effects
An accurate adverse effect profile for probenecid has not been determined for animal patients. In humans, probenecid occasionally causes headaches, GI effects (eg, inappetence, nausea, mild vomiting), or rashes. When probenecid is used for gout, it can initially cause an increased rate of gouty attacks unless prophylaxis with colchicine is used concurrently. Rarely, hypersensitivity, bone marrow suppression, hepatotoxicity, or nephrotic syndrome have been reported in humans.

Reproductive/Nursing Safety
Probenecid apparently crosses the placenta, but adverse effects to fetuses have not been reported.

It is unknown if probenecid enters milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
Limited information is available. One massive (ie, greater than 45 g) overdose in a human patient caused CNS stimulation, seizures, protracted vomiting, and respiratory failure. The reported LD_{50} in a dog following IV administration was 230 mg/kg.[4]

Generally, probenecid overdoses should initially be handled using standardized protocols for removal of drug from the gut to prevent absorption. Treat supportively but use caution co-administrating drugs that may compete with probenecid for tubular secretion.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving probenecid and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antineoplastics** (rapidly cytolytic): Increased chance of uric acid nephropathy
- **Aspirin** (and other salicylates): Salicylates antagonize the uricosuric effects of probenecid.
- **Benzodiazepines** (eg, **lorazepam, oxazepam**): Probenecid may prolong action or reduce time for onset of action.
- **Beta-Lactam Antibiotics** (eg, **penicillins**, some **cephalosporins**): Probenecid may increase serum concentrations by reducing renal excretion.
- **Beta-Lactamase Inhibitors** (eg, **sulbactam, tazobactam**, but not **clavulanic acid**): Probenecid may increase serum concentrations by reducing renal excretion.
- **Ciprofloxacin/Enrofloxacin**: Probenecid reduces renal tubular secretion of ciprofloxacin by ≈50%. In goats, probenecid significantly reduced renal excretion of enrofloxacin.[5,6]
- **Dapsone**: Possible accumulation of dapsone or its active metabolites

- **Furosemide**: Increased serum furosemide concentrations are possible.
- **Heparin**: Probenecid may increase and prolong heparin's effects.
- **Methotrexate**: Probenecid may increase methotrexate concentrations and increase the risk for toxicity.
- **Nonsteroidal Anti-Inflammatory Drugs** (eg, **carprofen, ketoprofen**): Probenecid may increase plasma NSAID concentrations and increase the risk for toxicity.
- **Nitrofurantoin**: Reduced urine nitrofurantoin concentrations causing an increased risk for therapeutic failure and systemic toxicity
- **Penicillamine**: May reduce penicillamine efficacy
- **Oseltamivir**: May increase serum oseltamivir concentrations by reducing renal excretion
- **Ranitidine**: May increase serum ranitidine concentrations by reducing renal excretion
- **Rifampin**: May reduce hepatic uptake of rifampin and serum concentrations can be increased; use together is not recommended, as effect is inconsistent and can lead to toxicity.
- **Sulfonamides**: Probenecid decreases renal elimination of sulfonamides; however, as free serum concentrations of sulfonamides are not increased, this interaction is not therapeutically beneficial and may increase risks for sulfonamide toxicity.

Laboratory Considerations

- Urine glucose determinations: When using cupric sulfate solution (Benedict's Solution, *Clinitest®*): Probenecid may cause false-positive results. Tests utilizing glucose oxidase (*Tes-Tape®*, *Clinistix®*) are not affected.
- Theophylline concentrations: Serum theophylline concentrations may be falsely elevated (Schack and Waxtler technique).
- 17-ketosteroid concentrations in urine: May be decreased
- Phosphorus: Probenecid may increase phosphorus reabsorption in hypoparathyroid patients.
- Aminohippuric acid (PAH) or phenolsulphonphthalein (PSP) clearance studies: Probenecid decreases renal clearance.
- Renal function studies using iodohippurate sodium I 123 or I 131, or technetium TC 99: Decreased kidney uptake
- Homovanillic acid (HVA) or 5-hydroxyindoleacetic acid (5-HIAA): Probenecid inhibits transport from CSF into blood.

Dosages

HORSES:

Adjunct to increase antibiotic serum concentration and/or increase dosing interval (extra-label): Limited data are available. Probenecid administered 75 mg/kg PO one hour prior to an IV ampicillin bolus increased AUC and prolonged elimination half-life. The authors concluded that with this protocol, ampicillin administration may be extended to every 12 hours.[7]

REPTILES:

NOTE: Dosages are not well defined for reptiles.

Gout (extra-label):

a) 250 mg/reptile (NOT mg/kg) PO every 12 hours; can be increased as needed. Suggested dosage based upon human data, as dose is not established for reptiles[8]

b) 40 mg/kg PO every 12 hours[9,10]

Monitoring

- Serum and urine uric acid; if concomitant urine alkalinization is used, consider monitoring acid-base balance.

Client Information

- This medicine may be used to treat reptiles with a joint disease caused by excess uric acid (gout).
- This medicine has many drug interactions. Be sure to tell your veterinarian and pharmacist what medications (including vitamins, supplements, or herbal therapies) you give your animal, including the amount and time you give each. Some interactions may be helpful while others may increase risk for side effects.
- Side effects caused by probenecid in small animals (eg, dogs, cats) are not well known. Be sure to contact your veterinarian if you have concerns about your animal.

Chemistry/Synonyms

Probenecid is a sulfonamide derivative that occurs as a white to practically white, practically odorless, fine, crystalline powder. It is practically insoluble in water and soluble in alcohol.

Probenecid may also be known as probenecidas, probenecidum, *Benemid®*, and *Benuryl®*.

Storage/Stability

Probenecid tablets should be stored at room temperature (15°C-30°C [59°F-86°F]) in well-closed containers protected from light. Expiration dates are generally 3 to 5 years after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated probenecid as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information. The International Federation for Equestrian Sports (FEI) lists this drug as a "prohibited substance – banned."

HUMAN-LABELED PRODUCTS:

Probenecid Tablets: 500 mg; generic; (Rx)

Procainamide

(proe-kane-***a***-mide) *Procanbid®, Pronestyl®*

Antiarrhythmic

Prescriber Highlights

- ► Used primarily for treatment of atrial fibrillation, premature ventricular complexes (PVC), and ventricular tachycardia
- ► Contraindications include myasthenia gravis; hypersensitivity to drug, procaine, or other chemically related drugs; torsade de pointes; second- or third-degree AV block (unless artificially paced)
- ► Use with extreme caution in patients with cardiac glycoside intoxication or systemic lupus.
- ► Use with caution in patients with significant hepatic and/or renal disease or congestive heart failure; consider dose reduction in these patients and in those that are critically ill.
- ► Adverse effects are related to serum drug concentrations and include GI effects, weakness, hypotension, negative inotropism, widened QRS complex and QT intervals, AV block, and multiform ventricular tachycardias. Fever and leukopenia are also possible.
- ► Profound hypotension can occur if injected too rapidly IV.
- ► Oral products are no longer commercially marketed and must be compounded.
- ► Many potential drug interactions

Uses/Indications

Procainamide may be used to treat premature ventricular complexes (PVC), ventricular tachycardia, or supraventricular tachycardias (SVTs). For a wide complex tachycardia that is present on ECG and that cannot be definitively identified as supraventricular or ventricular in origin, procainamide is an ideal first-line IV therapeutic agent because of its broad spectrum of activity for atrial and ventricular arrhythmias.[1]

In an open-label human study comparing IV procainamide and IV amiodarone for acute termination of stable wide QRS complex tachycardia (likely ventricular tachycardia), procainamide was more effective at terminating the tachycardic episode within 40 minutes. In the following 24 hours, procainamide was also associated with fewer major cardiac adverse events.[2]

Pharmacology/Actions

A class 1A antiarrhythmic agent, procainamide binds and inhibits fast sodium channels. It exhibits cardiac action similar to that of quinidine. It is considered both a supraventricular and ventricular antidysrhythmic. Procainamide prolongs the refractory times in both the atria and ventricles, decreases myocardial excitability, and depresses automaticity and conduction velocity. It has anticholinergic properties that may contribute to its effects. Procainamide's effects on heart rate are unpredictable, but it usually causes only slight increases or no change. It may exhibit negative inotropic actions on the heart, although cardiac outputs are generally not affected. One ex vivo study using rat hearts found that procainamide did not negatively affect contractility, cardiac output, or diastolic function.[3]

On ECG, QRS widening and prolonged PR and QT intervals can be seen. The QRS complex and T wave may occasionally show some slight decreases in voltage.

Pharmacokinetics

After IM or IV administration, the onset of action is practically immediate. After oral administration in humans, ≈75% to 95% of a dose is absorbed in the intestine, but some patients absorb less than 50% of a dose. Food, delayed gastric emptying, or decreased stomach pH may delay oral absorption. In dogs, it has been reported that the oral bioavailability is ≈85% and the absorption half-life is 0.5 hours[4]; however, there is an apparent large degree of variability in both bioavailability and half-life of absorption.

FDA-approved oral procainamide products are no longer available, but a small (n = 6) pharmacokinetic study was performed in healthy dogs using a compounded delayed-release formulation.[5] After dosing at 30 mg/kg PO, the average time that procainamide serum concentrations were above 4 µg/mL was 9.65 hours. The authors concluded: *Although specific dosing recommendations cannot be made from this data due to individual animal variability, it appears that twice daily administration of delayed-release procainamide could be efficacious in dogs. Due to individual patient variability, evaluation of serum trough concentrations should be considered to confirm concentrations within the reported therapeutic range.*

Distribution of procainamide is highest into the CSF, liver, spleen, kidneys, lungs, heart, and muscles. The volume of distribution in dogs is ≈1.4 to 3 L/kg.[4] It is only ≈20% protein-bound in humans and 15% in dogs. The elimination half-life in dogs has been reported to be variable; most studies report values between 2 and 3 hours.[4] In humans, procainamide is metabolized to N-acetyl-procainamide (NAPA), an active metabolite. Dogs do not form appreciable amounts of NAPA from procainamide, as they are unable to appreciably acetylate aromatic and hydrazine amino groups.[2,4] In dogs, ≈90% (50% to 70% unchanged) of an IV dose is excreted in the urine as procainamide and metabolites within 24 hours of dosing.

Contraindications/Precautions/Warnings

Procainamide may be contraindicated in patients with myasthenia gravis, as it may worsen clinical signs (see ***Drug Interactions***). Procainamide is contraindicated in patients hypersensitive to it, procaine, or other local anesthetic esters. In humans, procainamide is contraindicated in patients with systemic lupus erythematosus (SLE), but it is unknown if it adversely affects dogs with this condition. Procainamide should not be used in patients with torsade de pointes, or with second- or third-degree heart block (unless artificially paced).

Procainamide should be used with extreme caution, if at all, in patients with cardiac glycoside (eg, digitalis, digoxin) intoxication. It should be used with caution in patients with significant hepatic or renal disease or with congestive heart failure. Dosages should usually be reduced in patients with renal failure, congestive heart failure, or those that are critically ill.

It has been recommended to not use procainamide in Doberman pinschers and boxers with dilated cardiomyopathy or dogs with subaortic stenosis; the drug may be proarrhythmic in certain patients susceptible to tachyarrhythmic-induced sudden death.[6]

Adverse Effects

In dogs, adverse effects are generally related to dose and serum drug concentrations. GI effects may include anorexia, vomiting, or diarrhea. Effects related to the cardiovascular system can include weakness, hypotension, negative inotropism, widened QRS complex and QT intervals, AV block, and multiform ventricular tachycardias. Fevers and leukopenias are a possibility. Profound hypotension can occur if injected too rapidly IV. In humans, an SLE syndrome can occur, but its incidence has not been established in dogs.

Agranulocytosis, neutropenia, bone marrow suppression, hypoplastic anemia, and thrombocytopenia have been rarely reported in humans (≈0.5%).

Reproductive/Nursing Safety

Procainamide can cross the placenta. Both procainamide and NAPA are excreted in maternal milk and absorbed in nursing offspring. It should be used with caution in nursing patients; consider using milk replacer if the drug is to be continued.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs of overdose can include hypotension, lethargy, confusion, nausea, vomiting, and oliguria. Cardiac signs may include widening of the QRS complex, junctional tachycardia, ventricular fibrillation, or intraventricular conduction delays.

If the overdose is from an oral ingestion, GI decontamination and charcoal administration may be beneficial to remove any unabsorbed drug. IV fluids, plus dopamine, phenylephrine, or norepinephrine could be considered to treat hypotensive effects. A 1/6 molar IV infusion of sodium lactate may be used in an attempt to reduce the cardiotoxic effects of procainamide. Forced diuresis using fluids and diuretics along with reduction of urinary pH can enhance the renal excretion of the drug. Temporary cardiac pacing may be necessary should severe AV block occur.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving procainamide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

Use with caution with other antidysrhythmic agents, as additive cardiotoxic or other toxic effects may result.

- **Anticholinesterase Agents** (eg, **neostigmine, pyridostigmine**): Procainamide may antagonize effects in patients with myasthenia gravis.
- **H2 Antagonists** (eg, **cimetidine, ranitidine**): May increase procainamide concentrations
- **Hypotensive Drugs** (eg, **amlodipine, enalapril**): Procainamide may enhance effect.
- **Neuromuscular Blocking Agents** (eg, **atracurium, succinylcholine**): Procainamide may potentiate or prolong the neuromuscular blocking activity.
- **Trimethoprim**: May increase procainamide concentrations

Concurrent use with the following drugs may increase risk for cardiotoxicity, including QT prolongation, torsades de pointes, or cardiac arrest:

- **Amiodarone**: May increase procainamide concentrations, procainamide dose may need to be reduced
- **Amitriptyline**
- **Azithromycin**
- **Azole Antifungals** (eg, itraconazole, fluconazole)
- **Buprenorphine**
- **Cisapride**
- **Clomipramine**
- **Erythromycin**
- **Fluoroquinolones** (eg, ciprofloxacin)
- **Fluoxetine**
- **Hydroxychloroquine**
- **Hydroxyzine**
- **Isoflurane**
- **Lidocaine**: Toxic effects may be additive, and cardiac effects are unpredictable. Cardiotoxicity may include decreases in cardiac output, total peripheral resistance, and mean arterial pressure.
- **Methadone**
- **Metronidazole**
- **Mirtazapine**
- **Ondansetron**
- **Quinidine**
- **Sevoflurane**
- **Sodium Phosphate**
- **Sotalol**: Discontinue use of procainamide for at least 3 half-lives before dosing sotalol.
- **Tacrolimus**
- **Trazodone**

Laboratory Considerations

- Propranolol and very high concentrations of lidocaine can affect fluorescent tests for procainamide or NAPA.

Dosages

DOGS:

Severe or clinical ventricular tachycardia (extra-label): Lidocaine is usually the drug of first choice, but procainamide can be considered when lidocaine is ineffective and serum potassium and magnesium concentrations are adequate. Dosage recommendations vary. Consider procainamide slow IV boluses (over 2 to 5 minutes) of 2 – 4 mg/kg to a maximum of 20 mg/kg. If successful, follow with 20 – 50 µg/kg/minute IV CRI. If a CRI is not feasible, 7 – 10 mg/kg IM every 6 to 8 hours.

Compounded oral delayed-release procainamide may be useful for maintenance therapy but documentation of efficacy is lacking. One pharmacokinetic study[5] using a compounded product at 30 mg/kg PO every 12 hours concluded that dosing every 12 hours could be efficacious, but evaluation of serum drug concentrations should be considered.

Acute management of supraventricular tachycardias (SVTs) (extra-label): After drugs have been used to slow AV nodal conduction (eg, diltiazem), procainamide 6 – 8 mg/kg IV over 3 minutes or 6 – 20 mg/kg IM may terminate atrial tachyarrhythmias.[7]

CATS:

Acute, clinical ventricular tachycardia or SVTs (extra-label): 1 – 2 mg/kg IV slowly over 20 minutes.[8] For maintenance therapy, 3 – 8 mg/kg PO every 6 to 8 hours.[9] Rarely used, but could be considered in refractory arrhythmia

HORSES:

Atrial fibrillation (extra-label): 1 – 2 mg/kg/minute IV CRI, not to exceed 20 mg/kg (10 to 20 minutes) total dose. Alternatively, administer 25 – 35 mg/kg PO every 8 hours.[10] Not as effective as quinidine

Ventricular tachycardia (extra-label): 1 – 2 mg/kg/minute IV CRI up to a total dose of 20 mg/kg (10 to 20 minutes) has been suggested.[10,11]

Monitoring

- Cardiovascular parameters: ECG (continuous with IV administration); blood pressure; heart rate
- Adverse effects (eg, vomiting, diarrhea)
- Therapeutic drug monitoring: Because of the variability in pharmacokinetics reported in the dog, it is recommended to monitor therapy using serum drug concentrations. Because dogs do not form the active metabolite NAPA in appreciable quantities, the therapeutic range for procainamide is controversial. Therapeutic ranges from 3 – 8 µg/mL to 8 – 20 µg/mL have been suggested. Due to the lack of conversion to NAPA (which contributes to the antiarrhythmic effects of procainamide) in dogs, a higher procainamide concentration may be required. This author (Plumb) would suggest using the lower range as a guideline to initiate therapy, but not to hesitate increasing doses to attain higher concentrations if efficacy is not achieved and toxicity is not a problem. Digitalis-induced ventricular arrhythmias may require substantially higher blood concentrations for control. Trough drug concentrations are usually specified when monitoring oral therapy. Because NAPA is routinely monitored with procainamide in human medicine, it may be necessary to tell the laboratory that NAPA values need not be automatically run for canine patients.
- In horses, therapeutic levels have been suggested as 4 – 10 µg/mL for procainamide and 10 – 30 µg/dL as procainamide and NAPA together.[10]
- Because of serious and potentially fatal blood dyscrasias seen in humans, it is recommended to perform a CBC at weekly intervals for the first 3 months of therapy, and periodically thereafter.[12]

Client Information

- Procainamide oral medicine should be administered at evenly spaced intervals throughout the day/night. Unless otherwise directed, give the medication on an empty stomach, at least 1 hour before feeding or 2 hours after.
- Notify your veterinarian if your animal's condition gets worse or clinical signs of toxicity (eg, vomiting, diarrhea, weakness) occur.

- While your animal is taking this medication, it is important to return to your veterinarian for laboratory work, physical examination, and testing of heart rate and rhythm. Do not miss these important follow-up visits.

Chemistry/Synonyms

Structurally related to procaine, procainamide is used as an antiarrhythmic agent. Procainamide HCl differs from procaine by the substitution of an amide group for the ester group found on procaine. It occurs as an odorless, white to tan, hygroscopic, crystalline powder with a pK_a of 9.23 and a melting range from 165°C to 169°C (329°F-336°F). It is very soluble in water and soluble in alcohol. The pH of the injectable product ranges from 4 to 6.

Procainamide may also be known as novocainamidum, procainamidi chloridum, procainamidi hydrochloridum, *Biocoryl®*, *Procan®*, *Procanbid®*, or *Pronestyl®*.

Storage/Stability

The solution may be used if the color is no darker than light amber. Refrigeration may delay the development of oxidation, but the solution may be stored at room temperature.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

The injectable product is reportedly physically **compatible** with sodium chloride 0.9% injection, and water for injection. Procainamide is also physically **compatible** with dobutamine HCl, lidocaine HCl, and verapamil HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Procainamide HCl Injection Solution: 100 mg/mL in 10 mL vials and 500 mg/mL in 2 mL vials; generic; (Rx)

Procainamide HCl Immediate Release Capsules in 250 mg, 375 mg, and 500 mg, and Extended-Release Tablets in 250 mg, 500 mg, and 750 mg are available in Canada; generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Procarbazine

(proe-***kar***-ba-zeen) *Matulane®*

Antineoplastic

Prescriber Highlights

- ► Atypical alkylating agent that is used in multiagent lymphoma protocols for dogs/cats and for granulomatous meningoencephalitis (GME) in dogs; enters CNS
- ► Contraindicated in patients that are hypersensitive to the drug and have myelosuppression
- ► Use with caution in patients with hepatic and renal impairment and when used with other CNS depressant drugs.
- ► Adverse effects include GI (eg, vomiting, diarrhea, acute hemorrhagic diarrhea syndrome), myelosuppression, and hepatotoxicity.
- ► Potentially teratogenic and embryotoxic. The National Institute for Occupational Safety and Health (NIOSH) classifies procarbazine as a hazardous drug; use appropriate precautions when handling it.

Uses/Indications

Procarbazine is used as part of MOPP (mechlorethamine, vincristine, procarbazine, prednisone),[1–4] MPP (mechlorethamine, procarbazine, prednisone),[5] LOPP (lomustine, vincristine, procarbazine, prednisone),[6–9] LPP (modified LOPP; lomustine, procarbazine, prednisone),[10] and BOPP (bendamustine, vincristine, procarbazine, prednisone)[7] protocols to treat both naïve and relapsed/refractory lymphoma in dogs and cats.

It may be of benefit in treating granulomatous meningoencephalitis (GME) in dogs.[11]

Pharmacology/Actions

Procarbazine's precise mode of action is not well understood, but it is considered to be an alkylating agent, and it appears to inhibit protein, RNA, and DNA synthesis. Procarbazine is auto-oxidized into hydrogen peroxide, which may also directly damage DNA.

Pharmacokinetics

No data specific for dogs or cats are available. In humans, procarbazine is completely absorbed after oral administration and rapidly equilibrates between the CSF and plasma.[12] Peak concentrations in plasma occur in ≈1 hour; in the CSF, ≈30 to 90 minutes after dosing. Procarbazine is almost entirely metabolized in the liver and kidney. Metabolic products are cytotoxic, and nearly 70% are excreted in the urine within 24 hours.

Contraindications/Precautions/Warnings

Procarbazine is contraindicated in patients known to be hypersensitive to the drug. The risk vs benefits of therapy must be carefully considered in patients with pre-existing myelosuppression or concurrent infections. Additive myelosuppression may occur in patients undergoing concomitant radiation therapy. Because procarbazine can cause CNS depression, use it with extreme caution with other CNS depressant drugs. Use procarbazine with caution in patients with impaired renal or hepatic function.

Only veterinarians with the experience and resources to monitor the toxicity of this agent should administer procarbazine.

Significant treatment-related toxicities in humans include the long-term risk for secondary cancers, infertility, neuropathy, and monoamine oxidase (MAO) inhibition.[12]

The National Institute for Occupational Safety and Health (NIOSH) classifies procarbazine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[13]

Adverse Effects

When dosed as recommended for dogs and cats, procarbazine is relatively well tolerated. GI effects (eg, nausea, vomiting), hepatotoxicity, and myelosuppression (eg, thrombocytopenia, leukopenia) can be seen. Platelet nadir usually occurs at ≈3 to 4 weeks.

Many dogs receiving chemotherapy will have minor hair coat changes (eg, shagginess, loss of luster). Breeds with continuously growing hair coats (eg, poodles, terriers, Afghan hounds, or old English sheepdogs) are more likely to experience significant alopecia.

Because it is often used in combination with other chemotherapy agents, myelosuppression, and GI effects (hemorrhagic gastritis) may be enhanced. Alternate-day dosing or concurrent administration of antiemetics and appetite stimulants may alleviate severe anorexia in cats.

In humans, CNS effects may be noted and include sedation or agitation. Peripheral neuropathy can occur and includes loss of tendon reflexes, paresthesias, and myalgia.[12] Other reported adverse effects in humans include thrombosis, stomatitis, pancreatitis, ataxia, convulsions, cardiotoxicity, retinal hemorrhage, pulmonary toxicity, dermatitis, pruritus, nervousness, confusion, and hearing loss.[14]

In humans, it is recommended to discontinue or withhold therapy if any of the following occur: CNS signs, leukopenia (WBC less than 4000/µL), thrombocytopenia (platelets less than 100,000/µL), hypersensitivity, stomatitis (at the sign of first ulceration), diarrhea, and hemorrhage or bleeding. Resume therapy at a lower dose only if adverse effects resolve.

Reproductive/Nursing Safety

Procarbazine is potential teratogen. For sexually intact patients, verify pregnancy status prior to administration. It is unknown if procarbazine enters the milk. It is recommended to use milk replacer if the dam requires procarbazine. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The LD_{50} for laboratory animals ranges from 150 mg/kg (rabbits) to 1.3 g/kg (mice).[15] There is no known antidote, and treatment is supportive. If the overdose was within a few hours, it is recommended to treat aggressively to remove the drug from the gut. Anticipated adverse effects would be extensions of the drug's adverse effect profile (eg, GI, myelosuppression, CNS effects).

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving procarbazine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antidepressants** (eg, **amitriptyline, clomipramine, fluoxetine**): Procarbazine exhibits some monoamine oxidase inhibitory (MAOI) activity. Do not use concurrently with antidepressant drugs.
- CNS **Depressant Drugs** (eg, **barbiturates, opiates, antihistamines, phenothiazines**): Because procarbazine can cause CNS depression, use with extreme caution with other CNS depressant drugs. Coma and death have been reported when procarbazine has been used with opiates.
- **Ethanol**: May cause severe nausea and vomiting
- **Foods and Supplements With High Tyramine Content** (eg, aged cheese, yogurt, pepperoni/salami/summer sausage, ginseng): Procarbazine exhibits some MAOI activity; serious hypertension may result.
- **Myelosuppressive Agents** (eg, antineoplastics, immunosuppressants, iron chelators): Concurrent use with other bone marrow depressant medications may result in additive myelosuppression; avoid combination when possible.
- **Sympathomimetics** (eg, **phenylpropanolamine**): Procarbazine exhibits some MAOI activity; serious hypertension may result.
- **Vaccines** (live and inactivated): Procarbazine may diminish vaccine efficacy and enhance adverse effects of vaccines.

Laboratory Considerations

- None were noted.

Dosages

NOTES:

- Because of the potential toxicity of this drug to patients, veterinary staff, and pet owners, and because chemotherapy indications, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[16–20] are strongly recommended.
- Dose calculations should be checked thoroughly to avoid overdosing because of the potential for serious toxicity associated with this agent.

DOGS:

Lymphoma, first-line (T-cell), or rescue (extra-label): When procarbazine is used, it is as part of a protocol in combination with other antineoplastic agents (MOPP, MPP, LOPP, LPP, BOPP protocols) and is usually given for the first 14 days of the treatment cycle.[1,2,5–7] The usual dose for dogs is 50 mg/m^2 (NOT mg/kg) PO daily.

Granulomatous meningoencephalitis (GME) (extra-label): 25 – 50 mg/m^2 (NOT mg/kg) PO once daily, initially with prednisone treatment. After the first month of therapy, attempt to reduce the procarbazine dose to every other day.

CATS:

Lymphoma, rescue (extra-label): When procarbazine is used, it is as part of a protocol in combination with other antineoplastic agents (MOPP protocol) and is usually given for the first 14 days of the treatment cycle. Usual doses for cats are 50 mg/m^2 (NOT mg/kg) PO daily or every other day; 10 mg/cat (NOT mg/m^2 or mg/kg) PO once daily has also been reported.[4]

Monitoring

- Baseline and weekly CBC, particularly platelet count. When giving the drug long term as part of treatment for granulomatous meningoencephalitis (GME), monitor CBC weekly for the first month and then monthly thereafter.
- Baseline and periodic serum liver and renal chemistry panels

Client Information

- Procarbazine is a chemotherapy (anticancer) medicine. It can be hazardous to other animals and humans that come in contact with them. Wear gloves when handling and administering procarbazine. On the day your animal gets the medicine, and then for ≈72 hours afterward, handle all bodily waste (ie, urine, feces, litter), blood, or vomit while wearing disposable gloves. Seal the waste in a plastic bag and then place both the bag and gloves in with the regular trash.
- Gastrointestinal toxicity (eg, ulcers, diarrhea) can occur. If diarrhea is severe or continues, contact your veterinarian.

- Bone marrow suppression can occur and make your animal at risk for developing infections. The greatest effects on bone marrow usually occur within a few weeks after treatment. Your veterinarian will do blood tests to watch for this problem. Do not miss these important follow-up visits.
- Contact your veterinarian right away if you see bleeding, bruising, or fever (indicating an infection) or if your animal becomes tired easily.
- Procarbazine can also be toxic to the nerves and cause numbness, tingling, or lameness. Contact your veterinarian if you have any concerns that your animal is having these side effects.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Procarbazine HCl, a derivative of hydrazine, occurs as a white to a pale-yellow crystalline powder having a slight odor. It is soluble but unstable in water or aqueous solutions.

Procarbazine may also be known as ibenzemethyzin, NSC-77213, Ro-4-6467/1, MIH, N-Methylhydrazine, *Matulane®*, *Natulan®*, and *Natulanar®*.

Storage/Stability

Store procarbazine capsules in airtight containers, protected from light at temperatures between 20°C and 25°C (68°F-77°F).

Compatibility/Compounding Considerations

Procarbazine is a hazardous drug and should only be compounded by trained personnel with adequate hazardous drug facilities and precautions. Precautions (eg, use of a biological safety cabinet) must be taken to avoid exposure from capsule contents when compounding dosage forms from commercially available capsules.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Procarbazine HCl Capsules: 50 mg; *Matulane®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Prochlorperazine

(proe-klor-***per***-a-zeen) *Compazine®, Compro®*
Phenothiazine Antiemetic

Prescriber Highlights

► Used as an antiemetic in dogs and cats
► Relatively contraindicated in patients that are hypovolemic, dehydrated, or in shock, and in patients with tetanus or strychnine intoxication
► Use with caution in patients with hepatic dysfunction, cardiac disease, general debilitation, and in very young animals.
► Adverse effects include sedation and hypotension.

Uses/Indications

Prochlorperazine is used in dogs and cats as an antiemetic. It has a mild sedative effect that may be advantageous in an inpatient setting. There is limited published information to support clinical use in dogs or cats.

Prochlorperazine was FDA-approved in combination with isopropamide, with or without neomycin, for vomiting, nonspecific gastroenteritis, drug-induced diarrhea, infectious diarrhea, spastic colitis, and motion sickness in dogs and cats; however, these products are no longer marketed in the United States.

Pharmacology/Actions

Prochlorperazine is a phenothiazine derivative. It has multiple mechanisms of action, including antagonism of dopamine, histamine type-1, alpha-2-adrenergic, and muscarinic receptors. The antiemetic activity of prochlorperazine is due to its effects primarily in the brain's emetic center and chemoreceptor trigger zone, but it also has some peripheral activity. Prochlorperazine has weak anticholinergic effects, strong extrapyramidal effects, and moderate sedative effects.

Pharmacokinetics

Limited information is available regarding the pharmacokinetics of prochlorperazine in animals, although it likely follows the general pattern of other phenothiazine agents in absorption, distribution, and elimination.

In humans, the onset of action is 10 to 20 minutes after IM administration with a duration of 3 to 4 hours. IV administration is generally avoided due to the increased risk for hypotension; SC administration is avoided due to local irritation.

Contraindications/Precautions/Warnings

Prochlorperazine is contraindicated in patients with a known hypersensitivity to it or other phenothiazines and in patients in comatose states due to large amounts of CNS depressants. Phenothiazines are relatively contraindicated in patients with hypovolemia, dehydration, or shock due to their hypotensive effects. Do not use prochlorperazine for tetanus or strychnine intoxication due to its effects on the extrapyramidal system.

Use prochlorperazine with caution in animals with hepatic dysfunction, cardiac disease, or general debilitation; smaller doses are recommended. Phenothiazines may exacerbate CNS depression. Use prochlorperazine with caution in very young or debilitated animals. Animals may require lower doses of general anesthetics following phenothiazines.

Some dosage forms contain large amounts of benzyl alcohol.

Avoid skin contact with the injectable solution during dose preparation and administration, as contact dermatitis has occurred. Do not confuse prochlorPERAZINE with chlorproMAZINE.

Adverse Effects

The most frequent adverse effects of prochlorperazine are sedation and hypotension. Muscle fasciculations, tremors, and prolactin release have been reported in small animal species.

In humans, the most common adverse effects include drowsiness, dizziness, skin reactions, and hypotension.

Reproductive/Nursing Safety

It is unknown if prochlorperazine is excreted in milk; however, other phenothiazines have been detected in maternal milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The reported LD_{50} in dogs following PO and IV administration was 102 and 100 mg/kg, respectively.[1] Acute extrapyramidal clinical signs such as torticollis, tremor, and salivation have been successfully treated with injectable diphenhydramine in humans. Treatment is supportive as there is no known antidote, and prochlorperazine is unlikely to be removed via dialysis. Refer to ***Overdose/Acute Toxicity*** in ***Acepromazine*** for further information.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and

toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving prochlorperazine or other phenothiazines and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate, hyoscyamine**): Increased risk for anticholinergic effects (eg, dry mucous membranes, constipation, urinary retention)
- **Beta-Adrenergic Receptor Antagonists**: May increase risk for hypotension
- **CNS Depressant Agents** (eg, anesthetics, barbiturates): May cause additive CNS depression
- **Dopamine**: Phenothiazines may decrease pressor effects.
- **Emetics** (eg, **apomorphine, ropinirole**): Prochlorperazine may decrease the effectiveness of emetics and increase risk for sedation and hypotension
- **Epinephrine**: Contraindicated in the treatment of acute hypotension produced by prochlorperazine or other phenothiazines, as further depression of blood pressure can occur (also referred to as epinephrine reversal)
- **Metoclopramide**: Phenothiazines may potentiate the extrapyramidal effects of metoclopramide.
- **Opioids** (eg, **buprenorphine, morphine, tramadol**): May enhance the hypotensive effects of the phenothiazines; dosages of prochlorperazine may need to be reduced when used with an opioid.
- **Organophosphate Agents**: Phenothiazines should not be given within 1 month of deworming with organophosphates, as organophosphate toxicity may be potentiated.
- **Paraquat**: Toxicity of the herbicide paraquat may be increased by prochlorperazine.
- **Physostigmine**: Toxicity may be enhanced by prochlorperazine.
- **Procaine**: Activity may be enhanced by phenothiazines.
- **QT Prolonging Agents** (eg, **cisapride, fluoroquinolones, sotalol, selective serotonin reuptake inhibitors** [**SSRIs**]): Increased risk for QT prolongation and torsade de pointes

Dosages

DOGS/CATS:

Antiemetic (extra-label): 0.1 – 0.5 mg/kg SC every 6 to 8 hours; ensure adequate hydration

Monitoring

- Heart rate, rhythm, and blood pressure if indicated
- Antiemetic/antispasmodic efficacy
- Periodic chemistry and hydration status as indicated by clinical presentation
- Body temperature (especially if the ambient temperature is very hot or cold)

Client Information

- Observe animals for at least 1 hour following dosing. Keep treated animal in a quiet environment at a comfortable temperature.
- This medicine may cause your animal's urine color to change to a pink or red-brown color. This change does not cause any harm.
- Vomiting and diarrhea that does not improve or worsens can be a serious problem. Contact your veterinarian if this occurs.
- Contact your veterinarian if you notice abnormal behavior, rigidity, or other abnormal body movements.

Chemistry/Synonyms

Prochlorperazine is a piperazine phenothiazine derivative that is available commercially as the base in rectal formulations, the edisylate salt in injectable and oral solutions, and as the maleate salt in oral tablets and capsules. Each 8 mg of the maleate salt and 7.5 mg of the edisylate salt are ≈5 mg of prochlorperazine base.

The base occurs as a clear to pale-yellow, viscous liquid that is very slightly soluble in water and freely soluble in alcohol. The edisylate salt occurs as white to very light yellow, odorless, crystalline powder. Five hundred milligrams are soluble in 1 mL of water or 750 mL of alcohol. The maleate salt occurs as a white or pale-yellow, practically odorless, crystalline powder. It is practically insoluble in water or alcohol.

The commercial injection is a solution of the edisylate salt in sterile water. It has a pH of 4.2 to 6.2.

Prochlorperazine may also be known as chlormeprazine, prochlorpemazine, *Compazine®*, *Compro®*, *Prochlor®*, *Prorazin®*, *Stemetil®*, or *Tementil®*.

Storage/Stability

Store intact vials and tablets between 20°C and 25°C (68°F-77°F); avoid freezing. Protect from light. Slight yellowing of oral or injectable solutions does not affect potency or efficacy. Do not use if precipitate forms or if the solution is substantially discolored.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

The following products have been reported to be physically **compatible** when mixed with prochlorperazine edisylate injection: all usual IV fluids, ascorbic acid injection, atropine sulfate, butorphanol tartrate, chlorpromazine HCl, dexamethasone sodium phosphate, fentanyl citrate, glycopyrrolate, hydroxyzine HCl, lidocaine HCl, meperidine HCl, metoclopramide, morphine sulfate, nalbuphine HCl, pentazocine lactate, perphenazine, promazine HCl, promethazine, scopolamine HBr, sodium bicarbonate, and vitamin B complex with C.

The following drugs have been reported to be physically **incompatible** when mixed with prochlorperazine edisylate: aminophylline, amphotericin B, ampicillin sodium, calcium gluceptate, chloramphenicol sodium succinate, dimenhydrinate, hydrocortisone sodium succinate, methohexital sodium, penicillin G sodium, phenobarbital sodium, pentobarbital sodium, and thiopental sodium. Do not mix with other drugs/diluents having parabens as preservatives.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None; *Darbazine®* is no longer available.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information. The FEI (International Federation for Equestrian Sports) lists this drug as a "prohibited substance – banned."[2]

HUMAN-LABELED PRODUCTS:

Prochlorperazine for Injection: 5 mg/mL in 2 mL vials (as edisylate); generic; (Rx)

Prochlorperazine Tablets: 5 mg and 10 mg (as maleate); generic; (Rx)

Prochlorperazine Suppositories: 25 mg (as base); *Compro®*, generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Promethazine

(proe-***meth***-a-zeen) *Phenergan®*

Phenothiazine

Prescriber Highlights

- ► Used as an antiemetic and antihistamine in small animal species
- ► In horses, may cause less sedation and peripheral vasodilation than acepromazine
- ► Limited experience with promethazine in veterinary medicine
- ► Contraindications include hypersensitivity, hypovolemia, and shock. Do not inject IA or SC.
- ► Use with caution in patients with hepatic dysfunction, patients with cardiac disease, very young patients, and debilitated patients.
- ► Adverse effects include sedation and anticholinergic effects.

Uses/Indications

Promethazine has been used in dogs and cats as an antiemetic. A small study in cats found that IM doses of 2 and 4 mg/kg given 1 hour prior to xylazine administration significantly reduced the frequency of emesis.[1] Despite its antihistamine actions, efficacy for treatment of pruritus in atopic dogs has been poor. Oral H_1 antihistamines may provide limited benefit in some dogs with atopic dermatitis for preventing pruritus when given before a flare but are of little to no benefit for long-term treatment.[2]

A study in standing horses compared the sedative and hemodynamic effects of acepromazine 0.1 mg/kg IV with those of promethazine 0.1, 0.2, and 0.3 mg/kg IV. At the doses used, promethazine appeared to have less sedative and peripheral vasodilator effects than acepromazine.[3] Promethazine may be safer than acepromazine in horses at risk for hypotension[3] and may be of benefit in horses suffering from shock or cardiovascular depression if anti-inflammatory and antioxidative properties are confirmed in vivo.[4]

Pharmacology/Actions

Promethazine is similar to other phenothiazines with multiple mechanisms of action, including antagonism of H_1, alpha$_2$-adrenergic, and muscarinic receptors; it also antagonizes dopamine but to a lesser extent than other phenothiazines. Antiemetic activity of promethazine is primarily due to its effects in the brain's emetic center and chemoreceptor trigger zone, but it also has some peripheral activity.

Pharmacokinetics

Limited pharmacokinetic information is available in animals. Oral bioavailability in dogs is very low at ≈10%.[5]

In humans, promethazine is well absorbed following oral, rectal, and IM administration. Sedative effects occur within minutes of IV administration and persist for several hours. Promethazine is widely distributed. It is metabolized in the liver and metabolites are eliminated primarily in the urine.[6] Elimination half-life in humans is ≈10 hours.

Contraindications/Precautions/Warnings

Promethazine is contraindicated in patients that are hypersensitive to it or other phenothiazines. In humans, promethazine is contraindicated in children less than 2 years old due to risk for fatal respiratory depression.[6,7] Phenothiazines are relatively contraindicated in patients with hypovolemia or shock due to their hypotensive effects. Do not use in patients with tetanus or strychnine intoxication due to effects on the extrapyramidal system.

Promethazine is absolutely contraindicated for intra-arterial injection due to the likelihood of arteriospasm, which could lead to gangrene. It should not be given SC as chemical irritation and necrotic lesions are possible.[7]

Use with caution in patients with hepatic dysfunction, or cardiac disease; smaller doses may be required. Use cautiously in very young or debilitated animals. Drugs with anticholinergic properties such as promethazine should be used with caution in patients with narrow-angle glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction, or bladder-neck obstruction.

Animals may require lower doses of general anesthetics following phenothiazine administration. Promethazine discolors blood on contact, making it difficult to assess needle placement upon drawback.

Adverse Effects

Limited information is available in animals but sedation and anticholinergic effects such as dry mucous membranes, constipation, and urinary retention occur with other phenothiazines. Promethazine can cause paradoxical CNS stimulation leading to hyperexcitability, tremors, abnormal muscle movements, or convulsions. Promethazine may lower seizure threshold. Injection-site reactions are also possible.

Reproductive/Nursing Safety

Whether promethazine is distributed in milk is unknown; however, a related compound, chlorpromazine, has been detected in maternal milk. In humans, it is recommended to either discontinue promethazine or discontinue nursing due to the risk for serious adverse effects in nursing infants.[6,7]

Because safety has not been established in pregnant animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute extrapyramidal clinical signs of overdose such as torticollis, tremor, and salivation have been treated successfully with injectable diphenhydramine in humans. See ***Acepromazine*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving promethazine or other phenothiazines and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids**: May reduce GI absorption of oral phenothiazines
- **Antidiarrheal Mixtures** (eg, **kaolin/pectin, bismuth subsalicylate**): May reduce GI absorption of oral phenothiazines
- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate, hyoscyamine**): May have additive effects when used with promethazine
- **CNS Depressant Agents** (eg, **anesthetics, barbiturates, narcotics, sedatives**): May cause additive CNS depression if used with phenothiazines
- **Emetics** (eg, **apomorphine, ropinirole**): Prochlorperazine may decrease the effectiveness of emetics and increase risk for sedation and hypotension
- **Epinephrine**: Phenothiazines may reduce or reverse pressor effects of epinephrine.
- **Metoclopramide**: Phenothiazines may potentiate the extrapyramidal effects of metoclopramide.

- **Monoamine Oxidase Inhibitors (MAOIs;** eg, **amitraz, linezolid, selegeline**): May potentiate extrapyramidal effects
- **Myelosuppressants**: Promethazine may potentiate the myelosuppressive effects.
- **Opioids** (eg, **buprenorphine, morphine, tramadol**): May enhance the hypotensive effects of the phenothiazines; dosages of promethazine may need to be reduced when used with an opioid.
- **Organophosphate Agents**: Phenothiazines should not be given within 1 month of deworming with organophosphates as their effects may be potentiated.
- **QT Prolonging Agents** (eg, **cisapride, fluoroquinolones, sotalol, SSRIs**): Increased risk for QT prolongation and torsade de pointes; concurrent administration of cisapride and promethazine is contraindicated in humans.

Laboratory Considerations

- Promethazine can cause false-positive results for salicylates in urine.
- Promethazine can cause false-positive or false-negative results for chorionic gonadotropin in urine.

Dosages

NOTE: Do not administer intra-arterially or SC (see ***Contraindications/Precautions/Warnings***). IM is the preferred parenteral route.

DOGS:

Antiemetic | Prevention of motion sickness (extra-label): 0.2 – 0.5 mg/kg PO every 6 to 8 hours; oral bioavailability is low so efficacy may be limited.[8]

CATS:

Antiemetic (extra-label): 2 mg/kg IM given 1 hour prior to xylazine administration has been shown to significantly reduce the frequency of emesis.[1]

HORSES:

Alternative to acepromazine in horses at risk for hypotension (extra-label): 0.1 – 0.2 mg/kg IV based on one small study[3]

Monitoring

- Efficacy (eg, signs of nausea, vomiting)

Client Information

- This medicine may cause dry mouth. Applying small amounts of water to the animal's tongue for 10 to 15 minutes may provide relief.
- Promethazine may cause sedation or behavior changes. Contact your veterinarian if these are a concern.
- Vomiting or diarrhea that does not resolve can be serious. Contact your veterinarian if these signs worsen or do not stop.
- Contact your veterinarian if your animal develops abnormal movements, tremors, or becomes rigid.

Chemistry/Synonyms

Promethazine HCl occurs as a white to faint yellow, practically odorless, crystalline powder. It slowly oxidizes and acquires a blue color on prolonged exposure to air. Promethazine HCl is freely soluble in water, hot dehydrated alcohol, or chloroform, but practically insoluble in acetone, ether, or ethyl acetate. The pH of a 5% solution in water is between 4 and 5.

Promethazine may also be known as Lilly 01516, PM 284, RP 3277, diprazinum, prometazina, or *Phenergan*®. There are many other branded products available.

Storage/Stability

Store tablets at room temperature (20°C-25°C [68°F-77°F]) in tight, light-resistant containers. Store the syrup at 15°C-25°C (59°F-77°F) and protect it from light and freezing.

Store the injection at room temperature (20°C-25°C [68°F-77°F]) and protect it from light. Keep in covered carton until time of use. Do not use if a precipitate forms or the solution is discolored. Promethazine can be adsorbed to plastic IV bags and tubing.

Store promethazine suppositories in the refrigerator (2°C-8°C [36°F-46°F]).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

The following products have been reported to be physically **compatible** when mixed with promethazine injection: all commonly used IV fluids, amikacin, ascorbic acid, buprenorphine, butorphanol, calcium salts, cimetidine, diphenhydramine, fentanyl, fluconazole, gentamicin sulfate, glycopyrrolate, hydromorphone, hydroxyzine, ketamine, lidocaine, meperidine, metoclopramide, midazolam, ondansetron, pancuronium, pentazocine, procainamide, and ranitidine.

Solutions of promethazine hydrochloride are **incompatible** with alkaline substances, which can precipitate promethazine base.

The following drugs have been reported to be physically **incompatible** when mixed with promethazine HCl: aminophylline, amphotericin B (all forms), ampicillin, barbiturates, benzylpenicillin salts, most cephalosporins, chloramphenicol sodium succinate, dexamethasone sodium phosphate, diazepam, dimenhydrinate, doxorubicin (in a liposomal formulation), furosemide, heparin sodium, hydrocortisone sodium succinate, morphine sulfate, nalbuphine HCl, and pantoprazole.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Promethazine HCl for Injection: 25 mg/mL and 50 mg/mL in 1 mL ampules; generic; (Rx)

Promethazine HCl Oral Syrup: 1.25 mg/mL in 118 mL and 473 mL; generic; (Rx)

Promethazine HCl Oral Tablets: 12.5 mg, 25 mg, and 50 mg; generic; (Rx)

Promethazine HCl Rectal Suppositories: 12.5 mg, 25 mg, and 50 mg; *Phenadoz*®, *Promethegan*®, generic; (Rx)

Propantheline

(proe-***pan***-the-leen) *Pro-Banthine®*

Quaternary Antimuscarinic

Prescriber Highlights

- ► Quaternary antimuscarinic agent used for its antispasmodic/antisecretory effects for the treatment of diarrhea, detrusor hyperreflexia or urge incontinence, and anticholinergic responsive bradycardias. In horses, it is used IV to reduce colonic peristalsis and relax the rectum to allow easier examination and surgery.
- ► Contraindications include hypersensitivity to anticholinergics, tachycardia secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy, or myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy).
- ► Use with extreme caution in patients that have known or suspected GI infections or autonomic neuropathy.
- ► Use with caution in patients that have hepatic or renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, or esophageal reflux, and in geriatric or pediatric patients.
- ► Adverse effects are similar to atropine (eg, dry mouth, dry eyes, urinary hesitancy, tachycardia, constipation), but there are fewer effects on the eye or CNS. Cats may exhibit vomiting and hypersalivation. High doses may cause ileus.

Uses/Indications

In small animal medicine, propantheline has been used for its antispasmodic/antisecretory effects in the treatment of diarrhea. It is also employed in the treatment of detrusor hyperreflexia or urge incontinence, and as an oral treatment for anticholinergic responsive bradycardias.

In horses, propantheline has been used IV to reduce colonic peristalsis and for relaxing the rectum to allow easier rectal examination and surgery.

Pharmacology/Actions

Propantheline, an antimuscarinic with similar actions as atropine, is a quaternary ammonium compound and does not cross appreciably into the CNS. It should not exhibit the same extent of CNS adverse effects that atropine possesses. After a 100 mg IV injection to horses, propantheline reduced GI tract sounds for 2-plus hours and elevated heart rate relative to the control. Maximum heart rates were noted between 60 and 90 minutes postinjection.[1]

Pharmacokinetics

Quaternary anticholinergic agents are not completely absorbed after oral administration because they are completely ionized. In humans, peak concentrations occur 1 to 2 hours after oral administration. Propantheline's half-life in humans is 1.6 hours. Food apparently decreases the amount of drug absorbed. Propantheline is reportedly variably absorbed in dogs; dosages should be adjusted for each patient.

The distribution of propantheline has not been extensively studied, but, like other quaternary antimuscarinics, propantheline is poorly lipid-soluble and does not extensively penetrate into the CNS or eye.

Propantheline is believed to be primarily metabolized in the GI tract and/or liver; its primary pathway in humans is by hydrolysis to inactive metabolites. Less than 5% of an oral dose is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

The equine product (Australia) is labeled as contraindicated in cases of tympanic colic. Do not use propantheline in cases of dry choke where saliva is deficient, as the anticholinergic properties will further inhibit the secretion of saliva. Propantheline should be considered contraindicated if the patient has a history of hypersensitivity to anticholinergic drugs, tachycardia secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy, glaucoma, or myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy).

Propantheline should be used with extreme caution in patients with known or suspected GI infections, as it can decrease GI motility and prolong retention of the causative agent(s) or toxin(s), resulting in prolonged clinical signs. Antimuscarinic agents must also be used with extreme caution in patients with autonomic neuropathy.

Antimuscarinic agents should be used with caution in patients with hepatic disease, renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, esophageal reflux, and in geriatric or pediatric patients. The human product contains a warning for heat prostration; use caution in the presence of high environmental heat.

Adverse Effects

With the exception of fewer effects on the eye and the CNS, propantheline can be assumed to have a similar adverse reaction profile as atropine (eg, dry mouth, dry eyes, urinary hesitancy, tachycardia, constipation). Vomiting and hypersalivation have also been reported in cats. High doses may lead to the development of ileus with resultant bacterial overgrowth in susceptible animals. For more information, refer to the ***Atropine*** monograph.

Reproductive/Nursing Safety

Although anticholinergics (especially atropine) may be excreted in milk and cause toxicity and reduce milk production, it is unknown if propantheline enters maternal milk. Use propantheline with caution in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Because of propantheline's quaternary structure, it would be expected that minimal CNS effects would occur after an overdose when compared to atropine. See the information listed in the ***Atropine*** monograph for more information on the clinical signs that may be seen following an overdose.

In case of recent oral ingestion, GI decontamination and administration of activated charcoal and saline cathartics may be warranted. Treat clinical signs supportively and symptomatically. Do not use phenothiazines, as they may contribute to anticholinergic effects. Fluid therapy and standard treatments for shock may be instituted. The oral LD_{50} of propantheline bromide is 780 mg/kg in a mouse and 370 mg/kg in a rat.

The use of physostigmine is controversial and should likely be reserved for cases where the patient exhibits either extreme agitation and is at risk for injuring themselves or others, or where supraventricular tachycardias and sinus tachycardias are severe or life-threatening. The usual human dose for physostigmine is 2 mg IV slowly (for an average-sized adult); if there is no response, it may be repeated every 20 minutes until reversal of toxic antimuscarinic effects or cholinergic effects takes place. The human pediatric physostigmine dose is 0.02 mg/kg slow IV (repeat every 10 minutes as above) and may be a reasonable choice for the treatment of small animals. Physostigmine adverse effects (eg, bronchoconstriction, bradycar-

dia, seizures) may be treated with small doses of atropine IV.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving propantheline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antihistamines, first generation** (eg, **diphenhydramine**): May enhance the activity of propantheline
- **Antiarrhythmics, Type 1** (eg, **procainamide, quinidine**): May enhance the activity of propantheline
- **Benzodiazepines** (eg, **diazepam**): May enhance the activity of propantheline
- **Cimetidine**: Propantheline may decrease the absorption of cimetidine.
- **Corticosteroids** (eg, **dexamethasone, predniso(lo)ne**): May increase intraocular pressure (IOP) with long-term use
- **Digoxin**: May cause increased serum digoxin levels
- **Nitrates** (eg, **nitroglycerine, nitroprusside**): May potentiate the adverse effects of propantheline
- **Nitrofurantoin**: Propantheline may enhance actions.
- **Opioids** (eg, **buprenorphine, hydrocodone, meperidine, morphine**): May have additive anticholinergic effects
- **Phenothiazines** (eg, **acepromazine**): May enhance the activity of propantheline
- **Prokinetic Agents** (eg, **cisapride, metoclopramide**): Propantheline may decrease prokinetic effects.
- **Sympathomimetics** (eg, **phenylpropanolamine**): Propantheline may enhance actions.
- **Ranitidine**: Propantheline delays the absorption but increases the peak serum level of ranitidine; the relative bioavailability of ranitidine may be increased by 23% when propantheline is administered concomitantly with ranitidine.
- **Thiazide Diuretics** (eg, **hydrochlorothiazide**): Propantheline may enhance actions.

Dosages

DOGS/CATS:

Detrusor hyperreflexia, urge incontinence (extra-label): Dogs: 7.5 – 30 mg/dog (NOT mg/kg) PO every 8 to 24 hours. Cats: Suggested dosages vary significantly, ranging from 5 – 7.5 mg/cat (NOT mg/kg) PO every 8 hours to 7.5 mg/cat (NOT mg/kg) PO every 3 days. Use the lowest dose that will control clinical signs.

Chronic diarrhea (noninfectious) (extra-label): Dogs: 2.5 mg/kg PO 2 to 3 times per day[2]

Antiemetic (extra-label): 0.25 mg/kg PO 2 to 3 times per day has been suggested. However, propantheline is a poor antiemetic when compared with other options and has the negative effect of altering GI motility.[2]

Short-term treatment of sinus bradycardia, incomplete AV block (extra-label): Dogs: 7.5 – 30 mg/dog (NOT mg/kg) PO every 8 to 12 hours. Cats: 7.5 mg/cat (NOT mg/kg) PO every 8 to 12 hours. Improvement is usually partial and often temporary.[3]

HORSES:

Parasympatholytic (extra-label): **For rectal palpation**: 50 – 100 mg/horse (NOT mg/kg) IV. **Acute spasmodic colic**: 100 – 300 mg/horse (NOT mg/kg) IV. **Rectal tears**: If rectal tears are suspected, use immediately at a dose of 50 – 100 mg/horse (NOT mg/kg) IV. Rectal relaxation will usually follow within 1 minute.[4]

Monitoring

- Clinical efficacy
- Heart rate and rhythm, if indicated
- Adverse effects

Client Information

- It is best to give this medicine on an empty stomach, but if the animal vomits after getting a dose, give with a small amount of food or treat to see if this helps. If vomiting continues, contact your veterinarian.
- Side effects can include dry mouth, dry eyes, trouble urinating or defecating, fast heartbeat, vomiting (in cats), and drooling/hypersalivation (in cats).
- Dry mouth may be relieved by applying small amounts of water to the animal's tongue for 10 to 15 minutes.
- Severe constipation can be serious. If your animal has not passed any stool for several days, contact your veterinarian right away.

Chemistry/Synonyms

Propantheline bromide, a quaternary ammonium antimuscarinic agent, occurs as bitter-tasting, odorless, white or practically white crystals, with a melting range of 156°C to 162°C (313°F-324°F; with decomposition). It is very soluble in both water and alcohol.

Propantheline bromide may also be known as bromuro de propantelina, propanthelini bromidum, *Propan* B®, or *Pro-Banthine*®.

Storage/Stability

Store propantheline bromide tablets at room temperature 20° to 25°C (68°F-77°F) in tight, light-resistant containers.

Store the dry powder for reconstitution (*Propan* B®) below 25°C (77°F). Protect this product from light. Use prepared solution within 10 days.

Compatibility/Compounding Considerations

Reconstitute the powder for injection with 10 mL of sterile water for injection. As there is no commercially available injectable product available in the United States, if preparation is made from oral tablets, it should be freshly prepared and filtered through a 0.22-micron filter before administering. Use this product with caution. If using a compounded product, reconstitute as directed.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the United States. In Australia: Propantheline Bromide 300 mg sterile powder for reconstitution (for IV use) in 10 mL vials; *Propan* B®; S4-By Veterinary Prescription (APVMA 51275). The meat withholding period for horses is 28 days.

HUMAN-LABELED PRODUCTS:

None. Propantheline Bromide Tablets: 15 mg; generic; (Rx) have been discontinued.

Propionibacterium Acnes Injection

(***proe***-pee-nuh-ohe-bak-***ter***-ee-um ***ak***-nees) *ImmunoRegulin®, EqStim®*

Immunostimulant

Prescriber Highlights

- ► Indicated as adjunct treatment for canine pyoderma and equine respiratory disease complex; anecdotally used for canine viral papillomatosis, FeLV, and feline herpes infections
- ► Contraindications include hypersensitivity, cardiac dysfunction, and canine lymphoma or leukemia with CNS involvement.
- ► Adverse effects include lethargy, hyperthermia, chills, and anorexia. Anaphylactic reactions are possible.
- ► Extravasation may cause local tissue inflammation.

Uses/Indications

Propionibacterium acnes is a USDA-licensed immunostimulant indicated in dogs as adjunct treatment for controlling and reducing lesions of chronic recurring pyoderma.[1] In horses, it is indicated for adjunctive treatment of equine respiratory disease complex (ERDC).[2]

Anecdotally, *P acnes* may be of benefit as a treatment for canine papillomatosis.[3] It has also been used anecdotally in the adjunctive treatment of canine oral melanoma and mastocytoma. *P acnes* injection has been used as an immunostimulant for the adjunctive treatment of feline rhinotracheitis (feline herpesvirus-1) and feline leukemia virus-induced disease. Controlled studies documenting efficacy for these potential indications were not located.

A study in neonatal foals less than 30 days old did not demonstrate any effect from *P acnes* injection on interferon-gamma production.[4] Another study in neonatal foals exposed ex vivo to *Rhodococcus equi* had similar negative effects on interferon-gamma, but treated foals did have significantly less intracellular proliferation of *R equi* within monocyte-derived macrophages on day 12 compared to control foals.[5] Another study showed that *P acnes* administration had no effect on the incidences of nasal shedding of respiratory pathogens or other clinical parameters in 21 weaning pony foals; however, it did appear to modulate rises in cortisol after weaning and possibly enhance innate immunity.[6]

Pharmacology/Actions

Propionibacterium acnes products are nonspecific immunostimulants derived from nonviable *P acnes*, a gram-positive anaerobic bacterium currently known as *Cutibacterium acnes*. They induce macrophage activation and lymphokine production, increase natural killer cell activity, enhance cell-mediated immunity, and display oncolytic properties. They may not provide protection against direct infection or transmission of respiratory pathogens, but they may contribute to the reduction of the disease severity, subsequently reducing the frequency of complications and improving the rate of recovery.[7]

Pharmacokinetics

No information was noted.

Contraindications/Precautions/Warnings

Propionibacterium acnes injection is contraindicated in patients that are hypersensitive to it and should not be used in patients with cardiac conditions.[1] It should not be used in dogs that have lymphoma or leukemia with CNS involvement. Glucocorticoids should be discontinued at least 7 days prior to starting *P acnes* treatment.[1,2]

Anaphylactic reactions can occur and should be treated with epinephrine.[1]

Adverse Effects

Adverse effects include lethargy, increased body temperature, chills, and anorexia, which can occur within hours after injection.[1,2] Anaphylactic reactions have also been reported. Injection extravasation may cause local tissue inflammation. Pain at the injection site is possible, particularly with larger volumes and repeated administration. In these cases, administration may be divided into different muscle sites.

Long-term toxicity studies have demonstrated vomiting, anorexia, malaise, fever, acidosis, increased water consumption, and hepatitis.

Reproductive/Nursing Safety

Propionibacterium acnes immunostimulant is not recommended for use during pregnancy or when pregnancy is suspected.[1,2]

Overdose/Acute Toxicity

No overdose information was noted.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving *Propionibacterium acnes* and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- ■ **Glucocorticoids** (eg, **dexamethasone, prednis(ol)one**): Immunostimulant effects may be compromised if given concomitantly; discontinue glucocorticoid therapy at least 7 days prior to starting P acnes treatment.[1,2]
- ■ **Immunosuppressants** (eg, **azathioprine, cyclosporine, mycophenolate**): Immunostimulant effects may be compromised if given concomitantly.

Dosages

DOGS:

Adjunct treatment for chronic recurring pyoderma (label dosage; USDA-approved): Administer IV according to body weight twice weekly for the first 2 weeks, then once weekly until week 12, then once monthly until clinical signs abate or stabilize.[1] Shake well before use.

***ImmunoRegulin®* Recommended Dosage**

Body weight in kg (lb)	IV dose/dog (NOT mL/kg [lb])
Up to 6.8 (15)	0.25 mL
6.8-20.4 (15-45)	0.5 mL
20.4-34 (45-75)	1 mL
34 (75) or greater	2 mL

Adjunctive treatment for severe cases of oral and cutaneous viral papillomatosis (extra-label): 2 mg/dog (NOT mg/kg) as a deep IM injection every 5 to 7 days. Repeat until regression of lesions occurs; may take 6 doses for complete resolution. Dose may be divided into different muscle sites if pain at the injection site is noted.[3]

CATS:

Immunostimulant for adjunctive treatment of FeLV and feline herpesvirus infections (extra-label):

a) **For a 2.3 kg (5 lb) cat**: Anecdotally, give 0.25 mL/cat (NOT mL/kg) IV or IP twice weekly for 2 weeks, then once weekly until remission, then once monthly to maintain clinical improvement.

b) **For a 4.5 kg (10 lb) cat**: Anecdotally, give 0.5 mL/cat (NOT mL/kg) IV or IP twice weekly for 2 weeks, then once weekly for

3 weeks, then once monthly for 2 months to maintain clinical improvement for a total of 9 injections. Some protocols suggest follow-up with injections once weekly for 20 weeks or longer as needed. Other clinicians suggest once-weekly dosing until clinical remission, then once-monthly administration. It has also been suggested to discontinue treatment after 12 weeks if no improvement is seen.

HORSES:

Immunostimulant for adjunctive therapy of equine respiratory disease complex (ERDC) (label dosage; USDA-approved):

a) **Foals**: 1 mL/foal (NOT mL/kg) IV; repeat dose on day 3 or 4, day 7, and weekly as needed[2]

b) **Adult horses**: 1 mL/114 kg (250 lb; NOT mL/kg) IV; repeat dose on day 3 or 4, day 7, and weekly as needed[2]

Adjunctive treatment to improve fertility in mares with endometritis (extra-label): 1 mL/114 kg (250 lb) IV on days 0, 2, and 6. Best results occur in mares bred 2 days before to 8 days after initial administration.[8,9]

Monitoring

- Efficacy
- Adverse effects (eg, lethargy, chills, fever, anorexia)

Chemistry/Synonyms

Propionibacterium acnes injection is an immunostimulant agent that contains nonviable *P acnes* suspended in 12.5% ethanol in saline.

P acnes may also be known as *Corynebacterium parvum* and *Cutibacterium acnes*; NSC-220537, *Arthrokehlan A®, Coparvax®, Corymunun®, EqStim®, Imunoparvum®*, and *ImmunoRegulin®*.

Storage/Stability

Store this product refrigerated; do not freeze. Shake well before using.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Propionibacterium acnes (nonviable) IV: 0.4 mg/mL in 5 mL vials; *ImmunoRegulin®*; (Rx). USDA-licensed biologic labeled for use in dogs

Propionibacterium acnes (nonviable) IV: 0.4 mg/mL in 5 mL and 50 mL vials; *EqStim®*; (Rx). USDA-licensed biologic labeled for use in horses

HUMAN-LABELED PRODUCTS: NONE

Propofol

(***proe***-poe-fol) *PropoFlo®, Diprivan®, Rapanofal®*

Injectable Anesthetic

Prescriber Highlights

- ► Injectable (IV) sedative-hypnotic anesthetic agent labeled for dogs and cats, extra-label in other species
- ► Rapid onset of action; titrated to effect
- ► Short duration of action so additional doses may be needed in unpremedicated patients transitioning to inhalants
- ► Rapid, smooth recoveries. Repeated doses in greyhounds and cats may cause prolonged anesthetic recovery; however, this is generally clinically insignificant.
- ► Adverse effects include transient respiratory depression, which is common but usually clinically tolerable, and vasodilation, which can be significant. Apnea is also possible, especially if given too rapidly.
- ► Debilitated patients generally require lower doses of propofol and may experience exaggerated cardiovascular and respiratory depression.
- ► No analgesia is provided.
- ► Lower doses are needed when premedications (eg, alpha-2 agonists, opioids) and/or co-induction agents (eg midazolam, ketamine) are used.
- ► Continuous monitoring is required; respiratory and cardiovascular support must be readily available.

Uses/Indications

In dogs and cats, propofol's labeled indications are for use as a single injection to provide general anesthesia for short procedures; induction and maintenance of anesthesia, using incremental doses to effect, for short periods of up to 20 minutes; or induction of general anesthesia in which maintenance is provided by inhalant anesthetics.

In both dogs and cats, the dose to achieve induction of general anesthesia can be significantly reduced when used in combination with premedications, such as an opioid and/or alpha-2 agonists and acepromazine.[1] Co-administration with a benzodiazepine or ketamine also decreases the propofol dose.

For relatively short procedures, propofol can be used as a CRI for total intravenous anesthesia (TIVA) beyond 20 minutes, especially when inhalants may be contraindicated to maintain general anesthesia; however, it is important to note that propofol does not provide analgesia. The dose required to maintain dogs under general anesthesia and propofol minimum infusion rate (MIR) can be reduced when midazolam or ketamine, but not systemic lidocaine, are added to the induction protocol.[2,3] Propofol combined with ketamine for induction and TIVA in dogs increases heart rate and blood pressure, causes respiratory depression, and has no difference in recovery quality as compared with propofol given alone.[4]

Propofol is also used to treat refractory status epilepticus, as it tends to cause less cardiovascular depression and respiratory depression as compared with barbiturates, and recovery can be smoother and shorter than with pentobarbital; however, apnea is possible and supplemental oxygen and ventilatory support should be readily available.

Propofol may be safely used in animals with liver or renal disease and mild to moderate cardiac disease.

Propofol administered to dogs prior to chemical euthanasia with pentobarbital/phenytoin did not require a change in the euthanasia dose or reduce the incidence of adverse events, other than a significant decrease in perimortem muscle activity, related to euthanasia.[5] However, injection of propofol prior to administration of euthanasia solution is clinically perceived to decrease perimortem muscle activ-

ity (eg, paddling, involuntary movement and fasciculations) and agonal breathing and is a commonly used technique in both dogs and cats. Sedation or anesthesia is recommended prior to euthanasia.[6]

Pharmacology/Actions

Propofol is a short-acting sedative-hypnotic injectable anesthetic unrelated to other general anesthetic agents. The mechanism of action is similar to barbiturates. Propofol potentiates the effects of gamma-aminobutyric acid (GABA; an inhibitory neurotransmitter) by decreasing the rate of dissociation of GABA from its receptors. This prolonged binding results in an influx of chloride, causing hyperpolarization of the postsynaptic cell membrane. Propofol may also have activity at the glycine and *N*-methyl-D-aspartate (NMDA) receptors, but this is unclear.

In dogs and cats, propofol produces rapid, smooth, and excitement-free anesthesia induction in 20 to 60 seconds when administered IV slowly (ie, over 60 to 90 seconds) with a duration of ≈10 minutes following a single injection. Time to unconsciousness may be longer (up to 2 minutes) in patients with low cardiac output states and the drug should be slowly titrated to effect. Subanesthetic doses produce sedation, restraint, and an unawareness of surroundings. Anesthetic dosages produce unconsciousness and muscle relaxation.

During induction of general anesthesia, propofol can cause a dose-dependent decrease in systemic vascular resistance without increased heart rate, which causes transient vasodilatory hypotension; decreased cardiac output is possible (especially in combination with opioid premedications). Propofol does not appear to be arrhythmogenic at clinical doses, but it can enhance the ability of epinephrine to induce arrhythmias.[7] Propofol causes significant respiratory depression, particularly with rapid administration or high doses. The drug does not precipitate malignant hyperthermia.

Propofol decreases cerebral oxygen consumption, intracranial pressure, and cerebral perfusion pressure.[8] This is an advantage when used to treat patients with intracranial disease, including seizures, tumors, hydrocephalus, and traumatic brain injury.

In dogs, propofol can cause an initial increase in intraocular pressure (IOP),[9] which decreases below baseline values 5 minutes after induction[10]; muscle-relaxing premedication[11] or gabapentin[12] may blunt propofol-induced increases in IOP. IOP did not change in dogs with glaucoma that received propofol for anesthetic induction.[11] The drug minimally (8%) increased IOP in horses[13] but does not appear to increase IOP in sheep.[14]

Recoveries are smooth. Recoveries are documented to be longer in greyhounds (effects in other sighthounds are unknown) and cats as compared with dogs.[15,16]

Pharmacokinetics

After IV administration, propofol rapidly crosses the blood–brain barrier and has an onset of action usually within 1 to 2 minutes. Speed of induction depends on drug dose, delivery rate, and patient cardiac output. Propofol is preferentially distributed into highly perfused tissues and is highly bound to plasma proteins (95% to 99%). In dogs, the steady state volume of distribution is greater than 3 L/kg.[17]

In dogs, the duration of action after a single IV induction dose lasts ≈5 to 7 minutes and ≈2 to 6 minutes following maintenance doses. In cats, the duration of action after induction and maintenance doses is 5 to 12 minutes and 5 to 7 minutes, respectively. Propofol's short duration of action is principally due to its rapid redistribution from the CNS to other tissue. The drug is rapidly and almost completely biotransformed in the liver via glucuronide conjugation (predominantly) and hydroxylation to inactive metabolites, which are then excreted primarily by the kidneys. In dogs, the elimination half-life is ≈1.4 hours, and clearance is ≈50 mL/kg/minute.[17] Canine CYP2B11 may be the isoenzyme responsible for propofol metabolism in dogs. Plasma clearance exceeds hepatic blood flow, suggesting extrahepatic metabolism.[18] In humans, propofol may accumulate in tissue during prolonged infusion (ie, over several days), with slower clearance and elimination half-life.

The addition of 2% benzyl alcohol (as found in *PropoFlo® 28*) does not appear to significantly alter propofol pharmacokinetics or pharmacodynamics (single-dose induction) in cats.[19]

Contraindications/Precautions/Warnings

Propofol is contraindicated in animals hypersensitive to it or any component of the product, including eggs and soybeans, and it should not be used in animals in which general anesthesia or sedation is contraindicated.

Propofol does not provide analgesia; peri-, intra-, and postoperative analgesics should be considered.

Theoretically, recoveries from propofol could be slower in cats as the drug is metabolized in part by glucuronidation and cats have a lower glucuronidation capacity; however, slow recovery times have only been reported after propofol infusions of longer than 30 minutes, leading to the recommendation that infusions be of short duration in cats.[15] A benzyl alcohol-containing formulation of propofol (ie, *PropoFlo® 28*) is only labeled for use in dogs in the US but has been shown to be safe in cats.[20] In addition, the benzyl alcohol-containing propofol formulation available in the EU/UK is approved for anesthetic induction or short-duration use in both species.[21]

As with all anesthetics, continuous monitoring and readily available respiratory and cardiovascular support are recommended.

Patients that are debilitated will generally require lower doses of propofol and may experience exaggerated cardiovascular and respiratory depression.

Propofol may have both anticonvulsant and seizure-causing properties. Theoretically it should be used with caution in animals with a history of or active seizure disorders; however, propofol-induced seizures are rare and propofol is commonly used to treat seizures[22] and as an anesthetic to study dogs with seizures.[23] Thus, propofol is often a component of the anesthetic protocol in patients with a history of seizures.

Propofol should be used with caution in patients with pre-existing cardiac arrhythmias,[24,25] as propofol has demonstrated both proarrhythmic and antiarrhythmic effects.[26] Anecdotally, it has been safely used in dogs with pre-existing arrhythmias.

A decrease in the dose of ≈40% to 60% (from the single-agent dose) should be anticipated in cases in which propofol is used in combination with other CNS depressants (eg, acepromazine, opioids, diazepam), especially in debilitated or critically ill animals or those with moderate to severe cardiac disease. A reduction in dose should also be anticipated in animals with poor body condition due to a potential for decreased volume of distribution. Induction of general anesthesia with propofol in overweight dogs may occur at lower doses than in normal weight dogs.[27]

A study in dogs found that propofol administered before midazolam resulted in less benzodiazepine-induced excitation and a greater reduction of total propofol requirements than when midazolam was administered before propofol.[28] With this technique, ≈1 mg/kg of propofol is administered slowly followed by the total dose of midazolam or diazepam. Once the patient is relaxed (1 to 2 minutes), the remainder of the propofol is slowly titrated until the patient is anesthetized to a depth that allows smooth intubation.

Greyhounds metabolize propofol more slowly than beagles or crossbreed dogs, potentially resulting in prolonged recovery; however, prolonged recovery is more likely with multiple repeat doses or infusions and generally does not occur with 1 to 2 propofol boluses for anesthesia induction, especially if followed by inhalants as the propofol has time to undergo metabolism. Slow metabolism of

propofol in greyhounds is due to decreased cytochrome P450 (CYP) 2B11 gene expression.[29,30] Interestingly, American Kennel Club greyhounds have greater deficiency compared to racing greyhounds.[29] In addition, caution should be used when extrapolating greyhound information to other breeds as not all sighthounds had a deficiency whereas some other breeds of dogs were deficient.

Theoretically, as propofol is highly bound to plasma proteins, animals with hypoproteinemia may be susceptible to adverse effects; this interaction has not been shown to be of clinical concern.

Theoretically the benefits of propofol should be weighed against risks in animals with a history of hyperlipidemia; however, use of propofol did not increase morbidity or fatalities in cats with primary hepatic lipidosis undergoing anesthesia for placement of feeding tubes.[31]

Adverse Effects

Transient respiratory depression is common but usually clinically tolerable. However, because there is a relatively high incidence of apnea with occasional cyanosis if propofol is given rapidly, the drug should be given slowly. Treatment of apnea is endotracheal intubation and assisted ventilation until spontaneous ventilation resumes. The incidence of hypoxemia can increase when combined with opioids (eg, alfentanil).[32] One study in cats premedicated with medetomidine showed that alfaxalone had less adverse influence on respiration as compared with propofol[33]; however, most studies report that propofol and alfaxalone have similar cardiovascular and respiratory effects. There were no differences in cardiopulmonary parameters or apnea in dogs induced with propofol, alfaxalone, or ketamine/diazepam.[34] Respiratory depression following induction is more common when either drug is administered rapidly IV.[35] Following premedication with dexmedetomidine and methadone, propofol administered at 4 mg/kg/minute caused apnea in 100% of dogs, whereas propofol at 1 mg/kg/minute caused apnea in 25%.[36] In addition, slow administration also resulted in a lower induction dose needed to achieve endotracheal intubation.[37]

Propofol can cause histamine release in some animals and anaphylactoid reactions, although rare, have been noted.[38] Propofol can cause direct myocardial depression, arrhythmias, and hypotension. In dogs, the number of interventions needed to deepen the plane of anesthesia or treat hemodynamic depression is significantly lower with propofol as compared with inhalant anesthesia (eg, isoflurane).[39] A study in dogs premedicated with methadone and acepromazine showed a drop in arterial pressure in cases in which propofol was used for induction, but cardiac output was maintained by compensatory chronotropic response.[40]

Propofol combined with a benzodiazepine can cause hypothermia and longer time to return to preanesthetic temperature than in animals induced with ketamine combined with a benzodiazepine.[41]

Dogs may occasionally exhibit seizure-like clinical signs (eg, paddling, opisthotonus, myoclonic twitching) during induction that, if persistent, may be treated with a benzodiazepine (eg, diazepam, midazolam), low-dose ketamine, or paralytic agent (eg, atracurium); the mechanism of action is unknown and it occurs in ≈1.2% of dogs.[42] Sneezing and paddling during recovery has also been observed in dogs and cats.

A potentially clinically significant increase in IOP may occur in dogs following induction with propofol.[10,11,43] Increased IOP appears to be transient and may be mitigated with muscle-relaxing premedication (eg, midazolam[11]) or gabapentin.[12]

In cats, increased Heinz body production, prolonged recovery, anorexia, lethargy, malaise, and diarrhea have been noted (but do not occur commonly) in cases in which propofol has been used repeatedly or as a prolonged CRI.[44] Consecutive use in dogs appears to be safe.

Pain on injection has been reported in humans; dogs and cats very occasionally react to an IV propofol injection, but this does not appear to be a clinically significant problem in dogs or cats.[45] Extravasation of propofol injection is not irritating nor does it cause tissue sloughing.

Propofol infusion syndrome is a very rare complication reported in humans receiving prolonged administration of propofol. Neonates and sick patients appear to be at higher risk, and clinical signs include metabolic acidosis, rhabdomyolysis, hyperlipidemia, cardiac arrhythmia, and cardiac and renal failure.[46,47] A case of propofol infusion-like syndrome in a dog has been published.[48]

Reproductive/Nursing Safety

Propofol crosses the placenta, and its safe use during pregnancy has not been established. Fetal toxicity was not observed in studies with pregnant laboratory animals given propofol at clinical doses. In humans, brain development may be negatively affected by prolonged or repeated use of anesthetic or sedative drugs. The significance in dogs and cats has not been determined. Puppies delivered via C-section from bitches that received propofol generally had high Apgar scores, with the lowest Apgar scores occurring in cases in which extra propofol doses were required.[49] Apgar scores were higher when an alpha-2 agonist was used as a premedicant before propofol administration[49,50] or when an opioid epidural was used as part of the intraoperative analgesia.[51]

In humans, propofol is not recommended for use in nursing mothers because propofol is excreted in maternal milk, and the effects of oral absorption of small amounts of propofol are not known.[52] Should potentially be used with caution in nursing animals, however propofol is a common induction drug for dogs and cats undergoing cesarean sections with no clinical reports of adverse effects.

Overdose/Acute Toxicity

The LD_{50} in mice and rats given propofol IV is 53 mg/kg and 42 mg/kg, respectively.[53] Single doses of 19.5 mg/kg IV did not cause harm in dogs. A cumulative dose of 19.5 mg/kg IV in cats was tolerated, but 38.6 mg/kg produced prolonged recovery in all treated cats and paraesthesia in 1 cat.[54] Overdoses are likely to cause significant respiratory and cardiovascular depression.

Treatment should consist of discontinuation of propofol, artificial ventilation with oxygen after endotracheal intubation, and supportive care measures for cardiovascular depression (eg, IV fluids, vasopressors, anticholinergics) if necessary.

Drug Interactions

Propofol is a substrate of CYP2B6 in humans and CYP2B11 in dogs. Propofol has been used in association with anticholinergics, phenothiazines, alpha-2 agonists, opioids, and benzodiazepines, as well as inhalant anesthetics.[24,25] The following drug interactions have either been reported or are theoretical in humans or animals receiving propofol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-2-Adrenergic Receptor Agonists** (eg, **clonidine, dexmedetomidine, medetomidine**): Propofol given after medetomidine or dexmedetomidine may result in hypoxemia; a reduction in the propofol dose should be anticipated and respiratory monitoring and support available. Premedication with dexmedetomidine caused a dose-dependent decrease in the induction dose of propofol or barbiturates in dogs (30% to 61% reduction) and propofol in cats (48.9% reduction).[55]
- **Anesthetics, Inhalation** (eg, **isoflurane**): Propofol serum concentrations may be increased.
- **Anesthetics, Local** (eg, **bupivacaine, lidocaine**): Use of local anesthetics can reduce propofol dose requirements for sedation.

- **Benzodiazepines** (eg, **diazepam, midazolam**): Concurrent use has been shown to increase the risk for hypothermia in dogs.[41] Midazolam may have synergistic effects with propofol, and midazolam plasma concentrations may be increased up to 20%.
- **Drugs That Inhibit The Hepatic P-450 Enzyme System** (eg, **chloramphenicol,**[56] **cimetidine, ketoconazole**): May potentially prolong the recovery times associated with propofol; clinical significance is unclear
- **Epinephrine**: Propofol enhances epinephrine-induced arrhythmia in a dose-dependent manner in dogs.[7]
- **Melatonin**: Administration 2 hours prior to induction may modestly reduce the propofol dose required for intubation and anesthetic induction.[57]
- **Metoclopramide**: In humans, metoclopramide reduced the propofol dose required for induction by 20% to 25%.
- **Opioids** (eg, **fentanyl, hydromorphone, meperidine, morphine, remifentanil**): May increase the serum concentrations of the opioid and propofol if used together. Propofol dose requirements may be reduced. In dogs, fentanyl causes a small reduction in heart rate,[58] and remifentanil decreased heart rate, cardiac index, and stroke volume and increased systemic vascular resistance index, central venous pressure, and pulmonary artery occlusion pressure.[59]
- **Phenothiazines** (eg, **acepromazine**): Increased sedation and cardiorespiratory depression are possible.
- **St. John's Wort**: Concurrent use may result in an increased risk for cardiovascular collapse and/or delayed emergence from anesthesia.

Laboratory Considerations

None noted

Dosages

DOGS:

Label dosages

NOTES:

1. Product labels state clearly that all dosages are provided *for guidance only* and that individual animal response should dictate the dose used.
2. Because the label dosage is different for each of the veterinary products, the details listed below in the tables compile dosages from 3 veterinary-labeled propofol products.[24,25,60]
3. Use of premedications reduces propofol dose requirements.
   a) **Induction of general anesthesia** (label dosage; FDA approved): IV dosing should be titrated against the response of the animal over 30 to 60 seconds or until clinical signs show the onset of anesthesia. Rapid injection of propofol (ie, less than 5 seconds) may be associated with an increased incidence of apnea. An inadequate plane of anesthesia may occur if injected too slowly; additional propofol may need to be administered if this occurs. The average propofol induction dose rates for healthy dogs given propofol alone, or in cases in which propofol is preceded by a premedication, are indicated in the table, which should be used for guidance only.

NOTE: Premedications reduce propofol requirements by 40% to 60%. As with other sedative-hypnotic agents, the amount of opioid and/or alpha-2 agonist premedication influences the animal's response to an induction dose of propofol. With premedications, the propofol dose may also need to be reduced with increasing age of the animal. During induction, additional low doses of propofol, similar to those used for maintenance with propofol, may be administered to facilitate intubation or the transition to inhalant maintenance anesthesia.

Induction Dosage Guidelines for *Dogs*[24,25,60]

Preanesthetic agent(s)	Propofol INDUCTION dose (mg/kg)	Propofol rate of administration (seconds)
None#†‡	5.5 – 7.6	40-90
Acepromazine#†	4 – 4.4† 3.7#	60-90 30-50
Xylazine†	2.2 – 3.3	60-90
Medetomidine†	2.2 – 2.8	60-90
Benzodiazepine + opioid‡	4.7	60-90
Acepromazine + opioid‡	4‡ 2.6#	60-90 30-50
Alpha-2 agonist + opioid‡	3.2	60-90

#*Propoflo®*, †*Rapanofal®*, ‡*Propoflo® 28*

b) **Maintenance of general anesthesia by intermittent IV propofol injection** (label dosage; FDA-approved): Anesthesia can be maintained by administering propofol in intermittent IV injections. The clinical response will be determined by the amount and frequency of maintenance injections. The following table is provided for guidance.

NOTE: Maintenance dose sparing was ≈48% with benzodiazepine and opioid preanesthesia and 37% in dogs preanesthetized with phenothiazine and an opioid.[25] Repeated maintenance doses of propofol do not result in increased recovery times or administration intervals, indicating the anesthetic effects of propofol are not cumulative.

Maintenance Dosage Guidelines Using Intermittent IV Propofol Injection for *Dogs*[24,25,60]

Preanesthetic agent(s)	Intermittent propofol MAINTENANCE dose (mg/kg)	Propofol rate of administration (seconds)
None	1.1 – 3.2	10 - 60
Acepromazine#†	1.1	30 - 60
Xylazine†	1.1	30 – 60
Medetomidine†	1.1	30 – 60
Benzodiazepine + opioid‡	1.7	60
Acepromazine + opioid#‡	2	30 – 60

#*Propofol®*,†*Rapanofal®*, ‡*Propoflo® 28*

c) **Maintenance by inhalant anesthetics** (label dosage; FDA approved): Because of the rapid metabolism of propofol, additional low doses of propofol (similar to those used for maintenance with propofol) may be required to complete the transition to inhalant maintenance anesthesia.[24,25] Because of the rapid recovery from propofol, clinical trials using propofol have shown higher initial concentrations of the inhalant anesthetic halothane may be needed than is usually required following induction using barbiturate anesthetics.[57]

Extra-label dosages

NOTE: There are many extra-label drug combinations for induction and maintenance of anesthesia using propofol. The following

are representative, but not necessarily inclusive; it is suggested to refer to a recent anesthesia reference.[61,62]

Anesthetic induction (extra-label): 30 minutes after IM premedication (ie, methadone/acepromazine or methadone/dexmedetomidine), propofol 1 – 1.3 mg/kg/minute IV infusion safely and effectively replaced propofol bolus 4 mg/kg IV to facilitate intubation and reduced overall propofol requirements in healthy dogs.[37,63]

Total intravenous anesthesia (TIVA) maintenance (extra-label):

a) Propofol for induction is dosed to effect. Most clinicians recommend between 2 – 8 mg/kg IV slowly (over ≈60 seconds) to effect. Preanesthetic medications can reduce propofol requirements for induction by 25% or more. Using propofol to maintain general anesthesia: 0.1 – 0.5 mg/kg/minute IV CRI.

b) A study in healthy dogs undergoing ovariohysterectomy (OHE) compared propofol with alfaxalone.[64] Dogs received acepromazine 0.01 mg/kg and morphine 0.4 mg/kg SC ≈30 minutes prior to general anesthesia. Induction was performed with propofol ≈6 mg/kg IV over ≈40 seconds to effect. Using propofol to maintain general anesthesia: 0.3 – 0.5 mg/kg/minute IV CRI.

c) Propofol for induction (dosed to effect) 6.5 mg/kg IV slowly; premedication that includes an alpha-2 agonist may reduce the propofol dose by as much as 85%. Using propofol to maintain general anesthesia (dosed to effect): 0.25 – 0.5 mg/kg/minute IV[62]

Refractory status epilepticus (extra-label): 2 – 8 mg/kg IV bolus, followed by 0.1 – 0.25 mg/kg/minute IV CRI.[22] The propofol dose should be kept as low, and duration of treatment kept as short, as possible. Infusion should be maintained for 6 to 12 hours and then gradually decreased. The maximum duration of propofol CRI is ≈48 hours.

CATS:

Label dosages

a) **Induction of general anesthesia** (label dosage; FDA-approved): The average propofol induction dose ranges and rates for healthy cats given propofol alone, or in cases in which propofol is preceded by a premedication, are indicated in the table, which should be used for guidance only. The dose and rate should be based on animal response. Preanesthetic agent and dose influences the animal's response to an induction dose of propofol. The induction dose will also be influenced by the interval between the administration of premedication and induction and by the rate of administration of propofol.

NOTE: Many clinicians consider the labeled propofol dosages to be higher than necessary. Expect larger dose reductions than are indicated in this table when premedicants are used.

Induction Dosage Guidelines for *Cats*[60]

Preanesthetic agent(s)	Propofol INDUCTION dose (mg/kg)	Propofol rate of administration (seconds)
None	8 – 13.2	60-90
Acepromazine	8 – 13.2	60-90
Butorphanol	8 – 13.2	60-90
Oxymorphone	8 – 13.2	60-90
Xylazine	7 – 12	60-90

b) **Maintenance of general anesthesia by intermittent IV propofol injection for *cats*** (label dosage; FDA-approved): Anesthesia can be maintained by administering propofol in intermittent IV injections. The clinical response will be determined by the amount, rate of administration, and frequency of maintenance injections. The following table is provided for guidance.

NOTE: Repeated maintenance doses of propofol do not result in increased recovery times or administration intervals, indicating that the anesthetic effects of propofol are not cumulative in cats.[60]

Maintenance of General Anesthesia by Intermittent IV Propofol Injection for *Cats*[60]:

Preanesthetic agent(s)	Intermittent propofol MAINTENANCE dose (mg/kg)	Propofol rate of administration (seconds)
None	1.1 – 4.4	30-60
Acepromazine	1.1 – 4.4	30-60
Butorphanol	1.1 – 4.4	30-60
Oxymorphone	1.1 – 4.4	30-60
Xylazine	1.1 – 2.2	30-60
Acepromazine + butorphanol	1.1 – 3.3	30-60
Acepromazine + opioid	1.1 – 3.3	30-60

c) **Maintenance by inhalant anesthetics** (label dosage; FDA-approved): Because of the rapid recovery from propofol injections, clinical trials using propofol have shown higher initial concentrations of the inhalant anesthetic may be needed than is usually required following induction using barbiturate anesthetics.[60]

Extra-label dosages:

Anesthetic induction and total intravenous anesthesia maintenance:

a) Propofol for induction is dosed to effect. Most recommend a dose between 2 – 8 mg/kg IV slowly (over ≈60 seconds) to effect.[65–67] Induction doses as high as 11.7 mg/kg have been used.[33] Preanesthetic medications can reduce propofol requirements for induction by 25% (or more). General anesthesia can be maintained with 0.1 – 0.5 mg/kg/minute IV CRI.[33] **NOTE**: Cats may be susceptible to long recoveries when propofol is used alone as a CRI, or with continuous, prolonged exposure.

b) 30 minutes after IM premedication, propofol 1 mg/kg/minute IV infusion facilitated intubation and resulted in a lower propofol induction dose (≈5.3 mg/kg IV) and slower anesthetic induction (≈5.5 minutes) as compared with a rapid propofol bolus (induction dose ≈8 mg/kg IV, induction time ≈2.3 minutes) in healthy female cats undergoing OHE.[68]

c) **Propofol/Ketamine TIVA**: In cats undergoing OHE, anesthesia was induced with a combination of propofol 2 mg/kg and ketamine 2 mg/kg administered IV ± dexmedetomidine 3 µg/kg IV.[69] Anesthesia was maintained with propofol 10 mg/kg/hour IV CRI and ketamine 10 mg/kg/hour IV CRI. Short-term infusions produced smooth recovery and adequate analgesia during the postoperative period. The number of RBCs with Heinz bodies was not increased. **NOTE**: Although both ketamine and dexmedetomidine provide analgesia, a more potent analgesic (eg, opioid, local anesthetic) is recommended as an addition to this protocol for clinical use.[70]

Refractory status epilepticus (extra-label): 2 – 8 mg/kg IV initial bolus, followed by 0.1 – 0.25 mg/kg/minute IV CRI.[22] The propofol dose should be kept as low, and duration of treatment as short as possible. Infusion should be maintained for 6 to 12 hours and then gradually decreased.

HORSES:

NOTE: Use of propofol as a single agent (ie, without premedication or co-induction agent) for anesthesia induction typically results in poor induction quality.[71]

Induction of general anesthesia using ketamine and propofol after xylazine sedation (extra-label): In a retrospective study (n = 100), all horses were sedated with xylazine 0.99 ± 0.2 mg/kg IV; some horses also received IV butorphanol.[72] After visually apparent sedation, a combination of propofol 0.4 ± 0.1 mg/kg and ketamine 2.8 ± 0.3 mg/kg were given via IV bolus. The order of administration was not standardized, and in some cases, the 2 drugs were mixed together before administration. Following induction, 6 horses required a one-time administration of additional ketamine 0.7 ± 0.4 mg/kg. Anesthesia was maintained with GKX (ie, guaifenesin/ketamine/xylazine) in 34 horses and isoflurane in oxygen in 66 horses. Anesthetic recoveries were satisfactory.

Maintenance of general anesthesia (extra-label):

a) Propofol 0.5 mg/kg IV loading dose, followed by propofol 0.2 mg/kg/minute with ketamine 1 mg/kg/hour and medetomidine 1.25 µg/kg/hour IV CRI provided satisfactory quality and control of anesthesia with minimal cardiovascular depression for ≈175 minutes.[73]

b) **Arthroscopic surgery**: propofol 8 mg/kg/hour with dexmedetomidine 1.5 µg/kg/hour and ketamine 1 mg/kg/hour IV[74]

c) **Adjuvant during inhalant anesthesia** (extra-label): propofol 3 mg/kg/hour with medetomidine 1.25 – 3 µg/kg/hour IV CRI significantly decreases the amount of isoflurane[75] or sevoflurane[76] required for general anesthesia, improves stability of blood pressure, and provides good quality of recovery.

d) **Alternative to GKX** (extra-label): Following sedation with xylazine and induction with ketamine, propofol 0.05 to 0.1 mg/kg/minute IV CRI with xylazine 0.016 mg/kg/minute IV CRI and ketamine 0.03 mg/kg/minute IV CRI[77]

DONKEYS:

Maintenance of general anesthesia (extra-label):

a) After premedication with xylazine 1 mg/kg IV and induction with ketamine 1.5 mg/kg and propofol 0.5 mg/kg IV, giving propofol 0.15 mg/kg/minute with ketamine 0.05 mg/kg/minute IV CRI produced a stable plane of anesthesia. Hypoxemia was noted during the study, but no other cardiorespiratory complications were recorded.[78]

b) After premedication with acepromazine 0.04 mg/kg IV and induction with propofol 2 mg/kg IV, donkeys were maintained with propofol 0.2 mg/kg/minute IV CRI. This protocol provided good cardiovascular stability.[79]

SHEEP, GOATS:

General anesthesia (goats) (extra-label): Induction dose 3 – 7 mg/kg IV is smooth and rapid, but myoclonic activity of the face or limbs may occur; anesthesia lasts 5 to 10 minutes and is suitable for endotracheal intubation. Anesthesia can be maintained with 0.3 – 0.6 mg/kg/minute IV CRI.[80]

ALPACAS:

Induction of general anesthesia (extra-label): 3.3 mg/kg IV was sufficient to achieve an adequate plane of anesthesia to allow tracheal intubation.[81]

RABBITS, RODENTS, SMALL MAMMALS:

Rabbits:

a) 5 – 14 mg/kg IV slow to effect or 20 mg/kg/minute IV CRI; not recommended as the sole agent for maintenance

b) **Maintenance of anesthesia**: propofol 0.6 – 0.8 mg/kg/minute alone[82,83] or combined with sufentanil 0.033 mg/kg/minute IV.[84] The sufentanil combination resulted in a significant drop in blood pressure.

c) Propofol 5 mg/kg IV admixed in same syringe with ketamine 5 mg/kg produced a smooth anesthetic induction; hypoxemia, respiratory depression, and apnea were observed[85]

Mice: 26 mg/kg IV

Rats: 10 mg/kg IV

REPTILES:

Sedation/Anesthesia (extra-label):

Chelonians: *Sedation*: 2 – 5 mg/kg IV (also provides light anesthesia)[86]; *Anesthesia*: 2 – 10 mg/kg IV[86–88]

Lizards: *Sedation*: 3 – 5 mg/kg IV or IO[86,87]; *Anesthesia*: 5 to 10 mg/kg IV, IO[87,89]

Snakes: *Sedation*: 3 – 5 mg/kg IV [90]; *Anesthesia*: 3-10 mg/kg IV, IC[86]

Anesthesia induction (extra-label): 5 – 15 mg/kg IV or IO; in snakes, intracardiac route is usually used[91]

Monitoring

- Depth of anesthesia and CNS effects (eg, excitement, paddling, myoclonus)
- Respiratory effects (eg, respiratory rate, pulse oximetry (SpO_2), end-tidal CO_2 ($ETCO_2$)
- Cardiovascular effects (eg, heart rate and rhythm; blood pressure)
- Cats: CBC to check for Heinz body anemia with repeated exposure

Chemistry/Synonyms

Propofol is an alkylphenol derivative (2,6-diisopropylphenol). Commercially available 1% injections are isotonic, milky white macroemulsions, containing soybean oil, glycerol, and egg lecithin.

Propofol products are not identical; some contain oleic acid. *Propoflo® 28* is preserved with benzyl alcohol. Disodium edetate is the antimicrobial agent in *Diprivan®*, but human generic products use either sodium metabisulfite or benzyl alcohol. *Propoflo® 28*, *Diprivan®*, and the generic human propofol with benzyl alcohol have a pH range of 7 to 8.5. In products that use sodium metabisulfite, pH is adjusted to ≈4.5 to 6.5.

Propofol may also be known as disoprofol, ICI-35868, propofolum, *Ansiven®, Bioprofol®, Cryotol®, Diprivan®, Diprofol®, PropoFlo®, Propoflo® Plus, Propothesia®, Propovan®, Provive®, Rapinovet®*, or *Recofol®*.

Storage/Stability

NOTE: Storage varies by manufacturer and product. Consult the product label to ensure proper storage. Do *not* confuse storage of *PropoFlo®* with that of *PropoFlo® 28*. For all products, store protected from light; do not freeze. Shake the vial thoroughly before opening. Do not use if there is evidence of excessive creaming or aggregation, if large droplets are visible, or if there are other forms of phase separation indicating the stability of the product has been compromised. Slight creaming, which should disappear after shaking, may be visible after prolonged standing. Do not use if particulate matter and discoloration are present. Do not use if contamination is suspected.

PropoFlo® 28: Store at room temperature. Open vials should be placed in a covered container, stored at room temperature, and discarded after 28 days.[25]

Other veterinary-labeled products: Store between 4°C to 25°C (40°F-77°F) but not below 4°C (40°F). Unused product should be discarded within 6 hours of opening.

Human-labeled products: Store below 22°C (72°F) but not below 4°C (40°F). The manufacturer recommends discarding any unused

portion at the end of the anesthetic procedure or after 12 hours of opening, whichever occurs first. If using inline filters, do not use sizes less than 5 µm.

Compatibility/Compounding Considerations

Propofol labels state: *The emulsion should not be mixed with other therapeutic agents or into infusion fluids prior to administration.*

Propofol (macroemulsion; *Diprivan®* human-label product): If dilution is necessary, only dilute with dextrose 5% injection, and do not dilute to a concentration of less than 2 mg/mL. In diluted form, the drug is more stable when in contact with glass than with plastic (95% potency after 2 hours of running infusion in plastics).

Propofol macroemulsion (human-label) is physically **compatible** with the commonly used IV solutions (eg, lactated Ringer's solution (LRS), D_5W) when injected into a running IV line.

Drugs that are reported to be **compatible** with propofol (macroemulsion) at Y-site administration include (partial listing): alfentanil, ampicillin, butorphanol, calcium gluconate, cefazolin, cefoxitin, clindamycin, dexamethasone sodium phosphate, dexmedetomidine, diphenhydramine, esmolol, fentanyl, furosemide, glycopyrrolate, heparin sodium, insulin, isoproterenol, ketamine, lorazepam, magnesium sulfate, mannitol, midazolam, morphine sulfate, naloxone, nitroprusside sodium, norepinephrine, ondansetron, pentobarbital, phenobarbital, potassium chloride, propranolol, sodium bicarbonate, succinylcholine, thiopental, and vecuronium.

Drugs known to be **incompatible** with propofol at Y-site administration include amphotericin B, atracurium, calcium chloride, ceftazidime, diazepam, gentamicin, lidocaine (concentration dependent), methylprednisolone sodium succinate, metoclopramide, tobramycin, and verapamil. Refer to specialized references or a veterinary pharmacist for more information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Propofol Injection: 10 mg/mL in 20 mL (single use) vials; *PropoFlo®*; (Rx). FDA-approved for use in dogs. NADA# 141-098

Propofol Injection: 10 mg/mL in 20 and 50 mL (multi-dose) vials; *Propoflo® 28*; (Rx). FDA-approved for use in dogs. NADA# 141-098

Propofol Injection: 10 mg/mL in 20 mL vials; *Rapanofal®*; *Propothesia®*; (Rx). FDA-approved for use in dogs and cats. NADA# 141-070

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Propofol Injectable Emulsion: 10 mg/mL in 20 mL amps and vials, 10 mL, 50 mL, and 100 mL vials; 50 mL and 100 mL infusion vials; and 50 mL prefilled single-use syringes; *Diprivan®*; generic; (Rx)

The Drug Enforcement Agency does not list propofol as a federally controlled substance, but it is regulated as a controlled drug in some states. Report dispensing to state monitoring programs where required.

Propranolol

(proe-***pran***-oh-lole) *Inderal®*

Beta-Adrenergic Antagonist

Prescriber Highlights

- ► Nonspecific beta-adrenergic antagonist primarily used in veterinary medicine as an antiarrhythmic agent. Sometimes used for short-term treatment of clinical signs associated with thyrotoxicosis or pheochromocytoma
- ► Contraindications include congestive heart failure (unless secondary to a tachyarrhythmia responsive to beta-adrenergic antagonist therapy), hypersensitivity to this class of agents, sinus bradycardia, second- or third-degree atrioventricular block, or bronchospastic lung disease.
- ► Use with caution in labile diabetic patients, digitalized or digitalis intoxicated patients, with significant renal or hepatic insufficiency, with first-degree heart block, or with sinus node dysfunction.
- ► Adverse effects include bradycardia, lethargy and depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, syncope, diarrhea, hypoglycemia, and bronchoconstriction.
- ► If discontinuing drug, consider gradual withdrawal if it has been used chronically.
- ► Many potential drug interactions

Uses/Indications

In veterinary medicine, propranolol is used in small animal species and horses primarily for tachyarrhythmias or when a beta-blocker is indicated in a patient with a right-to-left shunt (eg, tetralogy of Fallot).

Propranolol has also been used for the short-term treatment of systemic hypertension and clinical signs associated with thyrotoxicosis and pheochromocytoma in small animal species,[1] although a cardioselective beta-1-adrenergic antagonist (eg, atenolol, esmolol) may be preferred if the effects of beta-2 blockade are not desired. Propranolol may also be useful in the management of beta-2-agonist (eg, albuterol, terbutaline) toxicity.[2,3] It has also been used in ferrets as adjunctive treatment of hypertrophic cardiomyopathy to prolong cardiac filling and decrease myocardial ischemia.[4]

Other beta-adrenergic antagonists have largely supplanted propranolol's use due to propranolol's poor oral bioavailability, short half-life, and nonspecificity.

Pharmacology/Actions

Propranolol blocks both beta-1- and beta-2-adrenergic receptors in the myocardium, bronchi, and vascular smooth muscle. Propranolol does not have any intrinsic sympathomimetic activity (ISA). Additionally, propranolol possesses membrane-stabilizing effects (quinidine-like) affecting the cardiac action potential and direct myocardial depressant effects. Cardiovascular effects secondary to propranolol include decreased sinus node rate, depressed conduction through the atrioventricular node, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, decreased hepatic and renal blood flow, reduced systemic blood pressure, and inhibition of isoproterenol-induced tachycardia. Electrophysiologic effects on the heart include decreased automaticity, increased or no effect on effective refractory period, and no effect on conduction velocity.

The nonselective effects of propranolol may be beneficial in the setting of a right-to-left shunting ventricular septal defect (eg, tetralogy of Fallot) as blocking the beta-1-adrenergic receptor may limit hypercontraction of the right ventricle while the beta-2-adrenergic receptor blockade may limit peripheral vasodilation.[5]

Additional pharmacologic effects of propranolol include increased airway resistance (especially in patients with bronchoconstrictive disease), prevention of migraine headaches, increased uterine activity (more so in the nonpregnant uterus), decreased platelet aggregability, inhibited glycogenolysis in cardiac and skeletal muscle, and increased numbers of circulating eosinophils.

Propranolol has been proposed as adjunctive therapy for hyperthyroidism in cats due to its ability to inhibit the conversion of thyroxine (T_4) to triiodothyronine (T_3).[6]

Pharmacokinetics

Propranolol is well absorbed after oral administration, but a rapid first-pass effect through the liver reduces systemic bioavailability to ≈2% to 27% in dogs, thereby explaining the significant difference between PO and IV dosages. These values reportedly increase with chronic dosing. Hyperthyroid cats may have increased bioavailability of propranolol when compared with healthy cats.[7]

Propranolol is highly lipid soluble and readily crosses the blood-brain barrier. The apparent volume of distribution has been reported to be 3.3 to 11 L/kg in the dog. In horses receiving 1 mg/kg IV bolus, peak concentration, volume of distribution at steady state, and elimination half-life were 628 ng/mL, 3070 mL/kg, and 180 minutes, respectively.[8] In humans, propranolol is ≈90% bound to plasma proteins.

Propranolol is metabolized principally by the liver and the CYP2D15 isoenzyme is responsible for a significant percentage of its metabolism in dogs. An active metabolite, 4-hydroxypropranolol, has been identified after oral administration in humans. Less than 1% of a dose is excreted unchanged into the urine. The half-life has been reported to range from 0.77 to 2 hours in dogs, and less than 2 hours in horses. Hyperthyroid cats may have a decreased clearance of propranolol when compared with healthy cats.[7]

Contraindications/Precautions/Warnings

Propranolol is contraindicated in patients with hypersensitivity to this class of agents, second- or third-degree atrioventricular heart block, sick sinus syndrome, or sinus bradycardia. Nonspecific beta-blockers are also generally contraindicated in patients with CHF unless secondary to a tachyarrhythmia responsive to beta-blocker therapy. They are also contraindicated in patients with bronchospastic lung disease.

Propranolol should be used cautiously in patients with significant renal or hepatic insufficiency. In humans, it has been suggested to reduce dosage by 50% (or more) in patients with impaired renal or hepatic function. Patients with sinus node dysfunction, first degree atrioventricular block, or conduction disorders may be at increased risk for bradycardia (including sinus pause, heart block, and cardiac arrest).[9]

Propranolol given by the IV route is considered a high alert medication (medication that requires special safeguards to reduce the risk for errors). Consider instituting practices such as redundant drug dosage and volume checking and special alert labels.

Propranolol can mask tachycardia associated with hypoglycemia. It can also cause hypoglycemia or hyperglycemia and, therefore, should be used cautiously in labile diabetic patients.

Propranolol can mask the clinical signs associated with thyrotoxicosis.

Use propranolol cautiously with digoxin or in digoxin-intoxicated patients; severe bradycardia may result.

Adverse Effects

Clinically relevant adverse effects include bradycardia, lethargy and depression, impaired AV conduction, negative inotropy, CHF or worsening of heart failure, hypotension, hypoglycemia, and bronchoconstriction. Syncope and diarrhea have also been reported in canine patients. Adverse effects may be more likely in geriatric animals or those that have acute decompensating heart disease.

Exacerbations of clinical signs (eg, rebound hypertension, thyrotoxicosis) have been reported following abrupt cessation of beta-blockers in humans. Significance in veterinary patients is unclear but it is recommended to withdraw therapy gradually in patients that have been receiving the drug chronically.

Reproductive/Nursing Safety

Propranolol crosses the placenta and enters milk at very low concentrations. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The predominant clinical signs of an overdose include hypotension and bradycardia. Other possible effects include CNS (eg, depressed consciousness, seizures), bronchospasm, hypoglycemia, hyperkalemia, respiratory depression, pulmonary edema, other arrhythmias (especially AV block), and asystole. Seizures are reported in humans but have not been reported in animals.

If overdose is secondary to a recent oral ingestion, GI decontamination and charcoal administration may be considered. Monitor patient's ECG, blood glucose, potassium, and blood pressure; treatment of cardiovascular and CNS effects are based on clinical presentation. Use IV fluids and/or vasopressor agents to treat hypotension. Bradycardia may be treated with atropine or isoproterenol; a transvenous pacemaker may be necessary. Glucagon 5 – 10 mg/hour IV (human dose) may increase heart rate and blood pressure and reduce the cardiodepressant effects of propranolol. Branchospasm may be treated with aminophylline or isoproterenol. Seizures will generally respond to diazepam IV. Intravenous lipid emulsion therapy may be beneficial.[10,11]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving propranolol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-2-Adrenergic Agonists** (eg, **clonidine, dexmedetomidine, romifidine**): Concurrent administration may increase the degree of sedation but may also cause severe bradycardia. Concurrent use is not recommended.[8]
- **Amiodarone**: Concurrent use may increase risk for bradycardia, hypotension, sinus arrest, and AV block.
- **Anesthetic Agents, General**: Additive myocardial depression may occur with the concurrent use of propranolol and myocardial depressant anesthetic agents.
- **Anticholinergics** (eg, **atropine**): May negate bradycardic effects of beta-blockers
- **Beta-2-Adrenergic Agonists** (eg, **albuterol, terbutaline**): At higher doses, atenolol may impair bronchodilation.
- **Calcium Channel Blockers** (eg, **amlodipine,diltiazem, verapamil**): May increase risk of hypotension and bradycardia, and may precipitate heart failure in patients with pre-existing cardiac conditions
- **Cimetidine**: May decrease the metabolism of propranolol and increase propranolol blood concentrations
- **Digoxin**: Concurrent use may increase risk for bradycardia and digitalis toxicity.

- **Epinephrine, Norepinephrine**: Unopposed alpha-adrenergic agonist effects of epinephrine may lead to a rapid increase in blood pressure and decrease in heart rate.
- **Fluoxetine**: May decrease propranolol metabolism
- **Furosemide**: Concurrent use may increase risk for hypotension and bradycardia.
- **Hydrochlorothiazide**: Concurrent use may increase risk for hypotension, hyperglycemia, and hypertriglyceridemia.
- **Hypotensive Agents** (eg, **enalapril, telmisartan**): Concurrent use may increase the risk for hypotension.
- **Insulin** and other **Antidiabetic Drugs**: Propranolol may prolong the hypoglycemic effects of insulin therapy.
- **Local Anesthetics** (eg, **bupivacaine, lidocaine**): Clearance may be impaired by propranolol.
- **Methimazole**: Propranolol dosages may need to be decreased when initiating therapy.
- **Nonsteroidal Anti-Inflammatory Drugs** (eg, **carprofen, meloxicam, robenacoxib**): Concurrent use may decrease antihypertensive effect.
- **Phenobarbital**: May increase the metabolism of propranolol
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**): May increase risk for hypotension
- **Quinidine**: Concurrent use may increase risk for hypotension, bradycardia, arrhythmias, and heart failure.
- **Reserpine**: May have additive effects with propranolol
- **Succinylcholine, Tubocurarine**: Effects may be enhanced with propranolol therapy
- **Sympathomimetics** (eg, **phenylpropanolamine**): May have their actions blocked by propranolol
- **Theophylline/Aminophylline**: Bronchodilatory effects may be blocked by propranolol.
- **Thyroid Hormones** (eg, **levothyroxine**): May decrease the effects of beta-blocking agents
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Concurrent use may increase risk for postural hypotension. Amitriptyline may increase propranolol exposure.

Laboratory Considerations

None noted

Dosages

NOTE: Because of a high first-pass effect after oral dosing, IV dosages are ≈10% of oral dosages. Do not confuse the dosages.

DOGS:

Susceptible cardiac arrhythmias (extra-label):

a) IV dosage: 0.02 mg/kg IV slowly over 2 to 3 minutes, titrate dosage up to effect (to a maximum of 0.1 mg/kg). Can be repeated every 8 hours

b) Oral dosage: 0.1 – 0.2 mg/kg PO initially (practically 2.5 – 10 mg/dog [NOT mg/kg] PO) every 8 hours, titrated to effect up to a maximum of 1.5 mg/kg every 8 hours (practically 10 – 80 mg/dog [NOT mg/kg] PO every 8 hours)

Tetralogy of Fallot (extra-label): Initially 0.25 mg/kg PO every 8 hours, increase gradually to 1 mg/kg PO every 8 hours over 4 weeks[12]

Antihypertensive agent (extra-label): 0.2 – 1 mg/kg PO every 8 hours[1]

CATS:

Susceptible cardiac arrhythmias (extra-label):

a) IV dosage: 0.02 mg/kg IV slowly over 2 to 3 minutes, titrate dosage up to effect (to a maximum of 0.1 mg/kg). Can be repeated every 8 hours

b) Oral dosage: 2.5 – 10 mg/cat (NOT mg/kg) PO every 8 to 12 hours. Start at the low end of the dosage range and titrate to effect.

Tetralogy of Fallot (extra-label): Initially 0.25 mg/kg PO every 8 hours, increase gradually to 1 mg/kg PO every 8 hours over 4 weeks[12]

Antihypertensive agent (extra-label): 2.5 – 5 mg/cat (NOT mg/kg) PO every 8 hours[1]

Adjunctive treatment of severe thyrotoxicosis (extra-label):

a) IV dosage: 0.02 mg/kg IV slowly over 1 minute

b) Oral dosage: 2.5 – 5 mg/cat (NOT mg/kg) PO every 8 hours[5,13]

HORSES:

Refractory ventricular tachycardia and management of rapid ventricular response rate during quinidine therapy for atrial fibrillation (extra-label): 0.03 – 0.16 mg/kg IV or 0.38 – 0.78 mg/kg PO every 8 hours. Considered not as effective as lidocaine; decreases ventricular rate even if it does not restore sinus rhythm[14]

FERRETS:

Hypertrophic cardiomyopathy (extra-label): 0.5 – 2 mg/kg PO or SC once a day to twice a day

Monitoring

- Adverse effects (eg, CNS changes, bronchospasm, respiratory depression)
- Electrocardiogram to monitor heart rate and rhythm
- Blood pressure

Client Information

- Give this medicine as prescribed by your veterinarian.
- This medicine can be given with or without food.
- The most common side effects include tiredness/lack of energy and weakness. Contact your veterinarian if your animal becomes exercise-intolerant, has difficulty breathing, develops a cough, or has a change in behavior or attitude.
- When starting this medicine, your veterinarian may start with a low dose and gradually increase it over time to see how your animal reacts to it. Do not administer more than your veterinarian prescribes.
- Do not suddenly stop giving propranolol to your animal as it can make your animal's condition worse.
- Your veterinarian will need to monitor your animal closely while it is receiving this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

A nonspecific beta-adrenergic blocking agent, propranolol HCl occurs as a bitter tasting, odorless, white to off-white powder with a pK_a of 9.45 and a melting point of ≈161°C (321°F). One gram of propranolol is soluble in ≈20 mL of water or alcohol. At a pH from 4 to 5, solutions of propranolol will fluoresce. The commercially available injectable solutions are adjusted with citric acid to a pH 2.8 to 3.5.

Propranolol may also be known as AY-64043, ICI-45520, NSC-91523, propranololi hydrochloridum; many trade names are available.

Storage/Stability

All propranolol preparations should be stored at room temperature (15°C-30°C [59°F-86°F]) and protected from light. Propranolol solutions will decompose rapidly at alkaline pH.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Propranolol injection is reported to be physically **compatible** with 5% dextrose, 0.9% sodium chloride, or lactated Ringer's injection. It is also physically **compatible** with dobutamine HCl and verapamil HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Propranolol HCl Oral Tablets: 10 mg, 20 mg, 40 mg, 60 mg, and 80 mg; generic; (Rx)

Propranolol HCl Extended/Sustained-Release Capsules: 60 mg, 80 mg, 120 mg, and 160 mg; *Inderal® LA*, *Inderal XL®*, *InnoPran® XL*, generic; (Rx)

Propranolol for Injection: 1 mg/mL in 1 mL ampules or vials; *Inderal®*, generic; (Rx)

Propranolol Oral Solution: 4 mg/mL and 8 mg/mL in 500 mL; generic; (Rx)

Pseudoephedrine

(soo-doe-e-***fed***-rin) *Equiphed®, Sudafed®*

Sympathomimetic

Prescriber Highlights

- ► Oral sympathomimetic primarily used for urethral sphincter hypotonus. Therapeutic index is narrow in dogs; use is controversial.
- ► Contraindications include hypersensitivity and severe hypertension.
- ► Use with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension.
- ► Adverse effects include restlessness, irritability, hypertension, and anorexia.
- ► Restricted drug in the United States; has been used to manufacture methamphetamine

Uses/Indications

Pseudoephedrine is primarily used as a substitute for phenylpropanolamine for the treatment of urinary incontinence in dogs; however, it has a narrow therapeutic index and can result in severe toxicity (see ***Overdose/Acute Toxicity***). One study in dogs with urinary incontinence found that it was not as effective as phenylpropanolamine (PPA) and had more adverse effects.[1] Pseudoephedrine is typically not recommended due to the availability of alternative FDA-approved agents.

Pseudoephedrine could be useful as a decongestant or for treating retrograde ejaculation; however, efficacy and safety is lacking.

Pharmacology/Actions

The exact mechanism of actions for pseudoephedrine are unknown. It is thought that it indirectly stimulates both alpha- and, to a lesser degree, beta-adrenergic receptors by causing the release of norepinephrine.

Pharmacologic effects of pseudoephedrine include vasoconstriction, increased heart rate, increase coronary blood flow, increased blood pressure, mild CNS stimulation, decreased nasal congestion, and decreased appetite. Pseudoephedrine can also increase urethral sphincter tone and produce closure of the bladder neck.[2]

Pharmacokinetics

Pseudoephedrine is rapidly and nearly completely absorbed from the GI tract. Food may delay the absorption of pseudoephedrine but not the extent. In children, the apparent volume of distribution is ≈2.5 L/kg. Pseudoephedrine is only partially metabolized, and the bulk is excreted unchanged in the urine. Urine pH can affect excretion rates. Alkaline urine (ie, pH ≈ 8) can prolong half-life while acidic urine (ie, pH ≈ 5) can decrease it.

Contraindications/Precautions/Warnings

Pseudoephedrine is contraindicated in patients that are hypersensitive to it or in patients with severe hypertension. It should be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension.

Because it may be used to manufacture methamphetamine, pseudoephedrine is a restricted drug and regulations may vary by state. Use caution when prescribing pseudoephedrine and be alert for drug seeking behavior.

Adverse Effects

Adverse effects are dose-related and adrenergic in nature. Panting, decreased appetite, lethargy, and rapid heart rate are the most likely adverse effects at typical doses; however, CNS excitement, restlessness, insomnia, and other behavioral changes are possible. Increases in blood pressure and arrhythmias can occur in susceptible individuals, particularly at high doses.

Reproductive/Nursing Safety

Safe use has not been established during pregnancy. In humans, pseudoephedrine enters maternal milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of pseudoephedrine can cause hyperactivity/agitation, hyperthermia, mydriasis, tachycardia, hypertension, vomiting, disorientation, and seizures. In small animal species, adverse reactions may develop at doses of 5 – 6 mg/kg. Fatalities have occurred at doses greater than 10 – 12 mg/kg.

Large overdoses should be treated with GI decontamination protocols when indicated. Treatment is otherwise supportive and based on clinical signs. Carvedilol (0.5 mg/kg PO twice daily) was successfully used in a dog to treat tachycardia from a pseudoephedrine overdose.[3] Phenothiazines are preferred to treat hyperactivity, agitation, and tremors; benzodiazepines are not recommended, as they may worsen dysphoria.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pseudoephedrine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate**.**

- ■ **Monoamine Oxidase Inhibitors** (**MAOIs**, eg, **amitraz, selegiline**): Pseudoephedrine should not be given within 2 weeks of MAOI administration.

- **Reserpine**: Increased risk for hypertension if given concomitantly
- **Sympathomimetic Agents, Other** (eg, **phenylpropanolamine**): Increased risk for toxicity
- **Tricyclic Antidepressants** (eg, **clomipramine, amitriptyline**): Increased risk for hypertension if given concomitantly

Dosages

DOGS:

Increase urethral tone (extra-label): 1.5 mg/kg PO 2 to 3 times daily. Nighttime incontinence may be effectively managed with once-daily dosing at night.

Retrograde ejaculation (extra-label): **NOTE**: Doses at or above 5 mg/kg have been associated with significant toxic effects (see ***Overdose/Acute Toxicity***).

a) 4 – 5 mg/kg PO 3 times daily

b) 4 – 5 mg/kg PO 1 to 3 hours before semen collection or attempted breeding

CATS:

Decongestant (extra-label): 1 mg/kg PO every 8 hours[4]

Monitoring

- Efficacy
- Adverse effects including tachycardia, CNS stimulation, and increased appetite

Client Information

- Side effects of this medicine include lack of appetite, restlessness (unable to settle down), reduced energy, and rapid heartbeat.
- Overdoses can be serious. Only give this medicine as directed by your veterinarian.
- Store this medicine out of reach of other animals and children.

Chemistry/Synonyms

A sympathomimetic, pseudoephedrine HCl is the stereoisomer of ephedrine. It occurs as a fine, white to off-white powder or crystals. Approximately 2 grams are soluble in 1 mL of water.

Pseudoephedrine may also be known as pseudoephedrini, pseudoephedrina, or *Sudafed*®.

Storage/Stability

Oral pseudoephedrine products should be stored at room temperature in tight containers. Oral liquid preparations should be protected from light and freezing.

Dosage Forms/Regulatory Status

Pseudoephedrine is classified as a DEA List I chemical, as it can be used as a precursor to manufacture methamphetamine. Regulations vary by state; it may be a controlled substance in some states or have other restrictions placed upon its sale. Pseudoephedrine products are available without a prescription, but sales are restricted to behind-the-counter status; purchase quantities are limited, and purchases are tracked.

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Pseudoephedrine HCl Tablets: 30 mg and 60 mg; *Sudafed*®, generic; (OTC, restricted)

Pseudoephedrine HCl Capsules: 30 mg; *Zephrex D*®; (OTC, restricted)

Pseudoephedrine HCl Extended-Release Tablets: 120 mg and 240 mg; *Sudafed*®, *Contac*®, generic; (OTC, restricted)

Pseudoephedrine Liquid: 3 mg/mL and 6 mg/mL; *Sudafed*®, generic; (OTC, restricted)

NOTE: Pseudoephedrine is also available in a wide variety of cold and allergy combination products; use caution when selecting and recommending products.

Psyllium

(***sill***-i-yum) *Metamucil*®

Bulk-Forming GI Laxative/Antidiarrheal

Prescriber Highlights

► Bulk-forming agent used for the treatment and prevention of sand colic in horses, as a laxative, and to increase stool consistency in patients with chronic, large-bowel diarrhea

► Contraindications include use in rabbits, situations when prompt intestinal evacuation is required, and situations when a fecal impaction or intestinal obstruction is present.

► Adverse effects include flatulence; if insufficient fluids are given, there is increased risk for esophageal or bowel obstruction.

Uses/Indications

Bulk-forming laxatives may be used in patients with constipation resulting from a lack of dietary fibers or when straining to defecate may be deleterious.

Psyllium is considered the laxative of choice in the treatment and prevention of sand colic in horses. The combination of psyllium with magnesium sulfate or mineral oil was more effective than any of the products given alone.[1,2]

Psyllium has also been used to increase stool consistency in patients with chronic, large-bowel diarrhea.[3,4]

Psyllium added to the diet may help to control metabolic syndrome in horses.

Pharmacology/Actions

Psyllium is a soluble, slowly fermenting fiber. By swelling into a gel after absorbing water, psyllium increases bulk in the intestine and is believed to induce peristalsis and decrease intestinal transit time. The total amount of water in the stool remains unchanged. In the treatment of sand colic in horses, psyllium is thought to help collect sand and lubricate its passage through the GI tract.

In normal, non-obese, unexercised horses, psyllium fed for 60 days reduced postprandial blood glucose (at 90, 180, and 270 g/day) and insulin levels (at 270 g/day).[5]

Pharmacokinetics

Psyllium is not absorbed when administered orally. Laxative action may take up to 72 hours to occur and is likely highly dependent on species being treated.

Contraindications/Precautions/Warnings

Bulk-forming laxatives should not be used where prompt intestinal evacuation is required or when fecal impaction (no feces being passed) or intestinal obstruction is present. Psyllium products are not recommended for rabbits as they may damage intestinal mucosa and cause bowel obstruction.

In dogs and cats, initiating treatment at ¼ – ½ of the recommended dosage and gradually increasing the dosage may facilitate adaptation to the effects of psyllium fermentation in the GI tract.

Do not confuse teaspoon dosages with tablespoon dosages.

Adverse Effects

With the exception of increased flatulence, psyllium very rarely produces any adverse reactions if adequate water is given or is available to the patient. If insufficient fluids are given, there is increased risk for esophageal or bowel obstruction.

Reproductive/Nursing Safety

Because there is no appreciable systemic absorption of psyllium from the GI tract, it should be safe to use in pregnant and lactating animals.

Overdose/Acute Toxicity

If psyllium is administered with sufficient liquid, overdose should cause only an increased amount of soft or loose stools. A horse receiving 4 times the recommended dosage of a pelleted psyllium product experienced a gastric rupture caused by 2 psyllium bezoars (1 in the pylorus and 1 in the proximal duodenum).[6]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving psyllium and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antidiabetic Agents**: Concurrent use may result in an increased risk for hypoglycemia
- **Aspirin** (and other **Salicylates**): Potential exists for psyllium to bind and reduce absorption if given with aspirin; if possible, separate doses by 3 or more hours.
- **Digoxin**: Potential exists for psyllium to bind and reduce absorption if given with digoxin; if possible, separate doses by 3 or more hours.
- **Lithium**: Concurrent use may result in decreased plasma levels and effectiveness of lithium
- **Nitrofurantoin**: Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 or more hours

Dosages

DOGS:

Adjunctive treatment of idiopathic large bowel diarrhea (extra-label): Median dose is 2 tablespoons (30 cc) daily (1.33 g of psyllium/kg/day; range: 0.31 – 4.9 g/kg/day) added to a highly digestible diet.[3] It is recommended to start with ¼ – ½ of this dosage and gradually titrate upward to effect. Four tablespoons (60 cc) added to the diet daily improved stool frequency and consistency in police working dogs.[4]

Adjunct for treatment of hepatic encephalopathy (extra-label): 1 – 3 teaspoons (5 to 15 cc) daily as a source of soluble fiber[7]

CATS:

Chronic constipation (extra-label): 1 – 4 teaspoons (5 to 20 cc) per meal added to canned cat food. It is recommended to start with ¼ – ½ of this dosage and gradually titrate upwards to effect. Be sure the cat is properly hydrated.[8]

HORSES:

Adjunctive treatment of sand colic (extra-label):

a) 1 g/kg twice daily. Mix ≈0.45 kg (1 lb) of psyllium (in powdered form) with water and administer immediately via NG tube; delayed administration will cause the mixture to thicken. If giving this mixture orally to foals, esophageal obstruction can occur. Give small amounts of the mixture at a time, and confirm the foal swallows after each bolus. A liquid-like mixture (versus a paste-like one) can also help. Pelleted psyllium is also available, and most horses find this form more palatable than if the powdered form is mixed with dry or moistened feed. If the horse refuses the pelleted form, experimentation with different flavors and smells produced by different suppliers of psyllium pellets may be helpful. Another option is to blend the psyllium pellets with the horse's favorite treat or grain source to improve intake.[9]

b) 1 g/kg twice daily in combination with magnesium sulfate 1 g/kg via NG tube once daily for 4 days cleared sand accumulation in horses presented without clinical signs of colic.[10]

c) In this experimental study, 0.5 kg psyllium was mixed with 1 L of mash and given twice daily, and 2 L of mineral oil via NG tube was administered once daily. This combination was more effective (measured ash content of feces) than giving mineral oil alone.[2]

Monitoring

- Stool consistency, frequency

Client Information

- Be sure your animal always has plenty of clean water to drink while taking psyllium.
- Psyllium is available OTC (over-the-counter; without a prescription). Do not give psyllium (or any other OTC medications) to your animal without consulting your veterinarian.
- Psyllium products are not recommended for use in rabbits.

Chemistry/Synonyms

Psyllium is obtained from the ripe seeds of varieties of *Plantago* species. The seed coating is high in the content of hemicellulose mucilage that absorbs and swells in the presence of water.

Psyllium is also known as *Metamucil*®; many other trade names are available.

Storage/Stability

Store psyllium products in tightly closed containers; protect from excess moisture or humidity.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: There are numerous psyllium products sold for use in animals, however, none have been evaluated or approved by the FDA for safety and efficacy in animals.

Equine Enteric Colloid®, *Equi-Phar*® *Sweet Psyllium* (not for horses intended for food), *Sandclear*®, *Anipsyll*® *Powder* (AHC), *Purepsyll*® *Powder*, *Vita-Flex Sand Relief*®, *Equa Aid Psyllium*®; (OTC). Products may be available in 28 oz, 56 oz, 1 lb, 10 lb, and 30 lb pails and are labeled for use in horses.

Vetasyl Fiber Tablets for Cats® 500 mg and 1000 mg tablets in bottles of 60 and 180; (OTC); Labeled for use in cats. Contains barley malt extract powder, acacia, and thiamine.

HUMAN-LABELED PRODUCTS:

There are many human-approved products containing psyllium; most products have ≈3.4 g of psyllium per rounded teaspoonful. Dosages of sugar-free products may be different from those containing sugar. Many products on the human market are orange flavored, but unflavored products are available and may be more palatable for veterinary patients.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pyrantel

(pie-***ran***-tel) *Strongid T®, Nemex®*

Antiparasitic

Prescriber Highlights

- ► Pyrimidine anthelmintic FDA-approved in dogs and horses and used in a variety of species primarily for treatment of ascarids
- ► Due to poor absorption, pyrantel is only useful for GI parasites.
- ► Use is contraindicated in severely debilitated animals.
- ► Adverse effects are uncommon, but emesis and diarrhea are possible in small animal species.

Uses/Indications

Pyrantel is FDA-approved for removal of ascarids (eg, *Toxocara canis, Toxascaris leonina*) and hookworms (eg, *Ancylostoma caninum, Uncinaria stenocephala*) in dogs.[1] *A caninum* resistance to pyrantel has been reported.[2,3] In greyhounds naturally infected with *T canis*, fenbendazole had a slightly greater reduction in fecal egg count reduction (FECR) than pyrantel.[4]

Pyrantel is not FDA-approved as a single entity for use in cats; however, its use is considered safe to address similar internal parasites as described for dogs.

Pyrantel is FDA-approved in horses for the removal of *Strongylus vulgaris, S equinus*, and *Parasacaris equorum*.[5] It has variable activity against *Oxyuris equi, S edentatus*, and small strongyles. Pyrantel at twice the recommended dose is active against ileocecal tapeworms (eg, *Anoplocephala perfoliata*); however, resistance has been reported. Resistance to pyrantel is an ongoing concern,[6] particularly for large strongyles[7] and cyathostomins.[8] It is recommended to perform fecal egg count reduction (FECR) testing for strongyle nematodes. A value of greater than 90% in treated horses is the suggested cutoff for determining pyrantel efficacy in an individual horse and on a given farm; FECR testing values less than 90% indicate resistance.[9]

Although no pyrantel products are FDA-approved for use in cattle, sheep, or goats, the pyrantel tartrate is effective for the removal of *Haemonchus* spp, *Ostertagia* spp, *Trichostrongylus* spp, *Nematodirus* spp, *Chabertia* spp, *Cooperia* spp, and *Oesophagostomum* spp.[10,11]

In swine, pyrantel tartrate medicated feed is indicated for the prevention or removal and control of large roundworms (ie, *Ascaris suum*) and nodular worms (ie, *Oesophagostomum* spp). The drug also has activity against the swine stomach worm (ie, *Hyostrongylus rubidus*).

Pyrantel has also been used in birds and llamas, although use is not FDA-approved. See ***Dosages*** for more information.

Pyrantel resistance is a growing concern for canine hookworms.[3,12]

Pharmacology/Actions

Pyrantel is a cholinergic agonist that binds to the nicotinic receptors of susceptible parasites to cause depolarization and acts as a neuromuscular-blocking agent to paralyze the organism. It also inhibits cholinesterase.

Pharmacokinetics

Because pyrantel pamoate is poorly absorbed from the GI tract, its antiparasitic effects remain active in the lower GI tract of dogs, cats, and horses. Pyrantel tartrate is absorbed more readily than the pamoate salt. In swine and dogs, pyrantel tartrate reaches peak plasma concentrations 2 to 3 hours after administration. Peak plasma concentrations occur at highly variable times in ruminants. In horses given pyrantel embonate (not available in the United States), peak concentration was reached 7.5 hours after administration.[13]

The absorbed drug is rapidly metabolized and excreted into urine and feces. Elimination half-life is 1.4 hours in cats and 13.4 hours in horses.[14] The maximum pyrantel concentration in equine feces is ≈11 times higher than that reached in plasma.[13]

Contraindications/Precautions/Warnings

Pyrantel is contraindicated in patients that are hypersensitive to it. Use with caution in severely debilitated animals.

In humans, it is recommended to use with caution in patients with hepatic disease.[15]

Adverse Effects

Adverse effects are unlikely when pyrantel is administered at recommended doses. Emesis, diarrhea, or inappetence can occur in small animal species receiving pyrantel pamoate and may be related to expulsion of parasites.

In humans, abdominal cramps, nausea, vomiting, diarrhea, and dizziness have been reported.[15]

Reproductive/Nursing Safety

Pyrantel does not appear to impact the reproductive performance of pregnant mares or stud horses.[5] There has been no evidence of impaired fertility in rats.

Pyrantel is considered safe for use in nursing animals. Several over the counter (OTC) products labeled for dogs contain dosing information for lactating bitches.

Overdose/Acute Toxicity

Pyrantel has a moderate margin of safety. Doses up to ≈7 times the label dose generally do not result in toxic reactions. In horses, doses of 20 times the label dose yielded no adverse effects. The LD_{50} for pyrantel tartrate is 170 mg/kg in mice and rats, and the LD_{50} for pyrantel *base* is more than 690 mg/kg in dogs.[1] Oral dosages of ≈200 mg/kg/day for up to 90 days did not cause morphologic abnormalities in dogs.[1]

In dogs, chronic administration of pyrantel pamoate at 50 mg/kg/day, but not at 20 mg/kg/day over 3 months, resulted in clinical signs of toxicity (eg, increased respiratory rate, profuse sweating [in species with sweat glands], ataxia, other cholinergic effects).

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyrantel and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Levamisole**: Because of similar mechanisms of action (and toxicity), do not use concurrently with pyrantel.
- **Morantel**: Because of similar mechanisms of action (and toxicity), do not use concurrently with pyrantel.
- **Organophosphates**: Increased risk for adverse effects
- **Piperazine**: Pyrantel and piperazine have antagonistic mechanisms of action; do not use together.

Dosages

NOTE: Listed dosages specify whether dose is based on the salt (ie, pyrantel pamoate) or pyrantel base; always check the product label to determine the appropriate dose for the specific product being prescribed. For additional information on using this drug in dogs and cats, see the Companion Animal Parasite Council recommendations at capcvet.org.

DOGS:

Pyrantel as a single agent:

Susceptible parasites (label-dosage; FDA-approved): Using pyrantel base, for dogs weighing less than 2.3 kg (5 lb), 10 mg/kg PO; for dogs weighing more than 2.3 kg (5 lb), 5 mg/kg PO. Treat puppies at 2, 3, 4, 6, 8, and 10 weeks of age. Treat lactating bitches 2 to 3 weeks after whelping; perform follow-up fecal examinations 2 to 4 weeks after treating to determine need for retreatment. Adult dogs kept in a heavily contaminated environment may need to be treated at monthly intervals.[1]

Susceptible parasites (extra-label):

a) **Hookworms or roundworms**: Pyrantel pamoate 5 mg/kg PO once after a meal; repeat after 7 to 10 days[16]

b) **Puppies**: To prevent environmental contamination, all puppies should be routinely treated with pyrantel pamoate (10 mg/kg for dogs weighing less than 2.3 kg [5 lb]; 5 mg/kg for dogs weighing more than 2.3 kg [5 lb]) at 2, 4, 6, and 8 weeks of age and then placed on a monthly heartworm preventative with efficacy against *Toxocara* spp.[17]

c) ***Physaloptera* spp nematodes**:

i. Pyrantel pamoate 5 mg/kg PO once[18]

ii. Pyrantel pamoate 20 mg/kg PO every 2 weeks for at least 3 treatments[19]

Combination Products:

Pyrantel/Praziquantel/Febantel (*Drontal*® Plus) label indications (FDA-approved): Available in several weight-based sizes that provide minimum dosages of 5 mg/kg pyrantel pamoate, 5 mg/kg praziquantel and 25 mg/kg febantel. See ***Praziquantel/Praziquantel Combination Products***.

Pyrantel/Moxidectin/Sarolaner (*Simparica Trio*®) label indications (FDA-approved): Available in several weight-based sizes that provide minimum dosages of 5 mg/kg pyrantel pamoate, 1.2 mg/kg sarolaner, and 24 µg/kg moxidectin PO once monthly. See ***Sarolaner*** and ***Moxidectin/Moxidectin Combination Products***.

Pyrantel/Ivermectin (*Heartgard Plus*®, *Tri-Heart Plus*®, *Iverhart Plus*®) label indications (FDA-approved): Available in several weight-based sizes that provide minimum dosages of 5 mg/kg pyrantel pamoate and 6 µg/kg ivermectin PO once monthly. See ***Ivermectin***.

CATS:

Pyrantel as a single agent:

Susceptible parasites (extra-label):

a) Pyrantel pamoate 20 mg/kg PO; repeat when necessary[20]

b) **Kittens**: Can be treated as early as 2 to 3 weeks of age at 5 – 10 mg/kg PO; dose can be repeated every 2 to 3 weeks until kittens are at least 12 weeks of age.[21]

c) ***Physaloptera* spp nematodes**: 20 mg/kg PO every 2 weeks for at least 3 treatments[19]

Combination Products:

Pyrantel/Praziquantel (*Drontal*®) label indications (FDA-approved): The tablet provides a minimum dosage of 20 mg/kg pyrantel pamoate and 5 mg/kg praziquantel. See ***Praziquantel/Praziquantel Combination Products***.[22]

HORSES:

Removal and control of mature infections of large strongyles (*Strongylus vulgaris, S edentatus, S equinus*), small strongyles, pinworms (*Oxyuris equi*), and large roundworms (*Parascaris equorum*) in horses and ponies (label dosage; FDA-approved): Pyrantel pamoate 6.6 mg/kg PO. It is recommended that foals (2 to 8 months of age) be given a dose every 4 weeks. Treat mares 1 month before the anticipated foaling date and give retreatment 10 days to 2 weeks after birth in order to minimize any potential source of infection the mare may pose to the foal. Horses and ponies over 8 months of age should be routinely treated every 6 weeks.[5,23]

Control of mature infections of adult large strongyles, adult and larval stages of small strongyles, pinworms, and ascarids in horses (label dosage; FDA-approved): pyrantel tartrate 2.64 mg/kg PO administered on a continuous basis either as a top dress or mixed in the daily grain.[24]

Removal and control of mature infections of large strongyles, small strongyles, pinworms, and large roundworms (extra-label): Pyrantel pamoate 13.2 mg/kg PO (two times the label dosage) may be effective in herds with documented pyrantel resistance.[25]

Control of cestodes (extra-label): 13.2 mg/kg PO (two times the labeled dose)[26]

Combination treatment with oxibendazole (extra-label): Pyrantel pamoate 6.6 mg/kg PO combined with oxibendazole 10 mg/kg PO achieved a more than 90% FECR for cyathostomins on all studied farms, including farms in which FECR was less than <90% for the agents given individually.[27]

DONKEYS

Removal of GI nematodes in donkeys (extra-label): Pyrantel pamoate 20 mg/kg PO using equine oral paste[28,29]

LLAMAS:

Susceptible parasites (extra-label): 18 mg/kg PO once[30,31]

BIRDS:

Intestinal nematodes (extra-label):

a) ***Ascaridia* spp in psittacines**: In endemic areas, outdoor breeding birds and their offspring should be routinely dewormed for ascarids: pyrantel pamoate 25 mg/kg PO every 2 weeks.[32]

b) 7 mg/kg PO; repeat after 14 days[33]

c) 100 mg/kg PO once in psittacines and passerines[34]

RABBITS, RODENTS, SMALL MAMMALS:

Rabbits (extra-label): 5 – 10 mg/kg PO, repeat after 2 to 3 weeks[35]

Monitoring

- Efficacy (eg, fecal float, fecal egg count reduction test)

Client Information

- This medicine may be given with or without food; can be mixed into food.
- Usually no side effects. Rarely, some small animal species may vomit after receiving the drug; give with food if this happens.
- In small animal species, dose is usually repeated at various weekly intervals; follow your veterinarian's recommendation for best control of parasites.
- If using a liquid suspension, shake the container thoroughly before each use; protect from sunlight.
- Most intestinal parasites are digested after treatment; it is uncommon to see parasites passed in the stool.

Chemistry/Synonyms

Pyrantel pamoate, a pyrimidine-derivative anthelmintic, occurs as yellow to tan solid and is practically insoluble in water and alcohol. Each gram of pyrantel pamoate is ≈347 mg (34.7%) of the base.

Pyrantel may also be known as CP-10423-16, pyrantel embonate, pirantel pamoate, *Anthel*®, *Antiminth*®, *Ascarical*®, *Aut*®, *Bantel*®, *Cobantril*®, *Combantrin*®, *Early Bird*®, *Helmex*®, *Helmintox*®, *Jaa Pyral*®, *Lombriareu*®, *Nemex*®, *Nemocid*®, *Pin-X*®, *Pirantrim*®, *Pyrantin*®, *Pyrantrin*®, *Pyrapam*®, *Reese's*® *Pinworm*, *Strongid*®, *Trilombrin*®, or *Vertel*®.

Storage/Stability

Pyrantel pamoate products should be stored in tight, light-resistant containers at room temperature (15°C-30°C [59°F-86°F]) unless otherwise directed by the manufacturer. Do not expose pyrantel products to direct sunlight.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: Many products are available; a partial listing of products follows:

Pyrantel Pamoate Tablets: 22.7 mg (of base), 113.5 mg (of base); (OTC). FDA-approved for use in dogs. A commonly known product is *Nemex® Tabs*.

Pyrantel Pamoate Oral Suspension: 2.27 mg/mL and 4.54 mg/mL (as base) (for dogs only); in 60 mL, 120 mL, 280 mL, and 473 mL bottles. Many products are available; a commonly known trade name is *Nemex-2®*; (OTC).

Pyrantel Pamoate Oral Suspension: 50 mg/mL (of base). Many products are available; a commonly known trade name *is Strongid®* T; (OTC). FDA-approved for use in horses and foals 2 months of age and older and not intended for food purposes

Pyrantel Pamoate Oral Paste: 43.9% w/w pyrantel base in 23.6 g paste (171 to 180 mg pyrantel base/mL); *Strongid®* Paste, Exodus® Paste, generic; (OTC). FDA-approved for use in horses and foals 2 months of age and older and not intended for food purposes

Pyrantel Tartrate 1.06% (4.8 g/lb) Top Dress: in 25 lb pails: *Strongid®* C; (OTC). Labeled for use in horses not intended for food purposes.

Pyrantel Tartrate 2.12% (9.6 g/lb) Top Dress: in 10 lb, 25 lb, and 50 lb pails: *Strongid®* C 2X; (OTC). Labeled for use in horses not intended for food purposes.

Pyrantel embonate is available in countries outside the United States. Dose requirements differ from that of pyrantel pamoate and pyrantel tartrate; consult the product label.

Combination Products:

With Febantel and Praziquantel: Tablets and Taste Tabs: For Puppies and Small Dogs (0.9 to 11.3 kg [2 to 25 lb]): praziquantel, 22.7 mg/pyrantel pamoate, 22.7 mg/febantel, 113.4 mg; For Medium-Sized Dogs (11.8 to 27.2 kg [26 to 60 lb]): praziquantel, 68 mg/pyrantel pamoate, 68 mg/febantel, 340.2 mg; For Large Dogs (more than 20.4 kg [45 lb]): praziquantel, 136 mg/pyrantel pamoate, 136 mg/febantel, 680.4 mg; *Drontal®* Plus (Rx, OTC). Approved for use in dogs 3 weeks of age and older. See ***Fenbendazole*** and ***Praziquantel/Praziquantel Combination Products*** for more information.

With Ivermectin: Chewable Tablets: For dogs up to 11.3 kg (25 lb): ivermectin 68 µg/pyrantel pamoate 57 mg; For dogs 11.8 to 22.7 kg (26 to 50 lb): ivermectin 136 µg/pyrantel pamoate 114 mg; For dogs 23.1 to 45.4 kg (51 to 100 lb): ivermectin 272 µg/pyrantel pamoate 227 mg; *Heartgard®* Plus Chewables, generic; (Rx). FDA-approved for use in dogs 6 weeks of age and older. See ***Ivermectin*** for more information.

With Ivermectin and Praziquantel: Ivermectin/Pyrantel Pamoate/Praziquantel Oral Chewable Tablets: For dogs 2.7 to 5.4 kg (6 to 12 lb): 34 µg/28.5 mg/28.5 mg; For dogs 5.5 to 11.3 kg (12.1 to 25 lb): 68 µg/57 mg/57 mg; For dogs 11.4 to 22.7 kg (25.1 to 50 lb): 136 µg/114 mg/114 mg; For dogs 22.7 to 45.4 kg (50.1 to 100 lb): 272 µg/228 mg/228 mg; *Iverhart®* Max; (Rx). FDA-approved for use in dogs 6 weeks of age and older. See ***Ivermectin*** and ***Praziquantel/Praziquantel Combination Products*** for more information.

With Moxidectin and Sarolaner: Chewable (flavored) Tablets: For dogs, 1.3 to 2.5 kg (2.8 to 5.5 lb): moxidectin 0.06 mg, pyrantel pamoate 12.5 mg, and sarolaner 3 mg; For Dogs, 2.5 to 5 kg (5.6 to 11 lb): moxidectin 0.12 mg, pyrantel pamoate 25 mg, and sarolaner 6 mg; For dogs, 5 – 10 kg (11.1 to 22 lb): moxidectin 0.24 mg, pyrantel pamoate 50 mg, and sarolaner 12 mg; For Dogs, 10 to 20 kg (22.1 to 44 lb): moxidectin 0.48 mg, pyrantel pamoate 100 mg, and sarolaner 24 mg; For dogs, 20 to 40 kg (44.1 to 88 lb): moxidectin 0.96 mg, pyrantel pamoate 200 mg, and sarolaner 48 mg; For dogs, 40 to 60 kg (88.1 to 132 lb): moxidectin 1.44 mg, pyrantel pamoate 300 mg, and sarolaner 72 mg; *Simparica Trio®* (Rx). Approved for use in dogs 8 weeks of age and older and weighing 1.3 kg (2.8 lb) or greater. NADA# 141-521. See ***Moxidectin*** and ***Sarolaner*** for more information.

With Praziquantel: Tablets: 18.2 mg praziquantel/72.6 mg pyrantel pamoate (of base); *Drontal®* Tablets; some sizes may be available as generics or under various trade names (OTC). FDA-approved for use in cats and kittens older than 2 months of age and weighing more than 0.9 kg (2 lb). See ***Praziquantel/Praziquantel Combination Products*** for more information.

With Praziquantel: Chewable Tablets: Praziquantel 30 mg/pyrantel pamoate 30 mg and praziquantel 114 mg/pyrantel pamoate 114 mg; *Virbantel®*; generic; (OTC). FDA-approved for use in dogs 12 weeks of age and older. See ***Praziquantel/Praziquantel Combination Products*** for more information.

HUMAN-LABELED PRODUCTS:

Pyrantel Pamoate Oral Suspension: 144 mg/mL (equivalent to 50 mg/mL pyrantel base); generic; (OTC)

Pyrantel Pamoate Chewable Oral Tablets: 180 mg and 720.5 mg (equivalent to 62.5 mg and 250 mg pyrantel base, respectively); *Pin-X®, Vermisol®*; generic; (OTC)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pyridostigmine

(peer-id-oh-***stig***-meen) *Mestinon®*

Anticholinesterase Agent

Prescriber Highlights

- ► Anticholinesterase inhibitor used for treatment of myasthenia gravis
- ► Contraindications include hypersensitivity to this class of compounds or bromides, as well as patients with mechanical (physical) obstructions of the urinary or GI tract.
- ► Use with caution in patients with bronchospastic disease, epilepsy, hyperthyroidism, bradycardia or other arrhythmias, vagotonia, or GI ulcer diseases.
- ► Adverse effects are usually dose-related cholinergic signs, including GI effects (nausea, vomiting, diarrhea, salivation), respiratory effects (increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic effects (miosis, blurred vision, lacrimation), cardiovascular effects (bradycardia or tachycardia, cardiospasm, hypotension, cardiac arrest), muscle cramps, sweating, and weakness.

Uses/Indications

Pyridostigmine is used in the treatment of myasthenia gravis (MG) in dogs and, rarely, in cats. It is considered to be much more effective in treating acquired MG than congenital MG.

Pharmacology/Actions

Pyridostigmine inhibits the hydrolysis of acetylcholine by directly competing with acetylcholine for attachment to acetylcholinesterase.

Because the pyridostigmine-acetylcholinesterase complex is hydrolyzed at a much slower rate than the acetylcholine-acetylcholinesterase complex, acetylcholine tends to accumulate at cholinergic synapses with resultant cholinergic activity. Compared with neostigmine, pyridostigmine is ≈4.4 times less potent, has a slower onset and longer duration of action, and has fewer adverse GI effects.

At usual doses, pyridostigmine does not cross into the CNS (quaternary ammonium structure), but overdoses can cause CNS effects.

Pharmacokinetics

Pyridostigmine is only marginally absorbed from the GI tract (≈10% to 20%). Absorption may be delayed by food and be more erratic with the extended-release tablets than the regular tablets. In humans, oral dosage is ≈30 times greater than IV dosage. The onset of action after oral dosing is generally within 1 hour.

At recommended dosages, pyridostigmine is apparently distributed to most tissues except the brain, intestinal wall, fat, or thymus.

Pyridostigmine is both hydrolyzed by cholinesterases and metabolized by the liver (≈25% of the dose administered) but is largely excreted unchanged in the urine. Elimination half-life is ≈1.5 to 3 hours in humans. Patients with renal failure will have prolonged elimination.

The extended-release tablet is intended to have an immediate effect equivalent to a 60 mg tablet, and the effect is then sustained over time.

Contraindications/Precautions/Warnings

Pyridostigmine is contraindicated in patients that are hypersensitive to this class of compounds or bromides, or in those that have mechanical (physical) obstructions of the urinary or GI tract.

The drug should be used with caution in patients with bronchospastic disease, epilepsy, hyperthyroidism, bradycardia or other arrhythmias, vagotonia, or GI ulcer diseases. Lower doses may be needed in patients with renal impairment. Atropine sulfate should be readily available to block excessive cholinergic effects.

Do not confuse PYRIDostigmine with PHYSostigmine.

Adverse Effects

Adverse effects are generally dose-related and cholinergic in nature such as increased GI motility, salivation, urination, abdominal pain, diarrhea, bradycardia, and increased lacrimation. These effects are usually mild and easily treatable with dosage reduction, but severe adverse effects are possible (see ***Overdose/Acute Toxicity***).

Reproductive/Nursing Safety

Pyridostigmine crosses the placenta and is excreted in maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of pyridostigmine may induce a cholinergic crisis. Clinical signs of cholinergic toxicity can include GI effects (eg, nausea, vomiting, diarrhea, salivation), respiratory effects (eg, increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic effects (eg, miosis, blurred vision, lacrimation), cardiovascular effects (eg, bradycardia or tachycardia, cardiospasm, hypotension, cardiac arrest), sweating (ie, species with sweat glands), muscle cramps, and weakness.

Overdoses in myasthenic patients can be difficult to distinguish from the effects associated with a myasthenic crisis. The time of onset of clinical signs or an edrophonium challenge may help to distinguish between the two.

Treatment of pyridostigmine overdose consists of both respiratory and cardiac supportive therapy and administration of atropine, if necessary. Refer to the ***Atropine*** monograph for more information on its use for cholinergic toxicity.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyridostigmine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **atropine, diphenhydramine**): Concurrent use may reduce efficacy of both agents.
- **Beta-Blockers** (eg, **atenolol, propranolol**): May result in adverse effects in heart rate or blood pressure
- **Bethanechol**: Additive cholinergic effects (eg, salivation, diarrhea, micturition) are possible.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May decrease the anticholinesterase activity of pyridostigmine. After stopping corticosteroid therapy, drugs like pyridostigmine may cause increased anticholinesterase activity.
- **Dexpanthenol**: Theoretically, dexpanthenol may have additive effects when used with pyridostigmine.
- **Drugs With Neuromuscular Blocking Ability** (eg, **aminoglycoside antibiotics**): May necessitate increased dosages of pyridostigmine in treating or diagnosing myasthenic patients
- **Magnesium**: Parenteral magnesium can have a depressant effect on skeletal muscle, necessitating increased dosages of pyridostigmine.
- **Neuromuscular Blocking Agents, Depolarizing** (eg, **succinylcholine, decamethonium**): Pyridostigmine may prolong the phase I block of depolarizing muscle relaxants.
- **Neuromuscular Blocking Agents, NonDepolarizing** (eg, **pancuronium, tubocurarine, gallamine, vecuronium, atracurium**): Pyridostigmine antagonizes the actions of nondepolarizing neuromuscular blocking agents.
- **Quinidine**: Recurrent paralysis may occur when quinidine is administered during recovery from use of nondepolarizing neuromuscular blocking agents, necessitating increased dosages of pyridostigmine.

Laboratory Considerations

- None known

Dosages

DOGS:

Adjunctive treatment of myasthenia gravis (extra-label):

a) 0.2 – 2 mg/kg PO every 8 to 12 hours with food once able to swallow.[1] Practically, either round dose to nearest ¼ of a regular 60 mg tablet or use the oral liquid for more precise dosing. Dose should start low and be carefully titrated to effect to minimize adverse effects and maximize muscle strength.

b) 0.01 – 0.03 mg/kg/hour IV CRI for patients unable to swallow, especially in critically ill animals[1,2]

CATS:

Myasthenia gravis (extra-label): Rarely used but can be dosed similarly as dogs[3–7]

FERRETS:

Myasthenia gravis (extra-label): 1 mg/kg PO every 12 hours in combination with prednisolone[8]

Monitoring

- Animals should be routinely monitored for clinical signs of cholinergic toxicity (see ***Overdose/Acute Toxicity***) and efficacy of the therapy.

Client Information

- Give this medicine as directed by your veterinarian. It may be given with or without food but give the same way each time.
- Dosage adjustments may occur frequently early in the course of treatment, and periodically thereafter. Always follow your veterinarian's instructions. Do not change the amount you give your animal without speaking to your veterinarian first.
- Giving a dose too early or too late should be avoided. Discuss with your veterinarian if you are having difficulty giving the medication at the prescribed dosing interval.
- Contact your veterinarian if your animal has side effects such as excessive salivation, gastrointestinal disturbances (nausea, vomiting, diarrhea), weakness, or difficulty breathing.
- Overdoses can be very serious. Be sure to measure liquid doses very carefully.
- Keep this medicine out of reach of children and animals.

Chemistry/Synonyms

An anticholinesterase agent, pyridostigmine bromide is a synthetic quaternary ammonium compound that occurs as an agreeable smelling, bitter tasting, hydroscopic, white or practically white, crystalline powder. It is freely soluble in water and alcohol. The pH of the commercially available injection is ≈5.

Pyridostigmine bromide may also be known as pyridostigmini bromidum, *Distinon®*, *Gravitor®*, *Kalymin®*, *Mestinon®*, or *Regonol®*.

Storage/Stability

Unless otherwise instructed by the manufacturer, store pyridostigmine products at room temperature. The oral solution and injection should be protected from light and freezing. Pyridostigmine tablets should be kept in tight containers.

The extended-release tablets may become mottled with time, but this does not affect their potency.

Pyridostigmine injection is unstable in alkaline solutions. It contains 1% benzyl alcohol.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Pyridostigmine injection is reportedly physically **compatible** with glycopyrrolate, heparin sodium, hydrocortisone sodium succinate, potassium chloride, and vitamin B complex with C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Pyridostigmine Bromide Tablets: 60 mg; *Mestinon®*, generic, (Rx)

Pyridostigmine Bromide Extended-Release Tablets: 180 mg; *Mestinon®*, generic; (Rx)

Pyridostigmine Bromide Syrup: 12 mg/mL (labeled as 60 mg/5 mL) in 480 mL; *Mestinon®*; (Rx)

Pyridostigmine Bromide Injection: 5 mg/mL in 2 mL ampules; *Regonol®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pyridoxine

Vitamin B_6

(peer-ih-***dox***-een)

Nutritional B Vitamin; Antidote

Prescriber Highlights

- ► Pyridoxine may be beneficial in the treatment of isoniazid, crimidine, or hydrazine mushroom toxicity, delaying cutaneous toxicity of *Doxil®* (liposomal doxorubicin), or to supplement while patients are receiving penicillamine.
- ► Use caution when using in patients with renal insufficiency or are hypersensitive to pyridoxine.
- ► Overdoses may cause peripheral neuropathy.

Uses/Indications

Pyridoxine use in veterinary medicine is relatively infrequent. It may be of benefit in the treatment of isoniazid (INH) or crimidine (an older rodenticide) toxicity. Pyridoxine deficiency is extremely rare in dogs or cats that are able to ingest food. Cats with severe intestinal disease may have a greater requirement for pyridoxine in their diet. Experimentally, pyridoxine has been successfully used in dogs to reduce the cutaneous toxicity associated with doxorubicin containing pegylated liposomes (*Doxil®*). Pyridoxine has been demonstrated to suppress the growth of feline mammary tumors (cell line FRM) in vitro.

In humans, labeled uses for pyridoxine include pyridoxine deficiency and intractable neonatal seizures secondary to pyridoxine dependency syndrome.[1] Pyridoxine has also been used in humans for sideroblastic anemia associated with elevated serum iron levels. Unlabeled uses include premenstrual syndrome (PMS); carpal tunnel syndrome; tardive dyskinesia secondary to antipsychotic drugs; nausea and vomiting in pregnancy; hyperoxaluria type 1 and oxalate kidney stones; and for the treatment of INH, cycloserine, hydrazine, or *Gyromitra* mushroom poisonings.

Pharmacology/Actions

In erythrocytes, pyridoxine is converted to pyridoxal phosphate and, to a lesser extent, pyridoxamine, which serve as coenzymes for amino acid metabolism, as well as lipid and carbohydrate utilization. Pyridoxine is necessary for tryptophan conversion to serotonin or niacin, glycogen breakdown, heme synthesis, synthesis of GABA in the CNS, and oxalate conversion to glycine. Pyridoxine can act as an antidote by enhancing the excretion of cycloserine or isoniazid.

Pyridoxine requirements increase as protein ingestion increases, with carnivores having higher pyridoxine requirements than omnivores.

Pharmacokinetics

Pyridoxine is absorbed from the GI tract, primarily in the jejunum. Malabsorption syndromes can significantly impair pyridoxine absorption. Pyridoxine is not bound to plasma proteins, but pyridoxal phosphate is completely bound to plasma proteins. Pyridoxine is stored primarily in the liver, with smaller amounts stored in the brain and muscle. It is biotransformed in the liver and various other tissues and excreted almost entirely as metabolites into the urine. Elimination half-life in humans is ≈15 to 20 days.[1]

Contraindications/Precautions/Warnings

Weigh potential risks versus benefits in patients with documented sensitivity to pyridoxine. Parenteral pyridoxine solutions contain aluminum and prolonged use should be undertaken with caution in patients with renal impairment.

Adverse Effects

Pyridoxine is generally well tolerated unless doses are large (see ***Overdose/Acute Toxicity***). In humans, nausea and vomiting, headache, paresthesia, and somnolence have been reported with long-term use at high doses. Reduced serum folic acid levels have occurred. Worsening of metabolic acidosis has occurred following rapid infusion of large doses of pyridoxine injection, which has a pH of 2 to 3.8.

Reproductive/Nursing Safety

Pyridoxine crosses the placenta reaching concentrations 5 times higher in the fetus than in maternal plasma concentrations. Although pyridoxine is a nutritional agent and very safe at recommended doses during pregnancy, large doses during pregnancy can cause a pyridoxine dependency syndrome in neonates. Pyridoxine requirements increase during pregnancy.

Pyridoxine is excreted in breast milk. Pyridoxine administration at low dosages should be safe during nursing. Pyridoxine requirements of the dam may be increased during nursing.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Single overdoses are not considered overly problematic unless they are massive. Single doses of up to 1 g/kg are tolerated by dogs, rats, and rabbits. A dose of 1 g/kg caused ataxia in dogs, with recovery within 1 week. Laboratory animals given 3 – 4 g/kg developed seizures and died. Chronic excessive doses of pyridoxine have been associated with severe peripheral neuropathy. Beagles given 50 mg/kg/day developed no signs, although there was a bilateral loss of myelin in the dorsal nerve roots; 150 mg/kg/day caused ataxia, muscle weakness, and loss of balance after 40 to 75 days.[2,3] Beagles repeatedly given 3 g oral daily doses developed uncoordinated gait and neurologic signs. Neuronal lesions were noted in sensory, dorsal root ganglia, and trigeminal ganglia. Signs generally resolved over a 2-month drug-free period.[4,5]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyridoxine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Chloramphenicol**: May cause increased pyridoxine requirements
- **Estrogens**: May cause increased pyridoxine requirements
- **Hydralazine**: May cause increased pyridoxine requirements
- **Immunosuppressants** (eg, **azathioprine, chlorambucil, cyclophosphamide, corticosteroids**): May cause increased pyridoxine requirements
- **Isoniazid**: May cause increased pyridoxine requirements
- **Penicillamine**: May cause increased pyridoxine requirements
- **Phenobarbital, Primidone**: High-dose pyridoxine may decrease phenobarbital serum concentration.

Laboratory Considerations

- Urobilinogen in the spot test using Ehrlich reagent: Pyridoxine may cause false-positive results.
- AST: Excessive dosages of pyridoxine may elevate AST.

Dosages

DOGS/CATS:

Isoniazid (INH) toxicity in dogs (extra-label): If the quantity of INH ingested is known, give pyridoxine on an mg-for-mg (1:1) basis. If it is not known, give pyridoxine initially at 71 mg/kg as a 5% to 10% IV infusion over 30 to 60 minutes. (Some sources say it can be given as an IV bolus.) Pyridoxine injection can usually be obtained from human hospital pharmacies. Do not use injectable B-complex vitamins.[6–8]

Provide cofactors for the metabolism of toxic compounds, including ethylene glycol (extra-label): 1 – 2 mg/kg IV every 6 hours[9]

Replace pyridoxine antagonized by crimidine ingestion (extra-label): 20 mg/kg IV[10]

Adjunctive treatment (acute seizures) of hydrazine mushroom (*Gyromitra* spp) poisoning (extra-label): 75 – 150 mg/kg IV[11]

Supplementation while on penicillamine (extra-label): 25 mg/animal (NOT mg/kg) per day PO given concurrently with d-penicillamine to prevent pyridoxine depletion[10]

To delay the development of cutaneous toxicity (palmar-plantar erythrodysesthesia) associated with doxorubicin containing pegylated liposomes *(Doxil®)* in dogs (extra-label): 50 mg/animal (NOT mg/kg) PO 3 times daily during chemotherapy protocol period[12]

Interruption of lactation during pseudopregnancy in dogs (extra-label): 50 mg/kg PO once daily[13]

Monitoring

- Other than evaluating efficacy for its intended use, no significant monitoring is required.

Client Information

- Very safe; usually no side effects
- Do not give more medicine than your veterinarian has ordered.

Chemistry/Synonyms

Pyridoxine (vitamin B_6) is a water-soluble vitamin that is present in many foods (eg, liver, meat, eggs, cereals, legumes, and vegetables). The commercially available form (pyridoxine HCl) found in medications is obtained synthetically. Pyridoxine HCl occurs as white or practically white crystals or crystalline powder with a slightly bitter, salty taste. It is freely soluble in water and slightly soluble in alcohol.

Pyridoxine or vitamin B_6 may also be known by the following synonyms or analogues: adermine, pyridoxal, pyridoxal-5-phosphate, pyridoxamine, pirodoxamina, piridossima, piridoxolum, piridossina, *Aminoxin®*, and *Vitelle Nestrex®*.

Storage/Stability

Unless otherwise specified by the manufacturer, store pyridoxine tablets below 40°C (104°F), preferably between 15°C and 30°C (59°F-86°F), in well-closed containers protected from light.

Store pyridoxine HCl injection at 20°C to 25°C (68°F-77°F), protected from light and freezing.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Pyridoxine HCl injection can be administered undiluted or added to commonly used IV solutions. It is reportedly **compatible** with

ascorbic acid, atropine sulfate, buprenorphine, butorphanol, calcium salts, dexamethasone sodium phosphate, diphenhydramine, dobutamine, famotidine, glycopyrrolate, heparin sodium, lidocaine, magnesium sulfate, metoclopramide, midazolam, ondansetron, potassium chloride, and thiamine HCl.

It is reportedly **incompatible** with alkaline or oxidizing solutions, iron salts, and the following drugs (partial list): cefazolin, diazepam, furosemide, hydrocortisone sodium succinate, and methylprednisolone sodium succinate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No single ingredient pyridoxine products were located. There is a multitude of veterinary-labeled products that contain pyridoxine as one of several ingredients.

HUMAN-LABELED PRODUCTS:

Pyridoxine Tablets: 25 mg, 50 mg, 100 mg; generic; (OTC)

Pyridoxine HCl Injection: 100 mg/mL in 1 mL vials; generic; (Rx)

Pyridoxine is also an ingredient in many combination products (eg, B-Complex, multivitamins).

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Pyrilamine

(pye-***ril***-a-meen) *Histall*®

Antihistamine

Prescriber Highlights

- ► Used for allergic conditions in horses
- ► Use with caution in patients with narrow-angle glaucoma, prostatic hypertrophy, pyloroduodenal or bladder neck obstruction, or asthma.
- ► Adverse effects in horses include CNS stimulation (eg, nervousness, insomnia, convulsions, tremors, ataxia) or CNS depression (eg, sedation), palpitation, GI disturbances, muscle weakness, inappetence, and lassitude.

Uses/Indications

Pyrilamine is a first-generation antihistamine that may provide an alternative to glucocorticoids in managing allergic conditions in horses.

Pharmacology/Actions

Antihistamines competitively inhibit histamine at H_1 receptor sites. They do not inactivate or prevent the release of histamine but can prevent histamine's action on the cell. H_1 receptor antagonists also have varying degrees of anticholinergic activity and CNS effects such as sedation. Pyrilamine is considered to be less potent, cause less sedation, and have fewer anticholinergic effects than most other first-generation antihistamines.

Pharmacokinetics

The pharmacokinetics of this agent have not been extensively studied in cattle, dogs, or cats. In horses, pyrilamine is poorly bioavailable (18%) after oral administration. After IV administration, elimination half-life was ≈1.7 hours. After a single dose, the principal metabolite, *O*-desmethylpyrilamine (O-DMP), can be detected in urine for at least two days, and possibly up to one week after administration.[1]

Contraindications/Precautions/Warnings

Although there are no specific contraindications or precautions listed for pyrilamine, first-generation antihistamines should be used with caution in patients with narrow-angle glaucoma, prostatic hypertrophy, pyloroduodenal or bladder neck obstruction, and asthma due to their anticholinergic activity.

Adverse Effects

Adverse effects in horses can include CNS stimulation (eg, nervousness, insomnia, convulsions, tremors, ataxia), palpitation, temporary anhidrosis, GI disturbances, CNS depression (eg, sedation), muscular weakness, inappetence, and lassitude.

Reproductive/Nursing Safety

Rats and mice treated with 10 to 20 times the human dose had an increased frequency of embryonic, fetal, or perinatal death, but a study in pregnant women showed no increase in teratogenic or fetocidal rates. It is unknown if pyrilamine enters milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Treatment of overdoses is supportive and based on clinical signs. For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyrilamine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **heparin, warfarin**): Antihistamines may partially counteract the anticoagulation effects of heparin or warfarin.
- **CNS Depressants** (eg, **benzodiazepines, detomidine, methocarbamol**): Increased sedation can occur if pyrilamine is combined with other CNS depressant drugs.
- **Epinephrine**: Pyrilamine may enhance the effects of epinephrine.

Laboratory Considerations

- Antihistamines can decrease the wheal and flare response to antigen skin testing. In humans, it is suggested that antihistamines be discontinued at least 4 days before testing. In dogs, it is recommended to discontinue antihistamines a minimum of 2 days before testing, with 7 days being optimal.[2]

Dosages

HORSES:

Treatment of conditions in which antihistaminic therapy will alleviate clinical signs (label dosage; FDA-approved):

a) **Foals**: 0.44 mg/kg IV slowly every 6 to 12 hours as needed[3]

b) **Adult horses**: 0.88 – 1.3 mg/kg IV slowly every 6 to 12 hours as needed[3]

Antihistamine (label dosage; not FDA-approved): 0.66 mg/kg PO every 12 hours as needed.[4]

Monitoring

- Clinical efficacy
- Adverse effects

Chemistry/Synonyms

An ethylenediamine antihistamine, pyrilamine maleate occurs as a white, crystalline powder with a melting range of 99°C to 103°C (210°F-217.4°F). One gram is soluble in ≈0.5 mL of water or 3 mL of alcohol.

Pyrilamine maleate may also be known as pyranisamine hydrochloride, pyrilamine hydrochloride, mepyramine hydrochloride, mepyramini maleas, myranisamine maleate, myrilamine maleate, mepyramine maleate, *Anihist®*, *Alergitanil®*, *Antemesyl®*, *Anthisan®*, *Anthisan®*, *Equi-Phar® Equi-Hist®*, *Equiphed®*, *Fluidasa®*, *Histall®*, *Histagranules®*, *Histamed®*, *Mepyraderm®*, *Mepyrimal*, *Pyramine®*, *Pyripea®*, *Relaxa-Tabs®*, and *Tri-Hist®*.

Storage/Stability
Keep lid tightly closed and store in a dry place below 30°C (86°F).

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
NOTE: The marketing status of pyrilamine products changes frequently. Marketed products may not be FDA-approved for safe and effective use.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Pyrilamine Maleate Solution for Injection: 20 mg/mL; (Rx). This product is still listed in the FDA Green Book of approved animal drugs but is no longer commercially available.

Pyrilamine Granules: 600 mg/oz in 20 oz containers; *Histall®* (OTC). Labeled for use in horses

Pyrilamine is also available in combination with guaifenesin or pseudoephedrine:

Pyrilamine Maleate 600 mg/oz and Pseudoephedrine HCl 600 mg/oz Granules: 20 oz, 5 lb and 10 lb containers; *Tri-Hist® Granules* (Rx). Labeled for use in horses. Not for use in horses intended for food. **NOTE**: Pseudoephedrine regulations may vary by state. See ***Pseudoephedrine*** for more information.

Pyrilamine 600 mg/oz and Guaifenesin 2400 mg/oz Granules: 20 oz and 5 lb containers; *Anihist®*; (OTC). Labeled for use in horses

HUMAN-LABELED PRODUCTS:
Pyrilamine is available in OTC combination products marketed for allergies, cough, and colds.

For the complete list of references, see **wiley.com/go/budde/plumb**

Pyrimethamine
(pye-ri-***meth***-a-meen) *Daraprim®*
Antiprotozoal

NOTE: Also see the ***Pyrimethamine/Sulfadiazine*** and ***Sulfadiazine/Trimethoprim*** monographs

Prescriber Highlights
- ► Folic acid inhibitor used primarily in combination with a sulfonamide for toxoplasmosis, *Hepatozoon americanum,* neosporosis, and equine protozoal encephalomyelitis
- ► Contraindications include hypersensitivity to pyrimethamine, and hematologic disorders caused by folate deficiency.
- ► Adverse effects in small animals, which may be more severe in cats, include anorexia, malaise, vomiting, depression, and bone marrow depression (eg, anemia, thrombocytopenia, leukopenia); adverse effects in horses include leukopenias, thrombocytopenia, and anemias.
- ► Potentially teratogenic; avoid use in pregnancy
- ► Dosage form (25 mg tab only) may be inconvenient for accurate dosing; unpalatable to cats

Uses/Indications
Pyrimethamine is used to treat *Hepatozoon americanum* infections, canine neosporosis, and toxoplasmosis in small animals (often in combination with sulfonamides). In horses, it is approved, in combination with sulfadiazine, to treat equine protozoal myeloencephalitis.

In humans, pyrimethamine is used for the treatment of toxoplasmosis when used in combination with a sulfonamide[1]; drug resistance has rendered it ineffective as an anti-malarial agent.

Pharmacology/Actions
Pyrimethamine is a folic acid antagonist similar to trimethoprim. It acts by inhibiting dihydrofolate reductase, which catalyzes the conversion of dihydrofolic acid to tetrahydrofolic acid. It more readily binds to protozoal dihydrofolate reductase than the mammalian enzyme. The resulting depletion of folic acid impairs protozoal production of proteins and nucleic acids. Pyrimethamine has in vitro activity against *Toxoplasma gondii*; adding sulfadiazine can synergistically enhance activity.

Pharmacokinetics
Pyrimethamine administered to adult horses at 1 mg/kg IV or PO for 1 dose and 1 mg/kg PO once daily for 10 days resulted in oral bioavailability ≈55%. Food, including alfalfa hay, may reduce pyrimethamine absorption by up to 50%. Steady-state plasma concentrations were reached within 5 days, with CSF concentrations 25% to 50% of plasma values. The steady-state volume of distribution was ≈1.5 L/kg, and the elimination half-life was 12 hours.[2,3]

In humans, pyrimethamine is well absorbed from the gut after oral administration. It is distributed primarily to the kidneys, liver, spleen, and lungs but does cross the blood–brain barrier. It has a volume of distribution of ≈3 L/kg and is 80% bound to plasma proteins. Pyrimethamine enters milk in concentrations greater than those found in serum and can be detected in milk up to 48 hours after dosing. In humans, plasma half-life is ≈3 to 5 days. It is metabolized at least in part by the liver, and metabolites are found in the urine.

Contraindications/Precautions/Warnings
Pyrimethamine is contraindicated in patients that are hypersensitive to it and in patients with pre-existing hematologic disorders caused by folate deficiency. Pyrimethamine has a narrow therapeutic window; reduce the dose or discontinue if signs of folate deficiency develop. Use pyrimethamine with caution in patients with pre-existing folate deficiency or that have hepatic or renal impairment.[1] Some clinicians recommend avoiding pyrimethamine in cats because of its

adverse effect profile.

In humans with seizure disorders, it is recommended to initiate therapy at a lower dose to avoid potential CNS toxicity.

Adverse Effects

In small animals, anorexia, malaise, vomiting, depression, and bone marrow depression (eg, anemia, thrombocytopenia, leukopenia) have been seen. Adverse effects may be more prominent in cats and noted 4 to 6 days after starting combination therapy. Some clinicians recommend avoiding its use in this species. Hematologic effects can develop rapidly, and frequent monitoring is recommended, particularly if therapy persists longer than 2 weeks. Administration of folinic acid (leucovorin) has been suggested to alleviate adverse hematologic effects.

The drug is unpalatable to cats when mixed with food, and the 25 mg tablet dosage size makes accurate dosing a challenge.

In horses, pyrimethamine has caused leukopenias, thrombocytopenia, and anemias when used in combination with sulfonamides.

In humans, hypersensitivity reactions have been reported, including Stevens-Johnson syndrome and toxic epidermal necrolysis. Other reported adverse effects in humans include megaloblastic anemia, thrombocytopenia, neutropenia, hematuria, and cardiac rhythm disorders.[1]

Reproductive/Nursing Safety

In stallions, pyrimethamine did not affect semen quality or sperm production, but physical performance (eg, mounting, thrusting, ejaculatory force) was adversely impacted.[4] Pyrimethamine has been demonstrated to be teratogenic in rats. Fetal abnormalities have been seen in foals after mares have been treated; however, it has been used in treating women with toxoplasmosis during pregnancy. Clearly, the risks associated with therapy must be weighed against the potential for toxicity, the severity of the disease, and any alternative therapies available (eg, clindamycin in small animals). Concomitant administration of folinic acid has been recommended (strongly recommended for humans) if the drug is to be used during pregnancy by some clinicians, but others state that pregnant mares should not receive folic acid during therapy, as it may exacerbate fetal abnormalities or mortality.[5]

Pyrimethamine is excreted in maternal milk; consider using milk replacer.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Reports of acute overdose of pyrimethamine in animals were not located. In humans, vomiting, nausea, anorexia, CNS stimulation (including seizures), and hematologic effects can be seen. Neurologic effects may occur within a few hours. Recommendations for treatment include GI decontamination, parenteral benzodiazepines (eg, midazolam) for seizures, folinic acid for hematologic effects, and long-term monitoring (at least 1 month) of renal and hematopoietic systems.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyrimethamine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Dapsone**: May increase the risk for myelosuppression
- **Folic Acid**: May reduce pyrimethamine efficacy
- **Methotrexate**: Antifolate effects may be additive, increasing the risk of myelosuppression
- **Sulfonamides** (eg, **sulfadiazine, sulfadimethoxine**): Pyrimethamine is synergistic with sulfonamides in activity against toxoplasmosis (and malaria).
- **Trimethoprim**: Use with pyrimethamine/sulfa is not recommended in humans, as adverse effects may be additive. Although this combination has been used clinically in horses, it is currently not recommended as trimethoprim competitively inhibits pyrimethamine, thus decreasing the efficacy of the more effective dihydrofolate reductase inhibitor.[6]
- **Zidovudine**: May reduce pyrimethamine efficacy; also may increase the risk for myelosuppression

Laboratory Considerations

- Pyrimethamine may cause inaccurate results for vitamin B_{12} and folic acid blood assays.

Dosages

DOGS:

Toxoplasmosis (extra-label): Pyrimethamine 0.25 – 0.5 mg/kg twice daily plus a sulfonamide 30 mg/kg twice daily for 2 to 4 weeks to treat disseminated toxoplasmosis and to reduce oocyst shedding[7]

Hepatazoon americanum (extra-label): Pyrimethamine 0.25 mg/kg PO every 24 hours in combination with trimethoprim/sulfadiazine 15 mg/kg PO every 12 hours and clindamycin 10 mg/kg every 8 hours. Once remission is attained, decoquinate 15 mg/kg mixed in food every 12 hours for 2 years can maintain a disease-free interval.[8,9]

Canine neosporosis (extra-label): Pyrimethamine 1 mg/kg PO every 24 hours for 4 weeks in combination with trimethoprim/sulfadiazine 15 – 20 mg/kg PO every 12 hours for 4 weeks. If observable clinical improvement is slow, treatment should be extended beyond the recommended 4 weeks until 2 weeks after clinical signs have plateaued. All littermates of affected puppies should be treated regardless of clinical signs.

CATS:

NOTE: See ***Contraindications/Precautions/Warnings*** above.

Toxoplasmosis (extra-label):

a) For disseminated toxoplasmosis, pyrimethamine 0.25 – 0.5 mg/kg PO twice daily with a sulfonamide 30 mg/kg PO twice daily for 2 to 4 weeks can be used to treat disseminated toxoplasmosis and to reduce oocyst shedding.[7]

b) In critical cases of pulmonary toxoplasmosis, pyrimethamine 0.25 – 0.5 mg/kg PO every 12 hours in combination with clindamycin 12.5 mg/kg PO once daily (follow with food or water) may be a better option than using clindamycin alone, especially in cats immunosuppressed with cyclosporine.[11]

HORSES:

See ***Pyrimethamine/Sulfadiazine.***

BIRDS:

Coccidian organisms in raptors (extra-label): 0.5 mg/kg PO twice daily for 14 to 28 days (especially effective against toxoplasmosis, atoxoplasmosis, and sarcocystis)[12]

Monitoring

- CBC with platelet count
- Adverse effects (eg, GI signs, malaise, depression)
- Clinical efficacy

Client Information

- For dogs, cats, and birds, this medicine can be given with or with-

out food. It is unpleasant tasting if mixed into food.
- Cats may be more likely to develop side effects while on this drug; use with caution.
- Side effects include vomiting, lack of appetite, depression/malaise (tiredness/lack of energy), and bone marrow depression. If bleeding, extreme tiredness/lack of energy, infection, or fever are seen, contact veterinarian right away.
- Pregnant women should handle this drug very carefully.
- While your animal is taking this medication, it is important to return to your veterinarian for blood tests. Do not miss these important follow-up visits.

Chemistry/Synonyms
Pyrimethamine, an aminopyrimidine agent structurally related to trimethoprim, occurs as an odorless, white, or almost white crystalline powder or crystals. It is practically insoluble in water and slightly soluble in alcohol.

Pyrimethamine may also be known as BW-50-63, pirimetamina, pyrimethaminum, RP-4753, *Daraprim*®, *Malocide*®, or *Pirimecidan*®.

Storage/Stability
Store pyrimethamine tablets at 15°C to 25°C (59°F-77°F) in tight, light-resistant containers.

Compatibility/Compounding Considerations
Pyrimethamine tablets may be crushed to make oral suspensions of the drug. Although stable in an aqueous solution, sugars tend to adversely affect the stability of pyrimethamine. If cherry syrup, corn syrup, or sucrose-containing liquids are used in the preparation of the suspension, it is recommended to store the suspension at room temperature and discard it after 7 days.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Pyrimethamine Tablets: 25 mg; *Daraprim*®; (Rx)

Pyrimethamine/Sulfadiazine
(pye-ri-***meth***-a-meen/sul-fa-***dye***-a-zeen) *ReBalance*®
Antiprotozoal

Prescriber Highlights
- ► Combination antiprotozoal labeled for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona.*
- ► Use with caution in patients with pre-existing hematologic abnormalities, renal or hepatic dysfunction, or patients with folate deficiency.
- ► Adverse effects include myelosuppression, GI effects, and worsening of neurologic signs after beginning therapy (treatment crisis).
- ► Daily treatment may be required for 3 to 9 months.

Uses/Indications
Pyrimethamine/sulfadiazine is FDA-approved in horses for the treatment of equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*. Anecdotally, some combine pyrimethamine/sulfadiazine with ponazuril or diclazuril when treating relapsing EPM.

Although not labeled for use in small animal species, it potentially could be used for treating protozoal infections, such as toxoplasmosis, in cats or neosporosis in dogs.

Pharmacology/Actions
Pyrimethamine is a dihydrofolate reductase inhibitor that blocks the conversion of dihydrofolic acid (DFA) to tetrahydrofolic acid by inhibiting dihydrofolate reductase. Sulfonamides inhibit the conversion of para-aminobenzoic acid (PABA) to DFA by competing with PABA for dihydropteroate synthase binding sites. Sulfonamides and dihydrofolate reductase inhibitors are synergistic when used together. Although trimethoprim is more active than pyrimethamine against bacterial dihydrofolate reductase, pyrimethamine is more active against protozoal dihydrofolate reductase.

When used as labeled for EPM in horses, the estimated success rate is 60% to 70%, with a 10% estimated relapse rate.[1]

Pharmacokinetics
No specific pharmacokinetic information was located for this drug combination and dosage form (oral suspension) in horses. Previous reports in horses using other dosage forms reported pyrimethamine oral bioavailability as ≈56% and elimination half-life of ≈12 hours. Food, including alfalfa hay, may reduce pyrimethamine absorption by up to 50%. CNS concentrations are ≈25% to 50% of those found in plasma.[2,3]

Sulfadiazine is well absorbed after oral administration to horses. It has a volume of distribution of ≈0.58 L/kg and distributes into the CSF. Sulfonamides are metabolized via acetylation and other pathways and are primarily removed via the kidneys, with an elimination half-life of ≈3 to 4 hours.

Contraindications/Precautions/Warnings
Pyrimethamine/sulfadiazine is contraindicated in horses that are hypersensitive to either drug. Do not use in horses intended for human consumption.[4]

Use with caution in horses with pre-existing hematologic abnormalities due to the potential for myelosuppression. Use cautiously in patients with renal or hepatic impairment, or those with folate deficiency. EPM should be distinguished from other ataxic conditions prior to beginning treatment with pyrimethamine/sulfadiazine.[4]

Adverse Effects
Adverse effects reported in horses include reversible myelosuppression (eg, anemia, leukopenia, neutropenia, thrombocytopenia), reduced appetite or anorexia, loose stools/diarrhea, and urticaria.[4] CNS effects such as seizures and depression are also possible but are more likely signs of EPM.

Baker's yeast or folinic acid have been suggested to antagonize the drug combination's myelosuppressive effects, but evidence of efficacy is lacking.

Neurologic signs may worsen (treatment crisis) during the first few days of treatment and may persist up to 5 weeks.[4] This may be the result of an inflammatory reaction secondary to dying parasites in the central nervous system.

Reproductive/Nursing Safety
The safe use of pyrimethamine/sulfadiazine combination in horses for breeding purposes, during pregnancy, or in lactating mares has not been evaluated.[4]

Pyrimethamine has been demonstrated to be teratogenic in rats,[5] and fetal abnormalities have been seen in foals following treatment of pregnant mares[6]; however, it has been used to treat pregnant women with toxoplasmosis when the benefits outweigh the risks.[5] Similarly, in horses, risks associated with therapy must be weighed against the potential for toxicity, the severity of the disease, and any alternative therapies available. Some clinicians have recommended concomitant administration of folinic acid if pyrimethamine is to be used during pregnancy, but others state that pregnant mares should not receive folic acid during therapy as it may exacerbate fetal abnormalities or mortality.[7] Additionally, pyrimethamine may adversely impact the

physical performance (eg, mounting, thrusting, ejaculatory force) of stallions.[8]

Sulfonamides cross the placenta and fetal serum concentrations may be up to 50% of that found in maternal serum. Teratogenicity has been reported in some laboratory animals when given at high doses. Sulfonamides should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

Pyrimethamine and sulfonamides are distributed into milk. Safety for nursing offspring has not been established[4]; consider using milk replacer.

Overdose/Acute Toxicity

Acute overdose information for pyrimethamine/sulfadiazine in horses was not located. At 2 times the label dose for 92 days in 49 horses, signs included loose stools, slight increases in ALP in some horses, declines in RBC, HCT, Hgb, and PCV, and decreased appetite.[4]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The safety of pyrimethamine/sulfadiazine has not been evaluated with concomitant therapies in horses. In humans, the following drug interactions with pyrimethamine and/or sulfonamides have been reported or are theoretical and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids**: May decrease the bioavailability of sulfonamides if administered concurrently
- **Cyclosporine**: May decrease cyclosporine effectiveness
- **Highly Protein-Bound Drugs** (eg, **methotrexate, phenylbutazone, thiazide diuretics, salicylates, probenecid, phenytoin, warfarin**): Because sulfonamides are highly bound to plasma proteins, they could theoretically displace other highly bound drugs causing a transient increase in serum concentrations of each drug. These interactions are unlikely to be of clinical concern because increased free drug concentrations will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.
- **Para-Aminobenzoic Acid (PABA)**: PABA is reportedly antagonistic towards the activity of pyrimethamine; the clinical significance is unclear.
- **Trimethoprim**: Use with pyrimethamine/sulfadiazine is not recommended as adverse effects may be additive. Although this combination has been used clinically in horses, it is not recommended as trimethoprim competitively inhibits pyrimethamine, thus decreasing the efficacy of the more effective dihydrofolate reductase inhibitor.[1]
- **Warfarin**: Sulfonamides may potentiate the effects of warfarin.

Laboratory Considerations

The following laboratory alterations have been reported in humans taking sulfonamides or pyrimethamine and may be of significance in veterinary patients.

- Urine glucose: Sulfonamides may give false-positive results when using Benedict's method.
- Vitamin B_{12} and folic acid: Pyrimethamine may cause inaccurate results for blood assays.

Dosages

HORSES:

Equine protozoal myeloencephalitis (EPM) (label dosage; FDA-approved): Pyrimethamine 1 mg/kg and sulfadiazine 20 mg/kg PO once daily, at least 1 hour before feeding with hay or grain.[4] Treatment duration is based upon clinical response but typically ranges from 90 to 270 days.

Monitoring

- Baseline and monthly CBC with platelets
- GI adverse effects
- Clinical efficacy, including improvement in neurologic signs and negative CSF Western Blot test

Client Information

- Shake this medicine well before each use.
- Give this medicine at least 1 hour before feeding with hay or grain.
- Use an oral dosing syringe to give this medicine to your horse. Place the tip of the syringe in the interdental space (entering side of the mouth behind front teeth) and apply the dose on the back of the tongue.
- During the first few days of treatment, neurologic signs (eg, weakness, trouble walking) may get worse and may last up to 5 weeks. These signs may be due to inflammation caused by dying parasites.
- Side effects include loose stools, diarrhea, reduced appetite, and itching.
- This medicine can put your horse at risk for developing infections. Contact your veterinarian immediately if you notice bleeding, extreme tiredness or lack of energy, fever, or other signs of infection.

Chemistry/Synonyms

Pyrimethamine is an aminopyrimidine agent structurally related to trimethoprim. It occurs as an odorless, white, or almost white crystalline powder or crystals. It is practically insoluble in water and slightly soluble in alcohol.

Sulfadiazine occurs as an odorless or nearly odorless, white to slightly yellow powder. It is practically insoluble in water and sparingly soluble in alcohol.

Sulfadiazine and Pyrimethamine may also be known as *ReBalance®*. Sulfadoxine and pyrimethamine may also be known as *Fansidar®*.

Storage/Stability

Store suspension at controlled room temperature (20°C-25°C [68°F-77°F]), with excursions permitted between 15°C and 30°C (59°F- 86°F) and protected from light and freezing.[4]

Quinacrine

(***qwin***-a-krin)

Antiprotozoal

Prescriber Highlights

- ► May be used for treatment of a variety of protozoans and helminths
- ► Use should be avoided in patients with hepatic dysfunction.
- ► Adverse effects include benign yellowing of skin and urine, GI effects (eg, anorexia, nausea, vomiting, diarrhea), abnormal behaviors (eg, fly biting, agitation), lethargy, pruritus, and fever.
- ► Give with meals; ensure plenty of water is available.
- ► Not commercially available in the United States

Uses/Indications

Quinacrine has activity against a variety of protozoans and helminths; however, it is no longer available in the United States. Newer, safer, or more effective agents have largely replaced its use in small animal species, except as an alternative treatment for *Giardia* spp or *Trichomonas* spp.

In humans, quinacrine is an antimalarial drug that has been used for treatment of mild to moderate discoid lupus erythematosus.

Pharmacology/Actions

Quinacrine's mechanism of action for its antiprotozoal activity against *Giardia* spp is not understood; however, it is known that it binds to DNA by intercalation to adjacent base pairs, thereby inhibiting RNA transcription and translocation. Additionally, quinacrine interferes with electron transport and inhibits succinate oxidation and cholinesterase. Quinacrine binds to nucleoproteins that, in humans, can suppress lupus erythematosus cell factor.

Pharmacokinetics

Quinacrine is absorbed well from the GI tract or after intrapleural administration. It is distributed throughout the body, but CSF concentrations are only 1% to 5% of those found in plasma. Quinacrine is concentrated in the liver, spleen, lungs, and adrenals. It is relatively highly bound to plasma proteins in humans (80% to 90%).

Quinacrine is metabolized slowly and eliminated slowly, primarily by the kidneys. Its half-life in humans ranges from 5 to 14 days. Acidifying the urine may increase renal excretion. Significant amounts may be detected in urine up to 2 months after drug discontinuation.

Contraindications/Precautions/Warnings

Use quinacrine with extreme caution in patients with hepatic dysfunction. In humans, quinacrine is relatively contraindicated in patients with psychotic disorders, psoriasis, or porphyria, as it may exacerbate these conditions; relevance for veterinary patients is unknown.

Do not confuse quinaCRINE with quiniDINE. Consider writing part of the drug's name in uppercase letters (tall-man designations) on prescriptions/orders to reduce the risk for errors.

Adverse Effects

In small animal species, a benign yellowing of skin and urine color can occur; yellowing does not indicate jaundice. GI disturbances (eg, anorexia, nausea, vomiting, diarrhea), abnormal behaviors (eg, fly biting, agitation), lethargy, pruritus, and fever have also been noted.

In humans, hypersensitivity reactions, hepatopathy, aplastic anemia, corneal edema, and retinopathy have rarely been reported, primarily with high-dose, long-term use.

Reproductive/Nursing Safety

Quinacrine crosses the placenta and has been implicated in causing a case of renal agenesis and hydrocephalus in a human infant. In high doses, it has caused increased fetal death rates in rats. Quinacrine enters maternal milk in only small amounts. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Severity of overdose is dose dependent. In humans, a dose as low as 6.8 g administered intraduodenally was fatal. Clinical signs associated with acute toxicity include CNS excitation (including seizures), GI disturbances, vascular collapse, and cardiac arrhythmias. Treatment consists of GI decontamination protocol, and supportive and symptomatic therapies. Urinary acidification with ammonium chloride and forced diuresis with adequate fluid therapy may enhance urinary excretion of the drug.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving quinacrine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Ethanol**: Quinacrine may cause a disulfiram-reaction if used with alcohol.
- **Hepatotoxic Drugs** (eg, **androgens, azole antifungals, estrogens, NSAIDs**): Quinacrine concentrates in the liver and should be used cautiously with other hepatotoxic drugs.
- **Primaquine**: Quinacrine increases the toxicity of primaquine; use together is contraindicated.

Laboratory Considerations

- Quinacrine may cause acidic urine to turn a deep yellow color.
- Quinacrine can cause falsely elevated values of plasma and urine cortisol values by causing an interfering fluorescence.

Dosages

DOGS:

Last-line drug for treatment of *Giardia* spp or other susceptible protozoa (extra-label): 6.6 mg/kg PO every 12 hours for 5 days[1,2]

CATS:

Last-line drug for treatment of *Giardia* spp (extra-label): 9 mg/kg PO once daily for 6 days[1,2]

Last-line drug for treatment of *Coccidia* spp (extra-label): 10 mg/kg PO once daily for 5 days[1,2]

REPTILES:

Hemoprotozoal infections (extra-label): 19 – 100 mg/kg PO every 48 hours for 2 to 3 weeks[3]

Monitoring

- Fecal examinations
- Efficacy: resolution of clinical signs associated with infection being treated
- Adverse effects

Client Information

- Give this medicine after meals with access to plenty of fresh water to drink.
- Watch for signs of adverse effects, including vomiting, diarrhea, decreased appetite, abnormal behaviors, low-energy level, itching, or fever.
- Yellowing of skin or urine is due to the dye characteristics of quin-

acrine and is not serious. However, you should contact your veterinarian if yellowing of the eyes occurs.

Chemistry/Synonyms
Quinacrine is a synthetic acridine derivative anthelmintic that occurs as a bright-yellow, odorless, crystalline powder and has a bitter taste. It is sparingly soluble in water.

Quinacrine HCl may also be known as mepacrine HCl, acrichinum, or acrinamine.

Storage/Stability
Tablets should be stored in tight, light-resistant containers at room temperature. Quinacrine is not stable in solution for any length of time; however, it may be crushed and mixed with foods to mask its very bitter taste.

Compatibility/Compounding Considerations
No specific information noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

There currently are no quinacrine products being marketed in the United States. It may be available from compounding pharmacies.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Quinidine
(***qwin***-i-deen)

Antiarrhythmic (Systemic Drug)

Prescriber Highlights
- ► Antiarrhythmic agent used in horses and, less commonly, in small animals
- ► Contraindications include hypersensitivity, myasthenia gravis, complete AV block with an AV junctional or idioventricular pacemaker, intraventricular conduction defects, digitalis intoxication with associated arrhythmias or AV conduction disorders, aberrant ectopic impulses, and abnormal rhythms secondary to escape mechanisms.
- ► Use extreme caution with any form of AV block or any clinical signs of digoxin toxicity.
- ► Use caution with uncorrected hypokalemia, hypoxia, or acid-base imbalances; hepatic or renal insufficiency; congestive heart failure.
- ► Adverse effects in dogs include GI effects, weakness, hypotension (especially with too rapid IV administration), negative inotropism, widened QRS complex and QT intervals, AV block, and multiform ventricular tachycardias and hypotension.
- ► Adverse effects in horses include inappetence, depression, swelling of the nasal mucosa, ataxia, diarrhea, colic, hypotension, and, rarely, laminitis, paraphimosis, and the development of urticarial wheals; cardiac arrhythmias including AV block, circulatory collapse, and sudden death.
- ► Consider monitoring blood concentrations.
- ► Administer at evenly spaced intervals throughout the day and night.
- ► Many possible drug interactions, including some with significant risk for patient harm

Uses/Indications
Quinidine is used in equine medicine for medical cardioconversion of atrial fibrillation. In small animals it is used for the treatment of ventricular arrhythmias (PVCs, ventricular tachycardia), refractory supraventricular tachycardias, and supraventricular arrhythmias associated with anomalous conduction in Wolff-Parkinson-White (WPW) syndrome. Long-term use of quinidine for controlling ventricular arrhythmias and supraventricular tachycardia in dogs has diminished over the years as other drugs appear to be more effective. It is still used in dogs and horses to convert atrial fibrillation to sinus rhythm. One retrospective study in horses found quinidine to be more effective than flecainide at achieving cardioversion in horses with naturally occurring, recent-onset atrial fibrillation.[1] Oral therapy is generally not used in cats.

Pharmacology/Actions
Quinidine is a class IA antiarrhythmic, which has effects similar to that of procainamide. It blocks the fast sodium channels during the depolarization of the action potential (phase 0). It depresses myocardial excitability, conduction velocity, and contractility. Quinidine prolongs the duration of the action potential and the effective refractory period, which prevents the reentry phenomenon and increases conduction times. Quinidine also possesses anticholinergic activity, which decreases vagal tone and may facilitate AV conduction.

Pharmacokinetics
After oral administration, quinidine salts are nearly completely absorbed from the GI tract; however, the amount that reaches systemic circulation is reduced due to the hepatic first-pass effect. The extended-release formulations of quinidine sulfate and gluconate, as well as the polygalacturonate tablets, are more slowly absorbed than the conventional tablets or capsules.

Quinidine is distributed rapidly to all body tissues except the brain. Protein binding varies from 82% to 92%. The reported volumes of distribution in various species are as follows: dogs, ≈2.9 L/kg; cats, ≈2.2 L/kg; horses, ≈15.1 L/kg; and cattle, ≈3.8 L/kg. Quinidine is distributed into milk and crosses the placenta.

Quinidine is metabolized in the liver, primarily by hydroxylation. Approximately 20% of a dose may be excreted unchanged in the urine within 24 hours of dosing. Serum half-lives reported in various species are as follows: dogs, ≈5.6 hours; cats, ≈1.9 hours; horses, ≈8.1 hours; cattle, ≈2.3 hours; swine, ≈5.5 hours; and goats, ≈0.9 hours. Acidic urine (pH less than 6) can increase renal excretion of quinidine and decrease its serum half-life.

Contraindications/Precautions/Warnings
Quinidine is generally contraindicated in patients that have demonstrated previous hypersensitivity reactions to it, or in patients with myasthenia gravis, complete AV block with an AV junctional or an idioventricular pacemaker, intraventricular conduction defects (especially with pronounced QRS widening), digitalis intoxication with associated arrhythmias or AV conduction disorders, aberrant ectopic impulses, or abnormal rhythms secondary to escape mechanisms. It should be used with extreme caution, if at all, in any form of AV block or if any clinical signs of digitalis toxicity are exhibited. In humans, mortality associated with the use of quinidine was 3 times higher than placebo when quinidine was used to prevent recurrence of atrial flutter/fibrillation. Mortality associated with quinidine was also higher than other antiarrhythmics when used for various non-life–threatening ventricular arrhythmias.[2,3] The significance of these findings for veterinary patients is unclear.

Quinidine should be used with caution in patients with uncorrected hypokalemia, hypoxia, and acid-base imbalances. Quinidine and other class IA antiarrhythmics prolong the QT interval, which can potentially lead to torsades de pointes. In humans, this risk is increased in patients with hypokalemia, hypomagnesemia, or high quinidine concentrations. In humans with sick sinus syndrome, sinus node depression and bradycardia can occur. Use quinidine cautiously in patients with hepatic or renal insufficiency, as accumulation of the drug and subsequent toxicity may result. Use quinidine with caution in patients with congestive heart failure, as apparent

volume of distribution is reduced, which can lead to quinidine toxicity. Consider dose reduction.[2,3]

Quinidine has many significant drug interactions; see ***Drug Interactions***.

When using quinidine to cardiovert horses with atrial fibrillation, monitor the ECG throughout treatment. Indicators to discontinue medication include heart rates above 80 bpm, a widening of QRS beyond 125% of baseline, and abnormal complexes.[4]

Adverse Effects

In dogs, GI effects may include anorexia, vomiting, or diarrhea. Effects related to the cardiovascular system can include weakness, hypotension (especially with too rapid IV administration), negative inotropism, widened QRS complex and QT intervals, AV block, and multiform ventricular tachycardias.

In horses, inappetence and depression are commonly seen after quinidine therapy, but this does not necessarily indicate toxicity. Signs of toxicity can include swelling of the nasal mucosa; ataxia; diarrhea; colic; ventricular rate exceeding 120 bpm; QRS broadening by 25% of baseline or more; hypotension; and, rarely, laminitis, paraphimosis, and the development of urticarial wheals. Urticaria or upper respiratory tract obstruction can be treated, if required, by discontinuing the drug and administering corticosteroids. If obstruction persists, nasotracheal tube placement or tracheostomy may be required. Horses may develop cardiac arrhythmias including AV block, circulatory collapse, and sudden death.

Patients exhibiting signs of toxicity or lack of response may be candidates for therapeutic serum monitoring. The therapeutic range is thought to be 2.5 to 5 µg/mL in dogs. Quinidine concentrations above 5 µg/mL are associated with adverse effects.[5]

Reproductive/Nursing Safety

No animal data were located. In humans, quinidine crosses the placenta; maternal and fetal quinidine concentrations are roughly equivalent.[6]

Quinidine is excreted into maternal milk with a milk to serum ratio of ≈0.71. Use caution when quinidine is administered to nursing patients. The American Academy of Pediatrics considers quinidine compatible with breastfeeding.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs of overdose can include depression, hypotension, lethargy, confusion, seizures, vomiting, diarrhea, and oliguria. Cardiac signs may include depressed automaticity and conduction, or tachyarrhythmias. The CNS effects are often delayed after the onset of cardiovascular effects but may persist after the cardiovascular effects have begun to resolve.

If the overdose was from a recent oral ingestion, GI decontamination may be beneficial to remove any unabsorbed drug. IV fluids, plus metaraminol or norepinephrine, can be considered to treat hypotensive effects. Digoxin has been recommended for treating quinidine-induced profound hypotension or supraventricular tachycardia (more than 200 bpm) in horses.[7] A 1/6 molar IV infusion of sodium lactate may be used in an attempt to reduce the cardiotoxic effects of quinidine. Forced diuresis using fluids and diuretics along with urinary acidification may enhance the renal excretion of the drug. Temporary cardiac pacing may be necessary should severe AV block occur. Hemodialysis will effectively remove quinidine, but peritoneal dialysis will not.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving quinidine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetazolamide**: May reduce quinidine clearance
- **Amiodarone**: May significantly increase quinidine concentrations and risk for cardiotoxicity
- **Antacids, Aluminum-, Calcium-, or Magnesium-Containing**: May delay oral absorption; separate dosages
- **Anticholinesterases** (eg, **pyridostigmine, neostigmine**): Quinidine may antagonize the effects of anticholinesterases in patients with myasthenia gravis.
- **Antihypertensive Agents** (eg, **amlodipine, enalapril, sildenafil, telmisartan**): Quinidine may potentiate hypotensive effects.
- **Aurothioglucose**: Increased risk for blood dyscrasias
- **Azole Antifungals** (eg, **fluconazole, itraconazole, ketoconazole**): Increased risk for cardiotoxicity. Combination contraindicated in humans
- **Cimetidine**: Cimetidine may increase the concentrations of quinidine by inhibiting hepatic microsomal enzymes.
- **Cisapride**: Increased risk for QTc interval prolongation
- **Colchicine**: Quinidine may increase colchicine concentrations.
- **Dexamethasone**: In dogs, dexamethasone increased quinidine volume of distribution (49% to 78%) and elimination half-life (1.5 to 2.3 times).[8]
- **Digoxin**: Digoxin concentrations may increase considerably in patients stabilized on digoxin that receive quinidine. Some cardiologists recommend decreasing the digoxin dose by ½ when adding quinidine. Therapeutic drug monitoring of both quinidine and digoxin may be warranted in these cases. Digoxin has been recommended for treating quinidine-induced profound hypotension or supraventricular tachycardia (more than 200 bpm) in horses.[7]
- **Diltiazem**: Possible decreased clearance; increased elimination half-life of quinidine. Diltiazem has been recommended for treating quinidine-induced profound hypotension or supraventricular tachycardia (more than 200 bpm) in horses.[7]
- **Doxorubicin**: Concurrent use may increase doxorubicin exposure.
- **Hydroxyzine**: Concurrent use may increase the risk for QT interval prolongation.
- **Fluoroquinolone Antibiotics** (eg, **ciprofloxacin, enrofloxacin**): Increased risk for cardiotoxicity
- **Lidocaine, Mexiletine**: Concurrent use may increase risk for cardiotoxicity.
- **Macrolide Antibiotics** (eg, **clarithromycin, erythromycin**): Concurrent use may increase risk for cardiotoxicity.
- **Methadone**: Concurrent use may increase risk for QT interval prolongation.
- **Metronidazole**: Concurrent use may increase risk for QT interval prolongation.
- **Morphine**: Concurrent use may increase morphine exposure.
- **Neuromuscular Blocking Agents** (eg, **succinylcholine, tubocurarine, atracurium**): Quinidine may increase the neuromuscular blocking effects of these drugs.
- **Ondansetron**: Concurrent use may increase risk for QT interval prolongation.

- **Paroxetine**: Concurrent use may increase paroxetine plasma concentrations and risk for paroxetine toxicity.
- **Phenobarbital, Primidone**: May induce hepatic enzymes that metabolize quinidine, thus reducing quinidine serum half-life by 50%
- **Phenothiazines** (eg, **acepromazine**): Additive cardiac depressant effects may be seen.
- **Procainamide**: Concurrent use may increase risk for cardiotoxicity.
- **Rifampin**: May induce hepatic enzymes that metabolize quinidine, thus reducing quinidine serum half-life by 50%
- **Sotalol**: Concurrent use may increase risk for QT interval prolongation.
- **Trazodone**: Concurrent use may increase risk for QT interval prolongation.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine, doxepin, imipramine**): Increased risk for QTc interval prolongation and tricyclic adverse effects
- **Urinary Acidifiers** (eg, **methionine, ammonium chloride**): Drugs that acidify the urine may increase the excretion of quinidine and decrease serum concentration.
- **Urinary Alkalinizers** (eg, **carbonic anhydrase inhibitors, thiazide diuretics, sodium bicarbonate, antacids**): Drugs that alkalinize the urine may decrease the excretion of quinidine, prolonging its half-life.
- **Verapamil**: Possible decreased clearance; increased elimination half-life of quinidine; increased risk for hypotension
- **Vincristine**: Concurrent use may increase vincristine plasma concentrations.
- **Warfarin**: Coumarin anticoagulants with quinidine may increase the likelihood of bleeding problems.

Laboratory Considerations

- None noted

Dosages

DOGS:

PVCs or ventricular tachycardia (extra-label): immediate-release products, 6 – 16 mg/kg PO every 6 hours; extended-release products, 6 – 16 mg/kg PO every 8 hours[9]

Conversion of atrial fibrillation to sinus rhythm in dogs without underlying heart disease (extra-label): Initially attempted with quinidine gluconate 6 – 11 mg/kg IM every 6 hours. Some dogs will convert in the first 24 hours of therapy. If rapid ventricular response occurs, may give either digoxin or a beta-blocker to slow rate of conduction across AV node.[10,11]

HORSES:

Atrial fibrillation in a horse without heart failure (extra-label): Quinidine sulfate 22 mg/kg via nasogastric (NG) tube every 2 hours until cardioversion occurs, toxic effects are noted, or 6 doses have been given (4 doses if quinidine plasma concentrations cannot be monitored).[5,12] If atrial fibrillation remains, continue quinidine 22 mg/kg via NG tube every 6 hours until cardioversion or adverse effects. Check ECG prior to administering each dose. Do not administer directly into the mouth, as quinidine is a mucosal irritant.[12] Alternate IV dosing: 0.5 – 2.2 mg/kg IV bolus every 5 to 10 minutes to effect or until adverse effects seen. Maximum IV dose is 12 mg/kg. Conversion of ventricular tachycardia has occurred with a single 0.5 mg/kg dose.

Sustained narrow-QRS tachycardia (extra-label): From a case report: 22 mg/kg via NG tube every 2 hours for 3 doses. The rate of the tachycardia slowed gradually from 150 bpm to ≈100 bpm. Approximately 1 hour after the third dose, the cardiac rhythm abruptly converted to sinus tachycardia at a rate of 80 bpm.[13]

Monitoring

- ECG, continuous if possible
- Blood pressure, during IV administration
- Clinical signs of toxicity (see ***Overdose/Acute Toxicity*** and ***Adverse Effects***)
- Serum quinidine concentrations. Therapeutic serum concentrations are believed to range from 2 to 7 µg/mL in dogs and 2 to 5 µg/mL in horses. Concentrations more than 10 µg/mL are considered toxic.
- Atrial fibrillatory rate (AFR); one study found that a lower AFR may be associated with successful quinidine cardioversion[14]
- When using quinidine to cardiovert horses with atrial fibrillation, monitor the ECG throughout treatment. Indicators to discontinue medication include heart rates above 80 bpm, a widening of QRS beyond 125% of baseline, and abnormal complexes, or signs of toxicity (eg, nasal edema, diarrhea or colic, neurologic signs; see ***Adverse Effects***).[4]

Client Information

- Oral products should be administered at evenly spaced intervals throughout the day and night. Gastrointestinal upset (eg, anorexia, vomiting, or diarrhea) may be decreased if administered with food.
- Do not allow your animal to chew or crush sustained-release oral dosage forms.
- Notify your veterinarian if your animal's condition deteriorates or signs of toxicity (eg, vomiting, diarrhea, weakness) occur.

Chemistry/Synonyms

Used as an antiarrhythmic agent, quinidine is an alkaloid obtained from cinchona or related plants, or prepared from quinine. It is available commercially in two salts: gluconate and sulfate. Quinidine polygalacturonate is no longer commercially available.

Quinidine gluconate occurs as a very bitter tasting, odorless, white powder. It is freely soluble in water and slightly soluble in alcohol. The injectable form has a pH of 5.5 to 7. Quinidine gluconate contains 62% anhydrous quinidine alkaloid. Quinidine sulfate occurs as very bitter tasting, odorless, fine, needle-like, white crystals that may cohere in masses. One gram is soluble in ≈100 mL of water or 10 mL of alcohol. Quinidine sulfate contains 83% anhydrous quinidine alkaloid.

Quinidine gluconate may also be known as quinidinium gluconate, *Duraquin®*, *Quinaglute®*, *Quinalan®*, and *Quinate®*.

Quinidine sulfate may also be known as chinidini sulfas, chinidinsulfate, chinidinum sulfuricum, or quinidini sulfas; many trade names are available.

Storage/Stability

All quinidine salts darken on exposure to light (acquire a brownish tint) and should be stored in light-resistant, well-closed containers. Use only colorless, clear solutions of quinidine gluconate for injection.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Quinidine gluconate is reported to be physically **compatible** with bretylium tosylate, cimetidine HCl, and verapamil HCl. It is reportedly physically **incompatible** with alkalis and iodides.

Quinidine gluconate injection is usually administered IM but may be given very slowly (1 mL/minute) IV. It may be diluted by adding 10 to 40 mL of 5% dextrose.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Quinidine Sulfate (83% anhydrous quinidine alkaloid) Tablets: 200 and 300 mg; generic; (Rx)

Quinidine Gluconate (62% anhydrous quinidine alkaloid) Sustained-Release Tablets: 324 mg; generic; (Rx)

Quinidine Gluconate Injection has been discontinued.

Rabacfosadine

(***ra***-bak-***fos***-a-deen) *Tanovea*®

Antineoplastic

Prescriber Highlights

- ► Guanine nucleotide analogue that is FDA-approved for the treatment of lymphoma in dogs
- ► Narrow therapeutic index; calculate dosages carefully
- ► Most common adverse effects include diarrhea, vomiting, decreased/loss of appetite, neutropenia, lethargy, and cumulative dermatopathy (dermatitis, hyperpigmentation, alopecia, pruritus, and otitis).
- ► More serious adverse effects can occur, requiring treatment delay or dose reduction.
- ► Administration can be associated with life-threatening or fatal pulmonary fibrosis in a small percentage of patients (less than 5%). Contraindicated in dogs with or susceptible to pulmonary fibrosis, including West Highland white terriers
- ► Careful monitoring is essential, including CBC, renal function, and liver enzymes.
- ► Precautions required for handling waste for 5 days following administration

Uses/Indications

Rabacfosadine is indicated for the treatment of lymphoma in dogs. The drug appears to show promise for combined chemotherapy of naïve canine lymphoma[1] as well as relapsed or refractory lymphoma,[2] and as a single agent for the treatment of canine cutaneous Tcell lymphoma[3] and multiple myeloma.[4]

In 2 pilot field studies, the overall response rate (ORR) in 22 dogs with B-cell or T-cell lymphoma receiving rabacfosadine once every 21 days was 77% (46% complete response; 32% partial response). The ORR was 100% (8 of 8 dogs) in naïve dogs and 64% (9 of 14 dogs) in pretreated dogs. The overall median progression-free survival time in the 17 dogs experiencing response was 134 days.[5]

In a study of 60 treatment-naïve dogs, the ORR was 87%. The ORR in dogs with B-cell lymphoma was 97% compared to an ORR of 50% in dogs with T-cell lymphoma.[6] Considering these results, the novel mechanism of action, and the unique toxicities that do not overlap with other chemotherapeutics, the authors concluded that rabacfosadine could potentially be combined with other agents or incorporated into standard first-line protocols.

In a multicenter, randomized, double-blinded, placebo-controlled study, dogs with both naïve and relapsed lymphoma treated with rabacfosadine had a statistically significant improvement in progression-free survival (PFS) compared to placebo.[7] ORR was calculated for a given study visit and ranged from 48.2% to 63.4%. One month after the last treatment, 33% of rabacfosadine-treated dogs were progression-free compared to 0% of placebo dogs. Similar to previous studies, PFS was longer in dogs with B-cell lymphoma compared to those with T-cell lymphoma.

In an open-label, single-arm study, the combination of rabacfosadine and L-asparaginase appeared to be effective in dogs with lymphoma that had relapsed after previous treatment with a doxorubicin protocol.[2]

Pharmacology/Actions

Rabacfosadine is a guanine nucleotide analogue. Intracellularly, the prodrug is sequentially hydrolyzed, deaminated, and then undergoes 2 separate phosphorylation reactions. Its active form, 9-[2-(phosphonomethoxy)ethyl] guanine diphosphate (PMEGpp), is a potent, chain-terminating inhibitor of the major deoxyribonucleic acid (DNA) polymerases. In vitro studies have demonstrated the drug to inhibit DNA synthesis, resulting in S phase arrest and induction of apoptosis.[8] It also inhibits the proliferation of mitogen-stimulated lymphocytes and lymphoma/leukemia cell lines.[9]

Resistance may be mediated by mutations in the deamination gene[10] and by the acquisition of point mutations in the enzyme guanidylate kinase, impairing PMEG phosphorylation to PMEGpp.[11]

Pharmacokinetics

Rabacfosadine is not orally absorbed. Following a 30-minute IV infusion, the mean peak plasma concentrations for rabacfosadine and an interim metabolite occurred at ≈30 minutes (T_{max}) and 1 to 2 hours, respectively.[9] After administration, the drug and metabolites are widely distributed throughout the body. Some of the highest rabacfosadine concentrations are found in lymphoid tissue, and the drug preferentially accumulates in peripheral blood mononuclear cells (PBMCs). It is not known if rabacfosadine or metabolites cross the placenta or enter the milk; it does not penetrate the CNS. In dogs with lymphoma, rabacfosadine and the interim metabolite had a plasma half-life of less than 0.5 and 6 hours, respectively. In lymphoid cells, high concentrations of the active metabolite PMEGpp accumulate and persist for more than 24 hours. In PBMCs, the active metabolite PMEGpp showed a terminal half-life of 68.7 hours. Overall elimination of [^{14}C]-rabacfosadine after IV dosing was 80% over 120 hours. It undergoes both fecal and renal elimination.[9]

Contraindications/Precautions/Warnings

The drug is contraindicated in dogs with pulmonary fibrosis, a history of chronic pulmonary disease that could lead to fibrosis, and in West Highland white terriers or other breeds with a genetic predisposition for the development of pulmonary fibrosis.[9] Rabacfosadine was associated with life-threatening or fatal pulmonary fibrosis in a small percentage of patients in the field studies (less than 5%). Pulmonary fibrosis may be an idiosyncratic toxicity. This adverse effect generally occurs several months after treatment has been discontinued and can range from clinically normal to life-threatening. While pulmonary fibrosis is a rare adverse toxicity, baseline thoracic radiographs can be recommended prior to and during treatment with rabacfosadine.

Rabacfosadine can cause severe toxicity. It should only be used where adequate monitoring and support can be administered. It should be used with caution in patients with pre-existing myelosuppression or infection. Safety and effectiveness in conjunction with other chemotherapeutic agents or other treatment modalities have not been evaluated.

There is increasing evidence that chronic exposure by health care givers to antineoplastic drugs increases the mutagenic, teratogenic,

and carcinogenic risks associated with these agents. Proper training and precautions in the handling, preparation, administration, and disposal of these drugs and supplies associated with their use are strongly recommended. Use caution when handling this medication. See the product's package insert and client information sheet for more details.

Adverse Effects

The most common acute adverse effects observed with rabacfosadine in dogs include diarrhea, vomiting, decreased/loss of appetite, weight loss, lethargy, and neutropenia.[9] Leukopenia nadirs were observed between Days 6 and 9 following administration, with recovery by Day 12. Other adverse effects include hematochezia, tachypnea, dyspnea, tachycardia, thrombocytopenia, anemia, hypokalemia, hypophosphatemia, otitis media, and dermal changes (eg, alopecia, dermatitis, pyoderma). A cumulative dermatopathy can be observed, consisting of erythema and alopecia, which can progress to crusting and exudate; the ears/periauricular region, the dorsum, the axillae, and inguinal regions are most commonly affected and generally appear following 2 to 4 treatments. GI toxicity and dermatopathy have been reported as dose-limiting toxicities.[2] Most adverse effects are Veterinary Cooperative Oncology Group grade 1 or 2 and resolve with supportive therapy and/or dose reduction/delay.

Rabacfosadine was associated with suspected or confirmed pulmonary fibrosis in a small percentage of patients in the field studies (less than 5%).

Similar to other cytotoxic agents, sequential dose reductions and/or delays can be utilized to reduce the severity of adverse effects. Treatment with antiemetics (eg, maropitant, ondansetron), antidiarrheals (eg, metronidazole, loperamide, tylosin), topical or systemic anti-inflammatories (eg, NSAIDs, corticosteroids), and/or antibiotics may mitigate adverse effects and are not in violation of the FDA label.

Rabacfosadine may cause pain and tissue damage at the site of injection; avoid extravasation injuries.[9] If signs of extravasation occur, it is recommended to stop the infusion immediately and, if possible, withdraw 3 mL to 5 mL of blood to remove some of the drug, and try to aspirate additional fluids from any swelling through separate percutaneous aspirations using a 25-gauge needle. Remove the infusion catheter. Delineate the infiltrated area on the patient's skin with a felt tip marker. Consider cold packing the affected area for 48 to 72 hours. Avoid pressure or friction; do not rub the area. Observe for signs of increased erythema, pain, or skin necrosis. Ensure that no medication is given distal to the extravasation site. After 48 hours, encourage the patient to use the extremity normally to promote a full range of motion. The use of an Elizabethan collar may prevent self-trauma.

Reproductive/Nursing Safety

Rabacfosadine is contraindicated in dogs that are pregnant, lactating, or intended for breeding.[9] It is a likely teratogen. For sexually intact patients, verify pregnancy status prior to administration. Its effects on male fertility have not been studied.

It is not known if rabacfosadine or metabolites cross the placenta or enter the milk. Because of possible risks to nursing offspring, consider using milk replacer if the dam is receiving rabacfosadine.

Overdose/Acute Toxicity

Dogs receiving single IV doses of 2.5 mg/kg (2.5 times the label dose) developed moderate to severe GI signs (eg, diarrhea, vomiting, hyporexia, weight loss) starting on Day 4 and resolving by Day 10.[9] Moderate to severe neutropenia and leukopenia were observed, with the nadir occurring between Days 6 and 9 and recovery occurring by Day 12. Dogs receiving doses of 8.2 mg/kg IV (8.2 times the label dose) developed severe neutropenia, GI signs, salivation, fever, tremors, and weakness, resulting in a moribund state, and were either preterminally found dead or were euthanized by Day 7. For sequential dosing, dogs receiving up to 0.82 mg/kg IV every 24 hours for 5 days experienced dose-related neutropenia, dehydration, anorexia, vomiting, abnormal feces, fever, and decreased activity. When administered at doses up to 1 mg/kg IV every 7 days, dose-related neutropenia, anorexia, and weight loss were noted. Pathology changes across all dosage groups included dosedependent atrophy and/or necrosis in lymphoid tissue, GI tract, pancreas, mandibular salivary gland, kidneys, adrenal cortex, and the male reproductive tract.[9]

In case of accidental overdose, aggressive supportive care measures (eg, IV fluids, antiemetics, antidiarrheals, antibiotics, ± granulocyte colony-stimulating factor) are indicated.

Because of the narrow therapeutic index of this agent, iatrogenic overdoses must be avoided. Recheck dosage calculations carefully.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions are theoretical in animals receiving rabacfosadine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate. The use of concomitant medications with rabacfosadine has not been evaluated by the FDA for safety or efficacy.

- **Other Cytotoxic Antineoplastic Agents** (eg, **other antineoplastics, immunosuppressives, chloramphenicol, flucytosine, colchicine**): May cause additive myelosuppression and/or GI toxicity when used with rabacfosadine. Safety and effectiveness with other chemotherapy drugs or treatment agents have not been evaluated. The effect of concomitant medications on the metabolism of rabacfosadine has also not been evaluated.[9]
- **Radiation Therapy**: Rabacfosadine is a potent inhibitor of DNA repair.[12] There is the potential for enhancement of radiation-associated acute effects when coadministered with rabacfosadine.

Laboratory Considerations

- None were noted.

Dosages

NOTE: There is a significant amount of ongoing research evaluating rabacfosadine for use with other drugs, other species, and for extra-label indications. Because of the potential toxicity of this drug to patients, veterinary staff, and pet owners and because chemotherapy indications, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references are strongly recommended.[13–16]

DOGS:

Treatment of lymphoma (label dosage; FDA-approved): 1 mg/kg administered as a 30-minute IV infusion, once every 3 weeks for up to 5 doses.[9] For dogs intolerant of 1 mg/kg dosing, noninferior clinical activity can be achieved with 0.82 mg/kg dosing. Stepwise dose reductions to 0.8 mg/kg and 0.66 mg/kg or dose delays may be used to manage adverse reactions. After adding 2 mL 0.9% sodium chloride for injection to the vial, gently invert the vial several times until the drug has completely dissolved and the solution is particle free. Do not use the solution if particulates are observed. The reconstituted solution contains 8.2 mg/mL. Add the calculated volume of reconstituted drug to

0.9% sodium chloride in a polyvinyl chloride (PVC) infusion bag or polypropylene infusion syringe to yield a total infusion volume of 2 mL/kg body weight. See the product label for an example dosage and administration chart.

Monitoring

- Baseline complete blood count, serum biochemistry profile, urinalysis, and thoracic radiographs
- CBC 7 days after the first treatment and immediately before each subsequent treatment
- Baseline and periodic (eg, every 2 to 3 treatments) serum biochemistry profile, including renal and hepatic parameters
- Monitoring for signs of pulmonary dysfunction consistent with pulmonary fibrosis, including serial monitoring of thoracic radiographs every 2 to 3 months, is recommended, or if clinical signs support respiratory compromise (tachypnea, coughing, exercise intolerance)
- Antitumor efficacy
- Monitor infusion site for signs of extravasation.

Client Information

- Always provide Client Information Sheet with prescription. In addition, it is highly recommended to verbally reiterate key points found on the sheet. Specifically, those sections related to when the veterinarian should be contacted and how to minimize exposure to the drug.
- Rabacfosadine is a cytotoxic (anti-cancer) medicine. The medicine can be hazardous to other animals and people that come in contact with it. On the day that your animal gets the medicine and then for 5 days afterward, handle all bodily waste (eg, urine, feces, litter), blood, or vomit only while wearing chemotherapy-resistant gloves. Place all waste materials in a plastic bag and seal before disposal in the regular trash. Those who are pregnant, attempting to conceive, or nursing should not clean up the animal's waste.
- Do not wash any items soiled with waste, vomit, or saliva from your dog with other laundry. Take precautions in handling the dog's toys, food bowl, and water bowl. All items should be washed separately from other household items.
- Your veterinarian will need to perform regular monitoring, including blood tests and/or radiographs, to be sure this drug is not causing toxic effects to your animal. Do not miss these important follow up visits.
- Observe your dog for lack of appetite, vomiting, or diarrhea. If these signs are severe, or if you notice your dog having difficulty breathing or signs of infection (eg, fever, lack of energy), contact your veterinarian immediately.

Chemistry/Synonyms

Rabacfosadine is an acyclic nucleotide phosphonate with a molecular weight of 526.5 g/mole. It is supplied as a sterile white to off-white lyophilized powder in the form of a cake contained in a 3 mL amber glass vial. Each single-use vial contains 16.4 mg of rabacfosadine, present as the succinate salt, along with 20 mg of mannitol and 1.6 mg of citrate as excipients. Once reconstituted with 0.9% sodium chloride injection, USP, the resulting solution contains 8.2 mg rabacfosadine per mL.

Rabacfosadine may also be known as GS-9219, VDC-1101, and *Tanovea*®.

Storage/Stability

Refrigerate the vials at 2°C to 8°C (36°F-46°F). Retain in the original package to protect from light. After reconstitution, dilute the solution further within 4 hours. Discard the unused infusion solution within 24 hours of admixture and within 4 hours of attachment to an IV administration set. Dispose of any unused product or waste materials in accordance with proper procedures for cytotoxic drugs.

Compatibility/Compounding Considerations

None were noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Rabacfosadine Injection: 16.4 mg vial for reconstitution; *Tanovea*®; (Rx). NADA # 141-475

Ramipril

(***ram***-ih-prill) *Altace*®, *Vasotop*®

Angiotensin-Converting Enzyme (ACE) Inhibitor

Prescriber Highlights

- ► Used primarily as a vasodilator in the treatment of heart failure or systemic hypertension; may be of benefit in the treatment of chronic kidney disease or protein-losing nephropathies
- ► Not as much information or experience available as some other angiotensin-converting enzyme (ACE) inhibitors (eg, enalapril, benazepril) in dogs or cats
- ► Contraindications include in animals that are hypersensitive it or to other ACE inhibitors.
- ► Use with caution during pregnancy, in patients with vascular stenosis or obstructive hypertrophic cardiomyopathy, in patients taking potassium-sparing diuretics, and in hypovolemic patients
- ► Appears well-tolerated in both dogs and cats. Adverse effects may include GI distress (eg, anorexia, vomiting, diarrhea), and, less commonly, weakness, hypotension, and hyperkalemia.

Uses/Indications

Ramipril is a long-acting angiotensin-converting enzyme (ACE) inhibitor that may be useful in treating heart failure or systemic hypertension in dogs or cats. It is an approved product in the UK for treating heart failure in dogs. However, in dogs in heart failure due to MMVD, ramipril was less effective than pimobendan[1], and the addition of ramipril to the combination of pimobendan plus furosemide did not improve survival.[2] In cats, ramipril has been used for treating arterial hypertension. A study did not show any significant benefit in using ramipril in treating Maine coon cats with hypertrophic cardiomyopathy without heart failure.[3]

Like other ACE inhibitors, ramipril may be useful as adjunctive treatment in chronic kidney disease and protein-losing nephropathies. In dogs with moderate renal impairment (such as might be found with heart failure), there is apparently no need to adjust the ramipril dose.[4]

In healthy horses, oral benazepril was found to be more effective than ramipril (0.3 or 0.1 mg/kg) at inhibiting serum ACE activity.[5] When ramipril 0.2 mg/kg PO was administered to healthy horses before exercise, the exercise-induced increase in systolic blood pressure was reduced by 26.6%, and the diastolic blood pressure was reduced by 16.6%. Mean maximum serum ACE inhibition 2 hours after ramipril administration was 55%.[6]

Pharmacology/Actions

Ramipril is a prodrug that has little pharmacologic activity until it is converted into ramiprilat. Ramiprilat prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE

has a much higher affinity for ramiprilat than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced, and plasma renin activity is increased.

The cardiovascular effects of ramiprilat in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure with no change or decrease in heart rate. Increased cardiac index and output, stroke volume, and exercise tolerance also occur. Renal blood flow can be increased with little change in hepatic blood flow. In animals with glomerular disease, ACE inhibitors likely decrease proteinuria and help to preserve renal function.

Pharmacokinetics

After oral administration to dogs, ramipril is rapidly converted via de-esterification into ramiprilat. The bioavailability of ramiprilat after a dose of 0.25 mg/kg per day of ramipril is ≈6.7%. At this dose, angiotensin-converting enzyme (ACE) activity never exceeded 60% in either healthy dogs or those with experimentally induced renal dysfunction (GFR reduced to 58%).[4]

After oral administration to cats with ramipril doses ranging from 0.125 mg/kg to 1 mg/kg once daily for 9 days, ramipril peak concentrations occurred in ≈0.5 hours. Absorption was not significantly affected by food. Ramipril is rapidly converted into its active metabolite ramiprilat, which peaks at 1 to 1.5 hours postadministration. Half-life was ≈20 hours and excretion occurred primarily in the feces. Repeated doses of ramipril 0.125 mg/kg inhibited serum ACE activity by 94% at maximum and 55% inhibited 24 hours postdose. At a dose of 1 mg/kg, ACE activity was 97% inhibited at maximum, and it was 83% inhibited 24 hours postdose.[7,8]

When cats were administered radiolabeled ramipril PO, 85% to 89% of the radioactivity was recovered in the feces. It is unclear how much of this represents the unabsorbed drug or absorbed parent compound/metabolites eliminated in the feces. Approximately 10% of the administered drug was recovered in the urine. Excretion of radiolabeled compounds was complete by 168 hours after dosing.

In horses, after ramipril 0.05 mg/kg IV and 0.05, 0.1, 0.2, 0.4, and 0.8 mg/kg PO, the serum ACE activity was only suppressed by 84.27% at the 0.8 mg/kg dose and by 98.88% with the IV dose. The PO availability of ramipril at doses ranging from 0.05 to 0.8 mg/kg was low. It is unknown if 80% suppression would be sufficient to counteract vasoconstriction in pathological conditions.[9]

Contraindications/Precautions/Warnings

Ramipril is contraindicated in patients that are hypersensitive to it or to any other ACE inhibitor. The labeling for the UK product approved for dogs states that it should not be used in clinical cases of obstructive heart disease (eg, aortic/subaortic stenosis and hypertrophic obstructive cardiomyopathy), or with potassium-sparing diuretics (see ***Drug Interactions***).[10] In humans, dosage reduction may be recommended in cases of hepatic or renal impairment.

The use of ACE inhibitors in dehydrated patients can lead to acute hypotension. In patients at risk for hypovolemia, starting at a ½ dose and gradually increasing over 1 week is recommended.

Ramipril is a prodrug that is converted to the active form in the liver. This conversion may be reduced in patients with hepatic dysfunction.

Pregnant women should exercise caution to avoid exposure and wash their hands after handling.

Adverse Effects

Although information is limited, ramipril appears to be well tolerated in dogs and cats. GI effects are probably the most likely adverse effects to be noted. Weakness, hypotension, or hyperkalemia are possible. The UK product label states that if clinical signs of hypotension occur (apathy or ataxia), treatment should be suspended until signs resolve, then continued at 50% of the original dose.

In humans, bradykinin accumulation caused by angiotensin-converting enzyme (ACE) inhibitors can lead to angioedema and cough. These effects appear to be rare but possible in dogs. ACE inhibitors can rarely cause cholestatic jaundice in humans that may progress fulminant hepatic necrosis.

Reproductive/Nursing Safety

No studies have been carried out to assess the use of ramipril in pregnant bitches.[10] Doses of ramipril up to 500 mg/kg/day did not impair fertility in rats. Although no teratogenic effects have been detected with ramipril in studies performed in mice, rats, rabbits, and cynomolgus monkeys, there is increased fetal risk for humans.

If used in humans during the second and third trimesters, increased rates of fetal death, neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios leading to fetal limb contractures, craniofacial deformation, and hypoplastic lung development were noted. In humans, ramipril has a black box warning regarding its use in pregnancy, which states, *When used in pregnancy during the second and third trimesters, angiotensin-converting enzyme (ACE) inhibitors can cause injury and even death to the developing fetus. When pregnancy is detected, ramipril should be discontinued as soon as possible.*

No studies have been carried out to assess the use of ramipril in lactating bitches. The human (US) label recommends not using the drug during nursing.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In dogs, ramipril appears quite safe; dosages as high as 1 g/kg induced only mild GI distress. Lethal doses in rats and mice were noted at 10 to 11 g/kg. No information was located on overdoses in cats. In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Because of the drug's long duration of action, prolonged monitoring and treatment may be required.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ramipril and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics**: Concurrent use may increase the risk for hypotension.
- **Angiotensin Receptor Blockers** (eg, **losartan, telmisartan**): In humans, dual blockade of the RAAS system with angiotensin-converting enzyme (ACE) inhibitors and ARBs is associated with an increased risk for hypotension, hyperkalemia, and changes in renal function. The ONTARGET trial in humans found no benefit with dual therapy compared to ACE or ARB therapy alone but found an increased incidence of renal dysfunction.[11]
- **Antacids, Aluminum-, Calcium-, and Magnesium-Containing**: Reduced oral absorption of ramipril may occur if given concomitantly with antacids; it is suggested to separate dosing by at least 2 hours.
- **Antihypertensive Agents/Vasodilators** (eg, **amlodipine,**

hydralazine, prazosin, sildenafil): Concurrent use may increase the risk for hypotension and other adverse effects.
- **Baclofen**: Concurrent administration may increase the risk for hypotension.
- **Buspirone**: Concurrent use may increase the risk for hypotension.
- **Cabergoline**: Concurrent use may lead to additive hypotension.
- **Cimetidine**: Use with ACE inhibitors has caused neurologic dysfunction in 2 human patients
- **Corticosteroids** (eg, **dexamethasone, fludrocortisone, predniso(lo)ne**): May decrease the antihypertensive effects of ACE inhibitors
- **Darbepoetin Alfa**: ACE inhibitors may interfere with erythropoietin.
- **Digoxin**: Concentration may increase 15% to 30% when ACE inhibitors are added; automatic reduction in dosage is not recommended but monitoring of serum digoxin concentration should be performed.
- **Diphenhydramine**: Concurrent use may increase the risk for hypotension.
- **Disopyramide**: Hypoglycemic effects may be enhanced.
- **Diuretics** (eg, **furosemide**): Concomitant diuretics may cause hypotension if used with ramipril; titrate dosages carefully.
- **Doxepin**: Concurrent use may increase the risk for hypotension.
- **Glycerin, Oral**: Concurrent use may increase the risk for hypotension.
- **Heparin, Low Molecular Weight Heparins** (eg, **dalteparin, enoxaparin**): Concurrent use may increase the risk for hyperkalemia.
- **Nonsteroidal Anti-inflammatory Agents (NSAIDs;** eg, **carprofen, meloxicam**): May reduce the clinical efficacy of ramipril when it is being used as an antihypertensive agent
- **Opioids** (eg, **buprenorphine, hydrocodone, morphine**): Concurrent use may increase the risk for hypotension.
- **Potassium** or **Potassium Sparing Diuretics** (eg, **spironolactone**): Hyperkalemia may develop.
- **Probenecid**: Can decrease renal excretion of ramipril and possibly enhance the clinical and toxic effects of the drug

Laboratory Considerations

- Angiotensin-converting enzyme (ACE) inhibitors may cause a reversible decrease in localization and excretion of iodohippurate sodium I123/I134 or Technetium Tc99 pententate renal imaging in the affected kidney in patients with renal artery stenosis, which could lead to confusion in test interpretation.

Dosages

DOGS:

Heart failure (extra-label): Initially, 0.125 mg/kg PO once daily; depending on the severity of pulmonary congestion, the dose may be increased to 0.25 mg/kg PO once daily[10]

CATS:

Systemic hypertension (extra-label): Initially, 0.125 mg/kg PO once daily. In cats where systemic blood pressure (SBP) was still above 160 mm Hg on Day 14, the dose was increased to 0.25 mg/kg PO once daily up to the end of the trial (Day 63). A total of 62% had a decrease in SBP of 20 mm Hg or more; of these cats, 69% had had a final SBP below 160 mm Hg.[12]

Monitoring

- Clinical signs
- Renal function; baseline and 7 days after initiation or alteration in the dose of ramipril or concurrently administered diuretics[10]
- Serum electrolytes, liver enzymes, creatinine, BUN, urine protein:creatinine ratio
- CBC with differential, periodic
- Blood pressure (if treating hypertension or clinical signs associated with hypotension arise)

Client Information

- Ramipril is used to treat heart failure, high blood pressure, and some forms of kidney disease in dogs and cats.
- This medicine is usually well tolerated but vomiting and diarrhea can occur. Give this medicine with food if vomiting or lack of appetite becomes a problem. If a rash or signs of infection occur (eg, fever), contact your veterinarian immediately.
- It is important to give this medicine exactly as prescribed. Do not stop or reduce the dosage without first talking with your veterinarian.
- While your animal is taking this medication, it is important to return to your veterinarian for blood pressure and laboratory tests. Do not miss these important follow-up visits.

Chemistry/Synonyms

Ramipril occurs as a white to almost white, crystalline powder that is sparingly soluble in water and freely soluble in methyl alcohol.

Ramipril may also be known as Hoe-498, ramiprilis, or ramiprilium. There are many international trade names, including *Altace*®, *Cardase*®, *Delix*®, *Ramase*®, *Triatec*®, and *Vasotop*®.

Storage/Stability

Store capsules at room temperature (15°C-30°C [59°F-86°F]) protected from light in tight containers.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the United States. In some countries, ramipril is available in 1.25 mg, 2.5 mg, and 5 mg tablets.

HUMAN-LABELED PRODUCTS:

Ramipril Oral Capsules: 1.25 mg, 2.5 mg, 5 mg, and 10 mg; *Altace*®, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Ranitidine

(rah-***nih***-tih-deen) *Zantac*®

H_2 Receptor Antagonist; Prokinetic

Prescriber Highlights

► Used to reduce acid output in the stomach, to prevent and/or treat esophageal reflux, esophagitis, gastritis, and GI ulcers; also has prokinetic activity

► Contraindications include hypersensitivity. Use caution in geriatric patients and in patients with hepatic or renal insufficiency

► Adverse effects are rare. IV boluses may cause vomiting. Pain at the injection site after IM administration. Potentially: agranulocytosis, and transient cardiac arrhythmias (too rapid IV injection)

► Product may not be commercially available due to an FDA total market recall announced April 2020.

Uses/Indications

In veterinary medicine, ranitidine has been used to decrease gastric acid production for the treatment and/or prophylaxis of gastric, abomasal, and duodenal ulcers; uremic gastritis; stress-related or drug-induced erosive gastritis; esophagitis; and duodenogastric and esophageal reflux. One study did not demonstrate any reduction in the incidence of gastroesophageal reflux in anesthetized dogs from either ranitidine or metoclopramide.[1] Ranitidine has also been employed to treat hypersecretory conditions associated with gastrinomas and systemic mastocytosis. Because of its effects on gastric motility, ranitidine may be useful in increasing gastric emptying, particularly when delayed gastric emptying is associated with gastric ulcer disease. Ranitidine may also be useful for stimulating colonic activity in cats via its prokinetic effects. Ranitidine had no effect on gastric emptying in healthy foals.[2]

Increased intragastric pH has been reported to diminish after twice-daily famotidine administration to dogs,[3] cats,[4] and cattle[5]; however, this effect did not occur with ranitidine.[6]

Pharmacology/Actions

At the H_2 receptors of the parietal cells, ranitidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, amino acids, pentagastrin, histamine, or insulin. Ranitidine is 3 to 13 times more potent (on a molar basis) than cimetidine.

Ranitidine may stimulate GI motility, especially in the stomach, by inhibiting acetylcholinesterase (thereby increasing acetylcholine at muscarinic receptors). Lower esophageal sphincter pressures may be increased by ranitidine. By decreasing the amount of gastric juice produced, ranitidine decreases the amount of pepsin secreted.

Ranitidine, unlike cimetidine, does not appear to have any appreciable effect on serum prolactin levels, although it may inhibit the release of vasopressin.

Pharmacokinetics

In dogs, the oral bioavailability is ≈81%, serum half-life is 2.2 hours, and volume of distribution is 2.6 L/kg.

In horses, oral ranitidine has a bioavailability of ≈27% in adults and 38% in foals. Peak levels after oral dosing occur in ≈100 minutes in adults and 60 minutes in foals. Apparent volume of distribution is ≈1.1 L/kg and 1.5 L/kg in adults and foals, respectively. Clearance in adults is ≈10 mL/minute/kg and 13.3 mL/minute/kg in foals. A recent study reported that the terminal half-life in performance horses after 8 mg/kg PO twice daily (7 doses total) was 7.4 hours, which is higher than previous reports (1.5 hours). Since the use of this drug is regulated in racing horses (class 5 foreign substance by the Association of Racing Commissioners International), an extended withdrawal time may be necessary prior to competition.[7]

In humans, ranitidine is absorbed rapidly after oral administration, but undergoes extensive first-pass metabolism with a net systemic bioavailability of ≈50%. Peak levels occur at ≈2 to 3 hours after oral dosing. Food does not appreciably alter the extent of absorption or the peak serum levels attained.

Ranitidine is distributed widely throughout the body and is only 10% to 19% bound to plasma proteins. Ranitidine is distributed into human milk at levels 25% to 100% of those found in plasma.

Ranitidine is excreted in the urine by the kidneys (via glomerular filtration and tubular secretion) and metabolized in the liver to inactive metabolites; accumulation of the drug can occur in patients with renal insufficiency. The serum half-life of ranitidine in humans averages 2 to 3 hours. The duration of action at usual doses is 8 to 12 hours.

Contraindications/Precautions/Warnings

Ranitidine is contraindicated in patients who are hypersensitive to it. It should be used cautiously and possibly at a reduced dose in patients with diminished renal function. Use with caution in patients with impaired hepatic function. Ranitidine has caused increased serum ALT levels in humans receiving high IV doses for longer than 5 days. The manufacturer recommends that with high-dose chronic therapy, serum ALT values be considered for monitoring.

Acid-suppressing therapy has been associated with increased risk for pneumonia in humans.[8]

Do not confuse raNITIdine with riMANTAdine, or amantadine, or *Zantac®* with *Zyrtec®* or *Zofran®*.

Adverse Effects

Adverse effects appear to be uncommon in animals at clinical dosages. Potential adverse effects in humans include mental confusion and headache; relevance to animals is unknown. Rarely, agranulocytosis may develop and, if given rapidly IV, transient cardiac arrhythmias may be seen. Pain at the injection site may be noted after IM administration. IV boluses have been associated with vomiting in small animals and transient hypotension in cats.

Reproductive/Nursing Safety

Studies in laboratory animals have revealed no evidence of fetal toxicity.

Ranitidine is excreted in human breast milk with milk:plasma ratios of ≈5:1 to 12:1. Use with caution in nursing veterinary patients.

Overdose/Acute Toxicity

Clinical experience with ranitidine overdose is limited. In laboratory animals, very high dosages (225 mg/kg/day) have been associated with muscular tremors, vomiting, and rapid respiration. Single doses of 1 g/kg PO in rodents did not cause death.

Treatment of overdoses in animals should be handled using standard protocols for oral ingestions of drugs; clinical signs may be treated symptomatically and supportively if necessary. Hemodialysis and peritoneal dialysis have been noted to remove ranitidine from the body.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Unlike cimetidine, ranitidine appears to have much less effect on the hepatic metabolism of drugs and is unlikely to cause clinically relevant drug interactions via this mechanism. The following drug interactions have either been reported or are theoretical in humans or animals receiving ranitidine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetaminophen**: Ranitidine (dose-dependent) may inhibit acetaminophen metabolism.
- **Antacids** (high doses) (eg, **calcium carbonate, magnesium/aluminum combinations**): May decrease the oral absorption of ranitidine; give at separate times (2 hours apart) if used concurrently.
- **Azole Antifungals** (eg, **ketoconazole, itraconazole, fluconazole**): By raising gastric pH, ranitidine may decrease the absorption of these agents; if both drugs are required, administer the azole 1 hour prior to ranitidine.
- **Cefpodoxime, Cefuroxime**: Ranitidine may decrease the absorption of these cephalosporins; giving with food may alleviate this effect.
- **Iron Salts** (oral): Ranitidine may decrease the absorption of oral iron; administer iron at least 1 hour prior to ranitidine.
- **Metoprolol**: Ranitidine may increase metoprolol half-life and peak levels.

- **Probenecid**: May reduce the excretion of ranitidine
- **Procainamide**: Concurrent use may result in increased serum concentrations of procainamide.
- **Propantheline**: Delays the absorption but increases the peak serum level of ranitidine; relative bioavailability of ranitidine may be increased by 23% when propantheline is administered concomitantly with ranitidine.
- **Vitamin B12**: Long-term ranitidine use may reduce oral absorption of B12.

Laboratory Considerations

- Ranitidine may cause a false-positive urine protein reading when using *Multistix*®. The sulfosalicylic acid reagent is recommended for determining urine protein when the patient is concomitantly receiving ranitidine.
- Gastric acid secretion testing: H_2 blockers may antagonize the effects of histamine and pentagastrin in the evaluation of gastric acid secretion; it is recommended that H_2 blockers be discontinued at least 24 hours before performing this test.
- Intradermal allergy testing: H_2 antagonists may inhibit histamine responses[9]; consider discontinuation at least 24 hours before performing this test.

Dosages

NOTE: In humans, the manufacturer recommends dilution of ranitidine when administering IV; doses must be diluted to a concentration of 2.5 mg/mL using dextrose 5%, 0.9% NaCl, or another suitable IV solution and be administered at a 10 – 25 mg/minute. Significance in animals is not known, but precautions should be considered.

DOGS:

Esophagitis, ulcer disease, gastritis, or gastric prokinetic (extra-label): Common anecdotal dosages generally range from 1 – 2 mg/kg PO, SC, IM, or slow IV (max = 25 mg/minute) every 8 to 12 hours,[10] but one study found that ranitidine at 2 mg/kg IV every 12 hours did not significantly increase gastric pH as compared with saline.[6] One source states *Therefore, current dose recommendations (0.5 – 2 mg/kg every 8 to 12 hours) seem to be too low to be of any effect.*[11] *Currently, clinical studies on the effect of ranitidine on gastric disorders in dogs and cats are lacking.*

CATS:

Esophagitis, ulcer disease, or as a prokinetic agent to stimulate colonic motility (extra-label): Based on pharmacokinetic data: 2.5 mg/kg slow IV twice daily or 3.5 mg/kg PO twice daily.[12] One study found that 1.4 – 2.3 mg/kg PO every 12 hours did not significantly suppress gastric acid.[13]

FERRETS:

Helicobacter mustelae (extra-label): Ranitidine bismuth citrate (**NOTE**: Not available commercially in US; must be compounded) 24 mg/kg PO every 8 to 12 hours and clarithromycin 12.5 mg/kg PO every 8-12 hours for 14 days[14]

HORSES:

Gastroprotectant/reduce stomach acid (extra-label): 1.5 – 2 mg/kg IV every 8 hours or 6.6 – 10 mg/kg PO every 8 hours

SMALL MAMMALS:

Rabbits: **Prokinetic**: 0.5 mg/kg IV every 24 hours with cisapride (0.5 mg/kg PO every 8 hours)[15]

Suspected gastric ulceration: 2 – 5 mg/kg PO twice daily[16]

Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in clinical signs, endoscopic examination, and blood in feces.

Client Information

- Used to treat or prevent stomach ulcers
- Usually well tolerated; side effects are uncommon.
- Works best if given before the first meal of the day
- Ranitidine is available OTC (over the counter; without a prescription), but only give it to your animal if recommended by your veterinarian.

Chemistry/Synonyms

An H_2-receptor antagonist, ranitidine HCl occurs as a white to pale yellow granular substance with a bitter taste and a sulfur-like odor. The drug has pK_as of 8.2 and 2.7. One gram is soluble in ≈1.5 mL of water or 6 mL of alcohol. The commercially available injection has a pH of 6.7 to 7.3.

Ranitidine HCl may also be known as AH-19065, ranitidini hydrochloridum. Many trade names are available; a common trade name is *Zantac*®.

Storage/Stability

Ranitidine tablets and syrup/solution should be stored in tight, light-resistant containers at room temperature 20°C to 25°C (68°F-77°F). The injectable product should be stored protected from light and at a temperature less than 30°C (86°F). A slight darkening of the injectable solution does not affect the potency of the drug.

Compatibility/Compounding Considerations

Ranitidine injection is reportedly stable for up to 48 hours when mixed with commonly used IV solutions (including 5% sodium bicarbonate).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 5 substance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

NOTE: Product may not be commercially available due to an FDA total market recall announced April 2020.

Ranitidine HCl Oral Tablets: 75 mg, 150 mg, & 300 mg; *Zantac*®, generic; (Rx or OTC)

Ranitidine HCl Oral Capsules: 150 and 300 mg (traditional and liquid filled); generic; (Rx or OTC)

Ranitidine HCl Oral Solution/Oral Syrup: 15 mg/mL in 473 mL and 480 mL; generic; (Rx) May contain alcohol or sorbitol

Ranitidine HCl Injection: 25 mg/mL in 2 mL, 6 mL, and 40 mL vials; *Zantac*®, generic; (Rx)

Remifentanil

(rem-i-***fen***-ta-nil) *Ultiva®*

Ultrashort-Acting Opioid Analgesic

Prescriber Highlights

- ► Opioid similar to fentanyl with an even shorter duration of action, which may reduce recovery times; used primarily as an anesthesia adjunct.
- ► Degraded by esterases in plasma, red blood cells, and tissues; can be used for prolonged procedures in patients with renal or hepatic dysfunction
- ► Currently much more expensive than fentanyl
- ► DEA Schedule II (C-II) controlled substance

Uses/Indications

Remifentanil is a mu-opioid that is structurally related to fentanyl. Because remifentanil is primarily metabolized by plasma, tissue, and red blood cell esterases, it can safely be used in patients with either hepatic or renal impairment, and patients with hepatic dysfunction (eg, hepatic shunts) still have a constant and predictable excretion of this drug.[1] Its short duration of action is also beneficial, because if adverse effects occur (eg, respiratory depression, bradycardia), reversal with naloxone should rarely be required. One possible advantage of using remifentanil instead of fentanyl as an anesthesia adjunct is that recovery times may be faster with remifentanil.

Pharmacology/Actions

Remifentanil is a mu-opioid agonist that is structurally related to fentanyl with a rapid onset of analgesic action and peak effect and short duration of action. Mu receptors are found primarily in the pain-regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opioids. Receptors for opioid analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the GI tract, urinary tract, and other smooth muscles. The pharmacology of the opioid agonists is discussed in more detail in ***Opioids, General Information***.

Unlike other opioids, remifentanil is rapidly metabolized by hydrolysis of the propanoic acid-methyl ester linkage by nonspecific blood and tissue esterases. Remifentanil is not appreciably metabolized by the liver or plasma cholinesterase (pseudocholinesterase). Adverse effects (eg, bradycardia, respiratory depression, hypotension) are dose-dependent and similar to other mu-opioids. When used as an anesthesia adjunct, remifentanil, like other opioids, has a ceiling effect (ie, increased doses do not enhance analgesia).

Antagonists such as naloxone antagonize the opioid activity of remifentanil. Hourly dosages of naltrexone (600 µg/kg IV) antagonized the behavioral and antinociceptive effects of a high dose of remifentanil in cats.[2]

In dogs, remifentanil is equally efficacious but about half as potent as fentanyl; recovery from remifentanil anesthesia is much more rapid, especially after continuous infusions maintained for 6-plus hours.[3] Remifentanil reduced sevoflurane MAC similarly to fentanyl in dogs but allowed shorter recovery times.[4] In another dog study, remifentanil given as an IV CRI reduced the dosage requirements of propofol for maintaining target-controlled infusion system-based anesthesia.[5] A dose of 0.3 µg/kg/minute IV CRI resulted in nearly maximal isoflurane-sparing effects; a ceiling effect was observed at higher infusion rates.[6] Remifentanil infusions of 0.25 – 0.5 µg/kg/minute IV CRI combined with propofol 0.2 mg/kg per minute IV CRI produced minimal effects on arterial blood pressure and led to a good recovery, and analgesia was sufficient to control the nociceptive response applied by electrical stimulation.[7] Another study showed a significant decrease in heart rate and cardiac index and no difference in mean arterial pressure when anesthesia was maintained with remifentanil 0.3 µg/kg/minute IV CRI combined with a target-controlled infusion of propofol compared to propofol alone.[8] The principal carboxylic acid metabolite of remifentanil (GR90291) has been shown to be at least 4000 times less potent in dogs as the parent drug.[9]

In cats, remifentanil reduced isoflurane MAC similarly (≈25% reduction) at the 3 doses studied[10]; however, in another cat study, remifentanil did not alter the MAC value of isoflurane but did produce analgesia, reflected by increased thermal thresholds.[11]

In horses anesthetized with isoflurane and receiving dexmedetomidine 1 µg/kg/hour IV CRI with remifentanil 6 µg/kg/hour, a decreased heart rate and increased systemic vascular resistance were seen during the anesthetic event (60 minutes). Remifentanil was not associated with adverse effects during anesthesia and did not affect recovery time or recovery score.[12]

Pharmacokinetics

In dogs, remifentanil is rapidly distributed into the CNS with a blood–brain equilibration half-life of 2.3 to 5.2 minutes. It has a terminal elimination half-life of 6 minutes.[9] On termination of an IV infusion, dogs recover in 5 to 20 minutes regardless of the infusion duration.

In cats, remifentanil has a moderately high volume of distribution (7.6 L/kg), a high clearance (766 mL/minute/kg), and a short terminal elimination half-life (17.4 minutes). In anesthetized (isoflurane) cats, the volume of distribution of remifentanil is decreased (1.65 L/kg), but elimination half-life is not significantly altered.[13]

In horses, after remifentanil IV infusions of 6 µg/kg/hour for a minimum of 60 minutes while anesthesia was maintained with isoflurane, the mean peak remifentanil concentration was 7.14 ng/mL at 50 minutes postinfusion start, mean Vd was 268 ± 40 mL/kg, and mean half-life was 12.8 minutes. Blood concentration decreased to 1 ng/mL 27 minutes after the infusion was terminated.[14]

In humans after IV doses, remifentanil is rapidly distributed into the CNS and has a peak effect 1 to 3 minutes after administration. Remifentanil is ≈70% bound to plasma proteins with the majority bound to alpha-1-acid-glycoprotein. Remifentanil has an effective biological half-life of 3 to 10 minutes in human patients. The pharmacokinetics of remifentanil are not appreciably altered in patients with renal or hepatic failure.

Contraindications/Precautions/Warnings

Remifentanil is contraindicated in patients that are hypersensitive to it or other fentanyl analogues.[15] As the injection contains glycine, it is contraindicated for epidural or intrathecal administration.

Because of the possibility of significant respiratory depression or bradycardia, it should only be administered in a monitored anesthesia care setting. Continuous infusions should only be administered with an infusion device.

In morbidly obese patients, the drug dose should be based on ideal body weight.

Opioid analgesics are contraindicated in patients stung by scorpions (eg, *Centruroides* spp), as they may potentiate venom effects.[16]

Adverse Effects

Remifentanil has an adverse effect profile similar to other mu-opioids. Respiratory depression, including apnea, bradyarrhythmias, and hypotension, is possible. Increased body temperatures in cats may be noted. Anaphylaxis is rare, but possible.

In cats, doses higher than 1 µg/kg/minute IV CRI may be associated with dysphoria and frenetic locomotor activity.[11]

Reproductive/Nursing Safety

Remifentanil appears to be relatively safe to use during pregnancy. No teratogenic effects were observed after administration of remifentanil at doses up to 5 mg/kg in rats and 0.8 mg/kg in rabbits. It is unknown if remifentanil is excreted into milk, but clinical effects in offspring seem unlikely.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

As with all potent opioid analgesics, overdoses manifest as enhancement of the drug's nonanalgesic pharmacological effects. Clinical signs may include apnea, chest-wall rigidity, seizures, hypoxemia, hypotension, and bradycardia.

If an overdose occurs, discontinue drug administration and give supportive therapy including mechanical ventilation and oxygen administration. Often, this is all that is required because the drug is cleared rapidly. Additional supportive therapy can include IV fluids and glycopyrrolate or atropine for bradycardia or hypotension. Naloxone may also be used to reverse the drug's mu-activity but can lead to acute pain and sympathetic hyperactivity.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Remifentanil clearance is not altered by concomitant administration of thiopental, isoflurane, or propofol.

The following drug interactions with remifentanil and fentanyl have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-2 Agonists** (eg, **dexmedetomidine, xylazine**): Concurrent use may increase the risk for CNS and/or respiratory depression.
- **Anesthetic Agents** (eg, **alfaxalone, isoflurane, ketamine, propofol**): Concurrent use may increase the risk for CNS and/or respiratory depression.
- **Anticholinergic Agents** (eg, **acepromazine, atropine, disopyramide**): Concurrent use may increase the risk for urinary retention, constipation, and CNS and respiratory depression.
- **Antihypertensive Agents** (eg, **atenolol, lisinopril, spironolactone**): Concurrent use may increase the risk for bradycardia, hypotension, and orthostasis. Use cautiously and monitor blood pressure and heart rate. Opioids may decrease therapeutic effects of diuretics.
- **Benzodiazepines** (eg, **diazepam, midazolam**): Concurrent use may increase the risk for CNS and/or respiratory depression.
- **Bethanechol**: Concurrent use may antagonize the beneficial effects of bethanechol on GI motility. Avoid combination.
- **CNS Depressants** (eg, **methocarbamol, phenobarbital**): Concurrent use may increase the risk for CNS and/or respiratory depression. Monitor and adjust doses accordingly.
- **Desmopressin**: Concurrent use may increase concentrations of oral desmopressin and increase the risk for water intoxication and/or hyponatremia, which can progress to seizures, coma, respiratory arrest, and death. Monitor electrolytes and renal function.
- **Domperidone**: Concurrent use may antagonize the GI effects of domperidone.
- **Drugs That Inhibit Hepatic Isoenzymes** (eg, **cimetidine, diltiazem, erythromycin, fluconazole, itraconazole, ketoconazole**): May increase the half-life and decrease the clearance of fentanyl, leading to prolonged effects and an increased risk for respiratory depression. However, a study in dogs showed that ketoconazole did not significantly alter the elimination of fentanyl.[17] Monitor and considering adjusting doses accordingly.
- **Drugs That Induce Hepatic Isoenzymes** (eg, **griseofulvin, mitotane, phenobarbital**): Current use may decrease concentrations of fentanyl. Monitor clinical response and adjust doses accordingly.
- **Drugs That Depress Cardiac Function Or Reduce Vagal Tone** (eg, **beta-blockers** or **other anesthetic agents**): May produce bradycardia or hypotension if used concurrently with fentanyl
- **Ifosfamide**: Concurrent use may increase risk for neurotoxicity including somnolence, confusion, hallucinations, blurred vision, urinary incontinence, seizures, and coma. Use cautiously and monitor
- **Iohexol**: Concurrent use of opioids with intrathecal iohexol may increase risk for seizures. Opioids should be withheld for 48 hours before and 24 hours after intrathecal administration of iohexol.
- **Loperamide**: Concurrent use may increase risk for constipation.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, selegiline**): Concurrent use may increase the risk for anxiety, confusion, hypotension, respiratory depression, cyanosis, and coma. MAOIs should be withheld for 14 days prior to administration of opioids. Avoid combination.
- **Metoclopramide**: Concurrent use may antagonize the prokinetic effects of metoclopramide.
- **Neuromuscular Blocking Agents** (eg, **atracurium, pancuronium**): Concurrent use may increase the risk for tachycardia, bradycardia, and/or hypotension. Use cautiously and monitor.
- **Propofol**: Concurrent use has been shown to decrease heart rate, cardiac index, and stroke volume. Systemic vascular resistance index, central venous pressure, and pulmonary artery occlusion pressure increased in dogs.[18]
- **Serotonin Receptor Antagonists** (eg, **dolasetron, fluoxetine**): Concurrent use may increase the risk for serotonin syndrome. Avoid combination.
- **Tramadol**: Concurrent use may increase risk for seizures, serotonin syndrome, urinary retention, and constipation. Risk for CNS and respiratory depression may be additive.
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): Concurrent use may increase the risk for urinary retention, constipation, and CNS and respiratory depression.

Laboratory Considerations

- Because opioids can increase biliary tract pressure and raise serum amylase and lipase values, these values may be unreliable for 24 hours after sufentanil is administered.

Dosages

NOTE: Do not confuse CRI dosages listed as µg/kg/*HOUR* with those listed as µg/kg/*MINUTE*.

DOGS:

Analgesic adjunct to general anesthesia (extra-label): 1 µg/kg bolus IV, followed by 0.1 – 0.3 µg/kg/*MINUTE* IV CRI.[5,19–24] IV boluses prior to CRI administration are generally avoided due to potential severe bradycardia. Because of the drug's short duration of activity, consider additional analgesia on termination of remifentanil if painful condition persists.

CATS:

Analgesic adjunct to general anesthesia (extra-label): 2.5 µg/kg IV bolus followed by 0.2 – 0.4 µg/kg/*MINUTE* IV CRI.[25–27] IV boluses prior to CRI administration are generally avoided due to potential severe bradycardia.

HORSES:

Adjunct for general anesthesia (extra-label): Remifentanil 3 µg/kg/*HOUR* IV CRI in combination with dexmedetomidine 1 µg/kg/*HOUR* IV CRI ± alfaxalone 6 µg/kg/*HOUR* IV CRI[28,29]

Standing sedation (extra-label): Remifentanil 6 µg/kg/*HOUR* IV CRI in combination with xylazine 0.65 µg/kg/*HOUR*.[30] Prior to administration of remifentanil/xylazine IV CRI, horses were premedicated with xylazine 0.8 mg/kg IV.

Monitoring

- Anesthetic and/or analgesic efficacy
- Cardiac and respiratory rate
- Pulse oximetry or other methods to measure blood oxygenation when used for anesthesia
- Blood pressure

Client Information

- Remifentanil is a very potent opioid that should only be used by professionals in a setting where adequate animal monitoring is available.

Chemistry/Synonyms

Remifentanil hydrochloride has a pK_a of 7.07 and partition coefficient n-octanol:water of 17.9 at pH 7.3. The commercially available injection has a pH of 2.5 to 3.5.

Remifentanil may also be known as GI-87084B, remifentanilo, rémifentanil, or remifentanili. Trade names include *Ultiva*® and *Remicit*®.

Storage/Stability

Prior to reconstitution, store lyophilized powder for solution between 2°C and 25°C (36°F-77°F). It is stable for 24 hours at room temperature after reconstitution and further dilution to concentrations of 20 – 250 µg/mL with the following IV fluids: sterile water for injection, 5% dextrose, 5% dextrose and 0.9% sodium chloride, 0.9% sodium chloride, 0.45% sodium chloride, and 5% dextrose in lactated Ringer's injection. It is stable for 4 hours at room temperature after reconstitution and further dilution to concentrations of 20 – 250 µg/mL with lactated Ringer's injection. The UK licensed product information states that it should **NOT** be mixed with lactated Ringer's injection with or without 5% glucose.

Remifentanil is a DEA Schedule II (C-II) controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

To reconstitute solution, add 1 mL of diluent per mg of remifentanil. Shake well to dissolve. When reconstituted as directed, the solution contains ≈1 mg of remifentanil activity per mL. It should then be further diluted to a final concentration of 20, 25, 50, or 250 µg/mL prior to administration. Do not administer remifentanil without dilution.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 1 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Remifentanil HCl Powder for reconstitution (IV use only): 1 mg (3 mL vial), 2 mg (5 mL vial), and 5 mg (10 mL vial); *Ultiva*®; (Rx, C-II controlled substance)

Reserpine

(re-***ser***-peen)

Rauwolfia Alkaloid

Prescriber Highlights

- ► Used as a long-term tranquilizer to sedate excitable or difficult horses or horses on forced stall rest
- ► Reserpine is contraindicated in patients that are hypersensitive to it.
- ► Horses may experience a prolonged hypotensive effect. Use this medicine with extreme caution in patients with hypotension or bradycardia. Concurrent or subsequent administration of sedative agents that can lower BP (eg, xylazine) must also be undertaken with caution.
- ► Relatively narrow therapeutic index–dose carefully
- ► Not commercially available in the United States

Uses/Indications

Reserpine is a long-acting central monoamine-depleting agent used for long-term sedation in horses.[1] It may be beneficial in managing difficult horses or horses on forced stall rest. Reserpine has historically been used as a treatment for agalactia in mares with fescue toxicosis; however, this use has mainly been replaced by domperidone.

Reserpine was used in humans for the treatment of hypertension and schizophrenia but has been replaced with safer, more effective therapies.

Pharmacology/Actions

Reserpine irreversibly blocks the transport of norepinephrine, serotonin, and dopamine into storage vesicles. Without storage, the neurotransmitters are metabolized in the cytoplasm of presynaptic nerve terminals by monoamine oxidase and catechol-O-methyltransferase. Depletion of brain amines and serotonin causes sedation and behavior changes, and long-term use may induce extrapyramidal effects (eg, dystonia, dyskinesia, akinesia). The actions of reserpine are long-lasting, as it can take days to weeks for the body to replenish the depleted neurotransmitters.

Reserpine's use in fescue toxicosis is related to the depletion of dopamine, which counteracts the effects of the dopaminergic alkaloids found in tall fescue. Dopamine itself decreases prolactin production and, therefore, milk production. In one study, reserpine was ineffective in treating prepartum agalactia and prolonged gestation from fescue toxicosis but did resolve postpartum agalactia.[1]

Pharmacokinetics

Reserpine is highly lipid-soluble and can penetrate the blood–brain barrier, resulting in further prolonged duration of action. After a single 2.5 mg IM administration of reserpine (0.0045 – 0.005 mg/kg) in horses, peak plasma concentrations occurred at 6 hours, and the drug was detectable for 28 to 56 hours.[2] Following oral administration of the same dose, concentrations similarly peaked at 6 hours, but concentrations were low (C_{max} 0.2 ng/mL) and more variable than with IM dosing; half-life was ≈24 hours.[3] Maximum effects of reserpine have been seen 5 days after repeated dosing. After administration of reserpine, serotonin uptake was decreased for 3 days and returned to normal after 7 days.[4] Reserpine is widely distributed in

the brain, liver, kidneys, and adipose tissue.

In humans, the oral bioavailability of reserpine is ≈50%, with peak concentrations achieved ≈2 hours after administration. Reserpine undergoes hepatic metabolism in humans and is excreted predominantly in feces (30% to 60%) and urine (10%).

Contraindications/Precautions/Warnings

Reserpine is contraindicated in patients that are hypersensitive to it or its inactive ingredients. Use reserpine with extreme caution in patients with low blood pressure or low heart rate.

Reserpine is considered a prohibited substance in most sanctioned competitions and can be detected through high-performance liquid chromatography.

Reserpine was withdrawn from the human market because of risks for serious adverse effects, such as severe depression, seizures, and drug-induced Parkinson disease, and the availability of safer alternatives.

Adverse Effects

Adverse effects of reserpine in horses are associated with decreased sympathetic tone and adrenergic inhibition. Common adverse effects reported in horses include diarrhea with or without signs of abdominal pain or colic (eg, pawing, getting up and down, pacing, restlessness, rolling, kicking or biting at the side, stretching out/straining, shifting weight), muscle tremors/fasciculations, bradycardia, and hypotension.[5,6] There are anecdotal reports of severe, prolonged, and sometimes fatal hypotension, and many clinicians recommend waiting 3 to 4 weeks after discontinuation of reserpine before elective anesthetic procedures. Transient or permanent penile prolapse, paralysis, and paraphimosis may occur in male horses.[7] Increases in dose or IM dosing of reserpine may increase the severity of adverse effects, although the individual patient response is variable. In vitro, equine platelets exposed to reserpine demonstrated increased aggregation and adhesion,[3] although bleeding has not been reported.

Reproductive/Nursing Safety

Reserpine crosses the placenta, resulting in potential teratogenic effects. Nasal discharge, lethargy, and anorexia have been reported in newborns exposed to reserpine in the third trimester.[8] Reserpine is excreted into breast milk, although no adverse effects have been reported.

A possible adverse effect is a penile paralysis in stallions, resulting in paraphimosis and penile edema.[7]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited information is available. Reports have shown that 10 mg (total dose) of reserpine IV in horses causes generalized sweating and flatulence within 3 hours.[9] Pupillary miosis, upper eyelid ptosis, and marked depression may last for 48 hours. Doses of 5 – 10 mg (total dose) have caused colic, sweating, flatulence, miosis, and depression. Dose-dependent increases in the frequency and severity of adverse effects have been noted.

Methamphetamine is considered an antidote in cases of severe hypotension caused by reserpine overdose[6,9]; presumably other (legal) amphetamines (eg, dextroamphetamine) may be used, although no data were located. Other treatments include supportive care and supplemental vitamin C and vitamin E.[10]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions (partial listing) have either been reported or are theoretical in humans or animals receiving reserpine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetic Agents, General** (eg, **isoflurane, propofol**): Reserpine may potentiate hypotensive effects.
- **Antihypertensive Agents**: Reserpine may potentiate the hypotensive effects of these agents.
- **Alpha-2 agonists** (eg**, detomidine, xylazine**): Reserpine may potentiate the hypotensive effects of these agents.
- **CNS Depressants**: Reserpine may enhance CNS depressant effects.
- **Digoxin**: Coadministration may result in additive bradycardia.
- **Insulin And Other Diabetic Agents**: Reserpine may mask clinical signs associated with hypoglycemia.
- **Monoamine Oxidase Inhibitors (MAOIs;** eg**, furazolidone, methylene blue)**: Initially may increase the risk for hypertensive crisis. Concurrent long-term use may increase the risk for hypotension. The combination is contraindicated.
- **Pentoxifylline**: May increase the risk for hypotension
- **Quinidine**: May increase the risk for hypotension, orthostasis, and cardiac depression and/or arrhythmias
- **St. John's Wort**: Antagonizes the effects of reserpine
- **Sympathomimetics** (eg**, epinephrine, norepinephrine, pseudoephedrine)**: Increased risk for hypertension and arrhythmias

Laboratory Considerations

- Reserpine may increase serum prolactin levels.
- Urinary catecholamine excretion may initially increase but is reduced with long-term use.
- May interfere with colorimetric assays for 17-hydroxycorticosteroids and 17-ketosteroids

Dosages

HORSES:

Tranquilizer (extra-label): 0.002 – 0.008 mg/kg (1 – 4 mg/500 kg [1102 lb] horse) PO once daily.[11] Dosages are not well established and should be adjusted to the individual horse based on response. A similar IM dose is recommended; however, the administration is every 48 hours to once weekly, or even less often, based on response.[12,13]

Fescue toxicosis (extra-label): 0.01 mg/kg by mouth every 24 hours[1]

Monitoring

- Clinical efficacy, signs of sedation
- Heart rate, blood pressure, mucous membrane color, capillary refill time
- Adverse effects: signs of hypotension (eg, pale mucous membranes, mental dullness, cold extremities, weakness), colic, and diarrhea

Client Information

- A veterinary professional must administer this medication. Consult with your veterinarian before using reserpine.
- Monitor for signs of side effects (eg, diarrhea, decrease in blood pressure, colic).
- Reserpine may cause male horses to drop their penises.
- Reserpine is a prohibited substance in most sanctioned competitions.

Chemistry/Synonyms

Reserpine is a natural indole alkaloid purified from the *Rauwolfia*

serpentine shrub. Reserpine is available as a white to slightly yellow crystalline powder, with a pK_a of 6.6. It is odorless with a slightly bitter taste.

Reserpine may also be known as NSC-757309, raunervil, raupasil, rausedil, and *Serpasil*®.

Storage/Stability

Store powder at controlled room temperature between 20°C and 25°C (68°F-77°F) and protect from light. Compounded products should be stored according to the product label.

Compatibility/Compounding Considerations

It is suggested to consult specialized references or a veterinary compounding pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None. Products may be available from compounding pharmacies.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix.***

HUMAN-LABELED PRODUCTS:

None. The product has been discontinued in the United States.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Rifampin

Rifampicin

(***rif***-am-pin) *Rifadin*®

Antimicrobial

Prescriber Highlights

- ► Antimicrobial with activity against a variety of microbes (*Rhodococcus* spp, mycobacteria, staphylococci)
- ► Contraindications include hypersensitivity to it or other rifamycins.
- ► Use with caution in pre-existing hepatic dysfunction; dogs may be more susceptible to hepatotoxic effects.
- ► Adverse effects include increases in liver enzymes (especially in dogs). Uncommon adverse effects include rashes, GI distress, and hepatitis.
- ► Preferable to give this drug on an empty stomach
- ► May cause red/orange urine, tears, and sweat (harmless, but can stain fabrics)
- ► Many drug interactions are possible.

Uses/Indications

Rifampin is primarily used to treat *Rhodococcus equi* infections in young horses. A combination of rifampin with a macrolide (eg, erythromycin, azithromycin, or clarithromycin) is the recommended treatment for infection caused by *R equi*[1]; however, a controlled, randomized, double-blinded clinical trial found no difference in efficacy between foals with mild pneumonia associated with *R equi* that received azithromycin/rifampin and those that received azithromycin alone.[2] Studies suggest a macrolide/tetracycline combination (eg, azithromycin or clarithromycin with doxycycline or minocycline) can be used for treatment of *R equi* in foals.[3,4] Rifampin may also be useful to treat proliferative enteropathy caused by *Lawsonia intracellularis* in foals.[5–8]

In dogs, rifampin may be a useful adjunctive antibiotic for treating methicillin-resistant *Staphylococcus pseudintermedius* pyoderma or as an alternative treatment of *Ehrlichia canis;* however, resistance emerges rapidly when rifampin is used alone, so combination therapy with another effective antimicrobial is recommended. When canine brucellosis treatment is attempted (not recommended[9,10]), rifampin may be used in combination with doxycycline and gentamicin. In small animals, rifampin is sometimes combined with other antimycobacterial drugs to treat nontubercular mycobacterial infections or with other antifungal agents (amphotericin B and flucytosine) in the treatment of histoplasmosis or aspergillosis with CNS involvement.

The World Health Organization (WHO) has designated rifampin as a Critically Important (High Priority) Antimicrobial for human medicine.[11] The Office International des Epizooties (OIE) has designated rifampin as a Veterinary Highly Important Antimicrobial (VHIA) Agent in equine species.[12]

Pharmacology/Actions

Rifampin may act as either a bactericidal or bacteriostatic antimicrobial depending on the susceptibility of the organism and the concentration of the drug. For *Rhodococcus equi,* it is considered a time-dependent antibiotic. Rifampin inhibits bacterial, but not mammalian, DNA-dependent RNA polymerase, thereby suppressing the initiation of chain formation for RNA transcription in susceptible organisms. Rifampin is most active against susceptible bacteria undergoing cell division. Rifampin is active against a variety of mycobacterium species and gram-positive bacteria such as staphylococci, *Neisseria* spp, and *Haemophilus* spp.

Although the prevalence of equine *R equi* isolates that are resistant to rifampin is relatively low, tolerance by *R equi* with increasing MICs appears to be growing. Rifampin is used in combination with another active antibiotic in an attempt to reduce the potential for resistance development.[13] Resistance is thought to occur via mutation with resistant strains spreading clonally.

Rifampin has some antifungal activity when combined with other antifungal agents.

Pharmacokinetics

After oral administration, rifampin is relatively well absorbed from the GI tract. Oral bioavailability is reportedly ≈40% to 70% in horses and 37% in adult sheep. If food is given concurrently, peak plasma concentrations may be delayed and slightly reduced.

Rifampin is very lipophilic and readily penetrates into, and achieves effective concentrations in, most body tissues (including bone and prostate), cells, and fluids (including CSF). It also penetrates abscesses and caseous material. Rifampin is 70% to 90% bound to serum proteins, is distributed into milk, and crosses the placenta. Mean volume of distribution is ≈0.9 L/kg in horses, and 1.3 L/kg in sheep.

Rifampin is metabolized in the liver to a deacetylated form that also has antibacterial activity. Both this metabolite and unchanged drug are excreted primarily in the bile, but up to 30% may be excreted in the urine. The parent drug is substantially reabsorbed in the gut but the metabolite is not. Reported elimination half-lives for various species are 6 to 8 hours in horses, 8 hours in dogs, and 3 to 5 hours in sheep. Because rifampin can induce hepatic microsomal enzymes, elimination rates may increase with time.

Contraindications/Precautions/Warnings

Rifampin is contraindicated in patients that are hypersensitive to it or other rifamycins. It should be used with caution in patients with pre-existing hepatic dysfunction. Small animal species should be closely monitored for signs of hepatopathy; dogs may be more susceptible to hepatotoxicity than some other species.[13] To reduce chances for hepatopathy, some clinicians have suggested that PO doses should not exceed 10 mg/kg/day in dogs.

Adverse Effects

Rifampin can cause red/orange colored urine, tears, sweat, and saliva. There are no harmful consequences from this effect. A retrospective study in dogs found that at dosages from 2.9 – 16 mg/kg per day, 16% of treated dogs showed adverse effects, including vomiting (7%), anorexia (6%), and lethargy (4%).[14] Commonly used dosages can cause increased liver enzymes (ALT) in ≈25% of treated dogs.[1] Hepatitis has been reported in some treated dogs.

If rifampin is used in cats for mycobacterial infections, signs of liver dysfunction, including inappetence, vomiting, or jaundice, may occur. Hepatopathy can be fatal.

In some species (eg, humans), rashes, GI distress, and increases in liver enzymes may occur, particularly with long-term use.

Oral dosage forms may be unpalatable.

Adverse effects in horses are apparently rare, but when rifampin is combined with erythromycin, mild diarrhea (self-limiting) to severe enterocolitis in foals and mares, hyperthermia, and acute respiratory distress can occur. When it is used in combination with doxycycline, rifampin can result in hemolytic anemia and elevated liver enzymes.[15] Although not commercially available, IV rifampin has caused CNS depression, sweating, hemolysis, and anorexia in horses.

Reproductive/Nursing Safety

Rodents given high doses of rifampin (150 – 250 mg/kg/day) showed some congenital malformations in their offspring, but the drug has been used in pregnant women with no reported increases in teratogenicity.[16]

Rifampin is excreted in maternal milk; use with caution in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs associated with oral rifampin overdose are generally extensions of the adverse effects outlined in the ***Adverse Effects*** section (GI, red/orange coloring of fluids and skin), but massive overdoses may cause hepatotoxicity.

Should a massive oral overdose occur, standard GI decontamination protocols should be followed. Liver enzymes should be monitored, and supportive treatment should be initiated if necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

There are a multitude of potential drug interactions with rifampin. The following drug interactions (partial listing) have either been reported or are theoretical in humans or animals receiving rifampin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetaminophen**: Rifampin may increase acetaminophen toxicity.
- **Atovaquone**: Rifampin may decrease serum concentrations of atovaquone.
- **Clarithromycin**: Rifampin may reduce clarithromycin concentrations and oral bioavailability may be significantly decreased in foals[17–19]; however, effective clarithromycin concentrations against *Rhodococcus equi* are still achieved.[18,20]
- **Clopidogrel**: Rifampin may increase the risk for bleeding by increasing formation of clopidogrel's active metabolite.
- **Cyclophosphamide**: Rifampin may increase concentrations of active metabolites of cyclophosphamide.
- **Isoniazid**: Increased risk for hepatotoxicity
- **Fluoroquinolones** (eg, **enrofloxacin**): Rifampin may reduce fluoroquinolone concentrations. In vitro antagonism also has been reported when rifampin is used concurrently with fluoroquinolone antibiotics, and concurrent use should be avoided.
- **Ifosfamide**: Rifampin may increase the risk for nephrotoxicity and neurotoxicity by increasing formation of the ifosfamide-active metabolite.
- **Leflunomide**: Rifampin may increase the risk for hepatotoxicity by increasing the formation of the active leflunomide metabolite.
- **Propofol**: Rifampin may enhance the hypotensive effect of propofol.

Because rifampin has been documented to induce hepatic microsomal enzymes, drugs that are metabolized by these enzymes, such as cytochrome P450, may have their elimination half-lives shortened and serum levels decreased. This effect may persist for up to one month after rifampin is discontinued. Examples of drugs/classes that may be affected include:

- **Amiodarone**
- **Azole Antifungals** (eg, **fluconazole, itraconazole, ketoconazole, voriconazole**)
- **Benzodiazepines** (eg, **diazepam, midazolam**)
- **Beta Blockers** (eg, **carvedilol, propranolol**)
- **Buspirone**
- **Calcitriol**
- **Cannabidiol**
- **Chloramphenicol**
- **Corticosteroids** (eg, **dexamethasone, prednisone/prednisolone**)
- **Cyclosporine**
- **Dapsone**
- **Digoxin**
- **Diltiazem**
- **Doxorubicin**
- **Doxycycline**
- **Enalapril**
- **Estrogens**
- **Glipizide**
- **Ketamine**
- **Lidocaine, Mexiletine**
- **Mycophenolate**
- **Ondansetron**
- **Opioids** (eg, **fentanyl, hydrocodone, morphine, tramadol**)
- **Phenobarbital**
- **Praziquantel** (combination is contraindicated in humans)
- **Progestins**
- **Proton Pump Inhibitors** (eg, **omeprazole, pantoprazole**)
- **Quinidine**
- **Rivaroxaban**
- **Sertraline**
- **Sulfa-/Trimethoprim**
- **Theophylline**
- **Vincristine**
- **Warfarin**

Laboratory Considerations

- Microbiologic methods of assaying serum folate and vitamin B12 are interfered with by rifampin.

- Rifampin can cause false positive BSP (bromosulfophthalein, sulfobromophthalein) test results by inhibiting the hepatic uptake of the drug.

Dosages

DOGS:

Superficial bacterial folliculitis (extra-label):

a) 5 – 10 mg/kg PO twice daily when empirical selection of a first-tier systemic antimicrobial agent (eg, cephalexin, amoxicillin/clavulanate, clindamycin) and topical therapy are not appropriate and when cultures indicate susceptibility.[21] Use in combination with another antimicrobial agent is recommended to reduce development of resistance; consultation with a specialist is recommended prior to using this treatment.

b) **Methicillin-resistant *Staphylococcus* spp pyoderma**: 5 mg/kg PO twice daily in combination with topical antimicrobials for 4 to 5 weeks[22]; consultation with a specialist is recommended prior to using this treatment.

Canine leproid granuloma (extra-label): 10 – 15 mg/kg (maximum of 600 mg total) PO once daily in combination with antimicrobial agents known to be effective against slow-growing nontuberculous mycobacteria (eg, clofazimine, clarithromycin, pradofloxacin) may facilitate disease resolution.[23] A combination of rifampin 10 – 15 mg/kg PO once daily and clarithromycin 7.5 – 12.5 mg/kg PO 2 to 3 times a day is recommended for treating severe or refractory canine leproid granuloma in concert with topical silver sulfasalazine.[24]

Canine brucellosis (extra-label): Antibiotic therapy is not encouraged except in select cases due to the zoonotic risk and because there is no known cure.[9,10] If therapy is attempted, infected dogs must be isolated from other dogs and breeding animals. Use combination therapy of rifampin 5 mg/kg PO once daily with doxycycline 10 mg/kg PO every 12 hours and gentamicin 5 mg/kg SC once daily for 3 months. After this antibiotic trial, retest and repeat treatment until the patient has a negative test. After reaching a negative serology test, continue to test every 4 to 6 months and repeat treatment as necessary.[25]

CATS:

Feline leprosy syndromes (extra-label): 10 – 15 mg/kg PO once daily in combination with antimicrobial agents known to be effective against slow-growing nontuberculous mycobacteria (eg, clofazimine, clarithromycin, pradofloxacin) may facilitate disease resolution.[24]

HORSES:

***Rhodococcus equi* infections in foals** (extra-label): There does not appear to be a clear consensus on the treatment of choice for *R equi* in foals. Commonly, rifampin 5 mg/kg PO twice daily is used in combination with either clarithromycin 7.5 mg/kg PO every 12 hours OR azithromycin 10 mg/kg PO once a day for 5 days, then every 48 hours (every other day).[1] Treatment may be required for 4 to 9 weeks but can be reduced with early diagnosis and treatment.

Proliferative enteropathy caused by *Lawsonia intracellularis* in foals (extra-label): Primary treatment consists of a macrolide antibiotic; rifampin 10 mg/kg PO once daily can be added as adjunctive therapy; treat for a minimum of 21 days.[5–8]

Monitoring

- Clinical efficacy
- For monitoring *Rhodococcus equi* infections in foals and response to rifampin/macrolide: Chest radiographs and plasma fibrinogen levels have been suggested as prognostic indicators when performed after 1 week of treatment.
- Adverse effects (especially clinical signs for hepatopathy in small animal species)
- Liver function monitoring (especially in dogs or cats): baseline liver enzymes with rechecks at 10 to 14 days, then at least monthly with long-term therapy

Client Information

- This medicine is best given on an empty stomach. If it causes stomach upset or vomiting, give the medicine with food to see if this helps.
- Rifampin causes red/orange urine, tears, and saliva (and sweat in horses). This effect is not harmful but can stain fabrics.
- Rifampin can have a bitter taste, especially for horses, and may cause your animal to avoid food and develop a decreased appetite during treatment.
- Other medications can interact with rifampin, so be sure to tell your veterinarian and pharmacist what medications (including vitamins, supplements, or herbal therapies) you give your animal, including the amount and time you give each.
- This medicine may cause liver damage, which may be worse in older animals. Your veterinarian will do periodic blood tests to monitor for this problem. Do not miss these important follow-up visits.

Chemistry/Synonyms

A semi-synthetic zwitterion derivative of rifamycin B, rifampin occurs as a red-brown, crystalline powder with a pK_a of 7.9. It is very slightly soluble in water and slightly soluble in alcohol.

Rifampin may also be known as rifampicin, Ba-41166/E, L-5103, NSC-113926, rifaldazine, rifampicinum, or rifamycin AMP; many trade names are available.

Storage/Stability

Rifampin capsules should be stored in tight, light-resistant containers, preferably at room temperature (15°C-30°C [59°F-86°F]).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Rifampin for injection is reported as wholly or variably **incompatible** with typical IV solutions as well as other drugs for injection. It is suggested to consult specialized references or a hospital pharmacist for more specific information. If used, rifampin for injection must be administered only by IV infusion over at least 30 minutes in 5% dextrose solution within 4 hours of preparation. Extravasation must be avoided, and never administer rifampin by IM or SC routes.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Rifampin Oral Capsules: 150 mg and 300 mg; *Rifadin*®, generic; (Rx)

Rifampin Lyophilized Powder for Injection Solution: 600 mg; *Rifadin*®, generic; (Rx)

Rifaximin

(rif-***ax***-i-min) *Xifaxan®*

Antimicrobial

Prescriber Highlights

- ► Nonsystemic antibiotic used to treat hepatic encephalopathy and diarrhea in humans
- ► Has induced remission in dogs with chronic enteropathy but is rarely used clinically
- ► Drug interactions are limited and likely clinically insignificant.
- ► Significantly more expensive than metronidazole or lactulose

Uses/Indications

Rifaximin can be used orally to modify the gut microbiota, as a treatment for chronic diarrhea, or in an attempt to ameliorate hepatic encephalopathy in dogs. In a study with dogs, rifaximin induced complete (86%) or partial (14%) remission of chronic enteropathy; it was shown to be as effective as metronidazole.[1] Rifaximin may have utility in treating or preventing recurrence of hepatic encephalopathy in veterinary patients, but use is limited, as it is prohibitively more expensive than current, accepted treatments.

Rifaximin is used in humans to treat uncomplicated traveler's diarrhea caused by *Escherichia coli* and diarrhea due to irritable bowel syndrome and to treat and reduce the risk for hepatic encephalopathy.

The World Health Organization has designated rifaximin as a Critically Important antimicrobial for human medicine.[2]

Pharmacology/Actions

Rifaximin inhibits bacterial protein synthesis by binding the beta-subunit of bacterial DNA-dependent RNA polymerase. In humans, it is effective against *Escherichia coli* but is ineffective against *Campylobacter jejuni*; efficacy for other causes of infectious diarrhea (eg, *Salmonella* spp, *Shigella* spp) has not been established. Rifaximin may also be active against some protozoa (eg, *Blastocystis hominis*, *Cryptosporidium parvum*).[3]

Pharmacokinetics

In a study of dogs receiving rifaximin at either 25 mg/kg PO as a single dose or at 10 mg/kg PO per day for 8 days, serum rifaximin was not detectable.[4]

Systemic exposure to rifaximin is limited after oral administration. In patients with hepatic impairment, systemic exposure increases 10- to 25-fold after oral administration, although dosage adjustment is usually not necessary.[5] Administration with food increases systemic exposure, but this effect is clinically insignificant. Over 95% of the drug is excreted unchanged in the feces. Of the limited drug that is absorbed, ≈65% is protein-bound, and extensive hepatic metabolism occurs via CYP 3A4. The elimination half-life is ≈6 hours.

Contraindications/Precautions/Warnings

Rifaximin is contraindicated in patients with a known hypersensitivity to it or other rifamycin antimicrobials.[5] The effectiveness of rifaximin in humans with infectious diarrhea caused by pathogens other than *Escherichia coli* has not been demonstrated. Rifaximin use has been associated with the development of *Clostridium difficile* infection in humans. Severe hepatic impairment may lead to increased systemic exposure and may be substantially increased with concurrent use of rifaximin with P-glycoprotein inhibitors (eg, verapamil). Hypersensitivity reactions, including exfoliative dermatitis, rash, angioneurotic edema, urticaria, flushing, pruritus, and anaphylaxis, have occurred as early as within 15 minutes of drug administration. It is not appropriate for use in patients with bloody diarrhea or with diarrhea and fever.

Do not confuse rifaXIMin with rifaMPin.

Adverse Effects

Rifaximin appears to be well tolerated. Adverse effects reported in humans include peripheral edema, dizziness, fatigue, pruritus, anemia, and nausea.

Reproductive/Nursing Safety

Rifaximin was teratogenic when given to rats at 150 – 300 mg/kg and in rabbits receiving 62.5 – 1000 mg/kg.[5] Data about the safe use of rifaximin in pregnant women are lacking. It is unknown if rifaximin is excreted into milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdosage/Acute Toxicity

Because rifaximin is not systemically absorbed, clinical signs from overdoses are unlikely. Gut decontamination is not considered necessary. Provide supportive care and monitor the patient closely. Consultation with a veterinary poison center can be considered.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Induction of hepatic enzymes by rifaximin is not expected in humans receiving recommended rifaximin doses. Rifaximin is a substrate of CYP 3A4 in humans, as well as a substrate and possible inhibitor of P-glycoprotein and several organic-anion-transporting polypeptides (OATPs). Clinically significant alteration of rifaximin by other drugs is unlikely because of the limited bioavailability of rifaximin. The following drug interactions have either been reported or are theoretical in humans or animals receiving rifaximin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cyclosporine**: May increase rifaximin exposure
- **CYP 3A4 Inhibitors** (eg, **clarithromycin, fluoxetine, ketoconazole, verapamil**): May increase rifaximin exposure
- **P-Glycoprotein Inhibitors** (eg, **amiodarone, clarithromycin, itraconazole, verapamil**): May increase rifaximin exposure
- **Vaccines (Live, oral)**: Antibiotics may reduce immunologic response to the live vaccines.
- **Warfarin**: Prothrombin time (PT) and anticoagulant effect may be reduced.

Laboratory Considerations

- None were noted.

Dosages

DOGS:

Chronic enteropathy (extra-label): 25 mg/kg PO every 12 hours for 21 days was as effective as metronidazole.[1] All dogs concurrently received metoclopramide and ranitidine for the first 15 days, a weekly cyanocobalamin injection, and were fed a limited diet of boiled chicken and rice; the study lacked a control group to account for the possible therapeutic role of these interventions.

Monitoring

- Clinical efficacy
- Development of antibiotic-related diarrhea

Client Information

- This medicine may be given with or without food.
- Report bloody diarrhea to your veterinarian immediately.

Chemistry/Synonyms
Rifaximin is a semi-synthetic derivative of rifamycin SV and is structurally related to rifampin. It occurs as a red-orange crystalline powder that is insoluble in water and soluble in acetone and methanol.

Rifaximin is also known as L/105, rifaxidin, rifaximinum, and *Xifaxin®*.

Storage/Stability
Store rifaximin protected from light at controlled room temperature 20°C to 25°C (68°F-77°F); excursions are permitted to 15°C to 30°C (59°F-86°F).[5]

Compatibility/Compounding Considerations
No information was noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Rifaximin Tablets: 200 mg and 550 mg tablets; *Xifaxin®*; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Rivaroxaban
(riv-a-***rox***-a-ban) *Xarelto®*
Factor Xa Inhibitor

Prescriber Highlights
- ► Oral anticoagulant used to prevent or treat thrombosis in high-risk patients, with prompt and predictable anticoagulant effect
- ► Contraindicated in patients with uncontrolled pathologic bleeding, severe hepatic disease, hepatic disease associated with coagulopathy, or with significant renal impairment.
- ► Appears to be well tolerated but use in veterinary patients is limited. Minor bleeding is possible.
- ► Specific guidelines for monitoring therapy in clinical patients are lacking.
- ► Cost may be a limiting factor.

Uses/Indications
Rivaroxaban has been used to treat thromboembolic disease in dogs[1–7] and cats.[8] Rivaroxaban may be preferred over unfractionated heparin in dogs due to evidence of equivalent efficacy, as well as reliable pharmacokinetics and the ease of oral administration. Direct Xa inhibitors can be considered in cats based on reliable pharmacokinetics and favorable safety profile.[9]

In humans, it is used to treat deep-vein thrombosis (DVT) and pulmonary embolism (PE) for the prevention of DVT following orthopedic surgery or before DVT/PE, and for stroke and systemic embolism prevention in patients with atrial fibrillation. Rivaroxaban has not been proven to be either safer or more effective than other available anticoagulants.

Pharmacology/Actions
Rivaroxaban is an inhibitor of activated clotting factor X (FXa) and prothrombinase activity. Unlike heparins, its anticoagulant effect does not require a cofactor. It indirectly inhibits platelet aggregation induced by thrombin.

In vitro data suggest FXa in dogs has a lower affinity for rivaroxaban than in humans; a concentration of ≈0.4 µg/mL was required to inhibit 50% thrombin generation.[10] Peak anti-FXa activity occurred 2 to 4 hours after administration to dogs,[11] and 2 to 3 hours after administration to cats.[12]

Pharmacokinetics
In healthy dogs given a single dose of rivaroxaban 1 mg/kg PO, the drug was rapidly absorbed, with 60% to 85% bioavailability.[13] Food does not appear to have a clinically relevant effect on rivaroxaban aborption.[11] Peak concentrations were 1.28 µg/mL and occurred 30 minutes after administration. The elimination half-life was ≈1 hour.[13]

In healthy cats, a single 2.5 mg/cat (NOT mg/kg) rivaroxaban dose PO resulted in peak concentrations of 0.27 µg/mL attained 2.5 hours after administration. The elimination half-life was 7.5 hours.[12]

In humans, rivaroxaban is 66% to 100% bioavailable after oral administration, although absorption decreases with increasing doses. Peak concentrations occur within 2 to 4 hours after dosing. Food increases the extent of the drug's absorption while delaying the time to peak concentration, but this effect only occurs at higher doses. Absorption is greatest when rivaroxaban is administered into the stomach and diminishes when it is administered directly into the intestinal tract. It is ≈95% protein-bound to albumin. Rivaroxaban is hepatically metabolized, including cytochrome P450 3A4 isozyme (CYP3A4). It is also a P-glycoprotein substrate. The drug and metabolites are renally eliminated, with an elimination half-life between 5 and 9 hours. Half-life is prolonged in elderly patients (11 to 13 hours) and in patients with renal (8 to 10 hours) or hepatic (10 hours) dysfunction.

Contraindications/Precautions/Warnings
Rivaroxaban is contraindicated in patients that are allergic to it or have uncontrolled pathologic bleeding. The drug should be avoided in patients with severe hepatic disease, a hepatic disease associated with coagulopathy, or with significant renal impairment. It may be used with caution in patients with moderate hepatic impairment; a lower dose is recommended in patients with moderate renal impairment. Use rivaroxaban with caution in patients with minor bleeding and in patients with bleeding disorders or coagulopathies. Patients undergoing neuraxial anesthesia or spinal puncture are at increased risk for epidural or spinal hematoma.

Thrombotic events have been observed in humans following discontinuation of rivaroxban.[14] The significance for veterinary patients is unclear, but it has been suggested to taper rivaroxaban before discontining.[15]

In humans with atrial fibrillation, a rebound risk for stroke has been noted after discontinuing rivaroxaban; alternative anticoagulant coverage may be needed during that time. Rivaroxaban should be stopped at least 24 hours before surgery or high-risk procedures; resume rivaroxaban once hemostasis has been established.[16] Consult the product label for guidance when transitioning to and from rivaroxaban with other anticoagulants to ensure continuous anticoagulation while minimizing the risk for bleeding.

Adverse Effects
The most common adverse effect in humans is bleeding.[16] Nausea, vomiting, diarrhea, and an increase in liver enzymes can also occur. Pruritus and rash have been noted but are uncommon.

Rivaroxaban is generally safe and well tolerated in dogs and cats, although the number of animals that have received rivaroxaban is small. Reported adverse effects include minor bleeding (eg, epistaxis, hematemesis, hematuria, hematochezia, and anemia) and vomiting.[8,17–19]

Reproductive/Nursing Safety
Rivaroxaban crosses the placenta of rats and rabbits.[16] Pronounced maternal hemorrhagic complications have occurred in rats, and decreased fetal weights occurred in pregnant rats receiving 120 mg/kg (14 times the human exposure). Postimplantation pregnancy losses have occurred in rabbits, as has fetal toxicity (eg, decreases in fe-

tal weights, live fetuses, increased resorption) in rabbits receiving 10 mg/kg (4 times the human exposure) or more during organogenesis. In animal studies, during labor and delivery, increased maternal bleeding and death and increased fetal death occurred in animals receiving 40 mg/kg.[16]

Rivaroxaban is excreted into the breast milk of rats[16]; use with caution in lactating animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses are expected to increase the risk for hemorrhage, but overdoses in humans have not been universally associated with significant bleeding. Treatment is supportive and based on clinical signs; monitoring with prothrombin time (PT), international normalized ratio (INR), activated partial thromboplastin time (aPTT), thromboelastography, and thrombin generation tests may also be helpful. GI decontamination can be considered for recent ingestions. Hemorrhagic complications may be treated with appropriate blood products. It is not dialyzable. An antidote to FXa anticoagulants (andexanet alfa [recombinant coagulation factor Xa, inactivated zhzo])[20] is available and may be considered, but its use in animals is limited.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In humans, rivaroxaban is a substrate of CYP3A4 and P-glycoprotein. Drugs that inhibit both enzyme pathways may increase rivaroxaban exposure and the risk for bleeding. The following drug interactions have either been reported or are theoretical in humans or animals receiving rivaroxaban and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Azole Antifungals** (eg, **itraconazole, ketoconazole, voriconazole**): May substantially increase rivaroxaban exposure and increase the risk for bleeding
- **Anticoagulants, Other** (eg, **heparins, warfarin**): May increase the risk for bleeding
- **Antiplatelet Agents** (eg, **aspirin, clopidogrel**): May increase the risk for bleeding
- **CYP3A4 Inducers** (eg, **rifampin, phenobarbital**): May increase rivaroxaban metabolism and increase the risk for a thrombotic event
- **Fluoxetine**: May increase the risk for bleeding
- **Macrolide Antibiotics** (eg, **clarithromycin, erythromycin**): May substantially increase rivaroxaban exposure and increase the risk for bleeding
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, deracoxib, firocoxib, meloxicam, robenacoxib**): May increase the risk for bleeding

Laboratory Interactions

- Rivaroxaban may result in a decreased factor VIII: C serum level because of assay interference.
- Falsely elevated INR has been noted.

Dosages

NOTE: Thrombotic events have been observed in humans following discontinuation of rivaroxaban. The significance for veterinary patients is unclear, but it has been suggested to taper rivaroxaban before discontining.[15]

DOGS:

Antithrombotic agent (extra-label):

a) 0.5 –1 mg/kg PO every 24 hours.[2–7] Based on in vivo coagulation assessments, administration every 12 hours may be more appropriate.[21]

b) 1 – 2 mg/kg PO every 24 hours[22,23]

CATS:

Antithrombotic agent (extra-label):

a) 1.25 mg/cat (NOT mg/kg) PO every 24 hours provided less than 12 hours of anti-FXa activity in healthy cats. Further studies of higher doses are warranted.[12]

b) 0.5 – 1 mg/kg PO every 12 to 24 hours[12,23]; practically, 2.5 – 5 mg/cat (NOT mg/kg) PO every 24 hours

c) 2.5 mg/cat (NOT mg/kg) PO every 24 hours in combination with clopidogrel 18.75 mg/cat (NOT mg/kg) PO every 24 hours[8]

Monitoring

- Routine coagulation monitoring is not required[17]; however, prothrombin time (PT) and thromboelastography can be considered.[24,25]
- CBC with platelets
- Renal and hepatic function
- Clinical efficacy
- Signs of bleeding (eg, lethargy, dyspnea, collapse)

Client Information

- Give this medicine as directed by your veterinarian.
- Your animal may bruise or bleed more easily while taking this medication. Contact your veterinarian immediately if you notice bleeding or suspect your animal may be experiencing internal bleeding.
- If you miss a dose, give it as soon as you remember then restart the regular schedule.
- Give this medicine with or without food and at the same time each day.
- Do not stop giving this medicine to your animal without discussing with your veterinarian.

Chemistry/Synonyms

Rivaroxaban occurs as an odorless white to yellowish powder that is practically insoluble in water and only slightly soluble in organic solvents. The commercial tablets contain pure (*S*)-enantiomer.

Rivaroxaban is also known as Bay-59-7939, rivaroxabana, rivaroxabanum, and *Xarelto*®.

Storage/Stability

Store rivaroxaban at room temperature (ie, 25°C [77°F]); excursions to 15°C to 30°C (59°F-86°F) are permitted. Store out of reach of pets and children.

Compatibility/Compounding Considerations

Rivaroxaban may be crushed and mixed with applesauce immediately before oral administration. It may also be crushed and suspended in 50 mL of water for administration via nasogastric or gastric feeding tube. The drug is stable for up to 4 hours when crushed and mixed in water or applesauce.[16]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Rivaroxaban Tablets: 2.5 mg, 10 mg, 15 mg, and 20 mg tablets; *Xarelto*®; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Robenacoxib

(roe-ben-ah-***cox***-ib) *Onsior®*

Nonsteroidal Anti-inflammatory Drug (NSAID)

Prescriber Highlights

- ► COX-2–selective NSAID for use in dogs and cats to control postoperative pain for up to 3 days
- ► Only NSAID approved for multiple doses in cats in the United States
- ► In cats, the oral dose is different than the injection dose.
- ► Contraindications include hypersensitivity, known NSAID intolerance, and GI ulceration.
- ► Use with caution in patients with impaired renal and hepatic function, that are dehydrated, hypovolemic, or hypotensive, and in patients with a risk for GI ulceration.
- ► GI effects are the most common adverse effect.

Uses/Indications

Robenacoxib is a cyclooxygenase-2 (COX-2)–selective NSAID that is FDA-approved for use in dogs and cats 4 months of age and older, weighing 2.5 kg (5.5 lb) or more. In the United States, it is indicated for use in cats for the control of postoperative pain and inflammation associated with orthopedic surgery, ovariohysterectomy, and castration for a maximum of 3 days.[1,2] In dogs, robenacoxib is indicated for the control of postoperative pain and inflammation associated with soft tissue surgery for a maximum of 3 days.[1,3]

In other countries, the oral tablets are labeled for the treatment of pain and inflammation associated with chronic osteoarthritis in dogs and for the treatment of acute pain and inflammation associated with musculoskeletal disorders in cats. The injection is labeled for the treatment of pain and inflammation associated with orthopedic or soft tissue surgery in dogs and for the treatment of pain and inflammation associated with soft tissue surgery in cats.[4]

In cats, robenacoxib had equivalent (noninferior) efficacy and tolerability as compared with ketoprofen tablets,[5,6] meloxicam injection,[7] and tolfenamic acid injection.[8] Robenacoxib given SC prior to hysterectomy provided analgesia for up to 24 hours and was more effective than a single dose of buprenorphine (0.02 mg/kg SC) for the first 8 hours after surgery.[9] Robenacoxib did not change the extent of blood–aqueous barrier breakdown in cats undergoing anterior chamber paracentesis.[10] The tablets and injection can safely be interchanged in cats, although the dose is different for each formulation.[11]

In an acute synovitis model in dogs, robenacoxib had equivalent analgesic and anti-inflammatory efficacy as meloxicam.[12] In a multicenter, prospective, randomized, blinded field trial, robenacoxib provided efficacy and tolerability similar to that of meloxicam for the management of perioperative pain and inflammation in dogs undergoing orthopedic surgery[13] and to carprofen in dogs with arthritis.[14,15] Meloxicam appeared more effective than robenacoxib in dogs undergoing combined laparoscopic ovariectomy and laparoscopic-assisted gastropexy.[16] Robenacoxib tablets appear safe when given daily for up to 6 months in dogs.[17] The tablets and injection can safely and effectively be interchanged in dogs without interruption of daily therapy.[18]

Pharmacology/Actions

Robenacoxib is a selective inhibitor of cyclooxygenase-2 (COX-2) in cats[19,20] and dogs.[21,22] It is ≈130 times more selective for COX-2 than COX-1 in dogs[21] and ≈500 times more selective in cats[19] when using an in vitro whole blood assay. COX-2 is the inducible form of the enzyme and is primarily responsible for the production of mediators (eg, prostaglandin E) that can induce pain, inflammation, and fever.

In dogs, robenacoxib 2 mg/kg given SC 1 hour before administration of sevoflurane decreased the sevoflurane minimum alveolar concentration (MAC) for blunting the adrenergic response (BAR) by ≈16%.[23]

Creatinine clearance in cats was not altered when determined immediately after a single dose (2 mg/kg SC) of robenacoxib or ketoprofen.[24]

Pharmacokinetics

In dogs, peak blood concentrations occur ≈30 minutes after oral administration. Oral bioavailability is 62% when robenacoxib is given with food and 84% when it is given without food; SC bioavailability is 67% to 100%.[1,25] Peak concentration occurred 90 minutes after SC administration in conscious dogs but 120 minutes in sevoflurane-anesthetized mechanically ventilated dogs.[26] The volume of distribution (steady state) is 0.24 L/kg.[25] It is highly bound to plasma proteins (greater than 98%). Robenacoxib is metabolized by the liver. Terminal half-life in blood is ≈0.9 to 1.2 hours after oral administration and 1 to 4 hours when given SC. Robenacoxib persists longer and at higher concentrations at sites of inflammation than in blood.[27] Excretion is primarily via the biliary route (≈65%); the remainder is excreted renally.[28] Robenacoxib does not appear to induce hepatic enzymes in dogs.

In cats, bioavailability is ≈69% after SC administration. After PO administration, peak blood concentrations of robenacoxib occur at ≈30 minutes, and, although the presence of a small amount of food does not significantly affect bioavailability, full rations may significantly reduce oral bioavailability (49% fasted vs 10% full ration).[29] The volume of distribution is 0.19 L/kg, and robenacoxib is 99% bound to plasma proteins. It is extensively metabolized by the liver, with ≈25% converted into a gamma-lactam metabolite. Terminal elimination half-life is ≈1.1 hours after SC injection and 1.7 hours after oral administration. Elimination is 60% biliary and 17% renal. Robenacoxib crossed the blood-aqueous barrier in 5 of 6 cats.[10]

Contraindications/Precautions/Warnings

Robenacoxib is contraindicated in patients with hypersensitivity to robenacoxib or known intolerance to NSAIDs or with GI ulcers.[4] Robenacoxib injection contains sodium metabisulfite and should not be used in patients with sulfite hypersensitivity.[4] Robenacoxib should not be used concurrently with corticosteroids or other NSAIDs.[1–3]

Use robenacoxib with caution in patients with impaired renal function, patients that are dehydrated, hypovolemic, or hypotensive, and in patients with a risk for GI ulceration. Use with caution in dogs and cats with hepatic dysfunction[1–3]; on some foreign labels, hepatic dysfunction is listed as being a contraindication.[30] Robenacoxib has been shown to prolong the QT interval and should be used with caution in patients with cardiac disease. Use with other QT prolonging agents is not recommended.[1,2] If use cannot be avoided in these cases, careful monitoring is required.

Stop administration in patients that develop hyporexia or patients that become lethargic. Use has not been evaluated in cats or dogs less than 4 months of age, weighing less than 2.5 kg (5.5 lb), that are used for breeding, or are pregnant or lactating.[1–3]

Concurrent use with other anti-inflammatory drugs may result in additional or increased adverse effects; therefore, a treatment-free period from all other anti-inflammatories should be observed for at least 24 hours before beginning treatment with robenacoxib.[4,31] The treatment-free period, however, should take into account the pharmacokinetic properties of the products used previously. Use robenacoxib under strict veterinary monitoring in dogs or cats with a risk for GI ulcers, or if the animal previously displayed intolerance to other NSAIDs.

Robenacoxib should be used cautiously with other drugs that may affect renal blood flow (eg, diuretics, ACE inhibitors), and additional clinical monitoring is recommended. Avoid use with other potentially nephrotoxic drugs, as this may increase risk for renal toxicity. When NSAIDs are used, fluid therapy during surgery is recommended to decrease potential renal complications.[1,2]

Adverse Effects

Adverse effects commonly reported in dogs include GI effects (eg, decreased appetite, vomiting, soft feces, diarrhea)[1,3] and pain on injection and are usually mild and self-limiting.[1,31] Blood in the feces was seen in some patients. Increased liver enzymes were common in dogs given robenacoxib for longer than 2 weeks. No significant adverse cardiovascular effects were noted in healthy dogs.[32] Injection site reactions (eg, swelling, necrosis, and abscesses) have been reported.[1]

Robenacoxib administered IV to healthy adult beagles did not alter ECG readings, arterial blood pressure, clinical chemistry, coagulation or hematologic parameters, or mucosal bleeding time for up to 8 hours after administration.[32] Another study in healthy adult beagles demonstrated no decrease in GFR when robenacoxib was given orally alone or with benazepril; however, different effects may occur in dogs with cardiovascular or renal disaease.[33]

Adverse effects reported in cats include infections, dehiscence, and increased bleeding at *incision* sites.[1,2] Decreased appetite, vomiting, lethargy, and pain at the *injection* site may also occur. Patients at greatest risk for adverse effects are those that are dehydrated, on concomitant diuretic therapy, or with existing renal, cardiovascular, and/or hepatic dysfunction. Acute kidney injury and death have been reported.

Administration of the labeled dose for 28 days was well-tolerated in cats with osteoarthritis.[34] Administration of the label-recommended dose to cats with chronic musculoskeletal disease for 4 to 12 weeks was not associated with an increased risk for adverse effects compared to placebo.[35]

Reproductive/Nursing Safety

Because the safety of robenacoxib has not been established during pregnancy or lactation in dogs or cats used for breeding, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No acute toxicity data were located. Acute overdoses may potentially cause GI, kidney, or liver toxicity.

In chronic toxicity studies in healthy young (ie, 6 to 7 months old) beagles, robenacoxib up to 10 mg/kg/day for 6 months did not produce any signs of toxicity.[22] In preclinical safety studies, dosages in beagles of up to 20 times the label dose (40 mg/kg) PO for 1 month and 5 times the label dose (10 mg/kg) for 6 months did not cause significant clinical adverse effects, hematologic and clinical chemistry variables, or macroscopic or microscopic lesions at necropsy.[22] Oral robenacoxib administered daily for 21 days to healthy beagles resulted in microscopic mucosal lesions in the descending colon of 4 of 7 dogs.[36] The clinical relevance of this finding is uncertain.

In healthy young cats (ie, 10 months of age), dosages of 4 mg/kg (2 times label dose) SC every 24 hours for 2 days and 10 mg/kg (5 times label dose) SC for 3 consecutive days did not produce any signs of toxicity. Safety trials in healthy young cats receiving up to 10 mg/kg (≈5 times label dose) PO every 24 hours for 28 days or PO every 12 hours for 42 days showed that robenacoxib, as compared with placebo, did not cause toxicologically significant effects on general observations of health, hematologic and clinical chemistry variables, urinalyses, or postmortem organ weight, gross pathology, or histopathology assessment.[37]

Supportive therapy based on clinical presentation, including administration of GI protective agents and forced diuresis, may be appropriate.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

See the ***Contraindications/Precautions/Warnings*** section for the manufacturer's warnings regarding use of robenacoxib with other medications. In addition, the following drug interactions have either been reported or are theoretical in humans or animals receiving NSAIDs and may be of significance in animals receiving robenacoxib. Unless otherwise noted, use of these drugs with robenacoxib is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): NSAIDs can reduce effects on blood pressure.
- **Anesthetic Agents** (eg, **alfaxalone, propofol, sevoflurane**): Anesthetic use may reduce renal perfusion, which may alter robenacoxib pharmacokinetics[26] and possibly increase the risk for renal complications. Robenacoxib has a minimum alveolar concentration (MAC)-sparing effect in dogs.[23]
- **Aspirin**: May increase the risk for GI toxicity (eg, ulceration, bleeding, vomiting, diarrhea)
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May increase the risk for GI toxicity (eg, ulceration, bleeding, vomiting, diarrhea); use together is contraindicated.
- **Digoxin**: NSAIDs may increase serum digoxin concentrations.
- **Fluconazole**: Administration has increased plasma concentrations of celecoxib in humans and could potentially affect robenacoxib concentrations in dogs.
- **Furosemide**: NSAIDs may reduce the saluretic and diuretic effects.
- **Highly Protein Bound Drugs** (eg, **anticoagulants [oral], phenytoin, other anti-inflammatory agents, salicylates, sulfonamides, sulfonylurea antidiabetic agents, valproic acid**): Because robenacoxib is highly bound to plasma proteins (more than 99%) in dogs and cats, it could theoretically displace other highly bound drugs. These interactions are unlikely to be of clinical concern because increased free drug concentrations will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.
- **Methotrexate**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution.
- **Nephrotoxic Drugs** (eg, **aminoglycosides, amphotericin B, furosemide**): May enhance the risk for nephrotoxicity
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs;** eg, **carprofen, deracoxib, meloxicam)**: Concurrent use with robenacoxib duplicates therapy and is contraindicated.
- **QT Prolongation Drugs** (eg, **cisapride, quinidine, sotalol**): Robenacoxib prolongs the QT interval; use with other QT prolonging drugs is not recommended.[1,2]

Laboratory Considerations

- None noted

Dosages

DOGS:

Control of postoperative pain and inflammation associated

with soft tissue surgery (label dosage; FDA-approved): 2 mg/kg SC, PO once daily for a maximum of 3 days. The first dose should be administered ≈45 minutes before surgery, at the same time as preanesthetic agents. Subsequent doses can be given as SC injections (rotate injection sites) or using oral tablets. Use the lowest effective dose for the shortest duration consistent with individual response. Giving without food increases bioavailability; however, it may also be given with food. Tablets are not scored and should not be broken.[1]

Pain and inflammation associated with chronic osteoarthritis (extra-label): 1 mg/kg with a range of 1 – 2 mg/kg PO every 24 hours (at the same time every day). A clinical response is normally seen within a week; discontinue and reassess diagnosis if no clinical improvement is seen after 10 days. For long-term treatment, dose can be adjusted to lowest effective dose for the patient.[4]

CATS:

Control of postoperative pain and inflammation associated with orthopedic surgery, ovariohysterectomy, and castration (label dosage; FDA-approved): **NOTE**: In cats, the dosages of robenacoxib tablets and injection are different.[1,2]

a) **SC**: 2 mg/kg SC once daily for a maximum of 3 days.[1] The first dose should be administered ≈30 minutes prior to surgery, at the same time as preanesthetic agents. Subsequent doses can be given as SC injection (rotate injection sites) or using oral tablets.

b) **PO**: 1 mg/kg with a range of 1 – 2.4 mg/kg PO once daily; dosed based on body weight according to table below.[2] The first dose should be administered ≈30 minutes prior to surgery, at the same time as preanesthetic agents. May be given with or without food. Tablets are not scored and should not be broken.

Robenacoxib Tablet Dosing Chart for Cats

Body weight in kg (lb)	Number of robenacoxib 6 mg tablets PO daily
2.5-6 (5.5-13.2)	1
6.1-12 (13.3-26.4)	2

Acute or chronic pain and inflammation associated with musculoskeletal disorders (extra-label): 1 mg/kg; with a range of 1 – 2.4 mg/kg PO once daily (at the same time each day) for up to 6 days for acute pain. This equates to 1 tablet for cats weighing 2.5 kg (5.5 lb) to less than 6 kg (13.2 lb) and 2 tablets for cats weighing 6 to 12 kg (13.2 to 26.4 lb). Giving without food increases bioavailability; however, it may also be given with food. Tablets are not scored and should not be broken. Duration of treatment for chronic musculoskeletal disorders should be decided on an individual basis.[38]

Osteoarthritis (extra-label): 1 – 2.4 mg/kg PO every 24 hours for 28 days was well tolerated in cats with osteoarthritis, including cats with evidence of concurrent CKD. After 28 days of administration, there was no clinical indication of damage to the GI tract, kidneys, or liver.[34]

Monitoring

- Baseline and periodic physical examination, including clinical efficacy and adverse effect queries
- GI adverse effects; appetite in cats
- Baseline and periodic CBC
- With long-term therapy, baseline and periodic serum liver chemistry profile (eg, 2, 4, and 8 weeks after beginning treatment, then every 3 to 6 months); discontinue treatment if liver enzyme activity increases markedly or increases in liver enzymes are accompanied by clinical signs (eg, anorexia, lethargy, vomiting)[30]
- Baseline and periodic serum renal chemistry profile with electrolytes and urinalysis

Client Information

- NSAID that is approved for short-term treatment (up to 3 days) of postoperative pain and inflammation in dogs and cats.
- For dogs, give this medicine at the same time each day about 30 minutes before letting the dog eat; however, if the dog vomits shortly after being given the drug, try giving another dose with food to see if this helps. If vomiting continues, contact your veterinarian. Most dogs tolerate the drug well, but in rare cases some dogs can develop ulcers or serious kidney and liver problems.
- Contact your veterinarian if your animal has any decreased or increased appetite; vomiting; change in bowel movements; change in behavior or activity (eg, more or less active than normal); incoordination/weakness (eg, stumbling, clumsiness); seizures (convulsions); aggression (threatening behavior/actions); yellowing of gums, skin, or whites of the eyes (jaundice); and changes in drinking (eg, frequency, amount consumed) or urination habits (eg, frequency, color, or smell).
- If your animal is taking this medicine long term, your veterinarian will need to monitor your animal closely for side effects by doing examinations and blood tests. Do not miss these important follow-up visits.
- Do not divide or break tablets. Store chewable tablets out of reach of animals and children.
- Wash hands after handling tablets. Pregnant women who are near term should wear gloves when handling this medicine.

Chemistry/Synonyms

A coxib-class NSAID, robenacoxib is a diclofenac analogue. The commercially available injection is a clear, colorless to slightly pink solution. A lactam degradation product is formed over time with normal storage.[1]

Robenacoxib may also be known as robenacoxibum or robénacoxib. Its trade name is *Onsior®*.

Storage/Stability

Store tablets at controlled room temperature of 15°C to 25°C (59°F-77°F). The injection should be stored in the refrigerator at 2°C to 8°C (36°F-46°F) in its original outer carton.

Compatibility/Compounding Considerations

Robenacoxib must not be mixed with other drugs as compatibility studies have not been done.[31]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Robenacoxib-Flavored (yeast) Tablets: 6 mg; *Onsior®*; (Rx). FDA-approved for use in cats. NADA# 141-320. Tablets are not scored and should not be split. The *Information for Cat Owners* sheet should be included whenever tablets are dispensed for administration by clients at home.

Robenacoxib-Flavored (yeast, pork liver) Oral Tablets: 10 mg, 20 mg, and 40 mg; *Onsior®*; (Rx). FDA-approved for use in dogs. NADA# 141-463. Tablets are not scored and should not be split. The *Information for Dog Owners* sheet should be included whenever tablets are dispensed for administration by clients at home.

Robenacoxib Solution for Injection: 20 mg/mL in 20 mL multi-dose vials; *Onsior®*; (Rx). FDA-approved for dogs and cats. NADA# 141-443

HUMAN-LABELED PRODUCTS: NONE

Rocuronium

(roe-kyoo-***roe***-nee-um) *Zemuron®*

Nondepolarizing Neuromuscular Blocker

Prescriber Highlights

- ► Nondepolarizing neuromuscular blocking agent with a rapid to intermediate onset and intermediate duration of action
- ► Faster onset of action than vecuronium and atracurium and fewer adverse effects than succinylcholine
- ► Use with caution in patients with renal or hepatic dysfunction or myasthenia gravis.
- ► Adverse effects may include changes in heart rate and blood pressure.
- ► Not for use as a sole agent; no analgesic or sedative actions
- ► Must only be used under close monitoring with intubation and mechanical ventilation
- ► High alert medication; consider extra dosage checks and warning labels

Uses/Indications

Clinical experience with rocuronium in veterinary patients is relatively limited, but it potentially can be used in dogs, cats, and horses for muscle relaxation during surgery. Rocuronium can be used under general anesthesia during ophthalmic procedures to achieve a central position of the eye.

In cats, it has been shown that recovery of the train-of-four (TOF) ratio of 0.9 does not reliably exclude residual block, and it is prudent to reverse rocuronium and other neuromuscular blocking agents even when no fade can be detected by objective means.[1]

Pharmacology/Actions

Rocuronium is an aminosteroidal competitive, nondepolarizing neuromuscular blocking agent structurally similar to vecuronium. It has a dose-dependent rapid to intermediate onset and intermediate duration of action. Rocuronium onset is nearly as rapid onset as succinylcholine and is 2 to 3 times faster than vercuronium. Its duration is similar to vercuronium and atracurium. It antagonizes acetylcholine by competitively binding cholinergic receptor sites on the motor end plate, resulting in paralysis of striated muscles. Rocuronium does not appear to induce malignant hyperthermia (MH) as it did not cause hyperthermia in MH-susceptible swine. Rocuronium is mildly vagolytic, and a slight, transient tachycardia is occasionally seen in humans.

Pharmacokinetics

In dogs, rocuronium 0.4 mg/kg IV produces complete neuromuscular blockade in ≈2 to 3 minutes.[2] Complete neuromuscular blockade was observed in 90% of cats receiving 0.6 mg/kg IV within 30 to 60 seconds without significant effects on HR. At doses of 0.6 mg/kg, the duration of action of rocuronium is 20 minutes in dogs, 13 minutes in cats, and 55 minutes in horses.[3,4]

It has been reported that rocuronium is eliminated primarily by the liver in dogs and cats. The principal metabolite, 17-desacetyl-rocuronium, has ≈1/20 the neuromuscular blocking potency of rocuronium in cats.

In humans, rocuronium is ≈30% bound to plasma proteins.[5] The half-life ranges from 66 to 144 minutes; ≈26% of the drug is excreted by the kidneys, and the remainder is excreted in the bile (31%). Patients with hepatic impairment or cirrhosis exhibited prolonged plasma half-lives and 2.5 times longer recovery periods compared to patients with normal function.

Contraindications/Precautions/Warnings

Rocuronium is contraindicated in patients hypersensitive to it or other neuromuscular blocking agents. In humans, severe anaphylactic reactions have been reported.

Rocuronium should only be used in patients that are adequately anesthetized and mechanically ventilated. It should only be used in settings where patients can be fully monitored and where oxygen therapy and antagonist drugs are immediately available. Rocuronium has no analgesic or sedative/anesthetic actions.

Atracurium may be preferred in patients with renal or hepatic impairments as there are conflicting reports on whether rocuronium should be used in these patients. Use with caution in patients with myasthenia gravis as small doses of nondepolarizing neuromuscular blocking agents may have profound effects.[5] Extravasation may result in local irritation.

Rocuronium is considered a high alert medication, meaning it requires special safeguards to reduce the risk for errors. Consider instituting practices, such as redundant drug dosage and volume checking or special alert labels.

Adverse Effects

Rocuronium has fewer adverse effects than succinylcholine, as it has minimal cardiovascular and histamine-releasing effects. Other than the effects associated with pharmacologic neuromuscular blockade, rocuronium appears to be well tolerated. Changes in heart rate and blood pressure may be noted.

In humans, the most common adverse reactions are hypotension or hypertension which are reported in ≈2% of patients.[5] These effects are transient and typically mild. Severe anaphylaxis has also been reported. Although rocuronium has minimal histamine-releasing effects, histaminoid reactions have been reported. Rocuronium can cause severe burning pain at the injection site; giving only after a deep stage of anesthesia has been achieved has been recommended.

Reproductive/Nursing Safety

In pregnant laboratory animals, rocuronium did not demonstrate teratogenic effects; however, rate of embryonic death was increased likely due to oxygen deficiency. The molecular weight of rocuronium is low enough for excretion into milk, but because the drug is ionized at physiologic pH, clinical effect in offspring would likely be minimal. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses with neuromuscular blocking agents may result in a prolonged neuromuscular blockade. The primary treatment is the maintenance of the patient's airway, mechanical ventilation and oxygenation, and adequate sedation until recovery of normal neuromuscular function is assured.[5] Only after evidence of recovery is seen should the administration of an acetylcholinesterase inhibitor (eg, neostigmine) with an anticholinergic agent (eg, atropine) be considered. Sugammadex is the specific reversal agent for rocuronium.[6] Blood pressure and heart rate should be monitored during an overdose, with any necessary supportive treatment performed.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving rocuronium and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetylcholinesterase Inhibitors** (eg, **neostigmine, pyridostigmine**): Antagonize the effects of rocuronium

- **Anesthetics, General**: In humans, rocuronium use with general anesthetics can prolong the QT interval.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May decrease rocuronium effectiveness, prolong muscle weakness, and result in myopathy
- **Nondepolarizing Muscle Relaxant Drugs, Other**: Some nondepolaring muscle relaxant drugs may have a synergistic effect if used with rocuronium
- **Succinylcholine**: May speed the onset of action and enhance the neuromuscular blocking actions of rocuronium; do not give rocuronium until succinylcholine effects have subsided.
- **Sugammadex**: Antagonizes the effects of rocuronium

The following agents may enhance or prolong the neuromuscular blocking activity of rocuronium:

- **Aminoglycoside Antibiotics** (eg, **gentamicin**)
- **Anesthetics, Inhalation** (eg, **halothane, isoflurane**)
- **Antiarrhythmic Agents** (eg, **procainamide, quinidine**)
- **Bacitracin or Polymyxin B, Systemic**: Consider therapy modification.
- **Calcium Channel Blockers** (eg, **amlodipine, diltiazem**)
- **Cyclosporine, Systemic**
- **Lincosamide Antibiotics** (eg, **clindamycin**)
- **Lithium**
- **Magnesium Salts**
- **Polymyxin B**
- **Quinine**: Avoid combination
- **Tetracyclines** (eg, **doxycycline, minocycline**)
- **Vancomycin**

Laboratory Considerations

- None were noted.

Dosages

DOGS:

Neuromuscular blocker (extra-label): 0.5 mg/kg IV followed by 0.2 mg/kg/hour IV CRI. The authors concluded that rocuronium administered in this way was effective in dogs and easily applicable to clinical practice, but that further work is required on infusion titration.[7]

To achieve a central position of the eye for ophthalmic procedures: 0.03 – 0.05 mg/kg IV in combination with isoflurane may be useful for short ophthalmic procedures.[8]

CATS:

Neuromuscular blocker (extra-label): 0.3 – 0.6 mg/kg IV[1,3,9]

HORSES:

Neuromuscular blocker (extra-label): Although a formal dose-finding study for rocuronium has not yet been reported, doses ranging between 0.2 and 0.6 mg/kg have been used extensively in horses under inhalational anesthesia; doses of 0.2 mg/kg provide ≈90% twitch depression and 0.4 – 0.6 mg/kg produces full blockade. Block lasts less than 20 minutes at 0.2 mg/kg and as long as 1 hour at 0.6 mg/kg.[4,10,11]

Monitoring

- When nondepolarizing neuromuscular blocking agents are administered, the paralysis should be monitored via acceleromyography (train-of-four or TOF) or electromyography. A recent study in dogs showed that, after rocuronium administration, the laryngeal neuromuscular function recovered 36% slower than the pelvic limb. Monitoring the recovery from paralysis induced by rocuronium at the pelvic limb site might not exclude residual block at the larynx.[12]
- Heart rate and blood pressure

Client Information

- This drug should only be used by professionals familiar with using neuromuscular blocking agents in a supervised setting with adequate ventilatory support.

Chemistry/Synonyms

Rocuronium bromide is an aminosteroidal competitive, nondepolarizing neuromuscular blocking agent. It occurs as an almost white or pale yellow, slightly hygroscopic powder. It is freely soluble in water or dehydrated alcohol. A 1% solution (in water) has a pH of 8.9 to 9.5. The commercially available injection is a sterile, nonpyrogenic, isotonic solution that is clear, colorless to yellow/orange. Each mL contains 10 mg rocuronium bromide and 2 mg sodium acetate and is adjusted to isotonicity with sodium chloride. The pH is adjusted to 4 with acetic acid and/or sodium hydroxide.

Rocuronium may also be known as ORG-9426, rocuronii, rocuronio, rokuroniowy, or rokuronyum. Rocuronium may also be known by the trade names *Zemuron*® or *Esmeron*®.

Storage/Stability

Store intact rocuronium vials at 2°C to 8°C (36°F-46°F) and protect against freezing. When removed from refrigeration to room temperature storage conditions (25°C [77°F]), use within 60 days. Use opened vials of rocuronium within 30 days. Infusion solutions are stable for 24 hours at room temperature at dilutions up to 5 mg/mL. Discard unused portions of infusion solutions.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Unlike both vecuronium and atracurium, rocuronium is stable in aqueous solutions.

Rocuronium is **compatible** with 0.9% sodium chloride, 5% dextrose in water, 5% dextrose in 0.9% sodium chloride, and lactated Ringer's for dilution.

Rocuronium is physically **incompatible** when mixed with amphotericin B, hydrocortisone sodium succinate, amoxicillin, insulin, azathioprine, lipid emulsion (*Intralipid*®), cefazolin, ketorolac, cloxacillin, lorazepam, dexamethasone, methohexital, diazepam, methylprednisolone, erythromycin, thiopental, famotidine, trimethoprim, furosemide, or vancomycin.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Rocuronium Bromide for Injection: 10 mg/mL in 5 mL and 10 mL multi-dose vials; generic; (Rx)

Romifidine

(roe-***mif***-ih-deen) *Sedivet®*

Alpha-2 Agonist Sedative Analgesic

Prescriber Highlights

- ► Indicated for use in adult horses as a sedative and analgesic to facilitate handling, clinical examinations, procedures, and minor surgical procedures and as a preanesthetic agent prior to the induction of general anesthesia
- ► Contraindicated in patients hypersensitive to it. Do not use in horses with respiratory, hepatic, or renal disease, dehydration, or other systemic conditions of compromised health.
- ► Adverse effects in horses may include profound bradycardia, first- and second-degree atrioventricular heart block, dose-dependent sinus arrhythmias, hypertension followed by hypotension, ataxia, sweating, piloerection, salivation, muscle tremors, penile-relaxation, urination, stridor, decreased GI motility, flatulence, and mild colic; passive congestion and swelling of the face, lips, and upper airways can also be seen due to head lowering
- ► Anaphylactic reactions are possible.
- ► Decrease dose of concurrent anesthetics as romifidine has anesthetic sparing effects.

Uses/Indications

Romifidine is FDA-approved for use as a sedative and analgesic in adult horses to facilitate handling, clinical examinations, clinical procedures, and minor surgical procedures and for use as a preanesthetic prior to the induction of general anesthesia.

Romifidine has been used extra-label in cattle and foals.

Pharmacology/Actions

Romifidine is a potent alpha-2-adrenergic agonist with sedative, analgesic, and muscle relaxant properties. Alpha-2-adrenergic receptors are found in the CNS and several tissues peripherally both presynaptically and postsynaptically. In the CNS, the primary action is feedback inhibition of norepinephrine release. Opioids and alpha-2 agonists may have synergistic analgesic effects.

Pharmacologic effects of romifidine include sedation, analgesia, muscle relaxation, and reduced catecholamine release from the CNS. Thermoregulatory mechanisms may be altered. Peripherally, an initial vasoconstrictive response occurs with increases in blood pressure. Within 45 to 60 minutes, a hypotensive phase may occur. Heart rate can significantly decrease secondary to a vagal response to hypertension. A second-degree atrioventricular block may also occur. Antimuscarinic agents can prevent bradycardia, but their use is controversial as they can potentially cause hypertension, increase myocardial oxygen demand, and reduce GI motility. Alpha-2-receptor agonists can transiently slow duodenal motility and increase micturition in horses and can inhibit insulin release from pancreatic islet cells, resulting in hyperglycemia. Other effects seen in horses include sweating, mydriasis, decreases in hematocrit, and increased uterine pressure in nonpregnant mares.

In horses, romifidine may cause less ataxia and postural sway than xylazine or detomidine.[1,2] Romifidine may decrease reactivity to visual and acoustic stimulation at sedative doses compared to xylazine.[3] Romifidine has the longest duration of sedation.[1–3] For these reasons, romifidine may be preferred to other alpha-2 agonists for standing procedures and during recovery after inhalant anesthesia. The duration of analgesia is shorter than the duration of sedation, which may last up to 2 hours. Romifidine has a ceiling effect whereby increasing the dose beyond a certain amount can increase the duration of sedation but not sedation intensity. Romifidine has been shown to decrease intraocular pressure in healthy horses.[4,5]

Pharmacokinetics

In horses, the onset of action of romifidine is 30 seconds to 5 minutes and the effect gradually decreases over 2 to 4 hours. Romifidine 80 µg/kg IV has a volume of distribution of ≈2 L/kg, a clearance of ≈32 mL/minute/kg, and an elimination half-life of ≈135 minutes.[6]

In dogs and cats, bioavailability after IM administration is 86% and 95%, respectively. Bioavailability after SC injection in dogs is 92%. Peak levels after IM injection occur in ≈50 minutes in dogs and 25 minutes in cats. After IV injection, volumes of distribution are ≈3 L/kg in dogs and 6 L/kg in cats. Romifidine is biotransformed in the liver. In dogs, ≈80% of an administered dose is eliminated in the urine, 20% in the feces. Elimination half-lives are ≈2 hours for dogs and 6 hours for cats.

Contraindications/Precautions/Warnings

Romifidine is contraindicated in patients that are hypersensitive to it. Do not use in combination with IV potentiated sulfonamides. Do not use in horses with respiratory, hepatic, or renal disease, dehydration, or other systemic conditions of compromised health.

Romifidine has not been evaluated in horses with colic or in foals. Use with caution in horses with pre-existing cardiac conditions due to the effects on heart rhythm and blood pressure. Romifidine should only be used in situations in which sufficient monitoring and patient-support capabilities (eg, intubation, ventilation) are available. Although animals may appear to be deeply sedated, some may respond (eg, kick) to external stimuli; use appropriate caution. Raising the horse's head can help prevent sudden kicking. Anesthetic doses should be reduced to prevent overdose as romifidine has anesthetic sparing effects.

This medication can be absorbed through the skin and via oral routes; handle with caution to avoid accidental exposure.

Do not use in horses intended for human consumption.

Adverse Effects

In horses, romifidine may cause profound bradycardia, first- and second-degree atrioventricular heart block, and dose-dependent sinus arrhythmias. Initially, hypertension may occur, followed by hypotension. Other adverse effects can include ataxia, sweating, piloerection, salivation, muscle tremors, penile relaxation, urination (occurs ≈1 hour after dose), stridor, decreased GI motility, flatulence, and mild colic. Passive congestion and swelling of the face, lips, and upper airways can also be seen due to head lowering. When used alone as a premedication agent, romifidine can cause twitching. Paradoxical excitation is also possible. Anaphylactic reactions to alpha-2 agonists have rarely been reported in horses.

Reproductive/Nursing Safety

Romifidine is contraindicated for use in pregnant mares.[7]

Overdose/Acute Toxicity

Horses that received romifidine up to 600 µg/kg (5 times the maximum recommended dose) exhibited sinus bradycardia, second-degree heart block, occasional apnea and mild respiratory stridor, deep sedation, severe ataxia, frequent urination, and sweating. No clinically significant alterations in blood gases, acid-base, or hematological or chemical parameters were noted. If necessary, a reversal agent (eg, atipamezole, yohimbine) may be used to reduce the duration and extent of adverse effects associated with acute toxicity.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are

theoretical in humans or animals receiving romifidine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, Opioids, Sedative/Hypnotics**: Effects may be additive; dosage reduction of 1 or both agents may be required; potential for increased risk for arrhythmias when used in combination with thiopental, ketamine, or halothane
- **Epinephrine**: May potentiate adverse effects of alpha-2 agonists
- **Other Alpha-2 Agonists** (eg, **clonidine, detomidine, medetomidine, xylazine**): May potentiate adverse effects of romifidine; concurrent use not recommended
- **Phenothiazines** (eg, **acepromazine**): Severe hypotension can result.
- **Potentiated Sulfonamides, Intravenous** (eg, **trimethoprim/sulfa**): Use with IV potentiated sulfonamides may result in fatal dysrhythmias; combination is contraindicated.

Laboratory Considerations

- ADP-induced platelet aggregation: Can be inhibited in cats by medetomidine (a related alpha-2 agonist); not known if romifidine can have this effect in horses.
- PCV and TS: Clinically significant transient changes have been observed in horses.[8]

Dosages

HORSES:

Sedation and analgesia (label dosage; FDA-approved): 40 – 120 µg/kg IV slowly once.[9] The degree of sedation and analgesia is dose- and time-dependent. The duration of analgesia is shorter than the duration of sedation.

Preanesthetic agent (label dosage; FDA-approved): 100 µg/kg as a single, slow IV injection.[9] Induce anesthesia after maximal sedation is achieved. Anesthetic dose should be decreased to prevent overdose as romifidine has anesthesia-sparing effects.

Part of a 'GKR triple drip' total intravenous anesthesia (TIVA) protocol (extra-label): Add romifidine 40 mg (total; NOT mg/kg) and ketamine 3.3 g (total; NOT mg/kg) to 500 mL of 5% guaifenesin. Resultant solution contains guaifenesin 50 mg/mL, ketamine 6.6 mg/mL, and romifidine 80 µg/mL. Infuse at a rate of 1 mL/kg/hour.[10]

Part of a ketamine/romifidine partial intravenous anesthesia (PIVA) protocol (extra-label): After induction of general anesthesia, a surgical plane of anesthesia can be maintained with a combination of isoflurane and romifidine 18 – 24 µg/kg/hour and ketamine 1.8 – 2.4 mg/kg/hour IV CRI.[11]

Postanesthesia sedation (extra-label): 20 µg/kg IV administered once the breathing circuit is disconnected and the patient is spontaneously breathing.[12]

Standing sedation (extra-label):

a) **Single injection in ponies**: 50 µg/kg IV in combination with tramadol 3 mg/kg provides sedation and antinociceptive effects for up to 120 minutes. Slight ataxia was noted without excitatory behavioral adverse effects.[13]

b) **Constant rate infusion in horses**: 46 µg/kg IV loading dose, followed by 126 µg/kg/hour IV CRI[1]

CATTLE:

Epidural anesthesia for paralumbar analgesia or laparotomy: Romifidine 50 µg/kg in combination with morphine 0.1 mg/kg administered epidurally. The duration of analgesia is 12 hours maximum.[14] Doses of 30, 40, and 50 µg/kg diluted in sterile saline to a total volume 25 mL were administered epidurally to dairy cows. Antinociceptive effects were dosedependent and covered the tail, anus, perineum, vulva, and inguinal area and extended to the pelvic limb and thoracic area. Moderate sedation was observed at 30 and 40 µg/kg and deep sedation at 50 µg/kg.[15]

Monitoring

- Level of sedation and analgesia
- Heart rate and rhythm, blood pressure, pulse oximetry
- Respiratory depth and rate, $ETCO_2$
- Body temperature

Client Information

- This medication is only to be administered by veterinary professionals.
- After receiving romifidine, your horse may look fully sedated but may still respond defensively (eg, kick) when stimulated.

Chemistry/Synonyms

Romifidine HCl is an alpha-2-adrenoreceptor agonist that is structurally related to clonidine. It has a molecular weight of 258.1 and occurs as a crystalline, white, odorless substance that is soluble in water.

Romifidine may also be known as STH-2130, romifidini, romifidin, romifidina, romifidinum, *Romidys®*, *Sedivet®*, and *Sedivan®*.

Storage/Stability

Store romifidine HCl injection at controlled room temperature (15°C to 30°C [59°F-86°F]).

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Romifidine HCl 1% (10 mg/mL) Injection; *Sedivet®*; (Rx). FDA-approved for use in horses not intended for human consumption. Although this product is still listed in FDA's Green Book of approved animal drugs, it may no longer be commercially available in the US. In the UK, slaughter withdrawal is 6 days for horses.

HUMAN-LABELED PRODUCTS: NONE

Ronidazole

(roe-***nid***-ah-zole)

Antiprotozoal

Prescriber Highlights

- ► Nitroimidazole antibiotic/antiparasitic drug for treating *Tritrichomonas* foetus infections in cats; also used to treat *Trichomonas* spp infections in birds not intended for consumption. Potentially useful as an alternative treatment for giardiasis.
- ► Prohibited by the FDA for use in food animals
- ► Contraindications include hypersensitivity to it or other nitroimidazole derivatives.
- ► Potentially carcinogenic; avoid human exposure
- ► Adverse effects include reversible neurotoxicity (more likely at higher doses but can occur at lower dosages) and GI effects.
- ► Many potential drug interactions
- ► Must be compounded from bulk powder and, ideally, put in gelatin capsules

Uses/Indications

Ronidazole is a nitroimidazole antibiotic/antiparasitic drug that is considered the treatment of choice for *Tritrichomonas foetus* infections,[1–3] with resolution of diarrhea occurring in 60% to 70% of cats.[4,5] Formulations that delay ronidazole release until arrival of the drug in the large intestine may limit neurotoxicity while maintaining efficacy.[6,7] Ronidazole is also used for treating *Trichomonas* spp infections in birds not intended for consumption. Ronidazole is prohibited in food animals and belongs to a class of antibiotics important for human medicine. It should only be used for *Tritrichomonas* when infection has been confirmed.

Ronidazole may also be a viable alternative treatment for giardiasis in dogs and cats.[8]

The drug is not commercially available in the United States and must be compounded from bulk powder by a compounding pharmacy. To improve palatability, compounded capsules are recommended over flavored liquids.

The World Health Organization (WHO) has designated ronidazole as a Critically Important, Highest Priority antimicrobial for human medicine.[9] The Office International des Epizooties (OIE) Antimicrobial Classification has designated ronidazole as a Veterinary Critically Important antimicrobial.[10]

Pharmacology/Actions

Ronidazole, like other 5-nitroimidazoles such as metronidazole, is converted by hydrogenosomes (an organelle found in trichomonads) into polar autotoxic anion radicals. *T foetus* infections in cats have been resistant to treatment by metronidazole, and ronidazole appears to have greater activity against the organism, but ronidazole resistance has been documented.[11]

Pharmacokinetics

In cats, ronidazole is completely absorbed and bioavailable after oral dosing. Volume of distribution (steady-state) is ≈0.7 L/kg and clearance is ≈0.8 mL/kg/minute. Elimination half-life is ≈10 hours.[12]

A guar gum-coated colon-targeted delayed-release tablet formulation had negligible release until 6 hours after administration. Peak plasma concentrations occurred at ≈14.5 hours, coinciding with colonic arrival. Repeated dosing did not appreciably affect bioavailability or other pharmacokinetic parameters.[7]

Contraindications/Precautions/Warnings

Ronidazole should not be used in patients hypersensitive to it or other 5-nitroimidazoles (eg, metronidazole).

The compound has been demonstrated to be carcinogenic in mice but not rats. Although humans should avoid contact with this compound or animal waste from treated patients, it can be safely compounded using a biological safety cabinet.

The FDA prohibits the use of this drug in food animals.

Adverse Effects

Reversible neurotoxicity similar to that reported with metronidazole has been reported with ronidazole in cats. Initial signs may include tremors, lethargy, anorexia, ataxia, nystagmus, seizures, or behavior changes (agitation). If neurotoxicity is diagnosed, discontinue ronidazole, treat supportively, and, if necessary, consider administering a benzodiazepine such as diazepam to competitively inhibit GABA receptors in the CNS. The incidence of neurotoxicity appears to be higher with a 50 mg/kg twice-daily dosage, but may occur at lower doses as well. Potentially, GI effects can occur (anorexia, vomiting). Ronidazole is very bitter and should be administered to cats in capsule form.

Ronidazole has been shown to increase the risk for benign mammary tumors in rats, and benign and malignant pulmonary tumors in mice at dosages more than or equal to 20 mg/kg/day.

Dogs given 30 mg/kg per day for 2 years (40 mg/kg/day the first month) showed some testicular toxicity (type not specified), but no tumors.

Reproductive/Nursing Safety

Safety of this compound during pregnancy has not been established. Teratology studies have been performed in mice, rats, and rabbits. In rabbits given 30 mg/kg/day, no embryotoxicity occurred, but fetal weights were significantly decreased. Mice demonstrated no teratogenic effects at dosages up to 200 mg/kg/day. Rats given up to 150 mg/kg/day demonstrated no embryotoxic effects, but at dosages of 200 mg/kg/day, both maternal and fetal weights were decreased.

It is not known if ronidazole is distributed into milk and safety cannot be assured. Consider using milk replacer if treating nursing queens.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located. Cats receiving doses of 50 mg/kg twice daily appear to have greater incidences of neurotoxicity (see ***Adverse Effects***). A case report of an overdose causing neurotoxicity, hemorrhage, and death in society finches after consuming ronidazole in drinking water has been published.[13] If overdoses cause neurotoxicity, discontinue further therapy and treat supportively. Consider administering a GABA inhibitor such as diazepam to competitively inhibit GABA receptors in the CNS.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In humans, the following drug interactions with metronidazole, a compound similar to ronidazole, have been reported or are theoretical and may be of significance in veterinary patients in patients receiving ronidazole. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- ■ **Alcohol**: May induce a disulfiram-like (nausea, vomiting, cramps) reaction
- ■ **Cimetidine, Ketoconazole**: May decrease the metabolism of ronidazole and increase the likelihood of dose-related adverse effects

- **Cyclosporine, Tacrolimus** (systemic): Ronidazole may increase the serum concentrations of cyclosporine or tacrolimus.
- **Fluorouracil** (systemic): Ronidazole may increase the serum concentrations of fluorouracil and risk for toxicity.
- **Lithium**: Ronidazole may increase lithium serum concentrations and risk for lithium toxicity.
- **Oxytetracycline**: May antagonize the therapeutic effects of metronidazole (and presumably ronidazole)
- **Phenobarbital, Rifampin, or Phenytoin**: May increase the metabolism of ronidazole thereby decreasing blood concentrations
- **Warfarin**: Metronidazole (and potentially ronidazole) may prolong INR/PT in patients taking coumarin anticoagulants; avoid concurrent use if possible; otherwise intensify monitoring.

Laboratory Considerations

- AST, ALT, LDH (lactic dehydrogenase), triglycerides, hexokinase glucose: A related compound, metronidazole can cause falsely decreased readings when determined using methods measuring decreases in ultraviolet absorbance when NADH is reduced to NAD. It is not known if ronidazole also causes falsely decreased values.

Dosages

DOGS:

***Giardia* spp** (extra-label): Study was in a kennel setting and combined strict hygiene control/disinfection, chlorhexidine shampoos, and ronidazole 30 – 50 mg/kg PO twice daily for 7 days. Authors concluded this "*was highly effective in reducing Giardia cyst excretion and may therefore constitute an alternative control strategy for canine giardiasis.*"[8]

CATS:

***T foetus* infections** (extra-label): 30 mg/kg PO every 24 hours for 14 days[5,6,14]

Monitoring

- Clinical efficacy (diarrhea improvement)
- Adverse effects (neurotoxicity, vomiting, anorexia)
- PCR testing can be used to confirm infection, but negative results after treatment do not conclusively prove that infection has been eradicated.

Client Information

- Keep medicine stored in the freezer.
- Give with food to avoid stomach or intestinal problems.
- Side effects in cats can include fever, loss of appetite, ataxia (eg, trouble keeping balance, trouble walking or climbing stairs), muscle twitching or weakness, seizures, lethargy (tiredness/lack of energy), nystagmus (eyes uncontrollably moving back and forth). Contact your veterinarian immediately if any of these signs are seen.
- This drug has caused cancer at high doses in laboratory animals. Do not open or crush capsules; administer whole. Wear disposable gloves when handling and wash your hands afterwards.
- After treatment has started, wear disposable gloves when cleaning the litter box, double-bag feces, and throw both gloves and feces in trash. Do not flush feces down toilet.
- Must not be used in any animals that will be consumed by humans.

Chemistry/Synonyms

Ronidazole is a 5-nitroimidazole compound that occurs as a white to yellowish-brown, odorless or almost odorless, bitter powder. It is very slightly soluble in water or alcohol.

Ronidazole may also be known as ronidazol, ronidazolum, *Belga*®, *Ridsol-S*®, *Ronida*®, *Ronivet*®, *Ronizol*®, *Turbosol*®, *Tricho Plus*®, *Trichocure*®, or *Trichorex*®.

Storage/Stability

Compounded capsules should be stored in child-resistant, airtight containers protected from light. Until further stability studies can be performed, capsules should be stored in the freezer.

Aqueous solutions are reportedly not very stable. It is recommended that fresh solutions using the 10% powder for addition to drinking water (used for pigeons) be freshly prepared every day.

Compatibility/Compounding Considerations

No specific information noted. See additional information in ***Dosage Forms/Regulatory Status*** section.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the United States; a 10% ronidazole powder to be added to drinking water for treating *Trichomonas* infections in pigeons is available in some countries, but these products are unsuitable for use in cats due to the dosage required and the unpalatability (bitter taste) of the powder and solution. Capsules prepared from 100% bulk powder for individual feline patient should be obtained from a compounding pharmacy that can prepare the capsules in a bio-safety hood that will protect the compounder from drug exposure.

The FDA prohibits the use of this drug in food animals.

HUMAN-LABELED PRODUCTS: NONE.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Ropinirole

(roe-***pin***-i-role) *Clevor*®

Emetic

Prescriber Highlights

- ► Ophthalmic formulation FDA-approved to induce vomiting in dogs 4.5 months of age and older and weighing at least 1.8 kg (4 lb)
- ► On average, the onset of vomiting is ≈12 minutes, the dog vomits 4 to 5 times, and vomiting typically subsides within 25 minutes after administration.
- ► Most dogs (95%) vomit within 30 minutes of application. A second dose can be administered 20 minutes after the first dose if the dog has not vomited.
- ► Contraindications include dogs with hypersensitivity, lack of laryngeal reflexes, neurological impairment or conditions that increase the risk for aspiration, or corneal ulceration or ocular injury/irritation, as well as when vomiting is contraindicated (eg, shock, seizures, ingestion of sharp foreign objects, corrosive agents). Use cautiously in cases in which stimulating vomiting may be detrimental (eg, history of aspiration pneumonia, CNS stimulant ingestion). Do not use in species that cannot vomit.
- ► Adverse effects include tremors, lethargy, hypotension, tachycardia, and hypotension. Ocular effects (eg, redness, discharge, blepharospasm, ptosis, ulceration) may occur.
- ► Metoclopramide can be used to halt protracted vomiting and relieve other dopaminergic signs. Maropitant may be used to ameliorate protracted vomiting but must be administered via the IV route and has no effects on other dopaminergic signs.
- ► Wear gloves when handling, as absorption across human skin can occur with resultant potential for human exposure. Those who are pregnant, breastfeeding, or attempting to become pregnant should avoid contact with the product.

Uses/Indications

In situations in which vomiting is appropriate, ropinirole is FDA-approved to induce vomiting in dogs. In a study, 50% of dogs vomited within 10 minutes of administration (range, 3 to 37 minutes), 87% vomited within 20 minutes, and 95% vomited within 30 minutes.[1] The number of vomiting episodes was 4 to 5 per dog (range, 1 to 13), and the duration of vomiting was 16 to 25 minutes (maximum, 108 minutes).[1,2] In European approval studies, vomiting occurred within 5 to 7 minutes of administration and lasted ≈20 to 25 minutes with 6 to 10 vomiting episodes.[3]

Ropinirole is a dopaminergic agent indicated for the treatment of Parkinson's disease and restless leg syndrome in humans.

Pharmacology/Actions

Dopamine receptor subtypes belong to 2 families of dopamine receptors: D1 (including the D_1 and D_5 subtypes) and D2 (including D_2, D_3, and D_4 receptor subtypes).[4] Ropinirole is a dopamine agonist that preferentially targets the D2 family receptors, specifically the D_2 and D_3 receptor subtypes.[4] Ropinirole stimulates emesis via activity on both the peripheral and central dopamine receptors but primarily via the D_2 receptor in the chemoreceptor trigger zone. Unlike other available emetics, ropinirole is more selective for dopamine receptors and is expected to have less off-target effects due to binding of other receptors (eg, serotonergic, adrenergic).

Ropinirole's dopaminergic effects may blunt norepinephrine action, resulting in hypotension and tachycardia. In beagles receiving ropinirole IV, mean arterial pressure decreased by 16 mm Hg, heart rate increased by 29 bpm, and (on ECG) PR interval shortened by 13 milliseconds and QTc length increased by 33 milliseconds.[5] Peak ropinirole concentration was 5.9 ng/mL, which is ≈¼ that achieved after ophthalmic administration. Studies performed in canine myocytes suggest ropinirole may carry a proarrhythmic risk in patients with inherited or acquired long QT syndrome.[6]

As a dopamine agonist specific for the D_2 receptor subtype, ropinirole suppresses prolactin.

Pharmacokinetics

Bioavailability is 18% to 28% after ocular administration to dogs.[2,7] The drug is rapidly absorbed into systemic circulation, with peak concentration (C_{max}) of 26 ng/mL occurring ≈15 minutes after application; however, vomiting may occur before C_{max} is reached.[2,7] Volume of distribution is 5.6 L/kg, and protein binding is ≈40%.[2] Terminal half-life is 4 to 6 hours.[2,3] Metabolism occurs by dealkylation, hydroxylation, and subsequent conjugation with glucuronic acid or oxidation to carboxylic acid. Excretion occurs mainly as metabolites in the urine.[2] Although duration of vomiting does not appear to correlate with plasma ropinirole concentration, vomiting occurred earlier in dogs receiving doses at the higher end of the dosage range.[7]

In humans, bioavailability of the immediate-release tablet is ≈50%.[8] Peak concentration occurs 1 to 2 hours after oral administration but taking the drug along with a high-fat meal can delay peak concentration to 2.5 hours. Protein binding is 40%, apparent volume of distribution is 7.5 L/kg, and half-life is ≈6 hours. Ropinirole is extensively metabolized, predominantly via N-despropylation and hydroxylation pathways with subsequent conjugation, forming inactive metabolites. CYP1A2 is the major cytochrome P450 isoenzyme involved in phase I metabolism. The drug is eliminated in the urine, principally as metabolites.

Contraindications/Precautions/Warnings

Emetics can be an important aspect in the treatment of orally ingested toxins, but they must be used judiciously. Most emetics cause emesis when administered within 2 hours of foreign material or toxin ingestion[9]; however, induction of emesis should be performed as soon as possible, especially for cases of toxin ingestion. Emetics should not be used in rodents or rabbits because these patients are either unable to vomit or do not have stomach walls strong enough to tolerate emesis. Emetics are also contraindicated in patients that are hypoxic, have evidence of cardiovascular shock or respiratory distress, are actively having seizures, and/or lack normal pharyngeal reflexes (ie, laryngeal paralysis). The risks and benefits of administering an emetic should also be considered for animals with a recurrent history of aspiration pneumonia, seizures, coma, severe CNS depression or deteriorating CNS function, or extreme physical weakness. Emetics should also be withheld in patients that have previously vomited repeatedly. Because of the risk for additional esophageal or gastric injury with emesis, emetics are contraindicated in patients that have ingested a sharp object, strong acids, alkalis, or other caustic agents. Because of the risk for aspiration, emetics are usually contraindicated after petroleum distillate ingestion but may be employed when the risk for toxicity of the compound is greater than the risk for aspiration. Use of emetics after ingestion of strychnine or other CNS stimulants may precipitate seizures.

Ropinirole is contraindicated in patients hypersensitive to it. Do not use ropinirole in dogs with CNS depression or seizures, ocular irritation or injury, or corneal ulceration, or in dogs that have ingested sharp foreign objects, corrosive agents (eg, acids, alkalis), volatile substances, or organic solvents.[2,7] Use cautiously in patients with conditions that may increase the risk for aspiration pneumonia. Safety has not been studied in dogs that have ingested foreign material or in dogs with GI disease, cardiac disease or cardiovascular compromise, hepatic impairment, younger than 4.5 months old, or weighing less than 1.8 kg (4 lb).[3,7] Dogs that weigh less than 1.8 kg (4 lb) cannot be accurately dosed; 1 drop in one eye would deliver a higher dose than the target dose range.

In an effectiveness study, 99 dogs were given ropinirole.[10] Three dogs did not vomit (even after multiple administrations). Two dogs required a second dose when no vomiting occurred after 20 minutes—vomiting then occurred between 30 to 40 minutes after the first administration. Repeating administration of medication(s) prescribed for chronic conditions may be necessary if they were impacted by emesis.

Ropinirole may be absorbed across intact skin. Exposure to humans handling ropinirole, particularly when opening the unit-dose container, may cause adverse effects (eg, headache, nausea, vomiting, dizziness, orthostatic hypotension, sleepiness). This product should be handled with caution. Use of personal protective equipment (eg, gloves, eye protection) is recommended. In cases of accidental exposure, rinse the affected area immediately with plenty of fresh water, and seek medical attention if symptoms occur. Ropinirole ophthalmic solution should not be administered those who are pregnant, breastfeeding, or attempting to become pregnant.[2,7]

Do not confuse rOPINIRole with reserpine, risperiDONE, or *Rocaltrol®*.

Adverse Effects

The most common systemic adverse effect with ropinirole use in dogs is lethargy (41%). Other adverse effects (less than 5%) include diarrhea, salivation, and CNS signs (eg, ataxia, tremors).[2,3] Elevated ALT (3%) has also been reported.[2] CNS adverse effects resolved within 8 hours after administration.[10]

Prolonged emesis (ie, more than 60 minutes) occurred in 8% of dogs.[10] Metoclopramide (0.5 mg/kg IV or SC) terminates protracted vomiting and may reverse other ropinirole adverse effects (eg, lethargy, muscle tremors).[2,3] Maropitant given by the IV route (not SC) stops protracted vomiting but has no effect on other dopaminergic signs. See ***Overdose/Acute Toxicity***.

Tachycardia was noted in 14% of dogs after ophthalmic administration.[3] The average heart rate increased ≈55 bpm within 10 minutes of administration; however, this resolved within 4 hours after administration.

Moderate eye irritation (eg, conjunctival hyperemia [51%], third eyelid protrusion [38%], conjunctival discharge [30%], blepharospasm [19%]) may occur but typically improves within 2 hours after administration and is usually completely resolved within 8 to 24 hours.[2,3]

Reproductive/Nursing Safety

The manufacturer does not recommend ropinirole use during pregnancy or lactation.[2,7]

Implantation was disrupted in rats given ropinirole 20 mg/kg/day PO. In rats, developmental effects occurred at clinically used doses, and teratogenicity and embryo lethality occurred at 120 mg/kg/day PO. No developmental toxicity was noted in rabbits receiving 20 mg/kg/day PO.[3]

Ropinirole reduces serum prolactin concentration due to its activity at D_2 receptor subtypes, and prolonged use would be expected to reduce lactation. Ropinirole is excreted in maternal milk, but effects on offspring are unknown. Use with caution in nursing patients or consider a milk replacer.

Safe use of ropinirole during pregnancy has not been established; thus, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

Oral LD_{50} in rats is 400 – 500 mg/kg.[3] Clinical signs in dogs receiving up to ≈50 – 59 mg/m^2/day (up to 5 times the labeled dose) mirrored the drugs clinical and adverse effects, including vomiting, retching, hunched posture, salivation, hypotension, tachycardia, lethargy, and tremors.[2,3] At these doses, vomiting lasted up to 2 hours, and other clinical signs returned to normal 6 hours after administration.[2]

The effects of ropinirole overdose are mild to moderate and transient; therefore, supportive therapy is likely sufficient. Ophthalmic irrigation is likely of limited value, as ropinirole reaches peak concentration (C_{max}) within 12 minutes of administration, and vomiting may occur prior reaching C_{max}. Metoclopramide (0.5 mg/kg SC or IV) ameliorates clinical signs (eg, protracted vomiting, lethargy, tremors) caused by ropinirole in 100% of dogs.[2,7] Maropitant must be administered via the IV route to stop protracted vomiting; however, it is important to note that maropitant does not relieve ropinirole's other dopaminergic signs (eg, lethargy, tremors).[2,7,10]

For patients that have experienced or are suspected of having experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Laboratory Considerations

- None

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ropinirole and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Antiemetics** (eg, **maropitant, ondansetron**): May reduce emetogenic effects of ropinirole[7,10]
- **Antihistamines, First Generation** (eg, **dimenhydrinate, meclizine**): Antihistamines with antiemetic effects may reduce emetogenic effects of ropinirole.
- **Antihypertensive Agents** (eg, **amlodipine, enalapril, sildenafil, telmisartan**): Additive hypotensive effects may occur.
- **CNS Depressants** (eg, **phenobarbital**): Additive CNS depressant effects (eg, lethargy, ataxia) may occur.
- **Dopamine Antagonists** (eg, **domperidone, metoclopramide**): May antagonize ropinirole action at dopaminergic receptors and block its emetogenic effect. May be used to treat or reverse adverse ropinirole effects—see ***Overdose/Acute Toxicity***
- **Phenothiazines** (eg, **acepromazine, promethazine**): May reduce emetogenic effects of ropinirole

In humans, ropinirole is metabolized by CYP1A2, and inhibitors of this enzyme increase ropinirole concentration and AUC. Veterinary significance of this interaction is unclear, but, theoretically, prolonged vomiting may occur when ropinirole is combined with the following CYP1A2 inhibitors:

- **Amiodarone**
- **Ciprofloxacin**: In humans, coadministration of ciprofloxacin with immediate-release ropinirole tablets increased ropinirole AUC by 84% and C_{max} by 60%.[8]
- **Erythromycin**
- **Mexiletine**

Dosages

DOGS:

Induction of vomiting (labeled dose, FDA-approved): Administer the appropriate number of drops to deliver a target dose of 3.75 mg/m^2 (NOT mg/kg; dose range 2.7 – 5.4 mg/m^2 [NOT mg/kg]) according to the table below.* A second dose of the same number of drops may be administered if the dog does not vomit within 20 minutes of receiving the first dose.[2]

Ropinirole Dose Administration

Body weight (kg)	Body weight (lb)	Total number of eye drops	Example administration
1.8-5	4-11.1	1	1 drop in one eye (either left **OR** right)
5.1-10	11.2-22.1	2	1 drop in each eye
10.1-20	22.2-44.1	3	2 drops in one eye, and 1 drop in the other eye
20.1-35	44.2-77.2	4	2 drops in each eye
35.1-60	77.3-132.3	6	An initial dose of 2 drops in each eye, followed 2 minutes later by 1 drop in each eye
60.1-100	132.4-220.5	8	An initial dose of 2 drops in each eye, followed 2 minutes later by 2 drops in each eye

*Table adapted from *CLEVOR*® ropinirole ophthalmic solution US product label, 2020[2]

Monitoring

- Clinical efficacy
- Blood pressure and heart rate
- Signs of ocular irritation (eg, conjunctival hyperemia, blepharospasm, protrusion of the third eyelid)
- Adverse effects (eg, protracted vomiting, aspiration of vomitus)

Client Information

- Ropinirole ophthalmic solution should be administered only under the supervision of your veterinarian to induce vomiting when it is appropriate and safe to do so.
- Visibility of the third eyelid and eye irritation (eg, redness, discharge, squinting) may occur after administration but should resolve within 24 hours.

- Your dog may appear sleepy, have difficulty walking, or have a reduced appetite for a short period of time after administration. Contact your veterinarian if your dog's appetite has not returned to normal within 1 to 2 days.

Chemistry/Synonyms

Ropinirole is a nonergoline indoline that occurs as white or cream-colored crystalline powder that is freely soluble in water. The log-P n-octanol:water coefficient is 2.7. The commercial solution (*Clevor*®) is a clear, slightly yellow, sterile aqueous solution that contains citric acid monohydrate, sodium citrate, and sodium chloride.

Ropinirole may also be known as ORM-145704, SKF 101468, *Clevor*®, or *Requip*®.

Storage/Stability

Store ropinirole solution at room temperature between 20°C to 25°C (68°F-77°F) and protected from light. Opened droppers may be stored upright inside the manufacturer's pouch for up to 30 minutes after opening; discard any unused portion.

Compatibility/Compounding Considerations

None noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Ropinirole Ophthalmic Solution: 3% in 0.3 mL prefilled single dose dropper (contains 9 mg ropinirole; each mL contains 30 mg of ropinirole [equivalent to 34.2 mg of ropinirole hydrochloride]) packaged in an opaque foil pouch in cartons of 1 or 5 droppers. Each drop delivers 27 µL (810 µg). *Clevor*®; (Rx). NADA# 141-534.

HUMAN-LABELED PRODUCTS:

Ropinirole Tablets: 0.25 mg, 0.5 mg, 1 mg, 2 mg, 3 mg, 4 mg, and 5 mg tablets; *Requip*®, generic; (Rx). An extended-release tablet (*Requip XL*®) is also available.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Ropivacaine

(roe-***piv***-a-kane***)*** *Naropin*®

Local Anesthetic

Prescriber Highlights

- ► Local anesthetic with delayed onset (20 minutes) and intermediate duration of action (3 to 5 hours) compared to others in its class
- ► Local anesthetics are absorbed from the site of administration and may have systemic effects.
- ► Adverse effects are usually minimal when ropivacaine is used correctly, but cardiac and CNS toxicity may occur.
- ► Use should be limited to clinicians experienced in the diagnosis and management of local anesthetic toxicity; resources for treating acute emergencies must be readily available.

Uses/Indications

Ropivacaine is used to produce local or regional analgesia or anesthesia for surgery and diagnostic or therapeutic procedures. The local block can have a MAC-sparing effect on general anesthesia and results in better postoperative recovery. The duration of analgesia can be extended by combining ropivacaine with opioids or alpha-2 agonists, and the accuracy of the block can be increased with use of a nerve stimulator[1] or with ultrasound-guided administration. Ropivacaine can be used for epidural and spinal anesthesia, and, when combined with magnesium sulfate for intrathecal administration, it increases the intensity and duration of analgesia, but prolonged motor block may be a limiting factor.[2] Ropivacaine also provides corneal anesthesia when applied topically to the eye.[3]

In dogs, epinephrine does not appear to alter the onset ropivacaine effect but may slightly prolong its duration of action.[4]

Pharmacology/Actions

Local anesthetics block sodium ion channels on the nerve cell membrane, thereby altering electrical excitability, depolarization, and action potential propagation. They block the generation and conduction of impulses in motor, sensory, and autonomic nerve fibers around the site of application. Nerve fiber diameter, conduction velocity, and myelination determine the loss of nerve function. Clinically, the progressive loss of nerve function occurs in the following order: pain, temperature, touch, proprioception, and skeletal muscle tone. The anesthetic effect is lost in reverse order. Ropivacaine produces less motor block than bupivacaine.[4,5]

After epidural administration, ropivacaine produces analgesia typically within 3 to 15 minutes, and the analgesic effect persists for 3 to 5 hours. Compared to lidocaine, ropivacaine has a slower onset but longer duration of action. When ropivacaine is used as a peripheral nerve block, analgesia onset occurs after ≈10 minutes, and the analgesic effect lasts ≈3.5 hours but varies with nerve block location and technique.

Pharmacokinetics

Local anesthetics are absorbed from their site of administration into the systemic circulation. The rate and extent of systemic absorption increase with the dose and volume given, repeated administration, administration in the head and neck region, and administration into highly vascularized sites.

In dogs, peak arterial concentrations occurred 5 to 10 minutes after epidural administration of ≈1.5 mg/kg, and the elimination half-life and clearance were ≈200 minutes and ≈25 mL/minute/kg, respectively. The elimination half-life and clearance after IV administration were ≈26 minutes and 41 mL/minute/kg, respectively.[6]

In humans, peak concentrations occur ≈35 to 45 minutes after epidural block and ≈1 hour after brachial plexus block. Systemically absorbed drug distributes into all tissues, including the CNS. Protein binding is ≈95% to alpha-1-acid glycoprotein, which may limit but not prevent ropivacaine from crossing the placenta and being excreted in milk. It is metabolized in the liver by cytochrome P450 1A2 isozyme and is excreted in the urine principally as metabolites. Elimination half-life after IV administration is ≈1.8 hours in adults and ≈8 hours in neonates; with epidural use, the half-life is ≈4 hours.

Contraindications/Precautions/Warnings

Ropivacaine is contraindicated in patients with a known hypersensitivity to it or to another amide-type local anesthetic agent. It is not recommended for obstetrical paracervical block, spinal anesthesia, or IV regional anesthesia (Bier block). Epidural injections should be administered incrementally, with aspiration before each dose. Local anesthetics with preservatives should not be used for epidural or intrathecal anesthesia.

Use it with caution in patients with hepatic or renal disease or impaired cardiovascular function.

Ropivacaine products in which epinephrine has been added should be used with caution, or not at all, in patients with hypertension or for anesthesia of extremities without collateral circulation, such as digits, ears, nose, or penis, as it may cause tissue necrosis.

Ropivacaine should only be used in situations in which sufficient monitoring and patient-support capabilities (eg, intubation, ventilation) are available.

Adverse Effects

Local anesthetics are generally well tolerated when administered correctly. Adverse effects are related to high plasma concentrations, which may result from the dosage or ropivacaine concentration used, rapid absorption from the injection site, and unintentional intravascular or subarachnoid injection.

Cardiovascular effects include hypotension, bradycardia, AV block, and decreased cardiac output; severe hypotension caused by epidural ropivacaine was deemed responsible for the death of a healthy beagle enrolled in an experimental study.[7] It has greater cardiac toxicity (eg, hypotension, QRS widening) than lidocaine but less than bupivacaine.[8] It slows respiratory rate, but the rate typically remains within normal parameters. CNS excitation (eg, restlessness, tremors), depression (eg, drowsiness, loss of consciousness), or both may occur. Other noted adverse effects include nausea, vomiting, fever, urinary retention, and transient Horner's syndrome. Ataxia may occur with epidural administration.[9,10]

Chondrolysis has occurred with an intra-articular infusion of local anesthetics.

Reproductive/Nursing Safety

Local anesthetics readily cross the placenta. Animal reproductive studies with ropivacaine in rats and rabbits have not revealed adverse effects on fetal development, viability, or mortality.

Approximately 4% of the maternal dose is estimated to reach the nursing pup in breast milk; use with caution during lactation.

Overdose/Acute Toxicity

Toxic blood levels are most likely to occur after unintended intravascular ropivacaine administration. Toxic effects may occur rapidly and simultaneously. Cardiac conduction and excitability are depressed and may lead to AV block, ventricular arrhythmias, and cardiac arrest; arrhythmias may be refractory to treatment. In addition, myocardial contractility is depressed, and peripheral vasodilation occurs, leading to decreased cardiac output and arterial blood pressure. CNS stimulation (eg, restlessness, tremors, and shivering progressing to convulsions) may precede CNS depression, coma, and respiratory arrest. The mean dose that induced seizures in dogs and sheep was 4.9 mg/kg and 6.1 mg/kg, respectively.

Management must begin with the delivery of oxygen via a patent airway. Benzodiazepines or barbiturates can be used for seizure management but may cause further CNS depression. Cardiovascular support should be provided and may include IV fluids and vasopressor drugs. Prolonged resuscitative efforts may be required. Lipid emulsion therapy may be beneficial.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ropivacaine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amiodarone**: May increase the risk for cardiac toxicity
- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): Increased risk for bradycardia and hypotension
- **Beta-Adrenergic Antagonists**: (eg, **atenolol, esmolol, propranolol, sotalol**): May increase serum bupivacaine concentrations by reducing bupivacaine clearance
- **Ciprofloxacin/Enrofloxacin**: May impair ropivacaine metabolism
- **Theophylline**: May impair ropivacaine metabolism

Severe, prolonged hypertension may result when using ropivacaine/epinephrine combination products with the following:

- **Antidepressants, Tricyclic** (eg, **amitriptyline, clomipramine**): Use in combination with epinephrine-containing ropivacaine products may produce severe, prolonged hypertension.
- **Ergot Alkaloids** (eg, **bromocriptine, pergolide**)
- **Monoamine Oxidase Inhibitors** (eg, **selegiline, linezolid, amitraz**)
- **Vasopressors** (eg, **dobutamine, norepinephrine**)

Laboratory Considerations

- None were noted.

Dosages

NOTE: Ropivacaine product concentration, administration volume, site of administration, administration technique, and underlying patient condition(s) are important interrelated factors that determine ropivacaine's safe and effective use. Local anesthetics should be used only by clinicians well versed in correct administration technique, diagnosis, and management of local anesthetic toxicity and who have complete resuscitative resources immediately available.

DOGS:

Local analgesia (extra-label):

a) 2 mg/kg is a generally recommended dosage for local block.

b) Using ropivacaine 0.75% solution, give 0.75 mg/kg perineurally. **NOTE**: The combination with dexmedetomidine 0.1 µg/kg provided analgesia similar to ropivacaine alone.[11]

c) **Peribulbar injection**: Using ropivacaine 1% solution, administer 3 mg/kg (0.3 mL/kg). Ultrasound-guided injection resulted in lower postinjection intraocular pressure, faster restoration of conjugate eye movement, and lower risk for a subconjunctival hemorrhage.[12] Another separate study found satisfactory results using ropivacaine 0.75% solution.[13]

d) **Tumescent local anesthesia**: Ropivacaine 0.05% and 0.1% solutions (diluted in lactated Ringer's solution) at temperatures between 8°C and 12°C (46°F and 54°F) infused through a multi-hole needle at 15 mL/kg over 10 minutes provided analgesia for 7 hours following mastectomy.[14]

e) **Intraperitoneal administration during ovariohysterectomy**:

- 3 mg/kg using 1% ropivacaine diluted in saline solution 0.9% to a final volume of 1.2 mL/kg (final concentration of ropivacaine 0.25%) administered after the abdomen had been surgically opened and before ligation of the ovarian pedicles and uterus.[15]
- 3 mg/kg ropivacaine using 0.75% solution diluted with sterile water to 0.5% and administered just prior to closure.[16]

Epidural analgesia and anesthesia (extra-label): 0.2 – 1.65 mg/kg alone or in combination with an opioid (eg, methadone, morphine), alpha-2 agonist (xylazine) or both (ie, ropivacaine + opioid + xylazine).[17–24]

a) Using ropivacaine 1% solution, give 0.2 mg/kg with preservative-free morphine 0.2 mg/kg epidurally at L7-S1; total volume delivered is 1 mL/4.5 kg (10 lb) of body weight to a maximum of 10 mL.[21]

b) Using ropivacaine 0.75% solution, give 1.65 mg/kg with methadone 0.1 mg/kg. This dosage reduced intraoperative isoflurane and fentanyl requirements and prolonged postoperative analgesia; time to standing was also delayed.[17,18]

c) Using butorphanol 0.1 mg/kg with ropivacaine 0.75% solution

2.175 mg/kg to make a final total volume (butorphanol + ropivacaine) of 0.3 mL/kg allowed ovariosalpingohysterectomy without the need for anesthesia in 12 of 16 bitches.[20]

d) In a study comparing 1 mg/kg ropivacaine to 0.5 mg/kg ropivacaine alone or in combination with sufentanil or sufentanil-epinephrine: the combination of ropivacaine-sufentanil-epinephrine resulted in no rescue analgesia and the lowest postoperative pain scores. The 1 mg/kg ropivacaine group had a significantly greater motor block.[19]

e) Ropivacaine 0.75 mg/kg with morphine 0.1 mg/kg ± xylazine 0.1 mg/kg[22]

CATS:

Local analgesia (extra-label): 1.5 – 2 mg/kg is a generally recommended dose for local block.

Epidural analgesia and anesthesia (extra-label): Using ropivacaine 1% solution, administer 2 mg/kg in the L7-S1 epidural space.[25] Morphine can be added to ropivacaine. In another study, ropivacaine 1.95 mg/kg with morphine 0.1 mg/kg decreased postoperative analgesic requirement.[26]

HORSES:

Local analgesia (extra-label): Palmar digital nerve block: Using ropivacaine 0.75% solution, inject 1.5 mL SC just palmar to the medial and lateral neurovascular bundles and just proximal to the collateral cartilages of the foot.[27]

Intra-articular analgesia (extra-label): Using ropivacaine 1% solution, 20 mg (NOT mg/kg) combined with morphine 20 mg (NOT mg/kg) administered into the radio-carpal joint produced a strong analgesic effect for 24 hours under experimental conditions. Ropivacaine alone (40 mg total dose) produced analgesia for ≈2.5 to 3.5 hours.

Epidural analgesia and anesthesia (extra-label):

a) **Lumbosacral epidural**: 0.15 mg/kg administered between the first and second coccygeal vertebrae. The study used 0.3% ropivacaine in saline solution.[9]

b) **Caudal epidural**: Using ropivacaine 0.5% solution, 0.08 mg/kg with fentanyl citrate 100 µg (total dose, NOT µg/kg) produced perineal analgesia within an average of ≈7 minutes, and the analgesic effect lasted ≈3.6 hours. Ropivacaine alone (0.1 mg/kg) had a slower onset (≈12 minutes) and shorter duration (≈3 hours) with inferior quality of surgical analgesia.[28]

CATTLE:

Caudal epidural analgesia and anesthesia (extra-label): Using ropivacaine 0.75% solution, 0.11 mg/kg induced perineal analgesia within 15 minutes and lasted for 6 hours. Mild ataxia occurred in 50% of patients.[10]

SWINE:

Epidural analgesia and anesthesia (extra-label): Using ropivacaine 0.75% solution, 1.5 mg/kg reduced isoflurane requirement while improving blood pressure and heart rate in pigs undergoing abdominal and nonabdominal surgery.[29]

SHEEP/GOATS:

Local analgesia (extra-label): Using ropivacaine 0.5% solution, 12 mL (1.3 mg/kg) for thoracolumbar paravertebral nerve block for ruminal fistulation provided ≈9 to 10 hours of analgesia.[30]

Epidural analgesia and anesthesia (extra-label): 0.6 mg/kg administered lumbosacrally provided complete analgesia of the tail, perineum, thighs, and inguinal region of healthy goats.[31]

Monitoring

- Adequacy of analgesia and anesthesia
- Cardiovascular and respiratory function as well as state of consciousness after each injection
- ECG for patients taking class III antiarrhythmics (eg, sotalol, amiodarone) and for patients with a history of arrhythmias

Client Information

- This drug should only be used systemically by professionals familiar with its use and in a setting in which adequate patient monitoring can be performed.
- This medication causes temporary loss of feeling. The injected area may not have the usual function for several hours.

Chemistry/Synonyms

Ropivacaine hydrochloride is an amide-class local anesthetic. It occurs as a white crystalline powder that is soluble in water and alcohol. Commercial solutions contain only the S-enantiomer. Solubility is limited at pH above 6.

Ropivacaine hydrochloride is also known as AL-281, ropivacaini hydrochloridum, and *Naropin®*.

Storage/Stability

Store ropivacaine at controlled room temperature between 20°C and 25°C (68°F and 77°F); excursions are permitted to 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

Ropivacaine HCl is **compatible** with 0.9% sodium chloride solutions and the following drugs (partial list): ketamine, methylprednisolone acetate, and morphine sulfate. Ropivacaine HCl is reported to be **variably compatible** with fentanyl citrate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. See ***Appendix*** for more information.

Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Ropivacaine Hydrochloride Injection: 0.2%, 0.5%, 0.75%, and 1% solution in 10 mL, 20 mL, 30 mL, and 100 mL single-dose ampules, bottles, or vials; *Naropin®*, generic; (Rx)

S-Adenosyl-Methionine (SAMe)

(***ess***-ah-***den***-oh-seel meth-***ie***-oh-neen) *Denosyl®*

Hepatoprotectant

See also ***S-Adenosyl-Methionine (SAMe)/Silybin*** and ***Silymarin***

Prescriber Highlights

- ► Nutraceutical that has been used in small animals as an adjunctive treatment for acute and chronic liver disease (hepatitis) including hepatotoxicity and for cognitive dysfunction
- ► Evidence is scant supporting clinical efficacy, but it is well tolerated.
- ► Should be administered on an empty stomach but may be hidden in a small amount of food if necessary
- ► Not a regulated drug; choose products carefully

Uses/Indications

S-adenosyl-methionine (SAMe) is most commonly used in small animal species as an adjunctive treatment for liver disease[1] (chronic hepatitis, hepatic lipidosis, cholangiohepatitis), feline triaditis, gallbladder leiomyoma[2] or mucocele,[3] and blue-green algae ingestion.[4]

It potentially could be of benefit for age-related cognitive dysfunction,[5,6] treatment of acute hepatotoxin-induced liver toxicity (eg, acetaminophen,[7,8] xylitol,[9] amatoxin), and in at-risk patients on long-term therapy using drugs with hepatotoxic potential. The authors in a 2013 review assessing the evidence for nutraceuticals for treating canine liver disease state: *Despite the lack of data supporting the use of SAMe as a hepatoprotectant, the compound is frequently recommended for dogs with hepatobiliary disease. Before veterinarians recommend use of SAMe, they should ensure that owners understand (informed consent) that data on its efficacy is lacking.*[10]

Although a benefit has been reported for in vitro use of SAMe combined with glucosamine in preserving the integrity of bovine articular cartilage, a double-blinded, placebo-controlled clinical trial (6 weeks) evaluating SAMe efficacy for the treatment of clinically inferred osteoarthritis (OA) did not find that it was an effective standalone treatment for reducing clinical signs of OA in dogs.[11]

Pharmacology/Actions

S-adenosyl-methionine (SAMe) is an endogenous molecule synthesized by cells throughout the body. It is formed from the amino acid methionine and ATP, in conjunction with SAMe synthetase enzyme (an enzyme manufactured in the liver; a rate-limiting step in the presence of liver compromise). SAMe is an essential part of three major biochemical pathways: transmethylation, transsulfuration, and aminopropylation. Normal function of these pathways is especially vital to the liver as many metabolic and detoxifying reactions occur there.

In the transmethylation pathway, SAMe serves as a methyl donor (necessary for many substances and drugs to be activated and/or eliminated). Transmethylation is essential in phospholipid synthesis important to cell membrane structure, fluidity, and function. In aminopropylation, SAMe donates aminopropyl groups and is a source of polyamines. Aminopropylation is important in producing substances that have anti-inflammatory effects, protein and DNA synthesis, and promoting cell replication and liver mass regeneration.

In transsulfuration, SAMe generates sulfur-containing compounds important for conjugation reactions used in detoxification and as a precursor to glutathione (GSH). Glutathione is important in many metabolic processes and cell detoxification. The conversion of SAMe to glutathione requires the presence of folate, cyanocobalamin (B_{12}), and pyridoxine (B_6). Normally, the liver produces ample SAMe, but in liver disease or in the presence of hepatotoxic substances, endogenous conversion to glutathione may be deficient. Exogenous SAMe has been shown to increase liver and red blood cell glutathione levels and/or prevent its depletion. SAMe inhibits apoptosis secondary to alcohol or bile acids in hepatocytes.

In humans, the mechanism for its antidepressant effects is not well understood, but it apparently increases serotonin turnover and increases dopamine and norepinephrine levels. Neuro-imaging studies in humans show that SAMe affects the brain similarly to other antidepressant medications.

Pharmacokinetics

Oral bioavailability is dependent on the salt used to stabilize SAMe. Oral bioavailability of the tosylate salt is reportedly 1% whereas the 1,4-butanedisulfonate form has a bioavailability of 5%. Regardless of oral dosage form administered, presence of food in the gut can substantially reduce the amount of drug absorbed. Peak concentrations occur in 1 to 6 hours after oral dosing with the enteric-coated tablets. Once absorbed, SAMe enters the portal circulation and is primarily metabolized in the liver. In humans, 17% of a dose of radiolabeled SAMe was recovered in the urine within 48 hours of dosing and 27% in the feces; veterinary significance is unclear.

In dogs, a chewable non-hygroscopic formulation of SAMe yielded similar areas under-the-curve when compared with the enteric-coated tablets, but peak levels occurred sooner with the chewable tablets.[12]

Contraindications/Precautions/Warnings

There are no apparent contraindications to the use of SAMe.

An analysis comparing the measured amount of SAMe present in commercial dosage forms compared with the amount stated on product labels found a greater than 3-fold variance.[13]

Adverse Effects

Adverse effects appear to be minimal or nonexistent in treated animals. Most studies in humans have shown adverse effects similar to that of placebo.

Reproductive/Nursing Safety

The safety of exogenous SAMe has not been proven in pregnancy; use with caution. Limited studies in laboratory animals and pregnant women with liver disease have not demonstrated any ill effects to mother or fetus.

It is unknown if SAMe enters maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

SAMe appears to be quite safe. LD_{50} in rodents exceeds 4.65 g/kg, and toxicity studies in dogs and cats at the usual prescribed doses demonstrated no deleterious effects.[14] In the case of an overdose, GI effects may be observed, but are unlikely to require treatment.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No drug interactions have been documented with SAMe; however, theoretically, some drug interactions in humans may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Cholestyramine**: Decreased efficacy of SAMe possible

The following drugs can theoretically cause additive serotonergic effects:

- **Dextromethorphan**
- **Meperidine**
- **Mirtazapine**
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **selegiline**)
- **Pentazocine**
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine**)
- **Tramadol**
- **Trazodone**
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**)

Laboratory Considerations

- No specific laboratory interactions or considerations noted

Dosages

NOTE: None of these dosages are FDA-approved and should be treated as extra-label. Use a product from a reputable manufacturer and with proven bioavailability.[13,15] See ***Contraindications/Precautions/Warnings***.

DOGS:

Increase hepatic glutathione levels (product insert dosage; not FDA-approved): Administer the appropriate number of tablets according to body weight using the dosing table below. The daily dosage may also be calculated based on 20 mg/kg of body weight and rounded to the closest tablet size or combination of sizes.[16] Product should be given on an empty stomach, at least one hour before feeding. The daily dose can be gradually increased or decreased based on the dog's needs. Many dogs are maintained long-term using every-other-day or every-third-day dosing. If giving more than one tablet, may divide total daily dose and give twice daily.

Body weight	Tablet size (mg)	Number of tablets daily
Up to 5.5 kg (12 lb)	90	1
6 to 15.5 kg (13-34 lb)	225	1
16 to 29.5 kg (35-65 lb)	425	1
30 to 54.5 kg (66-120 lb)	425	2
Over 54.5 kg (120 lb)	425	3

Adjunctive treatment of necro-inflammatory/cholestatic liver disease, vacuolar hepatopathy: 20 mg/kg PO once daily on an empty stomach[15]

CATS:

Increase hepatic glutathione levels (product insert dosage; not FDA-approved): Administer the appropriate number of tablets according to body weight using the dosing table below. The daily dosage may also be calculated based on 20 mg/kg of body weight and rounded to the closest tablet size or combination of sizes.[16] Product should be given on an empty stomach, at least one hour before feeding. Because tablets can become lodged in the esophagus, administer 3 to 6 mL of water immediately after SAMe. The daily dose can be gradually increased or decreased based on the cat's needs. Many cats are maintained long-term using every-other-day or every-third-day dosing. If giving more than one tablet, may divide total daily dose and give twice daily.

Body weight	Tablet size (mg)	Number of tablets daily
Up to 5.5 kg (12 lb)	90	1
Over 5.5 kg (12 lb)	90	2

Adjunctive treatment of necro-inflammatory/cholestatic liver disease, vacuolar hepatopathy, or feline hepatic lipidosis: 20 mg/kg PO once daily on an empty stomach[17]

Monitoring

- Clinical signs (appetite, activity, attitude)
- Liver enzymes, bilirubin, bile acids; may require 1 to 4 months before any changes in lab values are noted

Client Information

- Keep tablets in original packaging until administration. Do not crush or split enteric-coated tablets.
- Very well tolerated, usually with no side effects
- Give on an empty stomach, at least an hour before or 2 hours after feeding. Total daily dosage may be given as 1 dose or divided and given as 2 doses.
- For cats: follow all oral tablets with 3 to 6 mL of water to make sure tablets pass into the stomach.
- SAMe is considered a nutritional supplement by the FDA, not a medication. Product quality (and thus effectiveness) may vary between manufacturers. Use only the medication prescribed by your veterinarian.
- While your animal is taking this medication, it is important to return to your veterinarian for any recommended bloodwork or physical exam rechecks. Do not miss these important follow-up visits.

Chemistry/Synonyms

S-adenosyl-methionine (SAMe) is a naturally occurring molecule found throughout the body. Because pure SAMe is highly reactive and unstable, commercially available forms of SAMe are salt forms; sulfate, sulfate-p-toluenesulfonate (also known as tosylate), and butanedisulfonate salts can all be procured.

SAMe may also be known as S-adenosyl-L-methionine, S-adenosylmethionine, SAM, SAM-e, ademetionine, adenosylmethionine, Sammy, or methioninyl adenylate. Many trade names are available.

Storage/Stability

Unless otherwise labeled, SAMe tablets should be stored at room temperature. Avoid conditions of high temperature or humidity. SAMe is inherently unstable in acidic or aqueous environments; store in tightly sealed, moisture-resistant containers.

Compatibility/Compounding Considerations

No specific information noted. SAMe is inherently unstable in acidic or aqueous environments.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None as a pharmaceutical. The FDA considers SAMe a nutritional supplement. No standards have been accepted for potency, purity, safety, or efficacy by regulatory bodies. Supplements are available from a wide variety of sources and dosage forms include tablets in a variety of strengths.

There are specific products marketed for use in animals, including:

Enteric-coated tablets: *Denosyl® for cats and small dogs* (SAMe 90 mg), *Denosyl® for medium dogs* (SAMe 225 mg), and *Denosyl® for large dogs* (SAMe 425 mg); (OTC)

Chewable tablets: SAMe 225 mg; *Denosyl®*; (OTC)

A combination product *Denamarin®*, containing SAMe and silybin (silymarin), is also labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

Many OTC products available.

For the complete list of references, see **wiley.com/go/budde/plumb**

S-Adenosyl-Methionine (SAMe)/ Silybin

(***ess***-ah-***den***-oh-seel meth-***ie***-oh-neen/***sill***-eh-bin) *Denamarin®*

Hepatoprotectant

See also ***S-Adenosyl-Methionine***.

Prescriber Highlights

- ► Nutraceutical combination used in small animal species as adjunctive treatment for acute and chronic liver disease (eg, chronic hepatitis), including hepatotoxicity
- ► Evidence supporting clinical efficacy is scant, but the combination is well tolerated; GI effects are possible.
- ► Should be administered on an empty stomach but may be hidden in a small amount of food if necessary
- ► Products are not regulated and should be chosen carefully.
- ► Some drug interactions may be possible.

Uses/Indications

The FDA considers S-adenosyl-methionine (SAMe)/silybin to be a combination nutritional supplement (not a medication); thus, no standards for potency, purity, safety, or efficacy have been accepted by regulatory bodies. An analysis comparing the measured amount of SAMe present in commercial dosage forms compared with the amount stated on product labels found a greater than 3-fold variance.[1]

In small animal medicine, SAMe (ie, ademetionine) combined with silybin is most commonly used as an adjunctive treatment for liver disease (eg, chronic hepatitis, hepatic lipidosis, cholangiohepatitis, feline triad disease). This combination may potentially be beneficial for treatment of acute hepatotoxin-induced liver toxicity (eg, acetaminophen, xylitol toxicity, amatoxins) and for at-risk animals receiving long-term therapy involving drugs with hepatotoxic potential.

Silymarin (silybin) is used to treat a variety of liver diseases in humans and domestic companion animals (eg, dogs, cats, horses, birds, rabbits), although controlled clinical studies demonstrating the efficacy for a standardized form and concentration are lacking. Silymarin (silybin) is most commonly used for treatment of chronic and acute liver disease and cirrhosis and as a hepatoprotective agent when hepatotoxic agents (eg, *Amanita phalloides*; death cap mushroom) are ingested. A study in cats found that silymarin had some hepatoprotective effects on hepatotoxicity induced by acetaminophen and tetracycline.[2,3] Silymarin appears to attenuate gentamicin-induced nephrotoxicity in dogs.[4]

The proprietary combination of silybin and SAMe (ie, *Denamarin®*) minimized liver enzyme elevations in dogs receiving lomustine (ie, CCNU) chemotherapy, which increased the likelihood that dogs could complete the prescribed lomustine therapy course.[5] However, according to a later review, the original study had several weaknesses, including a low number of dogs undergoing additional liver testing with bile acids, abdominal ultrasonography examination, and liver biopsies; low incidence of dogs with severe liver disease; lack of placebo in the control group; the study was nonblinded; some dogs had pre-existing occult liver disease; use of a fixed combination of 2 distinct agents; and potential author conflicts of interest.[6] In a small study in dogs with experimentally induced endotoxemia, the proprietary combination of silybin and SAMe protected the dog's hepatorenal function and had beneficial effects on coagulation.[7]

Pharmacology/Actions

SAMe, an endogenous molecule synthesized by cells throughout the body, is formed from the amino acid methionine and adenosine triphosphate (ATP) in conjunction with the SAMe synthetase enzyme (an enzyme manufactured in the liver; a rate-limiting step in the presence of liver compromise). SAMe is an essential part of 3 major biochemical pathways: transmethylation, transsulfuration, and aminopropylation. Normal functioning of these pathways is particularly vital to the liver, as the liver is where many metabolic and detoxifying reactions occur.

In the transmethylation pathway, SAMe serves as a methyl donor, which is necessary for the activation and/or elimination of many substances and drugs. Transmethylation is essential to phospholipid synthesis that is important to cell membrane structure, fluidity, and function.

In the aminopropylation pathway, SAMe donates aminopropyl groups and is a source of polyamines. Aminopropylation is important in producing substances that have anti-inflammatory effects, for protein and DNA synthesis, and in promoting cell replication and liver mass regeneration.

In the transsulfuration pathway, SAMe generates sulfur-containing compounds important for conjugation reactions used in detoxification and as a precursor to glutathione (GSH). GSH is important in many metabolic processes and cell detoxification. The conversion of SAMe to GSH requires the presence of folate, cyanocobalamin (vitamin B_{12}), and pyridoxine (vitamin B_6). The liver typically produces ample SAMe, but endogenous conversion to GSH may be deficient in animals with liver disease or in the presence of hepatotoxic substances. Exogenous SAMe has been shown to increase liver and erythrocyte GSH levels and/or prevent GSH depletion. SAMe inhibits apoptosis secondary to alcohol or bile acids in hepatocytes.

Silybin, which is the major active constituent of silymarin, has a variety of pharmacologic actions that may contribute to its apparent treatment for liver disease. Silymarin inhibits lipid peroxidase and beta-glucoronidase and acts as an antioxidant and free radical scavenger. Silymarin also inhibits the cytotoxic, inflammatory, and apoptotic effects of tumor necrosis factor (TNF); apparently silymarin can alter outer hepatocyte cell membranes that can prevent toxin penetration. Silymarin is thought to reduce hepatic collagen formation and increase hepatic GSH concentrations.

Pharmacokinetics

Oral bioavailability is dependent on the salt used to stabilize SAMe. Oral bioavailability of the tosylate salt is reportedly 1%, whereas the 1,4-butanedisulfonate form has a bioavailability of 5%. The presence of food in the gut can substantially reduce the amount of drug absorbed, regardless of the oral dose administered. Peak concentrations occur 1 to 6 hours after oral administration of enteric-coated tablets. After SAMe is absorbed, it enters the portal circulation and is primarily metabolized in the liver. In humans, 17% of a dose of radiolabeled SAMe was recovered in urine within 48 hours of administration; 27% of a dose was recovered in feces.

Few pharmacokinetic data exist regarding silymarin use in animals. Oral silybin absorption is increased in dogs, cats, and horses when the drug is administered as a phosphatidylcholine complex.[8–10] Oral bioavailability of silybin phosphatidylcholine complex was 7% in cats and 2.9% in horses.[9,10]

In humans, silymarin has an oral bioavailability of less than 50% and peak concentrations occur 2 to 4 hours after administration. Oral absorption can increase when silybin (ie, silibinin, sylibin) is complexed with phosphatidylcholine. The drug undergoes extensive enterohepatic circulation and has significantly higher concentrations in liver cells and bile than in plasma. The elimination half-life in humans averages 6 hours. The majority of the drug is eliminated unchanged in feces, but 20% to 40% is converted into glucuronide and sulfate conjugates, which are eliminated in feces; only about 8% of the drug is excreted in urine.

Contraindications/Precautions/Warnings

None

Adverse Effects

Adverse effects appear to be minimal or nonexistent in treated animals. Most studies in humans have shown adverse effects similar to that of placebo treatment; there have been reports of vomiting, anorexia, and anxiety immediately after administration. Oral SAMe in humans may cause anorexia, nausea, vomiting, diarrhea, flatulence, constipation, dry mouth, insomnia/nervousness, headache, sweating, and dizziness.

Reproductive/Nursing Safety

Exogenous SAMe/silybin should be used with caution during pregnancy, as it has not been proven to be safe during pregnancy. Limited studies in laboratory animals and pregnant women with liver disease did not demonstrate any adverse effects.

It is unknown whether SAMe/silybin enters maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

SAMe appears to be safe. LD_{50} in rodents exceeds 4.65 g/kg, and toxicity studies in dogs and cats demonstrated no adverse effects at the usual prescribed doses. Overdoses are unlikely to cause significant morbidity. GI effects may be noted and treated as necessary in a supportive manner.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No drug interactions have been documented with SAMe/silybin; however, theoretically, some drug interactions in humans may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

The following drugs can theoretically cause additive serotonergic effects:

- **Dextromethorphan**
- **Meperidine**
- **Mirtazapine**
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid, selegiline**)
- **Pentazocine**
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine**)
- **Tramadol**
- **Trazodone**
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**)

Other potential drug interactions include:

- **Antiviral Drugs**: Decreased efficacy possible
- **Cholestyramine**: Decreased SAMe absorption
- **Drugs Affected By Cytochrome P450 Inhibition** (eg, **amitriptyline, NSAIDs, verapamil, warfarin**): Silybin may inhibit CYP2C9. Drugs with narrow therapeutic indexes that are metabolized by this isoenzyme should be used with caution.
- **Drugs Cleared Via Hepatic Glucuronidation** (eg, **acetaminophen, diazepam, metronidazole**[11]**, morphine**): Silybin may increase the clearance of drugs that undergo hepatic glucuronidation (interaction does not apply to cats).

Laboratory Considerations

- No specific laboratory interactions or considerations are noted.

Dosages

DOGS/CATS: **NOTE**: Dosing is different for regular and chewable tablet formulations; chewable formulations are only available for dogs.

Adjunctive treatment in animals with acute hepatopathies or hepatic fibrosis: Recommended dosages are often significantly higher than what is listed on the label. Anecdotally, SAMe 20 – 40 mg/kg PO daily has been suggested for dogs and 200 – 400 mg/cat (NOT mg/kg) PO daily for cats. For chronic hepatitis or other acute hepatopathies, silybin (ie, silymarin) 7 – 15 mg/kg PO daily has been suggested. To attempt to reduce fibrosis, silybin 20 – 50 mg/kg PO daily has been suggested.

- Tablets should be given on an empty stomach at least 1 hour before feeding, as food decreases absorption of SAMe.
- Enteric-coated tablets may be hidden in a small amount of food if there is difficulty in pilling.
- Dry-pilling cats is not recommended; 3 – 6 mL of water can be given immediately after pilling to facilitate passage to the stomach.
- The number of tablets given can be gradually reduced or increased at any time depending on the animal's needs.
- Many animals can be maintained long-term with every-other-day or every-third-day administration.

***Denamarin*® Tablets**[12]

Species	Body weight*	Tablet size (SAMe/Silybin)	Number of tablets	Frequency of administration
Dogs, cats	Less than 5.5 kg (12 lb)	90 mg/9 mg	1	Once daily
Dogs, cats	More than 5.5 kg (12 lb)	90 mg/9 mg	1	Twice daily
Dogs	6-15.5 kg (13-34 lb)	225 mg/24 mg	1	Once daily
Dogs	16-29.5 kg (35-65 lb)	425 mg/35 mg	1	Once daily
Dogs	30-54.5 kg (66-120 lb)	425 mg/35 mg	2	Once daily or 1 tablet twice daily
Dogs	More than 54.5 kg (120 lb)	425 mg/35 mg	3	Once daily or divided and given twice daily

*Manufacturer lists dosages per lb, not per kg.

***Denamarin*® *Advanced* Tablets**[13]

Species	Body weight*	Tablet size (SAMe/Silybin)	Number of tablets	Frequency of administration
Cats	All sizes	30 mg/9 mg	1	Once daily
Dogs	Less than 5.5 kg (12 lb)	30 mg/9 mg	1	Once daily
Dogs	5.5-15.5 kg (12-34 lb)	82 mg/24 mg	1	Once daily
Dogs	16-29.5 kg (35-65 lb)	172 mg/35 mg	1	Once daily
Dogs	30-54.5 kg (66-120 lb)	172 mg/35 mg	2	Once daily

Dogs	More than 58.9 kg (130 lb)	215 mg/ 70 mg	2	Once daily

*Manufacturer lists dosages per lb, not per kg.

Monitoring

- Clinical signs (eg, changes in appetite, activity, temperament)
- Liver enzymes, bilirubin, liver function testing (eg, serum bile acids or ammonia); may require 1 to 4 months before any changes in laboratory values are noted

Client Information

- Keep tablets in original packaging until used. Do not crush or split enteric-coated tablets.
- SAMe/silybin is well tolerated in animals and typically does not have side effects.
- Give this medicine on an empty stomach, at least an hour before or 2 hours after feeding. Total daily dose may be given as a single dose or divided and given as 2 separate doses.
- For cats, follow all oral tablets with 3 to 6 mL of water to ensure tablets pass into the stomach.
- SAMe/silybin is considered a combination nutritional supplement by the FDA (not a medication). Use only the medication prescribed by your veterinarian.
- Your veterinarian will need to monitor your animal while it is taking this medication. Do not miss these important follow-up visits.

Chemistry / Synonyms

S-adenosyl-methionine (SAMe) is a naturally occurring molecule found throughout the body. Because pure SAMe is highly reactive and unstable, commercially available forms of SAMe are salt forms (eg, sulfate, sulfate *p*-toluenesulfonate [also known as tosylate], 1,4-butanedisulfonate).

Silybin (ie, silibinin, sylibin, silibide) is a flavolignan and is the most biologically active component found in silymarin, which is the medicinal extract from the seeds of milk thistle (*Silybum marianum*).

Silymarin is reportedly fairly insoluble in water but is soluble in organic solvents (eg, ethanol, dimethylsulfoxide [DMSO]).

Storage / Stability

Unless otherwise labeled, store in a cool dry place not to exceed 30°C (86°F). Keep tablets in original bottle or blister pack until used; do not discard the desiccant that comes in the bottle.

Tablets are sensitive to moisture and extreme heat and should not be split or crumbled.

Compatibility / Compounding Considerations

No specific information was noted.

Dosage Forms / Regulatory Status

VETERINARY-LABELED PRODUCTS:

The FDA considers SAMe and silymarin (silybin) to be nutritional supplements. No standards for potency, purity, safety, or efficacy have been accepted by regulatory bodies.

Specific products are marketed for use in animals, including *Denamarin*®, which is a patented product labeled for use in dogs and cats.

Enteric-Coated Tablets: *Denamarin*® *for Cats and Small Dogs* (SAMe 90 mg/silybin 9 mg); *Denamarin*® *for Medium Dogs* (SAMe 225 mg/silybin 24 mg); *Denamarin*® *for Large Dogs* (SAMe 425 mg/silybin 35 mg). Silybin provided as phosphatidylcholine complex.

Hard Tablets: *Denamarin*® *Advanced Hard Tablets for Cats and Small Dogs* (SAMe 30 mg, Silybin 9 mg); *Denamarin*® *Advanced Hard Tablets Medium Dogs* (SAMe 82 mg, Silybin 24 mg); *Denamarin*® *Advanced Hard Tablets for Cats and Small Dogs* (SAMe 172 mg, Silybin 35 mg). SAMe provided as a proprietary formulation; silybin provided as phosphatidylcholine complex

Chewable Tablets:

Denamarin® *Chewable Tablets for Dogs* (SAMe 225 mg/silybin 24 mg);

Denamarin® *Advanced Chewable Tablets for Small to Medium Dogs* (SAMe 120 mg/Silybin 35 mg); *Denamarin*® *Advanced Chewable Tablets for Large Dogs* (SAMe 215 mg/Silybin 70 mg). SAMe provided as a proprietary formulation; silybin provided as phosphatidylcholine complex

HUMAN-LABELED PRODUCTS: None as an FDA-approved pharmaceutical

Saline Cathartics

Magnesium Citrate, Magnesium Hydroxide, Magnesium Oxide, Magnesium Sulfate, Sodium Sulfate

Laxative/Cathartic

See also ***Magnesium Hydroxide***.

Prescriber Highlights

- ► Hyperosmotic agents used for constipation or to increase elimination of GI toxins
- ► Contraindications include dehydration and long-term use. Sodium sulfate is also contraindicated in patients with CHF or congenital megacolon.
- ► Use with extreme caution in patients with renal insufficiency, pre-existing water imbalance, electrolyte abnormalities, or cardiac disease.
- ► Adverse effects include cramping and nausea. Electrolyte disturbances are possible, particularly with repeated use. Hypermagnesemia (muscle weakness, ECG changes, and CNS effects) can occur with chronic use of magnesium salts.
- ► Many drug interactions are possible.

Uses/Indications

Saline cathartics (laxatives) include oral magnesium sulfate (Epsom salts), magnesium hydroxide (milk of magnesia), magnesium citrate, and sodium sulfate (Glauber's salt). Saline cathartics can be used to relieve constipation or shorten intestinal transit time to reduce the absorption of orally ingested toxicants. In small animal species, saline cathartics are rarely recommended for treating constipation or obstipation but can be used with or without activated charcoal to enhance toxin removal. Sodium sulfate is typically preferred to magnesium sulfate in small animal species.

Pharmacology/Actions

It is thought that the hyperosmotic effect of poorly absorbed magnesium cations causes water retention, stimulates stretch receptors, and enhances peristalsis in the small intestine and colon. Magnesium ions may also directly shorten transit times and increase cholecystokinin release.

Pharmacokinetics

Up to 30% of an orally administered dose of magnesium salts can be absorbed.

The onset of action of saline cathartics (characterized by a loose, watery stool) typically occurs in 3 to 12 hours after administration in monogastric animals and within 18 hours in ruminants.

Contraindications/Precautions/Warnings

Saline cathartics are contraindicated in dehydrated patients. Saline cathartics are not for long-term use. Sodium-containing laxatives are contraindicated in patients with congestive heart failure or congenital megacolon.

Saline cathartics should be used with extreme caution in patients with significant diarrhea, renal insufficiency, pre-existing water imbalance, electrolyte abnormalities, or cardiac disease, and in severely depressed animals. Routine use as a sole treatment is not recommended due to risk for volume depletion, hypotension, and electrolyte disturbances.

Adverse Effects

Adverse effects are uncommon in healthy patients but may include cramping and nausea. Electrolyte disturbances (eg, hypernatremia, hypermagnesemia) are possible but typically only occur with chronic use or overdoses. Hypermagnesemia may manifest as muscle weakness, ECG changes, or CNS depression.

Reproductive/Nursing Safety

Magnesium emulsions administered orally did not affect the stools of nursing infants, although magnesium content in breast milk was slightly elevated compared with untreated patients. In veterinary patients, magnesium-containing cathartics should be safe to use during nursing if used infrequently. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

An overdose of saline cathartics can result in electrolyte disturbances such as hypernatremia or hypermagnesemia. Hypermagnesemia may result in muscle weakness, ECG changes, and CNS depression. Treatment consists of monitoring and correcting fluid imbalances with parenteral fluid therapy. Concurrent furosemide may be used to enhance the renal excretion of excess magnesium. Calcium has been suggested to help antagonize the CNS effects of magnesium.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

All orally administered saline cathartics may alter the rate and extent of absorption of other *orally* administered drugs by shortening intestinal transit times; however, the extent of these effects has not been well characterized for individual drugs. The following drug interactions have either been reported or are theoretical in humans or animals receiving magnesium-containing oral products and may be of significance in veterinary patients receiving saline cathartics. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Quinidine**: Increased risk for quinidine toxicity
- **Sodium Polystyrene Sulfonate**: Increased risk for metabolic acidosis

The following drugs or drug classes may have reduced oral bioavailability if administered with magnesium-containing cathartics; separate dosages by at least 2 hours:

- **Allopurinol**
- **Captopril**
- **Digoxin**
- **Fexofenadine**
- **Fluoroquinolones** (eg, **ciprofloxacin, enrofloxacin, marbofloxacin**)
- **Gabapentin**
- **Iron**
- **Ketoconazole, Itraconazole**
- **Levothyroxine**[1]
- **Misoprostol**
- **Mycophenolate**
- **Penicillamine**
- **Quinidine**
- **Sotalol**
- **Sucralfate**
- **Tacrolimus**
- **Tetracyclines** (eg, **doxycycline, minocycline**)

Laboratory Considerations

- No specific information was noted.

Dosages

DOGS/CATS:

Cathartic to enhance toxin removal from the GI tract (extra-label):

a) **Magnesium hydroxide (milk of magnesia)**: Rarely used in small animals as a laxative but has been recommended as a cathartic for zinc phosphide ingestions at 5 – 15 mL/dog or cat PO[1]

b) **Magnesium sulfate or sodium sulfate** (extra-label): 250 mg/kg administered as a suspension in water up to a concentration of 20%. Activated charcoal (AC) 1 – 4 g/kg may also be combined with the cathartic as a suspension in water (10 times water). In cases where repeated doses of AC are indicated and magnesium sulfate is used, the cathartic should *only* be given with the initial dose of AC.[1]

HORSES:

Cathartic for plant intoxications using magnesium sulfate or sodium sulfate (extra-label): 250 – ≈500 mg/kg mixed with an activated charcoal (AC) slurry dosed at 1 – 5 g/kg (≈1 g of AC/5 mL of water). There is little need to administer a cathartic if significant diarrhea is already present.[2]

Cecal impactions using magnesium sulfate (extra-label): 1 g/kg dissolved in water and given via NG tube concomitantly with a balanced electrolyte solution IV.[3]

RUMINANTS:

Cathartic in cattle using sodium sulfate (extra-label): 500 – 750 g PO as a 6% solution via stomach tube[4]

Cathartic for plant intoxications using magnesium sulfate or sodium sulfate (extra-label): 250 – 500 mg/kg mixed in an activated charcoal (AC) slurry dosed at 1 – 5 g/kg (≈1 g of AC/5 mL water). There is little need to administer a cathartic if significant diarrhea is already present.[2]

Monitoring

- Clinical efficacy
- Hydration status
- Baseline and periodic serum electrolytes in susceptible patients, especially with high or repeated doses

Client Information

- Give this medicine as directed by your veterinarian.
- Contact your veterinarian if your animal begins vomiting.

Chemistry/Synonyms

Magnesium cation containing solutions of magnesium citrate, magnesium hydroxide, magnesium oxide, and magnesium sulfate act as saline laxatives. Magnesium citrate solutions contain magnesium 4.71 mEq/5 mL. Magnesium hydroxide contains magnesium 34.3 mEq /g and milk of magnesia contains magnesium 13.66 mEq/5 mL. One gram of magnesium sulfate (Epsom salt) contains ≈8.1 mEq of magnesium.

Sodium sulfate (hexahydrate form) occurs as large, colorless, odorless crystals or as white crystalline powder. It will effloresce in dry air and partially dissolve in its own water of crystallization at about 33°C (91°F). One gram is soluble in ≈2.5 mL of water. Sodium sulfate may also be known as E514, Glauber's Salt, natrii sulphas, natrio sulfata, or natrium sulfuricum.

Storage/Stability

Store milk of magnesia at temperatures less than 35°C (95°F), but do not freeze.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Saline cathartic products are not FDA-approved for use in veterinary species. They are available without a prescription (OTC).

HUMAN-LABELED PRODUCTS:

Saline Laxatives: **NOTE**: Many commercial products exist; below is a representative list and is not all-inclusive.

Magnesium Hydroxide Suspension (Milk of Magnesia): 400 mg/5 mL (80 mg/mL); generic; (OTC)

Magnesium Hydroxide Suspension concentrated (Milk of Magnesia concentrated): 800 mg/5 mL (160 mg/mL); generic; (OTC)

Magnesium Sulfate (Epsom Salt) Granules: 120 g, 0.5 kg (1 lb), and 2 kg (4 lb) bags; generic; (OTC)

Magnesium Citrate Solution: 1.75 g/30 mL in 296 mL bottles; generic; (OTC)

Sodium sulfate (hexahydrate) is available from chemical supply houses. **NOTE**: A 24-hour meat withdrawal is recommended as sodium sulfate is rapidly excreted.[5]

For the complete list of references, see **wiley.com/go/budde/plumb**

Sarolaner

(***sar***-oh-***lan***-er) *Simparica®, Simparica TRIO®*

Isoxazoline Ectoparasiticide

See also ***Selamectin/Sarolaner, Moxidectin/Moxidectin Combination Products.***

Prescriber Highlights

- ► Monthly chewable ectoparasiticide (insecticide/acaricide) for use in dogs and puppies 6 months of age and older weighing more than or equal to 1.3 kg (2.8 lb)
- ► Indicated for treatment and prevention of flea infestations and treatment and control of tick infestations
- ► Combination product with moxidectin and pyrantel is used in dogs as a monthly heartworm preventive that also kills adult fleas, treats and prevents flea infestation, and treats and controls tick infestation, roundworms, and intestinal hookworms.
- ► Extra-label use of the single-agent product for treatment of generalized demodicosis, scabies, and ear mites.
- ► FDA has warned that drugs in the isoxazoline class have the potential for causing neurologic adverse effects (eg, muscle tremors, ataxia, and seizures) in dogs and cats.

Uses/Indications

Sarolaner is FDA-approved for use in dogs for the treatment and prevention of flea infestations (*Ctenocephalides felis*) and for treatment and control of tick infestations (*Amblyomma americanum* [lone star tick], *Amblyomma maculatum* [Gulf Coast tick], *Dermacentor variabilis* [American dog tick], *Ixodes scapularis* [black-legged tick, also called deer tick], and *Rhipicephalus sanguineus* [brown dog tick]) for 1 month in dogs 6 months of age or older and weighing 1.3 kg (2.8 lb) or more.[1]

Sarolaner effectively treats (extra-label) dogs naturally infested with the mite species *Demodex canis,*[2] *Sarcoptes scabiei,*[3] and *Otodectes cynotis.*[4]

In dogs exposed to ticks under experimental conditions, sarolan-

er at label dosages prevented transmission of *Babesia canis*,[5] *Borrelia burgdorferi,* and *Anaplasma phagocytophilum*.[6] At 35 days after administration, sarolaner was 99.6% effective against *Amblyomma cajennense* nymphs (Cayenne tick),[7] 100% effective against adult *Haemaphysalis elliptica* (African yellow dog tick),[8] and more than 97% effective against *Haemaphysalis longicornis* nymphs (New Zealand cattle tick, Asian long-horned bush tick).[9] It demonstrated 100% larvicidal effect in dogs 24 hours after a single dose for *Cochliomyia hominivorax* (New World screwworm).[10]

In experimental, comparative speed-of-kill studies, sarolaner-treated dogs had significantly lower mean tick counts than afoxolaner at 8 and/or 12 hours post-treatment against *Rhipicephalus sanguineus sensu lato*[11] and *Ixodes* spp.[12,13] Similarly, sarolaner-treated dogs had lower flea counts at 8 hours after administration compared with the combination milbemycin/spinosad[14] or afoxolaner.[15] In all studies, equivalent efficacy was demonstrated at 24 hours after administration of all drugs. Sarolaner appeared to have equivalent speed-of-kill times as fluralaner against *R sanguineus sensu lato*[16,17] and *Ctenocephalides felis*.[18]

In dogs, the European label indicates sarolaner for the treatment of infestations of the tick species *Dermacentor reticulatus* (ornate cow tick), *Ixodes hexagonus* (hedgehog tick), *Ixodes ricinus* (castor bean tick), and *R sanguineus*; flea species *C felis* and *Ctenocephalides canis*; as well as *Sarcoptes scabiei* (sarcoptic mange) and *Otodectes cynotis* (ear mites).[19]

Sarolaner/selamectin is available as a topical spot-on solution for cats (8 weeks of age and older and weighing more than 1.3 kg [2.8 lb]) to treat and prevent parasitic infestations by ticks, fleas, lice, mites, and GI nematodes, and for prevention of heartworm infection. See also ***Selamectin/Sarolaner***.

Sarolaner/moxidectin/pyrantel is labeled for dogs 8 weeks of age and older and weighing 1.3 kg (2.8 lb) or more as a monthly oral treatment for prevention of heartworm disease caused by *Dirofilaria immitis,* treatment and prevention of flea infestations (*C felis*), treatment and control of tick infestations of *A americanum*, *A maculatum*, *D variabilis*, *Ixodes scapularis*, and *R sanguineus*, and for the treatment and control of roundworms (*Toxocara canis, Toxascaris leonina*) and hookworms (*A caninum, Uncinaria stenocephala*).[20]

Pharmacology/Actions

Sarolaner is an isoxazoline acaricide/insecticide that inhibits gamma-aminobutyric acid (GABA) and glutamate receptors at the neuromuscular junction in insects or acarines, resulting in uncontrolled neuromuscular activity leading to death of the parasite. Sarolaner does not interact with known insecticidal binding sites of nicotinic or other GABAergic insecticides (eg, neonicotinoids, fiproles, milbemycins, avermectins, cyclodienes).[19] Sarolaner kills adult fleas and ticks only after they have bitten and fed.

Controlled laboratory studies have demonstrated that fleas start dying 3 hours after the dose is administered. Live fleas are reduced by 96.2% or more within 8 hours. A 100% effectiveness within 24 hours of treatment has been reported, with 100% effectiveness maintained against weekly reinfestations for 35 days.[11,13] For 35 days after administration, sarolaner kills fleas before they can lay eggs.[1]

For indicated tick species, sarolaner demonstrated 99% or more effectiveness against initial infestation 48 hours after administration and maintained more than 96% effectiveness 48 hours after reinfestation for 30 days.[1]

Pharmacokinetics

After oral administration, absorption of sarolaner is extensive and rapid; mean oral bioavailability is 86% and 107% in fasted and fed dogs, respectively. Sarolaner has wide distribution with a mean volume of distribution (steady-state) of 2.81 L/kg (after IV dose of 2 mg/kg). Sarolaner is highly bound to canine plasma proteins (more than or equal to 99.9%). Clearance is low (0.12 mL/minute/kg) and the mean half-life after oral administration is 10 to 12 days. Primary route of drug elimination is thought to occur via biliary excretion of unchanged drug into the feces. Metabolism appears to be minimal.[1,19]

Contraindications/Precautions/Warnings

There are no known contraindications for the use of sarolaner; however, it is not labeled for use in dogs weighing less than 1.3 kg (2.8 lb) or less than 6 months of age, or as a single agent for oral use in cats.[1] Sarolaner may cause abnormal neurologic signs (eg, tremors, decreased conscious proprioception, ataxia, decreased or absent menace, seizures).[1] The FDA has warned that drugs in the isoxazoline class have the potential for causing neurologic adverse effects in dogs and cats, including muscle tremors, ataxia, and seizures.[21]

No adverse effects were noted after 3 times the label doses were administered to collies homozygous for the *MDR1* genetic mutation (also known as *ABCB1*-1delta).[22]

Sarolaner/moxidectin/pyrantel should be used with caution in dogs with a history of seizures or neurologic disorders. Dogs should return a negative result for heartworm infection prior to being treated with this product. This product is not an effective treatment for adult *Dirofilaria immitis* infections. Not to be used in dogs less than 8 weeks of age or weighing less than 1.3 kg (2.8 lb).[20]

Adverse Effects

Sarolaner appears to be well tolerated in the majority of dogs. In a 3-month field study in dogs, vomiting, diarrhea, inappetence, and lethargy were the most commonly reported adverse effects. Isoxazolines, including sarolaner, have been associated with neurologic adverse effects (eg, muscle tremors, ataxia, seizures) even in dogs with no known history of neurologic problems.[1,20]

Field safety studies in dogs receiving sarolaner/moxidectin/pyrantel reported vomiting (14.3%), diarrhea (13.2%), and lethargy (8.5%).[20]

Reproductive/Nursing Safety

The safety of sarolaner has not been established during pregnancy or lactation or in animals intended for breeding. Studies performed in rats and rabbits have not produced evidence of teratogenic effects.[19]

Safe use of the combination product sarolaner/moxidectin/pyrantel has not been evaluated in dogs used for breeding and those that are pregnant or lactating.[20]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In rats, the oral (acute) LD_{50} is 783 mg/kg and dermal (acute) LD_{50} is greater than 2020 mg/kg.[19] In one study, 8-week-old beagle puppies were given up to 5 times (20 mg/kg) doses PO at 28-day intervals for 10 doses. Some animals in the 3 times and 5 times groups showed transient and self-limiting neurologic signs: ataxia, lethargy, disorientation, hypersalivation, absent menace, and tremors at 3 times the labeled dose; and convulsions, tremors, and abnormal head coordination at 5 times the labeled dose. All dogs recovered without treatment.[1]

Following single oral administration at 5 times the recommended dose, sarolaner as a single agent is reportedly well tolerated in collies with the *MDR1* gene mutation (also known as *ABCB1*-1delta). No treatment-related clinical signs were observed.[1]

Eight-week-old puppies receiving 5 times the maximum recommended dose of sarolaner/moxidectin/pyrantel (*Simparica TRIO*®) did not have any clinically relevant adverse effects.[20] Collies with the *MDR1* mutation demonstrated signs of avermectin sensitivity (eg, ataxia, muscle fasciculations, mydriasis) after receiving 5 times the

recommended dose of the combination product.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No clinically significant drug interactions have been reported to date with sarolaner or sarolaner/selamectin when used at label dosages. See also ***Moxidectin/Moxidectin Combination Products*** and ***Pyrantel*** for potential drug interactions for the sarolaner combination product containing moxidectin and pyrantel.

In one field study, 1 dog developed lethargy, ataxia while posturing to eliminate, elevated third eyelids, and inappetence 1 day after receiving sarolaner concurrently with ivermectin and pyrantel pamoate combination. Clinical signs resolved 1 day later.[1] No causation of a drug interaction should be inferred from this single case.

Dosages

DOGS:

Single-agent Product:

Label indications (label dosage; FDA-approved): Administer orally once a month at the recommended minimum dose of 2 mg/kg (0.91 mg/lb).[1]

Body weight in kg (lb)	Sarolaner (mg) per tablet	Number of tablets administered
1.3-2.5 (2.8-5.5)	5	1
2.5-5 (5.6-11)	10	1
5-10 (11.1-22)	20	1
10-20 (22.1-44)	40	1
20-40 (44.1-88)	80	1
40-60 (88.1-132)	120	1
Greater than 60 (132.1)	Administer appropriate combination of tablets	

Susceptible ectoparasites (extra-label): 2 – 4 mg/kg PO has effectively treated the following:

1. Mites:
   a. *Otodectes cynotis*: 1 or 2 doses administered 30 days apart[4,23]
   b. Generalized demodicosis: 3 to 5 monthly doses achieved parasitological cure in client-owed dogs.[2] Cure was achieved after 2 doses in an experimental (induced) infection.[23]
   c. *Sarcoptes scabiei*: 2 doses administered 30 days apart achieved parasitological cure in 100% of dogs.[3]
2. Ticks: Naturally occurring infestations with *Ixodes ricinus, Ixodes hexagonus, Rhipicephalus sanguineus,* and *Dermacentor reticulatus*: 3 monthly (as per label) doses resulted in 97% to 100% reduction of all tick species 14 days after the first dose, and 100% of dogs becoming tick-free after 90 days.[24] Experimentally induced infestation with adult *R sanguineus,*[11,16,17] *Haemaphysalis elliptica,*[8] *Amblyomma cajennense,*[7] and *Haemaphysalis longicornis* nymphs[9] also showed effectiveness with sarolaner at labeled dosages.
3. Myiasis caused by *Cochliomyia hominivorax* (New World screwworm) larvae: A single dose of sarolaner 2 mg/kg had a 100% larvicidal effect after 24 hours.[10]

Prevention of tick-borne disease (extra-label): 2 – 4 mg/kg PO in single doses under laboratory conditions prevented transmission of *Babesia canis*[5], as well as *Borrelia burgdorferi* and *Anaplasma phagocytophilum*.[6]

Combination Products:

Sarolaner/Moxidectin/Pyrantel (label dosage; FDA-approved): Each tablet is formulated to provide minimum dosages of 1.2 mg/kg (0.54 mg/lb) sarolaner, 24 µg/kg (0.011 mg/lb) moxidectin, and 5 mg/kg (2.27 mg/lb) pyrantel (as pamoate salt) PO with or without food once monthly.[20]

Body weight in kg (lb)	Sarolaner (mg) per tablet	Moxidectin (mg) per tablet	Pyrantel (mg) per tablet	Number of tablets administered
1.3-2.5 (2.8-5.5)	3	0.06	12.5	1
2.5-5 (5.6 -11)	6	0.12	25	1
5-10 (11.1-22)	12	0.24	50	1
10-20 (22.1-44)	24	0.48	100	1
20-40 (44.1-88)	48	0.96	200	1
40 -60 (88.1-132)	72	1.44	300	1
Greater than 60 (132.1)	Administer appropriate combination of tablets			

CATS:

See ***Selamectin/Sarolaner***

Monitoring

- Efficacy of parasiticide activity
- Adverse effects (eg, muscle tremors, ataxia, seizures)

Client Information

- Treatment may start at any time of the year. In areas where fleas and ticks are common year-round, monthly treatment should continue for the entire year without stopping.
- Prior to being treated with the combination product sarolaner/moxidectin/pyrantel, dogs should return a negative test for heartworm infection.
- Tablets are chewable, palatable, and readily consumed by dogs. If the dog does not take the tablet voluntarily, the tablet can also be given with food.
- Be sure your dog consumes the complete dose. Watch your dog for a few minutes after giving the dose to be sure it does not spit out any part of the dose.
- Sarolaner kills adult fleas and ticks only after they have bitten your animal but before the fleas or ticks can lay eggs or transmit disease. Existing flea eggs will hatch and must feed in order to be killed. Keep this medicine out of the reach of other animals and children. Keep the tablets in the original packaging until you are ready to give the medicine to your animal.
- Report any side effects, including tremors, difficulty walking, or seizures, to your veterinarian as soon as possible.

Chemistry/Synonyms

Sarolaner is in the isoxazoline class of parasiticides. Its chemical name is 1-(5'-((5S)-5-(3,5-Dichloro-4-fluorophenyl)-5-(trifluoromethyl)-4,5-dihydroisoxazol-3-yl)-3'-Hspiro(azetidine-3,1'-(2)benzofuran)-1-yl)-2-(methylsulfonyl)ethanone. The commercially available product is the *S*-enantiomer. The CAS registry number is 1398609-39-6 and ATC vet code is QP53BX06.

The commercially available chewable tablets also contain the excipients hydrolyzed soy protein, corn starch, sucrose, wheat germ, anhydrous dibasic calcium phosphate, corn syrup, and gelatin.[1,19]

Sarolaner may also be known by its trade names, which also include the following combination products: *Revolution® Plus*, *Simparica®*, *Simparica TRIO®*.

Storage/Stability

Store at or below 30°C (86°F) with excursions permitted up to 40°C (104°F).

Compatibility/Compounding Considerations

No known incompatibilities.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Single-agent Products:

Sarolaner Chewable (flavored) Tablets: 5 mg, 10 mg, 20 mg, 40 mg, 80 mg, and 120 mg. Each tablet size is available in packages of 1, 3, or 6 tablets. *Simparica®* (NADA 141-452; approved by FDA); (Rx)

Combination Products:

Sarolaner with Moxidectin and Pyrantel Pamoate Chewable (flavored) Tablets for dogs: 1.3 to 2.5 kg (2.8 to 5.5 lb): moxidectin 0.06 mg, pyrantel pamoate 12.5 mg, and sarolaner 3 mg; 2.5 to 5 kg (5.6 to 11 lb): moxidectin 0.12 mg, pyrantel pamoate 25 mg, and sarolaner 6 mg; 5 to 10 kg (11.1 to 22 lb): moxidectin 0.24 mg, pyrantel pamoate 50 mg, and sarolaner 12 mg; 10 to 20 kg (22.1 to 44 lb): moxidectin 0.48 mg, pyrantel pamoate 100 mg, and sarolaner 24 mg; 20 to 40 kg (44.1 to 88 lb): moxidectin 0.96 mg, pyrantel pamoate 200 mg, and sarolaner 48 mg; 40 to 60 kg (88.1 to 132 lb): moxidectin 1.44 mg, pyrantel pamoate 300 mg, and sarolaner 72 mg. Each tablet size is available in packages of 1, 3, or 6 tablets; *Simparica TRIO®* (Rx). Approved for use in dogs 8 weeks of age and older that weigh 1.3 kg (2.8 lb) or greater. NADA 141-521

Sarolaner and Selamectin Topical Solution: 60 mg/mL selamectin and 10 mg/mL sarolaner in 0.25 mL, 0.5 mL, and 1 mL tubes, available in boxes of 1, 3, or 6 single-dose tubes; *Revolution® Plus*; (Rx). Each tube provides a minimum of 6 mg/kg selamectin and 1 mg/kg sarolaner. For use on cats and kittens 8 weeks of age or older weighing at least 1.3 kg (2.8 lb). NADA# 141-502. See ***Selamectin/Sarolaner***.

Selamectin

(sell-a-***mek***-tin) *Revolution®*

Avermectin (Topical) Antiparasitic

See also ***Selamectin/Sarolaner***.

Prescriber Highlights

- ► FDA-approved as a monthly endo- and ectoparasiticide for use in dogs and cats
- ► Some extra-label indications only require one-time dosing while more frequent dosing may be necessary for others.
- ► Adverse effect profile appears minimal when used as labeled. Oral exposure should be avoided.

Uses/Indications

Topical selamectin is indicated for the prevention and control of flea infestations (*Ctenocephalides felis*), prevention of heartworm disease (*Dirofilaria immitis*), and the treatment and control of ear mites (*Otodectes cynotis*) in dogs 6 weeks of age or older and cats 8 weeks of age or older.[1] Additionally, in dogs, it is indicated for treatment and control of sarcoptic mange (*Sarcoptes scabiei*) and control of tick infestations (*Dermacentor variabilis*). In cats, it is indicated for treatment and control of hookworms (*Ancylostoma tubaeforme*) and roundworms (*Toxocara cati*). A systematic review of treatments for ear mites in cats found fair evidence for recommending topical selamectin.[2]

Selamectin is labeled as not effective against adult heartworms or for clearing circulating microfilariae, but it has some efficacy with prolonged, continuous administration.[3]

Topical selamectin has been successfully used extra label to treat a variety of ectoparasites in small animal species, including notoedric mange (*Notoedres cati*); nasal mites in dogs (*Pneumonyssoides caninum*); cheyletiellosis in dogs, cats, and rabbits; and cordylobiolosis (cutaneous myiasis, *Cordylobia anthropophaga*) in dogs.

Selamectin has not been successful for treating generalized demodicosis; other treatments (eg, isoxazolines) are preferred.

Pharmacology/Actions

Like other compounds in its class, selamectin is believed to act by enhancing chloride permeability or enhancing the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the postsynaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. By stimulating the release of GABA, selamectin causes paralysis and eventual death of the parasite. As liver flukes and tapeworms do not use GABA as a peripheral nerve transmitter, selamectin is unlikely to be effective against these parasites.

Pharmacokinetics

After topical administration to dogs, ≈5% of the drug is bioavailable and peak plasma concentrations occur ≈3 days later.[4] Selamectin bioavailability may be higher in female dogs.[5] Elimination half-life after topical administration is ≈11 days.

After topical administration to cats, ≈75% of the drug is bioavailable and peak plasma concentration occur ≈15 hours later.[4] Peak concentrations may be 64 times those in dogs. Elimination half-life after topical administration is ≈8 days.

In rabbits given topical selamectin at doses of 10 or 20 mg/kg, mean terminal half-life was slightly less than 1 day. Maximum plasma concentrations of selamectin were 91.7 ng/mL (10 mg/kg) and 304.2 ng/mL (20 mg/kg).[6]

The persistence of selamectin in the body is believed to be due to the drug forming reservoirs in skin sebaceous glands. It is secreted into the intestine to kill susceptible endoparasites in cats.

Contraindications/Precautions/Warnings

The manufacturer recommends caution when using in sick, underweight, or debilitated dogs or cats. At labeled doses of selamectin, dogs positive for the *MDR1* mutation (also known as *ABCB1*-1delta; eg, collies, Australian shepherds, shelties, long-haired whippets) should tolerate the medication, but use cautiously. Higher doses may cause neurological toxicity in these dogs.

Adverse Effects

In field trials (limited numbers of animals), adverse effects were rare. Approximately 1% of cats showed a transient, localized alopecia at the area of administration. Other effects reported (less than or equal to 0.5% incidence) include diarrhea, vomiting, muscle tremors, anorexia, pruritus/urticaria, erythema, lethargy, salivation, and tachypnea. Rarely, seizures and ataxia have been reported in dogs. Adverse effects are more likely after oral exposure to selamectin.

Reproductive/Nursing Safety

Selamectin appears to be safe to use in pregnant or lactating dogs or cats.[1] However, because safety has not been established in animals,

this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Dogs: Oral overdoses of the topical product up to 15 mg/kg did not cause adverse effects except for transient ataxia in 1 avermectin-sensitive collie after receiving a 5 mg/kg oral dose[1] ; hypersalivation and polydipsia have been observed. Topical overdoses (10 times the label dosage) to puppies caused no adverse effects; topical overdoses to avermectin-sensitive collies caused salivation. Selamectin was also administered at 3 times the recommended dose to heartworm-infected dogs, and no adverse effects were observed.

Cats: Oral ingestion of the topical product may cause hypersalivation and vomiting[1] ; anorexia and lethargy may also be observed. Topical overdoses of up to 10 times the label dosage caused no observable adverse effects in 6-week-old kittens.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No drug interactions have been documented. In controlled clinical studies, selamectin was used safely in animals receiving other frequently used veterinary products such as vaccines, anthelmintics, antiparasitics, antibiotics, steroids, collars, shampoos, and dips.

Caution is advised if using other drugs that can inhibit p-glycoprotein. Those dogs at risk for the *MDR1* mutation (also known as *ABCB1*-1delta; eg, collies, Australian shepherds, shelties, long-haired whippets, "white feet" breeds) should probably not receive selamectin with the following drugs and drug classes, unless confirmed to not possess the mutation:

- Amiodarone
- Carvedilol
- Clarithromycin
- Cyclosporine
- Diltiazem
- Erythromycin
- Itraconazole
- Ketoconazole
- Quinidine
- Spironolactone
- Tamoxifen
- Verapamil

Laboratory Considerations

- None were reported.

Doses

DOGS:

Labeled indications (label dosage; FDA-approved): For prophylaxis of dirofilariasis, it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information. The recommended minimum topical dose is 6 mg/kg[1]; dosed based on body weight (see table below). **NOTE**: Dogs weighing greater than 59.1 kg (130 lb) should receive the appropriate combinations of tubes. Dosing frequency: Heartworm prevention, flea control = monthly; *Dermacentor variabilis* ticks = monthly (if heavy infestations, may repeat 2 weeks after the first dose); ear mites, *Sarcoptes* spp = once, repeat in one month if necessary. See package for specific instructions on administration technique.

Body weight in kg (lb)	mg selamectin/ tube	mg/mL	Volume (mL)
Up 2.3 (up to 5)	15	60	0.25
2.3-4.5 (5.1-10)	30	120	0.25
4.6-9.1 (10.1-20)	60	120	0.5
9.1-18.2 (20.1-40)	120	120	1
18.2-38.6 (40.1-85)	240	120	2
38.7-59.1 (85.1-130)	360	120	3

Sarcoptic mange (extra-label): 6 – 13 mg/kg topically every 2 weeks for 4 to 6 treatments[7]

Nasal mites in dogs (*Pneumonyssoides caninum*) (extra-label): 6 – 24 mg/kg topically for 3 times at 2-week intervals[8]

Cheyletiellosis (extra-label): 6 – 12 mg/kg topically every other week for a total of 4 treatments[9]

Biting lice (extra-label): 6 mg/kg topically once[10]

***Cordylobia* spp** (extra-label): 6 mg/kg topically once, repeat monthly for control[11]

CATS:

Labeled indications (label dosage; FDA-approved): The recommended minimum topical dose is 6 mg/kg[1]; dosed based on body weight (see table below). **NOTE**: Cats weighing greater than 10 kg (22 lb) should receive the appropriate combinations of tubes. Dosing frequency: Heartworm prevention, flea control = monthly; ear mites = once, repeat in one month if necessary; hookworms, roundworms = once. See package for specific instructions on administration technique.

Body weight in kg (lb)	mg selamectin/ tube	mg/mL	Volume (mL)
Up to 2.3 (up to 5)	15	60	0.25
4.5-6.8 (5.1-15)	45	60	0.75
6.9-10 (15.1-22)	60	60	1

Ancylostoma ceylanicum (extra-label): 6 – 12 mg/kg topically once[12]

Cheyletiellosis (extra-label): 6 – 12 mg/kg topically once monthly for a total of 3 treatments[7]

Notoedric (face/head) mange (*Notoedres cati*) (extra-label): 6 mg/kg topically once[13]

Biting lice (extra-label): 6 mg/kg topically once[10]

FERRETS:

Heartworm prevention (extra-label): 18 mg/kg topically every 30 days[14]

Ear mites (*Otodectes cynotis*) (extra-label): 45 mg/ferret (NOT mg/kg) topically every 30 days

Sarcoptes scabiei (extra-label): 15 mg/kg topically[15]

SMALL MAMMALS:

Rabbits; ear mites (*Psoroptes cuniculi*) (extra-label): 6 – 18 mg/kg topically[16]

Rabbits; psoroptic mange, sarcoptic mange, *Cheyletiella* spp (extra-label): 6 – 18 mg/kg topically every 30 days. *Cheyletiella* spp may require treatment as high as 20 mg/kg repeated every 2 to 4 weeks[17–19]

Rabbits; fleas (*Ctenocephalides felis, Ctenocephalides canis*) (extra-label): Results of a safety, efficacy and pharmacokinetic study suggested that topical administration at 20 mg/kg every 7 days is efficacious; further studies are needed to assess long-term

safety in rabbits following repeated applications.[6]

Guinea pigs; *Trixacarus caviae* mange (extra-label): Results from the study suggested that a single topical application of selamectin 15 mg/kg can eliminate *T caviae* mites from guinea pigs within 30 days.[20]

Guinea pigs; ear mites (extra-label): 6 – 10 mg/kg topically[21]

Monitoring

- Clinical efficacy
- Owner compliance with treatment regimen

Client Information

- Follow label directions for administration technique. Part hair and apply directly to skin; do not massage into skin, and do not apply if hair coat is wet. Because the product contains alcohol, do not apply to broken skin.
- Ensure entire contents of the tube are applied.
- Stiff or clumped hair, discoloration of hair, or a powdery residue may be seen after administration. This is temporary and does not affect the safety or efficacy of the product.
- Wait 2 hours or more after applying to bathe the animal (or allow to go swimming).
- Avoid contact with animal while the application site is wet.
- Avoid getting the product on human skin; if contact occurs, wash off immediately. If eye contact occurs, flush eyes with copious amounts of water. If ingestion occurs, contact a physician immediately.
- Dispose of empty tubes in regular household refuse.
- Do not expose to flame, as the product is flammable.

Chemistry/Synonyms

A semi-synthetic avermectin, selamectin occurs as a white hygroscopic powder. It is practically insoluble in water, soluble in acetone and freely soluble in isopropyl alcohol. Selamectin is commercially available as a colorless to yellow solution (flammable).

Selamectin may also be known as UK-124114, *Revolution®*, *Paradyne®* or *Stronghold®*, *Revolt®*, *Selarid®*, *Selaspot®*, or *Senergy®*.

Storage/Stability

The commercially available solution should be stored below 30°C (86°F). Keep away from flame or other igniters.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Selamectin Topical Solution for Cats; *Revolution®*, generic; (Rx). For use in cats 8 weeks of age and older. For cats over 10 kg (22 lb) use the appropriate combination of tubes. NADA 141-152.

Up to 2.3 kg (5 lb), Pkg. Color: mauve. 15 mg/tube. Tube volume: 0.25 mL

4.5 to 6.8 kg (5.1 to 15 lb), Pkg. Color: blue. 45 mg/tube. Tube volume: 0.75 mL

6.9 to 10 kg (15.1 to 22 lb), Pkg. Color: taupe. 60 mg/tube. Tube volume: 1 mL

Selamectin Topical Solution for Dogs; *Revolution®*, generic; (Rx). For use in dogs 6 weeks of age and older. For dogs over 59.1 kg (131 lb), use the appropriate combination of tubes. NADA 141-152.

Up to 2.3 kg (5 lb), Pkg. Color: mauve. 15 mg/tube. Tube volume: 0.25 mL

Selamectin/Sarolaner

(sell-a-***mek***-tin; ***sar***-oh-***lan***-er) *Revolution® Plus*

Avermectin Antiparasitic and Isoxazoline Ectoparasiticide (Topical)

See also ***Selamectin*** and ***Sarolaner***

Prescriber Highlights

- ► Topical combination antiparasitic agent FDA-approved for use in cats and kittens 8 weeks of age and older, and weighing 1.3 kg (2.8 lb) or more
- ► Monthly heartworm preventive that also kills adult fleas; treats and prevents flea infestation; and treats and controls tick infestation, ear mites, roundworms, and intestinal hookworms
- ► Use with caution on cats that are debilitated and underweight for their size and age.
- ► Use with caution in cats with a history of neurologic disease.
- ► FDA has warned that drugs in the isoxazoline class have the potential to cause neurologic adverse effects (eg, muscle tremors, ataxia, seizures) in dogs and cats.
- ► Adverse effects may include lethargy, anorexia, alopecia, administration site reactions, and other skin changes.

Uses/Indications

The combination selamectin/sarolaner topical solution is FDA-approved for monthly use in cats and kittens 8 weeks of age and older and weighing 1.3 kg (2.8 lb) or more.[1] This combination is indicated for the prevention of heartworm disease (*Dirofilaria immitis*), treatment and prevention of flea infestations (*Ctenocephalides felis*), and the treatment and control of ear mite (*Otodectes cynotis*) infestations, roundworm (*Toxocara cati*) and intestinal hookworm (*Ancylostoma tubaeforme*) infections, and tick infestations with *Ixodes scapularis* (black-legged tick), *Amblyomma maculatum* (Gulf Coast tick), and *Dermacentor variabilis* (American dog tick) for one month. Selamectin/sarolaner topical solution prevented transmission of the parasite *Cytauxzoon felis* from lone star ticks under experimental conditions.[2] Monthly selamectin/sarolaner application was more consistently effective against *Ixodes ricinus* than a single application of fluralaner topical solution when assessed at 8 and 12 weeks after fluralaner application.[3] The combination of selamectin/sarolaner has been shown to be effective at eradicating natural flea infestations in a heavy flea-challenged environment[4] and under a range of geological conditions, including tropical and subtropical environments.[5] In one case report, once monthly administration of selamectin/sarolaner applied topically to the back of the neck was effective at treating otodemodicosis caused by *Demodex cati*. Complete resolution was seen after 4 doses.[6]

An experimental combination of selamectin 6 mg/kg and sarolaner 2 mg/kg (double the sarolaner dose of approved products) was effective at preventing the development of a macrocyclic lactone re-

sistant strain of *D immitis*. In 10 cats that were infected with L3 larvae and then given monthly selamectin/sarolaner for 3 consecutive doses, no adult heartworms were found in any cat at study conclusion; however, selamectin alone was also highly effective. It is also uncertain whether macrocyclic lactone resistance can be reversible, as the strain of *D immitis* used had not been exposed to any macrocyclic lactones for ≈2.5 years prior to this study.[7]

In other countries, the selamectin/sarolaner combination products are also indicated for the treatment of biting lice infestations (*Felicola subrostratus*).[8–10]

Pharmacology/Actions

Selamectin is thought to enhance chloride permeability or the release of gamma-aminobutyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks postsynaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. Stimulating the release of GABA causes paralysis and eventual death of the parasite. Selamectin is likely ineffective against liver flukes and tapeworms, as they do not use GABA as a peripheral nerve transmitter.

Sarolaner is an isoxazoline acaricide/insecticide that inhibits GABA and glutamate receptors at the neuromuscular junction in insects and acarines, which results in uncontrolled neuromuscular activity leading to death. Sarolaner does not interact with known insecticidal binding sites of nicotinic or other GABAergic insecticides (eg, neonicotinoids, fiproles, milbemycins, avermectins, cyclodienes).[11]

Under experimental conditions, a single application of selamectin and sarolaner topical solution starts killing adult fleas within 6 to 12 hours for up to 5 weeks.[12] Adult fleas are killed before eggs can be laid. Most ticks (90% to 95%) are killed within 24 to 72 hours post-infestation for up to one month after application.[13]

Labels in other countries state that the selamectin and sarolaner topical combination solution has ovicidal and larvicidal action against fleas.[8–10]

Pharmacokinetics

Bioavailability is ≈40% for selamectin (elimination half-life, ≈12.5 days) and 58% for sarolaner (elimination half-life, 41.5 days) after topical administration.[1] When administered monthly, drug accumulation will plateau after the third selamectin and sixth sarolaner dose. Elimination occurs primarily via hepatobiliary excretion, and ≈50% of the dose is excreted in the feces.

Contraindications/Precautions/Warnings

There are no known contraindications for the use of selamectin/sarolaner[1]; however, the UK label lists contraindications for cats with concomitant disease, hypersensitivity, and that are debilitated and underweight for their age and size.[9] Use product with caution when treating cats with a history of neurologic disease.[1] The FDA has warned that drugs in the isoxazoline class have the potential to cause neurologic adverse effects in dogs and cats, such as muscle tremors, ataxia, and seizures, including in animals that do not have a history of neurologic disease.[14]

Do not apply when the cat's hair coat is wet. Do not apply directly to the ear canal. The product is highly flammable, so it is important to keep treated animals away from heat, sparks, open flames, or other sources of ignition for at least 30 minutes after application or until the site of application is dry.[15]

In humans, reactions including redness, hives, and itching have rarely been reported following accidental dermal exposure; children should not be allowed to play with treated cats for 4 hours after application.[9]

Adverse Effects

Adverse effects were uncommon in field trials using a limited number of animals. In a field study that evaluated the safety and efficacy of selamectin and sarolaner topical solution in treating fleas, the following adverse effects were reported: lethargy (4.3%), nonapplication site skin lesions (3.5%), anorexia (3.2%), pruritus (2.5%), conjunctivitis (2.5%), and application site skin changes or alopecia (2.5%).[16] Adverse effects reported in other field studies included emesis, diarrhea, ataxia, seizures, and tremors.[1]

Reproductive/Nursing Safety

Safe use of selamectin and sarolaner topical solution has not been evaluated in breeding, pregnant, or lactating cats; however, selamectin is considered safe for use in breeding, pregnant, or lactating cats.[1,8–10,15] Laboratory studies of sarolaner in rats and rabbits have not shown evidence of teratogenic effects, but safety in cats has not been established.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The death of a single cat exposed to 3.75 times the label dose under experimental conditions was determined to be caused by thrombocytopenia and internal hemorrhage.[1] The role of selamectin and sarolaner in the cat's death was undetermined and no other significant changes were noted in other subjects that received up to 5 times the labeled dose. Oral ingestion of the highest recommended topical dose of selamectin and sarolaner topical solution may cause vomiting, soft stools, reduced food intake, mild tremors, and salivation.

Topical overdoses up to 10 times the label dose of selamectin (without sarolaner) caused no observable adverse effects in kittens 6 weeks of age.[17] Commonly reported findings in cats with an overdose recorded in decreasing frequency included hypersalivation, licking lips, vomiting, anorexia, depression, and lethargy.

In rats, the oral (acute) LD_{50} for sarolaner is 783 mg/kg and dermal (acute) LD_{50} is greater than 2020 mg/kg.[11]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No drug interactions have been documented. In controlled field studies, selamectin and sarolaner topical solution, as well as selamectin and sarolaner individually, were used safely on animals receiving other frequently used veterinary products (eg, vaccines, cestocide anthelmintics, antibiotics, sedatives, anesthetics, opioids, corticosteroids, NSAIDs).[1]

Laboratory Considerations

- None reported

Dosages

CATS:

Label indications (FDA-approved): The recommended minimum topical dose is selamectin 6 mg/kg and sarolaner 1 mg/kg[1]; dosed based on body weight according to table below. Administer monthly for heartworm prevention, flea control, and ticks. Administer once as a single dose for ear mite, hookworms, and roundworms. Cats weighing over 10 kg (22 lb) should be treated with the appropriate combination of tubes. See package for specific instructions on administration technique.

Body weight in kg (lb)	Tube cap color	Tube volume (mL)	Selamectin (mg/tube)	Sarolaner (mg/tube)
1.3-2.5 (2.8-5.5)	Gold	0.25	15	2.5
2.6-5 (5.6-11)	Orange	0.5	30	5
5.1-10 (11.1-22)	Green	1	60	10
Over 10 (22)	Use the appropriate combination of tubes			

Treatment of chewing lice (extra-label): Apply topically based on body weight dosage listed on the product label, corresponding to a minimum of selamectin 6 mg/kg and sarolaner 1 mg/kg) once as a single dose.[15]

Monitoring

- Clinical efficacy (eg, heartworm antigen testing, fecal float, FECR testing)
- Owner compliance with treatment regimen

Client Information

- Treatment may be started any time of the year and should continue year-round. If not administered year-round, monthly treatment should begin at least 1 month before fleas and/or ticks become active and within 1 month of the first exposure to mosquitos. Monthly treatment should continue until the end of the mosquito season, with the final dose given within 1 month of the last exposure to mosquitos.
- Fleas and ticks need to start feeding on the animal before they will die.
- Read label directions for full administration technique. Part the cat's hair and apply directly to the skin in one spot at the base of the neck, in front of the shoulder blades.
- Clumping or spiking of the hair, greasiness, and dry white deposits may occur; these are normal and do not affect the medication's safety or efficacy.
- Do not massage medication into the skin
- Do not apply to wet hair or coat, to broken skin, or inside the ear canal.
- Do not bathe the cat for at least 24 hours after application.
- Avoid contact with human skin and avoid contact with the animal while the application site is wet. If contact occurs, wash the affected area immediately.
- This product is flammable and should not be exposed to flames. Empty tubes may be disposed in regular household refuse.
- Report any side effects, including nerve-related effects (eg, tremors, difficulty walking, seizures), to your veterinarian.

Chemistry/Synonyms

A semi-synthetic avermectin, selamectin occurs as a white hygroscopic powder. It is practically insoluble in water, soluble in acetone, and freely soluble in isopropyl alcohol. Selamectin is commercially available as a flammable, colorless to yellow solution.

Selamectin may also be known as UK-124114, *Revolution®*, *Paradyne®*, or *Stronghold®*.

Sarolaner is an isoxazoline class of parasiticides. Sarolaner may also be known as *Simparica®*.

Storage/Stability

The commercially available solution should be stored at or below 30°C (86°F) and should be kept away from flames or other igniters.

Compatibility/Compounding Considerations

No specific information noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Selamectin and Sarolaner Topical Solution: 60 mg/mL selamectin and 10 mg/mL sarolaner in 0.25 mL, 0.5 mL, and 1 mL tubes; *Revolution® Plus*; (Rx). NADA# 141-502

HUMAN-LABELED PRODUCTS: NONE

Selegiline

L-deprenyl

(se-***le***-ji-leen) *Anipryl®, Eldepryl®*

Monoamine Oxidase Inhibitor (MAOI)

Prescriber Highlights

- ► May be useful for cognitive dysfunction syndrome (CDS) in dogs or cats, or for canine hyperadrenocorticism (efficacy in doubt for hyperadrenocorticism)
- ► May require 2 to 6 weeks of administration to show clinical improvement for CDS
- ► Adverse effects include vomiting and diarrhea; CNS effects manifested by restlessness, repetitive movements, or lethargy; salivation and anorexia. Diminished hearing/deafness, pruritus, licking, shivers/trembles/shakes are possible.
- ► Many serious drug interactions are possible.

Uses/Indications

Selegiline is FDA-approved for use in dogs to control the clinical signs associated with canine cognitive dysfunction syndrome (CDS; "old dog dementia") as well as the clinical signs associated with uncomplicated canine pituitary-dependent hyperadrenocorticism (PDH). Although selegiline is FDA-approved, its use for PDH is controversial, as clinical studies evaluating its efficacy have shown disappointing results.[1,2] Selegiline may have a role in treating dogs with chronic anxiety, particularly those that have high prolactin levels.[3] Combined with a benzodiazepine and a beta-blocker such as propranolol, selegiline may be particularly useful in treating social or noise phobias.

Selegiline may be of use in feline cognitive dysfunction syndrome.[4]

In humans, selegiline's primary indication is for the adjunctive treatment of Parkinson disease.[5]

Pharmacology/Actions

Selegiline's mechanism of action for treatment of pituitary-dependent hyperadrenocorticism (PDH) is complex; a somewhat simplified explanation follows: In the hypothalamus, corticotropin-releasing hormone (CRH) acts to stimulate the production of ACTH in the pituitary, and dopamine acts to inhibit the release of ACTH. As dogs age, there is a tendency for a decrease in dopamine production that can contribute to the development of PDH.

As dopamine is metabolized by monoamine oxidase-B (MAO-B) and selegiline irreversibly inhibits MAO-B, dopamine concentrations can be increased at receptor sites after selegiline administration.[5] In theory, this allows the concentration of dopamine and CRH to be in balance in the hypothalamus, thereby reducing the amount of ACTH produced and, ultimately, cortisol.

Although selegiline is labeled as a MAO-B inhibitor, at higher-than-label dosages, the drug loses its MAO-B specificity and also

inhibits MAO-A. Two of the 3 metabolites of selegiline are amphetamine and methamphetamine. These metabolites may contribute to both the efficacy and the adverse effects of the drug.

Pharmacokinetics

There is only limited information on the pharmacokinetics of selegiline in dogs. A study done in 4 dogs showed that selegiline was absorbed rapidly and had an absolute bioavailability of ≈10%.[6] The volume of distribution of the central compartment was measured at ≈7 L/kg. Terminal half-life was ≈1 hour.

In humans, selegiline pharmacokinetics have wide interpatient variability. The drug has a high first pass effect where extensive metabolism to N-desmethylselegiline, L-methamphetamine, and L-amphetamine occurs.[5] Each of these metabolites is active. N-desmethylselegiline inhibits monoamine oxidase-B (MAO-B). The other 2 metabolites are CNS stimulants and do not inhibit MAO-B. The drug is excreted in the urine, primarily as conjugated and unconjugated metabolites.

Contraindications/Precautions/Warnings

Selegiline is contraindicated in patients that are known to be hypersensitive to it. In humans, severe CNS toxicity has resulted from concurrent use of selegiline with certain medications (eg, antidepressants, meperidine, tramadol), and some combinations are considered contraindicated. See ***Drug Interactions***.

Selegiline should only be used to treat hyperadrenocorticism that is of pituitary origin.[7] Be sure to confirm the diagnosis before starting therapy.

During clinical trials, 3 dogs showed an increase in aggression while on selegiline[7]; therefore, it is not recommended for the treatment of aggression or other behavioral problems aside from those associated with canine cognitive dysfunction.

Selegiline has not been tested for safety in animals with debilitating diseases other than hyperadrenocorticism[7]; use with caution.

Do not confuse selegiline with sertraline.

Adverse Effects

Adverse effects reported in dogs include vomiting, diarrhea, CNS effects manifested by restlessness, disorientation, aggression, repetitive movements or lethargy, salivation, and anorexia. Should GI effects be a problem, discontinue the drug for a few days and then restart it at a lower dose. Diminished hearing/deafness, pruritus, licking, and shivers/trembles/shakes have also been reported. The manufacturer advises to observe animals carefully for atypical responses.

Adverse effects that have been reported in humans include nausea (10%), hallucinations, confusion, depression, loss of balance, insomnia, and hypersexuality.[5] These effects are noted because of their subjective nature and if they occur, they could help explain untoward behavioral changes in canine patients.

Because selegiline could potentially be abused by humans, veterinarians should be alert for the potential for drug diversion.

Reproductive/Nursing Safety

Safety of selegiline in pregnant, breeding, or lactating animals has not been established. Rat studies have not demonstrated overt teratogenicity.

It is not known whether selegiline is excreted in maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Oral LD_{50} in laboratory animals was ≈200 – 445 mg/kg.[8,9] In limited data, dogs that received 3 times the labeled doses showed signs of decreased weight, salivation, decreased pupillary response, panting, stereotypic behaviors, and decreased skin elasticity (dehydration).[7] Overdoses, if severe, should be treated with appropriate GI decontamination and supportive treatments.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Evaluating the potential for drug interactions for selegiline in dogs and cats is problematic. There is a plethora of significant interactions with monoamine oxidase inhibitors in humans for selegiline, but because there are significant species differences in quantities and locations of monoamine oxidase-A and monoamine oxidase-B (MOA-A and MOA-B), and the effect of selegiline at various dosages on these enzymes, may not apply to dogs and cats. However, the following are some of the more significant interactions reported (or theoretical) in humans or animals; caution is advised, particularly if using selegiline at higher than label dosages:

- **Alpha-2 Agonists** (eg, **medetomidine**): Concurrent use in humans has resulted in extreme blood pressure fluctuations; however, concurrent administration of selegiline with medetomidine to healthy dogs did not affect cardiopulmonary parameters (eg, heart rate, blood pressure, mean arterial pressure, systemic vascular resistance, cardiac output) beyond those caused by medetomidine alone.[10]
- **Atropine**: Increased risk for hypertension and hypertensive crisis
- **Buspirone**: Increased risk for hypertension
- **CNS Stimulants** (eg, **doxapram, methylphenidate**): Increased risk for hypertension
- **Dextromethorphan**: Increased risk for serotonin syndrome; avoid combination
- **Diphenoxylate**: Increased risk for hypertension; avoid combination
- **Meperidine/Opioids**: In humans, severe agitation, hallucinations, serotonin syndrome, and death have occurred in some patients receiving meperidine and a monoamine oxidase inhibitor (MAOI).[5] Until the data can be clarified, it is recommended not to use selegiline and meperidine together. A separation of 2 weeks has been recommended. Other opioids (eg, **morphine**) should be safer, but use with extreme caution, if at all.[10]
- **Monoamine oxidase inhibitors** (**MAOIs**; eg, **amitraz, linezolid, methylene blue**): Concurrent use can contribute to serotonin syndrome. The manufacturer recommends not using selegiline concurrently with amitraz (*Mitaban®*) in dogs. Avoid combination
- **Metoclopramide**: Concurrent use may result in increased risk for hypertensive crisis and loss of selegiline efficacy.
- **Mirtazapine**: Potential for serotonin syndrome with concurrent use
- **Phenylpropanolamine (PPA), Pseudoephedrine**: Possibility for increased risk for hypertension and hyperpyrexia; however, adverse effects were not observed when selegiline was given with PPA to healthy dogs.[11]
- **Serotonin 5-HT3 receptor Antagonists** (eg, **ondansetron**): Increased risk for hypertension
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine**): Potential for serotonin syndrome could occur if selegiline is used concurrently with SSRIs; several sources recommend a 5-week washout before administering selegiline to dogs after fluoxetine is discontinued, and to wait 2 weeks if switching from selegiline to an SSRI.

- **Sympathomimetic Agents** (eg, **dopamine, ephedrine, epinephrine, norepinephrine, phenylephrine**): Concurrent selegiline use may enhance hypertensive effects.
- **Tramadol**: Use together is contraindicated in humans due to the potential for serotonin syndrome or cardiovascular collapse.
- **Trazodone**: Concurrent use may increase risk for serotonin syndrome.
- **Tricyclic Antidepressants** (eg, **clomipramine, amitriptyline**): Potential for serotonin syndrome to occur if selegiline is used concurrently with these agents, and use together is not advised at this time; a 2-week separation between these compounds and selegiline is recommended.

Dosages

DOGS:

Canine pituitary-dependent hyperadrenocorticism (label dosage; FDA-approved): 1 mg/kg PO in the AM (with food as needed). Reevaluate clinically over the next 2 months[7]; if no improvement, may increase to 2 mg/kg once daily; if no improvement or signs increase after 1 month at the higher dose, reevaluate diagnosis or consider alternate treatment. Dogs should be monitored closely for possible adverse effects associated with any increase in dose.

Canine cognitive dysfunction (label dosage; FDA-approved): 0.5 – 1 mg/kg, PO once daily, preferably in the AM.[7] Initially, dose to the nearest whole tablet; adjustments should then be made based upon response and tolerance to the drug.

CATS:

Feline cognitive dysfunction syndrome (extra-label): 0.25 – 1 mg/kg PO once daily[4,12,13]

Monitoring

- Clinical efficacy
- Adverse effects: There is no correlation between low-dose dexamethasone suppression test results and clinical efficacy of the drug. The manufacturer recommends physical examination and history as the primary methods to measure response to therapy.

Client Information

- This medicine may be given with or without food. Dogs usually get the daily dose in the morning and cats in the evening.
- It may take several weeks to see if this medicine is working.
- Talk with your veterinarian before making changes to your animal's diet, medications, and flea/tick treatments (eg, collars, spot-ons) before giving selegiline to your animal.
- Side effects include gastrointestinal problems (eg, vomiting, diarrhea, lack of appetite, drooling) and behavioral changes.

Chemistry/Synonyms

Selegiline HCl, also commonly called L-deprenyl, occurs as a white to off-white crystalline powder that is freely soluble in water. It has a pK_a of 7.5.

Selegiline HCl may also be known as deprenyl, l-deprenyl, selegilini hydrochloridum; many trade names are available including *Anipryl*® and *Selgian*®.

Storage/Stability

Commercially available veterinary tablets should be stored at controlled room temperature 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Selegiline HCl Oral Tablets: 2 mg, 5 mg, 10 mg, 15 mg, and 30 mg in blister-packs of 30 tablets; *Anipryl*®; (Rx). FDA-approved for use in dogs. NADA #141-080

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Selegiline HCl Tablets and Capsules 5 mg; *Eldepryl*®, generic; (Rx)

Selegiline Orally Disintegrating Tablets 1.25 mg; *Zelapar*®; (Rx)

Selegiline HCl Transdermal Patch: 6 mg/24 hours (20 mg/20 cm^2); 9 mg/24 hours (30 mg/30 cm^2), and 12 mg/24 hours (40 mg/40 cm^2); *Emsam*®; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Sertraline

(***sir***-trah-leen) *Zoloft*®

Selective Serotonin Reuptake Inhibitor (SSRI)

Prescriber Highlights

- ► May be useful in treating a variety of behavior-related diagnoses in dogs and cats, including aggression, anxiety-related behaviors, and other obsessive-compulsive behaviors
- ► Use with caution in diabetic or geriatric patients or those with severe hepatic disease.
- ► Adverse effect profile is not well established for this drug. In dogs, sertraline can potentially cause anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. In cats, sedation, decreased appetite/anorexia, vomiting, diarrhea, and behavior changes (eg, anxiety, irritability, sleep disturbances) could occur.
- ► Many potential drug interactions

Uses/Indications

Sertraline may be considered for use in treating a variety of behavior-related diagnoses in dogs and cats, including aggression and anxiety-related or other obsessive-compulsive behaviors,[1] as well as inappropriate elimination in cats.

Pharmacology/Actions

Sertraline is a highly selective inhibitor of the reuptake of serotonin (5-hydroxytryptamine, 5-HT) in the CNS, thus potentiating its pharmacologic activity. Sertraline apparently has little effect on dopamine or norepinephrine, and no effect on other neurotransmitters.

Pharmacokinetics

In dogs, sertraline's volume of distribution is 25 L/kg, and it is 97% bound to plasma proteins.[2] High first-pass metabolism occurs; clearance is greater than 35 mL/minute/kg. Bile appears to be the major route of excretion.

In humans, sertraline peak concentrations occur ≈4.5 to 8 hours after oral dosing.[3] It is 98% bound to plasma proteins. Sertraline appears to be highly metabolized primarily to N-desmethylsertraline, which is active. Elimination half-lives for sertraline and desmethylsertraline average 26 and 80 hours, respectively.

Contraindications/Precautions/Warnings

Sertraline is contraindicated in patients that are hypersensitive to it or any selective serotonin reuptake inhibitor (SSRI), or are receiving a monoamine oxidase inhibitor (MAOI). Use with caution in geriatric patients and in those with hepatic impairment; doses may need to be decreased, or dosing interval may need to be increased. Sertraline

may alter blood glucose and should be used with caution in diabetic patients.

Do not confuse sertraline with selegiline or cetirizine.

Adverse Effects

Because there has been limited use of sertraline in dogs or cats, it is difficult to compare its adverse effect profile with other selective serotonin reuptake inhibitors (SSRIs; eg, fluoxetine, paroxetine, fluvoxamine). In dogs, SSRIs can cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common adverse effect in dogs (this effect is usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). SSRIs in cats can cause sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (eg, anxiety, irritability, sleep disturbances), and changes in elimination patterns.

In humans, sertraline use may precipitate serotonin syndrome, which is a potentially life-threatening condition with symptoms that may include CNS (eg, agitation, seizures), GI (eg, vomiting, diarrhea), autonomic (eg, blood pressure changes, tachycardia, hyperthermia), and neuromuscular (eg, tremor, rigidity, myoclonus) changes. Other adverse effects noted in humans include hyponatremia, QTc prolongation, and torsade de pointes, as well as increased risks for bleeding and angle-closure glaucoma attacks.

Reproductive/Nursing Safety

Delayed fetal ossification occurred when sertraline, at doses used clinically, was administered to pregnant rats and rabbits during the period of organogenesis.[3] Increased stillbirths and neonatal pup death occurred after sertraline use during the third trimester.

Sertraline enters maternal milk at low levels.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

An overdose of a selective serotonin reuptake inhibitor (SSRI) can cause vomiting, diarrhea, hypersalivation, and lethargy. Serotonin syndrome may occur with clinical signs that include muscle tremors, rigidity, agitation, hyperthermia, vocalization, hypertension or hypotension, tachycardia, seizures, coma, and death. Most exposures below 20 mg/kg in dogs are not serious. The reported median lethal dosage for dogs following a single ingestion is 80 mg/kg of body weight.[4]

A retrospective review of sertraline ingestions reported to Pet Poison Helpline found ≈⅓ of reports of ingestions in dogs had clinical signs, including CNS depression (60%), CNS stimulation (24%), cardiovascular signs (8%), respiratory signs (12%), GI signs (16%), and hyperthermia (8%).[5] The median dose for causing clinical signs was 11.6 mg/kg, but the range was very wide (0.4 – 264 mg/kg). More severe signs such as tremoring and hyperthermia were not seen until the dose reached between 8 – 10 mg/kg of sertraline, and seizure activity was not noted until the dose exceeded 25 mg/kg. No deaths were reported.

Management of sertraline overdoses should be handled aggressively with supportive therapy based on clinical presentation.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving sertraline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **heparins, rivaroxaban, warfarin**): Increased risk for bleeding has been reported in humans.
- **Antiplatelet Agents** (eg, **aspirin, clopidogrel**): Increased risk for bleeding has been reported in humans.
- **Buspirone**: Increased risk for serotonin syndrome
- **CYP3A Inhibitors** (eg, **clarithromycin, ketoconazole**): May decrease sertraline metabolism and increase risk for adverse effects
- **CYP3A Inducers** (eg, **phenobarbital, rifampin**): May increase sertraline metabolism; higher dosage may be required to achieve clinical response
- **Cyproheptadine**: May decrease or reverse the effects of selective serotonin reuptake inhibitors (SSRIs)
- **Diazepam**: Sertraline may decrease diazepam clearance.
- **Isoniazid**: Increased risk for serotonin syndrome
- **Metoclopramide**: May enhance adverse/toxic effects of SSRIs and increase the risk for serotonin syndrome
- **Mexiletine**: SSRIs may decrease the metabolism of mexiletine.
- **monoamine oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid, selegiline**): High risk for serotonin syndrome; use is contraindicated. In humans, a 5-week washout period is required after discontinuing sertraline, and a 2-week washout period is required if first discontinuing the MAO inhibitor.
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam, robenacoxib**): Increased risk for bleeding
- **Opioids** (eg, **fentanyl, meperidine**): Serotonin syndrome-like adverse effects possible
- **Pentazocine**: Serotonin syndrome-like adverse effects possible
- **QT Prolonging Agents** (eg, **amiodarone, ciprofloxacin, cisapride, erythromycin, ondansetron, quinidine**): Increased risk of QT prolongation and arrhythmias
- **Serotonergic Agents, Other** (eg, **dextromethorphan, mirtazapine, trazodone**): Increased risk for serotonin syndrome
- **St John's Wort**: Increased risk for serotonin syndrome. Avoid use if possible.
- **Tramadol**: SSRIs can inhibit the metabolism of tramadol to the active metabolites, decreasing its efficacy and increasing the risk for toxicity (serotonin syndrome, seizures).
- **Tricyclic Antidepressants** (eg, **clomipramine, amitriptyline**): Sertraline may increase TCA blood levels and the risk for serotonin syndrome.
- **Warfarin**: Sertraline may increase the risk for bleeding.

Laboratory Considerations

- False-positive benzodiazepine urine immunoassay screening tests[3]

Dosages

DOGS:

Adjunctive treatment (with behavior modification) of behavior disorders (eg, **obsessive/compulsive disorders, anxiety**) (extra-label): Anecdotal dosage recommendations range from 0.5 – 4 mg/kg PO every 24 hours.[1] Most clinicians recommend starting at the low end of the dosing range in combination with behavioral therapy. No specific studies supporting any one dosage were located. Anecdotally, dosing every 12 hours has also been used. A minimum of a 6- to 8-week trial is usually recommended before assessing efficacy. If discontinuing treatment, wean off over at least 2 to 3 weeks (or longer).

CATS:

Adjunctive treatment (with behavior modification) of behavior disorders (eg, **obsessive/compulsive disorders, anxiety, spraying**) (extra-label): Anecdotal dosage recommendations range

from 0.5 – 1.5 mg/kg PO every 24 hours.[1] Most clinicians recommend starting at the low end of the dosing range. No specific studies supporting any one dosage were located. Anecdotally, dosing every 12 hours has also been used. A minimum of a 6- to 8-week trial is usually recommended before assessing efficacy. If discontinuing treatment, wean off over at least 2 to 3 weeks (or longer).

Monitoring

- Efficacy
- Adverse effects (eg, lethargy, hyporexia)
- Baseline and periodic serum liver enzymes and ECG

Client Information

- This medicine may take several days or weeks to see how well it works.
- The most common side effects with this medicine are drowsiness/sleepiness and a decreased appetite.
- Rare side effects that can be serious include seizures and aggression (threatening behavior/actions). Contact your veterinarian immediately if your pet experiences any of these side effects.
- Let your veterinarian know if your animal has worn a flea/tick collar in the past 2 weeks as some of these collars may make your animal sick if worn while taking this medicine.
- Do not stop giving this medicine to your animal without speaking with your veterinarian. A gradual withdrawal of the medicine is usually recommended if your animal has been taking this medicine for an extended period of time.

Chemistry/Synonyms

A selective serotonin reuptake inhibitor (SSRI), sertraline hydrochloride is a white crystalline powder that is slightly soluble in water and isopropyl alcohol; it is sparingly soluble in ethanol. The commercially available oral solution contains 12% ethanol and has a menthol scent.

Sertraline may also be known as CP-51974-01; *Altruline®*, *Anilar®*, *Aremis®*, *Atenix®*, *Besitran®*, *Bicromil®*, *Gladem®*, *Insertec®*, *Irradial®*, *Lustral®*, *Novativ®*, *Sealdin®*, *Serad®*, *Sercerin®*, *Serlain®*, *Serta®*, *Tatig®*, *Tolrest®*, *Tresleen®*, or *Zoloft®*.

Storage/Stability

Store commercially available sertraline tablets and oral solution at controlled room temperature (25°C [77°F]); excursions permitted to 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

The manufacturer states to dilute the oral solution before administration, and to dilute only in the following liquids: water, orange juice, ginger ale, lemonade, or lemon-lime soda; use immediately after dilution.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Sertraline HCl Tablets: 25 mg, 50 mg, and 100 mg (as base); *Zoloft®*, generic; (Rx)

Sertraline HCl Oral Solution Concentrate: 20 mg/mL in 60 mL; *Zoloft®*, generic; (Rx)

Sevelamer

(se-***vel***-a-mer) *Renagel®, Renvela®*

Phosphorus-Binding Agent

Prescriber Highlights

- ► Orally administered phosphorus-binding agent used to treat hyperphosphatemia associated with chronic kidney disease
- ► May be useful when aluminum- or calcium-containing phosphate binders cannot be used
- ► Expensive when compared to aluminum hydroxide or calcium carbonate products
- ► Caution of drug–drug interactions including nutrients

Uses/Indications

Sevelamer may be useful for treating hyperphosphatemia associated with chronic kidney disease, particularly when dietary phosphorus restriction fails and aluminum- or calcium-containing phosphorus-binding agents are not tolerated.

Pharmacology/Actions

Sevelamer binds phosphorus in the gut; when combined with decreased phosphorus in the diet it can substantially reduce serum phosphorus levels. Sevelamer also binds bile acids, which interferes with fat and fat-soluble vitamin absorption. It also reduces serum low-density lipoproteins and total cholesterol.

Pharmacokinetics

Sevelamer is administered orally but is not absorbed systemically.

Contraindications/Precautions/Warnings

Sevelamer is contraindicated in patients with hypophosphatemia or bowel obstruction and in patients that are hypersensitive to it. Safety of sevelamer products has not been established in patients with dysmotility, dysphagia, or history of major GI surgery; use with caution in these patients. Worsening of metabolic acidosis has been reported in humans that take the hydrochloride salt (ie, *Renagel®*).

Adverse Effects

Adverse effects in humans include nausea, vomiting, diarrhea, dyspepsia, constipation, and abdominal pain.[1] Esophageal tablet retention and ileus have also been reported. Absorption of certain vitamins (eg, A, D, E, K) may be reduced by sevelamer; consider vitamin supplementation during therapy. In theory, sevelamer HCl could exacerbate metabolic acidosis; this would not be expected with sevelamer carbonate.

Reproductive/Nursing Safety

Safety of sevelamer during pregnancy is not established; because of the potential for binding vitamins, additional vitamins (both fat- and water-soluble) may be necessary. There are no adequate and well-controlled studies in nursing mothers, but as sevelamer is not absorbed, safe use during nursing would be expected.[1]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

As sevelamer is not absorbed, acute toxicity potential appears to be negligible,[1] but chronic overdoses may affect serum electrolytes and nutrient absorption.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sevelamer and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Fluoroquinolones**: Concurrent administration with sevelamer may decrease absorption by 50%; administer oral fluoroquinolones at least 1 hour before or 3 hours after sevelamer.
- **Mycophenolate**: Sevelamer may reduce absorption; administer 2 hours after mycophenolate.
- **Oral Medications**: There are only a few medications that have documented reductions in oral absorption when administered with sevelamer; consider dosing other oral drugs separately, particularly for drugs with narrow therapeutic indexes.
- **Thyroid Hormones**: Sevelamer may reduce absorption; separate administering the 2 drugs by at least 4 hours.
- **Vitamins**: Sevelamer may reduce vitamin absorption from food; consider administering vitamin supplements separately from sevelamer dose.
- **Warfarin**: Single-dose studies demonstrated no drug interaction between warfarin and sevelamer, but reduced vitamin K absorption with long-term use may alter warfarin requirements.

Dosages

DOGS/CATS:

Adjunctive treatment of hyperphosphatemia in animals with chronic kidney disease (extra-label): No specific studies were noted that support any dosage. 30 – 150 mg/kg PO daily, divided into 2 or 3 doses and given with meals.[2–4] Practically, cats and small dogs would receive 200 – 400 mg/dose (NOT mg/kg) PO every 8 to 12 hours with meals. Medium to large dogs would receive 400 – 1600 mg/dose (NOT mg/kg) PO every 8 to 12 hours with meals. Adjust dose based on serum electrolytes and phosphorous. **NOTE**: When switching between carbonate and hydrochloride forms, it is recommended in humans to use an equivalent dose and then titrate if needed.

Monitoring

- Baseline and periodic serum phosphorus and other electrolytes (eg, calcium, bicarbonate, chloride)
- Consider a baseline coagulation-screening test before and after sevelamer therapy implementation as vitamin K absorption may be impacted.
- After beginning therapy, check serum phosphorus (after a 12-hour fast) every 4 to 6 weeks until target phosphorous levels are attained. Once phosphorous levels are stable, check phosphorous levels at the time of renal chemistry rechecks (eg, every 12 weeks). For chronic kidney disease (CKD), the International Renal Interest Society (IRIS) recommends a target phosphorous range for dogs and cats at each stage5,6:
  - Stage 2 CKD target phosphorous levels: greater than 2.7 and less than 4.6 mg/dL (0.9 – less than 1.5 mmol/L)
  - Stage 3 CKD target phosphorous levels: greater than 2.7 and less than 5 mg/dL (0.9 – less than 1.6 mmol/L)
  - Stage 4 CKD target phosphorous levels: greater than 2.7 and less than 6 mg/dL (0.9 – less than 1.9 mmol/L)

Client Information

- Give this medicine with meals.
- Sevelamer powder may be mixed with water or into a small amount of food. Do not add this medicine to hot foods or liquids or heat the powder.
- Give this medicine separately (at least an hour apart) from other oral medicines or vitamins.
- Sevelamer is well tolerated, but may cause reduced appetite, vomiting, constipation, or diarrhea.
- Follow-up blood tests to measure phosphorus and other electrolytes are necessary. Do not miss these important follow-up visits.

Chemistry/Synonyms

A phosphorus-binding agent, sevelamer HCl is a complex chemical that is hydrophilic but insoluble in water. Sevelamer carbonate is also insoluble in water but is hygroscopic.

Sevelamer may also be known as GT16-026A, sevelamerum, *Renagel®*, or *Renvela®*.

Storage/Stability

Sevelamer capsules should be stored at room temperature 25°C (77°F), with excursions permitted to 15°C to 30°C (59°F-86°F).[1] Protect from moisture.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Sevelamer HCl Oral Tablets: 400 mg and 800 mg; *Renagel®*; (Rx)

Sevelamer Carbonate Oral Tablets: 800 mg; *Renvela®*; (Rx)

Sevelamer Carbonate Powder for Oral Suspension: 0.8 g/packet and 2.4 g/packet; *Renvela®*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Sevoflurane

(see-voe-***floo***-rane) *SevoFlo®, Ultane®*

General Anesthetic, Inhalant

Prescriber Highlights

- ► Inhalant general anesthetic similar to isoflurane, but with more rapid induction and recovery
- ► MAC is reduced by concurrent use of injectable premedicants and/or induction agents.
- ► Contraindicated in patients with a history or predisposition to malignant hyperthermia
- ► Use with caution in patients with elevated intracranial pressure or head injury, or renal insufficiency.
- ► Adverse effects (cardiovascular or respiratory depression, nausea, vomiting) are uncommon at maintenance doses providing surgical anesthesia but are more common when it is used for masked anesthetic induction.
- ► Currently more expensive than isoflurane

Uses/Indications

While only FDA-approved for use in dogs and humans, sevoflurane may be useful in a variety of species (including cats, horses, small mammals, and ruminants, birds, reptiles) when rapid induction and/or rapid recoveries are desired with an inhalant anesthetic. When mask inductions are necessary, sevoflurane is preferred over isoflurane because of the faster onset of action and over desflurane as it is better accepted and inductions are smoother. Sevoflurane may be of particularly useful in debilitated or geriatric patients as it is more easily dosed to effect than isoflurane because of lower blood solubility (blood–gas partition coefficient).

Pharmacology/Actions

While the precise mechanisms of how inhalant anesthetics produce their general anesthetic effects are not precisely known, they may

interfere with the functioning of nerve cells in the brain by acting on the lipid matrix of the membrane. They alter the activity of neuronal ion channels, particularly the fast synaptic neurotransmitter receptors. Sevoflurane has low blood–gas partition coefficient (0.6), allowing very rapid anesthesia induction and recovery. Rapid mask induction is possible.

Pharmacologic effects of sevoflurane are similar to isoflurane when used at equipotent doses and include CNS depression, depression of body temperature regulating centers, increased cerebral blood flow, respiratory depression, hypotension, vasodilation, myocardial depression (less than with halothane), and muscular relaxation.

Approximate minimal alveolar concentration (MAC) in oxygen reported for sevoflurane in various species: Dog = 2.1% to 2.4%; Cat = 2.6% to 3.4%; Horse = 2.3% to 2.8%; Sheep = 1.9% to 2%; Swine = 2% to 2.7%; Human (adult) = 1.6% to 2.1%.[1,2] Several factors, including acid/base status, temperature, other CNS depressants or stimulants on board, age, ongoing acute disease, pregnancy, severe hypoxemia, and hypercarbia, may alter MAC.

Pharmacokinetics

At the labeled dose, surgical anesthesia is obtained in 3 to 14 minutes. Because of its low solubility in blood, only small concentrations of sevoflurane in the blood are required before alveolar partial pressures are in equilibrium with arterial partial pressures. This low solubility means that sevoflurane is rapidly removed from the lungs. It is unknown what percent sevoflurane is bound to plasma proteins. The majority of sevoflurane is excreted via the lungs, but ≈3% to 5% is metabolized in the liver via the cytochrome P450 2E1 isoenzyme.

Contraindications/Precautions/Warnings

Sevoflurane is contraindicated in patients with a history or predisposition toward malignant hyperthermia. It should be used with caution (benefits vs risks) in patients with elevated intracranial pressure or head injury, or renal insufficiency.

Because of its rapid action, use caution not to overdose during the induction phase. Because of the rapid recovery associated with sevoflurane, use caution (and appropriate sedation during the recovery phase), particularly with large animals.

Geriatric animals may require less inhalant anesthetic.

In rabbits and other small mammals, sevoflurane (and isoflurane) can cause breath-holding and struggling; premedication and close observation are required. Sevoflurane may have a low margin of safety in guinea pigs.[3]

Sevoflurane can react with carbon dioxide absorbents to produce compound A, which is nephrotoxic. After extensive clinical use in humans and dogs, nephrotoxicity has not been demonstrated to be of clinical concern. However, sevoflurane should be used with good maintenance of the carbon dioxide absorbent (ie, should be changed regularly to prevent exhaustion or excessive drying) and should not be used with extremely low oxygen flows (ie, less than 500 mL/minute).[4] Fluoride is another degradation product of sevoflurane, which has been associated with renal damage; however, it has not been shown to cause significant changes in renal function.[5]

Sevoflurane should be used in precision, agent-specific, out-of-circuit vaporizers. Sevoflurane should only be used in situations in which sufficient monitoring and patient-support capabilities (eg, intubation, ventilation) are available.

The National Institute for Occupational Safety and Health (NIOSH) has recommended that no worker should be exposed at ceiling concentrations greater than 2 ppm of any halogenated anesthetic agent over a sampling period not to exceed 1 hour.

Adverse Effects

Sevoflurane seems to be well-tolerated. Hypotension and respiratory depression may occur and are considered dose dependent. GI effects (nausea, vomiting, ileus) have been reported. Cardiodepression (ie, decreased heart rate and contractility) is possible but generally minimal at sevoflurane doses causing surgical planes of anesthesia. Chamber or facemask induction can significantly increase the risks for respiratory or cardiovascular depression because of the high percentage of inspired inhalant used during this phase.

Like other inhalant anesthetics, sevoflurane may rarely trigger malignant hyperthermia in predisposed patients.

A study in dogs found a decrease in gastric motility during sevoflurane anesthesia. While gastric motility returned to normal within 12 to 15 hours, gastric emptying was delayed for 30 to 40 hours, possibly increasing the risk for postoperative ileus.[6]

Sinus arrhythmias have been detected when used in birds.[7] Prolongation of the QT interval has been reported in humans.

In ferrets, sevoflurane (and isoflurane) can cause temporary decreases in erythrocyte and white blood cell counts and total protein. Within 45 minutes after discontinuation of sevoflurane, this effect begins to revert to normal and is reversed within 2 hours.

Volatile anesthetics contribute to the greenhouse effect. When scavenged to the atmosphere, sevoflurane rises to the troposphere and remains nondegraded for 1.1 years. This degradation time equates to a global warming potential of 130 years. However, sevoflurane does not react with the highly reactive ozone in the stratosphere and does not damage the earth's protective ozone barrier like isoflurane and nitrous oxide do. The shorter degradation time and the absence of reaction with the ozone in the stratosphere make sevoflurane the inhalant with the least negative impact on the environment.

Reproductive/Nursing Safety

No overt fetotoxicity or teratogenicity has been demonstrated in lab animal studies, but safety has not been definitively established for use during pregnancy.

The MAC of inhalation agents is 25% to 40% lower during pregnancy.[8]

Limited information is available regarding lactation. In humans, sevoflurane appears compatible with breastfeeding, and breastfeeding may resume after recovery from anesthesia.[9]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In the event of an overdose, discontinue sevoflurane, maintain a patent airway, and support respiratory and cardiac function as necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sevoflurane and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides, Lincosamides**: May enhance neuromuscular blockade
- **Barbiturates** (eg, **phenobarbital, pentobarbital**): May increase concentrations of inorganic fluoride
- **Dexmedetomidine**: May potentiate sevoflurane effects; decrease MAC[10]
- **Isoniazid**: May increase concentrations of inorganic fluoride
- **Ketamine**: May decrease MAC requirements
- **Lidocaine**: IV lidocaine can significantly reduce MAC in horses[11] and dogs.[12]

- **Methimazole**: May decrease the metabolism of sevoflurane and prolong recovery
- **Midazolam**: May potentiate sevoflurane effects; decrease MAC
- **Nondepolarizing Neuromuscular Blocking Agents** (eg, **atracurium, pancuronium, vecuronium**): Additive neuromuscular blockade may occur.
- **Opioids**: May potentiate sevoflurane effects; decrease MAC
- **Propofol**: IV propofol CRI can significantly reduce MAC in dogs in a dose-dependent manner.[13]
- **QT Prolonging Agents** (eg, **amiodarone, cisapride, quinidine, sotalol**): May increase the risk for arrhythmias
- **Sildenafil**: May decrease the metabolism of sevoflurane and prolong recovery
- **St. John's Wort**: Increased risk for anesthetic complications; recommend discontinuing St. John's Wort 5 days in advance of surgery.
- **Succinylcholine**: Sevoflurane may enhance effects.
- **Sympathomimetics** (eg, **dopamine, epinephrine, norepinephrine, ephedrine, metaraminol**): While sevoflurane sensitizes the myocardium to the effects of sympathomimetics less than halothane, arrhythmias may still result; caution and monitoring are advised.
- **Tramadol**: May decrease MAC requirements
- **Verapamil**: May cause cardiovascular depression

Laboratory Considerations

- Inhalant anesthetics may cause transient increases in **liver enzymes, WBCs, and glucose**.

Dosages

Minimal alveolar concentration (MAC; %) in oxygen reported for sevoflurane in various species: dog = 2.1% to 2.4%; cat = 2.6% to 3.4%; horse = 2.3% to 2.8%; sheep = 1.9% to 2%; swine = 2% to 2.7%; human (adult) = 1.6% to 2.1%.[1,2]

NOTES:

1. Sevoflurane should be used with well-maintained anesthetic machines with proper scavenging equipment and in areas with adequate ventilation to prevent escape of gases that could result in exposure of veterinary personnel to anesthetic vapors.
2. General anesthesia using inhalants must be performed with adequate monitoring and support and cannot be dosed in a purely textbook fashion.
3. MAC is affected by many variables, including:
   a) type and location of stimulus,
   b) concurrent administration of MAC reducing drugs,
   c) type of ventilation, type of breathing system,
   d) age of the animal (younger animals may have higher MAC values), and
   e) patient variables (acid/base status, temperature, ongoing acute disease, pregnancy, severe hypoxemia, and hypercarbia)

DOGS/CATS:

General anesthesia (label dosage; FDA-approved): **Dogs**: Inspired Concentration: The delivered concentration of *SevoFlo*® (sevoflurane) should be known. Since the depth of anesthesia may be altered easily and rapidly, only vaporizers producing predictable percentage concentrations of sevoflurane should be used. Sevoflurane should be vaporized using a precision vaporizer specifically calibrated for sevoflurane. Sevoflurane contains no stabilizer. Nothing in the drug product alters the calibration or operation of these vaporizers. The administration of general anesthesia must be individualized based on the patient's response. **When using sevoflurane, patients should be continuously monitored, and facilities for maintenance of patient airway, artificial ventilation, and oxygen supplementation must be immediately available.**

Replacement of Desiccated CO_2 Absorbents: When a clinician suspects that the CO_2 absorbent may be desiccated, it should be replaced. An exothermic reaction occurs when sevoflurane is exposed to CO_2 absorbents. This reaction is increased when the CO_2 absorbent becomes desiccated.

Premedication: No specific premedication is either indicated or contraindicated with sevoflurane. The necessity for and choice of premedication is left to the discretion of the veterinarian. Preanesthetic doses for premedicants may be lower than the label directions for their use as a single medication.

Induction: For mask induction using sevoflurane, inspired concentrations of up to 7% sevoflurane with oxygen are employed to induce surgical anesthesia in the healthy dog. These concentrations can be expected to produce a deep plane of anesthesia in 3 to 14 minutes. **Because of the rapid and dose-dependent changes in anesthetic depth, care should be taken to prevent overdosing. Respiration must be monitored closely in the dog and supported when necessary with supplemental oxygen and/or assisted ventilation. If painful procedures are performed, analgesic drugs should be administered as sevoflurane has no analgesic effects.**

Maintenance: *SevoFlo*® may be used for maintenance of anesthesia following mask induction using sevoflurane or following injectable induction agents. The concentration of vapor necessary to maintain anesthesia is much less than that required to induce it. Surgical levels of anesthesia in the healthy dog may be maintained with inhaled concentrations of 3.7% to 4% sevoflurane in oxygen in the absence of premedication and 3.3% to 3.6% in the presence of premedication. The use of injectable induction agents without premedication has little effect on the concentrations of sevoflurane required for maintenance. Anesthetic regimens that include opioid, alpha-2-agonist benzodiazepine, or phenothiazine premedication will allow the use of lower sevoflurane maintenance concentrations.[14]

Extra-label doses:

a) **Dogs/Cats**: Where required, mask induction (particularly of cats) is achieved easily via a nonrebreathing system, usually starting at a concentration of around 4% to 4.5%. Maximum concentration (8%) is possible using the vaporizer can be used for fresh gas flow for chamber inductions as the concentrations in the box take time to reach high levels. However, concentrations administered must be reduced as soon as the animal loses consciousness (ie, take the animal out of the box). For maintenance, a vaporizer setting of 3% for a circle system is a reasonable initial concentration that can be adjusted based on the residual effects of injectable drugs and/or the patient's health status.[15]

b) **Cats**: From a retrospective review of studies reporting sevoflurane MAC. Average MAC for sevoflurane in cats was 3.08% ± 0.4% but ranged from 2.5% ± 0.2% to 3.95% ± 0.33%, reflecting a relatively wide range. Multiple variables and study methodology likely contributed to this wide range.[16]

SMALL MAMMALS:

General anesthesia: (extra-label): Induction: 4% to 6% sevoflurane to effect has been used in hedgehogs via induction chamber or facemask. Maintenance: 0.5% to 3% sevoflurane to effect with facemask has been used in hedgehogs.[17]

HORSES:

General anesthesia: (extra-label): Approximate MAC is 2.31% to 2.84%.

ALPACAS:

General anesthesia: (extra-label): Induction: sevoflurane 6% in oxygen delivered by face mask from a circle system attached to a small animal anesthetic machine. Maintenance: sevoflurane 2.3%. MAC is 1.9 to 2.3.[18]

SHEEP/GOATS:

General anesthesia (extra-label): Small animal anesthetic circuits can be used to deliver inhalational anesthetics in small ruminants. During maintenance, the vaporizer setting should be adjusted to 2.5% to 4%. The oxygen flow rate should be 2 to 4 L/minute during induction and reduced to 0.5 to 1 L/minute during maintenance.[19]

BIRDS:

General anesthesia (extra-label): Induction: 5% to 8% sevoflurane via a mask using a nonrebreathing (Bain) system.[20] Maintenance: 1% to 4% sevoflurane to effect via a mask or endotracheal tube.[17] Approximate MAC was found to be 3 in pigeons.[7] Birds should always be intubated during general anesthesia.

AMPHIBIANS:

General anesthesia (extra-label): A 38% sevoflurane jelly has been compounded for use in cane toads and applied at 37.5 µL/g of body weight for induction. (See ***Compatibility/Compounding Considerations***)

Monitoring

- Respiratory and ventilatory status
- Cardiac rate/rhythm; blood pressure (particularly with at-risk patients)
- Level of anesthesia

Client Information

- Sevoflurane is used for general anesthesia only by veterinarians.

Chemistry/Synonyms

Sevoflurane is an isopropyl ether inhalational anesthetic with a molecular weight of 200, a saturated vapor pressure of 20°C (68°F) of 160 mm Hg, and a boiling point of 58.5°C (137°F). It is reported to have a pleasant odor and is not irritating to the airways. It is nonflammable and nonexplosive. Sevoflurane is a clear, colorless liquid that is miscible with ethanol or ether and slightly soluble in water.

Sevoflurane may also be known as BAX-3084, MR-654, *Sevocris®*, *SevoFlo®*, *Sevorane®*, *Petrem®*, or *Ultane®*.

Storage/Stability

Store sevoflurane at room temperature. Sevoflurane does not react with metal but can react with Lewis acids to form hydrofluoric acid.

Compatibility/Compounding Considerations

A 38% sevoflurane jelly was compounded for use in amphibians, composed of 3 parts liquid sevoflurane, 3.5 parts aqueous nonspermacidal jelly, and 1.5 parts distilled water. Each component of the mixture was added to a catheter-tip 60 mL syringe, and the syringe was shaken vigorously while the end of the syringe was occluded with a finger. When mixed thoroughly, the mixture changed from colorless to an opaque, white jelly of uniform consistency. Attempts at higher concentrations of sevoflurane were unsuccessful as this caused separation. No stability analysis was performed. See cited study for more information.[21]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sevoflurane in 250 mL bottles; *SevoFlo®*, *Petrem®*; (Rx). FDA-approved for use in dogs

HUMAN-LABELED PRODUCTS:

Sevoflurane in 250 mL bottles; *Ultane®*, *Sojourn®*, generic; (Rx)

Sildenafil

(sil-***den***-ah-fil) *Viagra®, Revatio®*

Vasodilator; Phosphodiesterase Type 5 Inhibitor

Prescriber Highlights

- ► Used in veterinary medicine for the treatment of pulmonary arterial hypertension or to improve clinical signs associated with congenital megaesophagus
- ► Contraindicated in patients receiving organic nitrates (eg, nitroglycerin)
- ► Adverse effects appear to be uncommon; inguinal flushing and possible GI effects have been reported.

Uses/Indications

Sildenafil may be of benefit in the adjunctive treatment of pulmonary hypertension of a variety of causes in small animals. Studies have demonstrated reduced estimates of pulmonary arterial pressure, lessened clinical signs, and improved exercise capacity and quality of life after sildenafil administration.[1-5] An open label study in 5 dogs with Eisenmenger's syndrome found that sildenafil improved clinical signs and secondary erythrocytosis.[6] Sildenafil has also been shown to resolve alveolar infiltrates in dogs with pulmonary arterial hypertension[5] and to slow the rate of cardiac remodeling in dogs with myxomatous mitral valve disease, as compared with dogs receiving no therapy.[7] Sildenafil and pimobendan administered to 4 dogs with heartworms entangled in the tricuspid apparatus resulted in worm migration to the pulmonary arteries.

In a study of puppies with congenital megaesophagus, sildenafil reduced the number of regurgitation episodes and improved weight gain.[8] Sildenafil also reduced basal tone and increased electrically induced relaxation of the lower esophageal sphincter (in vitro) in a dose-dependent manner, thus, suggesting that sildenafil may be useful as an alternative treatment for controlling signs related to congenital megaesophagus.

In cattle, an intrauterine sildenafil infusion increased intensity of blood flow in the uterine wall; this may be beneficial in conditions of reduced uterine blood flow (eg, endometritis) or help initiate luteolysis.[9]

In humans, sildenafil is indicated for erectile dysfunction or pulmonary arterial hypertension.

Pharmacology/Actions

Sildenafil inhibits cyclic guanosine monophosphate (cGMP) specific phosphodiesterase type-5 (PDE5) found in the smooth muscle of the pulmonary vasculature, corpus cavernosum, and elsewhere where PDE5 is responsible for degradation of cGMP. Sildenafil increases cGMP thereby, resulting in nitric oxide mediated vasodilation within pulmonary vascular smooth muscle cells.

In Thoroughbred horses, sildenafil 5 mg/kg PO did not alleviate pulmonary hemorrhage or enhance performance-related indices.[10]

Pharmacokinetics

The pharmacokinetics of sildenafil have been reported in dogs.[11-13] Oral bioavailability is ≈50% to 80% (approximately the same as in humans); giving the drug with food significantly reduces peak concentration. Volume of distribution is 4.5 to 6.5 L/kg (vs 1.2 L/kg in humans); elimination half-life is ≈3 to 6 hours (significant interpatient variability; average human half-life is ≈4 hours). Humans metabolize sildenafil (mainly via CYP3A4) to an active metabolite, which has an elimination half-life of ≈4 hours.

Contraindications/Precautions/Warnings

Sildenafil should not be used concurrently with nitrates (see ***Drug Interactions***) or in patients documented as being hypersensitive to the drug.

Pulmonary arterial vasodilators may significantly worsen the cardiovascular status of patients with pulmonary veno-occlusive disease (PVOD). Sildenafil should be used cautiously in animals with pulmonary arterial hypertension from congenital cardiac shunts or left-sided heart disease because vascular reactivity or responsiveness to sildenafil can be hard to predict, and sildenafil may increase venous return to the left side of the heart, resulting in congestive heart failure in some cases.[4]

An in vitro study demonstrated that sildenafil at supratherapeutic concentrations possesses direct, positive inotropic and chronotropic effects together with coronary vasodilator action. Caution should be used when giving sildenafil to patients with ischemic heart disease, obstructive hypertrophic cardiomyopathy, or ventricular arrhythmias.[14]

Use with extreme caution in patients with resting hypotension, fluid depletion, severe left ventricular outflow obstruction, bleeding disorder, or autonomic dysfunction. One dose of sildenafil caused acute decompensation leading to euthanasia in a cat with a vasoproliferative disorder resembling pulmonary capillary hemangiomatosis.[15] Dosage reduction may be required in patients with significant hepatic or renal impairment.

Adverse Effects

Sildenafil appears to be well tolerated. Cutaneous flushing of the inguinal region has been reported,[1] and GI adverse effects (eg hyporexia, vomiting, diarrhea)[12,13,16] are possible. The magnitude of systolic blood pressure reduction (12 – 24 mm Hg) did not reach statistical significance in clinical reports.[1,3,17] In humans, hypotension, headache, visual disturbances (including retinal toxicity and vision loss), dyspepsia, epistaxis, nasal congestion, hearing loss, myalgia, priapism, dizziness, and back pain have been reported.

Reproductive/Nursing Safety

No evidence of teratogenicity, embryotoxicity, or fetotoxicity was observed in pregnant rats or rabbits given sildenafil 200 mg/kg/day during organogenesis. In a pre- and postnatal development study in rats given 30 mg/kg/day, there were no observed adverse effects. Sildenafil did not impair fertility in male or female rats.

Sildenafil and its metabolites are excreted into maternal milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Little information is available. An adult woman ingested 2000 mg and survived but developed tachycardia, nonspecific ST-T changes on ECG, headache, dizziness, and flushing.

It is expected that overdoses in animals would mirror the drug's adverse effect profile; treat supportively.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sildenafil and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **ACE Inhibitors** (eg, **benazepril, enalapril**): Potential to increase hypotensive effects
- **Alpha-1-Adrenergic Receptor Antagonists** (eg, **phenothiazines [eg, acepromazine], phenoxybenzamine, phentolamine, prazosin**): May increase hypotensive effects
- **Alpha-2-Adrenergic Receptor Agonists** (eg, **dexmedetomidine, xylazine**): Potential to increase hypotensive effects
- **Amlodipine**: Potential to increase hypotensive effects
- **Angiotensin Receptor Blockers** (**ARBs**, eg, **telmisartan**): Potential to increase hypotensive effects
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**): May reduce sildenafil metabolism and increase AUC; consider lower sildenafil dosages
- **Cimetidine**: May reduce sildenafil metabolism and increase AUC
- **Ciprofloxacin**: May reduce sildenafil metabolism and increase AUC
- **Clarithromycin, Erythromycin** (not azithromycin): May reduce sildenafil metabolism and increase AUC; consider lower sildenafil dosages
- **Furosemide**: Concurrent use may increase the risk for hearing loss. May increase concentration of sildenafil active metabolite
- **Heparin**: May increase bleeding risks
- **Nitrates** (eg, **isosorbide, nitroglycerin**): Significant potentiation of vasodilatory effects; life-threatening hypotension is possible. Combination is contraindicated
- **Nitroprusside Sodium**: Significant potentiation of vasodilatory effects; life-threatening hypotension is possible. May increase bleeding risks
- **Paclitaxel**: May alter paclitaxel plasma concentrations
- **Phenobarbital**: May decrease sildenafil concentrations
- **Propranolol**: May increase concentration of sildenafil active metabolite
- **Rifampin**: May decrease sildenafil concentrations

Laboratory Considerations

- None noted

Dosages

DOGS:

Pulmonary hypertension (extra-label): Initially, 0.5 – 1 mg/kg PO every 8 hours, may increase to 3 mg/kg PO every 8 hours based on clinical signs[1-3,5,16,17]

Congenital idiopathic megaesophagus (extra-label): 1 mg/kg PO every 12 hours; from a prospective study[8]

Eisenmenger's syndrome (extra-label): 0.5 mg/kg PO twice daily improved clinical signs and secondary erythrocytosis[6]

Subclinical myxomatous mitral valve disease (extra-label): 1 – 3 mg/kg PO every 12 hours[7,18]

CATS:

Pulmonary hypertension (extra-label): A case report of a cat with atrial septal defect that developed pulmonary hypertension leading to Eisenmenger's syndrome (ie, right to left shunting) was treated with sildenafil 0.25 to 1.6 mg/kg PO every 12 hours for 10 months. There was improvement in clinical signs but increasing doses of sildenafil were required. After 10 months the cat deteriorated and was euthanized.[19]

Monitoring

- Clinical efficacy: improved exercise capacity, cough, respiratory effort, regurgitation frequency, or weight gain; fewer episodes of syncope
- Pulmonary arterial pressure, systemic blood pressure
- Adverse effects

Client Information

- Give this medicine on an empty stomach (ie, 1 hour before or 2

hours after feeding). If your animal vomits or acts sick after receiving this drug on an empty stomach, try giving the next dose with food or a small treat. If vomiting continues, contact your veterinarian.

- Be sure to give this medicine exactly as prescribed.
- This medicine may cause flushing (ie, redness) in the groin area; gastrointestinal side effects (eg, lack of appetite, vomiting, diarrhea) are also possible.

Chemistry/Synonyms

Sildenafil citrate occurs as a white to off-white crystalline powder with a solubility of 3.5 mg/mL in water and a molecular weight of 666.7.

Sildenafil may also be known as UK 92480, UK 92480-10, *Aphrodil*®, *Revatio*®, or *Viagra*®.

Storage/Stability

Sildenafil tablets and oral suspension should be stored at room temperature (25°C [77°F]); excursions are permitted to 15°C to 30°C (59°F-86°F). Oral suspension may be refrigerated at 2°C to 8°C (36°F-46°F) after reconstitution; do not freeze. Discard 60 days after reconstitution. Store sildenafil injection at room temperature of 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

A stable 2.5 mg/mL sildenafil citrate oral suspension can be made with tablets and either a 1:1 mixture of methylcellulose 1% and simple syrup NF or a 1:1 mixture of *Ora-Sweet*® and *Ora-Plus*®. Crush 30 sildenafil 25 mg tablets in a mortar and reduce to a fine powder. Add small portions of the chosen vehicle and mix to a uniform paste. Continue to add the vehicle in incremental proportions to almost 300 mL and then transfer to a graduated cylinder, rinse mortar with vehicle, and add a quantity of the vehicle sufficient to make a total of 300 mL. Store in amber plastic bottles and label "shake well." The drug is stable for 90 days at room temperature or when refrigerated.[20]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Sildenafil Citrate Oral Tablets: 20 mg, 25 mg, 50 mg, and 100 mg (of sildenafil); *Revatio*® (20 mg only), *Viagra*®, generic; (Rx)

Sildenafil Citrate Oral Powder for Suspension: 10 mg/1 mL; *Revatio*®, generic; (Rx). Cost may be prohibitive.

Sildenafil Injection Solution: 10 mg/12.5 mL (dextrose 50.5 mg/mL) in 12.5 mL single-use vials; *Revatio*®, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Sodium Bicarbonate

(soe-***dee***-um bye-***kar***-boe-nate)

Alkalinizer

Prescriber Highlights

- ► Alkalinizing agent used to treat metabolic acidosis and to alkalinize urine; may also be used adjunctively for hypercalcemic or hyperkalemic crises. Not commonly used secondary to potential complications/adverse effects
- ► Contraindications include patients with metabolic or respiratory alkalosis, excessive chloride loss secondary to vomiting or GI suction, patients at risk for developing diuretic-induced hypochloremic alkalosis, and patients with hypocalcemia where alkalosis may induce tetany.
- ► Use with extreme caution in patients with hypocalcemia.
- ► Caution in patients with CHF, nephrotic syndrome, hypertension, oliguria, or volume overload
- ► Adverse effects, especially with parenteral administration or high doses, include metabolic alkalosis, hypokalemia, hypocalcemia, overshoot alkalosis, hypernatremia, volume overload, CHF, shifts in the oxygen dissociation curve causing decreased tissue oxygenation, and paradoxical CNS acidosis leading to respiratory arrest.
- ► If used during CPR, hypercapnia can occur if the patient is not well ventilated; patients may be predisposed to ventricular fibrillation.

Uses/Indications

Sodium bicarbonate may be used to treat severe metabolic acidosis. It is not a substitute for diagnosing and treating the underlying cause of the acid/base disturbance. In small animal species, acidotic conditions that may be amenable to bicarbonate therapy include those that occur as a result of cardiopulmonary arrest, renal failure, renal tubular acidosis, or toxin exposure. The use of bicarbonate for metabolic acidosis secondary to diabetic crises (eg, diabetic ketoacidosis) is controversial.

Sodium bicarbonate can also be used as adjunctive therapy for the treatment of hypercalcemia or hyperkalemia crises and to alkalinize the urine.

Pharmacology/Actions

The bicarbonate ion is the conjugate base component of bicarbonate:carbonic acid buffer, the principal extracellular buffer in the body.

Contraindications/Precautions/Warnings

Parenterally administered sodium bicarbonate is considered generally contraindicated in patients with metabolic or respiratory alkalosis, excessive chloride loss secondary to vomiting or GI suction, those at risk for development of diuretic-induced hypochloremic alkalosis, or with hypocalcemia where alkalosis may induce tetany. Patients that are unable to adequately ventilate are at risk for developing hypercapnia.

Use with extreme caution and give very slowly in patients with hypocalcemia. Ideally, low calcium or potassium serum concentrations should be corrected prior to administration. Bicarbonate therapy during a diabetic crisis (ie, diabetic ketoacidosis) is rarely indicated. Administering sodium bicarbonate before potassium replenishment can be detrimental and potentially life-threatening as it can exacerbate hypokalemia.

Because of the potential sodium load, use with caution in patients with CHF, renal insufficiency, nephrotic syndrome, hypertension, oliguria, or volume overload.

Rapid IV boluses of sodium bicarbonate should be avoided because of the production of carbon dioxide and its diffusion into the

central nervous system, making CSF acidosis even worse. Other disadvantages of sodium bicarbonate administration include shifting of the oxygen/hemoglobin dissociation curve to the left and increasing osmolality.

Sodium bicarbonate is generally not effective for treating lactic acidosis, and fluid therapy remains the mainstay of treatment.

Adverse Effects

Sodium bicarbonate therapy (particularly high-dose parenteral use) can lead to metabolic alkalosis, hypokalemia, hypocalcemia, overshoot alkalosis, hypernatremia, volume overload, CHF, shifts in the oxygen dissociation curve causing decreased tissue oxygenation, and paradoxical CNS acidosis, leading to depression, stupor, coma, respiratory arrest, and death.

When sodium bicarbonate is used during cardiopulmonary resuscitation, hypercapnia may result if the patient is not well ventilated; patients may be predisposed to ventricular fibrillation.

Oral and parenteral bicarbonate (especially at higher doses) may contribute significant amounts of sodium and result in hypernatremia and volume overload; use with caution in patients with CHF or acute kidney injury. Inadvertent extravasation during IV administration of hypertonic sodium bicarbonate solutions has caused cellulitis, tissue necrosis, and sloughing at the infiltration site.

Reproductive/Nursing Safety

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Sodium bicarbonate can cause severe alkalosis if overdosed or given too rapidly, with signs including irritability or tetany. Doses should be thoroughly checked prior to administration, and patients should be frequently monitored of electrolyte and acid/base status performed. Treatment of mild alkalosis may only require discontinuing bicarbonate or use of a rebreathing mask. Severe alkalosis may require IV calcium therapy. Sodium chloride or potassium chloride may be necessary if hypokalemia is present.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sodium bicarbonate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **hyoscyamine, oxybutynin**): Concomitant oral sodium bicarbonate may reduce absorption of oral anticholinergic agents; administer separately.
- **Azole Antifungals** (eg, **ketoconazole, itraconazole**): Concomitant oral sodium bicarbonate may reduce absorption; administer separately.
- **Ciprofloxacin; Enrofloxacin**: The solubility of ciprofloxacin and enrofloxacin is decreased in an alkaline environment; patients with alkaline urine should be monitored for signs of crystalluria.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): Patients receiving high dosages of sodium bicarbonate and ACTH or glucocorticoids may develop hypernatremia.
- **Digoxin**: Concomitant oral sodium bicarbonate may reduce digoxin concentrations.
- **Diuretics** (eg, **furosemide, thiazides**): Concurrent use of sodium bicarbonate in patients receiving potassium-wasting diuretics may cause hypochloremic alkalosis.
- **Ephedrine**: When urine is alkalinized by sodium bicarbonate, excretion may be decreased.
- **Histamine Type 2 Receptor Antagonists** (eg, **famotidine**): Concomitant oral sodium bicarbonate may reduce absorption; separate dosages by at least 2 hours.
- **Iron Products**: Concomitant oral sodium bicarbonate may reduce absorption; separate dosages by at least 2 hours.
- **Methenamine**: Methenamine efficacy may be decreased when urine is alkalinized by sodium bicarbonate.
- **Oral Medications**: Because oral sodium bicarbonate can either increase or reduce the rate and/or extent of absorption of many orally administered drugs, it is recommended to avoid giving other drugs within 1 to 2 hours of oral sodium bicarbonate.
- **Quinidine**: When urine is alkalinized by sodium bicarbonate, excretion may be decreased.
- **Salicylates**: (eg, **aspirin**): When urine is alkalinized by sodium bicarbonate, excretion of weakly acidic drugs may be increased.
- **Sucralfate**: Oral sodium bicarbonate may reduce the efficacy of sucralfate if administered concurrently; separate dosages by at least 2 hours.
- **Tetracyclines** (eg, **doxycycline**): Concomitant oral sodium bicarbonate may reduce absorption; separate dosages by at least 2 hours.

Dosages

NOTE: In most cases it is suggested to administer sodium bicarbonate IV infusions as an isotonic 1.4% sodium bicarbonate solution (≈150 mEq/L). See ***Compatibility/Compounding Considerations*** for preparation instructions.

DOGS/CATS:

Severe metabolic acidosis (extra-label): The main therapeutic goal should be to first eliminate the underlying cause of acidosis. If causes are not readily reversible, arterial pH is less than 7 to 7.2, and fluid therapy and ventilatory procedures have not reduced acidemia, bicarbonate therapy should be considered.

a) Sodium bicarbonate requirement (dose, in mEq) = 0.3 × body weight (kg) × (desired HCO_3^- - measured patient HCO_3^-). Administer ¼ to ⅓ of the calculated dose as a slow IV bolus, and the remaining amount via IV infusion over 4 to 6 hours.[1] To minimize the risk for alkalinization, recheck blood gases and assess the clinical status of the patient.

b) **Prolonged cardiac arrest (ie, greater than 10-15 minutes) or if blood gas measurement is not possible, and it is believed that the animal is severely acidotic**: 1 – 2 mEq/kg slow IV/IO.[2,3]

Adjunctive therapy for hyperkalemic crisis (extra-label): Must be used judiciously. Hyperkalemia associated with hypoadrenocorticism typically improves with fluid resuscitation alone.[4] Empirical dosage of 1 – 2 mEq/kg slow IV (over 10 to 20 minutes) can be used[5]; alternatively, bicarbonate dose in mEq can be calculated as 0.3 × body weight (kg) × (desired HCO_3^- - measured HCO_3^-).[6]

Alkalinizing the urine (extra-label): Rarely recommended. Initially, 650 mg – 5.85 g/animal (NOT mg or g/kg) PO daily, depending on the size of the patient and the pretreatment urine pH value. Dosage must be individualized to the patient, with the goal of maintaining a urine pH of ≈7 to 7.5.[7]

HORSES:

Metabolic acidosis associated with colic (extra-label): If pH is less than 7.3 and the base deficit is greater than 10 mEq/L, esti-

mate the sodium bicarbonate requirement (dose in mEq) = base deficit (mEq/L) × body weight (kg) × 0.4 (use 0.6 for foals[8]). It is suggested to administer as an isotonic sodium bicarbonate 1.4% solution (150 mEq/L). Alternatively, may administer as a sodium bicarbonate 5% solution, which contains 600 mEq of bicarbonate/L (hypertonic) and should be administered IV but at a rate no faster than 1 – 2 L/hour.[9,10]

CATTLE:

Correction of acidosis in mature cattle (extra-label): Estimate the sodium bicarbonate requirement (dose in mEq) = base deficit (mEq/L) × body weight (kg) × 0.3. When laboratory data are unavailable, estimate a base deficit of 10 mEq/L.[11] Sodium bicarbonate may be administered IV as an isotonic (1.4%, 150 mEq/L) or hypertonic (8.4%) solution.

Severely dehydrated (10% to 16% dehydrated) acidotic calves (usually comatose) (extra-label): Using isotonic sodium bicarbonate (1.4%, 150 mEq/L), most calves require ≈2 L of this solution IV given over 1 to 2 hours, then change to isotonic saline and sodium bicarbonate or a balanced electrolyte solution.[12] Isotonic saline and sodium bicarbonate can be made by mixing 1 L of isotonic saline with 1 L of isotonic sodium bicarbonate.

Empiric correction of acidosis in calves dehydrated due to diarrhea (extra-label): For situations where prolonged IV fluid administration is difficult or impractical: using sodium bicarbonate 8.4% solution, administer 10 mL/kg IV over 10 to 20 minutes. Sodium bicarbonate may be given alone, followed by oral administration of isotonic electrolyte solutions or given concurrently with IV fluids.[13]

CAMELIDS:

Correction of acidosis in New World Camelids (extra-label): Determine the bicarbonate requirement and give up to ½ of the calculated dose IV over 2 to 4 hours, with adjustments made based on blood gases and patient status to avoid over alkalinization. Sodium bicarbonate may be administered as an isotonic (1.4%) or hypertonic (8.4%) solution. Calculate the bicarbonate requirement with the following formulas:

a) Neonates: mEq bicarbonate needed = base deficit × body weight (kg) × 0.6

b) Adults: mEq bicarbonate needed = base deficit × body weight (kg) × 0.3.

GOATS:

Floppy kid syndrome in goats (extra-label): Give 1 or 2 doses of 2.5 – 3 g/kid (NOT g/kg) PO mixed in water. For severe cases or cases where the kid is unable to swallow, determine the bicarbonate requirement and administer IV as an isotonic (1.4%, 150 mEq/L) sodium bicarbonate solution, giving up to ½ of the calculated dose over 2 to 4 hours, with adjustments made based on blood gases and patient status to avoid over alkalinization. Estimate the sodium bicarbonate requirement (dose in mEq) = base deficit (mEq/L) × body weight (kg) × 0.5.

BIRDS:

Metabolic acidosis (extra-label): 1 mEq/kg initially IV (then SC) for 15 to 30 minutes to a maximum of 4 mEq/kg[14]

Monitoring

- Acid/base status. Blood gas analysis should be performed ≈2 to 4 hours after initiating sodium bicarbonate treatment, and periodically as treatment continues.[2]
- Serum electrolytes
- IV infusion site for infiltration
- Urine pH (if being used to alkalinize urine)

Chemistry/Synonyms

Sodium bicarbonate is an alkalinizing agent that occurs as a white, crystalline powder and has a slightly saline or alkaline taste. It is soluble in water and insoluble in alcohol. One gram of sodium bicarbonate contains ≈12 mEq (mMol) each of sodium and bicarbonate; 84 mg of sodium bicarbonate contains 1 mEq each of sodium and bicarbonate. Instructions to prepare an isotonic sodium bicarbonate solution are found in ***Compatibility/Compounding Considerations***.

Sodium bicarbonate may also be known as baking soda, E500, monosodium carbonate, natrii bicarbonas, natrii hydrogenocarbonas, sal de vichy, sodium acid carbonate, $NaHCO_3$, sodium hydrogen carbonate; many trade names are available.

Storage/Stability

Store sodium bicarbonate tablets in tight containers at room temperature (15°C-30°C [59°F-86°F]). Store sodium bicarbonate injection at temperatures less than 40°C (104°F), preferably at room temperature; avoid freezing.

Sodium bicarbonate powder is stable in dry air but will slowly decompose upon exposure to moist air.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist can be consulted for more specific information.

Sodium bicarbonate for injection is reportedly physically **compatible** with the following IV solutions and drugs: Dextrose in water, dextrose/sodium chloride combinations, sodium chloride injections, amikacin sulfate, aminophylline, atropine sulfate, cefazolin, ceftazidime, ceftriaxone sodium, chloramphenicol sodium succinate, clindamycin phosphate, cyclosporine, dexamethasone sodium phosphate, dexmedetomidine, erythromycin gluceptate/lactobionate, fentanyl citrate, fluconazole, furosemide, gentamicin sulfate, glycopyrrolate, heparin sodium, hyaluronidase, hydrocortisone sodium succinate, regular insulin, labetalol HCl, mannitol, naloxone HCl, oxytocin, pamidronate disodium, penicillin G potassium, phenobarbital sodium, phenylephrine HCl, phenytoin sodium, phytonadione, piperacillin/tazobactam, potassium chloride, propofol, ranitidine HCl, sodium iodide, vasopressin, vincristine, and zoledronic acid.

Sodium bicarbonate for injection **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: lactated Ringer's injection, Ringer's injection, sodium lactate 1/6 M, ampicillin sodium, bupivacaine HCl, doxorubicin, famotidine, hydralazine, methylprednisolone sodium succinate, pentobarbital sodium, promazine HCl, thiopental sodium, verapamil HCl, vitamin B-complex with C, and voriconazole.

Sodium bicarbonate for injection is reportedly physically **incompatible** with the following solutions or drugs: alcohol 5%/dextrose 5%, D5-lactated Ringer's, amiodarone HCl, amphotericin B (all formulations), ascorbic acid injection, atracurium besylate, buprenorphine HCl, butorphanol HCl, calcium chloride/gluconate, carboplatin, cefoxitin sodium, ciprofloxacin, codeine phosphate, corticotropin, diazepam, diphenhydramine HCl, dobutamine HCl, dolasetron HCl, dopamine HCl, epinephrine HCl, glycopyrrolate, hydromorphone HCl, imipenem-cilastatin, isoproterenol, lidocaine HCl, HCl, ketamine HCl, levorphanol bitartrate, magnesium sulfate, meperidine HCl, meropenem, metoclopramide HCl, midazolam, morphine sulfate, norepinephrine bitartrate, ondansetron HCl, oxytetracycline HCl, pantoprazole sodium, pentazocine lactate, and succinylcholine chloride.

A 1.4% solution of sodium bicarbonate (≈13 g sodium bicarbonate/L) is approximately isotonic. An 8.4% solution of sodium bicarbonate, with a calculated osmolarity of 2000 mOsm/L, can be made isotonic by diluting each mL with 4.6 mL of sterile water for injection; remove 150 mL from a 1 L bag of sterile water for injection (or other isotonic fluid) and add 150 mL of 8.4% sodium bicarbonate for injection. Practically, a slightly hypertonic solution can be prepared

by adding 200 mL of sodium bicarbonate 8.4% solution to a 1000 mL bag of sterile water for injection or other isotonic solution; ***do not*** remove any fluid from the bag prior to adding sodium bicarbonate.

Because converting volume measurements into weights is not very accurate for powders, it is recommended to actually weigh powders when using them for pharmaceutical purposes. However, if this is not possible, one (1) level teaspoon (5 mL) of commercially available baking soda contains ≈4.8 to 5.9 g of sodium bicarbonate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sodium Bicarbonate Injection: 8.4% (1 mEq/mL) in 50 mL and 100 mL vials; generic; (Rx). Not FDA-approved

HUMAN-LABELED PRODUCTS:

Injectable Products:

Sodium Bicarbonate Neutralizing Additive Solution: 4% (0.48 mEq/mL) in 5 mL vials; 4.2% (0.5 mEq/mL) in 5 mL vials (2.5 mEq); *Neut*®, generic; (Rx).

Sodium Bicarbonate Injection: 4.2% (0.5 mEq/mL) in 10 mL syringes; generic; (Rx)

Sodium Bicarbonate Injection: 7.5% (0.9 mEq/mL) in 50 mL syringes; generic; (Rx)

Sodium Bicarbonate Injection: 8.4% (1 mEq/mL) in 10 mL syringes, 50 mL syringes, and 50 mL vials; generic; (Rx)

Oral Products:

Sodium Bicarbonate Tablets: 325 mg and 650 mg; generic; (OTC)

Sodium Bicarbonate Powder: 113 g, 120 g, and 0.5 kg (1 lb); generic; (OTC)

Omeprazole/Sodium Bicarbonate Capsules (immediate release): 20 mg or 40 mg omeprazole/1100 mg sodium bicarbonate; *Zegerid*®, generic; (Rx)

Omeprazole/Sodium Bicarbonate Powder for Oral Suspension: 20 mg or 40 mg omeprazole/1680 mg sodium bicarbonate in unit-dose packets; *Zegerid*®; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Sodium Stibogluconate

(sti-boe-***gloo***-koe-nate) *Pentostam*®

Antileishmanial

Prescriber Highlights

- ► Antimony compound for treatment of leishmaniasis in dogs
- ► Not commercially available in the United States
- ► Contraindicated in patients with renal failure or pre-existing arrhythmias
- ► Many potential severe adverse effects are possible.

Uses/Indications

Sodium stibogluconate has been used for the treatment of leishmaniasis in dogs. Availability and adverse effects limit clinical use; therefore, meglumine antimoniate is typically the preferred antimony product.

Pharmacology/Actions

Sodium stibogluconate is a pentavalent antimonial. Its exact mechanism of action is unknown, but it is believed to reduce ATP and GTP synthesis in susceptible amistagotes.[1] It may also alter membrane permeability or active transport mechanisms.

Pharmacokinetics

In dogs, the steady-state volume of distribution of sodium stibogluconate was 0.25 L/kg, with a clearance of 1.71 L/kg/hr. Terminal half-life ranged from 0.6 to 1.5 hours.[2] The main route of excretion is via the kidneys; glomerular filtration rate determines excretion rate.

Contraindications/Precautions/Warnings

Sodium stibogluconate is contraindicated in patients with pre-existing cardiac arrhythmias or significantly impaired renal function. It should not be used in patients that have had a serious adverse reaction to a previous dose.

Adverse Effects

Dogs given stibogluconate 40 mg/kg developed increased AST levels.[2] Other reported adverse effects include pain on injection, musculoskeletal pain, hemolytic anemia, leukopenia, vomiting, diarrhea, pancreatitis, myocardial injury and arrhythmias, renal toxicity, shock, and sudden death. IV administration can cause thrombophlebitis. The incidence of adverse effects reportedly increases with duration of use longer than 2 months.

Reproductive/Nursing Safety

Sodium stibogluconate has not been shown to cause fetal harm, but it should be withheld during pregnancy unless the benefits outweigh the risks. Sodium stibogluconate use during nursing is controversial; it is usually compatible with nursing,[3] the manufacturer states that it should not be used in nursing mothers. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Antimony can potentially be chelated with dimercaprol (BAL in oil), dimercaptosuccinic acid (DMSA) or d-penicillamine.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

- No specific drug interactions were noted. Stibogluconate has reportedly been used with allopurinol, paromomycin, or pentamidine without problems.

Laboratory Considerations

- No specific laboratory interactions or considerations noted.

Dosages

DOGS:

Cutaneous leishmaniasis (extra-label): 30 – 50 mg/kg IV or SC daily for 3 to 4 weeks. May be administered every other day for longer durations if adverse effects occur. If administered IV, give slowly over 5 minutes or longer using a fine needle or catheter to avoid thrombophlebitis. Concomitant allopurinol (10 mg/kg PO twice daily) is recommended.[4,5]

Monitoring

- Baseline and periodic (ie, 1 month after therapy begins then every 3 to 4 months) CBC, serum chemistry panel including amylase and lipase, urinalysis with urine:protein creatinine ratio[6]
- Baseline and periodic ECG
- Clinical efficacy; serology +/- PCR at least 6 months after the start of therapy then every 6 months[6]

Client Information

- Clients should understand the potential public health implications of this disease in dogs (dependent on country), the guarded

prognosis (even with treatment), risks of treatment, and associated expenses.

Chemistry/Synonyms

Sodium stibogluconate is a pentavalent antimony compound that contains between 30% and 34% antimony. It is a colorless, odorless or almost odorless, amorphous powder. Sodium stibogluconate is very soluble in water and practically insoluble in alcohol or ether. The injection commercially available in other countries has a pH between 5 and 5.6.

Sodium stibogluconate may also be known as sodium antimony gluconate, *stiboglucat-natrium*, natriumstibogluconat-9-wasser, solusurmin, stibogluconat, *sodio stibogluconato*, and *natrii stibogluconas*.

Storage/Stability

Store the injection at temperatures below 25°C (76°F) and protect from freezing and exposure to light. After removing the first dose, the vial should not be used after one month. Use of a 5 micron filter during preparation is recommended to remove particulates that may be formed by an interaction between the vial stopper and the solution's preservative.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Sodium Stibogluconate for Injection: Sodium antimony gluconate 100 mg (of pentavalent antimony) per mL in 100 mL vials; *Pentostam®*. Not available in the United States. Check with the Centers for Disease Control and Prevention (CDC) for availability. https://www.cdc.gov/laboratory/drugservice/formulary.html

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Sodium Thiosulfate

(soe-***dee***-um thye-oh-***sul***-fayte) *Sodium Hyposulfite*

Antidote (Arsenic, Cyanide)

Prescriber Highlights

- ► Used for cyanide, arsenic, or copper poisoning; localized treatment for chemotherapy extravasation injuries
- ► No known contraindications
- ► Adverse effects may include profuse diarrhea when large doses are given by mouth.
- ► Injectable forms should be given slowly IV.

Uses/Indications

Sodium thiosulfate is used in the treatment of cyanide toxicity, including poisoning from cyanogenic glycoside-containing plants. It has synergistic effects when used in sequence with sodium nitrate. It has been used in treating arsenic toxicosis in cattle,[1,2] and has been proposed for other heavy metal poisonings but its efficacy is in question for these purposes. When used in combination with sodium molybdate, sodium thiosulfate may be useful for the treatment of copper poisoning,[3] although penicillamine may be preferable but cost may be an issue.

In humans, sodium thiosulfate has been used to reduce cisplatin nephrotoxicity[4,5] and has been shown to reduce cisplatin related ototoxicity.[6] A 3% or 4% solution has been used to infiltrate the site of extravasations of cisplatin, carboplatin, or dactinomycin.[7,8] Sodium thiosulfate has been used in the management of mechlorethamine extravasation,[9,10] and, in combination with steroids, sodium thiosulfate may reduce the healing time associated with doxorubicin extravasation. It is also used in humans in the management of calciphylaxis in dialysis patients.

Pharmacology/Actions

Administration of thiosulfate provides an exogenous source of sulfur to the body, thereby hastening the detoxification of cyanide using the enzyme rhodanese. Rhodanese (*thiosulfate cyanide sulfurtransferase*) converts cyanide to the relatively nontoxic thiocyanate ion; thiocyanate is then excreted in the urine.

Sodium thiosulfate's topical antifungal activity is probably due to its slow release of colloidal sulfur.

Although sodium thiosulfate has been recommended for treating arsenic (and some other heavy metal) poisoning, the proposed mechanism of action is not known and its efficacy is in question. Presumably, the sulfate moiety may react with and chelate the metal allowing its removal.

Pharmacokinetics

Sodium thiosulfate is relatively poorly absorbed from the GI tract. When substantial doses are given PO, it acts as a saline cathartic. When administered IV, it is distributed in the extracellular fluid and then rapidly excreted via the urine. In dogs, a therapeutic IV dose is eliminated in urine within 90 minutes. In dogs with renal failure, metabolic clearance rate is reduced, and the plasma thiosulfate concentration is increased and remains elevated for at least 16 hours.[11]

Elimination half-life in humans is ≈1.5 hours.

Contraindications/Precautions/Warnings

Sodium thiosulfate may exacerbate hypertension or edema and should be used with caution in patients who may have these signs including those with congestive heart failure or renal impairment.

NOTE: With cyanide poisoning, sodium nitrite is given first, followed by sodium thiosulfate, except in cases involving smoke inhalation, as nitrite acts by converting hemoglobin to methemoglobin; however, in subjects with carbon monoxide inhalation (from smoke) increasing the concentration of methemoglobin would worsen oxygen carrying capacity already reduced by CO exposure. In cyanide poisoning the dose of sodium thiosulfate can be repeated if required, but only one dose of sodium nitrite should be given because of the risk of producing a high concentration of methemoglobinemia and exacerbating tissue hypoxia.

Adverse Effects

Sodium thiosulfate is relatively nontoxic. Large doses by mouth may cause profuse diarrhea. Hypernatremia and edema are possible. Injectable forms should be given slowly IV to minimize the risk of nausea, vomiting, and hypotension.

In humans, hypernatremia, hypotension, nausea and vomiting, diarrhea, diuresis, and metabolic acidosis have been reported and are thought to be due to both the intrinsic osmotic properties of sodium thiosulfate, and from thiocyanate formed when it is used to treat cyanide poisoning. Increased clotting times 1 to 3 days after dosing have also been reported. Sodium thiosulfate preparations may contain trace impurities of sodium sulfite; however, in an emergency sodium thiosulfate should not be withheld in subjects with sulfite hypersensitivity.

Reproductive/Nursing Safety

There were no teratogenic effects in the offspring of hamsters treated with sodium thiosulfate during pregnancy. Sodium thiosulfate reduces cyanide maternal toxicity in animal studies.[12,13] In addition sodium thiosulfate was not embryotoxic or teratogenic in rodents or rabbits at maternal doses of up to 580 mg/kg/day.

No lactation information was found; use when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In dogs the LD_{50} of IV sodium thiosulfate is greater than 3000 mg/kg.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

No specific drug interactions were noted.

Laboratory Considerations

- Sodium thiosulfate may produce clinically significant falsely increased chloride measurements, depending on the analyzer used.[14,15]

Dosages

DOGS, CATS:

Cyanide toxicity (extra-label): First give sodium nitrite 3% solution 10 – 20 mg/kg IV followed by sodium thiosulfate 25% solution 150 – 500 mg/kg IV bolus or CRI.[16] In mild cases sodium thiosulfate alone may be sufficient.

Treating extravasation injuries secondary to doxorubicin, carboplatin, cisplatin, and mechlorethamine infusions (extra-label): Prepare a 0.17 Mol/L solution by mixing 4 mL sodium thiosulfate 10% w/v with 6 mL sterile water for injection. Inject into extravasation site. **NOTE**: These are recommendations for human patients.[8–10]

HORSES:

Cyanide toxicity (extra-label): First give sodium nitrite 20% solution 10 – 20 mg/kg IV followed by sodium thiosulfate 20% solution 30 – 40 mg/kg IV[17]

Arsenic toxicity (extra-label): Sodium thiosulfate 20 – 30 grams per horse (NOT mg/kg) in 300 mL of water orally with dimercaprol (BAL) 3 mg/kg IM every 4 hours[18]

RUMINANTS:

Note: When used in food animals, FARAD states that this salt is rapidly excreted and not considered a residue concern in animal tissues; therefore a 24-hour preslaughter withdrawal interval (WDI) would be sufficient.[19]

Copper poisoning in combination with sodium molybdate (extra-label): In conjunction with fluid replacement therapy, sodium thiosulfate 500 mg with ammonium or sodium molybdate 200 mg PO daily for up to 3 weeks will help decrease total body burden of copper[20]

Cyanide toxicity secondary to cyanogenic plants (extra-label): Sodium thiosulfate in a 30% solution 660 mg/kg IV given rapidly using a 12- or 14- gauge needle.[21]

Arsenic poisoning: (extra-label) In a meta-analysis, the most commonly administered antidote was sodium thiosulfate 20 – 40 mg/kg IV every 8 hours and 80 mg/kg PO once a day, but one study using 40 mg/kg IV every 8 hours and 80 mg/kg PO once a day reported better outcomes. Administration of oral or IV fluids was highly associated with survival.[1]

Monitoring

For cyanide poisoning, vital signs (eg, respiratory rate, heart rate, blood pressure, CNS) and acid-base status.

For heavy metal poisoning, blood and/or urinary concentrations of the metal.

Client Information

- This agent should only be used with close professional supervision.

Chemistry/Synonyms

Sodium thiosulfate occurs as large, colorless, odorless crystals or coarse, crystalline powder. It is very soluble in water, deliquescent in moist air and effloresces in dry air at temperatures greater than 33°C (91.4°F).

Sodium thiosulfate may also be known as natrii thiosulfas, natrium thiosulfuricum, sodium hyposulphite, sodium thiosulphate, *Consept Step 2®*, *Hiposul®*, *Hyposulfene®*, or *S-hydril®*.

Storage/Stability

Unless otherwise stated by the manufacturer, store at room temperature 20° to 25°C (68°F-77°F); excursions permitted from 15°C to 30°C (59°F-86°F). Crystals should be stored in tight containers.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Sodium thiosulfate is **compatible** with sodium nitrate and sodium nitroprusside and is **not compatible** mixed with hydroxocobalamin.

No chemical incompatibility has been reported between sodium thiosulfate and sodium nitrite, when administered sequentially through the same IV line.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Sodium Thiosulfate for Injection: 10% (100 mg/mL, as pentahydrate) and 25% (250 mg/mL as pentahydrate) preservative-free in 10 mL and 50 mL single-use vials; generic; (Rx)

Sodium thiosulfate crystals or powder may be available from chemical suppliers, and the use of pharmaceutical grade (USP- or NF- designation) is recommended.

For the complete list of references, see **wiley.com/go/budde/plumb**

Somatotropin

Growth Hormone

(soe-ma-toe-***troe***-pin) *Posilac®*

Hormone

Prescriber Highlights

- ► Used for treatment of canine hypopituitary dwarfism; it may also be used to increase milk production in cows.
- ► Hypersensitivity reactions are possible. May cause irreversible diabetes mellitus in dogs
- ► Products used for dogs may be expensive and difficult to obtain.

Uses/Indications

Somatotropin may be useful in treating hypopituitary dwarfism. Historically, it was used to treat alopecia X (also previously known as growth hormone-responsive dermatosis) in adult dogs; however, somatotropin is no longer recommended given the current understating of the disease etiology.

Bovine somatotropin is indicated for increasing production of marketable milk in healthy lactating dairy cattle.

Pharmacology/Actions

Somatotropin (growth hormone) is responsible for and contributes to musculoskeletal growth (linear growth and increased bone and muscle mass) as well as other cellular and organ growth. It is also a factor in protein, carbohydrate, lipid, connective tissue, and mineral

metabolism, and it plays an important role in thymus development and T-cell function.

Pharmacokinetics

No canine-specific information was located. Somatotropin is a peptide, and elimination via the liver and kidneys would be expected.

Contraindications/Precautions/Warnings

Growth hormone is contraindicated in patients that are hypersensitive to it.

In humans, active malignancy is considered a contraindication for use of recombinant growth factor and increased risk for neoplasm is listed as a warning[1]; however, this is controversial.[2] The drug should not be used for growth promotion in pediatric patients with closed epiphyses.[1] Use somatotropin with caution in patients with impaired glucose tolerance or diabetes mellitus, and hypoadrenocorticism. Concurrent secondary adrenocortical insufficiency and hypothyroidism must be treated appropriately. Patients with hypothyroidism may experience a suboptimal response to somatotropin.

Lactating cows receiving bovine somatotropin may require diets that meet or exceed typical nutritional requirements.[3]

Adverse Effects

Growth hormone may cause diabetes mellitus in dogs and may be transient or permanent even after discontinuing treatment. Blood and urine glucose should be routinely monitored. Discontinue therapy if hyperglycemia occurs. Hypersensitivity reactions are possible, but less so if using products of porcine origin in dogs; porcine growth hormone appears to have little immunogenicity in dogs. Long-term treatment at high doses may cause acromegaly. Acromegaly in dogs can cause increased size of paws and head, increased skin folds around head and neck area, prognathism, and inspiratory stridor.

Cows receiving somatotropin may have increased body temperature and injection site reactions and are at increased risk for clinical mastitis.[3]

In humans receiving recombinant growth hormone, adverse effects include upper respiratory infections, fever, pharyngitis, otitis media, edema, arthralgia, paresthesia, myalgia, peripheral edema, hypothyroidism, pancreatitis, hyperglycemia, and impaired glucose tolerance.[1,4]

Reproductive/Nursing Safety

Because safety has not been established in small animal species, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute overdoses could cause hypoglycemia initially and then hyperglycemia. Blood glucose should be monitored, and supportive treatment (eg, dextrose or insulin) should be provided.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving somatotropin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- Glucocorticoids (eg, **dexamethasone, prednis(ol)one**): May inhibit the growth-promoting effect of somatotropin. If concurrent adrenal insufficiency is diagnosed, adjust glucocorticoid dose carefully to avoid negative effects on growth.
- Insulin/Oral Hypoglycemic Agents (eg, **glipizide, metformin**): Doses of hypoglycemic agents may require modification when somatotropin is initiated and/or discontinued.

Dosages

DOGS:

Hypopituitary dwarfism using porcine growth hormone (extra-label): 2 units/dog (NOT units/kg) SC every other day OR 0.1 unit/kg SC 3 times weekly for 4 to 6 weeks[5,6]; adjust dose based on clinical response and IGF-1 measurements. See ***Monitoring***. Improvement of skin and hair coat signs can be seen within 6 to 8 weeks. Because growth plates close rapidly, no significant change in stature (ie, minimal linear growth) is noted.

CATTLE:

Increasing production of marketable milk in lactating dairy cows: 500 mg (one syringe) SC every 14 days.[3] Start during the ninth or tenth week after calving and continue until the end of lactation. Recommended administration sites are the neck area, behind the shoulder, or in the depression on either side of the tailhead.

Monitoring

When used in dogs:

- Clinical efficacy
- Blood glucose (weekly)
- Urine glucose (daily)
- Baseline and periodic thyroid function and adrenal function

When used in lactating dairy cows:

- Milk output
- Mastitis

Client Information

- Clients should be instructed on the methods for SC injection and testing urine glucose.
- Be sure to understand the cost of this medicine, as it may be a barrier to treatment.
- Dogs treated with this medicine may develop diabetes mellitus that does not go away once the medicine is stopped.

Chemistry/Synonyms

Somatotropin may also be known as CB-311, hGH, human growth hormone, LY-137998, somatropinum; many trade names are available. The bovine somatotropin product is also known as sometribove zinc, BGH, rBGH. Synthetic recombinant human forms (rhGH) are known as somatropin.

Storage/Stability

Porcine growth hormone should be stored according to product label. Store the bovine somatotropin product under refrigeration (2°C-8°C [36°F-46°F]); do not freeze.[3] Avoid prolonged exposure to excessive heat or sunlight. Allow syringes to warm to room temperature (15°C-30°C [59°F-86°F]) before use.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

No FDA-approved formulations of porcine growth hormone are commercially available.

Bovine somatotropin, prolonged-release injectable: 500 mg sin-

gle-dose syringes in 25 or 100 count boxes; *Posilac*®; (OTC). Approved for use in lactating dairy cattle. Withdrawal intervals: slaughter, 2 weeks; milk, none. **NOTE**: This formulation is not suitable for canine use as it is a sustained release formulation and not easily diluted to smaller doses that are required for dogs.

HUMAN-LABELED PRODUCTS:
There are several manufacturers of human recombinant growth hormone (somatropin) products; however, these products are expensive, can cause immunogenicity reactions in dogs, and are not sold for veterinary use.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Sorbitol
(***sore***-bit-ahl)
Laxative/Cathartic

Prescriber Highlights
- ► Orally administered cathartic that is often used in combination with activated charcoal to accelerate expulsion of GI toxins or with sodium polystyrene sulfonate (SPS) for hyperkalemia
- ► Do not use as part of a retention enema due to risk for colonic necrosis.
- ► Adverse effects include loose stools, diarrhea, vomiting, and potential fluid and electrolyte disturbances (eg, hypernatremia).

Uses/Indications
Sorbitol is an osmotic laxative that can is typically used in combination with activated charcoal for GI decontamination or with sodium polystyrene sulfonate (SPS) for treating mild hyperkalemia. Sorbitol is also used as a sweetener (½ the sweetening power of sucrose).

Pharmacology/Actions
Sorbitol is a nonabsorbable sugar alcohol that acts as an osmotic laxative. Stool pH may be reduced in patients taking sorbitol, thus trapping ammonia in the stool, which may be useful in patients with hepatic encephalopathy.

Pharmacokinetics
Depending on dose and additional fluid consumed, sorbitol can have a laxative effect within 1 hour of dosing.

Contraindications/Precautions/Warnings
Do not use sorbitol mixed with sodium polystyrene sulfonate (SPS) as a retention enema. Retention enemas with sorbitol and SPS have been implicated in some human cases of colonic necrosis,[1] presumably secondary to sorbitol causing cellular dehydration.

When sorbitol is used in combination with activated charcoal, only the first dose should contain sorbitol, as multiple doses can increase the risks for hypernatremia and dehydration.

Adverse Effects
Products containing sorbitol may cause loose stools, diarrhea, and vomiting. Fluid and electrolyte imbalances are also possible.

There have been reports of hypernatremia occurring in small dogs and cats after activated charcoal and sorbitol administration, presumably due an osmotic effect pulling water into the GI tract. Administration of reduced-sodium IV fluids (eg, 5% dextrose, 0.45% sodium chloride with 2.5% dextrose) in conjunction with warm water enemas may be helpful to alleviate hypernatremia.

Reproductive/Nursing Safety
Safe use during nursing has not been established but it is unlikely to pose much risk to nursing offspring. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
Overdoses or multiple doses can cause fluid and electrolyte disorders including dehydration and hypernatremia.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving sorbitol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.
- **Sodium Polystyrene Sulfonate (SPS)**: Although commonly used together for oral administration in veterinary patients, there is an increased risk for colon necrosis, especially if used as a retention enema.

Laboratory Considerations
- Sorbitol may cause false-positive ethylene glycol test results.

Dosages
DOGS/CATS:

Adjunctive treatment for toxin ingestion using sorbitol with activated charcoal (extra-label): Using activated charcoal containing sorbitol, 1 – 2 g/kg PO but doses up to 5 g/kg have been described. Charcoal with sorbitol is commonly employed (only with the first dose) to shorten GI transit time. For drugs and toxins that undergo enterohepatic recirculation (eg, caffeine, phenobarbital, theobromine, theophylline, bromethalin, pyrethrins, marijuana, NSAIDs, organophosphate insecticides, ivermectin, digoxin, antidepressants), multiple subsequent doses of activated charcoal WITHOUT sorbitol at 1 – 2 g/kg PO every 4 to 8 hours for 24 to 48 hours are recommended. Dogs and cats with no clinical signs may freely consume the charcoal suspension if administered via syringe. A small amount of food may be added to the solution to enhance palatability.[2] In animals exhibiting clinical signs, administration of activated charcoal suspensions may be done via a nasogastric tube, as it may be better accepted, easier to place (especially in cats), and offer a greater margin of safety; always ensure adequate airway protection.[3–6] There is little need to administer a cathartic if significant diarrhea is already present. See also ***Charcoal, Activated.***

Adjunctive treatment of hyperkalemia using sorbitol with sodium polystyrene sulfonate (SPS) (extra-label): SPS resin 2 g/kg mixed with 70% sorbitol PO, DIVIDED into 3 to 4 doses per day. Do not mix with potassium-rich foods (eg, bananas, potatoes).[7,8] See also ***Sodium Polystyrene Sulfonate***.

Shorten GI transit time, cathartic (extra-label): 0.5 – 2 mL/kg PO once daily, adjusted to effect[9]

HORSES:

Cathartic for plant intoxications using sorbitol with activated charcoal (extra-label): 70% sorbitol 3 mL/kg mixed with an activated charcoal slurry 1 – 5 g/kg (≈1 g of activated charcoal/5 mL of water). There is little need to administer a cathartic if significant diarrhea is already present.[10] See also ***Charcoal, Activated.***

Monitoring
- Monitoring for efficacy of charcoal is usually dependent on the toxin/drug's mechanism of action, extent of toxicity, and patient's clinical signs.

- When sorbitol is given with activated charcoal, repeated serum sodium measurements (eg, every 8 to 12 hours) are recommended to address potential hypernatremia before clinical signs (eg, tremors, ataxia, seizures) occur. Serum sodium increases can be seen 6 to 10 hours after cathartic administration.[11]
- Hydration status

Client Information

- This medicine may cause diarrhea, excess gas (flatulence), cramping, and vomiting.
- Although sorbitol is available without a prescription, do not give this medicine without first consulting your veterinarian.

Chemistry/Synonyms

Sorbitol is a sugar alcohol and occurs as a white, odorless, hygroscopic powder, granules, or crystalline masses having a sweet taste with a cold sensation. It is very soluble in water; it is sparingly soluble in alcohol and practically insoluble in solvent ether.

Sorbitol may also be known as D-glucitol, E420, D-sorbitol, sorbitoli, sorbitolis, sorbitolum, or szorbit.

Storage/Stability

Store the 70% oral solution at controlled room temperature (20°C-25°C [68°F-77°F]).

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Only available in combination products.

Oral Suspension: Sorbitol 10%, activated charcoal 10%, and kaolin 6.25% in 240 mL bottles; *Toxiban® Suspension with Sorbitol*; (OTC)

Oral Granules: Sorbitol 20%, activated charcoal 47.5%, and kaolin 10% in 1 lb jars and 5 kg pails; *Toxiban® Granules*; (OTC)

HUMAN-LABELED PRODUCTS:

Sorbitol 70% Enema Solution: 16 oz; generic; (OTC)

In combination with activated charcoal:

Activated Charcoal Oral Suspension in Sorbitol Base: Sorbitol 26 g and activated charcoal 25 g in 120 mL; *Insta-Char®;* and Sorbitol 48 g and activated charcoal 25 g in 120 mL containers and sorbitol 96 g and activated charcoal 50 g in 240 mL containers; *ActiDose® with Sorbitol*; (OTC)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Sotalol

(***soh***-ta-lole) *Betapace®*

Beta-Adrenergic Antagonist

Prescriber Highlights

- ► Nonselective beta-adrenergic receptor antagonist and potassium channel blocker commonly used to control ventricular tachyarrhythmias, as well as some forms of supraventricular tachyarrhythmia in dogs, cats, and horses
- ► Contraindicated in patients hypersensitive to it, with asthma, sinus bradycardia, second- or third-degree AV block, sick sinus syndrome, hypokalemic bradycardia, long QT syndromes, cardiogenic shock, or uncontrolled congestive heart failure (CHF).
- ► Use with caution in patients with controlled CHF, decreased myocardial function, diabetes mellitus, or hyperthyroidism.
- ► Dose reduction or extended dosing intervals may be needed for patients with renal dysfunction.
- ► Most serious adverse effects include negative inotropic and pro-arrhythmic effects but dyspnea, bronchospasm, fatigue, and nausea or vomiting are also possible.

Uses/Indications

Sotalol can be useful in the long-term oral management of ventricular and supraventricular tachycardias in dogs, cats, and horses. It is used alone or as combination therapy (eg, mexiletine) in dogs with ventricular tachycardia that are refractory to IV antiarrhythmic therapy (eg, lidocaine, procainamide, amiodarone), in boxer dogs, and in other breeds with arrhythmogenic right ventricular cardiomyopathy (ARVC), and in German shepherd dogs with inherited arrhythmias.[1] Although research data support its efficacy to suppress ventricular ectopy, it is unknown if it significantly impacts survival, particularly when compared with other therapies.[2,3] Sotalol has been used for the treatment of supraventricular tachyarrhythmias such as in dogs with accessory pathway-mediated reciprocating tachycardia,[4] in a dog with atrial flutter,[5] and in a cat with supraventricular tachycardia.[6]

In horses, it has been used to treat both supraventricular and ventricular tachyarrhythmias.[7–9] Based on a small clinical trial,[10] sotalol may lower the cardioversion threshold for atrial fibrillation in horses and has been postulated to have potential for limiting recurrence of atrial fibrillation in that species.[11]

Pharmacology/Actions

Sotalol is a nonselective beta-blocker and class III antiarrhythmic agent (potassium channel blocker). The beta-blocking activity of sotalol is ≈30% that of propranolol. The pharmacologic action is believed to be caused by selectively inhibiting potassium channels. Like other class III drugs, it prolongs repolarization and refractoriness without affecting conduction. In animals with supraventricular tachycardias, sotalol may be more effective in preventing recurrence of the arrhythmia than in terminating it.

Pharmacokinetics

Unlike propranolol, sotalol does not have any appreciable first pass effect after oral administration. Food may reduce the bioavailability of sotalol by ≈20% in humans and, if given on an empty stomach, bioavailability is 90% to 100%. Peak plasma concentrations occur between 2 to 4 hours after a dose. The drug has relatively low lipid solubility and virtually no protein binding. Elimination is almost all via the kidney and most of the drug is excreted unchanged. In dogs, sotalol's elimination half-life is 5 hours; in humans, it is ≈12 hours.

In horses, after IV administration of 1 mg/kg, maximum plasma concentration, clearance, and elimination half-life were 1624 ng/mL, 0.15 L/hour/kg, and 8.7 hours, respectively. When the same dose was administered orally, maximum plasma concentration, time to reach

maximum plasma concentration, clearance, elimination half-life, and bioavailability were 317 ng/mL, 0.9 hours, 0.15 L/hour/kg, 15.2 hours, and 47.8%, respectively.[12] In a follow-up study, mean steady-state plasma concentrations were 287 ng/mL (range 234 to 339), 409 ng/mL (359 to 458), and 543 ng/mL (439 to 646) for oral dosages of 2, 3, and 4 mg/kg (respectively) of sotalol given orally every 12 hours over 9 days.[13] Pharmacodynamic effects in the horse include a significant increase in QT interval and the effective refractory period after oral dosing.[13]

In dogs, sotalol administered at 1 – 2 mg/kg orally twice daily for 12 to 16 days resulted in a 5.8% mean reduction in ejection fraction by echocardiography and a reduction in maximum heart rate of 17 beats per minute on 24-hour Holter monitor, demonstrating mild negative inotropic and chronotropic effects in healthy dogs.[14]

Contraindications/Precautions/Warnings

Sotalol is contraindicated in patients hypersensitive to it and in patients with asthma, sinus bradycardia, second- or third-degree heart block (unless artificially paced), sick sinus syndrome, hypokalemia, long QT syndromes, cardiogenic shock, or uncontrolled congestive heart failure (CHF). Because of the potential for negative inotropic effects, use with caution in controlled CHF and in those with decreased myocardial function. Also, use sotalol with caution in patients with diabetes mellitus or hyperthyroidism, as it may mask clinical signs associated with both conditions. Use with caution in patients with renal dysfunction; dosages may need to be decreased or dosage intervals may need to be extended.

Adverse Effects

Primary concerns with sotalol in dogs are the potential for negative inotropic, chronotropic, and proarrhythmic effects. These effects generally are not clinically important if dosage is not excessive. Rarely, dogs receiving sotalol will demonstrate an increase in arrhythmia number or complexity on follow-up ambulatory ECG; it is not well studied how often this perceived proarrhythmic effect occurs nor is it known which patient factors may contribute. Other potential adverse effects include dyspnea, bronchospasm, fatigue/dizziness, nausea, and vomiting.[15] Sotalol's beta-blocking effects can worsen syncope or cause lethargy, particularly if the ventricular tachyarrhythmia coexists with intermittent bradycardia (eg, AV block).

Reproductive/Nursing Safety

Sotalol did not cause any fetotoxicity or teratogenicity when given to pregnant laboratory animals at high dosages, but clear safety in pregnancy has not been established.

Sotalol enters human breastmilk in concentrations ≈5 times those found in the serum and is not recommended for use in nursing humans.[15] Consider using a milk replacer in nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses may result in panting, bradycardia, lethargy, vomiting, hypotension, CHF, bronchospasm, and hypoglycemia. Use GI decontamination (if not contraindicated) when significant risk of morbidity is possible. Treat adverse effects symptomatically and supportively.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sotalol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amiodarone**: May prolong refractory periods; concurrent use not recommended in human patients
- **Anesthetics, General**: Additive myocardial depression may occur with the concurrent use of sotalol and myocardial depressant anesthetic agents.
- **Antacids, Aluminum- or Magnesium- Containing**: May reduce oral sotalol absorption; separate doses by at least 2 hours.
- **Antiarrhythmics, Class 1A** (eg, **disopyramide, procainamide, quinidine**): May prolong refractory periods; concurrent use not recommended in human patients; may also prolong QT interval
- **Antiarrhythmics, Class 1B, 1C** (eg, **lidocaine, mexiletine, phenytoin**): May prolong QT interval
- **Azithromycin**: May increase risk for cardiotoxicity
- **Beta-2-Adrenergic Agonists** (eg, **metaproterenol, terbutaline, albuterol**): May have their actions blocked by sotalol
- **Calcium Channel Blockers** (eg, **diltiazem, verapamil**): Potential to increase hypotensive effects; may have additive effects on AV conduction or ventricular function; use with caution, particularly in patients with pre-existing cardiomyopathy or CHF.
- **Cisapride**: May prolong QT interval
- **Clonidine**: If clonidine is discontinued after concomitant therapy with sotalol, there is an increased risk for rebound hypertension.
- **Digoxin**: Potential for increased risks for proarrhythmic events
- **Diuretics** (eg, **furosemide**): May increase risk for cardiotoxicity
- **Erythromycin; Clarithromycin**: May prolong QT interval
- **Fluoroquinolones**: May increase risk for QT interval prolongation
- **Fluoxetine**: May increase risk for cardiotoxicity
- **Lidocaine**: Clearance may be impaired by sotalol
- **Methimazole, Carbimazole**: May result in altered metabolism of sotalol
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs**; May decrease antihypertensive effect of sotalol
- **Phenothiazines** (eg, **acepromazine**): May prolong QT interval
- **Reserpine**: May have additive effects (hypotension, bradycardia) with sotalol
- **Sympathomimetics** (eg, **phenylpropanolamine**): May have their actions blocked by sotalol
- **Tricyclic Antidepressants (TCAs;** eg, **amitriptyline, clomipramine**): May prolong QT interval

Laboratory Considerations

- Beta-adrenergic antagonists may potentiate hypoglycemia and interfere with **glucose** or insulin tolerance tests.
- Sotalol may falsely elevate urine **metanephrine** concentrations (pheochromocytoma screen) if using a fluorometric or photometric assay.

Dosages

DOGS/CATS:

Nonurgent control of ventricular tachyarrhythmias ± supraventricular tachycardia (extra-label): Anecdotal dosage range recommendations are 1 – 3.5 mg/kg (most clinicians advocate 2 – 2.5 mg/kg) PO every 12 hours. Often, patients are initially started at the low end of the dosing range and the dosage is escalated based on control of the arrhythmia. Patients with significant

renal dysfunction may require reduced dosages or increased time between dosages.

Ventricular tachyarrhythmias associated with arrhythmogenic right ventricular cardiomyopathy (ARVC; eg in boxers) (extra-label):

a) **Single agent**: 1.5 – 3.5 mg/kg PO twice daily[2]

b) **In combination with mexiletine**: Sotalol 1.5 – 3 mg/kg PO twice daily in combination with mexiletine 5 – 7.5 mg/kg PO 3 times daily.[16,17] Evidence in normal dogs suggests that when mexiletine is used with sotalol in dogs weighing more than 10 kg, mexiletine could be dosed at 8 – 10 mg/kg PO every 12 hours, though confirmation in clinically affected dogs is needed.[18]

Ventricular arrhythmias in German shepherds with inherited arrhythmias (extra-label): Sotalol 2.5 mg/kg PO every 12 hours in combination with mexiletine 8 mg/kg PO every 8 hours were more effective than either drug alone in suppressing ventricular premature complexes. Mexiletine concentrations were also higher when sotalol was added.[1]

HORSES:

Lower cardioversion threshold and prevent recurrence of atrial fibrillation in horses (extra-label): Sotalol at 2 – 3 mg/kg PO twice daily used for 3 days before cardioversion and for a few weeks after has been proposed as a potential strategy to reduce the risk of recurrent atrial fibrillation though this has not been confirmed by clinical studies.[10,11]

Control of ventricular arrhythmias (extra-label): Sotalol 1 – 2 mg/kg PO twice daily for 1 day, followed by 2 – 3 mg/kg PO twice daily[9]

Monitoring

- Efficacy: ECG, heart rate, and pulse
- Resting respiratory rate
- Blood pressure
- Adverse effects (eg, dyspnea, bronchospasm, lethargy, syncope, nausea/vomiting, worsening of arrhythmias, and progression of heart failure)

Client Information

- Sotalol is best given on an empty stomach.
- Most common side effects include lack of energy and weakness, poor appetite, and vomiting. Contact your veterinarian if these signs persist or worsen.
- If your animal has trouble breathing or has episodes of collapse, call your veterinarian immediately.
- Your veterinarian may start with a low dose and gradually increase the dose. Do not administer more than your veterinarian prescribes.
- Your veterinarian will need to monitor your animal closely while it is taking this medication. Do not miss these important follow-up visits.

Chemistry/Synonyms

A non-selective beta-adrenergic antagonist and class III antiarrhythmic agent, sotalol HCl is a racemic mixture of the d- and l- forms. Both isomers exhibit antiarrhythmic (class II) activity, but only the levo- form has beta-adrenergic receptor antagonist activity. Sotalol HCl occurs as white, crystalline solid that is soluble in water.

Sotalol may also be known as MJ-1999, d,l-sotalol hydrochloride, or sotaloli hydrochloridum; many trade names are available.

Storage/Stability

Store tablets at room temperature.

Compatibility/Compounding Considerations

Spectinomycin

(spek-ti-noe-***mye***-sin) *Spectogard®*

Aminocyclitol Antibiotic

Prescriber Highlights

- ► Aminocyclitol antibiotic used primarily in food-producing animals; relatively broad spectrum but minimal activity against anaerobes and most strains of *Pseudomonas* spp
- ► Contraindicated in patients hypersensitive to it
- ► Adverse effects appear to be minimal at labeled dosages; can cause neuromuscular blockade and swelling at SC injection sites

Uses/Indications

Spectinomycin is FDA-approved for infectious synovitis and *chronic respiratory disease* in chickens and for *bacterial enteritis* (scours) in swine. It is only rarely used in dogs, cats, and horses for susceptible infections, and there are no suitable dosage forms available for these species. There are FDA-approved uses in cattle and dogs but no currently available products. In addition, spectinomycin/lincomycin combination products are FDA-approved for *airsacculitis and chronic respiratory disease in chickens*.

The World Health Organization (WHO) has designated spectinomycin as an Important antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) Antimicrobial Classification has designated spectinomycin as a Veterinary Critically Important antimicrobial.

Pharmacology/Actions

Spectinomycin is primarily a bacteriostatic antibiotic that inhibits protein synthesis in susceptible bacteria by binding to the 30S ribosomal subunit.

Spectinomycin has activity against a wide variety of gram-positive and gram-negative bacteria, including *Escherichia coli*, *Klebsiella* spp, *Proteus* spp, *Enterobacter* spp, *Salmonella* spp, *Streptococcus* spp, and *Staphylococcus* spp. It has minimal activity against anaerobes, most strains of *Pseudomonas* spp, *Chlamydia* spp, *Moraxella bovis,* or *Treponema* spp.

In human medicine, spectinomycin is used principally for its activity against *Neisseria gonorrhoeae*.

Pharmacokinetics

After oral administration, only ≈7% of the dose is absorbed, but the drug that remains in the GI tract is active. When injected SC or IM, the drug is reportedly absorbed well, with peak levels occurring in ≈1 hour.

Tissue levels of the absorbed drug are lower than those found in

the serum. Spectinomycin does not appreciably enter the CSF or the eye and is not bound significantly to plasma proteins.

The absorbed drug is excreted via glomerular filtration into the urine, mostly unchanged. In cattle, the terminal half-life is ≈2 hours.

Contraindications/Precautions/Warnings

Spectinomycin is contraindicated in patients hypersensitive to it.

Adverse Effects

When used as labeled, adverse effects are unlikely with this drug. It is reported that parenteral use of this drug is much safer than with other aminocyclitol antibiotics, but little is known regarding its prolonged use. Hypersensitivity reactions and injection site reactions have been reported.[2] Spectinomycin could potentially cause neuromuscular blockade; parenteral calcium administration will generally reverse the blockade.

Adverse effects that have been reported in human patients receiving the drug in single or multidose studies include soreness at the injection site, rash, increases in BUN, alkaline phosphatase, and ALT, and decreases in hemoglobin, hematocrit, and creatinine clearance. Although increases in BUN and decreases in creatinine clearance and urine output have been noted, overt renal toxicity has not been demonstrated with this drug.

Cattle receiving the sulfate form subcutaneously have developed swelling at the injection site.

Reproductive/Nursing Safety

It is unknown whether spectinomycin crosses the placenta. Spectinomycin is excreted into milk.[3]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located on oral overdoses, but because the drug is negligibly absorbed after oral administration, significant toxicity is unlikely via this route.

Cattle receiving 150 mg/kg/day SC for 5 days experienced injection site reactions.[2] Injected doses of 90 mg produced transient ataxia in turkey poults.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with spectinomycin have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Chloramphenicol**: Antagonism has been reported when used with spectinomycin.
- **Tetracycline**: Antagonism has been reported when used with spectinomycin.

Dosages

SMALL MAMMALS:

Rabbits; susceptible infections (extra-label): 1 g/L in drinking water for 7 days in weanling rabbits; may cause diarrhea[4]

SWINE:

Bacterial enteritis (white scours) in piglets associated with *E coli* susceptible to spectinomycin (label dose; FDA-approved): Piglets weighing less than 4.5 kg (10 lb): 50 mg/piglet (NOT mg/kg) PO twice daily for 3 to 5 days; Piglets weighing more than 4.5 kg (10 lb): 100 mg/piglet (NOT mg/kg) PO twice daily for 3 to 5 days.[5]

BIRDS:

Prevention and control of chronic respiratory disease associated with *Mycoplasma gallisepticum* in broilers (label dose; FDA-approved): Add sufficient amount to drinking water to attain a final concentration of 2 g/gallon. (Label directions; *Spectam® Water-Soluble*)[6]

Infectious synovitis associated with *Mycoplasma synoviae* in broilers (label dose; FDA-approved): Add sufficient amount to drinking water to attain a final concentration of 1 g/gallon. (Label directions; *Spectam® Water-Soluble*)[6]

Monitoring

- Clinical efficacy

Chemistry/Synonyms

Spectinomycin, an aminocyclitol antibiotic obtained from *Streptomyces spectabilis*, is available as the dihydrochloride pentahydrate and hexahydrate sulfate salts. It occurs as a white to pale buff, crystalline powder with pK_a of 7 and 8.7. It is freely soluble in water and practically insoluble in alcohol.

Spectinomycin may also be known as M-141, actinospectacin, spectinomycini, U-18409AE, *Adspec®*, *Amtech Spectam®*, *Kempi®*, *Kirin®*, *Spectoguard Scour-Chek®*, *Stanilo®*, *Togamycin®*, *Trobicin®*, *Trobicine®*, or *Vabicin®*.

Storage/Stability

Unless otherwise instructed by the manufacturer, store spectinomycin products at room temperature (15°C to 30°C [59°F to 86°F]). Protect from freezing.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Spectinomycin Water Soluble Powder: 0.5 g of spectinomycin per gram in 1 kg containers. *Spectogard® Water Soluble Powder*; (Rx). FDA-approved for use in broiler chickens (not layers). Slaughter withdrawal (at labeled doses) = 5 days.

Spectinomycin Oral Solution: 50 mg/mL in 240 mL pump bottle, 1000 mL pump bottle, and 1-gallon refill without pump; *Spectogard Scour-Chek®*, (OTC). FDA-approved for use in swine (weighing less than 6.8 kg [15 lb] and not older than 4 weeks of age). Slaughter withdrawal (at labeled doses) = 21 days.

The following products are listed in FDA's Green Book of approved animal drugs but may no longer be commercially available in the US:

- Spectinomycin Dihydrochloride Oral Tablets: 100 mg; (Rx)
- Spectinomycin Dihydrochloride Injection: 100 mg/mL; (Rx)
- Spectinomycin Sulfate Injection: 100 mg/mL in 500 mL vials; *Adspec®*; (Rx). When used as labeled, slaughter withdrawal in cattle = 11 days; not to be used in veal calves or in dairy cattle 20 months of age or older
- Spectinomycin Dihydrochloride Pentahydrate Injection: 100 mg/mL, *Prospec®*; (OTC). For use in 1 to 3 days old chicks and poults
- Spectinomycin/Lincomycin in a 2:1 ratio; in 2.65 oz packets. Each packet contains lincomycin 16.7 g and spectinomycin 33.3 g; *LS 50 Water Soluble Powder®*, *SepcLinx-50®*, generic; (Rx). FDA-approved for use in chickens up to 7 days of age

HUMAN-LABELED PRODUCTS: NONE

Spinosad

(***spin***-oh-sad) *Comfortis®, Trifexis®*

Oral Flea Adulticide

Prescriber Highlights

- ► Oral flea adulticide for dogs and cats; labeled for one month prevention/treatment; not effective for flea eggs or other immature flea forms
- ► Combination product with milbemycin approved for dogs for heartworm prevention, prevention and treatment of flea infestations, and for the treatment and control of adult hookworms, roundworms, and whipworms.
- ► Fast onset of action; fleas begin to die within 30 minutes of administration
- ► Appears safe and well tolerated in dogs and cats.
- ► Give with food.
- ► Potentially serious drug interaction with extra-label doses of ivermectin (and possibly other drugs)

Uses/Indications

In dogs, oral spinosad is FDA-approved for the prevention and treatment of flea (*Ctenocephalides felis*) infestations for one month in dogs 14 weeks of age and older and weighing 2.2 kg (5 lb) or more.[1] Spinosad has also been shown to be effective in the prevention of *Pulex irritans* (human flea) infestation in dogs that live in close proximity to flea-infested sheep.[2]

In cats, oral spinosad is FDA-approved to kill fleas (*C felis*) and for the prevention and treatment of flea infestations (*C felis*) for one month in cats 14 weeks of age and older and weighing 1.8 kg (4.1 lb) or more.[1]

Spinosad is not labeled for use against ticks and it has been stated as not effective for this use; however, in a pilot study evaluating the efficacy of spinosad dosed at 50 mg/kg (1.7 times minimum flea dose) and 100 mg/kg (3.3 times minimum flea dose) against adult brown dog tick (*Rhipicephalus sanguineus*) infestations in dogs, ≈95% of ticks were killed within 24 hours of dosing. The results suggested that some posttreatment residual tick control persisted up to 1 month.[3]

The spinosad/milbemycin combination product is FDA-approved for the prevention of heartworm infection (*Dirofilaria immitis*), for the prevention and treatment of flea infestations (*C felis*), and for the treatment and control of adult hookworm (*Ancylostoma caninum*), adult roundworm (*Toxocara canis* and *Toxascaris leonina*) and adult whipworm (*Trichuris vulpis*) infections in dogs 8 weeks of age or older and weighing 2.2 kg (5 lb) or more.[4] Monthly treatments with spinosad/milbemycin may prevent *Angiostrongylus vasorum* (French heartworm) infection in dogs.[5]

Pharmacology/Actions

Spinosad is a macrocyclic lactone containing a combination of two naturally occurring macrocyclic lactones (spinosyn A and spinosyn D). Its primary mode of action in insects is as a nicotinic acetylcholine D-alpha receptor agonist causing involuntary muscle contractions and tremors secondary to motor neuron activation.[6] Prolonged exposure causes paralysis and flea death. Flea death is rapid, beginning within 30 minutes of dosing and is complete in 4 hours in dogs and 24 hours in cats.[1] In insects, spinosad also opens chloride channels similarly to other macrocyclic lactones.

Pharmacokinetics

After oral administration of spinosad (with food) to dogs, peak plasma concentrations for spinosyn A and spinosyn D occur in ≈2 and 3 hours, respectively. Spinosyn D concentrations are ≈5 times greater than those of spinosyn A. Spinosyn A and D are extensively bound (≈99%) to canine plasma proteins. Spinosad is hepatically biotransformed with glutathione conjugates and 70% to 90% is eliminated in the feces via the bile. The plasma elimination half-life is ≈10 days.

Contraindications/Precautions/Warnings

There are no labeled contraindications.

For treatment of flea infestations, it is recommended to combine treatment with an insect growth regulator or insect development inhibitor (eg, methoprene, lufenuron) as well as environmental control measures.

It has been recommended not to use spinosad in combination with high extra-label doses of ivermectin due to potential severe neurotoxicity.[7,8]

Use with caution in breeding females and dogs with pre-existing epilepsy at higher than label dosages as this may decrease seizure threshold.[1,4]

The chewable tablets are beef flavored and although they do not contain beef proteins, pork proteins and hydrolyzed soy are used. Dogs with pork or soy allergies may develop adverse effects.[9]

A study evaluating the safety of spinosad (doses up to 5 times the maximum label recommendation) with or without milbemycin (doses up to 10 times the maximum label recommendation) in collies homozygous and heterozygous for the *MDR1* mutation (also known as *ABCB1*-1delta) did not cause signs of neurotoxicosis.[10]

When using the spinosad/milbemycin combination product for dogs, ensure the patient has recently tested negative for heartworm; do not use in patients with heartworm infection.

Adverse Effects

Spinosad appears to be well tolerated in dogs and most animals will not show any adverse effects after dosing. In field studies, vomiting was the most frequent adverse effect, occurring in up to 12% of dogs.[6] The following additional adverse effects are possible and based on postapproval adverse drug event reporting (listed in decreasing order of frequency): depression/lethargy, anorexia, ataxia, diarrhea, pruritus, trembling, hypersalivation, and seizures.[1]

In cats, adverse effects are infrequent but vomiting (≈14%), lethargy, reduced appetite, weight loss, and diarrhea have been reported.[1]

Reproductive/Nursing Safety

Use spinosad and spinosad/milbemycin with caution in breeding bitches; however, the drug appears to be relatively safe to use during pregnancy and lactation.[1,4] In female beagles dosed at 1.3 times and 4.4 times the recommended dose every 28 days prior to mating, during gestation, and during a 6 week lactation period, no changes in dam conception rates or mortality, body temperature, necropsy, or histopathology were seen in dams or puppies.[6] Treated dams experienced more frequent vomiting, especially at 1 hour postdose, than control dams.[11] Puppies from dams treated at 1.3 times the recommended rate had lower body weights; those from the 4.4 times group experienced more lethargy, dehydration, weakness, and felt cold to the touch. Safe use in breeding males has not been evaluated.

Safe use in breeding, pregnant, or lactating cats has not been evaluated.[6]

In a pilot study in 3 dogs, spinosyns were excreted in milk at concentrations ≈2.5 times of that found in the plasma.[6] Puppy mortality and morbidity was highest in puppies from the dam with the highest spinosyn milk concentrations, but causal effect cannot be inferred due to the small sample size of the study.

Overdose/Acute Toxicity

Spinosad appears to be safe in mammals, with an oral LD_{50} in mice and rats of more than 5000 mg/kg.[12] Acute overdoses in dogs appear to be relatively harmless. Common adverse effects seen in dogs with a spinosad overdose include lethargy, vomiting, ataxia, and trembling; with vomiting the most common adverse effect in cats. In a

dose tolerance study in adult beagles dosed orally up to 100 mg/kg PO once daily (16.7 times recommended dose) for 10 consecutive days, vomiting was routinely seen after the dose was administered.[6] No significant changes in hematology, blood coagulation, or urinalysis parameters were noted, but phospholipidosis (vacuolation) of the lymphoid tissue and mild elevations in ALT occurred in all dogs.

Vomiting and anorexia was noted in kittens receiving monthly oral doses as high as 500 mg/kg.[6] Phospholipidosis occurred in the liver, lung, and adrenal gland of dogs (4.4 times label dosage for 6 months) and cats (3 times label dosage for 6 months)[6]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving spinosad and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Ivermectin**: It has been recommended not to use spinosad with high extra-label doses of ivermectin,[7] as spinosad can increase the plasma concentrations of ivermectin in dogs with the area under curve (AUC) increasing 3.6-fold.[13] When used with heartworm preventives at their label dosages, spinosad appears safe to use. No signs of neurotoxicosis were seen in collies homozygous and heterozygous for the MDR1 genetic mutation receiving up to 5 times the recommended spinosad label dose with or without milbemycin (up to 10 times the recommended label dose).[10]
- **Other Drugs Affected By P-Glycoprotein Inhibitors**: Spinosad has been shown to be a substrate and potent inhibitor of canine p-glycoprotein, and other orally dosed drugs such as cyclosporine, verapamil, ketoconazole, or loperamide could potentially interact at the level of the intestinal tract. Because spinosad is so highly bound to plasma proteins, the risk for additional interactions at the blood-brain barrier appear to be limited.[14]

Laboratory Considerations

- No specific concerns noted.

Dosages

DOGS:

Spinosad as a single agent - prevention and treatment of flea infestations in dogs 14 weeks of age and older and weighing 2.2 kg (5 lb) or more (label dosage; FDA-approved): Given orally once a month with food at the minimum dosage of spinosad 30 mg/kg.[1] Dogs weighing more than 54.5 kg (120 lb) should be administered the appropriate combination of tablets. See weight-based dosage table below specifically for dogs. **NOTE**: Do not use the cat dosing table for dogs as overdoses could occur.

Body weight in kg (lb)	Spinosad per tablet (mg)	Number of tablets to administer
2.3-4.5 (5-10)	140	1
4.6-9.1 (10.1-20)	270	1
9.1-18.2 (20.1-40)	560	1
18.2-27.3 (40.1-60)	810	1
27.3-54.5 (60.1-120)	1620	1

Spinosad/Milbemycin - prevention of heartworm disease, prevention and treatment of flea infestations, and treatment and control of adult hookworm, adult roundworm, and adult whipworm infections in dogs 8 weeks of age or older and weighing 2.2 kg (5 lb) or more (label dosage; FDA-approved): Given orally once a month at the minimum dosage of spinosad 30 mg/kg with milbemycin oxime 0.5 mg/kg.[4] For heartworm prevention, give once monthly for at least 3 months after exposure to mosquitoes. Dogs weighing more than 54.5 kg (120 lb) should be administered the appropriate combination of tablets. See weight-based dosage table below.

Body weight in kg (lb)	Spinosad/Milbemycin per tablet (mg)	Number of tablets to administer
2.3-4.5 (5-10)	140/2.3	1
4.6-9.1 (10.1-20)	270/4.5	1
9.1-18.2 (20.1-40)	560/9.3	1
18.2-27.3 (40.1-60)	810/13.5	1
27.3-54.5 (60.1-120)	1620/27	1

CATS:

Prevention and treatment of flea infestations in cats 14 weeks of age and older and weighing 1.8 kg (4.1 lb) or more (label dosage; FDA-approved): Given orally once a month at the minimum dosage of spinosad 50 mg/kg just prior to or after feeding, once monthly.[1] Alternatively, it may be offered in food or administered like other tablet medications. For cats weighing more than 10.9 kg (24 lb), the appropriate combination of tablets should be administered. See weight-based dosage table below specifically for cats. **NOTE**: Do not use the dog dosing table for cats as underdosing could occur.

Body weight in kg (lb)	Spinosad per tablet (mg)	Number of tablets to administer
1.9-2.7 (4.1-6)	140	1
2.8-5.5 (6.1-12)	270	1
5.5-10.9 (12.1-24)	560	1

Monitoring

- Efficacy and adverse effects
- Heartworm status prior to administration of *Trifexis*® to dogs

Client Information

- Spinosad is an oral tablet given monthly that kills adult fleas on dogs and cats. It begins to kill fleas 30 minutes after dosing. When used alone, this medicine does not kill flea eggs or other immature flea forms. Your veterinarian will talk with you about a flea control program. This medicine does not kill ticks.
- The spinosad/milbemycin oral combination product is given monthly to kill adult fleas, prevent heartworm infection, and control hookworms, roundworms, and whipworms in dogs. This combination product does not kill ticks.
- Give this medicine with food or immediately after a meal.
- When used as directed on the label, this medication appears safe.
- Keep chewable tablets well out of reach of children and animals.

Chemistry/Synonyms

Spinosad is a spinosyn class insecticide and contains two major factors, spinosyn A and spinosyn D, that are both derived from the naturally occurring bacterium, *Saccharopolyspora spinosa*. Spinosad may also be known as spinosyn A and D, DE-105, or XDE-105. Trade names include *Comfortis*®, *Natroba*® (human topical), *Acuguard*®, or *Extinosad*®.

Storage/Stability

Chewable tablets should be stored at 20°C to 25°C (68°F-77°F). Excursions are permitted between 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

No specific information noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Spinosad Chewable Tablets: 140 mg (dogs 2.3-4.5 kg [5-10 lb]), 270 mg (dogs 4.6-9.1 kg [10.1-20 lb]), 560 mg (dogs 9.1-18.2 kg [20.1-40 lb]), 810 mg (dogs 18.2-27.3 kg [40.1-60 lb]), 1620 mg (dogs 27.3-54.5 kg [60.1-120 lb]); *Comfortis*®; (Rx). FDA-approved for use in dogs. Dogs over 54.5 kg (120 lb) should be administered the appropriate combination of tablets.

Spinosad Chewable Tablets: 140 mg (cats 1.9-2.7 kg [4.1-6 lb]), 270 mg (cats 2.8-5.5 kg [6.1-12 lb]), 560 mg (cats 5.5-10.9 kg [12.1-24 lb]); *Comfortis® for Cats*; (Rx). FDA-approved for cats. Cats over 10.8 kg (24 lb) should be administered the appropriate combination of tablets.

Spinosad/Milbemycin Chewable Tablets: 140 mg/2.3 mg (dogs 2.3-4.5 kg [5-10 lb]); 270 mg/4.5 mg (dogs 4.6-9.1 kg [10.1-20 lb]); 560 mg/9.3 mg (dogs 9.1-18.2 kg [20.1-40 lb]); 810 mg/13.5 mg (dogs 18.2-27.3 kg [40.1-60 lb]); 1620 mg/27 mg (dogs 27.3-54.5 kg [60.1-120 lb]); *Trifexis*®; (Rx). FDA-approved for use in dogs. Dogs over 54.5 kg (120 lb) should be administered the appropriate combination of tablets.

NOTE: Tablets are beef flavored (but contain pork and soy proteins), and the sizes are color-coded and provided in packets of 6 or 12 tablets.

HUMAN-LABELED PRODUCTS:

None for systemic use

Spinosad 0.9% Topical Suspension (120 mL): *Natroba*®; (Rx)

Spironolactone

(speer-on-oh-***lak***-tone) *Aldactone*®

Aldosterone Antagonist

Prescriber Highlights

- ► Aldosterone antagonist used as a potassium-sparing diuretic and for adjunctive treatment for heart failure or ascites; should not be substituted for furosemide in patients with CHF
- ► Contraindications include hyperkalemia, Addison's disease, anuria, acute kidney injury, or significant renal impairment.
- ► Caution in patients with renal impairment or hepatic disease
- ► Adverse effects include facial dermatitis in cats. Hyperkalemia, hyponatremia, and dehydration possible; increased BUN and mild acidosis in patients with renal impairment. GI distress (eg, vomiting, anorexia), CNS effects (eg, lethargy, ataxia), and endocrine changes (eg, reduced testosterone, increased estrogen) possible.
- ► The National Institute of Occupational Safety and Health (NIOSH) classifies spironolactone as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Spironolactone may be used in patients with congestive heart failure (CHF) for its cardioprotective effects. It is also administered to patients that develop hypokalemia while receiving other diuretics and are unwilling or unable to supplement with exogenous potassium sources. In a study evaluating spironolactone's efficacy for improving survival in dogs with naturally occurring mitral regurgitation in myxomatous mitral valve disease (MMVD), the authors concluded that spironolactone added to conventional cardiac therapy decreased the risk for cardiac-related death, euthanasia, or severe worsening of the disease.[1] However, the clinical relevance of these findings has been questioned due to the study design, event rate, patient withdrawals, and patient categorization with regard to heart failure.[2] A prospective, randomized, single-blinded, placebo-controlled study evaluating the efficacy of spironolactone in combination with benazepril in dogs with preclinical MMVD failed to demonstrate a protective effect of the 2 drugs as compared with placebo.[3] Although efficacy remains in doubt, a randomized, double-blinded, prospective study found that spironolactone added to conventional treatment (ACE inhibitors, furosemide ± digoxin) did not increase risk for adverse effects, death caused by cardiac disease, renal disease, hyperkalemia, or azotemia.[4]

Spironolactone may also be effective in treating ascites, as it has less potential to increase ammonia concentrations than other diuretics.

Spironolactone may find a role in treating renal disease. In rats, it has been shown to decrease proteinuria and glomerulosclerosis in experimental models of renal disease, but clinical effectiveness in dogs has been disappointing. It has potential therapeutic benefit in feline chronic kidney disease,[5] but studies demonstrating efficacy are lacking.

Pharmacology/Actions

Spironolactone is also categorized as a potassium-sparing diuretic or a mineralocorticoid-receptor antagonist. Aldosterone is competitively inhibited by spironolactone in the distal renal tubules with resultant increased excretion of sodium, chloride, and water, and decreased excretion of potassium, ammonium, phosphate, and titratable acid. Spironolactone has no effect on carbonic anhydrase or renal transport mechanisms and has its greatest effect in patients with hyperaldosteronism. When used alone in healthy dogs, spironolactone does not appear to cause significant diuresis.[6] As a diuretic, spironolactone is not commonly used alone, as most sodium is reabsorbed at the proximal tubules. Combining it with a thiazide or loop diuretic maximizes its diuretic effect. Aldosterone also plays a role in the progression of myocardial fibrosis, vascular remodeling, and endothelial dysfunction in heart failure. In humans with heart failure, spironolactone has been shown to reduce remodeling, cardiac fibrosis, and the progression of left ventricular dysfunction.[7] Whether this occurs in veterinary patients with heart failure is controversial. One study in Maine Coon cats with hypertrophic cardiomyopathy but not heart failure showed that spironolactone did not cause significant changes in diastolic function or left ventricular mass after 4 months of treatment.[8]

Pharmacokinetics

Because spironolactone is unstable if frozen and thawed, pharmacokinetic studies in animals are not readily performed. In fasted dogs, oral bioavailability of spironolactone (measured via its main metabolites) is ≈50% but increases up to 90% when the drug is given with food. Approximately 70% of a dose is found in the feces and 18% in the urine. In a recent pharmacodynamic study in 15 beagles, the dose required to inhibit the action of aldosterone by 50% was estimated to be ≈1.1 mg/kg, and the authors suggest that the dose for spironolactone would be ≈2 mg/kg PO once daily to effectively inhibit the aldosterone concentrations associated with CHF in dogs.[9]

In humans, spironolactone is more than 90% bioavailable and peak concentrations are reached within 1 to 2 hours. The diuretic action of spironolactone when used alone is gradually attained and generally reaches its maximal effect on the third day of therapy. Spironolactone and its active metabolite, canrenone, are both ≈98% bound to plasma proteins. Both spironolactone and its metabolites may cross the placenta. Canrenone has been detected in breast milk.

Spironolactone is rapidly metabolized (half-life of 1 to 2 hours) to several metabolites, including canrenone, which has diuretic activity. Canrenone is more slowly eliminated, with an average half-life of ≈20 hours.

Contraindications/Precautions/Warnings

Spironolactone is contraindicated in patients hypersensitive to it and those with hyperkalemia, Addison's disease, anuria, or acute renal failure. It should be used cautiously in patients with significant renal impairment or hepatic disease but is often used to treat ascites.

The label for *Prilactone®Next* (the canine product licensed in the UK) states *Do not use in dogs suffering from hypoadrenocorticism, hyperkalemia, or hyponatremia. Do not administer spironolactone in conjunction with NSAIDs to dogs with renal insufficiency. As spironolactone has an antiandrogenic effect, it is not recommended to administer the product to growing dogs.*

The National Institute for Occupational Safety and Health (NIOSH) classifies spironolactone as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk of exposure.[10]

Adverse Effects

Adverse effects are usually considered mild and reversible upon discontinuation of the drug. The most likely adverse effects are GI effects (eg, anorexia, vomiting, diarrhea) and electrolyte (hyperkalemia, hyponatremia) and water balance (dehydration) abnormalities. In dogs, electrolytes do not appear to be significantly affected. After cats received spironolactone 2.7 mg/kg PO twice daily for 7 to 9 days, the following serum values significantly increased (on average): potassium 0.39 mEq/L, calcium 0.48 mg/dL, creatinine 0.22 mg/dL, phosphorus 0.63 mg/dL, and total protein 0.51 mg/dL.[12]

A study in dogs found that spironolactone added to conventional treatment (ACE inhibitors, furosemide ± digoxin) did not increase risk for adverse effects, death caused by cardiac disease, renal disease, hyperkalemia, or azotemia.[4] In the prospective study evaluating the efficacy of spironolactone in combination with benazepril in dogs with preclinical MMVD, there was no difference in adverse events between those dogs receiving active medication as compared with the placebo group.[3]

In cats, an interim report of a study using spironolactone 1.7 – 3.3 mg/kg PO once daily (n = 16) with benazepril and furosemide reported no severe adverse events except worsening of heart failure (death, euthanasia, aortic thromboembolism, and one case of severe anorexia). However, of the original 16 cats enrolled, 11 died or were euthanized, 2 were withdrawn, 1 completed 15 month follow-up ,and 2 cats remain in the study.[13] The final report from this study reported that 9 of 11 cats in the placebo group reached the primary endpoint of death due to cardiac causes as compared with 2 of 9 cats in the spironolactone group.[14] In the study in Maine Coon cats,[8] ≈⅓ of treated subjects developed severe facial dermatitis.

Transient increases in BUN and mild acidosis may occur in patients with renal impairment. Use of spironolactone in patients with severe renal impairment may lead to hyperkalemia.

Spironolactone reportedly inhibits the synthesis of testosterone and may increase the peripheral conversion of testosterone to estradiol; gynecomastia has been reported in human males. Long-term toxicity studies in rats have demonstrated that spironolactone is tumorigenic in that species.

Reproductive/Nursing Safety

Spironolactone or its metabolites may cross the placental barrier. Feminization occurs in male rat fetuses, and endocrine dysfunction in females with in utero spironolactone exposure.

Canrenone, a metabolite of spironolactone, appears in maternal milk. In humans, the estimated maximum dose to the infant is ≈0.2% of the mother's daily dose. Use with caution in nursing patients, but it is unlikely to have clinical significance in veterinary patients.

Overdose/Acute Toxicity

Information on spironolactone overdoses is limited. Dose-dependent adverse effects (see ***Adverse Effects***) were noted in healthy dogs after administration of up to 10 times the recommended dose. If an acute overdose occurs, it is suggested to follow the guidelines outlined in the ***Chlorothiazide*** and ***Furosemide*** monographs.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving spironolactone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **ACE Inhibitors** (eg, enalapril, lisinopril): Hyperkalemia is possible but unlikely and usually clinically irrelevant if it occurs.[4,11]
- **Angiotensin Receptor Blockers (ARBs)** (eg, **irbesartan, telmisartan**): Hyperkalemia is possible.
- **Beta-Adrenergic Antagonists** (eg, **atenolol, carvedilol, propranolol**): Hyperkalemia is possible.
- **Cholestyramine**: Hyperkalemic metabolic acidosis is possible.
- **Deoxycorticosterone Pivalate (DOCP)**: May reduce diuretic and natriuretic effects of spironolactone
- **Digoxin**: Spironolactone may increase the half-life of digoxin; enhanced monitoring of digoxin serum concentrations and effects is warranted when spironolactone is used with these agents.
- **Mitotane**: Spironolactone may mute the effects of mitotane if given concurrently, but very limited information is available on this potential interaction; monitor carefully.
- **Neuromuscular Blockers, Non-Depolarizing** (eg, **pancuronium, rocuronium, vecuronium**): Increase in neuromuscular blockade effects is possible
- **Nonsteroidal anti-inflammatory drugs** (**NSAIDs**; eg, **carprofen, robenacoxib**): NSAIDs may reduce diuretic and natriuretic effects of spironolactone. Ensure adequate hydration before using combination.[15]
- **Potassium-Sparing Diuretics, Other** (eg, **triamterene**): Hyperkalemia is possible.
- **Potassium Supplements**: Hyperkalemia is possible.
- **Salicylates** (eg, **aspirin, bismuth subsalicylate**): Spironolactone's diuretic effects may be decreased if aspirin or other salicylates are administered concomitantly.

Laboratory Considerations

- Spironolactone may give falsely elevated **digoxin** values if using a radioimmunoassay (RIA) method.
- Fluorometric methods of determining plasma and urinary **17-hydroxycorticosteroids** (cortisol) may be interfered with by spironolactone.

Dosages

DOGS:

Preclinical myxomatous mitral valve disease (extra-label): 2 – 4 mg/kg PO once daily in combination with benazepril, although this study failed to demonstrate the drug combination could delay onset of heart failure compared to placebo.[3]

Compensated MMVD (extra-label): 2 mg/kg PO once daily in

combination with ACE-inhibitor and furosemide. Pilot study suggestive of benefit from spironolactone, but further studies are warranted.[16]

Adjunctive treatment of congestive heart failure caused by MMVD (extra-label):

a) 2 mg/kg PO once daily with food[17,18]

b) 1 – 2 mg/kg PO every 12 to 24 hours[19]; dosing ranges of 0.5 – 4 mg/kg PO every 12 to 24 hours have been noted.

Ascites (extra-label): 1 – 2 mg/kg PO once daily. If no response observed within 7 to 10 days, titrate dose upward every 3 to 5 days to a maximum of 4 mg/kg/day.[20]

Adjunctive treatment of hypertension (extra-label): 1 – 2 mg/kg PO every 12 hours.[21] Not first-line therapy; effectiveness has been marginal when the drug is used as sole therapy for the management of hypertension.[22]

CATS:

Diuretic in heart failure (extra-label): No definitive studies documenting efficacy were located. Anecdotally, some may add spironolactone using dog dosages when furosemide and ACE inhibitors do not control fluid accumulation in refractory CHF.

Cardiomyopathy (extra-label): 1.7 – 3.3 mg/kg once daily.[14] This was a pilot study, and the authors suggest further study is warranted.

Adjunctive treatment of hypertension (extra-label): 1 – 2 mg/kg PO every 12 hours.[21] Not first-line therapy; effectiveness has been marginal when the drug is used as sole therapy for the management of hypertension, even in cats with hyperaldosteronism. Cutaneous drug reactions may also limit usefulness.[22]

Monitoring

- Serum electrolytes, BUN, creatinine. Initially, 5 to 14 days after starting therapy and every 2 months thereafter[23]
- Hydration status and body weight
- Respiratory rate and effort
- Blood pressure, if indicated
- Clinical signs of edema and ascites; serial girth measurements

Client Information

- When beginning this medicine, your animal may urinate more often than normal.
- Administer with a meal.
- Because this drug can change electrolytes (salts) in the blood, more frequent blood testing may be required. Do not miss these important follow-up visits.
- If your animal shows any of the following signs, contact your veterinarian immediately: sores or face scratching (cats), severe or continuing vomiting or diarrhea, acting extremely tired, trouble walking or keeping balance, or stopping eating, drinking, or urinating.

Chemistry/Synonyms

Spironolactone is a synthetically produced aldosterone antagonist that occurs as a cream to light tan, crystalline powder with a faint mercaptan-like odor. Spironolactone is practically insoluble in water and soluble in alcohol.

Spironolactone may also be known as espironolactona, SC-9420, spirolactone, and spironolactonum; many trade names are available.

Storage/Stability

Spironolactone tablets should be stored at room temperature in tight, light-resistant containers.

Compatibility/Compounding Considerations

An extemporaneously prepared oral suspension can be prepared by pulverizing commercially available tablets and adding cherry syrup, simple syrup, or a mixture of *Ora-Sweet*® and *Ora-Plus*®. This preparation is reportedly stable for 60 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No single-agent FDA-approved formulations in the United States; may be available in other countries

Spironolactone/Benazepril Tablets: 20 mg/2.5 mg, 40 mg/5 mg, and 80 mg/10 mg; *Cardalis*®;(Rx)

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Spironolactone Oral Tablets: 25 mg, 50 mg, and 100 mg; *Aldactone*®, generic; (Rx)

Spironolactone/Hydrochlorothiazide Oral Tablets: 25 mg/25 mg and 50 mg/50 mg; *Aldactazide*®, generic; (Rx)

Spironolactone/Benazepril

(speer-on-oh-***lak***-tone /ben-***a***-za-pril) *Cardalis*®

Aldosterone Antagonist/Angiotensin-Converting Enzyme (ACE) Inhibitor

Prescriber Highlights

- ► Indicated for the adjunctive management of clinical signs of mild, moderate, or severe congestive heart failure in dogs due to atrioventricular valvular insufficiency (AVVI)
- ► Contraindications include hypersensitivity, hypoadrenocorticism, hyperkalemia, hyponatremia, in cases of cardiac output failure due to aortic or pulmonary stenosis, pregnancy, or in growing dogs or dogs with renal impairment that are receiving NSAIDs.
- ► Use with caution in dogs with renal or hepatic impairment.
- ► Adverse effects include vomiting and elevations of serum magnesium and potassium.
- ► The National Institute of Occupational Safety and Health (NIOSH) classifies spironolactone as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

The spironolactone/benazepril combination product is FDA-approved with concurrent therapy (eg, furosemide) for the management of clinical signs related to mild, moderate, or severe congestive heart failure in dogs due to atrioventricular valvular insufficiency (AVVI). In a field study,[1] all dogs received furosemide in addition to spironolactone/benazepril; digoxin or calcium channel blockers were used to control supraventricular arrhythmias.[1]

Spironolactone/benazepril delayed the onset of cardiac death, recurrent or worsening pulmonary edema, new cardiogenic ascites, or clinical signs of heart failure requiring high-dose furosemide, although treatment failure rates were high (81% for spironolactone/benazepril; 88% for benazepril alone).[2] In contrast, a prospective, randomized, single-blinded, placebo-controlled study evaluating the efficacy of the spironolactone/benazepril combination in dogs with *preclinical* MMVD failed to demonstrate a protective effect from the combination product compared with placebo.[3]

Pharmacology/Actions

Spironolactone is an aldosterone antagonist and a potassium-sparing diuretic; it also has an affinity for androgen and progesterone receptors. Aldosterone is competitively inhibited by spironolactone in the distal renal tubules with resultant increased excretion of sodium, chloride, and water, and decreased excretion of potassium, ammonium, phosphate, and titratable acid. In dogs, aldosterone also plays a role in the progression of myocardial fibrosis, vascular remodeling, and endothelial dysfunction in heart failure, and spironolactone has been shown to reduce these effects in dogs.[4] The addition of spironolactone to an ACE inhibitor treatment regimen helps prevent the unwanted effects of aldosterone synthesized from other (ie, non-ACE) pathways.

In a pharmacodynamic study in 15 beagles,[5] the spironolactone dose required to inhibit the action of aldosterone by 50% was estimated to be ≈1.1 mg/kg, and the authors suggest that the dose for spironolactone would be ≈2 mg/kg PO once daily to obtain concentrations effective at inhibiting the aldosterone levels associated with CHF in dogs. The spironolactone/benazepril combination inhibited plasma ACE activity by 95% at peak effect, and by over 80% over 24 hours.[6]

Benazepril is a prodrug and has little pharmacologic activity of its own. After being hydrolyzed in the liver to benazeprilat, the drug inhibits angiotensin converting enzyme (ACE), preventing the conversion of angiotensin-I to angiotensin-II. Angiotensin-II is a potent vasoconstrictor and stimulates production of aldosterone in the adrenal cortex. By blocking angiotensin-II formation, ACE inhibitors reduce blood pressure in hypertensive patients and vascular resistance in patients with congestive heart failure. Aldosterone breakthrough (ie, insufficient suppression of aldosterone secretion) has been documented with ACE inhibitor administration to healthy dogs.[7]

Pharmacokinetics

In fasted dogs, oral bioavailability of spironolactone (measured via its primary active metabolites: 7-alpha-thiomethyl-spironolactone and canrenone) is ≈50%, but increases up to 90% when given with food.[6] Metabolite half-lives are ≈7 to 10 hours.[2,6] Approximately 70% of a dose is found in the feces and 20% in the urine.[2,6]

After oral administration in healthy dogs, benazepril is rapidly absorbed and converted into the active metabolite benazeprilat, with peak concentrations of benazeprilat occurring 85 to 120 minutes after administration.[8-11] Protein binding is ≈85%. Benazeprilat half-life is 12 to 21 hours[9,11] and it is cleared via both renal (45%) and hepatic (55%) routes.[2] Renal impairment does not alter benazeprilat clearance.[8]

Contraindications/Precautions/Warnings

Spironolactone/benazepril is contraindicated in patients hypersensitive to either spironolactone or ACE inhibitors, and in patients with hypoadrenocorticism, hyperkalemia, or hyponatremia.[2,6] Do not use in cases of cardiac output failure due to aortic or pulmonary stenosis.[6] Pulmonary edema should be stabilized prior to use of the combination.[2] Use with caution in growing dogs due to antiandrogenic effects associated with spironolactone, and in patients with renal or hepatic impairment.[2,6]

Do not administer spironolactone/benazepril in conjunction with NSAIDs to dogs with renal insufficiency.[2,6] Adequate hydration should be ensured in all treated dogs to reduce the risk for renal toxicity.

The National Institute for Occupational Safety and Health (NIOSH) classifies spironolactone as a hazardous drug. Therefore, personal protective equipment (PPE) should be used to minimize the risk for exposure.[12]

Do not confuse *Cardalis*® with *Cialis*® or *Cardizem*®.

Adverse Effects

Adverse effects reported in FDA field studies included anorexia, vomiting, lethargy, diarrhea, renal insufficiency, collapse, hepatopathy, and urinary incontinence.[1] In one study,[3] adverse effects from the combination did not differ from dogs that received placebo. Renal insufficiency was seen more frequently in dogs treated with the spironolactone/benazepril combination; however, renal function values were not statistically different between the treatment groups. In dogs receiving spironolactone/benazepril, elevations of serum magnesium and potassium can be significantly higher than dogs receiving only benazepril. Reversible prostatic atrophy has been observed in male dogs.[6] Spironolactone inhibits the synthesis of testosterone and may increase the peripheral conversion of testosterone to estradiol. Adverse endocrine effects in humans include menstrual irregularities and gynecomastia; significance in veterinary patients is unclear.

Reproductive/Nursing Safety

Spironolactone/benazepril is contraindicated during pregnancy.[6] In rats, use of ACE inhibitors (eg, benazepril) at labeled dosages during the second and third trimesters is associated with fetal malformation and fetal and neonatal morbidity and mortality. Spironolactone or its metabolites may cross the placental barrier. Feminization occurs in male rat fetuses, and endocrine dysfunction in females with utero spironolactone exposure. Reversible prostatic atrophy has been observed in male dogs treated with spironolactone, and in dogs receiving 3 to 5 times the labeled dosage of the spironolactone/benazepril combination.[2,6]

Canrenone, a metabolite of spironolactone, appears in maternal milk. Benazepril is excreted in maternal milk. Use this combination product with caution in nursing patients.

Overdose/Acute Toxicity

Clinical signs associated with an overdose typically are extensions of the adverse effects of both drugs and may include hypotension and vomiting. Hyperkalemia and hyponatremia may occur. Compensatory hypertrophy of the zona glomerulosa occurred at doses 3 times or greater than the recommended dose.[2]

Supportive treatment including volume expansion with appropriate IV fluid therapy is recommended if hypotension is documented. Because of benazepril's long duration of action, prolonged monitoring and treatment may be required. The manufacturer recommends inducing vomiting, gastric lavage, and electrolyte monitoring as appropriate.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving spironolactone and/or benazepril and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Allopurinol**: Concurrent use may cause severe hypersensitivity reactions, neutropenia, agranulocytosis, or serious infections.
- **Alpha-2-Adrenergic Agonists** (eg, **clonidine, dexmedetomidine**): Concurrent use may result in additive effects on blood pressure and heart rate.
- **Antidiabetic agents** (eg, **glipizide, insulin**): Possible increased risk for hypoglycemia; enhanced monitoring is recommended
- **Histamine H1 Receptor Antagonists** (eg, **diphenhydramine**): Concurrent use may result in additive hypotension.
- **Apomorphine**: Concurrent use may result in additive hypoten-

sion.

- **Angiotensin Receptor Blockers** (**ARBs**; eg, **candesartan, telmisartan**): Concurrent use may increase the risk for adverse effects such as hypotension, syncope, hyperkalemia, changes in renal function, or acute renal insufficiency.
- **Aspirin**: Aspirin may potentially negate the decrease in systemic vascular resistance induced by ACE inhibitors; however, one study in dogs using low-dose aspirin showed that the hemodynamic effects of enalaprilat (active metabolite of enalapril, a related drug) were not affected.[13]
- **Azathioprine**: Concurrent use may result in an increased risk for neutropenia or leukopenia.
- **Barbiturates** (eg, **phenobarbital**): Concurrent use may enhance the hypotensive effects of benazepril.
- **Benzodiazepines** (eg, **diazepam, midazolam**): Concurrent use may lead to low blood pressure.
- **Beta-Blockers** (eg, **atenolol, propranolol**): Concurrent use may result in additive hypotension or hyperkalemia.
- **Buspirone**: Concurrent use may increase risk for hypotension.
- **Cabergoline**: Concurrent use may lead to additive hypotension.
- **Calcium Channel Blockers** (eg, **amlodipine, diltiazem**): Concurrent use may result in hypotension.
- **Cholestyramine**: Concurrent use may increase risk for hyperkalemic metabolic acidosis due to spironolactone.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May decrease antihypertensive effects by causing fluid and sodium retention
- **Cyclosporine**: Concurrent administration may increase the risk for hyperkalemia or precipitate acute renal failure.
- **Dalteparin/Enoxaparin**: Concurrent use may increase risk for hyperkalemia.
- **Desoxycorticosterone Pivalate (DOCP)**: DOCP may cause moderate reduction in the natriuretic effect of spironolactone.6 Spironolactone may reduce the effect of DOCP.[2]
- **Diazoxide**: Concurrent use may lead to hypotension and orthostasis.
- **Digoxin**: Spironolactone may increase the half-life of digoxin; however, field studies supported that digoxin can be safely used with the spironolactone/benazepril combination.[1] Enhanced monitoring of digoxin serum levels and effects should be considered.
- **Diuretics** (eg, **furosemide, hydrochlorothiazide**): Potential for increased hypotensive effects. Field studies demonstrated that furosemide can be safely used with the spironolactone/benazepril combination.
- **Diuretics, Potassium-Sparing** (eg, **triamterene**): Concurrent use may increase hyperkalemic effects. Enhanced monitoring of serum potassium is recommended.
- **Fenoldopam**: Concurrent administration may theoretically increase the risk for severe hypotension.
- **Heparin**: Concurrent use may increase the risk for hyperkalemia.
- **Interferon Alfa**: Concurrent use may increase risk for granulocytopenia.
- **Iodinated Contrast Agents** (eg, **iohexol**): Concurrent use may increase risk for nephrotoxicity.
- **Iron**: Benazepril may increase severity and risk for systemic adverse effects associated with parenteral administration of iron.
- **Lanthanum**: In theory, lanthanum may bind with drugs in the GI tract and interfere with absorption. Lanthanum should be given 2 hours before or after benazepril.
- **Methotrexate**: Concurrent use may potentiate risk for liver injury.
- **Mirtazapine**: Concurrent administration may result in additive hypotension and orthostasis.
- **Mitotane**: Spironolactone may mute the effects of mitotane if given concurrently, but very limited information is available on this potential interaction; monitor carefully.
- **Muscle Relaxants** (eg, **baclofen, methocarbamol**): Concurrent use may have additive blood pressure lowering effects.
- **Naltrexone**: Concurrent administration may increase risk for hepatotoxicity.
- **Nitroglycerin**: Benazepril may enhance the vasodilatory and hypotensive effects.
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam, robenacoxib**): Potentially could increase the risk for nephrotoxicity and/or reduce efficacy of the ACE inhibitor in animals with cardiac or renal disease. Combination is considered contraindicated in dogs with renal insufficiency.[2,6,14,15]
- **Opioids** (eg, **butorphanol, morphine**): Concurrent use may result in additive hypotension and orthostasis.
- **Pentoxifylline**: Concurrent use may increase risk for hypotension.
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**): Concurrent administration may cause orthostatic hypotension and syncope associated with vasodilation.
- **Polyethylene Glycol 3350**: Concurrent use may increase risk for fluid and electrolyte imbalances leading to renal impairment, cardiac arrhythmias, or seizures.
- **Potassium Supplements**: Increased risk for hyperkalemia
- **Prazosin**: Concurrent use can cause additive hypotension.
- **Pregabalin**: Concurrent use may increase risk for angioedema.
- **QT Prolonging Agents** (eg, **amiodarone, cisapride, fluoroquinolones, ondansetron, sotalol**): Concurrent use may increase risk for QTc prolongation and arrhythmias.
- **Salicylates** (eg, **aspirin**): Spironolactone's diuretic effects may be decreased if aspirin or other salicylates are administered concomitantly.
- **Selegiline**: Concurrent use can cause additive hypotension and orthostasis.
- **Sildenafil**: Concurrent use may potentiate the blood pressure lowering effects of benazepril and cause orthostasis and hypotension.
- **Sulfa-/Trimethoprim**: Concurrent use may increase the risk for hyperkalemia.
- **Trazodone**: Concurrent use may result in additive hypotension and orthostasis.
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): Concurrent use may result in additive hypotension and orthostasis.

Laboratory Considerations

- Spironolactone may give falsely elevated digoxin values, if using a radioimmunoassay (**RIA**) method.
- Fluorometric methods of determining plasma and urinary 17-hydroxycorticosteroids (cortisol) may be interfered with by spironolactone.

Dosages

DOGS:

Management of clinical signs of mild, moderate, or severe congestive heart failure due to AVVI (label dosage, FDA-approved): Spironolactone 2 mg/kg with benazepril 0.25 mg/kg PO once

daily with food, using an appropriate combination of whole and/or half tablets.[1] Begin use once pulmonary edema is stabilized; use in conjunction with concomitant therapy (eg, furosemide).

Monitoring

- Clinical efficacy: respiratory rate and effort and other clinical signs of heart failure
- Hydration status and body weight
- Clinical signs of pulmonary edema and ascites; serial girth measurements
- Baseline and periodic serum electrolytes (particularly potassium and magnesium), BUN, and creatinine[2,16]
- Measure digoxin levels regularly if dog is receiving concomitant digoxin; spironolactone can decrease the elimination (and thus increase plasma concentrations) of digoxin and cause toxicity.
- Cardiovascular parameters: blood pressure, ECG, thoracic radiographs, echocardiogram

Client Information

- This medicine should be given with food, or within 30 minutes of feeding.
- Ensure that your dog always has access to fresh water
- It is important to give this medicine as prescribed. Do not stop or change the amount you are giving your dog without your veterinarian's guidance.
- Your dog will need to have periodic examinations, blood pressure measurements, and blood tests performed while taking this medicine. Do not miss these important follow-up visits.
- If your dog shows any of the following side effects, contact your veterinarian immediately: severe or continuing vomiting or diarrhea, acting extremely tired, panting or increased breathing rate, trouble walking or keeping balance, or stopping eating, drinking, or urinating.
- The National Institute for Occupational Safety and Health (NIOSH) classifies spironolactone as a hazardous drug; wearing gloves should be considered (especially if you are pregnant) when giving this medicine to your dog.

Chemistry/Synonyms

Spironolactone is a synthetically produced aldosterone antagonist that occurs as a cream to light tan crystalline powder with a faint mercaptan-like odor and is practically insoluble in water and soluble in alcohol. Benazepril HCl occurs as a white to off-white crystalline powder that is soluble in water and ethanol.

Storage/Stability

Store in the manufacturer's original container at room temperature 20°C to 25°C (68°F-77°F), with excursions permitted between 15°C to 30°C (59°F-86°F). Store securely out of reach of pets or children.

Compatibility/Compounding Considerations

No information noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Spironolactone and Benazepril HCl Chewable Tablets (scored; in a fixed 8:1 ratio of spironolactone to benazepril hydrochloride): 20 mg spironolactone + 2.5 mg benazepril, 40 mg spironolactone + 5 mg benazepril, and 80 mg spironolactone + 10 mg benazepril in 30-count bottles; *Cardalis*®; (Rx). NADA # 141-538. Contains meat flavoring.

HUMAN-LABELED PRODUCTS:

None, although separate formulations of spironolactone and benazepril as a sole agent are readily available and generic.

Stanozolol

(stah-***no***-zo-lahl) *Winstrol*®*-V*

Anabolic Steroid

Prescriber Highlights

- ► FDA-approved controlled substance that is no longer marketed in the United States. Potentially useful in dogs for medical treatment of tracheal collapse
- ► Contraindications include in pregnant animals, breeding stallions, and food animals.
- ► Use extreme caution if using in cats or animals with hepatic dysfunction, hypercalcemia, history of myocardial infarction, pituitary insufficiency, prostate carcinoma, mammary carcinoma, benign prostatic hypertrophy, or are in the nephrotic stage of nephritis.
- ► Use caution in animals with cardiac and renal dysfunction; perform enhanced fluid and electrolyte monitoring.
- ► Adverse effects include high incidence of hepatotoxicity in cats. Other possible effects include sodium, calcium, potassium, water, chloride, and phosphate retention; hepatotoxicity; behavioral (androgenic) changes; and reproductive abnormalities (oligospermia, estrus suppression).
- ► Drug interactions and laboratory interactions are possible.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies androgens as hazardous drugs; use appropriate precautions when handling.

Uses/Indications

The previously marketed veterinary stanozolol product *Winstrol*®*-V* was approved as an adjunct to other specific and supportive therapy, including nutritional therapy to improve appetite, promote weight gain, and increase strength and vitality in dogs, cats, and horses. In a review of the evidence supporting anabolic steroid use in horses, the authors conclude: *Level 1 evidence for the efficacy of anabolic steroids in horses for therapeutic uses is not found in the biomedical literature. Evidence in other species exists for the efficacy of anabolic steroids in treating anemia and increasing muscle mass after illness or injury, but that evidence is not unequivocal, and the applicability to horses has not been demonstrated. There is little evidence in other species for the efficacy of anabolic steroids for increasing appetite.*[1]

In sheep, a study that used an experimental model of osteoarthritis (OA) found intra-articular stanozolol reduced osteophytes formation and subchondral bone reaction and promoted articular cartilage regeneration.[2] Intra-articular administration once weekly to horses with both acute and chronic OA improved physical characteristics of synovial fluid as well as lameness scores.[3] Intra-articular bilateral stanozolol improved clinical signs in police dogs with OA, but was less effective than hyaluranate.[4]

Stanozolol has been used to treat anemia of chronic disease. Because stanozolol has been demonstrated to enhance fibrinolysis after parenteral injection, it may be efficacious in the treatment of feline aortic thromboembolism or thrombosis in nephrotic syndrome; however, clinical studies and/or experience are apparently lacking for this indication at present. In humans, stanozolol may also raise plasma antithrombin III and plasminogen levels.

A controlled study in dogs using stanozolol as a conservative treatment for collapsing trachea (without bronchitis) reported that at the end of the study (75 days), 93% of dogs in the stanozolol group had an improvement in the tracheal collapse grade. Eight of the 14 treated dogs were deemed cured.[5]

Pharmacology/Actions

Stanozolol possesses the actions of other anabolic agents, but it may be less androgenic than other anabolics used in veterinary medicine.

In the presence of adequate protein and calories, anabolic steroids promote body tissue-building processes and can reverse catabolism. As these agents are either derived from or are closely related to testosterone, the anabolics have varying degrees of androgenic effects. Endogenous testosterone release may be suppressed by inhibiting luteinizing hormone (LH). Large doses can impede spermatogenesis by negative feedback inhibition of follicle stimulating hormone (FSH).

Anabolic steroids can also stimulate erythropoiesis, possibly by stimulation of erythropoietic stimulating factor. Anabolics can cause nitrogen, sodium, potassium, and phosphorus retention and decrease the urinary excretion of calcium.

For medical treatment of tracheal collapse in dogs, it is postulated that stanozolol could increase tracheal wall strength via enhancing protein or collagen synthesis, increasing chondroitin sulfate content, increasing lean body mass, and decreasing inflammation.

Pharmacokinetics

In horses (n = 26), following a 0.55 mg/kg IM injection of compounded stanozolol suspension, peak levels occur at 7 days.[6] The median halflife was 3 to 4 days but ranged from 1.6 to 14.7 days.[6]

In horses (n = 10), following a 5 mg intra-articular injection into both tarsal joints, a maximum plasma concentration (1.7 ng/mL) was observed 6 hours postdose.[7] The elimination half-life was between 4 and 12 hours and was completed cleared from plasma within 36 hours after dosing.

In humans, stanozolol is extensively metabolized by the liver.

Contraindications/Precautions/Warnings

Stanozolol is contraindicated in pregnant animals and in breeding stallions and should not be administered to horses intended for food purposes.

Because of reported hepatotoxicity associated with stanozolol in cats, it should only be used in this species with extreme caution.

The manufacturer recommends using stanozolol cautiously in patients with cardiac and renal dysfunction with enhanced fluid and electrolyte monitoring.

In humans, anabolic agents are contraindicated in patients with hepatic dysfunction, hypercalcemia, patients with a history of myocardial infarction (can cause hypercholesterolemia), pituitary insufficiency, prostate carcinoma, benign prostatic hypertrophy, during the nephrotic stage of nephritis, and in selected patients with breast carcinoma. In children, anabolic agents should be used with caution because of hormonal effects and possible effects on bone growth.

The National Institute for Occupational Safety and Health (NIOSH) classifies androgens as hazardous drugs representing an occupational hazard to healthcare workers; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[8]

Adverse Effects

The manufacturer lists only *mild androgenic effects* in dogs, cats, and horses and then only when used with excessively high doses for a prolonged period.

One study in cats demonstrated a high incidence of hepatotoxicity associated with stanozolol use.

Transient postinjection swelling was observed after IA administration to horses.[3] A horse that received stanozolol monthly for 8 years developed adrenal insufficiency following abrupt discontinuation, which the authors attributed to stanozolol-induced adrenal suppression.[9]

Potentially (from human data), adverse reactions of the anabolic agents in dogs and cats could include sodium, calcium, potassium, water, chloride, and phosphate retention, hepatotoxicity, behavioral (androgenic) changes, and reproductive abnormalities (eg, oligospermia, estrus suppression).

Reproductive/Nursing Safety

Stanozolol is contraindicated in pregnant animals and in breeding stallions. It is not known whether anabolic steroids are excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, use it with extreme caution in patients that are nursing.

Overdose/Acute Toxicity

No information was located for this specific agent. In humans, sodium and water retention can occur after overdosage of anabolic steroids. It is suggested to treat supportively and monitor liver function should an inadvertent overdose be administered.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving stanozolol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **heparin, warfarin**): Anabolic agents as a class may potentiate the effects of anticoagulants; monitor anticoagulation (eg, aPTT, PT) closely and adjust dosage if necessary.
- **Corticosteroids** (eg, **dexamethasone, predniso(lo)ne**): Anabolics may enhance the edema that can be associated with ACTH or adrenal steroid therapy.
- **Insulin**: Diabetic patients receiving insulin may need dosage adjustments if anabolic therapy is added or discontinued; anabolics may decrease blood glucose and decrease insulin requirements.

Laboratory Considerations

- Concentrations of protein-bound iodine (PBI) can be decreased in patients receiving androgen/anabolic therapy, but the clinical significance of this is probably not important. Androgen/anabolic agents can decrease amounts of thyroxine-binding globulin and decrease total T_4 concentrations and increase resin uptake of **T_3 and T_4**. Free thyroid hormones are unaltered, and there is no evidence of dysfunction.
- Both **creatinine** and **creatine** excretion can be decreased by anabolic steroids.
- Anabolic steroids can increase the urinary excretion of **17-ketosteroids**.
- Androgenic/anabolic steroids may alter **blood glucose** levels.
- Androgenic/anabolic steroids may suppress clotting factors II, V, VII, and X.
- Anabolic agents can affect **liver function tests** and **liver enzymes** (BSP retention, AST, ALT, bilirubin, and ALP).

Dosages

DOGS:

Anabolic agent (label dosage; FDA-approved): Small breeds: 1 – 2 mg/dog (NOT mg/kg) PO twice daily or 25 mg/dog (NOT mg/kg) deep IM, may repeat weekly. Large breeds: 2 – 4 mg/dog (NOT mg/kg) PO twice daily or 50 mg/dog (NOT mg/kg) deep IM, may repeat weekly. Treatment should continue for several weeks, depending on the response and condition of the animal.[10–12]

Tracheal collapse: (extra-label): In the study, dogs in the treatment group received 0.15 mg/kg PO twice daily for 2 months, then tapered for 15 days.[5]

Hip osteoarthritis (extra-label): 0.3 mg/kg via intra-articular injection into both hip joints[4]

CATS:

NOTE: See ***Contraindications/Precautions/Warnings*** regarding hepatotoxicity in cats. Most clinicians do not recommend using stanozolol in cats.

Anabolic agent (label dosage; FDA-approved): 1 – 2 mg/cat (NOT mg/kg) PO twice daily or 25 mg/cat (NOT mg/kg) deep IM; may repeat weekly. Treatment should continue for several weeks, depending on the response and condition of the animal.[11,12]

HORSES:

Anabolic agent per (former) labeled indications: 0.55 mg/kg (25 mg/45 kg [100 lb] of body weight) deep IM. May repeat weekly for not more than 4 weeks[11]

Acute or chronic osteoarthritis (OA) (extra-label): 5 mg/joint (NOT mg/kg) via intra-articular injection into affected joint, repeated weekly up to 4 times (acute OA) or 6 times (chronic OA)[3]

BIRDS:

Anabolic agent to promote weight gain and recovery from disease (extra-label): 0.5 – 1 mL/kg (25 – 50 mg/kg) IM once or twice weekly. Use with caution in birds with renal disease.[13]

FERRETS:

Anabolic agent (extra-label): 0.5 mg/kg PO or SC twice daily; use with caution in ferrets with hepatic disease.[14]

RABBITS, RODENTS, SMALL MAMMALS:

Rabbits; Appetite stimulant (extra-label): 0.5 – 2 mg/rabbit (NOT mg/kg) PO once[15]

REPTILES:

Most species postsurgically and in debilitated animals (extra-label): 5 mg/kg IM once weekly as needed[16]

Monitoring

- Androgenic adverse effects
- Fluid and electrolyte status, if indicated
- Liver enzymes, if indicated
- RBC count, indices, hemoglobin, if indicated
- Weight, appetite

Client Information

- This medicine may be given with or without food. If your animal vomits or acts sick after receiving the drug on an empty stomach, try giving the next dose with food or a small treat. If vomiting continues, contact your veterinarian.
- This medicine can cause behavior changes, including more sexual behaviors.
- Cats may be prone to developing liver problems while receiving this medication.
- Pregnant women should handle this medicine with caution.
- This medicine is a controlled substance in the United States. It is against federal law to use, give away, or sell this medication to others than for whom it was prescribed.

Chemistry/Synonyms

Stanozolol is an anabolic steroid that occurs as an odorless, nearly colorless, crystalline powder that can exist in 2 forms: prisms that melt at ≈235°C (455°F) and needles that melt at ≈155°C (311°F). It is sparingly soluble in alcohol and insoluble in water.

Stanozolol may also be known as androstanazole, estanozolol, methylstanazole, NSC-43193, stanozololum, win-14833, *Menabol®*, *Neurabol®*, *Stanol®*, *Stromba®*, *Strombaject®*, and *Winstrol®*.

Storage/Stability

Store stanozolol in light-resistant packaging, preferably at room temperature; store tablets in tight containers.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

Although *Winstrol®-V* tablets and injections still appear in the FDA's Green Book, they are no longer commercially marketed but may be available from reputable compounding pharmacies. See ***Compounding: How to Find a Quality Assured Pharmacy.***

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS: NONE

Staphylococcus Aureus Phage Lysate

(***staf***-ih-loe-***kok-us or***-ee-us fayj ***lie***-sayt) *Staphage Lysate®*

Immunostimulant

Prescriber Highlights

- ► Used to treat dogs with recurrent and idiopathic staphylococcal pyodermas
- ► Use with caution in highly allergic patients; desensitizing doses are required.
- ► May cause local or systemic hypersensitivity reactions, including redness, itching, swelling, and anaphylaxis

Uses/Indications

Staphylococcus aureus phage lysate (SPL) is USDA-licensed for treatment of canine pyoderma and related staphylococcal hypersensitivity or polymicrobial skin infections with a staphylococcal component. SPL, or similar *Staphylococcus aureus* bacterins, reduces pruritus and recurrence of superficial and deep pyodermas in dogs.[1–3] One small study in dogs showed a 77% reduction of recurrent canine pyoderma caused by *Staphylococcus pseudintermedius* when treated with antibiotics and SPL compared to antibiotics alone.[4]

Pharmacology/Actions

Staphylococcus aureus phage lysate (SPL) enhances cell-mediated immunity and increases the capability of macrophages to inactivate staphylococci. It stimulates production of tumor necrosis factor, interleukin-6, interleukin-gamma, and gamma-interferon.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

In highly allergic patients, it is recommended to first perform a skin test to evaluate the patient's response to Staphylococcus aureus phage lysate (SPL); if the skin test indicates tolerance, then weekly doses should be gradually increased until the full weekly label dose is achieved.[5] Use SPL with extreme caution, if at all, in patients with prior systemic hypersensitivity reactions to SPL or documented hypersensitivity reactions to beef products, as the product contains ul-

trafiltered beef heart infusion broth.

Avoid administering subsequent doses at the same injection site.[5] The product contains no preservative so it must be handled aseptically.

Adverse Effects

Adverse effects reported for Staphylococcus aureus phage lysate (SPL) include vaccine-type reactions (eg, fever, malaise) and injection site reactions, including redness, itching, and swelling, that may occur within 2 to 3 hours after injection and persist up to 3 days.[5] Reduce dose by 50% if significant injection site reaction occurs.

Although thought to be rare, systemic hypersensitivity reactions are possible. Signs may include weakness, vomiting, diarrhea, severe itching, rapid breathing, and fatigue or lassitude. Should an anaphylactic-type reaction occur, treat the patient supportively (eg, epinephrine and atropine).

Reproductive/Nursing Safety

Studies performed in rats and rabbits demonstrated no impaired fertility or fetal harm.[5] No information was located on safety during nursing. Because safety has not been established, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located. Other than an increased risk for local or systemic hypersensitivity reactions, significant morbidity appears unlikely.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in animals receiving SPL. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Immunosuppressants** (eg, **corticosteroids, cyclosporine**): May reduce the efficacy of Staphylococcus aureus phage lysate (SPL)

Laboratory Considerations

- No significant concerns noted

Dosages

DOGS:

Treatment of canine pyoderma and related staphylococcal hypersensitivity or treatment of polymicrobial skin infections with a staphylococcal component (label dosage; USDA-licensed): **NOTE**: It is recommended to administer this agent with concomitant topical and/or systemic antibiotic therapy according to current antimicrobial stewardship guidelines. Avoid administration in previous injection sites.

a) **Highly allergic patients**: Skin test with 0.05 – 0.1 mL intradermally. If no immediate reactions are seen within 1 hour and no delayed reactions are seen after 48 hours, initiate treatment at 0.2 mL SC. Incrementally increase by 0.2 mL once weekly to 1 mL (a total of 5 injections). Then continue at 1 mL SC weekly for ≈10 to 12 weeks.[5]

b) **Nonallergic patients**: 0.5 mL SC twice weekly for 10 to 12 weeks, then 0.5 – 1 mL SC every 1 to 2 weeks. Skin testing is not required prior to treatment.[5]

c) **All patients**: Dosage adjustments should be guided by infection severity and patient response to treatment.[5] The maximum dose should be decreased in small dogs and can be cautiously increased to 1.5 mL in large dogs if necessary. Continue this dosage regimen until clinical signs improve, then gradually lengthen dosing interval to the longest interval that maintains adequate clinical control.

Adjunctive treatment of chronic recurrent idiopathic pyoderma (extra-label):

a) 0.5 mL SC twice weekly, slowly reducing to 0.5 mL every 2 weeks[6]

b) 1 mL SC once weekly or 0.5 mL twice weekly for 4 to 6 months. If no significant recurrence of pyoderma, decrease administration to every 2 weeks, then every 3 weeks. SPL is best used to prevent pyoderma from recurring and should be used with antibiotics initially to induce remission.[7]

Recurrent staphylococcal infection in dogs with atopic dermatitis following treatment with antibiotics to resolve active pyoderma (extra-label): 0.5 mL SC twice weekly for 12 weeks, then 1 mL once weekly for 4 weeks, then 1 mL every 15 days for 2 doses, then 1 mL every 3 weeks for 2 doses[3]

Monitoring

- Clinical efficacy
- Local and systemic reactions which may occur within 2 to 3 hours after injection and persist up to 3 days

Client Information

- The first dose of this medication should be administered at a veterinary practice where suitable treatment can be given if a serious reaction to the medicine (eg, anaphylaxis) occurs.
- Report any side effects to your veterinarian, including injection site redness or irritation, itching, changes in behavior or activity level, difficulty breathing, unexplained rapid breathing, vomiting, or diarrhea.

Chemistry/Synonyms

Staphylococcus aureus phage lysate (SPL) is prepared by lysing cultures of *Staphylococcus aureus* (Cowan serologic types I and III; human strains) by a staphylococcal bacteriophage. Pre-lysed cell counts (120 to 180 CFU/mL) are used to standardize the product; ultrafiltration achieves bacteriologic sterility. The prepared solution contains *Staphylococcus aureus* components (protein A extracts), bacteriophage, and unfiltered beef heart infusion.

Storage/Stability

Staphylococcus aureus phage lysate (SPL) should be stored in the refrigerator at 2°C to 7°C (36°F-45°F); do not freeze.[5]

Unopened, properly stored vials and ampules have an average expiration date of one year past the shipment date. The product contains no preservative and must be handled aseptically. Do not use if contents are cloudy.

Compatibility/Compounding Considerations

Do not mix Staphylococcus aureus phage lysate (SPL) with other drugs or solutions prior to administration.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Staphylococcal Phage Lysate (serotypes I and III): in 1 mL ampules and 10 mL multi-dose vials; *Staphage Lysate (SPL)*®; (OTC); USDA license #339

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Streptozocin

(strep-toe-***zoe***-sin) *Zanosar®*

Antineoplastic

Prescriber Highlights

- ► Used primarily for treating recurrent insulinoma in dogs
- ► Severe nephrotoxicity is known to occur with streptozocin; myelotoxicity and hepatotoxicity are also possible.
- ► Adverse effects include severe vomiting after treatment, transient hypoglycemia, or diabetes mellitus.
- ► Saline diuresis is required before, during, and after administration to reduce risk for nephrotoxicity.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies streptozocin as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

The primary indication for streptozocin use in veterinary medicine is for treatment for insulinomas in dogs, particularly those with refractory hypoglycemia and when tumors are nonresectable or have metastasized. Its use has been limited by high rates of nephrotoxicity and other serious adverse effects. Streptozocin potentially could be used for other neoplastic conditions as well.

Pharmacology/Actions

Streptozocin is a nitrosourea antineoplastic. Although its antineoplastic activity is not well understood, streptozocin is considered an alkylating agent, and it inhibits DNA synthesis, likely by inhibiting precursor incorporation into DNA and cross-linking DNA strands. It is cell cycle–phase nonspecific.

Streptozocin also exhibits a diabetogenic effect by reducing nicotinamide adenine dinucleotide (NAD) concentration in pancreatic beta cells. This effect is usually irreversible in animals with a pre-existing normal beta cell function. Although streptozocin has activity against gram-positive and gram-negative bacteria, its cytotoxicity prevents it from clinical usefulness for this purpose.

Pharmacokinetics

Streptozocin must be administered IV. Its distribution characteristics are not well known, but the drug does distribute to most tissues; concentrations in the pancreas are higher than those found in plasma. Streptozocin is metabolized, probably in the liver and kidneys. Both the unchanged and metabolized drug are excreted in the urine.

Contraindications/Precautions/Warnings

Streptozocin should only be used for recurrent insulinoma in dogs that have undergone previous surgery in which complete tumor resection was not possible. A confirmed histologic diagnosis is mandatory.

Streptozocin must be used with extreme caution in patients with decreased renal, bone marrow, or hepatic function. Streptozocin is known to cause renal toxicity. In humans, nephrotoxicity is dose-related, cumulative, can be irreversible, and can be fatal.[1] Monitor renal function before and after each treatment. Streptozocin is a tissue irritant and may cause severe irritation or necrosis if extravasated.

Streptozocin is known to be carcinogenic and tumorigenic in lab rodents. The National Institute for Occupational Safety and Health (NIOSH) classifies streptozocin as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[2]

Adverse Effects

The primary concern with streptozocin is the potential for serious, permanent renal toxicity. In dogs, Fanconi syndrome and likely nephrogenic diabetes insipidus have been reported.[3] In humans, nephrotoxicity is dose-related, cumulative, can be irreversible, and can be fatal. Nephrotoxicity in humans can present as azotemia, anuria, hypophosphatemia, glycosuria, and renal tubular acidosis.[1] Adequate hydration during drug administration is strongly recommended in order to reduce the risk for nephrotoxicity.

GI effects (eg, nausea, vomiting) often occur and can be severe or protracted; increased liver enzymes (ALT) may also occur. Acute, transient hypoglycemia has been reported secondary to streptozocin-damaged tumor cells releasing intracellular insulin stores. Permanent diabetes mellitus has also been reported. Less commonly, hematologic changes such as mild myelosuppression can be seen. Injection site reactions (including severe necrosis) can occur if the drug extravasates.[1]

In one small study, adverse effects included GI signs (eg, nausea, anorexia, vomiting, regurgitation, diarrhea, colitis) diabetes mellitus, renal injury, increased ALT, and hypoglycemic collapse or seizure; no neutropenia or thrombocytopenia was observed.[3]

Many dogs receiving chemotherapy will have minor hair coat changes (eg, shagginess, loss of luster). Breeds with continuously growing hair coats (eg, poodles, terriers, Afghan hounds, or old English sheepdogs) are more likely to experience significant alopecia.

Reproductive/Nursing Safety

Streptozocin has been shown to be teratogenic in rats and abortifacient in rabbits. For sexually intact patients, verify pregnancy status prior to administration.

It is not known whether streptozocin is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, milk replacer should be used if treating nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Severe toxicity may result if acutely overdosed (see ***Adverse Effects***); calculate dosages carefully.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving streptozocin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Doxorubicin**: Streptozocin may prolong the half-life of doxorubicin; dosage adjustment may be required.[4]
- **Myelosuppressive Drugs, Other**: When streptozocin is used with other myelosuppressive drugs (eg, **lomustine**), additive or synergistic myelosuppression may occur.
- **Nephrotoxic Drugs, Other** (eg, **aminoglycosides, amphotericin B, cisplatin**): May cause additive nephrotoxicity when used with streptozocin
- **Niacinamide/Nicotinamide**: Can block the diabetogenic effects of streptozocin without altering its antineoplastic activity; this may be beneficial or detrimental depending on the reason for use.

Dosages

DOGS:

NOTE: Because of the potential toxicity of this drug to patients, veterinary personnel, and clients, and since chemotherapy indi-

cations, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[5–9] are strongly recommended.

Insulinoma (extra-label):

a) Dilute 500 mg/m^2 (NOT mg/kg) in 36.6 mL/kg of 0.9% sodium chloride and administer IV over 2 hours every 2 weeks for a total of 5 doses. Administer 0.9% sodium chloride 18.3 mL/kg per hour IV CRI for 3 hours before streptozocin and continuing for 2 hours after streptozocin administration. Prophylactic antiemetics may be administered with each dose, and prednisone 0.5 – 1 mg/kg PO every 24 hours or divided every 12 hours may be used for patients with persistent hypoglycemia.[3]

b) 500 mg/m^2 (NOT mg/kg) IV over 2 hours. Prior to administration of streptozocin, administer 0.9% sodium chloride 18.3 mL/kg/hour IV CRI for 3 hours. Dilute the dose of streptozocin to the appropriate volume of IV fluids to be administered over 2 hours. Following the streptozocin infusion, continue 0.9% sodium chloride 18.3 mL/kg/hour IV CRI for an additional 2 hours. May repeat this protocol at 3week intervals until evidence of tumor progression, recurrence of hypoglycemia, or drug toxicity occurs. Give with antiemetics.[10]

c) 500 mg/m^2 (NOT mg/kg) IV over 2 hours every 3 weeks. Administer only with aggressive saline diuresis: 0.9% sodium chloride 18 to 20 mL/kg/hour IV CRI for 7 to 8 hours, starting 4 hours before streptozocin administration. Give maropitant at the beginning of the 0.9% sodium chloride infusion and continue daily for 3 to 4 days following streptozocin administration.[11]

Monitoring

- Blood glucose (efficacy)
- Baseline and periodic (eg, prior to each treatment) CBC, serum chemistry profile with electrolytes, and urinalysis; proteinuria is usually the first indicator of renal toxicity.
- Hydration status, especially for the first few days after treatment or if vomiting is persistent
- Baseline and periodic (eg, every 2 to 3 months) abdominal ultrasound or CT scan to assess tumor size during therapy

Client Information

- Streptozocin is a chemotherapy (anticancer) drug. This medicine can be hazardous to other animals and people that come in contact with it. On the day your animal gets the drug and then for a few days afterward, wear disposable gloves when handling all bodily waste (urine, feces, litter), blood, and vomit of the animal. Seal the waste in a plastic bag and then place both the bag and gloves in with the regular trash.
- Be sure that your animal has ready access to plenty of clean drinking water.

Chemistry/Synonyms

Streptozocin is a nitrosourea antineoplastic antibiotic produced by *Streptomyces achromogenes*, although the commercial product is prepared synthetically. It occurs as an ivory-colored, crystalline powder. It is very soluble in water and saline and has a pK_a of 1.35.

Streptozocin may also be known as NSC-85998, streptozotocin, U-9889, and *Zanosar®*.

Storage/Stability

Store the lyophilized powder for injection in the refrigerator at 2°C to 8°C (36°F-46°F) and protect it from light. It is stable for at least 3 years after manufacture when refrigerated. If stored at room temperature, it is stable for at least 1 year after manufacture.

After reconstitution, the lyophilized powder for injection has a pH of 3.5 to 4.5. Add citric acid to buffer the solution at a concentration of 22 mg/mL. The solution is stable for 48 hours at room temperature and 96 hours if refrigerated, but as there is no preservative, the manufacturer recommends using the drug within 12 hours of mixing.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Reconstitute the vial using 9.5 mL of either 5% dextrose or 0.9% sodium chloride, and it can be further diluted with either solution if desired. Streptozocin is reported to be **Y-site compatible** with the following drugs (partial list): dolasetron, hydromorphone, octreotide, and ondansetron. It is **incompatible** with amphotericin B (lipid complex), pantoprazole, and piperacillin-tazobactam.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Streptozocin Powder for Injection: 1 g (100 mg/mL) vials; *Zanosar®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Succimer

(***sux***-i-mer) *Chemet®*

Antidote; Chelator

Prescriber Highlights

- ► Oral heavy metal chelator used for lead poisoning in dogs, cats, and birds
- ► Appears to be safe and effective despite limited experience
- ► Most common adverse effects noted are GI in nature; may also cause increased liver enzymes or rash.
- ► Unpleasant odor of capsules may cause odorous feces, urine, and saliva.
- ► May be cost prohibitive

Uses/Indications

Succimer may be useful for the oral treatment of lead poisoning in dogs, cats, and birds. It may also be beneficial for the treatment of other toxic heavy metals such as arsenic or mercury. Succimer is not nephrotoxic, does not increase lead absorption from the GI tract and does not significantly increase elimination of other essential minerals.

Pharmacology/Actions

Succimer physically chelates heavy metals such as lead, mercury, and arsenic. These water-soluble chelates are then excreted via the kidneys. Succimer-lead complexes are also eliminated in the feces and undergo enterohepatic recycling.

Pharmacokinetics

The absorption of oral succimer is less than or equal to 20% in monkeys and less than or equal to 32% in rabbits. In rats, oral succimer is rapidly absorbed and 95% is eliminated from the body by 24 hours. In experimental animals succimer is eliminated in feces and urine after oral administration. After IV administration, most is eliminated in the urine with only trace amounts in the feces.

In humans, the drug is rapidly but incompletely absorbed after oral ingestion. Absorbed drug is excreted primarily through the kidneys into the urine. Half-life in humans is ≈2 days.

Contraindications/Precautions/Warnings

Succimer is contraindicated in patients that are hypersensitive to it.[1] Chelation therapy should only be attempted after the source of lead is removed to prevent further exposure. Use with caution in patients with renal or hepatic impairment. In humans, treatment courses longer than 3 weeks have not been proven safe.

Adverse Effects

In humans, the most common adverse effects are GI related (eg, vomiting, diarrhea) or flu-like symptoms (eg, body aches, fatigue, rhinitis, cough).[1] Clinically insignificant increases in liver enzymes occur in up to 60% of patients. Rashes and allergic mucocutaneous reactions (which can be severe) may occur; skin reactions occur in ≈6% of patients. Mild to moderate neutropenia has also been reported. Adverse effects in humans are usually mild, self-limiting and do not require cessation of therapy. In humans succimer produces a small increase in urinary excretion of zinc and copper.

Reproductive/Nursing Safety

It is unknown if succimer is safe to use during pregnancy. At high doses, it was fetotoxic and teratogenic in mice and rats.[1] It is not known whether this drug is excreted in breast milk, but mothers are discouraged from nursing when taking succimer. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Succimer is generally well tolerated in overdoses. In toxicology studies, there was no renal toxicity in dogs given 50 mg/kg/day orally for 14 days.[1] In a 28-day oral toxicity study dogs given 30 or 100 mg/kg/day had lower urine specific gravity and an increase in renal tubular regenerative hyperplasia. Doses of less than or equal to 200 mg/kg/day in dogs did not cause overt toxicity. Doses of 300 mg/day did cause fatalities in dogs; primarily kidney and GI tract lesions were seen. Doses of 80 mg/kg PO every 12 hours caused a significant number of fatalities in cockatiels (but 40 mg/kg every 12 hours did not). Doses up to 270 mg/kg twice daily for 15 days caused an initial increase in plasma uric acid concentration but did not cause significant adverse effects in pigeons with experimental lead-intoxication.[2]

If overdose occurs, standard GI decontamination protocols with subsequent activated charcoal may be used.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succimer and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Chelating Agents, Other** (eg, **CaEDTA, dimercaprol, penicillamine, trientine**): Concomitant use with other chelating agents is not recommended in humans.1 Succimer may be used 4 weeks after CaEDTA treatment.

Laboratory Considerations

- False positive urine ketones can be reported when using nitroprusside reagents (eg, *Ketostix*®).
- Falsely low measurements of CPK or serum uric acid can be caused by succimer.

Dosages

DOGS/CATS:

Lead poisoning (extra-label): 10 mg/kg PO every 8 hours for 5 to 10 days. Blood lead concentrations should be rechecked a few days following the last dose of succimer; a second round of chelation therapy may be necessary to reduce the lead load.[3] The total length of treatment should be based on clinical improvement and blood lead concentrations.[4]

HORSES:

Lead poisoning (extra-label): Anecdotally, 30 mg/kg/day PO in divided doses

BIRDS:

Lead poisoning (extra-label): 20 – 40 mg/kg twice daily for a minimum of 7 days[5,6]

Monitoring

- Baseline and periodic complete blood count and measurement of blood lead concentration
- GI adverse effects
- Baseline and periodic liver enzymes (AST, ALT)

Client Information

- This medicine is used to remove excess metals, particularly lead, from the body
- Capsules can be opened and sprinkled on soft food. The capsules may have an unpleasant odor, which may increase the odor of saliva, urine, and feces.
- Animals should always have plenty of clean drinking water available while taking this medicine.
- This medicine may cause diarrhea and vomiting. Contact your veterinarian if you have any concerns.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

A heavy metal chelating agent also known as meso-2,3 dimercaptosuccinic acid (DMSA), succimer is a water-soluble analog of dimercaprol. It occurs as a white crystalline powder with a sulfurous odor.

Succimer may also be known as meso-2,3 dimercaptosuccinic acid, dimercaptosuccinic acid, DIM-SA, DMSA, *Chemet*®, or *Succicaptal*®.

Storage/Stability

Unless otherwise labeled, store succimer capsules in tight containers at room temperature. Protect from light.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Succimer Capsules: 100 mg; *Chemet*®; (Rx)

Succimer 200 mg capsules may be available in some countries.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Succinylcholine

(***suks***-sin-nil-***koe***-leen) *Anectine®*

Neuromuscular Blocking Agent

Prescriber Highlights

- ► Used for short-term muscle relaxation during surgery, diagnostic procedures, or mechanical ventilation
- ► No analgesic or anesthetic effects
- ► Contraindications include severe liver disease, chronic anemia, malnourishment, glaucoma or penetrating eye injuries, predisposition to malignant hyperthermia, and increased CPK values with resultant myopathies.
- ► Use with extreme caution in patients with traumatic wounds or burns, patients receiving quinidine or digoxin therapy, and patients with hyperkalemia or other electrolyte imbalances.
- ► Use with caution in patients with pulmonary, renal, cardiovascular, metabolic, or hepatic dysfunction.
- ► Adverse effects include muscle soreness, malignant hyperthermia, excessive salivation, hyperkalemia, rash, myoglobinemia/myoglobinuria, and cardiovascular effects (eg, bradycardia, tachycardia, hypertension, hypotension, arrhythmias).
- ► High-alert drug; ensure appropriate respiratory support, reversal agents, and error-reducing safeguards are in place to minimize risk for patient harm.

Uses/Indications

Succinylcholine is indicated for short-term muscle relaxation needed during surgery, diagnostic procedures, and mechanical ventilation. Newer nondepolarizing agents with fewer adverse effects (eg, atracurium, vecuronium, rocuronium) have largely replaced succinylcholine.

In humans, succinylcholine can be used to facilitate endotracheal intubation.[1]

Pharmacology/Actions

Succinylcholine is an ultrashort-acting depolarizing skeletal muscle relaxant that binds to motor endplate nicotinic cholinergic receptors to produce depolarization (perceived as fasciculations). The neuromuscular block remains as long as sufficient quantities of succinylcholine remain and is characterized by flaccid paralysis.

Pharmacokinetics

After IV administration, the onset of action with complete muscle relaxation is usually within ≈60 seconds.[1] In humans, this effect lasts for 2 to 3 minutes and then gradually diminishes within 10 minutes. The very short duration of action after a single IV dose is thought to occur because the drug diffuses away from the motor endplate. If multiple injections or a continuous infusion are performed, the brief activity is a result of rapid hydrolysis by pseudocholinesterases at the site of action. After IM injection, the onset of action is generally within 2 to 3 minutes and may persist for 10 to 30 minutes. Dogs exhibit a prolonged duration of action of ≈20 minutes; this species appears unique in this idiosyncratic response.

Succinylcholine is metabolized by plasma pseudocholinesterases to succinylmonocholine and choline; 10% is excreted unchanged in the urine. Succinylmonocholine is partially excreted in the urine and may accumulate in patients with impaired renal function. Succinylmonocholine has ≈1/20 the neuromuscular blocking activity of succinylcholine, but if it accumulates, prolonged periods of apnea may result.

Contraindications/Precautions/Warnings

Succinylcholine is contraindicated in patients with severe liver disease, chronic anemia, chronic malnourishment, increased intracranial pressure, glaucoma or penetrating eye injuries, predisposition to malignant hyperthermia, and increased creatine phosphokinase (CPK) values with resultant myopathies. As succinylcholine can exacerbate the effects of hyperkalemia, it should be used with extreme caution in patients that have suffered traumatic wounds or burns, are receiving quinidine or digoxin therapy, or have pre-existing hyperkalemia or electrolyte imbalances, as arrhythmias or cardiac arrest may occur. Use succinylcholine with caution in patients with pulmonary, renal, cardiovascular, metabolic, or hepatic dysfunction.

Succinylcholine should only be used in patients that are adequately anesthetized as it has no analgesic or sedative/anesthetic actions. Respiratory support (eg, intubation, mechanical ventilation), neuromuscular blocker reversal agents, and staff experienced in the use of these agents must be readily available. Inadvertent administration of neuromuscular blocking agents to patients for which they were not intended may cause significant harm, including death. Neuromuscular blocking agents should be sequestered from other medications, and with access limited to those familiar with their use.[2] Prominent placement of warning labels (eg, *paralyzing agent- causes respiratory arrest, causes respiratory paralysis; patient must be ventilated*) on storage containers is highly recommended.

Ruminants are deficient in pseudocholinesterase, and succinylcholine is considered contraindicated these species.[3] The drug should be used with caution in horses due to the risk for malignant hyperthermia.[4–6]

Succinylcholine should not be used if organophosphate agents have been given or applied recently.[7]

Adverse Effects

Succinylcholine chloride can cause muscle soreness, malignant hyperthermia, excessive salivation, hyperkalemia, rash, and myoglobinemia/myoglobinuria. Cardiovascular effects can include bradycardia, tachycardia, hypertension, hypotension, or arrhythmias.

Reproductive/Nursing Safety

It is unknown if succinylcholine can cause fetal harm. The drug does cross the placenta in low concentrations, and a newly delivered neonate may show signs of neuromuscular blockade if the dam received high doses or prolonged administration of the drug prior to delivery. It is not known whether this drug is excreted into milk; exercise caution when succinylcholine is administered to a nursing patient. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Inadvertent overdoses or standard doses in patients deficient in pseudocholinesterase may result in prolonged apnea. Mechanical ventilation with oxygen should be used until recovery.

Repeated or prolonged high doses may cause patients to convert from a phase I to a phase II block.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succinylcholine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- ■ **Acetylcholinesterase Inhibitors** (eg, **neostigmine, pyridostigmine**): May prolong depolarizing phase I block but may antagonize phase II block

- **Amphotericin B**: May increase succinylcholine's effects by causing electrolyte imbalances
- **Digoxin**: Succinylcholine may cause a sudden outflux of potassium from muscle cells, thus causing arrhythmias in digitalized patients.
- **Opioids**: Potential for increased incidences of bradycardia and sinus arrest
- **Thiazide Diuretics** (eg, **hydrochlorothiazide**): May increase succinylcholine's effects by causing electrolyte imbalances

The following drugs/drug classes may increase or prolong neuromuscular blockade if used concurrently with succinylcholine:

- **Aminoglycosides**
- **Anesthetics, Inhalation** (eg, **desflurane, isoflurane**)
- **Antiarrhythmics** (eg, **quinidine, lidocaine, procainamide**)
- **Beta-Adrenergic Receptor Antagonists** (eg, **atenolol**)
- **Chloroquine**
- **Clindamycin**
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**)
- **Cyclophosphamide**
- **Magnesium Salts**
- **Monoamine Oxidase Inhibitors**
- **Metoclopramide**
- **Organophosphates**
- **Oxytocin**
- **Pancuronium**
- **Phenothiazines** (eg, **acepromazine**)
- **Terbutaline**

Dosages

DOGS:

Neuromuscular blockade (extra-label): 0.3 – 0.4 mg/kg IV are recommended[8]; rarely used today

CATS:

Neuromuscular blockade (extra-label): 0.2 mg/kg IV1 mg/kg IV[8]; rarely used today

HORSES:

Neuromuscular blockade (extra-label): 0.12 – 0.15 mg/kg IV[8]

SWINE:

Intubation/abolish laryngospasm (extra-label): 1 – 2 mg/kg IV[9–11]

REPTILES:

Neuromuscular blockade in *Crocodilia* spp, chelonians, and lizards (extra-label): 0.4 – 1 mg/kg IM with time to onset of 5 to 30 minutes. The recovery period is based on the administered dose and the patient's metabolic activity; however, recovery generally occurs within 1 hour with doses in this range. Some large crocodiles require 2 – 5 mg/kg IM, which results in a recovery of 7 to 9 hours. Administration of an anxiolytic prior to induction is helpful. The clinician must have the means to ventilate the patient.[12]

Monitoring

- Level of neuromuscular blockade. It is strongly recommended to be familiar with techniques required to monitor the level of neuromuscular blockade (eg, acceleromyography, train-of-four twitch ratio) when using succinylcholine.[13] Visual or tactile assessments of the level of blockade are inaccurate and unreliable. Correct placement of electrodes is essential to minimize direct muscle stimulation and prevent misinterpretation of the degree of the blockade and minimize risk for overdose.
- Assess ventilation (eg, arterial blood gas, $ETCO_2$)
- Heart rate and rhythm
- Blood pressure

Client Information

- Only professionals familiar with the use of succinylcholine should use this drug.

Chemistry/Synonyms

Succinylcholine chloride is a depolarizing neuromuscular blocking agent that occurs as an odorless, white, crystalline powder. The dihydrate form melts at 190°C (374°F) and the anhydrous form at 160°C (320°F). Aqueous solutions are acidic, with a pH of ≈4. One gram is soluble in ≈1 mL of water and ≈350 mL of alcohol. Commercially available injections have a pH from 3 to 4.5.

Succinylcholine chloride may also be known as choline chloride succinate, succicurarium chloride, succinylcholine chloride, suxamethonii chloridum, suxametonklorid, suxamethonium chloride; many trade names are available.

Storage/Stability

Store commercial injectable solutions refrigerated (2°C-8°C [36°F-46°F]). One manufacturer states that multiple-dose vials are stable for up to 2 weeks at room temperature with no significant loss of potency.[14]

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Succinylcholine chloride is physically **compatible** with all commonly used IV solutions, amikacin sulfate, isoproterenol HCl, meperidine HCl, norepinephrine bitartrate, and scopolamine HBr. It **may not be compatible** with pentobarbital sodium and is physically **incompatible** with sodium bicarbonate and thiopental sodium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Succinylcholine Chloride Injection: 20 mg/mL; *Anectine®*, *Quelicin®*; (Rx)

Succinylcholine Chloride Injection: 100 mg/mL; *Quelicin-1000®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Sucralfate

(soo-***kral***-fate) *Carafate®*

GI-Mucosal Protectant

Prescriber Highlights

- ► Local-acting treatment for GI ulcers/esophagitis; may also protect somewhat against GI ulceration
- ► No contraindications have been identified; however, sucralfate should be used with caution when decreased GI transit times may be harmful.
- ► Adverse effects are unlikely, although constipation is possible. Vomiting has been reported in cats.
- ► Tablets should be dissolved in water before administration. Should be administered on an empty stomach, if possible
- ► To avoid possible drug interactions (eg, drug binding, decreased drug bioavailability), other medications should be administered 2 hours before sucralfate is administered.

Uses/Indications

Sucralfate has been used to treat oral, esophageal, gastric, and duodenal ulcers and to prevent drug (eg, aspirin)-induced gastric erosions. Despite sucralfate's theoretical benefits and widespread use, research has shown limited or no evidence to support the effectiveness of sucralfate for these indications.[1–3] A consensus panel has determined that evidence supporting sucralfate use in small animal species for the prevention or treatment of esophageal injury is weak[4]; however, sucralfate in combination with omeprazole is recommended for treating horses with equine glandular gastric disease.[5]

Sucralfate has been used in humans with hyperphosphatemia secondary to renal failure and could be useful for this indication in animals; however, in a study, sucralfate did not significantly change serum or urine phosphorus levels in healthy cats or normophosphatemic cats with CKD, and adverse effects (eg, vomiting, anorexia, constipation, worsening azotemia) may interfere with treatment.[6]

Pharmacology/Actions

Although the exact mechanism of action of sucralfate as an antiulcer agent is unknown, the drug appears to have a local effect rather than a systemic one. After oral administration, sucralfate may react with hydrochloric acid in the stomach to form a paste-like complex that preferentially binds to the proteinaceous exudates that are generally found at ulcer sites (eg, albumin, fibrinogen). This insoluble complex may form a barrier at the site and protect the ulcer from further damage caused by pepsin, acid, or bile. Sucralfate can bind bile acids and reduce pepsin activity. As an aluminum salt, sucralfate can bind to GI phosphorus.

Sucralfate may have some cytoprotective effects, possibly by stimulation of prostaglandins E_2 and I_2. It also has some antacid activity, although this may not be of clinical importance. Sucralfate may also bind to intact GI mucosa to form a protective layer.

Sucralfate does not significantly affect gastric acid output or trypsin or pancreatic amylase activity. It may slightly decrease the rate of gastric emptying but will not alter peristalsis.

Pharmacokinetics

By reacting with hydrochloric acid in the gut, most of the drug is converted to sucrose sulfate, which is excreted in the feces within 48 hours.[7] The duration of action (binding to ulcer site) may persist up to 6 hours after oral administration. A negligible amount of an oral dose is absorbed into the systemic circulation and excreted in the urine unchanged within 48 hours.[8]

Dissolving tablets in water before administration to dogs and cats is recommended to increase the dispersion of the drug, as tablet fractions have been observed in dog feces.[9]

Contraindications/Precautions/Warnings

Sucralfate is contraindicated in patients with known hypersensitivity to it. Because it may cause constipation, it should be used with caution in animals in which decreased GI transit times might be deleterious. Hyperglycemia has been reported rarely in diabetic humans receiving sucralfate suspension. Small amounts of aluminum may be absorbed following oral administration and may accumulate in patients with renal failure.

Concurrent use of sucralfate with proton pump inhibitors (eg, omeprazole) or histamine-H_2 receptor antagonists (eg, ranitidine) does not enhance the treatment of gastroduodenal injury in small animal species.[4]

Adverse Effects

Adverse effects are uncommon with sucralfate therapy. Constipation is the most prominent adverse effect reported in humans (2%) and dogs receiving the drug. Vomiting has been reported in cats. Sucralfate can have an unpalatable taste, and patient acceptance may be a problem.

Sucralfate administration to cats with CKD resulted in clinical decompensation (vomiting, anorexia, constipation, worsening azotemia) in 3 of the 5 studied cats.[6]

Reproductive/Nursing Safety

In rats, sucralfate doses up to 38 times those used in humans have not been shown to cause impaired fertility, and doses up to 50 times normal used in humans have not been shown to cause signs of teratogenicity.[7]

Sucralfate is most likely not excreted in breast milk because of minimal systemic absorption.

Overdose/Acute Toxicity

Overdoses are unlikely to cause significant problems. Laboratory animals receiving up to 12 g/kg PO have demonstrated no incidence of mortality.[7]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sucralfate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids, Aluminum Containing**: Additive absorption of aluminum may occur, particularly in patients with renal insufficiency.

Sucralfate may impair the oral absorption of the following medications; administration should be separated by at least 2 hours to minimize this effect (with other medication being administered before sucralfate)[4]:

- **Alendronate**: Other oral bisphosphonates should be assumed to have the same effects.
- **Antacids, Aluminum Containing**: Can decrease sucralfate effectiveness; administration should be separated by 30 minutes. Additive absorption of aluminum may occur, particularly in patients with renal insufficiency.
- **Antacids, Calcium/Magnesium Containing**: Can decrease sucralfate effectiveness; administration should be separated by 30 minutes.
- **Ciprofloxacin**: Other oral fluoroquinolones, except enrofloxacin, should be assumed to be affected.[9,10]

- Diclofenac
- Digoxin
- Feeding, Enteral: Administration should be separated by an hour.
- Ferrous Sulfate
- Furosemide
- Ketoconazole
- Lanthanum
- Levothyroxine: Administration should be separated by 4 hours.
- Macrolide Antibiotics (eg, azithromycin, clarithromycin, erythromycin)
- Penicillamine
- Tetracyclines (eg, doxycycline, minocycline, tetracycline)[11,12]
- Theophylline
- Vitamins, Fat Soluble
- Warfarin

Dosages

DOGS/CATS:

GI-mucosal protectant for conditions such as esophagitis, gastric or duodenal ulcers, and uremic gastritis (extra-label): Empirically administered at ¼ to ½ of a 1 g tablet (250 – 500 mg)/animal (NOT g/kg) for toy-breed dogs and cats and 1 g/animal (NOT g/kg) PO 2 to 4 times daily for large-sized dogs. When using tablet formulations, it is recommended to crush the tablet then suspend it in a small amount of water prior to administration.

FERRETS:

GI-mucosal protectant (extra-label):

a) 75 mg/kg PO every 4 to 6 hours; should be administered 10 minutes prior to feeding[13]

b) 25 – 125 mg/kg PO every 8 to 12 hours[14]

HORSES:

GI-mucosal protectant (extra-label):

a) **Gastric glandular disease**: Sucralfate 12 – 20 mg/kg PO twice daily in combination with omeprazole 4 mg/kg PO once daily.[5,15,16]

b) **Prevention of stress-induced ulcers (used with acid-suppressive drugs) in foals**:

i. 10 – 20 mg/kg PO every 6 to 8 hours[17]

ii. 20 – 40 mg/kg PO every 6 hours[18]

iii. 2 – 4 g/foal (NOT g/kg) PO every 6 hours[18]

c) **Right dorsal colitis | colonic ulcers**: 22 mg/kg PO every 6 to 8 hours[19,20]

REPTILES:

GI irritation in most species (extra-label): 500 – 1000 mg/kg PO every 6 to 8 hours[21]

BIRDS:

Upper GI mucosal hemorrhage (extra-label): 50 – 100 mg/kg PO every 12 hours[22]

Monitoring

- Clinical efficacy (dependent on the reason for use); may be monitored by a decrease in clinical signs, endoscopic examination, and fecal occult blood testing

Client Information

- This medicine is best given on an empty stomach and not at the same time as other medications. If you are giving your animal any other medication, be sure to give the other medications 2 hours before you give the sucralfate.
- Sucralfate be given several times a day to be most effective.
- Shake liquids well before using. If using tablets, it is best to dissolve the tablets in lukewarm water just before giving them.
- This medicine is usually tolerated well. Some animals may develop constipation. Some cats may vomit after receiving this medicine. Contact your veterinarian if you have concerns about your animal taking this medicine.

Chemistry/Synonyms

Sucralfate, a basic aluminum complex of sucrose sulfate, can occur as a white, amorphous powder. It is practically insoluble in alcohol or water. Each 1 g sucralfate tablet contains ≈207 mg of aluminum.

Sucralfate is structurally related to heparin but does not possess any appreciable anticoagulant activity. It is also structurally related to sucrose but is not utilized as sugar by the body.

Sucralfate is also known as basic aluminum sucrose sulfate and *Carafate®*, *Sulcrate®*, and *Cytogard®*.

Storage/Stability

Store sucralfate tablets in tight containers at room temperature (15°C-30°C [59°F-86°F]). Store sucralfate suspension at controlled room temperature (20°C-25°C [68°F-77°F]); do not freeze.

Compatibility/Compounding Considerations

A sucralfate 200 mg/mL suspension can be extemporaneously prepared. For a volume of 100 mL, twenty (20) sucralfate 1 g tablets should be crushed, and a sufficient quantity of distilled water added to bring the volume to 100 mL. Suspending agents (eg, acacia, tragacanth) should not be used, as they can bind to sucralfate and make it inactive. "Shake well" and "refrigerate" should be labeled on the compounded solution. When refrigerated, it is stable for 14 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Sucralfate Tablets: 1 g; *Carafate®*, generic; (Rx)

Sucralfate Suspension: 1 g/10 mL in 10 mL unit-dose cups and 415 mL bottles; *Carafate®*, generic; (Rx)

Formulations are available as oral mucosal coating agents and regulated by the FDA as medical devices.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Sufentanil

(soo-***fen***-ta-nil) *Sufenta®*

Opioid Agonist

Prescriber Highlights

► Injectable opioid that is 5 to 7 times more potent than fentanyl. May be useful for adjunctive anesthesia or epidural analgesia

► Dose-related respiratory and CNS depression most likely adverse effects

► DEA Schedule II (C-II) controlled substance

Uses/Indications

Sufentanil is an opioid analgesic that may be useful as an anesthesia adjunct or as an epidural analgesic. In humans, it has been used as the primary anesthetic in intubated patients with assisted ventilation and as a postoperative analgesic.

Pharmacology/Actions

Sufentanil is a potent mu opioid with the expected sedative, analgesic, and anesthetic properties. When comparing analgesic potencies when injecting IM, 0.01 to 0.04 mg of sufentanil is equivalent to

0.4 to 0.8 mg of alfentanil, 0.1 to 0.2 mg of fentanyl, and ≈10 mg of morphine. Like fentanyl, sufentanil appears to have less circulatory effects than morphine. Sufentanil has a rapid onset of action (1 to 3 minutes) and a faster recovery time than fentanyl.

Pharmacokinetics

In isoflurane-anesthetized cats, a sufentanil 1 µg/kg IV bolus had a volume of distribution (at steady-state) of ≈0.77 L/kg, a clearance of ≈17.6 mL/minute/kg, and a terminal half-life of ≈54 minutes. Elimination of sufentanil is expected to be more rapid than either fentanyl or alfentanil because of a small volume of distribution and moderate clearance.[1]

In humans, the drug has a rapid onset of action (1 to 3 minutes) after IV injection. The drug is highly lipid-soluble and has a volume of distribution in the central compartment of 0.1 L/kg. Approximately 93% is bound to plasma proteins. Plasma concentrations rapidly decline because of redistribution, and its terminal elimination half-life is ≈2.5 hours. Plasma clearance has been reported to be ≈12 mL/minute/kg. Sufentanil is metabolized primarily in the liver and small intestine via O-demethylation and N-dealkylation. The parent drug and these metabolites are excreted primarily in the urine. Although the manufacturer states to use sufentanil with caution in patients with impaired renal or hepatic function, limited pharmacokinetic studies in these patients rarely showed any drug accumulation.

Contraindications/Precautions/Warnings

Sufentanil is contraindicated in patients that are hypersensitive to it or other opioids.[2] It should be used with caution in debilitated or geriatric patients and those with severely diminished renal or hepatic function. Initial dose reduction may be required in geriatric or debilitated patients, particularly those with diminished cardiopulmonary function.

Because of the drug's potency, the use of a tuberculin syringe to measure doses less than 1 mL in addition to a double-check system for dose calculations and measurement is recommended. It should only be used in situations where patient vital signs can be continuously monitored.

Opioid analgesics are contraindicated in patients stung by scorpions (eg, *Centruroides* spp), as they may potentiate venom effects.[3]

Do not confuse SUfentanil with fentanyl or ALfentanil.

Adverse Effects

Adverse effects are generally dose-related and consistent with other opioid agonists. Respiratory depression and/or CNS depression are most likely to be encountered and can be exacerbated if sufentanil is given with other drugs that can cause those effects.

In humans, bradycardia may occur, but it is usually responsive to anticholinergic agents. Dose-related skeletal muscle rigidity has been reported, particularly with high doses and/or rapid IV administration and can be managed with concurrent use of neuromuscular blockers. Sufentanil has rarely been associated with asystole, hypercarbia, and hypersensitivity reactions.

Reproductive/Nursing Safety

Although sufentanil is indicated for epidural use (mixed with bupivacaine ± epinephrine) in women for labor/delivery, it should not be administered systemically to a dam close to giving birth, as offspring may show behavioral alterations (eg, hypotonia, depression) associated with opioid administration.

The effects of sufentanil on lactation and its safety for nursing offspring are not well defined, but sufentanil milk levels approximate those found in serum. This, coupled with its low oral bioavailability, makes it unlikely to cause significant effects in nursing offspring.

Overdose/Acute Toxicity

In dogs, the LD_{50} of IV sufentanil is 10.1 to 19.5 mg/kg. Severe IV overdoses may cause apnea, circulatory collapse, pulmonary edema, seizures, cardiac arrest, and death. Treatment is a combination of supportive therapy and administration of an opioid antagonist, such as naloxone. Although sufentanil has a fairly rapid half-life, multiple doses of naloxone may be necessary.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sufentanil and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-2 Receptor Agonists** (eg, **dexmedetomidine, xylazine**): Concurrent use may increase the risk for CNS and/or respiratory depression.
- **Anesthetic Agents** (eg, **alfaxalone, isoflurane, ketamine, propofol**): Concurrent use may increase the risk for CNS and/or respiratory depression.
- **Anticholinergic Agents** (eg, **acepromazine, atropine, glycopyrrolate**): Concurrent use may increase the risk for urinary retention, constipation, and CNS and respiratory depression.
- **Antihypertensive Agents** (eg, **atenolol, lisinopril**): Concurrent use may increase the risk for bradycardia, hypotension, and orthostasis. Use cautiously and monitor blood pressure and heart rate. Opioids may decrease the therapeutic effects of diuretics.
- **Benzodiazepines** (eg, **diazepam, midazolam**): Concurrent use may increase the risk for CNS and/or respiratory depression.
- **Bethanechol**: Concurrent use may antagonize the beneficial effects of bethanechol on GI motility. Avoid combination.
- **CNS Depressants** (eg, **methocarbamol, phenobarbital**): Concurrent use may increase the risk for CNS and/or respiratory depression. Monitor and adjust dosages accordingly.
- **Desmopressin**: Concurrent use may increase levels of oral desmopressin and increase the risk for water intoxication and/or hyponatremia, which can progress to seizures, coma, respiratory arrest, and death. Monitor electrolytes and renal function.
- **Domperidone**: Concurrent use may antagonize the GI effects of domperidone.
- **Drugs That Inhibit Hepatic Isoenzymes** (eg, **cimetidine, diltiazem, erythromycin, fluconazole, itraconazole, ketoconazole**) May increase the half-life and decrease the clearance of sufentanil, leading to prolonged effects and an increased risk for respiratory depression. Consider adjusting doses accordingly.
- **Drugs That Induce Hepatic Isoenzymes** (eg, **griseofulvin, mitotane, phenobarbital**): Current use may decrease levels of sufentanil. Monitor clinical response and adjust doses accordingly.
- **Drugs That Depress Cardiac Function Or Reduce Vagal Tone** (eg, **beta-blockers or other anesthetic agents**): May produce bradycardia or hypotension if used concurrently with sufentanil
- **Ifosfamide**: Concurrent use may increase the risk for neurotoxicity, including somnolence, confusion, hallucinations, blurred vision, urinary incontinence, seizures, and coma. Use cautiously and monitor.
- **Iohexol**: Concurrent use of opioids with intrathecal iohexol may increase the risk for seizures. Opioids should be withheld for 48 hours before and 24 hours after intrathecal administration of iohexol.

- **Loperamide**: Concurrent use may increase the risk for constipation.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, selegiline**): Concurrent use may increase the risk for anxiety, confusion, hypotension, respiratory depression, cyanosis, and coma. MAOIs should be withheld for 14 days prior to administration of opioids. Avoid combination.
- **Metoclopramide**: Concurrent use may antagonize the prokinetic effects of metoclopramide.
- **Neuromuscular Blocking Agents** (eg, **atracurium**): Concurrent use may increase the risk for tachycardia, bradycardia, and/or hypotension. Use cautiously and monitor
- **Serotonin Receptor Antagonists** (eg, **dolasetron, fluoxetine**): Concurrent use may increase the risk for serotonin syndrome. Avoid combination.
- **Tramadol**: Concurrent use may increase the risk for seizures, serotonin syndrome, urinary retention, and constipation. The risk for CNS and respiratory depression may be additive.
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): Concurrent use may increase risk for urinary retention, constipation, and CNS and respiratory depression.

Laboratory Considerations

- Because opioids can increase biliary tract pressure and raise serum amylase and lipase values, these values may be unreliable for 24 hours after sufentanil is administered.

Dosages

NOTE: In obese patients, calculate doses based on lean body weight.

DOGS/CATS:

Opioid analgesic (extra-label): 0.5 – 1 µg/kg slow IV followed by 0.5 – 1 µg/kg/*HOUR* IV CRI has been noted.[1,4–8] Dosage is titrated to effect. Dosages as high as 2.5 µg/kg slow IV followed by 2 – 4 µg/kg/*HOUR* IV CRI have been noted.[9]

Epidural analgesia in dogs (extra-label): 0.5 – 1 µg/kg diluted to a volume of 0.2 – 0.36 mL/kg with sterile saline. The onset of action is 10 to 15 minutes; duration 1 to 4 hours.[10–12]

RABBITS:

Anesthesia (extra-label): 0.5 µg/kg IV bolus, followed by 0.72 µg/kg/*HOUR* IV CRI[13]

Monitoring

- Anesthetic and/or analgesic efficacy
- Cardiac and respiratory rate
- Pulse oximetry or other methods to measure blood oxygenation when used for anesthesia
- Blood pressure

Client Information

- Sufentanil is a very potent opioid that should only be used by professionals in a setting where adequate patient monitoring is available.

Chemistry/Synonyms

Sufentanil citrate is a phenylpiperidine derivative opioid related to fentanyl. It occurs as a white or almost white powder that is soluble in water and sparingly soluble in alcohol, acetone, and chloroform. The commercially available injection has a pH (adjusted with citric acid) of 3.5 to 6.

Sufentanil citrate may also be known as R-33800, sufentanili citras, fentathienel citrate, sufentanyl citrate, sulfentanil citrate, *Fastfen®*, *Fentaientel®*, and *Sufenta®*.

Storage/Stability

Unless otherwise labeled, store sufentanil injection protected from light at room temperature 20°C to 25°C (68°F-77°F). Sufentanil citrate is hydrolyzable in acidic solutions.

Sufentanil citrate is a DEA Schedule II (C-II) controlled substance; store it in a substantially constructed and securely locked area. Follow applicable local, state, and federal rules regarding the disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

Sufentanil citrate is reportedly **compatible** with 5% dextrose and bupivacaine. Sufentanil is **Y-site compatible** with solutions containing atropine, dexamethasone sodium phosphate, diazepam, diphenhydramine, etomidate, metoclopramide, midazolam, phenobarbital, and propofol. It is **incompatible** with lorazepam, phenytoin, and thiopental.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 1 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Sufentanil Citrate Injection: 50 µg/mL (as base) in 1 mL, 2 mL, and 5 mL ampules; *Sufenta®* (preservative free), generic; (Rx, C-II)

Bactrim®, EquiSul-SDT®, Uniprim®

Potentiated Sulfonamide Antimicrobial

NOTE: In the United States, 2 FDA-approved combinations of sulfonamide with trimethoprim (ie, sulfa-/trimethoprim) are used clinically in animals: sulfadiazine/trimethoprim for parenteral and oral use in dogs, cats, and horses and sulfamethoxazole/trimethoprim for oral use in humans. In Canada, sulfadoxine is also available in combination with trimethoprim for veterinary use.

Prescriber Highlights

- Combination antimicrobial agent, often referred to as a potentiated sulfonamide, used to treat bacterial and protozoal infections
- Contraindications include hypersensitivity to sulfonamides and severe renal or hepatic impairment.
- Caution is advised in cases of diminished renal or hepatic function, urinary obstruction, urolithiasis, and in dog breeds predisposed to sulfonamide hypersensitivity (eg, Doberman pinschers).
- Adverse effects in dogs include keratoconjunctivitis sicca, hypersensitivity (type 1 or type 3), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, crystalluria, hematuria, polyuria, cholestasis, hypothyroidism, anemia, agranulocytosis, and idiosyncratic hepatic necrosis.
- Adverse effects in cats include anorexia, crystalluria, hematuria, leukopenia, and anemia.
- Adverse effects in horses include diarrhea, hypersensitivity reactions, and hematologic effects (eg, anemia, thrombocytopenia, leukopenia) when administered orally and transient pruritus after IV injection.
- Local injection adverse effects (eg, warmth, edema, pain) are possible.
- Sulfa-/trimethoprim is potentially teratogenic; weigh the risks versus the benefits before prescribing.
- In the United States, extra-label use of sulfonamides is prohibited in lactating dairy cattle.

Uses/Indications

Although sulfadiazine/trimethoprim is only FDA-approved for use in dogs and horses, this drug is used to treat infections caused by susceptible bacteria and parasitic organisms in various species.

Sulfadiazine/trimethoprim is commonly used in horses because it is 1 of a limited number of safe oral options. Although use in dogs is more limited because of concerns about adverse effects and availability of other antimicrobial options, this antibiotic is a potential choice for treatment of various infections (eg, cystitis, prostatitis) and is also sometimes used for treatment of atypical pathogens (eg, *Nocardia* spp). Prophylactic use of sulfadiazine/trimethoprim reduced morbidity in dogs receiving doxorubicin.[1]

The World Health Organization (WHO) has designated sulfamethoxazole/trimethoprim as a Highly Important antimicrobial for human medicine.[2] The Office International des Epizooties (OIE) Antimicrobial Classification has designated sulfadiazine/trimethoprim as a Veterinary Critically Important antimicrobial.[3]

Pharmacology/Actions

Sulfonamides are bacteriostatic agents while trimethoprim is bactericidal; both agents are time-dependent antibiotics. When used in combination, the resulting potentiated sulfonamides are bactericidal. Potentiated sulfonamides sequentially inhibit enzymes in the folic acid pathway, inhibiting bacterial thymidine synthesis. Sulfonamides compete with para-aminobenzoic acid (PABA) to reduce bacterial dihydrofolic acid (DFA) formation, and trimethoprim blocks the conversion of DFA to tetrahydrofolic acid by preferentially inhibiting bacterial dihydrofolate reductase. Infected tissue and cellular debris can inhibit the activity of sulfa-/trimethoprim by secreting PABA and thymidine. The effects of sulfa-/trimethoprim on the equine GI microbiome appear to be reversible.[4]

The in vitro optimal ratio for most susceptible bacteria is ≈1:20 (trimethoprim:sulfonamide), but synergistic activity can reportedly occur with ratios of 1:1 to 1:40. The serum concentration of the trimethoprim component is considered more important than the sulfonamide concentration.

Potentiated sulfonamides have a fairly broad spectrum of activity. Generally susceptible gram-positive bacteria include most streptococci and staphylococci and *Nocardia* spp. Many gram-negative organisms of the Enterobacteriaceae family are inherently susceptible to potentiated sulfonamides but acquired resistance can occur. Sulfa-/trimethoprim is ineffective against *Pseudomonas aeruginosa*; some protozoa (ie, *Pneumocystis jiroveci*, *Coccidia* spp, *Neospora* spp, *Toxoplasma* spp) are also inhibited. Potentiated sulfonamides appear to have little activity against most atypical bacteria and anaerobes; methicillin-resistant staphylococci are usually resistant. *Enterococcus* spp infections may appear to be susceptible to sulfonamide-containing antibiotics in vitro; however, they are intrinsically resistant, so sulfa-/trimethoprim should not be used for these bacteria.

Resistance development is thought to occur more slowly to the combination of drugs than to either drug alone. In gram-negative organisms, sulfamethoxazole resistance is usually plasmid mediated, although a point mutation for dihydropteroate synthase also may confer resistance.

Pharmacokinetics

Sulfa-/trimethoprim is relatively well absorbed after oral administration, with peak concentrations occurring ≈1 to 4 hours after administration; however, the drug is absorbed more slowly after SC absorption. Oral bioavailability in fed horses after a single dose of 30 mg/kg paste was 74% for sulfadiazine and 46% for trimethoprim.[5] Bioavailability was ≈84% in male goats.[6] Food has no apparent effect on the absorption of sulfadiazine, but trimethoprim absorption is decreased.

In calves 1 day and 1 week of age, trimethoprim and sulfadiazine were absorbed after oral administration, although serum trimethoprim concentration was diminished in the 1-week-old calves. In calves 6 weeks of age, peak sulfadiazine concentration was only 60% as compared with calves 1 day of age, and trimethoprim was undetectable.[7] In a separate study, sulfadiazine half-life was 8.5 to 10 hours in calves 6 weeks of age and ≈8 to 13 hours in calves 12 weeks of age.[8] In ruminants older than 8 weeks of age, trimethoprim is apparently trapped in the ruminoreticulum after oral administration and undergoes some degradation that limits its usefulness.

Sulfa-/trimethoprim is well distributed in the body; however, in horses, concentrations are lower in the pulmonary epithelial lining fluid than in plasma.[5] Both sulfadiazine and trimethoprim attain therapeutic concentrations in the equine endometrium.[9] In dogs, therapeutic concentrations of both agents are reached in the skin.[10] In patients with inflamed meninges, the drugs enter the CSF in concentrations ≈50% of those found in the serum. Sulfa-/trimethoprim

is relatively well distributed into the prostate, and both drugs concentrate in the urine. The volume of distribution for trimethoprim is 1.49 L/kg in dogs; 0.59 to 1.51 L/kg in horses; and 2.7 L/kg in donkeys.[11] The volume of distribution for sulfadiazine is 1.02 L/kg in dogs and 0.6 L/kg in donkeys.[11] Sulfadiazine and trimethoprim are 20% and 35% bound to equine plasma proteins.[12]

Sulfa-/trimethoprim is both renally excreted unchanged via glomerular filtration and tubular secretion and metabolized by the liver. Sulfonamides are primarily acetylated (not in dogs) and conjugated with glucuronic acid, and trimethoprim is metabolized to oxide and hydroxylated metabolites. Trimethoprim may be more extensively metabolized in the liver of adult ruminants than in other species. The serum elimination half-life for trimethoprim is 2.5 hours in dogs, ≈2 to 3 hours in horses, 10.9 hours in goats,[6] and 1.5 hours in cattle. The serum elimination half-life for sulfadiazine is 9.84 hours in dogs, ≈4 to 8 hours in horses, and 2.5 hours in cattle. Sulfadiazine and trimethoprim clearances in donkeys were 1.7 and 4.4 mL/minute/kg, respectively.[11] Although trimethoprim is rapidly eliminated from the serum, the drug may persist for a longer period of time in tissue.

Because of the number of variables involved, it is extremely difficult to apply pharmacokinetic values in making dosage recommendations with these combinations. Each drug (ie, trimethoprim, sulfonamide) has different pharmacokinetic parameters (eg, absorption, distribution, elimination) in each species. Because different organisms have different MIC values and the optimal ratio of trimethoprim to sulfonamides differs from organism to organism, this problem is exacerbated.

Considerable controversy exists regarding the frequency of administration of these combinations. Sulfadiazine/trimethoprim is labeled for once daily administration in dogs and horses, but many clinicians believe that sulfa-/trimethoprim is more efficacious if given twice daily, regardless of the sulfonamide used.

Contraindications/Precautions/Warnings

The veterinary manufacturer states that sulfadiazine/trimethoprim should not be used in dogs or horses with marked liver parenchymal damage, impaired hepatic function, blood dyscrasias, or a history of sulfonamide or trimethoprim sensitivity. Sulfadiazine/trimethoprim is not for use in horses (or FDA-approved for other animals) intended for food. Sulfonamides are *not* considered contraindicated in patients allergic to thiazide diuretics or sulfonylurea agents.[13]

Doberman pinschers, Samoyeds, and miniature schnauzers appear to be more susceptible to sulfonamide-induced polysystemic immune complex disease[14]; use sulfa-/trimethoprim with caution in these breeds.

Sulfa-/trimethoprim should be used with caution in patients with pre-existing hepatic or renal disease or folate deficiency. In animals with moderate to severe renal dysfunction, consider dosage reduction; avoid products containing sulfadiazine.

Sulfadiazine has potential for crystallization in the urine, so use should be avoided in dogs with uroliths, at increased risk for developing uroliths, with highly concentrated urine (from dehydration), or with acidic urine.

Horses receiving sulfadiazine/trimethoprim that are under conditions of stress may develop potentially fatal acute diarrhea.[15] Discontinue antimicrobial therapy if acute diarrhea or persistent changes in fecal consistency are observed and initiate appropriate treatment. Sulfadiazine/trimethoprim should not be administered to horses with drug-induced cardiac arrhythmias (eg, anesthetic and sedative agents) and it should not be given IV concurrently or with previous administration of CNS depressants (eg, anesthetic agents, phenothiazines).[16]

In humans, sulfamethoxazole/trimethoprim is contraindicated in patients younger than 2 months of age, with known hypersensitivity to either drug component, with marked hepatic or renal impairment, and with megaloblastic anemia due to folate deficiency.

Adverse Effects

Adverse effects noted in dogs include keratoconjunctivitis sicca (KCS; which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria, and cholestasis. Potentiated sulfonamides may cause clinical hypothyroidism in dogs, particularly with extended therapy. Acute hypersensitivity reactions manifesting as type I (ie, anaphylaxis) or type III (ie, formation of antigen:antibody complexes) reactions can be seen. Hypersensitivity reactions appear to be more common in large-breed dogs. Doberman pinschers, Samoyeds, and miniature schnauzers may be more susceptible to hypersensitivity reactions than other breeds.[14] Other hematologic effects (eg, anemia, agranulocytosis) are possible but are rare, although the incidence may increase with prolonged use of high doses.[17] Sulfa-/trimethoprim has rarely caused an idiosyncratic, moderate to massive hepatic necrosis in dogs.[18] Use of sulfa-/trimethoprim may increase the risk for developing acute pancreatitis,[14] but cause and effect have not been definitively shown.

Adverse effects noted in cats may include anorexia, leukopenia, and anemia.

In horses, transient pruritus has been noted after IV injection. Oral therapy has resulted in dose-related diarrhea, but incidence is relatively low. Previous administration of potentiated sulfonamides has been implicated in increasing the mortality rate associated with severe diarrhea. If the 48% injectable product is administered IM or SC, or if it extravasates after IV administration, swelling, pain, and minor tissue damage may result. Hypersensitivity reactions, neurologic effects (eg, gait alterations, behavior changes), cutaneous vasculitis, and hematologic effects (eg, anemia, thrombocytopenia, leukopenia) may also be seen.[19] In experimental models, trimethoprim inhibited equine voltage-gated K+ channel K(v)11.1, suggesting that trimethoprim could induce repolarization disorders in horses[20,21]; validation with in vivo studies are needed. Neurologic adverse effects (agitation, erratic behavior, hypermetric gait) have been noted in horses being treated with typical doses of sulfa-/trimethoprim; all adverse effects resolved with discontinuation of the drug.[22]

Sulfonamides (and their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Acidic or highly concentrated urine may also contribute to increased risk for crystalluria, hematuria, and renal tubule obstruction.

Regurgitation may occur in birds.

Sulfamethoxazole/trimethoprim can markedly reduce tear production in rabbits,[23] but sulfadiazine/trimethoprim had no effect in horses.[24]

Reproductive/Nursing Safety

Trimethoprim and sulfonamides cross the placenta. Safety of sulfa-/trimethoprim has not been clearly established in pregnant animals. Reports of teratogenicity (eg, cleft palate, fetal loss) have been reported in rats and rabbits. Studies in male animals have not demonstrated reduced reproductive performance. First trimester exposure in humans has been associated with increased risk for congenital malformations.

Trimethoprim and sulfonamides are distributed into milk. Use sulfa-/trimethoprim products in nursing animals with caution. Sulfonamides are distributed into maternal milk, but in humans are considered compatible with breastfeeding in healthy, full-term infants.[25,26] Premature infants and infants with hyperbilirubinemia may be at risk for adverse effects.

Overdose/Acute Toxicity

Manifestations of an acute overdose can include clinical signs of GI distress (eg, nausea, vomiting, diarrhea), CNS toxicity (eg, depression,), facial swelling, bone marrow depression, and increased serum aminotransferase (ie, ALT, AST) activity. Oral overdoses can be

treated by emptying the stomach (following typical protocols) and initiating supportive therapy based on clinical signs. Acidification of the urine may increase the renal elimination of trimethoprim but could also cause sulfonamide crystalluria, particularly with sulfadiazine-containing products. CBC and other laboratory parameters should be monitored as necessary. Severe bone marrow suppression associated with chronic overdoses can be treated with folinic acid (leucovorin). Peritoneal dialysis is not effective in removing trimethoprim or sulfonamides from circulation.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

In humans, trimethoprim may be a substrate of p-glycoprotein, sulfamethoxazole is a substrate of the CYP2C family, and both trimethoprim and sulfamethoxazole may inhibit CYP2C enzymes. The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfa-/trimethoprim and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amantadine**: A human patient developed toxic delirium while receiving amantadine in conjunction with sulfamethoxazole/trimethoprim.[27]
- **Amiodarone**: May reduce sulfonamide metabolism and increase the risk for adverse effects.
- **Anesthetic Agents**: Concurrent IV administration is contraindicated. Ester-type local anesthetics (eg, **procaine, tetracaine**) may locally inhibit sulfonamide effects.[28,29]
- **Angiotensin II-Receptor Blockers** (**ARBs**; eg, **telmisartan**): May increase the risk for hyperkalemia when used with potassium-sparing drugs
- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): May increase the risk for hyperkalemia when used with potassium-sparing drugs
- **Antacids**: Concurrent administration may decrease sulfonamide bioavailability.
- **Azathioprine, Mercaptopurine**: Increased risk for myelosuppression
- **Cyclosporine**: Sulfa-/trimethoprim may increase the risk for nephrotoxicity.
- **Detomidine**: Concurrent use has resulted in fatal arrhythmias in horses.[21]
- **Digoxin**: Sulfa-/trimethoprim may increase digoxin concentration.
- **Diuretics, Thiazide**: May increase the risk for thrombocytopenia
- **Hypoglycemic Agents, Oral** (eg, **glipizide, metformin**): Sulfa-/trimethoprim may potentiate hypoglycemic effects.
- **Leucovorin**: May reduce therapeutic effect of sulfa-/trimethoprim
- **Methenamine**: May form an insoluble precipitate in the urine
- **Methotrexate** (MTX): Sulfa-/trimethoprim may displace from plasma proteins and increase the risk for toxic effects; it can also interfere with MTX assays (competitive protein binding technique, but not when measured by radioimmunoassay).
- **Phenothiazines** (eg, **acepromazine, promethazine**): Concurrent administration is contraindicated.
- **Potassium Supplements**: Increased risk for hyperkalemia
- **Procainamide**: Sulfa-/trimethoprim may increase the concentration of procainamide and its active metabolite.
- **Pyrimethamine**: May increase the risk for megaloblastic anemia and myelosuppression
- **Rifampin**: May reduce serum concentrations of trimethoprim and sulfonamide
- **Spironolactone**: May increase the risk for hyperkalemia when used with potassium-sparing drugs
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): Sulfa-/trimethoprim may decrease efficacy.
- **Warfarin**: Sulfa-/trimethoprim may prolong prothrombin time and INR.

Laboratory Considerations

- When using the Jaffe alkaline picrate reaction assay for **creatinine** determination, sulfa-/trimethoprim may cause an overestimation of ≈10%.
- Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

Dosages

NOTE: There is significant controversy regarding the frequency of administration of these drugs. See ***Pharmacokinetics*** for more information. Unless otherwise noted, doses are for combined sulfa-/trimethoprim. See ***Monitoring*** if treatment is expected to be longer than 7 days.

DOGS:

For systemic antibacterial action against sensitive organisms, either alone or as an adjunct to surgery or debridement with associated infection; treatment of acute urinary tract infections, acute bacterial complications of distemper, acute respiratory tract infections, acute alimentary tract infections, wound infections, and abscesses (label dosage; FDA-approved): 30 mg/kg PO once daily. Alternatively, especially in severe infections, the initial dose may be followed by 15 mg/kg every 12 hours.[30]

Superficial bacterial folliculitis (extra-label): 15 – 30 mg/kg PO twice daily.[31] Potentiated sulfonamides (ie, sulfa-/trimethoprim, sulfadimethoxine/ormetoprim) are first-tier drugs only if regional susceptibility of *Staphylococcus pseudintermedius* is known.

Bacterial cystitis (extra-label): Potentiated sulfonamides (ie, sulfa-/trimethoprim, sulfadimethoxine/ormetoprim) are first-tier drugs only if regional pathogen susceptibility patterns are known.[32]

a) **Uncomplicated UTI**: 15 mg/kg PO every 12 hours. Treatment may be as short as 3 days.[32,33]
b) **Complicated UTI**: 15 – 30 mg/kg PO every 12 hours[32]

Parasitic diseases (extra-label):

Coccidiosis:

a) Body weight less than 4 kg (8.8 lb): 15 – 30 mg/kg PO every 12 to 24 hours[34]
b) Body weight greater than 4 kg (8.8 lb): 30 – 60 mg/kg PO every 24 hours[34]

Neosporosis: Sulfadiazine/trimethoprim 15 – 20 mg/kg PO every 12 hours for 4 weeks in combination with pyrimethamine 1 mg/kg PO once daily for 4 weeks. If observable clinical improvement is slow, treatment should be extended beyond the recommended 4 weeks until 2 weeks after clinical signs have plateaued. All littermates of affected puppies should be treated regardless of clinical signs. Alternative treatment is clindamycin 12.5 – 25 mg/kg PO or IM every 12 hours for 4 weeks.[35] **NOTE**: There is no approved or curative treatment for canine neosporosis. Arrestment of clinical disease is best achieved when treatment is initiated before the occurrence of contracture or paralysis.

Toxoplasmosis: Sulfa-/trimethoprim 15 mg/kg PO every 12 hours for 4 weeks can be used. Supportive care should be provided as needed.[35] There is no approved treatment for toxoplasmosis in dogs.

Pneumocystosis (*Pneumocystis jiroveci*): 15 mg/kg PO every 8 hours for 3 weeks or 30 mg/kg PO every 12 hours for 3 weeks

American canine hepatozoonosis (*Hepatozoon americanum*): Triple-combination therapy (TCP) consists of sulfadiazine/trimethoprim 15 mg/kg PO every 12 hours for 14 days, clindamycin 10 mg/kg PO every 8 hours for 14 days, and pyrimethamine 0.25 mg/kg PO every 24 hours for 14 days or ponazuril 10 mg/kg PO every 12 hours for 14 days. Prolonged therapy consists of decoquinate 10 – 20 mg/kg mixed in food twice daily; treatment is continued for 2 years. If relapse occurs, either ponazuril or TCP should be administered again for 14 days, followed by long-term decoquinate therapy.[36] **NOTE**: No treatment is effective in eliminating *H americanum* in infected dogs. Treatment can increase survival time, improve quality of life, and decrease the number and severity of clinical relapses. Supportive care can ensure hydration, and NSAIDs can assist with pain control.

CATS:

Bacterial cystitis (extra-label): Potentiated sulfonamides (ie, sulfa-/trimethoprim, sulfadimethoxine/ormetoprim) are first-tier drugs only if regional pathogen susceptibility patterns are known.[32]

a) **Uncomplicated UTI**: 15 mg/kg PO every 12 hours. Treatment may be as short as 3 days.[32,33]
b) **Complicated UTI**: 15 – 30 mg/kg PO every 12 hours.[32]

Parasitic diseases (extra-label):

Coccidiosis: 15 – 30 mg/kg PO every 12 to 24 hours[34]

Toxoplasmosis: 15 mg/kg PO every 12 hours for 4 weeks can be used. Supportive care should be provided as needed.[35]

HORSES:

Control of bacterial infections of horses during treatment of acute strangles, respiratory tract infections, acute urogenital infections, wound infections, and abscesses (label dosage; FDA-approved):

a) **Powder and paste formulations**: 75 mg/kg PO once daily; administer in a small amount of feed. Continue treatment for 2 to 3 days after clinical signs have subsided. Usual treatment course is 5 to 7 days.[37,38]
b) **IV injection formulation**: 21.3 mg/kg IV once daily[38]

Lower respiratory tract infections by susceptible strains of *Streptococcus equi* subsp *zooepidemicus* (label dosage; FDA-approved): 24 mg/kg (combined active ingredients) PO twice daily for 10 days[15]

Respiratory infections (extra-label): 30 mg/kg PO or IV twice daily.[5] **NOTE**: Potentiated sulfonamides for treatment of lower airway infections in horses should be restricted to treatment against highly susceptible pathogens.

***Pneumocystis jiroveci* (formerly *P carinii*) in foals** (extra-label): 30 mg/kg PO every 12 hours

Dermatologic infections (extra-label): 15 – 30 mg/kg PO every 12 hours, often in conjunction with topical antibacterial shampoo. Treatment for 3 weeks may be necessary.[39]

BIRDS:

Susceptible infections (extra-label):

a) **Respiratory and enteric infections in psittacines** using the 24% (240 mg/mL) injectable suspension: 0.22 mL/kg IM once to twice daily
b) **Respiratory and enteric infections in hand-fed baby psittacines**: Using the sulfamethoxazole/trimethoprim oral suspension 240 mg/5 mL (48 mg/mL): 0.22 mL/30 g 2 to 3 times daily for 5 to 7 days
c) **Coccidiosis in toucans and mynahs**: Using the sulfamethoxazole/trimethoprim oral suspension 240 mg/5 mL (48 mg/mL): 2.2 mL/kg once daily for 5 days; may be added to feed.
d) **Canaries, finches, and mynah birds**: Sulfadiazine/trimethoprim 100 mg/kg PO twice daily is recommended for treatment of avian coccidian parasitic diseases.[40] **NOTE**: *Atoxoplasma* spp treatment is difficult.
e) **GI protozoal infections in pigeons**: 25 – 50 mg/kg PO twice daily for 10 to 14 days[41]

FERRETS:

Susceptible infections (extra-label):

a) 30 mg/kg PO twice daily
b) **Coccidiosis**: 30 mg/kg PO once daily for 14 days

RABBITS, RODENTS, SMALL MAMMALS:

Susceptible infections (extra-label):

a) **Rabbits**:
   i. 15 – 30 mg/kg PO every 12 to 24 hours; 30 – 48 mg/kg SC every 12 hours. Sulfadiazine has a very short half-life (ie, ≈1 hour) in rabbits.[42]
   ii. **GI protozoal infections**: 25 – 30 mg/kg PO twice daily for 10 to 14 days[41]
b) **Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats**: 15 – 30 mg/kg PO every 12 hours
c) **Chinchillas, Hedgehogs**: 30 mg/kg PO or SC every 12 hours[43]

REPTILES:

Susceptible infections (extra-label):

a) **Most species**: 30 mg/kg IM (upper part of body) once daily for 2 treatments, then every other day for 5 to 12 treatments; may be useful for enteric infections.[44]
b) **All species**: 30 mg/kg IM, first 2 doses should be 24 hours apart, then every other day[45]
c) 15 – 25 mg/kg/day IM for 7 to 14 days[46]
d) **GI protozoal infections in bearded dragons**: 15 – 20 mg/kg PO once daily for 7 to 14 days; may consider giving dose every other day after the second dose.[41]

Monitoring

- Clinical efficacy
- Adverse effects
- Renal function (creatinine, BUN) and potassium
- If prolonged therapy (ie, greater than 7 days) is anticipated, the following is recommended:
- Baseline and periodic CBC and hepatic profile
- In dogs, baseline Schirmer tear testing, with periodic re-evaluation (eg, in 5 days, then every 2-3 weeks) and owner monitoring for ocular discharge
- Thyroid function tests should also be considered (baseline and ongoing) in dogs

Client Information

- Shake the oral suspension well before using. It does not need to be refrigerated.
- Give to horses on an empty stomach.
- Animals must be allowed free access to water and not become dehydrated while receiving this medication.
- If the animal's eyes are dry, develop a discharge, or become irritated, contact your veterinarian.
- In horses, discontinue treatment and contact your veterinarian immediately if there are changes in stool consistency or diarrhea.

Chemistry/Synonyms

Trimethoprim occurs as odorless, bitter-tasting, white to cream-col-

ored crystals or crystalline powder. It is very slightly soluble in water and slightly soluble in alcohol.

Sulfadiazine occurs as an odorless or nearly odorless, white to slightly yellow powder. It is practically insoluble in water and sparingly soluble in alcohol.

Sulfamethoxazole occurs as a practically odorless and tasteless, white to off-white, crystalline powder. Approximately 0.29 mg is soluble in 1 mL of water, and 20 mg is soluble in 1 mL of alcohol.

In combination, sulfadiazine and trimethoprim may be known as co-trimazine, sulfadiazine/trimethoprim, trimethoprim/sulfadiazine, SDZ-TMP, TMP-SDZ, and various trade names.

In combination, sulfamethoxazole and trimethoprim may be known as co-trimoxazole, sulfamethoxazole/trimethoprim, trimethoprim/sulfamethoxazole, SMX-TMP, TMP-SMX, and various trade names.

Storage/Stability

Unless otherwise instructed by the manufacturer, sulfa-/trimethoprim products should be stored at room temperature of 20°C to 25°C (68°F-77°F) in tight containers and protected from freezing. Shake suspensions well before use.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Trimethoprim/Sulfadiazine Oral Suspension: Each gram contains 67 mg trimethoprim and 333 mg sulfadiazine (proprietary formulation) in 135 mL, 280 mL, 560 mL, and 900 mL bottles; *Equisul-SDT®*; (Rx). FDA-approved for use in horses not intended for food. NADA# 141-360

Trimethoprim/Sulfadiazine Powder: Each gram contains 67 mg trimethoprim and 333 mg sulfadiazine; *Uniprim® Powder* in 37.5 g and 1125 g packets; 200 g, 400 g, and 1200 g jars; 2000 g pails; and 12 kg box; (Rx). FDA-approved for use in horses not intended for food. NADA# 200-033

Trimethoprim/Sulfadiazine Oral Paste: Each gram contains 67 mg trimethoprim and 333 mg sulfadiazine. Available in 37.5 g (total weight) syringes; *Tribrissen® 400 Oral Paste*; (Rx). FDA-approved for use in horses not intended for food. **NOTE**: Not currently marketed in the United States; approved products are available in other countries.

Trimethoprim/Sulfadiazine Sterile Injection: 48% in 100 mL vials: *Di-Biotic® 48%*, *Tribrissen® 48% Injection*; (Rx). FDA-approved for use in horses not intended for food. **NOTE**: Not currently marketed in the United States; approved products are available in other countries under different trade names. A 24% solution may also be available.

In Canada, trimethoprim and sulfadoxine are available for use in cattle and swine (*Trimidox®*; *Borgal®*). Slaughter withdrawal = 10 days; milk withdrawal = 96 hours. (In the United States, extra-label use of sulfonamides is prohibited in lactating dairy cattle.)

In the United Kingdom, trimethoprim and sulfamethoxazole oral drops (*Sulfatrim®*) are available for use in rabbits, pigeons, and bearded dragons.

HUMAN-LABELED PRODUCTS:

Trimethoprim Tablets: 100 mg; generic; (Rx). A 50 mg/5 mL oral solution (trimethoprim HCl, *Primsol®*) is also available.

Trimethoprim and Sulfamethoxazole (Co-Trimoxazole; TMP-SMZ) Oral Tablets: 80 mg trimethoprim and 400 mg sulfamethoxazole; Double Strength Tablets: 160 mg trimethoprim and 800 mg sulfamethoxazole; *Bactrim®* and *Bactrim® DS*; generic; (Rx)

Trimethoprim 8 mg/mL and Sulfamethoxazole 40 mg/mL (labeled as 40 mg/5 mL and 200 mg/5mL) oral suspension; *Sulfatrim®*; generic; (Rx)

Trimethoprim and Sulfamethoxazole Injection: 80 mg sulfamethoxazole, 16 mg trimethoprim per mL in 5 mL single-use vials, 10 mL, or 30 mL multiple-dose vials; generic; (Rx). Contains benzyl alcohol, propylene glycol (40%); pH ≈10. **NOTE**: Refer to product label for administration guidelines.

Sulfadimethoxine

(sul-fa-***dye***-meth-***ox***-een) *Albon®*

Sulfonamide Antimicrobial

See also ***Sulfadimethoxine/Ormetoprim***

Prescriber Highlights

- ► Used to treat bacterial and protozoal infections
- ► Contraindications include hypersensitivity to sulfonamides and severe renal or hepatic impairment.
- ► Use with caution in breeds that are prone to sulfonamide hypersensitivity (ie, Doberman pinschers, Samoyeds, miniature schnauzers).
- ► Adverse effects include the possibility of the drug precipitating in the urine (particularly with high doses administered for prolonged periods, acidic urine, or highly concentrated urine). In dogs, keratoconjunctivitis sicca, hypersensitivity reactions (eg, rashes, fever, bone marrow suppression, dermatitis, nonseptic polyarthritis), focal retinitis, and vomiting are possible. Diminished renal or hepatic function or urinary obstruction may occur.
- ► Potentially teratogenic; potential risks versus benefits should be considered.
- ► In the United States, extra-label use of sulfonamides is prohibited in lactating dairy cattle.

Uses/Indications

Sulfadimethoxine injection and tablets are FDA-approved for use in dogs and cats for respiratory, genitourinary, enteric, and soft tissue infections caused by susceptible organisms. Efficacy is greater when treatment is initiated early in the course of disease. Sulfadimethoxine is also used to treat coccidial infections in small animals.

In horses, sulfadimethoxine injection is FDA-approved for the treatment of respiratory infections caused by *Streptococcus equi*.

In cattle, sulfadimethoxine is FDA-approved for treatment of shipping fever complex, calf diphtheria, bacterial pneumonia, and foot rot caused by susceptible organisms.

In poultry, sulfadimethoxine is added to drinking water to treat coccidiosis, fowl cholera, and infectious coryza.

Although sulfadimethoxine is not used in human medicine, the World Health Organization (WHO) has designated sulfonamides as highly important antimicrobials for human medicine.[1] The Office International des Epizooties (OIE) has designated sulfonamides as Veterinary Critically Important Antimicrobial (VCIA) Agents for veterinary species.[2]

Pharmacology/Actions

Sulfonamides are time-dependent, bacteriostatic agents when used alone, but are considered bactericidal when used in combination with dihydrofolate reductase inhibitors (eg, ormetoprim, trimethoprim). They are thought to prevent bacterial replication by competing with

para-aminobenzoic acid (PABA) in the biosynthesis of tetrahydrofolic acid in the pathway to form folic acid. Only microorganisms that synthesize their own folic acid are affected by sulfonamides.

Microorganisms usually affected by sulfonamides include some gram-positive bacteria, including some strains of streptococci, staphylococcus, *Bacillus anthracis*, *Clostridium tetani*, *Clostridium perfringens*, and many strains of *Nocardia* spp. Sulfonamides also have in vitro activity against some gram-negative species, including some strains of *Shigella* spp, *Salmonella* spp, *Escherichia coli*, *Klebsiella* spp, *Enterobacter* spp, *Pasteurella* spp, and *Proteus* spp. Sulfonamides have activity against some protozoa (eg, *Toxoplasma* spp, *Coccidia* spp). Sulfonamides are inactive against atypical bacterial, viral, or fungal infections.

Sulfonamides are less efficacious in pus, necrotic tissue, or in areas with extensive cellular debris.

Pharmacokinetics

In dogs, cats, swine, and sheep, sulfadimethoxine is reportedly readily absorbed and well distributed. Relative volumes of distribution range from 0.17 L/kg in sheep to 0.35 L/kg in horses and cattle. Parameters in dogs include 33% bioavailability, 75% protein binding, and 13.1-hour elimination half-life.[3] Bioavailability was 52% in llamas and ≈100% in camels.[4,5]

In most species, sulfadimethoxine is acetylated in the liver to acetylsulfadimethoxine and excreted unchanged in the kidneys. In dogs, the drug is not appreciably metabolized by the liver; renal excretion is the major route of drug elimination as the unchanged drug. Sulfadimethoxine's long elimination half-lives are a result of its appreciable reabsorption in the renal tubules. Serum half-lives reported in various species are 9 to 10 hours in llamas, 11.7 hours in camels, 13 hours in swine, 15 hours in sheep, and 11.3 hours in horses.[4–6]

Contraindications/Precautions/Warnings

Sulfonamides are contraindicated in patients that are hypersensitive to them. They are also considered contraindicated in patients with severe renal or hepatic impairment. They should be used with caution in animals with diminished renal or hepatic function or urinary obstruction. Sulfonamides are *not* considered contraindicated in patients that are allergic to thiazide diuretics or sulfonylurea agents.[7]

Doberman pinschers, Samoyeds, and miniature schnauzers appear to be highly susceptible to sulfonamide-induced polysystemic immune complex disease,[8–11] and these drugs should be used with caution in these breeds.

IV injection of sulfonamides given too rapidly can cause muscle weakness, blindness, ataxia, and collapse.

Adverse Effects

Sulfonamides (or their metabolites) can precipitate in the urine, particularly when given at high doses for prolonged periods. Acidic urine or highly concentrated urine may also contribute to increased risk for crystalluria, hematuria, and renal tubule obstruction. Different sulfonamides have different solubilities at various pH levels. Alkalinization of the urine using sodium bicarbonate may prevent crystalluria, but the amount available for tubular reabsorption decreases. Crystalluria can usually be avoided with most commercially available sulfonamides by maintaining an adequate urine flow. Normal urine pH in herbivores is usually 8 or more, so crystalluria is not frequently a problem. Sulfonamides can also cause various hypersensitivity reactions or diarrhea by altering the normal gut flora.

In dogs, keratoconjunctivitis sicca, hypersensitivity reactions (eg, rashes, dermatitis, fever, myelosuppression, nonseptic polyarthritis), focal retinitis, and vomiting have been reported with sulfonamides.[8] Dose-dependent hypothyroidism has been reported in dogs receiving sulfonamides.[12]

Oral sulfonamides can depress the normal cellulytic function of the ruminoreticulum, but this effect is generally temporary, and the animal typically adapts.

Because solutions of sulfonamides are usually alkaline, they can cause tissue irritation and necrosis if injected IM or SC.

Reproductive/Nursing Safety

Sulfonamides cross the placenta and may reach fetal concentrations of greater than or equal to 50% of those found in maternal serum; teratogenicity has been reported in some laboratory animals when sulfonamides are given at high doses.

Sulfonamides are distributed into maternal milk, but in humans, they are considered compatible with breastfeeding in healthy, full-term infants.[13,14] Premature infants and infants with hyperbilirubinemia may be at risk for adverse effects.

Overdose/Acute Toxicity

Acute toxicity secondary to overdoses apparently occurs only rarely in veterinary species. Dogs receiving single oral doses of 3.2 g/kg of body weight experienced only diarrhea. Dogs receiving 160 mg/kg PO daily for 13 weeks showed no signs of toxicity.[15] In addition to the adverse effects listed above, CNS stimulation and myelin degeneration have been noted after high doses are given.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfonamides and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Amiodarone**: May reduce sulfonamide metabolism and increase the risk for adverse effects
- **Antacids, Aluminum-, Calcium- and Magnesium-Containing**: May decrease oral bioavailability of sulfonamides if administered concurrently
- **Azathioprine, Mercaptopurine**: Increased risk for myelosuppression
- **Cyclosporine**: Increased risk for cyclosporine nephrotoxicity; decreased cyclosporine concentration is possible.
- **Leucovorin**: May reduce therapeutic effect of sulfadimethoxine
- **Methotrexate**: Concurrent use of sulfonamides may potentiate methotrexate toxicity by interfering with plasma protein binding and/or renal clearance of methotrexate and its toxic metabolite.
- **Pyrimethamine**: Concurrent use of sulfonamides with high doses of pyrimethamine may increase the risk for megaloblastic anemia and pancytopenia through additive antifolate effects.
- **Warfarin**: Sulfonamides may prolong prothrombin time (PT).

Laboratory Considerations

- Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

Dosages

DOGS/CATS:

Sulfadimethoxine-susceptible bacterial infections in dogs and cats and bacterial enteritis associated with coccidiosis in dogs (label dosage; FDA-approved): 55 mg/kg PO once on the first day, with subsequent daily doses of 27.5 mg/kg PO every 24 hours.[15] Length of treatment depends on the clinical response. Treatment should be continued until the animal shows no clinical signs for 48 hours. In most cases, treatment for 3 to 5 days is adequate.

Coccidiosis (extra-label): 50 – 60 mg/kg PO once daily for 5 to 20 days[16]

Coccidiosis in dogs (extra label): 25 mg/kg PO in combination with amprolium 150 mg/kg PO once daily for 14 days[17]

HORSES:

Susceptible infections (label dosage; FDA-approved): 55 mg/kg IV initially, then 27.5 mg/kg every 24 hours IV until free of clinical signs for 48 hours[18]

CATTLE:

Susceptible infections (label dosage; FDA-approved):

a) **Bolus tablets**: 55 mg/kg PO initially, then 27.5 mg/kg PO every 24 hours.[19] Length of treatment depends on the clinical response but should not exceed 5 days.

b) **Injection**: 55 mg/kg IV initially, then 27.5 mg/kg IV every 24 hours until free of clinical signs for 48 hours.[20] The injection should be made moderately slow, never rapidly.

NEW-WORLD CAMELIDS:

Coccidiosis (*Eimeria alpacae, Eimeria lamae, Eimeria punoensis, Eimeria peruviana*) (extra-label): 15 mg/kg PO twice daily for 5 days; monitor for signs of polioencephalomalacia[21]

***Eimeria* spp infection** (extra-label): Treatment is generally directed at clinically affected animals using sulfadimethoxine 110 mg/kg PO every 24 hours (or amprolium). Treatments are effective only against the immature stages and therefore may not have a significant impact on fecal oocyst count initially. *Eimeria macusaniensis* infections have a long prepatent period, treatment should last 10 to 15 days and should be directly administered to the animal rather than by medicating water supplies.[22]

FERRETS:

Coccidiosis (extra-label): 50 mg/kg PO once, then 25 mg/kg every 24 hours for 5 to 10 days. Alternatively, 25 mg/kg PO every 24 hours for 21 days.[23] Treatment may not clear the organism.

RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits** (extra-label): 10 – 15 mg/kg PO every 12 hours[24]

b) **Coccidiosis in rabbits** (extra-label):

i. 25 mg/kg PO once daily[25]

ii. 50 mg/kg PO once, followed by inclusion in drinking water at 1 g/4 L for 9 days[26]

c) **Hedgehogs** (extra-label): 2 – 20 mg/kg/day IM, SC, or PO[27]

d) **Coccidiosis in mice, rats, gerbils, hamsters, guinea pigs, chinchillas** (extra-label): 50 mg/kg PO once, then 25 mg/kg PO once daily for 10 to 20 days or 75 mg/kg PO for 7 to 14 days

REPTILES:

***Coccidia* spp** (extra-label): 90 mg/kg PO once initially, followed by 45 mg/kg PO every 24 hours for 5 successive days; may also be given IM or IV. Maintain adequate hydration during treatment.[28]

***Isospora* spp** (extra-label): 50 mg/kg PO once daily for 21 days has been recommended for bearded dragons.[29]

Monitoring

- Clinical efficacy
- Adverse effects
- Baseline and periodic CBC and serum liver chemistry panel should be considered with long-term therapy.
- Baseline Schirmer tear testing is recommended in dogs if prolonged therapy (ie, more than 7 days) is anticipated or in dogs with a predisposition for KCS (eg, shih tzus, cocker spaniels). Dogs should be re-evaluated periodically (ie, within 5 days of starting therapy, then every 2 to 3 weeks during treatment). Owners should monitor dogs for red eye and ocular discharge.

Client Information

- If using the oral suspension, shake well before using. The oral suspension does not need to be refrigerated.
- It is important that your animal has access to plenty of fresh water while taking this medicine.
- Contact your veterinarian if the dog's eyes are dry, become red or irritated, or develops a discharge. You should also contact your veterinarian if your dog develops a rash or other skin lesions, low energy level, poor appetite, or has difficulty walking.

Chemistry/Synonyms

Sulfadimethoxine, a long-acting sulfonamide, occurs as an odorless or almost odorless, almost tasteless white powder. It is practically insoluble in water and slightly soluble in alcohol.

Sulfadimethoxine may also be known as solfadimetossina, solfadimetossipirimidina, sulphadimethoxine, *Albon®*, *Bactrovet®*, *Agribon®*, *Chemiosalfa®*, *Deltin®*, *Di-Methox®*, *Levosin®*, *Risulpir®*, *Ritarsulfa®*, *SDM®*, *Sulfadren®*, *Sulfastop®*, *Sulfasol®*, and *Sulfathox®*.

Storage/Stability

Unless otherwise instructed by the manufacturer, store sulfadimethoxine products protected from light at a room temperature of 15°C to 30°C (59°F-86°F). Solutions may discolor if exposed to direct sunlight. If crystals form due to exposure to cold temperatures, either gently warm the vial in a warm water bath or store at room temperature until crystals dissolve. Freezing and discoloration of liquid formulations do not alter potency.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sulfadimethoxine Injection: 400 mg/mL (40%) in 250 mL vials; generic; (OTC). FDA-approved for use in cattle. Not to be used in calves to be processed for veal. Slaughter withdrawal (at labeled doses) is 5 days (cattle); milk withdrawal (at labeled doses) is 60 hours (5 milkings). A withdrawal period has not been established for preruminating calves.

Sulfadimethoxine Oral Tablets: 125 mg, 250 mg, and 500 mg; *Albon® Tablets*; (Rx). FDA-approved for use in dogs and cats

Sulfadimethoxine Oral Suspension: 50 mg/mL (5%) in 60- and 473-mL bottles; *Albon®*; (Rx). FDA-approved for use in dogs and cats

Sulfadimethoxine Oral Boluses: 2.5 g, 5 g, and 15 g; *Albon®*; (OTC). FDA-approved for use in cattle. Not to be used in calves to be processed for veal. No withdrawal period has been established for preruminating calves. Slaughter withdrawal (at labeled doses) is 7 days (cattle); milk withdrawal (at labeled doses) is 60 hours.

Sulfadimethoxine Soluble Powder: 94.6 g sulfadimethoxine/107 g packet (88.4% w/w) (for addition to drinking water); *Albon®*, generic; (OTC). FDA-approved for use in dairy calves, dairy heifers, beef cattle, broiler and replacement chickens only, and meat-producing turkeys. Slaughter withdrawal (at labeled doses) is 5 days in poultry (not for use in chickens older than 16 weeks or in turkeys older than 24 weeks) and 7 days in dairy calves, dairy heifers, and beef cattle only (withdrawal for preruminating calves has not been established; not to be used in calves to be processed for veal).

Sulfadimethoxine 12.5% Concentrated Solution: 3.8 L (1 gal) containers (for addition to drinking water): *Albon®*, generic; (OTC). FDA-approved for use in chickens, turkeys, and cattle. Slaughter withdrawal (at labeled doses) is 7 days in dairy calves, dairy heifers, and beef cattle only (withdrawal for preruminating calves has not been established; not to be used in calves to be processed for veal) and 5 days in poultry (not for use in chickens older than 16 weeks or in turkeys older than 24 weeks).

HUMAN-LABELED PRODUCTS: NONE

Sulfadimethoxine/Ormetoprim

(sul-fa-***dye***-meth-***ox***-een/or-meh-***toe***-prim) *Primor* ®

Potentiated Sulfonamide Antimicrobial

Prescriber Highlights

- ► Potentiated sulfa similar to sulfa-/trimethoprim but may have fewer adverse effects and is labeled for once daily administration

NOTE: The following points apply to sulfa-/trimethoprim and may also apply to sulfadimethoxine/ormetoprim.

- ► Contraindications include hypersensitivity to sulfonamides, thiazides, or sulfonylurea agents; severe renal or hepatic impairment; and Doberman pinschers.
- ► Caution is advised in diminished renal or hepatic function, urinary obstruction, and urolithiasis.
- ► Adverse effects in dogs include keratoconjunctivitis sicca (KCS), hypersensitivity reactions (type 1 or type 3), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, crystalluria, hematuria, polyuria, cholestasis, hypothyroidism, anemia, agranulocytosis, and idiosyncratic hepatic necrosis.
- ► Sulfadimethoxine/ormetoprim is potentially teratogenic; weigh the risks versus the benefits before prescribing.
- ► In the United States, extra-label use of sulfonamides is prohibited in lactating dairy cattle.

Uses/Indications

In dogs, sulfadimethoxine/ormetoprim is FDA-approved for the treatment of skin and soft tissue infections caused by susceptible strains of *Staphylococcus aureus* and *Escherichia coli* and UTIs caused by *E coli*, *Staphylococcus* spp, and *Proteus mirabilis*. Sulfadimethoxine/ormetoprim effectively treats superficial pyoderma. Sulfadimethoxine/ormetoprim may have fewer adverse effects in dogs as compared with sulfa-/trimethoprim and can be given once daily.

Pharmacology/Actions

Sulfadimethoxine/ormetoprim shares mechanism of action and (probably) the bacterial spectrum of activity with sulfa-/trimethoprim. Sulfonamides are bacteriostatic agents. When used in combination with either ormetoprim or trimethoprim, the resulting potentiated sulfonamides are bactericidal. Combining sulfonamides and dihydrofolate reductase inhibitors (eg, ormetoprim, trimethoprim) results in synergistic antimicrobial effects.[1] Potentiated sulfonamides sequentially inhibit enzymes in the folic acid pathway, inhibiting bacterial thymidine synthesis. The sulfonamide competes with para-aminobenzoic acid (PABA) to reduce bacterial dihydrofolic acid (DFA) formation, and ormetoprim blocks the conversion of DFA to tetrahydrofolic acid by preferentially inhibiting bacterial dihydrofolate reductase.

Potentiated sulfonamides have a fairly broad spectrum of activity. Generally susceptible gram-positive bacteria include most streptococci, many strains of staphylococcus, and *Nocardia* spp. Although many gram-negative organisms of the Enterobacteriaceae family are susceptible to potentiated sulfonamides, this does not include *Pseudomonas aeruginosa*. Some protozoa (ie, *Pneumocystis jiroveci*, *Coccidia* spp, *Toxoplasma* spp, *Neospora* spp) are also inhibited by the combination. Potentiated sulfonamides appear to have little activity against most atypical bacteria and anaerobes; methicillin-resistant staphylococci are usually resistant. *Enterococcus* infections may appear to be susceptible to sulfonamide-containing antibiotics in vitro; however, they are intrinsically resistant, so sulfonamide-containing antibiotics should not be used for these bacteria.

Resistance development is thought to occur more slowly to the combination of drugs than to either drug alone.[1] In gram-negative organisms, sulfamethoxazole resistance is usually plasmid mediated, although a point mutation for dihydropteroate synthase also may confer resistance.

The Office International des Epizooties (OIE) Antimicrobial Classification is a Veterinary Critically Important antimicrobial.[2]

Pharmacokinetics

In dogs, cats, swine, and sheep, sulfadimethoxine is reportedly readily absorbed and well distributed. Relative volumes of distribution range from 0.17 L/kg in sheep to 0.35 L/kg in cattle and horses. Parameters in dogs include 33% bioavailability, 75% protein binding, and 13.1-hour elimination half-life.[3] Bioavailability was 52% in llamas and ≈100% in camels.[4,5]

In most species, sulfadimethoxine is acetylated in the liver to acetylsulfadimethoxine and excreted unchanged in the kidneys. In dogs, the drug is not appreciably metabolized by the liver; renal excretion is the major route of drug elimination. Sulfadimethoxine's long elimination half-lives are a result of its appreciable reabsorption in the renal tubules. Serum half-lives reported in various species are 9 to 10 hours in llamas, 11.7 hours in camels, 13 hours in swine, 15 hours in sheep, and 11.3 hours in horses.[4-6]

Pharmacokinetic data for ormetoprim are not currently available, but the manufacturer states that therapeutic levels are maintained over 24 hours at recommended doses.[7]

Contraindications/Precautions/Warnings

The manufacturer states that sulfadimethoxine/ormetoprim should not be used in dogs with marked liver parenchymal damage, blood dyscrasias, or history of sulfonamide sensitivity.

Avoid use of this antibiotic in dogs that may be sensitive to potential adverse effects (eg, keratoconjunctivitis sicca, hepatopathy, hypersensitivity, skin eruptions).[8]

Doberman pinschers, Samoyeds, and miniature schnauzers appear to be more susceptible to sulfonamide-induced polysystemic immune complex disease[9]; use sulfadimethoxine/ormetoprim with caution in these breeds.

Sulfonamides (and their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Sulfadimethoxine is less likely to cause formation of sulfonamide crystalluria because it has a relatively high solubility at the normal pH found in the kidney; however, acidic or highly concentrated urine may cause precipitation.

This drug combination should be used with caution in patients with pre-existing hepatic or thyroid disease.

Adverse Effects

In dogs, sulfadimethoxine/ormetoprim may have adverse effects similar to sulfa-/trimethoprim, including keratoconjunctivitis sicca (KCS; which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria, and cholestasis.[7] Acute hypersensitivity reactions manifesting as type I (ie, immediate) or type III (ie, formation of antigen:antibody complexes) reactions can also be seen. Hypersensitivity reactions appear to be more common in large breed dogs.[9] Doberman pinschers may be more susceptible to this effect than other breeds. In humans, other hematologic effects (eg, anemia, agranulocytosis) are possible but are rare.[10]

Long-term therapy (ie, 8 weeks) at recommended doses of sulfadimethoxine/ormetoprim (27.5 mg/kg once daily) resulted in elevated serum cholesterol, thyroid and liver weights, mild follicular thyroid hyperplasia, and enlarged basophilic cells in the pituitary.

The manufacturer states that the principal treatment-related effect of extended or excessive use is hypothyroidism.

Reproductive/Nursing Safety

Sulfonamides cross the placenta and may reach fetal levels of greater than or equal to 50% of those found in maternal serum; teratogenicity (eg, cleft palate, fetal loss) has been reported in some laboratory animals given sulfonamides at high doses.

Sulfonamides are distributed into milk. This drug should be used in pregnant animals only when the benefits clearly outweigh the risks.

Overdose/Acute Toxicity

In experimental studies in dogs, doses greater than 80 mg/kg resulted in slight tremors and increased motor activity in some dogs.[11] Higher doses may result in depression, anorexia, or seizures.

It is suggested that very high oral overdoses be handled by gastric decontamination using standard precautions and protocols and by treating clinical signs supportively and symptomatically.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

None have been noted for sulfadimethoxine/ormetoprim, but the potential interactions for sulfa-/trimethoprim (listed below) may also apply to this drug combination; refer to ***Sulfa-/Trimethoprim*** for more information.

- **Amantadine**: A human patient developed toxic delirium when receiving amantadine with sulfamethoxazole/trimethoprim.[12]
- **Anesthetic Agents**: Concurrent IV administration is contraindicated. Ester-type local anesthetics (eg, **procaine, tetracaine**) may locally inhibit sulfonamide effects.[13,14]
- **Angiotensin II-Receptor Blockers** (**ARBs**; eg, **telmisartan**): May increase risk of hyperkalemia when used with potassium-sparing drugs
- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): May increase risk of hyperkalemia when used with potassium-sparing drugs
- **Antacids**: Concurrent administration may decrease sulfonamide bioavailability.
- **Azathioprine**: Increased risk for myelosuppression
- **Cyclosporine**: May increase the risk for nephrotoxicity
- **Detomidine**: Concurrent use has resulted in fatal arrhythmias in horses.[15]
- **Digoxin**: May increase digoxin levels
- **Diuretics, Thiazide**: May increase risk for thrombocytopenia
- **Hypoglycemic Agents, Oral** (eg, **glipizide, metformin**): May potentiate hypoglycemic effects
- **Methenamine**: May form an insoluble precipitate in the urine
- **Methotrexate (MTX)**: May displace from plasma proteins and increase risk for toxic effects; can also interfere with MTX assays (competitive protein binding technique, but not when measured by radioimmunoassay)
- **Phenothiazines** (eg, **acepromazine, promethazine**): Concurrent administration contraindicated[13]
- **Phenytoin**: May increase half-life
- **Potassium Supplements**: Increased risk of hyperkalemia
- **Procainamide**: May increase levels of procainamide and its active metabolite
- **Pyrimethamine**: May increase risk for megaloblastic anemia and myelosuppression
- **Rifampin**: May reduce serum concentrations of both trimethoprim and sulfonamide
- **Spironolactone**: May increase risk for hyperkalemia when used with potassium-sparing drugs
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): May decrease efficacy
- **Warfarin**: May prolong prothrombin time and INR

Laboratory Considerations

NOTE: The following points apply to sulfa-/trimethoprim and may also apply to sulfadimethoxine/ormetoprim.

- When using the Jaffe alkaline picrate reaction assay for **creatinine** determination, sulfa-/trimethoprim may cause an overestimation of ≈10%.
- Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

Dosages

DOGS:

NOTE: Unless otherwise noted, doses are for combined amounts of sulfadimethoxine and ormetoprim. See ***Monitoring*** if treatment is expected to be longer than 7 days.

Labeled indications (skin and soft tissue infections caused by susceptible strains of *Staphylococcus aureus* and *Escherichia coli*; UTIs caused by susceptible strains of *E coli, Staphylococcus* spp, and *Proteus mirabilis*) (FDA-approved): 55 mg/kg (combined drug) PO on the first day of therapy, then 27.5 mg/kg PO once daily, continuing for at least 2 days after remission of clinical signs. Not approved for treatment longer than 21 days.[7]

***Isospora* spp infections** (extra-label): 66 mg/kg (combined drug) PO once daily for 23 days[16]

Superficial bacterial folliculitis (extra-label): 55 mg/kg PO the first day, then 27.5 mg/kg PO once daily.[8] Potentiated sulfonamides (ie, sulfa-/trimethoprim, sulfadimethoxine/ormetoprim) are first-tier drugs only if regional susceptibility of *Staphylococcus pseudintermedius* is known.

Bacterial cystitis (extra-label): Potentiated sulfonamides (ie, sulfa-/trimethoprim, sulfadimethoxine/ormetoprim) are first-tier drugs only if regional pathogen susceptibility patterns are known.[17]

a) Uncomplicated UTI: 15 mg/kg PO every 12 hours. Treatment may be as short as 3 days.[17,18]
b) Complicated UTI: 15 – 30 mg/kg PO every 12 hours[17]

Monitoring

- Clinical efficacy
- Adverse effects
- Renal function (creatinine, BUN) and potassium
- If prolonged therapy (ie, greater than 7 days) is anticipated in dogs, the following is recommended:
- Baseline Schirmer tear testing, with periodic reevaluation (eg, in 5 days, then every 2 to 3 weeks) and owner monitoring for ocular discharge[8]
- Baseline and periodic CBC and hepatic profile
- Thyroid function tests should be considered (baseline and ongoing) particularly in dogs receiving long-term treatment.

Client Information

- Animals must be allowed free access to water and not become dehydrated while receiving this medication.
- If dog's eyes are dry, develop a discharge, or become irritated, contact your veterinarian.

Chemistry/Synonyms

Ormetoprim is a diaminopyrimidine structurally related to tri-

methoprim and occurs as a white, odorless, almost tasteless powder.

Sulfadimethoxine, a long-acting sulfonamide, occurs as an odorless or almost odorless, almost tasteless white powder. It is practically insoluble in water and slightly soluble in alcohol.

Sulfadimethoxine may also be known as solfadimetossina, solfadimetossipirimidina, sulphadimethoxine, *Albon®, Chemiosalfa®, Deltin®, Di-Methox®, Levosin®, Risulpir®, Ritarsulfa®, SDM®, Sulfadren®, Sulfasol®, Sulfastop®, and Sulfathox®*.

Ormetoprim may also be known as NSC-95072, ormetoprima, ormétoprime, ormetoprimum, or Ro-5-9754.

Storage/Stability

Unless otherwise instructed by the manufacturer, store tablets in tight, light-resistant containers at room temperature of 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

Sulfasalazine

(sul-fa-***sal***-a-zeen) *Azulfidine®*

Sulfonamide/Salicylate Antibacterial/Immunosuppressive

Prescriber Highlights

- ► Sulfa-analogue that has GI antibacterial and anti-inflammatory activity used for inflammatory bowel disease; has also been used for vasculitis
- ► Contraindications include hypersensitivity to sulfasalazine, sulfas, or salicylates; intestinal or urinary obstructions; and Dobermans.
- ► Use with caution in cats and in patients that have liver, renal, or hematologic diseases.
- ► Adverse effects in dogs include keratoconjunctivitis sicca (KCS), anorexia, vomiting, cholestatic jaundice, hemolytic anemia, leukopenia, vomiting, decreased sperm counts, and allergic dermatitis.
- ► Adverse effects in cats include anorexia, vomiting, anemia.

Uses/Indications

Sulfasalazine may be used as adjunctive treatment of inflammatory large bowel (colonic) disease in dogs and cats. It has also been suggested for adjunctive use in treating vasculitis in dogs. It is not effective for small intestinal inflammation, as colonic bacteria are required to cleave the drug into sulfapyridine and 5-aminosalicylic acid (5-ASA, mesalamine). In humans, sulfasalazine is also used as adjunctive treatment for inflammatory arthropathies.

Pharmacology/Actions

Sulfasalazine is cleaved into sulfapyridine and 5-aminosalicylic acid (5-ASA, mesalamine) by colonic bacteria. Although the exact mechanism of action for its therapeutic effects in treating colitis in small animal species has not been determined, it is believed that mesalamine's local (not systemic) anti-inflammatory activity, including cyclooxygenase and lipoxygenase inhibition, provides the main therapeutic effect. Its antibacterial (sulfapyridine) and/or immunomodulatory activity may contribute to controlling clinical signs and course of the disease. In humans, concentrations of both metabolites in the colon are higher than by giving them orally as separate agents.

Pharmacokinetics

No pharmacokinetic data for dogs or cats were located.

In humans, only ≈10 to 33% of an orally administered dose of sulfasalazine is absorbed.[1] Of the absorbed drug, sulfasalazine is 99.3% bound to albumin, and sulfapyridine is 70% bound to albumin. Both sulfasalazine and sulfapyridine are widely distributed to the synovial fluid and connective tissue. Sulfasalazine reaches high concentrations in the intestinal wall. Some of the absorbed drug is then excreted unchanged in the bile and some is metabolized in the liver.

Unabsorbed and biliary excreted drug is cleaved into 5-ASA and sulfapyridine in the colon by bacterial flora. The sulfapyridine component is rapidly absorbed, but only a small percentage of the 5-ASA is absorbed. Absorbed sulfapyridine and 5-ASA are hepatically metabolized and then renally excreted. Unabsorbed sulfapyridine and 5-ASA is excreted in the feces. Elimination half-life is prolonged in elderly human patients, but clinical impact has yet to be established.

Contraindications/Precautions/Warnings

Sulfasalazine is contraindicated in animals hypersensitive to it, sulfonamides, or salicylates. Doberman pinschers, Samoyeds, and miniature schnauzers appear to be more susceptible to sulfonamide-induced polysystemic immune complex disease[2]; use sulfasalazine with caution in these breeds. Alternative medications should be considered in these dogs. It is also contraindicated in patients with intestinal or urinary obstructions.

Sulfasalazine should be used with caution in animals with pre-existing liver, renal, or hematologic diseases. Because cats can be sensitive to salicylates (see ***Aspirin***), use this drug cautiously in this species.

Do not confuse sulfaSALAzine with sulfaDIAzine.

Adverse Effects

Adverse effects occur relatively uncommonly in dogs and may include anorexia, vomiting, cholestatic jaundice, hemolytic anemia, leukopenia, hypersensitivity reactions, vomiting, decreased sperm counts, and allergic dermatitis. Yellow or orange discoloration of skin and body fluids may occur (harmless but may stain clothing). Keratoconjunctivitis sicca (KCS) has also been reported.[3–5] If decreased tear production is noted early, either reducing the dose or discontinuing the drug may prevent progression of KCS or increase tear production.

Cats can occasionally develop anorexia and vomiting, which may be alleviated by use of the enteric-coated tablets. Anemias secondary to sulfasalazine are also potentially possible in cats.

Adverse effects in humans are associated with serum sulfapyridine concentrations greater than 50 µg/mL. Blood dyscrasias (eg, agranulocytosis, aplastic anemia) and severe dermatologic reactions (eg, Stevens-Johnson reaction, drug reaction with eosinophilia and systemic symptoms [DRESS]) have been reported in humans receiving sulfasalazine or other sulfonamides.[1]

Reproductive/Nursing Safety

Sulfonamides cross the placenta. Although sulfasalazine has not been proven harmful to use during pregnancy and incidences of neonatal kernicterus in infants born to women taking sulfasalazine are low, it should only be used when it is clearly indicated. In laboratory animal studies (rats, rabbits), doses of 6 times the normal (human) amount caused impairment of fertility in male animals[1]; this effect is thought to be caused by the sulfapyridine component

and was reversible upon discontinuation of the drug. Folic acid supplementation may be advised for women taking sulfasalazine during pregnancy.[1] Sulfasalazine has caused oligospermia in humans.

Sulfonamides, including sulfasalazine, are excreted in milk. In human newborns, they compete with bilirubin for binding sites on plasma proteins and may cause kernicterus. Use with caution in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Little specific information is available regarding overdoses with this agent, but because massive overdoses could cause significant salicylate and/or sulfonamide toxicity, standard decontamination protocols (empty stomach, cathartics) should be considered. Urine alkalinization and forced diuresis may also be beneficial in selected cases. Dialysis may remove sulfasalazine and its metabolites.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Sulfasalazine and sulfapyridine are metabolized primarily by acetylation, along with glucuronidation and hydroxylation pathways. The following drug interactions either have been reported or are theoretical in humans or animals receiving sulfasalazine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antibacterial Agents**: Reduction in GI flora caused by antibiotics may reduce bacterial cleavage of sulfasalazine and subsequent production of 5-ASA.
- **Cyclosporine**: Sulfadiazine has been reported to decrease cyclosporine concentrations in humans; interaction may apply to sulfasalazine. Monitor serum cyclosporine concentrations if using this combination.[6]
- **Digoxin**: Concomitant use may reduce absorption of digoxin.
- **Ferrous Sulfate** or **Other Iron Salts**: Concomitant use may decrease the blood concentrations of sulfasalazine; clinical significance is unknown.
- **Folic Acid**: Concomitant use may reduce oral absorption of folic acid.
- **Methenamine**: In humans, concurrent use may result in the formation of an insoluble precipitate in the urine, and the combination is considered contraindicated.
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, flunixin, meloxicam, robenacoxib**): Concomitant use of NSAIDs may increase risk for bleeding.
- **Warfarin**: Concomitant use may potentiate the anticoagulant effects of warfarin.

Laboratory Interactions

- Sulfasalazine may cause false-positive urinary normetanephrine performed by liquid chromatography.
- Sulfasalazine may interfere with ALT, AST, ammonia, thyroxine, or glucose tests that use ultraviolet absorbance around wavelength 340 nm.[1]

Dosages

NOTE: Unless otherwise noted, assume the following dosages are for the standard-release tablets.

DOGS:

Inflammatory large bowel disease (extra-label):

a) Initial dosages range from 15 – 30 mg/kg PO every 8 to 12 hours, not to exceed a total daily dose of 6 g.[7] Anecdotal dosage recommendations vary considerably, and no definitive studies were located supporting any one dose. After 2 to 4 weeks (longer if at the low end of the dosing range) most taper off (reducing dosage every 2 weeks) until eventual drug discontinuation while maintaining dietary treatment. Some dogs may require long-term therapy.

b) As adjunct to dietary modification: 10 – 30 mg/kg (maximum dose of 1 g) PO with food every 8 hours for 4 to 6 weeks, then reduce dosing interval to every 12 hours.[8] If clinical signs remain controlled after 10 to 14 days, then decrease again to once-daily dosing.

Adjunctive treatment of vasculitis (extra-label): 20 – 40 mg/kg PO every 8 hours[9,10]

CATS:

Inflammatory large bowel disease (extra-label):

a) Use cautiously in cats because of their sensitivity to salicylates. Dosages range from 10 – 20 mg/kg PO 1 to 3 times a day (most clinicians recommend once daily). Anecdotal dosage recommendations vary somewhat, and no definitive studies were located supporting any one dose. Some clinicians state to treat no longer than 10 days and other clinicians advise to taper to the lowest effective dose.

b) As adjunct to dietary modification: 5 – 12.5 mg/kg PO with food every 8 hours for 2 to 3 weeks[8]

HORSES:

Chronic diarrhea (extra-label): Sulfasalazine (with dietary adjustment) 16 mg/kg PO once a day for 5 days, followed by 8 mg/kg PO once a day for 10 days.[13] **NOTE**: The product used in this case report (*Salazopyrin® EN*) was a delayed-release product.

FERRETS:

a) 10 – 20 mg/kg PO 2 to 3 times a day[11]

b) 25 mg (total dose) PO twice daily[12]

Monitoring

- Efficacy
- Baseline and periodic Schirmer tear tests, especially for breeds that are predisposed to developing keratoconjunctivitis sicca (KCS)
- Adverse effects
- Occasional CBC, liver enzymes are warranted with long-term therapy.

Client Information

- Give this medicine with food. Dose is often increased until diarrhea is controlled and then reduced to the lowest effective dose.
- Contact your veterinarian if your animal begins to have discharge from the eye(s) or the eyes become red.
- Cats may be sensitive to this medicine. Contact your veterinarian if you have any concerns about your cat.
- People allergic to sulfa drugs should handle this drug with caution.
- Skin or body fluids may become yellow-orange in color while your animal is taking this medicine. The fluids may cause staining.

Chemistry/Synonyms

Sulfasalazine is basically a molecule of sulfapyridine linked by a diazo bond to the diazonium salt of salicylic acid. It occurs as an odorless, bright yellow to brownish-yellow fine powder. Less than 0.1 mg is soluble in 1 mL of water and ≈0.34 mg is soluble in 1 mL of alcohol.

Sulfasalazine may also be known as salazosulfapyridine, salicylazosulfapyridine, sulfasalazinum, sulphasalazine, *Sulfazine®* and *Azulfidine®*.

Storage/Stability
Sulfasalazine tablets (either plain or enteric-coated) should be stored protected from light at temperatures less than 40°C (104°F) and preferably at room temperature 20°C to 25°C (68°F-77°F) in well-closed containers.

Compatibility/Compounding Considerations
No specific information is noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Sulfasalazine Tablets: 500 mg; *Azulfidine®*, *Sulfazine®*, generic; (Rx)

Sulfasalazine Delayed-Release Tablets: 500 mg (enteric coated); *Azulfidine® EN-tabs®*, *Sulfazine EC®*, generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Tadalafil
(ta-***dal***-a-fil) *Cialis®*

Phosphodiesterase Type 5 Inhibitor

Prescriber Highlights
- ► Used for treating pulmonary arterial hypertension and possibly benign prostatic hyperplasia in dogs
- ► Limited clinical experience or published data for use in dogs
- ► Appears to have a longer duration of action than sildenafil
- ► Contraindicated in patients receiving organic nitrates (eg, nitroglycerin, isosorbide)
- ► Adverse effects not well known for dogs; decreased appetite has been noted, as well as inguinal flushing and GI effects

Uses/Indications
Tadalafil is a phosphodiesterase-5 (PDE5) inhibitor, related to sildenafil, that is used to treat pulmonary arterial hypertension (PAH) in dogs.[1–3]

In dogs with PAH, tadalafil added to conventional heart failure therapy decreased diastolic pulmonary arterial pressure (PAP), mean PAP, and tricuspid regurgitation.[1] Both tadalafil and sildenafil improved quality of life and activity measures in dogs with moderate to severe pulmonary hypertension with various etiologies.[3] Because of its longer duration of action, tadalafil has some advantages over sildenafil. A study in humans has suggested that tadalafil may be tolerated in some patients experiencing sildenafil intolerance.[4]

Tadalafil reduced biochemical markers of benign prostatic hyperplasia (BPH) in dogs with experimentally induced BPH;[5] further research is needed to determine the drug's effect on clinical signs of BPH.

In humans, tadalafil is approved for use in treating pulmonary artery hypertension and erectile dysfunction. Offlabel uses include treating Raynaud's phenomenon.

Pharmacology/Actions
Tadalafil is a selective inhibitor of cyclic guanosine monophosphate (cGMP)-specific phosphodiesterase type 5 (PDE5). PDE5 is the enzyme responsible for the degradation of cGMP and is found (in humans) in the corpus cavernosum smooth muscle, pulmonary vascular and visceral smooth muscle, skeletal muscle, platelets, kidney, lung, cerebellum, and pancreas. In patients with PAH, vascular endothelium nitric oxide release is impaired with an associated reduction of cGMP. PDE5 is the primary phosphodiesterase in the pulmonary vasculature, and tadalafil's PDE5 inhibition increases cGMP, thereby relaxing pulmonary vascular smooth muscle with resultant vasodilation.

Pharmacokinetics
In healthy dogs, peak plasma concentration occurred ≈1.5 hours after oral administration, and half-life was 4.2 hours.[6] In the same study, tadalafil plasma concentration peaked ≈1.7 hours following intranasal administration, and half-life was 5.8 hours.

In humans, after oral administration, maximum plasma concentrations occur in ≈4 hours in patients with PAH. Food does not alter the rate or extent of absorption. Tadalafil is 94% bound to human plasma proteins. Tadalafil is metabolized by CYP3A4 to a catechol metabolite that then undergoes methylation and glucuronidation. These metabolites are not thought to be active. In PAH patients, the mean terminal half-life is 35 hours. Excretion is primarily of the drug's metabolites via fecal routes (61%), with the majority of the remainder in the urine (≈36%).

Contraindications/Precautions/Warnings
Tadalafil is contraindicated in human patients using any form of organic nitrate (either regularly or intermittently) and in those with serious hypersensitivity to tadalafil. Dosage reductions may be required in patients with severe hepatic or renal impairment.

Adverse Effects
An adverse effect profile for dogs at suggested doses for PAH has not been determined. GI effects are possible, and decreased appetite has been noted.[3] In a 12-month tadalafil chronic toxicity study done in dogs, no disseminated arteritis was observed as was seen in rodent studies, but 2 dogs exhibited marked decreases in neutrophils and moderate decreases in platelets with inflammatory signs when dosed at ≈4 to 18 times the equivalent human dose. These effects were reversible within 2 weeks after discontinuing the drug. Cutaneous flushing of the inguinal region has been reported with sildenafil, a related drug, in dogs.

The most common adverse effects of tadalafil reported in humans with PAH include dyspepsia, nausea, back pain, myalgia, nasal congestion, flushing, and headache. Rare but serious adverse effects include optic neuropathy, seizures, hypersensitivity reactions (eg, Stevens-Johnson syndrome, exfoliative dermatitis), and deafness.

Reproductive/Nursing Safety
Tadalafil animal reproduction studies in rats and mice demonstrated no evidence of teratogenicity, embryotoxicity, or fetotoxicity when tadalafil was given to pregnant rats or mice at exposures of up to 11 times (human equivalent dose).

Tadalafil and/or its metabolites are secreted into the milk in lactating rats at concentrations ≈2.4-fold those found in the plasma. It is unlikely to pose much risk to nursing offspring.

Overdose/Acute Toxicity
Little information is available. Single doses of up to 500 mg have been given to healthy men, and multiple daily doses of up to 100 mg have been given to men with erectile dysfunction; adverse reactions were similar to those seen at lower doses.

It is expected that overdoses in animals would mirror the drug's adverse effect profile; treat supportively.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consulta-

tion center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tadalafil and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-Adrenergic Blockers** (eg, **tamsulosin, prazosin, phenothiazines** [eg, **acepromazine**], **phenoxybenzamine**): May increase hypotensive effects
- **Amlodipine**: Potential to increase hypotensive effects
- **Antihypertensive, Hypotensive Drugs**: Potentially could increase hypotensive effects
- **Azole Antifungals** (eg, **ketoconazole, itraconazole**): May reduce tadalafil metabolism and increase AUC
- **Cimetidine**: May reduce tadalafil metabolism and increase AUC
- **Clarithromycin/Erythromycin**: May increase tadalafil bioavailability, reduce tadalafil metabolism, and increase AUC
- **Nitrates** (eg, **nitroglycerin, isosorbide**): Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **Nitroprusside Sodium**: Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **Phenobarbital**: May decrease tadalafil concentrations
- **Rifampin**: May decrease tadalafil concentrations
- **Rivaroxaban**: Tadalafil decreased P-glycoprotein mediated efflux of rivaroxaban in an in vitro model; clinical significance remains unclear.[7]

Laboratory Considerations

- None was noted.

Dosages

DOGS:

Pulmonary arterial hypertension (extra-label):

a) 1-2 mg/kg PO once daily[3,8]

b) From a case report in a Yorkshire terrier: 1 mg/kg PO every 48 hours (every other day) was added to the background treatment (furosemide, spironolactone, benazepril, dexamethasone, and oxygen). The dog's condition rapidly improved (less than 24 hours), and a 7-day follow-up showed a decrease (up to 26 mm Hg) in systolic pulmonary arterial pressure and disappearance of all respiratory and cardiac signs of PAH (cyanosis, syncope, and tachypnea).[9]

Benign prostatic hyperplasia (extra-label): 5 mg/dog (NOT mg/kg) PO once daily[5]

Monitoring

- Clinical efficacy: improved exercise capacity, cough, respiratory effort; fewer episodes of syncope
- Pulmonary artery pressure, systemic blood pressure
- Adverse effects

Client Information

- May give this medicine with or without food. Be sure to give it exactly as prescribed.
- Tadalafil may cause flushing (redness) in the groin area. Lack of appetite, vomiting, and diarrhea are also possible.
- This medicine has not been used often in veterinary medicine, so it is important to report any other side effects to your veterinarian.
- Do not give with nitroglycerin or isosorbide, as it may cause severely low blood pressure.
- While your animal is taking this medication, it is important to return to your veterinarian for important tests. Do not miss these important follow-up visits.

Chemistry/Synonyms

Tadalafil has a molecular weight of 389.41. It is insoluble in water and slightly soluble in ethanol.

Tadalafil may also be known as GF-196960, IC-351, tadalafiili, tadalafilo, or tadalafilum. *Cialis*® and *Adcirca*® are trade names for tadalafil.

Storage/Stability

Store tadalafil tablets at room temperature between 15°C and 30°C (59°F-86°F).

Compatibility/Compounding Considerations

A method of preparing a stable 5 mg/mL oral suspension from tablets has been published. Crush fifteen 20 mg tadalafil tablets to a fine powder in a glass mortar. Mix together 30 mL of *Ora-Sweet*® and 30 mL of *Ora-Plus*®; stir vigorously. Add 30 mL of this solution in geometric proportions to the powder and mix to form a smooth suspension. Transfer the mixture to a 2-ounce (60 mL) amber plastic prescription bottle. Rinse mortar with a quantity of the vehicle sufficient to make a final volume of 60 mL. Label "shake well." Suspension is stable for 91 days when stored at room temperature in an amber plastic prescription bottle.[10]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Tadalafil Oral Tablets: 2.5 mg, 5 mg, 10 mg, and 20 mg: *Cialis*®, *Adcirca*® (20 mg only); generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Tamsulosin

(tam-suh-***low***-sin) *Flomax*®

Alpha-1 Adrenergic Antagonist

Prescriber Highlights

- ► Potentially useful as a lower urinary tract (ureteral/urethral) relaxant in dogs and cats; limited published clinical experience
- ► Contraindications include use in patients known to be hypersensitive to it.
- ► Higher doses could cause hypotension.
- ► Do not crush sustained-release pellets in capsules as rapid oral absorption may result in hypotension.

Uses/Indications

Tamsulosin is an alpha-1 adrenergic blocking agent that is similar to prazosin and phenoxybenzamine but longer-acting. Although evidence for efficacy in animals is limited, tamsulosin could be useful to facilitate passage of nephroliths and ureteroliths and for treating functional urinary obstruction, benign prostatic hypertrophy, or detrusor-urethral dyssynergia in dogs and cats, and postobstructive urethral spasm in cats.

In humans, tamsulosin is labeled for treatment of benign prostatic hyperplasia (BPH). It is also used for ureteral relaxation to facilitate passage of urinary calculi.

Pharmacology/Actions

Tamsulosin blocks sympathetic nervous stimulation of alpha-1 adrenoceptors. It is more selective for the 1A receptor subtype, which is the primary alpha-1 adrenoceptor found in the prostate, prostatic capsule, prostatic urethra, and bladder neck and is less common in

vascular or other smooth muscle. Blockade of these adrenoceptors can cause smooth muscles in the bladder neck and prostate to relax resulting in improvement in urine flow rate and expulsion of urinary calculi. In conscious male dogs, tamsulosin caused a sustained inhibitory effect on phenylephrine-induced prostatic intraurethral pressure (IUP) response that was related to higher concentrations in the prostate and urethra, rather than in plasma and vascular tissues.[1]

Pharmacokinetics

Tamsulosin exhibits significant interspecies variation in its pharmacokinetics. After oral dosing of a nonsustained release formulation in dogs, tamsulosin bioavailability was ≈30% and peak plasma concentrations occurred ≈0.5 hours postdose. Volume of distribution Vd_{ss} was 1.74 L/kg; protein binding was 90%; clearance was 4 L/hour/kg (estimated unbound clearance: 31 to 41 L/hour/kg), and elimination half-life was ≈1.5 hours.[2] Tamsulosin concentrations are significantly higher and retained longer in prostatic and urethral tissues than in plasma. At 6 hours postdose (0.03 mg/kg), prostate/plasma and urethra/plasma ratios were 10.5 and 6.6 respectively.[1,3] Therefore despite a relatively fast plasma half-life, once or twice daily dosing may be possible in dogs, although pharmacokinetic/pharmacodynamic studies using the commercially available sustained-release formulation are required to determine appropriate dosages. In dogs, cytochrome CYP3A4 is responsible for metabolism of tamsulosin to the M1 and AM-1 metabolites.[4]

Pharmacokinetic data for cats were not located.

In humans, fasted state oral bioavailability is essentially complete (more than 90%). Tamsulosin exhibits linear kinetics following single and multiple dosing, with achievement of steady-state concentrations by the fifth day of once-a-day dosing. Plasma protein binding in humans is significant (98% to 99%). The terminal half-life of tamsulosin in humans is ≈6 to 15 hours.[2]

Contraindications/Precautions/Warnings

Tamsulosin is contraindicated in patients known to be hypersensitive to it. Some humans with sulfonamide drug allergies have reportedly experienced hypersensitivity reactions (skin rash, urticaria, pruritus, angioedema, and respiratory symptoms).[5] Priapism has been reported in humans; significance for veterinary patients is unknown.

Tamsulosin capsules are manufactured in a sustained-release (beads) presentation to avoid rapid absorption and associated hypotensive effects; therefore, they should not be crushed or compounded into an oral suspension.

Adverse Effects

The adverse effect profile in animals is not well documented, but hypotensive effects are possible. Hypotension may be more likely at high doses or in older dogs.[6] When tamsulosin was administered to anesthetized female beagles at doses from 0.003 – 0.01 mg/kg IV, urethral pressures were reduced in a dose-dependent fashion; almost no effect on mean arterial blood pressure was seen.[7]

In humans, reported adverse effects include headache, dizziness, blurred vision, rhinitis, muscle weakness, abnormal ejaculation, decreased libido, back pain, diarrhea, and nausea.[5] Intraoperative floppy iris syndrome and other postoperative ophthalmic adverse effects have also been reported in humans receiving tamsulosin undergoing cataract surgery; significance for veterinary patients is unknown. Administration on an empty stomach improves absorption, but also increases the risk for orthostasis.

Reproductive/Nursing Safety

Teratogenic effects or fetal harm were not observed when tamsulosin was administered to pregnant rats and rabbits. Tamsulosin may impair or alter ejaculation in humans and in rats[5]; it is presumed this effect may also occur in breeding males.

Tamsulosin is present in the milk of lactating rats.[5] Use with caution in nursing veterinary patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Moderate toxicity in humans generally occurs at 10 times recommended doses, but severe toxicity is uncommon. If hypotension occurs, it is usually responsive to IV fluid therapy; severe hypotension may require vasopressors. Dialysis is unlikely to be of benefit.

Adverse effects in dogs and cats with a tamsulosin overdose include lethargy/sedation, tachycardia, vomiting, and hypotension; older dogs may be at higher risk for hypotension.[6]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In humans, tamsulosin is a substrate of CYP 2D and 3A enzyme families. The following drug interactions have either been reported or are theoretical in humans or animals receiving tamsulosin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-1 Adrenergic Receptor Agonists** (eg, **phenylephrine**): May decrease the effects of each other
- **Cimetidine**: May increase tamsulosin concentration
- **Clarithromycin & Erythromycin**: May increase plasma concentration of tamsulosin
- **Hypotensive Agents** (eg, **amlodipine, atenolol, enalapril, telmisartan**): May have additive hypotensive effects
- **Ketoconazole**: May increase plasma concentration of tamsulosin
- **Phosphodiesterase Type 5 (PDE5) Inhibitors** (eg, **sildenafil, tadalafil**): May have additive hypotensive effects
- **Terbinafine**: May increase plasma concentration of tamsulosin
- **Warfarin**: Drug interaction studies with tamsulosin are inconclusive; use together with caution.

Laboratory Considerations

- No laboratory test interactions reported

Dosages

DOGS:

Ureteral/urethral relaxant (extra-label): 0.01 – 0.2 mg/kg PO once daily.[8–10] Anecdotally, may increase frequency to every 12 hours if no effects are seen with once-daily dosing. Safety, efficacy, and dosages have not been determined; compounded capsules may be required for dosing.

CATS:

Ureteral/urethral relaxant (extra-label): An anecdotal dosage of 0.004 – 0.006 mg/kg PO once daily has been noted.[11] Safety, efficacy, and dosages have not been determined; compounded capsules are required.

Monitoring

- Clinical efficacy
- Baseline blood pressure; periodic blood pressure checks if adverse effects related to hypotension occur

Client Information

- Do not crush or allow animal to chew beads found inside capsule.
- This medicine may take several days to work at its peak effect.

Chemistry/Synonyms
Tamsulosin hydrochloride is a white or almost white crystalline powder that melts with decomposition at ≈230°C (446°F). It is slightly soluble in water or ethanol, sparingly soluble in methanol, and practically insoluble in ether.

Tamsulosin may also be known as LY253351, YM-12617-1, YM617, *Flomax®*, *Flowmaxtra®*, *Omexel®*, or *Omnic®*.

Storage/Stability
Do not store tablets above 25°C (77°F); protect from moisture.

Compatibility/Compounding Considerations
Tamsulosin capsules are manufactured in a sustained-release presentation to avoid rapid absorption and the associated hypotensive effects; therefore, they should not be crushed or compounded into an oral suspension. Capsule contents are small sustained-release beads that could be compounded into smaller sized capsules for use in dogs or cats.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Tamsulosin HCl Capsules: 0.4 mg; *Flomax®*, generic; (Rx)

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Taurine
(***tor***-een)
Amino Acid Nutritional

Prescriber Highlights
- ► Used primarily for the treatment of taurine deficiency cardiomyopathies in dogs and cats
- ► Because of its low cost, low potential for toxicity, and the limitations of testing for taurine deficiency, routine taurine supplementation in cats with dilated cardiomyopathy (DCM) is advised.
- ► May also be useful for many other conditions (eg, seizures, hepatic lipidosis), but little or no supporting data available

Uses/Indications
Taurine has proven beneficial in preventing retinal degeneration and the prevention and adjunctive treatment of dilated cardiomyopathy (DCM) in cats caused by taurine deficiency. These conditions are rarely seen today when a modern, reputable commercial feline diet is fed. Supplementation with taurine (± carnitine) is also used in dogs with DCM in susceptible breeds (eg, American cocker spaniels, golden retrievers).[1] Studies have shown that taurine supplementation may be useful as adjunctive treatment for DCM in animals even if taurine deficiency is not present.[2] Because of taurine's low toxicity, some clinicians have also suggested it can be tried for a multitude of conditions (eg, seizures, hepatic lipidosis) in humans and animals; unfortunately, little scientific evidence exists for these other uses.

Pharmacology/Actions
Taurine is an important amino acid for bile acid conjugation, especially in dogs and cats. In vivo, taurine is synthesized from methionine. Cysteinesulfinic acid decarboxylase (CSAD) and vitamin B_6 are involved with this synthesis. Deficiencies of either will depress taurine synthesis. Cats are particularly susceptible to taurine deficiency, as they have low CSAD activity and use taurine almost exclusively for bile acid conjugation.

Additionally, taurine is important in the modulation of calcium flux, thereby reducing platelet aggregation, stabilizing neuronal membranes, and affecting cardiac function. Taurine's effects on cardiac function include positive inotropic activity without affecting resting potential and modulating ionic currents across the cell membrane. Taurine is important for normal development of the CNS, and it has a GABA-like effect that may make it useful for treating some seizure disorders.

Pharmacokinetics
No specific information was located. Excess taurine is rapidly excreted in the kidneys, but if a deficiency exists, urinary excretion is reduced via reabsorption.

Contraindications/Precautions/Warnings
Although taurine is safe, it should not be used as a substitute for adequate diagnosis.

Adverse Effects
Taurine appears to be well tolerated. Minor GI distress potentially could occur after oral dosing.

Overdose/Acute Toxicity
No specific information was located, but toxic potential appears to be low.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
- None noted

Laboratory Considerations
- To determine actual status of taurine in the body, whole blood taurine levels are preferred to plasma levels. Intracellular levels of taurine are much higher than in plasma, and hemolysis or collection of the buffy coat will negate the results. However, whole blood assays may also yield false-positive results in animals that are in a prolonged fasting state or anorectic; false-negative results may be obtained after postprandial sampling, a recent dietary change, or recent thromboembolism.[3]

Dosages
DOGS:

Dilated cardiomyopathy (DCM) (extra-label):

a) 500 – 1000 mg/dog (NOT mg/kg) PO every 8 to 12 hours for dogs weighing less than 25 kg (55.1 lb) and 1 – 2 g/dog (NOT g/kg) PO every 8 to 12 hours for dogs weighing more than 25 kg (55.1 lb)[4,5]

b) 30 – 100 mg/kg/day PO subjectively improved some echocardiographic left ventricular measurements in English cocker spaniels.[6]

Adjunctive antiepileptic (extra-label): 22 mg/kg PO twice daily may help decrease seizure activity.[7]

CATS:

Adjunctive therapy for DCM associated with taurine deficiency (extra-label): 250 mg/cat (NOT mg/kg) PO every 12 hours[8]

Adjunctive antiepileptic (extra-label): 100 – 400 mg/cat (NOT mg/kg) PO once daily[9]

Adjunctive treatment of hepatopathies (extra-label): Anecdotally, 250 – 500 mg/cat (NOT mg/kg) PO twice daily. No clinical studies document efficacy, but some in vitro data support use.

Monitoring
- Clinical efficacy. Clinical improvement in cats with taurine-responsive dilated cardiomyopathy (DCM) is usually seen within 2 weeks; significant echocardiographic improvement may take 4 weeks or more.[3]
- Taurine levels: whole blood levels preferable to plasma/serum

levels

Client Information
- This medicine is usually tolerated well but may cause vomiting. If your animal vomits or acts sick after receiving the medicine on an empty stomach, try giving the next dose with food or a small treat. If vomiting continues, contact your veterinarian.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.
- If using a powder form of this medicine, it can be mixed into your animal's food.

Chemistry/Synonyms
Taurine, an amino acid also known as 2-aminosulphonic acid, has a molecular weight of 125. Solubility in 100 mL of water at 20°C (68°F) is 8.8 grams.

Storage/Stability
Unless otherwise labeled, store taurine tablets or capsules at room temperature. Protect this product from light and moisture.

Compatibility/Compounding Considerations
No specific information was noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
The following products are labeled (not FDA-approved drugs) for use in animals:

Taurine Tablets: 250 mg; *Formula V® Taurine Tablets*. Labeled for use in cats

Taurine Liquid: 375 mg/4 mL (one pump); *Dyna-Taurine®*. Labeled for use in dogs and cats

HUMAN-LABELED PRODUCTS:
There are several oral dosage form products available for taurine. Technically considered a nutrient they are all OTC and may need to be obtained from health food stores. Most dosage forms available range from 125 mg to 500 mg.

Telmisartan
(***tel***-mi-***sar***-tan) *Semintra®, Micardis®*
Angiotensin-II Receptor Blocker (ARB)

Prescriber Highlights
- ► Indicated in cats for control of systemic hypertension and for treatment of proteinuria associated with chronic kidney disease (CKD)
- ► May also be useful in dogs for the adjunctive treatment of proteinuria and systemic hypertension secondary to CKD
- ► GI effects (vomiting, diarrhea) and lethargy are the most commonly reported adverse effects in cats. Hypotension, increases in liver enzymes, and anemia are possible but uncommon.
- ► Not safe for use during pregnancy
- ► Dispense with Client Information Sheet

Uses/Indications
Telmisartan is used for the adjunctive treatment of systemic hypertension and proteinuria in both dogs and cats.

Telmisartan is approved for control of systemic hypertension in cats. In both a United States clinical trial[1] as well as a European clinical trial,[2] telmisartan significantly reduced mean systolic blood pressure compared to placebo in hypertensive cats. In the United States trial, systolic blood pressure at 28 days decreased on average by ≈24 mm Hg compared to ≈12 mm Hg in the placebo group and this decrease persisted over the 6 months of the trial.[1] In the European trial, telmisartan reduced mean baseline systolic blood pressure by ≈25 mm Hg compared to an ≈11 mm Hg decrease in the placebo group.[2] In the EU, the drug is approved for the reduction of proteinuria associated with chronic kidney disease (CKD) in cats.

An open-label study of telmisartan in 28 dogs with proteinuric chronic kidney disease found that telmisartan reduced the urine protein-to-creatinine ratio by 65% and the systolic blood pressure by 10% compared to placebo.[3] A prospective, randomized, double-masked clinical trial in 39 dogs found that telmisartan resulted in a greater decrease (-65%) in urine protein-to-creatinine ratio compared to enalapril (-35%).[4] Finally, in an observational study of 42 dogs, telmisartan in combination with an angiotensin-converting enzyme inhibitor significantly reduced systolic blood pressure and urine protein-to-creatinine ratio.[5]

Telmisartan is being investigated as an adjunctive antiepileptic drug in dogs with refractory idiopathic epilepsy.[6]

Pharmacology/Actions
Telmisartan is an angiotensin-II receptor blocker (ARB). By selectively blocking the AT1-receptor, aldosterone synthesis and secretion is reduced causing vasodilation and decreased potassium and increased sodium excretion. While plasma concentrations of renin and angiotensin-II are increased, this does not counteract the blood pressure lowering effects of telmisartan. Telmisartan does not interfere with substance P or bradykinin responses. The product label (UK) for cats states that, *…telmisartan does not affect potassium excretion, as shown in the clinical field trial in cats.*

A study in healthy cats (n = 6) found that telmisartan 3 mg/kg PO, when compared to benazepril 2.5 mg/cat PO, significantly better attenuated blood pressure increases secondary to angiotensin I administration at 90 minutes and 24 hours.[7]

Pharmacokinetics
In cats, telmisartan oral solution bioavailability is ≈33% and peak concentrations occur in ≈30 minutes. Food delays the magnitude of and time to peak concentration, and also reduces overall absorption.[8,9] Systemic exposure is ≈60% lower in female cats compared to male cats.[8] Distribution data for cats were not located, but the drug is highly lipophilic and, in other species (rats, dogs, humans), is highly bound (greater than 99.5%) to plasma proteins. Absorbed drug is primarily metabolized via glucuronidation; the cat genetic defect UGT1A6 does not affect glucuronidation.[10] The major metabolite is telmisartan-O-acylglucuronide, which is not active. Elimination half-life is ≈8 hours.[8,9]

In dogs, peak plasma concentrations occur 45 minutes after oral administration and the half-life is 5.4 hours.[11]

In humans, oral bioavailability of telmisartan is dose dependent and ranges from 42% (40 mg) to 58% (160 mg).[12] Food slightly reduces bioavailability. Absorbed drug is highly protein bound (greater than 99.5%) and volume of distribution ≈500 L. It is conjugated via glucuronidation to the pharmacologically inactive acylglucuronide. Elimination kinetics are bi-exponential and the terminal half-life is ≈1 day.

Contraindications/Precautions/Warnings
Telmisartan is contraindicated in patients that are hypersensitive to it. It is not known if cross-reactivity occurs between other ARBs and telmisartan. The drug has not been evaluated in patients with systolic blood pressure greater than 200 mmHg, with hepatic disease, or less than 6[13] to 9 months old.[8]

Hypotensive patients should not receive this drug. Patients that are volume or electrolyte depleted should not receive this drug until blood volume and electrolytes have been replenished and corrected.

This drug should not be used in pregnant animals. The human label has the following black box warning[12]: *Fetal toxicity: When pregnancy is detected, discontinue telmisartan as soon as possible. Drugs that act directly on the renin-angiotensin system can cause injury and even death to the developing fetus.* See ***Reproductive/Nursing Safety***.

Telmisartan should be used with caution in patients with moderate to severe hepatic impairment; dose reduction may be warranted.

Adverse Effects

In FDA field studies in cats, gastrointestinal distress (vomiting, diarrhea), lethargy, dehydration and weight loss were the most commonly reported side effects.[8,9] Hypotension, requiring dosage reduction, occurred in 16% to 24% of patients. Non-regenerative anemia occurred in 5% to 15% of patients.[9] Less commonly, increases in liver enzyme values, tachycardia, azotemia, and renal insufficiency or failure have been noted.[8,9]

Adverse effects in dogs are comparable, with adverse GI signs (eg, inappetence, vomiting, diarrhea) being the most common (11% of dogs in one study[5]).[4,5] A greater than 30% increase in serum creatinine has been reported in 5% to 25% of dogs.[4,5] Hyperkalemia at 6.2 mEq/L was noted in one of 42 dogs that was also receiving an angiotensin converting enzyme inhibitor in another study.[14]

Reproductive/Nursing Safety

Telmisartan is not considered safe to use during pregnancy. The EU label for the cat product reads: *Do not use during pregnancy or lactation. The safety of Semintra® has not been established in breeding, pregnant or lactating cats.*

Studies in pregnant rats given high doses of ARBs demonstrated a variety of fetal abnormalities (renal pelvic cavitation, hydroureter, absence of renal papilla). Smaller doses in rabbits caused increased maternal death and spontaneous abortion. In humans, the drug is considered teratogenic, particularly during the second and third trimesters. If pregnancy is detected in patients receiving telmisartan, the drug should be discontinued as soon as possible.

It is not known if telmisartan is excreted into cat or dog milk and it is recommended to either halt nursing and use milk replacer or discontinue the drug in nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited information is available. Hypotension and tachycardia are possible; bradycardia could occur from parasympathetic (vagal) stimulation. Patients may present with lethargy, anorexia, trembling, and vomiting. Treat supportively. Telmisartan is not removed by hemodialysis.

In chronic toxicity studies done in cats of up to 5 mg/kg/day (5 times recommended dose) for 6 months, telmisartan did not cause lethality. Hypotension, decreased red blood cell and reticulocyte counts, and reduced food intake occurred[9]; increased BUN and gastrointestinal effects are possible.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving telmisartan and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): Increased risk for adverse effects (eg, hypotension, hyperkalemia, renal function changes); increased monitoring may be warranted.
- **Aspirin**: Possible reduced antihypertensive effect of telmisartan and increased risk for renal impairment; increased monitoring may be warranted.
- **Baclofen**: Concurrent use may have additive blood pressure lower effects.
- **Benzodiazepines** (eg, **diazepam, lorazepam**): Concurrent use may increase risk for hypotension.
- **Buspirone**: Concurrent use may increase risk for hypotension.
- **Cabergoline**: Concurrent use may increase risk for hypotension.
- **Corticosteroids** (eg, **betamethasone, dexamethasone**): May decrease the antihypertensive effects of ARBs
- **Dexmedetomidine**: Concurrent use may result in additive effects on blood pressure and heart rate.
- **Diazoxide**: Concurrent use may increase risk for hypotension.
- **Dichlorphenamide**: Concurrent use may increase risk for hypotension.
- **Digoxin**: Concurrent use may increase digoxin levels. Closely monitor digoxin levels and therapeutic effects.
- **Diphenhydramine**: Concurrent use may increase risk for hypotension.
- **Doxepin**: Concurrent use may increase risk for hypotension.
- **Insulin**: Concurrent use may increase risk for hypoglycemia.
- **Heparin, Low Molecular Weight Heparins** (eg, **dalteparin, enoxaparin**): Concurrent use may increase risk for hyperkalemia.
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam**): Possible reduced antihypertensive effects of telmisartan and increased risk for renal impairment; increased monitoring may be warranted.
- **Opioids** (eg, **buprenorphine, butorphanol**): Concurrent use may increase risk for hypotension.
- **Potassium Preparations** (including potassium bromide): Increased risk for hyperkalemia; increased monitoring of serum potassium may be warranted.
- **Potassium–Sparing Diuretics** (eg, **spironolactone**): Increased risk for hyperkalemia; increased monitoring of serum potassium may be warranted.
- **Yohimbine**: Concurrent use may decrease the efficacy of ARBs.

Laboratory Considerations

No specific information noted.

Dosages

DOGS:

Reduction of proteinuria associated with chronic kidney disease | CKD (extra-label): 1 mg/kg PO once daily.[3–5] One study escalated the dosage to a maximum of 3 mg/kg PO once daily for cases with persistent proteinuria.[4]

Systemic hypertension (extra-label): 1 mg/kg PO once daily[15]

CATS:

Control of systemic hypertension (label dosage; FDA-approved): 1.5 mg/kg PO twice daily for the first 14 days, then 2 mg/kg PO once daily. Reduce dose in 0.5 mg/kg increments to manage hypotension; the minimum dose is 0.5 mg/kg PO once daily. May be administered either directly into the cat's mouth or on top of a small amount of food (do not mix into food). Cats that vomit within 30 minutes of administration may be redosed.[8]

Reduction of proteinuria associated with chronic kidney disease | CKD (extra-label): Using the oral solution: 1 mg/kg PO (directly into mouth or with a small amount of food) once daily.[16]

Monitoring

- Blood pressure, signs of target organ damage (eg, retinal lesions). In field studies in cats, dosage reduction for systolic BP less than 120 mm Hg was allowed.
- Depending on reason for use and patient's clinical condition: baseline and periodic serum chemistry panel (including renal values, liver enzymes, and electrolytes [especially potassium]), urine protein, UPC, volume/hydration status, and body weight
- Baseline and periodic CBC[17]
- Monitor for vomiting, diarrhea, or weight loss after initiating therapy.

Client Information

- Dispense with Client Information Sheet
- This medication is best absorbed when given on an empty stomach but may be given with or without food.
- The most common side effects are vomiting, diarrhea, lack of appetite, low energy level, anemia, dehydration, and low blood pressure (fainting, weakness, inability to exercise).
- This medicine has caused birth defects and should not be used in pregnant animals. If a human in the household is pregnant, they should be very careful not to ingest the medication and should avoid contact with telmisartan (ie, wear disposable gloves when administering doses and wash their hands after handling).

Chemistry/Synonyms

Telmisartan [CAS Registry: 144701-48-4; ATCvet code: QC09CA07] occurs as a white or slightly yellowish, crystalline powder. It is practically insoluble in water, slightly soluble in methyl alcohol, sparingly soluble in dichloromethane, and dissolves in 1M sodium hydroxide.

The feline product (*Semintra*®) is a clear, colorless to yellowish viscous oral solution; excipients include: hydroxyethylcellulose, manitol, and benzalkonium chloride.

Telmisartan may also be known as BIBR 277 SE. Trade names include *Micardis*® and *Semintra*®.

Storage/Stability

Telmisartan solution for cats may be stored at room temperature (at or below 25°C; 77°F) with excursions permitted up to 40°C (104°F) with the cap tightly closed. The label states that shelf life is 6 months after first opening the bottle. Telmisartan tablets should be stored at room temperature (up to 30°C; 86°F); do not remove from blisters until immediately before administration.

Compatibility/Compounding Considerations

The UK label for the cat product states: "In the absence of compatibility studies, this veterinary medicinal product must not be mixed with other veterinary products."

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Telmisartan Oral Solution: 10 mg/mL in 35 mL bottle with oral measuring syringe; *Semintra*®; (Rx). NADA# 141-501.

Telmisartan Oral Solution: 4 mg/mL in 30 mL bottle with oral measuring syringe; *Semintra*®; (In the UK/EU and Canada: POM-V).

HUMAN-LABELED PRODUCTS:

Oral Tablets: 20 mg, 40 mg, and 80 mg; *Micardis*®, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Terbinafine

(***ter***-bih-nah-feen) *Lamisil*®

Antifungal

Prescriber Highlights

- ► Used primarily for dermatophytosis; may also be useful for systemic fungal infections
- ► Fewer drug interactions than azole antifungals
- ► Appears to be well tolerated; adverse effects are primarily GI related (eg, vomiting, diarrhea)
- ► Use with caution in patients with liver or renal disease.

Uses/Indications

Terbinafine may be useful for treating dermatophyte and systemic fungal infections (eg, blastomycosis, histoplasmosis, coccidioidomycosis, cryptococcosis, sporotrichosis) in dogs, cats, birds, and other species. Terbinafine may also be used for the treatment of *Malassezia* spp dermatitis, and *Aspergillus* spp and *Candida* spp infections.

Pharmacology/Actions

Terbinafine is an inhibitor of the synthesis of ergosterol, a component of fungal cell membranes. By blocking the enzyme squalene monooxygenase (ie, squalene 2,3-epoxidase), terbinafine inhibits the conversion of squalene to sterols (especially ergosterol) and causes accumulation of squalene. Both of these effects are thought to contribute to its antifungal action.

Terbinafine has far greater activity (1000 times or more) on fungal squalene monooxygenase as compared with the similar human enzyme. Unlike azole antifungals, terbinafine's mechanism for inhibiting ergosterol is not mediated via the cytochrome P450 enzyme system and therefore does not alter testosterone or cortisol production and has fewer drug interactions. However, terbinafine is a competitive inhibitor of CYP2D6 in humans.

Terbinafine primarily has clinical activity (fungicidal) against dermatophytes (eg, *Microsporum* spp, *Trichophyton* spp). It may only be fungistatic against the yeasts (eg, *Candida* spp). Terbinafine has activity against *Aspergillus* spp, *Blastomyces dermatitidis*, *Coccidioidomyces immitis, Histoplasma capsulatum*, *Sporothrix schenckii*, and *Cryptococcus neoformans*. When used by itself, terbinafine is not very effective for pythiosis, but it displays synergy when combined with other antifungals.[1] Terbinafine resistance in *Microsporum canis* has been documented in a cat.[2]

In an in vivo human experimental model, terbinafine was shown to possess anti-inflammatory properties, although the exact mechanism and veterinary clinical significance remains unclear.[3]

Pharmacokinetics

In dogs, a single-dose study of terbinafine (30 – 35 mg/kg with food) showed maximum serum concentrations of ≈3.5 µg/mL and average time to maximum concentration of ≈3.5 hours after administration.[4] In greyhounds, the same dose resulted in slightly higher maximum serum concentrations (≈4 µg/mL) and a shorter time to maximum concentration (≈2 hours). Terbinafine is widely distributed and highly protein bound (more than 99%).[5] A half-life of ≈8.6 hours was reported for greyhounds.[6] Following the 30 – 35 mg/kg PO dose, the time above MIC was maintained for ≈18 to 19 hours.[4] After 21 days of 30 mg/kg PO once-daily dosing, low skin and sebum concentrations were seen compared to serum. Maximum concentration in the stratum corneum and the sebum barely exceeded *Malassezia* spp MIC_{90}.[7]

In cats, after a single fasted oral dose of 30 mg/kg, peak concentrations (≈3.2 µg/mL) occurred ≈1.3 hours after dosing. Elimination half-life was ≈8 to 10 hours.[8] Although oral bioavailability was low at ≈30%, terbinafine appears to achieve high enough concentrations at

the site of action; cats dosed at 34 – 46 mg/kg PO once daily for 14 days had terbinafine concentrations in hair that persisted above the MIC of most dermatophytes for several weeks.[9]

In horses, maximum plasma concentration after oral dosing was ≈0.3 µg/mL,[6,10] and time to maximum concentration was ≈1.5 hours. Half-life is ≈8 hours.[6,10] Volume of distribution (Vd/F) was ≈131 L/kg, and clearance was 187 mL/minute/kg. Because IV terbinafine was not administered, volume of distribution and clearance are reported as per fraction of drug available.[11] Rectal administration resulted in low plasma concentrations compared with oral administration.[10]

In humans, more than 70% of terbinafine given orally is absorbed; after first-pass metabolism, bioavailability is ≈40%. Food may increase absorption by up to 20%. Terbinafine is distributed into and attains high concentration in hair, nails, skin, and sebum. More than 99% of drug in plasma is bound to plasma proteins. Drug in the circulation is metabolized in the liver and the effective half-life is ≈36 hours. Approximately 70% of the drug is renally excreted as metabolites, and another 20% is excreted in the feces.[12] Terbinafine clearance is decreased ≈50% in patients with renal impairment or hepatic cirrhosis. The drug may persist in adipose tissue and skin for long periods of time.

Contraindications/Precautions/Warnings

Terbinafine is contraindicated in patients that are hypersensitive to it and in patients with active or chronic liver disease.[12] Use terbinafine with caution in patients with significantly impaired renal function. If terbinafine is to be used in veterinary patients with markedly impaired liver or renal function, do so with extreme caution; dosage adjustments should be considered. Liver failure leading to transplant or death has occurred in humans with and without pre-existing liver disease.

In humans, loss of taste and smell have been reported.[12] It is unknown if this effect occurs in animals; use terbinafine with caution in working dogs that rely on olfaction.

Do not confuse LamISIL with LaMICtal or LOMOtil, or terbINAafine with terBUTaline.

Adverse Effects

Because of limited use in veterinary patients, the adverse effect profile is not well defined. In general, terbinafine appears to be well tolerated. GI effects (eg, vomiting, inappetence, diarrhea) are possible. Reportedly, the oral tablets can have an unpleasant taste and may contribute to GI or behavioral adverse effects or dosing avoidance.

In dogs, excessive panting and elevated liver enzymes have been noted.[13] Ocular effects have also been reported in 2 dogs including periocular swelling, chemosis, and conjunctival erythema. Signs resolved within 24 to 36 hours of terbinafine administration, and ophthalmological examination after study completion was within normal limits. No recurrence of ocular effects was seen with follow-up administration.[4]

In a case report in 2 cats, 1 cat developed lethargy.[14] Facial pruritus in some treated cats has also been reported.[9]

In horses, signs of unpleasant taste or oral irritation (eg, lip curling, pawing at ground, opening/closing mouth, head shaking, excessive tongue movements, nostril flaring) were seen after PO administration.[6,10] Subclinical fever was reported in 1 horse.[10] Signs resolved spontaneously, but transient colic could not be ruled out.

Regurgitation was common in red-tailed hawks.[15]

In humans, photosensitivity has been reported with terbinafine use. Very rarely, liver failure, neutropenia, or serious skin reactions (eg, toxic epidermal necrolysis [TEN], Stevens-Johnson syndrome) have occurred after terbinafine use. Disturbances or loss of smell and taste have also been reported[12]; whether or how this may impact working animals is uncertain.

Reproductive/Nursing Safety

It is unknown if terbinafine crosses the placenta. High-dose studies in pregnant rabbits and rats have not demonstrated overt fetotoxicity or teratogenicity. Although risk appears low, use with caution in pregnant animals.

The drug enters maternal milk at concentrations 7 times that found in plasma; the manufacturer recommends that mothers do not nurse while taking this drug.

Because safety has not been established, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

Limited information available; humans have taken doses up to 5 g (total dose) without serious effects. Clinical signs are expected to be extensions of the drug's adverse effects. See ***Adverse Effects***.

For patients that have experienced or are suspected of having experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving terbinafine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cimetidine**: Inhibits terbinafine metabolism and increases terbinafine absorption and exposure[10]
- **Cyclosporine**: Terbinafine may increase the elimination of cyclosporine.
- **Fluconazole**: Inhibits terbinafine metabolism and increases terbinafine exposure
- **Rifampin**: May increase terbinafine clearance

Because terbinafine is an inhibitor of CYP2D6 in humans, it could reduce the metabolism of:

- **Antiarrhythmics** (eg, **lidocaine, mexiletine, procainamide**)
- **Beta-Blockers** (eg, **metoprolol, propranolol**)
- **Codeine** (blocks the conversion to morphine)
- **Dextromethorphan**
- **Doxorubicin**
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, selegiline**)
- **Methadone**
- **Metoclopramide**
- **Ondanestron**
- **Selective Serotonin Receptor Inhibitors** (**SSRIs**; eg, **fluoxetine, sertraline**)
- **Tamsulosin**
- **Tramadol**
- **Trazodone**
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine, doxepin**)

Laboratory Considerations

- None

Dosages

DOGS:

Systemic mycoses | blastomycosis, coccidioidomycosis, cryptococcosis, histoplasmosis, sporotrichosis (extra-label): 30 mg/kg PO every 24 hours.[16–19] Based on a pharmacokinetic study, twice-daily dosing may be considered.[4] Use of terbinafine

as a single agent is not recommended.[4]

Cryptococcosis (extra-label): From a case report, after primary therapy with amphotericin B and fluconazole had failed, a dog received terbinafine 30 mg/kg PO once daily. Insufficient data are currently available to recommend terbinafine as a first-line agent, but in cases where primary therapy has failed to yield a response, it may prove beneficial.[19]

Colonic pythiosis (extra-label): Terbinafine 6 – 12 mg/kg PO once daily in combination with itraconazole 5 – 10 mg/kg PO once daily.[20–24] This combination may be used in conjunction with mefenoxam 4 mg/kg PO every 12 hours[20–22] or prednisone.[23] Terbinafine as a single agent is not recommended for treatment of pythiosis.[4]

Refractory sinonasal aspergillosis (extra-label): For dogs that have not responded to conventional topical and systemic therapy for sinonasal aspergillosis, terbinafine 30 mg/kg PO every 12 hours in combination with posaconazole 5 mg/kg PO every 12 hours and doxycycline 5 mg/kg PO every 12 hours; treatment continued for 6 to 18 months. 70% of dogs achieved complete remission and 30% partial remission.[25]

Dermatophytosis (extra-label): 30 – 40 mg/kg PO every 24 hours[26]; treatment should continue until mycological cure (ie, 2 negative skin cultures taken 2 weeks apart).

***Malassezia* spp dermatitis** (extra-label): 30 mg/kg PO once daily.[7] **NOTE**: Terbinafine was only partially effective, and concentration achieved in the stratum corneum and sebum was only slightly higher than *Malassezia* spp MIC_{90}. Higher terbinafine doses or other drug therapy (eg, ketoconazole, itraconazole) may be required.

CATS:

Systemic mycoses:

Cryptococcal CNS infections (extra-label): 10 mg/kg PO once daily can rectify the clinical signs though cats with CNS cryptococcosis usually require lifelong treatment.[27]

Sporotrichosis (extra-label): 30 mg/cat (NOT mg/kg) PO once daily as an alternative for the treatment of cats that do not tolerate itraconazole, in cases that respond poorly, and/or if an azole resistance is suspected. May be used in combination with itraconazole 5 – 10 mg/kg PO every 24 hours[28,29] or posaconazole.[30]

Dermatophytosis (extra-label):

a) **Pulse therapy**: 20 mg/kg PO once daily for 7 days, then 21 days off, followed by 40 mg/kg PO daily for 7 days[31]
b) Using terbinafine 250 mg tablets, cats weighing less than 2.8 kg (6.1 lb) received ¼ of a tablet (62.5 mg) per dose, cats weighing 2.8 to 5.5 kg (6.1 to 12.1 lb) received ½ a tablet (125 mg) per dose, and cats weighing greater than 5.5 kg (12.1 lb) received 1 tablet (250 mg) per dose. Administered once daily with food for 21 days in combination with twice-weekly lime sulfur rinses[32]

Sinonasal aspergillosis (extra-label): 15 mg/kg PO every 12 hours.[33] Lower dosages 5 – 10 mg/kg PO every 12 to 24 hours also have been reported,[34–36] and are based primarily on author experience or case reports.

BIRDS:

Aspergillosis (extra-label):

a) Terbinafine 10 – 15 mg/kg PO every 12 to 24 hours in combination with itraconazole 5 – 10 mg/kg PO every 12 hours[37]
b) A single oral dose pharmacokinetic study in red-tailed hawks concluded that terbinafine 22 mg/kg PO once a day results in steady-state trough plasma concentrations above the MIC and is recommended as a potential treatment option for aspergillosis in raptors; however, additional research is required to determine both treatment efficacy and safety.[38]
c) **Nebulization therapy**: A pharmacokinetic study using nebulized terbinafine (1 mg/mL solution nebulized for 15 minutes) in Hispaniolan Amazon parrots concluded that higher concentrations of nebulization solutions, nebulization times greater than 15 minutes, or more frequent nebulization is likely needed to reach clinically relevant systemic terbinafine concentrations.[39] The relationship between plasma concentrations and lung or air sac concentrations after nebulization of terbinafine still needs to be determined and further studies are warranted to determine the optimal technique for dissolving terbinafine in solution, as well as to determine the best concentration of terbinafine and particle size to nebulize. Pharmacodynamic studies are also necessary to determine therapeutic plasma concentrations.

REPTILES:

Antifungal (extra-label):

a) **Nebulization therapy**: From a pharmacokinetic study, 18 mg/reptile (NOT mg/kg) delivered via 30-minute nebulization into a sealed 10-gallon aquarium achieved therapeutic plasma concentrations.[40] Terbinafine 2 mg/mL solution was prepared by dissolving terbinafine powder, USP in sterile saline. Efficacy would need to be confirmed with clinical studies.
b) From a case report in an Aldabra tortoise, 3.3 mg/kg PO once daily for 15 months was used to treat phaeohyphomycosis of the carapace.[41]

HEDGEHOGS:

Dermatophytosis (extra-label): 100 mg/kg PO twice daily for 28 days reduced clinical lesions and resulted in ≈99% mycological cure rate. The mycological cure rate was significantly better than with itraconazole.[42]

Monitoring

- Clinical efficacy
- Baseline liver enzymes; repeat periodically as needed (especially if treating long-term) based on clinical signs and development of adverse effects.
- Fungal cultures (eg, Dermatophyte Test Media [DTM]) for dermatophytosis

Client Information

- This medicine may be given with or without food.
- This medicine is usually tolerated well. The most common side effect is vomiting.
- If your animal vomits after receiving this medicine on an empty stomach, try giving it with food. Contact your veterinarian if your animal continues to vomit after receiving this medicine.
- Your veterinarian will need to monitor your animal while it is taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

A synthetic allylamine antifungal, terbinafine HCl occurs as a white to off-white, fine, crystalline powder. It is slightly soluble in water and soluble in ethanol.

Terbinafine HCl may also be known as *Alamil®*, *Daskil®*, *Daskyl®*, *DesenexMax®*, *Finex®*, *Lamisil®*, *Micosil®*, *Terbinex®*, *Terbisil®*, or *Terekol®*.

Storage/Stability

Terbinafine tablets should be stored at room temperature (25°C [77°F]) in tight containers, with excursions permitted from 15°C to 30°C (59°F-86°F); protect from light.

Compatibility/Compounding Considerations

In a pharmacokinetic study for terbinafine nebulization in parrots, one 250 mg tablet was crushed and dissolved into 250 mL sterile water to make a 1 mg/mL solution. Before nebulization, the solution was agitated before being mixed with a stir bar for 12 hours. Terbinafine concentrations of solutions made with a crushed tablet were significantly lower than those made with raw powder, but plasma concentrations did not differ significantly.[43]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No oral products are FDA-approved. An otic solution containing terbinafine (1.48%), florfenicol (1.66%), and mometasone furoate (0.22%) is FDA-approved for treatment of otitis externa in dogs; *Claro*®; (Rx)

HUMAN-LABELED PRODUCTS:

Terbinafine HCl Oral Tablets: 250 mg; *Lamisil*®**,** generic; (Rx)

A topical cream and a spray (1%) are also available (OTC)

Terbutaline

(ter-***byoo***-ta-leen) *Brethine*®

Beta-2-Adrenergic Agonist, Tocolytic

Prescriber Highlights

- ► Used as a bronchodilator or tocolytic; sometimes used to treat bradyarrhythmia or hyperkalemia
- ► Oral administration is not practical in horses due to low bioavailability.
- ► May be used in horses to confirm and quantitate anhidrosis
- ► Caution should be used in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).
- ► Adverse effects include increased heart rate, tremors, CNS excitement (eg, nervousness), and hypotension; after parenteral injection in horses, sweating and CNS excitation are possible.

Uses/Indications

Terbutaline is used as a bronchodilating agent in the adjunctive treatment of bronchospasm caused by pulmonary disease (including tracheobronchitis, collapsing trachea, chronic bronchitis, and asthma) in small animal species. Its use for airway collapse in dogs is controversial, as some sources state that terbutaline is not helpful for the treatment of airway collapse,[1,2] while others advocate that it may be helpful in certain patients.[1,3,4] Terbutaline is primarily used as adjunctive therapy in cats with asthma that are already receiving corticosteroid therapy. The drug may be used pre-emptively or intraoperatively for management of bronchospasm in cats undergoing transtracheal wash, bronchoscopy, and bronchoalveolar lavage.[5–9]

Terbutaline may also be beneficial in the treatment of bradyarrhythmias and hyperkalemia in dogs and cats.

In horses, terbutaline has occasionally been used for its bronchodilating effects, but adverse effects, short duration of activity after IV administration, and poor oral absorption have limited its use. Terbutaline can help diagnose anhidrosis in horses after intradermal injection.[10]

Oral and parenteral terbutaline has been used successfully as a tocolytic agent in humans, dogs, and cats for short-term inhibition of premature labor.

Pharmacology/Actions

Terbutaline is a sympathomimetic drug that preferentially stimulates beta-2-adrenergic receptors found primarily in vascular smooth muscle (including bronchial, GI, and uterine tissues) to cause relaxation of bronchial smooth muscle cells, reduced airway resistance, vasodilation, and tocolysis, as well as to inhibit release of bronchoconstrictive mediators from mast cells. At recommended doses, terbutaline spares the beta-1 receptor found primarily in the heart, thus lowering the likelihood for cardiac adverse events; terbutaline's specificity is not as precise at higher doses and some beta-1 activity may occur, resulting in tachycardia and increased myocardial contractility. Occasionally, tachycardia may develop at recommended doses and can be a result of either direct beta-1 stimulation or a reflex response secondary to peripheral vasodilation. Terbutaline also promotes intracellular shift of potassium through activation of Na^+ K^+ ATPase enzyme system.

Terbutaline has virtually no alpha-adrenergic activity.

Pharmacokinetics

Studies in dogs found that 16.9% to 46.6% of the IV dose was excreted within 2 to 4 hours and greater than 95% of doses administered IV, SC, or PO were excreted within 24 hours.[11,12] Peak serum concentrations of terbutaline administered SC in dogs occurred within ≈30 minutes; peak serum concentrations following PO administration occurred between 2 to 6 hours.[12]

In horses, terbutaline is poorly absorbed after oral administration and has a bioavailability less than 1%.[13] Mean residence time is ≈30 minutes in horses when the drug is given IV; administration via IV CRI appears to be necessary to maintain therapeutic serum concentrations.

In humans, only ≈33% to 50% of an oral dose is absorbed; peak bronchial effects occur within 2 to 3 hours and activity persists up to 8 hours.[14]

Terbutaline is well absorbed following SC administration in humans; onset of action occurs within 15 minutes, peak effects are at 30 to 60 minutes, and duration of activity is up to 4 hours. Although terbutaline is principally excreted unchanged in the urine (60%), it is also metabolized in the liver to an inactive sulfate conjugate.[15]

Contraindications/Precautions/Warnings

Terbutaline is contraindicated in patients hypersensitive to it and should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, glaucoma, or cardiac disease (especially with concurrent arrhythmias).

Adverse Effects

Most adverse effects are dose-related and are similar to those of sympathomimetic agents, including increased heart rate, tremors, CNS excitement (eg, nervousness), and dizziness. These effects are generally transient, mild, and do not require discontinuation of therapy. Tachycardia, trembling, sweating, and CNS excitation were reported after IV injection in horses.[13] In horses under injectable general anesthesia, terbutaline at 2 μg/kg IV (once) did not improve PaO_2 and was associated with adverse cardiovascular effects (eg, increased heart rate, decreased blood pressure).[16]

Transient hypokalemia has been reported in humans receiving beta-adrenergic agents. Hyperglycemia, cardiac arrhythmias, and pulmonary edema have been reported in humans.

Reproductive/Nursing Safety

Terbutaline crosses the placenta. No teratogenic effects were noted in pregnant laboratory animals given terbutaline during embryofetal development, but alterations in neonatal behavior and brain development have been noted. Increased fetal heart rate and neonatal hypoglycemia may occur when terbutaline is administered in late

pregnancy. Terbutaline has tocolytic effects, but it is recommended that use in humans for this effect be limited to 48 to 72 hours due to adverse maternal effects. In humans, use of this drug should be avoided or minimized during early pregnancy due to the risk for asthma and cardiac defects, and prolonged use should be avoided in the second and third trimesters.[17]

Although terbutaline is excreted in milk at concentrations similar to those found in maternal plasma, use is only recommended when the potential maternal benefit outweighs possible risks for offspring.[15,17]

Overdose/Acute Toxicity

Clinical signs of significant overdose after systemic administration may include arrhythmias (eg, bradycardia, tachycardia, heart block, extrasystoles), hypokalemia, hypertension, fever, muscle tremors, vomiting, mydriasis, and CNS stimulation resulting in seizures. Recent oral ingestion should be handled like other overdoses (eg, gastrointestinal decontamination) if the animal does not have significant cardiac or CNS effects. Treatment should be supportive and based on clinical presentation. Potassium supplementation may be required. If cardiac arrhythmias require treatment, a beta-blocking agent (eg, propranolol[18]) can be used but may precipitate bronchoconstriction.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation centers that specialize in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving terbutaline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, Inhalation** (eg, **isoflurane**): Use with inhalation anesthetics may predispose the patient to ventricular arrhythmias, particularly in patients with pre-existing cardiac disease—use cautiously.
- **Beta-Adrenergic Receptor Antagonists** (eg, **propranolol**): May antagonize the actions of terbutaline
- **Digoxin**: Use with digitalis glycosides may increase the risk for cardiac arrhythmias.
- **Diuretics** (eg, **furosemide, hydrochlorothiazide**): Beta-agonists may increase the risk for hypokalemia.
- **Monoamine Oxidase Inhibitors (MAOIs;** eg, **amitraz, linezolid, selegiline**): May potentiate the vascular effects of terbutaline
- **Succinylcholine**: Concurrent use may result in enhanced neuromuscular blockade.
- **Sympathomimetics, Other** (eg, **phenylpropanolamine**): Use of terbutaline with other sympathomimetic amines may increase the risk for developing adverse cardiovascular effects.
- **Theophylline**: May result in decreased theophylline concentrations. Combination may precipitate cardiac arrhythmias; sudden death has occurred in humans.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): May potentiate the vascular effects of terbutaline

Laboratory Considerations

- **Macrolide Antibiotics** (eg, azithromycin, clarithromycin): Macrolides induce anhidrosis in foals and may interfere with quantitative intradermal terbutaline sweat test (QITST).[19]

Dosages

NOTES:

1. Do not confuse mg/kg dosages with mg/dog or mg/cat.
2. Terbutaline should not be administered as an IV bolus; administer slowly if IV use cannot be avoided.

DOGS:

Bradyarrhythmias (extra-label): 0.2 mg/kg PO every 8 to 12 hours; improvement is usually partial and often temporary.[20]

Hyperkalemia (extra-label): 0.01 mg/kg IV over 5 to 10 minutes[21,22]

Bronchodilator for small airway collapse/disease (extra-label): 0.625 - 5 mg/dog (NOT mg/kg) every 8 to 12 hours.[3,4,23] Efficacy is debatable for its use in airway collapse/disease in dogs; however, it may be useful in some cases.[1,3,4] If used, it is often instituted for a 1-to-2-week trial to determine its effectiveness in the individual patient, and continued use is based on efficacy as well development of unwanted side effects.

Premature labor as a tocolytic (extra-label): 0.03 mg/kg PO every 8 hours as an initial dose to suppress uterine contractility in bitches with historical loss of otherwise normal pregnancies preterm. The dose should ideally be titrated to effect using tocodynamometry. Terbutaline should be discontinued 48 hours prior to the calculated delivery date so normal labor and delivery can occur. Exogenous progesterone can be added if myometrial contractility cannot be controlled with tocolytics.[24]

Nonischemic priapism (extra-label): 1.25 – 5 mg/dog (NOT mg/kg) PO every 8 to 12 hours in combination with other conservative therapies (eg, lubrication, analgesia) may be beneficial.[24]

CATS:

Bronchodilator (extra-label):

a) **Status asthmaticus**: 0.01 mg/kg SC, IM, or slow IV. Can be considered for home management (SC or IM only) of acute asthma in cats that cannot or will not tolerate use of an albuterol metered-dose inhaler (see ***Albuterol***); positive response (ie, decrease of respiratory rate or effort by 50%) occurs in 15 to 30 minutes.[25,26]

b) **To minimize bronchospasm prior to tracheal wash or bronchoalveolar lavage (BAL)**: 0.625 mg/cat (NOT mg/kg) PO (alternatively, 0.01 mg/kg IM or SC if the cat is intolerant of oral administration) twice daily administered 12 to 24 hours prior to the procedure, with the last dose given 2 to 4 hours before anesthesia induction.[9]

Bradyarrhythmias (extra-label): 0.625 mg/cat (NOT mg/kg) PO every 8 to 12 hours; improvement is usually partial and often temporary.[20]

Hyperkalemia (extra-label): 0.01 mg/kg slow IV over 5 to 10 minutes[21,22]

Premature labor as a tocolytic (extra-label): 0.03 mg/kg PO every 8 hours as an initial dose to suppress uterine contractility in queens with historical loss of otherwise normal pregnancies preterm. The dose should ideally be titrated to effect using tocodynamometry. Terbutaline should be discontinued 48 hours prior to the calculated delivery date so normal labor and delivery can occur. Exogenous progesterone can be added if myometrial contractility cannot be controlled with tocolytics.[24]

HORSES:

Quantitative intradermal terbutaline sweat test (QITST) to identify anhidrosis (extra-label): Prepare eight 0.1 mL intradermal injections of serial 10-fold terbutaline dilutions (0 [control], 0.001, 0.01, 0.1, 1, 10, 100, and 1000 mg/L) using 0.9% so-

dium chloride; sequentially administer diluted solutions with a 25-gauge needle at ≈5 cm intervals. Apply preweighed absorbent padding over each injection site. After 30 minutes, remove and reweigh padding. Anhidrotic horses do not sweat, even at the highest concentrations. See ***Laboratory Considerations***.[10]

BIRDS:

Adjunctive treatment of respiratory distress (extra-label): Terbutaline 0.01 mg/kg IM every 6 to 8 hours in combination with butorphanol 1 – 2 mg/kg IM every 2 to 3 hours are usually given to birds in respiratory distress before placing them in an oxygen-enriched incubator. Treatment can be continued via nebulizer.[27]

REPTILES:

Bronchodilator (extra-label): 0.01 – 0.02 mg/kg IM[28]

Monitoring

- Improvement in clinical signs (eg, cough, respiratory rate and effort); thoracic auscultation
- Cardiac rate and rhythm (if indicated)
- Serum potassium, early in therapy if animal is susceptible to hypokalemia (eg, diuretic therapy)
- Adverse effects, including signs of CNS excitation

Client Information

- This medication can increase heart rate and cause excitement.
- Terbutaline can delay labor in pregnant animals.
- Contact your veterinarian if your animal's condition deteriorates or it becomes acutely ill.
- Overdoses can be serious. Keep this medication out of reach of children and animals.

Chemistry/Synonyms

Terbutaline sulfate, a synthetic sympathomimetic amine, occurs as a slightly bitter-tasting, white to gray-white crystalline powder that may have a faint odor of acetic acid. One gram is soluble in 1.5 mL of water or 250 mL of alcohol. The commercially available injection has its pH adjusted to 3 to 5 with hydrochloric acid.

Terbutaline may also be known as KWD-2019, terbutaline sulphate, or terbutalini sulfas; there are many trade names, including *Brethine®*.

Storage/Stability

Terbutaline should be stored in tight containers at room temperature of 20°C to 25°C (68°F-77°F) and protected from light. Discolored solutions should not be used. Unused portions of terbutaline injection should be discarded.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Terbutaline injection is physically **compatible** with sodium chloride solutions, 5% dextrose, aminophylline, doxapram, and regular insulin.

Dosage Forms/Regulatory Status
