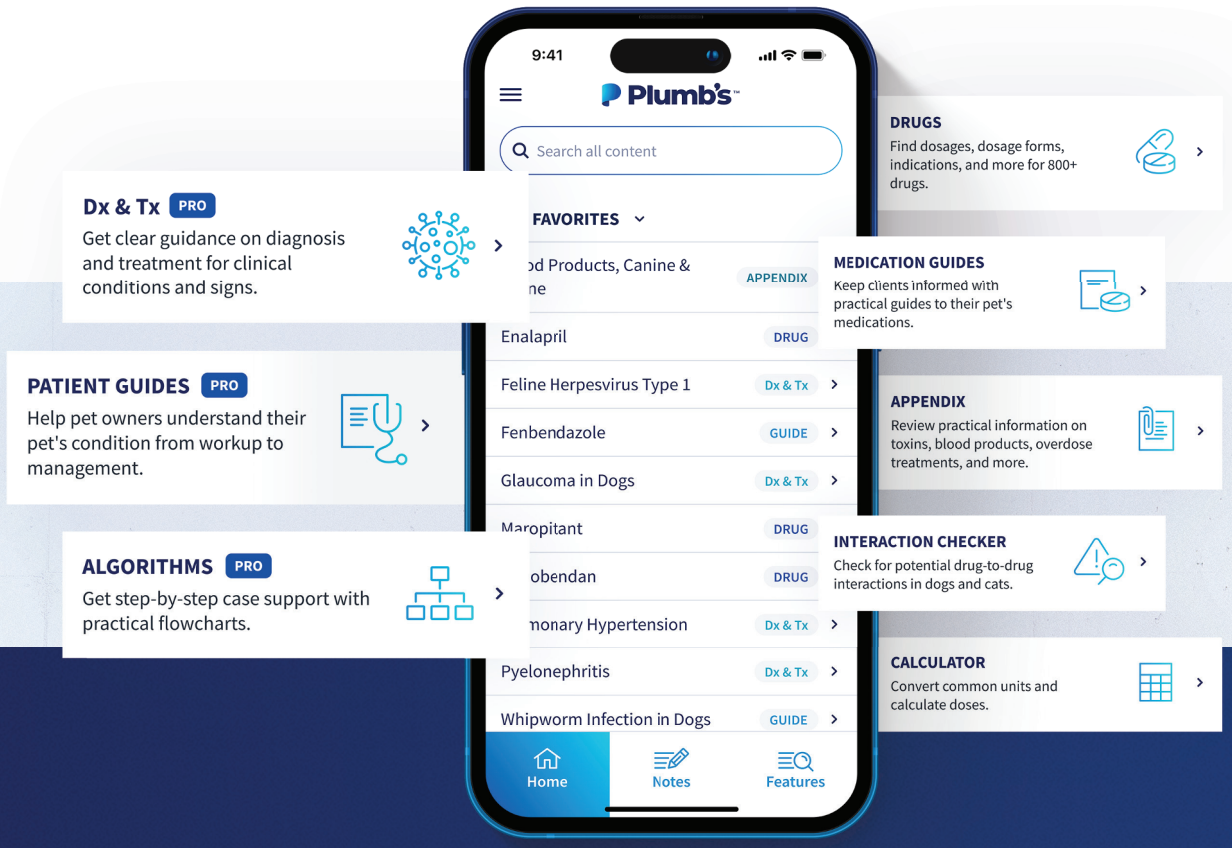
Plumb's™

VETERINARY DRUG HANDBOOK

10TH EDITION

James A. Budde
Dawn M. McCluskey

WILEY Blackwell

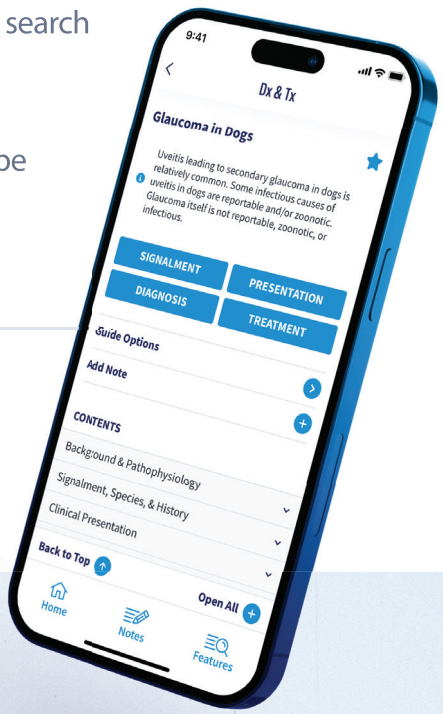


EXCLUSIVE OFFER WITH YOUR BOOK PURCHASE

Plumb's™

Work up cases
Confirm diagnoses
Choose treatments
Educate pet owners
All from one Plumb's™

Get **50% off** your first year of on-the-go clinical decision support with Plumb's Pro™



Easy access to diagnostic and treatment information, pet owner education tools, and the continually updated drug information you trust—on all of your devices

Plumb's Pro™ goes beyond prescribing to help you find a practical path forward for every case.

Even the ones that don't go as planned.

- Find practical diagnostic and treatment guidance in seconds with **Dx & Tx monographs** that cover common clinical conditions and signs.
- Keep the most up-to-date version of Plumb's on hand, so you can access **drug information** like dosing, side effects, and more—from anywhere.
- Plot your path forward with **practical diagnostic and treatment algorithms**.
- Answer client questions before they turn to an internet search with **pet owner guides** that are easy to share and easy to understand.
- See the potential interactions for the drugs you prescribe with the **drug interaction checker**, so you can make treatment decisions with peace of mind.

Access trusted clinical decision support wherever you practice, all on one easy-to-use, continually updated platform.

If you purchased this book, you're eligible for a discount! Scan the QR code or visit **plumbs.com/beyond-the-book** to get your unique code and save 50% on a year of Plumb's Pro™

To Donald Plumb,
for his vision and determination to create, nurture,
and grow *Plumb's® Veterinary Drug Handbook* into the most respected
and valued veterinary drug information resource.

To the veterinarians, veterinary healthcare staff, students, and pharmacists
who rely on this resource as they care for animals large and small.

James A. Budde and Dawn M. McCluskey,
on behalf of the entire Plumb's® Team

Editor Emeritus

Donald C. Plumb, PharmD, FSVHP (Honorary)

In Appreciation

Let's consider just what Donald Plumb started back in 1991. From its utilitarian roots as the University of Minnesota Veterinary Pharmacy Formulary, that spiral-bound "orange virus" was elevated into the first edition of *Plumb's® Veterinary Drug Handbook*. With a distribution center located in his basement and staffed by his wife, Shirley Werlein Plumb, veterinary medicine finally had a drug information resource.

The subsequent editions of *Plumb's® Veterinary Drug Handbook* expanded not only the book's content, but also its reach. The handbook has been printed in multiple languages and has been sold to veterinarians around the world. With his same entrepreneurial spirit, Dr. Plumb forayed into digital publication as a way to provide easy access to the information found in the handbook. In 2014, with vision inspired by VetMedux CEO and founder, Elizabeth Green, Dr. Plumb was able to bring the handbook onto a modern web platform and mobile app.

By 2018, Dr. Plumb was pleased with the roadmap that the Brief Media (now VetMedux) team had designed for the handbook, and he entrusted his life's work to our care. The Plumb's® team is honored to carry on this legacy through close collaboration with veterinary specialists, veterinary pharmacists, and our audience—without whom the content of Plumb's® would not be possible.

In this 10th edition of *Plumb's® Veterinary Drug Handbook*, we on the Plumb's® team, on behalf of veterinarians and their patients across the globe, offer our most profound gratitude to Dr. Plumb for his vision and commitment to the safety of animals under veterinary care.

Just look at what he started.

Preface

From its utilitarian inception as a formulary for the University of Minnesota Veterinary Teaching Hospital, to the subsequent 9 editions of *Plumb's® Veterinary Drug Handbook*, Donald Plumb created a widely respected and profoundly impactful veterinary drug reference. Today, a new Plumb's® team is answering the call to transform content to meet the emerging informational needs of a fast-paced clinical setting, as well as to serve the need for up-to-date information not limited by the confines of a printed book. Alongside the digital innovations in how veterinary drug information is delivered at **plumbs.com**, the 10th edition of *Plumb's® Veterinary Drug Handbook* continues the mission to serve as a single-volume reference to assist veterinarians when making critical therapy decisions about their patients as well as provide trusted counsel to pharmacists serving pet owners.

This 10th edition presents trusted drug information in the consistent, easy-to-use (and understand) Plumb's® format readers far and wide have become accustomed to in their daily clinical practice. From the ***Prescriber Highlights*** that capture the most important elements for at-a-glance comprehension to the ***Dosage Forms*** section and everything in between, Plumb's® provides pertinent information needed when prescribing drugs to veterinary patients. The sequence of the monograph sections provides fine details about what conditions the drug is used for (***Uses/Indications***), the drug's mechanism of action (***Pharmacology/Actions***), ***Pharmacokinetics***, and what concerns the prescriber should be aware of before prescribing a drug to a patient (eg, ***Contraindications/Precautions/Warnings, Adverse Effects, Reproductive/Nursing Safety, Overdose/Acute Toxicity, Drug Interactions***); ***Monitoring*** of drug therapy and information related to drug characteristics (eg, ***Chemistry/Synonyms, Storage/Stability, Compounding/Compatibility Considerations***) may also influence treatment. The ***References*** section has been significantly expanded and is available digitally; readers may explore specific details from the cited literature by accessing each drug's references at **wiley.com/go/budde/plumb**.

Plumb's® is committed to antimicrobial stewardship and has included globally accepted designations for each antibiotic monograph to alert the prescriber to the critically important choice to be made when using this class of drugs.

All of these important details factor into the decisions of whether and how to use a particular drug for a particular patient; dosages should be chosen only based on the totality of information, and response to therapy should be monitored accordingly.

This edition also includes rigorous peer review and infusion of relevant clinical details to further support a veterinarian's critical decisions when treating patients. Every effort has been made to continue presenting information in a manner that will help to minimize misunderstandings and reduce the risk for a medication error.

The reference that was once compiled by one person has now been expanded to include the efforts of a team of board-certified veterinary specialists and veterinary pharmacists. The Plumb's® team recognizes that information changes so rapidly that it is impossible for one person to keep up and have all the answers; as a result, we have assembled a team of experts to scour the primary and secondary literature and revise the monograph content to incorporate updates from these sources. Woven throughout this entire process are the tireless and never-ending efforts of the editors, who ensure that the content herein is clear and concise.

Each monograph, including the ***Ophthalmic*** and ***Topical Dermatologic and Otic Agents***, in this edition has been updated and 36 new monographs have been added (see ***Table***). These new monographs include therapeutic entities recently introduced into the veterinary marketplace, or are human drugs that either have been increasingly incorporated into veterinary practice, or were determined (often via feedback submitted from readers via plumbs.com) to be useful additions to this reference. Converse to the additions of new content, some content has been removed, either because the drug is no longer marketed, more effective or safer alternatives are now available, available information supporting the drug's use is lacking, or because the drug is no longer considered to have a place in therapy.

As with the first edition of *Plumb's® Veterinary Drug Handbook,* it may still be helpful to describe what this book is *not*. It is not intended to be a pharmacology textbook, nor medical chemistry tome, nor compounding manual. It is not merely a compilation of pharmacokinetic data, recitation of drug interactions, or simple repetition of product labels. Instead, *Plumb's® Veterinary Drug Handbook* captures the best of all of these—and more.

With information ever-changing, the Plumb's® team recognizes the need for regularly updated resources to be delivered at the speed of clinical practice. Digital advancements to Plumb's® content—including drug monograph updates, medication guides, and the profession's first and only veterinary-specific drug interaction checker—are available to those who purchase a subscription at **plumbs.com**.

Our vision in this 10th edition is to guide the most critical decisions in veterinary medicine. We hope this edition of *Plumb's® Veterinary Drug Handbook* helps busy veterinary practitioners provide the best possible care for their patients.

Notes and Cautions

How to Use This Book

The information found in this reference is meant to be an aggregate of drug information that is relevant and important to clinical settings. The core focus of the content is to help veterinary and pharmacy professionals make safe, informed prescribing decisions when treating the animals in their care. The content is not meant to be an exhaustive text of related pharmacology or case management information; readers are encouraged to consult other resources and experts for these purposes. Pharmacologic and clinical case management concepts are not discussed.

Although this reference is used globally, it presents information in the context of US regulations. It is the responsibility of the reader to understand relevant local regulations related to, but not limited by, the use, storage, and withdrawal times for specific drugs in specific species.

Great care has been taken to carefully organize the content in this reference so that readers can readily find the information they need. Although the most commonly accessed information is in the ***Dosages*** section, it is important for readers to turn their attention to other sections of the monograph (eg, ***Contraindications/Precautions/Warnings, Drug Interactions***) to understand the complete drug profile.

The ***Client Information*** section is now presented with language from the perspective of the prescriber speaking to the client. This presentation allows the information to be readily copied into client handouts. The bullet points are not exhaustive and are intended to convey the most important information to the client. A complete set of thorough Veterinary Medication Guides with client-friendly language can be accessed with a subscription to plumbs.com.

Dosages and Extra-Label Drug Use

The drug dosages listed for the various species in this reference come from a variety of sources, and there has been a concerted effort to ensure all dosages are referenced to their primary source and to indicate where dosages only have anecdotal support. Although a sincere effort has been made to ensure that the dosages and information included in this book are accurate and reflect the original source's information, errors can occur; it is recommended that the reader refer to the original reference or the approved labeling information of the product for additional information and verification of all dosages. Please note that the ***References*** section from each monograph is available digitally; specific details from the cited literature can be found by accessing each drug's references at **wiley.com/go/budde/plumb**.

Information in the ***Dosages*** section is organized by species so that prescribers can quickly access the dosage they need. Each monograph lists the applicable species in the same order for a consistent format; when relevant, label dosages of a particular species are always presented first. Any dosage listing that deviates from the US label is clearly delineated as extra-label. Please note that the presentation of drug information is centered on US-labeled products; foreign labels that differ from US labels are considered extra-label in this US-based reference. Extra-label dosages are not necessarily endorsed by the manufacturer, the Food and Drug Administration (FDA), or the Plumb's® authors. Veterinarians are responsible, per the Animal Medical Drug Use Clarification Act (AMDUCA), for the appropriate use of medications. For further information, see ***Extra-Label Drug Use*** in the ***Appendix*** section.

Drug Interactions

Drug interaction identification and evaluation is an art and is slowly emerging in veterinary medicine; relatively little specific information is known on this subject for the variety of species treated. Although drug interactions can be clinically significant and potentially life-threatening in veterinary patients, most of the interactions listed in the drug monographs are derived from human medicine (which is only slightly more informed than veterinary medicine on this topic) and are often included primarily to serve as cautions to the prescriber to be alert for unforeseen outcomes or to enhance monitoring associated with the drug therapy. Additionally, it is likely there are many other clinically significant interactions between drugs that are not listed; prescribers are reminded that the risk for adverse drug interactions increases with the number of different medications given to an individual patient. For situations when a patient is receiving multiple medications, consultation with a veterinary pharmacist or veterinary clinical pharmacologist is highly encouraged.

Abbreviations

To minimize medication errors, abbreviations such as SID, BID, or q8h are not used. In the ***Dosage Forms*** section, the terms Rx or OTC are noted in parentheses after a listed dosage form. If Rx, the drug is considered to be a prescription or legend product and requires a prescription. OTC denotes that the item is available "over-the-counter" and does not legally require a prescription for purchase. Note, however, that use of "human" OTC medications in veterinary species is considered extra-label drug use and, per AMDUCA, must be undertaken only under the supervision of a veterinarian.

Trade and Proprietary Names

Trade names or proprietary names are both italicized and capitalized and then followed by the registered trademark

symbol (eg, *Amoxi-Tabs*®). This notation may not accurately represent the drug's official registered copyright, trademark, or licensed status (eg, ™). For clarity, the registered trademark symbol (®) and italics have not been used in the index. Where listed, trade names are typically the innovator product(s), particularly those names listed at the top of each monograph. Additional names, including chemical and foreign trade names, can be found in the ***Chemistry/Synonyms*** section. Newly branded, generic products are continually released and ever-changing, and the listing in this reference may not be complete.

Errors

If an error is found or suspected, please contact our team at **plumbs.com/about/contact-us/** so the concern can be appropriately addressed. Errors that have been found in this edition and previous editions can be found at **plumbs.com/handbook-errata-10th-edition/**.

DISCLAIMER

The author/publisher/distributor assume no responsibility for and make no warranty with respect to results that may be obtained from the uses, procedures, or dosages listed, and do not necessarily endorse such uses, procedures, or dosages. The author/publisher shall not be liable to any person whatsoever for any damages, or equivalencies, or by reason of any misstatement or error, negligent or otherwise, obtained in this work. Should the purchaser not wish to be bound by the above, the reference may be returned to the distributor for a full refund.

Acarbose

(ay-***kar***-bose) *Precose®, Glucobay®*

Antidiabetic Agent, Alpha Glucosidase Inhibitor

Prescriber Highlights

- ► Antihyperglycemic agent that reduces the rate and amount of glucose absorbed from the gut after a meal; may be useful in dogs and cats with mild hyperglycemia; unlikely to be effective when used as the sole therapy for management of diabetes mellitus
- ► Contraindications include a known hypersensitivity to the drug, diabetic ketoacidosis, inflammatory bowel disease, colonic ulceration, partial intestinal obstruction or predisposition to obstruction, or chronic intestinal disease with marked disorders of digestion or absorption, as well as in patients that are underweight or in cases in which excessive GI gas formation would be detrimental.
- ► Adverse effects can limit the drug's usefulness and include dose-dependent loose stools, diarrhea, and flatulence.
- ► Give with meals (preferably right before feeding); this drug is not as effective if feeding ad libitum.

Uses/Indications

Acarbose may be useful in reducing blood glucose concentrations in cases of mild to moderate hyperglycemia (250-350 mg/dL range) in dogs and cats with non-insulin-dependent diabetes mellitus and as adjunctive treatment for insulin-dependent diabetes mellitus. Acarbose may be useful in dogs or cats when insulin activity peaks too soon.[1]

In healthy cats, acarbose resulted in a 5% to 7.5% reduction in postprandial glucose area under the curve (AUC) and a 35% to 45% reduction in postprandial insulin AUC as compared to no treatment.[2] In diabetic cats, acarbose apparently is most effective in cats that refuse to eat a low carbohydrate diet and consume their food within a short time after acarbose is given. Acarbose given in conjunction with a high carbohydrate diet has an effect similar to feeding an ultra-low carbohydrate diet.[3] Acarbose is usually not effective in animals with reduced appetites (eg, cats with advanced chronic kidney disease). Acarbose may be considered in dogs when glycemic control is poor and the cause is not determined.[4] Acarbose is unlikely to give adequate glucose control when used alone; dietary therapy and other antihyperglycemic agents (eg, insulin) are typically recommended instead.

Pharmacology/Actions

Acarbose competitively inhibits pancreatic alpha-amylase and alpha-glucosidases found in the small intestine. This inhibition delays the digestion of complex carbohydrates and disaccharides to glucose and other monosaccharides, which causes glucose to be absorbed in lesser amounts lower in the GI tract. This reduced absorption decreases blood glucose and insulin requirements during the postprandial hyperglycemic phase. Acarbose has no effect on lactase nor does it enhance insulin secretion.

Pharmacokinetics

In dogs, ≈4% of an oral dose is absorbed; in humans, only ≈2% of an oral dose is absorbed from the gut and then excreted by the kidneys. Practically all of the remaining drug in the gut is metabolized by intestinal bacterial flora. Patients with severe renal dysfunction attain serum levels ≈5 times those of normal patients.

Contraindications/Precautions/Warnings

Acarbose is contraindicated in patients with known hypersensitivity to the drug, diabetic ketoacidosis, inflammatory bowel disease, colonic ulceration, partial intestinal obstruction or predisposition to obstruction, and chronic intestinal disease with marked disorders of digestion or absorption, as well as when excessive GI gas formation would be detrimental. Acarbose is contraindicated in patients with low body weight (may also apply to patients with normal body weight), as the drug may have deleterious effects on nutrition status. Use caution in patients with renal dysfunction or severe liver disease.

Adverse Effects

Adverse effects reported in cats include flatulence, soft stools, and diarrhea. In dogs, adverse effects include soft or watery stools, diarrhea, and weight loss.[4] These adverse effects are more likely at higher doses and may outweigh treatment benefits.[5]

Although acarbose alone does not cause hypoglycemia, it may contribute to it by reducing the rate and amount of glucose absorbed when the patient is receiving other hypoglycemic agents (eg, insulin, oral hypoglycemic drugs).

Dose-related increases in hepatic transaminases have been reported rarely in humans.

Reproductive/Nursing Safety

Studies in laboratory animals have demonstrated no evidence of fetal harm or impaired fertility. Weigh any potential risks versus benefits in pregnant animals.

It is not known if acarbose is excreted in maternal milk. Acarbose is likely safe to use during nursing because it is minimally absorbed.

Overdose/Acute Toxicity

Acute overdoses are likely to only cause diarrhea and flatulence; no treatment should be necessary. If acute hypoglycemia occurs secondary to other hypoglycemic agents, parenteral glucose should be administered. Use glucose (eg, dextrose) instead of sucrose when treating orally, as the absorption of oral glucose is not inhibited by acarbose.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acarbose and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Charcoal, Activated**: Intestinal adsorbents may reduce the efficacy of acarbose.
- **Digoxin**: Acarbose may reduce digoxin blood concentrations.
- **Hyperglycemic Agents** (eg, **calcium channel blockers, corticosteroids, estrogens, phenothiazines, thiazides, thyroid hormones**): May reduce or negate the effects of acarbose
- **Hypoglycemic agents** (eg, **insulin, sulfonylureas**): May increase the risk for hypoglycemia
- **Pancreatin, Pancrelipase,** or **Amylase**: Exogenous enzyme formulations may reduce the efficacy of acarbose.

Laboratory Considerations

- Increased serum aminotransferase (ALT) and bilirubin levels have been noted in some humans taking high dosages for a long period.

Dosages

DOGS:

Adjunctive treatment for diabetes mellitus (extra-label): Initially, 12.5 – 25 mg/dog (NOT mg/kg) PO with each meal (usually twice daily). Give only at time of feeding (right before). If response is in-

adequate after 2 weeks, the dosage may be titrated up to 50 mg/dog (NOT mg/kg) PO twice daily. For dogs weighing greater than 10 to 25 kg (22 to 55.1 lb), a further increase up to 100 mg/dog (NOT mg/kg) twice daily may be considered if response has been inadequate.

CATS:

Adjunctive treatment for diabetes mellitus (extra-label): 12.5 mg/cat (NOT mg/kg) PO twice daily with a meal.[2,3,6,7] One study found acarbose to be ineffective in healthy cats fed a low carbohydrate diet.[6]

Monitoring

- Serum glucose
- Adverse effects (eg, diarrhea, flatulence)
- Liver enzymes

Client Information

- For best results, give this drug right before feeding your animal. Tablets may be split or crushed and mixed with food just prior to administration.
- Diarrhea and/or gas are the most likely side effects.
- Acarbose does not cause low blood sugar; however, it may contribute to it if the animal is getting other drugs that lower blood sugar (including insulin). Call your veterinarian immediately if you see signs of low blood sugar (eg, seizures [ie, convulsions], collapse, rear leg weakness or paralysis, muscle twitching, unsteadiness, tiredness, depression).
- It may take up to 2 weeks for the drug to work.

Chemistry/Synonyms

Acarbose, a complex oligosaccharide antihyperglycemic agent, occurs as a white to off-white powder, is soluble in water, and has a pK_a of 5.1.

Acarbose may also be known as Bay-g-5421, *Asucrose®*, *Glicobase®*, *Glucobay®*, *Glucor®*, *Glumida®*, *Prandase®*, or *Precose®*.

Storage/Stability

Do not store tablets above 25°C (77°F), and protect them from moisture.

Compatibility/Compounding Considerations

Tablets may be split or crushed and mixed with food just prior to administration.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Acarbose Oral Tablets: 25 mg, 50 mg, and 100 mg; *Precose®*, generic; (Rx)

Acepromazine
Acetylpromazine

(***ase***-pro-ma-zeen) *PromAce®*

Phenothiazine Sedative/Tranquilizer

Prescriber Highlights

- ► Used as a sedative/tranquilizer, or in balanced anesthetic or analgesic protocols; also used as adjunctive treatment of urethral obstruction in male cats and laminitis in horses
- ► Clinical dosages are significantly lower than those listed on the United States-approved label.
- ► Time to onset (15 minutes, up to 30 minutes for full effect) and duration of action (3 to 4 hours, up to 6 to 8 hours in some animals) are relatively long as compared with other sedatives such as the alpha-2 agonists.
- ► Does not have a reversal agent
- ► Provides no analgesic effects but can be combined with analgesics (eg, opioids) to enhance sedation and increase duration of analgesia (ie, neuroleptanalgesia). Use a low dose of acepromazine when combining with other sedatives or anesthetic drugs.
- ► Acepromazine has minimal to no impact on respiratory function but may cause significant hypotension and hypothermia; it should be avoided or dose-reduced in debilitated animals, especially those with predicted or pre-existing hypotension or hepatic insufficiency; and used with caution in patients with moderate to severe cardiac disease that cannot tolerate reduced blood pressures.
- ► Dogs with the multidrug sensitivity gene *(MDR1) mutation (also known as ABCB1-*1delta) are overly sensitive to effects and require dose reduction or avoidance.
- ► Use with caution as a sole sedative in aggressive dogs as dogs may be prone to startling and occasional dogs experience worsening of aggression and CNS stimulation.
- ► May cause penile prolapse in horses, but associated permanent penile dysfunction is very rare.

Uses/Indications

Acepromazine is FDA-approved for use in dogs, cats, and horses. Labeled indications for dogs and cats include as an aid in controlling intractable animals and alleviating itching as a result of skin irritation, as an antiemetic to control vomiting associated with motion sickness, and as a preanesthetic agent.[1]

Acepromazine has a wide safety margin and is one of the most commonly used sedatives/tranquilizers in small animal species, with less frequent use in large animal species. The injectable formulation is used primarily as a preanesthetic agent or for procedural sedation. Sedation with acepromazine is mainly indicated for use in healthy patients or patients with mild systemic disease. Because acepromazine has minimal effects on respiratory function, it can be a useful tranquilizer/sedative in small animal species with upper airway obstruction (eg, laryngeal paralysis). The long duration of action can be advantageous in some situations (eg, can promote smoother recovery from anesthesia in excited/anxious animals) but can be problematic in others (eg, can delay discharge in same-day sedation/anesthesia procedures).

Acepromazine has been used as one part of a multimodal protocol to resolve urethral obstruction in male cats without the need for urethral catheterization[2]; this protocol may be beneficial in situations where client financial constraints limit treatment and would otherwise result in euthanasia.

Acepromazine has no analgesic effects; however, when combined with opioid analgesics, acepromazine can enhance sedation and pro-

long the opioid analgesic effect (neuroleptanalgesia). Acepromazine also has antihistamine and antiemetic effects; however, it is not commonly used for these indications due to availability of more specific and effective treatment options.

The oral form of acepromazine is most commonly used to decrease an animal's response to stress or fear-inducing stimuli like loud noises (eg, fireworks, thunder) or travel. Whether acepromazine causes anxiolysis or only sedation in these situations is unknown and controversial. Specific drugs that cause fewer adverse effects are available for behavioral modification associated with anxiety in dogs and cats.

In horses, acepromazine is labeled for use as an aid in controlling fractious animals and in conjunction with local anesthesia for various procedures and treatments.[1] It is also commonly used in horses at low doses (0.005 – 0.04 mg/kg) as a preanesthetic agent for mild sedation and for its potential antiarrhythmic effects.[3] Acepromazine has also been administered to horses with laminitis to improve blood flow to the distal limb.[4–6]

Although not FDA-approved, acepromazine is used as a tranquilizer in other species such as cattle, sheep, goats, swine, and rabbits. Acepromazine has been shown to reduce the incidence of halothane-induced malignant hyperthermia in susceptible pigs.[7]

Pharmacology/Actions

Acepromazine is a phenothiazine neuroleptic agent. Although the exact mechanisms of action are not fully understood, phenothiazines block postsynaptic dopamine receptors in the CNS and may inhibit the release of dopamine and increase its turnover rate. They are thought to depress portions of the reticular activating system that assist in the control of body temperature, basal metabolic rate, emesis, vasomotor tone, hormonal balance, and alertness. In addition, phenothiazines have varying degrees of anticholinergic, antihistaminic, antispasmodic, and alpha-adrenergic blocking effects.

The primary desired effect for the use of acepromazine in veterinary medicine is tranquilization/sedation. Additional desirable pharmacologic actions of acepromazine include its use as a muscle relaxant, antiemetic, antiarrhythmic (blockade of myocardial alpha-1 receptors), and antispasmodic. Examples of muscle relaxant/antispasmodic effects include relief of clinical signs in a mare with urethral spasms[8] and reduction of urethral pressure in cats anesthetized with halothane.[9]

Vasodilation secondary to alpha-1 receptor blockade can contribute to hypotension with potential reflex tachycardia; however, mild vasodilation can be beneficial in some dogs and cats with cardiac disease in which systemic vasodilation or a decrease in afterload is desired, as in moderate to severe mitral regurgitation. In this case, acepromazine 0.005 – 0.01 mg/kg is adequate. A combination of acepromazine and an opioid is commonly used for sedation of patients for cardiac imaging because of the limited to no impact on cardiac function. In one study, acepromazine 0.02 mg/kg combined with butorphanol 0.2 mg/kg administered IM to dogs provided adequate sedation for echocardiography with only mild changes on measured variables.[10] In dogs, premedication with acepromazine caused a moderate decrease in blood pressure without significantly altering glomerular filtration rate or renal blood flow.[11]

Acepromazine may decrease respiratory rate, but studies have demonstrated that little or no effect occurs with regard to blood gas status, pH, and/or oxyhemoglobin saturation.[12–15]

A dose-dependent decrease in hematocrit can be seen within 30 minutes after administration to dogs and horses. Hematocrit values in horses may decrease ≈20% of predose values; this change is due to increased splenic sequestration of red blood cells, which has been demonstrated in dogs.[13,16–18] Although the red blood cells return to circulation, this effect may not occur until after recovery from anesthesia and could exacerbate decreased oxygen delivery during anesthesia of anemic patients. Acepromazine may transiently reduce platelet count and aggregation; however, platelet function and hemostasis are not altered.[19,20]

Although acepromazine use was historically avoided in epileptic animals and in those that were susceptible to seizures (eg, postmyelography), recent research has disproved this effect and shown that acepromazine may have some anticonvulsant activity. In a study, acepromazine did not significantly alter EEG in healthy dogs.[21] In other studies, acepromazine caused no seizures, even in high-risk dogs, and actually decreased seizures in some actively convulsing dogs.[22–24]

Acepromazine can delay gastric emptying, reduce lower esophageal tone, and slow GI motility in dogs, cats, horses, cattle, and likely other species.[25–28] This effect is not likely to have a clinical impact in most animals but could influence GI motility studies[25] and potentially increase the risk for gastric reflux.

Other pharmacologic actions are discussed in the ***Adverse Effects*** section.

Pharmacokinetics

In dogs that receive acepromazine 1.3 – 1.5 mg/kg, oral bioavailability is ≈20% and elimination half-lives are ≈7.1 hours (IV) and 16 hours (PO).[29]

In horses, acepromazine 0.3 mg/kg IV has a fairly high volume of distribution (6.6 L/kg) and is more than 99% protein bound.[17] The onset of action is fairly slow, requiring up to 15 minutes following IV administration, with peak effects seen in 30 to 60 minutes. Elimination half-life is ≈3 hours. In one study, horses appeared sedated (based on chin-to-ground measurement) within 5 minutes of IV administration as compared with 15 minutes for oral and sublingual administration (0.09 mg/kg for all routes); sedation lasted 2 hours.[30] Elimination half-lives after oral, sublingual, and IV administration were 8.6 hours, 6.7 hours, and 5.2 hours, respectively.

Acepromazine is metabolized in the liver with both conjugated and unconjugated metabolites eliminated in the urine.[1,31] Metabolites may be found in equine plasma up to 24 hours and urine up to 144 hours after IV administration.[32]

Contraindications/Precautions/Warnings

Acepromazine potentiates the toxicity of organophosphates (including those found in flea collars) and procaine hydrochloride, and it is contraindicated in patients that are receiving or exposed to those agents.[1] There are no other absolute contraindications.

In the United States, the parenteral formulation is only available as a 10 mg/mL concentration. Dilution of the drug or use of very small syringes (eg, tuberculin syringes, U-100 insulin syringes) is important for safe administration to small animal patients. For instance, at a dose of 0.03 mg/kg, a 10-kg (22-lb) dog would receive 0.03 mL of 10 mg/mL acepromazine.

In all species, the tranquilization effects of acepromazine can be overridden by patient arousal, so it cannot always be relied on when used alone as a restraining agent. The effects of acepromazine may be individually variable and breed dependent. Animals will require lower doses of general anesthetics after receiving acepromazine. This is a dose-dependent effect that is true for all species and all inhalant anesthetics in current clinical use.

Acepromazine has no analgesic effects; animals should be treated with appropriate analgesics to control pain. Sedation of painful patients without provision of analgesia can result in the inability to identify pain behaviors with a subsequent negative impact on animal health and welfare.

Acepromazine does not have a reversal agent and requires hepatic metabolism for termination of effect; thus, it should either not be used or should be used cautiously at the low end of the dose range in animals with moderate hepatic dysfunction (eg, some geriatric and pediatric patients) and avoided if the disease/dysfunction is severe.[1,33]

Because of its potential hypotensive effects, acepromazine should either not be used or be used cautiously at the low end of the dose range in patients with mild cardiac disease that may not tolerate drops in blood pressure or in those with decreased sympathetic nervous system response to hypotension (eg, general debilitation, obtundation, neonates, some pediatric and geriatric patients) and avoided in patients with significant cardiac disease, hypovolemia, dehydration, hypotension, or shock.[1,33]

Acepromazine may decrease platelet aggregation and should be avoided or used with caution in patients with coagulopathies or thrombocytopenia.[19,20] Use acepromazine with caution in anemic animals, as splenic red blood cells will exacerbate signs associated with the anemic condition.[34] Acepromazine-mediated splenic engorgement (see ***Pharmacology/Actions***) can make performing a splenectomy difficult; consider other premedication agents for this surgery.

In all species, IV injections should be administered slowly,[1] which is recommended for most sedatives/anesthetic agents to avoid sudden profound sedation or paradoxical excitement. Acepromazine should not be administered intra-arterially, as it may cause severe CNS excitement/depression, seizures, and death.

Acepromazine's vasodilatory effects may be deleterious in compromised horses (eg, acute colic, cantharidin toxicosis, dehydration/hypovolemia, hypotension/shock). In a study of healthy horses, IV infusion of norepinephrine at 1 µg/kg/minute reversed the hypotensive effects of 0.1 mg/kg acepromazine IV.[35]

Breed-specific concerns include dogs with *MDR1* gene mutation (also known as *ABCB1*-1delta), which may develop a more pronounced sedation that persists longer than expected.[36] The drug is best completely avoided in *MDR1*-mutant dogs because there is no reversal, but if no other option is available, the dose should be reduced by 25% in dogs that are heterozygous and by 30% to 50% in dogs that are homozygous for the *MDR1* gene mutation (mutant/mutant).[36,37] Spontaneous fainting or syncope due to sinoatrial block caused by excessive vagal tone has been observed in some dogs, particularly boxers and other brachycephalic breeds; a low acepromazine dose should be used with or without atropine in these patients.[38] **NOTE**: This issue has only been reported in boxers (and *not* other brachycephalic breeds) and may be present in a familial line, as it is rarely reported, especially outside the UK. When there is a history of this type of syncope, or if it is suspected because of excessive sinus arrhythmia, it may be advantageous to control the dysrhythmia with atropine administered just before the acepromazine.[38]

Acepromazine should be used very cautiously as a restraining agent in aggressive dogs, as it may make the animal more prone to startle and react to noises or other sensory inputs and can potentially make them more aggressive; it is best used in combination with other restraining agents in these situations. In some geriatric patients, very low doses have been associated with prolonged effects of the drug, likely due to slowed hepatic metabolism. Anecdotally, giant breeds appear to be sensitive to the drug, whereas terrier breeds appear to be somewhat resistant to its effects; however, this is most likely based on use of body weight instead of body surface area for dose calculation.[34]

Adverse Effects

The potential for acepromazine-mediated hypotension and possible reflex tachycardia should be considered during treatment planning. This effect is mediated by central mechanisms and through the alpha-adrenergic antagonistic action of the drug. Secondary tachycardia may accompany the hypotension.[1] Cardiovascular collapse (secondary to bradycardia and hypotension) can occur after rapid IV injection[1] and has been reported in dogs following IM administration of supraclinical doses (1 mg/kg).[39] Atropine may be used to treat this effect.[38] Splenic sequestration of red blood cells may cause transient decreases in PCV. See ***Pharmacology/Actions***.

Occasionally, an animal may develop the contradictory clinical signs of aggressiveness and generalized CNS stimulation after receiving acepromazine. For orally administered acepromazine tablets, mild respiratory distress (ie, reverse sneeze) has been reported and does not have an effect on the desired action of the drug.

Acepromazine causes prolapse of the nictitating membrane and has been shown to decrease tear production in cats[40] and rabbits.[41]

In horses, acepromazine may cause protrusion of the penis; this effect is dose-related and may last for 2 or more hours.[17] Permanent penile dysfunction in horses and ponies is possible, but a retrospective study found the risk to be extremely low (less than or equal to 1 in 10,000).[42] The main contributor to permanent penile dysfunction is prolonged protrusion and subsequent penile edema followed by inability to retract the penis and worsening edema. If using acepromazine in male horses, ensure penile retraction occurs within 1 hour of protrusion.

Acepromazine inhibits the voltage-gated K+ channel (Kv11.1), which may induce repolarization disorders and lead to drug–drug interactions that prolong the QT interval[43]; however, this seems to have no clinical impact.

IM administration may cause transient pain at the injection site, which is possibly related to the injection itself rather than the drug. SC administration may be less painful than IM while providing similar sedation.[44]

In addition to the legal aspects (ie, extra-label; not FDA-approved) of using acepromazine in cattle, the drug may cause regurgitation of ruminal contents when sedation is followed by general anesthesia.

Reproductive/Nursing Safety

Acepromazine injection is listed as contraindicated in pregnant animals on at least one international drug label[38]; however, acepromazine has been used safely in late-term pregnant cattle[45] and ferrets.[46] Use of the drug in cesarean sections in dogs and cats is not recommended because of the prolonged duration of recovery and potential for hypotension. Excretion of the drug in milk has not been evaluated; however, acepromazine has been used in mares to promote lactation (secondary to increased prolactin production) and facilitate adoption of orphan foals. In one case report, acepromazine (30 mg IM every 8 hours for 48 hours) administered to a thoroughbred mare increased milk production, calmed the mare, and promoted bonding with an orphan foal while having no impact on the mare's concurrent pregnancy.[47]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

LD_{50} in mice is 59 mg/kg after IV administration, 130 mg/kg after SC administration, and 200 mg/kg after oral administration.[48] A toxicity study in dogs reported no adverse effects in dogs receiving 20 – 40 mg/kg over 6 weeks[1]; however, anecdotally, adverse effects have been reported in dogs receiving single doses between 20 and 42 mg/kg. Dogs have survived oral doses up to 220 mg/kg, but overdoses can cause severe hypotension, CNS depression, pulmonary edema, and/or hyperemia of the internal organs.[1] Acepromazine overdose can also cause extrapyramidal effects (eg, tremor, catalepsy, rigidity, excitement, sweating, seizures) via dopamine blockade.[49]

Because of the relatively low toxicity of acepromazine, most overdoses can be handled by monitoring the animal and treating clinical signs as they occur; massive oral overdoses should be treated by gastric decontamination if possible. Hypotension should be treated initially with IV fluids; alpha-adrenergic pressor agents (eg, norepi-

nephrine, phenylephrine; *not* epinephrine) can be considered if IV fluid therapy does not maintain adequate blood pressure. **NOTE:** Epinephrine is contraindicated for treatment of acute hypotension produced by phenothiazine-derivative tranquilizers since further depression of blood pressure can occur.[1,33] This phenomenon is known as epinephrine reversal and could occur when epinephrine is administered after an alpha-adrenergic antagonist (eg, acepromazine). In these situations, the peripheral beta-adrenergic effects of epinephrine will predominate, resulting in relaxation of the vascular smooth musculature and hypotension.

Seizures may be controlled with benzodiazepines. Doxapram has been suggested as an antagonist to the CNS depressant effects of acepromazine, and one study in dogs found that doxapram 1.25 mg/kg IV significantly reduced sedation scores and did not induce panting.[50] See ***Doxapram***.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acepromazine or other phenothiazines and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed, and additional monitoring performed when appropriate.

- Alpha-2 Agonists (eg, **dexmedetomidine, xylazine**): Additive risk for CNS depression when used with acepromazine
- Anesthetic Agents (eg, **alfaxalone**, **isoflurane, ketamine**): Additive CNS depression is possible.
- Antipyretics (eg, **acetaminophen, dipyrone, NSAIDs**): Possible increased risk for hypothermia with concurrent use
- Antacids, Aluminum-, Calcium- or Magnesium-Containing: Concomitant use of acepromazine or other phenothiazines with antacids may cause reduced GI absorption of oral phenothiazines; administration should be separated by at least 2 hours to minimize this effect (with acepromazine being administered before the antacid).[51]
- Anticholinergic Agents (eg, **atropine, glycopyrrolate, hyoscyamine**): Increased risk of anticholinergic effects (eg, dry mucous membranes, constipation, urinary retention)
- Antidiarrheal Mixtures (eg, **bismuth subsalicylate, kaolin/pectin**): Concomitant use of acepromazine or other phenothiazines with antidiarrheal mixtures may reduce GI absorption of oral phenothiazines; administration should be separated by at least 2 hours to minimize this effect (with acepromazine being administered before the antidiarrheal mixture).[51]
- Barbiturates (eg, **pentobarbital, phenobarbital**): Causes additive CNS depression when used with acepromazine. Although this effect is desirable when the 2 drugs/drug classes are used for anesthesia or euthanasia, it may not be desirable if the barbiturates are being used for seizure control in conscious patients.
- Benzodiazepines (eg, **diazepam, midazolam**): Additive risk for CNS depression when used with acepromazine
- Cannabidiol: Additive risk for CNS depression
- Cimetidine: Cimetidine may increase chlorpromazine concentrations; no information for structurally related acepromazine, but combination could lead to excessive sedation and hypotension. Avoid combination if possible.
- Cisapride: Concurrent use with acepromazine and other phenothiazines may increase risk for QT interval prolongation, cardiac arrhythmias, torsade de pointes, and death. Acepromazine may reduce prokinetic effect of cisapride. Concurrent use of cisapride with acepromazine or other phenothiazines should be avoided.
- Dopaminergic Agonists (eg, **bromocriptine, cabergoline, pergolide**): Concurrent use may reduce the efficacy of both drugs and should be avoided
- Emetics (eg, **apomorphine, ropinirole**): Acepromazine may reduce the effectiveness of emetics as well as increased risk for sedation and hypotension.
- Epinephrine: Contraindicated in the treatment of acute hypotension produced by acepromazine or other phenothiazines, as further depression of blood pressure can occur (also referred to as epinephrine reversal)
- Fluoxetine: May increase chlorpromazine concentration in humans due to inhibition of CYP2D6; the relevance of this interaction for acepromazine use in veterinary species is uncertain
- Hypotensive Agents (eg, **amlodipine, benazepril, enalapril, telmisartan**): Concurrent use of acepromazine with hypotensive agents may increase risk for hypotension; monitor blood pressure.
- Methocarbamol: Concurrent use may cause additive CNS depression.
- Metoclopramide: Concurrent use may increase risk for extrapyramidal adverse effects (eg, tremor, catalepsy, rigidity, excitement, sweating, seizures). Acepromazine may reduce prokinetic effect of metoclopramide.
- Opioids (eg, **buprenorphine, fentanyl, morphine**): May enhance the hypotensive effects of the phenothiazines; dosage of acepromazine may need to be reduced when used with an opioid
- Organophosphate Agents: Acepromazine should not be given within one month of treatment with or accidental exposure to these agents as organophosphate toxicity may be potentiated.
- QT Prolonging Agents (eg, **cisapride, domperidone, erythromycin, sotalol**): Concurrent use may increase risk for QT prolongation and should be avoided.
- Procaine: Although not clinically documented, procaine activity may be enhanced by phenothiazines and some resources state that concurrent use with acepromazine is contraindicated.[1,33]
- Propranolol: Increased blood concentrations of both propranolol and acepromazine may result if administered concurrently.
- Quinidine: Concurrent use with acepromazine or other phenothiazines may cause additive cardiac depression.
- Sucralfate: May reduce GI absorption of oral phenothiazines

Laboratory Considerations

- Acepromazine does not alter the results of **glucose tolerance testing** in dogs.[52]
- Because acepromazine has antihistamine effects, it can decrease the wheal-and-flare response to antigens during **intradermal skin testing**. In dogs and cats, it has been suggested that antihistamines be discontinued at least 2 weeks before testing.[53]

Dosages

NOTES:

1. Acepromazine does not provide analgesia; addition of an analgesic agent is required when pain relief is needed.
2. Administer IV doses slowly; allow at least 15 minutes for onset of action.[1]

DOGS & CATS:

NOTE: The label dosage for dogs and cats is considered by most clinicians to be 10 to 100 times (or more) greater than is necessary for most indications. The labeled indications are provided below, but the use of lower, extra-label dosages is strongly recommended.

Dogs: **As an aid in tranquilization, controlling intractable ani-**

mals, and alleviating itching as a result of skin irritation; as an antiemetic to control vomiting associated with motion sickness; and as a preanesthetic agent (label dosage; FDA-approved): 0.55 – 2.2 mg/kg PO (dose may be repeated as required), or 0.55 – 1.1 mg/kg IV, IM, or SC[1,33]

Cats: **As an aid in controlling intractable animals and alleviating itching as a result of skin irritation, as an antiemetic to control vomiting associated with motion sickness, and as a preanesthetic agent** (label dosage; FDA approved): 1.1 – 2.2 mg/kg IV, IM, or SC[1]

Sedation, tranquilization, premedication, or restraint (extra-label):

1. Injectable: 0.01 – 0.1 mg/kg IV (slowly), IM, or SC generally as a single dose but could be repeated if initial dose is ineffective or after sedative effects have dissipated and continued sedation is desired. Maximum sedation in most patients likely occurs at 0.05 mg/kg.[34] Numerous anesthesia references recommend that total dose should not exceed more than 3 mg (total dose/dog; NOT mg/kg)[54,55]; however, some references recommend a maximum dose of 4 mg (total dose/dog; NOT mg/kg).[38,56] This is especially true in large breed dogs[55] who appear more "sensitive" to higher dosages of acepromazine, which is actually due to dosing on a mg/kg basis rather than on a body surface area basis.[34]
   a. Anesthetic premedication: 0.02 – 0.05 mg/kg IM, SC, or slow IV. Lower doses (ie, 0.02 – 0.03 mg/kg) are sufficient for most patients, especially when the drug is combined with an opioid. The lower end of the dosing range should be used for IV administration. Following acepromazine administration, anesthetic induction agent doses can often be reduced by ≈30%.
   b. Tranquilization/sedation: 0.03 – 0.125 mg/kg IM, SC, or slow IV.[38] Dosages in the preanesthetic range are often sufficient, especially when combined with an opioid. The lower end of the dosing range should be used for IV administration. Lower doses should be used for tranquilization and higher doses used for sedation. Typically administered as a single dose but could be repeated if initial dose was ineffective or after sedative effects have dissipated and continued sedation is desired; long-term use is not recommended.
2. Oral: Anecdotal dose recommendations vary widely but generally these are similar to the labeled dose range of 0.55 – 2.2 mg/kg PO, although some clinicians think that doses at the higher end of this range are too high. If oral doses require repeating, they are usually given every 6 to 12 hours. Acepromazine also may be given in combination with an anxiolytic medication (eg, gabapentin, trazodone).
3. Transmucosal (TM)
   a. Sedation for cats (anecdotal): Using injectable formulations, 0.05 – 0.1 mg/kg combined with buprenorphine 0.03 mg/kg and administered TM 30 to 90 minutes prior to appointment
   b. Sedation for dogs: Acepromazine 0.025 – 0.05 mg/kg OTM should be administered 30 minutes before the scheduled appointment given in combination with an anxiolytic medication (eg, gabapentin, trazodone), as in the "Chill Protocol" in which the animal receives gabapentin ≈12 hours prior to leaving the home for the veterinary hospital and melatonin and gabapentin PO ≈ 2 hours prior.[57]

Adjunctive treatment of urethral obstruction in male cats (extra-label): 0.25 mg/cat (NOT mg/kg) IM OR 2.5 mg/cat (NOT mg/kg) PO every 8 hours in combination with medetomidine 0.1 mg IM every 24 hours and buprenorphine 0.075 mg PO every 8 hours.[2] Acepromazine is not recommended in obtunded cats as profound hypotension and hypoventilation could occur. See ***Contraindications/Precautions/Warnings***.

HORSES:

As an aid in controlling fractious animals and in conjunction with local anesthesia for various procedures and treatments (label dosage; FDA-approved): 0.044 – 0.088 mg/kg (2 – 4 mg/100 lb [45 kg] body weight) IV (slowly), IM, or SC[1]

Sedation, tranquilization, premedication (extra-label): When used alone, acepromazine is usually dosed similarly to the label: 0.02 – 0.1 mg/kg IM, IV, or SC. When used in combination with drugs such as butorphanol as a premedication or to increase blood flow in the treatment of laminitis, recommended doses are usually on the low end of this range. Repeat doses should be limited and ideally not given more frequently than every 36 hours.

Anesthetic premedication, to facilitate restraint, or for sedation during travel (extra-label): Preanesthetic: 0.02 – 0.05 mg/kg IM or slow IV; sedation/restraint: 0.05 – 0.1 mg/kg IM or slow IV. Administer up to 15 minutes prior to the desired effect and await clinical signs of tranquilization before travel or subsequent administration of anesthetic. The low end of the dose range is generally adequate. For tranquilization, adjust dose to maintain desired effect for the duration of travel or procedure.[58,59] These doses can also be used to sedate mares during extended separation from their foals.

Sedation in donkeys: 0.1 mg/kg IV produced sedation ≈10 minutes after administration, which lasted ≈80 minutes.[60,61] In general, horse doses are appropriate for donkeys, but the higher end of the dose range may be necessary to adequately sedate mules.

Laminitis (extra-label): 0.04 – 0.066 mg/kg IM, IV, or SC[5,6,62]

CATTLE:

All dosages are extra-label.

a) **Sedation**: 0.01 – 0.02 mg/kg IV or 0.03 – 0.1 mg/kg IM[63]
b) **Mild sedation or tranquilization**: 0.02 – 0.05 mg/kg IV, 0.02 – 0.1 mg/kg IM[64]
c) **Sedative 1 hour before local anesthesia**: 0.1 mg/kg IM[64]

SHEEP & GOATS:

Sedation (extra-label): 0.05 – 0.1 mg/kg IM.[65] Sedation in sheep was equivalent when acepromazine 0.03 mg/kg IM was administered either with morphine 0.3 mg/kg IM or buprenorphine 0.02 mg/kg IM.[66] The low end of the dose is generally adequate.

SWINE:

NOTE: When used as a single agent in swine, the effects of acepromazine are inconsistent and may be inadequate.

Sedation (extra-label)**:**

a) 0.1 – 0.2 mg/kg IV, IM,[67] or SC[68]
b) 0.03 – 0.1 mg/kg IM[65,69]

Brief periods of immobilization (extra-label)**:** Acepromazine 0.5 mg/kg in combination with ketamine 15 mg/kg IM.[67] Atropine 0.044 mg/kg IM will reduce salivation and bronchial secretions.[70]

FERRETS:

All dosages are extra-label.

a) **Tranquilization**: 0.25 – 0.75 mg/kg IM or SC[46] ; the lower to mid-range of the dosage is generally adequate.
b) **Premedication**: 0.1 – 0.25 mg/kg IM or SC; may cause hypotension/hypothermia[71]

RABBITS, RODENTS, & SMALL MAMMALS:

All dosages are extra-label.

a) **Rabbits: Sedative/tranquilization**: 0.75 – 1 mg/kg IM. Effect should begin 10 minutes after administration and last for 1 to 2 hours.[63,72]

b) **Rabbits: Premedication**: 0.2 – 1 mg/kg SC, IM[73,74]
c) **Mice, rats, hamsters, guinea pigs, chinchillas**: 0.5 – 1.5 mg/kg IM, SC; 0.5 – 2.5 mg/kg PO. Can be used IP in some species. Use in gerbils is not recommended by some clinicians.[75]

Monitoring

- Cardiac rate and rhythm, blood pressure (critical), end-tidal carbon dioxide ($ETCO_2$), and pulse oximetry (recommended)
- PCV and total protein, especially in borderline anemic patients and patients with current or expected blood loss
- Degree of sedation/tranquilization
- Male horses should be checked to make sure the penis retracts and is not injured.
- Body temperature (especially if ambient temperature is very hot or cold)

Client Information

- This medicine will have the best effect when it is given by mouth 45 to 60 minutes before the procedure or travel. Sedative or tranquilizing effects (sleepiness) and side effects may last up to 24 hours. Your veterinarian may recommend a trial dose a few days before travel to see how your animal reacts to the medicine.
- Animals sedated with this medicine may startle easily in response to sounds or other sudden stimuli. Use caution when approaching your animal as this effect can occasionally make them more aggressive. If this occurs, isolate your animal in a safe environment and contact your veterinarian.
- Keep treated animal in a quiet environment at a comfortable temperature.
- This medicine may cause a harmless pinkish to reddish-brown discoloration of your animal's urine. This change is not to be worried about.
- Do not give additional medicines to tranquilize or sedate your animal unless instructed to do so by your veterinarian.

Chemistry/Synonyms

Acepromazine maleate (formerly acetylpromazine maleate) is a phenothiazine derivative that occurs as an odorless, bitter-tasting, yellow powder. One gram is soluble in 27 mL of water, 13 mL of alcohol, or 3 mL of chloroform. The injection is a clear, pale yellow to yellow solution.

Acepromazine maleate may also be known as ACE, *Aceproject®*, *Aceprotabs®*, acetylpromazine maleate, *Acevet®*, ACP, *Atravet®*, *Notensil®*, *PromAce®*, and *Plegicil®*.

Storage/Stability

Store tablets and injection protected from light at 20°C to 25°C (68°F-77°F), with excursions permitted between 15°C and 30°C (59°F-86°F). Tablets should be stored in tight containers. There is no limit to the number of vial punctures throughout the full expiry period.[1]

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

A study evaluating the stability, sterility, pH, particulate formation, and efficacy of compounded ketamine, acepromazine, and xylazine (KAX) in laboratory rodents supported the finding that the drugs are stable and efficacious for at least 180 days after mixing if stored at room temperature in the dark.[76] When injectable acepromazine is mixed with ketamine and xylazine and diluted with 0.9% saline, drug potency dropped below 90% between 1 and 2 months when stored in syringes at room temperature but retained more than 90% potency for 3 months when stored in syringes under refrigeration.[77] **NOTE:** Admixtures with ketamine or other controlled substances must be stored according to DEA requirements.

Combinations of acepromazine mixed with atropine, buprenorphine, chloral hydrate, meperidine, and oxymorphone have been commonly used, but studies documenting their compatibility and stability were not located. Both glycopyrrolate and diazepam have been reported to be physically **incompatible** with phenothiazines; however, glycopyrrolate has been demonstrated to be **compatible** with promazine HCl for injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Acepromazine Maleate for Injection: 10 mg/mL for injection in 50 mL vials; *PromAce®*, generic; (Rx). FDA-approved forms available for use in dogs, cats, and horses not intended for food. Requires dilution or small syringes for safe and accurate dosing in small animals.

Acepromazine Maleate Tablets: 10 mg and 25 mg in bottles of 100 and 500 tablets; *PromAce®*, generic; (Rx)

In other countries, acepromazine is formulated in oral gels and powders and in varying strengths of injectable solutions (eg, 2 mg/mL, 25 mg/mL).

When used in an extra-label manner in food animals, it is recommended to contact Food Animal Residue Avoidance Databank (FARAD; see ***Appendix***) for further guidance.

HUMAN-LABELED PRODUCTS: NONE

Acetaminophen

APAP, Paracetamol

(ah-seet-a-***min***-a-fen) *Tylenol®*

Analgesic, Antipyretic

Prescriber Highlights

- ► **Contraindicated in cats and ferrets at any dosage**
- ► At recommended dosages, not overly toxic to dogs, rodents, or rabbits. Dogs are more susceptible than humans to red blood cell toxicity, so dose carefully.
- ► Often used in combined dosage forms with codeine, tramadol, or hydrocodone

Uses/Indications

Acetaminophen is used as an oral analgesic or antipyretic in dogs, horses, and small mammals. It may be particularly beneficial for the treatment of chronic pain conditions in dogs for which other analgesics (eg, NSAIDS, opioids) should not be used. In a clinical trial, acetaminophen was as effective as meloxicam and carprofen for postsurgical analgesia in bitches undergoing elective ovariohysterectomy.[1] For moderate pain, acetaminophen may be used in combination products containing codeine, hydrocodone, or tramadol. See the ***Codeine***, ***Tramadol***, and ***Hydrocodone Combinations*** monographs for more information on the use of acetaminophen combination preparations.

Acetaminophen has also been used for research purposes to measure gastric emptying in a variety of large animal species.[2–5]

Pharmacology/Actions

Acetaminophen's exact mechanisms of action are not completely un-

derstood. It produces analgesia and antipyresis via inhibition of cyclooxygenase and peroxidase sites on prostaglandin H_2 synthetase.[6] In addition, serotonergic activity may contribute to the drug's analgesic effect.[7] Unlike aspirin, acetaminophen does not possess significant anti-inflammatory activity or inhibit platelet function when given at clinically recommended dosages.

Pharmacokinetics

In dogs, acetaminophen oral bioavailability is 45%. Peak concentrations occur 20 to 50 minutes after oral dosing. Protein binding is ≈25%, and volume of distribution is 0.9 L/kg. Clearance is 1.5 to 2 L/kg/hour. Elimination half-life is ≈1 to 4 hours and appears to vary by breed.[8–13] Maximum plasma concentration, time at maximum concentration, and bioavailability are not affected by feeding in dogs.[14] In a study of hospitalized dogs receiving acetaminophen orally or rectally, rectal absorption was only 30% that of oral administration, and the drug did not reach concentrations associated with efficacy.[12]

In horses, peak concentration is reached ≈60 to 80 minutes after oral administration. Bioavailability is 91%. Volume of distribution is 0.82 to 2.7 L/kg and protein binding is 49%. Clearance is ≈0.25 L/kg/hour and elimination half-life is ≈2 to 4 hours.[11,15–17]

Acetaminophen was found to be stable in rumen fluid from cattle[18] and goats.[5] Oral bioavailability in cattle was 70%, peak concentration was reached after 1.4 hours, and elimination half-life was 2.4 hours.[18] In goats, oral bioavailability (16%) appeared to be limited, not by ruminal activity, but by first-pass metabolism.[5] Volume of distribution was 1.4 L/kg, and clearance was 53 mL/kg/minute.[19]

Similar bioavailability (42% to 75%) and half-lives (0.6 to 1.2 hours) were observed in a multi-species study that included pigs, turkeys, and chickens.[11]

Contraindications/Precautions/Warnings

Acetaminophen is contraindicated in cats at any dosage. Severe methemoglobinemia, hematuria, and icterus can be seen. Cats are deficient in glucuronyl transferases and are therefore unable to sufficiently glucuronidate acetaminophen; this leads to formation of active toxic metabolites (eg, free oxygen radicals) that cause oxidative injury and results in methemoglobinemia and formation of Heinz bodies in red blood cells. Acetaminophen should not be used in ferrets,[20] as in vitro studies indicate they may be as sensitive to acetaminophen as cats. At this time, acetaminophen should also not be used in sugar gliders or hedgehogs, as its safety has not been determined.

Dogs do not metabolize acetaminophen as well as humans do and its use must be judicious. Although dogs are not as sensitive as cats to acetaminophen, they may still be susceptible to methemoglobinemia when acetaminophen is prescribed at high dosages. Anecdotally, some dogs may be idiosyncratically sensitive to acetaminophen and some dogs may develop hepatotoxicity if acetaminophen is used chronically at therapeutic doses.[21]

Adverse Effects

At suggested dosages in dogs, there is potential for adverse renal, hepatic, GI, and hematologic effects. Higher dosages (3 times recommended) can cause keratoconjunctivitis sicca. In horses given acetaminophen for 14 days, increased total bilirubin and reduced sorbitol dehydrogenase activity were noted, and evidence of mild portal inflammation was noted on liver biopsies.[15]

Reproductive/Nursing Safety

Acetaminophen crosses the placenta.[22] Absolute reproductive safety has not been established; however, acetaminophen is considered relatively safe for occasional use in pregnancy.[23–25] In laboratory animals given acetaminophen at doses 0.85 to 1.2 times the maximum human dose (MHD, 4 g/day), reduced fetal weight and skeletal ossification, and focal renal and hepatic necrosis were observed.[26] Abnormal sperm and reduced testicular weight were noted in animals given 1.2 times MHD.[26]

Acetaminophen is excreted in milk in low concentrations with reported milk:plasma ratios of 0.91 to 1.42 at 1 and 12 hours, respectively; it is considered acceptable to administer to pregnant women.[27] In nursing human infants, no adverse effects have been reported.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Cats are highly susceptible to methemoglobinemia development because of their inability to glucuronidate acetaminophen, and there is no dose for cats that is considered safe. In the first few hours following ingestion, cats may present with swelling of the face and limbs. Doses of 40 mg/kg can cause methemoglobinemia, although some cats have been reported to develop it at 10 mg/kg. Because cats can develop methemoglobinemia rapidly after ingestion of acetaminophen, do not delay N-acetylcysteine treatment, and preferably give the first dose IV. See ***N-Acetylcysteine***. Clinical signs associated with methemoglobinemia include respiratory distress, cyanosis, depression, hypothermia, weakness, edema, and death. Hepatotoxicity occurs at higher doses; most cats are presented with methemoglobinemia signs before signs of hepatotoxicity develop.[28]

In dogs, hepatotoxicity generally occurs at doses greater than 75 – 100 mg/kg,[29,30] and clinical signs (eg, icterus, vomiting, anorexia, abdominal pain; coagulopathy, hypoglycemia, hepatic encephalopathy in severe cases) usually develop within 24 to 48 hours after ingestion. Many authors advise intervention with doses greater than 50 mg/kg. Methemoglobinemia generally occurs with doses greater than 200 mg/kg with clinical signs similar to those seen in cats. Signs typically develop 1 to 4 hours postexposure and persist for 12 to 48 hours. If the patient is left untreated, death can occur between 18 to 36 hours postexposure. Keratoconjunctivitis sicca can be seen with doses greater than 30 mg/kg, with clinical signs first seen 48 to 72 hours after exposure.[28]

For overdoses in dogs or cats, standard GI decontamination techniques with supportive care should be administered when applicable. Further treatment with N-acetylcysteine, *S*-adenosyl-methionine (SAMe), oxygen, and blood transfusions may be warranted.[29,31–34]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with acetaminophen have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, Local** (eg, **bupivacaine, lidocaine, mepivacaine, ropivacaine**): Concurrent use may increase the risk for methemoglobinemia.
- **Barbiturates** (eg, **phenobarbital, primidone**): Increased conversion of acetaminophen to hepatotoxic metabolites; potentially increased risk for hepatotoxicity
- **Cholestyramine**: May reduce oral acetaminophen absorption; administer separately
- **Chloramphenicol:** Increased acetaminophen concentration noted in humans; veterinary significance is unclear.
- **Dipyrone:** Combined used may increase risk for hepatocellular injury.

- **Doxorubicin**: May deplete hepatic glutathione, leading to increased hepatic toxicity
- **Fenbendazole**: May increase the risk for hepatotoxicity (study done in mice)[35]
- **Isoniazid**: Increased conversion of acetaminophen to hepatotoxic metabolites with possible increased risk for hepatotoxicity
- **Leflunomide**: May increase the risk for hepatotoxicity
- **Metoclopramide:** May increase acetaminophen absorption
- **Metyrapone**: May reduce acetaminophen conjugation, potentially increasing formation of toxic acetaminophen metabolites
- **Penicillin G Benzathine and/or Procaine**: Concurrent use of the benzathine and/or procaine penicillin G salts may increase risk for methemoglobinemia.
- **Phenothiazines** (eg, **acepromazine**): Possible increased risk for hypothermia
- **Probenecid**: May increase acetaminophen concentration and alter its metabolism, potentially increasing formation of toxic acetaminophen metabolites
- **Propylene Glycol**: Foods containing propylene glycol (often found in wet cat foods) may increase the severity of acetaminophen-induced methemoglobinemia or Heinz body formation.
- **Rifampin**: May increase the risk for hepatotoxicity
- **Verdinexor**: Increases of serum concentration of either drug are possible due to competitive inhibition of glutathione S-transferase. Avoid combination if possible or monitor closely for adverse effects of each drug if combination cannot be avoided.
- **Warfarin**: Although acetaminophen is relatively safe to use, large doses may potentiate anticoagulant effects.

Laboratory Considerations

- False positive results may occur for urinary **5-hydroxyindoleacetic acid** (serotonin metabolite).

Dosages

NOTE: For dosages of acetaminophen combination products (with codeine or hydrocodone), refer to the individual ***Codeine*** and ***Hydrocodone Combinations*** monographs, respectively.

DOGS:

Analgesic or antipyretic (extra-label): 10 – 15 mg/kg PO or rectally every 8 hours; if using long-term (ie, more than 5 days), consider giving every 12 hours at the lower end of dosing range.

HORSES:

Analgesic or antipyretic (extra-label): 20 mg/kg PO once as single dose, or given twice daily[36,37]

RABBITS/RODENTS/SMALL MAMMALS:

Analgesic (extra-label): Using Children's *Tylenol®*, 1 – 2 mg acetaminophen/mL of drinking water. Effective for controlling mild to moderate pain[38–41]

Monitoring

- When used at recommended doses for pain control in otherwise healthy patients, little monitoring should be necessary. However, with chronic therapy, baseline and periodic liver, renal, and hematologic monitoring may be warranted, particularly when clinical signs occur.

Client Information

- Must **NEVER** be used in **cats**. Do **NOT** use in ferrets.
- Watch for side effects and contact your veterinarian if you see any of the following: dog stops eating, whites of the eyes become yellowish, continued vomiting or diarrhea, or blood seen in vomit or stool.
- Do **NOT** give more than your veterinarian prescribes. Unless your veterinarian instructs, do **NOT** give with other pain or fever medicine.
- Keep out of reach of children.

Chemistry/Synonyms

A synthetic nonopioid analgesic, acetaminophen (also known as paracetamol) occurs as a crystalline white powder with a slightly bitter taste. It is soluble in boiling water and freely soluble in alcohol. Acetaminophen is known in the UK as paracetamol.

Acetaminophen may also be known as paracetamol, *N*-acetyl-*p*-aminophenol, MAPAP or APAP; many trade names are available, *Tylenol®* is one common name.

Storage/Stability

Acetaminophen products should be stored at temperatures less than 40°C (104°F). Do not freeze the oral solution or suspension.

Compatibility/Compounding Considerations

Nonextended-release tablets may be split or crushed and mixed with food immediately prior to administration.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

There are many different trade names and products of acetaminophen available commercially. The most commonly known trade name is *Tylenol®*. Acetaminophen is available in 160 mg, 325 mg, and 500 mg tablets, capsules, or caplets; 80 mg chewable tablets; 650 mg extended-release tablets; 32 mg/mL oral liquids, and 60 mg, 80 mg, 120 mg, 125 mg, 250 mg, 325 mg, and 650 mg rectal suppositories. Combinations with other analgesics (aspirin, codeine phosphate, hydrocodone, tramadol, or oxycodone) or antihistamines (diphenhydramine) are also available.

For the complete list of references, see **wiley.com/go/budde/plumb**

Acetazolamide

Acetazolamide Sodium

(a-set-a-***zole***-a-mide) *Diamox®*

Carbonic Anhydrase Inhibitor Diuretic; Antiglaucoma Agent

Prescriber Highlights

- ► May be used to treat metabolic alkalosis or glaucoma in small animals and hyperkalemic periodic paralysis (HYPP) in horses
- ► Contraindicated in patients with significant hepatic, renal, pulmonary, or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis, or electrolyte imbalance
- ► Give oral doses with food if GI upset occurs.
- ► Electrolytes and acid–base status should be monitored with chronic or high-dose therapy.
- ► Monitor with tonometry if using for glaucoma.

Uses/Indications

Acetazolamide has been used principally in veterinary medicine for its diuretic action and its effects on aqueous humor production in the treatment of metabolic alkalosis and glaucoma, respectively. This drug may be useful as an adjunctive treatment for increased CSF pressures associated with syringomyelia in dogs[1]; however, acetazolamide was ineffective in reducing clinical signs or the ventricle:brain

ratio in dogs with idiopathic communicating hydrocephalus.[2]

In horses, acetazolamide is used as a preventive and/or treatment for HYPP.

In humans, the drug has been used as adjunctive therapy for treatment of epilepsy and acute high-altitude sickness.

Pharmacology/Actions

Carbonic anhydrase inhibitors (CAIs) act via a noncompetitive, reversible inhibition of the enzyme carbonic anhydrase. Inhibition reduces the formation of hydrogen and bicarbonate ions from carbonic acid, which reduces the availability of these ions for active transport into body secretions.

Within the eye, the pharmacologic effect of CAIs is decreased formation of aqueous humor, which reduces intraocular pressure (IOP). Within the kidney, the pharmacologic effect of CAIs is increased renal tubular secretion of sodium and potassium and, to a greater extent, bicarbonate, leading to increased urine alkalinity and volume. Acetazolamide has some anticonvulsant activity, which is independent of its diuretic effects. This mechanism is not fully understood but may be caused by an effect on carbonic anhydrase in the brain or induction of metabolic acidosis.

In a study comparing the effects of acetazolamide and methazolamide in anesthetized cats, methazolamide did not reduce the hypoxic ventilatory response, but acetazolamide did. The study authors believe this response was not a result of carbonic anhydrase inhibition but instead was caused by acetazolamide's effects on carotid bodies or type I cells.[3]

Pharmacokinetics

One report states that in small animal species given acetazolamide 22 mg/kg (2 to 5 times the standard dosage), the onset of action for reduction of IOP is 30 minutes, maximal effects occur after 2 to 4 hours, and duration of action is ≈4 to 6 hours.[4]

In horses, IV administration of acetazolamide results in a high mean clearance rate (4.5 mL/kg/min) and a short mean residence time (1.71 hours). Immediate-release formulations show a low oral bioavailability (25%) with maximum concentrations of 1.9 µg/mL.[5]

In humans, the drug is well absorbed after oral administration, with peak concentrations occurring within 1 to 3 hours. The drug is distributed throughout the body, and the highest concentrations are found in the kidneys, plasma, and erythrocytes. Within 24 hours of oral tablet administration, an average of 90% of the drug is excreted unchanged into the urine by tubular secretion and passive reabsorption processes.

Contraindications/Precautions/Warnings

Carbonic anhydrase inhibitors (CAIs) are contraindicated in patients hypersensitive to them and in patients with significant hepatic disease (may precipitate hepatic coma), renal or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis, or other electrolyte imbalances. This class of drugs should not be used in patients with severe pulmonary obstruction that are unable to increase alveolar ventilation.

Acetazolamide should be used with caution in patients with severe respiratory acidosis or in those with pre-existing hematologic abnormalities. Chronic, high-dose administration may lead to decreased exercise capacity, hypercapnia, and respiratory acidosis in healthy horses during exercise.[6]

Although acetazolamide is a sulfonamide, cross-reactivity with antibacterial sulfonamides or furosemide does not appear to occur.[7] Do not confuse acetaZOLAMIDE with acetoHEXAMIDE or acetaMINOPHEN.

Adverse Effects

Potential adverse effects include GI disturbances (eg, nausea, vomiting, diarrhea, anorexia), CNS effects (eg, sedation, depression, weakness, excitement, paresthesias), hematologic effects (eg, bone marrow depression), renal effects (eg, crystalluria, dysuria, renal colic, polyuria), hypokalemia, hyperchloremia, hyperglycemia, hyponatremia, hyperuricemia, hepatic insufficiency, dermatologic effects (eg, rash), and hypersensitivity reactions, which includes Stevens-Johnson syndrome and toxic epidermal necrolysis. Acidosis occurred after IV administration of high-dose acetazolamide in dogs, and 3 dogs displayed mild tremors that resolved within 1 hour after administration.[8]

At the dosages used for HYPP in horses, adverse effects are reportedly uncommon.[9]

Reproductive/Nursing Safety

Acetazolamide crosses the placenta in unknown quantities. Acetazolamide has caused limb defects in laboratory animals and reduced fetal weight and incisor development in rats.[10] No effects on fertility were noted in rats. Fetal toxicity has been noted when the drug has been used in pregnant humans.

Acetazolamide is excreted in milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring. If unavoidable, use milk replacer instead of allowing offspring to nurse.

Overdose/Acute Toxicity

Information regarding overdose with this drug is not available. Monitor serum electrolytes, venous blood gases (including pH), hydration status, and CNS status during an acute overdose; treat clinical signs and provide supportive treatment. Acetazolamide is dialyzable.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acetazolamide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cyclosporine**: Acetazolamide may increase concentrations.
- **Digoxin**: As acetazolamide may cause hypokalemia, there is an increased risk for digoxin toxicity.
- **Drugs Affecting Potassium** (eg, **amphotericin B, corticosteroids** [eg, **dexamethasone, prednis(ol)one**], **corticotropin, or other diuretics**): Concomitant use may exacerbate potassium depletion.
- **Folic Acid Antagonists** (eg, **pyrimethamine, sulfadiazine, sulfadimethoxine, trimethoprim**): May augment folic acid antagonism
- **Insulin**: Rarely, CAIs interfere with the hypoglycemic effects of insulin.
- **Methenamine Compounds**: Acetazolamide may negate methenamine effects in the urine.
- **Methotrexate:** May augment folic acid antagonism
- **Phenobarbital**: Acetazolamide-induced alkaline urine may increase urinary excretion and compromise efficacy.
- **Primidone**: May reduce primidone absorption and serum concentration
- **Procainamide**: Acetazolamide-induced alkaline urine may decrease urinary excretion of procainamide; procainamide toxicity is possible.
- **Quinidine**: Acetazolamide-induced alkaline urine may decrease urinary excretion of quinidine; quinidine toxicity is possible.

- **Salicylates** (eg, **aspirin, bismuth subsalicylate**): Increased risk for acetazolamide accumulation and toxicity; increased risk for metabolic acidosis
- **Sodium Bicarbonate**: Increased risk for development of renal calculi
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): Acetazolamide-induced alkaline urine may decrease TCA urinary excretion.

Laboratory Considerations

- CAIs alkalinize the urine, which can cause false positive results for **urine protein** when using bromphenol blue reagent (*Albustix®, Albutest®, Labstix®*), sulfosalicylic acid (*Bumintest®, Exton's® Test Reagent*), nitric acid ring test, or heat and acetic acid test methods.
- Carbonic anhydrase inhibitors may **decrease iodine uptake** via the thyroid gland in hyperthyroid or euthyroid patients and, therefore, lower thyroid hormone concentrations.
- May interfere with HPLC determination of **theophylline** concentrations.

Dosages

DOGS:

Adjunctive therapy for treatment of glaucoma or metabolic alkalosis (extra-label): 4 – 10 mg/kg PO every 8 to 12 hours or IV once

Paroxysmal dyskinesias (extra-label): From a case report, 4 mg/kg PO every 8 hours[11]

CATS:

Adjunctive therapy for treatment of glaucoma (extra-label): 6 – 8 mg/kg PO every 8 to 12 hours

HORSES:

Prevention or adjunctive therapy for treatment of hyperkalemic periodic paralysis (HYPP) episodes (extra-label): 2.2 – 4.4 mg/kg PO twice daily[9,12]

Monitoring

- Intraocular pressure (tonometry) if used for glaucoma
- Venous blood gases if used for treatment of metabolic alkalosis
- Serum electrolytes
- Baseline and periodic CBC with differential and serum chemistry profile if using chronically
- Other adverse effects (eg, vomiting diarrhea, sedation, weakness)

Client Information

- The most common side effect of this drug is stomach upset; giving with food may help reduce this effect.
- Contact your veterinarian immediately if unusual panting or rapid breathing, weakness, staggering, behavior changes, tremors, or seizures (ie, convulsions) are seen.
- Horses must have access to **fresh** water and food while taking this medication.
- Animals will need ongoing laboratory tests while taking this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

Acetazolamide, a CAI, occurs as a white to faintly yellowish-white, odorless, crystalline powder with pK_as of 7.4 and 9.1. It is slightly soluble in water and sparingly soluble in hot water (90°C-100°C [194°F-212°F]) and alcohol. Acetazolamide sodium occurs as a white lyophilized solid and is freely soluble in water. The injection has a pH of 9.2 after reconstitution with sterile water for injection.

Acetazolamide may also be known as acetazolam, acetazolamidum, or sodium acetazolamide; *Diamox®* is one of many trade names that are available.

Storage/Stability

Acetazolamide tablets or unreconstituted powder for injection should be stored at room temperature of 20°C to 25°C (68°F-77°F) in a tightly closed container.

After reconstitution, the injection is stable for 3 days when refrigerated or 12 hours at room temperature and should be used within 12 hours.

Compatibility/Compounding Considerations

Acetazolamide sodium for injection is reportedly physically **compatible** with all commonly used IV solutions and cimetidine HCl for injection. Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Directions for reconstitution of injection: Reconstitute 500 mg vial with at least 5 mL of sterile water for injection; use within 12 hours after reconstitution. For IV use only due to alkaline pH.

Compounded preparation stability: Acetazolamide oral suspension stability when compounded from commercially available tablets has been published.[13] Triturating 12 250 mg tablets with 60 mL of *Ora-Plus®* and qs ad to 120 mL with *Ora-Sweet®* (or *Ora-Sweet® SF*) yields a 25 mg/mL suspension that retains greater than 90% potency for 60 days stored at both 5°C (41°F) and 25°C (77°F). The optimal stability of acetazolamide aqueous liquids is within a pH range of 3 to 5; stability decreases at pH values greater than 9. Compounded preparations of acetazolamide should be protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Acetazolamide Oral Tablets: 125 mg, 250 mg; generic; (Rx)

Acetazolamide Extended-Release Oral Capsules: 500 mg; generic; (Rx)

Acetazolamide Sodium Injection (Lyophilized Powder for Solution): 500 mg; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Acetic Acid
Vinegar

(ah-***see***-tick ***ass***-id)

GI Acidifier

Prescriber Highlights

- ► Used primarily for treatment of nonprotein nitrogen-induced ammonia toxicosis (eg, secondary to urea poisoning) in ruminants or enterolith prevention in horses
- ► Do not use concentrated acetic acid; use only vinegar (3%-5% acetic acid).
- ► Contraindicated if lactic acidosis (eg, grain overload, rumen acidosis) is possible
- ► Administered via stomach tube

Uses/Indications

Acetic acid is used for its acidifying qualities in ruminants to treat nonprotein nitrogen-induced (eg, urea poisoning) ammonia toxi-

cosis. It is also used as a potential adjunctive treatment to prevent enterolith formation in horses by reducing colonic pH.

Pharmacology/Actions
Acetic acid in the rumen lowers pH by shifting ammonia (NH_3) to ammonium ions (NH_4^+) to reduce ammonia absorption; it may also slow the hydrolysis of urea.

Pharmacokinetics
No information is noted.

Contraindications/Precautions/Warnings
Acetic acid should not be administered to ruminants until lactic acidosis (eg, grain overload, rumen acidosis) is ruled out.

Do **NOT** use concentrated forms of acetic acid; use only vinegar (3%-5% acetic acid).

Adverse Effects
Because of the unpleasant taste and potential for causing mucous membrane irritation, it is generally recommended to administer acetic acid via stomach tube.

Overdose/Acute Toxicity
When acetic acid is used for appropriate indications, there is little likelihood of serious toxicity occurring after minor overdoses. Because of its potential corrosiveness, the greatest concern is when a concentrated form of acetic acid is mistakenly used.

Drug Interactions
There are no documented drug interactions with oral acetic acid. Because of its acidic qualities, acetic acid could theoretically affect the pharmacokinetics of several drugs, which may have clinical significance in veterinary species. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Aspirin**: Acidified urine can decrease the excretion of salicylates.
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**): Acetic acid may increase absorption of azole antifungal agents.
- **Iron**: Acetic acid may increase iron absorption.
- **Phenobarbital**: Acidified urine can decrease the excretion of phenobarbital.
- **Quinidine**: Acidified urine can decrease the excretion of quinidine.

Dosages
CATTLE/RUMINANTS:

Urea poisoning/nonprotein nitrogen-induced ammonia toxicosis (extra-label): Using 5% acetic acid (ie, vinegar), infuse 4 – 10 L (for cattle) or 250 mL – 1 L (sheep/goats) into the rumen.[1] Follow with cold water (up to 30 L in cattle; 2 – 8 L in sheep/goats) to reduce rumen temperature and reduce formation of urea. Repeat treatment as required if clinical signs reoccur.

HORSES:

Adjunctive treatment for enterolith prevention (extra-label): Using 5% acetic acid (ie, vinegar), add 250 mL/450 kg (250 mL/990 lb) body weight to food once daily.

Chemistry/Synonyms
Glacial acetic acid is $C_2H_4O_2$. Acetic acid has a distinctive odor and a sharp acid taste. It is miscible with water, alcohol, or glycerin. Much confusion can occur with the percentages of $C_2H_4O_2$ contained in various acetic acid solutions. Acetic Acid USP is defined as having a concentration of 36% to 37% $C_2H_4O_2$. Diluted Acetic Acid NF contains 5.7% to 6.3% w/v of $C_2H_4O_2$. Solutions containing ≈3% to 5% w/v of $C_2H_4O_2$ are commonly known as vinegar. Be certain of the concentration of the product you are using and your dilutions.

Acetic acid may also be known as E260, eisessig (glacial acetic acid), essigsäure, etanoico, or ethanoic acid.

Storage/Stability
Acetic acid solutions should be stored in airtight containers.

Compatibility/Compounding Considerations
If diluting more concentrated forms of acetic acid to concentrations equivalent to vinegar (3% to 5%), use safety precautions to protect eyes and skin. It is strongly recommended to have someone check your calculations to prevent potentially serious consequences.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

No systemic products are commercially available. Acetic acid (in various concentrations) may be purchased from chemical supply houses. Distilled white vinegar is available in gallon sizes from grocery stores or mass merchandisers.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Acetylcysteine
N-Acetylcysteine
NAC, ACC
(assah-teel-***sis***-tay-een) *Mucomyst®*

Antidote; Mucolytic

Prescriber Highlights

- ► Used primarily as a treatment for acetaminophen toxicity or other hepatotoxic conditions in which glutathione synthesis is inhibited or oxidative stress occurs
- ► When using as an antidote, if possible, give first dose IV; oral doses should be given on an empty stomach and via gastric tube.
- ► Has also been used as an inhaled solution for its mucolytic effect and, anecdotally, orally for treating degenerative myelopathy
- ► Administration via nebulization has caused hypersensitivity and bronchospasm.
- ► Dilute prior to IV administration; use a 0.2 micron in-line filter if administering inhalation solution IV

Uses/Indications
Acetylcysteine (*N*-acetylcysteine, NAC) is used in veterinary medicine as both a mucolytic agent in the pulmonary tree and as a treatment for acetaminophen, xylitol, or phenol toxicity in small animals. It potentially could be useful in the adjunctive treatment of sulfonamide hypersensitivity, sago palm hepatotoxicity, mushroom hepatotoxicity, doxorubicin-induced hepatotoxicity, cadmium toxicity, or phenazopyridine toxicity.[1-4] Acetylcysteine may also be used topically in the eye to halt the melting effect of collagenases and proteinases on the cornea (see ***Acetylcysteine Ophthalmic***).

Acetylcysteine has been used anecdotally with aminocaproic acid to treat degenerative myelopathy in dogs, but efficacy data are lacking.

In horses with strangles (ie, *Streptococcus equi* subsp *equi* infection), acetylcysteine instilled into the guttural pouch has been used to help break up chondroids and avoid the need for surgical removal.[5] Acetylcysteine enemas have been used in neonatal foals to break up meconium refractory to repeated enemas. In mares in estrus, intrauterine acetylcysteine instillation could potentially be useful as an adjunctive treatment of endometritis, as acetylcysteine appears to have anti-inflammatory effects on equine endometrial cells and improves pregnancy rates.[6,7]

Pharmacology/Actions

When administered into the pulmonary tree, acetylcysteine reduces the viscosity of both purulent and nonpurulent secretions and expedites the removal of these secretions via coughing, suction, or postural drainage. The free sulfhydryl group on the drug is believed to reduce disulfide linkages in mucoproteins; this effect is most pronounced at a pH from 7 to 9. The drug has no effect on living tissue or fibrin.

In the management of toxicity, acetylcysteine acts as a thiol donor, stimulating glutathione synthesis, and is a free radical scavenger. It also improves hepatic blood flow through increased production of nitric oxide. In acetaminophen hepatotoxicity, glutathione stores are maintained allowing elimination via nontoxic metabolites.

When administered to sick dogs ($n = 30$) during the first 48 hours of hospitalization, acetylcysteine stabilized erythrocyte glutathione concentrations, but when compared with the placebo group, illness severity scores and survival rates were unchanged.[8]

Pharmacokinetics

When given orally, some acetylcysteine is absorbed from the GI tract. Oral bioavailability in healthy cats has been reported as ≈20%.[9] When administered via nebulization or intratracheally into the pulmonary tract, most of the drug is involved in the sulfhydryl-disulfide reaction and the remainder is absorbed. Absorbed drug is converted (deacetylated) into cysteine in the liver and then further metabolized. Elimination half-life in cats is ≈0.8 hours (IV) and ≈1.3 hours (PO). The authors postulated that oral doses of 100 mg/kg may be effective in cats when treating chronic diseases, but additional studies are required to confirm safety and efficacy.[9]

Contraindications/Precautions/Warnings

Acetylcysteine is contraindicated (for pulmonary indications) in animals hypersensitive to it. Use as an antidote has no contraindications.

Acetylcysteine administration via inhalation (nebulization) may cause bronchospasm, and this drug should be used very cautiously, if at all, in animals with bronchospastic conditions (eg, asthma, bronchitis).

Oral or IV administration requires dilution to a 5% (50 mg/mL) solution. Although acetylcysteine is not labeled for injection, this route is used anecdotally; a 0.2 micron in-line filter must be used when giving IV. The taste and smell of the solution is unpleasant (sulfurous), and taste-masking agents (eg, colas, juices) have been used in humans. Because oral dosing of these drugs may be difficult in animals, gastric tubes may be necessary.

Adverse Effects

When given orally for acetaminophen toxicity, acetylcysteine can cause GI effects (eg, nausea, vomiting) and rarely, urticaria.

IV administration appears to be well-tolerated in veterinary patients. IV boluses in humans have caused changes in blood pressure (ie, hyper- or hypotension), GI effects, erythema and flushing 30 to 60 minutes after infusion, and hypersensitivity reactions (eg, in humans, rash, hypotension, wheezing).

Adverse effects reported when acetylcysteine is administered into the pulmonary tract include hypersensitivity, stomatitis, chest tightness, bronchoconstriction, and bronchial or tracheal irritation. A sticky residue may be noted on the face following nebulization with a mask. A study in cats with experimentally induced asthma demonstrated that endotracheal nebulization with acetylcysteine increased airway resistance and caused other adverse effects in some cats, including increased airway secretions, cough, and unilateral strabismus.[10]

Reproductive/Nursing Safety

Acetylcysteine crosses the placenta. Reproduction studies in rabbits and rats have not demonstrated any evidence of teratogenic or embryotoxic effects when used in doses up to 3 times normal. Studies in laboratory animals have not demonstrated impaired fertility.

It is unknown whether acetylcysteine enters milk. Because safety has not been established, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

The LD_{50} of acetylcysteine in dogs is 1 g/kg (PO) and 700 mg/kg (IV). It is believed that acetylcysteine is quite safe (with the exception of the adverse effects listed above) in most overdose situations.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

- **Activated Charcoal**: The use of activated charcoal as a gut adsorbent of acetaminophen is controversial, as charcoal may also adsorb orally-administered acetylcysteine.
- **Nitroglycerin**: May enhance hypotension when given IV concomitantly with acetylcysteine

Dosages

DOGS/CATS:

Maintain or restore glutathione levels for the adjunctive treatment of hepatotoxicity associated with oxidative damage (extra-label): Initial dose 140 – 180 mg/kg IV (dilute to 5% and give via slow IV using a 0.2 micron filter over 15 to 20 minutes) or 280 mg/kg PO (via gastric tube), followed by 70 mg/kg PO or IV every 6 hours for a minimum of 7 treatments.[2,11-13] Large overdoses may require up to 17 doses. IV administration is preferred in serious intoxications or in animals with uncontrolled vomiting.

Canine degenerative myelopathy (extra-label): 25 mg/kg PO every 8 hours for 2 weeks, then every 8 hours every other day. The 20% solution should be diluted to 5% with chicken broth or suitable diluent. Used in conjunction with aminocaproic acid at a dosage of 500 mg per dog (NOT mg/kg) PO every 8 hours indefinitely. Adjunctive treatments may include prednisone (0.25 – 0.5 mg/kg PO daily for 10 days, then every other day), Vitamin C (1000 mg PO every 12 hours), and Vitamin E (1000 units PO every 12 hours). **NOTE:** No treatment has been shown to be effective in published trials.[14]

Adjunctive treatment of hepatic lipidosis (extra-label): Identify underlying cause of anorexia and provide a protein replete feline diet, give acetylcysteine at 140 mg/kg IV over 20 minutes, then 70 mg/kg IV every 12 hours; dilute 10% acetylcysteine with saline 1:4 and administer IV using a 0.2 micron filter.[15] See also ***Carnitine***.

HORSES:

To help break up chondroids in the guttural pouch (extra-label): Instill 20% solution.[5]

In neonatal foals to break up meconium refractory to repeated enemas (extra-label): 8 g in 20 g sodium bicarbonate in 200 mL water (pH of 7.6), give as enema as needed to effect[16] or with foal in lateral recumbency, insert a 30 Fr Foley catheter with a 30-cc bulb for a retention enema. Using gravity flow, slowly infuse 100 – 200 mL of 4% acetylcysteine solution and retain for 30 to 45 minutes. IV fluids and pain medication should be considered. Monitor for possible bladder distention.[17]

Monitoring

- When used for inhalational therapy (ie, nebulization), monitor

for bronchoconstriction (eg, coughing, wheezing, dyspnea)
- When used for applicable toxicities, monitoring will depend on inciting cause. Some examples include:
  - CBC with methemoglobin value when applicable (eg, acetaminophen toxicity)
  - Serum chemistry profile with electrolytes
  - Hydration status

Client Information
- This agent should be used only in a clinically supervised setting.

Chemistry/Synonyms
The *N*-acetyl derivative of *L*-cysteine, acetylcysteine occurs as a white, crystalline powder with a slight acetic odor. It is freely soluble in water or alcohol.

Acetylcysteine may also be known as *N*-acetylcysteine or *N*-acetyl-*L*-cysteine, NAC, 5052 acetylcysteinum, NSC-111180, *Acetadote*®, *Mucomyst*®, *Cetylev*®, or *ACC*®.

Storage/Stability
When unopened, vials of acetylcysteine should be stored at room temperature, 15°C to 30°C (59°F-86°F). The product labeled for IV use states that it should be used within 24 hours of first use, and that unused portions should be discarded. However, when stored at room temperature (under fluorescent lighting) or under refrigeration, 20% injection repackaged in 3 mL oral syringes (600 mg/3 mL; for oral use) is physically and chemically stable for 6 months.[18] Unopened vials of acetylcysteine solution for inhalation should be stored at 20°C to 25°C (68°F-77°F) with excursions permitted to 15°C to 30°C (59°F-86°F). Opened vials should be kept refrigerated and used within 96 hours.

The color of acetylcysteine solutions may turn from essentially colorless to a slight pink or purple once the vial is opened or the stopper is punctured, but color change does not affect quality or concentration.

Compatibility/Compounding Considerations
Acetylcysteine injection (20%) is hyperosmolar and must be diluted before IV administration. It is **compatible** with dextrose 5% (D5W), sodium chloride 0.45% injection (half-normal saline), and water for injection. Acetylcysteine is **incompatible** with oxidizing agents; solutions can become discolored and liberate hydrogen sulfide when exposed to rubber, copper, and iron, and during autoclaving. It does not react to aluminum, stainless steel, glass, or plastic. If the solution becomes light purple in color, potency is not appreciably affected, but it is best to use nonreactive materials when giving the drug via nebulization. Acetylcysteine solutions are **incompatible** with amphotericin B, ampicillin sodium, erythromycin lactobionate, tetracycline, oxytetracycline, iodized oil, hydrogen peroxide, and trypsin.

In veterinary medicine, acetylcysteine 20% is usually diluted with a compatible solution (see above) to a concentration of 5% (final concentration of 50 mg/mL). This concentration can be obtained by adding 1 part injection (20%) to 3 parts of diluent.

One study reports anacetylcysteine 1.25% solution (12.5 mg/mL) that was created using 0.05 mL of acetylcysteine 20% solution and 0.75 mL of Ciprodex® (ciprofloxacin 0.3% and dexamethasone 0.1%). This study found the solution to be stable for 15 days when refrigerated at 4°C (39°F).[19]

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Acetylcysteine Injection: 20% (200 mg/mL) in 30 mL single-dose vials, preservative free; *Acetadote*®, generic; (Rx). Contains EDTA

Acetylcysteine Oral Capsules: 500 mg and 600 mg; (Rx and OTC). May be labeled as a nutritional product

Acetylcysteine Inhalation or Oral Solution: 10% and 20% (as sodium) in 4 mL, 10 mL, and 30 mL vials; generic; (Rx) **NOTE**: If using this product for dilution and then intravenous dosing, it is preferable to use a 0.2 micron in-line filter. Contains EDTA

Antiviral, Nucleoside

Prescriber Highlights
- ► Used primarily in birds for *psittacid alphaherpesvirus*-1 (PsHV-1; Pacheco's Disease)
- ► May be nephrotoxic when given rapidly IV and cause tissue necrosis in birds when given IM
- ► Do not use in cats because of the risk for myelosuppression and significant renal and hepatic toxicity.
- ► Oral use may cause GI distress.
- ► Adjust dosage in patients with renal insufficiency.

Uses/Indications
Acyclovir may be useful in the treatment of herpes infections in a variety of avian species. Specifically, this drug may be effective in the treatment of *psittacid alphaherpesvirus*-1 (PsHV-1; formerly known as Pacheco's Disease) when administered early in the course of disease (ie, before clinical signs occur).

In horses, acyclovir was investigated as a treatment for equine herpesvirus type 5 (EHV-5)[1,2] and equine herpesvirus type 1 (EHV-1) myeloencephalopathy,[3] but clinical efficacy was not proven. Bioavailability of oral acyclovir is poor,[4,5] but IV acyclovir may be an option in neonatal foals. Valacyclovir has better bioavailability and has demonstrated clinical efficacy.[6-8]

Despite mild efficacy against feline herpesvirus type 1 (FHV-1), acyclovir should not be used in cats due to a high potential for toxicity and low bioavailability. Other, less toxic, antiviral agents in the same class (eg, famciclovir) can be considered for this indication.

Acyclovir has been used as adjunctive treatment for canine herpesvirus in puppies.[9] Acyclovir may be of benefit in the prophylactic treatment of canine parvovirus in dogs.[10]

Pharmacology/Actions
Acyclovir is a purine (guanine) analogue with antiviral activity against a variety of viruses, including herpes simplex (types I and II), cytomegalovirus, Epstein–Barr, and varicella-zoster. It is preferentially converted by viral thymidine kinase into the active triphosphate form, which is incorporated into viral DNA where it inhibits viral DNA replication.

Pharmacokinetics
After a single IV or IM acyclovir dose in Quaker parakeets, elimination half-life was ≈40 minutes, and IM bioavailability was 90%.[11]

Bioavailability in horses after oral administration is low (ie, less than 4%).[4-6] Oral doses of up to 20 mg/kg may not yield sufficient concentrations to treat equine herpes virus, but some accumulation may occur with prolonged oral administration. Elimination half-lives in dogs[12] and cats[13] is ≈3 hours. In horses, the elimination half-life is ≈2 hours for total plasma concentration of acyclovir and ≈12 hours for unbound (free) plasma concentration of acyclovir.[6]

In dogs, acyclovir bioavailability varies according to the dose. At doses of 20 mg/kg and below, bioavailability is ≈80% but declines

to ≈50% at 50 mg/kg. Sustained-release tablets (not commercially available in the United States) have better bioavailability than standard tablets.[12]

In humans, acyclovir is poorly absorbed after oral administration (ie, ≈20%), and absorption is not significantly affected by the presence of food. Acyclovir is widely distributed throughout body tissues and fluids, including the brain, semen, and CSF. It has low protein binding and crosses the placenta. Acyclovir is primarily metabolized in the liver and has a half-life of ≈3 hours in humans.

Contraindications/Precautions/Warnings

Acyclovir is contraindicated in patients hypersensitive to it or related antiviral drugs. Use with caution in patients with dehydration, pre-existing renal or hepatic impairment, hypoxia, neurologic deficits, or electrolyte abnormalities. Dosage reduction is recommended in humans with significant renal impairment.

Acyclovir for injection has a pH of ≈11 and should be administered by slow IV infusion (1 hour for humans) after dilution to a drug concentration less than or equal to 7 mg/mL.

Do not use in cats because of the risk for myelosuppression, hepatic necrosis, and renal tubular necrosis.[14]

Adverse Effects

With parenteral therapy, potential adverse effects include thrombophlebitis, acute renal failure, and encephalopathic changes (rare). IV administration of acyclovir over 15 minutes in a horse resulted in tremors, sweating, and colic.[5]

GI disturbances may occur with either oral or parenteral therapy.

Reproductive/Nursing Safety

Acyclovir crosses the placenta, but rodent studies have not demonstrated any teratogenic effects.[15]

Acyclovir crosses into maternal milk, but associated adverse effects have not been noted.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral overdose is unlikely to cause significant toxicity. GI signs (eg, vomiting, diarrhea) and lethargy predominate with overdoses less than 150 mg/kg. Acute kidney injury is possible with higher dosages; consider GI decontamination with acyclovir overdoses of 150 mg/kg or higher.[16] Crystalluria and increased renal values occurred with acyclovir 188.7 mg/kg in a dog.

Acyclovir is removed by hemodialysis but not by peritoneal dialysis. Precipitation of the drug in renal tubules and acute renal failure have been noted in humans.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with acyclovir have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminophylline/Theophylline**: Concurrent use may increase theophylline concentrations. Monitor theophylline concentrations.
- **Meperidine**: Concurrent use may increase concentrations of meperidine and normeperidine, increasing the risk for lethargy, agitation, and seizures. Avoid combination
- **Mycophenolate:** Concurrent oral administration may increase concentrations of both acyclovir and mycophenolate. Greatest risk may be in patients with impaired renal function. Use this combination cautiously. Monitor mycophenolate concentrations and signs of toxicity from both medications.
- **Nephrotoxic Medications** (eg, **aminoglycosides** [eg, **amikacin, gentamicin], amphotericin B, cyclosporine**): Concurrent administration of IV acyclovir with nephrotoxic medications may increase the potential for nephrotoxicity. Amphotericin B may potentiate the antiviral effects of acyclovir, but it also increases the chances for development of nephrotoxicity.
- **Probenecid**: Concurrent use may increase acyclovir exposure by inhibiting renal clearance.
- **Zidovudine**: Concurrent use with zidovudine may cause additional CNS depression.

Dosages

BIRDS:

Treatment and prophylaxis of *psittacid alphaherpesvirus*-1 (PsHV-1, Pacheco's Disease; extra-label):

Treatment: 80 mg/kg PO (oral gavage) or IM (once; can cause tissue necrosis) every 8 hours for 7 to 14 days

Prophylaxis: After an initial dose of 25 mg/kg IM, acyclovir may be added to drinking water at 1 mg/mL or to food at 400 mg/quart of seed for at least 7 days.

Herpesvirus:

1. 80 mg/kg PO (oral gavage) every 8 hours[17]
2. 240 mg/kg applied to feed[17]
3. Quaker parakeets: 80 mg/kg PO every 8 hours for 7 days[11,18]
4. Raptors: 330 mg/kg PO every 12 hours[19,20]

HORSES:

Equine herpes infections (extra-label): 10 mg/kg IV (over 1 hour) every 12 hours[4,5,21]

DOGS:

Adjunctive treatment of neonatal canine herpesvirus infection (extra-label): 10 mg/kg PO every 6 hours for 5 days[9]

Prophylaxis for canine parvovirus (CPV) infections in puppies (extra-label): In a small, experimentally induced CPV-2 infection study, acyclovir 20 mg/kg IV every 8 hours for 5 days prevented clinical signs and virus replication.[10]

Monitoring

- Renal function tests (BUN, serum creatinine) with prolonged or IV therapy

Client Information

- Side effects are usually limited to gastrointestinal problems (eg, diarrhea, vomiting, lack of appetite).
- For birds, acyclovir is usually given in water or mixed with seed or peanut butter.
- Your animal will need ongoing laboratory tests while taking this medication. Do not miss these important follow-up visits.

Chemistry/Synonyms

Acyclovir, an antiviral agent, occurs as a white, crystalline powder; 1.3 mg is soluble in 1 mL of water. Acyclovir sodium has a solubility greater than 100 mg/mL in water; however, at a pH of 7.4 at 37°C (98.6°F), it is practically all unionized with a solubility of only 2.5 mg/mL in water. Each gram of acyclovir sodium contains 4.2 mEq of sodium.

Acyclovir may be known as ACV, aciclovirum, acycloguanosine, acyclovir, BW-248U, *Acic®, Aciclobene®, Aciclotyrol®, Acivir®, Acyrax®, Cicloviral®, Geavir®, Herpotern®, Isavir®, Nycovir®, Supraviran®, Viclovir®, Virherpes®, Viroxy®, Xorox®,* or *Zovirax®*.

Storage/Stability

Acyclovir capsules and tablets should be stored in tight, light-resistant containers at room temperature (15°C-25°C [59°F-77°F]). Acyclovir suspension and sodium sterile powder should be stored at room temperature (20°C-25°C [68°F-77°F]); do not refrigerate. Reconstituted solution should be used within 12 hours. Unused portions of acyclovir injection should be discarded.

Compatibility/Compounding Considerations

When reconstituting acyclovir sodium, do not use bacteriostatic water with parabens, as precipitation may occur. The manufacturer does not recommend using bacteriostatic water for injection with benzyl alcohol because of the potential toxicity in neonates. After further dilution to a concentration less than or equal to 7 mg/mL with a standard electrolyte or dextrose solution, the resulting solution is stable at 25°C (77°F) for 24 hours.

Acyclovir is reportedly **incompatible** with biologic or colloidal products (eg, blood products or protein-containing solutions), dopamine, dobutamine, foscarnet, meperidine, and morphine. Many other drugs have been shown to be **compatible** in specific situations. Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Acyclovir Oral Tablets: 400 mg and 800 mg; *Zovirax*®,generic; (Rx)

Acyclovir Oral Capsules: 200 mg; *Zovirax*®, generic; (Rx)

Acyclovir Oral Suspension: 40 mg/mL in 473 mL bottles; *Zovirax*®, generic; (Rx)

Acyclovir Injection (for IV infusion only): 50 mg/mL (as sodium) in 10 mL vials or as 500 mg lyophilized powder for reconstitution; generic; (Rx)

Acyclovir Buccal Tablets: 50 mg; *Sitavig*®; (Rx). Tablet remains in contact with oral mucosa for ≈14 hours; veterinary use is doubtful.

Topical 5% creams and ointments are also available.

Afoxolaner

(ah-***fox***-ah-lan-er) *NexGard*®

Isoxazoline Ectoparasiticide

Prescriber Highlights

- ► Chewable oral tablet for use in dogs and puppies 8 weeks of age and older and weighing at least 1.8 kg (4 lb)
- ► Labeled for monthly treatment and prevention of flea infestations and for monthly treatment and control of American dog tick, black-legged tick, lone star tick, and brown dog tick infestations
- ► Indicated for the prevention of *Borrelia burgdorferi* infections as a direct result of killing *Ixodes scapularis* vector ticks before disease transmission occurs
- ► Used for extra-label treatment of generalized demodicosis and *Sarcoptes scabiei* var *canis*
- ► Appears to be well-tolerated when administered at the label dosage
- ► FDA has warned that drugs in the isoxazoline class have the potential to cause neurologic adverse effects (eg, muscle tremors, ataxia, seizures) in dogs and cats.

Uses/Indications

Afoxolaner chewable tablets are approved by the FDA for monthly treatment and prevention of flea infestations (*Ctenocephalides felis*) and for the monthly treatment and control of American dog tick (*Dermacentor variabilis*, also called wood tick), black-legged tick (*Ixodes scapularis*, also called deer tick), lone star tick (*Amblyomma americanum*), and brown dog tick (*Rhipicephalus sanguineus*) infestations in dogs and puppies 8 weeks of age and older with a body weight of 1.8 kg (4 lb) or greater. The drug is also indicated for the prevention of *Borrelia burgdorferi* infections via killing *Ixodes scapularis* vector ticks before disease transmission occurs.

Afoxolaner has demonstrated efficacy in dogs for the treatment of generalized demodicosis,[1–3] sarcoptic mange,[4,5] cutaneous myiasis,[6] bedbugs,[7] and ear mite (*Otodectes cynotis*) infestations,[8,9] as well as against sand fly (*Phlebotomus perniciosus;* vector for canine leishmaniosis) and dog flea (*Ctenocephalides canis*) infestations.[10–13] Afoxolaner has also been shown to be effective in the treatment of other tick infestations (eg, *Dermacentor reticulatus, Haemaphysalis longicornis, Ixodes hexagonus, Ixodes holocyclus, Ixodes ricinus*) in dogs.[12,13]

Afoxolaner's effectiveness with flea control has been shown to be effective in preventing infestations by *Dipylidium caninum* (flea tapeworm).[13] Under experimental conditions, an afoxolaner and milbemycin combination product (not available in the US) also effectively reduced flea exposure and thus reduced infections by *Dipylidium caninum* in dogs.[14] Monthly administration of the combination product was 100% effective against canine thelaziosis (*Thelazia callipaeda*) in a European field study.[15]

Afoxolaner was successfully used to treat otodectic mange in naturally infested cats, eradicating mites within 48 hours of treatment and maintaining efficacy for 65 days.[16] The drug controlled flea populations in cats under experimental conditions.[17]

Afoxolaner has demonstrated efficacy against *Sarcoptes scabiei* in pigs[18,19] and *Goniodes Pavonis* in peacocks and pheasants.[20]

Pharmacology/Actions

Afoxolaner is in the isoxazoline family of insecticides and acaracides. In the parasite CNS, isoxazolines block pre- and postsynaptic transfer of chloride ions across cell membranes by inhibiting gamma-aminobutyric acid (GABA)-mediated ligand-gated chloride channels. Prolonged neuronal hyperexcitation results in paralysis and death of susceptible insects and ticks. The difference between GABA receptor sensitivities of insects/acarines as compared with mammals is believed to be the reason for differential toxicity. Insects and acarines must feed on dogs to ingest afoxolaner. Onset of action against fleas is within 4 hours of administration, with 99% effectiveness at 8 hours (ie, before fleas can lay eggs). Against ticks, the onset of action is within 48 hours, and may be as fast as 8 to 12 hours after infestation for some tick species.[21,22] Afoxolaner kills adult fleas and ticks only after they have bitten and fed.

Pharmacokinetics

In dogs, afoxolaner is reported to be rapidly absorbed, with a bioavailability of ≈75% and peak concentrations occurring between 2 to 6 hours. Food does not impair absorption. Protein binding is very high (more than 99%). Elimination is via biliary excretion of free afoxolaner and renal excretion of hepatically biotransformed metabolites. Terminal elimination half-life is ≈15 days.

Contraindications/Precautions/Warnings

There are no contraindications when afoxolaner is used as directed on the product label. The drug is labeled for use in puppies 8 weeks of age and older and weighing more than 1.8 kg (4 lb). Use with caution in dogs with a history of seizures or epilepsy. Drugs in the isoxazoline class have the potential to cause neurologic adverse effects, including muscle tremors, ataxia, and seizures.[23] These effects have been noted in patients with and without a history of neurologic disorders.

Adverse Effects

In preapproval field studies (415 dogs given monthly afoxolaner doses for 3 consecutive months), serious adverse effects were not noted, although 2 dogs with a history of seizures had a seizure during the study (causation could not be determined). The most prevalent adverse effect noted was vomiting (4.1%). Other adverse effects reported (more than 1%) included dry flaky skin (3.1%), diarrhea (3.1%), lethargy (1.7%), and anorexia (1.2%). Neurologic (hyperactivity, panting, ataxia, muscle tremors, seizures),[23] dermal (erythema, dermatitis), and hypersensitivity (hives, swelling) reactions have been reported.

Reproductive/Nursing Safety

Although studies in laboratory animals have not demonstrated teratogenic effects or any adverse effect on male or female reproductive capacity,[12] the US product label states that safe use in breeding, pregnant, or lactating dogs has not been evaluated.[24]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No information was located for acute toxicity in dogs. Oral doses up to 1000 mg/kg in rats and 2000 mg/kg in mice were not lethal. Dogs receiving doses of 5 times the maximum label dose for 3 treatments every 28 days, followed by 3 treatments every 14 days (for a total of 6 treatments), did not show clinically relevant effects related to treatment on physical examination, body weight, food consumption, clinical pathology (hematology, clinical chemistries, or coagulation tests), gross pathology, histopathology, or organ weights.[24] Vomiting occurred throughout the study, with a similar incidence in the treated and control groups.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

None have been reported. In a field study, afoxolaner was safely used concurrently with vaccines, anthelmintics, antibiotics (including topicals), steroids, NSAIDS, anesthetics, and antihistamines.[24]

Laboratory Considerations

None were noted.

Dosages

DOGS:

Treatment and prevention of flea infestations *(Ctenocephalides felis)*, and the treatment and control of black-legged tick *(Ixodes scapularis)*, American dog tick *(Dermacentor variabilis)*, lone star tick *(Amblyomma americanum)*, and brown dog tick *(Rhipicephalus sanguineus)* infestations, and for the prevention of *Borrelia burgdorferi* infections in dogs and puppies 8 weeks of age and older, with a body weight of 1.8 kg (4 lb) or greater, for 1 month (label dosage; FDA-approved): Minimum dosage is 2.5 mg/kg (1.14 mg/lb) PO once per month.[24] The package insert has a dosing table for the various tablet sizes:

Body weight	Tablet size (mg)	Number of tablets
1.8 kg to 4.5 kg (4 lb to 10 lb)	11.3	1
4.6 kg to 10.9 kg (10.1 lb to 24 lb)	28.3	1
11 kg to 27.3 kg (24.1 lb to 60 lb)	68	1
27.4 kg to 55 kg (60.1 lb to 121 lb)	136	1
Greater than 54.6 kg (121 lb)	Administer the appropriate combination of chewable tablets.	

Generalized demodicosis (extra-label):

a) At least 2.5 mg/kg orally on days 0, 14, 28, and 56[1]

b) 2.7 – 7 mg/kg PO once per month until 2 negative skin scrapings are obtained 1 month apart[12]

***Sarcoptes scabiei var canis* infestations** (extra-label): At least 2.5 mg/kg orally on days 0 and 28[4,12,13]

***Otodectes synotis* infection** (extra-label): 2.5 mg/kg PO once,[13] or once monthly for 2 months[9]

CATS:

Ear mite (*Otodectes cynotis*) infestation (extra-label): 2.5 mg/kg PO as a single dose[16]

Cat flea (*Ctenocephalides felis*) infestation (extra-label): Under experimental conditions, 2.5 mg/kg PO as a single dose[16]

PIGS:

Sarcoptes scabiei var suis (extra-label): 2.5 mg/kg PO as a single dose[18,19,25]

BIRDS:

Bird louse (*Goniodes pavonis*) (extra-label): 2.5 mg/kg PO as a single dose [20,26]

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Afoxolaner can be administered with or without food.
- Be sure your animal consumes the complete dose. Watch your animal for a few minutes after giving the medication to be sure it doesn't spit out any part of the dose.
- If your animal vomits within 2 hours of receiving the medication, give another full dose. If a dose is missed, give it when you remember and start a new monthly dosing schedule.
- Treatment may start at any time of the year. In areas where fleas and ticks are common year-round, monthly treatment should continue for the entire year.
- To minimize the likelihood of flea and tick reinfestation, treat all animals within a household with an approved flea and tick control product.
- Afoxolaner kills adult fleas and ticks only after they have bitten your animal but before the fleas or ticks can lay eggs or transmit disease. Existing flea eggs will hatch and must feed in order to be killed.
- Keep this medicine out of the reach of other animals and children. Keep the tablets in the original packaging until you are ready to give the medicine to your animal.
- Contact your veterinarian if you see any side effects, including neurologic problems, such as tremors, difficulty walking, or seizures.

Chemistry/Synonyms

Afoxolaner has a molecular weight of 625.87 g/mol and has the chemical composition 1-Naphthalenecarboxamide, 4-[5-[3-chloro-5-(trifluoromethyl)-phenyl]-4,5-dihydro-5-(trifluoromethyl)-3-isoxazolyl]-N-[2-oxo-2-[(2,2,2 trifluoroethyl)amino]ethyl. Afoxolaner is lipophilic, hydrophobic, and non-ionizable. Its ATCvet code is QP-53BX04. It is also known as *NexGard®*, and *NexGard® Spectra* (afoxolaner and milbemycin).

Storage/Stability

Store chewable tablets at or below 30°C (86°F) with excursions permitted up to 40°C (104°F).

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Afoxolaner Chewable (beef-flavored) Tablets: 11.3 mg, 28.3 mg, 68 mg, and 136 mg; *NexGard®*; (Rx). Available in color-coded packages of 1, 3, or 6 chewables. FDA-approved (NADA 141-406) for use in dogs.

HUMAN-LABELED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Aglepristone

(a-gle-***pris***-tone) Alizin®, Alizine®

Progesterone Receptor Antagonist

Prescriber Highlights

- ► Injectable progesterone receptor antagonist used for pregnancy termination in many species; may also be of benefit to induce parturition in dogs, for medical treatment of pyometra complex in dogs or cats, and for mammary fibroadenomatous hyperplasia in cats
- ► Not currently available in the US; marketed for use in dogs in several other countries
- ► Adverse effects include anorexia, localized injection site inflammation, excitation, depression, injection-related pain, diarrhea, hematological/biochemical changes, and uterine infections.
- ► This medication should not be handled or administered by pregnant women.

Uses/Indications

Aglepristone is labeled (in the UK and elsewhere) for pregnancy termination in bitches up to 45 days after mating. In early pregnancy, aglepristone is nearly 100% effective at preventing implantation.[1] In midterm pregnancy, aglepristone terminates pregnancy in ≈95% of cases.[2]

In dogs, aglepristone, in combination with oxytocin, may also prove useful to induce parturition[3,4] or in treating pyometra complex[5-8] (often in combination with a prostaglandin F analogue such as cloprostenol). Additional potential clinical uses in dogs include treatment of insulin-resistant diabetes mellitus (for which ovariectomy/ovariohysterectomy is not an option),[9] acromegaly,[10] benign vaginal tumors,[11,12] and progesterone receptor-positive mammary carcinomas.[13]

In cats, aglepristone may be of benefit for pregnancy termination, but reports on its efficacy as a single agent range from only 50% to 87%.[14-18] In separate studies, the addition of misoprostol,[6] cabergoline,[7] or cloprostenol[8] each increased the abortion rate to 100%. Aglepristone may also be useful for treating mammary hyperplasia[19,20] or pyometra[21] in cats.

Aglepristone may be useful for parturition induction in ewes.[22,23]

In rabbits, aglepristone injected on days 6 and 7 after mating prevented implantation in 100% of does (n = 13).[24] Subsequent fertility was unaffected, with 5 of 5 does becoming pregnant.

Pharmacology/Actions

Aglepristone is a synthetic steroid that competitively antagonizes progesterone at the P4 progesterone receptor. In dogs, it has an affinity for uterine progesterone receptors ≈3 times that of endogenous progesterone.[25] In queens, affinity is ≈9 times greater than the endogenous hormone.[26] As progesterone is necessary for maintaining pregnancy, aglepristone terminates pregnancy or induces parturition. Pregnancy termination (resorption or abortion) occurs within 4 to 7 days of administration.[25,27]

When aglepristone is used for treating pyometra in dogs, it can cause opening of the cervix and resumption of myometrial contractility.

Aglepristone does not appreciably affect circulating plasma concentrations of progesterone, cortisol, prostaglandins, or oxytocin. Plasma concentrations of prolactin are increased within 12 hours when aglepristone is used in dogs during midpregnancy; this effect is likely the cause of mammary gland congestion often seen in these dogs. Aglepristone has been shown to have inhibitory effects on progesterone receptor-positive canine mammary carcinoma cells.[28] Endogenous progesterone secretion during diestrus or pregnancy, or administration of exogenous progesterone derivatives for contraception, can stimulate hypersecretion of mammary growth hormone (GH), which can secondarily lead to insulin resistance. Progesterone-induced acromegaly is the most common form of acromegaly in dogs and usually appears after prolonged administration of progestogens, or during the luteal phase in older intact females.

Aglepristone also binds to glucocorticoid receptors with affinity similar to dexamethasone but without glucocorticoid activity[25]; it can prevent endogenous or exogenously administered glucocorticoids from binding and acting at these sites.

Pharmacokinetics

In dogs, after injecting 2 doses of aglepristone 10 mg/kg SC 24 hours apart, peak serum concentrations occur ≈2.5 days later and mean residence time is ≈6 days.[25] Excretion of the drug occurs slowly, with 80% of the dose excreted over 24 days. The majority (90%) of the drug is excreted via the feces.

Contraindications/Precautions/Warnings

Aglepristone is contraindicated in animals with documented hypersensitivity to it and during pregnancy, unless it is used for pregnancy termination or inducing parturition.[25] Do not use aglepristone in animals in poor health, with diabetes, or with impaired hepatic or renal function. Because of its antagonistic effects on glucocorticoid receptors, the drug should not be used in animals with hypoadrenocorticism or a genetic predisposition to hypoadrenocorticism. Use with caution in animals with chronic obstructive-airway disease, or with cardiovascular disease, particularly bacterial endocarditis.

Medical management of pyometra (eg, aglepristone) is contraindicated in bitches with severe or life-threatening conditions (eg, hepatorenal failure, suspected peritonitis).[8,26]

This medication should not be handled or administered by pregnant women.

Adverse Effects

Aglepristone is in an oil-alcohol base and localized pain and inflammatory reactions (ie, edema, skin thickening, ulceration, localized lymph node enlargement) have been noted at the injection site.[25] Size and intensity of injection reactions have been correlated with injection volume. Resolution of pain generally occurs shortly after injection; other injection site reactions usually resolve within 2 to 4 weeks. The manufacturer recommends light massage of the injection site after administration. Larger dogs should not receive more than

5 mL at any one SC injection site; severe local reactions can be avoided if the drug is administered into the scruff of the neck.[25]

Systemic adverse effects reported from field trials include anorexia (25%), localized injection site inflammation (23%), excitation (23%), depression (21%), injection-related pain (17%), diarrhea (13%), uterine infections (3.4%), and vomiting (2%).[25] Tachycardia has also been reported in cats treated with aglepristone for fibroadenomatous hyperplasia.[19] Transient and reversible changes in hematologic (neutrophilia, neutropenia, thrombocytosis, hematocrit variation, lymphocytosis, lymphopenia) or biochemical (elevated BUN, creatinine, chloride, potassium, sodium, liver enzymes [ALT, ALP, AST]) laboratory parameters were seen in 4.5% of dogs treated.[25]

When aglepristone is used for pregnancy termination, a brown mucoid vaginal discharge can be seen ≈24 hours before fetal expulsion. This discharge can persist for an additional 3 to 5 days. If the drug is used in bitches after the 20th day of gestation, abortion may be accompanied with other signs associated with parturition (eg, inappetence, restlessness, mammary congestion, lactation). Bitches may return to estrus in as little as 45 days after pregnancy termination.[25]

Reproductive/Nursing Safety

Unless used for pregnancy termination or at term to induce parturition, aglepristone is contraindicated during pregnancy.

One study using aglepristone to induce parturition (day 58 post mating) demonstrated no significant differences in weight gain between those puppies in the treatment group as compared with those in the control group, suggesting that aglepristone did not have an effect on milk production of treated bitches.[4]

Overdose/Acute Toxicity

When aglepristone was administered at 3 times the recommended dose (30 mg/kg), bitches demonstrated no untoward systemic effects.[25] Localized reactions were noted at the injection site, presumably due to the larger volumes injected.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving aglepristone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Progestins** (**natural** or **synthetic**): Could theoretically reduce the efficacy of each other
- **Glucocorticoids** (eg, **prednis(ol)one**): Aglepristone could reduce the efficacy of glucocorticoid treatment.[25]
- **Ketoconazole, Itraconazole, Erythromycin**: May interact with aglepristone presumably via inhibiting CYP3A and/or P-glycoprotein[25]

Laboratory Considerations

None are noted.

Dosages

WARNING: Because accidental injection of this product can induce abortion, it should not be administered or handled by pregnant women.

DOGS:

Termination of pregnancy up to day 45 after mating (extra-label): 10 mg/kg SC; repeat one time, 24 hours after the first injection.[25] Administer into the scruff of the neck; a light massage of the injection site is recommended after administration. A maximum of 5 mL should be injected at any one site. In case of partial abortion or no abortion, repeat treatment may be recommended 10 days after the initial dose, between days 30 and 45 after mating.

Induction of parturition (extra-label): At day 60 (NOT before day 58), post-estimated luteinizing hormone (LH) surge, 15 mg/kg SC and another dose 24 hours later.[3,29] **NOTE:** This treatment may not be safe for all breeds and should only be done in conjunction with other modalities (eg, fetal ultrasound, drop in progesterone levels) to ensure adequate fetal maturation. Use standard protocols to assist with birth (including oxytocin to assist in pup expulsion if necessary) or to intervene if parturition does not proceed.

Adjunctive therapy for pyometra (extra-label): **NOTE:** Additional therapies (eg, IV fluids, antibiotics) may be necessary based on clinical presentation.

a. 10 mg/kg SC on days 1 and 2, and then every 7th and 8th day (eg, days 7 and 8, days 14 and 15) until the end of treatment (ie, return to clinically healthy status).[30] A median of 4 doses (range 2 to 5 doses) were given. Antimicrobial therapy was administered concurrently.
b. 10 mg/kg SC once daily on days 1, 2, and 8 in combination with cloprostenol 1 µg/kg SC on days 3 to 7.[5] If pyometra was not resolved, additional aglepristone doses were administered on days 14 and 28.[5,31]

Insulin-resistant diabetes mellitus in intact bitches for which ovariectomy/ovariohysterectomy is not an option (extra-label): In addition to PZI insulin, aglepristone 10 mg/kg SC at days 1, 2, 9, and 17 during the luteal phase improved glycemic control in diabetic bitches with diestrus-induced insulin resistance ($n = 8$).[9] The effects of the treatment were significant from day 12, with reductions in the dose of insulin needed to control glycemia.

Progesterone-induced acromegaly (extra-label): Aglepristone 10 mg/kg SC at days 1, 8, 15, and 22 resulted in a reduction in mean plasma concentrations of GH and IGF-1 in affected beagle bitches ($n = 5$).[10] Once the source of progesterone has been eliminated (eg, ovariectomy, withdrawal of exogenous progestogens), the prognosis is good. Long-term efficacy and safety data are lacking.

Benign vaginal tumors (extra-label): 10 mg/kg SC on days 1 (day of diagnosis), 2, 8, 15, 28, and 35 (based on a case report of a vaginal fibroma in which tumor size was noticeably reduced on day 45)[11]

Progesterone receptor-positive mammary carcinomas (extra-label): 20 mg/kg SC on days 1 and 8. On day 15, reduced proliferation was observed in progesterone receptor-positive tumors.[13]

CATS:

Termination of pregnancy up to day 45 (extra-label)**:** 10 mg/kg SC every 24 hours for 2 doses [14-18,32] One study used 15 mg/kg SC every 24 hours for 2 doses. [17] The addition of cabergoline,[16] cloprostenol,[18] or misoprostol[15] may increase efficacy.

Pyometra (extra-label): 10 mg/kg SC on days 1, 2, 7, and 14 (if not cured) with concurrent antibiotic therapy

Mammary fibroadenomatous hyperplasia (extra-label)**:**

a) 10 – 15 mg/kg SC on days 1, 2, and 7.[19,20,33] Weekly treatment should be made until resolution of signs and may be required for several weeks. Cats that have been treated with a long-acting progestin (eg, medroxyprogesterone acetate) may require longer durations of treatment to prevent relapse.
b) 20 mg/kg SC every 7 days also has been used[19]

SHEEP:

Parturition induction, pregnancy toxemia (extra-label): 5 – 10 mg/kg SC once daily for 2 consecutive days[22,23]

RABBITS:

Prevention of fetal implantation (extra-label): 10 mg/kg SC twice 24 hours apart on days 6 and 7 after mating[24]

Monitoring

- Clinical efficacy
- For pregnancy termination: Ultrasonography 10 days after treatment and at least 30 days after mating[25]
- For induction of parturition:
  - Ultrasonography to verify fetal viability (eg, fetal intestinal peristalsis, kidney corticomedullary distinction)
  - Serum progesterone concentration: A decrease in endogenous progesterone concentration may indicate the appropriate time to administer aglepristone. **NOTE:** Progesterone concentrations are not intended to monitor efficacy of aglepristone.
- For pyometra: CBC and chemistry panel, culture and susceptibility, ultrasonography
- For insulin-resistant diabetes mellitus: serial blood glucose
- Adverse effects (see ***Adverse Effects***)

Client Information

- Only veterinary professionals should handle and administer this product.
- This medication should not be handled or administered by pregnant women.
- It is essential that your dog be evaluated by your veterinarian 7 to 10 days after treatment to ensure it has been effective.
- When using this drug for pregnancy termination in bitches, it should be understood that it might only be 95% effective in terminating pregnancy when used between days 26 and 45.
- When aglepristone is used to terminate a pregnancy, a brown mucoid vaginal discharge can be seen ≈24 hours before fetal expulsion.
- Bitches may exhibit the following after treatment: inflammation at the injection site, lack of appetite, excitement, restlessness or depression, or diarrhea.
- Contact your veterinarian if your bitch exhibits a purulent or hemorrhagic discharge after treatment or if vaginal discharge persists 3 weeks after treatment.
- When this drug is used to treat pyometra, there is risk for treatment failure (10% treatment failure in cats and 19% recurrence after 2 years[5] in dogs), and ovariohysterectomy may be required.[8,30,32]

Chemistry/Synonyms

Aglepristone is a synthetic steroid. The manufactured injectable dosage form is in a clear, yellow, oily, nonaqueous vehicle that contains arachis oil and ethanol. No additional antimicrobial agent is added to the injection.

Aglepristone may also be known as *Alizin*®, *Alizine*®, RU-534, or RU-46534.

Storage/Stability

Aglepristone injection should be stored below 25°C (77°F) and protected from light. The manufacturer recommends using the product within 28 days of withdrawing the first dose.

Compatibility/Compounding Considerations

Although no incompatibilities have been reported, because of aglepristone's oil/alcohol vehicle formulation, it should not be mixed with any other medication.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: Not presently available or approved for use in the US. In other countries: Aglepristone Injection: 30 mg/mL in 5 mL, 10 mL, and 30 mL vials; *Alizin*® or *Alizine*®; (Rx)

HUMAN-LABELED PRODUCTS: NONE

Albendazole

(al-***ben***-da-zole) *Albenza*®,*Valbazen*®

Antiparasitic

Prescriber Highlights

- ► Broad-spectrum anthelmintic with activity against a variety of nematodes, trematodes, cestodes, and protozoa
- ► FDA-approved for cattle and sheep as well as nonlactating goats
- ► Contraindicated with hepatic failure, during the first trimester of pregnancy, and in lactating does and female dairy cattle of breeding age
- ► Usually well-tolerated when used at label dosage in indicated animal species
- ► Due to significant toxicity, extra-label use in dogs, cats, crias, pigeons, or doves is not recommended.

Uses/Indications

Albendazole is FDA-approved in cattle and sheep for the removal and control of adult liver flukes, heads and segments of tapeworms, adult and fourth-stage larvae of lung worms, stomach worms, and intestinal worms. Albendazole is FDA-approved for the treatment of adult *Fasciola hepatica* in nonlactating goats.

Albendazole has been used (extra-label) for the treatment of *Encephalitozoon cuniculi* in rabbits.[1,2]

Albendazole is also used (extra-label) in small mammals (eg, dogs and cats) and swine for endoparasite control. However, because of the availability of safer alternatives and concerns about bone marrow toxicity,[3,4] it is not recommended for use in dogs or cats.

Pharmacology/Actions

Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action disrupts intracellular microtubular transport systems by binding tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles are also believed to act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

In cattle, albendazole activity and efficacy have been demonstrated against adult and fourth-stage larvae of *Ostertagia ostertagi, Haemonchus* spp, *Trichostrongylus* spp, *Nematodius* spp, *Cooperia* spp, *Bunostomum phlebotomum, Oesphagostomum* spp, adult *Fasciola hepatica*, *Dictacaulus vivaparus*, and *Moniezia* spp.[5] Activity against other parasites species and/or life cycle stages is probable.

In sheep, albendazole activity and efficacy have been demonstrated against adult and fourth-stage larvae of *Ostertagia circumcincta, Marshallagia marshalli, Haemonchus contortus*, *Trichostrongylus* spp, *Nematodius* spp, *Cooperia* spp, *Oesphagostomum* spp, *Chabertia ovina*, adult and larval *Dictacaulus filaria*, adult *Fasciola hepatica*, *Fascioides magna*, *Moniezia expansa*, and *Thysanosoma actinoides*.[5] Activity against other parasites species and/or life cycle stages is probable.

Pharmacokinetics

Albendazole pharmacokinetics were studied in cattle, sheep, and goats.[6] The drug was undetectable in the plasma of all three species after oral administration due to rapid metabolism to albendazole sulfone (inactive) and albendazole sulfoxide (active; also known as ricobendazole). Peak albendazole sulfoxide concentration was reached after 11 hours in cattle, and ≈24 hours in sheep and goats. AUC_{last} was highest in goats (30 µg/hour/mL) compared to sheep

(23 µg/hour/mL) or cattle (14 µg/hour/mL), but AUC_{last}/dose was greatest in sheep (42 µg/hour/mL/mg, versus 17 and 10 µg/hour/mL/mg in goats and cattle, respectively).

Calves that were fasted 24 to 48 hours prior to receiving intraruminal albendazole had significantly higher peak albendazole sulfone concentration, area under the curve (AUC), and mean residence time (MRT) compared to fed calves,[7,8] whereas fasting periods of 6 to 12 hours increased AUC and MRT.[8] Albendazole sulfoxide peak concentration and AUC were higher in sheep that were fasted or had reduced feed rations compared to sheep that were fed normal rations.[9] However, in goats albendazole sulfoxide AUC and half-life were higher and longer when albendazole was administered with food.[10]

In humans, albendazole is widely distributed throughout the body. It is extensively metabolized in the liver.

Contraindications/Precautions/Warnings

The drug is not FDA-approved for use in lactating dairy cattle. The manufacturer recommends not administering to female cattle during the first 45 days of pregnancy or for 45 days after removal of bulls. In sheep or goats, it should not be administered to ewes or does during the first 30 days of pregnancy or for 30 days after removal of rams or bucks. Because a withdrawal time in milk has not been established, the drug is not to be used in lactating does or in female dairy cattle of breeding age.

Accurate estimates of animal weight result in the most effective use of the drug.

Pigeons and doves may be susceptible to albendazole toxicity (intestinal crypt epithelial necrosis and bone marrow hypoplasia).[11] Albendazole toxicosis also has been noted in rabbits, many of whom received higher dosages than are recommended[12]; use with caution.

Adverse Effects

Albendazole is tolerated without significant adverse effects when dosed in cattle, goats, or sheep at recommended dosages.

Dogs may develop anorexia. Cats may exhibit adverse effects of mild lethargy, depression, anorexia, and resistance to receiving albendazole when it is used to treat *Paragonimus kellicotti* infections. Albendazole has been implicated in causing neutropenia and aplastic anemia in dogs and cats.[3,4] In cases where fenbendazole is efficacious, it is preferred.

Reproductive/Nursing Safety

Albendazole has been associated with teratogenic and embryotoxic effects in rats and rabbits at doses less than those used clinically,[4] and dose-related teratogenic effects in sheep when given early in pregnancy.[13] The manufacturer recommends not administering to female cattle during the first 45 days of pregnancy or for 45 days after removal of bulls.[5] In sheep and goats, it should not be administered to ewes or does during the first 30 days of pregnancy or for 30 days after removal of rams or bucks.

Albendazole is excreted in milk.[14] Safety during nursing has not been established.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Doses of 300 mg/kg (30 times recommended) and 75 mg/kg (10 times recommended) have caused death in cattle[4] and sheep,[13] respectively. Doses of 45 mg/kg (4.5 times recommended) did not cause any adverse effects in cattle. Albendazole 19 – 100 mg/kg/day caused severe diarrhea, neutropenia, and multiple organ failure in crias, and lethargy, fever, diarrhea, and neutropenia in adult alpacas.[15] Cats receiving 100 mg/kg/day for 14 to 21 days showed signs of weight loss, neutropenia, and mental dullness.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with albendazole have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cimetidine**: May increase albendazole concentrations in bile and cystic fluid
- **Dexamethasone**: May increase albendazole serum concentrations
- **Ivermectin:** Albendazole sulfoxide (active metabolite) AUC was decreased, and ivermectin AUC was increased in lambs that received albendazole coadministered with ivermectin.[16,17]
- **Praziquantel**: May increase albendazole serum concentrations
- **Theophylline Derivatives** (eg, **aminophylline, theophylline**): May decrease theophylline concentrations

Laboratory Considerations

None are noted.

Dosages

CATTLE:

Removal and control of liver flukes, tapeworms, adult and fourth-stage larvae of stomach worms (including fourth-stage inhibited larvae of *Ostertagia ostertagi*), intestinal worms, and lungworms (label dosage; FDA-approved): 10 mg/kg PO (4 mL/45.3 kg [100 lb] of body weight) as a single dose.[5] Re-treat as necessary. **NOTE**: Not approved for use in female dairy cattle of breeding age.

SHEEP:

Removal and control of liver flukes, tapeworms, adult and fourth-stage larvae of stomach worms (including fourth-stage inhibited larvae of *Ostertagia ostertagi*), intestinal worms, and lungworms (label dosage; FDA-approved): 7.5 mg/kg PO (3 mL/45.3 kg [100 lb] of body weight) as a single dose.[5] Re-treat as necessary.

GOATS:

Treatment of adult liver flukes in nonlactating goats (label dosage; FDA-approved): 10 mg/kg PO (4 mL/45.3 kg [100 lb] of body weight) as a single dose.[5] Re-treat as necessary.

CAMELIDS:

Susceptible GI helminths (extra-label): 15 mg/kg PO as a single dose[18]

RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits**: ***E cuniculi*-induced phacoclastic uveitis** (extra-label): 30 mg/kg PO once daily for 30 days, then 15 mg/kg PO once daily for 30 days[19]

b) **Rabbits**: ***E cuniculi*** (extra-label): 20 mg/kg PO once daily for 10 days[20]

c) **Chinchillas**: ***Giardia* spp** (extra-label): 50 – 100 mg/kg PO once daily for 3 days[21]

Monitoring

- Efficacy (eg, pre- and post-fecal flotation or fecal egg count reduction test [FECRT])
- Adverse effects, particularly if used in non-FDA-approved species or at dosages higher than recommended
- Consider monitoring CBC and liver enzymes (every 4 to 6 weeks) if treating long-term (more than 1 month)

Client Information

- Shake well before administering.
- This medicine can be given with or without food. If your animal vomits or acts sick after receiving the drug on an empty stomach, try giving the next dose with food. If vomiting continues, contact your veterinarian.
- Contact your veterinarian if your animal develops vomiting, diarrhea, or yellowing of the eyes, skin, or gums (ie, jaundice).

Chemistry/Synonyms

A benzimidazole anthelmintic structurally related to mebendazole, albendazole has a molecular weight of 265. It is insoluble in water and soluble in alcohol.

Albendazole may also be known as albendazolum, SKF-62979, *Valbazen®*, or *Albenza®*. Many other trade names are available. Albendazole sulfoxide is also known as ricobendazole.

Storage/Stability

Albendazole suspension should be stored at room temperature 20°C to 25°C (68°F-77°F). Protect from freezing. Shake well before use. Albendazole tablets should be stored at 20°C to 30°C (68°F-86°F).

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/ Regulatory Status

VETERINARY-LABELED PRODUCTS:

Albendazole Suspension: 113.6 mg/mL (11.36%) in 500 mL, 1 L, 5 L; *Valbazen® Suspension*; (OTC). FDA-approved for use in cattle (see ***Contraindications/Precautions/Warnings),*** goats, and sheep (do not administer to does or ewes during the first 30 days of pregnancy or for 30 days after removal of bucks or rams). Slaughter withdrawal time for cattle is 27 days at labeled doses.[5] Slaughter withdrawal time for goats and sheep is 7 days at labeled dose. Because milk withdrawal time has not been established, do not use in lactating does or in female dairy cattle of breeding age.

HUMAN-LABELED PRODUCTS:

Albendazole Oral Tablets: 200 mg; *Albenza®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Albumin, Human

Albumin, Canine

(al-***byoo***-min)

Natural Protein Colloid

Prescriber Highlights

- ► Used to increase intravascular oncotic pressure and organ perfusion and decrease edema secondary to crystalloid fluid replacement, particularly in critically ill animals with reversible diseases or conditions when hypoalbuminemia is present
- ► Contraindications include in patients that have demonstrated hypersensitivity to albumin products.
- ► Significant adverse effects are possible, especially immune-mediated reactions when using albumin products in a species other than which it was derived (xeno-albumin products).
- ► Lyophilized canine albumin products are available commercially in the United States, but limited safety and efficacy data are available. Local or regional availability may vary.

Uses/Indications

Human serum albumin (HSA) and canine serum albumin (CSA) may be useful as colloid fluid replacement therapy in critically ill small animal species. Albumin therapy may be considered in patients that are severely hypoalbuminemic (albumin less than 2.0 g/dL), severely edematous, have systemic inflammatory response syndrome or sepsis, or have increased vascular permeability. Human albumin is typically used in small animal species due to availability; however, using albumin products in species other than which they are derived (xeno-albumin) can pose considerable risks. There is limited information available on the use of human albumin in cats.

The administration of 10% human albumin may be useful in dogs with reversible disease that are clinically affected by marked hypoalbuminemia (serum albumin less than 1.5 g/dL) and low colloid osmotic pressure (COP; less than 14 mm Hg). Dogs with surgical diseases and septic peritonitis should be especially considered because of the role of albumin in wound healing; however, given the risk for complications and uncertain positive outcomes, it should be used with extreme caution in critically ill dogs.[1]

One review of human albumin use in small animal species suggests the use of 25% human albumin in patients with refractory hypotension; refractory hypotension associated with gastric dilation-volvulus; patients that are severely hypoalbuminemic (albumin less than 1.5 g/dL or less than 1.8 g/dL) and dehydrated/hypovolemic with ongoing losses (eg, peritonitis, pleural effusion); septic patients that are hypoalbuminemic (combined with FFP); patients with protein-losing enteropathy before surgical biopsy; and markedly hypoalbuminemic patients that continue to vomit (likely attributable to bowel edema).[2]

Another review on fluid therapy in emergent small animal species recommended that the use of HSA be reserved for critically ill patients with a life-threateningly low albumin (eg, septic peritonitis) and that it should not be routinely used for patients with a low COP, as safer synthetic colloids (eg, hydroxyethyl starch) can be used. In dogs, CSA appears to be a safer option than HSA, but outcomes such as hospitalization time and survival time compared to untreated dogs with similar conditions are unknown. Comparative, prospective studies are needed.[3]

Pharmacology/Actions

Albumin provides 75% to 80% of the oncotic pressure of plasma. When albumin is given therapeutically, it increases intravascular oncotic pressure and can cause mobilization of fluids from the interstitial into the intravascular space.

Albumin (for its species) also has other actions, including binding and transport of drugs, ions, hormones, lipids, and metals (including iron); maintenance of endothelial integrity and permeability control; wound healing; antioxidant properties; free radical scavenging; metabolic and acid–base functions; decreasing platelet aggregation; and augmenting antithrombin and serving as a thiol-group. It is unknown what effect, if any, xeno-albumin has on these actions.

Pharmacokinetics

Endogenous circulating albumin represents 30% to 40% of total body albumin. Elimination of exogenously administered canine albumin is estimated to be between 20 to 24 days with a half-life of 10 to 12 days. The kinetics of human albumin in dogs or cats is not well described.

Contraindications/Precautions/Warnings

A history of hypersensitivity to human or canine albumin is a specific contraindication for use. Because of the risk for hypersensitivity, repeat administration of xeno-albumin is relatively contraindicated[4]; in otherwise healthy animals that are only volume depleted, its use should be avoided. In one study, no dog was eligible to receive additional human albumin 7 days following initial administration due to its antigenicity.[1]

Dogs with a pre-existing condition resulting in volume overload should be monitored carefully during administration of hyperos-

molar products such as canine albumin. Dogs with anemia or extreme dehydration should not receive canine albumin unless concurrent red blood cell products or appropriate fluid therapy is first administered.[5]

Adverse Effects

The incidence of adverse effects reported in retrospective studies in dogs and cats with human albumin vary widely, but these effects can be serious. Immediate (type I hypersensitivity; anaphylaxis) and delayed (type III hypersensitivity; serum sickness) hypersensitivity reactions are possible when using human albumin in dogs and cats[6]; these effects can be serious, and deaths have occurred. Immediate adverse effects reported include facial edema, vomiting, urticaria, hyperthermia, and shock. Should facial edema occur, diphenhydramine should be given at 1 – 2 mg/kg IM and repeated every 8 hours as required.[2] Delayed adverse effects can include lethargy, lameness, edema, cutaneous lesions/vasculitis, vomiting, inappetence, renal failure, and coagulopathies.

Although no hypersensitivity reactions were observed during 28-day follow-up periods in prospective trials with clinically ill dogs and cats, these finding contrast with previous research.[7,8] A retrospective study evaluating 25% albumin (human) in critically ill dogs and cats found that it could be safely administered and increased albumin levels and systemic blood pressure[9]; however, another retrospective study[1] evaluating human serum albumin (HSA) in 73 critically ill dogs found that although albumin increased serum albumin, total protein, and colloid osmotic pressure (COP), 23% of treated dogs developed at least 1 adverse effect that could potentially have been caused by albumin. The authors caution that given the risks for complications and uncertain positive influence, thoughtful consideration and extreme care must be taken when deciding whether to administer HSA transfusions to critically ill dogs; these concerns should be discussed with clients, and frequent monitoring should always be used.

An Italian retrospective study evaluating 5% HSA in 418 dogs and 170 cats with critical illnesses, severe hypersensitivity reactions such as anaphylaxis, angioedema, or urticaria were not noted in any patient record.[10] In no case was it necessary to discontinue or interrupt the albumin infusion due to adverse effects. Diarrhea, hyperthermia, or tremors were noted in 43% of dogs and 36% of cats treated. A combination of these adverse reactions was seen in 32% of dogs and 34% of cats. Adverse reactions that developed 1 day or more after treatment were noted in 28% of dogs and 11% of cats. Reactions beyond day 3 were not recorded. Perivascular inflammation at catheter sites following albumin administration were seen in 17% of dogs and 34% of cats. This study did not measure changes in total protein, colloid oncotic pressure, or albumin.

The incidence of adverse effects in dogs associated with HSA appears to be higher in healthy dogs than in critically ill dogs, possibly due to the blunted immune response that can be seen in critically ill patients. In a study of 6 healthy dogs given 2 mL/kg of 25% HSA during a 1-hour period, an immediate hypersensitivity reaction (eg, vomiting, facial edema) was seen in 1 dog; delayed adverse reactions were seen 5 to 13 days after albumin was administered in all 6 dogs (including lethargy, lameness, peripheral edema, ecchymoses, vomiting, and anorexia). Delayed complications in 2 of these dogs resulted in death due to renal failure and coagulopathy and were suspected to have occurred because of serum sickness secondary to type III hypersensitivity reactions. Another dog had shock and sepsis secondary to a multidrug-resistant *Escherichia coli* infection.[11] In another study in 9 healthy dogs that were given 1 or 2 infusions of HSA (25% at an initial infusion rate of 0.5 mL/kg/hour that was increased incrementally to a maximum of 4 mL/kg/hour), adverse effects were seen after the first or second infusion in 3 dogs. Anaphylactoid reactions were observed in 1 of 9 dogs during the first infusion and in the 2 dogs that were administered a second infusion. Two dogs developed severe edema and urticaria 6 or 7 days after the initial infusion. All dogs developed anti-HSA antibodies.[4]

The adverse effect profile for canine serum albumin (CSA) use in dogs is not well described. One study of 14 dogs with septic peritonitis demonstrated minimal adverse effects (1 dog developed tachypnea) that could have been attributable to albumin administration.[12] Safety studies in healthy normovolemic beagles where canine albumin was administered once weekly for 4 weeks did not show any evidence of adverse effects or antibody formation.

Although the risk appears low, transmission of infectious agents from albumin products is possible. Rash, nausea, vomiting, tachycardia, and hypotension have been reported in humans, but hypersensitivity reactions are very rare.

Reproductive/Nursing Safety

Albumin products are unlikely to pose much risk to the fetus, particularly when used appropriately. Albumin excretion into maternal milk is not known, but it is unlikely to be harmful.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

To avoid the effects of hyperalbuminemia/hyperproteinemia, albumin levels should be monitored. During treatment with albumin, it is thought that serum albumin should not exceed 2.5 g/dL. Some clinicians use a more conservative upper limit of 2 g/dL.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

Although the administration of exogenous albumin could bind drugs that are highly bound to plasma proteins and affect the amount of free drug circulating, clinical significance is unlikely.

Laboratory Considerations

- Exogenous administration of albumin may temporarily decrease serum concentrations of calcium.

Dosages

DOGS:

Using human albumin (extra-label):

a) In nonemergent situations, give a test dose of 0.25 mL/kg/hour over 15 minutes while monitoring heart rate, respiratory rate, and temperature (baseline before transfusion and at end of test dose). Discontinue infusion if facial swelling or other signs of anaphylaxis develop. The range for a CRI after a bolus administration is 0.1 – 1.7 mL/kg/hour (0.025 – 0.425 g/kg) over 4 to 72 hours. Suggested maximum volume for slow IV push to treat hypotension is 4 mL/kg (1 g/kg), with a reported average volume of 2 mL/kg (0.5 g/kg). Suggested maximum volume when administered continuously over 72 hours is 25 mL/kg (6.25 g/kg); the reported average of overall volume administered is 5 mL/kg (1.25 g/kg). Infusions are empirically selected to meet low normal values. Shorter infusion times are most commonly used for refractory hypotension.[2]

b) One protocol suggested to calculate albumin deficit (g) is 10 × (serum albumin desired – serum albumin of patient) × body weight (kg) × 0.3. Alternatively, 0.5 – 1.25 g/kg has been

suggested. Calculated dose of human albumin is aseptically diluted to a 10% solution with 0.9% sodium chloride and administered over a 12-hour period with a transfusion filter.[1]

c) 2 mL/kg of 25% human serum albumin (HSA) IV over 2 hours, followed by 0.1 – 0.2 mL/kg/hour IV for 10 hours (total dose of 2 g/kg). Alternatively, calculate the albumin deficit and replace it over 6 to 12 hours: albumin deficit = 10 × (desired albumin – patient albumin) × body weight in kg × 0.3.[13]

Using canine albumin: Reconstitute lyophilized powder with 0.9% sodium chloride, *Normosol R*®, or 5% dextrose to desired concentration according to product label.

a) **Hypovolemic shock**: Using a 16% solution, give 1 mL/minute up to a total of 2.5 – 5 g/kg (15.6 – 31.2 mL/kg).

b) **Hypoalbuminemia**:

i. Using a 5% solution, administer up to 2 g/kg/day based on clinical condition.[5]

ii. Using a 5% solution, give 800 mg/kg IV over 6 hours. **NOTE**: Study was done in hypoalbuminemic dogs following surgical source control for septic peritonitis.[12]

CATS:

Using 5% (NOT 25%) human albumin: 2 mL/kg/hour IV over 5 to 10 hours to a maximum of 10 – 20 mL/kg/day. Infusion was repeated on subsequent days if serum albumin concentration was less than 2 g/dL.[8] All cats showed clinical improvement, and 50% of cats attained serum albumin concentration above 2 g/dL.

Monitoring

- Pre- and post-treatment serum albumin; 2 – 2.5 g/dL is a common target for serum albumin concentrations.
- Pre- and post-treatment colloid osmotic pressure (COP), if possible; a target COP of 14 – 20 mm Hg has been suggested.[1]
- Baseline and periodic body temperature, respiratory rate, blood pressure, and heart rate
- Adverse effects
- Signs of volume overload (eg, increased respiratory rate, increased central venous pressure)
- Monitor for delayed reactions, which can occur weeks after administration.

Client Information

- This medicine must be given in an inpatient setting.
- Clients should understand and accept the risks, costs, and monitoring associated with the use of albumin.

Chemistry/Synonyms

Human serum albumin (HSA) is a highly soluble, globular protein with a molecular weight of 66,500. The 5% solution has a colloid osmotic pressure (COP) similar to that of normal plasma. Amino acid homology of HSA and canine serum albumin (CSA) is ≈79%, but the CSA molecule is 2 kDalton larger and has a different relative charge and isoelectric point.

HSA may also be known as Alb, albumine, HSA, or albuminum. "Salt-poor" albumin is a misnomer, but still occasionally used as a designation for 25% albumin. There are a variety of trade name products.

Storage/Stability

- 5% solution: Human serum albumin (HSA) 5% solution is stable for 3 years, providing storage temperature does not exceed 30°C (86°F). Protect this product from freezing.
- 25% and 20% solutions: Store this product at room temperature not exceeding 30°C (86°F). Do not freeze it. Do not use this product after expiration date.

Do not use solutions if they appear turbid or if sediment is noted. Solutions should not be used if more than 4 hours have passed since the container was entered, as they contain no preservatives. Do not use solutions that have been frozen.

The lyophilized canine serum albumin (CSA) product should be stored at 4°C to 6°C (39.2°F-42.7°F; refrigerated) until use.[5] Product is stable for 15 months as labeled. After rehydration, it should be used within 24 hours.

Compatibility/Compounding Considerations

Human serum albumin (HSA) may be administered either in conjunction with or combined with other parenteral products such as whole blood, plasma, saline, glucose, or sodium lactate. It is reportedly **compatible at Y-site** with usual carbohydrate or electrolyte solutions, diltiazem, or midazolam. The canine serum albumin (CSA) product label warns **not** to add supplementary medication or mix with other medicinal products including whole blood or plasma, but that it can be given in conjunction with saline.

Do not mix albumin with protein hydrolysates, amino acid solutions, or solutions containing alcohol.

When preparing HSA for administration, use only 16-gauge needles or dispensing pins with 20 mL vial sizes and larger. Needles or dispensing pins should only be inserted within the stopper area delineated by the raised ring. The stopper should be penetrated perpendicular to the plane of the stopper within the ring.

CSA 5 gram lyophilized should be rehydrated with 0.9% sterile saline (sodium chloride 0.9%) or *Normosol* R® as the diluent. Dextrose 5% may also be used. Adding 30 mL of sterile saline will yield a 16% (166 mg/mL) solution and 100 mL will yield a 5% (50 mg/mL) solution.

DO NOT use sterile water to rehydrate the product. After addition of the diluent, gently swirl the solution intermittently to avoid foaming until all the powder is rehydrated. Once diluent is added, the vial may be warmed in 37°C (98.6°F) water bath to speed rehydration. Do not aggressively agitate the bottle, as foaming may occur. Rehydration may take 15 to 30 minutes with gentle swirling. CSA may be administered in conjunction with or combined with whole blood, packed red blood cells, plasma, saline, or dextrose.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Albumin, Canine, lyophilized 5 g, without preservatives or plasma byproducts; (Animal Blood Resources International). Labeled for IV use in dogs by or on the order of licensed veterinarian. **NOTE**: This is not an FDA-approved product.

HUMAN-LABELED PRODUCTS:

Albumin, Human: 5%, 20%, 25%, in various sizes; *Albuked*®, *Albuminar*®, *AlbuRX*®, *Albutein*®, *Flexbumin*®, *Kedbumin*®, *Plasbumin*®, generic; (Rx). FDA-approved

Albuterol
Salbutamol

(al-***byoo***-ter-ole) *Proventil*®, *Ventolin*®

Beta-Adrenergic Agonist

Prescriber Highlights

► Used primarily as a bronchodilator; available in oral and inhaled dosage forms

► Can be used to improve hypoxemia in horses under general anesthesia

► Use with caution in patients with cardiac dysrhythmias or dysfunction, seizure disorders, hypertension, or hyperthyroidism

► May be teratogenic at high doses and delay labor

Uses/Indications

Albuterol is used principally in cats[1,2] and horses[3] for its effects on bronchial smooth muscle to alleviate acute bronchospasm. True bronchoconstriction is rare in dogs, but albuterol may be a useful treatment in these cases. The inhalation aerosol formulation has been used to improve hypoxemia in anesthetized horses[4]; however, in normal horses, albuterol does not appear to improve physiologic response to exercise.[5,6]

Administration of inhaled albuterol can be facilitated using masks combined with aerosol chambers. In horses, the device used does not appear to significantly impact drug delivery or response.[7] Under laboratory conditions, lack of adherence to the "best practice" inhaler technique (ie, angle device is held against the face, elapsed time, or shaking the inhaler between doses) did not change the amount of albuterol delivery.[8]

Pharmacology/Actions

Albuterol is a sympathomimetic drug that preferentially stimulates beta-2-adrenergic receptors found primarily in vascular smooth muscle (including bronchial, GI, and uterine tissues) to cause relaxation of bronchial smooth muscle, reduced airway resistance, vasodilation, and tocolysis, as well as to inhibit the release of bronchoconstrictive mediators from mast cells. At recommended doses, albuterol spares the beta-1 receptor found primarily in the heart, thus lowering the likelihood of cardiac adverse effects. Albuterol's specificity is not as precise at higher doses, and some beta-1 activity may occur, resulting in tachycardia and increased myocardial contractility. Beta-adrenergic agonists promote a shift of potassium from the serum into the cell, perhaps via stimulation of Na^+-K^+-ATPase, which may cause a temporary decrease in serum potassium concentration.

In horses, albuterol (racemic) produces bronchodilation for ≈30 to 60 minutes.[3,9] The bronchodilatory effects of the R-form (levalbuterol) are comparable to the racemic form but last twice as long (120 minutes).[9] In cats, inflammatory markers in bronchoalveolar lavage (BAL) fluid were lower after levalbuterol use (twice daily for 2 weeks) as compared with racemic albuterol.[10]

Pharmacokinetics

The specific pharmacokinetics of this agent have not been thoroughly studied in domestic animals.

In general, albuterol is absorbed rapidly and well after oral administration in humans. After nebulization, less than 20% of a dose is systemically absorbed. Effects occur within 5 minutes after oral inhalation and 30 minutes after oral administration (eg, tablets). Albuterol does not cross the blood-brain barrier but does cross the placenta. Duration of effect generally persists for 3 to 6 hours after nebulization and up to 12 hours after oral administration (depending on dosage form [eg, tablets, syrup]). The drug is extensively metabolized in the liver, principally to the inactive metabolite, albuterol 4'-O-sulfate. After oral administration, the serum half-life in humans has been reported to be 2.7 to 5 hours.

Contraindications/Precautions/Warnings

Albuterol is contraindicated in patients that are hypersensitive to it or to other sympathomimetics. It should be used with caution in patients with diabetes, glaucoma, hyperthyroidism, hypertension, hypokalemia, seizure disorders, or cardiac disease (especially if concurrent arrhythmias are present).

Do not confuse albuterol with atenolol, or salbutamol with salmeterol.

Adverse Effects

Most adverse effects are dose-related and are consistent with other sympathomimetic agents, including increased heart rate, tremors, CNS excitement (ie, nervousness), and dizziness. These effects are generally transient and mild and usually do not require discontinuation of therapy. Transient hypokalemia has been reported in humans receiving beta-adrenergic agents; potassium supplementation is rarely required. In humans, hyperglycemia, cardiac arrhythmia, paradoxical bronchospasm, immediate hypersensitivity reactions, and pulmonary edema have also been reported.[11]

In cats, the S-form of albuterol may potentially increase airway inflammation. As "regular" albuterol is the racemic form (R,S-albuterol), it may also increase airway inflammation, and its use in cats should likely be limited only to acute rescue treatment and not long-term treatment.[10] In addition, some cats do not like the hissing sound during the actuation of the metered-dose inhaler or the taste of the drug/vehicle.

Mild tachycardia, premature ventricular complexes, increases and decreases in blood pressure, and profound sweating have been reported when aerosol albuterol has been administered via the breathing system to horses under general anesthesia for improvement of partial pressure of oxygen in arterial blood.[4,12] Hypokalemia has also been noted.[13,14] When high doses of beta-agonists are administered to horses via nebulization, adverse effects can include twitching, sweating, and excitement.

Reproductive/Nursing Safety

Albuterol crosses the placenta and is teratogenic (cleft palate) in rodents at doses lower than that used clinically in humans. This drug should only be used during pregnancy (particularly the oral dosage forms) when the potential benefits outweigh the risks. Use during the late stages of pregnancy may inhibit uterine contractions, and it may delay pre-term labor after oral administration. Fetal hyperglycemia and tachycardia may occur.

It is not known whether albuterol is excreted in milk. Use it with caution in nursing patients.

Overdose/Acute Toxicity

The oral LD_{50} of albuterol in mice and rats is reported to be greater than 2 g/kg.[15] Significant toxicity can occur in small animals after an oral overdose, or in dogs that bite into the metered-dose inhalers. Clinical signs of significant overdose after systemic administration (including when dogs bite into an aerosol canister) can include arrhythmias (eg, tachycardia, extrasystole), hypertension, lethargy, fever, vomiting, panting/tachypnea, polyuria/polydipsia, mydriasis, hypokalemia, hyperlactatemia, hyperglycemia, tremors, and CNS stimulation.[16–19] A retrospective study of 501 dogs with acute exposure to albuterol (most commonly due to biting/piercing an inhaler) noted the following: signs were rapid in onset (within 1 to 3 hours); the most common clinical signs included tachycardia (≈81%), tachypnea (≈33%), depression (21%), and vomiting (≈19%); and hypokalemia was reported in ≈21%, and arrhythmias occurred in 3.4% of dogs.[20] Overall, 6% of dogs remained subclinical while 94% developed clinical signs, with 2 dogs (0.4%) dying. In a dog that received ≈4 times the recommended dose for 2 years, sinus tachycardia, marked QT interval prolongation, P waves partially merged with previous prominent T waves, and mild ST-segment depression were reported. Other findings included severe hypokalemia, metabolic acidosis, and hyperlactatemia.[17] One case report describes acute nontraumatic rhabdomyolysis in a greyhound after albuterol toxicosis.[21]

If an animal has recently ingested tablets and the animal does not have significant cardiac or CNS effects, the situation should be handled like other overdoses (ie, GI decontamination procedures). For inhalation exposure (eg, when a dog bites into an aerosol canister), decontamination is generally not effective. If cardiac arrhythmias require treatment, a beta-blocking agent (eg, propranolol[16] or esmolol[22]) can be used, and in one study ≈40% of dogs required a beta-blocker.[20] Diazepam can be used for tremors. Potassium supplementation may be required (16% in one study[20]), but be alert for

rebound hyperkalemia.[18]

For patients that have experienced or are suspected of having experienced an overdose, it is strongly encouraged to consult with a 24hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to the ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving albuterol (primarily when albuterol is given orally, not via inhalation) and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Adrenergic Blocking Agents** (eg, **atenolol, propranolol**): May antagonize the actions of albuterol
- **Digoxin**: Albuterol may increase the risk for cardiac arrhythmias.
- **Diuretics**: Hypokalemia caused by diuretics may be acutely exacerbated by albuterol use.
- **Inhaled Anesthetics** (eg, **isoflurane**): Albuterol may predispose patients to ventricular arrhythmias, particularly those with preexisting cardiac disease—use cautiously.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid, selegiline**): May potentiate the vascular effects of albuterol
- **Succinylcholine**: Concurrent use may result in enhanced neuromuscular blockade.
- **Sympathomimetic Amines, Other** (eg, **phenylpropanolamine**): Use with albuterol may increase the risk for developing adverse cardiovascular effects.
- **Theophylline**: May result in decreased theophylline concentrations. The combination may result in additive CNS stimulation and increased risk for hypokalemia and cardiac arrhythmias; sudden death has occurred in laboratory animals.
- **Tricyclic antidepressants** (eg, **amitriptyline, clomipramine**): May potentiate the vascular effects of albuterol

Dosages

DOGS:

Bronchodilator for bronchoconstriction (extra-label): 0.02 – 0.05 mg/kg (20 – 50 µg/kg) PO every 8 to 12 hours.[23] Start at the low end of the dosing range and assess for efficacy and adverse effects. Increase dose and/or frequency if the response is not adequate and adverse effects are acceptable.

CATS:

Bronchodilator for intermittent, short-term treatment of feline asthma (extra-label): 1 puff (90 µg) may be repeated up to 3 times every 5 to 15 minutes.[1,24] Use with an appropriate spacer and mask (eg, *Aerokat®*). **Albuterol** should not be used on a long-term basis (see ***Adverse Effects***); the continued need for this drug may indicate a lack of control of underlying inflammation. Inhaled corticosteroids (eg, fluticasone) are recommended for long-term use to control inflammation. **NOTE**: Cats with status asthmaticus may respond faster with injectable terbutaline. See ***Terbutaline***.

Bronchoconstriction associated with bronchoscopy, bronchoalveolar lavage (BAL), or endotracheal wash (extra-label): Using an albuterol plus ipratropium combination MDI, 2 puffs (albuterol 200 µg and ipratropium 40 µg) administered prior to sedation through a spacing chamber[2]

HORSES:

Bronchodilator for acute (rescue) treatment of severe equine asthma (SEA) (extra-label):

a. **Using a handheld device** (eg, *AeroHippus®*, *Equine Haler®*): 2 to 3 puffs (180 – 270 µg total dose; NOT µg/kg) initially; may repeat up to 3 times every 5 to 15 minutes. In addition to environmental management, consider using inhaled corticosteroids (eg, fluticasone 5 minutes after albuterol), as tolerance to albuterol alone can develop rapidly.
b. 3 to 6 puffs (360 – 720 µg total dose; NOT µg/kg) every 3 hours[3]

Hypoxemia under general anesthesia (extra-label): Use a canister adaptor between the Y-piece of the anesthesia machine breathing system and the endotracheal tube of the patient. Administer a total of 2 µg/kg just before the inhalation phase of the respiratory cycle.[4,25]

Recovery of BAL fluid (extra-label): 1 puff (1 µg/kg) as a single dose administered via *EquiHaler®* before sedation and 30 minutes before BAL[26]

CATTLE:

Respiratory distress syndrome in premature calves (extra-label): 25 µg/kg via nebulization every 6 hours; may also be nebulized in combination with fluticasone 15 µg/kg every 12 hours, furosemide 1 mg/kg nebulized every 12 hours, or both[27]

Monitoring

- Improvement of clinical signs
- Arterial blood gases (as indicated)
- Heart rate and rhythm (ECG if warranted)
- Thoracic auscultation
- Baseline and periodic serum potassium

Client Information

- Contact your veterinarian if your animal's condition deteriorates or the animal becomes acutely ill.
- If using the aerosol form, shake product canister well before using, then attach the canister to the spacer/mask. The device must be primed by depressing the canister prior to first use or if it has been unused for prolonged periods. Be certain how to appropriately administer the product to maximize effectiveness.
- Do not puncture or use near an open flame. Do not allow exposure to temperatures greater than 48.9°C (120°F), as the canister could explode if kept in the heat. Keep out of reach of children and animals.
- When using inhaled albuterol with an appropriate spacer/facemask (eg, *Aerokat®*) in cats, the following tips have been recommended:
  a. Allow the cat to get used to and investigate the device (eg, leave the device by food bowl) over several days.
  b. Reward (eg, via praise, food, catnip, stroking) fearless approaches to the device, and start placing the device near the cat's face.
  c. Practice placing the mask over the cat's face without anything in the chamber.
  d. Preload the chamber with a puff of albuterol (in addition to the dose required).
  e. Make sure the mask is placed snugly over the muzzle for 4 to 6 breaths.

Chemistry/Synonyms

Albuterol sulfate, a synthetic sympathomimetic amine, occurs as a white crystalline powder. It is soluble in water and slightly soluble in alcohol. Albuterol sulfate inhalation solution is a clear colorless to light yellow solution. One milligram of albuterol is equivalent to 1.2 mg of albuterol sulfate.

Albuterol sulfate may also be known as salbutamol hemisulphate,

salbutamol sulphate, or salbutamoli sulfas; many trade names are available.

Storage/Stability

Store oral albuterol products between 2°C and 30°C (36°F-86°F) in well-closed containers. Store inhaled metered-dose aerosols at room temperature (eg, 15°C-25°C [59°F-77°F]), as temperatures above or below may impair device performance; do not allow exposure to temperatures above 48.9°C (120°F) or the canister may explode. Solutions for nebulization may be stored in the refrigerator or at room temperature of 2°C to 25°C (36°F-77°F). Discard solutions if they become colored. Protect all albuterol products from light.

Compatibility/Compounding Considerations

Albuterol solution for nebulization may be mixed with other medications formulated for nebulization.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Albuterol Oral Tablets: 2 mg and 4 mg; generic; (Rx)

Albuterol Extended-Release Oral Tablets: 4 mg and 8 mg; generic; (Rx)

Albuterol Oral Syrup: 2 mg (as sulfate)/5 mL in 473 mL; generic; (Rx)

Albuterol Aerosol for Inhalation: Each actualization (puff) delivers 90 µg. Now labeled as 108 µg albuterol sulfate in 6.7 g, 8 g, 8.5 g, and 18 g. Some canisters have 60 actuations, and some have 200 actuations; *Proventil HFA®*, *Ventolin HFA®*, *ProAir HFA®*;(Rx)

Albuterol Solution for Inhalation (Nebulization): 0.083% (2.5 mg/3 mL) in 3 mL UD vials; 0.021% (0.63 mg/3 mL), and 0.042% (1.25 mg/3 mL) preservative-free in 3 mL UD vials; 0.5% (5 mg/mL) in 0.5 mL ampules and 20 mL with dropper (must be diluted); generic; (Rx)

Albuterol and Ipratropium Solution for Inhalation: 14.7 g aerosol metered-dose inhaler containing 20 µg ipratropium bromide (an inhaled anticholinergic) and 100 µg albuterol sulfate per puff; *Combivent® Respimat*, generic; (Rx); and 3 mL unit dose solution for inhalation (neb) containing 0.5 mg ipratropium bromide and 3 mg albuterol; *DuoNeb®*, generic; (Rx)

Also available: Albuterol dry-powder inhalers (requires deep inhalation to activate)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Alendronate

(a-***len***-droe-nate) *Fosamax®*

Bone Resorption Inhibitor

Prescriber Highlights

- ► Oral bisphosphonate that reduces osteoclastic bone resorption. Potentially useful for refractory hypercalcemia, bone pain, osteosarcoma, and feline tooth resorption
- ► There is little experience using this drug in animals; adverse effect profile and dosages may significantly change with more experience and clinical research.
- ► Potentially can cause esophageal erosions; risks are not clear for dogs or cats.
- ► Accurate dosing may be difficult; bioavailability is adversely affected by the presence of food in the stomach.

Uses/Indications

Use of alendronate in small animal species has been limited, but this drug has been used in treating idiopathic hypercalcemia in cats,[1-3] and reducing feline tooth resorption.[4] It can also be used in dogs for reducing pain associated with bone tumors and as an osteosarcoma treatment adjuvant.[5]

Pharmacology/Actions

Alendronate, like other bisphosphonates, binds to bone hydroxyapatite, inhibits osteoclast function and thereby reduces bone resorption. Secondary actions that may contribute to therapeutic usefulness in osteogenic neoplasms include promoting apoptosis and inhibiting osteoclastogenesis, angiogenesis, and cancer cell proliferation.[6]

Pharmacokinetics

Specific pharmacokinetic values are limited for dogs and unavailable for cats. Oral bioavailability in all species studied is less than 2%. In humans, alendronate sodium has very low oral bioavailability (less than 1%), and the presence of food in the stomach can reduce bioavailability further to negligible amounts. In women, taking the medication with coffee or orange juice reduced bioavailability by 60% when as compared with plain water.

Absorbed drug is rapidly distributed to bone or excreted in the urine. The drug is reportedly not highly plasma protein-bound in dogs, but it is in rats.[7] Alendronate appears to accumulate on subgingival tooth surfaces and bordering alveolar bone.[4] Plasma concentrations are virtually undetectable after therapeutic dosing.[7]

Alendronate is not metabolized, and drug taken up by bone is eliminated very slowly. It is estimated that the terminal elimination half-life is ≈1000 days in dogs and ≈10 years in humans; however, once incorporated into bone, alendronate is no longer active.

Contraindications/Precautions/Warnings

Alendronate is contraindicated in patients hypersensitive to it. Bisphosphonates may cause upper GI adverse reactions (eg, esophagitis, esophageal ulcers), and alendronate is contraindicated in human patients with esophageal abnormalities (eg, strictures, achalasia) that cause delayed esophageal emptying and those who cannot stand or sit upright for 30 minutes after administration. The drug is not recommended for use in human patients with severe renal dysfunction (CrCl less than 35 mL/minute). Hypocalcemia must be corrected prior to alendronate use. Calcium and vitamin D should be supplemented if dietary intake is inadequate.

Bisphosphonate use in humans has been associated with osteonecrosis of the jaw; one case has been reported in a cat.[8] Risk factors in humans include poor oral hygiene, invasive dental procedures (extractions, implants), cancer diagnosis, concurrent medication therapy (chemotherapy, corticosteroid use), and comorbidities (anemia, infection, coagulopathy).

Alendronate use in small animals should be considered investigational at this point. Limited research and experience, dosing questions, risks for esophageal irritation or ulcers, and medication expense all are potential hindrances to its therapeutic usefulness.

Adverse Effects

There is little information on the specific adverse effect profile of alendronate in dogs or cats. In humans, alendronate can cause upper GI irritation and erosions. See ***Contraindications/Precautions/Warnings.*** GI upset, vomiting, and inappetence have been anecdotally reported in dogs receiving the drug. It has been suggested that after administration, walking or playing with the dog for 30 minutes may reduce the incidence of esophageal problems. In cats, buttering the lips after administration to induce salivation and reduce esophageal transit time has been suggested.

Other potential adverse effects of concern include atypical fractures and musculoskeletal pain.

Reproductive/Nursing Safety

Alendronate at dosages of 2 mg/kg in rats caused decreased postimplantation survival rates and at 1 mg/kg caused decreased weight gain in healthy pups.[9] Higher dosages (10 mg/kg) caused incomplete fetal ossification of several bone types. Hypocalcemia in the dam resulted in protracted parturition. No adverse fetal effects were noted in pregnant rabbits given alendronate during periods of organogenesis.

Although it is unknown whether alendronate enters maternal milk, it would be unexpected that measurable quantities would be found in milk or that it would be absorbed in clinically significant amounts in nursing offspring.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No lethality was observed in dogs receiving doses up to 200 mg/kg.[9] Lethality in mice and rats was seen at dosages starting at 966 mg/kg and 552 mg/kg, respectively. Observed adverse effects associated with overdoses included hypocalcemia, hypophosphatemia, and upper GI reactions.

A recently ingested overdose should be treated with orally administered antacids or milk to bind the drug and reduce absorption. Do not induce vomiting. Monitor serum calcium and phosphorus, and treat the patient supportively.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to *Appendix.*

Drug Interactions

The following drug interactions with alendronate have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides (eg, amikacin, gentamicin):** Concurrent use may increase the risk of hypocalcemia and nephrotoxicity. Use combination cautiously and monitor for signs of hypocalcemia.
- **Aspirin**: Theoretically increased risk for GI toxicity and renal impairment; however, data are lacking.
- **Calcium, Aluminum,** and **Magnesium,** or **Other Polyvalent Cation-Containing Oral Products**: Likely to significantly decrease oral bioavailability of alendronate. Patients should receive nothing by mouth other than water for 2 hours before and 30 minutes after oral administration of alendronate.
- **Diuretics, Loop** (eg, **furosemide):** Concurrent use may increase risk for hypocalcemia. Monitor calcium levels and renal function.
- **Estrogens** (eg, **diethylstilbestrol, estradiol**): Concurrent use may increase effects on bone density.
- **H_2 Receptor Antagonists** (eg, **famotidine, ranitidine**): Concurrent use may increase levels of both drugs.
- **NSAIDs (eg, carprofen, meloxicam, robenacoxib):** Theoretically increased risk for GI toxicity and renal impairment; however, data are lacking. Use together cautiously and monitor renal function and signs of gastrointestinal toxicity.
- **Proton Pump Inhibitors** (eg, **omeprazole, pantoprazole):** Concurrent use may decrease effects of alendronate. Avoid combination.

Laboratory Considerations

- Alendronate may interfere with technitium-99m-diphosphonate bone scans.

Dosages

DOGS:

Refractory hypercalcemia or to reduce pain associated with bone tumors (extra-label): **NOTE**: There is little experience using this drug in dogs. Reported dosages include 10 mg/dog (NOT mg/kg) PO once daily on an empty stomach[5] or 2 mg/kg PO once daily on an empty stomach.[10]

CATS:

Idiopathic hypercalcemia (extra-label): Initially 5 – 10 mg/cat (NOT mg/kg) PO once weekly; most cats started treatment at 10 mg/cat (NOT mg/kg) weekly.[3] Following administration, give 6 mL tap water PO by syringe, then butter the nasal planum to increase salivation. By the end of the 6-month period, 1 cat was receiving 15 mg (total dose; NOT mg/kg) and 4 cats 20 mg (total dose; NOT mg/kg) per week. Alendronate was well-tolerated and decreased ionized Ca in most cats for the 6-month period of observation.

Tooth resorption (extra-label): 9 mg/kg PO twice per week slowed or arrested the progression of tooth resorption.[4]

Monitoring

- Serum ionized calcium (iCa). Usually repeated monthly; adjust alendronate dose to maintain iCa in the target range.
- GI adverse effects. **NOTE**: Depending on diagnosis (eg, hypercalcemia, adjunctive treatment of osteogenic sarcomas**,** or feline resorptive lesions), other monitoring of serum electrolytes (eg, total calcium, phosphorus, potassium, sodium) or disease-associated signs may be required.

Client Information

- Do not break, split, or crush tablets unless your veterinarian has instructed you to do so.
- Must be given with water on an empty stomach. Food can prevent the drug from being absorbed and make it ineffective; do not offer food for at least 30 minutes after a dose is given. Offer your animal water after dosing to reduce the chances of throat or esophagus problems.
- If your animal vomits or acts sick after receiving the drug, try walking, exercising, or playing with your animal after dosing; encouraging it to drink water; or spreading butter on the lips (to stimulate salivation).
- Alendronate has not been used in many animals. Possible side effects include vomiting, lack of appetite, throat or esophagus ulcers or sores, or bone pain. Contact your veterinarian if you see

any other side effects of concern while your animal is taking this medicine.
- This medication can be given for various lengths of time. Be sure you understand how long your veterinarian wants you to continue giving this medication. Prescription refills may be necessary before the therapy will be complete. Before stopping this medication, talk to your veterinarian, as there may be important reasons to continue its use.
- Your veterinarian will need to monitor your animal closely while receiving this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms
Alendronate sodium is a synthetic analogue of pyrophosphonate with the chemical name (4-amino-1-hydroxy-1-phosphono-butyl) phosphonic acid. One mg is soluble in 1 L of water.

Alendronate may also be known as alendronic acid, acide alendronique, acido alendronico, acidum alendronicum, *Adronat®, Alendros®, Arendal®, Onclast®*, or *Fosamax®*.

Storage/Stability
Alendronate tablets should be stored in tightly closed containers at room temperature 20°C to 25°C (68°F-77°F); excursions permitted to 15°C to 30°C (59°F-86°F). The oral solution should be stored at room temperature; do not freeze.

Compatibility/Compounding Considerations
No specific information noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Alendronate Oral Tablets: 5, 10, 35, 40, and 70 mg (also effervescent tablet); *Fosamax®*, generic; (Rx). A 70 mg tablet combined with vitamin D3 (*Fosamax® Plus D*, 70 µg or 140 µg) is also available.

Alendronate Oral Solution: 70 mg (as base) in 75 mL; raspberry flavor; *Fosamax®*, generic; (Rx)

Alfaxalone
(al-***fax***-ah-lone) *Alfaxan®*

Intravenous Anesthetic

Prescriber Highlights
- ► Injectable (IV) anesthetic agent labeled for dogs and cats and indexed for use in multiple minor species; used extra-label in many species
- ► Used extra-label IM for sedation/premedication/light anesthesia in cats, small dogs, and a variety of small mammals, and other species. IM administration can be limited to animals of a smaller body size because of the large injectate volume required in larger animals.
- ► Provides no analgesia
- ► Respiratory depression/apnea can occur, particularly if administered rapidly IV.
- ► When used as a sole agent, opisthotonos, muscle tremors, hyperreactivity, and excitement can occur. To facilitate smoother patient recovery, a lower alfaxalone dose can be used in conjunction with premedication drugs.
- ► DEA Schedule IV (C-IV) controlled substance

Uses/Indications
Alfaxalone is FDA approved for use in cats and dogs for induction and maintenance of anesthesia, and for induction of anesthesia followed by maintenance with an inhalant anesthetic.

Alfaxalone has been used, with mixed results, for light anesthesia in the assessment of laryngeal motion in dogs. One study in premedicated dogs (methadone 0.2 mg/kg IM and acepromazine 0.01 mg/kg IM) concluded that alfaxalone (0.5 – 2 mg/kg IV) was comparable to propofol (1 – 4 mg/kg IV) for assessing laryngeal motion in non-brachycephalic versus brachycephalic dogs[1]; however, another study showed that thiopentone 7.5 mg/kg IV (not currently available in the United States) or propofol 3 mg/kg IV may be superior for assessing laryngeal motion as compared with alfaxalone 1.5 mg/kg IV.[2] The addition of doxapram 2.5 mg/kg IV to the protocol improved assessment of laryngeal motion.[3]

Alfaxalone has also been administered alone as a deep IM injection (extra-label in the United States) to cats to provide dose-dependent light to heavy sedation but it may cause tremors, ataxia, and opisthotonos-like posture.[4] The level of sedation from alfaxalone alone is generally not adequate for fractious cats. IM administration is limited to patients with a small body size (domestic cat-sized and smaller) because a larger body size will require an inappropriately large volume of injectate.

In cats, alfaxalone combined with midazolam or butorphanol and administered IM has been used to facilitate echocardiography. Compared to dexmedetomidine, alfaxalone has less of an impact on echocardiographic parameters.[5,6]

Because of its fast onset, which facilitates titration of low doses administered IV 'to effect', alfaxalone may be considered for use in high-risk patients[7]; however, dose-dependent cardiorespiratory depression, similar to that caused by propofol, can occur so alfaxalone doses should be kept as low as possible in these patients. It is also useful in sighthounds.[7,8]

Although not approved for use in horses, alfaxalone may be useful as an injectable induction agent or part of a total IV anesthesia (TIVA) protocol for short-term field anesthesia procedures.[9–13] Alfaxalone may also be useful in combination with medetomidine and butorphanol for procedures lasting up to 60 minutes[14]; however, due to the large volumes required, it is not commonly used in this species.

Alfaxan® Mulitdose IDX is an FDA-index product indicated for a variety of routes of administration including IV, IM, and intraperitoneal in captive, nonfood-producing reptiles, amphibians, ornamental fish, birds, nonhuman primates, rodents, mustelids, marsupials, and ungulates.[15] Alfaxalone has also been used extra-label in a variety of species including small mammals, rabbits, sheep, alpacas, goats, pigs, deer, fish, primates, amphibians, and reptiles.[16–32] The absorption of alfaxalone from IM and intraperitoneal injection sites facilitates use in these species, especially when IV access is a challenge.

Pharmacology/Actions
Alfaxalone is a neuroactive steroid molecule with properties of a general anesthetic. The primary mechanism for the anesthetic action of alfaxalone is the modulation of neuronal cell membrane chloride ion transport, which is induced by binding alfaxalone to gamma-aminobutyric acid (GABA) cell surface receptors. Alfaxalone has no analgesic properties.

In dogs, recumbency typically occurs 60 seconds after the start of IV injection, and intubation can be performed within 1 to 2 minutes. In dogs not given a preanesthetic agent, the duration of anesthesia from a single induction dose of alfaxalone is ≈5 to 10 minutes; duration may be longer in dogs given preanesthetic agents. In cats, effects of anesthesia are typically observed within 60 seconds after the start of injection, and intubation can be performed within 1 to 2 minutes. In cats not given a preanesthetic agent, the duration of anesthesia after being given a single induction dose of alfaxalone ranges between 15 to 30 minutes; duration may be longer in cats given preanesthetic agents. However, in field trials, the duration was shorter in premedicated dogs and cats, likely due to a lower alfaxalone dose needed for induction.[33]

In preapproval field studies, patient recovery times (ie, extubation to head lift) following administration of alfaxalone averaged 22 minutes in dogs and 15 minutes in cats that did not receive a preanesthetic agent, and 15 minutes in dogs and 17 minutes in cats that did receive a preanesthetic agent. At labeled doses, dogs and cats are expected to recover to sternal recumbency in 60 to 80 minutes.[33]

Propofol 10 mg/kg compared to alfaxalone 5 mg/kg administered IV to unpremedicated cats caused rapid loss of consciousness without apnea or clinically relevant changes in physiologic parameters.[34] Transient hypoxemia was more profound with propofol whereas more adverse events (ataxia, muscle tremors) in recovery occurred with alfaxalone.[34]

Pharmacokinetics

In dogs, the volume of distribution after a single injection of alfaxalone at 2 mg/kg is ≈2.5 L/kg, clearance is ≈54 mL/kg/minute, and elimination terminal half-life is ≈27 minutes.[35] A study done in greyhounds showed similar results when dogs were not premedicated; however, greyhounds premedicated with acepromazine and morphine had substantially longer (ie, 5 times) anesthetic durations, elimination half-life was ≈19% longer, and clearance was ≈24% lower than dogs not premedicated.[8]

In cats, the volume of distribution of alfaxalone is ≈2 L/kg. Clearance is dosage dependent with doses of 5 mg/kg (clinical dose) averaging 25.1 mL/kg/minute and doses of 25 mg/kg (supraclinical dose) averaging 14.8 mL/kg/minute. The elimination half-lives at these doses are 45.2 and 76.6 minutes, respectively. Alfaxalone has nonlinear pharmacokinetics in cats, but there is no clinically relevant accumulation with administration of multiple doses.[36]

Cat and dog hepatocyte (in vitro) studies have shown that alfaxalone undergoes phase I (cytochrome P450-dependent) and phase II (conjugation-dependent) metabolism in both species. Cats and dogs form the same 5 phase I metabolites. Phase II metabolites in cats are alfaxalone sulfate and alfaxalone glucuronide, with only alfaxalone glucuronide found in dogs. Alfaxalone metabolites are likely to be eliminated from dogs and cats by hepatic/fecal and renal routes, which is similar to other species studied.[37]

In adult horses given IV premedication that consisted of acepromazine, xylazine, and guaifenesin, alfaxalone's plasma elimination half-life was ≈33 minutes, volume of distribution was 1.6 L/kg, and plasma clearance was 33 mL/kg/minute.[38] In neonatal foals given a premedication of butorphanol, alfaxalone's plasma elimination half-life was ≈23 minutes, volume of distribution was 0.6 L/kg, and plasma clearance was 20 mL/kg/minute.[39]

Contraindications/Precautions/Warnings

Alfaxalone is contraindicated in patients with a known hypersensitivity to alfaxalone or its components or when general anesthesia and/or sedation are contraindicated. This drug should not be used with other IV general anesthetic agents (eg, propofol).[40,41] Because postinduction apnea can occur, alfaxalone should only be used if the patient can be continuously monitored and if appropriate oxygen supplementation, maintenance of the patient's airway, and artificial ventilation can be immediately provided.

Appropriate pain control should be administered because alfaxalone does not provide analgesia.

For induction, administer IV over ≈60 seconds, to effect, until clinical signs show the onset of anesthesia, titrating administration against the response of the patient. **This drug must be given slowly IV (see *Dosages*); rapid IV administration or overdose can cause cardiorespiratory depression or apnea.** Apnea can occur following induction or after the administration of maintenance boluses. The use of preanesthetic agents may reduce the alfaxalone induction dose. The choice and amount of phenothiazine, alpha$_2$-adrenergic receptor agonist, benzodiazepine, or opioid will influence the response of the patient to an induction dose of alfaxalone.[33]

Patients should be in an appropriate facility and under sufficient supervision during the postanesthetic recovery period. Animals in recovery should not be handled or disturbed, as psychomotor excitement can occur; premedication with a benzodiazepine may increase this likelihood.[33]

Caution is advised in patients with significant hepatic dysfunction, as they may require lower doses or increased dose intervals to maintain anesthesia.[42] Caution is also advised for senior, critically ill, or debilitated animals.

IM use of the preservative-free formulation in cats is approved in some countries.[41] The multidose formulation that contains preservatives is approved for IV-only administration in all countries; however, it has been used IM (extra-label) in dogs and cats. IM administration is limited to patients with small body size (domestic cat-sized and smaller) because a larger body size will require an inappropriately large volume of injectate. Alfaxalone used IM in dogs produces dose-dependent neurologic depression; lateral recumbency; and decreases in respiratory rate, rectal temperature, and blood pressure. Transient hypoxemia and muscular tremors can occur, but recovery may be satisfactory, especially if appropriate premedications are administered.[43] Similar to dogs, alfaxalone used IM in cats causes dose-dependent sedation and lateral recumbency. Ataxia, muscular tremors, and opisthotonus-like posture can be observed after IM and IV administration.[4,44]

The US label states that safe use of alfaxalone in cats younger than 4 weeks and dogs younger than 10 weeks has not been evaluated. A study in kittens (n = 34; ≈6 to 11 weeks) concluded that alfaxalone is a suitable anesthetic induction agent for premedicated kittens younger than 12 weeks and anesthetic maintenance with supplemental doses of alfaxalone may be a suitable alternative in kittens when inhalant maintenance is not feasible.[45] A similar study in puppies (n = 25; ≈6-11 weeks) concluded that alfaxalone is a suitable induction agent for premedicated puppies younger than 12 weeks that require anesthesia for surgical or diagnostic procedures; however, 2 of the puppies had excited recoveries and 1 puppy had an unacceptable anesthetic maintenance period characterized by prolonged apnea.[46]

Adverse Effects

Alfaxalone is relatively safe for a general anesthetic agent; with respiratory depression and apnea being the biggest concerns. These adverse effects can be exacerbated depending on the administration rate and premedication agents used. Respiratory depression following induction is more common when alfaxalone is administered rapidly IV.[47]

In field studies, 40% of dogs and 16% of cats experienced postinduction apnea (defined as cessation of breathing for 30 seconds or more), with a mean duration of 100 seconds in dogs and 60 seconds in cats.[33] The drug should be given slowly IV and the patient should be closely monitored. Slow administration (≈0.5 mg/kg per minute, which equals 0.05 mL/kg/minute of the 10 mg/mL product) caused apnea in 25% of dogs premedicated with dexmedetomidine and methadone. Administration at 2 mg/kg/minute caused apnea in 100% of dogs with the same premedications.[47] Slow administration also resulted in a lower induction dose needed to achieve endotracheal intubation. Once the patient is sufficiently anesthetized, alfaxalone administration should be discontinued, and an endotracheal tube placed. It is advisable to provide supplemental oxygen and monitor oxygen saturation (SpO_2). Cardiac arrhythmias may occur but are thought to occur primarily due to hypoxemia/hypercapnia; oxygen therapy is recommended as the primary treatment, followed by specific therapy for the arrhythmia(s), if required.

The cardiodepressant effects of alfaxalone, along with the vasodilatory effects of inhalant anesthetics, can cause hypotension.

Transient hypertension can also be noted, possibly due to increased sympathetic activity. Minimal cardiac effects have been found in dogs when alfaxalone is used in combination with butorphanol and midazolam.[48] In dogs, the heart rate is preserved or increased when alfaxalone is used in combination with fentanyl.[49] Alfaxalone given IM with dexmedetomidine caused a mild decrease in heart rate and oxygen saturation in cats.[50] Tachycardia, hypertension, and hypoxemia were observed in calves anesthetized with alfaxalone.[51] The cardiac index in horses reached 68% of baseline value after alfaxalone induction and was maintained between 74% to 90% during TIVA[52]; however, another study did not detect differences in cardiovascular function between TIVA using either propofol or alfaxalone with medetomidine/gauifenesin.[53]

As with most anesthetics, hypothermia during and after anesthesia is likely; providing external heat sources and monitoring the patient's core body temperature are recommended.

Induction of general anesthesia with alfaxalone can increase intraocular pressure (IOP) in dogs. Administering premedication drugs (ie, acepromazine/butorphanol, dexmedetomidine/hydromorphone) did not counteract the effect of alfaxalone on IOP.[54] In another study, the increase in IOP was only transient up to 2 minutes after induction and was followed by a decrease in IOP. Alfaxalone also caused a decrease in tear production.[55]

Excitement (eg, disorientation, nervousness, violent movements), vocalization, paddling, trembling, and myoclonus have been reported in dogs and cats during recovery.[56–58] In dogs premedicated with morphine and acepromazine, administration of midazolam before alfaxalone reduced excitement as compared with administration of midazolam after alfaxalone.[59] Sedative drugs used in combination with alfaxalone can improve recovery[60] and, especially in cats, recovery should ideally be in a quiet room. Paddling and muscle tremors occurred during recovery in 6 out of 8 horses following administration of alfaxalone TIVA.[52]

One case of anaphylaxis to alfaxalone has been described in a dog.[61]

Reproductive/Nursing Safety

Safe use of alfaxalone has not been established in animals that are pregnant or lactating; however, alfaxalone is used routinely for cesarean sections in dogs and cats. A study that compared the survival time of puppies born to bitches that were given a constant rate infusion (CRI) of alfaxalone, as compared with bitches given isoflurane after induction with alfaxalone, found that although bitches given a CRI of alfaxalone had longer recovery times and their puppies had lower Apgar scores, no difference was found in the survival rate of puppies in both groups.[62] Studies in pregnant mice, rats, and rabbits have not demonstrated deleterious effects on gestation of the treated animals or on the reproductive performance of their offspring. The effects of alfaxalone on fertility have not been evaluated.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Hypoventilation, apnea, and hypotension are the most likely consequences of overdoses up to 5 times the induction dose (20 mg/kg IV in dogs and 50 mg/kg IV in cats).[33] Marked cardiorespiratory depression and prolonged apnea and hypoxia occurred in cats receiving 50 mg/kg[33,63] and in a cat that received an alfaxalone CRI at 10 times the recommended rate due to a calculation error.[64] Cardiac arrhythmias are possible. Extended monitoring with appropriate cardiopulmonary support may be required.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The US label states that alfaxalone may be used (**NOTE:** *therapeutic* compatibility, not *pharmaceutical* compatibility) with benzodiazepines, opioids, alpha$_2$ agonists, and phenothiazines, as commonly used in surgical practice. The Australia/New Zealand label states that alfaxalone has been safely used in combination with the following premedications: acepromazine, atropine, methadone, butorphanol, diazepam, and xylazine. Concomitant use of alfaxalone with other CNS depressants is expected to potentiate the depressant effects of either drug, and appropriate dose adjustments should be made.

The following drug interactions have either been reported or are theoretical in humans or animals receiving alfaxalone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighted and additional monitoring performed when appropriate.

- **Propofol, Thiopental**: The UK label states that alfaxalone **should not** be used with **other intravenous anesthetics**.

Laboratory Considerations

None noted

Dosages

NOTES:

1. Alfaxalone is used in many different combinations with other agents. The following are representative, but not necessarily inclusive; it is suggested to refer to a recent veterinary anesthesia reference for more information.[65,66]
2. Do not confuse CRI dosages listed as mg or mL per kg/*HOUR* with those listed as mg or mL per kg/*minute*.
3. Product label information should be referred to for more specific information. The distinction between the label and extra-label use and dosages (US, UK) for this drug should be noted, as approved label information varies between countries.

DOGS:

Induction of general anesthesia (label dosage; FDA-approved): 1.5 – 4.5 mg/kg IV in dogs with no preanesthetic agents given.[33] In dogs that received a preanesthetic drug, alfaxalone induction doses were reduced by 23% to 50%, depending on the combination of preanesthetic drugs given. Average IV alfaxalone induction doses ranged from 1.1 mg/kg in dogs that received an alpha$_2$-adrenergic agonist to 1.7 mg/kg in dogs that received benzodiazepine/opioid/acepromazine. Use of a preanesthetic drug appeared to decrease the occurrence of apnea following alfaxalone induction. The dose-sparing effect of alfaxalone depends on the potency, dose, and time of administration of the preanesthetic drugs used prior to induction. To avoid anesthetic overdose, titrate the administration of alfaxalone against the response of the patient. Additional doses of alfaxalone, similar to those used for anesthetic maintenance (1.2 – 2.2 mg/kg IV), may be administered to facilitate intubation in the patient.[33]

Maintenance of anesthesia (label dosage; FDA-approved): Following induction of anesthesia with alfaxalone and intubation, anesthesia may be maintained using intermittent IV boluses or an inhalant anesthetic agent.[33] A maintenance bolus of 1.2 – 1.4 mg/kg provides an additional 6 to 8 minutes of anesthesia in preanesthetized dogs. A dose of 1.5 – 2.2 mg/kg IV provides an additional 6 to 8 minutes of anesthesia in nonpreanesthetized dogs. Clinical responses may vary and are determined by the dose, rate of administration, and frequency of maintenance injections. Administration of additional low doses, similar to maintenance doses, may

be required to facilitate the transition to inhalant maintenance anesthesia.[33]

Induction of general anesthesia (extra-label):
Without premedication, 3 mg/kg IV; with premedication, 2 mg/kg IV[41,42]

a) Following premedication with either medetomidine 4 µg/kg (0.004 mg/kg) IM or butorphanol 0.1 mg/kg IM, the average alfaxalone induction dose was 1.2 mg/kg IV. When medetomidine 4 µg/kg (0.004 mg/kg) is combined with butorphanol 0.1 mg/kg IM for premedication, the average alfaxalone induction dose was 0.8 mg/kg IV.[67]
b) Following premedication with methadone 0.2 mg/kg IM, the average alfaxalone dose required to permit endotracheal intubation was ≈1.7 mg/kg IV. When methadone 0.2 mg/kg is combined with dexmedetomidine 3 µg/kg (0.003 mg/kg) IM, the average alfaxalone induction dose was ≈1.4 mg/kg IV (a 16% reduction of the alfaxalone dose).[68]

Maintenance of anesthesia (extra-label):

a) Following induction, the dog should be intubated, and anesthesia maintained with alfaxalone or an inhalation anesthetic agent. Maintenance doses of alfaxalone may be given as supplemental boluses or as an IV CRI. If alfaxalone is being used for anesthetic maintenance for procedures that last more than 5 to 10 minutes, a butterfly needle or catheter can be securely placed in the vein, and small amounts of alfaxalone can be subsequently injected to maintain the required level and duration of anesthesia. Alfaxalone has been used safely and effectively in dogs for procedures that last up to 1 hour. In most cases, the average duration of recovery when alfaxalone is given for anesthetic maintenance is often longer than when an inhalant gas is used as a maintenance agent.[33,42] Following are dosages suggested for maintenance of anesthesia, based on data taken from controlled laboratory and field studies and that represent the average amount of drug required to provide maintenance anesthesia for dogs; however, the actual dose should be based on the response of the individual patient[42]:

Bolus dose for each 10 minutes of maintenance	Unpremedicated dogs	Premedicated dogs
mg/kg	1.3 – 1.5	1 – 1.2
mL/kg (using 10 mg/mL concentration)	0.13 – 0.15	0.1 – 0.12

IV CRI dose	Unpremedicated dogs	Premedicated dogs
mg/kg/*HOUR*	8 – 9	6 – 7
mg/kg/*minute*	0.13 – 0.15	0.1 – 0.12
mL/kg/*minute* (using 10 mg/mL concentration)	0.013 – 0.015	0.01 – 0.012

b) After administration of premedications and induction drugs, general anesthesia can be maintained with dosages of 0.16 – 0.2 mg/kg/*minute* IV CRI.[69] This range should be considered as a starting point and should be modified according to the patient's response.

Sedation for short procedures - intramuscular (extra-label): Alfaxalone 0.5 or 1 mg/kg combined with dexmedetomidine 3 µg/kg (0.003 mg/kg) and methadone 0.3 mg/kg and administered IM provided recumbency and sedation that was deeper and had a longer duration than dexmedetomidine and methadone at these doses without alfaxalone, but without differences between the two alfaxalone doses.[70] Decreases for all physiologic variables (eg, heart and respiratory rate, body temperature), except for noninvasive blood pressure, occurred and oxygen supplementation was provided due to the low SpO_2. Recoveries were deemed 'acceptable.'

Heavy sedation/light anesthesia - intramuscular (extra-label): Alfaxalone 1 – 2.5 mg/kg combined with medetomidine 0.005 mg/kg and butorphanol 0.3 mg/kg and administered IM provided anesthetic depth appropriate for intubation with clinically acceptable physiologic parameters.[71] Increasing the alfaxalone to 5 mg/kg IM caused extreme hypoxemia in some dogs; however, when only medetomidine OR butorphanol (at the same doses) were combined with alfaxalone at 2.5 – 5 mg/kg IM, extreme hypoxemia did not occur.

CATS:

Induction of general anesthesia (label dosage; FDA-approved): 2.2 – 9.7 mg/kg IV in cats with no preanesthetic agents given. In cats that received a preanesthetic drug, alfaxalone induction doses were reduced by 10% to 43%, depending on the combination of preanesthetic drugs given. Average induction doses ranged from 2.3 mg/kg IV in cats that received benzodiazepine/opioid/phenothiazine to 3.6 mg/kg IV in cats that received benzodiazepine/phenothiazine or an $alpha_2$-adrenergic agonist with or without a phenothiazine. The dose-sparing effect of alfaxalone depends on the potency, dose, and time of administration of the preanesthetic drugs used prior to induction. To avoid anesthetic overdose, titrate the administration of alfaxalone against the response of the patient. Additional doses of alfaxalone, similar to those used for anesthetic maintenance (1.1 – 1.5 mg/kg IV), may be administered to facilitate intubation of the patient.[33]

Maintenance of anesthesia (label dosage; FDA-approved): Following induction of anesthesia with alfaxalone and intubation, anesthesia may be maintained using intermittent IV boluses or an inhalant anesthetic agent. A maintenance bolus of 1.1 – 1.3 mg/kg provides an additional 7 to 8 minutes of anesthesia in preanesthetized cats. A dose of 1.4 – 1.5 mg/kg provides an additional 3 to 5 minutes of anesthesia in nonpreanesthetized cats. Clinical responses may vary and are determined by the dose, rate of administration, and frequency of maintenance injections. Administration of additional low doses, similar to maintenance doses, may be required to facilitate the transition to inhalant maintenance anesthesia.[33]

Induction (extra-label):

1. With or without premedication, 5 mg/kg IV[41,42]
2. Administration of a 'priming dose' of alfaxalone 0.25 mg/kg IV over 60 seconds to cats sedated with dexmedetomidine and methadone IM followed by alfaxalone induction administered at 0.5 mg/kg/*minute* IV CRI resulted in a ≈30% lower overall alfaxalone dosage required for orotracheal intubation.[72]

Maintenance of anesthesia (extra-label):

1. Following induction, the cat should be intubated, and anesthesia maintained with alfaxalone or an inhalation anesthetic agent. Maintenance doses of alfaxalone may be given as supplemental boluses or as an IV CRI. If alfaxalone is being used for anesthetic maintenance for procedures that last more than 5 to 10 minutes, a butterfly needle or catheter can be placed in the vein, and small amounts of alfaxalone can be subsequently injected to maintain the required level and duration of anesthesia. Alfaxalone has been used safely and effectively in cats for procedures that last up to 1 hour. In most cases,

the average duration of recovery when alfaxalone is given for anesthetic maintenance is often longer than when an inhalant gas is used as a maintenance agent.[42] Following are dosages suggested for maintenance of anesthesia, based on data taken from controlled laboratory and field studies and that represent the average amount of drug required to provide maintenance anesthesia for cats; however, the actual dose should be based on the response of the individual patient[42]:

Bolus dose for each 10 minutes of maintenance	Unpremedicated cats	Premedicated cats
mg/kg	1.6 – 1.8	1.1 – 1.3
mL/kg (using 10 mg/mL concentration)	0.16 – 0.18	0.11 – 0.13

IV CRI dose	Unpremedicated cats	Premedicated cats
mg/kg/*HOUR*	10 – 11	7 – 8
mg/kg/*minute*	0.16 – 0.18	0.11 – 0.13
mL/kg/*minute* (using 10 mg/mL concentration)	0.016 – 0.018	0.011 – 0.013

2. After administration of premedications and induction drugs, general anesthesia can be maintained with alfaxalone 0.16 – 0.2 mg/kg/*minute*.[73] This range should be considered as a starting point and should be modified according to the patient's response.
3. Two studies were conducted in cats undergoing ovariohysterectomy. In the first study, alfaxalone was given at 1.7 mg/kg IV at induction with medetomidine 20 µg/kg (0.02 mg/kg) IM and morphine 0.3 mg/kg IM followed by alfaxalone at 0.18 mg/kg/*minute* for maintenance.[74] In the second study, alfaxalone was given at 0.2 mg/kg IV every 20 seconds to effect with butorphanol 0.2 mg/kg IM and either acepromazine 0.1 mg/kg IM or medetomidine 20 µg/kg (0.02 mg/kg) IM followed by alfaxalone at 10 mg/kg/*HOUR* for maintenance.[75] A 3-step infusion regimen produced alfaxalone concentrations closer to the target concentration than a single infusion rate.[76]

Sedation for short procedures - subcutaneous (extra-label): In a study in hyperthyroid cats, alfaxalone 3 mg/kg and butorphanol 0.2 mg/kg were drawn up in the same syringe and administered as a single SC injection in the region dorsal to the right hip; maximum sedation occurred 45 minutes after the injection was given. Blood pressure, heart rate, and respiration rate were all significantly decreased. Blood pressure monitoring is recommended. Further studies are required to determine whether these sedative, respiratory, and cardiovascular effects are similar in euthyroid cats.[77]

Sedation for short procedures - intramuscular (extra-label): Alfaxalone 3 mg/kg, dexmedetomidine 10 µg/kg (0.01 mg/kg), and butorphanol 0.2 mg/kg were drawn up in the same syringe and administered IM in the lumbar muscle prior to castration. Respiration rate decreased significantly but SpO_2 remained within normal limits during the procedure. The rectal temperature also decreased significantly.[78] Another study using alfaxalone 1 mg/kg IM, dexmedetomidine 5 µg/kg (0.005 mg/kg) IM, and butorphanol 0.2 mg/kg IM reported a sedation time of 90 minutes with excellent recovery quality and acceptable cardiovascular stability.[79] Alfaxalone 1.5 mg/kg combined with hydromorphone 0.1 mg/kg and midazolam 0.2 mg/kg administered IM provided more profound sedation and easier IV catheterization than alfaxalone and hydromorphone without midazolam.[80]

Sedation for blood donation - intramuscular (extra-label): Alfaxalone 2 – 3 mg/kg combined with butorphanol 0.2 – 0.4 mg/kg and given IM for healthy cats undergoing blood donation[81,82]

Sedation for echocardiography - intramuscular (extra-label): Alfaxalone 2 mg/kg combined with methadone 0.3 mg/kg +/- ketamine 1 mg/kg administered IM to cats provided sedation with no clinically meaningful effects on echocardiographic variables.[83] Sedation with alfaxalone in combination with methadone was mild whereas the addition of ketamine provided adequate sedation for diagnostic procedures.

Heavy sedation/light anesthesia - intramuscular (extra-label): 5 – 10 mg/kg IM. Variability in response may be minimized by giving a deep IM injection in the quadriceps muscle mass.[41] Most practitioners deem this unacceptable because of the large volume of drug injected IM, which may cause discomfort to the cat.

EQUINE:

Induction of general anesthesia (extra-label):

a. Premedication with medetomidine 6 µg/kg (0.006 mg/kg) and midazolam 0.02 mg/kg followed by alfaxalone 1 mg/kg IV bolus over 10 seconds resulted in sternal recumbency 49 seconds (median) after injection, and recovery (ie, time to first attempt to stand) 44 minutes after administration.[84] In a subsequent study, horses were given alfaxalone 1 or 2 mg/kg IV following IV administration of the same premedications.[85] Recovery occurred in 50 minutes after alfaxalone 1 mg/kg and in 90 minutes after 2 mg/kg. Hypoxemia occurred with both doses but was more profound following 2 mg/kg.
b. In donkeys sedated with xylazine 2 mg/kg IM followed by alfaxalone 1 mg/kg IV and midazolam 0.05 mg/kg IV, times to lateral recumbency, first movement, and standing were 29 seconds, 27 minutes, and 58 minutes, respectively. Although an alfaxalone and midazolam combination was deemed acceptable, donkeys given midazolam and ketamine recovered more quickly and with better quality.[86]

Constant rate infusion (extra-label): In a study, horses were premedicated with medetomidine 5 µg/kg (0.005 mg/kg) in combination with midazolam 20 µg/kg (0.02 mg/kg) IV. Anesthesia was induced with rapid injection of 5% guaifenesin 100 mg/kg IV with alfaxalone 1 mg/kg IV. Anesthesia was maintained with sevoflurane and alfaxalone 0.5 mg/kg/*HOUR* IV CRI in combination with medetomidine 3 µg/kg/*HOUR* (0.003 mg/kg/*HOUR*) IV CRI; sevoflurane requirements were reduced by ≈25%, but 20% of horses given alfaxalone experienced an excitatory response during recovery.[13]

Total IV anesthesia (extra-label):

a. After IV premedication with acepromazine 0.03 mg/kg and xylazine 1 mg/kg and induction with IV guaifenesin 35 mg/kg and alfaxalone 1 mg/kg, alfaxalone IV infusion was started at 5 mg/kg/*HOUR*; median TIVA infusion rate was 3.1 mg/kg/*HOUR*. TIVA was maintained for 180 minutes. Six of the 8 horses exhibited muscle tremors and paddling following cessation of the infusion but all horses stood without incident on the first or second attempt with a good to excellent recovery.[52]
b. After premedication with medetomidine 5 µg/kg (0.005 mg/kg) IV and butorphanol 0.02 mg/kg IV, anesthesia was induced with guaifenesin 10 mg/kg IV followed by alfaxalone 1 mg/kg IV; anesthesia was maintained with

guaifenesin 80 mg/kg/HOUR IV CRI, medetomidine 3 µg/kg/HOUR (0.003 mg/kg/HOUR) IV CRI, and alfaxalone 1.5 mg/kg/HOUR IV CRI. Mild cardiorespiratory depression occurred, and supplemental oxygen was provided to prevent hypoxemia. Recovery was good to excellent.[53]

CATTLE:

Sedation (extra-label): Alfaxalone 1.2 mg/kg IV given to calves premedicated with xylazine 0.1 mg/kg IM produced smooth induction and facilitated endotracheal intubation.[51]

GOATS:

Induction of general anesthesia (extra-label): Induction of anesthesia with alfaxalone 2 mg/kg IV in combination with lidocaine 1 – 4 mg/kg IV was followed by alfaxalone 6.7 mg/kg/HOUR IV CRI and lidocaine 6 mg/kg/HOUR IV CRI.[32] In a separate study, xylazine premedication (0.05 mg/kg IV) decreased the alfaxalone induction dose from 4 mg/kg IV to 2.3 mg/kg IV, provided antinociception, and supported stable cardiovascular parameters; however, SpO_2 was decreased for 20 minutes, and supplemental oxygen was needed.[87]

RABBITS:

Deep sedation (extra-label):

a) Alfaxalone 2.5 mg/kg IM in adult healthy rabbits[88]
b) Deeper sedation occurred with alfaxalone 5 mg/kg in combination with dexmedetomidine 100 µg/kg (0.1 mg/kg) either IV or IM than with alfaxalone alone at the same dose/route.[89] As with other species, dose-dependent respiratory depression is common and supplemental oxygen is recommended.

Induction of general anesthesia (extra-label): In adult healthy rabbits, alfaxalone 6 mg/kg IM in combination with butorphanol 0.3 mg/kg and dexmedetomidine 200 µg/kg (0.2 mg/kg) IM produced recumbency and sedation with a more consistent and prolonged (57 ± 3 minutes) loss of toe-pinch response than alfaxalone alone or combined with midazolam or with either butorphanol or dexmedetomidine alone.[90]

FERRETS:

Induction of general anesthesia (extra-label): **NOTE**: Alfaxalone is NOT recommended to be used as a single agent or in combination with tramadol in ferrets.[91] Death may result if alfaxalone is used at doses greater than or equal to 10 – 20 mg/kg IV.[91]

a) Satisfactory anesthesia is provided when alfaxalone is administered at 2.5 mg/kg IV in combination with medetomidine 20 µg/kg (0.02 mg/kg) IM and lasts ≈60 minutes.[91]
b) Alfaxalone 2.5 or 5 mg/kg combined with butorphanol 0.2 mg/kg administered IM in the epaxial muscles of young healthy ferrets resulted in dose-dependent sedation with only minor cardiorespiratory depression.[92] Because of the large volume, the 5 mg/kg alfaxalone dose was divided and half injected into both left and right epaxial muscles.

Monitoring

- Level of anesthesia/CNS effects
- Ventilatory status (eg, respiratory rate/depth/pattern, mucous membrane color, SpO_2, $ETCO_2$)
- Cardiovascular status (eg, cardiac rate/rhythm, blood pressure)
- Body temperature
- Intraocular pressure as indicated in susceptible animals

Chemistry/Synonyms

Alfaxalone is 3-alpha-hydroxy-5-alpha-pregnane-11,20-dione and has a molecular weight of 332.5. Alfaxalone is a white to creamy white powder and is practically insoluble in water or mineral spirits, soluble in alcohol, and freely soluble in chloroform.

The commercial injectable formulations occur as clear, colorless sterile solutions. Alfaxalone is a water-soluble formulation that contains 2-hydroxypropyl-beta-cyclodextrin (HPCD) as the solubilizing agent. Another product containing alfaxalone, *Saffan®*, was marketed in the 1970s as an IV anesthetic agent for cats, but it contained a polyethoxylated castor oil as the solubilizing agent, which caused significant histamine release via mast cell degranulation. *Saffan®* was subsequently removed from the market.

Alfaxalone may also be known as alfaksaloni, alfaxalon, alfaxalona, alfaxalonum, alphaxalone, or GR-2/234. A common trade name is *Alfaxan®*.

Storage/Stability

Alfaxalone solutions for injection should be stored at a controlled room temperature of 20°C to 25°C (68°F-77°F) with excursions permitted between 15°C to 30°C (59°F-86°F). The Australia and New Zealand labels state *…contains no preservatives. Solution should be removed from the vial using aseptic technique. Contents of broached vials should preferably be used within 24 hours, but may be stored if necessary, at 4°C* [49.2°F] *for up to 7 days provided contamination is avoided. Do not use broached vials if the solution is not clear, colorless and free from particulate matter.*[41]

Alfaxalone multidose vials contain preservatives, including ethanol, benzethonium chloride, chlorocresol, and should be used within 28 days of when the vial is first punctured. Discard unused drug after 28 days. *Alfaxan® Multidose IDX*, which contains the same preservatives, is approved for 56 days of use after first vial puncture. A preservative-free formulation remains available in some countries.

As a controlled substance, alfaxalone must be stored in an area that is substantially constructed and securely locked in accordance with DEA regulations. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

The US product label states that it should not be mixed with other therapeutic agents prior to administration.[33] When the alfaxalone formulation containing preservatives is mixed with some drugs, including butorphanol, in the same syringe, anecdotal reports describe a cloudy nature to the injectate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Alfaxalone Injection: 10 mg/mL in 10 and 20 mL multidose vials; *Alfaxan® Multidose*; (Rx). FDA approved for use in cats and dogs; NADA #141-342. (Rx; C-IV).

Alfaxalone Injection: 10 mg/mL in 10 mL multidose vials; *Alfaxan® Multidose IDX*; (Rx). FDA indexed (MIF 900-031) for a use in a variety of non-food-producing minor species including reptiles, amphibians, ornamental fish, birds, non-human primates, rodents, mustelids, marsupials, and minor species ungulates. (Rx; C-IV)

HUMAN-LABELED PRODUCTS: NONE

Alfentanil

(al-***fen***-ta-nil) *Alfenta®*

Opioid Agonist

Prescriber Highlights

- ► Injectable, potent opioid that may be useful for adjunctive anesthesia and analgesia in dogs and cats
- ► Use with caution in patients with head injury, pulmonary disease or impaired respiration, or impaired hepatic or renal function.
- ► Limited veterinary experience and published data available to draw conclusions on adverse effects in veterinary species; bradycardia has been observed in dogs; cats and horses may experience CNS excitation.
- ► Overdoses are associated with CNS and respiratory depression; naloxone may be used to reverse opioid effects.
- ► Dose may need adjustment in geriatric patients and those with hepatic disease; obese patients should have dose calculated based on lean body weight.
- ► DEA Schedule II (C-II) controlled substance

Uses/Indications

An opioid analgesic, alfentanil may be a useful alternative to fentanyl for anesthesia, analgesia, or sedation in dogs and cats.

Pharmacology/Actions

Alfentanil is a potent mu opioid agonist with the typical opioid sedative, analgesic, and anesthetic properties. When comparing analgesic potencies after IM injection, alfentanil 0.4 – 0.8 mg is equivalent to fentanyl 0.1 – 0.2 mg and morphine ≈10 mg.

In dogs, the use of alfentanil decreased the required dose of propofol target-controlled infusion to maintain the animal under general anesthesia, but did not provide any cardiovascular benefits and increased the incidence of hypoxemia compared to propofol alone.[1] In cats, plasma alfentanil concentrations of 500 ng/mL decreased the isoflurane MAC by 16% to 35%.[2,3] No significant reduction in halothane MAC was observed with alfentanil use in horses.[4]

Pharmacokinetics

In dogs, the drug's steady state volume of distribution is ≈0.6 L/kg, clearance is ≈19 to 30 mL/kg/minute, and the terminal half-life is ≈20 to 60 minutes.[5,6] In cats, alfentanil's elimination half-life is ≈2 to 3 hours, volume of distribution (steady state) is ≈0.9 L/kg, and clearance is 12 mL/minute/kg.[7,8]

In humans, onset of anesthetic action occurs within 2 minutes after IV dosing and within 5 minutes of IM injection. Peak effects occur ≈15 minutes after IM injection. Alfentanil has a volume of distribution of 0.4 to 1 L/kg.[9] Approximately 90% of the drug is bound to plasma proteins. Alfentanil is primarily metabolized in the liver to inactive metabolites that are excreted by the kidneys into the urine; only ≈1% of the drug is excreted unchanged into the urine. Total body clearance in humans ranges from 1.6 to 17.6 mL/minute/kg. Clearance is decreased by ≈50% in patients with alcoholic cirrhosis or in those that are obese. Clearance is reduced by ≈30% in geriatric patients. Elimination half-life in humans is ≈100 minutes.[9] Veterinary significance of this human data is unclear.

Contraindications/Precautions/Warnings

Alfentanil is contraindicated in patients hypersensitive to opioids. In humans, initial dose reduction may be required in geriatric or debilitated patients, particularly those with diminished cardiopulmonary function; the dose for obese patients is calculated based on lean body weight.[9] Use with caution in patients with head injury, with pulmonary disease or impaired respiration, and with impaired hepatic or renal function.

Because of alfentanil's potency and potential for significant adverse effects, it should only be used in situations in which sufficient monitoring and patient support capabilities (eg, intubation, ventilation) are available.

Opioid analgesics are contraindicated in patients stung by scorpions (eg, *Centruroides* spp) as they may potentiate venom effects.[10]

Do not confuse alfentanil with fentanyl, remifentanil, or sufentanil. Because of the potency of alfentanil, the use of a tuberculin syringe to measure doses less than 1 mL, in addition to a double-check system for dose calculation and measurement, is recommended.

Adverse Effects

Limited information is available regarding alfentanil's adverse effect profile in veterinary patients, and adverse effects are expected to be dose-related and consistent with other opioid agonists. Although tachycardia and increased blood pressure have been observed in cats,[11] bradycardia has been reported in dogs.[5,12] Bradycardia is usually responsive to anticholinergic agents; however, one study in dogs found that concurrent atropine improved heart rate but increased the risk of hypotension.[13] Clinicians should consider administration of atropine prior to or together with alfentanil.

In conscious cats, mydriasis and excitement after an IV bolus has been noted[7]; healthy cats anesthetized with alfentanil-propofol combination had a significant decrease in blood pressure as compared to cats anesthetized with remifentanil-propofol.[14] Respiratory depression has been recorded in cats[11] and horses.[15] Increased blood pressure[4] and locomotor activity[16-18] has been observed after IV administration to horses.

In humans, common adverse effects include nausea, vomiting, bradycardia or tachycardia, hyper- or hypotension, apnea, and postoperative respiratory depression. Dose-related skeletal muscle rigidity can also occur, and neuromuscular blockers are routinely used when the patient is under general anesthesia and mechanically ventilated to counteract this effect. Alfentanil has rarely been associated with asystole, hypercarbia, and hypersensitivity reactions. Significance of these findings remains unclear in veterinary patients.

Reproductive/Nursing Safety

Placental transfer of alfentanil has been reported in humans.[9] When alfentanil is administered systemically to women directly before parturition, infants may show behavioral alterations (hypotonia, depression) associated with opioids. High alfentanil doses given to laboratory animals for 10 to 30 days have been associated with embryotoxicity, which may be due to direct effects of the drug caused by prolonged administration. Teratogenicity was not observed in rats or rabbits.[9]

Alfentanil is excreted into human breast milk; caution is advised when administering alfentanil to nursing women.[9]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Alfentanil LD_{50} in dogs is 60 – 88 mg/kg IV.[9] Severe overdoses may cause circulatory collapse, pulmonary edema, seizures, cardiac arrest, and death. Less severe overdoses may cause CNS and respiratory depression, coma, hypotension, muscle flaccidity, and miosis. Doses of 30 micrograms/kg IV have caused agitation, incoordination, and excitement in dogs.[19]

Treatment is a combination of supportive therapy, as necessary, and the administration of an opioid antagonist (eg, ***Naloxone***). Although alfentanil has a relatively rapid half-life, multiple doses of naloxone may be necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information

is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with alfentanil have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **acepromazine, amitriptyline, atropine, clomipramine, glycopyrrolate**): Concurrent use may increase risk for urinary retention, constipation, and CNS and respiratory depression.
- **Bethanechol:** Concurrent use may antagonize the beneficial effects of bethanechol on GI motility. Avoid combination.
- **Bradycardia-Causing Agents** (eg, **amiodarone, anesthetic agents**, **beta-adrenergic antagonists** [eg, **atenolol, propranolol**], **digoxin**): May produce bradycardia or hypotension if used concurrently with alfentanil
- **CNS Depressants** (eg, **anesthetic agents, barbiturates** [eg, **phenobarbital**], **benzodiazepines** [eg, **diazepam, midazolam**], **cannabidiol**): Concurrent use may increase the risk for CNS and/or respiratory depression. Monitor and adjust doses accordingly.
- **Desmopressin:** Concurrent use may increase concentrations of desmopressin and increase risk for water intoxication and/or hyponatremia, which can progress to seizures, coma, respiratory arrest, and death. Monitor electrolytes and renal function.
- **Diuretics** (eg, **furosemide**): Opioids may decrease therapeutic effects of diuretics.
- **Domperidone:** Concurrent use may antagonize the GI effects of domperidone.
- **Drugs That Induce Hepatic Isoenzymes** (eg, **griseofulvin, mitotane, phenobarbital**): Concurrent use may decrease concentration of alfentanil. Monitor clinical response and adjust dosages accordingly.
- **Drugs That Inhibit Hepatic Isoenzymes** (eg, **cimetidine, diltiazem, erythromycin, fluconazole, itraconazole, ketoconazole**): May increase the half-life and decrease the clearance of alfentanil leading to prolonged effects and an increased risk for respiratory depression. Monitor for adverse effects, and consider adjusting doses accordingly.
- **Highly Protein-Bound Drugs** (eg, **amiodarone, furosemide, NSAIDs** [eg, **carprofen, meloxicam**]): Because alfentanil is highly bound to plasma proteins (greater than 90%), it could theoretically displace other highly bound drugs, causing a transient increase in serum concentrations of each drug. These interactions are unlikely to be of clinical concern because increased free drug concentrations will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.
- **Hypotensive Agents** (eg, **amlodipine, enalapril, telmisartan**): Concurrent use may increase risk for bradycardia, hypotension, and orthostasis. Use combination with caution; monitor blood pressure and heart rate.
- **Ifosfamide:** Concurrent use may increase risk for neurotoxicity including somnolence, confusion, hallucinations, blurred vision, urinary incontinence, seizures, and coma. Use cautiously and monitor.
- **Iohexol:** Concurrent use of opioids with intrathecal iohexol may increase risk for seizures. Opioids should be withheld for 48 hours before and 24 hours after intrathecal administration of iohexol.
- **Loperamide:** Concurrent use may increase risk for constipation.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, selegiline**): Concurrent use may increase risk for anxiety, confusion, hypotension, respiratory depression, cyanosis, and coma. MAOIs should be withheld for 14 days prior to administration of opioids. Avoid combination.
- **Neuromuscular Blocking Agents** (eg, **atracurium, pancuronium**): Concurrent use may increase risk for tachycardia, bradycardia, and/or hypotension. Use combination with caution; monitor heart rate and blood pressure.
- **Prokinetic Agents** (eg, **cisapride, erythromycin, metoclopramide**)**:** Concurrent use may antagonize the prokinetic effects.

Laboratory Considerations

- Opioids may increase biliary tract pressure, resulting in increased plasma **amylase** and **lipase** values up to 24 hours following their administration.

Dosages

NOTE: In obese patients, calculate doses based on lean body weight.

DOGS:

Anesthetic premedication (extra-label): Alfentanil 5 – 10 µg/kg IV[20,21]

Analgesia (extra-label)**:**

a. Loading dose of alfentanil 0.5 – 1 µg/kg IV followed by alfentanil 0.5 – 1 µg/kg/minute IV CRI[22]
b. Intraoperative analgesia in patients with intracranial disease: 0.2 µg/kg/minute IV[23]

Anesthetic agent (extra-label)**:**

a) Induction dose following premedication (choose one)
   i. Alfentanil 2.1 – 10 µg/kg in combination with propofol 2 mg/kg and administered IV [13,24] OR
   ii. Alfentanil 1 – 40 µg/kg IV in combination with midazolam[19]

b) Maintenance dose (choose one)
   i. Less than or equal to alfentanil 1 µg/kg/min IV CRI with concurrent propofol 0.4 mg/kg/min IV CRI (using 2 separate fluid pumps)[25] OR
   ii. Alfentanil 4 – 5 micrograms/kg/min IV CRI with concurrent midazolam 0.005 mg/kg/min IV CRI (using 2 separate fluid pumps)[19]

c) Adjunct to anesthesia: Alfentanil 2 – 5 µg/kg IV every 20 minutes[20,26]

CATS:

Analgesic adjunct to anesthesia (extra-label): Loading dose of alfentanil 5 – 10 µg/kg IV followed by alfentanil 0.8 – 1 µg/kg per minute IV CRI.[14,27] In both studies, anesthesia was induced with propofol and maintenance with alfentanil-propofol combination began 20 minutes after induction.

Monitoring

- Anesthetic and/or analgesic efficacy
- Cardiac and respiratory rate; blood pressure
- Pulse oximetry or other methods to measure blood oxygenation when used for anesthesia

Client Information

- Alfentanil is a potent opioid that should only be used under the guidance of licensed veterinarians in a setting where adequate patient monitoring is available.

Chemistry/Synonyms

A phenylpiperidine opioid anesthetic-analgesic related to fentanyl, alfentanil HCl occurs as a white to off-white powder. It is freely soluble in alcohol, water, chloroform, or methanol. The commercially available injection has a pH of 4 to 6 and contains sodium chloride for isotonicity. Alfentanil is more lipid soluble than morphine, but less so than fentanyl.

Alfentanil may also be known as alfentanyl, *Alfenta®*, *Alfast®*, *Fanaxal®*, *Fentalim®*, *Limifen®*, or *Rapifen®*.

Storage/Stability

Alfentanil injection should be stored protected from light at controlled room temperature (20°C-25°C; 68°F-77°F).

Alfentanil is a DEA schedule II controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

In concentrations up to 80 µg/mL, alfentanil injection has been shown to be **compatible** with sodium chloride 0.9%, dextrose 5%, dextrose 5% in sodium chloride 0.9%, and lactated Ringer's solution.[9]

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 1 substance. See the ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Alfentanil HCl for injection: 500 µg (as base)/mL in 2 mL, 5 mL, 10 mL, and 20 mL ampules; preservative-free; *Alfenta®*, generic; (Rx, C-II)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Allopurinol

(al-oh-***pyoor***-i-nol) *Zyloprim®*

Xanthine Oxidase Inhibitor; Purine Analogue

Prescriber Highlights

- ► Used to reduce uric acid in dogs, cats, reptiles, and birds; adjunctive treatment for leishmaniasis in dogs and cats
- ► Use with caution in patients with renal or hepatic dysfunction.
- ► Contraindicated in red-tailed hawks and should be used with caution, if at all, in other raptors
- ► A low purine diet is recommended with long-term treatment.
- ► Most common adverse effects are GI-related, but hypersensitivity reactions, increased liver enzymes, or renal events (eg, mineralization, uroliths) can occur.
- ► Many potential drug interactions

Uses/Indications

The primary veterinary uses for allopurinol are for the treatment and prevention of recurrent uric acid and hyperuricosuric calcium oxalate uroliths in dogs, particularly Dalmatians. It has also been used to treat gout in pet birds and reptiles.[1]

Allopurinol has been used as an alternative treatment for canine and feline leishmaniasis. Although it appears to have moderate clinical efficacy, treatment duration is several months and does not result in a full cure.[2]

There are also minimal data to support its use to treat trypanosomiasis infections.[3]

Pharmacology/Actions

Allopurinol and its metabolite, oxypurinol, inhibit the enzyme xanthine oxidase, which is responsible for the conversion of oxypurines (eg, hypoxanthine, xanthine) to uric acid. Allopurinol does not increase the renal excretion of uric acid, nor does it possess any anti-inflammatory or analgesic activity.

Allopurinol inhibits *Leishmania* spp activity by limiting available purines in the host that are required for protozoal survival. Allopurinol is taken up by the protozoa and metabolized into a toxic compound (4-amino-pyrazole-pyrimidine), which incorporates into the parasite's RNA, causing death.[4,5]

Allopurinol, by inhibiting xanthine oxidase, can inhibit the formation of superoxide anion radicals and provide protection against hemorrhagic shock and myocardial ischemia in laboratory conditions. However, the clinical use of the drug in cardiovascular diseases requires further study.[6]

Pharmacokinetics

In dogs, oral bioavailability was similar to that in humans (≈90%) with a serum half-life of ≈2 and 4 hours for allopurinol and oxypurinol, respectively. Food does not appear to alter absorption. Absorption is non-linear with oral and intravenous administration and therefore high doses are not recommended.[7] In Dalmatians, absorption rates were variable between subjects, with peak levels occurring within 1 to 3 hours after oral dosing. Elimination half-life is ≈2.7 hours.[8] The drug exhibits good systemic absorption, but CNS penetration is limited.

In horses, oral bioavailability of allopurinol is ≈15% and the drug is rapidly converted to oxypurinol.[9] Elimination half-life is ≈5 to 6 minutes for allopurinol and ≈1.1 hours for oxypurinol.

Neither allopurinol nor oxypurinol are bound to plasma proteins, but both drugs are excreted into milk.

Contraindications/Precautions/Warnings

Allopurinol is contraindicated in patients with previous hypersensitivity reactions and should be used with caution in patients with hepatic or renal dysfunction. Dosage reductions and increased monitoring are warranted in these cases.

Allopurinol does not appear to be effective in dissolving urate uroliths in dogs with portovascular anomalies.[10,11]

This drug is not recommended for use in red-tailed hawks. Dosages of 50 mg/kg PO once daily caused clinical signs of vomiting and hyperuricemia with renal dysfunction. Dosages of 25 mg/kg PO once daily were safe but not effective in reducing plasma uric acid.[12] Use with caution in other raptors.

Adverse Effects

Adverse effects in dogs are uncommon with allopurinol when fed low purine diets. Xanthine coatings have formed around ammonium urate uroliths in dogs consuming purines. Xanthinuria has been noted in dogs receiving allopurinol for the treatment of leishmaniasis.[13,14] Renal mineralization and urolithiasis were also noted in 6% of dogs.[14] Prolonged allopurinol at doses greater than 30 mg/kg/day may result in xanthine urolithiasis.[10] Consider a low purine diet if allopurinol is required for chronic therapy.[15] Adverse GI effects may include nausea, vomiting, anorexia, or diarrhea.

In humans, the most common adverse effects include rash, diarrhea, nausea, acute gout attacks, and ALT/AST elevations. Other less common adverse effects include bone marrow suppression, severe dermatologic reactions, hepatitis, and vasculitis. Humans with renal dysfunction are at risk for further decreases in renal function and other severe adverse effects unless dosages are reduced.

Reproductive/Nursing Safety

Although the safe use of allopurinol during pregnancy has not been established, dosages up to 20 times normal in rats and rabbits have not demonstrated decreases in fertility or evidence of fetal harm. Intraperitoneal administration to pregnant mice was associated with increased fetal death and malformations.

Allopurinol and oxypurinol are excreted into milk; use caution when allopurinol is administered to a nursing dam.

Overdose/Acute Toxicity

One source lists the allopurinol oral LD_{50} in mice as 78 mg/kg,[16-18] whereas other sources list 500 – 700 mg/kg. Clinical signs associated with overdose can include vomiting (seen in dogs at doses of more than 44 mg/kg) and trembling. There is no known antidote for allopurinol, but it is dialyzable.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with allopurinol have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aluminum Hydroxide**: May decrease absorption of allopurinol
- **Angiotensin-Converting Enzyme Inhibitors** (**ACEIs;** eg, **benazepril, enalapril**): In humans, this combination may increase risk for hypersensitivity reactions to allopurinol. The veterinary significance of this interaction is unknown.
- **Aminopenicillins** (eg, **amoxicillin, ampicillin**): In humans, this combination may increase risk for hypersensitivity reactions to allopurinol. The veterinary significance of this interaction is unknown.
- **Azathioprine** or **Mercaptopurine**: Allopurinol may increase the serum concentration of mercaptopurine (azathioprine's active metabolite) and promote formation of active thioguanine nucleotides. Consider therapy modification or reduce the dose of immunosuppressive agent by 25% to 33% initially.
- **Cyclophosphamide**: Increased risk for bone marrow suppression
- **Cyclosporine**: Increased cyclosporine concentration may occur.
- **Diuretics** (eg, **chlorothiazide, furosemide, hydrochlorothiazide**): May increase serum concentration of allopurinol
- **Theophylline/Aminophylline**: Allopurinol may decrease metabolism, thereby increasing their serum levels.
- **Uricosuric Agents** (eg, **probenecid, sulfinpyrazone**): May increase the renal excretion of oxypurinol and thereby reduce xanthine oxidase inhibition; in treatment of hyperuricemia, the additive effects on blood uric acid may be beneficial.
- **Urinary Acidifiers** (eg, **ammonium chloride, methionine**): May reduce the solubility of uric acid in the urine and induce urolithiasis

Dosages

DOGS:

Dissolution of urate uroliths (extra-label): 15 mg/kg PO every 12 hours for up to 4 weeks.[11] Use in conjunction with low-purine, alkalinizing, diuretic diets.

Prevention of urate uroliths (extra-label): 5 – 7 mg/kg PO every 12 to 24 hours.[11] **NOTE:** Prolonged high doses of allopurinol may result in xanthine uroliths; use in conjunction with increased water intake and low-purine, alkalinizing, diuretic diets to reduce recurrences and lessen need to use intermittent higher dose dissolution protocols.

Leishmaniasis (extra-label): Improved efficacy when used in combination with an antimonial drug

a) Allopurinol 10 – 15 mg/kg PO twice daily for 6 to 12 months plus meglumine antimoniate (N-methylglucamine antimoniate) 75 – 100 mg/kg SC once daily for 1 to 2 months.[19]

b) Alternatively, allopurinol 10 – 15 mg/kg PO twice daily for 6 to 12 months plus miltefosine 2 mg/kg PO once daily for 4 weeks[20,21]

c) As monotherapy, dosages range from 5 – 20 mg/kg PO every 12 hours for 2 to 24 months.[4] **NOTE:** Initiate allopurinol at 5 mg/kg PO twice daily in dogs with renal dysfunction.

CATS:

Leishmaniasis (extra-label): 10 – 20 mg/kg PO every 12 or 24 hours long-term[22]

BIRDS:

Gout (extra-label):

a) Highly variable dosages (300 – 830 mg/L) for drinking water administration have been reported.[23]

b) **In budgies and cockatiels**: Crush one 100 mg tablet into 10 mL of water. Add 20 drops of this solution to 30 mL (1 oz) of drinking water.[24]

c) **In parakeets**: As above for budgies and cockatiels or give 1 drop 4 times daily.[25]

REPTILES:

Gout in lizards or iguanas (extra-label): 20 – 25 mg/kg PO once daily.[1] Reported dosages in reptiles range from 10 to 50 mg/kg.[23]

Monitoring

- Hydration status
- Baseline and periodic CBC and serum chemistry profile
- Baseline and periodic urinalysis (including pH) to check if urine pH is greater than or equal to 7
- Periodic urinary tract imaging (eg, ultrasound) to monitor for recurrence of calculi
- In dogs with leishmaniasis, monitor clinical response, reduction in UPPC,[26-28] saliva IgG2 and IgA antibodies,[29] and normalization of acute-phase proteins (eg, C-reactive protein, haptoglobin, ferritin, paraoxanase).[30]

Laboratory Considerations

- None

Client Information

- May be given with food if vomiting occurs
- Always provide access to fresh clean water while your animal is taking this medicine.
- When this drug is used long-term in dogs, low-purine diets are recommended.
- Contact your veterinarian immediately if you observe a rash, unusual tiredness, or yellowing of the whites of the eyes.
- If using in drinking water for birds or reptiles, make a fresh solution every day.

Chemistry/Synonyms

A xanthine oxidase inhibitor, allopurinol occurs as a tasteless, fluffy white to off-white powder with a slight odor. Its melting point is more than 350°C (662°F) and it has a pK_a of 9.4. Oxypurinol, its active metabolite, has a pK_a of 7.7. Allopurinol is very slightly soluble in water and alcohol and insoluble in diethyl ether.

Allopurinol may also be known as allopurinolum, BW-56-158, HPP, or NSC-1390; many trade names are available.

Storage/Stability

Allopurinol tablets should be stored between 20°C to 25°C (68°F to 77°F) in tightly closed containers and protected from light.[31]

Compatibility/Compounding Considerations

Compounded preparation stability: An extemporaneous suspension for oral use can be prepared from the commercially available tablets. Triturate eight 300 mg tablets of allopurinol with 60 mL of *Ora-Plus*® and qs ad to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® *SF*). This formulation yields a 20 mg/mL suspension that retains more than 95% potency for at least 60 days stored at both 5°C (41°F) and 25°C (77°F). Compounded preparations of allopurinol should be protected from light.[32]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The FEI (International Federation for Equestrian Sports) lists this drug as a "prohibited substance - banned."[33]

HUMAN-LABELED PRODUCTS:

Allopurinol Oral Tablets: 100 and 300 mg; *Zyloprim*® generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Alprazolam

(al-***prah***-zoe-lam) *Xanax*®

Benzodiazepine

Prescriber Highlights

- ► Oral benzodiazepine that may be useful for adjunctive behavioral treatment in dogs and cats
- ► Contraindicated in aggressive animals (controversial) and animals with benzodiazepine hypersensitivity
- ► Use with caution in patients with hepatic or renal disease
- ► Adverse effects include sedation, unintended negative behavior changes, and paradoxical responses. Physical dependence is a possibility. May impede training or performance of working animals
- ► Many drug interactions are possible.
- ► DEA Schedule IV (C-IV) controlled substance

Uses/Indications

Alprazolam may be useful for adjunctive therapy in anxious and/or aggressive dogs or in dogs that demonstrate panic reactions and for managing anxiety while a long-term drug (eg, selective serotonin reuptake inhibitor [SSRI], other serotonin-enhancing drug) reaches therapeutic concentrations.[1,2] When alprazolam is used to treat anxiety related to a triggering event (eg, storm, fireworks), it is most effective when administered 30 to 60 minutes prior to the event. Alprazolam may be useful in cats for adjunctive treatment of anxiety disorders and inappropriate elimination, and, unlike oral diazepam, alprazolam has not been implicated in causing liver failure in cats. A case report described the successful use of alprazolam to facilitate bonding in a mare that was aggressive when her foal attempted to nurse.[3]

At low doses, alprazolam may have less of an effect on motor function than diazepam.

Pharmacology/Actions

Alprazolam exhibits similar pharmacologic actions as other benzodiazepines; subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed, which produces anxiolytic, sedative, skeletal muscle relaxant, and anticonvulsant effects. The exact mechanism of action is unknown, but postulated mechanisms include antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS.

Benzodiazepine-specific receptors have been located in the mammalian brain, kidney, liver, lungs, and heart. In all species studied, receptors are lacking in the white matter.

Pharmacokinetics

The pharmacokinetics of alprazolam have not been described for dogs or cats.

In adult horses, alprazolam was detected in serum 30 minutes after administration of a single oral dose (0.04 mg/kg), and peak plasma levels occurred in a median of 3 hours. Elimination half-life was ≈16 hours.[4]

In humans, alprazolam is well absorbed with peak plasma concentrations occurring in 1 to 2 hours. Alprazolam is widely distributed throughout the body and readily crosses the blood-brain barrier; it is 80% bound to plasma proteins. It is metabolized in the liver primarily by cytochrome P450 3A4 (CYP3A4) to at least 2 metabolites, including alpha-hydroxy-alprazolam, which is pharmacologically active.[5] Elimination half-lives range from 6 to 27 hours; half-life is extended in cases of hepatic disfunction and obesity. Alprazolam is primarily excreted in the urine as unchanged drug and metabolites.

Contraindications/Precautions/Warnings

Alprazolam is contraindicated in patients with known hypersensitivity to the drug. Some clinicians also believe that benzodiazepines are contraindicated in aggressive dogs, as anxiety may restrain the animal from aggressive tendencies; however, this remains controversial.[6] Some clinicians recommend administering alprazolam for the first time at the clinic with the owner present to monitor for adverse effects (eg, excessive sedation) or for a paradoxical reaction (ie, worsening of clinical signs [eg, CNS excitement, including increased excitability, aggression, and anxiety]) to the drug. If unacceptable sedation occurs, the dosage can be lowered. If a paradoxical response occurs, alprazolam may not be an acceptable treatment for that animal; however, it has been suggested that higher dosages may alleviate the paradoxical reaction.[6] Caution is advised in debilitated or geriatric patients and patients with hepatic or renal disease or narrow-angle glaucoma. Benzodiazepines may impair the abilities of working animals.

Chronic use of alprazolam may induce physical dependence,[7] and if the drug is to be discontinued, the dosage must be gradually decreased (tapered) over several weeks.

Alprazolam, like other benzodiazepines, has the potential for drug abuse and drug diversion in humans; caution is advised when prescribing this drug.

Adverse Effects

Benzodiazepines can cause sedation, increased appetite, and transient ataxia. Animals may rarely exhibit a paradoxical response following administration. See ***Contraindications/Precautions/Warnings***.

There have been sporadic reports of cats developing idiosyncratic hepatic failure after receiving oral, but not injectable, diazepam (not dose-dependent) for several days.[8] See ***Diazepam*** for more information related to hepatic changes that may occur. Although this adverse effect has not been reported for alprazolam, oral benzodiazepines should be used with caution in cats. See ***Monitoring***.

Benzodiazepines have an amnestic effect which may impede the ability of the animal to learn and may delay training.[5,6]

Reproductive/Nursing Safety

Diazepam and other benzodiazepines have been implicated in causing congenital abnormalities in humans when they are administered during the first trimester of pregnancy. Infants born to mothers that received large doses of benzodiazepines shortly before delivery have been reported to suffer from apnea, impaired metabolic response to cold stress, difficulty in feeding, hyperbilirubinemia, and hypotonia.[5] Withdrawal symptoms have occurred in infants whose mothers took

benzodiazepines chronically during pregnancy. The veterinary significance of these effects is unclear, but the use of these agents during the first trimester of pregnancy should only occur when the benefits clearly outweigh the risks associated with their use.

Alprazolam enters human breast milk. Case reports have noted drowsiness, depression, and withdrawal symptoms in infants exposed to alprazolam while breastfeeding.[5] In humans, alprazolam is not recommended while breastfeeding.[9]

Because safety of alprazolam has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdoses of alprazolam are generally limited to CNS signs. CNS depression can be seen, and the severity is generally dose-dependent. Hypotension, respiratory depression, and cardiac arrest have been reported in humans but apparently are rare. The acute LD_{50} in rats for alprazolam is greater than 330 mg/kg.[10] Life-threatening signs in small animals are rare. Some animals may be presented with a paradoxical-type reaction (eg, disorientation, vocalization, agitation). At times, those signs may be followed by CNS depression.

Common clinical signs seen in dogs with alprazolam overdose include ataxia, hyperactivity/agitation, lethargy/sedation, and vomiting; in cats, the common clinical signs include ataxia, vocalization, agitation, polyphagia, and lethargy.

Massive overdoses can lead to CNS and respiratory depression or hypotension. Gastric decontamination can be considered. The decision to give activated charcoal should be weighed carefully, as, in some cases, there is a risk for aspiration pneumonia in an obtunded patient, which may outweigh the benefit. Use of analeptic agents (eg, caffeine, doxapram) is generally not recommended. Flumazenil can be used to reverse respiratory depression or severe CNS depression. The half-life of flumazenil is short, and the animal may require multiple doses of the drug. See ***Flumazenil.***

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with alprazolam have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risk must be weighed and additional monitoring performed when appropriate.

- **Amiodarone**: Concurrent use may increase bioavailability and pharmacologic effects of benzodiazepines. Sedation levels should be monitored, and benzodiazepine doses adjusted accordingly.
- **Antacids, Aluminum-, Calcium- and Magnesium-Containing**: May slow the rate but not the extent of oral absorption; administering antacids 2 hours apart from alprazolam may help avoid this potential interaction
- **Antihypertensive Agents** (eg, **amlodipine, enalapril, telmisartan**): May increase risk for hypotension and orthostasis. Blood pressure monitoring is needed.
- **Azole Antifungals** (eg, **fluconazole, itraconazole, ketoconazole**): Metabolism of alprazolam may be decreased, and excessive sedation may occur. This combination is contraindicated in humans.
- **Carbonic Anhydrase Inhibitors (CAIs)** (eg, **acetazolamide**, **methazolamide**): Benzodiazepines may interfere with the beneficial effects of CAIs by inhibiting respiratory responses to hypoxia; combination should be avoided.
- **CNS Depressant Agents** (eg, **anesthetic agents, antihistamines** (first generation), **barbiturates, cannabidiol, narcotics**): Combination may increase the risk for CNS and/or respiratory depression. Sedation levels should be monitored and doses adjusted accordingly.
- **Digoxin**: Serum digoxin concentrations may be increased; monitor serum digoxin concentrations and for clinical signs associated with digoxin toxicity (eg, arrhythmias, vomiting, diarrhea, inappetence).
- **Fluoxetine, Fluvoxamine**: Metabolism of alprazolam may be decreased and cause excessive sedation.
- **Hepatic Enzyme Inducers** (eg, **dexamethasone, mitotane**): Concurrent use may decrease benzodiazepine concentrations. Clinical response should be monitored and doses adjusted accordingly.
- **Hepatic Enzyme Inhibitors** (eg, **cimetidine, diltiazem, grapefruit juice, isoniazid**): Metabolism of alprazolam may be decreased and cause excessive sedation.
- **Ifosfamide:** Concurrent use may increase the risk for ifosfamide-induced neurotoxic effects. Careful monitoring of the level of sedation is recommended, and both drugs should be discontinued if signs of encephalopathy occur.
- **Macrolide Antibiotics** (eg, **clarithromycin, erythromycin**): Metabolism of alprazolam may be decreased, and excessive sedation may occur.
- **Macrocyclic Lactones** (eg, **ivermectin, milbemycin oxime**): Benzodiazepine effects may be potentiated by concurrent macrocyclic lactone use.
- **Maropitant:** Concurrent benzodiazepine administration with the human drug aprepitant may increase benzodiazepine exposure via inhibition of CYP3A4. Interaction may apply to maropitant.
- **Non-Depolarizing Neuromuscular Blockers** (eg, **atracurium, pancuronium**): Concurrent use may potentiate, attenuate, or have no effect. Respiratory status should be monitored.
- **Opioids** (eg, **buprenorphine, hydromorphone, tramadol**): May increase the risk for cardiorespiratory and CNS depression
- **Phenobarbital:** Concurrent use of phenobarbital and benzodiazepines may increase the risk for respiratory depression.
- **Propofol:** May increase the risk for cardiorespiratory depression
- **Rifampin:** May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines
- **Theophylline/Aminophylline:** Concurrent use may decrease the levels and effectiveness of benzodiazepines. Withdrawing theophylline from a stable patient may increase the risk for benzodiazepine toxicity. Sedation levels should be monitored and doses adjusted accordingly.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine, imipramine**): Alprazolam may increase concentrations of these drugs; clinical significance is not known, and clomipramine and alprazolam have been used together anecdotally to manage phobias (eg, thunderstorm phobia). However, concurrent use may increase the risk for CNS and/or respiratory depression. Anticholinergic effects may be additive.
- **Yohimbine:** Limited data indicate that yohimbine may decrease therapeutic effects of anxiolytic drugs.

Laboratory Considerations

- Benzodiazepines may decrease the thyroidal uptake of I^{123} or I^{131}.

Dosages

DOGS:

Adjunctive treatment of canine anxiety disorders or phobias (extra-label): 0.02 – 0.1 mg/kg (usually 0.02 – 0.05 mg/kg initially) PO every 6 to 12 hours as needed. If used for acute phobias (eg, fireworks, thunderstorms), the drug should be given 30 to 60 minutes before the expected trigger.

CATS:

Adjunctive treatment of feline anxiety disorders, phobias, or house soiling/marking (extra-label): 0.125 – 0.25 mg/cat (NOT mg/kg) PO every 8 to 24 hours. If used for phobias, the drug should be given 30 to 60 minutes before the expected trigger.

Adjunctive treatment of highly aroused felines before transport to a veterinary visit (extra-label): 0.5 – 1 mg/cat (NOT mg/kg) 1 hour prior to leaving for veterinary visit[11]

HORSES:

Facilitating mare-foal bonding (extra-label): One case study reported 0.035 mg/kg PO every 8 to 12 hours for facilitating healthy mare–foal bonding and behavior in an aggressive mare.[3]

Monitoring

- Efficacy
- Adverse effects
- Monitoring hepatic enzymes should be considered, particularly with chronic therapy.

Client Information

- Alprazolam is often used to help treat or prevent fears and anxiety in dogs and cats.
- When alprazolam is used for thunderstorm phobias or other triggers (eg, separation anxiety) that upset your animal, try to give your animal the drug about 30 to 60 minutes before the triggering event.
- This medicine may be given with or without food. If your animal vomits or acts sick after receiving the drug on an empty stomach, try giving the next dose with food or a small treat. If vomiting continues, contact your veterinarian.
- Contact your veterinarian immediately if you see yellowing of the whites of the eyes of your animal or if your animal's gums have a yellowish tint.
- Sleepiness is the most common side effect, but sometimes the drug can change behavior or work in the opposite way (ie, cause hyperactive behavior) from what is expected.
- This drug may increase appetite, especially in cats.
- Alprazolam is classified as a schedule IV (C-IV) controlled drug by the federal Drug Enforcement Agency (DEA). Use of this medication in animals or humans other than those for whom it is prescribed is illegal.

Chemistry/Synonyms

Alprazolam is a benzodiazepine. It occurs as a white to off-white crystalline powder and is soluble in alcohol and insoluble in water.

Alprazolam may also be known as D65 MT, U 31889, or alprazolamum; many trade names are available internationally.

Storage/Stability

Alprazolam tablets should be stored at room temperature in tight, light-resistant containers. The orally disintegrating tablets should be stored at room temperature and protected from moisture. The oral solution should be stored at room temperature, protected from light, and discarded 90 days after opening. Alprazolam is a DEA Schedule IV (C-IV) controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

Compounded preparation stability: An alprazolam oral suspension compounded from commercially available tablets has been published.[12] Triturating sixty (60) alprazolam 2 mg tablets with 60 mL of *Ora-Plus®* and *qs ad* to 120 mL with *Ora-Sweet®* (or *Ora-Sweet®* SF) yields a 1 mg/mL oral suspension that retains more than 90% potency for 60 days when stored at 5°C (41°F) and 25°C (77°F). Compounded preparations of alprazolam should be protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Alprazolam Oral Tablets: 0.25 mg, 0.5 mg, 1 mg, and 2 mg; *Xanax®*, generic; (Rx; C-IV)

Alprazolam Extended-release Oral Tablets: 0.5 mg, 1 mg, 2 mg, and 3 mg; *Xanax XR®*, generic; (Rx; C-IV)

Alprazolam Orally Disintegrating Tablets: 0.25 mg, 0.5 mg, 1 mg, and 2 mg; *Niravam®*, generic; (Rx; C-IV)

Alprazolam Oral Solution: 1 mg/mL in 30 mL; *Alprazolam Intensol®*; (Rx; C-IV)

For the complete list of references, see **wiley.com/go/budde/plumb**

Altrenogest

(al-***tre***-noe-jest) *Regu-Mate®, Matrix®*

Oral Progestin

Prescriber Highlights

- ► Used in mares to suppress estrus or maintain pregnancy in those that are progestin deficient
- ► Used in swine to synchronize estrus
- ► Contraindicated in mares or gilts with previous or current uterine inflammation
- ► May be used in dogs for luteal deficiency or to prevent premature delivery
- ► Readily absorbed by the skin; wear protective gloves (not latex) when handling
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies progestins as hazardous drugs; use appropriate precautions when handling.

Uses/Indications

Altrenogest is FDA-approved for use in mares to suppress estrus and allow a more predictable occurrence of estrus following withdrawal of the drug.[1] It is used clinically to establish normal estrous cycles at the end of the transitional period from anestrus to the normal breeding season, to facilitate management of prolonged estrus conditions, or to facilitate scheduled breeding; it also helps maintain high-risk pregnancies (eg, placentitis, history of early embryonic loss, embryo transfer recipients). Mares with considerable follicular activity (mares with 1 or more follicles that are 20 mm or greater in size) are more likely to respond to altrenogest than are mares with inactive ovaries and small follicles.[1] Mares that have been in estrus for 10 days or more and have active ovaries are also considered excellent candidates for progestin treatment.

Altrenogest has been demonstrated to maintain pregnancy in ovariectomized mares and may be of benefit in mares that abort due to subtherapeutic progestin levels.[2]

Some altrenogest products are FDA-approved for synchronization of estrus in sexually mature gilts that have had at least 1 estrous cycle.[3] It has been shown that feeding altrenogest to sows that are nursing small litters during late lactation improves fertility and increases ovulation rate and subsequent litter size.[4]

Altrenogest has been used extra-label in dogs for luteal insufficiency and as a treatment to prevent premature delivery.

Pharmacology/Actions

Endogenous progestins are primarily produced by the corpus luteum; they transform proliferative endometrium to secretory endometrium, enhance myometrial hypertrophy, and inhibit spontaneous uterine contraction. Altrenogest acts via negative feedback to decrease plasma concentrations of endogenous gonadotrophin hormones (LH and FSH). Low gonadotrophin concentrations cause regression of large follicles and do not allow the growth of small follicles, resulting in an absence of estrus and ovulation during treatment. When treatment is discontinued, plasma LH concentration increases to stimulate follicular growth and maturation.

In normally cycling mares, altrenogest is effective for minimizing the necessity for estrus detection, for the synchronization of estrus, and for permitting scheduled breeding. Estrus typically occurs 2 to 5 days after treatment is completed and most mares ovulate between 8 to 15 days after withdrawal.

Progestins have some degree of estrogenic, anabolic, and androgenic activity.

Pharmacokinetics

After oral dosing of altrenogest 0.044 mg/kg PO (recommended dose) in horses, the time to peak concentration has been reported to range from 15 minutes to 4 hours.[5] Elimination half-life has been reported to be between 2.5 and 8.5 hours.[6] Altrenogest appears to be primarily eliminated in the urine. Peak urine concentrations occur 3 to 6 hours after oral dosing. Urine concentrations were detectable up to 12 days postadministration. Altrenogest 150 mg IM produced peak serum concentrations between 9 and 24 hours postdose.[7] The elimination half-life was ≈15 hours and plasma concentrations remained above 0.5 ng/mL for 148 hours after dosing.

Altrenogest has been shown to be rapidly absorbed after rectal administration to horses; however, rectal administration results in decreased bioavailability and shorter half-life and time at therapeutic concentration than oral dosing.[6]

In gilts that were given altrenogest 20 mg/kg PO once daily for 18 days, peak plasma concentrations were achieved after ≈2 to 3 hours.[8] Half-life on days 1 and 18 was ≈7 and 10 hours, respectively. There was no significant accumulation of drug seen after 18 days.

Contraindications/Precautions/Warnings

Altrenogest is contraindicated in stallions and geldings[9] and mares that have a history of uterine inflammation (ie, acute, subacute, or chronic endometritis).[1,9] Natural or synthetic gestagen therapy may exacerbate existing low-grade or "smoldering" uterine inflammation into a fulminating uterine infection[1]; therefore, the use of progestational agents in mares with chronic uterine infections should be avoided, as the agents may enhance the infection process. When altrenogest is used to maintain pregnancy, luteal insufficiency should be documented, and infectious causes of pregnancy loss should be ruled out prior to altrenogest therapy; altrenogest therapy should be discontinued within 24 hours of the mare's due date,[10] and 2 to 7 days prior to the bitch's anticipated whelping date.[11] Avoid administering altrenogest to pregnant bitches during the first trimester.[12]

Pregnant mares with GI disease may not absorb oral altrenogest adequately and injectable progesterone is preferred.[13]

In swine, underdosing can lead to the formation of cystic follicles.[3]

WARNING FOR THOSE HANDLING THIS DRUG[1]:

Individuals who should not handle this product include:

1. Women
   a. Who are or suspect they are pregnant
   b. With known or suspected carcinoma of the breast
   c. With known or suspected estrogen-dependent neoplasia
   d. With undiagnosed vaginal bleeding
2. Anyone with
   a. Thrombophlebitis or thromboembolic disorders or with a history of these events
   b. Cerebral-vascular or coronary artery disease
   c. A benign or malignant tumor that developed during the use of oral contraceptives or other estrogen-containing products
   d. Liver dysfunction/disease

Altrenogest is readily absorbed by the skin and can penetrate porous (eg, latex, rubber) gloves; absorption can be increased from areas covered by these occlusive materials. It is recommended to wear impermeable (eg, nitrile, vinyl) gloves for dermal protection.

If skin exposure occurs, wash the skin immediately with soap and water. If eye exposure occurs, flush the eyes immediately with water for 15 minutes and seek medical attention. If swallowed, seek medical attention and do NOT induce vomiting, as vomiting should be supervised by a physician because of potential pulmonary damage via aspiration of oil base.

Altrenogest should not enter water courses as this may be dangerous for fish and other aquatic organisms.[14]

The National Institute for Occupational Safety and Health (NIOSH) classifies progestins as hazardous drugs; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Adverse effects of altrenogest appear to be minimal when used at labeled dosages.[15]

Progestogens may induce cystic endometrial hyperplasia and pyometra in bitches.[16]

Reproductive/Nursing Safety

Altrenogest administration to rats during the embryogenic stage of pregnancy caused masculinization of female genitalia when it was given at high doses (manyfold greater than the recommended equine dose).

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The LD_{50} of altrenogest is 176 mg/kg in rats and 233 mg/kg in mice.[17] Dogs tolerated an oral dose up to 400 mg/kg.[17] No information was located regarding the effects of an accidental acute overdose in horses or other species.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with altrenogest have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together

is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Dinoprost:** Altrenogest may reduce the effects of dinoprost.
- **Heparins** (eg, **enoxaparin, heparin**): Concurrent use of progestins may decrease anticoagulant effects of heparin or low-molecular weight heparins.
- **Hypoglycemic Agents** (eg, **glipizide, insulins**): Altrenogest may reduce blood glucose-lowering effects.
- **Rifampin**: Concurrent use may decrease progestin activity, due to microsomal enzyme induction with resultant increase in progestin metabolism. The clinical significance of this potential interaction is unknown.
- **Phenobarbital**: Concurrent use may decrease progestin activity due to microsomal enzyme induction with resultant increase in progestin metabolism.

Laboratory Considerations

- Unlike exogenously administered progesterone, altrenogest does not interfere or cross-react with progesterone assays.

Dosages

DOGS:

Luteal insufficiency (extra-label): 0.05 – 0.1 mg/kg PO once daily[11,12,18,19]

HORSES:

Suppression of estrus for synchronization (label dosage; FDA-approved): Administer 1 mL/49.9 kg (110 lb) body weight (0.044 mg/kg) PO once daily for 15 consecutive days. May administer altrenogest directly on the animal's tongue using a dose syringe or on the usual grain ration[1]

Suppression of estrus in normally cycling mares (extra-label): 0.3 mg/kg IM every 5 to 7 days[9]

Long-term suppression of estrus (extra-label): 0.044 mg/kg PO daily[20]

Prevention of abortion/pregnancy loss (extra-label): 0.088 mg/kg PO once daily[21]

Maintain pregnancy in mares with deficient progesterone levels (extra-label): 0.044 mg/kg PO once daily. Three options for treatment:

a) Treat until day 60 of pregnancy or greater AND measurement of endogenous progesterone level of greater than 4 ng/mL;
b) Treat until day 120 of pregnancy; or
c) Treat until end of pregnancy[22]

Maintain pregnancy in mares with deficient progesterone levels and at risk of early embryonic death or abortion (extra-label): 0.3 mg/kg IM on the fifth day after ovulation; repeat every 5 days until day 120 of gestation[9]

Maintain pregnancy in mares with placentitis: 22 – 44 mg/mare (NOT mg/kg) PO daily[23]

Rectal administration for the above indications when oral administration is not possible (extra-label): 0.088 mg/kg rectally every 4 to 8 hours.[6] From a pharmacokinetic study; the clinical efficacy of this dosage has not been studied.

SWINE:

Synchronization of estrus in sexually mature gilts that have had at least 1 estrous cycle (label dosage; FDA-approved): Administer 6.8 mL (15 mg)/gilt (NOT mg/kg) once daily for 14 consecutive days.[3] Apply as a top-dressing on a portion of gilt's daily feed allowance. Estrus should occur 4 to 9 days after completing treatment. To synchronize estrus in a group of gilts, treat all gilts daily for the same 14-day period.

Synchronization of estrus in sexually mature gilts that have had at least 1 estrous cycle (extra-label): 15 mg/gilt (NOT mg/kg) once daily for 18 consecutive days[24]

Monitoring

- Monitor pregnancy via ultrasonography and progesterone concentration[12]

Client Information

MANUFACTURER WARNING FOR THOSE HANDLING THIS DRUG:

Individuals who should not handle this product include:

1. Women
   a. Who are or suspect they are pregnant
   b. With known or suspected carcinoma of the breast
   c. With known or suspected estrogen-dependent neoplasia
   d. With undiagnosed vaginal bleeding
2. Anyone with
   a. Thrombophlebitis or thromboembolic disorders or with a history of these events
   b. Cerebral-vascular or coronary artery disease
   c. A benign or malignant tumor which developed during the use of oral contraceptives or other estrogen-containing products
   d. Liver dysfunction/disease

- Additionally, the FDA has issued a warning that exposure to these products may cause reproductive system disorders or other adverse effects. Although both men and women can be affected, the FDA cautions that teenage girls may be at highest risk.
- Individuals handling altrenogest products should wear impermeable (eg, nitrile or vinyl; NOT latex) protective gloves.
- The outside of the medicine containers and syringes should be kept clean of medicine residue, and any medicine that is spilled should be cleaned and decontaminated according to package insert instructions.
- Altrenogest can be absorbed after skin contact. Absorption can be increased if the medicine is covered by occlusive materials (eg, under latex gloves). If this medicine comes into contact with skin, wash off immediately with soap and water. If the eyes are exposed, flush the eyes with water for 15 minutes and get medical attention. If the product is swallowed, do not induce vomiting and contact a physician or poison control center.
- This medication is prohibited from use in an extra-label manner to enhance food and/or fiber production in animals.
- Altrenogest should not enter water courses as this may be dangerous for fish and other aquatic organisms.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

An orally administered synthetic progestational agent, altrenogest has a chemical name of 17 alpha-allyl-17-beta-hydroxyestra-4,9,11-trien-3-one.

Altrenogest may also be known as allyl trenbolone, A-35957, A-41300, RH-2267, or RU-2267, *Regu-Mate®*, *Altren®*, *Altresyn®*, *ChronoMate®*, *Matrix®*, or *Virbagest®*.

Storage/Stability

Altrenogest oral solution should be stored at or below 25°C (77° F); do not expose to temperatures exceeding 50°C (122°F). Altrenogest is extremely sensitive to light; dispense in light-resistant containers.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Altrenogest 0.22% (2.2 mg/mL) in oil solution in 150 mL and 1000 mL bottles; *Regu-Mate®*, generic (Rx). FDA-approved for use in horses that are not intended for food. This medication is banned in racing animals in some countries.

Altrenogest 0.22% (2.2 mg/mL) in 1000 mL bottles; *Matrix®*, generic; (OTC). FDA-approved for use in sexually mature gilts that have had at least 1 estrous cycle. Gilts must not be slaughtered for human consumption for 21 days after the last treatment. The FDA prohibits the extra-label use of this medication, including to enhance food and/or fiber production in animals.

HUMAN-LABELED PRODUCTS: NONE

Aluminum Hydroxide

(ah-***loo***-min-um hye-***droks***-ide) *Amphojel®*

Oral Antacid/Phosphate Binder

Prescriber Highlights

- ► Used to treat hyperphosphatemia in small animals and sometimes as an antacid for gastric ulcers
- ► Chronic use may lead to electrolyte abnormalities; possible aluminum toxicity.
- ► Many potential drug interactions
- ► Bulk dried powder available from several sources

Uses/Indications

Orally administered aluminum hydroxide is used to reduce hyperphosphatemia in patients with chronic kidney disease when dietary phosphorus restriction fails to maintain serum phosphorus concentrations in the normal range. Occasionally, it has been used as an oral antacid in veterinary patients, although its short duration of action for this purpose may make its use less practical.

Pharmacology/Actions

Aluminum salts reduce the amount of phosphorus absorbed from the intestine by physically binding to dietary phosphorus to form insoluble aluminum phosphate, which is then excreted in the feces. When used as an antacid, the hydroxyl ion interacts with hydrogen ions in the stomach to increase gastric/abomasal pH.

Contraindications/Precautions/Warnings

Aluminum-containing antacids may inhibit gastric emptying; use cautiously in patients with gastric outlet obstruction. Also, use with caution in patients prone to developing constipation. Aluminum may accumulate in patients with renal failure.

Adverse Effects

In small animals, the most likely adverse effect of aluminum hydroxide is constipation. Hypophosphatemia can develop if the patient is receiving a low phosphate diet and chronically receives aluminum antacids.

Potentially, aluminum toxicity could occur with prolonged use. Although previously believed unlikely to occur in small animals, at least 2 dogs with renal failure have developed aluminum toxicity after receiving aluminum-containing phosphate binders.[1] Osteomalacia related to hypophosphatemia or aluminum accumulation is also possible with chronic use. Aluminum-containing and calcium-containing phosphate binders may be used in combination to reduce the dose of each and reduce the risk for aluminum toxicity or hypercalcemia.

Reproductive/Nursing Safety

Use during pregnancy and lactation has not been studied; however, it is considered generally safe since oral absorption of this drug is poor.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdosage/Acute Toxicity

Acute toxicity is unlikely with an oral overdose. If necessary, GI effects (eg, constipation) and electrolyte imbalances that may occur with acute or chronic overdose should be treated based on clinical presentation.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with aluminum hydroxide have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Diazepam**: Concurrent aluminum may increase diazepam absorption.
- **Quinidine:** Increased gastric pH caused by aluminum hydroxide can potentially **increase** the absorption of basic drugs such as **quinidine;** separate from aluminum hydroxide by at least 2 hours.
- **Vitamin D Analogues** (eg, **calcitriol, ergocalciferol**)**:** May increase aluminum absorption. Avoid combination.

Aluminum hydroxide can **decrease** the amount absorbed (orally) or the pharmacologic effect of the drugs listed below; separate oral doses of aluminum hydroxide and these drugs by at least 2 hours to help reduce the potential for this interaction.

- **Allopurinol**
- **Aspirin**
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**)
- **Cefpodoxime**
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**)
- **Digoxin**
- **Ethambutol**
- **Fexofenadine**
- **Fluoroquinolones** (eg, **enrofloxacin, marbofloxacin**)
- **Gabapentin**
- **H_2 Antagonists** (eg, **famotidine, ranitidine**)
- **Iron Salts** (eg, **ferrous sulfate**)
- **Isoniazid** (**INH**)
- **Mycophenolate**
- **Penicillamine**
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**)
- **Phenytoin**
- **Sotalol**
- **Tetracyclines** (eg, **doxycycline, minocycline**)
- **Thyroid Hormones**

Doses

NOTE: All dosages are extra-label.

DOGS/CATS:

Hyperphosphatemia secondary to chronic kidney disease (extra-label)**:** 30 – 100 mg/kg per day as adjunct to reduced dietary phosphorus.[2-4] Aluminum hydroxide gel powder (USP)

is preferred, as it can be mixed with food and is tasteless. Dose is divided and mixed with *each* meal. Start at low end of dosage range and adjust upward every 4 to 6 weeks until desired serum phosphorus is attained (see ***Monitoring***). If a reduced-phosphorus diet and higher dosages of aluminum hydroxide do not adequately control serum phosphorus, consider adding a lanthanum- or calcium-based (eg, calcium acetate, calcium carbonate) phosphate binder to reduce the chances for aluminum toxicity.

RABBITS/RODENTS/SMALL MAMMALS:

Hyperphosphatemia in chinchillas (extra-label): Aluminum hydroxide gel: 1 mL/animal (NOT mL/kg) PO as needed

Hyperphosphatemia in Guinea pigs (extra-label): 0.5 – 1 mL per animal (NOT mL/kg) PO as needed[5]

REPTILES:

Hyperphosphatemia (extra-label)**:** 100 mg/kg PO every 12 to 24 hours[6]

CATTLE:

Antacid (extra-label): 15 – 60 mg/kg PO every 8 – 24 hours.[7] Efficacy in adult cattle is questionable since the drug becomes diluted in the rumen and may not provide therapeutic benefit in the abomasum.

Abomasal ulcers in calves using a combination of aluminum hydroxide and magnesium hydroxide (extra-label): 25 mL (each mL contains aluminum hydroxide 0.1 g/mL and magnesium hydroxide 0.09 g/mL) PO every 8 hours.[8] **NOTE:** this study was done in healthy calves; based on the results from this study, this dose is expected to be beneficial for ill calves with abomasal ulcers.

HORSES:

Adjunctive gastroduodenal ulcer therapy in foals (extra-label)**:** Aluminum/magnesium hydroxide suspension: 15 mL (total dose) 4 times a day[9]

Monitoring

- After beginning therapy, check serum phosphorus (after a 12-hour fast) every 4 to 6 weeks until target phosphorous levels are attained. Once phosphorous levels are stable, check phosphorous levels at the time of renal chemistry rechecks (eg, every 12 weeks). For chronic kidney disease (CKD), the International Renal Interest Society (IRIS) recommends a target phosphorous range for dogs and cats at each stage:
  - Stage 2 CKD target phosphorous levels: greater than 2.7 and less than 4.6 mg/dL (0.9 – less than 1.5 mmol/L)
  - Stage 3 CKD target phosphorous levels: greater than 2.7 and less than 5.0 mg/dL (0.9 – less than 1.6 mmol/L)
  - Stage 4 CKD target phosphorous levels: greater than 2.7 and less than 6.0 mg/dL (0.9 – less than 1.9 mmol/L)
- To monitor for aluminum toxicity, watch for development of neuromuscular effects, progressive decreases in mean cell volume (MCV), and microcytosis.

Client Information

- Oral aluminum hydroxide products are available without prescription (OTC) but should be used under the supervision of your veterinarian.
- Bulk powder or compounded capsules are easier to administer than liquids or suspensions. Shake the suspension thoroughly prior to administration.
- Must be given either just before feeding or mixed in food to be effective.
- Can cause constipation or decreased appetite
- Report to your veterinarian any unusual signs, such as weakness, difficulty walking, or stumbling.

Chemistry/Synonyms

Dried Aluminum Hydroxide Gel (CAS Registry: 21645-51-2) occurs as a white, odorless, tasteless, amorphous powder. It is insoluble in water or alcohol. The USP 36 standard allows varying amounts of basic aluminum carbonate and bicarbonate, but it must contain no less than 76.5% of $Al(OH)_3$.

Aluminum hydroxide may also be known as aluminium hydroxide.

Storage/Stability

Store powder forms in airtight containers. Liquid formulations should not be allowed to freeze.

Compatibility/Compounding Considerations

Because aluminum hydroxide powder USP can vary in the concentration of aluminum hydroxide (must be 76.5% or greater) and powders can vary in density, volume measurements can only approximate actual weight. However, ¼ teaspoonful (1.25 mL) of the dried USP powder has been reported to contain ≈300 mg of aluminum hydroxide.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Aluminum Hydroxide Concentrated Gel Suspension/Liquid (**NOTE**: These products are usually flavored (mint) and not well accepted by dogs or cats): 320 mg/5 mL in 473 mL; UD 15 mL and 30 mL; generic; (OTC)

Aluminum Hydroxide Gel, Dried Powder, USP; bulk powder is available from a variety of sources including many compounding pharmacies. See: http://goo.gl/1lYJk for additional source information.

NOTE: There are also many products available that have aluminum hydroxide and a magnesium or calcium salt (eg, *Maalox®*) that are used as antacids. All oral aluminum and magnesium hydroxide preparations are OTC.

Amantadine

(a-***man***-ta-deen) *Symmetrel®*

Antiviral; NMDA Antagonist

Prescriber Highlights

- ► Limited published efficacy or safety data, although clinical experience suggests it is useful in adjunctive treatment for chronic pain in small animal species
- ► Historically dosed every 24 hours; however, based on pharmacokinetic data, the same dose given every 12 hours may be more effective
- ► Dogs may exhibit agitation and GI effects, especially early in treatment.
- ► Large interpatient variations of pharmacokinetics in horses limit its therapeutic usefulness.
- ► Overdoses are potentially very serious; it may need to be compounded to accurately dose small animals.
- ► Extra-label use is prohibited by the FDA in chickens, turkeys, and ducks.

Uses/Indications

Although amantadine may have efficacy and clinical usefulness against some veterinary viral diseases, presently the greatest interest for its use in small animal species is in the adjunctive treatment of

neuropathic[1] or chronic pain,[2] often in those in which opioids do not provide adequate analgesia or who are intolerant of higher opioid doses. It is generally considered ineffective when used alone[3]; use in combination with an NSAID, opioid, or gabapentin/pregabalin is typical.[1,4] Several weeks may be required to break a pain cycle.[5,6] It has been suggested for use as an early intervention in the treatment of pain associated with osteosarcomas.[7]

Amantadine has also been investigated for treatment of equine-2 influenza virus in a horse[8]; however, because of expense, interpatient variability in oral absorption and other pharmacokinetic parameters, and the potential for causing seizures after IV dosing, it is not commonly used for treatment.

In humans, amantadine is used for parkinsonian syndrome and drug-induced extrapyramidal effects; its use for the treatment and prophylaxis of influenza A is no longer recommended.[9] As in veterinary medicine, the effect of amantadine on NMDA receptors in humans is of active interest, particularly its use as a coanalgesic with opioids and in the reduction of opioid tolerance development.

Pharmacology/Actions

Like ketamine, dextromethorphan, and memantine, amantadine inhibits the NMDA receptor by stabilizing it in the closed state.[10] Within the CNS, chronic pain can be maintained or exacerbated when glutamate or aspartate bind to this receptor. It is believed that this receptor is particularly important in allodynia (ie, sensation of pain resulting from a normally non-noxious stimulus). Amantadine is expected to produce analgesic effects when pain or CNS sensitization is already present. Although there is limited evidence that amantadine alone provides analgesia,[2] it is thought that it may help alleviate chronic pain when used in combination with other analgesics (eg, opioids, NSAIDs).[3]

Amantadine's antiviral activity is limited to strains of influenza A. Although its complete mechanism of action is unknown, it inhibits viral replication by interfering with influenza A virus M2 protein, preventing release of viral RNA into the host cell, and possibly inhibiting viral replication. Influenza A variants have demonstrated resistance to amantadine's antiviral action, and it is currently not recommended for the treatment or prophylaxis of influenza A.[9]

Amantadine's antiparkinsonian activity is not well understood, but it apparently increases dopamine concentrations in the brain. The drug appears to have potentiating effects on dopaminergic neurotransmission in the CNS, is an NMDA antagonist, and has anticholinergic activity.

Pharmacokinetics

In dogs, oral bioavailability of amantadine is reportedly very high.[11] A study in nonfasted greyhounds showed an oral dose of 2.8 mg/kg was well tolerated, and maximum concentration, time to maximum concentration, and terminal half-life were 271 ng/mL, 1 to 4 hours, and 4.9 hours respectively. This study also suggested that the "every 24-hour dose interval" should be re-evaluated.[12] The drug is renally eliminated.[11]

In cats, bioavailability was very high after oral administration, and peak levels occurred ≈2 hours after dosing. After IV administration, the steady-state volume of distribution was ≈4.3 L/kg and clearance (mean) was 8.2 mL/minute/kg.[13] Elimination half-life was 5.5 to 6 hours.

In horses, amantadine had a very wide interpatient variability of absorption after oral dosing (10 – 20 mg/kg); bioavailability ranged from 40% to 60% and was not affected by feed.[8] The elimination half-life in horses was ≈3.5 hours, and the steady-state volume of distribution was ≈5 L/kg.

In Amazon parrots, the time to maximum concentration was ≈3 to 4 hours, and half-life was 21 to 23 hours.[14]

In humans, amantadine was well absorbed after oral administration with peak plasma concentrations occurring ≈3 hours after dosing.[15] Volume of distribution was 3 to 8 L/kg, and protein binding was ≈67%. Amantadine is primarily eliminated via renal mechanisms. Oral clearance was ≈0.28 L/hour/kg and half-life was ≈16 hours. Clearance is reduced in patients with renal impairment, and half-life may double.

Contraindications/Precautions/Warnings

In humans, amantadine is contraindicated in patients with known hypersensitivity to it[15] or to rimantadine, and in those with end-stage renal disease. It should be used with caution in patients with hepatic disease, renal disease (dosage adjustment may be required), congestive heart failure, active psychoses, eczematoid dermatitis, seizure disorders, or untreated angle-closure glaucoma. The drug is no longer recommended for the treatment or prevention of influenza A in humans due to high levels of amantadine resistance among circulating influenza strains.[9] In 2006, the FDA banned the use of amantadine and other influenza antivirals in chickens, turkeys, and ducks.

The human liquid dosage form has an unpleasant taste.

Do not confuse AMANTadine with RIMantadine, AMIOdarone, or RANITidine.

Adverse Effects

Experience with amantadine in domestic animals is limited, and its adverse effect profile is not well described. It has been reported that dogs given amantadine occasionally develop agitation, flatulence, loose stools, or diarrhea, particularly early in treatment. Experience in cats is limited, and an adverse effect profile has yet to be fully elucidated, but some clinicians report that GI effects are more likely than in dogs.

Reproductive/Nursing Safety

In rats, amantadine 50 – 100 mg/kg/day PO (ie, ≈1.5 to 3 times the maximum recommended human dose) throughout pregnancy was embryotoxic and caused fetal malformations and reduced fetal weight.[15] Fertility was slightly impaired in rats that were given 32 mg/kg/day.

Amantadine is excreted into maternal milk; its use is not recommended in nursing women.[16] Veterinary significance is unclear.

Because safety has not been established, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The oral LD_{50} in mice and rats is 700 to 800 mg/kg and 25 to 50 mg/kg in humans.[17] The toxic amantadine dose reported for cats is 30 mg/kg[18]; behavioral effects may be noted at 15 mg/kg in dogs and cats.

Clinical signs associated with overdose in dogs include tremors, anxiety, ataxia, hypersalivation, and/or vomiting.

In humans, overdoses as low as 1 gram (total dose) have been associated with fatalities. Cardiac dysfunction (eg, arrhythmias, hypertension, tachycardia), pulmonary edema, CNS toxicity (eg, tremors, seizures, psychosis, agitation, coma), hyperthermia, renal dysfunction, and respiratory distress syndrome have all been documented. There is no known specific antidote for amantadine overdose. Treatment should consist of GI decontamination when appropriate, intensive monitoring (including ECG), and supportive therapy. Hydration and urinary acidification, with or without diuresis, may increase renal amantadine excretion. The drug is poorly removed by hemodialysis. Physostigmine has been suggested for cautious use in treating CNS effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and

toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with amantadine have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Drugs** (eg, **atropine, glycopyrrolate, oxybutynin**): Amantadine may enhance anticholinergic effects.
- **Antihistamines** (eg, **diphenhydramine, hydroxyzine**): Amantadine may enhance anticholinergic effects.
- **Carbonic Anhydrase Inhibitors** (eg, **acetazolamide**): May increase amantadine concentration
- **CNS Stimulants** (eg, **caffeine, methylphenidate**, **selegiline**): Concomitant use with amantadine may increase the drug's CNS stimulatory effects.
- **Glucagon:** Amantadine's anticholinergic effects may increase GI adverse effects of glucagon.
- **Phenothiazines** (eg, **acepromazine**): Amantadine may enhance anticholinergic effects.
- **Quinidine, Quinine:** Renal clearance of amantadine may be reduced.
- **QT Prolonging Drugs** (eg, **amiodarone, cisapride, procainamide, sotalol**): May increase the risk for arrhythmias
- **Sulfa-/Trimethoprim:** May decrease the excretion of amantadine, yielding higher blood concentrations of amantadine
- **Tramadol:** Concomitant use with amantadine may increase the risk for seizures because tramadol at high doses has caused seizures in humans[19] and amantadine can lower the seizure threshold[15]; however, an increased risk for seizures with this drug combination appears unlikely in a clinical setting at recommended dosages. Monitor for sedation or other neurologic adverse effects if using this combination.
- **Triamterene:** May decrease the excretion of amantadine, yielding higher blood concentrations of amantadine
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): May enhance the anticholinergic effects of amantadine
- **Urinary Acidifiers** (eg, **methionine, ammonium chloride, ascorbic acid**): May increase the excretion of amantadine
- **Urinary Alkalinizers** (eg, **sodium bicarbonate, potassium citrate**): May decrease the excretion of amantadine

Laboratory Considerations

- No laboratory interactions identified

Dosages

DOGS/CATS:

Adjunctive analgesia, including neuropathic pain and to prevent "wind-up" pain (extra-label): 3 – 5 mg/kg PO once daily.[1,4] Anecdotally, it is suggested to start at the lower end of the dosing range and increase slowly, if needed. Pharmacokinetic studies suggest administration every 12 hours may be needed.[3,12,13]

Monitoring

- Adverse effects (ie, GI effects, anxiety, restlessness, dry mouth)
- Efficacy

Client Information

- Give this medicine as directed by your veterinarian. The benefits of this medicine may take a week or more to be seen.
- Gastrointestinal effects (eg, loose stools, gas, diarrhea) or some agitation may occur, particularly early in treatment. Contact your veterinarian if these become serious or persist.
- Overdoses with this medication can be serious. Be sure to keep this medicine out of reach of other pets and children.

Chemistry/Synonyms

An adamantane class antiviral agent with NMDA antagonist properties, amantadine HCl occurs as a white to off-white, bitter crystalline powder that is freely soluble in water and soluble in alcohol. Commercial dosage forms contain amantadine HCl, and strength is expressed and calculated as amantadine base. 1.24 mg amantadine HCl contains 1 mg amantadine.

Amantadine HCl may also be known as adamantanamine HCl, *Endantadine®*, *GOCOVRI®*, *Osmolex®*, and *Symmetrel®*.

Storage/Stability

Tablets, capsules, and the oral solution should be stored in tight, light-resistant containers at room temperature 20°C to 25°C (68°F-77°F), with excursions permitted to 15°C to 30°C (59°F-86°F). Avoid freezing the liquid.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The International Federation for Equestrian Sports lists this drug as a "prohibited substance – controlled medication."[20] Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Amantadine HCl Oral Tablets and Capsules: 100 mg; generic; (Rx)

Amantadine HCl Oral Solution/Syrup: 50 mg/5mL (10 mg/mL) in 480 mL; generic; (Rx). **NOTE:** It is reported that the oral liquid has a bad taste and may not be accepted by veterinary patients.

Amantadine HCl extended-release oral tablets and capsules (*Osmolex® ER*, *GOCOVRI®*) are available. They are not directly equivalent to immediate-release amantadine capsules and have not been studied in veterinary patients.

In 2006, the FDA banned the extra-label use of amantadine and other influenza antivirals in chickens, turkeys, and ducks.

For the complete list of references, see **wiley.com/go/budde/plumb**

Amikacin, Systemic

(am-i-***kay***-sin) *Amikin®, Amiglyde-V®*

Aminoglycoside Antibiotic

Prescriber Highlights

- ► Parenteral aminoglycoside antibiotic that has good activity against a variety of bacteria, predominantly gram-negative aerobic bacilli and staphylococci; ineffective against anaerobic bacteria
- ► Adverse effects include nephrotoxicity, ototoxicity, and neuromuscular blockade.
- ► Cats may be more sensitive to toxic effects.
- ► Risk factors for toxicity include pre-existing renal disease, age (both neonatal and geriatric), fever, sepsis, and dehydration.

Uses/Indications

Although parenteral use of amikacin is only FDA approved in dogs, it is often used in most species for treatment of serious gram-negative and

staphylococcal infections when the adverse effects of other aminoglycosides are a concern. Because aminoglycosides have an inherent toxicity and should be administered parenterally, use should be limited to treatment of serious infections with either a documented lack of susceptibility to other, less toxic antibiotics or in cases in which the clinical situation dictates immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

It is widely accepted that aminoglycosides should be given once a day in most patients (mammals). This dosing regimen yields higher peak concentrations with resultant greater bacterial kill. Because aminoglycosides exhibit a postantibiotic effect, surviving susceptible bacteria generally do not replicate as rapidly, even when antibiotic concentrations are below the MIC. Periods in which antibiotic concentrations are low may also decrease the "adaptive resistance" (ie, bacteria take up less drug in the presence of continuous exposure) that can occur.

Amikacin is also FDA-approved for intrauterine infusion in mares and is used via intraarticular injection (extra-label) in foals to treat gram-negative septic arthritis. In horses with septic arthritis, intravenous regional limb perfusion (IVRLP) using amikacin is actively being researched.[1-3]

Amikacin is also used topically for treatment of otitis externa in dogs—often in combination with EDTA-Triz[4]—and may be impregnated in materials (eg, PMMA beads, gels) for local treatment of infections, particularly implant-associated surgical site infections.

The World Health Organization (WHO) has designated amikacin as a Critically Important, High Priority antimicrobial for human medicine.[5]

Pharmacology/Actions

Similar to other aminoglycoside antibiotics, amikacin acts on susceptible bacteria by irreversibly binding to the 30S ribosomal subunit, thereby, inhibiting protein synthesis.[6] Amikacin is considered a bactericidal, concentration-dependent antibiotic.

Amikacin's spectrum of activity includes coverage against many aerobic gram-negative and some aerobic gram-positive bacteria, including *Escherichia coli* and most species of *Klebsiella* spp, *Proteus* spp, *Pseudomonas* spp, *Salmonella* spp, *Enterobacter* spp, *Serratia* spp, *Shigella* spp, *Mycoplasma* spp, and *Staphylococcus* spp. Several strains of *Pseudomonas aeruginosa*, *Proteus* spp, and *Serratia* spp that are resistant to gentamicin will be killed by amikacin. Amikacin is ineffective against anaerobic bacteria, viruses, fungi, and protozoa.

In an in vitro study with canine *E coli* isolates, amikacin demonstrated additive or synergistic antimicrobial activity when given in combination with ceftazidime and amoxicillin/clavulanate but not in combination with enrofloxacin or marbofloxacin.[7]

Antimicrobial activity of aminoglycosides is enhanced in an alkaline environment but inhibited by the presence of pus or organic debris.

Pharmacokinetics

Amikacin, like the other aminoglycosides, is not appreciably absorbed after oral, dermal, or intrauterine administration or urinary bladder irrigations but is absorbed when used in irrigations during surgical procedures or in regional limb perfusion. Systemic absorption of amikacin from impregnated beads is not described; plasma amikacin concentration was undetectable 24 hours after SC placement of an amikacin-impregnated dextrose cross-linked gel[8] but is minimal for gentamicin in PMMA beads on dogs[9] and in calcium sulfate beads in goats.[10] With IM administration in dogs and cats, peak concentrations occur after 30 to 60 minutes. SC injection results in slightly delayed peak concentrations and more variability than after IM injection. Bioavailability from extravascular injection (IM or SC) is greater than 90%.

After absorption, aminoglycosides are distributed primarily in the extracellular fluid and are found in ascitic, pleural, pericardial, peritoneal, synovial, and abscess fluids; high levels are found in sputum, bronchial secretions, and bile. Aminoglycosides are minimally protein bound (ie, less than 20%) to plasma proteins.[11] Aminoglycosides do not readily cross the blood-brain barrier and do not penetrate ocular tissue. CSF concentrations are unpredictable and range from 0% to 50% of those found in the serum. Therapeutic concentrations are found in bone, heart, gallbladder, and lung tissues after parenteral administration. Prostate concentrations have not been adequately assessed in animals, but amikacin has been shown to be effective for the treatment of chronic bacterial prostatitis in humans when fluoroquinolones cannot be used.[12] A maximum distal interphalangeal joint synovial fluid concentration of 600 µg/mL was reached 15 minutes after intravenous regional limb perfusion (IVRLP) in healthy adult horses; however, significant interpatient variability was noted. A maximum serum amikacin concentration of 19 µg/mL was reached 25 minutes after IVRLP.[13] Aminoglycosides tend to accumulate in certain tissues (eg, inner ear, kidneys), contributing to the toxicity seen in those tissues. Volumes of distribution have been reported to be 0.15 to 0.3 L/kg in adult cats and dogs, and 0.26 to 0.58 L/kg in horses. Volumes of distribution may be significantly larger in neonates and juvenile animals due to their higher extracellular fluid fractions. Aminoglycosides cross the placenta; fetal concentrations range from 15% to 50% of those found in maternal serum.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. The approximate elimination half-life for amikacin has been reported to be 5 hours in foals, 1.14 to 2.3 hours in adult horses, 2.2 to 2.7 hours in calves, 1 hour in cows, 1.5 hours in sheep, and 0.5 to 2 hours in dogs and cats. Patients with decreased renal function can have a significantly prolonged half-life. In humans with normal renal function, elimination rates can be highly variable with aminoglycoside antibiotics.

Contraindications/Precautions/Warnings

Aminoglycosides are contraindicated in animals that are hypersensitive to them. Often, these drugs are the only effective agents in treating severe gram-negative or multidrug resistant staphylococcal infections; thus, there are no absolute contraindications to their use. However, these drugs should be used with extreme caution in animals with pre-existing renal disease; concomitant monitoring and dosage interval adjustments should be used as needed. Other risk factors for the development of toxicity include patient age (neonatal and geriatric patients), fever, sepsis, and dehydration.

Aminoglycosides can cause irreversible ototoxicity, so they should be used with caution, especially in working and guide dogs, and should be avoided when treating otitis if an intact tympanic membrane cannot be confirmed. Amikacin is considered less ototoxic than gentamicin or streptomycin.[14]

Aminoglycosides should be used with caution in animals with neuromuscular disorders (eg, myasthenia gravis) because of the drug's neuromuscular blocking activity.

Sight hounds may require reduced dosages of aminoglycosides, as they have significantly lower volumes of distribution.

Aminoglycosides are eliminated primarily through renal mechanisms and should be used cautiously in neonatal or geriatric animals; consider periodic therapeutic drug monitoring and serum chemistry profiles with dosage adjustments as needed.

Adverse Effects

Aminoglycosides can be nephrotoxic and ototoxic. The nephrotoxic (ie, tubular necrosis) mechanisms are not completely understood but are probably related to interference with phospholipid metabolism in the lysosomes of proximal renal tubular cells, resulting in leakage

of proteolytic enzymes into the cytoplasm. The risk for nephrotoxicity increases with prolonged therapy and is predominantly associated with accumulation of amikacin within tubular cells, which is more likely to occur with repeated lower doses as compared with higher doses with prolonged (ie, every 24 hour) dosing intervals. Nephrotoxicity is usually manifested by nonoliguric renal failure, with increases in serum BUN and creatinine and decreases in urine specific gravity and creatinine clearance. Proteinuria and abnormal urine sediment (eg, casts, renal tubular cells, glycosuria) may be seen. Nephrotoxicity is usually reversible after the drug is discontinued. Although amikacin is less nephrotoxic than other aminoglycosides, the incidence of nephrotoxicity is poorly described, and caution and monitoring are required.

Ototoxicity (ie, eighth cranial nerve toxicity) can manifest through hearing loss and/or vestibular clinical signs (eg, nystagmus, head tilt) and may be irreversible. Vestibular clinical signs are more frequent with use of streptomycin, gentamicin, or tobramycin. Hearing loss is more frequent with use of amikacin or neomycin.[15] However, hearing loss or vestibular clinical signs can occur with use of any of these drugs. Cats are apparently more sensitive to the vestibular effects of aminoglycosides.[16]

Aminoglycosides can also cause neuromuscular blockade, facial edema, pain and inflammation at the injection site, peripheral neuropathy, and hypersensitivity reactions. Rarely, GI clinical signs and hematologic and hepatic effects have been reported.

An in vitro study found that amikacin caused rapid, dose-dependent cytotoxicity in equine joint cells[17]; additional in vivo studies are required to confirm these findings.

Reproductive/Nursing Safety

Aminoglycosides can cross the placenta and although rare, may cause eighth cranial nerve toxicity or nephrotoxicity in fetuses. Nephrotoxicity has occurred in fetal rats. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks. There is no evidence that amikacin impairs fertility; amikacin does not appear to affect sperm quality,[18] however, the preservative in the intrauterine infusion may impair sperm viability.[19]

Aminoglycosides are excreted in milk. Although it is possible that amikacin ingested with milk could alter the GI microbiota and cause diarrhea, low levels of amikacin in milk are unlikely to be of significant concern.

Overdose/Acute Toxicity

Two treatments have been recommended in case of inadvertent overdose:

1) Hemodialysis, which is effective in reducing serum drug concentrations but is not a viable option for most veterinary patients.
2) Peritoneal dialysis, which also reduces serum drug concentrations but is much less effective. Amikacin is less affected by this approach than are tobramycin or gentamicin, and it is assumed that reduction in serum concentrations will also be minimized.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amikacin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, General** (eg **isoflurane, ketamine, propofol**): Concomitant use with general anesthetics could potentiate neuromuscular blockade.
- **Cephalosporins**: Concurrent use of aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with aminoglycosides, but this interaction has only been well-documented with cephaloridine and cephalothin (both of which are no longer marketed). The potential synergistic effect[7] may outweigh these unlikely risks; however, concurrent use of third- or fourth-generation cephalosporins with amikacin, results in abundant and typically unnecessary duplication of the gram-negative spectrum.
- **Diuretics, Loop** (eg, **furosemide**, **torsemide**): Concurrent use with loop diuretics may increase the nephrotoxic or ototoxic potential of aminoglycosides.
- **Diuretics, Osmotic** (eg, **mannitol**): Concurrent use with osmotic diuretics may increase the nephrotoxic or ototoxic potential of the aminoglycosides.
- **Magnesium, Systemic** (eg, **magnesium sulfate**): Concomitant use could increase the risk for neuromuscular blockade.
- **Nephrotoxic drugs, Other** (eg, **amphotericin B, cisplatin, polymyxin B**, **vancomycin**): Potential for increased risk for nephrotoxicity
- **Neuromuscular Blocking Agents** (eg, **atracurium, pancuronium**): Concomitant use with neuromuscular blocking agents could potentiate neuromuscular blockade.
- **NSAIDs** (eg, **carprofen, firocoxib, flunixin, meloxicam, phenylbutazone, robenacoxib**): Increased risk of nephrotoxicity
- **Penicillins**: May have synergistic effects against some bacteria[7]; some potential for physical inactivation of aminoglycosides in vitro (do not mix together) and in vivo (patients in renal failure)

Laboratory Considerations

- **Amikacin serum concentrations** may be falsely decreased if the patient is also receiving **beta-lactam antibiotics** and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Dosages

DOGS:

Susceptible infections and empirical therapy (extra-label): 15 – 30 mg/kg IV, IM, SC once daily. Septic patients may be started at 20 – 30 mg/kg IV once daily. **NOTE**: Dosage should be adjusted based on kidney function and serum amikacin concentrations when possible. When renal function is significantly decreased (eg, IRIS stage II or III) and less nephrotoxic drugs cannot be used, the dose amount remains the same but the dosing interval should be increased. See *Monitoring*.

CATS:

Susceptible infections and empirical therapy (extra-label): 10 – 15 mg/kg IV, IM, SC once daily. Septic patients may be started at 20 mg/kg IV once daily. **NOTE**: Dosage should be adjusted based on renal function and serum levels when possible. When renal function is significantly decreased (eg, IRIS stage II or III) and less nephrotoxic drugs cannot be used, the dose amount remains the same but the dosing interval should be increased. See *Monitoring*.

HORSES:

Uterine infections (endometritis, metritis, pyometra) caused by susceptible organisms (label dosage; FDA approved): 2 g mixed with 200 mL sterile normal saline (0.9% sodium chloride for injection) and aseptically infused into the uterus daily for 3 consecutive days[19]

Susceptible infections and empirical therapy (extra-label):

Adults: 10 mg/kg IV or IM once daily

Neonatal foals: 20 – 25 mg/kg IV or IM once daily. It is strongly recommended to individualize the dose based on therapeutic drug monitoring.

Treatment of septic joints (extra-label): Intra-articular administration: 125 – 250 mg/horse (NOT mg/kg) IA once daily[20]

Intravenous regional limb perfusion (IVRLP) administration in standing adult horses (extra-label):

a) 2 g (diluted to 30 – 60 mL with sterile saline) via cephalic vein, with 10 to 20 minute tourniquet time.[13,21,22] The addition of penicillin G sodium at 10 million units has resulted in variable retention time in the synovium.[23,24]

b) 1 g (diluted to 30 – 120 mL with sterile saline), with 30 minute tourniquet time reached therapeutic concentration in the thoracic limb distal phalangeal joint but not in the radiocarpal joint.[25]

NOTE: Despite the procedure's name (ie, IVRLP), amikacin is absorbed systemically and potentially reaches therapeutic concentrations.[13]

NEW WORLD CAMELIDS:

Susceptible infections and empirical therapy: 18 mg/kg IV or IM every 24 hours (once daily)[26]

BIRDS:

Susceptible infections:

a) 15 mg/kg IM or SC every 12 hours[27]

b) **Gram-negative infections resistant to gentamicin**: Dilute commercial solution and administer 15 – 20 mg/kg (0.015 – 0.02 mg/g) IM once or twice daily.[28]

c) **Intravenous regional limb perfusion (IVRLP) administration in chickens:** From a case report: Using the medial metatarsal vein, 5.3 mg/kg IV with flunixin 1.3 mg/kg were infused, with 15 minute tourniquet time.[29]

d) **Mycobacterial infections in psittacines**: 15 mg/kg twice daily (route not specified, assume IM)[30]

REPTILES:

Gram-negative respiratory disease: 3.5 mg/kg IM, SC, or via lung catheter every 3 to 10 days for 30 days[31]

Snakes:

a) 5 mg/kg IM (forebody) loading dose, then 2.5 mg/kg IM every 72 hours for 7 to 9 treatments. Commonly used in respiratory infections. Use a lower dose for *Python curtus*.[32]

b) **Gopher snakes**: In a study, 5 mg/kg IM loading dose, then 2.5 mg/kg IM every 72 hours. House snakes were at the high end of their preferred optimum ambient temperature.[33]

TURTLES/TORTOISES:

a) **Bacterial shell diseases**: 10 mg/kg (route not specified; assume IM) daily in water turtles and every other day in land turtles and tortoises for 7 to 10 days. Used commonly with a beta-lactam antibiotic. It is recommended to begin therapy with 20 mL/kg fluid injection. Maintain hydration and monitor uric acid levels when possible.[34]

b) **Gopher tortoises**: 5 mg/kg IM every 48 hours at 30°C (86°F)[35]

c) **Crocodilians**: 2.25 mg/kg IM every 72 to 96 hours[36]

FERRETS:

Susceptible infections (extra-label):

a) 8 – 16 mg/kg IM or IV once daily[37]

b) 8 – 16 mg/kg/day SC, IM, IV divided every 8 to 24 hours[38]

RABBITS/RODENTS/SMALL MAMMALS:

Rabbits (extra-label):

a) 8 – 16 mg/kg SC, IM, or IV daily dose (may be divided and given every 8-24 hours). Increased efficacy and decreased toxicity are possible if given once daily. If given IV, dilute product into 4 mL/kg of saline and administer over 20 minutes.[39]

b) 5 – 10 mg/kg SC, IM, or IV divided every 8 to 24 hours

Guinea pigs (extra-label): 10 – 15 mg/kg SC, IM, or IV divided every 8 to 24 hours

Chinchillas (extra-label):

a) 10 – 15 mg/kg SC, IM, or IV divided every 8 to 24 hours

b) 2 – 5 mg/kg SC, IM every 8 to 12 hours[40]

Hamsters, rats, mice (extra-label): 10 mg/kg SC or IM every 12 hours (twice daily)

Prairie dogs (extra-label): 5 mg/kg SC or IM every 12 hours (twice daily)[38]

FISH:

Susceptible infections: 5 mg/kg IM loading dose, then 2.5 mg/kg every 72 hours for 5 treatments[41]

Monitoring

- Efficacy (eg, culture, clinical signs, WBC count, and clinical signs associated with infection).

  Therapeutic drug monitoring would be ideal but is rarely available. When available, collect plasma samples 30 minutes after administration and immediately before the next dose to measure peak and trough concentrations, respectively. Target concentrations in veterinary patients have not been well-established. In humans, peak levels of 20 – 25 µg/mL (25 – 40 µg/mL for sepsis) have been recommended, whereas in foals, a target peak of 40 µg/mL has been stated.[42] In humans, trough levels of less than 8 µg/mL are recommended.
- Adverse effect monitoring is essential. Baseline serum renal chemistry testing (eg, creatinine) and urinalysis (including specific gravity and sediment evaluation) are recommended and should be repeated every 3 to 5 days during therapy. **NOTE:** A decrease in urine specific gravity is often the initial sign of impending nephrotoxicity; casts in the urine can be transient and a lack of casts does not rule out renal toxicity.
- Gross monitoring of vestibular or auditory toxicity is recommended.

Client Information

- You may give subcutaneous injections at home if you have received appropriate training, but routine monitoring of therapy for efficacy and toxicity by a veterinarian is still required.
- Permanent hearing loss and severe damage to the kidneys can occur with use of this medicine. Contact your veterinarian immediately if your animal develops a head tilt, hearing loss (ie, not responding to noise), loss of balance, poor appetite, low energy level, and/or vomiting.
- While taking this medicine, your animal will need to be closely monitored by your veterinarian. Do not miss these important follow-up visits.
- Use in food producing animals is controversial. Be sure to talk with your veterinarian about the long withdrawal periods associated with this medicine.

Chemistry/Synonyms

Amikacin, a semisynthetic aminoglycoside derived from kanamycin, occurs as a white, crystalline powder that is sparingly soluble in water. The sulfate salt is formed during the manufacturing process. 1.3 g of amikacin sulfate is equivalent to 1 g of amikacin. Amikacin may also be expressed in terms of units. 50,600 units are equal to 50.9 mg of base. The commercial injection is a clear to straw-colored solution, and the pH is adjusted to 3.5 to 5.5 with sulfuric acid.

Amikacin sulfate may also be known as amikacin sulphate, amikacini sulfas, or BB-K8; many trade names are available.

Storage/Stability

Amikacin sulfate for injection should be stored at room temperature (20°C-25°C [68°F to 77°F]); freezing or temperatures above 40°C (104°F) should be avoided. Solutions may become very pale yellow with time, but this does not indicate a loss of potency.

Amikacin is stable for at least 2 years at room temperature. Autoclaving commercially available solutions at 15 pounds of pressure at 120°C (248°F) for 60 minutes did not result in any loss of potency. Gamma sterilization of amikacin-impregnated plaster of Paris (calcium sulfate) or polymethylmethacrylate beads did not alter antimicrobial efficacy.[43]

Compatibility/Compounding Considerations

When given IV, amikacin should be diluted into suitable IV diluent (eg, normal saline, D5W, LRS) and administered over at least 30 minutes. Amikacin diluted to 0.25 – 5 mg/mL is stable for 24 hours at room temperature, 60 days when refrigerated (4°C [39.2°F]), and 30 days when frozen (-15°C [5°F]). Discard solution if particulates or discoloration are present.[19]

Amikacin sulfate is reportedly **compatible** and stable in all commonly used IV solutions and with the following drugs: ascorbic acid injection, bleomycin sulfate, calcium chloride/gluconate, cefoxitin sodium, chloramphenicol sodium succinate, chlorpheniramine maleate, cimetidine HCl, clindamycin phosphate, dimenhydrinate, diphenhydramine HCl, epinephrine HCl, hyaluronidase, hydrocortisone sodium phosphate/succinate, lincomycin HCl, metronidazole (with or without sodium bicarbonate), norepinephrine bitartrate, pentobarbital sodium, phenobarbital sodium, phytonadione, prochlorperazine edisylate, promethazine HCl, sodium bicarbonate, succinylcholine chloride, vancomycin HCl, and verapamil HCl.

The following drugs or solutions are reportedly **incompatible** or only **compatible in specific situations** with amikacin: amphotericin B, ampicillin sodium, cefazolin sodium, chlorothiazide sodium, dexamethasone sodium phosphate, erythromycin gluceptate, heparin sodium, oxytetracycline HCl, penicillin G potassium, phenytoin sodium, potassium chloride (in dextran 6% in sodium chloride 0.9%; stable with potassium chloride in "standard" solutions), vitamin B complex with C, and warfarin sodium. Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

In vitro inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well-documented. Although amikacin is less susceptible to this effect, it is usually recommended to avoid mixing these compounds together in the same syringe or IV bag unless administration occurs promptly. See also ***Drug Interactions*** and ***Laboratory Considerations***.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Amikacin Sulfate Injection: 50 mg (of amikacin base) per mL in 50 mL vials; (Rx). FDA approved for use in dogs. Although this drug is still listed in the FDA's Green Book of approved animal drugs, it may not be commercially available.

Amikacin Sulfate Intrauterine Solution: 250 mg (of amikacin base) per mL in 48 mL vials; (Rx). FDA approved for use in horses not intended for food.

Warning: Amikacin is not FDA approved for use in cattle or other food-producing animals in the United States. Drug residues may persist for long periods, particularly in renal tissue. For guidance with determining use and withdrawal times, contact FARAD (see ***Appendix*** for contact information).

HUMAN-LABELED PRODUCTS:

Amikacin Injection: 50 mg/mL and 250 mg/mL in 2 mL and 4 mL; generic; (Rx)

Aminocaproic Acid

(a-***mee***-noe-ka-***proe***-ik ***as***-id)

Epsilon Aminocaproic Acid (EAC), *Amicar*®

Hemostatic

Prescriber Highlights

- ► May be useful for treating hypofibrinolysis in dogs and horses and postoperative bleeding in greyhounds; efficacy for the treatment of degenerative myelopathies in dogs is questionable
- ► Contraindicated in disseminated intravascular coagulation (DIC)
- ► Infrequently causes GI distress
- ► Rapid IV administration may cause hypotension and bradycardia

Uses/Indications

Aminocaproic acid is potentially useful for the treatment of hyperfibrinolysis and as a prophylaxis for postoperative bleeding, especially in greyhounds or other sighthounds.[1,2] In dogs, 20 – 100 mg/kg PO inhibited fibrinolysis in an in vitro model of hyperfibrinolysis.[3] A retrospective study did not show a correlation between administration of aminocaproic acid and the packed cell volume (PCV) prior to transfusion or packed red blood cell transfusion dose in dogs with different bleeding disorders, including neoplastic disease.[4] Aminocaproic acid has also been used to help stabilize clots and slow bleeding in horses with guttural pouch hemorrhage.[5] A study in horses found that aminocaproic acid was not effective in preventing or reducing the severity of exercise-induced pulmonary hemorrhage (EIPH).[6]

Aminocaproic acid has been used as a treatment for degenerative myelopathy (seen primarily in German shepherds), but no controlled studies documenting its efficacy have been noted. In one study evaluating aminocaproic acid given concurrently with acetylcysteine and vitamins B, C, and E, no improvement was noted and all dogs in the study had a worsening of neurological signs over time.[7]

There is some interest in evaluating aminocaproic acid for the adjunctive treatment of immune-mediated thrombocytopenia in dogs, but the drug's efficacy and safety for this purpose has yet to be investigated. In humans, the drug is primarily used for treatment of hyperfibrinolysis-induced hemorrhage.

Pharmacology/Actions

Aminocaproic acid inhibits fibrinolysis via its inhibitory effects on plasminogen activator substances and some antiplasmin activity. Much higher plasma concentrations (511.7 µg/mL) are required in dogs than in humans (122 µg/mL) to completely inhibit fibrinolysis.[8] In horses, a plasma concentration of 5.8 µg/mL is sufficient to inhibit fibrinolysis.[9]

Aminocaproic acid is thought to affect degenerative myelopathy via its antiprotease activity, thereby reducing the activation of inflammatory enzymes that damage myelin.

Pharmacokinetics

Pharmacokinetic data have been studied in dogs. After oral administration of an injectable aminocaproic acid solution at 20, 50, and 100 mg/kg maximum concentration was ≈30, 69, and 166 µg/mL

(respectively), time until maximum concentration was 63, 42, and 54 minutes (respectively), terminal half-life was 70, 69, and 77 minutes (respectively), volume of distribution/bioavailability was 594, 589, and 575 mL), and total body clearance/bioavailability was 6.1, 6, and 5.2 mL/minute (respectively). The pharmacokinetic data of an oral formulation (tablet) administered at 100 mg/kg were similar to the injectable formulation given orally at the same dose.[3]

In a study in which aminocaproic acid 70 mg/kg IV was given to horses over 20 minutes, the drug was distributed rapidly, and plasma levels remained above the proposed therapeutic concentration of 130 µg/mL for 1 hour after the end of the infusion.[10] Elimination half-life was 2.3 hours. The authors proposed that a 15 mg/kg/hour IV CRI after the original infusion would maintain more prolonged therapeutic levels.

In humans, the drug is rapidly and completely absorbed after oral administration. The drug is well distributed in both intravascular and extravascular compartments and penetrates cells, including RBCs. Aminocaproic acid does not bind to plasma proteins. Terminal half-life is ≈2 hours in humans, and the drug is primarily renally excreted as unchanged drug. Clearance is markedly reduced in patients with severe renal impairment.

Contraindications/Precautions/Warnings

Aminocaproic acid is contraindicated in patients with active intravascular clotting, especially those with disseminated intravascular coagulation (DIC), which can result in fatal thrombus formation. Do not administer in the absence of laboratory confirmation of hyperfibrinolysis (eg, thromboelastography). In patients with upper urinary tract bleeding, glomerular capillary thrombosis or clots in the renal pelvis and ureters can form. In patients with pre-existing cardiac, renal, or hepatic disease, this drug should only be used when the benefits outweigh the risks; dosage reduction may be needed in patients with renal impairment.

The product label states that rapid IV injection of undiluted aminocaproic acid is not recommended in humans.[11]

Subendocardial hemorrhage and fatty degeneration of the myocardium have been reported in dogs.

Do not confuse the brand names *Amicar*® with amikacin or *Omacor*® (omega-3-acid ethyl esters).

Adverse Effects

Aminocaproic acid appears to be well tolerated. Approximately 1% of dogs treated with oral aminocaproic acid show clinical signs of GI irritation. This drug can potentially cause hyperkalemia, particularly in renally impaired patients.

In humans, myositis and skeletal muscle weakness with muscle fiber necrosis has occurred rarely; if this occurs, the potential for cardiac muscle damage should also be considered. Rapid IV administration can cause hypotension or bradycardia.

Reproductive/Nursing Safety

Impaired fertility has been noted when aminocaproic acid was administered to rats of either sex. Animal studies for the safe use of aminocaproic acid during pregnancy have not been conducted.[12]

It is unknown if aminocaproic acid is excreted in milk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

There is very limited information on overdoses with aminocaproic acid. The IV lethal dose in dogs is reportedly 2.3 g/kg.[12] At lower IV overdoses, tonic-clonic seizures were noted in some dogs.[11] There is no known antidote, but the drug is dialyzable.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

- There are no reported drug interactions of clinical significance.
- Blood Products: Concurrent administration with factor IX complex concentrates or anti-inhibitor coagulant may increase the risk for thrombosis.

Laboratory Considerations

- **Serum potassium** may be elevated by aminocaproic acid, especially in patients with pre-existing chronic kidney disease.

Dosages

NOTE: Aminocaproic acid solution for injection administered orally to dogs produced a similar pharmacologic effect as aminocaproic acid tablets.[3]

DOGS:

Antifibrinolytic to reduce delayed-onset bleeding after surgery in greyhounds (extra-label): 500 mg/dog (≈15.6-17.5 mg/kg) PO every 8 hours for 5 days beginning the night of surgery.[1,2] Data suggest canine dosing extrapolated from human data may result in suboptimal plasma concentrations after in vitro thromboelastograph (TEG) analysis revealed canine plasma was hypercoagulable as compared with human plasma.[8]

Bleeding secondary to hyperfibrinolysis (extra-label): From a case report, 33 mg/kg IV every 6 hours.[13] Modified TEG analysis showed normalization of the fibrinolytic response after discontinuation of the drug.

Pericardial effusion secondary to right atrial mass (extra-label): 50 mg/kg PO 3 or 4 times daily. Compounded formulation did not significantly delay recurrence of pericardial effusion or improve survival.[14]

Active bleeding (extra-label): Average dose was ≈17.5 mg/kg IV in dogs presented with active bleeding caused by neoplastic disease, postsurgical bleeding, or bleeding from other causes.[4] **NOTE:** Dogs may require higher dosages of aminocaproic acid as compared with humans,[8] and an in vitro model found that a single dose of 100 mg/kg PO inhibited fibrinolysis more effectively than did 20 mg/kg PO.[3]

Adjunctive treatment of degenerative myelopathy (extra-label): Aminocaproic acid 500 mg/dog (NOT mg/kg) PO every 8 hours indefinitely. Other treatments included acetylcysteine 25 mg/kg PO 3 times daily, prednisolone 1 mg/kg PO daily for 15 days then every other day for 30 days, vitamin C 500 mg PO every 12 hours, and vitamin E 2000 IU PO every 24 hours. From a retrospective study of 12 dogs,[7] disease progressed in all the dogs, and the authors questioned the benefit of treatment.

HORSES:

Antifibrinolytic for guttural pouch hemorrhage (extra-label): 40 mg/kg IV bolus, followed by 10 – 20 mg/kg every 6 hours.[15] Data suggest current equine dosing regimens may be higher than necessary after in vitro analysis revealed that the aminocaproic acid plasma concentration needed to inhibit fibrinolysis in horses was $^{1}/_{20}$ of the concentration needed in human plasma.[9]

Monitoring

- Thromboelastography (TEG)
- Signs of bleeding
- Creatine kinase in patients receiving long-term therapy; discontinue the drug if elevations occur

Client Information

- Your veterinarian will need to do regular blood tests to monitor how well your animal is tolerating this medicine. Do not miss these important follow-up visits.
- Use of this drug for treatment of degenerative myelopathy is considered investigational—meaning there is not a large amount of evidence that this treatment is helpful for this condition. Contact your veterinarian if you have any concerns about your animal while it is receiving this medication.

Chemistry/Synonyms

Aminocaproic acid, an inhibitor of fibrinolysis, is a synthetic monamino carboxylic acid occurring as a fine, white crystalline powder. It is slightly soluble in alcohol, freely soluble in water, and has pK_as of 4.43 and 10.75. The injectable product is pH adjusted to ≈6.8.

Aminocaproic acid may also be known as acidum aminocaproicum, CL-10304 CY-116, EACA, epsilon aminocaproic acid, 6-aminohexanoic acid, JD-177, NSC-26154, *Acepramin®*, *Amicar®*, *Capracid®*, *Capramol®*, *Caproamin®*, *Caprolisin®*, *Epsicaprom®*, *Hemocaprol®*, *Hemocid®*, *Hexalense®*, or *Ipsilon®*.

Storage/Stability

Products should be stored at controlled room temperature (20°C-25°C [68°F-77°F]). Avoid freezing liquid preparations. Dilutions in normal saline or dextrose 5% in water at concentrations of 10 and 100 mg/mL had 98% potency that was retained for 7 days at 4°C (39.2°F) and 23°C (73.4°F).[16] Discoloration will occur if aldehydes or aldehydic sugars are present. Dilution with dextrose 5% in water produced discoloration but had no effect on potency.[16]

Compatibility/Compounding Considerations

Compatible with sodium chloride 0.9%, dextrose 5% in water, and lactated Ringer's injection for dilution

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The ARCI (Association of Racing Commissioners International) has designated this drug as a class 4 substance. See ***Appendix*** for more information. The FEI (International Federation for Equestrian Sports) lists this drug as a *prohibited substance - controlled medication*. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Aminocaproic Acid; Oral Tablets: 500 mg and 1000 mg; *Amicar®*; (Rx)

Aminocaproic Acid Oral Syrup: 250 mg/mL in 237 mL; *Amicar®*; (Rx)

Aminocaproic Acid Injection: 250 mg/mL in 20 mL vials; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Aminophylline

(am-in-***off***-i-lin)

Phosphodiesterase Inhibitor Bronchodilator

Prescriber Highlights

- ► Parenteral form of theophylline
- ► Bronchodilator drug with mild diuretic activity
- ► Used as an adjunct therapy for chronic cough caused by tracheitis and bronchitis associated with airway collapse; may also be used to relieve cough in patients with respiratory disease that complicates management of congestive heart failure
- ► Narrow therapeutic index in humans, but dogs appear to be less susceptible to toxic effects at higher plasma concentrations.
- ► Many potential drug interactions. Fluoroquinolones (eg, enrofloxacin) can increase theophylline concentrations substantially.

Uses/Indications

Aminophylline is the parenteral form for administering theophylline. Theophyllines (ie, aminophylline, theophylline) are used primarily for their bronchodilatory effects, especially in animals with cough. Aminophylline also may be used to manage sick sinus syndrome and other bradyarrhythmias.[1]

Theophylline could potentially be of benefit in dogs with pulmonary arterial hypertension if the underlying cause is chronic obstructive pulmonary disease (COPD).[2]

Although theophyllines are still used, especially in animals with cough, they must be used cautiously because of their adverse effects and toxicity.

Pharmacology/Actions

Aminophylline competitively inhibits phosphodiesterase (PDE) III (and PDE IV to a lesser extent), thereby increasing amounts of cyclic AMP (cAMP) that then increase the release of endogenous epinephrine. The increased concentrations of cAMP may also inhibit the release of histamine and the slow-reacting substance of anaphylaxis (SRS-A). The myocardial and neuromuscular transmission effects of aminophylline may be a result of translocating intracellular ionized calcium. Adenosine antagonism may contribute to CNS stimulant effects.

Methylxanthines have anti-inflammatory effects, increase mucociliary clearance, enhance corticosteroid activity, and support respiratory muscles.[3,4] Aminophylline directly relaxes smooth muscles in the bronchi and pulmonary vasculature; smooth muscle relaxant effects also occur in the uterus, as well as the biliary and GI tracts. In addition, aminophylline may induce diuresis, vasodilate arterioles and veins, increase gastric acid secretion, and inhibit mast cell release. Aminophylline has weak chronotropic and inotropic action, improves diaphragm contractility, stimulates the CNS, and can cause respiratory stimulation (centrally mediated).

Pharmacokinetics

Theophylline is distributed throughout the extracellular fluids and body tissues. It crosses the placenta and is distributed into milk (70% of serum concentrations). In dogs, at therapeutic serum concentrations, only ≈7% to 14% is bound to plasma proteins. After IV administration of aminophylline to greyhounds, mean theophylline Vdss was 0.72 L/kg.[5] The volume of distribution in cats is reported to be 0.46 L/kg,[6] and in horses, 0.85 to 1.6 L/kg.[7-9] Because of the low volumes of distribution and theophylline's low lipid solubility, obese patients should be dosed on a lean body weight basis.

In ruminating calves, oral bioavailability is 93%, volume of distribution is 0.8 L/kg, and elimination half-life is 6.4 hours.[10] In adult

camels, protein binding is ≈33%, volume of distribution is ≈0.8 L/kg, and elimination half-life is ≈11 hours.[11] Oral bioavailability in goats and camels is 90%.[12] In goats, volume of distribution is 1.4 L/kg and elimination half-life is ≈2 hours.[12]

Because of the low volume of distribution and theophylline's low lipid solubility, obese patients should be dosed on a lean body weight basis.

Theophylline is metabolized primarily in the liver (in humans) to 3-methylxanthine, which has weak bronchodilator activity. Renal clearance contributes only ≈10% to the overall plasma clearance of theophylline. In humans, wide interpatient variations in serum half-lives and resultant serum concentrations occur. It could be expected that similar variability exists in veterinary patients, particularly those with concurrent illnesses. The reported elimination half-lives (mean values) in various species are ≈9 hours in dogs,[5] ≈7.8 hours in cats,[6] ≈11 hours in pigs, and ≈12 to 17 hours in horses.[8,9] Note that the pharmacokinetics of long-acting theophylline products vary with the modified (ie, extended) release mechanism, and duration of effect may vary between 8 and 24 hours in humans.

Contraindications/Precautions/Warnings

Aminophylline is contraindicated in patients that are hypersensitive to xanthines (including aminophylline, theobromine, caffeine). Use in dogs with a history of epileptiform seizures is contraindicated.[13]

Aminophylline should be administered with caution in patients with severe cardiac disease, seizure disorders, gastric ulcers, hyperthyroidism, renal or hepatic disease, severe hypoxia, or severe hypertension. Aminophylline clearance is decreased ≈50% in patients with hepatic disease or CHF, and a 50% decrease in dosage has been suggested for patients in hepatic failure.[14] Clearance is decreased to a lesser extent by hypothyroidism, fever, and sepsis. Because it may cause or worsen pre-existing arrhythmias, patients with cardiac tachyarrhythmias should receive aminophylline only with caution and enhanced monitoring. Neonatal and geriatric patients may have decreased clearances of aminophylline and be more sensitive to its toxic effects.

In humans, exposure to secondhand smoke may increase aminophylline clearance; whether the same occurs in animals is unknown.

Aminophylline causes intense local pain when administered IM and is rarely used or recommended for administration via this route.

Adverse Effects

Aminophylline can produce CNS stimulation and GI irritation after administration by any route. Most adverse effects are related to the serum concentration of the drug and may be indicative of toxic blood concentrations; dogs appear to tolerate concentrations that may be toxic to humans.

Tachycardia was noted in dogs with a plasma theophylline concentration greater than 30 µg/mL.[15] Undiluted or rapid infusions of aminophylline can cause cardiac arrhythmias, hypotension, tremors, and acute respiratory failure. Under experimental conditions, 10 mg/kg aminophylline by rapid IV administration failed to elicit arrhythmias in healthy dogs.[16]

Tachycardia and excitement have been noted in horses.[17] Transient CNS excitement (eg, tremors) and GI disturbances (eg, vomiting, anorexia) may occur when starting therapy but generally are mild and resolve spontaneously.

Dogs and cats can exhibit clinical signs of nausea and vomiting, insomnia, increased gastric acid secretion, diarrhea, polyphagia, polydipsia, and polyuria. Adverse effects in horses generally are dose-related and may include nervousness, excitability (with auditory, tactile, or visual stimulation), tremors, diaphoresis, tachycardia, and ataxia. Seizures or cardiac arrhythmias may occur in cases of overdose.

Reproductive/Nursing Safety

Aminophylline has been shown to reduce uterine contractions; it crosses the placenta but has not been shown to be teratogenic in mice or rats.

Theophylline is distributed into milk (70% of serum concentrations). Use with caution in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In humans, clinical signs of toxicity (see ***Adverse Effects***) are usually associated with serum drug concentrations greater than 20 µg/mL and become more severe as the serum concentration exceeds that value. Tachycardia, arrhythmia, and CNS effects (eg, seizures, hyperthermia) are considered the most life-threatening aspects of toxicity. Hypokalemia and acid-base disturbances also may occur. Dogs and cats appear to tolerate serum concentrations greater than 20 µg/mL. The ASPCA Animal Poison Control Center (APCC) reported 86 single-agent exposures to theophylline from 2009 to 2013. Of the 75 dogs exposed, 27 had clinical signs, with tachycardia (48%) reported most commonly.

Treatment of theophylline toxicity is supportive. GI decontamination with activated charcoal, which blocks theophylline absorption, can be considered[18,19] and is more effective in reducing theophylline exposure than inducing emesis. Patients with seizures should have an adequate airway maintained and be treated with an IV benzodiazepine (eg, diazepam, midazolam). Patients should be continuously monitored for cardiac arrhythmias and tachycardia. Fluid and electrolytes should be monitored and corrected as necessary.

Hyperthermia may be treated with phenothiazines[20] and tachycardia treated with propranolol if either condition is considered life-threatening. Theophylline is removed by hemodialysis, which may be an option in cases in which activated charcoal cannot be administered.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with aminophylline or theophylline have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Ketamine**: Theophylline with ketamine can cause an increased incidence of seizures and cardiac arrhythmias.
- **Sympathomimetics** (eg, **beta agonists** [eg, **albuterol], ephedrine, isoproterenol, phenylpropanolamine**): Toxic synergism (eg, CNS stimulation, arrhythmias) can occur if theophylline is used concurrently with sympathomimetics (especially ephedrine) or possibly isoproterenol. Concurrent use with beta sympathomimetics is contraindicated according to the UK product label.[13]

The following drugs can ***increase*** or ***decrease*** theophylline concentrations:

- **Isoniazid**
- **Loop Diuretics** (eg, **furosemide**)

The following drugs can ***decrease*** theophylline concentrations:

- **Albendazole**
- **Barbiturates** (eg, **phenobarbital**): Can induce CYP enzymes and increase theophylline metabolism in dogs (not cats)
- **Charcoal, Activated**
- **Herbal Agents** (eg, **fenugreek, garden cress**)[21]
- **Ketoconazole**

- Rifampin
- Sympathomimetics (eg, **beta agonists** [eg, **albuterol**], **ephedrine, isoproterenol, phenylpropanolamine**)

The following drugs can *increase* theophylline concentrations:

- Allopurinol
- Beta-Blockers, Non-Selective (eg, **propranolol**)
- Calcium Channel Blockers (eg, **diltiazem, verapamil**)
- Chloramphenicol: Consider decreasing the dose of theophylline by 30% to 50% or extending the dosing interval.
- Cimetidine
- Corticosteroids (eg, **dexamethasone, prednis(ol)one**)
- Estrogen
- Fluconazole
- Fluoroquinolones (eg, **enrofloxacin, ciprofloxacin**): If adding either, consider reducing the dose of theophylline by 30% or extending the dosing interval. Monitor for toxicity/efficacy. **Marbofloxacin** decreases clearance of theophylline in dogs but not with clinical significance. In animals with renal impairment, marbofloxacin may interfere with theophylline metabolism in a clinically relevant manner.[22]
- Interferon Alfa
- Macrolides (eg, **clarithromycin, erythromycin**)
- Methotrexate
- Mexiletine
- Selective Serotonin Reuptake Inhibitors (SSRIs; eg, **fluoxetine**)
- Thiabendazole
- Thyroid Hormones (in hypothyroid patients)

Theophylline may *decrease* the effects of the following drugs:

- Benzodiazepines (eg, **diazepam, midazolam**)
- Lithium
- Pancuronium
- Propofol[23]

Laboratory Considerations

- Theophylline can cause falsely elevated values of **serum uric acid** if measured by the Bittner or colorimetric methods. Values are not affected if using the uricase method.
- Immunoassays are specific for theophylline. If using a spectrophotometric method of assay, theophylline serum concentrations can be falsely elevated by **furosemide, phenylbutazone, probenecid, theobromine, caffeine, sulfathiazole, chocolate**, or **acetaminophen**. **Cefazolin** may interfere with HPLC assays. The Schack and Wexler method of determining theophylline concentrations may be affected by large doses of **thiamine**.

Dosages

NOTES:

1. Theophyllines have a relatively low therapeutic index; determine doses carefully. Calculate doses based on lean body weight.
2. Dosage conversions between aminophylline and theophylline can be performed using the information found in the *Chemistry* section.

DOGS/CATS:

Bronchodilator (extra-label): 3 – 11 mg/kg IV or IM every 6 to 12 hours. Dogs may require the higher end of the dosage range and may be dosed every 6 to 8 hours. For cats, the low end of the dosing range is used and given every 12 hours. If effective, switch to oral therapy (theophylline) as soon as possible. When giving IV, do not push. Preferably administer over at least several minutes or as an infusion.

HORSES:

Adjunctive treatment of severe equine asthma (SEA; formerly known as recurrent airway obstruction [RAO]); (extra-label): 5 – 14 mg/kg IV every 8 to 12 hours.[17,24] IV infusion should be in ≈1 liter of IV fluids given over 20 to 60 minutes. Rarely recommended because of narrow therapeutic index. Consider monitoring serum aminophylline concentrations.

CATTLE

Bronchoconstriction secondary to smoke inhalation (extra-label): 6 – 10 mg/kg IV or PO three times daily[25]

Monitoring

- Therapeutic efficacy
- Clinical signs of toxicity: tachycardia, vomiting, diarrhea, seizures
- Consider measuring serum theophylline concentrations for patients not responding to therapy or that have clinical signs of toxicity. The therapeutic serum concentrations of theophylline in humans are generally described to be ≈10 µg/mL. In small animals, serum concentrations can be monitored by measuring the trough concentration; the concentration should be greater than 8 – 10 µg/mL. **NOTE**: Some clinicians recommend not exceeding 15 µg/mL in horses.[17]

Client Information

- Injectable aminophylline should only be used in an inpatient setting or under the direct supervision of a veterinarian.

Chemistry/Synonyms

Aminophylline occurs as bitter-tasting, white or slightly yellow granules or powder, with a slight ammoniacal odor and a pK_a of 5.

Aminophylline is soluble in water and insoluble in alcohol. One mg of aminophylline (hydrous) contains ≈0.79 mg of theophylline (anhydrous). Conversely, 1 mg of theophylline (anhydrous) is equivalent to 1.27 mg aminophylline (hydrous).

Aminophylline also may be known as aminofilina, aminophyllinum, euphyllinum, metaphyllin, theophyllaminum, theophylline and ethylenediamine, theophylline ethylenediamine compound, or theophyllinum ethylenediaminum; many trade names are available.

Storage/Stability

Aminophylline for injection should be stored in single-use containers in which carbon dioxide has been removed. It should be stored at 20°C to 25°C (68°F-77°F) and protected from freezing and light. Upon exposure to air (carbon dioxide), aminophylline will absorb carbon dioxide, lose ethylenediamine, and liberate free theophylline that can precipitate out of solution. Do not inject aminophylline solutions that contain either precipitate or visible crystals.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Aminophylline for injection is reportedly **compatible** when mixed with commonly used IV solutions, but it may be **incompatible** with 10% fructose or invert sugar solutions. Aminophylline is reportedly **compatible** when mixed with the following drugs: calcium gluconate, chloramphenicol sodium succinate, dexamethasone sodium phosphate, dopamine HCl, erythromycin lactobionate, heparin sodium, hydrocortisone sodium succinate, lidocaine HCl, metronidazole with sodium bicarbonate, phenobarbital sodium, potassium chloride, sodium bicarbonate, sodium iodide, terbutaline sulfate, and verapamil HCl.

Aminophylline is reportedly **incompatible** (or data conflict) with the following drugs: amikacin sulfate, ascorbic acid injection, bleomycin sulfate, clindamycin phosphate, corticotropin, dimen-

hydrinate, dobutamine HCl, doxorubicin HCl, epinephrine HCl, erythromycin gluceptate, hydralazine HCl, hydroxyzine HCl, insulin (regular), isoproterenol HCl, meperidine HCl, methadone HCl, methylprednisolone sodium succinate, morphine sulfate, norepinephrine bitartrate, oxytetracycline, penicillin G potassium, pentazocine lactate, procaine HCl, prochlorperazine, promazine HCl, promethazine HCl, vancomycin HCl, and vitamin B complex with C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Aminophylline Injection: 25 mg/mL (equivalent to 19.7 mg/mL of theophylline) in 10 mL and 20 mL vials; generic; (Rx)

Oral aminophylline tablets have been discontinued for the US market. See the ***Theophylline*** monograph for information on using oral products.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Amiodarone

(a-mee-oh-***da***-rone) *Cordarone®, Nexterone ®, Pacerone®*

Antiarrhythmic Class III

Prescriber Highlights

- ► Antiarrhythmic agent used in dogs for arrhythmias associated with systolic dysfunction or for cardioversion from atrial fibrillation to sinus rhythm; very limited experience warrants cautious use. May take several days to weeks to have an effect
- ► When combined with itraconazole, is an effective treatment for *Trypanosoma cruzi* infection (Chagas disease).
- ► May be useful in horses for cardioversion from atrial fibrillation, supraventricular tachycardia, or ventricular tachycardia to sinus rhythm
- ► Contraindications include cardiogenic shock, or bradyarrhythmias (eg, second- and third-degree heart block, sinus node dysfunction) and iodine hypersensitivity. Use caution in patients with thyroid dysfunction; can exacerbate or cause hypo- or hyperthyroidism
- ► Adverse effects in dogs include GI disturbances (eg, nausea, vomiting, anorexia). Corneal deposits, neutropenia, pulmonary fibrosis, thrombocytopenia, bradycardia, hepatotoxicity, and positive Coombs tests have been reported. IV formulations containing polysorbate 80 (*Tween® 80*) can cause serious histaminergic effects in dogs.
- ► Limited use in horses precludes a full adverse effect profile; pelvic limb weakness, diarrhea and increased bilirubin have been reported when used IV for cardioversion.
- ► Many potential drug interactions

Uses/Indications

Because of its potential toxicity and limited experience with use in canine and equine patients, amiodarone is generally used only when other less toxic or commonly used drugs are ineffective. Amiodarone may be useful in dogs and horses for cardioversion from atrial fibrillation to sinus rhythm and in dogs for arrhythmias in which the benefit outweighs the risk (eg, refractory arrhythmia associated with systolic dysfunction).

Amiodarone combined with itraconazole reduced mortality and clinical signs of *Trypanosoma cruzi* infection (Chagas disease) in dogs.[1]

Successful use of a constant rate infusion of amiodarone for cardioversion of supraventricular tachycardia has been reported in a horse.[2] It was unsuccessful in cardioverting a llama with lone atrial fibrillation.[3]

Pharmacology/Actions

Amiodarone's mechanism of action is not fully understood; it acts primarily as a potassium channel blocker that possesses unique pharmacology from other antiarrhythmic agents. It can be best classified as a class III antiarrhythmic agent that also blocks sodium and calcium channels and beta-adrenergic receptors. Major properties include prolongation of myocardial cell action-potential duration and refractory period.

The trypanocidal effects of amiodarone in *T cruzi* appear to be mediated by disruption of calcium homeostasis, sterol production, and blockade of the protease cruzipain.[1]

Pharmacokinetics

Amiodarone may be administered parenterally or orally. It is widely distributed throughout the body and can accumulate and persist in adipose tissue. Amiodarone concentrations in myocardial cells[4] and adipose tissue[5] are significantly higher than in plasma. Amiodarone is metabolized by the liver into desethylamiodarone, which is active. After oral administration of a single dose in healthy dogs, amiodarone's plasma half-life averaged 7.5 hours, but repeated dosing increased its half-life to 3.2 days.[5]

In horses, amiodarone has a low oral bioavailability (6% to 34%) and peak concentrations of amiodarone and desethylamiodarone occur ≈7 to 8 hours after an oral dose. After IV administration, amiodarone is rapidly distributed with a high apparent volume of distribution of 31 L/kg. In horses, amiodarone is highly bound to plasma proteins (96%). Clearance was 0.35 L/kg/hour and median elimination half-lives for amiodarone and desethylamiodarone after IV administration were ≈51 and 75 hours, respectively compared to 24 and 59 hours, respectively, after oral administration.[6]

In humans, oral absorption is slow and variable, with bioavailabilities ranging from 22% to 86%. Elimination half-lives for amiodarone and desethylamiodarone range from 2.5 to 10 days after a single dose but average 53 days and 60 days, respectively, with chronic dosing.

Contraindications/Precautions/Warnings

Amiodarone is considered contraindicated in patients that are hypersensitive to it or iodine, or that have cardiogenic shock, severe sinus node dysfunction with severe sinus bradycardia, second- and third-degree atrioventricular block, or bradycardial syncope. Amiodarone should be used with caution in patients with thyroid dysfunction.

One report has shown Doberman pinschers with ventricular arrhythmias to be at higher risk for toxicity, particularly hepatic and GI toxicity, from amiodarone. This report concludes that amiodarone should be used cautiously in Doberman pinschers with preclinical left ventricular systolic dysfunction prior to receiving other antiarrhythmic agents.[7]

Amiodarone inhibits peripheral conversion of thyroxine T4 to triiodothyronine T3, and in humans may cause hypothyroidism (more common); rarely, amiodarone can also lead to iodine-induced hyperthyroidism or a destructive thyroiditis in humans.[8]

Adverse Effects

GI effects (eg, anorexia, vomiting) are the most likely adverse effects in canine patients.[1] Hepatopathy (eg, bilirubinemia, increased hepatic enzymes) has been reported in dogs on amiodarone.[1,9] Because hepatic effects can occur before clinical signs are noted, routine serial evaluation of liver enzymes and bilirubin is recommended; laboratory abnormalities may require 6 to 8 weeks to resolve. Amiodarone dosage should be reduced, or the drug discontinued if hepatopathy

develops.[10] Other adverse effects reported in dogs include bradycardia, neutropenia, thrombocytopenia, keratopathy,[11,12] regenerative anemia, and a positive Coombs test.[13] Corneal deposits may be seen in dogs treated with amiodarone, but this affect apparently occurs less frequently in dogs than in humans.

A case series of 5 dogs administered IV amiodarone reported pruritus, erythema, subcutaneous edema, hives, agitation, tachypnea, and hypotension.[14] The authors postulated that the solvent polysorbate 80 found in the IV solutions could be the cause of these effects. A newer IV formulation, *Nexterone®*, does not contain polysorbate 80 or benzyl alcohol. One study of 17 dogs receiving *Nexterone®* showed no adverse effects after a 2 mg/kg bolus followed by a 0.8 mg/kg/hour infusion.[15] Under experimental conditions, decreased myocardial contractility was noted at 12.5 – 15 mg/kg IV.[16]

Horses treated with IV amiodarone for 36 hours or longer developed short-term hind limb weakness and diarrhea.[17,18]

In human patients, adverse effects are very common while on amiodarone therapy (eg, nausea and vomiting). The effects that most commonly cause discontinuation of the drug include pulmonary infiltrates or pulmonary fibrosis (sometimes fatal), liver enzyme elevations, congestive heart failure, bradycardia, paroxysmal ventricular tachycardia, peripheral neuropathy, and thyroid dysfunction (hypo- or hyperthyroidism). Some individuals develop a bluish tint to their skin. Optic neuropathy or neuritis has been reported.

Reproductive/Nursing Safety

In laboratory animals, amiodarone has been embryotoxic and fetotoxic at doses 3 times the maximum recommended human dose, and congenital bony malformations and thyroid abnormalities have been detected in offspring. Use during pregnancy only when the potential benefits outweigh the risks of the drug. Amiodarone may reduce male and female fertility.

Amiodarone is excreted in milk, and adverse effects in nursing infants have been reported. Use during nursing is not recommended.

Overdose/Acute Toxicity

Clinical overdose experience is limited; adverse effects include hypotension, bradycardia, cardiogenic shock, AV block, and hepatotoxicity. Treatment is supportive. Bradycardia may be managed with beta agonists (eg, isoproterenol) or a pacemaker; hypotension may be managed with positive inotropic agents or vasopressors. Neither amiodarone nor its active metabolite is dialyzable.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Several potentially significant interactions can occur with amiodarone. The following is a partial list of interactions that have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

Amiodarone may significantly **increase** the serum levels and/or pharmacologic or toxic effects of:

- **Beta-Adrenergic Antagonists** (eg, **atenolol, metoprolol, propranolol**)
- **Calcium-Channel Blockers** (**CCBs**; eg, **amlodipine, diltiazem**): Possible potentiation of bradycardia, AV block or sinus arrest
- **Digoxin:** May increase digoxin concentration and risk for bradycardia
- **Cyclophosphamide**
- **Cyclosporine:** May also increase creatinine
- **Dextromethorphan**
- **Lidocaine (Systemic)**
- **Methotrexate** (with prolonged amiodarone administration)
- **Procainamide**
- **Quinidine**
- **Warfarin**

Amiodarone may **prolong the QT interval**, which may be additive and lead to cardiac arrhythmias when administered with the following drugs:

- **Antiarrhythmics** (eg, **disopyramide, procainamide, quinidine, sotalol)**
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**)
- **Cisapride**
- **Fluoroquinolone Antibiotics** (some, such as **moxifloxacin**, possibly **pradofloxacin**, but NOT **enrofloxacin, marbofloxacin**)
- **Macrolide Antibiotics** (eg, **azithromycin, erythromycin**)
- **Opioids** (ie, **buprenorphine, methadone**)
- **Serotonin HT_3 Antagonists** (eg, **granisetron, ondansetron**)

Other amiodarone drug interactions:

- **Anesthetics, General** (eg, **isoflurane, propofol**): Increased risks for hypotension or arrhythmias
- **Cholestyramine:** May decrease amiodarone concentration
- **Cimetidine**: Increased amiodarone levels
- **Opioids** (eg, **fentanyl, morphine**): Possible hypotension, bradycardia
- **Rifampin**: Decreased amiodarone levels
- **Theophylline**: Amiodarone may reduce theophylline metabolism

Laboratory Considerations

- Although most human patients remain euthyroid while receiving amiodarone, it may cause an increase in **serum T_4** and **serum reverse T_3** concentrations, and a reduction in **serum T_3** concentrations.
- Amiodarone may cause a **positive Coombs** test result.[13]

Dosages

NOTE: Some human references state that because of the potential for drug interactions with previous drug therapies, the life-threatening nature of the arrhythmias being treated, and the unpredictability of response to amiodarone, the drug should initially be given (loaded) over several days in an inpatient setting where adequate monitoring can occur.

DOGS:

Atrial fibrillation or ventricular arrhythmias (extra-label): Dosages for oral amiodarone are not well established, and there is significant variation in recommendations. At present, no well-controlled, prospective studies evaluating dosage regimens in clinically ill dogs could be located.

1. 5 – 7.5 mg/kg per day PO[19]; a retrospective study concluded that amiodarone might be a safe and effective alternative drug for the treatment of arrhythmias with myocardial dysfunction that are not controlled with commonly used antiarrhythmic drugs.
2. Due to its unique pharmacokinetics, an initial loading dosage of 8 – 10 mg/kg PO twice daily for 1 week then reduce to 5 – 10 mg/kg PO once daily thereafter. [20,21]

Ventricular tachycardia, supraventricular tachycardia, or atrial flutter refractory to other antiarrhythmic therapy (extra-label): Using polysorbate 80-free formulation (ie, *Nexterone®*, 2 mg/kg IV

over 10 minutes followed by 0.8 mg/kg/hour IV CRI for 6 hours and then 0.5 mg/kg/hour thereafter).[15] A dedicated central venous catheter and an in-line filter are recommended for IV administration.[22] In the study, for patients in cardiopulmonary arrest, doses ranged from 3 – 12 mg/kg IV with a CRI of 0.05 – 18 mg/kg/hour.

***T cruzi* infection** (extra-label): Amiodarone loading dose: 15 mg/kg PO every 12 hours for 7 days, followed by 15 mg/kg PO every 24 hours for 14 days. Maintenance dose: 7.5 mg/kg PO every 24 hours. Itraconazole 10 mg/kg PO (rounded down to the nearest 100 mg increment dose) every 24 hours (**NOTE**: Itraconazole 100 mg PO every 48 hours was administered to dogs with low body weight) was concurrently initiated on the first day of amiodarone therapy. [1] Treatment continued for 12 months. A minority of dogs (15%) initiated amiodarone at the maintenance dose (ie, the loading dose was omitted). Amiodarone dose was reduced by half if adverse effects occurred.

HORSES:

Atrial fibrillation, supraventricular tachycardia, or ventricular tachycardia (extra-label): 5 mg/kg/hour IV CRI for 1 hour, followed by 0.83 mg/kg/hour IV CRI for 23 hours and then 1.9 mg/kg/hour IV CRI for the following 30 hours.[17,23] Infusion was discontinued when conversion occurred or when any adverse effects were noted. Four of 6 horses converted from atrial fibrillation as well as 1 horse from supraventricular tachycardia and 1 from ventricular tachycardia. One horse with supraventricular tachycardia also was given amiodarone at 5 mg/kg PO every 24 hours with strict stall rest for 2 weeks.[2]

Monitoring

- Intermittent or continuous ECG
- Adverse effects (eg, inappetence, vomiting, diarrhea)
- The human therapeutic serum amiodarone concentrations of 1 – 2.5 µg/mL are believed to apply to dogs as well. One study in horses[18] suggests adverse effects may be more common when amiodarone concentration exceeds 2.5 µg/mL, although a dose relationship was not noted in another study.[23]
- Baseline and periodic CBC, liver panel, thyroid function tests, blood pressure, and thoracic radiographs as indicated. One reference recommends that liver enzymes be monitored monthly during therapy; if liver enzymes become abnormal, it is recommended the dosage be reduced or the drug be discontinued.[10]
- *T cruzi*: PCR and/or serology to assess therapeutic effectiveness

Client Information

- This drug has not been used often in dogs, and therefore not all side effects are known. The most commonly reported side effects seen in dogs are vomiting and lack of appetite. Consult your veterinarian if there are any unexpected effects.
- Amiodarone may interact with other medications. Make sure your veterinarian is aware of all medications and supplements your animal is receiving.
- Your veterinarian will need to monitor your animal while on this medication. Do not miss these important follow-up visits.

Chemistry/Synonyms

An iodinated benzofuran, amiodarone is unique structurally and pharmacologically from other antiarrhythmic agents. Amiodarone occurs as a white to cream colored lipophilic powder having a pK_a of ≈6.6. Amiodarone 200 mg tablets each contain ≈75 mg of iodine. Generic forms of the injectable solution contain polysorbate 80 and benzyl alcohol. *Nexterone*® pre-filled IV bags contain dextrose 42.1 mg/mL but do not contain benzyl alcohol or polysorbate 80.

Amiodarone HCl may also be known as amiodaroni hydrochloridum, L-3428, 51087N, or SKF-33134-A; *Cordarone*®, *Nexterone*® and *Pacerone*® are among many trade names available.

Storage/Stability

Tablets should be stored in airtight containers, at room temperature 20°C to 25°C (68°F-77°F) and protected from light.

Injection should be stored at room temperature and protected from light, freezing, or excessive heat. While administering, light protection is not necessary.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

IV preparations should be diluted with 5% dextrose in water (D5W). Amiodarone is reportedly **compatible** with dobutamine, lidocaine, potassium chloride, procainamide, propafenone, and verapamil. Variable compatibility is reported with furosemide and quinidine gluconate. Do not admix supplemental medications with *Nexterone*®.

Compounded preparation stability: Amiodarone oral suspension compounded from commercially available tablets has been published.[24] Triturating 1 tablet of amiodarone 200 mg with 20 mL of *Ora-Plus*® and quantity sufficient to make to 40 mL with *Ora-Sweet*® (or *Ora-Sweet*®*SF*) yields a 5 mg/mL oral suspension that retains more than 90% potency for 91 days stored at 5°C. Compounded preparations of amiodarone should be protected from light. Amiodarone suspensions may be stored at room temperature during short periods (eg, travel).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Amiodarone Oral Tablets: 100 mg, 200 mg, and 400 mg; generic; (Rx)

Amiodarone Injection Solution: 50 mg/mL in 3 mL and 9 mL single-dose vials, and 18 mL single-dose vials or multi-dose vials; 3 mL prefilled syringes; generic; (Rx)

Amiodarone Injection Solution: 150 mg/100 mL and 360 mg/200 mL prefilled IV bags (contains 42.1 mg/mL dextrose as diluent); *Nexterone*®; (Rx)

Amitriptyline

(a-mih-***trip***-ti-leen) *Elavil*®

Tricyclic Antidepressant; Antipruritic; Neuropathic Pain Modifier

Prescriber Highlights

- ► Tricyclic antidepressant used primarily for behavior disorders, neuropathic pain, and pruritus in small animals
- ► May reduce seizure thresholds in epileptic animals
- ► The most likely adverse effects include sedation and anticholinergic effects; there is risk for serotonin syndrome when amitriptyline is used concurrently with serotonergic drugs.
- ► May take a few weeks to see clinical effects; taper medication when discontinuing
- ► Many possible drug interactions
- ► Overdose can be serious.
- ► Use may decrease total triiodothyronine (tT3), total thyroxine (tT4), and free T4 (fT4) concentrations in dogs and cats; baseline thyroid testing should be performed prior to initiating therapy.

Uses/Indications

Amitriptyline is a tricyclic antidepressant (TCA) that has been used for the treatment of behavior conditions (eg, separation anxiety, generalized anxiety) and pruritus[1] in dogs, as well as to treat excessive grooming, spraying, pica, and anxiety in cats. Clomipramine is an FDA-approved TCA for use in dogs and is therefore often chosen over amitriptyline in cases where a TCA is needed for the treatment of behavior-modifying indications. A retrospective study also suggests clomipramine is more effective than amitriptyline.[2] One study demonstrated that amitriptyline was not effective in the treatment of aggressive dogs that were concomitantly undergoing behavior modification; however, the dose may have been inadequate.[3]

Amitriptyline may be useful for adjunctive treatment of chronic neuropathic pain in dogs[4] and cats. Although studies have questioned the drug's use for adjunctive treatment of lower urinary tract disease in cats,[5,6] amitriptyline appears to still be anecdotally used for analgesic and/or urethral antispasmodic effects.

Amitriptyline appears effective in reducing feather plucking in birds.[7,8]

Pharmacology/Actions

Amitriptyline (and its active metabolite, nortriptyline) is a tricyclic antidepressant (TCA) with a complicated pharmacologic profile that includes blockage of serotonin and norepinephrine reuptake pumps (thereby increasing neurotransmitter concentrations), sedation, and central and peripheral anticholinergic activity. Other pharmacologic effects include alpha-1 adrenergic antagonism, stabilizing mast cells via H1 receptor antagonism, and antagonism of glutamate receptors and sodium channels. TCAs act similar to phenothiazines in altering avoidance behaviors in animals.

Amitriptyline potentiated the minimum alveolar concentration (MAC)-sparing effects of remifentanil in rats.[9]

Pharmacokinetics

Amitriptyline is rapidly absorbed from both the GI tract and parenteral injection sites, but transdermal (PLO gel-based) absorption in cats is poor.[10] Absolute bioavailability is low, with one study noting only 6% bioavailability after a single oral dose (4 mg/kg) was administered to greyhounds.[11] Absorption appears to be increased when amitriptyline is administered with food.[12] Low oral bioavailability in dogs may reflect both incomplete absorption and first-pass metabolism to inactive metabolites. Further investigation is necessary.[11]

Peak concentrations occur 1 to 2 hours after oral administration in dogs[11–13] and cats[10] and within 2 to 12 hours in other species. Amitriptyline is highly bound to plasma proteins and enters the CNS. The drug is metabolized in the liver to several metabolites, including nortriptyline, which is active. In a study of 12 crossbreed dogs, the elimination half-life of amitriptyline and nortriptyline was 4.5 hours and 12.3 hours, respectively.[13] In greyhounds, the mean terminal half-life was 4 to 10 hours, and the terminal half-life of nortriptyline was 6.2 to 9.6 hours.[11] Because tricyclic antidepressants (TCAs) are metabolized through glucuronidation, cats may be more sensitive to TCAs than dogs.[14]

Amitriptyline has been administered intrathecally and epidurally in sheep; the concentration-time profiles were highly variable, with a bioavailability of 55% and 1.3%, respectively.[15]

One study in birds saw significantly varied absorption and elimination constants. Elimination half-life varied from 1.6 to 91.2 hours.[16]

Contraindications/Precautions/Warnings

Amitriptyline is contraindicated in patients that are hypersensitive to it or other tricyclic antidepressants (TCAs). Concomitant use with monoamine oxidase inhibitors is contraindicated in humans. Use amitriptyline with extreme caution in animals with seizure disorders, as tricyclic agents may reduce seizure thresholds. In cats, at standard doses, epileptiform pathology was noted on EEG, and sustained discharges and generalized seizures occurred at higher (20 – 25 mg/kg IV) doses.[17] Use amitriptyline with caution in animals with thyroid disorders, urinary retention, hepatic disorders, renal disorders, KCS, glaucoma, cardiac rhythm disorders, diabetes, or adrenal tumors. Although amitriptyline may prolong the QTc interval in humans, ECG abnormalities did not occur in healthy dogs with behavioral conditions treated with standard doses of amitriptyline.[18,19]

Because data are lacking about the impact of amitriptyline on the QT interval in animals, this drug should be used with caution in patients that have pre-existing cardiac disease.

Amitriptyline should not be given on an as-needed basis; it needs to be given continuously and may require several weeks to see a positive response. If discontinuing amitriptyline, the dose should be slowly tapered over 2 to 3 weeks to minimize the risks for signs of withdrawal.

Adverse Effects

The most predominant adverse effects seen with tricyclic antidepressants (TCAs) are related to sedation and anticholinergic (eg, constipation, urinary retention) properties. Occasionally, dogs exhibit hyperexcitability and, rarely, develop seizures; however, adverse effects can affect various systems, including cardiac (eg, dysrhythmias), hematologic (eg, bone marrow suppression), GI (eg, vomiting, diarrhea), and endocrine (eg, hyperglycemia, hyponatremia). After oral administration, vomiting may be more likely in fasted dogs.[12]

Adverse effects seen in cats include sedation, hypersalivation, urinary retention, anorexia, thrombocytopenia, neutropenia, unkempt hair coat, vomiting/nausea, ataxia, disorientation, and cardiac conductivity disturbances.[5,20]

Reduced reverse triiodothyronine (rT3), total thyroxine (tT4), and free T4 (fT4) concentrations may occur in dogs and cats.[21,22]

Dystonia and akathisia were described in a macaw that was given a single dose of amitriptyline.[23]

Reproductive/Nursing Safety

In humans, amitriptyline crosses the placenta, and isolated reports of limb reduction abnormalities in fetuses have been noted. Amitriptyline enters maternal milk in levels similar to or greater than those found in maternal serum. In humans, amitriptyline is considered a drug for which the effect on nursing infants is unknown but may be of concern.[24]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh potential risks.

Overdose/Acute Toxicity

Overdose with tricyclic antidepressants (TCAs) can cause life-threatening conditions (eg, arrhythmias, cardiorespiratory collapse). Under experimental conditions, dogs receiving amitriptyline by IV infusion developed cardiotoxicity after an average cumulative dose of 36 mg/kg, and convulsions occurred in 42% of dogs.[25] Other common clinical signs in dogs and cats include lethargy, ataxia, and vomiting. IV fat emulsion therapy (*Intralipid*®) is thought to trap amitriptyline in plasma during overdose and lower brain concentration; however, severe hypotension occurred in 10% of pigs,[26] and amitriptyline mortality rates were not affected in rats.[27]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

In humans, amitriptyline is a substrate of CYP3A4, 2C9, and 2D6. The following drug interactions with amitriptyline either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetazolamide/Dichlorphenamide**: Concurrent use may increase amitriptyline concentrations by alkalinizing urine.
- **Alpha-2 Adrenergic Agonists** (eg, **clonidine**, **detomidine, dexmedetomidine, medetomidine**): Concurrent use may increase the risk for CNS and respiratory depression, hypertension, and bradycardia. Tricyclic antidepressants (TCAs) may interfere with the antihypertensive effects of alpha-2 agonists. Use cautiously in combination.
- **Amantadine**: Concurrent use may increase the risk for urinary retention, constipation, ileus, hyperthermia, heat stroke, anticholinergic intoxication syndrome, and QT interval prolongation. Use cautiously in combination.
- **Ammonium Chloride**: Concurrent use may decrease tricyclic antidepressant concentrations by acidifying urine.
- **Anesthetic Agents** (eg, **isoflurane**, **ketamine**): Concurrent use may increase the risk for hypotension, CNS depression, QT interval prolongation, torsade de pointes, and death.
- **Anthracyclines** (eg, **doxorubicin**): Concurrent use may cause additive effects on the QT interval.
- **Anticholinergic Agents** (eg, **atropine**, **doxepin**, **glycopyrrolate**, **meclizine**, **oxybutynin**): Concurrent use may increase the risk for constipation, ileus, urinary retention, CNS depression, and anticholinergic intoxication syndrome.
- **Antihistamines** (eg, **cetirizine**, **chlorpheniramine**, **diphenhydramine**, **hydroxyzine**): Concurrent use may increase the risk for constipation, ileus, urinary retention, CNS depression, and anticholinergic intoxication syndrome.
- **Antihypertensive Agents**: Concurrent use may result in additive hypotension and orthostasis.
- **Apomorphine**: Concurrent use may increase the risk for QT interval prolongation, torsade de pointes, and death.
- **Azole Antifungals** (eg, **itraconazole**, **ketoconazole**): Concurrent use increases the risk for CNS toxicity, constipation, ileus, urinary retention, and QT interval prolongation.
- **Barbiturates** (eg, **thiopental**): Concurrent use may cause additive respiratory depression. Amitriptyline concentrations may decrease.
- **Benzodiazepines** (eg, **diazepam**, **midazolam**): Concurrent use may increase the risk for CNS and/or respiratory depression. Anticholinergic effects may be additive.
- **Beta-2 Adrenergic Agonists** (eg, **albuterol**, **clenbuterol**): Concurrent use may increase the risk for arrhythmias, hypertension, hyperpyrexia, flattening of the T-wave, and QT interval prolongation. Use cautiously in combination.
- **Bethanechol**: Amitriptyline may antagonize the cholinergic effects of bethanechol. Avoid combination.
- **Bromocriptine**: Amitriptyline may enhance the CNS depression and respiratory depression effects of bromocriptine. Concurrent use may increase the risk for serotonin syndrome.
- **Buspirone**: Concurrent use may increase the risk for CNS depression and serotonin syndrome. Avoid combination.
- **Cannabidiol**: Concurrent use may increase the risk for CNS depression.
- **Carbamazepine**: Concurrent use may decrease concentrations of amitriptyline by induction of CYP450 enzymes, and carbamazepine concentrations may be increased by an undetermined mechanism. Amitriptyline may decrease anticonvulsant effects of carbamazepine.
- **Cimetidine**: May inhibit amitriptyline hepatic metabolism and increase the risk for toxicity
- **Cyproheptadine**: Concurrent use may decrease efficacy of amitriptyline by decreasing serotonin concentrations, may increase the risk for CNS depression, and anticholinergic effects may be additive.
- **Desmopressin**: Concurrent use may increase the risk for water intoxication and/or hyponatremia, which can progress to seizure, coma, respiratory depression, and death. Electrolytes and renal function should be monitored.
- **Diazoxide**: Concurrent use may increase the risk for hypotension and orthostasis, with greatest risk during initial treatment or dose escalation.
- **Diltiazem**: May increase amitriptyline concentrations
- **Dobutamine/Dopamine**: Concurrent use may increase the risk for hypertension, tremors, and cardiac dysrhythmias. Avoid concurrent use except in emergency cases.
- **Domperidone**: Concurrent use may increase the risk for QT interval prolongation, cardiac arrhythmias, torsade de pointes, and death. Efficacy of domperidone may be decreased. Avoid combination.
- **Erythromycin**: Concurrent use may increase the risk for QT interval prolongation and cardiac arrhythmias.
- **Estrogens**: May decrease effect and increase toxicity of amitriptyline; mechanism and clinical significance are not established.
- **Fluconazole**: Concurrent use may increase the risk for QT interval prolongation.
- **Flumazenil**: Flumazenil use in animals suspected of TCA overdose may increase the risk for seizures and arrhythmias.[25]
- **Fluoroquinolones** (eg, **ciprofloxacin**, **enrofloxacin**): Concurrent use may increase the risk for QT interval prolongation, torsade de pointes, and death.
- **Hydroxychloroquine**: Concurrent use may increase the risk for QT interval prolongation.
- **Ifosfamide**: Concurrent use may increase neurotoxicity of ifosfamide.
- **Iohexol**: Concurrent use may increase the risk for seizures associated with intrathecal administration of iohexol.
- **Leuprolide**: Concurrent use may increase the risk for QT interval prolongation, torsade de pointes, and death.
- **Levetiracetam**: Concurrent use may increase the risk for CNS and respiratory depression.
- **Lithium**: Concurrent use may increase the risk for neurotoxicity, including serotonin syndrome.
- **Macrolides** (eg, **azithromycin**, **clarithromycin**): Concurrent use may increase the risk for QT interval prolongation, torsade de pointes, and death.
- **Methylphenidate**: Concurrent use may increase concentrations of amitriptyline and increase the risk for hypertension, cardiac effects, and CNS stimulation, including increased risk for serotonin syndrome.
- **Metoclopramide**: Amitriptyline may reduce the prokinetic effect of metoclopramide. Combination may also result in additive sedation or CNS depression.
- **Metronidazole**: Concurrent use may increase the risk for QT interval prolongation, cardiac arrhythmias, and torsade de pointes.
- **Mirtazapine**: Concurrent use may increase the risk for constipation, urinary retention, CNS depression, and serotonin syndrome.

- **Mitotane**: Mitotane may induce CYP3A4 and reduce amitriptyline exposure and effectiveness.
- **Monoamine Oxidase Inhibitors** (eg, **amitraz**, **furazolidone**, **linezolid**, **methylene blue**, **procarbazine**, **selegiline**): There is a potential risk for life-threatening serotonin syndrome. Concurrent use is contraindicated. A 14-day washout period between the 2 drugs should be observed.
- **Muscle Relaxants** (eg, **baclofen**, **dantrolene**, **methocarbamol**): Concurrent use may increase the risk for CNS and respiratory depression. Loss of muscle tone and memory has been reported with baclofen use in humans.
- **Nitroglycerin**: Concurrent use may increase the risk for hypotension and orthostasis. Amitriptyline may reduce topical nitroglycerin absorption.
- **Nitroprusside**: Concurrent use may increase the risk for hypotension and orthostasis.
- **Nonsteroidal Anti-Inflammatory Drugs** (NSAIDS; eg, **carprofen**, **meloxicam**, **robenacoxib**): Concurrent use may increase the risk for bleeding. Use cautiously, especially in animals with other risk factors
- **Octreotide**: Concurrent use may increase the risk for serotonin syndrome, QT interval prolongation, and torsade de pointes. Avoid combination.
- **Opioids** (eg, **buprenorphine**, **butorphanol**, **fentanyl**, **methadone, morphine**): Concurrent use may increase the risk for constipation, urinary retention, CNS depression, respiratory depression, and serotonin syndrome.
- **Pergolide**: Concurrent use may increase the risk for CNS depression.
- **Phenothiazines** (eg, **acepromazine**, **chlorpromazine**): Concurrent use may increase concentrations of either drug, increasing the risk for CNS depression, hypotension, prolongation of the QT interval, constipation, ileus, urinary retention, and anticholinergic intoxication syndrome.
- **Phenoxybenzamine:** Concurrent use may increase the risk for hypotension and orthostasis.
- **Physostigmine:** Amitriptyline may negate the clinical effects of physostigmine
- **Potassium Chloride**: Concurrent use of oral, solid dosage forms of potassium chloride may increase the risk for upper GI injury. Combination is contraindicated.
- **Pregabalin**: Concurrent use may increase the risk for CNS depression.
- **Primidone/Phenobarbital:** Concurrent use may antagonize the anticonvulsant effects of primidone. Primidone may decrease amitriptyline concentration by inducing hepatic metabolism. CNS and respiratory depressant effects may be additive.
- **QT Prolonging Agents** (eg, **cisapride**, **procainamide**, **quinidine**, **sotalol**): Concurrent use may increase the risk for QT interval prolongation, cardiac arrhythmias, torsade de pointes, and death. May potentiate anticholinergic effects of some agents (eg, **quinidine**). Avoid concurrent use.
- **Rifampin**: Concurrent use may decrease amitriptyline concentrations by inducing hepatic metabolism.
- **Selective Serotonin Reuptake Inhibitors** (SSRIs; eg, **fluoxetine**, **paroxetine**, **sertraline**): Concurrent use may increase amitriptyline concentrations and increase the risk for serotonin syndrome. NOTE: SSRIs and TCAs (eg, **amitriptyline**) are often used together in veterinary behavior medicine, but enhanced monitoring for adverse effects is suggested.
- **Serotonin Receptor Antagonists** (eg, **dolasetron**, **ondansetron**): Concurrent use may increase the risk for serotonin syndrome, QT interval prolongation, and torsade de pointes.
- **Sulfamethoxazole/Trimethoprim:** Concurrent use may increase the risk for QT interval prolongation, torsade de pointes, and death.
- **Sulfonylureas** (eg, **glimepiride**, **glipizide**, **glyburide**): Concurrent use may increase hypoglycemia effects by an undetermined mechanism.
- **Sympathomimetic Agents** (eg, **phenylpropanolamine**): Concurrent use may increase the risk for hypertension, arrhythmias, tachycardia, and fever.
- **Tamsulosin:** Concurrent use may increase the risk for hypotension and orthostasis.
- **Terbinafine**: Concurrent use may increase amitriptyline concentrations. Interaction may persist for weeks following discontinuation of terbinafine. Avoid combination.
- **Thyroid Agents** (eg, **levothyroxine**): Concurrent use may potentiate effects of both drugs and may increase the risk for tachycardia, hypothyroidism, and thyrotoxicosis.
- **Tramadol**: Increased risk for serotonin syndrome; veterinary clinical significance is not known, but one source states that TCAs should not be administered concurrently with tramadol.[27,28]
- **Trazodone**: Concurrent use may increase the risk for constipation, ileus, urinary retention, CNS depression, serotonin syndrome, and anticholinergic intoxication syndrome. Avoid combination.
- **Vasopressors** (eg, **ephedrine**, **epinephrine**, **norepinephrine**, **vasopressin**): Concurrent use may increase the risk for hypertension, tremors, QT prolongation, cardiac dysrhythmias, and death. Avoid concurrent use except in emergency cases.
- **Warfarin**: Concurrent use may increase or decrease anticoagulant effects of warfarin.
- **Yohimbine**: Concurrent use may enhance the pressor effects of yohimbine by inhibiting reuptake of norepinephrine. Avoid combination.
- **Zonisamide**: Concurrent use may increase the risk for CNS depression and drowsiness

Laboratory Considerations

- **Metyrapone:** The response to metyrapone may be decreased by amitriptyline.
- **Blood glucose:** Tricyclics may alter (ie, increase or decrease) blood glucose levels.

Dosages

NOTE: Several weeks of therapy may be needed to see maximal effects. If discontinuing, taper the drug off slowly over 2 to 3 weeks, although more rapid taper can be undertaken when significant TCA toxicity is present.

DOGS:

Adjunctive treatment (with behavior modification and anxiolytics if required) of anxiety disorders (extra-label): Initially, 1 – 2 mg/kg PO every 12 hours for 2 to 4 weeks. May gradually increase dose by 1 mg/kg as tolerated to a maximum of 4 mg/kg PO twice daily

Adjunctive treatment of pruritus (after other more conventional therapies have failed) (extra-label): 1 – 2.2 mg/kg PO every 12 hours; ≈33% of dogs responded[1,29]

Adjunctive treatment of chronic (especially neuropathic) pain (extra-label): 1 – 2 mg/kg PO every 12 hours.[4] Doses up to 3 – 4 mg/kg PO every 12 hours may be tried.[25] If discontinuing, taper the drug slowly over 2 to 3 weeks.

CATS:

Clinical signs related to idiopathic cystitis (extra-label): 2.5 – 12.5 mg/cat (NOT mg/kg) PO once daily at night or

0.5 – 1 mg/kg PO once daily at night.[20,30] Neither 5 mg/cat[5] (NOT mg/kg) nor 10 mg/cat[6] (NOT mg/kg) once daily for 7 days reduced short-term lower urinary tract disease signs (eg, hematuria, pollakiuria).

Adjunctive treatment of behavior disorders amenable to tricyclics (anxiety, fear, adjunct in self-harm behaviors) (extra-label): 0.5 – 1.5 mg/kg PO every 24 hours.[31] Start at the lower end of the dosing range and gradually increase as tolerated. If discontinuing, gradually taper off the dosage.

Adjunctive treatment of pruritus (after other more conventional therapies have failed) (extra-label): 2.5 – 12.5 mg/cat (NOT mg/kg) PO once daily or 2.5 – 7.5 mg/cat (NOT mg/kg) twice daily.[32] To minimize adverse effects, start at the low end of the dosing range (2.5 mg/cat [NOT mg/kg] once daily) and gradually increase as tolerated. The drug may need to be compounded to give an accurate dose and to improve palatability (fish or cod liver oil).

Adjunctive treatment of chronic pain, including neuropathic (extra-label): 2.5 – 12.5 mg/cat (NOT mg/kg) PO once daily or 1 – 4 mg/kg PO every 12 to 24 hours[33]

BIRDS:

Adjunctive treatment of feather plucking (extra-label): 1 – 2 mg/kg PO every 12 to 24 hours.[7] Anecdotal reports indicate some usefulness. Barring adverse effects, a more prolonged course of therapy may be necessary to determine efficacy.[34] A pharmacokinetic study suggested doses up to 9 mg/kg may be necessary, although adverse effects are possible in some birds.[16]

Monitoring

- Clinical efficacy
- Adverse effects
- Baseline CBC, serum chemistry profile, urinalysis, and baseline thyroid testing[21,35] (eg, tT4, thyroid panel) prior to therapy, 1 month after initial therapy, and yearly thereafter
- Baseline ECG is recommended prior to therapy. Tricyclics can widen QRS complexes, prolong PR intervals, and invert or flatten T-waves on ECG; significance in animals is not fully understood.

Client Information

- This medication should be given with food.
- It can take several days to weeks to determine if the drug is effective.
- Consult your veterinarian before discontinuing this medication; do not stop suddenly.
- The most common side effects are drowsiness (sleepiness), dry mouth, and constipation; be sure your animal has access to water.
- Contact your veterinarian immediately if you see serious (rare) side effects like abnormal bleeding, fever, seizures, and/or very fast or irregular heart rate.
- Overdoses can be very serious; keep this medicine out of reach of animals and children.
- Tell your veterinarian if your animal has worn a flea and tick collar containing amitraz in the past 2 weeks.

Chemistry/Synonyms

Amitriptyline HCl, a tricyclic dibenzocycloheptene-derivative antidepressant, occurs as a white or practically white, odorless or practically odorless crystalline powder that is freely soluble in water or alcohol. It has a bitter, burning taste and a pK_a of 9.4.

Pharmaceutical dosage forms contain amitriptyline hydrochloride and express potency as amitriptyline base.

Amitriptyline may also be known as amitriptylini hydrochloridum; many trade names are available.

Storage/Stability

Amitriptyline tablets should be stored at room temperature.

Compatibility/Compounding Considerations

No specific information is noted. Transdermal (PLO-gel based) absorption is poor in cats.[10]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Amitriptyline HCl Tablets: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, and 150 mg; generic; (Rx)

Amlodipine

(am-loe-***di***-peen) *Norvasc®, Amodip®*

Calcium-Channel Blocker

Prescriber Highlights

- ► Dihydropyridine calcium-channel blocker often used for treatment of systemic arterial hypertension
- ► Caution should be used in patients with heart disease and hepatic dysfunction
- ► Potential to cause anorexia and hypotension in cats, especially early in therapy
- ► Gingival hyperplasia has been reported as a long-term adverse effect in dogs; may occur rarely in cats.

Uses/Indications

Oral amlodipine is used to treat systemic hypertension in dogs and cats and is considered the drug of choice for managing hypertension.[1–3] Hypertension in small animals is typically secondary to other diseases (eg, acute or chronic kidney disease, hyperthyroidism, hyperadrenocorticism) and is most often seen in middle-aged or geriatric cats and dogs.

Systemic activation of the renin-angiotensin-aldosterone system (RAAS) does not appear to be a major contributor of hypertension in cats with chronic kidney disease.[1] Cats are often presented with acute clinical signs (eg, blindness, seizures, collapse, disorientation, paresis/paralysis). Dogs and cats are considered hypertensive if repeated systolic blood pressure measurements exceed 160 mm Hg or if a single elevated blood pressure measurement is present in the setting of target organ damage (eg, eyes, heart, brain, kidneys). Antihypertensive therapy may improve ophthalmic lesions and restore vision in a minority of patients with blindness secondary to hypertension.[4] Amlodipine has been shown to significantly increase plasma renin activity in cats that are azotemic and hypertensive, which is a similar response to that seen in human studies.[5] Target systolic blood pressure values of less than 140 to 150 mm Hg[1,2] are recommended to minimize target organ damage from hypertension. Amlodipine has not been shown to reduce mortality in hypertensive cats.[2,5,6] In one study evaluating hypertensive cats treated with amlodipine 0.125 – 0.5 mg/kg for 28 days, the mean decrease in systolic blood pressure was 28 mm Hg,[7] but even larger blood pressure reduction (49 mm Hg) has been reported.[6]

In dogs, amlodipine therapy is typically initiated after a RAAS inhibitor (eg, ACE-inhibitor, angiotensin-receptor blocker) because of

the high prevalence of chronic kidney disease in hypertensive dogs.[2] In one study of hypertensive dogs, secondary to acute kidney injury, amlodipine therapy at a median dose of 0.38 mg/kg/day was associated with a decrease in systolic blood pressure of 24 mm Hg and correction of severe systemic hypertension in 10 of 11 dogs within 24 hours.[8] In a retrospective review of dogs with severe hypertension, dogs treated with amlodipine for 1 week had a reduction in blood pressure of 18 mm Hg, as compared with 29 mm Hg when treated with telmisartan and 46 mm Hg when treated with a combination of amlodipine and telmisartan.[9] In a small case series (n = 5 dogs), dogs with an average pretreatment systolic arterial blood pressure (SBP) of 215 mm Hg had their SBP reduced to 180 mm Hg when treated with a combination of amlodipine and benazepril, but SBP was reduced to 142 mm Hg when treatment was changed to amlodipine and telmisartan.[10]

Pharmacology/Actions

Amlodipine is a dihydropyridine L-type calcium-channel blocker, which inhibits voltage-gated calcium channels in cardiac and vascular smooth muscle. Amlodipine has a higher affinity for L-type calcium channels and some affinity for T-type calcium channels. In the kidney, L-type calcium channels are found primarily in afferent (prerenal) arterioles. Amlodipine has a greater effect on vascular smooth muscle, where it acts as a peripheral arteriolar vasodilator and reduces afterload. Amlodipine slightly depresses impulse formation (automaticity) and conduction velocity in cardiac muscle. Amlodipine has mild diuretic activity after an initial dose in dogs.[11,12] Amlodipine has been shown to activate the RAAS when used alone in healthy dogs at higher dosages (0.57 mg/kg twice daily).[13] Use of amlodipine with an ACE inhibitor partially blocks this effect.[13,14]

In client-owned cats with systemic hypertension treated with amlodipine as the sole antihypertensive agent (in combination with a phosphate-restricted diet if azotemic), a significant decline in UPC (urine protein:creatinine) was found in cats treated with amlodipine.[15]

Pharmacokinetics

In cats, amlodipine volume of distribution is ≈10 L/kg. In vitro protein binding in cat plasma is 97%. In healthy cats, plasma concentrations approach steady-state by 2 weeks at 0.125 mg/kg/day. Total plasma clearance is estimated to be 2.3 mL/minute/kg. Amlodipine is extensively metabolized by the liver, and elimination half-life is 53 hours.[16] In cats, effects on systemic blood pressure are usually seen within 4 hours of administration and may persist for an additional ≈30 hours.[17]

In dogs, amlodipine bioavailability is 88% after oral administration, with peak concentration occurring at 4 to 6 hours. Amlodipine is widely distributed (volume of distribution, 25 L/kg) and extensively metabolized. Reported elimination half-life ranges from 7 to 30 hours.[18,19]

In humans, amlodipine's bioavailability does not appear to be altered by the presence of food in the gut. The drug is slowly but almost completely absorbed after oral administration and is reported to be absorbed after rectal administration. In humans, peak plasma concentrations occur between 6 and 9 hours after administration and effects on blood pressure are correspondingly delayed. Amlodipine has high plasma protein-binding characteristics (≈93%). However, drug interactions associated with potential displacement from these sites have not been elucidated. Amlodipine is slowly but extensively metabolized to inactive compounds in the liver. Terminal plasma half-life is ≈35 hours in healthy humans but is prolonged in the elderly and in those patients with hypertension or hepatic dysfunction.

Contraindications/Precautions/Warnings

Amlodipine is contraindicated in patients hypersensitive to it, in shock, with documented hypotension, with severe aortic stenosis (due to an inability to increase stroke volume in response to peripheral vasodilation), or with severe hepatic failure. It should also be used cautiously in patients that are at risk for developing hypotension or patients with hepatic disease. Amlodipine use for pulmonary hypertension in dogs is not recommended, as systemic hypotension can occur without substantive improvements in pulmonary arterial pressures.[20]

There is concern that using amlodipine alone for treating hypertension with renal disease may expose glomeruli to higher pressures secondary to efferent arteriolar constriction, which is caused by localized increases in renin-angiotensin-aldosterone (RAAS) activity, allowing progressive damage to glomeruli. It is postulated that using an ACE inhibitor with amlodipine may help prevent this occurrence.[21] The concurrent use of ACE inhibitors with amlodipine in animals with chronic kidney disease and hypertension is routine, though evidence supporting this approach is lacking. Notably, treatment of hypertension in cats with amlodipine as a sole antihypertensive agent appeared to limit proteinuria, which led to improved survival.[15]

Adverse Effects

In a placebo-controlled study in hypertensive cats, the adverse effect profile for amlodipine-treated cats (eg, emesis, inappetence, diarrhea, lethargy, dehydration) was similar to placebo.[7] Hypotension and bradycardia are possible; however, because of amlodipine's relatively slow onset of action, these effects are usually absent in cats. Cats may infrequently develop azotemia, hypokalemia, reflex tachycardia, and weight loss. Gingival hyperplasia is also possible but occurs only rarely.[16]

Dogs may also experience inappetence, lethargy, and hypotension. Reversible gingival hyperplasia has been reported when amlodipine has been administered long term in dogs; incidence in the retrospective study was 8.5%.[22] Diffuse peripheral edema has been reported in dogs and this may or may not respond to medical treatment and discontinuation of amlodipine.[23]

Headache and peripheral edema are common side effects in humans taking amlodipine.

Reproductive/Nursing Safety

The UK-approved feline tablet product label states *the safety of amlodipine has not been established during pregnancy or lactation in cats*. Although no evidence of impaired fertility was noted in rats given 8 times the maximum human daily dose, amlodipine has been shown to be fetotoxic (ie, intrauterine death rates increased five-fold) in laboratory animals (eg, rats, rabbits) at very high doses.[24] No evidence of teratogenicity or mutagenicity was observed in laboratory animal studies. Amlodipine can prolong labor in rats.

Amlodipine enters maternal milk in small amounts.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited experience with other calcium-channel blockers in humans has shown that an overdose of amlodipine may result in profound hypotension and reflex tachycardia.[24] From 2009 to 2013, 578 dogs and 140 cats with single agent exposures to amlodipine were reported to the ASPCA Animal Poison Control Center; 19% of dogs and 22% of cats showed clinical signs (see ***Table***).

	DOGS	CATS
Total number reported	578	140
Number showing clinical signs	108 (19%)	31 (22%)
Hypotension	32%	23%
Tachycardia	39%	23%
Hypertension	13%	23%
Lethargy	26%	13%
Vomiting	18%	not reported

Other possible clinical signs in dogs are respiratory problems (including pulmonary edema), bradycardia, depression, hyperglycemia, and cardiac arrhythmias.[12] Rare clinical signs include azotemia, hypokalemia, hyponatremia, hyperkalemia, acidosis, tremors/fasciculations, and seizures.

The following treatments are recommended for patients with different levels of toxicosis:

- For massive overdoses, treat early with gut decontamination, crystalloid fluids, IV calcium, and supportive treatment.
- For subclinical patients exposed within 2 hours, gut decontamination strategies (eg, induction of emesis, gastric lavage, activated charcoal administration) should be considered.
- For stable, clinical patients, gastric lavage or activated charcoal should be considered; induction of emesis is contraindicated.
- For unstable, clinical patients, first stabilize the patient before gut decontamination strategies are attempted.

Intravenous fluid therapy, IV calcium, vasopressors, and atropine are considered first-line therapies, as is high-dose insulin euglycemic therapy, for patients showing clinical signs associated with an amlodipine overdose.[12] Additional interventions may include beta-agonists, IV lipid emulsion therapy,[25] glucagon, and/or a temporary pacemaker.[12] Close monitoring of the cardiovascular system (eg, blood pressure, ECG), respiratory system (eg, rate and character), nervous system (eg, mental status), electrolytes, and blood chemistry should be implemented 12 to 24 hours or longer following exposure.[12]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amlodipine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed, and additional monitoring performed when appropriate.

- **Beta-Adrenergic Receptor Antagonists** (eg, **atenolol, propranolol**): Concurrent use may reduce blood pressure, heart rate and contractility, particularly in animals with ventricular dysfunction.[16]
- **Calcium Channel Blockers, Other** (eg, **diltiazem**): Concurrent use may reduce blood pressure, heart rate and contractility, particularly in animals with ventricular dysfunction.[16]
- **Clopidogrel**: Amlodipine may decrease the antithrombotic effect of clopidogrel.
- **Cyclosporine**: Amlodipine may increase cyclosporine concentrations.
- **CYP3A4 Strong Inhibitors** (eg, **ketoconazole, itraconazole**): Amlodipine concentrations may be increased.
- **CYP3A4 Inducers** (eg, **rifampin**): Amlodipine concentrations may be decreased.
- **Tacrolimus:** Amlodipine may increase tacrolimus concentrations.
- **Hypotensive Agents** (eg, **enalapril, telmisartan**): Although antihypertensive combinations are commonly used to manage hypertension, they may have additive blood pressure lowering effects when used with amlodipine.

Laboratory Considerations

- No specific concerns noted.

Dosages

DOGS:

Adjunctive treatment of systemic hypertension and as an afterload reducer for refractory heart failure (extra-label): 0.1 – 0.25 mg/kg PO every 24 hours[2,26]; should begin at the low end of the dose range. In dogs, amlodipine is generally added after ACE-inhibitor (eg, benazepril) therapy has been initiated.

Hypertensive Emergency (extra-label): 0.2 - 0.4 mg/kg PO every 24 hours.[2] Doses of up to 0.6 mg/kg PO every 24 hours may used, but close monitoring is warranted.

CATS:

Systemic hypertension (extra-label):

a) 0.625 – 1.25 mg/cat (ie, ¼ – ½ of a 2.5 mg tablet/cat; NOT mg/kg) PO once daily. Therapy should be initiated with a lower dose (0.625 mg/cat [NOT mg/kg]) and blood pressure rechecked in 1 to 3 weeks; the dose can be doubled[1,7] (up to 2.5 mg/cat [NOT mg/kg] PO once daily maximum) if owner compliance is confirmed and blood pressure remains elevated (see ***Monitoring***). It has been suggested that higher doses (1.25 mg/cat [NOT mg/kg]) can be beneficial if systolic blood pressure is greater than 200 mm Hg and potassium plasma concentrations are low.[27] In cats with proteinuria, an ACE inhibitor (eg, benazepril) can be added.[1,2]

b) 0.125 – 0.25 mg/kg PO daily.[16] After 14 days of treatment, the dose may be doubled or increased up to 0.5 mg/kg once daily if adequate clinical response has not been achieved (eg, systolic blood pressure remaining over 150 mm Hg or a decrease of less than 15% from the pretreatment measurement).

Hypertensive Emergency (extra-label): 0.2 - 0.4 mg/kg PO every 24 hours.[2] Dosage up to 0.6 mg/kg PO every 24 hours may used, but close monitoring is warranted.

BIRDS:

Systemic hypertension (extra-label): Initially, 0.4 mg/kg PO every 24 hours[28]; increased dose or frequency may be needed.

Monitoring

- Blood pressure. A general guideline for treating hypertension is to maintain systolic blood pressure below 160 mm Hg, with a long-term goal of maintaining a systolic blood pressure less than 150 mm Hg to minimize the risk for target organ damage.[1] In cats without evidence of target organ damage, blood pressure should be reassessed every 1 to 3 weeks, with evaluation of clinical signs for target organ damage, until an adequate response is seen.[1] If the response is inadequate, dose increases are typically made at intervals of 7 days or more.[1] In cats with evidence of target organ damage at the time of diagnosis or cats with systolic blood pressure greater than 200 mm Hg, it is recommended to closely monitor the cat for the first 24 to 72 hours after initiation of therapy.[1] Dose adjustments can be made sooner than 7 days if systolic blood pressure remains above 200 mm Hg or if there is ongoing target organ damage.[1] If the response to amlodipine is inadequate, or if there is additional disease present (eg, persistent proteinuria), treatment with a secondary antihypertensive agent (eg, telmisartan or an ACE inhibitor) may be warranted in addition to amlodipine.[1] Once systolic blood pressure is controlled, patient reevaluation (including blood pressure and clinical signs of target organ damage) should occur at least every 3 months.[1] Although the preceding approach applies to cats, a comparable approach is considered for most dogs with systemic hypertension.[2]
- Fundic examination to monitor for retinal hemorrhage or retinal detachment
- Echocardiogram and/or thoracic radiographs to assess for target organ damage (ie, ventricular remodeling and/or cardiac enlargement caused by hypertension)

- Serum renal chemistry profile (BUN, creatinine), SDMA, and urine protein:creatinine should be monitored every 3 to 4 months in dogs and cats receiving amlodipine or more frequently if clinically indicated. As chronic kidney disease is a common condition underlying hypertension, monitoring renal function and proteinuria during antihypertensive therapy is appropriate. Serum potassium concentrations should also be evaluated periodically, again related to potential presence of chronic kidney disease.

Client Information

- Amlodipine may be given with or without food.
- Do not skip doses, as this may result in poor blood pressure control and organ damage.
- Side effects are not common but can include reduced appetite and low energy level, especially early in treatment. Overgrowth of the gums can occur, which is more common in dogs than cats.
- Amlodipine is typically a long-term medication and will require frequent follow-up veterinary visits. Once blood pressure is normalized and patients are feeling well, most cats and dogs are evaluated by their veterinarian every 3 to 4 months. Do not miss these important follow-up visits.

Chemistry/Synonyms

Amlodipine besylate, a dihydropyridine calcium channel-blocking agent, is a white crystalline powder that is slightly soluble in water and sparingly soluble in alcohol.

Amlodipine besylate may also appear as amlodipini besilas, UK-48340-26, or UK-48340-11 (amlodipine maleate); many trade names are available.

Storage/Stability

Store amlodipine tablets at 20°C to 25°C (68°F-77°F); excursions permitted to 15°C to 30°C (59°F-86°F) in tight, light-resistant containers. When splitting the UK-approved veterinary chewable tablets, the remaining portion should be returned to the blister packaging and discarded after 24 hours.[16]

Compatibility/Compounding Considerations

Compounded preparation stability: Amlodipine oral suspension compounded from commercially available tablets has been published.[29] Triturating six (6) amlodipine 5 mg tablets with 15 mL of *Ora-Plus*® and *qs ad* to 30 mL with *Ora-Sweet*® yields a 1 mg/mL oral suspension that retains more than 90% potency for 91 days stored at 5°C (41°F) and 25°C (77°F). Compounded preparations of amlodipine should be protected from light.

Amlodipine compounded into a topical PLO-based gel failed to control blood pressure in hypertensive cats.[30]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Amlodipine Chewable Tablets: 1.25 mg; *Amodip*® (available in the United Kingdom; not available in the United States); POM-V. Indicated for treatment of systemic hypertension in cats.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See the ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Amlodipine Oral Tablets: 2.5 mg, 5 mg, and 10 mg; *Norvasc*®, generic; (Rx)

Fixed-dose combination products with benazepril (*Lotrel*®) and atorvastatin (*Caduet*®) are available.

Ammonium Chloride

(ah-***moe***-nee-um)

Urinary-Acidifying Agent

Prescriber Highlights

- ► May be used for urinary acidification to treat and prevent struvite urolithiasis, to enhance renal excretion of some toxins (eg, strychnine), and to enhance the efficacy of certain antimicrobials when treating UTIs
- ► May also be used for ammonia tolerance testing in patients with normal baseline ammonia levels and without clinical signs of hepatic encephalopathy
- ► Contraindicated in patients with hepatic failure or uremia
- ► GI upset (nausea, vomiting, diarrhea) is the primary adverse effect of oral dosage forms.
- ► Urinary acidification may increase the risk for oxalate urolithiasis; metabolic acidosis can occur.
- ► Unpalatable; addition of sugar (not molasses) may improve palatability to goats and sheep.

Uses/Indications

Ammonium chloride can be used as an urinary-acidifying agent to help prevent and dissolve uroliths that form in alkaline urine (eg, struvite), to enhance renal excretion of some toxins (eg, strontium, strychnine) or drugs (eg, quinidine), or to enhance the efficacy of certain antimicrobials (eg, chlortetracycline, methenamine mandelate, nitrofurantoin, oxytetracycline, penicillin G, or tetracycline) when treating UTIs.

Feeding of acidifying commercial feline diets can successfully minimize struvite urolith formation,[1] and ammonium chloride can be considered for cats for whom these diets are not or cannot be fed.

Ammonium chloride is recommended to help prevent uroliths in small ruminants, but dietary changes can significantly affect the drug's efficacy for this purpose. When ammonium chloride is used continually, renal compensatory mechanisms may negate ammonium chloride's urinary pH-lowering effects, so pulse therapy may be more effective for these species.[2]

Ammonium chloride may also be used for ammonia tolerance testing in dogs and cats to test liver function.[3-5] See ***Contraindications/Precautions/Warnings***.

Pharmacology/Actions

The acidification properties of ammonium chloride are caused by its dissociation into chloride and ammonium ions in vivo. The ammonium cation is converted by the liver to urea with the release of a hydrogen ion. This ion combines with bicarbonate to form water and carbon dioxide. In the extracellular fluid, chloride ions combine with fixed bases and decrease the alkaline reserves in the body. The net effects are decreased serum bicarbonate levels and a decrease in blood and urine pH.

Excess chloride ions delivered to the kidney are not completely reabsorbed by the tubules and are excreted with cations (principally sodium) and water. This diuretic effect is usually compensated for in the kidneys after a few days of therapy.

Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, ammonium chloride is rapidly absorbed from the GI tract. The liver converts ammonium ions to urea, which is excreted in the urine.

Contraindications/Precautions/Warnings

Ammonium chloride is contraindicated in patients with severe hepatic disease or if the baseline ammonia measurement is elevated prior to ammonia tolerance testing, as ammonia may accumulate and cause toxicity (ie, hepatic encephalopathy).[6] In general, ammonium chloride should not be administered to uremic patients because it can intensify any existing metabolic acidosis in these patients. Additionally, ammonium chloride should not be used in patients with severe renal insufficiency that have metabolic alkalosis secondary to vomiting; sodium depletion can occur. In these cases, sodium chloride repletion, with or without ammonium chloride administration, should be performed to correct both sodium and chloride deficits.

Ammonium chloride is contraindicated in patients with urate or oxalate calculi or respiratory acidosis with high total CO_2 and buffer base. Ammonium chloride alone cannot correct hypochloremia with secondary metabolic alkalosis due to intracellular potassium chloride depletion; potassium chloride must be administered to these patients.

Use ammonium chloride with caution in patients with pulmonary insufficiency or cardiac edema.

A high roughage/concentrate ratio diet can decrease the urine pH, thus lowering the effect of ammonium chloride in horses.[7]

Adverse Effects

Development of metabolic acidosis (sometimes severe) can occur during or after treatment with ammonium chloride. Gastric irritation, nausea, and vomiting may be associated with oral dosing of the drug. Urinary acidification is associated with an increased risk for calcium oxalate urolith formation.

Reproductive/Nursing Safety

Ammonium chloride does not appear to cross the placenta, but large doses may result in metabolic acidosis in the dam and offspring. In humans, the drug is considered compatible for use during pregnancy and is likely compatible during lactation.[8] Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs of overdose may include nausea, vomiting, excessive thirst, hyperventilation, bradycardias or other arrhythmias, and progressive CNS depression. Profound metabolic acidosis and hypokalemia may be noted on laboratory results.

Treatment should consist of correcting the metabolic acidosis by administering sodium bicarbonate or sodium acetate IV. Hypokalemia should be treated using a suitable potassium product; frequent acid-base and electrolyte monitoring should be performed until the patient is stable.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ammonium chloride and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aluminum Hydroxide:** Avoid frequent use with ammonium chloride as urine acidification could be negated.
- **Aminoglycosides** (eg, **gentamicin**): Aminoglycoside antibiotics are more effective in an alkaline medium; urine acidification may diminish the effectiveness of these drugs in treating bacterial UTIs.
- **Aspirin:** Increased risk for salicylate toxicity as acidic urine can decrease the urinary excretion of salicylate.
- **Carbonic Anhydrase Inhibitors** (**CAIs**; eg, **acetazolamide, dichlorphenamide, methazolamide**): Concurrent use with ammonium chloride may increase risk for hyperchloremia and metabolic acidosis.
- **Erythromycin**: Erythromycin is more effective in an alkaline medium; urine acidification may diminish the effectiveness of this drug in treating bacterial UTIs**.**
- **Methadone:** Ammonium chloride may decrease methadone efficacy.
- **Quinidine**: Urine acidification caused by ammonium chloride may increase renal excretion of quinidine.

Dosages

DOGS:

Urine acidification (extra-label):

a. 20 mg/kg PO every 8 hours[9]
b. **Adjunctive toxicosis management:** 100 mg/kg PO every 12 hours[10]

Ammonia tolerance testing (extra-label): Patient must be fasted 12 hours prior to ammonia tolerance testing. Prior to beginning this test, measure a baseline ammonia level. **NOTE**: Special handling is required for accurate analysis of ammonia in blood samples. If the ammonia level is elevated, the patient has already failed the test; do not proceed with the administration of ammonium chloride, as this can result in profound hepatic encephalopathy. To complete the test, 2 options are available:

a. Administer 2 mL/kg of a 5% solution of ammonium chloride deep in the rectum. Measure serum ammonia concentrations at 20 minutes and 40 minutes post ammonium chloride administration.[4,5]
b. Oral challenge can be performed by administering ammonium chloride 100 mg/kg (maximum dose = 3 g) PO either in solution (dissolved in 20 to 50 mL warm water) or in gelatin capsules. Measure serum ammonia concentration at 30 minutes post ammonium chloride administration.

CATS:

Urine acidification (extra-label): 20 mg/kg PO every 12 hours[9,11]

Ammonia tolerance testing (extra-label): Patient must be fasted prior to ammonia tolerance testing. Prior to beginning this test, measure a baseline ammonia level. **NOTE**: Special handling is required for accurate analysis of ammonia in blood samples. If the ammonia level is elevated, the patient has already failed the test; do not proceed with the administration of ammonium chloride, as this can make the patient profoundly hepatic encephalopathy. To complete the test, 2 options are available:

a. Administer 2 mL/kg of a 5% solution of ammonium chloride deep in the rectum. Measure serum ammonia concentrations at 20 minutes and 40 minutes post ammonium chloride administration.
b. Oral challenge can be performed by administering with ammonium chloride 100 mg/kg (maximum dose = 3 grams) PO either in solution (dissolved in 20 to 50 mL warm water) or in gelatin capsules. Measure serum ammonia concentration at 30 minutes post ammonium chloride administration.

HORSES:

Urine acidification (extra-label): 100 mg/kg PO twice daily.[12] Ammonium salts are unpalatable and will have to be dosed via stomach tube or dosing syringe.

Urinary acidifier to enhance renal excretion of strychnine (extra-label): 132 mg/kg PO[13]

SHEEP/GOATS:

Urolithiasis prevention (extra-label):

a. 200 – 300 mg/kg PO twice daily for 3 days and then off for 4 days; continue 7-day recurring cycles. Start dose at 200 mg/kg, and increase dose until urine pH is less than 6.5.[2]
b. 450 mg/kg (2.25% of dry matter intake) PO daily maintained urine pH less than 6.5 in a study of goats.[14] Animals were fed orchard grass diet.
c. Of the daily dry matter, 0.5% to 1% will acidify urine but can be unpalatable. Table sugar (not molasses) may improve palatability.[15,16]

Monitoring

When using ammonium chloride as part of ammonia tolerance testing, be sure to record a baseline serum ammonia concentration prior to administration. If baseline ammonia is elevated, ammonia tolerance testing should not be done. See ***Contraindications/Precautions/Warnings.***

- Urine pH of less than or equal to 6.5 is the recommended goal of therapy
- Blood pH if there are clinical signs of toxicity or evidence of acid-base disturbance
- Clinical signs associated with ammonia toxicity (eg, hepatic encephalopathy)

When used to acidify the urine for the treatment of toxicosis[10]:

- Urine pH: baseline then hourly until treatment is complete
- Serum sodium and potassium: baseline then every 1 to 2 hours until treatment is complete
- Blood pressure: baseline then periodic as needed for patient's condition

Client Information

- Contact your veterinarian if your animal exhibits signs of nausea (may appear as excessive drooling, poor appetite), vomiting, excessive thirst, hyperventilation, progressive lethargy, or weakness.
- For this medication to work, give it exactly as your veterinarian has prescribed.
- Granules have a bitter taste. Mixing the medicine with food or giving the medicine with a dosing syringe may be helpful patients.
- While your animal is taking this medication, it is important to return to your veterinarian for all recommended examinations. Do not miss these important follow-up visits.

Chemistry/Synonyms

An acid-forming salt, ammonium chloride occurs as colorless crystals or as a fine or coarse white crystalline powder. It is somewhat hygroscopic and has a cool, saline taste. When dissolved in water, the temperature of the solution is decreased. One gram is soluble in ≈3 mL of water at room temperature and 1.4 mL at 100°C (212°F). One gram is soluble in ≈100 mL of alcohol.

One gram of ammonium chloride contains 18.7 mEq of ammonium and chloride ions. The commercially available concentrate for injection (26.75%) contains 5 mEq of each ion per mL and contains disodium edetate as a stabilizing agent. The pH of the concentrate for injection is ≈5.

Ammonium chloride may also be known as muriate of ammonia and sal ammoniac.

Storage/Stability

Ammonium chloride powder should be stored at room temperature, protected from moisture and light and with adequate ventilation.[17]

Compatibility/Compounding Considerations

Ammonium chloride should not be titrated with strong oxidizing agents (eg, potassium chlorate) as explosive compounds may result.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Dose Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: The following may not be FDA-approved products, as they are marketed for veterinary use but not located in the FDA Green Book.

Ammonium Chloride Solution: 20% (200 mg/mL) solution in 60 mL bottles; *Fus-Sol*® (OTC). Also contains dl-Methionine and unspecified B vitamins.

Ammonium Chloride Solution: 2% (20 mg/mL) in 1 L, 2.5 L, and 20 L bottles; generic; (OTC). (Also contains potassium iodide 2%)

When used in large animals, feed-grade ammonium chloride powder can be obtained from feed mills (OTC).

HUMAN-LABELED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Amoxicillin

(a-mox-i-***sill***-in) *Amoxi-Tabs®, Amoxi-Drops®, Bimox®*

Aminopenicillin

Prescriber Highlights

► Bactericidal aminopenicillin with the same spectrum as ampicillin; ineffective against bacteria that produce beta-lactamase
► Most common adverse effects are GI-related, but hypersensitivity and other adverse effects can occur (rare).

Uses/Indications

Amoxicillin is FDA-approved for oral use in dogs and cats to treat infections caused by many gram-positive and gram-negative bacteria (see ***Pharmacology/Actions***) and for intra-mammary infusion for the treatment of bovine mastitis in lactating cows. The drug also has been used in an extra-label fashion to treat a wide range of bacterial infections in other species. Amoxicillin is an effective first choice for bacterial cystitis, streptococcal infections, and other infections caused by non-beta-lactamase–producing bacteria. It is commonly used in treatment protocols for *Helicobacter* spp gastric infections in a variety of species. Amoxicillin/clavulanate is often used in small animals because of its enhanced efficacy against many beta-lactamase –producing bacteria. Amoxicillin may also be combined with an antibiotic that has greater gram-negative activity (eg, fluoroquinolones) for broad-spectrum empirical coverage.

The World Health Organization has designated amoxicillin as a Critically Important, High Priority antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) has designated amoxicillin as a Veterinary Critically Important Antimicrobial (VCIA) Agent in avian, bovine, caprine, equine, ovine, and swine species.[2]

Pharmacology/Actions

Amoxicillin is a time-dependent, bactericidal agent that acts by inhibiting cell wall synthesis. Amoxicillin generally shares the same spectrum of activity and uses as ampicillin, although there may be slight differences in activity against certain organisms. Higher serum concentrations may be attained with amoxicillin as compared with ampicillin because amoxicillin is better absorbed orally (in nonruminants). Separate serum and urinary clinical breakpoints are available; ampicillin sensitivity is used to predict amoxicillin activity.

Penicillins are bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall, which results in a

defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (eg, carboxypeptidases, transpeptidases, endopeptidases) in the bacterial cytoplasmic membrane involved with cell wall synthesis. Beta-lactam antibiotics have different affinities for these enzymes (ie, penicillin-binding proteins), which may help explain the difference in drug activity spectrums not explained by the influence of beta-lactam-ases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

Aminopenicillins (ie, broad-spectrum or ampicillin penicillins) have increased activity against many strains of gram-negative aerobes not covered by natural penicillins or penicillinase-resistant penicillins, including some strains of *Escherichia coli, Klebsiella* spp, and *Haemophilus* spp. Like the natural penicillins, aminopenicillins are susceptible to inactivation by beta-lactamase–producing bacteria (eg, many *Staphylococcus* spp, *E coli*). Although not as active as natural penicillins, aminopenicillins have activity against many anaerobic bacteria, including clostridial organisms. Organisms that are generally not susceptible include *Pseudomonas aeruginosa*, *Serratia* spp, indole-positive *Proteus* spp (*Proteus mirabilis* is susceptible), *Enterobacter* spp, *Citrobacter* spp, and *Acinetobacter* spp. Aminopenicillins are ineffective against methicillin-resistant staphylococci and are inactive against mycobacteria, *Mycoplasma* spp, *Rickettsia* spp, fungi, protozoa, and viruses.

Potassium clavulanate, sulbactam, and tazobactam are beta-lactamase inhibitors that, when combined with penicillins, can extend the spectrum of those penicillins. These combinations are often effective against many beta-lactamase–producing strains of otherwise resistant *E coli, Pasteurella* spp, *Staphylococcus* spp, *Klebsiella* spp, and *Proteus* spp.

Pharmacokinetics

Amoxicillin trihydrate is stable in the presence of gastric acid. After oral administration, amoxicillin bioavailability is highly variable between species. Food will decrease the rate but not the extent of oral absorption and many clinicians suggest giving the drug with food, particularly if there is concomitant GI distress. In dogs, amoxicillin bioavailability was 64% to 77% following oral administration.[3] In cats, one study found the bioavailability to be ≈77%.[4] Amoxicillin serum concentrations will generally be 1.5 to 3 times greater than those of ampicillin after equivalent oral doses. In dogs following oral administration, maximum plasma concentrations of 11 to 21 µg/mL were reached after ≈1.38 to 2 hours.[3,5] In cats following a 10 mg/kg oral dose, maximum plasma concentrations of 5.89 µg/mL were reached in 1.69 hours.[4]

In sheep and goats, peak concentrations occurred ≈4.2 hours after IM administration.[6]

After absorption, the volume of distribution for amoxicillin is ≈0.28 to 0.71 L/kg in dogs[33] and 0.86 L/kg in cats.[4] The drug is widely distributed to most body tissues and fluids. When meninges are inflamed, amoxicillin will cross into the CSF in concentrations ranging from 10% to 60% of those found in serum. Very low concentrations of the drug are found in the aqueous humor; low concentrations are found in tears, sweat, and saliva. Protein binding in dogs is ≈13%.

Amoxicillin is eliminated primarily unchanged via renal mechanisms, principally by tubular secretion; however, some of the drug is metabolized by hydrolysis to penicilloic acids (inactive) and then excreted in the urine. Elimination half-lives of amoxicillin have been reported to be 0.91 to 1.52 hours in dogs[7,8] and ≈1.25 hours in cats.[4] Clearance in cats is reportedly 0.45 L/hour/kg.[4] In cats with azotemic chronic kidney disease given amoxicillin-clavulanic acid, amoxicillin concentration was significantly lower in the urine and somewhat higher in serum when compared to cats without kidney disease.[9]

After IM administration, the elimination half-life is 4.7 hours in sheep and 6.9 hours in goats.[6]

Milk yield had no effect on amoxicillin pharmacokinetic parameters after intramammary administration in dairy cows.[10]

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Penicillins should be used cautiously in patients with a documented hypersensitivity to other beta-lactam antibiotics (eg, cephalosporins, cephamycins, carbapenems), as there may be cross-reactivity.

Systemic antibiotics should not be administered orally to patients with septicemia, shock, or other grave illnesses, as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral—preferably IV—routes should be used for these cases.

Oral beta-lactam antibiotics and macrolides should not be administered to rabbits, guinea pigs, chinchillas, hamsters, or other small mammals, as severe enteritis and clostridial enterotoxemia may occur.

Adverse Effects

Adverse effects caused by penicillins are not typically serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes (including severe cutaneous reactions), fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemia, lymphadenopathy, or anaphylaxis.

When penicillins are given orally, they may cause GI effects (eg, anorexia, vomiting, diarrhea). Because penicillins may alter gut flora, antibiotic-associated diarrhea can occur and can allow for the proliferation of resistant bacteria in the colon (ie, superinfections). Healthy dogs that are given oral amoxicillin have had their gut flora altered with a shift in balance toward gram-negative bacteria that included resistant species of Enterobacteriaceae.[11]

Neurotoxicity (eg, ataxia in dogs) has been associated with high doses or prolonged use of penicillins. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported with their use. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta; safe use during pregnancy has not been firmly established, but it is not believed to be teratogenic. Milk levels of amoxicillin are considered low. Amoxicillin concentration in milk is roughly half that found in plasma in lactating cows.[12]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see ***Adverse Effects***). In humans, very high dosages (≈300 mg/kg) of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with amoxicillin have either been reported or are theoretical in humans or animals and may be of sig-

nificance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Aminoglycosides** (eg, **amikacin**, **gentamicin**): Beta-lactam antibiotics can inactivate aminoglycosides in vitro (and in vivo in patients with chronic kidney disease).
- **Bacteriostatic Antimicrobials** (eg, **chloramphenicol, erythromycin,** other **macrolides, sulfonamides, tetracyclines**): Because there is evidence of in vitro antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together has not generally been recommended in the past, but the clinical significance of this is unclear.
- **Methotrexate (MTX)**: Amoxicillin may decrease the renal excretion of MTX, causing increased MTX concentrations and potential MTX toxic effects.
- **Mycophenolate**: May decrease mycophenolate concentrations by decreasing concentrations of mycophenolate's active metabolite
- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum concentrations and serum half-lives
- **Warfarin**: Concurrent use may increase risk for bleeding.

Laboratory Considerations

- Amoxicillin may cause false positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest®*). Tests utilizing glucose oxidase (*Tes-Tape®, Clinistix®*) are not affected by amoxicillin.
- As penicillins and other beta-lactams can inactivate **aminoglycosides** in vitro (and in vivo in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics, particularly when the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Dosages

NOTE: The following FDA-approved label indications and dosages are not accepted by most clinicians today as being consistently efficacious.

DOGS:

Respiratory tract infections (tonsillitis, tracheobronchitis), genitourinary tract infections (cystitis), GI tract infections (bacterial gastroenteritis), and soft tissue infections (abscesses, lacerations, and wounds) due to *Staphylococcus aureus*, *Streptococcus* spp, Escherichia *coli*, and *Proteus mirabilis*. Bacterial dermatitis due to *Staphylococcus aureus*, *Streptococcus* spp, and *Proteus mirabilis* (label dosage; FDA-approved): 11 mg/kg PO twice daily for 5 to 7 days or 48 hours after all clinical signs have subsided. If no improvement is seen in 5 days, review diagnosis and change therapy.[13]

Systemic infections (extra-label): 11 – 22 mg/kg PO every 8 hours; duration of treatment should be dictated by indication and clinical response.

Sporadic bacterial cystitis (extra-label): 11 – 15 mg/kg PO every 8 to 12 hours. Duration of treatment requires more study but recent recommendations for sporadic bacterial cystitis are 3 to 5 days of treatment.[14]

Recurrent (2 or more episodes of clinical bacterial cystitis per 6 months or 3 per 12 months) bacterial cystitis (extra-label): 11 – 15 mg/kg PO every 8 to 12 hours for 3 to 5 days, as for sporadic bacterial cystitis. Longer courses (1 to 2 weeks) may be considered for persistent or relapsing infections.[14]

Borreliosis (Lyme disease) (extra-label): 20 mg/kg PO 3 times daily for 30 days[15]

***Helicobacter* spp gastritis infections using triple therapy** (extra-label):

a) Amoxicillin 11 mg/kg PO every 8 hours in combination with metronidazole 15.4 mg/kg every 8 hours and bismuth subsalicylate suspension (original *Pepto-Bismol®*) 0.22 mL/kg (3.85 mg/kg) PO every 4 to 6 hours for 3 weeks[16]

b) Amoxicillin 15 mg/kg every 12 hours in combination with metronidazole 10 mg/kg PO every 12 hours and bismuth subsalicylate 262 mg tablets given based on body weight (less than 5 kg (11 lb) = 0.25 tablet; 5 to 9.9 kg (11 to 21.8 lb) = 0.5 tablet; 10 to 24.9 kg (22 to 54.8 lb) = 1 tablet; greater than 25 kg = 2 tablets) every 12 hours for 2 weeks[17]

c) Amoxicillin 22 mg/kg PO every 12 hours in combination with metronidazole 11 – 15 mg/kg PO every 12 hours and bismuth subsalicylate suspension 0.22 mL/kg (3.85 mg/kg) PO every 6 to 8 hours for 3 weeks[18]

CATS:

Upper respiratory tract infections due to *Staphylococcus aureus*, *Streptococcus* spp, and *E coli*. Genitourinary tract infections (cystitis) due to *Staphylococcus aureus*, *Streptococcus* spp, *E coli*, and *Proteus mirabilis*. GI tract infections due to *E coli*. Skin and soft tissue infections (abscesses, lacerations, and wounds) due to *Staphylococcus aureus*, *Streptococcus* spp, *E coli*, and *Pasteurella multocida* (label dosage; FDA-approved): 50 mg/cat (NOT mg/kg) or 11 – 22 mg/kg once daily for 5 to 7 days or 48 hours after all clinical signs have subsided. If no improvement is seen in 5 days, review diagnosis and change therapy[13]

Systemic infections (extra-label): 11 – 22 mg/kg PO every 8 hours; duration of treatment should be dictated by indication and clinical response.

Sporadic bacterial cystitis (extra-label): 11 – 15 mg/kg PO every 8 to 12 hours for 3 to 5 days[14]

Recurrent (2 or more episodes of clinical bacterial cystitis per 6 months or 3 per 12 months) bacterial cystitis (extra-label): 11 – 15 mg/kg PO every 8 to 12 hours for 3 to 5 days, as for sporadic bacterial cystitis.[14] Longer courses (1 to 2 weeks) may be considered for persistent or relapsing infections.

***Helicobacter* spp gastritis infections using triple therapy** (extra-label): Amoxicillin 11 – 22 mg/kg PO every 8 hours in combination with metronidazole 11 – 15.4 mg/kg PO every 8 - 12 hours and bismuth subsalicylate suspension (original Pepto-Bismol®) 0.22 mL/kg (3.85 mg/kg) PO every 4 to 8 hours and for 3 weeks[16,18]

***Helicobacter* spp gastritis infections using quadruple therapy** (extra-label): Amoxicillin 10 – 20 mg/kg PO 3 times daily in combination with metronidazole 10 mg/kg PO twice daily and bismuth subsalicylate (262 mg tablets; *Pepto-Bismol®*) ¼ tablet/cat (total dose) PO twice daily, ± H2 blocker (eg, famotidine) or omeprazole for 2 weeks[19]

CATTLE:

Mastitis in lactating cows (label dosage; FDA approved): 62.5 mg (contents of one syringe) intramammary infusion in each affected quarter every 12 hours for a total of 3 doses.[20] Before administration, milk udder completely, thoroughly wash and then dry udder and teat, and next clean and disinfect teat with alcohol swabs (provided with product). After completing the infusion, withdraw the syringe, and massage medication up into the milk cistern.

BIRDS:

Susceptible infections (extra-label):

a) 125 mg/kg PO every 12 hours. Mix oral solution to double strength to a final concentration of 125 mg/mL[21]
b) 100 mg/kg IM, SC, PO every 8 hours[22]

FERRETS:

***Helicobacter* spp gastritis infections using triple therapy** (extra-label):

a) Amoxicillin 20 mg/kg PO every 12 hours, with metronidazole 20 mg/kg PO every 12 hours and bismuth subsalicylate 17.5 mg/kg PO every 8 hours for 21 days. Sucralfate 25 mg/kg PO every 8 hours and famotidine 0.5 mg/kg PO every 24 hours may also be used. Fluids and assisted feeding should be continued while the primary cause of disease is investigated.[23]
b) Amoxicillin 10 mg/kg, metronidazole 20 mg/kg, and bismuth subsalicylate 17.5 mg/kg, all given PO 3 times daily for 3 to 4 weeks[24]
c) Amoxicillin 30 mg/kg, metronidazole 20 mg/kg, and bismuth subsalicylate 17.5 mg/kg, all given PO 3 times daily for 3 to 4 weeks[25]

RABBITS/RODENTS/SMALL MAMMALS:

See ***Contraindications/Precautions/Warnings***.

Hedgehogs (extra-label): 15 mg/kg IM, SC, or PO every 12 hours[26]

REPTILES:

Susceptible infections for all species (extra-label): 22 mg/kg PO every 12 to 24 hours; not useful unless used in combination with aminoglycosides.[27]

Monitoring

- Efficacy: resolution of clinical signs
- Culture and susceptibility as indicated for clinical condition being treated
- Urine culture may be considered after 5 to 7 days when treating bacterial cystitis for longer periods of time.[14] It is important to note that positive cultures taken at this time should prompt questioning the owner about compliance and further investigation as to why the infection has not been eliminated (eg, underlying pathology [eg, cystic calculi, neoplasia]); a positive culture at this time should not simply prompt a change in antibiotic choice. A negative culture during this time frame does not necessarily guarantee resolution of the infection.

Client Information

- It is preferred that the oral suspension be refrigerated but this is not absolutely necessary. Any unused oral suspension should be discarded after 14 days.
- This medicine can be given with or without food, but gastrointestinal side effects (eg, poor appetite, nausea, vomiting) might be prevented if this medicine is given with food.
- The most common side effects are diarrhea, vomiting, and loss of appetite.
- It is important to give this medication exactly as prescribed and to complete the full course of treatment, even if your animal seems better. Missing doses or stopping treatment early may result in treatment failure.
- Amoxicillin should not be given to rabbits, guinea pigs, chinchillas, hamsters, rodents, or other "pocket pets", as life-threatening diarrhea may occur.

Chemistry/Synonyms

Commercially available dosage forms contain amoxicillin trihydrate, which occurs as a practically odorless, white, crystalline powder that is sparingly soluble in water. Amoxicillin differs structurally from ampicillin only by having an additional hydroxyl group on the phenyl ring.

Amoxicillin may also be known as amoxycillin, p-hydroxyampicillin, or BRL 2333; many trade names are available.

Storage/Stability

Amoxicillin capsules, tablets, and powder for oral suspension should be stored at room temperature (15°C-30°C [59°F-86°F]) in tight containers. After reconstitution, the oral suspension can be stored at room temperature or refrigerated (refrigeration preferred); any unused product should be discarded after 14 days. Intramammary syringes should be stored at or below 24°C (75°F).

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Amoxicillin Oral Tablets: 50 mg, 100 mg, 150 mg, 200 mg, and 400 mg; *Amoxi-Tabs®*, *Bimox®*; generic; (Rx). FDA-approved for use in dogs and cats.

Amoxicillin Powder for Oral Suspension: 50 mg/mL (after reconstitution) in 15 mL or 30 mL bottles; *Amoxi-Drops®*, *Bimox®*, generic; (Rx). FDA-approved for use in dogs and cats.

Amoxicillin Intramammary Infusion: 62.5 mg in 10 mL syringes; *Amoxi-Mast®*; (Rx). FDA-approved to treat subclinical infectious mastitis in lactating cows. NADA 55-100. (Rx). Withdrawal times: milk— 60 hours after last treatment; slaughter—12 days

HUMAN-LABELED PRODUCTS:

Amoxicillin Oral Tablets (chewable): 125 mg, 200 mg, 250 mg, and 400 mg; *Amoxil®*, generic; (Rx)

Amoxicillin Oral Tablets: 500 mg and 875 mg; *Amoxil®*, generic; (Rx)

Amoxicillin Oral Capsules: 250 mg and 500 mg; *Amoxil®*, generic; (Rx)

Amoxicillin Powder for Oral Suspension: 125 mg/5 mL (25 mg/mL) in 80 mL, 100 mL, and 150 mL; 200 mg/5 mL (40 mg/mL) in 50 mL, 75 mL, and 100 mL; 250 mg/5 mL (50 mg/mL) in 80 mL, 100 mL, and 150 mL; 400 mg/5 mL (80 mg/mL) in 50 mL, 75 mL, and 100 mL; *Amoxil®*, *Trimox®*, generic; (Rx)

Amoxicillin Oral Extended-Release Tablets: 775 mg in 30s and UD 10s; *Moxatag®*; (Rx)

Amoxicillin/Clavulanate

Amoxicillin/Clavulanic Acid

(a-mox-i-***sill***-in clav-yue-***lan***-ate) *Clavamox®, Augmentin®*

Potentiated Aminopenicillin

Prescriber Highlights

- ► Bactericidal aminopenicillin with beta-lactamase inhibitor that expands its spectrum, increasing susceptibility of bacteria that are resistant to amoxicillin via beta-lactamase production.
- ► Most common adverse effects are GI-related; hypersensitivity and other adverse effects may occur but are rare.
- ► As compared with veterinary-labeled products, human-labeled products contain different ratios of amoxicillin:clavulanate and product strengths are expressed in terms of amoxicillin (only), whereas veterinary products are expressed as the sum of both compounds.

Uses/Indications

Amoxicillin/clavulanate potassium tablets and oral suspension prod-

ucts are used in dogs and cats for the treatment of urinary tract, skin (eg, wounds, pyoderma), canine periodontal disease, and soft tissue (eg, abscesses) infections caused by susceptible organisms, particularly gram-positive bacteria and anaerobes. It is also indicated for respiratory tract infections, although it is ineffective against *Mycoplasma* spp, and resistance to *Bordetella* spp is an increasing problem in some regions.

The World Health Organization has designated amoxicillin/clavulanate as a Critically Important antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) has designated amoxicillin/clavulanate as a Veterinary Critically Important Antimicrobial (VCIA) Agent in avian, bovine, caprine, equine, ovine, and swine species.[2]

Pharmacology/Actions

Amoxicillin is a time-dependent, bactericidal agent that acts by inhibiting cell wall synthesis. Amoxicillin generally shares the same spectrum of activity and uses as ampicillin but is better absorbed orally (in nonruminants) and attains higher serum levels. Separate serum and urinary clinical breakpoints are available.

Penicillins are bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall, which results in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (eg, carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins [PBPs]) help explain the differences in the drugs' spectrums of activity that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered to be more effective against actively growing bacteria.

Aminopenicillins (ie, broad-spectrum or ampicillin penicillins) have increased activity against many strains of gram-negative aerobes not covered by either the natural penicillins or penicillinase-resistant penicillins, including some strains of *Escherichia coli*, *Klebsiella* spp, and *Haemophilus* spp. Like the natural penicillins, aminopenicillins are susceptible to inactivation by beta-lactamase–producing bacteria (eg, *Staphylococcus* spp, *E coli*). Although not as active as natural penicillins, aminopenicillins have activity against many anaerobic bacteria, including clostridial organisms. Organisms that are generally not susceptible include *Pseudomonas aeruginosa*, *Serratia* spp, indole-positive *Proteus* spp (*Proteus mirabilis* is susceptible), *Enterobacter* spp, *Citrobacter* spp, and *Acinetobacter* spp. Aminopenicillins are ineffective against methicillin-resistant staphylococci and are inactive against mycobacteria, *Mycoplasma* spp, *Rickettsia* spp, fungi, protozoa, and viruses.

Clavulanic acid has only weak antibacterial activity when used alone and is only available in fixed-dose oral combinations with amoxicillin. Clavulanic acid acts by competitively and irreversibly binding to beta-lactamases (including types II, III, IV, and V) and penicillinases produced by staphylococci. Staphylococci that are resistant to penicillinase-resistant penicillins (eg, oxacillin) are considered resistant to amoxicillin/potassium clavulanate, despite susceptibility testing that may indicate otherwise. Amoxicillin with potassium clavulanate is usually ineffective against type I cephalosporinases. Members of the family Enterobacteriaceae, particularly *Pseudomonas aeruginosa*, often produce these plasmid-mediated cephalosporinases. When clavulanic acid is combined with amoxicillin, there is little, if any, synergistic activity against organisms already susceptible to amoxicillin, but amoxicillin-resistant strains (due to beta-lactamase inactivation) may be covered.

When Kirby-Bauer susceptibility testing is performed, the *Augmentin*® disk (human-product trade name) is often used. Because the amoxicillin:clavulanic acid ratio of 2:1 in the susceptibility tests may not correspond to in vivo drug levels, susceptibility testing may not always accurately predict efficacy for this combination. A urinary tract-specific breakpoint in dogs and cats for amoxicillin/clavulanate is reported as less than 8/4 µg/mL because of the greater drug levels that are achieved in urine. This breakpoint should only be used for cystitis—not pyelonephritis, for which serum breakpoints should be applied.

Pharmacokinetics

Amoxicillin trihydrate is stable in the presence of gastric acid. After oral administration, amoxicillin bioavailability is highly variable between species. Food will decrease the rate but not the extent of oral absorption, and many clinicians suggest giving the drug with food, particularly if there is concomitant GI distress. In dogs, amoxicillin bioavailability was 64% to 77% following oral administration.[3] In cats, one study found the bioavailability to be ≈77%.[4] Amoxicillin serum levels will generally be 1.5 to 3 times greater than those of ampicillin after equivalent oral doses. In dogs following oral administration, maximum plasma concentrations of 11 to 21 µg/mL were reached after ≈1.38 to 2 hours.[3,5] In cats following a 10 mg/kg oral dose, maximum plasma concentrations of 5.89 µg/mL were reached in 1.69 hours.[4]

After absorption, the volume of distribution for amoxicillin is ≈0.28 to 0.71 L/kg in dogs[3] and 0.86 L/kg in cats.[4] The drug is widely distributed to most body tissues and fluids. When meninges are inflamed, amoxicillin will cross into the CSF in concentrations ranging from 10% to 60% of those found in serum. Very low levels of the drug are found in the aqueous humor, and low levels are found in tears, sweat, and saliva. Protein binding in dogs is ≈13%.

Amoxicillin is eliminated primarily unchanged via renal mechanisms, principally by tubular secretion; however, some of the drug is metabolized by hydrolysis to penicilloic acids (inactive) and then excreted in the urine. Elimination half-lives of amoxicillin have been reported to be 0.91 to 1.52 hours in dogs[6] and ≈1.25 hours in cats.[4] Clearance in cats is reportedly 0.45 L/hour/kg.

There is no evidence to suggest that the addition of clavulanic acid significantly alters amoxicillin pharmacokinetics.[6] As a time-dependent antimicrobial, duration of time above the MIC is critical, so frequent dosing is necessary.

Clavulanate potassium is stable in the presence of gastric acid and is readily absorbed. In dogs following oral administration, maximum plasma concentrations of 2.06 to 2.3 µg/mL were reached after 0.95 to 1.05 hours.[5] In cats following oral administration, bioavailability of clavulanic acid was ≈98%, with maximum plasma concentrations of 1.41 µg/mL reached in 1.03 hours.[4]

Clavulanic acid has an apparent volume of distribution of 0.32 L/kg in dogs and 0.93 L/kg in cats.[4] It is distributed (with amoxicillin) into the lungs, pleural fluid, and peritoneal fluid. Low concentrations of both drugs are found in the saliva, sputum, and CSF (uninflamed meninges). Higher concentrations in the CSF are expected when meninges are inflamed,[7] but it is questionable whether therapeutic concentrations are attainable. Clavulanic acid is 13% bound to proteins in dog serum.

Clavulanic acid is apparently extensively metabolized in dogs and rats, primarily to 1-amino-4-hydroxybutan-2-one. It is unknown whether this compound possesses any beta-lactamase–inhibiting activity. The drug is also excreted unchanged in the urine via glomerular filtration. In dogs, 34% to 52% of a dose is excreted in the urine as unchanged drug and metabolites, 25% to 27% is eliminated in the feces, and 17% into respired air. Urine levels of active drug are considered high but may be only ≈20% of those of amoxicillin. In cats with azotemic chronic kidney disease given amoxicillin\clavulanic acid, amoxicillin concentration was significantly lower in the

urine and somewhat higher in serum when compared to cats without kidney disease.[8]

Elimination half-lives of clavulanic acid are reported to be 0.71 to 0.83 hours in dogs[5] and 0.71 hours in cats.[4] Clearance in cats is reportedly 0.92 L/hour/kg.[4]

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Penicillins should be used cautiously in patients with documented hypersensitivity to other beta-lactam antibiotics (eg, cephalosporins, cefamycins, carbapenems) as there may be cross-reactivity.

Systemic antibiotics should not be administered orally in patients with septicemia, shock, or other grave illnesses, as absorption of the medication from the GI tract may be significantly delayed or diminished. Parental routes should be used for these cases.

Oral beta-lactam antibiotics and macrolides should not be administered to rabbits, guinea pigs, chinchillas, or hamsters, as serious enteritis and clostridial enterotoxemia may occur.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes (including severe cutaneous reactions), fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemia, lymphadenopathy, or anaphylaxis.

When penicillins are given orally, they may cause GI effects (eg, anorexia, vomiting, diarrhea). Because the penicillins may alter GI microbiota, antibiotic-associated diarrhea can occur and can allow for the proliferation of resistant bacteria in the colon (ie, superinfections). Probiotic use reduced GI abnormalities and diarrhea in laboratory cats that received amoxicillin/clavulanate.[9]

Cats diagnosed with chronic kidney disease (CKD) that were azotemic were more likely to experience multiple adverse effects when compared to CKD cats without azotemia.[8]

Neurotoxicity (eg, ataxia in dogs) has been associated with high doses or prolonged use of penicillins. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported with their use. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta. Safe use during pregnancy has not been firmly established, but it is not believed to be teratogenic.

Amoxicillin and clavulanic acid are found in milk in low concentrations. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see ***Adverse Effects***). In humans, very high doses of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with amoxicillin/clavulanate have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring should be performed when appropriate.

- **Aminoglycosides** (eg, **gentamicin**): beta-lactams can inactivate aminoglycosides in vitro (and in vivo in patients with chronic kidney disease).
- **Bacteriostatic Antimicrobials** (eg, **chloramphenicol, erythromycin, minocycline** and other **macrolides, tetracyclines, sulfonamides**): Because there is evidence of in vitro antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together generally has not been recommended in the past; however, the clinical significance of this is unclear.
- **Leflunomide**: Prior, concurrent, or subsequent use of amoxicillin/clavulanate with leflunomide without observing washout may increase the risk for hepatotoxicity.
- **Methotrexate (MTX)**: Amoxicillin may decrease the renal excretion of MTX, causing increased MTX concentrations and potential MTX toxic effects.
- **Mycophenolate**: May decrease concentrations of mycophenolate by decreasing concentrations of mycophenolate's active metabolite
- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum concentrations and serum half-lives
- **Warfarin**: Concurrent use of amoxicillin/clavulanate may increase the risk for warfarin-induced bleeding.

Laboratory Considerations

- Amoxicillin may cause false positive **urine glucose determinations** when cupric sulfate solution (Benedict's Solution, *Clinitest®*) is used. Tests using glucose oxidase (*Tes-Tape®, Clinistix®*) are not affected by amoxicillin.
- Because penicillins and other beta-lactam antibiotics can inactivate **aminoglycosides** in vitro (and in vivo in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics, particularly when the serum is stored prior to analysis. It is recommended that if there is a delay in running the assay, samples should be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Dosages

NOTE: All dosages listed are for combined quantities of both drugs (unless otherwise noted).

DOGS:

Skin and soft tissue infections such as wounds, abscesses, cellulitis, superficial and deep pyoderma due to susceptible strains of the following organisms: beta-lactamase–producing *Staphylococcus aureus*, non-beta-lactamase–producing *Staphylococcus aureus*, *Staphylococcus* spp, *Streptococcus* spp, and *Escherichia coli*. Periodontal infections due to susceptible strains of both aerobic and anaerobic bacteria (label dosage; FDA-approved): 13.75 mg/kg PO twice daily.[10] Skin and soft tissue infections such as abscesses, cellulitis, wounds, superficial/juvenile pyoderma, and periodontal infections should be treated for 5 to 7 days or for 48 hours after all signs have subsided. If no response is seen after 5 days of treatment, therapy should be discontinued and the case reevaluated. Deep pyoderma may require treatment for 21 days; the maximum duration of treatment should not exceed 30 days.

Sporadic bacterial cystitis (extra-label): 12.5 – 25 mg/kg PO every 8 to 12 hours for 3 to 5 days is an acceptable option but is not recommended as empirical therapy (ie, without or before culture and susceptibility testing); amoxicillin (without clavulanic acid) achieves high concentrations in the urine and is preferred for em-

pirical therapy.[11]

Pyoderma (extra-label):

a) **Superficial pyoderma:** 12.5 – 25 mg/kg PO twice daily[12] for 21 to 28 days up to a maximum of 90 days[13]; fair evidence available to support moderate to high efficacy[13]

b) **Deep pyoderma:** 12.5 – 25 mg/kg PO twice daily for at least 28 days, up to a maximum of 90 days[13]; good level of evidence for high efficacy[13]

Endocarditis (chronic therapy) secondary to a susceptible strain of *Staphylococcus* spp (extra-label): 20 mg/kg PO 3 times daily for 6 to 8 weeks[14]

Canine infectious respiratory disease complex when a bacterial component is involved (extra-label): 11 mg/kg PO every 12 hours (twice daily) as a first-line treatment option for bacterial upper respiratory tract infection not suspected to be caused by *Mycoplasma* spp[15]

CATS:

Skin and soft tissue infections such as wounds, abscesses, and cellulitis/dermatitis due to susceptible strains of the following organisms: beta-lactamase–producing *Staphylococcus aureus*, nonbeta-lactamase–producing *Staphylococcus aureus*, *Staphylococcus* spp, *Streptococcus* spp, *E coli*, *Pasteurella multocida*, and *Pasteurella* spp. UTIs due to susceptible strains of *E coli*. (label dosage; FDA-approved): 62.5 mg/cat (NOT mg/kg) PO twice daily.[10] Skin and soft tissue infections such as abscesses and cellulitis/dermatitis should be treated for 5 to 7 days or 48 hours after all signs have subsided, not to exceed 30 days. If no response is seen after 3 days of treatment, therapy should be discontinued and the case re-evaluated. UTIs may require treatment for 10 to 14 days or longer. The maximum duration of treatment should not exceed 30 days. Therapy may be initiated prior to obtaining results from bacteriological and susceptibility studies. A culture should be obtained prior to treatment to determine susceptibility of the organisms to this drug. Following determination of susceptibility results and clinical response to medication, therapy may be reevaluated.

Sporadic bacterial cystitis (extra-label): 12.5 – 25 mg/kg PO every 8 to 12 hours for 3 to 5 days is an acceptable option but is not recommended as empirical therapy (ie, without or before culture and susceptibility testing); amoxicillin (without clavulanic acid) achieves high concentrations in the urine and is preferred for empirical therapy.[11]

Upper respiratory tract disease (URTD) with a bacterial component (extra-label): 12.5 mg/kg PO every 12 hours[15,16]

BIRDS:

Susceptible infections (extra-label): 50 – 100 mg/kg PO every 6 to 8 hours[17]

FERRETS:

Susceptible infections (extra-label): 10 – 20 mg/kg PO every 8 to 12 hours[18,19]

Monitoring

- Efficacy: resolution of clinical signs
- Culture and susceptibility as indicated for clinical condition being treated.
- Urine culture may be considered after 5 to 7 days when treating bacterial cystitis for longer periods of time.[11] It is important to note that positive cultures taken at this time should prompt questioning the owner about compliance and further investigation as to why the infection has not been eliminated (eg, underlying pathology [eg, cystic calculi, neoplasia]); a positive culture at this time should not simply prompt a change in antibiotic choice. A negative culture during this time frame does not necessarily guarantee resolution of the infection.

Client Information

- The oral suspension should preferably be refrigerated; any unused oral suspension should be discarded after 10 days.
- This medicine can be given with or without food, but gastrointestinal side effects might be prevented if this medicine is given with food.
- The most common side effects are diarrhea, vomiting, and loss of appetite
- It is important to give this medication exactly as prescribed and to complete the full course of therapy, even if your animal seems better. Missing doses or stopping treatment early may result in treatment failure.
- Do NOT give this drug to rabbits, guinea pigs, chinchillas, hamsters, rodents, or other "pocket pets," as life-threatening diarrhea may occur.

Chemistry/Synonyms

Commercially available dosage forms contain amoxicillin trihydrate, which occurs as a practically odorless, white, crystalline powder that is sparingly soluble in water. Amoxicillin differs structurally from ampicillin only by having an additional hydroxyl group on the phenyl ring.

Clavulanate potassium is a beta-lactamase inhibitor; it occurs as an off-white crystalline powder, has a pK_a of 2.7 (as the acid), and is very soluble in water and slightly soluble in alcohol at room temperatures. Although available in commercially available preparations as the potassium salt, potency is expressed in terms of clavulanic acid.

Amoxicillin may also be known as amoxycillin, p-hydroxyampicillin, or BRL 2333; many trade names are available. Clavulanate potassium may also be known as clavulanic acid, BRL-14151K, or kalii clavulanas.

Storage/Stability

Clavulanate products should be stored at temperatures below 25°C (77°F), and some tablet formulations specify storage at 20°C to 25°C (68°F-77°F). Potassium clavulanate is very susceptible to moisture and should be protected from excessive humidity.

After reconstitution, oral suspensions are stable for 10 days when refrigerated. Unused portions should be discarded after that time. At room temperature, suspensions labeled for human use are reportedly stable for 48 hours. The veterinary oral suspension requires refrigeration and is reconstituted by adding 14 mL of water and shaking vigorously.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oral Tablets and Chewable Tablets (4:1 amoxicillin:clavulanic acid ratio):

62.5 mg: Amoxicillin 50 mg/12.5 mg clavulanic acid (as the potassium salt); 125 mg: Amoxicillin 100 mg/25 mg clavulanic acid (as the potassium salt); 250 mg: Amoxicillin 200 mg/50 mg clavulanic acid (as the potassium salt); 375 mg: Amoxicillin 300 mg/75 mg clavulanic acid (as the potassium salt); *Clavamox® Tablets*, *Clavamox® Chewable*, generic; (Rx). FDA-approved for use in dogs and cats.

Powder for Oral Suspension:

Amoxicillin 50 mg/12.5 mg clavulanic acid (as the potassium salt) per mL in 15 mL dropper bottles; *Clavamox® Drops,* generic; (Rx). FDA-approved for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

NOTE: Human-labeled amoxicillin/clavulanate products have vary-

ing ratios of amoxicillin:clavulanate ranging from 2:1 to 7:1. Additionally, human products are generally expressed in potency only as the amoxicillin component (eg, *Augmentin® 875* contains 875 mg of amoxicillin and 125 mg of clavulanic acid), whereas the veterinary products are expressed as the total of both drugs.

Amoxicillin (as trihydrate)/Clavulanic Acid (as potassium salt) Tablets: Amoxicillin 250 mg/125 mg clavulanic acid; Amoxicillin 500 mg/125 mg clavulanic acid; Amoxicillin 875 mg/125 mg clavulanic acid; *Augmentin®*, generic (Rx)

Chewable Tablets: Amoxicillin 125 mg/31.25 mg clavulanic acid; Amoxicillin 200 mg/28.5 mg clavulanic acid; 250 mg/62.5 mg clavulanic acid and 400 mg/57 mg clavulanic acid; *Augmentin®*, generic; (Rx)

Powder for Oral Suspension—Amoxicillin/Clavulanic Acid (as potassium salt) after reconstitution: Amoxicillin 125 mg/31.25 mg clavulanic acid per 5 mL in 75 mL, 100 mL, and 150 mL; Amoxicillin 200 mg/28.5 mg clavulanic acid per 5 mL in 50 mL, 75 mL, and 100 mL; Amoxicillin 250 mg/62.5 mg clavulanic acid per 5 mL in 75 mL, 100 mL, and 150 mL; Amoxicillin 400 mg/57 mg clavulanic acid per 5 mL in 50 mL, 75 mL, and 100 mL; 600 mg/42.9 mg clavulanic acid per 5 mL in 75 mL, 100 mL, 125 mL, and 200 mL; *Augmentin®*and *Augmentin ES-600®*, *Amoclan®*, generic; (Rx)

Amoxicillin 1000 mg/62.5 mg clavulanic acid oral extended-release tablet; *Augmentin XR®*, generic; (Rx)

Amphotericin B

(am-foe-***ter***-i-sin ***bee***) *Abelcet®,AmBisome®, Fungizone®*

Antifungal

Prescriber Highlights

- ► Systemic antifungal used for serious mycotic infections
- ► Must be parenterally administered (IV or SC infusion) for systemic infections
- ► Three different forms available on US market: conventional, formulated with sodium deoxycholate (generic); lipid complex (*Abelcet®*); and liposomal (*AmBisome®*). Each form has different reconstitution instructions, dilution, stability, storage, and dosage recommendations; thus, they are not interchangeable.
- ► Nephrotoxicity is the biggest concern, particularly with the deoxycholate form; newer products (lipid complex and liposomal) are less nephrotoxic and penetrate into tissues better but are more expensive.
- ► Renal function monitoring is essential.
- ► Many potential drug interactions

Uses/Indications

Amphotericin B has activity against most systemic fungal pathogens in numerous animal species, but because the potential exists for severe toxicity, its use should generally be limited to severe, life-threatening infections, progressive disease unresponsive to other antifungals, or in cases in which antifungal susceptibility warrants its use.

The liposomal form of amphotericin B can also be used to treat leishmaniasis and, although this form can be clinically effective, relapses inevitably occur. Additionally, concerns about the development of amphotericin B-resistant *Leishmania* strains in human leishmaniasis has prompted the World Health Organization (WHO) to discourage the use of amphotericin B in the treatment of dogs with leishmaniasis.[1,2]

Pharmacology/Actions

Amphotericin B is generally fungistatic, but it can be fungicidal against some organisms depending on drug concentration. This drug acts by binding to sterols (primarily ergosterol) in the fungal cell membrane and altering the permeability of the membrane, allowing intracellular potassium and other cellular constituents to leak out. Because bacteria and rickettsial organisms do not contain sterols, amphotericin B has no activity against them. Mammalian cell membranes also contain sterols (primarily cholesterol) and the drug's toxicity may be a result of a similar mechanism of action, although amphotericin B binds less strongly to cholesterol than ergosterol.

Amphotericin B has in vitro activity against a variety of fungal organisms, including *Blastomyces* spp, *Aspergillus* spp, *Paracoccidioides* spp, *Coccidioides* spp, *Histoplasma* spp, *Cryptococcus* spp, *Mucor* spp, and *Sporothrix* spp. Although absolute resistance to amphotericin B is rare, some strains of *Aspergillus* spp and *Sporothrix* spp have high minimum inhibitory concentration (MIC) values. Additionally, amphotericin B has in vivo activity against some protozoa species, including *Leishmania* spp and *Naegleria* spp. *Leishmania* spp have ergostane-based sterols in their cell membranes, which may explain amphotericin B's efficacy for treating this organism.

Pharmacokinetics

In humans, amphotericin B is poorly absorbed from the GI tract and must be administered parenterally to achieve sufficient concentrations to treat systemic fungal infections. After IV injection, the drug reportedly penetrates well into most tissues except for the pancreas, muscle, bone, aqueous humor, or pleural, pericardial, synovial, and peritoneal fluids. The drug enters the pleural cavity and joints when inflamed. CSF concentrations are ≈3% of those found in the serum. Approximately 90% to 95% of amphotericin in the vascular compartment is bound to serum proteins.[3] The newer lipid forms of amphotericin B have higher penetration into the lungs, liver, and spleen than the conventional form. The lipid complex formulation reaches higher peak plasma concentrations and has a larger volume of distribution (131 L/kg) as compared with conventional formulations (5 L/kg).[4]

The metabolic pathways of amphotericin B are not known, but amphotericin B exhibits biphasic elimination. In humans, an initial serum half-life of ≈24 hours and a longer terminal half-life of ≈15 days have been described for the conventional formulation.[3] Seven weeks after treatment has stopped, amphotericin B can still be detected in the urine. Approximately 2% to 5% of the drug is recovered in the urine in unchanged (biologically active) form.

Contraindications/Precautions/Warnings

Amphotericin B is contraindicated in patients that are hypersensitive to it.[3] Only use amphotericin B to treat severe, life-threatening infections, progressive disease unresponsive to other antifungals, or in cases in which it is indicated by antifungal susceptibility results.

Because of the serious nature of the diseases treated with systemic amphotericin B, it is not absolutely contraindicated in patients with renal disease, but it should be used cautiously with adequate monitoring and only when safer options (eg, fluconazole, itraconazole) have failed.

Do not confuse amphotericin B formulations. Each amphotericin B formulation (ie, deoxycholate [conventional], lipid complex, or liposomal) has different reconstitution instructions, dilution, stability, storage, and dosage recommendations; thus, they are not interchangeable. Because of the toxicity of this drug, dose calculations and solution preparation procedures should be double-checked.

Adverse Effects

Amphotericin B is known for its nephrotoxic effects; most mammalian patients will show some degree of renal toxicity after receiving

the drug. The proposed mechanism of nephrotoxicity is via renal vasoconstriction, with a subsequent reduction in glomerular filtration rate. The drug may directly act as a toxin to renal epithelial cells. Renal damage may be more common, irreversible, and more severe in patients that receive higher doses or have pre-existing renal disease. Renal tubular acidosis, nephrogenic diabetes insipidus, hypokalemia, and hypomagnesemia can be associated with amphotericin B nephrotoxicity. Usually, renal function will return to normal after treatment is halted but may require several months to do so. As compared with dogs, cats may be more sensitive to nephrotoxic effects. Newer forms of amphotericin B (lipid complex and liposomal) are more hydrophobic than the deoxycholate form and significantly reduce the nephrotoxic qualities of the drug in humans.[3-6] Because higher doses may then be used, these forms may also have enhanced effectiveness. A study in dogs showed that amphotericin B lipid complex was 8 to 10 times less nephrotoxic than the conventional form.[7] However, newer forms may be associated with more infusion related-reactions such as phlebitis.

Several dosing regimens have been used in an attempt to reduce nephrotoxicity in dogs and cats treated with amphotericin B deoxycholate (conventional amphotericin B), including pretreatment with sodium[8] and/or mannitol,[6] but mannitol is not commonly used in veterinary medicine for this purpose. A tubuloglomerular feedback mechanism that induces vasoconstriction and decreased GFR has been postulated for amphotericin B toxicity, and increasing sodium load at the glomerulus may help prevent that feedback. Slow IV infusion with large volumes of fluid may also decrease nephrotoxicity.[9] A diluted SC infusion technique (see ***Dosages***) that may mimic slow IV infusion has been employed in dogs and cats to potentially reduce nephrotoxic potential and allow outpatient administration.[10] None of these techniques have been proven in animals to be superior over another.

Other adverse effects that have been reported with amphotericin B use in mammals include lethargy, restlessness, anorexia, vomiting, hypokalemia, distal renal tubular acidosis, hypomagnesemia, phlebitis, tachycardia, tachypnea, cardiac arrhythmia, bronchospasm, hypotension, nonregenerative anemia, fever (may be reduced by pretreatment with NSAIDs or a low dosage of steroids), polyuria, and collapse.[3] Sterile abscesses have been reported in dogs (20 kg [44.1 lb]) that were administered amphotericin B as a SC injection at concentrations of 25 mg/L (NOT mg/mL); however, these abscesses did not occur when the amphotericin B concentration was less than or equal to 20 mg/L (NOT mg/mL).[10] Calcinosis cutis has been reported in dogs that were treated with amphotericin B.[11,12] Cats with cryptococcosis (CNS involvement) may have increased neurologic signs within the first 3 days of treatment; this is possibly due to an inflammatory response to dying organisms.

In horses receiving amphotericin B via IV regional limb perfusion, adverse effects included limb edema and pain on palpation (42%) and inflammation at injection site (33%); adverse effects resolved within 14 days.[13]

In birds, nephrotoxicity does not appear to occur with amphotericin B use (possibly because of the drug's shorter half-life in birds[14]); however, it may cause myelosuppression.[15]

Amphotericin B has been documented to increase creatine kinase concentrations in humans.[16]

Reproductive/Nursing Safety

The safety of amphotericin B during pregnancy has not been established; however, in humans, amphotericin B has been shown to cross the placenta and enter fetal circulation. No reports of teratogenicity have been associated with any amphotericin formulation used at clinically relevant dosages and the drug is considered to be compatible with pregnancy in humans.[3,4,17,18]

It is unknown if amphotericin B crosses into breast milk. Although oral amphotericin B is poorly bioavailable, the risk to nursing offspring remains unknown.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No case reports were located regarding acute IV overdose of amphotericin B. The reported LD_{50} following IV administration is 6 mg/kg (nephrotoxicity) in dogs and 5 mg/kg (neurotoxicity) in rabbits.[19] Beagles receiving amphotericin B liposomal 8 – 16 mg/kg IV once daily for up to 30 days lost 25% or more of their body weight, beginning on the third day of treatment.[20] If an accidental overdose is administered, giving fluids and mannitol may minimize renal toxicity.[19]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amphotericin B and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May exacerbate the potassium-losing effects of amphotericin B
- **Digoxin**: Amphotericin B-induced hypokalemia may exacerbate digoxin toxicity.
- **Flucytosine**: In vitro synergy between amphotericin B and flucytosine may occur against strains of *Cryptococcus* spp and *Candida* spp, but increased flucytosine toxicity may also occur.
- **Highly Protein Bound Drugs** (eg, azole antifungals, furosemide, NSAIDs): Because amphotericin B is highly bound to plasma proteins (90%-95%), it could theoretically displace other highly bound drugs, causing a transient increase in serum levels of each drug. These interactions are unlikely to be of clinical concern because increased free drug levels will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.
- **Nephrotoxic Drugs** (eg, **aminoglycosides, cisplatin, cyclosporine**): Because the renal effects of other nephrotoxic drugs may be additive with amphotericin B, avoid the concurrent or sequential use of these agents if possible.
- **Potassium-Depleting Drugs** (eg, **thiazide** or **loop diuretics**): May increase risk for hypokalemia
- **Neuromuscular Blockers** (eg, **atracurium**, **tubocurarine**): Amphotericin B-induced hypokalemia may enhance neuromuscular blockade.
- **Zidovudine** (**AZT**): Potential for increased myelotoxicity or nephrotoxicity

Laboratory Interactions

- Amphotericin B liposomal may cause false elevations in **serum phosphate** when using the PHOSm assay[3]

Dosages

NOTE: Because of the potential toxicity, expense (drug, associated administration costs, and laboratory tests), and the necessity for parenteral administration, amphotericin B treatment in animals is generally reserved for treating serious systemic fungal infections. See ***Uses/Indications***. Dosage recommendations (initial dosages, frequency of administration, and cumulative doses) can vary widely depending on the disease/organism treated, formulation used, species, and route of administration. The cumulative dose is the total amount of amphotericin B administered to the patient over the entire treatment period. Solid evidence supporting any specific dose is lacking.

DOGS:

Serious susceptible systemic fungal infections (extra-label)**:**

Deoxycholate formulations (conventional amphotericin B)

a) Initially, 0.5 mg/kg IV every other day; practically, 3 times per week (eg, Monday, Wednesday, and Friday). The calculated drug dose should be diluted in dextrose 5% (1:50) and administered slowly IV over 4 to 6 hours; the slow IV route is more commonly recommended for dogs. Cumulative dose recommendations vary and are dependent on patient response and drug toxicity; most recommendations range from 9 – 12 mg/kg. Patients must be kept well hydrated before and during treatment, but care must be taken to avoid fluid overload.

b) Initially, 0.5 – 0.75 mg/kg SC 1 to 3 times per week.[10,21] The calculated drug dose should initially be diluted to a concentration of 5 mg/mL and then the patient's calculated dose is further diluted into 350 to 500 mL of sodium chloride 0.45%/dextrose 2.5% and injected SC between the scapulae. Alternatively, the SC fluid (without amphotericin B) can be injected first and then the amphotericin B dose can then be injected into the SC fluid "lump." Cumulative dose recommendations vary and are dependent on patient response and drug toxicity; most recommendations range from 8 – 26 mg/kg. [5,10,21-23] See ***Contraindications/Precautions/Warnings*** about SC administration.

Lipid formulations (**NOTE:** Most clinicians recommend using these formulations in animals with preexisting renal disease or that have developed renal toxicity with the deoxycholate form.)

a) Amphotericin B lipid complex (ABLC; *Abelcet*®): 1 – 3.3 mg/kg IV over 2 hours. Cumulative dose recommendations vary and depend on patient response and drug toxicity; recommended cumulative doses range from 8 – 12 mg/kg[24,25] to 24 – 30 mg/kg. One protocol published for use of ABLC treatment of blastomycosis in dogs follows[5,24]: Calculate the patient's ABLC dosage (1 mg/kg) and dilute the appropriate volume of reconstituted ABLC to a concentration of 1 mg/mL in dextrose 5%. For 30 minutes before ABLC administration, begin an LRS IV infusion at 2.5 times the maintenance rate. Immediately before ABLC administration, discontinue LRS, and flush the IV fluid line with dextrose 5%. Infuse the ABLC dose in dextrose 5% over 2 hours. Once the ABLC infusion is complete, flush the IV fluid line with dextrose 5% again and restart LRS at 2.5 times the maintenance rate and continue for 120 minutes after ABLC treatment.

b) Liposomal formulation (*Ambisome*®): 3.3 mg/kg IV once daily for 3 days (10 mg/kg cumulative dose); or 3 mg/kg IV once daily for either 4 doses (days 1, 2, 3, and 10) or 5 doses (days 1, 2, 3, 4, and 10 [cumulative dose: 12 – 15 mg/kg])[26]

CATS:

Serious susceptible systemic fungal infections (extra-label):

Deoxycholate formulations (conventional amphotericin B)

a) Initially, 0.25 mg/kg IV every other day[27]; practically, 3 times per week (eg, Monday, Wednesday, and Friday). The calculated drug dose should be diluted in dextrose 5% (1:50) and administered slowly IV over 4 to 6 hours. Cumulative dose recommendations vary and depend on patient response and drug toxicity; most recommendations range from 6 – 9 mg/kg, but recommendations as low as 4 mg/kg to as high as 16 mg/kg have been noted.[27] Patients must be kept well hydrated before and during treatment, but care must be taken to avoid fluid overload.

b) Initially, 0.5 mg/kg SC 1 to 3 times per week.[10,21] The calculated drug dose should initially be diluted to a concentration of 5 mg/mL and then patient's dose is further diluted into 350 mL of sodium chloride 0.45%/dextrose 2.5% and injected SC between the scapulae. Alternatively, the SC fluid (without amphotericin B) can be injected first, and the amphotericin B dose can then be injected into the SC fluid "lump." Cumulative dose recommendations vary and are dependent on patient response and drug toxicity; most recommendations range from 16 – 20 mg/kg.[10,21,22,28]

Lipid formulations: 1 – 3.3 mg/kg IV over 1 to 2 hours. Cumulative dose recommendations vary and are dependent on patient response and drug toxicity; most recommendations are in the 12 mg/kg range. See the above dosage protocol for dogs [5,29]

HORSES:

NOTE: Using amphotericin B systemically in adult equids can be inordinately expensive, and there is little consensus on dosage regimens.

Serious susceptible systemic fungal infections (extra-label): Using deoxycholate (conventional), initial dose 0.3 mg/kg IV (in 1 L of dextrose 5%) over at least 1 hour; increase dose by 0.1 – 0.15 mg/kg per day on each of the next 2 days. Withhold treatment for 1 to 3 days, then administer 0.5 – 0.6 mg/kg IV every 2 to 3 days (practically, 3 times per week). Treatment has continued for up to one month, or until a cumulative dosage of 6.75 mg/kg has been reached. Oral sodium chloride has been suggested to reduce nephrotoxicity. If toxicity occurs, a dose may be skipped, dosage may be reduced, or dosage interval may be lengthened.[30,31]

Limb pythiosis using IV regional limb perfusion (IRLP; extra-label): After surgical excision of granulation tissue and thermocautery, a catheter is placed in a superficial vein of the affected limb next to the lesion, and a tourniquet is placed above the injection site. Dilute amphotericin B 50 mg (formulation not specified) with 50 mL LRS and administer over 5 minutes. Remove IV catheter 10 minutes post-administration, and apply firm manual pressure over the injection site. Release the tourniquet 45 minutes after administration and bandage the debrided area. Administer a second treatment of amphotericin B if kunkers and/or dark red or black exuberant granulation tissue (necrotic areas) are still observed 14 days after surgery.[13]

Fungal endometritis: 200 – 250 mg/horse (NOT mg/kg) by intrauterine infusion. (NOTE: Amphotericin B formulation was not specified but is assumed to be the conventional/deoxycholate form.) Little science is available for recommending dosages, volume infused, frequency, or diluents. Most intrauterine treatments are commonly performed every day or every other day for 3 to 7 days.[32]

LLAMAS:

Serious susceptible systemic fungal infections (extra-label; from a single case report): Llama with coccidioidomycosis received a test dose of amphotericin 1 mg/llama (NOT mg/kg), then 0.3 mg/kg IV over 4 hours, followed by 3 L of LRS with 1.5 mL of B-complex and 20 mEq of KCl added. Subsequent doses were increased by 10 mg and given every 48 hours until reaching 1 mg/kg every 48 hours IV for 6 weeks. (NOTE: Amphotericin B formulation was not specified but is assumed to be the conventional/deoxycholate form.) The animal tolerated therapy well, but treatment was ultimately unsuccessful.[33]

BIRDS:

Susceptible systemic fungal infections (extra-label):

a) Amphotericin B (conventional) 1.5 mg/kg IV every 12 hours for 3 to 5 days or intratracheally at 1 mg/kg every 12 hours, or 0.3 – 1 mg/mL nebulized for 15 minutes 2 to 4 times daily[34]

b) **Raptors and psittacines with aspergillosis**: Deoxycholate formulation (conventional amphotericin B) 1.5 mg/kg IV every 8 hours for 3 days with flucytosine or follow with flucytosine. May also use intratracheally at 1 mg/kg diluted in sterile water every 8 to 24 hours for 3 days in conjunction with flucytosine or nebulized (1 mg/mL of saline) for 15 minutes every 12 hours. May cause bone marrow suppression[15]

c) **Macrorhabdiasis (*Microrhabdus ornithogaster*)**: Amphotericin B (conventional) 100 – 150 mg/kg PO every 12 hours for 30 days; treatment can be stressful, and failures are common especially with shorter durations of treatment.[35]

RABBITS:

Serious susceptible systemic fungal infections (extra-label): Amphotericin B (conventional) 1 mg/kg/day IV[36]

REPTILES (MOST SPECIES):

Susceptible fungal respiratory infections (extra-label): Anecdotally, amphotericin B (conventional) 1 mg/kg diluted in saline and given intratracheally every 24 hours for 14 to 28 treatments[37]

Monitoring

Also see *Adverse Effects*

- Baseline and periodic (eg, weekly, before each dose) CBC, chemistry panel including electrolytes, and urinalysis during treatment based on clinical presentation and progression of disease
- Several different recommendations have been made regarding stopping treatment when a certain BUN is reached. Most clinicians recommend stopping amphotericin B treatment—at least temporarily—if BUN reaches 30 to 40 mg/dL, if serum creatinine reaches more than 3 mg/dL, or if other clinical signs of systemic toxicity develop (eg, serious depression, vomiting).

Client Information

- Amphotericin B is used to treat serious infections in animals.
- Because the drug requires special handling and frequent bloodwork, it is administered in the veterinarian's clinic.
- Your veterinarian will need to monitor your animal while being treated with this medicine. Do not miss these important follow-up visits.

Chemistry/Synonyms

A polyene macrolide antifungal agent produced by *Streptomyces nodosus*, amphotericin B occurs as a yellow to orange, odorless, or practically odorless powder. It is insoluble in water and anhydrous alcohol. Amphotericin B is amphoteric and can form salts in acidic or basic media. These salts are more water-soluble but possess less antifungal activity than the parent compound. Each mg of amphotericin B must contain not less than 750 µg of anhydrous drug. Amphotericin A may be found as a contaminant in concentrations not exceeding 5%. The commercially available powder for injection contains sodium deoxycholate as a solubilizing agent.

Amphotericin B is available in several formulations. Amphotericin B deoxycholate may also be known as amphotericin generic, AMB, conventional amphotericin B, or *Fungizone®*. Amphotericin B lipid complex may also be known as ABLC or *Abelcet®*. Amphotericin B liposome may also be known as liposomal amphotericin B, lip-AmB, ABL, L-AMB, or *Ambisome®*.

Storage/Stability

The following information is for the conventional (deoxycholate; generic) and lipid complex (ABLC; *Abelcet®*) forms of amphotericin B. If using the liposomal form (*AmBisome®*), refer to the package insert for detailed information.

Vials of amphotericin B deoxycholate powder for injection (conventional; generic) should be stored in the refrigerator (2°C-8°C [36°F-46°F]) and protected from light and moisture. Reconstitution of the powder must be done with sterile water for injection (no preservatives—see directions for preparation in ***Dosage Forms/Regulatory Status***).

After reconstitution of conventional amphotericin B, if protected from light, the solution is stable for 24 hours at room temperature and for 1 week if kept refrigerated. After diluting with dextrose 5% (must have pH more than 4.3) for IV use, the manufacturer recommends continuing to protect the solution from light during administration. Additional studies, however, have shown that potency remains largely unaffected if the solution is exposed to light for 8 to 24 hours.

One reference states that for avian use, the conventional amphotericin B can be diluted with sterile water, divided into 10 mL aliquots using aseptic technique, and stored at -20°C (-4°F) for ≈1 month.[38] However, published data documenting the stability of the drug for this practice have not been located.

Amphotericin B lipid complex vials should be refrigerated at 2°C to 8°C (36°F-46°F) and protected from light and freezing. The manufacturer recommends keeping the vials in their original cartons until use. When diluted in dextrose 5% for administration, the manufacturer states that it can be stored for 48 hours when refrigerated and then an additional 6 hours at room temperature. However, other sources have stated that at a concentration of 1 mg/mL in dextrose 5%, it is stable for 10 days when refrigerated.

Amphotericin B liposomal vials should be stored at temperatures up to 25°C (77°F). Once reconstituted, the concentrated product may be stored for up to 24 hours at 2°C to 8°C (36°F-46°F); do not freeze. Administration should begin within 6 hours after the concentrated product is further diluted with dextrose 5%. Discard unused portions.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Amphotericin B deoxycholate (conventional; generic) is **compatible** with the following solutions and drugs: dextrose 5%, dextrose 5% in sodium chloride 0.2%, heparin sodium, heparin sodium with hydrocortisone sodium phosphate, hydrocortisone sodium phosphate/succinate, and sodium bicarbonate.

Amphotericin B (conventional; generic) is **incompatible** with the following solutions and drugs: sodium chloride 0.9%, lactated Ringer's, D5-sodium chloride 0.9%, D5-lactated Ringer's, amino acids 4.25%-dextrose 25%, amikacin, calcium chloride/gluconate, chlorpromazine HCl, cimetidine HCl, diphenhydramine HCl, dopamine HCl, edetate calcium disodium (CaEDTA), gentamicin sulfate, oxytetracycline HCl, penicillin G potassium/sodium, polymyxin B sulfate, potassium chloride, prochlorperazine mesylate, tetracycline

HCl, and verapamil HCl.[17]

Directions for reconstitution/administration: Using strict aseptic technique and a 20 gauge or larger needle, rapidly inject 10 mL of sterile water for injection (without a bacteriostatic agent) directly into the lyophilized cake; immediately shake well until solution is clear.[17] A 5 mg/mL colloidal solution results. Further dilute (1:50) for administration to a concentration of 0.1 mg/mL with D5W (pH more than 4.2). An in-line filter may be used during administration but must have a pore diameter more than 1 µm.

Amphotericin B lipid complex is **compatible** with dextrose 5%, but it is **incompatible** with sodium chloride 0.9% or other electrolyte solutions.[4]

Directions for dilution/administration: The suspension must be diluted in dextrose 5% for administration.[4] Shake the vial gently so that no sediment remains on the vial bottom. Withdraw the dose using a syringe and needle. Attach the 5 µm filter needle that is supplied with the vial, and add the drug suspension into a bag of D5W. One filter needle may be used for up to 4 vials of drug. The final concentration is usually 1 mg/mL, although 2 mg/mL may be used in cases that require a smaller infusion volume. The bag is shaken just prior to infusion; it should not be used if foreign matter is present. If delivery proceeds over more than 2 hours, the bag should be shaken every 2 hours. Use a separate infusion line or flush an existing line with D5W prior to administration.

Amphotericin B liposomal is **compatible** with D5W, but it is **incompatible** with sodium chloride 0.9%.[3]

Directions for reconstitution/administration: Reconstitute the lyophilized material by adding 12 mL sterile water for injection and shake immediately and vigorously for at least 30 seconds; continue shaking until completely dispersed.[3] Withdraw the required amount of amphotericin B liposomal from the vial into a sterile syringe, attach the provided 5 micron filter needle to the syringe, and add the drug suspension to a sufficient volume of dextrose to achieve a final amphotericin B concentration between 1 – 2 mg/mL, although lower concentration (0.2 – 0.5 mg/mL) may be used to provide an appropriate fluid volume for administration. Use a separate infusion line or flush an existing line with D5W prior to administration. An in-line filter may be used during administration but must have a pore diameter more than 1 µm. Administer amphotericin B liposomal IV infusion over a period of ≈120 minutes, although infusion time may be reduced to ≈60 minutes in patients in whom the treatment is well tolerated.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Amphotericin B (conventional; deoxycholate) Powder for Injection: 50 mg in vials; generic; (Rx)

Amphotericin B Lipid-complex Suspension Injection: 100 mg/20 mL (as lipid complex) in vials with 5 µm filter needles: *Abelcet®*; (Rx)

Amphotericin B Liposome for Injection: 50 mg in single-dose vials with 5 µm filter; *AmBisome®*; (Rx)

Ampicillin
Ampicillin Sodium
Ampicillin Trihydrate

(am-pi-***sill***-in) *Princillin®, Omnipen®, Polyflex®*

Aminopenicillin

Prescriber Highlights

- Bactericidal aminopenicillin with same spectrum as amoxicillin (ineffective against bacteria that produce beta-lactamase)
- Poor oral absorption in dogs and cats limits use to parenteral routes; amoxicillin is preferred for oral administration
- Ampicillin trihydrate (*Polyflex®*) must **not** be given IV.
- Adverse effects are infrequent; GI-related effects are most common, but hypersensitivity and other adverse effects occur rarely.

Uses/Indications

In dogs and cats, ampicillin is not well absorbed after oral administration, and its oral use has largely been supplanted by amoxicillin. Ampicillin is used commonly in parenteral dosage forms in all species when an aminopenicillin is indicated. At high doses, ampicillin is still an effective drug for treating penicillin-susceptible enterococci, particularly *Enterococcus faecium*, streptococci, staphylococci, and Enterobacterales. It is often used in combination with a drug with better gram-negative activity (eg, fluoroquinolone, aminoglycoside) when broad-spectrum empirical coverage is needed. It is highly effective against streptococci. The use of ampicillin for staphylococci and Enterobacteriaceae is limited by an increasing prevalence of beta-lactamase–producing strains. Ampicillin can be used as an alternate treatment for leptospirosis when oral doxycycline is not tolerated.[1–3] An aminoglycoside (eg, gentamicin) is often added to treat serious *Enterococcus* spp infections caused by penicillin-sensitive organisms for synergistic activity. Ampicillin is sometimes used for perioperative prophylaxis, but the lack of efficacy against beta-lactamase–producing bacteria limits its efficacy.

The World Health Organization has designated ampicillin as a Critically Important, High Priority antimicrobial for human medicine.[4] The Office International des Epizooties (OIE) has designated ampicillin as Veterinary Critically Important Antimicrobial (VCIA) Agents in avian, bovine, caprine, equine, ovine, and swine species.[5]

Pharmacology/Actions

Like other penicillins, ampicillin is a time-dependent, bactericidal agent that acts by inhibiting cell wall synthesis. Ampicillin and the other aminopenicillins have increased activity against many strains of gram-negative aerobes not covered by either the natural penicillins or penicillinase-resistant penicillins, including some strains of *Escherichia coli, Klebsiella* spp, and *Haemophilus* spp. Like the natural penicillins, aminopenicillilns are susceptible to inactivation by beta-lactamase–producing bacteria (eg, staphylococci, Enterobacterales).

Although they are not as active as the natural penicillins, aminopenicillins do have activity against many anaerobic bacteria, including clostridial organisms. Organisms that are generally not susceptible include *Pseudomonas aeruginosa, Serratia* spp, indole-positive *Proteus* (*Proteus mirabilis* is susceptible), *Enterobacter* spp, *Citrobacter* spp, and *Acinetobacter* spp. The aminopenicillins also are inactive against rickettsial organisms, mycobacteria, fungi, *Mycoplasma* spp, and viruses.

To reduce the inactivation of penicillins by beta-lactamases, potassium clavulanate and sulbactam have been developed to inactivate these enzymes and extend the spectrum of those penicillins. See ***Ampicillin/Sulbactam*** or ***Amoxicillin/Clavulanate***.

Pharmacokinetics

Ampicillin anhydrous and trihydrate are relatively stable in the presence of gastric acid. After oral administration, ampicillin is absorbed ≈30% to 55% in humans (taken on an empty stomach) and monogastric animals. Because amoxicillin oral absorption is ≈75% to 92%, ampicillin is not recommended for oral administration in animals. Food will decrease the rate and extent of oral absorption.

When ampicillin is administered parenterally (ie, IM, SC), the trihydrate salt will achieve serum concentrations of approximately one-half those of a comparable dose of the sodium salt. The trihydrate parenteral dosage form should not be used in cases in which higher MICs are required for treating systemic infections.

After absorption, the volume of distribution for ampicillin is ≈0.3 L/kg in humans and dogs, 0.167 L/kg in cats, and 0.16 to 0.5 L/kg in cattle. The drug is widely distributed to many tissues, including the liver, lungs, prostate (humans), muscle, bile, and ascitic, pleural, and synovial fluids. Ampicillin will cross into the CSF only when meninges are inflamed, reaching concentrations of 10% to 60% those found in serum. Low concentrations of the drug are found in the aqueous humor, tears, sweat, and saliva. Although ampicillin crosses the placenta, it is thought to be relatively safe to use during pregnancy. Ampicillin is ≈20% bound to plasma proteins, primarily albumin.

Ampicillin is eliminated primarily through renal mechanisms, principally by tubular secretion, resulting in high concentrations of active drug in the urine. Some of the drug is metabolized by hydrolysis to penicilloic acids (inactive) then excreted in the urine. Elimination half-lives of ampicillin have been reported as 45 to 80 minutes in dogs and cats and 60 minutes in swine.

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, penicillins should be used cautiously in patients with documented hypersensitivity to other beta-lactam antibiotics (eg, cephalosporins, cefamycins, carbapenems).

The trihydrate form (*Polyflex®*) must not be given IV, as there is a high risk for anaphylaxis and sudden death. Ampicillin sodium for injection is the only form of ampicillin that may be administered IV.

Ampicillin sodium should be used with caution in azotemic dogs; increased plasma drug concentrations, AUC, and increased elimination half-life have been documented in one study.[6] Dosage adjustment (ie, reduced dosing frequency) may be needed.

In humans, ampicillin has been shown to lower seizure threshold and should be used with caution with any drug that also lowers seizure threshold[7]; significance in veterinary patients is not known.

Penicillins, cephalosporins, and macrolides should not be administered to rabbits, guinea pigs, chinchillas, or hamsters, as serious enteritis and clostridial enterotoxemia may occur.

Adverse Effects

Adverse effects with penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemia, lymphadenopathy, or anaphylaxis.

When given orally, penicillins may cause GI effects (eg, anorexia, vomiting, diarrhea). Because penicillins may also alter the gut microbiota, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (ie, superinfections).

Neurotoxicity (eg, ataxia in dogs) has been associated with very high doses or prolonged use. Although penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta; although safe use during pregnancy has not been firmly established, there has not been any documented teratogenic problem associated with these drugs.

Milk concentrations of ampicillin are considered low. In lactating dairy cattle, the milk:plasma ratio is about 0.3.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see ***Adverse Effects***). In humans, high doses of parenteral penicillins, particularly in patients with renal disease, have induced CNS effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with ampicillin either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring should be performed when appropriate.

- **Allopurinol**: In humans, concurrent use has been implicated in increased occurrences of skin rashes; veterinary significance of this interaction is unknown.
- **Aminoglycosides** (eg, **amikacin**, **gentamicin**): Beta-lactam antibiotics can inactivate aminoglycosides in vitro (and in vivo in patients with chronic kidney disease).
- **Atenolol**: Concurrent oral use may decrease atenolol bioavailability.
- **Bacteriostatic Antimicrobials** (eg, **chloramphenicol, erythromycin,** and **other macrolides, tetracyclines, sulfonamides**): Because there is evidence of in vitro antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together has generally not been recommended, but actual clinical importance is not clear and is currently in doubt.
- **Dichlorphenamide:** Concurrent use may increase hypokalemia risk.
- **Methotrexate (MTX)**: Ampicillin may decrease the renal excretion of MTX, causing increased levels and potential toxic effects.
- **Mycophenolate**: Concurrent use may reduce levels or effects of mycophenolate.
- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives
- **Proton Pump Inhibitors** (**PPIs**; eg, **omeprazole**, **pantoprazole**): May reduce absorption of oral ampicillin
- **Warfarin**: Concurrent use may decrease vitamin K production and increase risk for bleeding.

Laboratory Considerations

- Ampicillin may cause false-positive **urine glucose determinations** with the use of cupric sulfate solution (Benedict's Solution, *Clinitest®*). Tests using glucose oxidase (*Tes-Tape®, Clinistix®*) are not affected by ampicillin.
- Because penicillins and other beta-lactams can inactivate **aminoglycosides** in vitro (and in vivo in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the

patient is also receiving beta-lactam antibiotics, particularly when the serum is stored prior to analysis. It is recommended that samples should be drawn at times when the beta-lactam antibiotic is at a trough level and, if the assay cannot be run right away, samples should be frozen immediately.

Dosages

DOGS/CATS:

Ampicillin *trihydrate* (*Polyflex*®) injection (label dosage; FDA-approved): **NOTE**: Although the following indications and dosages are on the FDA-approved label, the label dosages are not accepted by most clinicians today as being consistently efficacious because of the listed low doses and dosing interval.

Indications: Respiratory Tract Infections: Upper respiratory infections, tonsillitis and bronchopneumonia due to hemolytic streptococci, *Staphylococcus aureus*, *Escherichia coli*, *Proteus mirabilis,* and *Pasteurella* spp. Urinary Tract Infections due to *Proteus mirabilis, E coli, Staphylococcus* spp, hemolytic streptococci, and *Enterococcus* spp. GI Infections due to *Enterococcus* spp, *Staphylococcus* spp, and *E coli*. Skin, Soft Tissue, and Postsurgical Infections: Abscesses, pustular dermatitis, cellulitis and infections of the anal gland due to *E coli, Proteus mirabilis*, hemolytic streptococci, *Staphylococcus* spp, and *Pasteurella* spp. **Dosage**: 6.6 mg/kg SC or IM twice daily. [8]The dosage will vary according to the animal being treated, the severity of the infection, and the animal's response. Treatment for 3 days is usually adequate, but treatment should be continued for 48 to 72 hours after the animal has become afebrile or there is resolution of clinical signs associated with infection.

Adjunctive antibiotic therapy for sepsis (empiric therapy) or susceptible systemic infections (extra-label): Ampicillin *sodium* 20 – 40 mg/kg IV every 6 to 8 hours; usually used in combination with an antibiotic that enhances coverage for gram-negative organisms (eg, aminoglycoside, fluoroquinolone). Enterococci infections may require much higher ampicillin dosages (40 – 100 mg/kg).

Leptospirosis in dogs (extra-label): Ampicillin *sodium* 20 mg/kg IV every 6 hours if vomiting or other adverse reactions, or the need for parenteral treatment preclude doxycycline administration.[9]

Acute treatment in dogs of endocarditis secondary to a susceptible strain of *Streptococcus canis* (extra-label): Ampicillin *sodium* 20 – 40 mg/kg IV every 6 to 8 hours[10]

HORSES:

Ampicillin *sodium* injection (label dosage; FDA-approved): **NOTE**: Although the following indications and dosages are on the FDA-approved label, the label dosages are not accepted by most today as being consistently efficacious.

Indications: Respiratory Tract Infections: Bacterial infections caused by susceptible strains of *Staphylococcus* species, *Streptococcus* spp, *E coli,* and *Proteus mirabilis.* Skin and soft tissue infections: Bacterial infections caused by susceptible strains of *Staphylococcus* spp, *E coli,* and *Proteus mirabilis.* **Dosage**: 6.6 mg/kg IV or IM twice daily.[11] Treatment should be continued 48 hours after all clinical signs of infection have subsided.

Susceptible infections (extra-label): Ampicillin *sodium* 20 mg/kg IV or IM every 6 to 8 hours

Streptococcal lower airway infections (extra-label): Ampicillin *sodium* 15 mg/kg IV every 12 hours from a pharmacokinetic study. Ampicillin concentrations in pulmonary epithelial lining fluid (PELF) are above minimum inhibitory concentration (MIC) values for at least 12 hours. Treatment of other bacterial pathogens requires susceptibility testing and possibly more frequent dosing, depending on MIC.[12]

Foals (extra-label): Ampicillin *sodium* 15 – 30 mg/kg IV or IM every 6 to 8 hours[11]

CATTLE

Ampicillin *trihydrate* (*Polyflex*®) injection (label dosage; FDA-approved):

Indications: Respiratory Tract Infections: Bacterial pneumonia (shipping fever, calf pneumonia and bovine pneumonia) caused by *Aerobacter* spp, *Klebsiella* spp, *Staphylococcus* spp, *Streptococcus* spp, *Pasteurella multocida*, and *E coli* susceptible to ampicillin trihydrate. **Dosage**: 4.4 – 11 mg/kg once daily IM.[8] Do not treat for more than 7 days. Treatment for 3 days is usually adequate, but treatment should be continued for 48 to 72 hours after the animal has become afebrile or there is resolution of clinical signs associated with infection. One study looked at the effects of dosing twice daily and concluded that there was no significant effect of dosing interval on achieving therapeutic concentrations in the milk, lochial fluid, and endometrial tissue.[13]

Respiratory infections: (extra-label): Ampicillin *trihydrate* (*Polyflex*®) 22 mg/kg SC every 12 hours[14]

Surgical prophylaxis (extra-label): Ampicillin *sodium* 5 g IV as a single dose administered ≈15 minutes prior to the first incision[15]

FERRETS:

Susceptible infections (extra-label): 5 – 10 mg/kg IM, SC, or IV twice daily[16]

RODENTS/SMALL MAMMALS:

a) **Rabbits, Guinea pigs, Chinchillas, Hamsters** (extra-label): Not recommended as it can cause a fatal enterocolitis[17]
b) **Gerbils, Mice, Rats** (extra-label): 20 – 100 mg/kg PO, SC, or IM every 8 to 12 hours[18]
c) **Hedgehogs** (extra-label): 10 mg/kg IM or PO once daily[19]

REPTILES:

Respiratory tract infections (extra-label)**:** 50 mg/kg SC or IM every 12 hours[20]

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Antibiotic given by injection under the skin or into the muscle. Do not administer into the vein. Be sure you understand how to safely give this medicine to your animal.
- Your animal's signs of infections should improve within 2 or 3 days of starting treatment. Contact your veterinarian if your animal appears to not be responding to treatment.
- Follow recommended drug residue withholding times if you are administering to an animal that will be used for human food.

Chemistry/Synonyms

As semisynthetic aminopenicillins, ampicillin anhydrous and trihydrate occur as practically odorless, white, crystalline powders that are slightly soluble in water. At usual temperatures (less than 42°C [107.6°F]), ampicillin anhydrous is more soluble in water than the trihydrate (13 mg/mL vs 6 mg/mL at 20°C [68°F]). Ampicillin anhydrous or trihydrate oral suspensions have a pH of 5 to 7.5 after reconstitution with water. After reconstitution, ampicillin trihydrate for injection is pale white to yellow in color.

Ampicillin sodium occurs as an odorless or practically odorless,

white to off-white, crystalline hygroscopic powder. It is very soluble in water or other aqueous solutions. After reconstitution, ampicillin sodium has a pH of 8 to 10 at a concentration of 10 mg/mL. Commercially available ampicillin sodium for injection has ≈3 mEq of sodium per gram of ampicillin.

Potency of the ampicillin salts is expressed in terms of ampicillin anhydrous.

Ampicillin may also be known as aminobenzylpenicillin, ampicillinum, ampicillinum anhydricum, anhydrous ampicillin, AY-6108, BRL-1341, NSC-528986, or P-50; many trade names are available.

Storage/Stability

Ampicillin trihydrate (*Polyflex®*) powder for injection should be stored at or below 25°C (77°F), with excursions permitted up to 30°C (86°F). After reconstitution, it is stable for 3 months when refrigerated.

Ampicillin anhydrous or trihydrate capsules and powder for oral suspension should be stored at room temperature (15°C-30°C [59°F-86°F]). After reconstitution, the oral suspension is stable for 14 days if refrigerated (2°C-8°C [36°F-46°F]) or 7 days when kept at room temperature.

Ampicillin sodium powder for injection should be stored at room temperature (15°C-30°C [59°F-86°F]). The drug is relatively unstable after reconstitution and should be used within 1 hour of reconstitution. As the concentration of the drug in solution increases, the stability of the drug decreases. Dextrose may also speed the destruction of the drug by acting as a catalyst in the hydrolysis of ampicillin.

Although most sources recommend using solutions of ampicillin sodium immediately, studies have demonstrated that refrigeration at 4°C (39.2°F) increases stability of reconstituted solutions. In sterile water for injection, ampicillin sodium solutions are stable at 30 mg/mL for up to 48 hours and at 20 mg/mL or less for up to 72 hours. In 0.9% sodium chloride, ampicillin sodium solutions are stable at 30 mg/mL for up to 24 hours and at 20 mg/mL or less for up to 48 hours.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Ampicillin sodium is reportedly **Y-site compatible** with the following solutions and additives: aminocaproic acid, asparaginase, azithromycin, carboplatin, cisplatin, clarithromycin, cytarabine, dexmedetomidine hydrochloride, dexrazoxane, doxapram hydrochloride, doxorubicin hydrochloride (liposomal), fat emulsions, gemcitabine hydrochloride, heparin sodium, levofloxacin, mannitol, methadone hydrochloride, metronidazole, pantoprazole sodium, *Plasma-Lyte A*, potassium chloride, propofol, vinblastine sulfate, vincristine sulfate, voriconazole, and zoledronic acid.

Ampicillin sodium injection has ***variable or uncertain Y-site compatibility*** with amikacin sulfate, ascorbic acid (vitamin C), atracurium besylate, atropine sulfate, butorphanol tartrate, calcium chloride, calcium gluconate, cefazolin sodium, cefotaxime, cefotetan disodium, ceftazidime, ceftriaxone sodium, cefuroxime, chloramphenicol sodium succinate, clindamycin phosphate, cyclophosphamide, cyclosporine, dexamethasone sodium succinate, digoxin, diltiazem hydrochloride, dopamine hydrochloride, edetate calcium disodium, epinephrine hydrochloride, epinephrine sulfate, erythromycin lactobionate, esmolol hydrochloride, famotidine, fentanyl citrate, furosemide, gentamicin sulfate, glycopyrrolate, heparin sodium, hydralazine hydrochloride, hydrocortisone sodium succinate, hydromorphone hydrochloride, insulin (regular), lactated Ringer's solution, lidocaine hydrochloride, magnesium sulfate, mechlorethamine hydrochloride, metoclopramide hydrochloride, morphine sulfate, multiple vitamins injection, naloxone hydrochloride, nitroglycerin, nitroprusside, norepinephrine bitartrate, oxytocin, penicillin G potassium, penicillin G sodium, pentobarbital sodium, phenobarbital sodium, phytonadione (vitamin K_1), polymyxin B sulfate, potassium chloride, procainamide, propranolol hydrochloride, ranitidine hydrochloride, sodium bicarbonate, succinylcholine chloride, theophylline, thiamine hydrochloride (vitamin B_1), tobramycin sulfate, and vasopressin.

Ampicillin sodium is reportedly **incompatible** with the following additives: aminophylline, amiodarone hydrochloride, amphotericin B cholesteryl sulfate complex, amphotericin B conventional colloidal, amphotericin B lipid complex, amphotericin B liposome, buprenorphine hydrochloride, chlorpromazine hydrochloride, diazepam, diphenhydramine hydrochloride, dobutamine hydrochloride, doxorubicin hydrochloride, doxycycline hyclate, fluconazole, ketamine hydrochloride, lorazepam, midazolam hydrochloride, mitoxantrone hydrochloride, mycophenolate mofetil hydrochloride, ondansetron hydrochloride, phenytoin sodium, prochlorperazine edisylate, prochlorperazine mesylate, protamine sulfate, tranexamic acid, trimethoprim-sulfamethoxazole, and vinorelbine tartrate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Ampicillin Trihydrate Injection Powder for Suspension: 25 g (of ampicillin) vials; *Polyflex®*; (Rx). NADA 055-030. FDA-approved for use in dogs, cats, and cattle. Withdrawal times at labeled doses (cattle, do not treat for more than 7 days): Milk = 48 hours (4 milkings); Slaughter = 6 days (144 hours).

Ampicillin Sodium Powder for Injection: 1 g and 3 g vials; generic; (Rx). NADA # 200-335. FDA-approved for use in horses not intended for meat production.

The following products are listed in the FDA Green Book, but marketing status is uncertain.

Ampicillin Trihydrate Soluble Powder: 88.2 mg (of ampicillin) per gram of powder; *Princillin®*; (Rx). FDA-approved for use in swine. Withdrawal times at labeled doses: Slaughter = 24 hours.

Ampicillin Trihydrate Capsules: 125 mg, 250 mg, and 500 mg (of ampicillin) capsules; *Princillin®*; (Rx). FDA-approved for use in dogs and cats.

Ampicillin Trihydrate Tablets: 50 mg and 100 mg (of ampicillin) tablets; *Ampi-Tab®* (Rx). FDA-approved for use in dogs.

Ampicillin Anhydrous Capsules: 125 mg and 250 mg (of ampicillin) capsules; *Omnipen®*; (Rx). FDA-approved for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

Ampicillin Sodium Powder for Injection: 125 mg, 250 mg, 500 mg, 1 g, 2 g, and 10 g in vials; generic; (Rx)

Ampicillin Oral Capsules (as trihydrate): 250 mg and 500 mg; generic; (Rx)

Ampicillin (as trihydrate) Powder for Oral Suspension: 125 mg/5 mL (25 mg/mL) and 250 mg/5 mL (50 mg/mL) when reconstituted; generic; (Rx)

Ampicillin/Sulbactam

(am-pi-***sill***-in; sul-***bak***-tam) *Unasyn®*

Potentiated Aminopenicillin

Prescriber Highlights

- ► Parenteral potentiated aminopenicillin that may be used to treat infections for which amoxicillin/clavulanate would be appropriate, but an injectable antibiotic is required
- ► May be used for surgical prophylaxis
- ► Hypersensitivity reactions possible; contraindicated in patients with documented severe hypersensitivity to penicillins
- ► Usually administered SC, IM, or IV every 6 to 8 hours

Uses/Indications

The addition of sulbactam to ampicillin broadens ampicillin's spectrum through inhibition of some beta-lactamases.

Ampicillin/sulbactam may be indicated when parenteral therapy is required for the treatment of aerobic or anaerobic gram-positive and gram-negative infections. In dogs and cats, ampicillin/sulbactam may be considered when oral amoxicillin/clavulanate is not viable (eg, patient NPO, in cases of critical illness [eg, sepsis, pneumonia, other severe infections]), or for surgical prophylaxis. For broad-spectrum uses, ampicillin/sulbactam is often combined with another drug such as a fluoroquinolone or aminoglycoside to provide enhanced gram-negative coverage.

The World Health Organization (WHO) has designated ampicillin/sulbactam as a Critically Important, High Priority antimicrobial in human medicine.[1] The Office International des Epizooties (OIE) has designated ampicillin/sulbactam as Veterinary Critically Important Antimicrobial (VCIA) Agents in avian, bovine, and swine species.[2]

Pharmacology/Actions

Ampicillin is a time-dependent bactericidal agent that acts via inhibition of cell wall synthesis. Penicillins are bactericidal against susceptible bacteria and act by inhibition of mucopeptide synthesis in the cell wall, which results in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes in the bacterial cytoplasmic membrane that are involved with cell wall synthesis (eg, carboxypeptidases, transpeptidases, endopeptidases). Various beta-lactam antibiotics have different affinities for these enzymes (ie, penicillin-binding proteins), which helps explain the differences in spectrums of activity not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered to be more effective against actively growing bacteria.

Sulbactam has some intrinsic antibacterial activity against some bacteria (eg, *Neisseria* spp, *Moraxella* spp, *Bacteroides* spp); however, for most bacteria, sulbactam alone does not achieve levels sufficient to act as an antibacterial agent. Sulbactam binding to certain penicillin-binding proteins may explain its activity and, when used in combination with ampicillin, synergistic effects may result. On an mg-for-mg basis, clavulanic acid is a more potent beta-lactamase inhibitor than sulbactam, but sulbactam offers reduced likelihood of inducing chromosomal beta-lactamases, greater tissue penetration, and stability.

When sulbactam is combined with ampicillin, ampicillin's spectrum of activity is extended to bacteria (eg, *Escherichia coli*, *Pasteurella* spp, *Staphylococcus* spp, *Klebsiella* spp, *Proteus* spp) that produce beta-lactamases of Richmond-Sykes types II through VI that would otherwise render ampicillin ineffective. Sulbactam binds to beta-lactamases, thereby protecting the beta-lactam ring of ampicillin from hydrolysis. The efficacy of sulbactam involves how well it binds the specific beta-lactamase and the relative levels of sulbactam and beta-lactamase. In cases in which there is a high bacterial bioburden or bacteria are producing large amounts of beta-lactamase, efficacy may be limited. Other aerobic bacteria that may be susceptible to ampicillin/sulbactam include *Streptococcus* spp, *Listeria monocytogenes*, *Bacillus anthracis*, *Salmonella* spp, *Pasteurella* spp, and *Acinetobacter* spp. Anaerobic bacterial infections caused by *Clostridium* spp, *Bacteroides* spp, *Fusobacterium* spp, *Peptostreptococcus* spp, and *Propionibacterium* spp may also be susceptible to ampicillin/sulbactam.[3–5] Similar to amoxicillin/clavulanic acid, ampicillin/sulbactam can be used in the treatment of bacterial respiratory tract infections, although ampicillin/sulbactam is ineffective against *Mycoplasma* spp and resistance in *Bordetella* spp is an increasing problem in some regions. In general, ampicillin/sulbactam is excellent for beta-lactamase–producing gram-positive aerobic and anaerobic bacteria, but less effective for beta-lactamase–producing gram-negative bacteria.

Methicillin-resistant staphylococci are resistant to ampicillin/sulbactam. Ampicillin/sulbactam is usually ineffective against AmpC (type I) cephalosporinases, and efficacy against extended-spectrum beta-lactamase–producing bacteria is variable and often unpredictable. There is little—if any—synergistic activity against organisms already susceptible to ampicillin.

Pharmacokinetics

See ***Ampicillin*** for pharmacokinetic information.

Because sulbactam sodium is not appreciably absorbed from the GI tract, this medication must be given parenterally. A covalently linked double ester form of ampicillin/sulbactam (ie, sultamicillin) is orally absorbed, but this combination is not commercially available in the US. When sulbactam is administered parenterally (ie, IV, IM), its pharmacokinetic profile closely mirrors that of ampicillin's pharmacokinetic profile in most species studied. In a study of calves, plasma concentrations of sulbactam during the elimination phase were consistently higher than those of ampicillin, leading the study authors to propose using a higher ratio (greater than 2:1 ampicillin/sulbactam) if the combination is used in calves.[6]

A regional IV limb perfusion (RIVLP; 45-minute duration) with ampicillin/sulbactam (1.5 g; ratio, 2:1; total volume, 4 mL) administered in the dorsal common digital vein of the right rear limb of healthy, adult nonlactating cattle resulted in peak ampicillin serum concentrations of ≈5 mg/mL in the perfused limb and 2 mg/mL in the synovial fluid of the metatarsophalangeal joint 1 hour after RIVLP. Ampicillin concentration in synovial fluid remained above 8 µg/mL for 19 hours. Maximum systemic ampicillin concentration was 2.5 µg/mL 5.4 hours after RIVLP. Sulbactam pharmacokinetics followed trends similar to ampicillin.[7]

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of severe hypersensitivity (anaphylaxis) to them. Because cross-reactivity can occur, penicillins should be used cautiously in patients documented as being hypersensitive to other beta-lactam antibiotics (eg, cephalosporins, cephamycins, carbapenems).

Ampicillin/sulbactam is contraindicated in humans with a history of ampicillin/sulbactam-associated cholestatic jaundice or hepatic dysfunction; veterinary significance is unknown. In humans, ampicillin has been shown to lower seizure threshold and should be used with caution with any drug that also lowers seizure threshold[8]; significance in veterinary patients is not known.

Increased plasma ampicillin drug concentrations, AUC, and increased elimination half-life have been documented in azotemic dogs.[9] Dosage adjustment (ie, reduced dosing frequency) may be needed.

Penicillins, cephalosporins, and macrolides should not be administered to rabbits, guinea pigs, chinchillas, or hamsters, as serious enteritis and clostridial enterotoxemia may occur.

Adverse Effects

IM injections may be painful, as pH of the solution is high. IV injections may cause thrombophlebitis and phlebitis. Although hypersensitivity reactions to penicillins occur infrequently in animals, they can be severe (anaphylaxis), particularly after IV administration.

Hepatotoxicity (ie, cholestatic hepatitis, cholestasis) has been reported in some humans receiving ampicillin/sulbactam. Toxicity is usually reversible with discontinuation of therapy, but deaths have been reported. Veterinary significance is unknown.

High doses or increased CNS penetration of penicillins have been associated with neurotoxicity (eg, ataxia in dogs).[10] Although penicillins are not considered to be hepatotoxic, elevated liver enzymes have been reported in some dogs. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia. GI disturbances are possible, and *Clostridium difficile*-associated diarrhea (CDAD) has been reported in humans.

Reproductive/Nursing Safety

Both ampicillin and sulbactam have been shown to cross the placenta. Ampicillin/sulbactam should be used only when the potential benefits outweigh the risks.

Both ampicillin and sulbactam are distributed into human breast milk in low concentrations but are considered to be compatible with breastfeeding. Nursing offspring should be monitored for GI disturbances.

Overdose/Acute Toxicity

Neurologic effects (eg, ataxia) have rarely been reported, and risk increases with higher doses or conditions that can lead to increased CNS penetration (eg, meningitis); should these signs develop, the risks for continued use should be weighed with those associated with dose reduction or use of a different antibiotic. In humans, particularly those with renal disease, high doses of parenteral penicillins have induced CNS effects.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with ampicillin/sulbactam either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Allopurinol**: In humans, concurrent use has been implicated in increased occurrences of skin rashes; veterinary significance of this interaction is unknown.
- **Aminoglycosides** (eg, **amikacin, gentamicin**): Beta-lactam antibiotics can inactivate aminoglycosides in vitro (and in vivo in patients with chronic kidney disease).
- **Bacteriostatic Antimicrobials** (eg, **chloramphenicol, erythromycin and other macrolides, tetracyclines, sulfonamides**): Because there has been evidence of in vitro antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together generally has not been recommended, but actual clinical importance is not clear and is currently in doubt.
- **Dichlorphenamide:** Concurrent use may increase risk for hypokalemia.
- **Methotrexate (MTX)**: Ampicillin may decrease the renal excretion of MTX, causing increased MTX concentrations and potential toxic effects.
- **Mycophenolate**: Concurrent use may reduce concentrations or effects of mycophenolate.
- **Probenecid**: Can reduce the renal tubular secretion of both ampicillin and sulbactam, thereby maintaining higher systemic concentrations for a longer period. This potentially beneficial interaction requires further investigation before dosing recommendations can be made for veterinary patients.
- **Warfarin:** Concurrent use may decrease vitamin K production and increase risk for bleeding.

Laboratory Considerations

- Ampicillin may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's solution, *Clinitest*®). Tests using glucose oxidase (*Test-Tape*®, *Clinistix*®) are not affected by ampicillin.
- Because penicillins and other beta-lactams can inactivate **aminoglycosides** in vitro and in vivo in patients in renal failure or when penicillins are used in larger doses, serum concentrations of aminoglycosides may be falsely decreased, particularly when the serum is stored prior to analysis. It is recommended that samples should be drawn at times when the beta-lactam antibiotic is at a trough level, and if the assay cannot be run right away, samples should be frozen immediately.

Dosages

DOGS/CATS:

NOTE: Dosages are listed for combined amounts of ampicillin/sulbactam.

Empiric antibiotic therapy in critically ill animals (extra-label): 22 – 30 mg/kg IV every 6 to 8 hours; used in combination with a parenteral drug with gram-negative activity (eg, aminoglycoside, fluoroquinolone)

Infections susceptible to amoxicillin/clavulanate in patients unable to receive oral doses (extra-label): 22 mg/kg SC, IV, or IM every 8 hours

Surgical prophylaxis (extra-label): 22 mg/kg IV ≈1 hour prior to incision; redosing can be performed intraoperatively every 2 hours if needed based on duration of surgery.

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop.
- Periodic liver panel (eg, liver enzymes, bilirubin) in patients with pre-existing hepatic dysfunction
- Serum concentrations and therapeutic drug monitoring are not routinely performed.

Client Information

- Because of the dosing intervals required, this drug is best administered to inpatients only.

Chemistry/Synonyms

Commercial drug formulations contain sodium salts of both ampicillin and sulbactam in a 2:1 ratio (eg, ampicillin, 250 mg; sulbactam, 125 mg). Ampicillin sodium/sulbactam sodium for injection occurs as a white to off-white powder that is freely soluble in water or other aqueous solutions. The reconstituted solution is yellow to pale yellow and has a pH of 8 to 10.

Ampicillin/sulbactam may also be known as *Ampibactan*®, *Bacimex*®, *Begalin-P*®, *Bethacil*®, *Comabactan*®, *Galotam*®, *Loricin*®, *Sulam*®, *Sulperazon*®, *Synergistin*®, *Unacid*®, *Unacim*®, *Unasyn*®, or *Unasyna*®.

Storage/Stability
Ampicillin/sulbactam powder should be stored at temperatures at or below 30°C (86°F).

Compatibility/Compounding Considerations
Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Diluents for reconstituting the powder for IV use reported to be **compatible** with ampicillin/sulbactam include sterile water for injection and 0.9% sodium chloride. If the powder is reconstituted to a concentration of 30 mg/mL (combined concentration), the resultant solution is stable for 72 hours at 4°C (39.2°F) or 8 hours at room temperature. After reconstitution and before administration, the solution can either be given slowly IV over 5 to 20 minutes or be further diluted into a 50- or 100-mL bag of 0.9% sodium chloride and administered IV over 15 to 30 minutes.

When ampicillin/sulbactam is reconstituted for IM use, sterile water for injection or 0.5% or 2% lidocaine HCl for injection may be used as a diluent; 3.2 mL of diluent should be added to the 1.5 g vial and 6.4 mL of diluent to the 3 g vial. After reconstitution, the solution should be administered within 1 hour.

Ampicillin/sulbactam injection is **compatible** with vancomycin when mixed at concentrations of 50/25 mg/mL of ampicillin/sulbactam and 20 mg/mL or less of vancomycin. Ampicillin/sulbactam is **Y-site compatible** with aminocaproic acid, asparaginase, azithromycin, carboplatin, cisplatin, cytarabine, dexmedetomidine hydrochloride, doxorubicin hydrochloride (liposomal), fat emulsions, gemcitabine hydrochloride, hydromorphone hydrochloride, methadone hydrochloride, metronidazole, pamidronate disodium, pantoprazole sodium, sodium acetate, vinblastine sulfate, vincristine sulfate, voriconazole, and zoledronic acid.

Ampicillin/sulbactam injection has ***variable or uncertain Y-site compatibility*** with amikacin sulfate, aminophylline, ascorbic acid (vitamin C), atracurium besylate, atropine sulfate, buprenorphine hydrochloride, butorphanol tartrate, calcium chloride, calcium gluconate, cefazolin sodium, cefotetan disodium, cefotaxime, ceftazidime, ceftriaxone sodium, cefuroxime, chloramphenicol sodium succinate, clindamycin phosphate, cyclosporine, dexamethasone sodium succinate, dextrose 5% in water, digoxin, diltiazem hydrochloride, diphenhydramine hydrochloride, dopamine hydrochloride, epinephrine hydrochloride, erythromycin lactobionate, esmolol hydrochloride, famotidine, fentanyl citrate, fluconazole, furosemide, gentamicin sulfate, glycopyrrolate, heparin sodium, insulin (regular), lactated Ringer's solution (LRS), lidocaine hydrochloride, magnesium sulfate, mannitol, metoclopramide, morphine sulfate, multiple vitamins injections, naloxone hydrochloride, nitroglycerin, nitroprusside sodium, norepinephrine bitartrate, oxytocin, penicillin G potassium, penicillin G sodium, pentobarbital sodium, phenobarbital sodium, polymyxin B sulfate, potassium chloride, procainamide hydrochloride, ranitidine hydrochloride, sodium bicarbonate, thiamine hydrochloride (vitamin B_1), and vasopressin.

Administration of ampicillin diluted in LRS has been shown to decrease ampicillin concentrations by ≈30%; therefore, coadministration with LRS (ie, through the same fluid line) should be performed with caution.[11]

Ampicillin/sulbactam is **Y-site incompatible** with amiodarone hydrochloride, amphotericin B conventional, amphotericin B liposomal, ciprofloxacin, diazepam, dobutamine hydrochloride, doxorubicin hydrochloride, doxycycline hyclate, hydralazine hydrochloride, hydrocortisone sodium succinate, hydroxyzine hydrochloride, lorazepam, mechlorethamine hydrochloride, methylprednisolone sodium succinate, midazolam hydrochloride, mitoxantrone hydrochloride, mycophenolate mofetil hydrochloride, ondansetron hydrochloride, phenytoin sodium, quinidine gluconate, trimethoprim/sulfamethoxazole, tranexamic acid, and vinorelbine tartrate.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Ampicillin Sodium/Sulbactam Sodium Powder (injection): 1.5 g (ampicillin sodium 1 g; sulbactam sodium 0.5 g) and 3 g (ampicillin sodium 2 g; sulbactam sodium 1 g) in vials; 15 g (ampicillin sodium 10 g; sulbactam sodium 5 g) in bulk; *Unasyn®*, generic; (Rx)

Amprolium
(am-proe-***lee***-um) *AmproMed®, Corid®*
Anticoccidial

Prescriber Highlights
- ► Thiamine analogue coccidiostat
- ► Prolonged high doses may cause thiamine deficiency; length of treatment usually does not exceed 14 days
- ► Occasionally may cause GI or neurologic effects
- ► May be unpalatable

Uses/Indications
Amprolium is FDA-approved for the treatment and prevention of *Eimeria bovis* and *Eimeria zurnii* in calves, and for the treatment of coccidiosis in poultry.

Although there are no FDA-approved products in the US for dogs, swine, sheep, or goats, amprolium has also been used in these species for the control of coccidiosis.

Pharmacology/Actions
By mimicking the structure of thiamine, amprolium competitively inhibits thiamine utilization by the parasite preferentially; amprolium has this same effect in the host but to a far less extent.[1]

Amprolium is a coccidiostat. It has good activity against *Eimeria tenella* and *Eimeria acervulina* in poultry and can be used as a therapeutic agent against these organisms. Amprolium only has marginal activity or weak activity against *Eimeria maxima, Eimeria mivati, Eimeria necatrix*, and *Eimeria brunetti*; it is often used in combination with other agents (eg, ethopabate) to improve control against these organisms.

Amprolium acts primarily upon the first-generation trophozoites and schizonts in enterocytes, preventing differentiation of the merozoites; it also suppresses the sexual stages and sporulation of the oocysts.

Pharmacokinetics
Chickens receiving amprolium 20 mg/kg PO demonstrated the following pharmacokinetic values: maximum blood concentrations at 4 hours; volume of distribution, 0.5 L/kg; clearance, 1.98 mL/kg/min.[2]

Contraindications/Precautions/Warnings
Amprolium is not recommended to be used for more than 12 days in puppies.

The undiluted liquid is reportedly unpalatable. Excessive dietary thiamine can reduce or reverse the anticoccidial activity of the drug.

Adverse Effects
In dogs, neurologic disturbances (eg, "stargazing", opisthotonos, central blindness, circling, ataxia), depression, anorexia, and diarrhea have been reported but are rare and likely dose related. See ***Overdose/Acute Toxicity*** for treatment recommendations.

High dosages or long-term use of amprolium may induce neurologic signs because of thiamine deficiency (eg, polioencephalomalacia [PEM], cerebrocortical necrosis). Parenteral thiamine (vitamin B1) can be used for treatment.

Overdose/Acute Toxicity

Amprolium has induced polioencephalomalacia (PEM) in sheep when administered at 880 mg/kg (16 times the normal dose) for 3 to 6 weeks[3] and at 1000 mg/kg for 3 to 5 weeks. Erythrocyte production has also been shown to cease in lambs receiving these high dosages.

Overdoses of amprolium can produce neurologic signs (eg, "stargazing", opisthotonos, central blindness, circling, ataxia). Treatment should consist of stopping amprolium therapy and administering parenteral thiamine. See ***Thiamine*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretic in animals receiving amprolium and may be of significance in veterinary patients:

- **Thiamine**: Exogenously administered thiamine in high doses may reverse or reduce the efficacy of amprolium.

Dosages

DOGS:

Coccidiosis (extra-label):

a. **Using the 20% powder***[4]: a) Small dogs less than 10 kg [22 lb] anticipated adult weight): 60 – 100 mg/dog (NOT mg/kg) placed in a gelatin capsule and given PO once daily for 7 to 12 days. Large pups (greater than 10 kg [22 lb] anticipated adult weight): 110 – 200 mg/dog (NOT mg/kg) placed in a gelatin capsule and given PO once daily for 7 to 12 days. b) In food, for pups or bitches: 250 – 300 mg/dog (NOT mg/kg) using the 20% powder on food once daily for 7 to 12 days. ***NOTE**: Using the 20% powder, a 100 mg dose will equate to 500 mg powder; a 200 mg dose = 1 g powder; a 250 - 300 mg dose = 1.25 g - 1.5 g powder.

b. **In water**: a) 30 mL of the 9.6% solution in 3.8 liters (1 gallon) of water (no other water provided) for 7 to 10 days[4] OR b) 1.5 tablespoonsful (22.5 mL) of the 9.6% solution in 3.8 liters (1 gallon) of water to be used as the sole drinking water source; treatment not to exceed 10 days.[5] Monitor water consumption both for treatment and hydration assurance. Rarely, some dogs may not drink the amprolium water because of its bitter taste. In situations where dogs are cohabitants, it is necessary to place enough treated water for all to have access.

c. **Combination therapy**: Amprolium 150 mg/kg in combination with sulfadimethoxine 25 mg/kg PO every 24 hours for 14 days[6]

CATS:

Coccidiosis (extra-label):

1. **Using the 20% powder:** 60 – 100 mg/cat (NOT mg/kg) PO once daily for 7 days[6]
2. **In water:** 1.5 teaspoonful (7.5 mL) of the 9.6% solution in 3.8 liters (1 gallon) of water per day for 10 days[5]
3. **Combination therapy:** Amprolium 150 mg/kg in combination with sulfadimethoxine 25 mg/kg PO every 24 hours for 14 days[7]

CATTLE:

As an aid in the treatment and prevention of coccidiosis caused by *Eimeria bovis* and *Eimeria zuernii* in calves (label dosage; FDA-approved)): See product labels for additional information.

1. 5-day *treatment* protocol: 10 mg/kg daily PO for 5 days
2. 21-day *prevention* protocol: 5 mg/kg daily PO for 21 days. Can be administered either as an oral drench or mixed into the sole source of fresh drinking water. [8,9]

SHEEP/GOATS:

Coccidiosis (extra-label):

1. **Lambs**: 55 mg/kg daily PO for 19 days[10]
2. **Goat kids**: 50 mg/kg daily PO for 5 days will effectively reduce the fecal shedding of *Eimeria* spp oocysts without inducing neurologic disease.[11]

CAMELIDS (NEW-WORLD):

Eimeria macusaniensis (extra-label): Using a 1.5% solution, 10 mg/kg PO once daily for 10 to 15 days; supplement with thiamine 10 mg/kg SC every 5 days during treatment.[12]

SWINE:

Coccidiosis treatment (extra-label): 25 – 65 mg/kg PO once or twice daily for 3 to 4 days[10]

AVIAN:

1. **Treatment of coccidiosis in growing chickens, turkeys, and laying hens** (label dosage; FDA-approved): Administer 0.012% solution in the sole source of drinking water for 3 to 5 days, then as 0.006% solution for an additional 1 to 2 weeks.[13] Severe outbreaks may require higher initial dosages; see product labels for additional information.
2. **Coccidiosis in pet birds** (extra-label):
   a. 15 – 30 mg/kg/day PO for 1 to 5 days; repeat 5 days later[14]
   b. **In water**: Using the 9.6% solution, 1 – 2.5 mL per liter of water for 5 days or longer.[14,15] Cages should be steam cleaned to prevent reinfection. Supplement diet with B vitamins. Toucans and mynahs are resistant to some strains.

FERRETS:

Coccidiosis (extra-label): 19 mg/kg once daily[16]

RABBITS/RODENTS/SMALL MAMMALS:

Coccidiosis (extra-label):

1. **Rabbits**: Using 9.6% solution, 1 mL/7 kg (15 lb) (≈0.15 mL/kg) PO once daily for 5 days. Diluted in drinking water: 0.5 mL of 9.6% solution/500 mL for 10 days[17]
2. **Gerbils, Mice, Rats, Hamsters**: 10 – 20 mg/kg divided and given SC or IM every 8 to 24 hours
3. **Chinchillas**: 10 – 15 mg/kg per day divided and given SC, IM, or IV every 8 to 24 hours[18]

Monitoring

- Clinical efficacy
- Hydration, body weight
- If using in high dosages (extra-label), watch for neurologic signs (eg, "stargazing," opisthotonos, central blindness, circling, ataxia).

Chemistry/Synonyms

Amprolium hydrochloride, a structural analogue of thiamine (vitamin B_1), occurs as a white or almost white, odorless or nearly odorless powder. One gram is soluble in 2 mL of water and is slightly soluble in alcohol.

Amprolium may also be known as amprocidi, *Amprol®*, *Ampromed®*, *Corid®*, *Coxoid®*, or *Coxiprol®*.

Storage/Stability

Unless otherwise instructed by the manufacturer, store amprolium products at room temperature 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Amprolium Oral Solution: 9.6% (96 mg/mL) in 473 mL and 1 gallon bottles; *Corid®*, generic; (OTC). FDA-approved for use in calves (not veal calves). Slaughter withdrawal (when used as labeled) = 24 hours. A withdrawal period has not been established for preruminating calves.

Amprolium Oral Solution: 9.6% (96 mg/mL) in 473 mL and 1 gallon bottles; *Amprol®*, generic; (OTC). FDA-approved for use in growing chickens, turkeys, and laying hens. Withdrawal information is not included on the FDA label.

Amprolium Soluble Powder: 20% (200 mg/g) in 283.5 g pouches *Corid®*; (OTC). FDA-approved for use in calves (not veal calves). NADA #033-165. Slaughter withdrawal (when used as labeled) = 24 hours. A withdrawal period has not been established for preruminating calves.

Amprolium Soluble Powder: 20% (200 mg/g) in 283.5 g pouches *Amprol® 128*; generic; (OTC). FDA-approved for use in growing chickens, turkeys, and laying hens; withdrawal information is not included on the FDA label.

There are also available medicated feeds (amprolium alone) and combination products (medicated feeds, feed additives) containing amprolium with other therapeutic agents. These products may be labeled for use in calves, chickens, and/or turkeys.

HUMAN-LABELED PRODUCTS: NONE

Antivenom, *Latrodectus mactans*

Antivenom, Black Widow Spider

(an-tie-**ven**-nin lah-tro-dec-tus mack-tans) *Antivenom, Antidote*

Antivenin and antivenom are synonymous terms and are used interchangeably throughout the monograph to avoid confusion between the currently preferred term (antivenom) and the term used on the product label (antivenin). NOTE: Veterinary poison control centers can offer current, detailed treatment recommendations (consultation fees may apply). See ***Important Contact Information***.

Prescriber Highlights

- ► Neutralizes the venom of black widow spiders. Early antivenom administration (within 4 to 6 hours of envenomation) is associated with greater efficacy, but later administration can still be effective.
- ► May cause hypersensitivity reactions (acute and delayed)
- ► Product may be difficult for veterinarians to obtain in a timely manner in emergent situations; consider keeping this product on hand in areas where envenomation occurs more commonly.
- ► It is recommended to contact a veterinary poison control center for current treatment recommendations and assistance in locating and acquiring antivenom.

Uses/Indications

Black widow spider antivenom is used to treat envenomation by *Latrodectus mactans* (black widow spider). Cats, horses, and camels are considered to be extremely sensitive to the alpha-latrotoxin in the spider venom, whereas dogs are considered more resistant.[1,2] Clinical signs associated with envenomation occur within 8 hours of the spider bite and are primarily neuromuscular (eg, severe pain, seizures, muscle spasms [especially in the chest wall, abdomen, and other large muscle mass areas], which may progress to flaccid paralysis in cats) and cardiovascular (eg, hypertension, tachycardia, cardiovascular collapse); secondary respiratory compromise may result from muscular rigidity and lead to death if not treated. Within 24 hours, affected animals may lose up to 20% of their body weight. Cats may also develop hypersalivation and GI signs (eg, vomiting, diarrhea[3]); death is very common in this species.[1]

Pharmacology/Actions

Antivenoms act by binding to venom toxins and thereby neutralizing venom-induced effects in patients via passive immunization of immunoglobulins obtained from horses that are hyperimmunized with the venom of *Latrodectus mactans*.

The use of antivenom early in the course of therapy is emphasized. Improvement in clinical signs may occur as early as 30 minutes after administration,[1,2] and complete recovery may be seen within 6 to 8 hours.[2]

Pharmacokinetics

No pharmacokinetic information was located.

Contraindications/Precautions/Warnings

Because there is a risk for anaphylaxis secondary to the equine immunoglobulins contained in this product, many clinicians recommend performing sensitivity testing before administration; however, antivenom sensitivity testing is frequently unreliable, with false-positive and -negative results.[4] Delayed serum sickness may occur several days to a couple weeks following antivenom administration. Antivenom dilution with and administration in IV fluids should be undertaken with extreme caution because of the risk of hypertension resulting from envenomation.

Adverse Effects

Anaphylaxis secondary to the product's equine serum origin may occur; the incidence is rare in humans (less than 0.6%).[1] Although rare, there is the possibility of life-threatening hypersensitivity reactions; appropriate resuscitative drugs (eg, epinephrine) and equipment should be readily available. The FDA-approved product contains a small vial of normal equine serum to perform intradermal hypersensitivity testing. Alternatively, a 1:10 dilution of the antivenom administered intracutaneously at a dose of 0.02 – 0.03 mL has been suggested as a test for hypersensitivity. Wheal formation and erythema indicate a positive reaction and are generally seen within 30 minutes of administration. A negative response does not ensure that anaphylaxis will be avoided during treatment; slow IV administration is usually sufficient to identify animals that will react to the product. A pretreatment dose of diphenhydramine is often recommended before administering antivenom, primarily to sedate the patient and, theoretically, to reduce any possible allergic reactions to the antivenom.

Epinephrine (0.01 mg/kg IM and repeated at 15- to 20-minute intervals until the patient is stable) has been recommended if early signs of anaphylaxis occur (clinical signs vary by species and include vomiting/diarrhea [dogs], dyspnea [cats/ruminants], nausea, pruritus, pyrexia, and hyperemia of the inner pinnae). Stopping the infusion, administering histamine H_1- and H_2-receptor antagonists (eg, diphenhydramine and famotidine, respectively), and restarting the infusion 5 minutes later at a slower rate may allow the dose to be administered without further problems.[5] In severe envenomation, patients exhibiting allergic reactions to antivenom can still receive it; administration of antivenom as a slow IV infusion with concomitant diphenhydramine (and possibly epinephrine) has been suggested.

Muscle cramps have also been reported in humans following antivenom administration.

Reproductive/Nursing Safety

The safe use of black widow spider antivenom during pregnancy or lactation has not been established; however, it has been used successfully in human pregnancies.[6-8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Drug Interactions

The following drug interactions with black widow spider antivenom have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the veterinarian must weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Adrenergic Receptor Antagonists** (eg, **atenolol, propranolol**): May mask the early signs associated with anaphylaxis
- **Opioids** (eg, **morphine**): Opioid-induced histamine release may obscure clinical signs associated with anaphylaxis.
- **Respiratory Depressants** (eg, **alpha-2 agonists, barbiturates, benzodiazepines**): Concomitant use of respiratory depressant drugs may exacerbate the respiratory depression caused by envenomation.

Dosages

DOGS/CATS:

Black widow spider envenomation (extra-label):

a) After reconstituting the antivenom, add the contents of 1 vial to 100 mL of 0.9% sodium chloride and administer IV over 30 minutes. Pretreatment with diphenhydramine 2 – 4 mg/kg SC may help calm the patient and may protect against allergic reactions from the antivenom. If signs of an allergic reaction occur (eg, pyrexia, dyspnea, vomiting/diarrhea, pruritus), discontinue the infusion, and give a second dose of diphenhydramine. If allergic reactions abate, may restart infusion at a slower rate; if they recur, stop the infusion, and seek consultation. See ***Adverse Effects***. Use care with the administration of IV fluids, as envenomation can cause significant hypertension. Benzodiazepines (eg, diazepam, midazolam) or methocarbamol may alleviate muscle cramping.[3,9]

b) Dissolve contents of one vial of antivenom and add to 100 – 200 mL of warm 0.9% sodium chloride and infuse IV over 2 to 6 hours. Administer diphenhydramine 0.5 – 1 mg/kg SC prior to infusion.[10]

Monitoring

- Signs associated with an allergic response to the antivenom (eg, anaphylaxis, anaphylactic-like reactions, serum sickness); hyperemia of the inner ear pinnae may be a good marker.[1]
- Respiratory and cardiac rate
- Blood pressure
- Serum chemistry (in particular, blood glucose, which is commonly elevated with envenomations); creatine kinase
- CBC
- Urine output; urinalysis

Client Information

- Clients must be made aware of the potential for anaphylaxis, as well as the expenses associated with treatment, monitoring (including for delayed serum sickness), and hospitalization.
- Some animals may experience an allergic reaction ("serum sickness") to antivenom products 1 to 2 weeks after administration. Inform your veterinarian if your animal develops a fever, rash, or appears to have muscle or joint pain (eg, stiffness, limited ability to move around).

Chemistry/Synonyms

This product is concentrated serum immunoglobulins obtained from horses immunized with the venom of the black widow spider. It is provided as a refined, lyophilized product. When this product is reconstituted as directed, the color of the antivenom ranges from light (straw) to very dark (iced tea); however, the color has no effect on potency.

Storage/Stability

Store the product in the refrigerator 2°C to 8°C (36°F-46°F). Do not freeze. Discard unused portion.

Compatibility/Compounding Considerations

Reconstitute the lyophilized product by adding 2.5 mL of sterile water for injection; shake the vial to completely dissolve the contents. Inspect the dissolved product to make sure no particulate is evident. For IV use, further dilute the solution in 10 to 100 mL of normal saline injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Antivenin (*Latrodectus mactans*) Powder for Injection: greater than or equal to 6000 antivenin units/vial in single-use vials. Only 2 vials may be ordered at a time. (Rx). FDA-approved. Product comes packaged with a 1 mL vial of normal horse serum that may be used for sensitivity testing.

Antivenom, Crotalidae

(an-tie-**ven**-in cro-**tal**-ih-day)

Antivenin®, RattlerAntivenin®, VenomVet®

Antivenom, Antidote

Antivenin and antivenom are synonymous terms and are used interchangeably throughout the monograph to avoid confusion between the currently preferred term (antivenom) and the term used on the product label (antivenin). NOTE: Veterinary poison control centers can offer current, detailed treatment recommendations (consultation fees may apply). See ***Important Contact Information.***

Prescriber Highlights

- ► Neutralizes the venom of Crotalidae snakes. Early antivenom administration (within 4 to 6 hours of envenomation) is associated with greater efficacy, but later administration can still be effective.
- ► May cause hypersensitivity reactions (acute and delayed)
- ► Product may be difficult for veterinarians to obtain in a timely manner in emergent situations; consider keeping this product on hand in areas where envenomation occurs more commonly.
- ► Treatment with antivenom requires economic consideration, as product costs range from hundreds to thousands of dollars.
- ► It is recommended to contact a veterinary poison control center for current treatment recommendations and assistance in locating and acquiring antivenom.

Uses/Indications

Three equine-derived veterinary antivenom products are available and indicated for the treatment of envenomation from native North American Crotalidae snakes (ie, venomous pit viper snakes including rattlesnakes, copperheads, and cottonmouths/water moccasins) in dogs and horses. They also may be effective for envenomation from several Central and South American snake species (fer-de-lance, lancehead, Central and South American rattlesnake), or in other species (eg, habu, mamushi [Japanese moccasin]).[1]

An ovine-derived F(ab) product is indicated for North American Crotalidae snake envenomation in humans, and has been used successfully in dogs.[2] An equine-derived $F(ab')_2$ is approved for human use, but efficacy data in animals are lacking.

Many factors contribute to the potential for venom toxicity (eg, patient age, body weight, and general health; location of bite site[s]; number of bites; age, species, and size of snake). Antivenom treatment, along with crystalloid fluid therapy and analgesia, is considered the mainstay treatment for moderate to severe pit viper envenomation.[3] Early administration (within 4 to 6 hours) is ideal, but antivenom treatment administered up to 24 hours after a snakebite can still be effective.[3]

There are no studies comparing efficacy or safety of the various antivenom products, and antivenom use in animals can be dictated by local availability in veterinary clinics and affordability.

Pharmacology/Actions

Antivenoms are venom toxin-specific antibodies that bind venom toxins and thereby neutralize venom-induced toxic effects. Antivenom use is a passive immunization process that uses toxin-specific immunoglobulins or antibody fragments, such as F(ab) and $F(ab')_2$, obtained from horses or sheep hyperimmunized with snake venom(s) or specific venom components. Antivenom can be very effective in halting and reversing venom-related coagulation abnormalities or neurotoxicity (depending on the specific antivenom given and time to treatment).

Pharmacokinetics

Specific product-related information was not located. Because of their variable molecular mass differences, the 3 antibody types that compose individual antivenom types have different individual pharmacokinetics. IgG antibodies have a low volume of distribution, the longest half-life, and are eliminated via extrarenal mechanisms. F(ab) fragments reach the extravascular compartments easily, are catabolized by the kidney, and have a rapid clearance via the kidneys. $F(ab')_2$ fragments exhibit an intermediate pharmacokinetic profile between IgG and F(ab).[4] For example, it has been reported that the $F(ab')_2$ antibody fragment antivenom (*Antivipmyn®*) is cleared from the body faster than IgG (ACP, or *Polyvet-ICP®*) but slower than the F(ab) antibody fragment (*CroFab®*).[3]

Contraindications/Precautions/Warnings

Equine- or ovine-derived antivenoms should be used cautiously or not at all in animals with known sensitivities to equine or ovine proteins. Although rare, there is the possibility of life-threatening hypersensitivity reactions; appropriate resuscitative drugs (eg, epinephrine) and equipment should be readily available. Administer the antivenom IV slowly and monitor closely for the first 10 minutes of the infusion to observe for signs of hypersensitivity reactions. Use antihistamines, tranquilizers, sedatives, and analgesics with care as they may mask important clinical signs.[1] In particular, opioid-induced histamine release may obscure clinical signs associated with anaphylaxis.

Historically, diluted antivenom given intradermally (typically 1:10 dilution) was suggested as a test for hypersensitivity. This practice is no longer commonly recommended secondary to false negative and false positive results occurring.[5]

Adverse Effects

Three of the veterinary-labeled antivenom products (and the human-labeled product, *Anavip®*) are derived from equine proteins, and the risk for anaphylactic-like reactions in small animal species should be considered when administration is determined to be necessary.[5] Type I hypersensitivity was noted in dogs receiving an equine-derived polyvalent product, including both whole IgG[6-8] and $F(ab')_2$.[9] This same concern should be considered if using the ovine-derived F(ab) antivenom (*CroFab®*), although the risk for adverse effects, including anaphylaxis, may be lower.[2,5]

Epinephrine (0.01 mg/kg IM and repeated at 15- to 20-minute intervals until the patient is stable) has been recommended if early signs of anaphylaxis occur (clinical signs vary by species and include vomiting/diarrhea [dogs], dyspnea [cats/ruminants], nausea, pruritus, pyrexia, and hyperemia of the inner pinnae).[3] Stopping the infusion, administering histamine H_1- and H_2-receptor antagonists (eg, diphenhydramine and famotidine, respectively), and restarting the infusion 5 minutes later at a slower rate may allow the dose to be administered without further problems.[3,10] In severe envenomation, patients exhibiting allergic reactions to antivenom can still receive it; administration of antivenom as a slow IV infusion with concomitant diphenhydramine (and possibly epinephrine) has been suggested.[10]

In a case series, type I hypersensitivity was reported in 26 of 115 cats receiving antivenom and was more likely to occur when infusion time was completed in less than 1 hour.[11] Premedication with diphenhydramine ± corticosteroids did not significantly alter the occurrence of type I hypersensitivity reactions.

Antivenom-associated serum sickness has been reported in dogs after treatment using Antivenin (Crotalidae) Polyvalent (ACP),[6,7,12] and a retrospective study of 218 dogs reported signs of delayed hypersensitivity/serum sickness in 2 of the 218 dogs.[13] Although it is believed that the fractionated antibody products would have less antigenic potential than full IgG preparations, hypersensitivity reactions are still possible especially when an increased number of vials are required. Other potential adverse effects from antivenom administration include hypocalcemia, urticaria, GI effects (eg, vomiting, diarrhea), changes in heart rate and rhythm (eg, tachycardia, bradycardia), changes in blood pressure, and agitation/trembling.

Reproductive/Nursing Safety

There are no data available regarding Antivenin (Crotalidae) Polyvalent (ACP) use in pregnant or lactating bitches, queens, or mares. Potential benefits may warrant use of antivenom in pregnancy despite potential risks. *Crofab®* has been successfully used in humans during the third trimester of pregnancy.[14] Product has been used in late gestation with subsequent healthy litters.[15]

Safety during nursing has not been established but it would unlikely pose much risk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Drug Interactions

The following drug interactions with antivenin have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Analgesics/Sedatives** (eg, **acepromazine, dexmedetomidine, fentanyl):** Although analgesia, reducing excessive movement, and **administration of** other supportive treatments are important parts of treating envenomation; drugs that can mask the clinical signs associated with the venom (eg, analgesics and sedatives) should initially be used with caution.
- **Antihistamines, H_1 receptor Antagonists** (eg, **diphenhydramine**): Antihistamines may mask clinical signs of envenomation[1]; however, diphenhydramine is routinely used by many clinicians to treat snakebite in dogs.[3,8] Additionally, antihistamines are indicated for the management of antivenom hypersensitivity reactions.[3]
- **Beta-Adrenergic Receptor Antagonists** (eg, **atenolol, propranolol**): May mask the early signs associated with anaphylaxis
- **Opioids** (eg, **morphine):** Opioid-induced histamine release may obscure clinical signs associated with anaphylaxis.

Laboratory Considerations

- None noted

Dosages

NOTES:

1. Early administration of antivenom increases effectiveness.
2. The treatment of pit viper snakebite involves significant supportive treatment and monitoring beyond administration of antivenom. It is highly recommended to refer to specialized references[3,10] and consult with an animal poison control center for guidance beyond what is listed in this monograph. See ***Important Contact Information***.
3. The number of vials for each patient will depend on the bite size, relative amount of venom injected, the body mass of the patient (smaller patients may require higher doses as venom amount/kg body weight is higher), duration of time after the bite, snakebite severity score, coagulation times, and clinician judgment.[10]

DOGS:

***Antivenin®* — Crotalidae (North and South American Snakebite) polyvalent antiserum of equine origin**

a) **Label dosage; USDA-licensed**: Administer 1 to 5 rehydrated vials of antivenom (ie, 10 – 50 mL) IV. Additional doses may be given every 2 hours as required. If unable to give IV, may administer IM as close to bite as practical.[1]

b) **Extra-label:** Average dose required is 1 to 2 vials of antivenom (ie, 10 – 20 mL), although multiple vials may be necessary. Initially, give 1 vial by adding it to 100 – 250 mL of crystalloid fluids (eg, sodium chloride 0.9%) and administering IV slowly over 3 to 5 minutes; monitor patient for clinical signs related to an allergic reaction. See *Adverse Effects*. If no adverse effects are observed, increase the infusion rate and administer the remaining volume IV slowly over 30 minutes. In smaller patients, adjust infusion volume to prevent fluid overload.[10] Repeat antivenom treatment as clinically indicated, particularly if clotting defects persist.

RattlerAntivenin®* — North American Crotalidae polyvalent antivenom of equine origin** (label dosage; USDA-licensed)**:** Administer using a filtered IV set. Typically, 1 or 2 doses of antivenom (ie, 50 – **100 mL)** are adequate regardless of body size (small or large canine). Product can be administered prior to, concomitantly, or following other IV fluids. Administer antivenom IV slowly during the initial 10 minutes; monitor patient for clinical signs related to an allergic reaction. See ***Adverse Effects. If no adverse effects occur, administer the remaining volume IV slowly to effect over 20 to 60 minutes. If adverse effects develop, stop infusion for 5 to 10 minutes, and reinitiate at a slower infusion rate. If adverse effects persist, discontinue administration.[15]

VenomVet®* —North American Pit Viper polyvalent Crotalidae $F(ab')_2$ antivenom of equine origin** (label dosage; USDA-licensed): Dilute each vial of antivenom with 100 – 150 mL crystalloid fluid (eg, sodium chloride 0.9%). Administer IV slowly during the initial 10 minutes; monitor patient for clinical signs related to an allergic reaction. See ***Adverse Effects. Do not inject product at the site of snakebite or perifocal area. Full dose should be delivered IV slowly over 30 to 60 minutes. Treatment may be discontinued once clinical signs of envenomation resolve.[16]

Crotalidae polyvalent immune F(ab) antivenom of ovine origin (extra-label): Administer contents of a single vial either as a single dose, or by giving ½ of the vial contents initially and the remaining portion administered 6 hours later (keep product refrigerated in between dosing).[2] To administer, dilute antivenom vial contents with sodium chloride 0.9% 250 mL. Administer the first 25 – 50 mL IV slowly during the first 10 minutes; monitor patient for clinical signs related to an allergic reaction. See ***Adverse Effects***. If no adverse effects occur, administer the remaining volume IV slowly to effect over 45 to 60 minutes. Critical patients may need to have undiluted antivenom administered via IV push over 5 to 10 minutes.[17]

CATS:

Antivenin®* — Crotalidae (North and South American Snakebite) polyvalent antiserum of equine origin** (extra-label): Average dose required for cats is 1 to 2 vials of antivenom (ie, 10 – 20 mL), although multiple vials may be necessary. Initially, give 1 vial by adding it to 100 – 250 mL of crystalloid fluids (eg, sodium chloride 0.9%) and administering 1 to 2 mL IV slowly over 3 to 5 minutes; monitor patient for clinical signs related to an allergic reaction. See ***Adverse Effects. If no adverse effects are observed, increase the infusion rate and administer the remaining volume IV slowly over 30 minutes to 2 hours).[10,11] Adjust infusion volume to prevent fluid overload. A multicenter retrospective study in cats suggested no mortality benefit of antivenom administration (1 vial, 10 mL), but did not report on other envenomation sequelae (eg, hemostasis, neurologic status, or cardiovascular conduction abnormalities).

HORSES:

***RattlerAntivenin®* — North American Crotalidae polyvalent antivenom of equine origin** (label dosage; USDA-approved): Administer using a filtered IV set. Typically, 1 or 2 doses of antivenom (ie, 50 – 100 mL) are adequate regardless of body size, administered within 24 hours of envenomation. Product can be administered prior to, concurrently, or following other fluids. Administer IV slowly to effect over 20 to 60 minutes. Administer slowly during the initial 10 minutes; monitor for signs of hypersensitivity and anaphylaxis (eg, angioedema, hypotension, respiratory distress, urticaria). If these clinical signs develop, stop administration for 5 to 10 minutes, and reinitiate as a slower infusion rate. If adverse effects persist, discontinue administration.[15]

***Antivenin®* — North and South American Crotalidae polyvalent antiserum of equine origin** (extra-label): Administer 1 to 2 vials diluted in 250 – 500 mL saline or lactated Ringer's slowly IV.[1] **NOTE:** Use of this product is only recommended in horses exhibiting systemic effects from envenomation. Administer antihistamines as needed.

Monitoring

- Signs associated with an allergic response to the antivenom (eg, urticaria, facial swelling, dyspnea, anaphylaxis, anaphylactic-like reactions, serum sickness)
- CBC with platelets; coagulation parameters (eg, PT, aPTT, ACT), thromboelastography, and fibrinogen
- Serum chemistry profile; hydration status
- ECG

Client Information

- Clients must be made aware of the potential for anaphylaxis as well as the financial expenses associated with treatment, monitoring, and hospitalization.
- Some animals may experience an allergic reaction ("serum sickness") to antivenom products 1 to 2 weeks after administration. Inform your veterinarian if your animal develops a fever, rash, or appears to have muscle or joint pain (eg, stiffness, limited ability to move around).

Chemistry/Synonyms

Available veterinary (and human) antivenom products are concentrated serum immunoglobulins (either whole IgG, or the ven-

om-binding portion as either F(ab) or $F(ab')_2$ fragments) obtained from horses or sheep immunized with the venoms of several species of Crotalidae ("pit viper") snakes. Commercially available products are provided as refined, lyophilized products with diluent, presolubilized injectable solution, or plasma preparation.

Antivenin and antivenom are interchangeable terms.

Antivenin (Crotalidae) Polyvalent may also be known as ACP. Crotalidae Polyvalent Immune F(ab) (Ovine) may also be known as OPCA.

Storage/Stability

Antivenin (Crotalidae) Polyvalent (equine origin) North and South American Snakebite Antiserum; *Antivenin®*: Do not store above 37°C (98°F); avoid freezing and excessive heat. After reconstitution, the vial should be used immediately.

Antivenin Crotalidae Polyvalent (equine origin) North American Crotalidae Antivenom; *Rattler Antivenin®*: Product should be kept frozen below -5°C (23°F) until use. May be thawed in warm (not hot) water over 2 to 5 minutes (not to exceed 10 minutes). May be kept at room temperature 15°C to 27°C (60°F to 80°F) for up to 6 hours. May warm to body temperature immediately before administration.

Antivenin Polyvalent Crotalidae $F(ab')_2$ (equine origin) Injectable Solution North American Pit Viper Antivenin; *VenomVet®*: Refrigerate at 2°C to 8°C (36°F-46°F).

Crotalidae Polyvalent Immune F(ab) (ovine origin), human product, should be stored in the refrigerator at 2°C to 8°C (36°F-46°F) and used within 4 hours of reconstitution. Do not freeze. Storage at -20°C to 25°C (-4°F-77°F) is permitted for no longer than 7 days.

The Crotalidae Immune $(F(ab')_2$ (equine origin), human product, should be stored at a room temperature of 25°C (77°F), with brief temperature excursions up to 40°C (104°F) permitted; do not freeze. Use within 6 hours of reconstitution.

Compatibility/Compounding Considerations

Antivenin (Crotalidae) Polyvalent (ACP; equine origin) North and South American Snakebite Antiserum; *Antivenin®*: Reconstitute each vial with the diluent provided; gently swirl the vial (may require several minutes; do not shake) to prevent excessive foaming. Warming the vial to body temperature may speed up reconstitution. Once reconstituted, the vial contents are often added to a crystalloid IV solution (D_5W, normal saline often recommended) for infusion.

Antivenin Crotalidae Polyvalent (equine origin) North American Crotalidae Antivenom; *RattlerAntivenin®*: Product does not require reconstitution or dilution (do not mix with other fluids); however, other fluids can be administered concurrently. Administer using a filtered IV set.

Antivenin Polyvalent Crotalidae $F(ab')_2$ (equine origin) Injectable Solution North American Pit Viper Antivenin; *VenomVet®*: Product does not require reconstitution, but does require dilution to 100 to 150 mL in crystalloid fluid.

Crotalidae Polyvalent Immune Fab (ovine origin), human product: Each product vial requires reconstitution with 18 mL of 0.9% sodium chloride for injection and dissolution via manual inversion; do not shake. Further dilution of reconstituted product in 0.9% saline (250 mL total volume) is required.

The Crotalidae Immune $F(ab')_2$ (equine origin), human product: Each product vial requires reconstitution 10 mL 0.9% sodium chloride for injection. Further dilution of reconstituted product in 0.9% saline (250 mL total volume) is required.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Antivenin Crotalidae Polyvalent (equine origin) North and South American Snakebite Antiserum: Product is single-dose vial lyophilized IgG provided with a single 10 mL vial of diluent. *Antivenin®*; (Rx). USDA permit #124; labeled for use in dogs.

Antivenin Crotalidae Polyvalent (equine origin) North American Crotalidae Antivenom: 50 mL mini-IV bags of frozen, whole IgG antivenom. *RattlerAntivenin®*, Antidote 3 *RattlerAntivenin®*; (Rx). USDA veterinary license #614; labeled for use in dogs 8 weeks of age and older, and horses of any age.

Antivenin Polyvalent Crotalidae $F(ab')_2$ (equine origin) Injectable Solution North American Pit Viper Antivenin: Product box contains 1 liquid nonpyrogenic 10 mL sterile vial of antibody fragment preparation (antibodies in which the Fc fragments have been enzymatically removed, reducing the potential for allergic reactions). *VenomVet™*; (Rx). USDA veterinary license #444A; labeled for use in dogs 6 months of age and older.

Because product may be difficult for veterinarians to obtain in a timely manner during emergent situations, consider keeping this product on hand in regions where envenomation occurs more commonly.

HUMAN-LABELED PRODUCTS:

Antivenin Crotalidae Polyvalent Immune Fab (ovine origin) Powder for Injection (lyophilized): 1 g total protein per single-use vial; *CroFab®*; (Rx) FDA approved. **NOTE:** The cost of this product may prohibit its use in veterinary patients.

Crotalidae Immune $F(ab')_2$ (equine origin) Lyophilized Powder for Solution for Injection: 120 mg total protein per single-use vial; *Anavip®*; (Rx) FDA approved. **NOTE:** The cost of this product may prohibit its use in veterinary patients.

Antivenom, North American Coral Snake

(an-tie-***ven***-nin)

Antivenom; Antidote

Antivenin and antivenom are synonymous terms and used interchangeably throughout the monograph to avoid confusion between the currently preferred term (antivenom) and the term used on the product label (antivenin). ***NOTE:*** Veterinary poison control centers can offer current, detailed treatment recommendations (consultation fees may apply). See ***Important Contact Information***.

Prescriber Highlights

- ► Neutralizes the venom of Eastern and Texas coral snakes. Early antivenom administration (within 4 to 6 hours of envenomation) is associated with greater efficacy, but later administration can still be effective.
- ► May cause hypersensitivity reactions (acute and delayed)
- ► Patients may require mechanical ventilation despite antivenom therapy.
- ► Product may be difficult for veterinarians to obtain in a timely manner in emergent situations; consider keeping this product on hand in areas where envenomation occurs more commonly.
- ► Treatment with antivenom requires economic consideration, as product costs range from hundreds to thousands of dollars.
- ► It is recommended to contact a veterinary poison control center for current treatment recommendations and assistance in locating and acquiring antivenom.

Uses/Indications

This antivenom is indicated for the treatment of envenomation from North American coral snakes of the genus *Micrurus*. It is specific for the Eastern coral snake (*Micrurus fulvius fulvius*) and will provide cross-neutralization with the Texas coral snake (*Micrurus fulvius tenere*). Coral snake envenomation is relatively uncommon in the US and, of the bites that occur to humans, ≈60% do not result in clinically significant envenomation.[1]

Pharmacology/Actions

Coral snake venom primarily causes neurotoxicity (flaccid paralysis) and clinical signs may be delayed for hours. Intravascular hemolysis associated with anemia and hemoglobinuria has been reported in dogs.[1] Coral snake antivenom acts via venom toxin-specific antibodies that bind venom toxins, thereby neutralizing venom-induced toxic effects.

Toxin-specific immunoglobulins are obtained from horses that have been hyperimmunized with Eastern coral snake venom. Each vial of antivenom will neutralize ≈2 mg of *Micrurus fulvius fulvius* venom.

Pharmacokinetics

The pharmacokinetics of coral snake antivenom have not been described in veterinary species.

Contraindications/Precautions/Warnings

Coral snake antivenom should not be administered prophylactically to subclinical animals for which a bite is questionable. It should be administered with caution in animals with a confirmed history of hypersensitivity to equine serum and in animals with a history of asthma or other allergic tendencies.[2] Although rare, there is the possibility of life-threatening hypersensitivity reactions; appropriate resuscitative drugs (eg, epinephrine) and equipment should be readily available. Professional veterinary judgment is required to determine if the potential benefit of antivenom administration outweighs the risk. Performing sensitivity testing before antivenom administration may be considered, but this practice is questionable due to false negative and false positive results occurring[1] and most clinicians recommend particularly close observation during the initial IV infusion of 1 – 2 mL of diluted antivenom solution over 3 to 5 minutes.[3] Coral snake antivenom will not neutralize *Micruroides euryxanthus* (Sonoran or Arizona coral snake) venom.

Use antihistamines, tranquilizers, sedatives, and analgesics with care as they may mask important clinical signs and augment the respiratory depressant effects of the venom. Additionally, opioid-induced histamine release may obscure clinical signs associated with anaphylaxis.

Adverse Effects

The most significant adverse effects are associated with hypersensitivity reactions. Anaphylaxis (or anaphylactic-like reactions) secondary to the equine serum proteins in this product may occur, but the incidence is low. Serum sickness (fever, rash, arthralgia, myalgia) may also occur days following antivenom administration.

Epinephrine (0.01 mg/kg IM and repeated at 15- to 20-minute intervals until the patient is stable) has been recommended if early signs of anaphylaxis occur (clinical signs vary by species and include vomiting/diarrhea [dogs], dyspnea [cats/ruminants], nausea, pruritus, pyrexia, and hyperemia of the inner pinnae). Stopping the infusion, administering histamine H_1- and H_2-receptor antagonists (eg, diphenhydramine and famotidine, respectively), and restarting the infusion 5 minutes later at a slower rate may allow the dose to be administered without further problems.[1,4] In severe envenomation, patients exhibiting allergic reactions to antivenom can still receive it; administration of antivenom as a slow IV infusion with concomitant diphenhydramine (and possibly epinephrine) has been suggested.

Reproductive/Nursing Safety

Snake antivenoms have been successfully administered in humans during pregnancy, and typically what is beneficial for the mother's health is also beneficial for the fetus[5]; it is likely that this also applies to veterinary species.

Safety during nursing has not been established for snake antivenoms but it would unlikely pose much risk. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Drug Interactions

The following drug interactions with antivenom have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use of these together is not necessarily contraindicated, but the potential risks must be weighed, and additional monitoring performed as needed.

- **Beta-Adrenergic Receptor Antagonists**: May mask the early signs associated with anaphylaxis
- **CNS and/or Respiratory Depressants** (eg, **alpha-2 agonists, barbiturates, benzodiazepines**): Although analgesia, reducing excessive movement, and administration of other supportive therapy are important parts of treating envenomation, drugs that can mask the clinical signs, or potentially worsen CNS and respiratory depression associated with the coral snake envenomation (eg, analgesics, sedatives) should initially be used with caution.
- **Opioids** (eg, **morphine**): Concurrent use of opioids is considered contraindicated in coral snake envenomation as it may augment the respiratory depressant effects of the venom. Clinical signs caused by opioid-induced histamine release may also obscure the diagnosis of anaphylaxis to the antivenom.

Laboratory Considerations

None noted

Dosages

NOTES:

1. Early administration of antivenom increases effectiveness.
2. Treatment for coral snake envenomation may require significant supportive treatment and monitoring beyond administration of antivenom. It is highly recommended to refer to specialized references[6] and consult with an animal poison control center for guidance beyond what is listed in this monograph. See ***Important Contact Information***.
3. The dose required is based on the relative amount of venom injected and the body mass of the patient.[1] Smaller patients may require higher doses (as venom amount/kg body weight is higher).

DOGS/CATS:

Eastern and Texas coral snake envenomation (extra-label): Average dose required for a dog or cat is 1 to 2 vials of antivenom. Dilute each vial into 100 – 250 mL of crystalloid fluids (eg, sodium chloride 0.9%).[1,2] Initial infusion should be 1 – 2 mL IV slowly over 3 to 5 minutes; observe patient for clinical signs related to an allergic reaction. See ***Adverse Effects***. If no adverse effects are observed, the remaining dose can be administered at a rate that is comfortable for the patient based on body weight and general condition. Administer additional vials as indicated by the progression of the condition.[1]

HORSES:

Eastern and Texas coral snake envenomation (extra-label): Administer 1 to 2 vials slowly IV diluted in 250 – 500 mL sodium chloride 0.9% or lactated Ringer's.[7]

Monitoring

- Animals suspected of having a coral snake envenomation should be hospitalized with close observation for 24 to 48 hours postbite.
- Signs associated with an allergic reaction to the antivenom (eg, urticaria, facial swelling, dyspnea, anaphylaxis, anaphylactic-like reactions, serum sickness)
- Respiratory rate and character, pulse oximetry; mechanical ventilation may be necessary.
- Neurologic assessment: muscle weakness, paralysis, convulsions

Client Information

- Clients must be made aware of the potential for anaphylaxis as well as the economic costs associated with antivenom treatment, patient monitoring, and hospitalization.
- Some animals may experience an allergic reaction ("serum sickness") to antivenom products 1 to 2 weeks after administration. Inform your veterinarian if your animal develops a fever, rash, or appears to have muscle or joint pain (eg, stiffness, limited ability to move around).

Chemistry/Synonyms

Antivenom is composed of serum immunoglobulins obtained from horses that have been hyperimmunized with coral snake venom. The antivenom is provided as a refined lyophilized product with a suitable diluent. Antivenin and antivenom are interchangeable terms.

North American coral snake antivenom may also be known as NACSA or *Antivenin®*.

Storage/Stability

Unreconstituted product vials should be stored at 2°C to 8°C (36°F-46°F). Avoid freezing and excessive heat. After reconstitution, vials of antivenom that have been further diluted should be used within 4 hours.

Compatibility/Compounding Considerations

Reconstitute each vial of antivenom with 10 mL of the supplied diluent (sterile water for injection), aiming the diluent stream at the center of the lyophilized pellet. Gentle swirling may be used to hasten dissolution of the lyophilized powder; do not shake. Complete reconstitution may require 30 minutes or longer. Once vials have been reconstituted with the provided diluent, further dilution with normal saline for injection is required. Stability of the antivenom when diluted in other fluids (eg, LRS), and compatibility with other drugs, is unknown.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

North American Coral Snake Antivenin (Equine) Lyophilized for Solution for IV Injection provided as single-use vials with 1 vial of diluent (10 mL water for injection). FDA-approved biologic; (Rx). Product can be obtained through the human-labeled pharmaceutical supply chain.

Apomorphine

(a-poe-***mor***-feen) *Apokyn®, Emedog®*

Emetic

Prescriber Highlights

- ► Rapid-acting, centrally mediated emetic used in dogs; rarely used in cats because it is often ineffective
- ► Contraindicated in certain species that are unable to vomit (eg, rodents, rabbits) and when vomiting may be deleterious (eg, impending coma, seizures, aspiration, ingestion of a corrosive substance)
- ► Can cause protracted vomiting; naloxone should reverse CNS effects or cardiorespiratory depression but not vomiting or cardiovascular effects. Recovery is usually within a few hours.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies apomorphine as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Apomorphine is used primarily as an emetic in dogs; it induces vomiting in 90% to 100% of dogs.[1,2] In a retrospective study of foreign body ingestion, apomorphine-induced vomiting successfully removed the object in ≈75% of dogs.[3] Apomorphine is rarely used in cats; and if emesis is indicated, an alpha-2 adrenergic agonist (eg, dexmedetomidine) is generally preferred.[4]

Pharmacology/Actions

Apomorphine stimulates dopamine receptors in the chemoreceptor trigger zone, which induces vomiting. This drug can cause both CNS depression and stimulation, but it tends to cause stimulatory effects. At high doses, medullary centers can be affected with resultant respiratory depression. In humans, apomorphine has an affinity for alpha-adrenergic receptors.

Pharmacokinetics

Apomorphine is slowly absorbed after oral administration and has unpredictable efficacy when it is given by this route; therefore, it is usually administered parenterally or via the subconjunctival sac. After SC injection, the drug is rapidly and almost completely absorbed, with effective concentrations reached in 10 minutes and peak concentrations reached in 25 minutes.[5] When apomorphine is administered intranasally, the mean time to reach the maximum plasma concentrations (T_{max}), the mean C_{max}, and the mean half-life ($t_{1/2}$) were 19.17 minutes, 36.14 ng/mL, and 29.85 minutes, respectively.[6] Median time to cause emesis may occur as soon as 1 minute (range, 1-5 minutes) after IV administration[2,7] and ≈13.5 minutes (range, 3-32 minutes) after SC injection; IM administration appears to have the slowest onset.[5] Duration of emesis for each route is ≈30 to 45 minutes.[1,5]

Apomorphine is primarily conjugated in the liver and then excreted in the urine. Its elimination half-life in dogs is 30 to 64 minutes. In humans, higher peak concentration (25%) and overall drug exposure (10%) may occur in patients that have hepatic impairment.

Contraindications/Precautions/Warnings

Emetics can be an important aspect in the treatment of orally ingested toxins, but they must be used judiciously. Most emetics cause emesis when administered within 2 hours of foreign material or toxin ingestion[8]; however, induction of emesis should be performed as soon as possible, especially for cases of toxin ingestion. Emetics should not be used in rodents or rabbits because these patients are either unable to vomit or do not have stomach walls strong enough to tolerate emesis. Emetics are also contraindicated in patients that are hypoxic, have evidence of cardiovascular shock or respiratory distress, are actively having seizures, and/or

lack normal pharyngeal reflexes (ie, laryngeal paralysis). The risks and benefits of administering an emetic should also be considered for animals with a recurrent history of aspiration pneumonia, seizures, coma, severe CNS depression or deteriorating CNS function, or extreme physical weakness. Emetics should also be withheld in patients that have previously vomited repeatedly. Because of the risk for additional esophageal or gastric injury with emesis, emetics are contraindicated in patients that have ingested a sharp object, strong acids, alkalis, or other caustic agents. Because of the risk for aspiration, emetics are usually contraindicated after petroleum distillate ingestion but may be employed when the risk for toxicity of the compound is greater than the risk for aspiration. Use of emetics after ingestion of strychnine or other CNS stimulants may precipitate seizures.

Emetics generally do not remove more than 80% of the material in the stomach (usually 40% to 60%),[9] and successful induction of emesis does not signal the end of appropriate monitoring or therapy. In addition to the contraindications outlined above, apomorphine should not be used in patients with oral opioid or other CNS depressant (eg, barbiturates) toxicity or in patients hypersensitive to morphine. Patients with hepatic impairment may have prolonged drug effects.

If vomiting does not occur in the expected time after apomorphine administration, repeated doses are unlikely to induce emesis and may cause clinical signs of toxicity.

The use of apomorphine in cats is controversial, as it is thought to be much less effective than alpha-2 agonists and, possibly, less safe.

In humans, IV crystallization leading to thrombus formation and pulmonary embolism has occurred following administration of apomorphine IV and use by the IV route is not advised.[10] These adverse effects have not been reported in animals and the IV route is commonly used for toxicity cases due to rapid onset of emesis.

The National Institute for Occupational Safety and Health (NIOSH) classifies apomorphine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Protracted nausea and vomiting are the main adverse effects seen with typical apomorphine doses. The severity of emesis and CNS depression is increased in dogs with the multidrug sensitivity gene (*MDR1)* mutation (also known as *ABCB1-1*delta); use apomorphine with caution in these dogs.[11] Sedation (44%) and tachycardia (16%) were reported in a study and were more likely to occur when apomorphine was given in the subconjunctival sac.[2] Other adverse effects after ophthalmic administration include lethargy, hypersalivation, persistent nausea, and eye redness/irritation. Hypotension and CNS or respiratory depression are usually associated with overdoses. Protracted vomiting after ophthalmic administration may be averted by washing the conjunctival sac with sterile saline or ophthalmic rinsing solution. Anecdotal reports of corneal ulcers have been noted after conjunctival administration.

In humans, hypotension, syncope, prolongation of the QT interval, and sudden episodes of sleepiness have been reported.[10] In contrast, low dose of apomorphine (0.01 mg/kg IV) exerted positive chronotropic and inotropic effects in dogs without affecting any electrophysiological variables.[12] When 0.1 mg/kg IV was administered, no hemodynamic effects were noted, and only an increase in the effective refractory period was reported.

Reproductive/Nursing Safety

The reproductive safety of this drug has not been established; weigh the risks versus the potential benefits before use. Teratogenicity (eg, fetal malformation, death) has been noted in laboratory animals. There were no changes in reproductive parameters in male dogs treated daily (0.01 – 0.4 mg/kg/day) for 6 months.[13]

Apomorphine is excreted into maternal milk.[14] Monitor nursing puppies for adverse effects; consider a milk replacer.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Excessive doses of apomorphine may result in respiratory and/or cardiac depression, CNS stimulation (eg, excitement, seizures), depression, or protracted vomiting. Naloxone may reverse CNS and respiratory effects but does not reverse apomorphine-induced cardiovascular effects or necessarily stop the vomiting.[15] Naloxone increases and prolongs the emetic effect of apomorphine by blockading mu receptors.[5]

Recovery generally occurs in 2 to 3 hours. Atropine has been suggested to treat severe bradycardia. Protracted hypersalivation or vomiting can be treated with maropitant or metoclopramide.[16]

In experimental studies, high doses of apomorphine (after 0.1 mg/kg SC) caused decreased motor activity, behavior changes (eg, anxiety, pacing, limb flicking), hyperesthesia, hallucinations, and hypersalivation in cats (after 0.5 or 2 mg/kg SC).[17]

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison control center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to the ***Appendix.***

Drug Interactions

The following drug interactions with apomorphine either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antidopaminergic drugs** (eg, **metoclopramide, phenothiazines**): May negate the emetic effects of apomorphine
- **Antihistamines, Sedating** (eg, **chlorpheniramine, diphenhydramine**): Added sedative effects may occur.
- **Barbiturates** (eg, **phenobarbital**)**:** Additive CNS or respiratory depression and hypotension may occur.
- **CNS Depressant Drugs** (eg, **alpha-2 adrenergic agonists** [eg, **dexmedetomidine**], **benzodiazepines** [eg, **alprazolam, diazepam, midazolam**], **gabapentin, propofol**): Additive CNS or respiratory depression may occur.
- **Hypotensive Agents** (eg, **amlodipine, enalapril, furosemide, hydralazine, prazosin**): May have additive hypotensive effects
- **Maropitant:** Negates the emetic effects of apomorphine[18]
- **Meclizine**: May negate the emetic effects of apomorphine. Additive sedative effects may occur.
- **Naloxone:** Emetic effect may be prolonged.[5] Naloxone can reverse the respiratory depressant effects (but not the emetic or cardiovascular effects) of apomorphine.
- **Nitroglycerin:** May increase the risk for hypotension
- **Nitroprusside:** May increase the risk for hypotension
- **Ondansetron:** May negate the emetic effects of apomorphine. A human patient that received ondansetron and apomorphine developed severe hypotension.[10] In humans, use together is contraindicated.
- **Opioids** (eg, **hydromorphone, morphine**): Additive CNS or respiratory depression may occur; use together cautiously.
- **Pentoxifylline:** May increase the risk for hypotension
- **QT Prolonging Drugs** (eg, **amiodarone, cisapride, clomipramine, quinidine, sotalol**)**:** May increase the risk for QT prolongation

- **Serotonin Antagonists** (eg, **mirtazapine, trazodone**): May negate the emetic effects of apomorphine. A human patient that received ondansetron and apomorphine developed severe hypotension.[10] In humans, use together is contraindicated.
- **Sildenafil:** May increase the risk for hypotension

Dosages

DOGS:

Induction of emesis (extra-label):

a. 0.01 – 0.04 mg/kg IV, SC, or IM.[1,2,7,14,19–21] **NOTE**: Induction of emesis is fastest with IV administration followed by SC; IM route has the longest lag time until emesis occurs.
b. 0.25 mg/kg PO (one 6.5 mg tablet per 26 kg)[16]
c. Subconjunctival route: Place a 6.25 mg tablet (whole or crushed; not available in the US) under the conjunctiva.[16] Alternatively, a crushed tablet (typically 6.25 mg) can be dissolved in a saline solution (0.9% sodium chloride) instilled in the conjunctival sac. **NOTE**: Solutions must be prepared fresh to be effective. Remove the tablet and rinse with water or saline solution after emesis (resulting in a dose to effect).[1,22]

FERRETS:

Induction of emesis (extra-label):

a) 0.04 mg/kg IV, IM, or SC[23–25]
b) 0.25 mg/kg subconjunctivally[26]

Monitoring

- CNS, respiratory, and cardiac systems should be monitored.
- Vomitus should be quantified, examined for contents, and saved for possible later analysis.

Client Information

- This medicine should only be given by your veterinarian.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Apomorphine is a centrally acting emetic that occurs as a white powder or minute, white or grayish-white crystals, and is sparingly soluble in water or alcohol.

Apomorphine HCl may also be known as apomorphini hydrochloridum, *APO-go®*, *APO-go Pen®*, *Apofin®*, *Apokinon®*, *Apokyn®*, *Apometic®*, *Apomine®*, *Britaject®*, *Emedog®*, *Ixense®*, *Taluvian®*, or *Uprima®*.

Storage/Stability

Apomorphine soluble tablets should be stored in tight containers at room temperature (15°C-30°C [59°F-86°F]) and protected from moisture and light.

Apomorphine gradually darkens in color when exposed to light and air. Discolored (ie, green to turquoise) tablets and solutions should be discarded. Apomorphine solutions are more stable in acidic versus alkaline solutions. An apomorphine 0.3% solution has a pH of ≈3 to 4.

Compatibility/Compounding Considerations

Solutions of apomorphine can be made by solubilizing tablets in at least 1 to 2 mL of either sterile water for injection or 0.9% sodium chloride for injection. After being sterilized by filtration, the solution is stable for 2 days if protected from light and air and stored in the refrigerator. Do not use solutions that are discolored or form a precipitate after filtering.

Compounded preparation stability: Apomorphine injectable solution compounded from the active pharmaceutical ingredient (API) has been published.[27] Dissolving 10 mg apomorphine with 0.1% sodium metabisulfite in sterile water to a final volume of 10 mL and filtering through a 0.22 µm sterilizing filter yields a 2.5 mg/mL sterile solution that retains potency for 2 months stored at 25°C (77°F). Compounded preparations of apomorphine should be protected from light. Solutions of apomorphine should not be autoclaved, as autoclaving results in the development of a green color.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Apomorphine HCl Injection: 1 mg/mL in 1 mL ampules; *Emedog®*; available in the United Kingdom; (POM-V)

Apomorphine HCl Tablet: 6.5 mg; available in Australia/New Zealand; (Rx)

Pharmaceutical dosage forms of apomorphine can be difficult to obtain and compounding pharmacies may be required to obtain the drug.

HUMAN-LABELED PRODUCTS:

Apomorphine HCl Injection: 10 mg/mL in 3 mL cartridges; *Apokyn®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Apramycin

(a-pra-***mye***-sin) *Apralan®*

Aminoglycoside

Prescriber Highlights

- ► Orally administered antibiotic for bacterial enteritis in pigs, calves, and poultry
- ► Apramycin is no longer available in the US, but products labeled for use in pigs, calves, and poultry remain available in some countries.
- ► Contraindicated in animals hypersensitive to apramycin, animals with renal disease, calves with a functional rumen, and cats.
- ► May be partially absorbed in neonates

Uses/Indications

Apramycin is no longer commercially available in the US, but it is used in some countries for the treatment of bacterial enteritis (eg, colibacillosis, salmonellosis) in pigs, calves, and poultry.

The World Health Organization (WHO) has designated aminoglycosides as a Critically Important, High Priority antimicrobial in human medicine.[1] The Office International des Epizooties (OIE) has designated apramycin as a Veterinary Critically Important Antimicrobial (VCIA) in avian, bovine, lagomorph, ovine, and swine species.[2]

Pharmacology/Actions

Apramycin is an aminoglycoside-aminocyclitol that is bactericidal against many gram-negative bacteria (eg, *Escherichia coli*, *Pseudomonas* spp, *Salmonella* spp, *Klebsiella* spp, *Proteus* spp, *Pasteurella* spp, *Treponema hyodysenteriae*, *Bordetella bronchiseptica*), *Staphylococcus* spp, and *Mycoplasma* spp. It prevents protein synthesis by susceptible bacteria by binding to the 30S ribosomal subunit.

There are public health concerns about the widespread use of apramycin in pigs, as apramycin resistance in *E coli* caused by the *aac(3)-IV* gene also confers resistance toward other aminoglycosides (eg, gentamicin, tobramycin); treated animals may become a reservoir for transfer of resistant genes or bacteria to humans.[3,4]

Pharmacokinetics

After oral administration, apramycin is partially absorbed, particularly in neonates. Absorption decreases substantially with the age of the animal. The absorbed drug is eliminated unchanged via the kidneys.

Apramycin is absorbed when administered orally to neonatal swine at single dosage levels of 10, 30, and 100 mg/kg, with peak blood concentrations observed at 1 to 4 hours postadministration; detectable serum apramycin concentrations persist for 12 to 24 hours. Considerable variation in postadministration blood concentrations is observed; however, the concentration detected is generally commensurate with the dose.

After IV administration to goats, apramycin has a volume of distribution (steady-state) of 0.26 L/kg, clearance of 2.8 mL/minute/kg, and an elimination half-life of 1.3 hours.[5]

Contraindications/Precautions/Warnings

Do not use in known cases of apramycin hypersensitivity. The drug has a wide margin of safety when used orally. Apramycin is contraindicated in cats, in calves with a functional rumen and in patients with kidney disorders.[6]

Because apramycin is delivered in feed or drinking water, animals that are not eating or drinking should receive alternative (parenteral) antimicrobial therapy.

Adverse Effects

When used as labeled, the manufacturer does not list any adverse reactions. Fecal softness has been observed in 1- to 3-day-old piglets. Although not documented, as with other aminoglycosides, ototoxicity and nephrotoxicity could occur if significant amounts of apramycin are systemically absorbed.

Reproductive/Nursing Safety

Apramycin is safe to use in breeding swine.[7] Fetal toxicity has been observed in rabbits given apramycin between days 6 and 18 of pregnancy.[6]

Because safety has not been established in other animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No mortality was observed following oral doses of 1250 mg/kg in pigs, 520 mg/kg in dogs, or 5200 mg/kg in mice.[7]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral neomycin and may apply to apramycin and be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Cephalosporins** (eg, **ceftiofur, cephalexin**): Concurrent use may enhance the nephrotoxic effect of neomycin.
- **Cyclosporine**: Neomycin may increase the nephrotoxic potential of cyclosporine.
- **Digoxin**: Oral neomycin with orally administered digoxin may result in decreased absorption of digoxin. Separating the doses of the 2 medications may not alleviate this effect. Some human patients (less than 10%) metabolize digoxin in the GI tract, and neomycin may increase serum digoxin levels in these patients. It is recommended that therapeutic drug monitoring be performed if oral neomycin is added or withdrawn from the drug regimen of a patient stabilized on a digitalis glycoside.
- **Mannitol**: Concurrent use should be avoided, as it may enhance the nephrotoxic effect of neomycin.
- **Methotrexate**: Absorption may be reduced by oral neomycin but is increased by oral kanamycin (found in *Amforal*®).
- **Neuromuscular-Blocking Agents** (eg, **atracurium, pancuronium**): Concomitant use with neuromuscular blocking agents could potentiate neuromuscular blockade.[6]
- **Ototoxic, Nephrotoxic Drugs**: Although only minimal amounts of neomycin are absorbed after oral or rectal administration, concurrent use of other ototoxic or nephrotoxic drugs with neomycin should be done with caution. Topical use for the treatment of otitis should be avoided if an intact tympanic membrane has not been confirmed.
- **Penicillin V Potassium** (**oral**): Oral neomycin should not be given concurrently with oral penicillin V Potassium, as malabsorption of the penicillin may occur.
- **Vancomycin:** May enhance the nephrotoxic effect of neomycin
- **Vitamin K Antagonists** (eg, **warfarin**): Oral neomycin may decrease the amount of vitamin K absorbed from the gut; this may have ramifications for patients receiving oral anticoagulants.

Laboratory Considerations

None have been noted.

Dosages

NOTE: All dosages are expressed as mg/kg apramycin sulfate.

CATTLE:

Treatment of colibacillosis or salmonellosis in calves (extra-label): 72 mg/kg PO once daily for 5 consecutive days, administered in drinking water (as sole source of water), milk, or milk replacer.[6]

SWINE:

Bacterial enteritis in weaned piglets caused by *Escherichia coli* (extra-label)**:** 22.5 mg/kg PO once daily for 7 consecutive days, administered in drinking water (as sole source of water)[6]

POULTRY:

Treatment of *Escherichia coli* septicemia in young chickens (extra-label)**:** 144 mg/kg PO once daily for 5 consecutive days, administered in drinking water (as sole source of water)[6]

RABBITS:

Treatment and metaphylaxis of bacterial enteritis caused by *Escherichia coli* (extra-label)**:** 36 mg/kg PO once daily for 5 consecutive days, administered in drinking water (as sole source of water)[6]

Monitoring

- Clinical efficacy

Chemistry/Synonyms

Apramycin is an aminocyclitol antibiotic produced from *Streptomyces tenebrarius*; it is a light to medium brown powder that is soluble in water. Aminocyclitols are closely related to the aminoglycosides.

Apramycin may also be known as nebramycin factor 2, nebramcyin II, apramycine, apramicina, AIDS166733, *Apralan*®, *Actavis*®, or *Abylan*®.

Storage/Stability

Store apramycin powder in a cool dry place, in tightly closed containers, protected from moisture. Store at temperatures less than 25°C (77°F). If exposed to rust (eg, a rusty waterer), the drug can be inactivated. Opened product should be used within 28 days.[6,7]

- Discard any medicated water not consumed within 24 hours and milk replacer within 6 hours.

- Prepare solutions in milk and reconstituted milk replacer immediately before use. Discard any medicated milk or milk replacer not consumed within 1 hour. Milk replacer should not exceed 40°C (104°F) when mixing in apramycin powder.

Compatibility/Compounding Considerations

Do not mix with other medications.[6]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the US. A swine product, Apramycin Sulfate Soluble Powder 37.5 g and 48 g (base) bottle; *Apralan*®; (OTC), was formerly marketed in the US and is still available in several countries.

In the UK: Apramycin Soluble Powder: 1 g sachets and 50 g (apramycin activity) in 220 mL; *Apralan Soluble Powder*®; (POM-V). Refer to local regulations for withdrawal times.

HUMAN-LABELED PRODUCTS: NONE

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Ascorbic Acid

Vitamin C

(a-***skor***-bik ***ass***-id)

Vitamin, Antioxidant

Prescriber Highlights

- ► Used to prevent and treat scurvy in guinea pigs
- ► Antioxidant sometimes used in dogs and cats to treat ingestion of certain toxicants (eg, acetaminophen)
- ► At recommended dosages, there are minimal adverse effects; may exacerbate liver injury in copper toxicosis
- ► May alter laboratory results (eg, urine dipstick, fecal occult blood, serum bilirubin)

Uses/Indications

Ascorbic acid (vitamin C) is used to prevent and treat scurvy in guinea pigs.

Ascorbic acid is sometimes recommended as an antioxidant as part of treatment for ingestion of toxicants that can cause methemoglobinemia (eg, acetaminophen, phenazopyridine, monomethylhydrazine-containing mushrooms) or hepatotoxicity.

In small animal species, ascorbic acid can be a urinary acidifier, but its efficacy is questionable, and it is rarely used for this purpose. Previously, ascorbic acid was used to treat copper-induced hepatopathy in dogs but has fallen into disfavor (see ***Contraindications/Precautions/Warnings***). Supplementation to dogs that are experiencing a stressful situation (eg, intensive care) does not appear warranted.[1]

Pharmacology/Actions

Exogenously supplied ascorbic acid is a dietary requirement in some exotic species (eg, rainbow trout, coho salmon), guinea pigs, and primates. Domestic species synthesize ascorbic acid in vivo to meet their nutritional needs. Ascorbic acid is used in tissue repair and collagen formation; it is also important for maintaining blood vessel integrity and immune function. Some oxidation-reduction reactions and substrate metabolism (iron, folic acid, norepinephrine, histamine, phenylalanine, tyrosine, some drug enzyme systems) include ascorbic acid. Iron absorption and storage require ascorbic acid. Protein, lipid, and carnitine synthesis may require ascorbic acid. As an antioxidant for the adjunctive treatment of toxins that cause methemoglobinemia and/or hepatotoxicity, ascorbic acid serves as a reducing agent that neutralizes reactive oxygen compounds (eg, hydrogen peroxide), and it can increase conversion of methemoglobin to oxyhemoglobin, and act as a substrate for the antioxidant enzyme ascorbate peroxidase.

Pharmacokinetics

Human data suggest ascorbic acid is generally well absorbed in the jejunum after oral administration. Absorption is an active process and saturated at high doses. Only IV administration of vitamin C produces high plasma and urine concentrations.[2] Ascorbic acid is widely distributed with ≈25% bound to plasma proteins. Biotransformation of ascorbic acid occurs in the liver. When the body is saturated with ascorbic acid and blood concentrations exceed the renal threshold, the drug is readily excreted unchanged in the urine.

In guinea pigs, most ascorbic acid is eliminated in the urine.[3] Some ascorbic acid is metabolized to carbon dioxide, with peak elimination occurring 30 minutes after oral administration.[4]

Contraindications/Precautions/Warnings

High-dose ascorbic acid should be used cautiously in patients with diabetes mellitus because of laboratory interactions (see ***Laboratory Considerations***), and in patients that are susceptible to calcium oxalate, cystine, or urate urolithiasis.

In patients with copper-associated chronic hepatitis, ascorbic acid may increase copper's oxidative damage to the liver and should be avoided.[5]

Some dosage forms may contain benzyl alcohol as a preservative. In human newborns, benzyl alcohol and derivatives can potentially displace bilirubin from protein-binding sites, and caution for use in human neonates is advised. It is unclear if benzyl alcohol has the same effect in guinea pigs; formulations containing benzyl alcohol should not be administered to cats.

Adverse Effects

At usual doses, ascorbic acid has minimal adverse effects. Occasionally, GI disturbances have occurred in humans. Higher doses may increase urate, oxalate, or cystine urolithiasis, particularly in susceptible patients.

Reproductive/Nursing Safety

The reproductive safety of ascorbic acid has not been studied, but ascorbic acid is generally considered safe at moderate dosages during pregnancy and lactation.

Overdose/Acute Toxicity

Large doses may result in diarrhea (due to an osmotic effect and increased peristalsis) and potentially urolithiasis. Single doses of 0.5 g/kg in dogs; 1 g/kg in cats; 2 g/kg in rabbits; and 5 g/kg in guinea pigs, rats, and mice were well tolerated.[6] Treatment should consist of monitoring and hydration.

Drug Interactions

The following drug interactions with ascorbic acid (high dosages) have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aluminum Hydroxide**: Increased absorption of aluminum hydroxide may occur with coadministration with ascorbic acid; administration should be separated by at least 2 hours to minimize effects.
- **Aminoglycosides** (eg, **gentamicin**) These drugs are more effective in an alkaline medium; urine acidification may diminish these drugs' effectiveness in treating bacterial urinary tract infections.
- **Copper**: Add ascorbic acid to total parenteral nutrition last to minimize drug degradation from copper.
- **Cyclosporine**: Concentrations of cyclosporine may be decreased with concomitant ascorbic acid administration.

- **Deferoxamine**: Ascorbic acid may be synergistic with deferoxamine in removing iron and may cause cardiac muscle dysfunction. Use with caution, particularly in patients with pre-existing cardiac disease.
- **Erythromycin**: This antibiotic is more effective in an alkaline medium; urine acidification may diminish the antimicrobial's effectiveness in treating bacterial urinary tract infections.
- **Estrogens** (eg, **estradiol, estriol**): Ascorbic acid may increase estrogen concentration.
- **Iron Salts**: Presence of ascorbic acid may enhance the oral absorption of iron salts.
- **Quinidine:** Urine acidification may increase renal excretion.

Laboratory Considerations

- **Urine dipstick tests**: Large amounts of vitamin C can cause false increases in urine test results measured by copper reduction methods, and false decreases in results measured by glucose oxidase methods; significant interference with other urine dipstick test results (eg, blood) may also occur.[7]
- **Stool occult blood**: False-negative results may occur if vitamin C is administered within 48 to 72 hours of an amine-dependent test.
- **Bilirubin, serum**: Vitamin C may decrease concentrations.
- **Aspartate aminotransferase (AST):** Vitamin C may increase concentrations.
- **Creatinine:** Vitamin C can cause a false increase in serum and urine creatinine concentrations.

Dosages

DOGS/CATS:

Antioxidant for adjunctive treatment of toxin-induced (eg, **acetaminophen, phenazopyridine) methemoglobinemia** (extra-label): 30 – 33 mg/kg PO every 6 hours. Efficacy is questionable,[8] particularly because high plasma concentrations of ascorbic acid are probably not achieved after oral dosing.

HORSES:

Adjunctive treatment of erythrocyte oxidative injury (eg, red maple toxicity; extra-label):

1. 10 – 20 g/horse (NOT g/kg) PO once daily[9]
2. 30 – 50 mg/kg IV twice daily diluted in 5 – 10 L of crystalloid fluids[10]

Urinary acidifier (extra-label): 1 – 2 g/kg PO daily[11]

As adjunctive therapy for perinatal asphyxia syndrome in foals (extra-label): 100 mg/kg per day IV[12]

CATTLE:

Vitamin C-responsive dermatitis in calves (extra-label): 3 g/calf (NOT g/kg) SC once or twice[13]

RABBITS:

Stool softener (extra-label): 100 mg/kg PO every 12 hours[14]; may reduce cecal absorption of clostridial endotoxins

GUINEA PIGS:

Prevention of scurvy (extra-label): **NOTE:** Daily ascorbic acid requirement is 15 – 30 mg/kg/day[15,16] (daily requirements for adult, nonbreeding guinea pigs is 10 mg/kg/day, whereas breeding/growing animals require 30 mg/kg/day; pregnant females may require 30-45 mg/kg/day[17]).

1. 10 – 30 mg/kg/day PO, SC, or IM[18]
2. Add ascorbic acid 200 mg to 1 L of dechlorinated water and add to drinking water bottle; water must be changed daily to ensure adequate ascorbic acid concentrations. Use this route of administration with caution as the water supplementation may cause the guinea pig to not drink as well.[15]

Treatment of scurvy (extra-label): 100 mg/kg/day PO or SC during deficient states, pregnancy, stress, and illness.[19]

Monitoring

Monitoring depends on the underlying clinical condition being treated.

Client Information

- Vitamin C is most commonly used in guinea pigs to prevent scurvy (vitamin C deficiency).
- If mixing vitamin C in water, use dechlorinated water and change solution daily. Administering via syringe is preferable to placing in drinking water.

Chemistry/Synonyms

Ascorbic acid occurs as a white to slightly yellow crystal or powder. Although freely soluble in water, ascorbic acid is sparingly soluble in alcohol. The parenteral solution has a pH of 5.5 to 7.

Ascorbic acid may also be known as acidum ascorbicum, L-ascorbic acid, cevitamic acid, E300, or vitamin C; many trade names are available.

Storage/Stability

Protect from air and light. Ascorbic acid will slowly darken with light exposure; slight discoloration does not affect potency. Over time ascorbic acid will decompose with the production of CO_2. Open ampules carefully. To reduce potentially excessive pressure within ampules, store refrigerated and open while cold. Pressure release may be required prior to medication withdrawal.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Ascorbic acid for injection is **compatible** with most commonly used IV solutions (eg, lactated Ringer's solution), but is **incompatible** with many drugs when mixed in syringes or IV bags.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Parenteral Injection: 250 mg/mL (as sodium ascorbate) in 100 mL and 250 mL vials; generic; (Rx or OTC depending on labeling)

Ascorbic Acid Powder: Concentrations vary; (OTC)

HUMAN-LABELED PRODUCTS:

Vitamin C or Ascorbic Acid Oral Tablets and Capsules: 100 mg, 250 mg, 500 mg, 1000 mg, and 1500 mg; generic; (OTC)

Ascorbic Acid Oral Extended-release Tablets: 500 mg, 1000 mg, and 1500 mg; generic; (OTC)

Ascorbic Acid Oral Crystals or Powder: Concentrations vary; (OTC)

Ascorbic Acid Oral Liquid/Solution: 100 mg/mL in 50 mL and 500 mg/5 mL; *Cecon*®, generic; (OTC)

Ascorbic Acid Injection: 500 mg/mL in 50 mL vials; *Ascor L 500*® (0.025% EDTA, preservative-free), generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Asparaginase

(a-***spar***-a-gin-ase)

Antineoplastic

Prescriber Highlights

- ► Antineoplastic agent used in some protocols for treatment of lymphomas and leukemias in dogs and cats
- ► Adverse effects include hypersensitivity reactions (eg, vomiting, diarrhea, urticaria, pruritus, dyspnea, restlessness, hypotension, collapse) and effects on protein synthesis (eg, GI effects, hemorrhagic pancreatitis, hepatotoxicity, coagulation disorders).
- ► Bone marrow suppression is rare. Asparaginase does not cause significant GI mucosal toxicity.
- ► Teratogenic in laboratory animals
- ► Should be given IM or SC; not IV, as IV administration may increase the risk for anaphylaxis
- ► *Escherichia coli*-derived asparaginase is not therapeutically equivalent to asparaginase *Erwinia chrysanthemi* (*Erwinaze*®).
- ► Availability of commercial, *E coli*-derived asparaginase may be limited, and doses may need to be obtained from a compounding pharmacy.

Uses/Indications

Asparaginase has been used in combination with other agents in the treatment of lymphoid malignancies, most commonly high-grade lymphoma. The drug is thought to be most useful for inducing disease remission (in combinatorial regimens), rescue protocols, and treatment of fragile patients presented with severe comorbidities that preclude the safe use of traditional cytotoxic agents. Asparaginase may also be beneficial in the treatment of leukemias, particularly acute lymphocytic leukemia (ALL).

Asparaginase as part of an initial treatment canine lymphoma protocol is optional, as results of a retrospective study[1] in dogs showed no statistical difference in dogs treated with or without asparaginase (as part of a standard CHOP protocol) in regards to response rate, remission or survival rate, remission or survival duration, or prevalence of toxicity and treatment delay. Asparaginase is still commonly used at the beginning of the feline CHOP protocol because it has a favorable adverse effect profile and potent anticancer activities.

Pharmacology/Actions

Some malignant cells are unable to synthesize asparagine and are dependent on exogenous asparagine for DNA and protein synthesis. Asparaginase catalyzes asparagine into ammonia and aspartic acid. The antineoplastic activity of asparaginase is greatest during the postmitotic (G_1) cell phase. Although normal cells can synthesize asparagine intracellularly, some normal cells with a high rate of protein synthesis require exogenous asparagine and may be adversely affected by asparaginase.

Resistance to asparaginase can develop rapidly, but cross-resistance between asparaginase and other antineoplastic agents is not apparent.

Asparaginase possesses antiviral activity, but its toxicity prevents it from being clinically useful for this indication.

Pharmacokinetics

Asparaginase is not absorbed from the GI tract and must be given either SC or IM. After IM injection, serum concentrations of asparaginase are ≈½ of those after IV injection. Because of its high molecular weight, asparaginase does not diffuse readily out of the capillaries, and ≈80% of the drug remains within the intravascular space.

Asparaginase administered IM to cats significantly reduces asparagine concentrations within 2 days, but the effect is lost within 7 days.[2]

Contraindications/Precautions/Warnings

Asparaginase is contraindicated in patients that have exhibited anaphylaxis to the drug or have existing or a history of pancreatitis, thrombosis, or hemorrhagic events. Asparaginase should be used with caution in patients with pre-existing hepatic, renal, hematologic, GI, and CNS dysfunction or when high protein synthesis is required for tissue repair.

Monitor the patient for 1 hour after administration for signs of hypersensitivity reactions; epinephrine, diphenhydramine; corticosteroids should be readily available. Prior asparaginase use can increase the risk for immunologic hypersensitivity.

No specific precautions are required for handling asparaginase, but it is considered a contact irritant, and contact with eyes, skin, and the upper respiratory tract should be avoided.

Adverse Effects

Asparaginase adverse effects are classified in 2 main categories: hypersensitivity reactions and effects on protein synthesis. Clinical signs of hypersensitivity reactions include vomiting, diarrhea, urticaria, pruritus, dyspnea, restlessness, hypotension, and collapse. The likelihood of hypersensitivity reactions increases with subsequent doses because of the antigenicity of asparaginase. Following the first treatment cycle, many oncologists now recommend administering antihistamines (eg, diphenhydramine at 2 mg/kg) in dogs prior to administration of subsequent doses. If a hypersensitivity reaction occurs, diphenhydramine (0.2 – 0.5 mg/kg slow IV), dexamethasone sodium phosphate (1 – 2 mg/kg IV), IV fluids, and, if severe, epinephrine (0.1 – 0.3 mg IV [total dose]) have been suggested.[3] Hypersensitivity reaction in cats is considered unlikely.[4]

The effects of asparaginase on protein synthesis can result in hemorrhagic pancreatitis or other GI disturbances, hepatotoxicity, and coagulation defects. Large doses may be associated with hyperglycemia secondary to altered insulin synthesis. Subclinical hyperammonemia[5] and a case report of acute hyperammonemia in a dog have been reported.[6]

Reproductive/Nursing Safety

For sexually intact patients, verify pregnancy status prior to administration. Asparaginase is teratogenic in laboratory animals. At doses below those used clinically, asparaginase caused pulmonary, renal, and skeletal malformations. Therapeutic doses resulted in exencephaly and skeletal anomalies.

It is unknown if the drug is excreted in milk. Use with caution, if at all, in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited information was located regarding overdoses with this agent. Toxicity secondary to the protein-synthesis–altering effects of asparaginase would be expected. In dogs, it has been reported that the maximally tolerated dose of asparaginase is 10,000 units/kg and the LD_{50} is 50,000 units/kg. Supportive treatment is recommended in the event of overdose.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with asparaginase have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together

is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **clopidogrel, heparin, rivaroxaban, warfarin**): Increased risk for bleeding
- **Aspirin and Other Salicylates** (eg, **bismuth subsalicylate**): Increased risk for bleeding
- **Corticosteroids** (eg, **dexamethasone, predniso(lo)ne**): Use with asparaginase may increase the risk for hyperglycemia; in humans, asparaginase is usually administered after the corticosteroid. Asparaginase may increase dexamethasone concentration.
- **Cytarabine**: Asparaginase may reduce cytarabine effectiveness against tumor cells until serum asparagine concentrations return to normal.
- **Immunosuppressants** (eg, **cyclosporine, mycophenolate**): Excessive immune suppression may increase the risk for infection or lymphoproliferation.
- **Methotrexate**: Asparaginase may reduce methotrexate effectiveness against tumor cells until serum asparagine concentrations return to normal.
- **NSAIDs** (eg, **carprofen, meloxicam, robenacoxib**): Increased risk for bleeding
- **Vaccines, Modified Live Virus**: Use with caution during chemotherapy protocols.
- **Vincristine**: In humans, increased toxicity (neuropathy and erythropoiesis disruption) may occur when asparaginase is given IV concurrently with or before vincristine. Myelosuppression reportedly occurs in a minority of dogs treated with asparaginase (IM or SC) and vincristine (IV); some veterinary oncologists separate administration by a few days to a week, but others do not feel this is necessary.

Laboratory Considerations

- **Serum ammonia and urea nitrogen**: Concentrations may be increased by the action of the drug.
- **Thyroxine-binding globulin (TBG)**: Asparaginase may cause rapid (within 2 days) and profound decreases in circulating TBG, which may alter interpretation of thyroid function studies; values may return to normal after ≈4 weeks.
- **Serum hepatic chemistry abnormalities**: Hyperbilirubinemia and elevated transaminases have been reported in humans.

Dosages

NOTE: Because of the potential toxicity of this drug to patients, veterinary staff, and pet owners and because chemotherapy indications, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[7-11] are strongly recommended.

DOGS:

Lymphoreticular malignancies (eg, **lymphoma, leukemia**) (extra-label): 400 units/kg or 10,000 units/m^2 (NOT units/kg) IM or SC, with a maximum dose of 10,000 units per patient. **NOTE**: Many oncologists recommend pretreatment with an antihistamine such as diphenhydramine 2 mg/kg IM or SC.

Transmissible venereal tumor (**TVT**; extra-label): Asparaginase 200 units/kg or 5000 units/m^2 (NOT units/kg) SC in week 1, vincristine 0.025 mg/kg IV in week 2. The 2-week cycle was repeated until the tumor was undetectable; total duration ranged from 2 to 5 weeks. Complete response was reported in 12 out of 13 dogs.[12]

CATS:

Lymphoreticular malignancies (eg, **lymphoma, leukemia**): (extra-label): 400 units/kg or 10,000 units/m^2 (NOT units/kg) IM or SC, with a maximum dose of 10,000 units per patient

Monitoring

- Baseline and periodic CBC, serum chemistry profile (including amylase and lipase), and coagulation profile
- Bone marrow evaluation as necessary based on initial diagnosis

Client Information

- This drug can cause severe toxicity, including drug-related death.
- Contact your veterinarian if your animal shows signs of itching, difficulty breathing, very low energy levels, vomiting, poor appetite, severe diarrhea, abnormal bleeding (including bloody diarrhea), bruising, and/or yellowing of the eyes, skin, or gums (ie, jaundice).
- While taking this medicine, your animal will need to be closely monitored by your veterinarian. Do not miss these important follow-up visits.
- Exposure to other animals (eg, from dog parks, animal competitions) can put your animal at serious risk for infection during chemotherapy treatment. Talk with your veterinarian about when it will be safe to return to these activities.

Chemistry/Synonyms

Asparaginase is an enzyme derived from *Escherichia coli* and occurs as a white or almost white, slightly hygroscopic powder that is soluble in water. Asparaginase in this form is not commercially available. The only commercially available product in the United States is *Erwinaze*® (asparaginase *Erwinia chrysanthemi*), a lyophilized powder that is not therapeutically equivalent to *E coli*-derived asparaginase. Activity of asparaginase is expressed in terms of International Units (I.U.) or units.

Asparaginase may also be known as A-ase, ASN-ase, colo-aspase, L-asparaginase, L-asparagine amidohydrolase, MK-965 NSC-109229, Re-82-TAD-15, *Crasnitin*®, *Crasnitine*®, *Elspar*®, *Erwinase*®, *Kidrolase*®, *L-Asp*®, *Laspar*®, *Leucogen*®, *Leunase*®, *Paronal*®, or *Serasa*®.

Storage/Stability

Asparaginase powder for injection should be at 2°C to 8°C (36°F-46°F) unless labeling states otherwise. Reconstituted *Kidrolase*® may be stored refrigerated for more than 72 hours. Asparaginase prepared by compounding pharmacies should be stored in accordance with instructions on the product label.

Solutions should be used only if clear; turbid solutions should be discarded. Upon standing, gelatinous fibers may be noted in the solution occasionally. These may be removed with a 5-micron filter without loss of potency.[3] Some loss of potency may occur if a 0.2-micron filter is used. The solution may be gently mixed or swirled while reconstituting, but vigorous shaking or inversion of the vial should be avoided. Recommended IV diluents include D_5W or sodium chloride 0.9%.

Compatibility/Compounding Considerations

Compatible with sodium chloride 0.9% and dextrose 5% in water for dilution

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

No commercial products with *E coli*-derived asparaginase are available. *Elspar*® (asparaginase powder for injection) has been discontinued in the United States. Compounding pharmacies or FDA-registered outsourcing facilities may be able to compound asparaginase using bulk chemical, which has been shown to have a similar safety profile.[13] *Kidrolase*® is an equivalent Canadian product available in 10,000 unit vials.

Asparaginase *Erwinia chrysanthemi* Powder for Injection, lyophilized: 10,000 units in 3 mL vials (preservative-free); *Erwinaze*®;

(Rx). **NOTE**: *E coli*-derived asparaginase is not considered therapeutically equivalent to asparaginase *Erwinia chrysanthemi* because of differences in enzyme characteristics.

For the complete list of references, see **wiley.com/go/budde/plumb**

Aspirin

(***ass***-pir-in) *ASA, Acetylsalicylic Acid*

Antiplatelet agent; Nonsteroidal Anti-Inflammatory Drug (NSAID)

Prescriber Highlights

- ► NSAID historically used for analgesic, anti-inflammatory, and antiplatelet effects in various species. Use in dogs and cats has been superseded by safer and/or more effective alternatives.
- ► Contraindicated in patients hypersensitive to aspirin or that have active GI bleeding; relatively contraindicated in patients with bleeding disorders, GI disease, asthma, concurrent glucocorticoid or other NSAID use, or renal insufficiency
- ► Aspirin has a long half-life in cats (ie, ≈30 hours; dose carefully); dogs are relatively sensitive to GI adverse effects (eg, ulcerations, vomiting, diarrhea).
- ► Avoid use in pregnant animals.
- ► Many drug and laboratory interactions

Uses/Indications

Aspirin is an NSAID used for its analgesic, antipyretic, and antiplatelet effects.

When treatment with cyclosporine is required, aspirin therapy may be advisable to offset cyclosporine-induced thromboxane synthesis.[1] Although aspirin appears to be effective as an antiplatelet agent, clopidogrel appears to be a safer and more effective antiplatelet drug in cats and dogs.[2,3]

Experimental studies in healthy horses failed to demonstrate reliable antiplatelet effects.[4,5]

Pharmacology/Actions

Aspirin inhibits cyclooxygenase (COX-1, prostaglandin synthetase), thereby reducing prostaglandin and thromboxane (TXA2) synthesis. These effects are thought to be how aspirin produces analgesia and reduces fever, platelet aggregation, and inflammation. Most cells synthesize new COX; however, platelets are not able to synthesize new COX, resulting in an irreversible inhibition of platelet aggregation. A study in dogs investigated platelet function effects of various aspirin doses and showed that doses less than 1 mg/kg/day or at 10 mg/kg/day did not have a statistically significant effect on platelet aggregation. Doses of 12 mg/kg/day inhibited platelet function and aggregation.[6] Variability in canine platelet response to aspirin appears to be due both to interindividual patient sensitivity to aspirin and differences in pharmacokinetics.[7] Aspirin appears to have minimal effect on platelet aggregation in cattle[8] and horses.[9]

Aspirin may decrease the clinical signs of experimentally induced anaphylaxis in calves and ponies.

Although aspirin does not directly inhibit COX-2, aspirin along with lipoxygenase (LOX), can modify COX-2 to produce the aspirin-triggered lipoxin (ATL) compound, which may have gastric mucosal protective actions.[10-12] This effect may explain why aspirin tends to have reduced gastric damaging effects when used over time.

Pharmacokinetics

Aspirin is rapidly absorbed from the stomach and proximal small intestine in monogastric animals. The rate of absorption is dependent on stomach content, gastric emptying times, tablet disintegration rates, and gastric pH. In cattle, oral doses of 50 mg/kg did not achieve therapeutic concentrations.[13]

During absorption, aspirin is partially hydrolyzed to salicylic acid, which is distributed widely throughout the body. The highest concentrations of salicylate are found in the liver, heart, lungs, renal cortex, and plasma. Aspirin's plasma protein binding is variable depending on species as well as serum salicylate and albumin concentrations. Lower salicylate concentrations are 90% protein bound, and higher salicylate concentrations are 70% protein bound.

Salicylate is metabolized in the liver primarily by conjugation with glycine and glucuronic acid via glucuronyl transferase. Cats are deficient in this enzymatic pathway, resulting in prolonged half-lives of 27 to 45 hours; this may cause drug accumulation. Minor metabolites formed include gentisic acid; 2,3-dihydroxybenzoic acid; and 2,3,5-trihydroxybenzoic acid. Gentisic acid appears as the only active metabolite, but low concentrations have an insignificant therapeutic role. Metabolism is determined by first-order and dose-dependent kinetics, depending on the metabolic pathway. Serum half-life is ≈8 hours in dogs, ≈38 hours in cats, and an average of 1.5 hours in humans. In general, steady-state serum concentrations increase to levels (proportionally) higher than expected with dose increases. These effects have not been well studied in domestic animals.

Kidneys rapidly excrete salicylate and its metabolites via filtration and renal tubular secretion. Significant tubular reabsorption occurs and is pH dependent. Raising urine pH to 5 to 8 can significantly increase salicylate excretion. Salicylate and metabolites may be removed using peritoneal dialysis or more rapidly by using hemodialysis.

Contraindications/Precautions/Warnings

Aspirin is contraindicated in patients that have demonstrated previous hypersensitivity reactions to aspirin or other salicylates or have GI erosions and ulcerations. Concurrent corticosteroid use may significantly increase the risk for GI pathology (eg, mucosal hemorrhages, erosions, ulcerations)[14]; presumably, concurrent NSAIDs have a similar risk. Relative contraindications include patients with hemorrhagic disorders, asthma, or renal insufficiency.

Aspirin should be used cautiously in cats due to their inability to rapidly metabolize and excrete salicylates. Neonatal animals are at risk for toxicity if given adult doses of aspirin.

High protein binding to plasma albumin indicates that patients with hypoalbuminemia may require lower aspirin dosages to prevent clinical signs of toxicity. Aspirin should be used cautiously in patients with severe hepatic failure or diminished renal function.

Aspirin therapy should be discontinued 1 week prior to surgical procedures because of its effects on platelet aggregation. In animals at high risk for thrombotic complications, some studies have advocated that aspirin should be discontinued 48 hours prior to surgical procedures.[15] Desmopressin acetate has been shown to reverse aspirin-induced platelet dysfunction in 3 dogs that required emergent surgery.[16]

Adverse Effects

The most common adverse effect of aspirin at therapeutic doses is GI irritation (eg, nausea, anorexia, vomiting, diarrhea). Varying degrees of occult GI blood loss may occur[14]; severe blood loss can cause anemia and panhypoproteinemia. In dogs, plain uncoated aspirin may irritate the gastric mucosa more than buffered aspirin or enteric-coated tablets. Hypersensitivity reactions in dogs are rarely reported. See ***Overdose/Acute Toxicity***.

Reproductive/Nursing Safety

Salicylate crosses the placenta, and fetal levels may exceed those found in the mother. High-dose aspirin (ie, 400 mg/kg/day) was fetotoxic and teratogenic when administered to pregnant beagles.[17] Salicylates are possible teratogens and have been shown to delay parturition; their use should be avoided during pregnancy, particularly during the later stages.[18]

Aspirin is excreted in human breast milk; veterinary significance is uncertain. Use with caution in nursing animals.

Overdose/Acute Toxicity

Clinical signs of mild toxicity (ie, less than 50 mg/kg) in dogs and cats include depression, anorexia, vomiting (may contain fresh blood or look like coffee grounds [ie, digested blood]), and diarrhea. Ingestions of greater than 100 mg/kg (in dogs) and 80 mg/kg (in cats) may cause hyperthermia tachypnea (ie, hyperventilation secondary to an initial respiratory alkalosis), increased respiratory rate, muscular weakness, pulmonary and cerebral edema, hypernatremia, hypokalemia, ataxia, and seizures; coma and eventual death are possible if left untreated.

There were 1939 single agent exposures to aspirin reported to the ASPCA Animal Poison Control Center (APCC) from 2009 to 2013. Of the 1749 dogs exposed, 712 had clinical signs; common signs included vomiting (75%), lethargy (21%), panting (9%), hyperthermia (8%), and bloody vomiting (7%). Of the 177 cats exposed, 54 had clinical signs; common signs included vomiting (56%), anorexia (22%), lethargy (13%), and bloody vomiting (6%).

Acute overdose treatment initially consists of gastric decontamination (if ingestion occurred within 12 hours), activated charcoal with an oral cathartic, IV fluid therapy, and gastroprotectants (eg, misoprostol); serial laboratory monitoring (eg, venous blood gas, electrolytes) may also be necessary. Balanced isotonic crystalloid IV solutions (eg, lactated Ringer's, *Normosol-R*, Plasmalyte-A) are preferred to treat dehydration and acid–base disturbances; additional treatment for metabolic acidosis may be required. Animals with severe metabolic derangements may require peritoneal dialysis, continuous renal replacement therapy (CRRT), or hemodialysis.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving aspirin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **ACE inhibitors** (eg, **benazepril, enalapril**): The effects of ACE inhibitors may be decreased with concomitant aspirin use; nephrotoxic effects of ACE inhibitors may be increased with concomitant aspirin use.
- **Alendronate:** Increased risk for upper GI adverse effects when used concurrently with aspirin
- **Aminoglycosides** (eg, **amikacin, gentamicin**): Some clinicians feel aspirin should not be given concomitantly with aminoglycoside antibiotics because of an increased likelihood for developing nephrotoxicity; however, the clinical significance of this interaction is unclear. Weigh the risks versus benefits when contemplating therapy.
- **Anticoagulants, Oral** (eg, **rivaroxaban, warfarin**): Concomitant aspirin use may increase the risk for bleeding.
- **Calcium Channel Blockers, Nondihydropyridine** (eg, **diltiazem**): The antiplatelet effects of aspirin may be increased with concurrent use, increasing the risk for bleeding.
- **Carbonic Anhydrase Inhibitors** (eg, **acetazolamide, dichlorphenamide**): High dose aspirin therapy used concurrently with dichlorphenamide is considered contraindicated, as metabolic acidosis may result.[19] Use caution with other carbonic anhydrase inhibitors.
- **Clopidogrel**: Concomitant aspirin use may increase the risk for bleeding.
- **Corticosteroids** (eg, **dexamethasone**, **prednis(ol)one**): Corticosteroids may increase the clearance of salicylates, decrease salicylate serum levels, and increase the risk for GI bleeding. One study in dogs showed no significant difference in gastric mucosal injury when ultra-low–dose aspirin (0.5 mg/kg/day) was added to prednisone therapy[20]; however, the addition of aspirin increased the incidence of mild self-limiting diarrhea.
- **Digoxin**: In dogs, aspirin demonstrates increased plasma levels of digoxin by decreasing digoxin clearance.
- **Furosemide**: Furosemide may compete with renal excretion of aspirin and delay aspirin excretion. Accumulated aspirin may cause clinical signs of toxicity in animals receiving high aspirin doses. Furosemide diuretic effect may be diminished.
- **Glucosamine**: Concomitant aspirin use may increase the risk for bleeding.
- **Heparin**: Concomitant aspirin use may increase the risk for bleeding.
- **Hyaluronidase**: The therapeutic benefits of hyaluronidase may be decreased; higher hyaluronidase doses may be required.
- **Insulin**: Hypoglycemic effects may be potentiated by aspirin.
- **Methotrexate**: Aspirin may displace methotrexate from plasma proteins and reduce renal tubular methotrexate excretion, increasing the risk for methotrexate toxicity.
- **NSAIDs** (eg, **carprofen, deracoxib, meloxicam**): Increased chance for developing GI ulceration exists when used concomitantly. Animals receiving aspirin therapy that will be replaced with a COX-2 NSAID should have a washout period of 3 to 10 days from when aspirin is discontinued and the NSAID is started.[21] In cats, it is recommended that a washout period of ≈7 to 10 days be used when aspirin therapy is switched to another NSAID.[22]
- **Omega-3 Fatty Acids**: May augment antiplatelet effects and the risk for bleeding[23]
- **Pentosan Polysulfate Sodium**: May increase the risk for bleeding
- **Phenobarbital**: Hepatic enzyme induction by phenobarbital may increase aspirin metabolism.
- **Probenecid**: At usual doses, aspirin may antagonize the uricosuric effects of probenecid.
- **Selective Serotonin Reuptake Inhibitors (SSRIs**; eg, **fluoxetine, paroxetine, sertraline**): The antiplatelet effects of aspirin may be increased with concurrent use, increasing the risk for bleeding.
- **Spironolactone**: Aspirin may inhibit the diuretic activity of spironolactone.
- **Sulfonylureas** (eg, **glipizide, glyburide**): Hypoglycemic effects may be potentiated by aspirin.
- **Tetracycline**: Antacids in buffered aspirin may chelate tetracycline products if given simultaneously; separate doses by at least 1 hour.
- **Tiludronate**: Serum concentrations of tiludronate may be decreased with concurrent aspirin therapy.
- **Urinary Acidifying Drugs** (eg, **ammonium chloride, ascorbic acid, methionine**): Urine acidifiers can decrease renal excretion of salicylates.
- **Urinary Alkalinizing Drugs:** (eg, **acetazolamide, sodium bicarbonate**): Urine alkalinizers significantly increase the renal excretion of salicylates.
- **Valproic Acid, Divalproex**: Serum concentrations of valproate products may be increased with concurrent aspirin therapy.
- **Vitamin E**: The antiplatelet effects of aspirin may be increased with concurrent use, increasing the risk for bleeding.

Laboratory Considerations

- At high doses, aspirin may cause false-positive results for **urinary glucose** if using the cupric sulfate method (eg, *Clinitest®*, Benedict's solution) or false-negative results if using the glucose oxidase method (eg, *Clinistix®*, *Tes-Tape®*).
- **Urinary ketones** measured by the ferric chloride method (ie, Gerhardt's method) may be affected if salicylates are in the urine (reddish-color produced during reaction). Salicylates may interfere with fluorescent methods used to determine urine **5-hydroxyindoleacetic acid (5-HIAA)**. Falsely elevated **vanillylmandelic acid (VMA)** may be seen with most methods if salicylates are in the urine. Falsely lowered **VMA** levels may be seen if using the Pisano method.
- Urinary excretion of **xylose** may be decreased if aspirin is given concurrently.
- Falsely elevated **serum uric acid** values may be measured if using colorimetric methods.
- Aspirin can decrease serum concentrations of **total T4** (ie, **thyroxine**).

Dosages

NOTE: There are no FDA-approved products or dosages for veterinary patients; all dosages listed here are extra-label.

DOGS:

Decrease platelet aggregation; antithrombotic: 2 – 10 mg/kg PO once daily. The ideal aspirin dosage, if any, for prevention of thromboembolism in dogs is unknown due to conflicting data and study limitations.[24-26]

Immune-mediated hemolytic anemia (IMHA): 1 – 2 mg/kg PO every 24 hours in combination with clopidogrel.[27]

Analgesic/antipyretic/anti-inflammatory: Anecdotal dosages range from 10 – 20 mg/kg PO of buffered aspirin every 12 hours to 20 – 30 mg/kg PO every 8 to 12 hours. NSAIDs that are FDA approved for dogs are preferred over aspirin because they have significantly fewer GI effects.

CATS:

Analgesic/antipyretic/anti-inflammatory: 10 mg/kg PO every 2 to 3 days (anecdotal); practically, ½ to one 81 mg tablet (ie, baby aspirin) on Monday, Wednesday, and Friday weekly.

Antithrombotic: High dose: 10 mg/kg PO every 2 to 3 days. Low dose: 5 mg per cat (NOT mg/kg) PO every third day. Clopidogrel appears superior to aspirin as an antiplatelet agent.[28,29]

HORSES:

Antiplatelet adjunctive treatment of laminitis: 5 – 10 mg/kg PO every 24 to 48 hours or 20 mg/kg PO every 4 to 5 days[30]

CATTLE:

Analgesic: 100 mg/kg PO every 12 hours[31,32]

FERRETS:

Analgesic: 10 – 20 mg/kg PO once daily[33]

RABBITS/RODENTS/SMALL MAMMALS:

Rabbits: 5 – 20 mg/kg PO once daily for low-grade analgesia[34]

Mice, Rats, Gerbils, Hamsters: 100 – 150 mg/kg PO every 4 hours

Guinea pigs: 87 mg/kg PO[35]

Monitoring

- Analgesic and/or antipyretic effects
- Adverse effects such as inappetence, lethargy, vomiting, and/or diarrhea
- Platelet function (ie, buccal mucosal bleeding time [BMBT]), including platelet aggregometry or platelet activation[2,26,28,36,37]
- Packed cell volume (PCV) and fecal occult blood (eg, guaiac) tests if indicated

Client Information

- Contact your veterinarian if your animal shows any signs of a decreased or lack of appetite, vomiting, diarrhea, and/or excessive bleeding or bruising.
- Black, tarry feces are a sign of serious internal bleeding and should be reported to your veterinarian immediately.

Chemistry/Synonyms

Aspirin is the salicylate ester of acetic acid. The compound occurs as a white crystalline powder or tabular or needle-like crystals. Aspirin is a weak acid with a pK_a of 3.5; it is slightly soluble in water and freely soluble in alcohol. Each gram of aspirin contains ≈760 mg of salicylate.

Aspirin may also be known as ASA, acetylsal acid, acetylsalicylic acid, acidum acetylsalicylicum, polopiryna, or salicylic acid acetate; many trade names are available.

Storage/Stability

Aspirin tablets should be stored in tight, moisture-resistant containers. Do not use products past the expiration date or if a strong vinegar-like odor is emitting from the bottle.

Aspirin is stable in dry air but readily hydrolyzes to acetate and salicylate when exposed to water or moist air; it then exudes a strong vinegar-like odor. The addition of heat speeds the hydrolysis rate. In aqueous solutions, aspirin is most stable at a pH of 2 to 3 and least stable at a pH less than 2 or greater than 8. In cases in which an aqueous solution is needed as a dosage form, the commercial aspirin-containing product *Alka-Seltzer®* remains stable for 10 hours at room temperature after dissolving in water, and 90 hours when refrigerated.[38]

Compatibility/Compounding Considerations

Compounded preparation stability: Aspirin is hydrolyzed by water to degradative byproducts, acetic acid and salicylic acid.

Although pharmacists compound aspirin suspensions in fixed oils, the long-term stability of these preparations is unknown.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: There are no known products that are FDA approved for use in animals. Aspirin predates formal FDA-approval regulations for its use in animals. There are no meat or milk withdrawal times listed for food-producing animals. In the interest of public health of salicylate-sensitive humans, contact the Food Animal Residue Avoidance Databank (FARAD) for further guidance with determining use and withdrawal times. See ***Appendix***.

Aspirin Tablets (Enteric-Coated): 81 mg; (OTC). Labeled for use in dogs

Aspirin Tablets (Buffered, Microencapsulated, Chewable for dogs): 60 mg, 120 mg, 150 mg, 300 mg, and 450 mg; *Canine Aspirin Chewable Tablets for Small & Medium* (150 mg) or *Large Dogs®* (450 mg); (OTC). Labeled for use in dogs

Aspirin Tablets 60 grains (3.9 g): Aspirin 60 Grains (OTC, Rx); Rx is labeled for use in horses, foals, cattle, calves, sheep, and swine; not for use in horses intended for food or in lactating dairy animals

Aspirin Boluses 240 grains (15.6 g): Aspirin 240 Grains Boluses, Aspirin Bolus (various); (OTC). Labeled for use in horses, foals, cattle, and calves; not for use in lactating animals

Aspirin Boluses 480 grains (31.2 g): Aspirin 480 Grains Boluses (various); (OTC). Labeled for use in mature horses and cattle

Aspirin Powder: 1 lb (various); (OTC); Aspirin Powder Molas-

ses-Flavored 50% acetylsalicylic acid in base; Aspirin USP 204 g/lb (apple flavored); Acetylsalicylic acid; (OTC). Labeled for use in horses, foals, cattle, calves, sheep, swine, and poultry

Aspirin Granules: 2.5 gram per 39 mL scoop (apple and molasses flavor); *Arthri-Eze Aspirin Granules*®; (OTC). Labeled for use in horses

Aspirin Liquid Concentrate (equivalent to 12% aspirin) for Dilution in Drinking Water in 32 oz bottles; (OTC). Labeled for addition to drinking water for swine, poultry, beef cattle, and dairy cattle

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix***.

HUMAN-LABELED PRODUCTS:

Aspirin, Tablets; chewable: 81 mg (1.25 grains); many trade names, generic; (OTC)

Aspirin, Tablets; plain uncoated: 325 mg (5 grains), and 500 mg (7.8 grains); many trade names, generic; (OTC)

Aspirin, Tablets; enteric coated: 81 mg, 325 mg, 500 mg, and 650 mg (10 grains); many trade names, generic; (OTC)

Aspirin, Tablets; extended-controlled release: 81 mg, 650 mg; many trade names, generic; (OTC)

Aspirin, Tablets; buffered uncoated: 324 mg (5 grains) and 325 mg (5 grains), with aluminum and/or magnesium salts; many trade names, generic; (OTC)

Aspirin, Tablets; buffered coated: 325 mg and 500 mg; many trade names, generic; (OTC)

Rectal suppositories, chewing gum, and effervescent oral dosage forms are commercially available for humans.

For the complete list of references, see **wiley.com/go/budde/plumb**

Atenolol

(a-***ten***-oh-lol) *Tenormin*®

Beta-Adrenergic Blocker

Prescriber Highlights

- ► Relatively specific beta-1-blocker used primarily for ventricular hypertrophy and tachyarrhythmias in small animals
- ► Minimal beta-2-blocking activity at recommended doses; comparatively safe for use in animals with asthma
- ► Contraindicated in patients with bradycardic arrhythmias or that are hypersensitive to it
- ► Negative inotrope, so caution is advised in patients with CHF, chronic kidney disease, and sinus node dysfunction
- ► Higher dosages may mask clinical signs of hyperthyroidism or hypoglycemia; may cause hyper- or hypoglycemia—use with caution in fragile diabetics.
- ► Usually well-tolerated, but primary adverse effects are lethargy, hypotension, or diarrhea
- ► If discontinuing therapy, gradual withdrawal is recommended.

Uses/Indications

Atenolol may be useful in the treatment of supraventricular tachyarrhythmias, premature ventricular complexes (PVCs, VPCs), and systemic arterial hypertension. It has also been used to reduce clinical signs of thyrotoxicosis in cats. A study evaluating atenolol as monotherapy for treating systemic hypertension in cats with hyperthyroidism found that most cats had a decrease in heart rate, but blood pressure was not controlled (defined as less than 160 mmHg) in 70% of cases, and additional drug therapy (eg, amlodipine or ACE inhibitor) was required.[1]

Although atenolol has been used in cats with subclinical hypertrophic cardiomyopathy, its utility is unproven. Atenolol given to cats with subclinical HCM had decreased heart rate, murmur grade, and LVOT obstruction, and to a lesser degree, frequency of ventricular ectopy.[2] However, it is still unclear if occurrence of sudden cardiac death or long-term outcome is influenced by atenolol administration.[2] A study (prospective, observational, open-label, clinical cohort) found no significant difference in mortality between subclinical cats treated or not treated with atenolol.[3]

Atenolol is often prescribed for semilunar (ie, aortic, pulmonary) valve stenosis; however, a retrospective study of dogs with subvalvular aortic stenosis failed to identify increased survival in those receiving atenolol as compared with those receiving no treatment.[4] In dogs, atenolol has also been used in combination with mexiletine to control arrhythmias associated with arrhythmogenic right ventricular cardiomyopathy (also known as boxer cardiomyopathy).[5]

Atenolol is relatively safe to use in animals with bronchospastic disease (eg, asthma).

Pharmacology/Actions

Atenolol is a relatively specific beta-1-blocker. At higher dosages, this specificity may be lost and beta-2-blockade can occur. Atenolol does not possess intrinsic sympathomimetic activity like pindolol, nor does it possess membrane-stabilizing activity like pindolol or propranolol. Cardiovascular effects secondary to atenolol's negative inotropic and chronotropic actions include decreased sinus heart rate, slowed AV conduction, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, reduced blood pressure, and inhibition of isoproterenol-induced tachycardia.[6]

Pharmacokinetics

In humans, only ≈50% to 60% of an oral dose is absorbed, but it is absorbed rapidly. In cats, atenolol is reported to have a bioavailability of ≈90%.[6] The drug has very low protein binding characteristics (5% to 15%) and is distributed well into most tissues. Atenolol has low lipid solubility and, unlike propranolol, only small amounts of atenolol are distributed into the CNS. Atenolol is minimally biotransformed in the liver; 40% to 50% is excreted unchanged in the urine and the bulk of the remainder is excreted in the feces unchanged as unabsorbed drug. Reported half-lives are 3.2 hours in dogs, 3.7 hours in cats,[6] and 6 to 7 hours in humans.[7] Duration of the beta blockade effect lasts for ≈12 hours in cats[6] and between 6 to 12 hours in dogs.[8] A study investigating the ability of atenolol to attenuate the heart rate response to isoproterenol in healthy dogs supported a dosing interval of less than 24 hours.[8]

Contraindications/Precautions/Warnings

Atenolol is contraindicated in patients hypersensitive to it and in patients with overt or decompensated heart failure, cardiogenic shock, greater than first-degree heart block, or sinus bradycardia. Atenolol may cause increased morbidity in cats with left-sided CHF caused by hypertrophic cardiomyopathy.[9]

Atenolol should be used cautiously in patients with significant renal insufficiency; dosage reduction is suggested in cats with reduced renal function.[10]

At high dosages, atenolol can mask the clinical signs associated with hypoglycemia. It can also cause hypoglycemia or hyperglycemia and, therefore, should be used cautiously in labile diabetic patients. In humans, atenolol use should be avoided in patients with untreated pheochromocytoma, and this is most likely applicable for veterinary patients as well.

Atenolol can mask the clinical signs (eg, tachycardia, hypertension) associated with thyrotoxicosis.

Genetic variants in the canine adrenoreceptor-1 (*ADRB1*) gene have been identified in dogs, and dogs with the polymorphism had lower heart rates both at baseline and while receiving atenolol than unaffected dogs.[11]

Exacerbation of signs has been reported following abrupt cessation of beta-blockers in humans. It is recommended to withdraw therapy gradually when patients have been receiving this drug chronically.

Adverse Effects

Adverse effects most commonly occur in geriatric animals or those that have acute decompensating heart disease. Adverse effects that are considered to be clinically relevant include bradycardia, inappetence, lethargy and depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, hypoglycemia, and bronchoconstriction (less so with beta-1-specific drugs [eg, atenolol]). Syncope and diarrhea have also been reported in dogs with beta-blockers. Lethargy and hypotension may be noted within 1 hour of administration.

In a case report, atenolol therapy was suggested to have exacerbated keratoconjunctivitis sicca in a dog.[12]

Reproductive/Nursing Safety

Atenolol crosses the placenta, and maternal and fetal serum concentrations are similar. Use during pregnancy does not appear to cause fetal structural anomalies in laboratory animals, but embryotoxicity and fetotoxicity have been noted in animals given 50 mg/kg/day. Fetal growth restriction has been observed in humans and animals, and in humans is correlated with length of atenolol use. Atenolol use during the antenatal period may result in beta blockade (eg, hypoglycemia, bradycardia) in newborns.[13]

Atenolol is excreted into, and accumulates in, human breast milk, reaching concentrations significantly greater than in human plasma. Due to the possibility of beta blockade in nursing animals, consider use of milk replacer.[13]

Overdose/Acute Toxicity

In dogs, clinical signs associated with overdose include bradycardia or tachycardia, lethargy, vomiting, and hypotension. Clinical signs in cats include hypo- or hypertension, bradycardia or tachycardia, lethargy, and vomiting.

Humans have apparently survived doses up to 5 g.[7] Clinical signs in humans are extensions of the drug's pharmacologic effects (eg, hypotension, bradycardia, bronchospasm, cardiac failure, hypoglycemia, hyperkalemia).

If overdose is from a recent oral ingestion, GI decontamination, including charcoal administration, may be considered. Monitor ECG, blood glucose, potassium, and blood pressure. For adverse cardiovascular effects, treatment is based on clinical signs. Use fluids and pressor agents (ie, dopamine or norepinephrine) to treat hypotension. Bradycardia may be treated with atropine. If atropine fails, isoproterenol given cautiously has been recommended. Insulin and dextrose may be needed for treatment of hyperkalemia and hypoglycemia. Use of a temporary artificial pacemaker may be necessary. Cardiac failure can be treated with pimobendan, diuretics, and oxygen. Glucagon may increase heart rate and blood pressure and reduce the cardiodepressant effects of atenolol.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving atenolol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-1 Adrenergic Antagonists** (eg, **prazosin, tamsulosin**): Increased risk for hypotension
- **Amiodarone**: Increased risk for bradycardia, hypotension, and cardiac arrest
- **Ampicillin**: May decrease atenolol bioavailability
- **Anesthetics** (**myocardial depressant agents**; eg, **halothane**): Additive myocardial depression may occur with the concurrent use of atenolol and myocardial depressant anesthetic agents. Reduction in dose or avoidance the day of anesthesia has been advised.
- **Antacids, Aluminum-, Calcium-, or Magnesium-Containing:** Can reduce oral absorption of atenolol; separate oral doses by 2 hours if possible.
- **Antidiabetic Agents** (eg, **acarbose, chlorpropamide, insulin, sulfonylureas** [eg, **glipizide, glyburide**]): Beta-blockers can alter blood glucose levels and/or mask signs of hypoglycemia.
- **Beta-2 Adrenergic Agonists** (eg, **albuterol, terbutaline**): At higher doses, atenolol may impair bronchodilation.
- **Bethanechol:** Concurrent administration may increase the risk for adverse effects of bethanechol, including cardiac conduction abnormalities and bronchoconstriction.
- **Bromocriptine:** Atenolol may enhance the vasoconstriction of ergot alkaloids causing hypertension and peripheral ischemia.
- **Bupivacaine:** May increase bupivacaine concentration
- **Buspirone:** Concurrent use may increase the risk for hypotension and orthostasis.
- **Diazepam:** Concurrent use may increase the risk for hypotension and orthostasis.
- **Diazoxide:** Concurrent use may increase the risk for hypotension and orthostasis.
- **Diphenhydramine:** Concurrent use may increase the risk for hypotension and orthostasis.
- **Doxepin:** Concurrent use may increase the risk for hypotension and orthostasis.
- **Cabergoline:** Concurrent use may enhance vasoconstriction effects of cabergoline.
- **Calcium-Channel Blockers** (eg, **amlodipine, diltiazem, verapamil**): Concurrent use may increase the risk for hypotension and bradycardia.
- **Clonidine**: Atenolol may exacerbate rebound hypertension after clonidine therapy is stopped. Risk for AV block may be increased.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): May interfere with the effects of atenolol by causing sodium and fluid retention
- **Digoxin**: Potential for increased bradycardia and/or digitalis toxicity. If used together, digoxin levels, heart rate, and blood pressure should be closely monitored.
- **Disopyramide**: Increased adverse effects (eg, severe bradycardia, asystole, heart failure) of disopyramide may occur. If possible, avoid combination, or monitor closely if both must be used.
- **Diuretics, Loop** (eg, **furosemide**): Concurrent use may increase the risk for hyperglycemia and hypertriglyceridemia.
- **Dobutamine**: Concurrent use may lead to increased peripheral resistance, increasing the risk for hypertension.
- **Dolasetron**: Concurrent use may lead to PR and/or QRS interval prolongation, increasing the risk for bradycardia and heart block.
- **Dopamine:** Concurrent use may lead to increased peripheral resistance, increasing the risk for hypertension.
- **Glucagon:** Atenolol may inhibit the hyperglycemic effects of glucagon.

- **Hypotensive Agents** (eg, **enalapril, hydralazine, nitroprusside, sildenafil, telmisartan**): Concurrent use may increase the risk for hypotension.
- **Lidocaine:** May increase lidocaine concentration
- **Methimazole/Carbimazole:** Ability to alter the pharmacokinetics of atenolol
- **NSAIDs** (eg, **carprofen, meloxicam, robenacoxib**): Potential for reduced hypotensive effects
- **Opioid, Partial Agonists** (eg, buprenorphine, butorphanol): Concurrent use may increase the risk for hypotension and orthostasis.
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**): May exhibit enhanced hypotensive effects
- **Reserpine**: Potential for additive effects (eg, hypotension, bradycardia)
- **Sympathomimetics** (eg, **albuterol, beta-effects of epinephrine, clenbuterol, metaproterenol, phenylpropanolamine, terbutaline**): May have their actions blocked by atenolol and may, in turn, reduce the efficacy of atenolol
- **Warfarin:** Mild prolongation of prothrombin time is possible.
- **Yohimbine:** May reduce atenolol efficacy

Dosages

DOGS:

Beta-blockade indications (eg, **tachyarrhythmias, obstructive heart disease)** (extra-label): 0.25 – 1.5 mg/kg PO every 12 hours.[14,15] Practically 6.25 mg (1/4 of a 25 mg tablet) to 50 mg per dog twice daily. Dosage is often started on the low end and titrated upward with atrial fibrillation or left ventricular systolic dysfunction; the high end of the dosing range is used for subvalvular aortic stenosis or pulmonary valve stenosis.

Arrhythmogenic right ventricular cardiomyopathy (also known as boxer cardiomyopathy) (extra-label): Atenolol 0.3 – 0.6 mg/kg PO every 12 hours in combination with mexiletine 5 – 8 mg/kg PO every 8 hours[5]

CATS:

Beta-blockade indications (eg, hypertrophic cardiomyopathy, tachycardia due to hyperthyroidism, hypertension [usually in combination with other drugs]; extra-label):

a. Initially, 6.25 mg/cat (NOT mg/kg) (ie, ¼ of a 25 mg tablet) PO every 12 hours. Dosage may be titrated upward (eg, 12.5 mg in the morning and 6.25 mg in the evening)[3,16,17]
b. **Tachycardia due to hyperthyroidism** 1 – 2 mg/kg PO every 12 hours[1]
c. **Dosage adjustment based on IRIS CKD staging**[10]:
IRIS stage II: 0.19 mg/kg PO every 12 to 24 hours
IRIS stage III: 0.125 mg/kg PO every 12 to 24 hours
IRIS stage IV: 0.06 mg/kg PO every 24 hours

FERRETS:

Left ventricular hypertrophy (extra-label):

a) 6.25 mg/ferret (NOT mg/kg) PO once daily[18]
b) 3.125 – 6.25 mg/ferret (NOT mg/kg) PO once daily[19,20] (⅛ to ¼ of a 25 mg tablet)

Monitoring

- Heart rate, pulse quality
- ECG
- Blood pressure
- Cardiac function (ie, echocardiography)
- Baseline and periodic renal panel with electrolytes
- Adverse effects

Client Information

- To be effective, the animal must receive all doses as prescribed.
- Notify your veterinarian if your animal becomes lethargic or exercise intolerant, develops shortness of breath or a cough, or develops a change in behavior or attitude.
- Do not stop therapy without first discussing with your veterinarian.
- While on this medication, your animal will need to be monitored periodically with blood tests and special heart testing. Do not miss these important follow-up visits.

Chemistry/Synonyms

Atenolol, a beta-1-adrenergic blocking agent, occurs as a white, crystalline powder. At 37°C (98.6°F), 26.5 mg is soluble in 1 mL of water. The pH of the commercially available injection is adjusted to 5.5 to 6.5.

Atenolol may also be known as atenololum or ICI-66082; many trade names are available.

Storage/Stability

Tablets should be stored at room temperature of 20°C to 25°C (68°F-77°F) and protected from heat, light, and moisture.

Compatibility/Compounding Considerations

Atenolol tablets may be crushed or split/cut into quarters or halves for appropriate dosing.

Compounded preparation/stability:

1) Atenolol oral suspensions should be compounded with sugar-free vehicles. Atenolol oral suspension compounded from either active pharmaceutical ingredients (API) or commercially available tablets has been published.[21] Triturating an appropriate amount of API or tablets with equal volumes of *Ora-Plus®* and *Ora-Sweet® SF* yields a 2 mg/mL oral suspension that retains more than 90% potency for 90 days stored at both 5°C (41°F) and 25°C (77°F). This investigation also reveals that the presence of sugars (*Ora-Sweet®* and simple syrup) reduces the potency of compounded atenolol suspensions to less than 90% in 7 to 14 days after compounding. Atenolol preparations are most stable at pH 4. Atenolol should be stored protected from light, as exposure to ultraviolet light results in drug decomposition at all pH ranges.
2) Atenolol suspension (flavored) 25 mg/mL. In a study, 150 mL batches were prepared by adding atenolol powder (3.75 g), PEG 4500 (51 g), processed beef and pork flavor powder (15 g), sodium saccharin (1.8 g), and 50 mL of distilled water then vigorously shaken.[22] Distilled water was added to volume (150 mL), shaken again, and stored in the refrigerator. Stability is still to be established, but pharmacokinetics in cats were comparable to tablets.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Atenolol Oral Tablets: 25 mg, 50 mg, and 100 mg; *Tenormin®*, generic; (Rx). Atenolol oral solution (5 mg/mL) may be available in some countries.

Atipamezole

(at-i-***pam***-a-zole) *Antisedan®,Revertidine®*

Alpha-2-Adrenergic Antagonist

Prescriber Highlights

- ► Reversal agent for alpha-2-adrenergic agonists (eg, dexmedetomidine, medetomidine, xylazine)
- ► Effects of atipamezole may subside before nontoxic concentrations of the offending agent are reached; repeat dosing may be necessary
- ► May reverse effects rapidly, including analgesia; animals should be observed and protected from self-harm or causing harm to others. When appropriate, alternative analgesia (non- alpha-2-adrenergic agonists) is recommended prior to atipamezole administration.
- ► Adverse effects may include vomiting, diarrhea, hypersalivation, tremors, or excitation.
- ► No safety data are available for use of this drug in pregnant or lactating animals.

Uses/Indications

Atipamezole is labeled for use in dogs as a reversal agent for dexmedetomidine and medetomidine. It is also used for reversal of other alpha-2-adrenergic agonists (eg, amitraz, detomidine, xylazine) in a wide range of species.

Pharmacology/Actions

Atipamezole competitively inhibits alpha-2-adrenergic receptors, thereby acting as a reversal agent for alpha-2-adrenergic agonists (eg, dexmedetomidine, medetomidine). Atipamezole reduces sedation, decreases blood pressure, increases heart and respiratory rates, and reduces the analgesic effects of alpha-2-adrenergic agonists. Atipamezole antagonizes the diuretic action of xylazine in dogs[1] and decreases medetomidine-induced tear production in cats 15 minutes after administration.[2] Atipamezole does not completely reverse the sedative and bradycardic effects in horses when administered 1 hour after sublingual detomidine gel.[3]

Pharmacokinetics

In dogs, peak plasma concentration occurs within ≈10 minutes after IM administration. Atipamezole is metabolized in the liver to compounds that are eliminated in the urine. Average plasma elimination half-life is ≈2 to 3 hours.

In horses, atipamezole has an average clearance and elimination half-life of 25 mL/kg/min and 53 minutes, respectively, after sublingual administration of detomidine gel.[3]

Contraindications/Precautions/Warnings

Atipamezole is contraindicated in patients hypersensitive to it.

Because reversal can occur rapidly, care should be exercised, as animals emerging from sedation and analgesia may exhibit apprehensive or aggressive behaviors. After reversal, animals should be protected from falling. Additional analgesia with a non-alpha-2-adrenergic agonist (eg, opioids) should be considered, especially after painful procedures.

When used as a reversal agent or as an antidote for alpha-2-agonist toxicity, effects of atipamezole may subside before nontoxic concentrations of the offending agent are reached; repeat dosing may be necessary.

Adverse Effects

Potential adverse effects include occasional vomiting, diarrhea, hypersalivation, tremors, and brief excitation or apprehensiveness. Transient fluctuations in blood pressure (ie, hypotension followed by hypertension) and increased respiratory rate may occur. Severe arterial hypotension has been noted in cats.[4]

In reptiles, IV administration reportedly can cause profound hypotension.[5,6]

Reproductive/Nursing Safety

The manufacturer states that atipamezole is not recommended in pregnant or lactating animals or in animals intended for breeding due to lack of data establishing safety in these animals.[7]

Because safety has not been established in animals, atipamezole should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Dogs receiving up to 10 times the labeled dosage exhibited panting, excitement, trembling, vomiting, soft or liquid feces, vasodilation of sclera, and some muscle injury at the IM injection site. Increased serum ALT and creatine kinase activity may occur. Specific overdose therapy is generally not necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving atipamezole and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- ■ **Alpha-2-Adrenergic Agonists** (eg, **amitraz, brimonidine, clonidine, detomidine, xylazine**): Atipamezole reduces the effects (toxic or therapeutic) of these agents by competing for alpha-2-adrenergic receptors. **NOTE**: This action is an expected outcome when atipamezole is used as a reversal agent.
- ■ **Alpha-1-Adrenergic Antagonists** (eg, **prazosin**): Atipamezole is a relatively specific alpha-2 blocker, but it can also partially block alpha-1 receptors, especially at high dosages, and reduce the effects of prazosin.

Dosages

DOGS:

Reversal of dexmedetomidine or medetomidine (label dosage; FDA-approved): 3750 µg/m² (NOT µg/kg) IM to reverse IV dexmedetomidine or medetomidine, and 5000 µg/m² (NOT µg/kg) IM to reverse IM dexmedetomidine or medetomidine. The product label provides dose tables in µg/kg and mL based on body weight.[7]

Reversal of dexmedetomidine or medetomidine (extra-label): 100 µg/kg IV or IO (intraosseous) as part of CPR to reverse alpha-2 agonists. Dosage is based on dexmedetomidine 10 µg/kg. If a higher dose of dexmedetomidine was administered, increase this dose accordingly.[8]

Reversal of oral transmucosal alpha-2-adrenergic agonists (extra-label):

1. Under experimental conditions, atipamezole 100 µg/kg IM administered 150 minutes after administration of detomidine buccal gel reversed detomidine effects in ≈6 to 9 minutes.[9]
2. From case reports in 2 dogs, atipamezole doses of 0.16 mg/kg IM or 0.04 mg/kg IM successfully reversed the effects of transmucosally-administered dexmedetomidine injection solution.[10]

Amitraz toxicity (extra-label): 50 µg/kg IM; dose may need to be repeated every 4 to 6 hours, as the half-life of amitraz is longer than atipamezole in dogs.[11]

CATS:

Reversal of medetomidine, when used alone or in combination with other sedatives or analgesics (extra-label): Administer a volume of atipamezole IM equal to the administered volume of medetomidine.[12]

Reversal of dexmedetomidine or medetomidine (extra-label): 100 µg/kg IV or IO as part of CPR to reverse alpha-2 agonists. Dosage is based on a 10 µg/kg dexmedetomidine dosage. If a higher dose of dexmedetomidine was administered, increase this dose accordingly.[8] For example, atipamezole 125 µg/kg IM was used in cats receiving dexmedetomidine 25 µg/kg as part of a multimodal analgesic protocol,[13] and 200 µg/kg IM followed 80 µg/kg medetomidine administration.[14]

Reversal of dexmedetomidine constant rate infusion (extra-label): 15 – 30 µg/kg IM, given upon discontinuation of dexmedetomidine CRI.[15]

Reversal of xylazine when used as an emetic (extra-label): 25 – 50 µg/kg IM or IV (slowly)[16]

HORSES:

Reversal of alpha-2-adrenergic agonist (eg, amitraz, xylazine) toxicity (extra-label): 0.1 mg/kg IV has been suggested.[17]

Reversal of dexmedetomidine-containing total IV anesthesia in foals (extra-label): 50 µg/kg IM if recovery was prolonged without return of swallow reflex, with 30 minutes of sternal recumbency within 60 minutes[18]

CATTLE:

NOTE: As a rule of thumb, if induction included ketamine or tiletamine/zolazepam, do not reverse alpha-2-adrenergic agonist sooner than 30 minutes, ideally 60 minutes, after induction. This timeframe will allow enough ketamine or tiletamine to be metabolized.

Reversal of alpha-2-adrenergic agonists (eg, detomidine, xylazine; extra-label):

1. 0.02 – 0.1 mg/kg IV to effect[19]
2. 0.02 – 0.06 mg/kg IV; average dose 0.03 mg/kg.[20] Cattle were immobilized with detomidine and tiletamine-zolazepam; average atipamezole administration was ≈20 minutes after anesthetic combination, and time to standing was ≈13 minutes after atipamezole administration.

Reversal of medetomidine sedation in cattle (adults and calves; extra-label): 0.1 mg/kg IV[21] or 0.2 mg/kg IV[22]

Reversal of xylazine immobilization or sedation in bovine calves (extra-label):

1. 0.03 mg/kg IV.[21,23] Lateral recumbency occurred ≈10 minutes after atipamezole administration.[23]
2. IM atipamezole dose at ¼ the xylazine dose; IV atipamezole 1/5 or 1/8- times the xylazine doses[24]

Reversal of detomidine epidural in bovine calves (extra-label): 0.05 mg/kg IV[25]

SHEEP/GOATS:

NOTE: As a rule of thumb, if induction included ketamine or tiletamine/zolazepam, do not reverse alpha-2-adrenergic agonist sooner than 30 minutes, ideally 60 minutes, after induction. This timeframe will allow enough ketamine or tiletamine to be metabolized.

Reversal of alpha-2-adrenergic agonists (eg, **detomidine, xylazine**; extra-label):

1. 0.02 – 0.1 mg/kg IV to effect[19]
2. 0.1 – 0.2 mg/kg IM or slow IV[26,27]

Reversal of medetomidine in sheep and goats: 0.2 mg/kg IV[22,28,30]

CAMELIDS:

NOTE: As a rule of thumb, if induction included ketamine or tiletamine/zolazepam, do not reverse alpha-2-adrenergic agonist sooner than 30 minutes, ideally 60 minutes, after induction. This timeframe will allow enough ketamine or tiletamine to be metabolized.

Reversal of alpha-2-adrenergic agonists (eg, **detomidine, xylazine**; extra-label):

1. 0.02 – 0.1 mg/kg IV to effect[19]
2. 0.1 – 0.2 mg/kg IM or slow IV[26,27]

Reversal of medetomidine in llamas: 0.125 mg/kg IV[31]

BIRDS:

Reversal agent for alpha-2-adrenergic agonists (eg, xylazine, dexmedetomidine; extra-label):

1. 0.5 mg/kg IM[32]
2. 250 µg/kg intranasally has been reported in pigeons. Antagonism of adverse cardiorespiratory and sedative effects, but not complete recovery, was observed within 10 minutes of atipamezole administration.[33]

RABBITS/RODENTS/SMALL MAMMALS:

Rabbits: reversal of medetomidine (extra-label): 0.5 mg/kg IM or SC; 0.25 mg/kg IV.[34] Alternatively, 0.75 mg/kg IV or IM[35]

Mice, Rats, Chinchillas, Gerbils, Hamsters, Guinea pigs: reversal of xylazine or medetomidine (extra-label): 0.1 – 1 mg/kg IM, IP, IV, or SC[36,37]

REPTILES:

NOTE: Reversal in reptiles may take longer (up to 1 hour) than in other species. Do **NOT** give IV as profound hypotension can occur.[5]

Reversal agent for alpha-2-adrenergic agonists (extra-label):

1. **Ball pythons** (extra label): 0.5 mg/kg SC[38]
2. **American alligators** (extra label): Adults 0.7 mg/kg IM, juveniles 1.2 mg/kg IM; administer in either masseter (jaw), or in triceps muscle in the front leg opposite that used to administer medetomidine.[39]
3. **Leopard geckos** (extra label): 1 mg/kg SC[40]
4. **Western Santa Cruz tortoises** (extra label): 0.5 mg/kg IM[41]
5. **Chinese box turtles** (extra label): 0.5 mg/kg IM administered in the right pectoralis major[42]

Monitoring

- Level of sedation and analgesia
- Heart rate and blood pressure
- Body temperature

Client Information

- Atipamezole should be administered by veterinary professionals only.
- Vomiting, diarrhea, hypersalivation, excitation, and tremors may occasionally be seen.
- If side effects are severe or persist after leaving the veterinary hospital, contact your veterinarian.

Chemistry/Synonyms

Atipamezole is an imidazole alpha-2-adrenergic antagonist. The injection is a clear, colorless solution.

Atipamezole HCl may also be known as MPV-1248 or *Antisedan*®, *Revertidine*®.

Storage/Stability

Atipamezole HCl injection should be stored at room temperature of 15°C to 30°C (59°F-86°F) and protected from light. Use within 90 days of first vial puncture.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Atipamezole HCl for Injection: 5 mg/mL in 10 mL multidose vials; *Antisedan*®, *Revertidine*®; (Rx). FDA-approved for use in dogs.

HUMAN-LABELED PRODUCTS: NONE

Atovaquone

(ah-***toe***-va-kwone) *Mepron®*

Oral Antiprotozoal Agent

Prescriber Highlights

- ► Atovaquone in combination with azithromycin appears effective in treating dogs with *Babesia gibsoni* infections and in cats for treating cytauxzoonosis. Alone, atovaquone is a second-line agent (after potentiated sulfonamides) for pneumocystosis in dogs.
- ► Limited use thus far; appears well tolerated by dogs and cats

Uses/Indications

Atovaquone, as a single agent, may be of benefit for treating pneumocystosis in dogs, but it is considered second-line therapy after potentiated sulfonamides.

Atovaquone in combination with azithromycin appears effective in treating dogs with *Babesia gibsoni* (Asian genotype) infections, particularly in dogs not immunosuppressed or splenectomized. A prospective, unmasked study in dogs comparing atovaquone in combination with azithromycin (AA) with a protocol using clindamycin, diminazene, and imidocarb (CDI) found that CDI had higher recovery and lower relapse rates, albeit longer therapy duration and slower reduction in parasite numbers than AA. The authors concluded that CDI was effective for initial therapy and when the M121I gene in *B gibsoni* had mutated.[1] Atovaquone with proguanil (combination product *Malarone®*), alone or in combination with doxycycline, also has demonstrated efficacy in dogs with *Babesia gibsoni* (Asian genotype) infections.[2] Dogs infected with *Babesia conradae* were PCR negative for infection after receiving atovaquone in combination with azithromycin[3,4]; this combination was also effective for treating dogs with piroplasmosis caused by *B vulpes* (also known as *B microti*-like piroplasm and *Theileria annae*).[5]

Atovaquone in combination with azithromycin is recommended for treatment of *Cytauxzoon felis* infections in cats.[6,7]

Pharmacology/Actions

Atovaquone's antiprotozoal mechanism of action is not completely understood. It is believed that the hydroxynaphthoquinones, like atovaquone, target protozoal cytochrome b (cytb) which selectively inhibits protozoan mitochondrial electron transport and causes inhibition of *de novo* pyrimidine synthesis. Unlike mammalian cells, certain protozoa cannot salvage preformed pyrimidines. Mutations in the *Babesia gibsoni* cytochrome b gene (M121I, M128I, or M128V) confer atovaquone resistance by affecting the drug's site of action.[1,8,9] Atovaquone treatment for *B gibsoni* in dogs may reduce recurrent parasite susceptibility to the drug.[10,11]

Cytauxzoon felis genotype *cytb1* may predict response to treatment with azithromycin and atovaquone combination[12]; however, resistance to atovaquone may occur during treatment.[13]

Atovaquone is not effective against viral, fungal, or bacterial infections.

Pharmacokinetics

Pharmacokinetic data for dogs or cats were not located. In humans after oral administration, bioavailability ranges from 23% to 47%. The presence of food, particularly high in fat, can increase bioavailability significantly (2+ fold over fasted administration). The drug is highly bound to human plasma proteins (99.9%) and concentrations in the CSF are approximately 1% of those found in plasma.

Elimination half-life in people is about 70 hours presumably due to enterohepatic recycling. There may be limited hepatic metabolism, but the bulk of absorbed drug is eventually eliminated unchanged in the feces.

Contraindications/Precautions/Warnings

No absolute contraindications for using atovaquone in dogs or cats have been documented. Animals with malabsorption syndromes or that cannot take the drug with food should have alternate therapies considered.

The drug is contraindicated in human patients that develop or have a prior history of hypersensitivity reactions to the drug.[14]

Adverse Effects

Atovaquone use in dogs and cats has been limited and the adverse effect profile is not well known. One study[15] using atovaquone in combination with azithromycin for treating *Babesia gibsoni* infections in 10 dogs reported that no adverse effects were noted. The combination product containing atovaquone and proguanil (*Malarone®*) may cause vomiting in dogs.[2]

In humans treated with atovaquone, rashes (up to 39% of treated patients) and gastrointestinal effects (nausea, vomiting, diarrhea) are the most frequently reported adverse effects.[14] Rashes or diarrhea may necessitate discontinuation of therapy. Other adverse effects reported in humans include hypersensitivity reactions, increased liver enzymes, CNS effects (headache, dizziness, insomnia), hyperglycemia, hyponatremia, fever, neutropenia, and anemia.

Reproductive/Nursing Safety

Studies in pregnant rats with atovaquone plasma concentrations approximately 2 to 3 times those found in humans receiving therapeutic dosages revealed no increase in teratogenicity.[14] Similar studies in rabbits showed increased maternal and fetal toxicity (decreased fetal growth and increased early fetal resorption).[14]

Little information is available on the safety of this drug during lactation. In rats, milk levels were approximately ⅓ those found in maternal plasma.[14] It is unlikely atovaquone in milk poses much risk to nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited information is available for any species. Minimum toxic doses have not been established; laboratory animals have tolerated doses up to 31.5 grams. The current recommendation for treating overdoses is supportive, based on clinical signs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with atovaquone either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Highly Protein-Bound Drugs** (eg, **azole antifungals, furosemide, NSAIDs**)**:** Because atovaquone is highly bound to plasma proteins (99.9%), it could theoretically displace other highly bound drugs, causing a transient increase in serum levels of each drug. These interactions are unlikely to be of clinical concern because increased free drug concentrations will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.

- **Metoclopramide**: Can decrease atovaquone plasma concentrations; use together only when no other options are available[14]
- **Rifampin**: Can decrease atovaquone plasma concentrations; concomitant use with atovaquone is not recommended[14]
- **Tetracycline**: Can decrease atovaquone plasma concentrations[14]

Laboratory Considerations

- None

Doses

DOGS:

***Babesia gibsoni* (Asian genotype), *B conradae*, or *B microti-like* (also known as *Theileria annae* or *B vulpes*) infections** (extra-label): Atovaquone 13.3 mg/kg PO every 8 hours with a fatty meal in combination with azithromycin 10 mg/kg PO every 24 hours for 10 days. Reserve immunosuppressive therapy for cases that do not respond within 3 to 5 days.[1,8,15-18] Single-agent treatment with atovaquone 30 mg/kg PO twice daily for 7 days cleared parasites within 2 days, but parasites re-appeared on blood smears 33 days after the last treatment.[10]

***Babesia gibsoni* (Asian genotype) infections** (extra-label): Using atovaquone with proguanil (combination tablet, *Malarone*®), atovaquone 17 – 25 mg/kg PO and proguanil 7 – 10 mg/kg PO every 12 hours with a fatty meal for 10 days with or without doxycycline 5 mg/kg PO every 12 hours for 30 days[2]

Pneumocystosis (extra-label): 15 mg/kg PO every 24 hours for 3 weeks[19]

CATS:

Cytauxzoonosis| *Cytauxzoon felis* (extra-label): Atovaquone 15 mg/kg PO every 8 hours in combination with azithromycin 10 mg/kg PO once daily (every 24 hours) for 10 days. All cases were also treated with IV fluids and most received heparin.[6,7] Consider placing a feeding tube to reduce the stress of administering these oral medications and ensure food intake to maximize antimicrobial absorption.

Monitoring

- Monitoring for therapy for *Babesia gibsoni* in dogs should include surveillance for potential adverse effects and signs for clinical efficacy.
- Baseline and periodic CBCs

Client Information

- Store medication at room temperature and away from bright light.
- Before using, shake bottle gently. This medicine may come as a thick suspension that can make measurement difficult. After drawing the medicine into the syringe, allow the medicine to settle into the syringe to remove air bubbles and ensure the full amount has been measured.
- To increase absorption from the gastrointestinal tract, give with food high in fat (eg, ice cream, tuna oil, butter, meat fat).
- If your veterinarian has placed a feeding tube in your animal to help with feeding and medication delivery, be sure you understand how to care for it.
- Side effects in dogs and cats for this medication are not well known. Report any significant effects such as rash, or severe or persistent vomiting or diarrhea, to your veterinarian.

Chemistry/Synonyms

Atovaquone is a synthetic, hydroxy-1,4-naphthoquinone antiprotozoal agent. It occurs as a yellow powder that is highly lipid soluble, insoluble in water and slightly soluble in alcohol.

Atovaquone may also be known as BW-556C, Atovacuona, Atovakvon, Atovakvoni, Atovaquonnum, *Malanil*®, *Mepron*®, or *Wellvone*®.

Storage/Stability

The commercially available oral suspension should be stored in a tight container at room temperature (15°C-25°C [59°F-77°F]) in tight containers and protected from bright light; do not freeze.

Compatibility/Compounding Considerations

In one study, 39 of 42 dogs in a shelter facility responded to treatment with compounded atovaquone capsules.[17]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

HUMAN-LABELED PRODUCTS:

Atovaquone Oral Suspension: 150 mg/mL (750 mg/5mL) in 210 mL bottles and in 5 mL and 10 mL unit-dose containers; citrus flavor; *Mepron*®; (Rx)

A combination tablet product containing atovaquone and proguanil HCl is available that has labeled indications (human) for malaria prophylaxis and treatment. It is available in two formulations, atovaquone 62.5 mg with proguanil 25 mg (*Malarone Pediatric*®) and atovaquone 250 mg with proguanil 100 mg (*Malarone*®).

Atracurium

(a-tra-***cure***-ee-um) *Tracrium*®

Nondepolarizing Neuromuscular Blocker

Prescriber Highlights

- ► Nondepolarizing neuromuscular blocking agent with minimal cardiovascular effects. It is valuable in patients under general anesthesia for which complete muscle relaxation is desired.
- ► Intraurethral administration of atracurium may assist patients with upper motor neuron urinary bladder signs and assist with urethral plug removal in male cats.
- ► Should not be given as a sole agent. It does *not* provide analgesia or sedation. Administer after general anesthesia has been induced.
- ► Reversal agents should be readily available when atracurium is used; effects can be reversed with cholinesterase inhibitors (eg, neostigmine, pyridostigmine).
- ► Administration of atracurium requires familiarization with ventilatory support and the monitoring required for safe use and to minimize risk for overdose.
- ► Store neuromuscular blockers segregated from other medications and with prominent warnings to mitigate the risk of inadvertent use

Uses/Indications

Atracurium is indicated as an adjunct to inhalant or IV general anesthesia to produce complete muscle relaxation during surgical procedures or mechanical ventilation and to facilitate endotracheal intubation. Atracurium is also used to aid in central bulbus positioning during ophthalmic surgery.

Intraurethral administration of atracurium in male cats with urethral plugs has been shown to increase the proportion (64% vs. 15% control) of obstruction removal.[1] Intraurethral administration also assisted with manual urinary bladder expression in dogs and cats with urine retention secondary to upper motor neuron signs (eg, T3-L3 myelopathy).[2]

Atracurium can be used safely in patients with significant renal or hepatic insufficiency.[3]

Pharmacology/Actions

Atracurium is a nondepolarizing neuromuscular blocking agent; it does not provide any analgesia or sedation.[4] It competitively binds

cholinergic receptor sites on the motor end-plate to antagonize acetylcholine, and results in paralysis of striated muscles. Atracurium is considered ¼ to ⅓ as potent as pancuronium.

Neuromuscular blockade (NMB) can be variably potentiated when used with different general anesthetic agents. A study in dogs demonstrated that, when compared with propofol, sevoflurane prolonged atracurium-induced NMB by about 15 minutes.[5]

At recommended doses, atracurium exhibits minimal cardiovascular effects, unlike most nondepolarizing neuromuscular blockers, and will not counteract bradycardia or vagal stimulation induced by other agents. At doses in excess of those used clinically, atracurium can stimulate histamine release. In humans receiving atracurium, less than 1% exhibit clinically significant adverse reactions or histamine release.

Pharmacokinetics

Atracurium has low liposolubility, limiting its ability to cross biological membranes.[6] In humans, maximal neuromuscular blockade generally occurs within 3 to 5 minutes after IV administration.[4] The duration of maximal blockade increases as the dose increases. In conjunction with balanced anesthesia, the duration of blockade generally persists for 20 to 35 minutes.

Systemic alkalosis may diminish the degree and duration of blockade; acidosis may potentiate it. Recovery times do not appreciably change after giving maintenance doses, so predictable neuromuscular blocking effects can be attained when the drug is administered at regular intervals. However, resistance may develop with chronic use.

Atracurium is metabolized by ester hydrolysis and Hofmann elimination that occur independent of renal or hepatic function. Physiologic pH and temperature can affect the elimination of atracurium. Increased body temperature can enhance drug elimination. Ester hydrolysis is enhanced by decreases in pH, while Hofmann elimination is reduced by decreases in pH.

Contraindications/Precautions/Warnings

Atracurium should not be given as a sole agent; it does *not* provide analgesia or sedation.[4] Atracurium should only be administered once general anesthesia has been induced and when endotracheal and ventilatory support and anticholinesterase reversal agents are readily available.[4]

Atracurium is contraindicated in patients that are hypersensitive to it and should be used cautiously in patients with a history of hypersensitivity to other neuromuscular blocking agents due to the risk of cross-sensitivity.[4] Neuromuscular blocking agents must be used with extreme caution in patients suffering from conditions that may potentiate neuromuscular blockade, such as electrolyte abnormalities and myasthenia gravis (MG). Atracurium has been used safely in dogs with MG at 16 to 20% of the recommended dose with close monitoring of neuromuscular transmission throughout the procedure.[7]

Caution is advised in patients where significant histamine release would be hazardous (eg, severe cardiovascular disease, asthma). In anesthetized dogs, partial neuromuscular blockade with atracurium decreases spontaneous ventilation and impairs the response to hypercarbia.[8] Atracurium has also been administered to dogs with centronuclear myopathy without significant adverse effects; however, these dogs required a longer recovery time.[9]

Recurarization has occurred due to residual atracurium in IV ports and fluid lines.[10,11]

Inadvertent administration of neuromuscular blocking agents to patients for which they were not intended may cause significant harm, including death. Neuromuscular blocking agents should be sequestered from other medications, and with access limited to those familiar with their use.[12] Prominent placement of warning labels (eg, "paralyzing agent- causes respiratory arrest," "causes respiratory paralysis; patient must be ventilated") on storage containers is highly recommended.

Adverse Effects

Clinically significant adverse effects are rare (less than 1%) in humans receiving recommended doses of atracurium and are usually secondary to histamine release.[4] They can include allergic reactions, inadequate or prolonged neuromuscular blockade, hypotension (usually manifesting in patients with pre-existing cardiovascular disease), vasodilation, bradycardia, tachycardia, dyspnea, bronchospasm, laryngospasm, rash, urticaria, or a reaction at the injection site. The risk of histamine release can be reduced by decreasing the initial dose or administration over 1 to 2 minutes.

An atracurium metabolite, laudanosine, is a CNS stimulant that may induce seizures.[4] The risk of seizures appears quite low in most patients, but may be increased with prolonged atracurium use or possibly in patients with hepatic impairment (laudanosine is hepatically cleared). In a case series, 3 pediatric dogs that had received atracurium CRI experienced new-onset seizures in the initial 24 hours following extubation.[13]

Infusion of anatracurium 0.5 mg/mL solution into the urinary bladder via sterile catheter appears to deliver sufficient atracurium to cross the urethral mucosa to induce at least partial paralysis of the urethral muscles without causing systemic adverse effects.[2]

Reproductive/Nursing Safety

Atracurium has demonstrated teratogenicity in rabbits at clinically relevant doses.[4] It is unknown if atracurium is excreted in human milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The IV LD_{50} in non-ventilated male mice, female mice, and rats was 1.9, 2.01, and 1.31 mg/kg, respectively.[4] Deaths occurred within 2 minutes due to respiratory paralysis.

Monitoring muscle twitch responses to peripheral nerve stimulation can minimize overdose risk.[4] Overdose signs can include histamine release (see ***Adverse Effects***), prolonged duration of muscle blockade, and cardiovascular effects (primarily hypotension); death may occur due to respiratory failure. Significant cardiovascular adverse effects in dogs have been reported with inadvertent overdoses.[14]

In addition to maintaining the patient's airway and providing appropriate cardiovascular support (eg, IV fluid administration, vasopressors), reversal of blockade may be accomplished by administering an anticholinesterase agent (eg, neostigmine 0.02 – 0.04 mg/kg IV) in conjunction with an anticholinergic (eg, atropine, glycopyrrolate).[15-18] Reversal is typically complete within 8 to 10 minutes. Because the duration of action of atracurium may be longer than the reversal agent, careful observation and monitoring are required, and re-administration of the reversal agent may be necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with atracurium have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetylcholinesterase Inhibitors** (eg, **neostigmine, pyridostigmine**): Antagonizes effect of neuromuscular blocking

actions of atracurium. This effect can be used advantageously to reverse neuromuscular blockade.

- **Corticosteroids (eg, dexamethasone, prednis(ol)one**): May enhance unwanted neuromuscular effects of corticosteroids (eg, muscle weakness). Consider therapy modification.
- **Other Muscle Relaxant Drugs** (eg, **alpha-2 agonists [eg, dexmedetomidine, xylazine], diazepam, methocarbamol**): May cause a synergistic or antagonistic effect
- **Phenobarbital**: Concomitant administration may decrease the effects and duration of neuromuscular blockade.
- **Succinylcholine:** May speed the onset of action and enhance the neuromuscular blocking actions of atracurium. Do not give atracurium until succinylcholine effects have diminished.

The following drugs may enhance and/or prolong the neuromuscular blocking activity of atracurium:

- **Aminoglycosides** (eg, **amikacin, gentamicin**[19,20])
- **Amphotericin B**
- **Anesthetics, Inhalant** (eg, **isoflurane,**[21] **sevoflurane**[5])
- **Antiarrhythmic Agents** (eg, **procainamide, quinidine**)
- **Beta Adrenergic Receptor Antagonists** (eg, **atenolol, propranolol**)
- **Calcium Channel Blockers** (eg, **amlodipine, diltiazem**)
- **Cyclosporine** (systemic)
- **Diuretics** (eg, **furosemide, hydrochlorothiazide**)
- **Lincosamide Antibiotics** (eg, **clindamycin**)
- **Lithium:** Competes with sodium and decreases acetylcholine release
- **Magnesium Salts** (parenteral route only)
- **Polymyxin B**
- **Tetracyclines** (eg, **doxycycline, minocycline**)
- **Vancomycin**

Dosages

NOTE: Administration of atracurium requires familiarization with the monitoring required for safe use and to minimize risk for overdose; mechanical ventilation and cardiovascular monitoring are required when administering atracurium.

DOGS:

Muscle relaxation during surgical procedures or endotracheal intubation (extra-label): 0.1 – 0.25 mg/kg IV initially; subsequent doses 0.1 mg/kg IV. Do not dose more frequently than every 20 to 30 minutes in critical patients unless a peripheral nerve stimulator is applied or voluntary movement is observed. Positive pressure ventilation, preferably mechanical, is required.[15,18,22-25]

Induction of respiratory muscle paralysis during mechanical ventilation: Loading dose: 0.2 – 0.5 mg/kg IV, then 5 minutes later, 3 – 9 µg/kg/min IV CRI.[26] Use dextrose 5% or sodium chloride 0.9% for diluent; do not mix with other drugs. Respiratory and cardiovascular monitoring should be provided.

Central positioning of bulbus for ophthalmic surgery: One treatment of 0.2 mg/kg IV under general anesthesia.[27,28] Subsequent doses of atracurium 0.1 mg/kg IV if needed during prolonged surgery. **NOTE:** No obvious mydriatic effect was found.

Urinary retention post-spinal cord lesion: Infuse 2 – 4 mL of atracurium 0.5 mg/mL solution into the urinary bladder via sterile placement of a urinary catheter. The volume administered is 2 mL for dogs weighing less than 10 kg (22 lb), 3 mL for dogs weighing 10 to 20 kg (22 to 44 lb), and 4 mL for dogs weighing over 20 kg (44 lb). The catheter is left in place for 5 minutes following the infusion. The urethral infusion is made using 0.2 mL of 10 mg/mL atracurium diluted in 3.8 mL of 0.9% saline to obtain a final volume of 4 mL with a concentration of 0.5 mg/mL of atracurium.[2]

CATS:

Adjunctive muscle relaxation during IV anesthesia and analgesia (extra-label)**:** 0.1 – 0.25 mg/kg IV initially; subsequent doses 0.1 mg/kg IV. Do not dose more frequently than every 20 to 30 minutes in critical patients unless a peripheral nerve stimulator is applied or voluntary movement is observed. Positive pressure ventilation, preferably mechanical, is required.[23,25,29]

Induction of respiratory muscle paralysis during mechanical ventilation: Loading dose: 0.2 – 0.5 mg/kg IV, then 5 minutes later, 3 – 9 µg/kg/min IV CRI.[26,30] Use dextrose 5% or sodium chloride 0.9% for diluent; do not mix with other drugs. Respiratory and cardiovascular monitoring should be provided.

Removal of urethral plugs in male cats and urinary retention post spinal cord lesion (extra-label): 0.2 mL of 10 mg/mL injection diluted in 3.8 mL of normal saline; final concentration 0.5 mg/mL. Instill 2 mL of this diluted solution via a urinary catheter with steady, gentle pressure over 5 minutes while the urethra is pressed with two fingers to prevent leakage. Retrograde flushing with saline is performed for a maximum of 20 seconds. If the obstruction is not removed with the first attempt, repeat the procedure.[1,2]

RABBITS/RODENTS/SMALL MAMMALS:

Muscle relaxation for periophthalmic surgery in rabbits (extra-label): 0.1 mg/kg IV[31]

HORSES:

Muscle relaxation during surgical procedures (extra-label): 0.07 – 0.2 mg/kg IV.[32-35] Subsequent doses of 0.04 mg/kg IV have been used.[33] Another source reported repeat doses of 10 – 30 mg per horse (NOT mg/kg).[34]

Central positioning of bulbus for ophthalmic surgery (extra-label): 0.1 mg/kg IV under general anesthesia. Relaxation occurred after ≈9 minutes and lasted ≈25-30 minutes.[36,37]

LLAMAS:

Muscle relaxation during surgical procedures (extra-label): 0.15 mg/kg IV; subsequent doses 0.08 mg/kg IV[38]

Central positioning of bulbus for ophthalmic surgery (extra-label): 0.2 mg/kg IV under general anesthesia[39]

SHEEP:

Muscle relaxation during surgical procedures in lambs (extra-label): 0.5 mg/kg IV; subsequent doses 0.17 mg/kg IV[21,40]

Monitoring

- Level of neuromuscular blockade. It is strongly recommended to be familiar with techniques required to monitor the level of neuromuscular blockade (eg, acceleromyography, train of four twitch ratio) when using atracurium.[35] Visual or tactile assessments of the level of blockade are inaccurate and unreliable. Correct placement of electrodes is essential to minimize direct muscle stimulation and prevent misinterpretation of the degree of the blockade and minimize risk for overdose.
- Assess ventilation (eg, arterial blood gas, $ETCO_2$)
- Heart rate and rhythm
- Blood pressure

Labaratory Considerations

- None noted.

Client Information

- Only professionals familiar with the use of atrucurium should use this drug.

Chemistry/Synonyms

Atracurium is a synthetic, nondepolarizing neuromuscular blocking agent. It is a bisquaternary, non-choline diester structurally similar

to metocurine and tubocurarine. It occurs as white to pale yellow powder with a pH of 3.25 to 3.65; 50 mg is soluble in 1 mL of water, 200 mg is soluble in 1 mL of alcohol, and 35 mg is soluble in 1 mL of normal saline.

Atracurium besylate may also be known as 33A74, atracurium besilate, BW-33A, *Abbottracurium®*, *Atracur®*, *Faulcurium®*, *Ifacur®*, *Laurak®*, *Mycurium®*, *Relatrac®*, *Sitrac®*, *Trablok®*, *Tracrium®*, or *Tracur®*.

Storage/Stability

The commercially available injection occurs as a clear, colorless solution. Store intact atracurium vials between 2°C to 8°C (36°F to 46°F) and protect against freezing. According to the US prescribing information, once removed from refrigeration to room temperature (25°C [77°F]), use within 14 days is recommended.[4] At room temperature, ≈5% potency loss occurs each month; when refrigerated, a 6% potency loss occurs over a year's time. Dilutions of 0.2 mg/mL or 0.5 mg/mL in sodium chloride 0.9%, dextrose 5% in water, or dextrose 5% in sodium chloride 0.9% are stable for up to 24 hours at room temperature or under refrigeration.[4]

Compatibility/Compounding Considerations

Compatibility is dependent on factors, such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Compatible with sodium chloride 0.9%, dextrose 5% in water, and dextrose 5% in sodium chloride 0.9% for dilution. **Compatible** in a syringe with alfentanil, fentanyl, midazolam, and sufentanil.

Y-site administration is **incompatible** with propofol, diazepam, and thiopental. Atracurium should not be mixed in the same IV bag or syringe or given through the same needle as alkaline drugs (eg, barbiturates) or solutions (eg, sodium bicarbonate) as precipitation may occur.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. The use of this drug may not be allowed in some animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance.

The International Federation for Equestrian Sports (FEI) lists this drug as a prohibited substance - banned.

HUMAN-LABELED PRODUCTS:

Atracurium Besylate Injection: 10 mg/mL in 5 mL single-use and 10 mL multi-use vials; *Tracrium®*, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Atropine

(***a***-troe-peen)

Anticholinergic, Antidote

See also ***Atropine Ophthalmic***

Prescriber Highlights

- ► Prototype antimuscarinic agent used for a variety of indications (eg, treatment or prevention of bradycardia, anesthetic premedication, antidote for cholinergic agents and toxins)
- ► Contraindicated when anticholinergic effects would be detrimental (eg, narrow-angle glaucoma, tachycardia, ileus, urinary obstruction, hypertrophic or restrictive cardiomyopathy, isoxazole mushroom toxicity)
- ► Adverse effects are dose-related and anticholinergic in nature (ie, dry respiratory and gastrointestinal [including oral] secretions, initial bradycardia (occasionally) then tachycardia, slowed GI motility, urine retention, and mydriasis/cycloplegia).
- ► Many drug interactions

Uses/Indications

The principal veterinary indications for systemic atropine include:

- As a preanesthetic to prevent, or during anesthesia to treat, vagally-mediated bradycardia. Treatment of bradyarrhythmias as they occur is recommended/preferred over indiscriminate use of atropine to prevent arrhythmias because atropine-mediated adverse effects (eg, tachycardia) can be detrimental in some patients (eg, patients with cardiac disease). Anticholinergics are more commonly needed for procedures that increase vagal tone (eg, ophthalmologic procedures and procedures that result in traction of the viscera).
- As a preanesthetic agent to prevent or reduce secretions of the oral/respiratory tract. This use has significantly declined as modern inhalants are unlikely to cause hypersecretion.
- Treatment of sinus bradycardia, sinoatrial arrest, and incomplete atrioventricular (AV) block
- During cardiopulmonary resuscitation
- To differentiate vagally-mediated bradycardia from other causes
- As an antidote for overdoses of cholinergic agents (eg, physostigmine) or to mitigate adverse effects from therapeutic use (eg, prior to an edrophonium test for diagnosing myasthenia gravis, pretreatment for imidocarb diproprionate[1]
- As an antidote for organophosphate, carbamate, muscarinic mushroom, or blue-green algae intoxication
- To reduce secretions that are a result of hypersialosis
- Adjunctive treatment of bronchoconstrictive disease, although atropine use results in greater systemic adverse effects than does N-butylscopolammonium bromide (butylscopolamine)[2]
- In conjunction with anticholinesterases (edrophonium, neostigmine) administered for reversal of drugs used for nondepolarizing neuromuscular blockade (eg, curare derivatives)

Pharmacology/Actions

Atropine, like other antimuscarinic agents, competitively inhibits acetylcholine or other cholinergic stimulants at postganglionic parasympathetic neuroeffector sites. Pharmacologic effects are dose related. Salivation, bronchial secretions, and sweating (not in horses or other species under adrenergic rather than cholinergic control of sweating) are inhibited at low doses. At moderate systemic doses, atropine dilates and inhibits accommodation of the pupil,[3] increases intraocular pressure,[4,5] and increases heart rate (and myocardial oxygen consumption), although heart rate may decrease initially. High doses decrease GI and urinary tract motility, and very high doses inhibit gastric secretion. High doses may also block nicotinic receptors

at the autonomic ganglia and at the neuromuscular junction.

In a retrospective study, a positive response to atropine predicted successful medical treatment in dogs with sick sinus syndrome.[6] This is also true for most other vagally-mediated bradyarrhythmias.

Pharmacokinetics

Atropine sulfate is well absorbed after oral administration, IM injection, inhalation, or endotracheal administration.[7] After IV administration, peak effects in heart rates occur within 3 to 4 minutes. The pharmacokinetic profile after intraosseous administration to healthy pigs was comparable to the IV route.[8]

Atropine is well distributed throughout the body and crosses into the CNS and placenta.

Atropine is metabolized in the liver and excreted into the urine. Approximately 30% to 50% of a dose is excreted unchanged into the urine. The plasma half-life in humans has been reported to be between 2 and 3 hours.

As compared with glycopyrrolate, atropine has a faster onset, shorter duration of action, and causes more profound tachycardia. See ***Glycopyrrolate.***

In healthy horses administered topical atropine sulfate 1% ophthalmic solution in 1 eye every 6 hours the first day, then every 12 hours for 4 days, atropine was not detected in serum, and no objective evidence of ileus was noted.[9] A small but significant increase in heart rate was noted in healthy dogs receiving 3 doses of atropine 1% ophthalmic solution in each eye every 6 hours.[10] Gut sounds were reduced by ≈50% in healthy sheep given atropine eye drops.[11]

Contraindications/Precautions/Warnings

Atropine is contraindicated in those hypersensitive to it or other anticholinergic drugs and in those with narrow-angle glaucoma,[4] posterior synechiae, tachycardia secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, hypertrophic or restrictive cardiomyopathy, unstable cardiac status during acute hemorrhage, asthma, and urine retention caused by bladder outlet obstruction (eg, prostatic hyperplasia). Atropine is also contraindicated in the treatment of poisoning with isoxazole mushrooms (eg, *Amanita muscaria, A pantherine, Tricholoma muscarium*) that contain muscimol and/or ibotenic acid.[12] Atropine's pharmacologic actions are similar to ibotenic acid and may worsen clinical signs of isoxazole mushroom poisoning.

Alpha-2 agonist-mediated bradycardia is primarily a reflex secondary to alpha-2-mediated vasoconstriction with a resultant increase in blood pressure. Administration of anticholinergic agents in dogs or cats at the same time or after alpha-2 agonists leads to adverse cardiovascular effects (secondary tachycardia, prolonged hypertension, and cardiac arrhythmias).[13–15] The routine use of anticholinergics simultaneously with, or after, dexmedetomidine in dogs or cats is neither recommended nor necessary because blood pressure is generally normal to high. During anesthesia, if both the heart rate AND the blood pressure are low, an anticholinergic drug (atropine or glycopyrrolate) can be used as part of blood pressure support.[16] Another treatment option is reversal of the alpha-2 agonist (see ***Atipamezole***).

Antimuscarinic agents should be used with extreme caution in animals with known or suspected GI infections and inflammatory diseases (eg, severe ulcerative colitis), ileus, obstructive GI disease (eg, pyloric stenosis, foreign body obstruction), and GI toxin exposure. Atropine or other antimuscarinic agents can decrease GI motility and prolong retention of the causative agent(s) or toxin(s), resulting in prolonged clinical signs. Antimuscarinic agents must also be used with extreme caution in animals with autonomic neuropathy (eg, myasthenia gravis [unless used to reverse adverse muscarinic effects secondary to therapy]).

Antimuscarinic agents should be used with caution in animals with hepatic or renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmia, or esophageal reflux and in geriatric or pediatric animals. Antimuscarinic agents may also reduce the epinephrine dose at which epinephrine promotes arrhythmias.

Systemic atropine should be used cautiously, or not at all, in horses, as it may decrease gut motility and induce colic in susceptible animals. Use of atropine in ruminants may result in inappetence and rumen stasis that can persist for several days.

Atropine may aggravate some signs seen with amitraz toxicity, leading to hypertension and further inhibition of peristalsis. It is not recommended for treating bradycardia secondary to dexmedetomidine. See ***Drug Interactions***.

Atropine is reportedly not effective in treating bradycardia in puppies younger than 14 days of age or kittens younger than 11 days of age.[17] Anticholinergic induced tachycardia can exacerbate myocardial oxygen deficits and cause myocardial damage.[18]

Some rabbit populations have endogenous atropinesterase that breaks down atropine, rendering it ineffective; glycopyrrolate is often the anticholinergic of choice in this species. See ***Glycopyrrolate***.[19]

Atropine impairs sweat gland function in species with cholinergic control of sweating, and hyperthermia may develop in susceptible animals that receive the drug in warm ambient temperatures.

Adverse Effects

Adverse effects are exacerbations of the drug's pharmacologic effects and are generally dose related. At standard doses, effects tend to be mild in relatively healthy animals. The more severe effects typically occur with high or toxic doses. GI effects can include dry mouth (ie, xerostomia), increased viscosity of secretions, dysphagia, constipation, and vomiting. Respiratory secretions may become viscous and more difficult to clear from the airway. Genitourinary effects may include urinary retention. CNS effects may include stimulation, drowsiness, ataxia, seizures, and respiratory depression. Sedation and/or agitation can occur after atropine administration to conscious patients and could (rarely) impact anesthetic recovery. Ophthalmic effects include mydriasis, cycloplegia, photophobia, and an increase in intraocular pressure. Cardiovascular effects include sinus tachycardia (usually transient), increased myocardial oxygen consumption, bradycardia (initially, or at very low doses), hypertension, hypotension, tachyarrhythmia (eg, premature ventricular complexes [PVCs], ventricular tachycardia), and circulatory failure. The latter effects are generally related to excessively high dosages.

Reproductive/Nursing Safety

Atropine use in pregnancy may cause fetal tachycardia. In humans, atropine rapidly crosses the placenta,[20] but human data suggest there is low risk for use during pregnancy.

Atropine may be excreted into the breast milk; however, no human adverse events have been reported, and limited human data suggest it is probably compatible with lactation in humans.[20]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

For signs of atropine toxicity see ***Adverse Effects*** above. CNS depression occurs with larger doses, and medullary depression is the most common cause of overdose-related death.

GI decontamination with activated charcoal and saline cathartics may be warranted if there has been a recent oral ingestion. Treatment consists of supportive care measures (eg, maintaining hydration, providing respiratory support, managing arrhythmia). Do not use phenothiazines, as they may contribute to anticholinergic effects. Standard treatments for shock may be necessary. Atropine is not removed by dialysis.

The use of physostigmine is controversial and should probably be

reserved for animals that exhibit extreme agitation and are at risk for injuring themselves or others, or for cases in which supraventricular tachycardia or sinus tachycardia are severe or life-threatening.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with atropine have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetylcholinesterase Inhibitors** (eg, **edrophonium, neostigmine**): May reduce atropine effects. Atropine may intentionally be administered immediately prior AChI to prevent peripheral muscarinic effects.
- **Alpha-2 Agonists** (eg, **dexmedetomidine, medetomidine, xylazine**): Use of atropine with alpha-2 agonists may significantly increase arterial blood pressure, heart rate, and the incidence of arrhythmia.[21,22] Clinical use of atropine or glycopyrrolate to prevent or treat bradycardia caused by alpha-2 agonists is controversial and use together is discouraged; this may be particularly important when using higher doses of the alpha-2 agonist. See ***Contraindications/Precautions/ Warnings***.
- **Amitraz**: Atropine may aggravate some signs seen with amitraz toxicity, leading to hypertension and further inhibition of peristalsis.
- **Cholinergic Agents** (eg, **bethanechol, pilocarpine**): Concurrent use of cholinergic agonists and antagonists should be avoided.
- **Corticosteroids** (eg, **prednis(ol)one**): Long-term use may increase intraocular pressure.
- **Domperidone**: Atropine may reduce domperidone efficacy.
- **Epinephrine**: May reduce dose at which epinephrine promotes arrhythmias
- **Ketoconazole**: Increased gastric pH may decrease GI absorption; administer oral atropine 2 hours after ketoconazole.
- **Latanoprost**: Atropine counteracted the miotic effect of latanoprost without altering intraocular pressure (IOP) in healthy dogs.[23]
- **Loperamide:** Concurrent use may further reduce GI motility and increase risk of ileus and constipation.
- **Metoclopramide**: Atropine and its derivatives may antagonize the actions of metoclopramide.
- **Monoamine Oxidase (MAO) Inhibitors** (eg, **linezolid, selegiline**): Concurrent use with atropine may increase risk for hypertensive crisis.
- **Potassium Salts (oral)**: Reduced GI motility may increase risk for GI irritation from solid oral dosage forms of potassium.
- **Promotility Agents** (eg, **cisapride, erythromycin, metoclopramide**): Atropine may antagonize effects on GI peristalsis.

The following drugs may enhance the activity or toxicity of atropine and its derivatives:

- **Amantadine**
- **Anticholinergic Agents (other)** (eg, **glycopyrrolate, hyoscyamine, oxybutynin**)
- **Antihistamines** (eg, **diphenhydramine, hydroxyzine**)
- **Opioids** (eg, **fentanyl, hydromorphone, methadone, morphine**)
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**)
- **Procainamide**
- **Primidone**
- **Skeletal Muscle Relaxants** (eg, **cyclobenzaprine, dantrolene, dicyclomine, methocarbamol**)
- **Tricyclic antidepressants** (eg, **amitriptyline, doxepin, clomipramine**)

Laboratory Considerations

None noted

Dosages

NOTE: FDA approval has not been required for atropine products in animals. All dosages should be considered extra-label.

DOGS/CATS:

Preanesthetic adjuvant: Generally, 0.02 – 0.04 mg/kg IM or IV. Consider smaller doses (0.01 mg/kg) in geriatric or debilitated animals. The veterinary label lists 0.06 mg/kg IV, IM, or SC, but this is not currently recommended.

During cardiopulmonary cerebral resuscitation (CPCR) efforts to block vagal tone and treat/eliminate bradyarrhythmias: Atropine at 0.04 mg/kg IV or intraosseous (IO) is most likely to be useful (although not strongly supported in the literature) in dogs and cats with asystole or pulseless electrical activity (PEA) associated with high vagal tone. Due to a lack of any clear detrimental effects, routine use of atropine during CPR can be considered (0.04 mg/kg IV or IO; may repeat every other BLS [basic life support] cycle, which are 2 minutes in duration). Intratracheal administration (preferably past the level of the carina) at 0.15 – 0.2 mg/kg (diluted 1:10 in saline or water) can be considered when IV or IO access is not possible.[24]

Atropine response test (ART):

- **Rishniw Preference**: 1) Record ECG at baseline; 2) administer atropine at 0.04 mg/kg IV; 3) wait 15 minutes; and 4) record ECG for at least 2 minutes (use slow paper speed). If the response is incomplete, repeat steps 2 through 4. Persistent sinus tachycardia at greater than 140 bpm is expected in most dogs with vagally-mediated bradycardia.
- **Kittleson Preference**: 1) Record ECG at baseline; 2) administer atropine at 0.04 mg/kg SC; 3) wait 30 minutes; and 4) record ECG for at least 2 minutes (use slow paper speed). Persistent sinus tachycardia at greater than 140 bpm is expected in most dogs with vagally-mediated bradycardia.[25]

Organophosphate (OP) and carbamate toxicity:

a) If poisoning or overdose is suspected: Obtain baseline heart rate; give test dose of atropine at 0.02 mg/kg IV. If heart rate increases and pupils dilate, organophosphate toxicity is not likely. Look for other causes of signs, as it generally requires 10 times (0.2 mg/kg) the test dose to resolve muscarinic signs of OP/carbamate poisoning. Muscarinic signs (eg, SLUDDE [salivation, lacrimation, urination, defecation, dyspnea, emesis], miosis, bradycardia) can be treated with atropine at 0.2 mg/kg (administer ¼ of the dose IV, remainder IM or SC). Repeat as required. Atropine will not reverse nicotinic (eg, muscular weakness) or CNS (eg, seizures) effects.[26] See ***Overdose/Acute Toxicity***.

b) Atropine 0.025 – 0.2 mg/kg IV repeated until clinical signs of poisoning are relieved. Several sequential injections may be required, depending on the severity of the poisoning. In severe cases, give ¼ of the dose IM or by slow IV injection and the remainder SC; in less severe cases, give the whole dose SC. The frequency of the dose administered should be such that the recurrence of moderate or severe signs of poisoning are treated, typically at 3- to 4-hour intervals. Atropine is only effective

several minutes after administration and maximum effect may be delayed 5 to 10 minutes after injection.[27]

Muscarinic mushroom toxicity: Initially, atropine at 0.04 mg/kg (administer ¼ of the dose IV, remainder IM or SC). Dose can be titrated up and repeated if needed to control severe signs; avoid overtreating. Muscarinic signs (eg, SLUDDE [salivation, lacrimation, urination, defecation, dyspnea, emesis], miosis, bradycardia) usually resolve in 30 minutes. Give supportive care (eg, IV fluids) as needed.[28] **WARNING:** Atropine is contraindicated in the management of poisoning with isoxazole mushrooms (eg, *Amanita muscaria, A pantherine, Tricholoma muscarium*) that contain muscimol and/or ibotenic acid.[12]

FERRETS:

Premedication and treatment of vagally-mediated bradycardia: 0.04 – 0.05 mg/kg IV, SC, or IM[29] or intratracheally for CPR

RABBITS/RODENTS/SMALL MAMMALS:

Premedication and treatment of vagally-mediated bradycardia in rodents (rats, mice, guinea pigs): 0.04 – 0.05 mg/kg IM, SC, IP

Premedication and treatment of vagally-mediated bradycardia in rabbits: 0.05 – 0.25 mg/kg IM, SC. Atropine is ineffective in ≈50% of rabbits due to the presence of atropinase, so glycopyrrolate is preferred.

Organophosphate and carbamate toxicity: 10 mg/kg SC every 20 minutes[30]

CATTLE:

Organophosphate and carbamate toxicity: 0.5 – 1 mg/kg; give ¼ of the dose IV and the remainder SC or IM; repeat and titrate dose as required.

HORSES

Vagal-induced bradyarrhythmia: **NOTE**: This use is uncommon because bradycardia and bradyarrhythmias, like second-degree AV block (Mobitz Type 1) are normal in horses.

a) 0.01 – 0.02 mg/kg IV[31]
b) 0.03 – 0.06 mg/kg SC[27]

Bronchodilator: 0.1 – 0.15 mg/kg IV[32] (practically, 5 – 7 mg IV per horse [450 kg; 990 lb] [NOT mg/kg]) can serve as a rescue medication in cases of severe airway obstruction; however, it is not commonly used because it has a short duration of action (0.5 to 2 hours), and adverse effects (eg, ileus, CNS toxicity, tachycardia, increased mucus secretion, impaired mucociliary clearance) limit its use to a single rescue dose.[33] ***Butylscopolamine*** appears better tolerated and equally effective.[2]

Organophosphate and carbamate toxicity:

a) 0.2 mg/kg (administer ¼ of the dose IV, remainder IM or SC); repeat every 1.5 to 6 hours as necessary to control clinical signs associated with toxicity. Mydriasis and absence of salivation can be used as therapy endpoints. Do not overuse, as ileus is a concern.
b) 0.025 – 0.2 mg/kg repeated until clinical signs of poisoning are relieved. In severe cases, give ¼ of the dose IM or by slow IV injection and the remainder SC; in less severe cases, give the whole dose SC. The frequency of the dose administered should be such that the recurrence of moderate or severe signs of poisoning are treated, typically at 3- to 4-hour intervals. Atropine is only effective several minutes after administration and maximum effect may be delayed 5 to 10 minutes after injection.

SWINE:

Organophosphate and carbamate toxicity:

a) 0.2 mg/kg (administer ¼ of the dose IV, remainder IM or SC); repeat every 1.5 to 6 hours as necessary to control clinical signs associated with toxicity. Mydriasis and absence of salivation can be used as therapy endpoints.
b) 0.025 – 0.2 mg/kg repeated until clinical signs of poisoning are relieved. In severe cases, give ¼ of the dose IM or by slow IV injection and the remainder SC; in less severe cases, give the whole dose SC. The frequency of the dose administered should be such that the recurrence of moderate or severe signs of poisoning are treated, typically at 3- to 4-hour intervals. Atropine is only effective several minutes after administration and maximum effect may be delayed 5 to 10 minutes after injection.

Adjunctive preanesthetic agent: 0.02 – 0.04 mg/kg IV or IM[34,35]

SHEEP/GOATS:

Organophosphate and carbamate toxicity: 0.6 – 1 mg/kg (administer ¼ – ⅓ of the dose IV, remainder SC). Given every 4 to 5 hours as needed, but should be slowed down or stopped to avoid GI stasis and bloat.[36,37]

NEW WORLD CAMELIDS:

Organophosphate and carbamate toxicity: 0.2 – 0.4 mg/kg (administer ½ dose IV, ½ dose SC)

BIRDS:

Organophosphate and carbamate toxicity:

a) 0.2 mg/kg IM every 3 to 4 hours as needed. Use with pralidoxime (except in raptors) at 10 – 20 mg/kg IM every 8 to 12 hours as needed. Do not use pralidoxime to treat carbamate poisoning. To assist in diagnosing organophosphate poisoning (in conjunction with history and clinical signs) in birds presenting with bradycardia, atropine at 0.02 mg/kg IV may be given. If bradycardia does not reverse, organophosphate toxicity should be considered.[38]
b) **Raptors**: 0.5 mg/kg; (administer ¼ of the dose IV, remainder IM). Repeat 3 or 4 times per day if bradycardia persists.[39]

Preanesthetic agent: 0.04 – 0.1 mg/kg IM or SC once[40]

During cardiopulmonary cerebral resuscitation (CPCR) efforts for adjunctive treatment of bradycardia: 0.2 mg/kg IV with ventilation and epinephrine (0.1 mg/kg diluted in saline and into the trachea)[41]

REPTILES:

Organophosphate and carbamate toxicity in most species: 0.1 – 0.2 mg/kg SC or IM as needed[42]

Ptyalism in tortoises: 0.05 mg/kg SC or IM once daily[42]

Monitoring

Dependent on dose and indication:

- Heart rate and rhythm
- Blood pressure
- GI motility (via auscultation) in horses and potentially in ruminants
- Urination, defecation capability
- Hydration; dry mouth and secretions (eg, respiratory)

Client Information

- Injections of atropine should only be performed by veterinary staff and in the clinic where adequate monitoring is available.
- Be sure your animal has free access to plenty of fresh, clean water when receiving this medicine. Encourage drinking if dry mouth is a problem.
- Animals treated with atropine may have dilated pupils and experience difficulty urinating or passing feces (constipation) for a short period of time afterward. Contact your veterinarian if these problems continue, or if your animal appears weak, has low energy or is unable to urinate and defecate normally.

Chemistry/Synonyms

Atropine sulfate, the prototype tertiary amine antimuscarinic agent, is derived from naturally occurring atropine. Commercial dosage forms contain atropine sulfate, which has greater solubility than atropine. Atropine is a racemic mixture of D-hyoscyamine and

L-hyoscyamine. The L-form of the drug is active; the D-form has practically no antimuscarinic activity. Atropine sulfate occurs as colorless and odorless crystals or white, crystalline powder. One gram of atropine sulfate is soluble in 0.5 mL of water, 5 mL of alcohol, or 2.5 mL of glycerin. Aqueous solutions are practically neutral or only slightly acidic. Commercially available injections may have the pH adjusted to 3 to 6.5.

Atropine may also be known as DL-hyoscyamine. Atropine sulfate may also be known as atrop. sulph., atropine sulphate, or atropini sulfas; many trade names are available.

Storage/Stability

Atropine sulfate for injection should be stored at room temperature between 15°C and 30°C (59°F-86°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a veterinary hospital pharmacist for more specific information.

Atropine sulfate for injection is reportedly **compatible** with the following agents: butorphanol, chlorpromazine, cimetidine (not with pentobarbital), dimenhydrinate, diphenhydramine, dobutamine, fentanyl, glycopyrrolate, hydromorphone, meperidine, morphine, nalbuphine, pentazocine, pentobarbital (for 5 minutes, not 24 hours), perphenazine, prochlorperazine, promazine, promethazine (also with meperidine), and scopolamine.

Atropine sulfate is reported physically **incompatible** with methohexital (forms a haze after 15 minutes) and norepinephrine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Atropine Sulfate for Injection: 0.54 mg/mL (1/120 grain) in 100 mL vials; (Rx)

Atropine Sulfate for Injection: 15 mg/mL (organophosphate treatment), 100 mL vial; (Rx)

Atropine is labeled for use in dogs, cats, horses, cattle, sheep, and swine in the United States, but FDA approval has not been required. No withdrawal times are mandated when used in food animals in the United States, but the Food Animal Residue Avoidance Databank (FARAD) recommends a 28-day meat and 6-day milk withdrawal time when used in food animals at doses up to 0.2 mg/kg.[43] For guidance in determining use and associated withdrawal times, contact FARAD (see ***Important Contact Information*** in ***Appendix***).

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Atropine Sulfate for Injection:
0.05 mg/mL in 5 mL syringes; (Rx)

0.1 mg/mL in 5 mL and 10 mL syringes; (Rx)

0.3 mg/mL in 1 mL and 30 mL vials; (Rx)

0.4 mg/mL in 1 mL amps and 1 mL, 20 mL, and 30 mL vials; (Rx)

0.5 mg/mL in 1 mL and 30 mL vials and 5 mL syringes; (Rx)

0.6 mg/mL in 1 mL amps; (Rx)

0.8 mg/mL in 0.5 mL and 1 mL amps and 0.5 mL syringes; (Rx)

1 mg/mL in 1 mL amps and vials and 10 mL syringes; (Rx)

0.5 mg, 1 mg, and 2 mg prefilled auto-injectors; *AtroPen*®; (Rx)

Historically, atropine tablets (0.4 or 0.6 mg; Rx) have been available.

Auranofin

(au-***rane***-oh-fin) *Ridaura*®

Oral Gold Immunosuppressive

Prescriber Highlights

- ► May be used for pemphigus complex and idiopathic polyarthritis in dogs or cats, and possibly as adjunctive treatment for osteosarcoma in dogs
- ► Requires intensive monitoring
- ► Contraindications include systemic lupus erythematosus (as it exacerbates the condition) and hypersensitivity to gold products.
- ► Renal, hepatic, and GI toxicity possible; dose-dependent immune-mediated thrombocytopenia, hemolytic anemia, or leukopenia have been observed
- ► Expensive; doses may need to be compounded

Uses/Indications

Auranofin treats idiopathic polyarthritis and pemphigus complex in dogs and cats. It is also anecdotally reported to be useful for eosinophilic granuloma complex, plasma cell pododermatitis, and stomatitis in cats. Clinicians report that auranofin may be less toxic but also less efficacious than injectable gold (aurothioglucose; no longer marketed). Limited information is published on the safety and efficacy in dogs and cats; therefore, auranofin should be reserved for cases that are unresponsive to or do not tolerate more conventional immunomodulatory therapy, such as glucocorticoids and azathioprine.

Auranofin is also being studied for its potential anticancer effects.[1–3] In dogs with osteosarcoma, a significant increase in overall survival was observed when auranofin was added to standard-of-care treatment (ie, amputation and carboplatin), specifically in male dogs.[1]

Pharmacology/Actions

Auranofin is an orally available gold salt. Gold has anti-inflammatory, antirheumatic, immunomodulating, and antimicrobial effects. The exact mechanisms for these actions are not well understood. Gold is taken up by macrophages, which inhibits phagocytosis and may inhibit lysosomal enzyme activity. Gold inhibits the release of histamine and decreases prostaglandin production. Auranofin suppresses helper T cells without affecting suppressor T-cell populations. It also has in vitro inhibitory effect on DNA, RNA, and protein synthesis.

The antineoplastic effects of auranofin are thought to be due to inhibition of thioredoxin reductase (TrxR2) and reactive oxygen-induced apoptosis.[1–3] Inhibition of TrxR2 is thought to be the mechanism by which auranofin decreases lung metastases of osteosarcoma.[3,4]

Auranofin is also being studied for its potential antimicrobial effects,[5–12] including broad and potent in vitro and in vivo antifungal activity, which suggests that auranofin might be a promising novel antifungal, mainly considering its ability to cross the blood–brain barrier.[13] More research is needed to determine the clinical utility of these effects.

Pharmacokinetics

Auranofin is rapidly metabolized, and pharmacokinetic data are based on gold concentrations rather than auranofin drug concentrations.

In dogs, gold from orally administered auranofin was 15% to 38% absorbed, and the half-life of gold was 19.5 days; excretion occurred primarily via the feces.[14]

In humans, auranofin is absorbed when given by mouth (20% to 25% of the gold), primarily in the small and large intestines.[15] Auranofin is moderately plasma protein bound. Auranofin crosses the

placenta and is distributed into maternal milk. Tissues with the highest concentrations of gold are kidneys, spleen, lungs, adrenal glands, and liver. Accumulation of gold does not appear to occur. About 15% of an administered dose (60% of the absorbed dose) is excreted by the kidneys, the remainder in the feces.

Contraindications/Precautions/Warnings

Gold salts are contraindicated in systemic lupus erythematosus due to potential disease exacerbation, and in patients with a history of adverse reactions to gold products. Do not use in animals with suppressed bone marrow or animals receiving other bone marrow suppressive agents, such as azathioprine or cyclophosphamide. Only administer auranofin to animals when other less expensive and less toxic therapies are ineffective. Ensure all parties are aware of the potential pitfalls of auranofin therapy and are willing to accept the associated risks and expenses.

Adverse Effects

Dogs may exhibit dose-dependent immune-mediated thrombocytopenia,[16] hemolytic anemia, or leukopenia. If an immune response occurs, it is recommended to discontinue auranofin and administer steroids. Auranofin has a high incidence of dose-dependent GI disturbances, particularly diarrhea in dogs.[17,18] This generally resolves with dose reduction or discontinuation of the drug. Renal toxicity may manifest as proteinuria. Hepatotoxicity may occur. Renal and hepatic toxicities are less likely than either the GI or hematologic effects (eg, thrombocytopenia, anemia, leukopenia). Dermatoses (including toxic epidermal necrolysis) and corneal and oral ulcers have been associated with auranofin therapy.

Reproductive/Nursing Safety

Auranofin has been demonstrated to be teratogenic and maternotoxic in rabbits[15]; it should not be used during pregnancy unless the owner accepts the potential risks for use.

Following auranofin administration, gold is excreted in the milk of rodents. Trace amounts appear in the serum and red blood cells of nursing offspring. Gold may cause adverse effects in nursing offspring; switching to milk replacer is recommended if auranofin is continued. Gold is slowly excreted; persistence in milk will occur even after drug discontinuation.

Overdose/Acute Toxicity

Limited data are available. The minimum lethal oral dose in rats is 30 mg/kg. Recommend employing gastric-emptying protocols after acute overdoses when applicable. Chelating agents (eg, penicillamine, dimercaprol) for severe toxicities are controversial. One human patient overdosed over 10 days and developed various neurologic sequelae, but eventually (after 3 months) recovered completely after drug discontinuation and chelation therapy.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions with auranofin have either been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antimalarial Drugs** (eg, **primaquine**, **quinacrine**): Use with gold salts is not recommended due to the increased potential for hematologic or renal toxicity.
- **Immunosuppressive Agents** (eg, **azathioprine, high-dose corticosteroids, leflunomide, pyrimethamine**): Auranofin's safety when used with these agents has not been established; use with caution.
- **Myelosuppressive Agents** (eg, **chlorambucil, chloramphenicol, cyclophosphamide**): Concurrent use may increase the risk for myelosuppression.
- **Penicillamine**: Use with gold salts is not recommended due to the increased potential for hematologic or renal toxicity.
- **Theophylline, Aminophylline**: Decreased theophylline concentration may occur

Laboratory Considerations

- In humans, response to **tuberculin skin tests** may be enhanced; veterinary significance is unclear.

Dosages

DOGS:

Immune-mediated skin diseases in patients unresponsive to or that cannot tolerate conventional therapy (eg, glucocorticoids or azathioprine) (extra-label): 0.05 – 0.2 mg/kg PO every 12 hours (up to 9 mg/day total dose per dog); often in conjunction with glucocorticoids. Allow a 4-week "washout" before starting therapy after azathioprine discontinuation. A lag phase of 6 to 12 weeks can occur before seeing a response. If remission is achieved, pulse therapy of 1 – 2 mg/kg PO every other week for one month and then once monthly can be attempted. If remission is maintained for 6 months, one can attempt discontinuation.

Adjunct therapy for osteosarcoma in addition to standard first-line therapy (eg, surgery and carboplatin) (extra-label): 6 mg/dog (NOT mg/kg) PO every 3 days for dogs weighing less than 15 kg (33 lb), 9 mg/dog (NOT mg/kg) PO every 3 days for dogs weighing more than 15 kg (33 lb)[1]

CATS:

Immune-mediated skin diseases (eg, feline pemphigus, eosinophilic granuloma complex, plasma cell pododermatitis, and stomatitis) (extra-label): 0.2 – 0.3 mg/kg PO every 12 hours; must be reformulated for accurate dosing[19]

Monitoring

The following should be performed prior to therapy, then monthly for 2 to 3 months, then every other month:

- Hepatic and renal function tests
- Urinalysis
- CBC, with platelet counts; **NOTE**: eosinophilia may denote impending reaction.

Client Information

- May require several months before seeing a positive response.
- Requires commitment to the twice-daily dosing schedule
- Discuss therapy costs and potential side effects before initiating therapy.
- While your animal is taking this medication, it is important to return to your veterinarian for laboratory work. Do not miss these important follow-up visits.

Chemistry/Synonyms

Auranofin is an orally administered gold compound that occurs as a white, odorless, crystalline powder. It is slightly soluble in water and soluble in alcohol. Auranofin contains 29% gold.

Auranofin may also be known as SKF-39162, SKF-D-39162, *Crisinor®, Crisofin®, Goldar®, Ridaura®,* or *Ridauran®.*

Storage/Stability

Store capsules in tight, light-resistant containers at 15C° to 30°C (59°F-86°F).

Compatibility/Compounding Considerations
No specific information was noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

Azathioprine
(ay-za-***thye***-oh-preen) *Imuran®, Azasan®*
Immunosuppressant

Prescriber Highlights
- ► Purine-antagonist, immunosuppressive agent used in dogs for a variety of autoimmune diseases
- ► Not generally used in cats, as they are highly sensitive to myelosuppression
- ► May take several weeks for immunosuppression to occur; doses are given daily the first 2 weeks
- ► Often used in combination with corticosteroids to reduce doses and frequency of each drug
- ► Myelosuppression is the principal adverse effect; GI effects include GI distress, anorexia, pancreatitis, hepatotoxicity. Use with caution in patients with hepatic disease.
- ► Known mutagen and teratogen
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies azathioprine as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
In dogs, azathioprine is used primarily as an immunosuppressive agent in the treatment of immune-mediated diseases, but no large, controlled, prospective studies documenting its efficacy were located. In patients with immune-mediated hemolytic anemia, azathioprine is often recommended at the start of treatment in combination with other drugs. Azathioprine is often used in combination with corticosteroids (eg, prednis(ol)one) for synergy and to reduce the incidence of adverse effects of each drug by allowing dosage reductions and, eventually, every other day dosing of each drug.

When used in combination with cyclosporine, azathioprine has been used to prevent rejection of MHC-matched renal allografts in dogs.

Pharmacology/Actions
Azathioprine antagonizes purine metabolism by causing breaks in DNA and RNA secondary to incorporation into nucleic acids and termination of the replication process. Cellular metabolism may become disrupted by the drug's ability to inhibit coenzyme formation. Evidence suggests azathioprine interferes with CD28 costimulation of T lymphocytes by converting the costimulatory signal from CD28 to trigger apoptosis.[1]

Azathioprine has greater activity on delayed hypersensitivity and cellular immunity than on humoral antibody responses. Clinical response to azathioprine may not be observed for up to 5 weeks.

Pharmacokinetics
Azathioprine is poorly absorbed from the GI tract. It is rapidly metabolized to 6-mercaptopurine (6-MP), which is then taken up by lymphocytes and erythrocytes. The remaining drug in the plasma is further metabolized in the liver and GI tract and excreted by the kidneys. Only minimal amounts of either azathioprine or mercaptopurine are excreted unchanged. Half-life is variable and estimated to be 2 hours. Azathioprine and mercaptopurine are 30% protein bound.

Cats have low activity of thiopurine methyltransferase (TPMT) (ie, one of the routes used to metabolize azathioprine). Approximately 11% of humans have low TPMT activity; these patients have a greater incidence of bone marrow suppression but also greater azathioprine efficacy. Dogs have variable TPMT activity similar to that seen in humans. This may explain why some canine breeds respond better to and/or develop more myelotoxicity than others. TPMT activity is lower in giant schnauzers and much higher in Alaskan malamutes than in other breeds. However, one study in dogs did not show significant correlation between TPMT activity in RBCs and drug toxicity.[2]

Contraindications/Precautions/Warnings
Azathioprine is contraindicated in patients with previous hypersensitivity reactions and should be used cautiously in patients with hepatic or renal dysfunction. Because azathioprine suppresses the immune system, animals may be at an increased risk for infections or neoplastic illnesses with long-term use.

Use of azathioprine in cats is rarely recommended, as they are more susceptible to azathioprine's myelosuppressive effects because of TPMT deficiencies.

In humans, chronic immunosuppression with azathioprine has been shown to increase the risk for malignancy (eg, lymphoma, skin cancer) and serious infection.

Prescription/order errors have occurred when azithromycin and azathioprine have been confused. The use of "tall man" letters (ie, writing part of the drug's name in upper case) on prescriptions/orders may reduce the risk for errors: aZITHROmycin; azaTHIOprine.

The National Institute for Occupational Safety and Health (NIOSH) classifies azathioprine as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects
The principal adverse effects associated with azathioprine in dogs are GI effects (eg, vomiting, anorexia, diarrhea), bone marrow suppression, pancreatitis, and hepatotoxicity.[4] In dogs, there is a reported 8% incidence of myelosuppression, manifested primarily as leukopenia, but poorly regenerative anemia and thrombocytopenia have also been seen.[5,6] Myelosuppression typically occurs after several months of treatment.[5] Hepatotoxicity has also been described, and a retrospective study of 34 dogs reported a 15% incidence of subclinical increases in ALT and ALP activities occurring within the first several weeks of treatment, with only 1 dog showing signs related to hepatotoxicity (ie, anorexia, diarrhea).[5] However, marked myelosuppression and/or hepatotoxicity appear to be idiosyncratic (not dose dependent); these effects may be reversible if caught early enough and with drug withdrawal.[7]

In dogs recovering from immune-mediated hemolytic anemia, taper the drug dose slowly over several months and monitor for early signs of relapse. Rapid withdrawal can lead to a relapse of disease.

Reproductive/Nursing Safety
Azathioprine crosses the placenta and is mutagenic and teratogenic (eg, skeletal malformation, visceral anomalies) in laboratory animals at clinical doses. This drug has caused fetal harm during human pregnancies. Avoid use during pregnancy whenever possible. Decreased spermatogenesis and reduced sperm viability have been demonstrated in mice.[8]

The azathioprine metabolite 6-MP is distributed into maternal milk; a milk replacer should be used while the dam is receiving azathioprine.[8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The oral LD_{50} for single doses of azathioprine in mice and rats are 2500 mg/kg and 400 mg/kg, respectively.[9]

There were 122 single agent exposures to azathioprine reported to the ASPCA Animal Poison Control Center (APCC) from 2009 to 2013. Common clinical signs observed following an overdose include vomiting and anorexia; increased liver enzyme activity and thrombocytopenia may also occur. Supportive treatment and GI decontamination protocols are recommended in the event of an overdose. The drug is partially dialyzable (≈45% removed) because of moderate protein binding.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing information specific for veterinary patients be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving azathioprine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **ACE Inhibitors** (eg, **benazepril, enalapril**): Increased potential for hematologic toxicity
- **Allopurinol**: The hepatic metabolism of azathioprine may be decreased by concomitant administration of allopurinol; in humans, the azathioprine dose should be reduced to ¼ or ⅓ of the usual dose if both drugs will be used together.
- **Aminosalicylates** (eg, **mesalamine, olsalazine, sulfasalazine**): Increased risk for azathioprine toxicity
- **Myelosuppressive Agents, Other** (eg, **cyclophosphamide, leflunomide, sulfa-/trimethoprim**): Increased potential for hepatic and hematologic toxicities
- **NonDepolarizing Muscle Relaxants** (eg, **pancuronium, tubocurarine**): The neuromuscular blocking activity of these drugs may be inhibited or reversed by azathioprine.
- **Purine Antagonists** (eg, **mercaptopurine, mycophenolate, thioguanine**)**:** Increased risk for toxicity due to similar mechanism of action
- **Vaccines** (live and inactivated): May diminish vaccine efficacy and enhance adverse effects of vaccines
- **Warfarin**: Potential for reduced anticoagulant effect

Laboratory Considerations

- None

Doses

DOGS:

Immunosuppressive agent (all dosages listed below are extra-label; no prospective studies supporting any dosage protocol were noted): Many anecdotal protocols for use of azathioprine exist. General recommendations are to initially give 2 mg/kg PO every 24 hours for 1 to 4 weeks, then reduce the dosage to 0.5 – 2 mg/kg PO every other day. After treatment has started, a lag period of at least 1 week, and often as long as 3 to 5 weeks, is required before significant clinical immunosuppressive effect can be observed. Some treatment protocols include concurrent glucocorticoid administration. During the maintenance phase of treatment (ie, every other day administration), glucocorticoids are often given on days azathioprine is not given. Sample dosage protocols follow:

a) **Inflammatory bowel disease**: Initially, 2 mg/kg PO every 24 hours for 2 weeks, then tapered to 2 mg/kg PO every other day for 2 to 4 weeks, then 1 mg/kg PO every other day. It may take 2 to 6 weeks before beneficial effects are seen.[10]

b) **Immune-mediated hemolytic anemia (IMHA) and or immune-mediated thrombocytopenia (IMT)**: In conjunction with immunosuppressive doses of glucocorticoids (eg, prednis(ol)one), give azathioprine 2 mg/kg or 50 mg/m^2 PO every 24 hours for 2 to 3 weeks, then reduce azathioprine to every other day.[7,11,12]

c) **Adjunctive therapy for myasthenia gravis in nonresponsive patients**: 2 mg/kg PO every 24 hours for 2 weeks, then every 48 hours.[13] CBC should be repeated every week for the first month and then monthly thereafter. Azathioprine should be discontinued if WBC counts fall below 4,000 cells/µL or neutrophil counts are less than 1,000 cells/µL. Reevaluate serum AChR antibody concentrations every 4 to 6 weeks. Taper azathioprine to every other day when clinical remission occurs and serum AChR antibody concentrations are normalized.[14]

d) **Perianal fistulas (anal furunculosis)**: Initially, 2 mg/kg PO every 24 hours until there is a reduction in the size, number, or inflammation of the fistula, total WBC count is less than 5000 cells/µL, neutrophil count is less than 3500 cells/µL, or platelet count is less than 160,000 cells/µL. Then, reduce azathioprine to 2 mg/kg PO every other day for 12 weeks, unless myelosuppression develops. After 12 weeks, reduce dose to 1 mg/kg PO every other day for 12 months. In addition, give prednisone 2 mg/kg PO every 24 hours for the first 2 weeks of therapy, then 1 mg/kg PO every 24 hours for 2 weeks, and then discontinue. In a study in which all dogs were placed on a limited antigen diet, no correlation with efficacy and lymphocyte blastogenesis effect was seen.[15] The complete or partial remission rate was 64% of treated dogs, which is less than systemic cyclosporine or topical tacrolimus treatment.

e) **Reduce inflammation associated with chronic hepatitis**: Initially, 2.2 mg/kg PO every 24 hours in combination with corticosteroids. After 1 to 2 weeks, decrease dose to every other day.[16]

f) **Adjunctive therapy for with immune-mediated glomerular disease**: 2 mg/kg PO every 24 hours for 1 to 2 weeks, then 1 – 2 mg/kg PO every other day[17]

g) **Immune-mediated polyarthritis**: 2 mg/kg PO every 24 hours for 2 weeks, then tapered to a maintenance dosage of 0.5 mg/kg every other day[18]

h) **Meningoencephalomyelitis of undetermined etiology (MUE) in dogs**: In conjunction with corticosteroid therapy, azathioprine is initially started at 2 mg/kg PO every 24 hours for 2 weeks, then decreased to every other day.[19]

FERRETS:

Immunosuppressive agent for inflammatory bowel disease (extra-label; no prospective studies supporting any dosage protocol were noted): Treatment includes prednisone 1 mg/kg PO every 12 to 24 hours, azathioprine 0.9 mg/kg PO every 24 to 72 hours, and dietary management.[20]

HORSES:

Immunosuppressive agent (extra-label; no prospective studies supporting any dosage protocol were noted): 3 mg/kg PO every 24 hours. Although clinical experiences are still limited, azathioprine appears to be a relatively safe immunosuppressive treatment in horses.[21]

Monitoring

- Closely monitor CBC (including platelets) and serum chemistry profile (including liver enzymes [eg, ALT, ALP]). Baseline and periodic testing every 2 weeks for the first 2 months, then every 1 to 2 months during the course of therapy is recommended.[7]
  a. Some clinicians recommend reducing the dose by 25% if

the WBC count is between 5,000 to 7,000 cells/μL. If the WBC count is less than 5,000 cells/μL (or neutrophil count <1000 cells/μL), treatment should be discontinued until leukopenia resolves.

b. Hepatotoxicity is defined as a greater than 2-fold increase in ALT activity as compared to pretreatment values. In one study, 15% of dogs treated with azathioprine for clinical disease developed hepatotoxicity, requiring an azathioprine dosage adjustment in all affected dogs.[16]

- Serum cPLI analysis for possible pancreatitis, if indicated
- Signs of infection
- Efficacy

Client Information

- This drug can cause severe toxicity, including drug-related tumors or death; routine testing to detect toxic effects is necessary. Do not miss these important follow-up appointments.
- May be given with food to minimize gastrointestinal side effects
- May take up to 6 weeks to see positive effects
- Pregnant women should avoid handling this drug; caregivers should wash their hands or wear disposable gloves when handling this drug.
- Do not stop the drug unless your veterinarian tells you to do so.
- Watch for fever, reduced activity, bruising, bleeding, vomiting, lack of appetite, yellowing of whites of eyes, gums, skin).
- The medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Azathioprine, which is related structurally to adenine, guanine, and hypoxanthine, is a purine-antagonist antimetabolite that is used primarily for its immunosuppressive properties. Azathioprine occurs as an odorless, pale-yellow powder that is insoluble in water and slightly soluble in alcohol. Azathioprine sodium powder for injection occurs as a bright-yellow, amorphous mass. After reconstitution with sterile water for injection to a concentration of 10 mg/mL, azathioprine has a pH of ≈9.6.

Azathioprine/azathioprine sodium may also be known as azathioprinum, BW-57322, or NSC-39084; many trade names are available.

Storage/Stability

Azathioprine tablets should be stored between 20°C to 25°C (68°F-77°F) in well-closed containers and protected from light.[7]

The sodium powder for injection should be stored at room temperature and protected from light. The powder is reportedly stable at neutral or acidic pH but will hydrolyze to mercaptopurine in alkaline solutions. This conversion is enhanced upon warming or in the presence of sulfhydryl-containing compounds (eg, cysteine). After reconstitution, the injection should be used within 24 hours, as no preservative is present.

Compatibility/Compounding Considerations

Compatible with sodium chloride 0.45% or 0.9% and dextrose 5% in water for dilution

Compounded preparation stability: Azathioprine oral suspension has been compounded from commercially available tablets.[22] Triturating 120 azathioprine 50 mg tablets with 60 mL of *Ora-Plus*® and qs ad to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® *SF*) yields a 50 mg/mL suspension that retains greater than 90% potency for 60 days stored at both 5°C (41°F) and 25°C (77°F). The stability of azathioprine aqueous liquids decreases in the presence of alkaline pH. Optimal stability is reported to be between 5.5 to 6.5. Compounded preparations of azathioprine should be protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The International Federation for Equestrian Sports (FEI) lists this drug as a *prohibited substance - banned*. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Azathioprine Tablets: 50 mg, 75 mg, and 100 mg; *Azasan*®, *Imuran*®, generic (50 mg only); (Rx)

Azathioprine Sodium Injection: 100 mg (as sodium)/vial in 20 mL vials; generic; (Rx)

Azithromycin

(ay-zith-roe-***my***-sin) Zithromax®

Macrolide Antibiotic

Prescriber Highlights

- ► Oral and parenteral macrolide antibiotic useful for treating a variety of bacterial, rickettsial, and protozoal infections
- ► Long tissue half-lives in dogs and cats
- ► Contraindications include hypersensitivity to macrolides.
- ► Use with caution in patients with hepatic dysfunction and in adult horses
- ► Adverse effects include potential GI effects (eg, anorexia, vomiting, diarrhea), but this drug has fewer adverse effects as compared with erythromycin.

Uses/Indications

Azithromycin is used to treat a variety of bacterial, rickettsial, and protozoal infections. Azithromycin has some anti-inflammatory and immunomodulatory effects[1,2]; however, the clinical relevance of these effects in veterinary species is unknown. Azithromycin has GI promotility properties in humans, and it has been used anecdotally as a prokinetic in dogs and cats.[3]

Azithromycin has been used to treat canine papillomatosis[4,5]; however, its effectiveness for this indication is unclear as the lesions may have regressed without treatment.

Azithromycin is anecdotally used in cats with recurrent and refractory rhinosinusitis; however, this drug is best reserved for select cases (ie, when chlamydiosis is not likely and other antimicrobial agents [eg, doxycycline, amoxicillin] are not viable options).[6]

Azithromycin has potential in the treatment of *Rhodococcus equi* infections in foals. Azithromycin combined with doxycycline was as effective as an azithromycin/rifampin combination for the treatment of *Rhodococcus equi*.[7] Although azithromycin's pharmacokinetics support oral dosing in adult horses, concerns for potential antimicrobial-associated enterocolitis indicate necessary caution when using this antibiotic in adult horses.[8]

The World Health Organization (WHO) has designated azithromycin as a Critically Important, Highest Priority antimicrobial for human medicine.[9]

Pharmacology/Actions

Azithromycin inhibits protein synthesis by penetrating bacterial cell walls and binding the 50S ribosomal subunits in susceptible bacteria. Azithromycin is a bacteriostatic antibiotic. Azithromycin can accumulate and persist in macrophages, neutrophils, and pulmonary epithelial lining fluid.

Azithromycin has a relatively broad antibacterial spectrum with

excellent in vitro activity against most gram-positive bacteria, and greater gram-negative activity (including *Salmonella* spp, *Bordetella* spp, *Pasteurella* spp, and *Haemophilus influenzae*) than most other macrolides. Activity against *Campylobacter* spp, *Brucella* spp, *Bartonella* spp, and *Borrelia* spp is variable. It has good activity against *Mycoplasma* spp and *Chlamydia* spp; however, it is important to note that treatment regimens for *Mycoplasma haemofelis*[10] and *Chlamydophila felis*[11] in cats may result in clinical resolution, but azithromycin is ineffective in eradicating these infections, and thus treatment for these infections with azithromycin is not recommended. Azithromycin also has activity against *Mycobacterium* spp, but it is not recommended for *Mycobacterium avium* complex.

Azithromycin's antiprotozoal effect against *Babesia* spp and *Toxoplasma* spp is through inhibition of apicoplast (ie, DNA-containing organelles) protein translation, which results in protozoal progeny death.[12]

Azithromycin has been used to treat cryptosporidiosis in various species, but there is limited understanding of its potential efficacy for this use. In immunocompromised humans,[13] azithromycin has been shown to improve clinical symptoms related to infection but does not have an effect on *Cryptosporidium* spp shedding. It is unclear if azithromycin may have a similar result when it is used in animals. A positive effect on clinical signs and oocyst shedding has been identified in calves.[14] Azithromycin combined with toltrazuril was more effective than either agent alone in promoting rapid clinical recovery in calves with cryptosporidiosis.[15]

Azithromycin combined with atovaquone appears to be effective in the treatment of dogs with *Babesia gibsoni* infections[12,16,17] as well as piroplasmosis caused by *Babesia microti*-like piroplasm[18] and theileriosis.[19] Azithromycin (used alone or in combination with minocycline) demonstrated efficacy against *Pythium insidiosum* in an experimental rabbit model.[20]

Pharmacokinetics

In comparison to erythromycin, azithromycin has better absorption characteristics, longer tissue half-lives, and higher concentrations in tissues and WBCs. Concentrations of azithromycin are high in bronchial secretions and pulmonary epithelial lining fluid; it has excellent ocular penetration.

In dogs, azithromycin has 97% oral bioavailability. Peak serum concentration occurred ≈2 hours after oral administration. Tissue concentrations do not mirror serum concentrations after multiple doses. Serum half-life was ≈50 hours, and tissue half-lives in dogs may be up to 90 hours. Skin concentrations are 3.5 to 12 times higher than serum concentrations.[21] Azithromycin exhibits concentrations in canine external ear canals.[22] More than 50% of an oral dose is excreted unchanged in bile.[23]

In cats, azithromycin has 58% oral bioavailability and peak concentration is reached after 0.85 hours. Tissue half-lives in cats are less than in dogs and range from 13 hours in adipose tissue to 72 hours in cardiac muscle. Cats excrete ≈66% of a dose unchanged in bile.[23]

In foals, azithromycin is variably absorbed after oral administration, with a mean systemic bioavailability ranging from 40% to 60%. The effect of food on absorption is unclear. Azithromycin has a very high volume of distribution (11.6 to 18.6 L/kg). Elimination half-life is ≈20 to 26 hours. The drug concentrates in bronchoalveolar cells and pulmonary epithelial fluid. Elimination half-life in polymorphonuclear leukocytes is ≈2 days.[24–26] In adult horses, intragastric administration (tablets suspended in 500 mL of water) resulted in an average oral bioavailability of 45%, with peak levels occurring ≈1 hour after administration. Plasma elimination half-life after IV dosing was ≈18 hours. Plasma concentrations after a single intragastric dose remained above MIC_{90} for 6 to 12 hours for beta-hemolytic streptococci, *Pasteurella* spp, and *Staphylococcus* spp. For these bacteria, intracellular concentrations of azithromycin in alveolar macrophages were above MIC_{90} for at least 48 hours and in neutrophils for at least 120 hours after a dose.[8]

In goats, azithromycin has an elimination half-life of 32.5 hours (IV) and 45 hours (IM), an apparent volume of distribution (steady-state) of 34.5 L/kg, and a clearance of 0.85 L/kg/hour.[27]

In sheep, azithromycin has an average elimination half-life of 48 hours (IV) and 61 hours (IM), an apparent volume of distribution (steady-state) of 34.5 L/kg, and a clearance of 0.52 L/kg/hour.[28]

In rabbits, azithromycin has an elimination half-life of 24.1 hours (IV) and 25.1 hours (IM). IM injection has a high bioavailability but causes some degree of muscle damage at the injection site.[29]

Contraindications/Precautions/Warnings

Azithromycin is contraindicated in animals that are hypersensitive to any macrolide antibiotic. There have been anecdotal reports of fatal colitis in adult horses, and the drug should be used with extreme caution, if at all, in these patients.

Caution should be used when using azithromycin in patients with impaired hepatic function because this drug is primarily eliminated via liver metabolism.

Prolonged QT intervals can occur with use of azithromycin, which increases the risk for cardiac arrhythmias, including torsades de pointes. Caution should be used when combining azithromycin with other medications (eg, azole antifungals, cisapride, dolasetron, moxifloxacin, erythromycin, ondansetron) that may prolong QT intervals especially in animals with underlying heart disease. (See ***Drug Interactions***)

Exacerbation of symptoms related to myasthenia gravis or a new onset of syndromes have been reported in human patients taking azithromycin.[30] The clinical significance in veterinary patients is unknown.

Prescription order errors for azithromycin and azathioprine have occurred. Use of tall man letters (eg, aZITHROmycin, azaTHIOprine) may reduce the risk for errors.

Adverse Effects

Azithromycin can cause vomiting, reduced appetite, and diarrhea in small animals. As compared with erythromycin, azithromycin has significantly fewer GI adverse effects. Local reactions have occurred in patients receiving IV azithromycin.

In a small preliminary study of horses administered azithromycin 10 mg/kg PO once daily for 5 days, no life-threatening adverse effects were observed[8]; however, anecdotally, azithromycin use in adult horses has resulted in fatal colitis. Anhidrosis has been noted in foals but appears to be less significant than with erythromycin.[31] Some self-limiting GI adverse effects (eg, decreased appetite, change in fecal consistency) were observed, which raises concerns for potential serious antimicrobial-associated enterocolitis.[7]

Reproductive/Nursing Safety

Safe use of azithromycin during pregnancy has not been fully established; therefore, it should only be used when it is clearly necessary. Humans excrete low amounts of azithromycin in breast milk. The clinical significance in veterinary patients is unknown.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral overdoses are unlikely to cause significant morbidity other than vomiting, diarrhea, and GI cramping.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and

toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with azithromycin either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Amiodarone**: Increased risk for QT prolongation when combined with azithromycin
- **Antacids, Oral** (eg, **magnesium**- and **aluminum-containing**): May reduce the rate of absorption of azithromycin; administration is suggested to be separated by 2 hours.
- **Azole Antifungals** (eg, **ketoconazole, voriconazole**)**:** Azithromycin may prolong QT intervals. This effect may be increased when it is combined with other agents that also prolong QT intervals and/or alter azithromycin metabolism.
- **Cisapride**: No data exist on azithromycin, but other macrolides (eg, **clarithromycin**) are contraindicated with cisapride due to risk for QT prolongation; caution is advised.
- **Cyclosporine**: Azithromycin may increase cyclosporine blood levels; careful monitoring is necessary.
- **Digoxin**: Increased risk for digoxin toxicity when used concurrently
- **Estriol**: Azithromycin may decrease estriol's therapeutic effect.
- **Leflunomide**: Azithromycin may increase risk for hepatotoxicity.
- **Methotrexate**: Azithromycin may increase methotrexate levels and risk for hepatotoxicity.
- **Ondansetron**: Increased risk for QT prolongation when combined with azithromycin
- **P-Glycoprotein Substrates** (eg, **colchicine, doxorubicin, morphine, vincristine**): Azithromycin inhibits p-glycoprotein transport mechanisms and may increase serum concentrations of certain substrates mediated by this transport system.
- **Procainamide**: Increased risk for QT prolongation when combined with azithromycin
- **Quinidine**: Increased risk for QT prolongation when combined with azithromycin
- **Quinolones** (eg, **ciprofloxacin, enrofloxacin**): Increased risk for QT prolongation when combined with azithromycin
- **Sotalol**: Increased risk for QT prolongation when combined with azithromycin
- **Tacrolimus**: Azithromycin may increase tacrolimus blood levels; careful monitoring is necessary.
- **Theophylline**: Azithromycin may reduce theophylline metabolism and increase risk for toxicity.
- **Warfarin**: Increased risk for bleeding; careful monitoring is necessary.

Dosages

DOGS:

Susceptible infections (extra-label)**:** There is significant variability in anecdotal dosing recommendations. Most recommendations are 5 – 10 mg/kg PO once daily for 3 to 7 days. Because of the drug's pharmacokinetics, after a few days of once-a-day dosing, some clinicians recommend every-other-day dosing, or giving higher doses (eg, 10 – 15 mg/kg) twice per week; these dosing regimens may be effective for longer-term treatment of some infections. 10 mg/kg PO every 24 hours for 3 days, weekly, has been recommended for skin infections,[21] although clinical data are lacking and azithromycin is not a recommended drug in recent superficial bacterial folliculitis guidelines.[32]

a) ***Babesia gibsoni*** **or** *Babesia* ***microti*** (extra-label)**:** azithromycin 10 mg/kg PO every 24 hours in combination with atovaquone 13.3 mg/kg PO every 8 hours with a fatty meal for 10 days. Reserve immunosuppressive therapy for cases not rapidly responding (3 to 5 days) to antiprotozoal therapy.[16,18,33]

b) **Theileriosis** (extra-label)**:** Azithromycin 10 mg/kg PO every 24 hours in combination with atovaquone 13.3 mg/kg PO every 8 hours with a fatty meal for 10 days[19]

c) **Cryptosporidiosis** (extra-label): 5 – 10 mg/kg PO twice daily for 5 to 7 days

GI promotility (extra-label): 2 mg/kg IV, PO every 8 hours[3]

Reducing gingival hyperplasia caused by cyclosporine (extra-label): 10 mg/kg PO once daily for 4 to 6 weeks[34,35]

Papillomatosis (extra-label): 10 mg/kg PO every 24 hours for 10 days[4]

CATS:

Susceptible infections (extra-label)**:** There is significant variability in dosing recommendations. Most clinicians recommend 5 – 10 mg/kg PO every 24 hours for 3 to 7 days. Some infections require longer treatment durations (see below). Based on the drug's pharmacokinetics, after a few days of once-daily dosing, some clinicians recommend every-48-hour dosing or giving higher doses (eg, 10 – 15 mg/kg) twice weekly; these dosing regimens may be effective for longer-term treatment. Sample indications and treatment recommendations follow:

a) **Upper respiratory infections** (extra-label): 5 – 10 mg/kg PO every 24 hours for 5 days, then every 72 hours (ie, every third day) long-term. After an initial positive response to azithromycin, therapy should be continued for 6 to 8 weeks without changing the antibiotic.

b) **Bartonellosis** (extra-label)**:** 10 mg/kg PO every 24 hours for 21 days. Response to therapy is rapid; most cats with anterior uveitis will show significant improvement in less than one week. Recurrence after 21 days of treatment with good flea control is low. Treatment failure in *Bartonella*-positive cats indicates a polymicrobial disease syndrome.[36]

c) **Cryptosporidiosis** (extra-label): 10 mg/kg PO every 24 hours; optimal duration of therapy is unknown but is usually several weeks.[37] This treatment may be helpful for cats that are intolerant or nonresponsive to tylosin.

d) **Cytauxzoonosis** (extra-label): 10 mg/kg PO every 24 hours in combination with atovaquone 15 mg/kg PO every 8 hours for 10 days.[38,39] All cases were also treated with IV fluids and most received heparin.[38,39] Consider placing a feeding tube to reduce the stress of administering these oral medications, and ensure food intake to maximize antimicrobial absorption

e) **Toxoplasmosis** (extra-label): 10 mg/kg PO every 24 hours for a minimum of 4 weeks

GI promotility (extra-label): 2 mg/kg IV, PO every 8 hours[3]

HORSES:

Rhodococcus equi **in foals** (extra-label)**:** 10 mg/kg PO every 24 hours in combination with rifampin 5 mg/kg PO every 12 hours.[40,41] Based on the drug's pharmacokinetics (persistence in bronchoalveolar cells and pulmonary epithelial lining fluid) after 5 days of once-daily treatment, consideration should be given for every-48-hours dosing in foals responding to treatment.[41] **NOTE**: Combination therapy with azithromycin/rifampin was shown to be inferior to clarithromycin/rifampin.[40]

CATTLE:

Cryptosporidiosis in calves (extra-label)**:** 20 mg/kg PO once

daily for 6 days in combination with toltrazuril 20 mg/kg PO every other day for 3 treatments.[15] Alternatively, azithromycin 1500 mg/calf (NOT mg/kg) PO once daily for 7 days[14]

RABBITS:

Staphylococcal osteomyelitis (extra-label): 50 mg/kg PO every 24 hours in combination with rifampin 40 mg/kg PO every 12 hours[42]

Jaw abscesses (extra-label): 15 – 30 mg/kg PO every 24 hours. Systemic antibiotic treatment is continued for 2 to 4 weeks postoperatively. Owners need to be advised to discontinue treatment if anorexia or diarrhea occurs.[43]

GUINEA PIGS:

Pneumonia (extra-label)**:** 15 – 30 mg/kg PO every 24 hours. Owners need to be advised to discontinue treatment if their animal develops soft stools.[44]

BIRDS:

Chlamydiosis (study done in experimentally infected cockatiels) (extra-label): 40 mg/kg PO every 48 hours for 21 days was used to treat experimentally infected cockatiels; this treatment was effective as a 21- or 45-day treatment with doxycycline. Dosed via metallic feeding tube into crop using commercially available human oral suspension.[45]

Monitoring

- Clinical efficacy
- Adverse effects (eg, vomiting, diarrhea, inappetence)

Client Information

- Give this medicine as directed by your veterinarian.
- Oral suspension should be shaken well before each use. Store the suspension at room temperature (do not refrigerate). It is preferable to give suspension when the animal has an empty stomach.
- Any unused oral suspension should be discarded after 10 days.
- Contact your veterinarian if your animal develops persistent or severe diarrhea or vomiting, or if your animal's condition worsens after the start of therapy.

Chemistry/Synonyms

Semisynthetic azalide macrolide antibiotics azithromycin dihydrate and azithromycin monohydrate occur as white crystalline powder. In 1 mL of water at neutral pH and 37°C (98.6°F), 39 mg are soluble. Although commercial preparations are available as dihydrates and monohydrates, potency is noted as the anhydrous form.

Azithromycin may also be known as azithromycinum, acitromicina, CP-62993, or XZ-450; many trade names are available.

Storage/Stability

Commercially available tablets should be stored at room temperature less than 30°C (86°F). Oral suspension products for reconstitution should be stored at room temperatures between 5°C to 30°C (41°F-86°F) before reconstitution. After reconstitution, the multiple-dose product may be stored at room temperatures between 5°C to 30°C (41°F-86°F) for up to 10 days, then discarded. The single-dose packets should be given immediately after reconstitution.

Intact injectable product should be stored at room temperature below 30°C (86°F). After reconstitution with sterile water for injection, solutions containing 100 mg/mL will be stable for 24 hours if stored below 30°C (86°F). Further diluted solution of 2 mg/mL or less will remain physically and chemically stable for 24 hours at room temperature and up to 7 days if refrigerated at 5°C (41°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist can be consulted for more specific information.

500-mg vials can be reconstituted with 4.8 mL of sterile water for injection using a nonautomated 5-mL syringe (vials are supplied under vacuum). 1 mL will contain 100 mg of azithromycin.

Azithromycin injection must be further diluted in a compatible IV solution and administered by IV infusion over 1 to 3 hours. It is physically and chemically **compatible** with: 0.45% and 0.9% sodium chloride, 5% Dextrose, lactated Ringer's solution (LRS), 5% Dextrose with 0.225% or 0.45% sodium chloride, *Normosol-M* and 5% Dextrose, *Normosol R* and 5% Dextrose, and LRS and 5% Dextrose. When azithromycin injection is diluted into 250 to 500 mL of a compatible solution, it remains physically and chemically stable for 24 hours at room temperature and up to 7 days if refrigerated at 5°C (41°F).

Azithromycin is **Y-site compatible** with ampicillin, ampicillin/sulbactam, buprenorphine, butorphanol, calcium salts, doxycycline, hydromorphone, magnesium sulfate, mannitol, metronidazole, ondansetron, pantoprazole, ranitidine, sodium bicarbonate, and vasopressin. Azithromycin is **incompatible** or has **variable compatibility** with midazolam, amikacin, famotidine, furosemide, gentamicin, morphine, and potassium chloride (KCl).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

Preparations compounded for dogs and cats may be available from compounding pharmacies.

HUMAN-LABELED PRODUCTS:

Azithromycin Oral Tablets: 250 mg, 500 mg, and 600 mg (as dihydrate); *Zithromax*®, generic; (Rx)

Azithromycin Powder for Oral Suspension (banana-cherry and cherry flavors): After reconstitution: 100 mg/5 mL (20 mg/mL) in 15 mL bottles; 200 mg/5 mL (40 mg/mL) in 15 mL, 22.5 mL, and 30 mL bottles (as monohydrate); 1 gram per packet in single-dose packets (as dihydrate); *Zithromax*®, generic; (Rx); 2 grams; *Zmax*®, brand (Rx)

Azithromycin Powder for Injection (lyophilized): 500 mg in 10 mL vials (as dihydrate); *Zithromax*®, generic; (Rx)

Benazepril

(ben-***a***-za-pril) *Lotensin*®

Angiotensin Converting Enzyme (ACE) Inhibitor

See also ***Spironolactone/Benazepril***

Prescriber Highlights

- ► Used to treat heart failure, hypertension, chronic kidney disease (CKD), and proteinuria in dogs and cats
- ► Not recommended for use in patients with acute kidney injury. Should be used with caution in volume-depleted patients, and in patients with increased serum creatinine, hyponatremia, coronary or cerebrovascular insufficiency, collagen vascular disease (eg, systemic lupus erythematosus [SLE]), and hematologic disorders
- ► Adverse effects are uncommon. GI disturbances are the most likely adverse effect, but hypotension, renal dysfunction, and hyperkalemia are possible.
- ► Avoid use during pregnancy

Uses/Indications

Benazepril may be useful as a vasodilator in the treatment of congestive heart failure (CHF). Reasonable evidence exists to support the theory that angiotensin converting enzyme (ACE) inhibitors

increase survival (as compared with placebo) in dogs with dilated cardiomyopathy and mitral valve disease,[1,2] although pimobendan monotherapy appears to be superior to benazepril alone.[3–5] Benazepril/spironolactone was also superior to benazepril in dogs with CHF and receiving furosemide in a blinded, multi-center clinical trial.[6] Amlodipine was superior to benazepril in lowering left atrial pressure in a small study of dogs with experimentally induced mitral valve regurgitation.[7] In dogs with Stage C heart disease (myxomatous mitral valve disease and mitral regurgitation resulting in CHF) and Stage D heart disease (myxomatous mitral valve disease and mitral regurgitation resulting in CHF refractory to standard treatment), a consensus recommendation from the ACVIM is to use an ACE inhibitor such as benazepril as part of multimodal therapy.[8]

Use of benazepril in dogs with heart disease prior to CHF (eg, dogs with Stage B2 myxomatous mitral valve disease indicating mitral regurgitation and cardiac remodeling resulting in cardiomegaly but without clinical signs) remains controversial.[8,9,9–11] Although one retrospective study suggested a benefit of benazepril in subclinical dogs with myxomatous mitral valve disease,[9] a prospective placebo-controlled study failed to show the benefit of benazepril/spironolactone in subclinical disease with cardiac remodeling (Stage B2). In a retrospective study of Doberman pinschers with subclinical dilated cardiomyopathy, benazepril appeared to delay the progression to overt disease compared to dogs receiving no ACE inhibitor.[12] The benefit, or lack of benefit, of ACE inhibitors in dogs with heart disease may relate to dose, with a retrospective study suggesting a twice daily dosing of ACE inhibitors was predictive of 2-year survival.[13]

In cats with heart disease, including subclinical cats and those with CHF, no benefit of benazepril therapy was observed in a prospective, randomized, blinded clinical trial of 151 cats.[14] In horses, a short-term (28 day) study of benazepril showed improved echocardiographic changes for horses with left-sided valvular regurgitation compared to placebo.[15]

Benazepril may also be used in the treatment of systemic hypertension.[16] One study of dogs with hyperadrenocorticism found that benazepril controlled high blood pressure in 18 of 31 hypertensive dogs, with the other 13 dogs requiring additional medication (ie, amlodipine) for control.[17]

ACE inhibitors may also be used in the adjunctive treatment of chronic kidney disease (CKD)[18,19] and for treatment of protein-losing glomerulonephropathies. Studies demonstrate that benazepril reduces urine protein:creatinine (UP:C) ratios over the progression of canine[18] and feline[20] CKD. Benazepril has been shown to increase survival in cats with CKD associated with a UP:C ratio greater than or equal to 0.8.[21] In one comparative feline study, telmisartan and benazepril each reduced UP:C as compared with baseline, but only the reduction by telmisartan reached statistical significance.[22] Benazepril is cleared via both renal and hepatic routes in contrast to enalapril (primarily renal), potentially allowing it to be more safely administered in patients with decreased renal function. Benazepril may also be an effective treatment for idiopathic renal hematuria in dogs.[23]

Outside of the United States (eg, United Kingdom, Australia), benazepril is indicated for reducing protein loss associated with chronic kidney disease in dogs and cats and for the treatment of heart failure in dogs. In the United States, a combination product (*Cardalis*®) in a fixed dose with spironolactone is approved with concurrent diuretic therapy for the management of clinical signs of mild, moderate, or severe CHF in dogs.

Pharmacology/Actions

Benazepril is a prodrug and has little pharmacologic activity of its own. After being hydrolyzed in the liver to benazeprilat, the drug inhibits the conversion of angiotensin-I to angiotensin-II by inhibiting angiotensin-converting enzyme (ACE). Angiotensin-II is a vasoconstrictor that stimulates production of aldosterone in the adrenal cortex. By blocking angiotensin-II formation, ACE inhibitors generally reduce blood pressure in hypertensive patients and vascular resistance in patients with CHF. Decreased angiotensin-II and aldosterone also reduce sodium/water retention and can limit cardiac fibrosis and remodeling.[24,25] Aldosterone breakthrough (ie, insufficient suppression of aldosterone secretion) has been documented with ACE-I use in healthy dogs.[26,27]

When administered to dogs with heart failure at low doses (0.1 mg/kg every 12 hours), benazepril improved clinical signs but did not significantly affect blood pressure.[28]

ACE inhibitors' proteinuric-reducing effects are most likely a result of reduced intraglomerular hypertension from a vasodilating effect on efferent glomerular arterioles. Reduction in glomerular hypertension may be accompanied by an increase in serum creatinine concentration.

In cats with CKD, benazepril has been shown to reduce systemic arterial pressure and glomerular capillary pressure while increasing renal plasma flow and preserving glomerular filtration rate (GFR). It may also help improve appetite. There is no evidence that ACE inhibitors reduce pathologic cardiac hypertrophy in cats.

Benazepril (0.5 mg/kg PO once daily) effectively inhibited ACE in healthy adult horses[29] and, at higher doses (1 – 4 mg/kg PO as a single dose), attenuated response to angiotensin-I.[30] Benazepril use increased cardiac output in horses with left-sided valvular regurgitation, and echocardiographic assessments suggested a reduced afterload.[15]

Like enalapril and lisinopril, but not captopril, benazepril does not contain a sulfhydryl group. ACE inhibitors containing sulfhydryl groups (eg, captopril) may have a greater tendency to cause immune-mediated reactions.

Pharmacokinetics

After oral administration in healthy dogs, benazepril is rapidly absorbed and converted into the active metabolite benazeprilat, with peak concentrations of benazeprilat occurring ≈75 minutes after administration. Protein binding is ≈85%. Unlike enalaprilat, which is ≈95% cleared in dogs via renal mechanisms, benazeprilat is cleared via both renal (45%) and hepatic (55%) routes. Benazeprilat terminal half-life is ≈19 hours.[31]

In cats, peak benazeprilat concentrations are reached 2 hours after administration. Inhibition of ACE is long-lasting (half-life, 16 to 23 hours) due to high affinity of benazeprilat to ACE; however, free benazeprilat is eliminated relatively quickly (half-life, 2.4 hours). Only 15% of benazeprilat is eliminated via renal excretion in cats, with 85% excreted via biliary routes. Because benazeprilat exhibits nonlinear binding to ACE in cats, doses over 0.25 mg/kg PO produced only small incremental increases in peak effect or duration of ACE inhibition.[32]

In humans, ≈37% of the dose is absorbed after oral administration, and food apparently does not affect the extent of absorption. Approximately 95% of the parent drug and active metabolite are bound to serum proteins. Benazepril and benazeprilat are primarily eliminated via the kidneys, and mild-to-moderate renal dysfunction apparently does not significantly alter elimination, as biliary clearance may compensate somewhat for reductions in renal clearances. Hepatic dysfunction or age does not appreciably alter benazeprilat concentrations.

Contraindications/Precautions/Warnings

Benazepril is contraindicated in patients that have demonstrated hypersensitivity to ACE inhibitors.

ACE inhibitors should be used with caution in patients with hyponatremia or sodium depletion, hypotension, hypovolemia, coronary or cerebrovascular insufficiency, or preexisting hematologic

abnormalities,[21] or a collagen vascular disease (eg, systemic lupus erythematosus [SLE]). Patients with severe CHF or that recently received aggressive diuretic therapy should be monitored very closely for progressive azotemia following initiation of therapy.

Because ACE inhibitors may decrease GFR and worsen azotemia, they are generally avoided in critically ill patients with acute kidney injury.

Benazepril can potentially be confused with *Benadryl®* on written prescriptions and written or verbal orders. Use tall man letters to distinguish (ie, benAZEPril, benADRYl).

Adverse Effects

Benazepril's adverse effect profile in dogs is not well described. Adverse effects of other ACE inhibitors in dogs usually center around GI distress (eg, anorexia, vomiting, diarrhea); fatigue, lethargy, ataxia, and incoordination have also been observed. Potentially, hypotension, renal dysfunction, and hyperkalemia could occur. Plasma creatinine concentration may increase at the start of therapy in patients with CKD or dehydration.

In one study evaluating cats with CKD and nonazotemic cats with cardiac disease and comparing pretreatment and posttreatment values, with all cats receiving a mean dosage of benazepril 0.79 mg/kg orally once daily, no cats experienced systemic hypotension, and only 1 cat (out of 24) with CKD experienced hyperkalemia during days 31 through 60; no cats in the nonazotemic group experienced hyperkalemia.[15]

Reproductive/Nursing Safety

Benazepril crosses the placenta.[33] ACE inhibitor use in rodents has resulted in decreased fetal weights and increased fetal and maternal death rates. In rats, use of ACE inhibitors at label dosages during the second and third trimesters is associated with fetal malformation, and fetal and neonatal morbidity and mortality. In humans, benazepril is to be discontinued as soon as pregnancy is detected. In some countries where benazepril is approved for veterinary use, it is contraindicated to use during pregnancy or lactation.[31]

Benazepril is distributed into human breastmilk in very small amounts and is not expected to cause adverse effects in a nursing infant.[33,34]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In healthy cats given mild overdoses (2 mg/kg PO once daily for 52 weeks), only increased food consumption and weight gain were noted.[21] Reduced red blood cell (RBC) counts occurred in healthy cats given 10 mg/kg/day and healthy dogs receiving 150 mg/kg/day for 12 months.[21] A 200-fold overdose was tolerated in dogs without incident.[21] In overdose situations, the primary concern is hypotension. Supportive treatment is recommended, including volume expansion with appropriate IV fluid therapy if hypotension is documented and cardiac function will tolerate volume expansion. Because of the drug's long duration of action, prolonged monitoring and treatment may be required. Recent massive overdoses should be managed using standard decontamination protocols as appropriate.

There were 298 single agent exposures to benazepril reported to the ASPCA Animal Poison Control Center (APCC) between 2009 and 2013. Of the 256 dogs exposed, 30 showed clinical signs (ie, vomiting [33%], lethargy [27%], tachycardia [27%], hypotension [17%]).

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving benazepril and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Allopurinol:** Concurrent use may cause severe hypersensitivity reactions, neutropenia, agranulocytosis, or serious infections.
- **Alpha-2 Adrenergic Agonists** (eg, **dexmedetomidine**): Concurrent use may result in additive effects on blood pressure and heart rate.
- **Antidiabetic agents** (eg, **insulin, oral agents**): Possible increased risk for hypoglycemia; enhanced monitoring is recommended
- **Antihistamines** (eg, **diphenhydramine**): Concurrent use may result in additive hypotension.
- **Antihypertensive Agents** (eg, **amlodipine**)**:** Concurrent use may result in hypotension or hypovolemia. Concurrent use of multiple antihypertensive agents may be required to control hypertension in some animals.
- **Apomorphine:** Concurrent use may potentiate the hypotensive effects of benazepril.
- **Angiotensin Receptor Antagonists (ARBS)** (eg, **candesartan, telmisartan**): Concurrent use may increase the risk for adverse effects such as hypotension, syncope, hyperkalemia, changes in renal function, or acute renal insufficiency.
- **Aspirin**: Aspirin may potentially negate the decrease in systemic vascular resistance induced by ACE inhibitors; however, one study in dogs using low-dose aspirin showed that the hemodynamic effects of enalaprilat (active metabolite of enalapril, a related drug) were not affected.
- **Azathioprine**: Concurrent use may result in an increased risk for neutropenia or leukopenia.
- **Barbiturates**: Concurrent use may enhance the hypotensive effects of benazepril.
- **Benzodiazepines** (eg, **alprazolam, diazepam, midazolam**)**:** Concurrent use may lead to low blood pressure.
- **Buspirone:** Concurrent use may increase risk for hypotension.
- **Cabergoline:** Concurrent use may lead to additive hypotension.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**)**:** May decrease antihypertensive effects by causing fluid and sodium retention
- **Cyclosporine:** Concurrent administration may increase the risk for hyperkalemia or precipitate acute renal failure.
- **Dalteparin/Enoxaparin:** Concurrent use may increase risk for hyperkalemia.
- **Diazoxide:** Concurrent use may lead to hypotension and orthostasis.
- **Diuretics** (eg, **furosemide, hydrochlorothiazide**): Potential for increased hypotensive effects. May be used concurrently for management of heart failure.
- **Diuretics, Potassium-Sparing** (eg, **spironolactone, triamterene**): Concurrent use may increase hyperkalemic effects. Enhanced monitoring of serum potassium concentration is recommended.
- **Fenoldopam:** Concurrent administration may theoretically increase the risk for severe hypotension.
- **Furazolidone:** Concurrent use may increase risk for hypotension.

- **Glycerin:** Concurrent use may increase risk for hypovolemia and hypotension.
- **Heparin:** Concurrent use may increase the risk for hyperkalemia.
- **Interferon Alfa:** Concurrent use may increase risk for granulocytopenia.
- **Iodinated Contrast Agents** (eg, **iohexol**): Concurrent use may increase risk for nephrotoxicity.
- **Iron:** Benazepril may increase severity and risk for systemic adverse effects associated with parenteral administration of iron.
- **Lanthanum:** In theory, lanthanum may bind with drugs in the GI tract and interfere with absorption. Lanthanum should be given 2 hours before or after benazepril.
- **Lithium**: Increased serum lithium concentrations possible; increased monitoring is required
- **Methotrexate**: Concurrent use may potentiate risk for liver injury.
- **Mirtazapine**: Concurrent administration may result in additive hypotension and orthostasis.
- **Muscle Relaxants** (eg, **methocarbamol**): Concurrent use may have additive blood pressure lowering effects.
- **Naltrexone:** Concurrent administration may increase risk for hepatotoxicity.
- **Nitroglycerin:** Benazepril may enhance the vasodilatory and hypotensive effects.
- **Non-Steroidal Anti-Inflammatory Drugs (NSAIDs,** eg, **carprofen, meloxicam, robenacoxib):** Potentially could increase the risk for nephrotoxicity and/or reduce efficacy of the ACE inhibitor in animals with cardiac or renal disease; monitoring is advised[35,36]
- **Opioids** (eg, **hydrocodone**, **morphine**)**:** Concurrent use may result in additive hypotension and orthostasis.
- **Pentoxifylline:** Concurrent use may increase risk for hypotension.
- **Pergolide:** Concurrent use may increase risk for severe hypotensive episodes.
- **Phenothiazines** (eg, **acepromazine**): Concurrent administration may cause orthostatic hypotension and syncope associated with vasodilation.
- **Polyethylene Glycol 3350:** Concurrent use may increase risk for fluid and electrolyte imbalances leading to renal impairment, cardiac arrhythmias, or seizures.
- **Potassium Supplements**: Increased risk for hyperkalemia
- **Prazosin**: Concurrent use can cause additive hypotension.
- **Pregabalin**: Concurrent use may increase risk for angioedema.
- **Procarbazine**: Concurrent use can cause additive hypotension and orthostasis.
- **QT Prolonging Agents** (eg, **amiodarone, cisapride, fluoroquinolones, ondansetron**): Concurrent use may increase risk for QTc prolongation and arrhythmias.
- **Selegiline**: Concurrent use can cause additive hypotension and orthostasis.
- **Sildenafil**: Concurrent use may potentiate the blood pressure lowering effects of benazepril and cause orthostasis and hypotension.
- **Sulfamethoxazole/Trimethoprim**: Concurrent use may increase the risk for hyperkalemia.
- **Thioguanine**: Concurrent use may potentiate risk for liver injury.
- **Trazodone**: Concurrent use may result in additive hypotension and orthostasis.
- **Tricyclic Antidepressants** (eg, **amitriptyline**, **clomipramine**): Concurrent use may result in additive hypotension and orthostasis.

Laboratory Considerations

- When **iodohippurate sodium I^{123}/I^{134}** or **Technetium Tc^{99} pentetate renal imaging** is used in patients with renal artery stenosis, ACE inhibitors may cause a reversible decrease in localization and excretion of these agents in the affected kidney that may lead to confusion in test interpretation.

Dosages

DOGS:

Adjunctive treatment of heart failure (extra-label):

a. Initially, 0.25 – 0.5 mg/kg PO once daily. Dosage may be increased up to 0.5 – 1 mg/kg PO once daily[31] **NOTE:** ACE inhibitor dosing remains somewhat controversial with one retrospective study in dogs suggesting twice daily dosing of ACE inhibitors were predictive of 2-year survival.[13]
b. 0.5 mg/kg PO every 12 hours for chronic Stage C heart failure. Use in addition to furosemide (typically 2 mg/kg PO twice daily, up to 8 mg/kg total dose per day), pimobendan (0.25 – 0.3 mg/kg PO every 12 hours), and spironolactone (2 mg/kg PO every 12 to 24 hours).[8]

Adjunctive treatment of proteinuria (extra-label): Begin with 0.5 mg/kg PO every 24 hours. Many dogs will need dosage increases to minimize proteinuria (see ***Monitoring***). Dose can be gradually increased by 0.5 mg/kg per day to a maximum of 2 mg/kg PO per day. Total daily doses can be divided and given every 12 hours.[37] Combination therapy with telmisartan may result in better results than benazepril alone.[38]

Control of systemic hypertension (extra-label): 0.5 mg/kg PO every 12 to 24 hours initially; may increase incrementally up to 2 mg/kg PO twice daily[16]

CATS:

Adjunctive treatment of hypertrophic heart failure (extra-label): Although evidence of efficacy is lacking, some recommend 0.25 – 0.5 mg/kg PO every 12 to 24 hours.

Adjunctive treatment of hypertension (extra-label): Benazepril 0.5 mg/kg PO every 12 hours in cats that do not have blood pressure controlled with amlodipine alone or in those with concurrent proteinuria. Amlodipine or telmisartan are considered first-line agents.[16]

Reduction of proteinuria associated with CKD (extra-label): Most recommend 0.5 – 1 mg/kg PO once daily.[31] Some anecdotal dosage recommendations state that some cats may require the drug every 12 hours but that higher dosages may worsen preexisting azotemia; caution is advised.

HORSES:

Adjunctive treatment of valvular heart disease (extra-label): May have benefit at 1 mg/kg PO every 12 hours in horses with mitral and aortic valve regurgitation.[15]

Monitoring

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, and UP:C ratio (if abnormal at baseline) 3 to 14 days after initiation of therapy; recommendation is for dogs with Stage C heart failure[8] but likely applies for other indications as well. **NOTE:** Plasma creatinine concentration may increase at the start of therapy in patients with CKD.
- Blood pressure (if treating hypertension or if clinical signs associated with hypotension arise)

Client Information

- This medicine may be given with or without food. It is usually well

tolerated but vomiting and diarrhea can occur. Give with food if vomiting or lack of appetite becomes a problem.
- If your animal develops a rash or signs of infection occur (eg, fever), contact your veterinarian immediately.
- It is important to give benazepril to your animal as directed by your veterinarian. Do not stop or change the dose without your veterinarian's guidance.
- Your animal will need to have regular blood pressure and laboratory tests performed while receiving benazepril. Do not miss these important follow-up visits.

Chemistry/Synonyms

Commercial dosage forms contain benazepril HCl. Benazepril HCl occurs as a white to off-white crystalline powder that is soluble in water and ethanol. Benazepril does not contain a sulfhydryl group in its structure.

Benazepril may also be known as CGS-14824A (benazepril or benazepril hydrochloride). Many trade names are available; veterinary trade names include *Apex®, Benazemav®*, *Benefortin®*, *Bexepril®*, *Nelio®*, *Prilben®, and Vetace®*.

Storage/Stability

Benazepril tablets (and combination products) should be stored at temperatures less than 30°C (86°F) and protected from moisture. They should be dispensed in airtight containers. Unused half tablets of chewable veterinary formulations (approved outside the United States) should be returned to the original blister space inside the original carton and used within 1 to 2 days.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Available in a fixed-dose combination product with spironolactone (*Cardalis®*)**:** 20/2.5 mg spironolactone/benazepril, 40/5 mg, and 80/10 mg

None in the United States. Outside the United States (eg, Australia, Canada, EU, UK): Benazepril Tablets: 2.5 mg, 5 mg, and 20 mg; *Fortekor®* is one example; (POM-V/Rx). Labeled for use in cats to reduce proteinuria associated with chronic kidney disease and to treat heart failure in dogs. Also available as tablets combined with pimobendan or spironolactone.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Benazepril HCl Oral Tablets: 5 mg, 10 mg, 20 mg, and 40 mg; *Lotensin®*, generic; (Rx)

Also available in fixed-dose combination products containing amlodipine (*Lotrel®*) or hydrochlorothiazide (*Lotensin HCT®*)

Betamethasone (Systemic)

(bet-ta-**meth**-a-sone) *Celestone®*

Glucocorticoid

NOTE: For topical or otic use, see ***Betamethasone, Topical*** and ***Corticosteroid/Antimicrobial Preparations***

Prescriber Highlights

- ► Long-acting injectable glucocorticoid; 25 to 40 times more potent than hydrocortisone; no mineralocorticoid activity
- ► Primary use is intra-articular administration in horses; may be used to improve pulmonary condition in preterm puppies.
- ► Relatively safe when used intra-articularly; some systemic absorption occurs, although systemic adverse effects are uncommon.
- ► Teratogenic; may cause preterm labor if administered early in third trimester

Uses/Indications

In veterinary medicine, betamethasone for systemic or intra-articular effects is usually administered as an injection combining betamethasone sodium phosphate (prompt effect) and betamethasone acetate (sustained effect). It can be used when an injectable glucocorticoid that has both rapid- and long-acting effects is desired.

In dogs, prenatal maternal administration of betamethasone improves preterm neonatal pulmonary conditions (ie, improved gas exchange capacity) but not surfactant production, as occurs in humans.[1,2]

In horses, intra-articular injection of betamethasone sodium phosphate/acetate can be useful for treating pain and inflamed joints; pain relief can last up to 4 weeks after injection.[3]

Comparing IV or PO glucocorticoid potency, betamethasone 0.75 mg is approximately equivalent to dexamethasone 0.75 mg, prednisone 5 mg, methylprednisolone 4 mg, or hydrocortisone 20 mg (intra-articular or IM may be different).

Pharmacology

Betamethasone is a long-acting glucocorticoid with a biologic half-life of over 300 hours. Glucocorticoids have effects on almost every cell type and system in mammals.

Cardiovascular system: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A clinically insignificant positive inotropic effect can occur after glucocorticoid administration. This drug's vasoconstrictive properties and increased blood volume can result in increased blood pressure.

Cells: Glucocorticoids can inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes, and the cellular response to mediators of inflammation; they can also stabilize lysosomal membranes.

CNS/autonomic nervous system: Glucocorticoids can lower the seizure threshold, alter mood and behavior, diminish response to pyrogens, stimulate appetite, and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

Endocrine system: When an animal is not stressed, glucocorticoids suppress the release of corticotropin (adrenocorticotropic hormone [ACTH]) from the anterior pituitary, which reduces or prevents the release of endogenous corticosteroids. Stress factors (eg, renal disease, liver disease, diabetes) may occasionally nullify the suppressing aspects of exogenously administered steroids. The release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone may be reduced when glucocorticoids are administered at pharmacologic doses. Conversion of thyroxine (T4) to triiodothyronine (T3) may be reduced by

glucocorticoids, and plasma levels of parathyroid hormone may be increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (antidiuretic hormone [ADH]) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin receptors and the postreceptor effects of insulin.

Fluid and electrolyte balance: Glucocorticoids can increase renal potassium and calcium excretion, sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia rarely occur. Diuresis may develop following glucocorticoid administration.

GI tract and hepatic system: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased, whereas fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits in hepatocytes and increased serum levels of ALT and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum ALP. Glucocorticoids can cause minor increases in bromosulfophthalein (BSP) retention time.

Hematopoietic system: Glucocorticoids can increase the number of circulating platelets, neutrophils, and RBCs, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes, and eosinophils are seen because glucocorticoids can sequester these cells into the lungs and spleen and can prompt decreased release from bone marrow; removal of old RBCs becomes diminished. Glucocorticoids can cause involution of lymphoid tissue.

Immune system (also see **Cells and Hematopoietic system**): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; and inhibit phagocytosis, chemotaxis, antigen processing, and intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high doses and species have different responses.

Metabolic effects: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (eg, abdomen), and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

Musculoskeletal: Glucocorticoids may cause muscular weakness, atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion, and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

Ophthalmic: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

Skin: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended, and alopecia may occur.

Pharmacokinetics

Betamethasone is absorbed into systemic circulation after intra-articular administration to horses.[4] After administration of a 9 mg (total) dose in one joint, peak plasma concentration is reached within 4.5 to 8 hours, and terminal elimination half-life is 4 to 8 hours. After two 15 mg doses administered concurrently in 2 joints, peak plasma and urine concentrations occurred at 0.8 hours and 7.1 hours, respectively, and plasma half-life was 9.2 hours.[5]

Contraindications/Precautions/Warnings

Betamethasone is contraindicated in patients that are hypersensitive to it or any of its excipients. Intra-articular glucocorticoids are contraindicated in the presence of septic arthritis.[4] Because betamethasone injected into joints is absorbed systemically, it should not be used in the face of acute infections.[4]

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in patients with hypoadrenocorticism) and when administered IM in patients with idiopathic thrombocytopenia. Use of sustained-release injectable glucocorticoids is contraindicated for chronic corticosteroid therapy of systemic diseases.

Regardless of the route of administration, betamethasone should be used with caution in patients who have or have history of congestive heart failure (CHF); pre-existing cardiac disease; chronic kidney disease; diabetes mellitus; pre-existing GI disease or history of GI ulcers; or in horses with pituitary pars intermedia dysfunction (PPID) or are at high risk of developing laminitis (eg, history of laminitis, obesity).

Animals that have received chronic, systemic glucocorticoids should be tapered off the drug slowly to allow endogenous adrenocorticotrophic hormone (ACTH) and endogenous corticosteroid to return to function. If the animal undergoes a stressful event (eg, surgery, trauma, illness) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Do not administer betamethasone suspension for injection by the IV route.

Adverse Effects

Adverse effects are generally associated with long-term systemic administration of this class of drugs, especially if the drugs are administered at high doses or not on an alternate-day regimen. Effects generally manifest as clinical signs of hyperadrenocorticism (eg, polydipsia [PD], polyphagia [PP], polyuria [PU]). When administered to young, growing animals, glucocorticoids can delay growth. See ***Pharmacology***.

In dogs, PD, PP, and PU may all be seen with short-term "burst" therapy as well as with alternate-day maintenance therapy on days when the drug is administered. Adverse effects in dogs associated with long-term use can include dull, dry hair coat; weight gain; panting; poor wound healing; vomiting; diarrhea; elevated liver enzymes; pancreatitis; GI ulceration; hyperlipidemia; activation or worsening of diabetes mellitus; muscle wasting; and behavior changes (eg, depression, lethargy, aggression). Discontinuation of the drug may be necessary; changing to an alternate glucocorticoid (eg, prednis(ol)one) may also alleviate the problem. With the exceptions of PD, PP, and PU, adverse effects associated with anti-inflammatory dosages are relatively uncommon. Adverse effects associated with immunosuppressive dosages (eg, GI ulceration, infection, poor wound healing) are more common and potentially more severe (eg, pulmonary thromboembolism), especially with long-term use.

Cats generally require higher doses of betamethasone than dogs for clinical effect but tend to develop fewer adverse effects. Occasionally, PD, PP, PU with weight gain, GI ulceration, vomiting, diarrhea, or depression can be seen; however, the development of PU/PD/PP may indicate the development of diabetes mellitus, and diabetes mellitus should be ruled out if these signs develop. Long-term, high-dose therapy can lead to the similar effects seen in dogs.

When used systemically in horses, betamethasone, like other glucocorticoids, may potentially increase the risk for laminitis. Injection site reactions are the most common adverse effect in horses receiving

the drug by the intra-articular route. Although systemic absorption of corticosteroids is possible after intra-articular administration, when administered by that route to adult horses, betamethasone sodium phosphate/acetate does not appear to have deleterious effects.[6] However, there is a slight risk for infection (septic arthritis) and postcorticosteroid reactive synovitis after intra-articular injection. In one report, 2 horses developed hyperglycemia after receiving intra-articular betamethasone.[7]

Reproductive/Nursing Safety

Betamethasone has been demonstrated to cause decreased sperm output and semen volume and increased percentages of abnormal sperm in dogs. Corticosteroids have been shown to be teratogenic (eg, reduced fetal growth, cleft palate, deformed forelegs, phocomelia, and anasarca). In developing sheep, betamethasone reduced CNS myelination[8] and affected testicular development in male fetuses.[9] The first stage of parturition may be induced when corticosteroids, including betamethasone,[2] are administered in the third trimester of pregnancy. Betamethasone injection (0.5 mg on day 55) has been shown in pregnant dogs to induce premature labor. No long-term negative clinical effects in preterm puppies (delivered by C-section on day 58) were detected, and glucocorticoid treatment appeared to enhance vital organ maturation.[10]

Corticosteroids appear in milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects in the nursing offspring. Use with caution in nursing dams.

Overdose/Acute Toxicity

Acute overdoses of glucocorticoids rarely cause serious problems. Clinical signs associated with an overdose reflect the adverse effect profile. Should clinical signs occur, use supportive treatment (eg, fluid therapy, GI protection) as needed.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Drug interactions are considered unlikely with intra-articular betamethasone administration. The following drug interactions have either been reported or are theoretical in humans or animals receiving betamethasone *systemically* and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amphotericin B**: May cause hypokalemia when administered concomitantly with glucocorticoids
- **Anticholinesterase Agents** (eg, **neostigmine, pyridostigmine**): In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness; if possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**): Glucocorticoid clearance may be reduced, and the AUC increased.
- **Cholestyramine**: May increase glucocorticoid clearance
- **Cyclophosphamide**: Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **Cyclosporine**: Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each drug by mutually inhibiting hepatic metabolism; clinical significance is not clear.
- **Digoxin**: When glucocorticoids are used concurrently with digitalis glycosides, the risk for digitalis toxicity may be increased should hypokalemia develop; diligent monitoring of potassium and digitalis glycoside levels is recommended.
- **Diuretics, Potassium-Depleting** (eg, **furosemide, thiazides**): May cause hypokalemia when administered concomitantly with glucocorticoids
- **Estrogens** (eg, **DES, estriol**): May decrease glucocorticoid clearance
- **Insulin:** Requirements may increase in patients receiving glucocorticoids.
- **Isoniazid**: Serum levels may be decreased by glucocorticoid
- **Mitotane**: May alter the metabolism of glucocorticoids; higher-than-usual doses of glucocorticoids may be necessary to treat mitotane-induced adrenal insufficiency.
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs;** eg, **flunixin, phenylbutazone**): May result in increased risk for GI ulceration or bleeding
- **Phenobarbital**: May result in decreased betamethasone efficacy
- **Rifampin**: May increase the metabolism of glucocorticoids
- **Salicylates** (eg, **aspirin, bismuth subsalicylate**): Glucocorticoids may reduce salicylate blood levels and may increase the risk for GI ulceration.
- **Theophylline**: Alterations of pharmacologic effects of either drug can occur.
- **Vaccines, Modified-Live**: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids.

Laboratory Considerations

The following laboratory interactions have either been reported or are theoretical in humans or animals receiving betamethasone *systemically* and may be of significance in veterinary patients receiving betamethasone locally:

- Glucocorticoids may increase **serum cholesterol** and **urine glucose** levels.
- Glucocorticoids may decrease **serum potassium.**
- Glucocorticoids can suppress the release of thyroid-stimulating hormone (TSH) and reduce T_3 and T_4 values; thyroid gland atrophy has been reported after chronic glucocorticoid administration.
- Uptake of I^{131} by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids.
- False-negative results of the **nitroblue tetrazolium test** for systemic bacterial infections may be induced by glucocorticoids.
- Betamethasone does not cross-react with the cortisol assay.

Dosages

DOGS:

Control of pruritus (label dosage; FDA-approved): 0.25 – 0.5 mL/9 kg (20 lb; NOT mL/kg [lb]) body weight IM.[11] Dose chosen is dependent on severity of condition. May repeat when necessary. Relief averages 3 weeks in duration. Do not exceed more than 4 injections. **NOTE**: Product is no longer marketed in the US.

Pulmonary maturation in preterm puppies (extra-label): 0.5 mg/kg IM administered to the bitch at 55 to 57 days postovulation[1,2,12]

HORSES:

Control of pain and inflammation associated with osteoarthritis (label dosage; FDA-approved): 9 mg/joint (NOT mg/kg) by intra-articular injection in up to 2 joints[4]

Intra-articular administration (extra-label): Most dosage recommendations range from 3 – 18 mg/joint (NOT mg/kg) intra-articularly. Repeat doses should be limited to the minimum required to achieve soundness.

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used, dosage schedule (daily versus alternate day therapy), route of administration, duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Body weight, appetite, GI signs (eg, anorexia, vomiting, diarrhea)
- Signs of edema
- Serum electrolytes
- Total plasma protein, albumin
- Blood glucose
- Growth and development in young animals
- Adrenocorticotrophic hormone (ACTH) stimulation test, if concerned about iatrogenic hyperadrenocorticism

Client Information

- Carefully follow the instructions for how to give this medicine to your animal. Do not suddenly stop giving this medicine without talking to your veterinarian.
- Do not give other medications (including over-the-counter [OTC] medication) or nonsteroidal anti-inflammatory (NSAID) medications while your pet is on this medication without talking to your veterinarian first.
- There are many potential side effects that can be seen with these drugs, including increased or decreased appetite, vomiting, abnormal stool, and increased thirst and urination. Contact your veterinarian if these effects become severe or worsen.
- While your animal is taking this medication, it is important to return to your veterinarian for periodic examinations and blood work. Do not miss these important follow-up visits.

Chemistry/Synonyms

A synthetic glucocorticoid, betamethasone has been manufactured as the base and as the dipropionate, acetate, and sodium phosphate salts. The base is used for oral dosage forms. The sodium phosphate and acetate salts are used in injectable preparations. The dipropionate salt is used in topical formulations.

Betamethasone occurs as an odorless, white to practically white crystalline powder. It is insoluble in water and practically insoluble in alcohol. The acetate salt occurs as a white or creamy-white odorless powder. It is practically insoluble in water and soluble in alcohol. The sodium phosphate salt occurs as an odorless, white to practically white hygroscopic powder. It is freely soluble in water and slightly soluble in alcohol.

Betamethasone may also be known as flubenisolone, *BetaVet*®, or *Celestone*®.

Storage/Stability

The combination injectable product should be stored between 20°C to 25°C (68°F-77°F) and protected from light. Shake well before using.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

If coadministration with a local anesthetic is desired, lidocaine 1% or 2% (without parabens or phenol) mixed with betamethasone sodium phosphate/acetate injection has been suggested.[13] The lidocaine should be drawn into the syringe after the dose of betamethasone is drawn up. Do not add lidocaine to the vial of betamethasone.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated betamethasone as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Betamethasone Injectable suspension: 6 mg/mL as 3.15 mg betamethasone sodium phosphate and 2.85 mg betamethasone acetate in 5 mL single-dose vials; *BetaVet*®; (Rx). FDA-approved for use in horses. Not for use in horses intended for human consumption

Intra-articular injection: Betamethasone acetate 12 mg/mL (equivalent to 10.8 mg betamethasone) and 3.9 mg/mL betamethasone disodium phosphate (equivalent to 3 mg of betamethasone); *Betavet Soluspan Suspension*®; (Rx). FDA-approved for use in horses. This product is listed in the FDA Green Book is no longer marketed.

Betamethasone valerate is also found in several otic and topical products either as a single agent or in combination with gentamicin.

HUMAN-LABELED PRODUCTS:

Betamethasone Injection: betamethasone (as sodium phosphate) 3 mg/mL and betamethasone acetate 3 mg/mL suspension in 5 mL multi-dose vials; *Celestone Soluspan*®, generic; (Rx)

Various topical formulations are also available.

For the complete list of references, see **wiley.com/go/budde/plumb**

Bethanechol

(beh-***than***-e-kole) *Urecholine*®

Cholinergic

Prescriber Highlights

- ► Cholinergic agent used primarily to increase urinary bladder contractility; bethanechol can also be used as a prokinetic agent and for treatment of clinical signs associated with dysautonomia. May be useful for adjunctive treatment of equine gastric ulcer syndrome (EGUS)
- ► Principal contraindications are GI or urinary tract obstructions or when the integrity of the urinary bladder wall is of concern.
- ► Adverse effects are related to cholinergic effects and include salivation, lacrimation, urination, defecation, GI distress, emesis, and miosis (ie, SLUDGE-M).
- ► Cholinergic crisis is possible when injecting bethanechol IV or IM; atropine should be readily available.

Uses/Indications

Bethanechol can be used to stimulate urinary bladder contractions in small animal species. This drug appears to be most effective in the treatment of acute and partial detrusor atony secondary to acute urinary bladder overdistension and partial neurogenic lesions and when given in combination with other agents (eg, alpha-adrenergic antagonists, benzodiazepines) to reduce urethral resistance. A pilot study in healthy beagles showed no changes in urethral or urinary bladder function after bethanechol treatment was given for 15 days.[1] Bethanechol can be used as an esophageal prokinetic. This drug can also be used as a general GI prokinetic agent, but other agents (eg, metoclopramide, cisapride) are better tolerated.

Bethanechol has been shown to increase abomasum and duodenum contractility in both healthy dairy cattle and cattle with left displacement of the abomasum (LDA)[2]; however, bethanechol did not

alter the abomasal emptying rate in calves.[3]

In horses, bethanechol has been suggested as an adjunctive prokinetic agent for treatment of equine gastric ulcer syndrome (EGUS) and in cases with adynamic ileus and gastroduodenal reflux.[4-6]

Pharmacology/Actions

Bethanechol directly stimulates cholinergic receptors. Its effects are principally muscarinic and has negligible nicotinic activity at recommended dosages. This drug is more resistant to hydrolysis than acetylcholine by cholinesterase and, therefore, has an increased duration of activity.

Pharmacologic effects include increased esophageal peristalsis and lower esophageal sphincter tone, increased tone and peristaltic activity of the stomach and intestines, increased gastric and pancreatic secretions, increased tone of the detrusor muscle of the urinary bladder, and decreased bladder capacity. High parenteral dosages can result in adverse effects related to cholinergic effects on other systems (eg, increased bronchial secretions and constriction, miosis, lacrimation, salivation). When administered SC or PO, bethanechol's effects are predominantly seen in the GI and urinary tracts. A ceiling effect (ie, decreased response despite higher dosages) can be seen secondary to receptor desensitization and calcium depletion.

Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, bethanechol is poorly absorbed from the GI tract, and the onset of action is usually within 30 to 90 minutes after oral administration. After SC administration, effects begin within 5 to 15 minutes and usually peak within 30 minutes. The duration of action after oral administration may last up to 6 hours after large doses and 2 hours after SC administration. SC administration yields a more enhanced effect on urinary tract stimulation than oral administration.

Bethanechol does not enter the CNS when administered at recommended doses; other distribution aspects of the drug are not known. The metabolic and excretory fate of bethanechol has not been described.

Contraindications/Precautions/Warnings

Bethanechol is contraindicated in animals with a known hypersensitivity to the drug. Additional contraindications to bethanechol therapy include urinary outflow obstruction, when the integrity of the urinary bladder wall is of concern (eg, after recent bladder surgery), hyperthyroidism, peptic ulcer disease or when other inflammatory GI lesions are present, recent GI surgery with resection and anastomosis, GI obstruction or peritonitis, hypersensitivity to the drug, epilepsy, bronchoconstrictive disease (eg, asthma), hypotension, severe bradycardia or vagotonia, and vasomotor instability. Bethanechol should only be used in conjunction with another agent that will sufficiently reduce outflow resistance (eg, diazepam, dantrolene [striated muscle], phenoxybenzamine [smooth muscle]) when urinary outflow resistance is increased due to enhanced urethral tone (not mechanical obstruction).

Retrograde urinary reflux to the kidney may occur if bethanechol fails to relax the urethral sphincter.

Adverse Effects

When administered orally to small animal species, adverse effects are usually mild; vomiting, diarrhea, salivation, and anorexia are the effects most likely to occur. Cardiovascular effects (eg, tachycardia, arrhythmias, hypotension) and respiratory effects (eg, asthma, dyspnea) are typically only seen after overdose or with high doses given SC. Bethanechol may stimulate pancreatic stimulation of amylase and lipase, and serum bilirubin and AST may be increased due to retention caused by contraction of the sphincter of Oddi.

In horses, salivation, lacrimation, and abdominal pain (colic) are potential adverse effects.

IV or IM use is not recommended; however, the IV route may be necessary in an emergency situation. Severe cholinergic reactions are likely if the drug is given IV. **If injecting the drug (IV or IM), it is recommended that atropine be immediately available.**

Reproductive/Nursing Safety

No data were located regarding bethanechol use in pregnant animals. It is unknown if bethanechol is distributed into milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clinical signs of overdose are cholinergic in nature. Muscarinic effects (eg, salivation, urination, defecation) are usually seen with PO or SC administration. If given IM or IV, a cholinergic crisis can occur; circulatory collapse, bloody diarrhea, shock, and cardiac arrest are possible.

Treatment for bethanechol toxicity is atropine (see ***Atropine***). Epinephrine may also be used to treat clinical signs of bronchospasm (see ***Epinephrine***).

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bethanechol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Drugs** (eg, **atropine, glycopyrrolate, propantheline**): Can antagonize bethanechol's effects
- **Beta Adrenergic Antagonists**: May increase the risk for arrhythmias and bronchospasm
- **Cholinergic Drugs** (eg, **neostigmine, physostigmine, pyridostigmine**): Because of additional cholinergic effects, bethanechol should generally not be used concomitantly with other cholinergic drugs.
- **Ganglionic Blocking Drugs** (eg, **mecamylamine, trimethaphan**): Can produce severe GI and hypotensive effects
- **Quinidine, Procainamide**: Can antagonize the effects of bethanechol

Laboratory Considerations

- None noted

Dosages

NOTE: The injectable product is no longer commercially available in the United States.

DOGS:

Increase urinary bladder contractility caused by detrusor muscle atony or treatment for clinical signs related to dysautonomia (extra-label): 2.5 mg – 25 mg/dog (NOT mg/kg) PO 3 times daily. Some dogs may respond to twice-daily administration.

GI prokinetic (extra-label): 5 – 15 mg/dog (NOT mg/kg) PO every 8 hours. May give up to 25 mg/dog (NOT mg/kg) every 8 hours. Improvement in esophageal motility in dogs with megaesophagus is possible.[7,8]

CATS:

Increase urinary bladder contractility caused by detrusor muscle atony or treatment for clinical signs related to dysautono-

mia (extra-label): 1.25 mg (¼ of a 5 mg tablet) – 7.5 mg/cat (NOT mg/kg) PO 3 times daily. Some cats may respond to twice daily dosing.

HORSES:

Increase urinary bladder contractility caused by detrusor muscle atony (extra-label): 0.025 – 0.075 mg/kg SC every 8 hours for 2 to 3 doses, then 0.25 – 0.75 mg/kg PO 2 to 4 times daily. If no response after 5 days, discontinue therapy. **NOTE:** The PO dose is 10 times that of the SC dose.

Adjunctive treatment for equine gastric ulcer syndrome (EGUS) (extra-label): 0.025 – 0.03 mg/kg SC every 4 to 8 hours until no reflux, then 0.3 – 0.4 mg/kg PO 3 to 4 times daily[9-11]

CATTLE:

Adjunctive treatment for cecal dilation/dislocation (CDD); (extra-label): 0.07 mg/kg SC 3 times daily for 2 days, if clinical signs are mild, defecation is present, and rectal examination does not reveal torsion or retroflexion. If these criteria are not met or no improvement is seen within 24 hours of medical therapy, surgical therapy is recommended. **NOTE:** Compounded preparations are required, as no products are commercially available.[12]

Monitoring

- Clinical efficacy
- Urination frequency, urine volume, and urinary bladder palpation
- Adverse effects including signs of colic

Client Information

- This drug is prescribed to help animals urinate more easily. In horses, it may be used to treat gastric ulcer syndrome.
- It is recommended that food be given with this medicine to reduce nausea and/or vomiting.
- In dogs and cats, side effects include vomiting, diarrhea, lack of appetite, and increased drooling. Contact your veterinarian if any of these signs are severe, worsen, or continue to be a problem.
- In horses, side effects include watery eyes, drooling, and signs of colic. Contact your veterinarian if any of these signs are severe, worsen, or continue to be a problem.

Chemistry/Synonyms

Bethanechol, a synthetic cholinergic ester that is structurally and pharmacologically related to acetylcholine, occurs as a slightly hygroscopic white or colorless crystalline powder with a slight, amine-like or fishy odor. It exhibits polymorphism, with one form melting at 211°C (411°F) and the other form at 219°C (426°F). The drug is freely soluble in water and alcohol.

Bethanechol chloride may also be known as carbamylmethylcholine chloride, *Duvoid®, Miotonachol®, Muscaran®, Myo Hermes®, Myocholine®, Myotonine®, Ucholine®, Urecholine®, Urocarb®*, or *Urotonine®*.

Storage/Stability

Bethanechol tablets should be stored in air-tight, light-resistant containers at room temperature 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

No specific information has been noted.

Information on bethanechol oral suspension compounded from commercially available tablets has been published.[13] Triturating 12 bethanechol 50 mg tablets with 60 mL of *Ora-Plus®* and qs ad to 120 mL with *Ora-Sweet®* (or *Ora-Sweet® SF*) yields a 5 mg/mL oral suspension that retains more than 90% potency for 60 days stored at both 5°C (41°F) and 25°C (77°F). Compounded preparations of bethanechol should be protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See the ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Bethanechol Chloride Oral Tablets: 5 mg, 10 mg, 25 mg, and 50 mg; *Urecholine®*, generic; (Rx)

An injectable product was formerly commercially available; a compounding pharmacy may be able to prepare a bethanechol injectable form.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Bisacodyl

(bis-a-***koe***-dill) *Dulcolax®*

Laxative

Prescriber Highlights

- ► Stimulant laxative used short-term in dogs and cats
- ► Contraindicated in patients with GI obstruction
- ► Adverse effects include GI cramping and diarrhea
- ► Do not administer with milk products or liquid antacids; tablets should not be crushed or split.

Uses/Indications

Bisacodyl oral and rectal products are used as stimulant laxatives in dogs and cats. Efficacy is improved when patients are adequately hydrated prior to administration.

In preparation of dogs for colonoscopy, bisacodyl in combination with sodium phosphate +/- warm water enema produced a colon-cleansing effect which appeared to be less effective than that achieved with a polyethylene glycol (PEG)-electrolyte solution.[1]

Pharmacology/Actions

A stimulant laxative, bisacodyl is thought to produce catharsis by increasing peristalsis via direct stimulation on the intramural nerve plexuses of intestinal smooth muscle. Bisacodyl has been shown to increase fluid and ion accumulation in the colon thereby enhancing catharsis.

Pharmacokinetics

Bisacodyl is minimally absorbed after either oral or rectal administration. Intestinal or bacterial enzymes convert it to an active desacetyl metabolite, which is excreted in the feces. Onset of action is generally 6 to 10 hours after oral administration and 15 minutes to 1 hour after rectal administration.

Contraindications/Precautions/Warnings

Bisacodyl is contraindicated in patients that are hypersensitive to it. Stimulant laxatives are contraindicated in animals with GI obstruction (not constipation), undiagnosed rectal bleeding, or when the animal is at risk for intestinal perforation. Use with caution in patients with infiltrative bowel disease, acute GI conditions, or dehydration. Review specific product labels carefully as some may contain other active ingredients (eg, docusate).

Bisacodyl should only be used short-term, as long-term use can damage myenteric neurons.

Adverse Effects

Bisacodyl has relatively few adverse effects when used occasionally; abdominal discomfort (cramping), nausea, or diarrhea may be noted after use.

Reproductive/Nursing Safety
Because there is minimal bisacodyl absorption following administration, the risk to the fetus or the nursing offspring is expected to be limited.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity
The reported LD_{50} in a dog after oral administration is 15 g/kg.[2] Overdoses may result in severe cramping, diarrhea, vomiting and, potentially, fluid and electrolyte imbalances. Animals should be monitored and given replacement parenteral fluids and electrolytes as necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions
The following drug interactions either have been reported or are theoretical in humans or animals receiving bisacodyl and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids, Aluminum-, Calcium- or Magnesium-Containing/Milk**: Do not give antacids or milk within an hour of bisacodyl tablets as it may cause premature disintegration of the enteric coating resulting in a diminished therapeutic effect.
- **Oral Medications**: Stimulant laxatives may potentially decrease GI transit time thereby affecting absorption of other oral medications. Separate doses by 2 hours if possible.

Dosages
DOGS/CATS:

Cathartic (extra-label): Anecdotally, one 5 mg tablet/cat or small dog (NOT tablet/kg) PO once daily; one to three 5 mg tablets (5 – 15 mg)/dog (NOT tablets/kg) PO once daily for medium to large dogs. Do not break or crush tablets.

Client Information
- This medicine is a stimulant laxative used in dogs and cats.
- Do not crush, split, or allow your animal to chew tablets.
- Diarrhea, stomach pain, and cramping can occur.
- Do not give milk (dairy) products or liquid antacids within one hour of giving the oral tablets as it can dissolve the protective coating on the tablets.
- If you are giving other oral medicines to your animal, try to give them two hours apart from the bisacodyl oral dose. Bisacodyl can prevent other medicines from being absorbed properly.
- Bisacodyl should only be used on an occasional basis; long-term, regular use can cause harm to the intestinal tract.

Chemistry/Synonyms
A diphenylmethane laxative, bisacodyl occurs as white to off-white crystalline powder. It is practically insoluble in water and sparingly soluble in alcohol.

Bisacodyl may also be known as bisacodylum; many trade names are available.

Storage/Stability
Bisacodyl suppositories, enemas, and enteric-coated tablets should be stored at temperatures less than 25°C (77°F) and protected from humidity.

Compatibility/Compounding Considerations
Do not crush tablets. The 10 mg suppositories can be cut lengthwise to deliver a 5 mg rectal dose.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Bisacodyl Enteric-coated Oral Tablets: 5 mg; *Dulcolax®*, generic; (OTC). **NOTE**: Some *Dulcolax®* products may contain other active ingredients (eg, docusate); check product label carefully.

Bisacodyl Rectal Suppositories: 10 mg: *Dulcolax®*, generic; (OTC)

Bisacodyl Rectal Enema: 10 mg/30 mL; (OTC)

Bismuth Subsalicylate
BSS
(***biz***-mith sub-sa-***liss***-ih-layt) *Pepto-Bismol®*

Antidiarrheal; Gastroprotectant

Prescriber Highlights
- ► Used to treat diarrhea and as a component of triple/quadruple therapy for treating *Helicobacter* GI infections
- ► High doses may cause salicylism; use with caution in cats.
- ► Constipation/impaction may occur.
- ► May change feces color to gray-black or greenish-black
- ► Bismuth is radiopaque and may interfere with GI radiographic testing.
- ► Refrigeration may improve palatability.
- ► Possible teratogen

Uses/Indications
In veterinary medicine, bismuth subsalicylate products are used to treat diarrhea, as a gastroprotectant, and as a component of triple or quadruple therapy for treating *Helicobacter* GI infections.

In humans, bismuth subsalicylate is used to treat other GI symptoms (indigestion, cramps, gas pains) and in the treatment and prophylaxis of traveler's diarrhea.

Pharmacology/Actions
Bismuth subsalicylate is thought to possess gastroprotectant, anti-endotoxic, and weak antimicrobial properties in the GI tract. It is believed that the parent compound is cleaved in the small intestine into bismuth carbonate and salicylate. The protectant, anti-endotoxic, and weak antimicrobial properties are thought to be derived from the bismuth. The salicylate component has antiprostaglandin activity that may contribute to its effectiveness and reduce clinical signs associated with secretory diarrheas.

Pharmacokinetics
No pharmacokinetic information specific to veterinary medicine has been located. In humans, the amount of bismuth absorbed is negligible, whereas the salicylate component is rapidly and completely absorbed. Salicylates are highly bound to plasma proteins and are metabolized in the liver to salicylic acid. Salicylic acid, conjugated salicylate metabolites, and any absorbed bismuth are all excreted renally.

Bismuth subsalicylate did not alter gastric pH in healthy adult horses.[1]

Contraindications/Precautions/Warnings
Salicylate absorption may occur. Do not use in patients hypersensitive to aspirin or other salicylates. Use of this product in patients

with preexisting bleeding disorders or GI ulcers may exacerbate underlying conditions. Because of the potential for adverse effects caused by the salicylate component, this drug should be used cautiously, if at all, in cats. Antidiarrheal products are not a substitute for adequate fluid and electrolyte therapy when required.

Adverse Effects

Bismuth subsalicylate may change stool color to a gray-black or greenish-black; do not confuse with melena. One case report of a rhesus macaque suggests that chronic use may cause renal pigmentation.[2]

In human infants and debilitated individuals, use of this product may cause fecal impaction.

Reproductive/Nursing Safety

Salicylates are possible teratogens and have been shown to delay parturition; in humans, their use should be avoided during pregnancy, particularly during later stages.[3] Use with caution in pregnant animals.

Salicylates are excreted into human breast milk, and salicylate toxicity is possible.[3] Use with caution in nursing dams.

Overdose/Acute Toxicity

Bismuth subsalicylate liquid/suspension contains ≈8.7 mg/mL salicylate. Two tablespoons (30 mL) are approximately equivalent to one 325 mg aspirin tablet. Products containing bismuth may cause neurotoxicity at high doses. Common clinical signs in dogs include diarrhea, lethargy, vomiting, ataxia, weakness, and panting. Common clinical signs in cats include diarrhea, lethargy, and inappetence. See ***Aspirin*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bismuth subsalicylate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aspirin**: Because bismuth subsalicylate contains salicylate, concomitant administration with aspirin may increase salicylate serum concentrations and increase risk for adverse effects (eg, GI ulceration).
- **Angiotensin Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): Salicylates may enhance the nephrotoxic effects and reduce the effectiveness of ACE inhibitors. Monitor appropriately.
- **Anticoagulants** (eg, **heparin, rivaroxaban, warfarin**): May increase bleeding risk
- **Clopidogrel**: May have additive antiplatelet effects
- **Corticosteroids** (eg, **dexamethasone**, **prednis(ol)one**): Corticosteroids may increase the clearance of salicylates, decrease salicylate serum concentrations, and increase GI bleeding risk.
- **Loop Diuretics** (eg, **furosemide**): Salicylates may decrease the diuretic effect of loop diuretics. The serum concentration of salicylates may be increased by loop diuretics.
- **Methotrexate**: Aspirin may displace methotrexate from plasma proteins, increasing the risk for methotrexate toxicity.
- **NSAIDs** (eg, **carprofen, meloxicam, robenacoxib**): Concomitant administration with NSAIDs may increase the risk of bleeding.
- **Tetracycline Antibiotics** (eg, **doxycycline**): Products containing bismuth can decrease the absorption of orally administered tetracycline products. If both agents are to be used, separate drugs by at least 2 hours and administer tetracycline first. If necessary, tetracyclines may be given 6 hours after bismuth administration.

Laboratory Considerations

- At high doses, salicylates may cause false-positive results for **urinary glucose** if using the cupric sulfate method (*Clinitest*®, Benedict's solution) and false-negative results if using the glucose oxidase method (*Clinistix*® or *Tes-Tape*®).
- **Urinary ketones** measured by the ferric chloride method (Gerhardt) may be affected if salicylates are in the urine (reddish color produced).
- Salicylates in the urine may interfere with **5-HIAA** determinations by the fluorometric method.
- Falsely elevated **vanillylmandelic acid (VMA)** may be seen with most methods used if salicylates are in the urine. Falsely lowered VMA concentrations may be seen if using the Pisano method.
- Urinary excretion of **xylose** may be decreased if salicylates are given concurrently.
- Falsely elevated **serum uric acid** concentrations may be measured if using colorimetric methods.
- As bismuth is radiopaque, it may interfere with GI tract radiologic examinations.

Dosages

NOTE: Liquid doses below refer to suspensions of bismuth subsalicylate that are 17.5 mg/mL (1.75%) (eg, veterinary suspensions, original *Pepto-Bismol*® liquid) unless otherwise specified. Several over-the-counter products list dosages for dogs, cats, horses, cattle, and swine; however, none of the products or labeling are FDA-approved.

DOGS:

Acute diarrhea or as a GI "coating agent" (extra-label): Liquid: 0.25 – 2 mL/kg (4.4 – 35 mg/kg) PO 3 to 4 times per day

***Helicobacter* gastritis infections using triple therapy** (extra-label):

a) Bismuth subsalicylate suspension (original *Pepto-Bismol*®) 0.22 mL/kg (3.85 mg/kg) PO every 4 to 6 hours in combination with metronidazole 15.4 mg/kg and amoxicillin 11 mg/kg PO every 8 hours for 3 weeks[4]

b) Bismuth subsalicylate 262 mg tablets given based on body weight (less than 5 kg (11 lb) = 0.25 tablet; 5 to 9.9 kg (11 to 21.8 lb)= 0.5 tablet; 10 to 24.9 kg (22 to 54.8 lb) = 1 tablet; greater than 25 kg = 2 tablets) every 12 hours in combination with metronidazole 10 mg/kg PO every 12 hours and amoxicillin 15 mg/kg every 12 hours for 2 weeks[5]

c) Bismuth subsalicylate suspension 0.22 mL/kg (3.85 mg/kg) PO every 6 to 8 hours in combination with metronidazole 11 – 15 mg/kg PO every 12 hours and amoxicillin 22 mg/kg PO every 12 hours for 3 weeks[6]

CATS:

Diarrhea (extra-label): 0.5 – 1 mL/kg (8.8 – 17.5 mg/kg) PO every 12 hours. Use cautiously in cats; recommend not treating for more than 3 days[7]

***Helicobacter* gastritis infections using triple therapy** (extra-label): Bismuth subsalicylate suspension (original *Pepto-Bismol*®) 0.22 mL/kg (3.85 mg/kg) PO every 4 to 8 hours in combination with metronidazole 11 – 15.4 mg/kg PO every 8 to 12 hours and amoxicillin 11 – 22 mg/kg PO every 8 hours for 3 weeks[4,6]

***Helicobacter* gastritis infections using quadruple therapy** (extra-label): Bismuth subsalicylate (262 mg tablets; *Pepto-Bismol*®) ¼ tablet/cat (total dose) PO twice daily, ± H_2 blocker (eg, famotidine) or omeprazole in combination with metronidazole

10 mg/kg PO twice daily and amoxicillin 10 – 20 mg/kg PO 3 times daily for 2 weeks[8]

HORSES:

Diarrhea in foals (extra-label):

a) 60 – 120 mL/foal (NOT mL/kg) PO 2 to 4 times per day. **NOTE:** This dose equates to 21 – 42 mg/kg for a 50-kg foal (46.2-92.4 mg/lb for a 110-lb foal).
b) 2 – 5 mL/kg (35 – 87.5 mg/kg) PO divided into 2 to 4 doses[9]

CATTLE:

Diarrhea in cattle (labeled dose, not FDA-approved): 180 – 300 mL/calf (NOT mL/ kg) PO every 2 to 3 hours

Diarrhea in calves (labeled dose, not FDA-approved): 90 – 120 mL/calf (NOT mL/kg) PO every 2 to 3 hours

Diarrhea in calves (extra-label): 60 – 90 mL/calf (NOT mL/kg) PO 2 to 4 times per day

SWINE:

Diarrhea in baby pigs (extra-label): 2 – 5 mL/piglet (35 – 87.5 mg; total dose, NOT mg/kg) PO 2 to 4 times a day for 2 days

FERRETS:

***Helicobacter* gastritis infections using triple therapy** (extra-label):

a) Bismuth subsalicylate 7.5 mg/kg PO in combination with metronidazole 20 mg/kg PO and amoxicillin 30 mg/kg PO every 8 hours for 21-28 days[10]
b) Bismuth subsalicylate 17.5 mg/kg PO every 8 hours in combination with metronidazole 20 mg/kg PO every 12 hours and amoxicillin 20 mg/kg PO every 12 hours for 21 days. Used with gastroprotectants (famotidine and sucralfate)[11]

Monitoring

- Clinical efficacy
- Fluid and electrolyte status in severe diarrhea

Client Information

- Use with caution in cats, as they may be sensitive to the salicylate (aspirin-like compound).
- May cause constipation
- Do not give other drugs to your animal within 2 hours of this drug unless directed by your veterinarian.
- Shake the suspension well; store in the refrigerator to improve palatability. Do not mix with milk.
- May cause stool to change color to a gray-black or greenish-black. This may not indicate a problem. Contact your veterinarian if your animal tires easily or if the stool becomes tarry and black.
- May cause tongue discoloration

Chemistry/Synonyms

Bismuth subsalicylate occurs as a white or nearly white tasteless, odorless powder and contains ≈50% bismuth. It is insoluble in water, glycerin, and alcohol.

Bismuth subsalicylate may also be known as BSS, basic bismuth salicylate, bismuth oxysalicylate, bismuth salicylate, bismuthi subsalicylas, *Bismu-kote®*, *Bismukote®*, *Bismupaste®*, *Bismatrol®*, *Bismed®*, *Bismusal®*, *Bismylate®*, *Bisval®*, *Corrective®*, *Equi-Phar®*, *Gastrocote®*, *Jatrox®*, *Kalbeten®*, *Katulcin-R®*, *Oral-Pro Biz-Cote®*, *PalaBIS®*, *Peptic Relief®*, *Pink Biscoat®*, *Pink Bismuth Rose®*, or *Ulcolind Wismut®*; many other human trade names are available.

Storage/Stability

Bismuth subsalicylate should be stored protected from light. Unless otherwise labeled, store at room temperature (15 °C-30° C [59°F-86° F]); do not freeze.

Compatibility/Compounding Considerations

Bismuth subsalicylate is **incompatible** with mineral acids and iron salts. When exposed to alkali bicarbonates, bismuth subsalicylate decomposes with effervescence.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: Veterinary labeling does not imply that the product is FDA-approved.

Bismuth Subsalicylate Paste: 5% (50 mg/mL); 10% (100 mg/mL); (OTC). Depending on product, labeled for use in small, medium, and large dogs; 20% (200 mg/mL); (OTC). Labeled for use in horses

Bismuth Subsalicylate Oral Suspension: 1.75% (17.5 mg/mL; 262 mg/15 mL). Many trade names available, generic; (OTC). Available in gallons. Labeled for use in cattle, horses, calves, foals, dogs, and cats. Each mL contains ≈8.7 mg salicylate.

Bismuth Subsalicylate Tablets (each tablet contains 262 mg of bismuth subsalicylate): Labeled for use in dogs; (OTC). One tablet contains ≈102 mg salicylate.

HUMAN-LABELED PRODUCTS:

Bismuth Subsalicylate (BSS) Liquid/Suspension: 87 mg/5 mL; 130 mg/15 mL; 262 mg/15 mL; 524 mg/15 mL; 525 mg/15 mL; in 120 mL, 236 mL, 237 mL, 240 mL, 355 mL, 360 mL, and 480 mL; many trade names including *Pepto-Bismol®*, *Kaopectate®*, *Pink Bismuth*; (OTC). **NOTE**: Regular strength (262 mg BSS/15 mL) contains 8.7 mg/mL salicylate; Extra-Strength (525 mg BSS/15 mL) contains 15.7 mg/mL of salicylate.

Bismuth Subsalicylate Tablets and Caplets: 262 mg (regular and chewable); Many trade names including *Pepto-Bismol®*, *Kaopectate®*; (OTC). One tablet contains ≈102 mg of salicylate.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Bleomycin

(blee-oh-***mye***-sin) *Blenoxane®*

Antineoplastic

Prescriber Highlights

► Antibiotic antineoplastic agent infrequently used for a variety of neoplasms in dogs and cats; intralesional administration may have promise.
► Two main toxicity types: acute (fever, anorexia, vomiting, and allergic reactions) and delayed (dermatologic effects, stomatitis, pneumonitis, and pulmonary fibrosis)
► Do not exceed total dosage recommendations.
► Clinical monitoring for adverse toxicity required when used systemically
► The National Institute for Occupational Safety and Health (NIOSH) classifies bleomycin as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Bleomycin has been used in treatment of lymphomas, oral squamous cell carcinomas, teratomas, and nonfunctional thyroid tumors in both dogs and cats, although more recent evidence suggests extremely limited single-agent activity in canine lymphoma.[1] Bleomycin may be promising for intralesional treatment for localized tumors with or without concomitant electropermeabilization.[2,3] Intralesional bleomycin has been successfully used to treat dogs with acanthomatous ameloblastoma.[4,5]

Pharmacology/Actions

Bleomycin is an antibiotic that has activity against a variety of gram-negative and gram-positive bacteria and some fungi; however, its cytotoxicity to eukaryote cells prevents it from being clinically useful as an antimicrobial drug.

Bleomycin has both a DNA binding site and a site that binds to the ferrous form of iron. By serving as an electron acceptor from the ferrous ion to an oxygen atom in the DNA strand, bleomycin cleaves DNA and causes cellular apoptosis.

Resistance to bleomycin can result from reduced cellular uptake of the drug, reduced ability to damage DNA, increased rates of DNA repair by the cell and drug inactivation by the enzyme bleomycin hydrolase.

Pharmacokinetics

Pharmacokinetic information in veterinary species was not located. In humans, bleomycin is not appreciably absorbed from the GI tract and must be administered parenterally.[6] It is mainly distributed to the lungs, kidneys, skin, lymphatics, and peritoneum. Following IM or SC administration in humans, bleomycin reaches peak concentration within 30 to 60 minutes. In humans with normal renal function, terminal half-life is 2 to 4 hours. In humans, 60% to 70% of a dose is excreted as active drug in the urine.

Contraindications/Precautions/Warnings

Because bleomycin is a cytotoxic agent with a low therapeutic index, it should only be used in clinical facilities able to actively monitor and handle potential complications. Bleomycin is contraindicated in patients with previous hypersensitivity reactions and should be used cautiously in patients with preexisting pulmonary disease or adverse pulmonary effects from prior therapy. Dosage reduction may be necessary for patients with significant renal impairment. Bleomycin can be teratogenic; it should only be used in pregnant animals when the owners accept the associated risks.

A total cumulative bleomycin dose of 125 – 200 mg/m^2 should not be exceeded in order to reduce the risk of pulmonary toxicity.

The National Institute for Occupational Safety and Health (NIOSH) classifies bleomycin as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[7]

Adverse Effects

Toxicity falls into two broad categories: acute and delayed. Acute toxicities include fever, anorexia, mild vomiting, and allergic reactions including anaphylaxis. Delayed toxic effects include dermatologic effects (eg, erythema, hyperpigmentation, rash, and tenderness of the skin), stomatitis, pneumonitis, and pulmonary fibrosis. The latter 2 delayed toxic effects have been associated with drug-induced fatalities. Initial signs associated with pulmonary toxicity include pulmonary interstitial edema with alveolar hyaline membrane formation and hyperplasia of type II alveolar macrophages. Pulmonary toxicity is potentially reversible if cessation of treatment occurs prior to irreversible damage and appropriate supportive care instituted. Unlike many other antineoplastic agents, bleomycin does not usually cause myelotoxicity, but thrombocytopenia, leukopenia, and slight decreases in hemoglobin levels are possible. Renal toxicity and hepatotoxicity are also possible. When administered to dogs at 0.5 units/kg, adverse effects were infrequent and mostly GI related.[1]

To reduce the likelihood of pulmonary toxicity and other adverse effects, a total cumulative dose of 125 – 200 mg/m^2 should not be exceeded.

Reproductive/Nursing Safety

It is not known if bleomycin enters milk; it is not recommended to nurse while receiving the medication.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The intravenous LD_{50} in mice is 53 mg/kg.[8] Due to the potential for serious toxicity associated with this agent, dosage calculations should be checked thoroughly to avoid overdosing. There is no known antidote.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bleomycin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anesthetics, General**: Use of general anesthetics in patients treated previously with bleomycin should be done with caution. Bleomycin sensitizes lung tissue to oxygen (even to concentrations of inspired oxygen considered to be safe) and rapid deterioration of pulmonary function with postoperative pulmonary fibrosis can occur.
- **Prior or Concomitant Chemotherapy, Radiation Therapy, or Immunosuppressants:** Can lead to increased hematologic, mucosal, and pulmonary toxicities
- **Granulocyte Colony-Stimulating Factors** (eg, **filgrastim**): Can increase risk for pulmonary toxicity
- **Nephrotoxic Agents** (eg, **aminoglycosides, amphotericin B, cisplatin, iohexol**): Can increase risk for nephrotoxicity
- **Vaccines (Live and Inactivated):** Bleomycin may diminish vaccine efficacy and enhance adverse effects of vaccines.

Laboratory Considerations

None

Dosages

NOTE: Because of the potential toxicity of this drug to patients, veterinary personnel, and clients, and because chemotherapy indications, treatment protocols, monitoring, and safety guidelines change often, the following dosages should only be used as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[9,10–13] are strongly recommended.

SMALL ANIMALS:

Antineoplastic agent (extra-label): 10 mg/m^2 (NOT mg/kg) OR 0.3 – 0.5 mg/kg (**NOTE:** 1 unit = 1 mg), IV, SC, or intralesionally. Some protocols use the drug once daily for a few days and then reduce to once weekly; some give the drug once weekly initially.[4,14] To reduce the likelihood of pulmonary toxicity, a total cumulative dose of 125 – 200 mg/m^2 should not be exceeded. Bleomycin has also been administered in combination with electrochemotherapy.[3,15]

Monitoring

- Efficacy
- Pulmonary toxicity: Obtain thoracic radiographs (baseline and on a regular basis—in humans they are recommended every 1 to 2 weeks); lung auscultation (dyspnea and fine rales may be early signs of toxicity); other initial signs associated with pulmonary toxicity include pulmonary interstitial edema with alveolar hyaline membrane formation and hyperplasia of type II alveolar macrophages.
- Baseline and periodic CBC and serum chemistry profiles (to monitor for potential renal, hepatic, and hematologic toxicities.
- Total dose accumulation (not to exceed a total cumulative dose of 125 – 200 mg/m^2)

Client Information

- Bleomycin is a chemotherapy medicine. This medicine can be hazardous to other animals and people that come in contact with it. On the day your animal receives this medicine and then for a

few days afterward, all bodily waste (urine, feces, litter), blood, or vomit should only be handled while wearing disposable gloves. Seal the waste in a plastic bag and then place both the bag and gloves in with the regular trash.

- Bleomycin can have serious side effects, including lung damage that could result in death. Be sure to immediately report to your veterinarian any changes to your animal's breathing pattern or quality (eg, shortness of breath, wheezing).
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

An antibiotic antineoplastic agent, bleomycin sulfate is obtained from *Streptomyces verticullis*. It occurs as a cream colored, lyophilized powder that is soluble in water and slightly soluble in alcohol. After reconstitution, the pH of the solution ranges from 4.5 to 6. Bleomycin is assayed microbiologically. One unit of bleomycin is equivalent to 1 mg of the reference Bleomycin A_2 standard.

Bleomycin sulfate may also be known as bleomycin sulphate, bleomycini sulfas, *Bileco®*, *Blanoxan®*, *Blenamax®*, *Blenoxane®*, *Bleo®*, *Bleo-S®*, *Bleo-cell®*, *Bleocin®*, *Bleolem®*, *Blio®*, *Blocamicina®*, *Bonar®*, *Oil Bleo®*, or *Tecnomicina®*.

Storage/Stability

Store unopened vials at 2°C to 8°C (36°F-46°F). After reconstituting with sterile saline, sterile water, or bacteriostatic water, the resulting solution is stable for 24 hours.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Compatible with sodium chloride 0.9% for dilution. Dilution or reconstitution in dextrose 5% in water demonstrated a loss of potency. Bleomycin sulfate is reported to be **incompatible** for Y-site administration with the following drugs: amphotericin B, dantrolene, diazepam, phenytoin, and tigecycline.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Bleomycin Sulfate lyophilized powder for injection: 15 units and 30 units per vial; *Blenoxane®*, generic; (Rx)

Bromides

Potassium Bromide

Sodium Bromide

(***broe***-mide) *KBroVet®-CA1*

Anticonvulsant

Prescriber Highlights

- ► Primary or adjunctive therapy for seizure disorders in dogs; rarely used in cats, as it can cause eosinophilic bronchitis
- ► Very long half-life; must give loading dose to achieve therapeutic bromide concentrations faster.
- ► Most prevalent adverse effect in dogs is sedation, especially when the drug is used with phenobarbital. Polyphagia with resultant weight gain is also commonly noted, particularly in the first few months of therapy. Polydipsia and polyuria can also be seen.
- ► Monotherapy with bromide may require higher serum bromide concentration, and risk for toxicity is significantly increased.
- ► Do not feed salty snacks or make abrupt dietary changes; keep chloride in diet stable.
- ► Toxic effects include profound sedation to stupor, ataxia, tremors, hindlimb paresis, or other CNS manifestations.
- ► Dosages for sodium bromide are not the same as potassium bromide; check dosages carefully.

Uses/Indications

Bromide is used as both primary and adjunctive therapy to control seizures in dogs. Historically, bromide was only recommended for use as monotherapy in patients with phenobarbital hepatotoxicity. Potassium bromide is conditionally approved by the FDA for control of seizures due to idiopathic epilepsy.[1] Bromides also are used by some as a primary treatment or as add-on therapy in dogs with inadequate seizure control receiving phenobarbital alone. A study comparing phenobarbital with bromide as a first-choice antiepileptic drug for treatment of epilepsy in dogs found that although both were reasonable choices, phenobarbital was more effective (seizure eradication in 85% of phenobarbital treated and 52% of bromide treated) and better tolerated during the first 6 months of treatment.[2] Potassium bromide or phenobarbital have been demonstrated to be efficacious as add-on therapy for improved seizure control in dogs with idiopathic epilepsy refractory to imepitoin alone, with a response rate of 79% and 69%, respectively.[3]

The high incidence of adverse pulmonary effects precludes routine bromide use in cats.[4,5]

Pharmacology/Actions

Bromide's anti-seizure activity is thought to be the result of its generalized depressant effects on neuronal excitability and activity. Bromide ions compete with chloride transport across cell membranes resulting in membrane hyperpolarization, thereby raising seizure threshold and limiting the spread of epileptic discharges.

Pharmacokinetics

Bromides are well-absorbed after oral administration, primarily in the small intestine. Oral bioavailability in dogs averages 46%,[6] but there can be wide interpatient variability. The presence of food does not appear to affect absorption. Bromides are also well-absorbed after solutions are administered rectally in dogs (bioavailability, 60%-100%). Bromide is distributed in the extracellular fluid and mimics the volume of distribution of chloride (0.2 – 0.4 L/kg).[6,7] It is not bound to plasma proteins and readily enters the CSF (in dogs, ≈80% of serum concentration).[7] Bromide is predominantly excreted un-

changed via renal mechanisms. The half-life in dogs has been reported to be ≈15 days,[7] and steady-state serum concentrations are reached after ≈4 months.[7] Alterations in serum chloride levels[8] or diminished renal function can significantly affect bromide elimination rates.

In sheep, when sodium bromide is given IV, the half-life is ≈16 days, and when potassium bromide is given orally, the half-life is ≈14 to 15 days. The oral bioavailability of potassium bromide in sheep is ≈92%.[9]

Contraindications/Precautions/Warnings

Older animals and those with comorbidities may be prone to intolerance (see ***Adverse Effects***) at serum drug concentrations that are tolerated by younger, healthier dogs. Because bromides are primarily renally eliminated, patients with renal dysfunction may require dosage adjustments to minimize risk for bromide toxicity. Potentially, large loading doses of potassium bromide could affect serum potassium concentrations. Use with caution in dogs with an underlying condition that may predispose to electrolyte imbalances[1] (eg, unregulated hypoadrenocorticism or diabetes mellitus).

Potassium bromide must **never** be administered IV due to risk of cardiotoxicity from potassium; use sodium bromide if IV regimen is required.

Because bromides have been associated with serious adverse pulmonary effects in cats,[4,5] they should be used with extreme caution. Some state that the drug should not be used in cats.[1]

Adverse Effects

A systematic review and meta-analysis of adverse effects of antiepileptic drugs in dogs showed strong evidence for potassium bromide safety profile as monotherapy and weak as an adjunctive therapy.[10] Although no statistical significance was found, there was a trend for imepitoin, levetiracetam, and phenobarbital to have a safer profile than bromide. The most common type I adverse effects (dose-dependent and predictable) were ataxia followed by sedation, polyuria, polydipsia, polyphagia, paraparesis, hyperactivity, vomiting, and increased serum ALP and ALT activity. Less commonly, constipation or diarrhea, anorexia, aggression, tetraparesis, skin conditions (eg, panniculitis[11]), euthyroid sick syndrome, anisocoria, and chronic clinical hepatopathy/toxicity, as well as increased serum chloride, bile acids, and AST activity. Type II adverse effects (idiosyncratic dose-independent and unpredictable) were pancreatitis (most common adverse effect reported), followed by panniculitis, generalized appendicular repetitive myoclonus, neuromyopathy with generalized lower motor signs, and hyperchloremia with a negative anion gap.[10]

Ataxia and sedation are common and typically transient (lasting up to 3 weeks); conversely, some dogs show signs of irritability and restlessness. Bromide use reduced trainability in epileptic dogs.[12] GI effects, particularly during oral loading doses, may be reduced or avoided by giving with food or dividing the dose. If the patient cannot tolerate the GI effects (eg, vomiting) of potassium bromide and divided doses with food do not alleviate the problem, switching to sodium bromide may be considered. Potentially, large loading doses of potassium bromide could affect serum potassium concentrations.

In cats, pulmonary adverse effects (eg, cough, dyspnea, eosinophilic bronchitis) have been associated with bromide therapy,[4,5] and its use is rarely recommended. Peribronchial infiltrates may be seen on radiographs and dyspnea may be serious or fatal. Signs appear to be reversible in most cats once bromides are discontinued. Other adverse effects in cats include polydipsia, sedation, and weight gain.

Reproductive/Nursing Safety

Reproductive safety has not been evaluated in veterinary patients. Human infants have suffered bromide intoxication and growth delays after maternal ingestion of bromides during pregnancy. Bromide intoxication has also been reported in human infants breastfeeding from mothers taking bromides.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Toxicity is more likely with chronic overdoses, but acute overdoses are possible. Toxicity is generally associated with higher serum bromide concentrations (greater than 2.5 mg/mL), but some dogs can show toxic signs at lower concentrations. Neurotoxic effects are most common and present as profound sedation to stupor or coma, ataxia, tremors, mydriasis, or other CNS manifestations (eg, upper and lower motor neuron signs with tetraparesis/paraparesis, megaesophagus). Hypersalivation, vomiting, and diarrhea are common. In addition, animals that have developed bromism (acute or chronic) may develop signs of muscle pain, conscious proprioceptive deficits, anisocoria, hyporeflexia, and other neurologic deficits.

Standard GI decontamination should be employed after a known acute overdose. Death after an acute oral ingestion is apparently rare as vomiting generally occurs spontaneously. Administration of parenteral 0.9% sodium chloride or oral sodium chloride with parenteral glucose and diuretics (eg, furosemide) may be helpful in reducing bromide loads in either acutely or chronically intoxicated individuals.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bromides and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticonvulsants, Other** (eg, **levetiracetam, phenobarbital, zonisamide**): May increase risk for CNS depression
- **Antihistamines** (eg, **cetirizine**, **diphenhydramine**): May increase risk for CNS depression
- **Benzodiazepines** (eg, **alprazolam, diazepam, midazolam**): May increase risk for CNS depression
- **CNS Sedating Drugs, Miscellaneous** (eg, **acepromazine, methocarbamol, trazodone**): Because bromides can cause CNS depression, other CNS sedating drugs may cause additive sedation.
- **Diuretics** (eg, **furosemide**, **thiazides**): May enhance the excretion of bromides thereby affecting seizure control and dosage requirements
- **IV Fluids Containing Sodium:** Can reduce serum bromide concentrations. Lactated Ringer's and normal saline reduced serum bromide concentration by 14%.[13]
- **Low/High Salt (Sodium Chloride) Diets**: Bromide toxicity can occur if chloride ion ingestion is markedly reduced. Patients on low-salt diets may be at risk. Conversely, additional sodium chloride in the diet (including prescription diets high in chloride) could reduce serum bromide concentrations, affecting seizure control. Keep chloride content of diet relatively constant while bromides are being administered. If chloride content must be altered, monitor serum bromide concentrations more frequently.[14]
- **Opioids** (eg, **buprenorphine**, **hydrocodone, morphine, tramadol**): May increase risk for CNS depression. Tramadol appears

to lower seizure threshold in humans[15]; veterinary significance is uncertain.

- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): May increase risk for CNS depression

Laboratory Considerations

- **Gold chloride assay for serum bromide.** This assay is considered reliable for serum bromide concentrations below 4 mg/mL, but at concentrations above 4 mg/mL, results can become nonlinear and may not be accurate.
- **Chloride, serum**. See ***Drug Interactions*** regarding chloride. Bromide interferes with serum chloride determinations, yielding falsely high results.
- **Hypertriglyceridemia, lipemia.** May interfere with colorimetric assays for serum bromide and give falsely elevated bromide values. A 12-hour fast prior to drawing levels has been recommended.[16]
- Potassium bromide does not affect **canine thyroid function test** results.[17,18]

Dosages

DOGS:

NOTE: Unless otherwise noted, the following dosages are for potassium bromide. If substituting sodium bromide, reduce dosage by 15%.

Controls of seizures associated with idiopathic epilepsy (Label dosage; FDA-conditionally approved): 25 – 68 mg/kg PO once daily; adjust based on clinical response.[1,19] The median dosage in the efficacy trial was 37 mg/kg/day PO.

Epilepsy *loading* dosage (extra-label): Because of the long serum elimination half-life (weeks) in dogs (it may take up to 4 to 5 months for blood levels to reach steady-state concentrations), many dosing recommendations include an initial oral loading dose regimen to reduce the time required to attain therapeutic concentrations. In dogs that are unable to eat, the dose can be divided and given rectally every 4 hours.

1. Potassium bromide 450 mg/kg PO divided into 14 doses, given every 12 hours for 7 days (ie, 32 mg/kg PO every 12 hours for 7 days)[20]
2. Potassium bromide 600 mg/kg PO loading dose given in 5 to 10 equally divided doses over 17 to 48 hours in addition to the 30 mg/kg/day PO maintenance dose. 84% of dogs had bromide concentrations within the therapeutic range within 24 hours of completion of this protocol, 13% had concentrations below the therapeutic range, and 3% had a concentration above the therapeutic range.[21]
3. Sodium bromide 3% in sterile water can potentially be administered IV as an infusion over at least 8 hours, but this must be done with caution, as there is little clinical experience giving the drug IV and there are no commercially available IV preparations available; an in-line IV filter is required. Sodium bromide dosage is 15% less than the potassium bromide dosage. **NOTE:** Potassium bromide must **NOT** be administered IV; IV regimen is for sodium bromide only.

Epilepsy *maintenance* dosage (extra-label)**:** 30 – 40 mg/kg PO once daily or divided into 2 daily doses.[20-22] Some state that if using bromide as an add-on drug in dogs already on phenobarbital, a lower initial dosage of 15 – 30 mg/kg PO once daily should be used. Adjust dosages based on clinical efficacy, adverse effects, and serum bromide concentrations (see ***Monitoring***). Dosage increases should generally be in less than 5 mg/kg increments, particularly when prescribing at the higher end of the dosing range. A retrospective study found that dosage increases of 5 mg/kg increased the risk for toxicity (bromism) by almost 5-fold.[23]

Monitoring

- Efficacy/toxicity. One review of the safety of potassium bromide in dogs states that clinical signs may be a better indication of the appropriateness of treatment than is monitoring serum bromide concentration alone.[24]
- Serum bromide concentrations. In dogs, therapeutic bromide concentrations are generally agreed to be 1 to 3 mg/mL (100 to 300 mg/dL; 1000-3000 mg/L; 12.5-37.5 mmol/L). Concentrations in the lower range may be effective for dogs also receiving phenobarbital therapy and the higher range for dogs on bromide alone. Measure serum bromide concentration once steady state is achieved (ie, 3 to 4 months after initiating therapy or dose changes).[25] Thereafter, monitor bromide concentrations every 6 to 12 months or sooner if seizure control lessens (ie, patient has more than 3 seizures prior to next scheduled examination) or if signs of bromide toxicity occur.[22] Once steady state is reached, the time of day (hours postdose) for sampling for bromide measurement is not critical (ie, sample may be obtained regardless of when the last dose was administered)[22,25]; however, a 12-hour fast prior to blood draw is desirable to reduce interference from triglycerides.[16]

Client Information

- This medicine may be given with or without food.
- The dose may either be sprinkled on the dog's food (assuming the food is consumed entirely) or squirted in the side of the mouth. If mixed with food, elevate the food bowl.
- Dose measurements of bromide solutions should be done with an oral dosing syringe or other accurate measuring device.
- Dogs that cannot tolerate the gastrointestinal effects (eg, vomiting, poor appetite) of potassium bromide with single daily doses may better tolerate doses divided through the day and given with food.
- Do not give salty snacks or salty food or change your dog's diet without talking with your veterinarian first.
- Most common side effect is drowsiness (usually improves in a few weeks). Some dogs will consume more water or food than usual.
- Watch for serious side effects that may indicate that the dosage is too high, including behavior changes, difficulty walking, stumbling, incoordination, severe vomiting, difficulty swallowing.

Chemistry

Potassium bromide occurs as a white, odorless, cubical crystal or crystalline powder. One gram will dissolve in 1.5 mL of water. Potassium bromide contains 67.2% bromide. Each gram contains 8.4 mEq (mMol) of potassium and bromide.

Sodium bromide occurs as a white, odorless cubical crystal or granular powder. One gram will dissolve in 1.2 mL of water. Sodium bromide contains 77.7% bromide.

Because of the different molecular weights of sodium and potassium, with respect to actual bromide content, sodium bromide solutions of 250 mg/mL contain ≈20% more bromide than potassium bromide 250 mg/mL solution. This is generally not clinically significant *unless* changing from one salt to another in a given patient.

Storage/Stability

Unless otherwise labelled, store in tight containers at room temperature 15°C to 30°C (59°F-86°F). Compounded solutions may be stored for up to 1 year in clear or brown glass or plastic containers at room temperature. Refrigerating the solution may help reduce the chance for microbial growth but may cause crystals or precipitants to form. Should precipitation occur, warming the solution should resolubilize the bromide.

Compatibility/Compounding Considerations

Bromides can precipitate out alkaloids in solution. Mixing with strong oxidizing agents can liberate bromine. Metal salts can precipi-

tate solutions containing bromides. Sodium bromide is hygroscopic; potassium bromide is not.

To compound a solution with a concentration of 250 mg/mL, 25 g of potassium bromide is weighed; a sufficient amount of distilled water is added to a final volume of 100 mL; potassium bromide dissolves easily in water, sodium bromide may take longer to dissolve. Flavoring agents are not usually necessary for patient acceptance. USP grade (preferred) or reagent grade (specify American Chemical Society [ACS] grade) powder/crystals may be obtained from various chemical supply houses to compound an acceptable oral product.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Potassium Bromide Chewable Tablets: 250 mg and 500 mg in 60- or 180- count bottles; *KBroVet®-CA1; (Rx)*. Contains liver flavor. A potassium bromide 250 mg/mL oral solution using the same trade name is also commercially available but is not included in the conditional approval under NADA #141-544.

Bromocriptine

(broe-moe-***krip***-teen) *Cycloset®, Parlodel®*

Dopamine Agonist/Prolactin Inhibitor

Prescriber Highlights

- ► Synthetic ergot derivative historically used in dogs for estrus induction or treatment of pseudocyesis; in horses for pituitary pars intermedia dysfunction (PPID) or inappropriate lactation; in cats for acromegaly or mammary hyperplasia
- ► Cabergoline (another synthetic ergot derivative) is generally preferred for use in small animal species, due to its safety profile and low incidence of adverse effects as compared with bromocriptine.
- ► Pergolide is generally preferred (over bromocriptine) for the treatment of PPID in horses.
- ► Many adverse effects possible; GI (emesis), CNS depression, and hypotension are most common.
- ► Interferes with lactation

Uses/Indications

Bromocriptine has historically been used treat acromegaly in cats; inappropriate lactation[1] and pituitary pars intermedia dysfunction (PPID) in horses; and for pregnancy termination, pyometra, and pseudopregnancy in dogs; however, other dopamine agonists (eg, cabergoline for dogs and cats, pergolide for horses) have largely replaced bromocriptine due to their greater efficacy and safety as well as a more favorable adverse effect profile.

In humans, bromocriptine is used to treat hyperprolactinemia, Parkinson disease, and type 2 diabetes mellitus.

Pharmacology/Actions

Bromocriptine is an ergot alkaloid-derived dopamine (D_2) receptor agonist that exhibits multiple pharmacologic actions.[2] It inhibits prolactin release from the anterior pituitary, thereby reducing serum prolactin. The mechanism for this action is by a direct effect on the pituitary and/or stimulating postsynaptic dopamine receptors in the hypothalamus to cause the release of prolactin-inhibitory factor. Bromocriptine also activates dopaminergic receptors in the neostriatum of the brain and lowers growth hormone concentrations in patients with acromegaly. In humans with type 2 diabetes mellitus, it has been shown to counteract insulin resistance and subsequently reduce hepatic glucose output, serum triglycerides, and free fatty acids.

Pharmacokinetics

The pharmacokinetics of bromocriptine have not been reported in domestic animals. In humans, due to a high first-pass effect, only ≈7% of a bromocriptine dose reaches the systemic circulation.[3] Distribution characteristics are not well-described, but in humans, it is highly bound (90%-96%) to serum albumin. In humans, bromocriptine is metabolized by the liver primarily by CYP3A4 to inactive and nontoxic metabolites; it has a half-life of ≈5 to 6 hours.[2,3] Elimination occurs predominantly by the fecal route.

Contraindications/Precautions/Warnings

Bromocriptine is generally contraindicated in patients that are hypersensitive to ergot derivatives (eg, cabergoline)[3] or during pregnancy unless termination of pregnancy is desired. Patients that are intolerant of cabergoline may not tolerate bromocriptine.

In humans, bromocriptine is contraindicated in lactating or postpartum patients, and in patients that have uncontrolled hypertension as additive hypertension could occur.[3] Use with caution in patients with hypertension that are already being treated with antihypertensive medications as syncope may result. Bromocriptine should also be used with caution in patients with hepatic disease as the metabolism of the drug may be reduced.[3]

Adverse Effects

Bromocriptine may cause a plethora of adverse effects that are usually dose-related and minimized with dosage reduction. Common adverse effects include nausea, vomiting sedation, fatigue, and hypotension (particularly with the first dose, but it may persist). In dogs, bromocriptine is more likely to cause emesis as compared with cabergoline. Reducing the dose and administering with food may help minimize adverse GI effects. Cats may develop psychoactive effects with long-term administration.[4] Hypoglycemia has been documented in humans receiving bromocriptine[3]; incidence in veterinary species is unknown.

Reproductive/Nursing Safety

Because bromocriptine is an ergot alkaloid, toxicities associated with some of the naturally occurring ergot alkaloid toxins (eg, fescue toxicity) may occur and result in abortion, prolonged gestation with dystocia, and/or thickened or retained placenta in pregnant mares. Reduced implantation and embryolethality has been documented in laboratory species receiving high doses of bromocriptine.[3]

In humans, bromocriptine use during lactation is contraindicated because bromocriptine inhibits lactation.[3] The same effect is expected to occur in lactating veterinary patients and administration of bromocriptine to lactating animals is not recommended..

Overdose/Acute Toxicity

Overdoses may cause vomiting, severe nausea, lethargy, hypothermia, tachycardia, and profound hypotension. Standard GI decontamination techniques (eg, emesis induction, activated charcoal) should be employed when applicable; however, emesis often occurs spontaneously from the overdose, and induction of emesis may not be necessary. Cardiovascular monitoring (eg, blood pressure, heart rate) and supportive care should be provided based on clinical presentation.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bromocriptine and may be of significance in veterinary patients. Unless otherwise noted, use

together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amitriptyline**: May increase prolactin concentrations; bromocriptine dose may need to be increased
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**): May increase bromocriptine concentrations
- **Butyrophenones** (eg, **azaperone**, **haloperidol**)**:** May increase prolactin concentrations, and bromocriptine doses may need to be increased
- **Cyclosporine**: May increase cyclosporine concentrations
- **Erythromycin, Clarithromycin**: May increase bromocriptine concentrations
- **Estrogens** (eg, **estradiol, estriol**): May interfere with the intended effects of bromocriptine
- **Ergot Alkaloids, Other** (eg, **cabergoline, metergoline, pergolide**): Concomitant use of bromocriptine with other ergot alkaloids is not recommended. In humans receiving this combination, nausea, vomiting, lethargy, severe hypertension, and myocardial infarction has occurred[2,3]; a similar effect is expected in veterinary patients.
- **Ethanol**: Use of bromocriptine with alcohol may cause a disulfiram-type reaction (eg, nausea, vomiting).
- **Hypotensive Medications** (eg, **amlodipine, enalapril, opioids**): May cause additive hypotension if used with bromocriptine
- **Metoclopramide**: May cause prolactin release in dogs, thereby negating the effects of bromocriptine for treating pseudopregnancy
- **Monoamine Oxidase Inhibitors (MAOIs;** eg, **amitraz, linezolid, selegiline**): Avoid the use of bromocriptine with these compounds.
- **Octreotide**: May increase bromocriptine concentrations
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**): May increase prolactin concentrations; bromocriptine dose may need to be increased
- **Progestins**: May interfere with the intended effects of bromocriptine
- **Reserpine**: May increase prolactin concentrations; bromocriptine dose may need to be increased
- **Sympathomimetics** (eg, **phenylpropanolamine**): Enhanced bromocriptine effects have been reported in humans (rare), including ventricular tachycardia and cardiac dysfunction.[2]

Laboratory Considerations

- None

Dosages

DOGS:

Pseudocyesis (pseudopregnancy) | suppression of lactation (extra-label): 10 µg/kg PO every 8 to 12 hours for 7 to 10 days[5]

Adjunctive treatment of pyometra (extra-label): 25 µg/kg PO 3 times daily in combination with prostaglandin[6]

Estrus induction (extra-label): 20 – 50 µg/kg PO twice daily.[7] **NOTE**: Not often recommended for this indication

Pregnancy termination (extra-label): 15 – 30 µg/kg PO every 12 hours in conjunction with a prostaglandin (eg, cloprostenol).[8] **NOTE**: Not often recommended for this indication

CATS:

NOTE: Bromocriptine may need to be compounded for use in cats.

Adjunctive treatment of acromegaly (extra-label): Initial dose of 200 µg/cat (NOT µg/kg) PO once daily. May have some effect, especially in reducing insulin requirements[9]

Adjunctive treatment of mammary fibroadenomatous hyperplasia (extra-label): 250 µg/cat (NOT µg/kg) PO.[10] **NOTE**: Not often recommended for this indication.

HORSES:

Pituitary pars intermedia dysfunction (PPID; extra-label):

a) 30 – 90 µg/kg twice daily PO or SC, but its use is limited[11]
b) 5000 µg/horse (NOT µg/kg) IM every 12 hours for 6 weeks.[12] See **Compatibility/Compounding Considerations**.

Inappropriate lactation (extra-label): 40 µg/kg PO twice daily for 10 days. Dosage based on a case report and administered in conjunction with local hydrotherapy (20 minutes twice daily); milking restricted to times when the mare was in extreme discomfort[1]

Monitoring

- Monitoring for efficacy is dependent on the reason for use.
- Adverse effects (eg, lethargy, hyporexia, vomiting)
- Blood pressure
- Serum progesterone

Client Information

- In horses, this drug is usually injected into the muscle (IM) or under the skin (SC) twice a day. If your veterinarian has instructed you to give this medication by shot in the muscle or under the skin, be sure you understand the proper places and technique to give it.
- Vomiting, fatigue, and low blood pressure are possible. For dogs and cats, giving this medicine with food may help to decrease vomiting.
- Long-term use of this medicine in cats may cause behavior changes (eg, head and body shaking, flicking of legs). Contact your veterinarian if you have any concerns.

Chemistry/Synonyms

Bromocriptine mesylate—a dopamine agonist and prolactin inhibitor—is a semisynthetic ergot alkaloid derivative. It occurs as a yellowish-white powder and is slightly soluble in water and sparingly soluble in alcohol.

Bromocriptine mesylate may also be known as bromocryptine, brom-ergocryptine, 2-bromergocryptine, bromocriptine methanesulphonate, bromocriptini mesilas, 2-bromo-alpha-ergocryptine mesylate, 2-bromoergocryptine monomethanesulfonate, or CB-154 (bromocriptine); many trade names are available.

Storage/Stability

Protect tablets and capsules from light and store them in tight containers at 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

A case report described the preparation of an injectable formulation for IM use: bromocriptine mesylate 70 mg was added to 7 mL of a solution of 80% normal saline and 20% absolute alcohol (v/v). Final concentration is 1% (10 mg/mL).[12]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Bromocriptine Mesylate Oral Capsules: 5 mg; *Parlodel*®, generic; (Rx)

Bromocriptine Mesylate Oral Tablets: 0.8 and 2.5 mg; *Cycloset*®, *Parlodel*®, generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Budesonide

(bue-***des***-oh-nide) *Entocort EC®, Uceris®*
Glucocorticoid

Prescriber Highlights

- ► Orally administered, locally active glucocorticoid that may be useful in treating chronic inflammatory enteropathies in small animal species
- ► Has been proposed for treating patients that are intolerant of systemic steroids; evidence of fewer adverse effects as compared with other oral glucocorticoids is lacking, and HPA axis suppression has been documented.
- ► Inhalation therapy may be useful in cats with asthma or horses with severe equine asthma, but currently available inhaled dosage forms may preclude use.
- ► Drug interactions with CYP3A inhibitors and antacids have been reported.
- ► Embryocidal and teratogenic in rats and rabbits
- ► Expense may be an issue, but generic forms are available; may need to be compounded to smaller dosage strengths.

Uses/Indications

Most veterinary interest is in budesonide's potential oral use to treat inflammatory intestinal diseases in small animal species that are intolerant of systemic corticosteroids. In studies of dogs with chronic inflammatory enteropathies (previously termed inflammatory bowel disease [IBD]), modest clinical and/or histopathologic response was noted with commercial budesonide capsules, whereas all dogs receiving placebo had worsening of disease.[1,2] One study demonstrated that budesonide powder (not commercial capsules) and prednisone were equally efficacious at inducing remission in dogs with inflammatory bowel disease, but no difference in adverse effects was noted.[3] Anecdotally, budesonide may be effective for some cats with chronic inflammatory enteropathies.[4]

Inhalational dosage forms are available for treating asthma or allergic rhinitis in humans. Inhaled budesonide has improved clinical signs in cats with asthma and chronic bronchitis[5] and significantly improved pulmonary function in horses with severe equine asthma (SEA; formerly known as recurrent airway obstruction [RAO]).[6] However, in the US, the mode of inhalation of commercially available products is not compatible with the space chambers used in veterinary medicine, which may preclude usage.

Pharmacology/Actions

Budesonide is a potent glucocorticoid (15 times more potent than prednisolone) with high topical activity. It has weak mineralocorticoid activity. By delaying drug dissolution until reaching the duodenum, the commercial enteric-coated formulations control release of the drug so it can exert its topical anti-inflammatory activity in the intestines. Although the drug is absorbed from the gut into the portal circulation, it has a high first-pass metabolism effect through the liver that reduces systemic blood concentrations and resultant glucocorticoid effects of the drug. However, suppression of the HPA axis has been demonstrated in dogs,[7-10] cats,[5] and horses.[6]

Pharmacokinetics

Budesonide's pharmacokinetics have been reported in healthy dogs. With oral administration of a controlled-release formulation, the drug has a bioavailability of 10% to 20%. When dosed at 10 µg/kg, half-life is ≈2 hours and clearance 2.2 L/hour/kg. At 100 µg/kg, half-life is mildly prolonged to 2 to 3 hours. In dogs with inflammatory bowel disease, budesonide (as the commercial oral product) is apparently rapidly absorbed with peak concentrations occurring at 1 hour post dosing.[2]

Upon oral administration of the commercially available product in humans, budesonide is nearly completely absorbed from the gut, but time to achieve peak concentrations are widely variable (30 to 600 minutes). The presence of food in the gut may delay absorption but does not impact the amount of drug absorbed. Because of a high first-pass effect, only ≈10% of a dose is systemically bioavailable in healthy adults. In patients with Crohn's disease, oral bioavailability may be twice that initially, but with further dosing, reduces to amounts similar to healthy subjects. Budesonide's mean volume of distribution in humans ranges from 2.2 to 3.9 L/kg. The drug is completely metabolized, and metabolites are excreted in the feces and urine. Budesonide's terminal half-life is ≈4 hours.

After nebulization, budesonide is detectable in the plasma and urine of horses for up to 96 hours and 120 hours, respectively.[11]

Contraindications/Precautions/Warnings

Budesonide is contraindicated in patients hypersensitive to it. Because budesonide can cause systemic corticosteroid effects, it should be used with caution in any patient in which glucocorticoid therapy may be problematic, including those with GI ulcers, active infections, diabetes mellitus, or cataracts. Risk for systemic effects may be increased in patients with hepatic impairment; dosage reduction may be required.

Because budesonide suppresses the HPA axis, exogenous steroid administration should be considered for animals undergoing stressful procedures, such as surgery.

Adverse Effects

In humans, budesonide causes few glucocorticoid adverse effects when it is used for courses of therapy no longer than 8 weeks in duration. However, budesonide has been shown to cause significant HPA axis suppression in dogs when using commercial formulations,[8-10] and when using compounded budesonide powder.[7] One study failed to show a decreased incidence of adverse systemic effects compared to prednisone.[3] A tendency towards less severe adverse effects was observed with budesonide, but this finding was not statistically significant. Increases in liver enzyme activity were seen in this study but were not noted in other studies. Of note, as budesonide is a potent glucocorticoid that is locally active in the GI tract, local adverse effects, such as GI erosion, ulceration, and even perforation are possible when budesonide is overdosed.

Inhaled budesonide reduced cortisol concentration in horses,[6] and resulted in HPA axis suppression in cats.[5]

Reproductive/Nursing Safety

Budesonide had no effect on fertility in rats at SC doses up to 80 µg/kg. As with other corticosteroids, budesonide has been demonstrated to be embryocidal and teratogenic in rats and rabbits. Because safety has not been established in animal species, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Specific data on budesonide concentrations in maternal milk are not available and the manufacturer warns against use by nursing women; however, because of the drug's high first-pass effect, the amounts are unlikely to be of clinical significance to nursing animal offspring.

Overdose/Acute Toxicity

Budesonide doses of 200 mg/kg were lethal in mice. Overdoses of glucocorticoids used alone are unlikely to cause harmful effects, but GI signs that are sometimes severe can be seen in dogs. If clinical signs occur, use supportive treatment if required. Chronic use of glucocorticoids can lead to serious adverse effects. Refer to ***Adverse Effects*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving budesonide and may be of significance in veterinary patients. Unless otherwise noted, combined use is not necessarily contraindicated, but the potential risks should be carefully weighed and additional monitoring should be performed when appropriate.

- **Aspirin:** Increased risk for GI erosion, ulceration, or perforation
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs;** eg, **carprofen, meloxicam, robenacoxib**): Increased risk for GI erosion, ulceration, or perforation
- **Oral Antacids**: Because the dissolution of the drug's coating is pH dependent, separate the administration of oral antacids from budesonide by at least 2 hours. Other drugs that potentially would increase gastric pH (eg, famotidine, omeprazole) do not significantly impact the oral pharmacokinetics of the drug.[12]

Because the hepatic enzyme CYP3A extensively metabolizes budesonide, drugs that inhibit this isoenzyme can significantly increase the amount of drug that enters the systemic circulation.

- **Azole Antifungals** (eg, **fluconazole, itraconazole, ketoconazole):** Concomitant ketoconazole is known to increase budesonide area under the curve (AUC) by 8-fold.[12]
- **Cimetidine**[12]
- **Cyclosporine**
- **Diltiazem**
- **Erythromycin**
- **Grapefruit Juice Powder**

Laboratory Considerations

- **Intradermal skin testing (IDST)** for allergens: Inhaled budesonide (for 1 month) eliminated skin reactivity in 3/6 cats tested. A 2-week withdrawal period is suggested if performing IDST but may not be necessary if using serum IgE testing for allergies.[13]

Dosages

DOGS

Adjunctive treatment of chronic inflammatory enteropathies (extra-label)**:** Initial dosage recommendations vary, but practically: body weight 3 to 7 kg: 1 mg (must be compounded), 7.1 to 15 kg: 2 mg (must be compounded), 15.1 to 30 kg: 3 mg (commercially available), greater than 30 kg: 5 mg (must be compounded) PO once daily[3] OR 3 mg/m^2 (NOT mg/kg) PO once daily.[7] Once adequately controlled, gradual reductions in dosage amounts or frequency (every other day) are desirable.

CATS:

Adjunctive treatment of chronic inflammatory enteropathies (extra-label): Most cats tolerate oral glucocorticoids, but in those that cannot and especially in diabetic cats, budesonide can be considered: 3 mg/m^2 (NOT mg/kg) PO once daily[14,15] or 0.5 – 0.75 mg/cat (NOT mg/kg) PO once daily.[4] **NOTE**: These dosages require reformulation to provide the appropriate dose.

HORSES

Adjunctive treatment of severe equine asthma (**SEA**; extra-label): 1.8 mg total dose (NOT mg/kg) twice daily. The drug was delivered as 8 actuations via Respimat® inhalation device and using an equine-specific nostril adapter.[6]

Monitoring

- Efficacy (improved clinical signs)
- Adverse effects, including possible HPA axis suppression

Client Information

- Do not crush capsules or allow animals to chew them. Do not open capsules unless your veterinarian has instructed you to do so.
- Once your animal has been taking this drug for a while, don't stop giving it unless instructed to do so by your veterinarian. Serious withdrawal effects can occur if the medication is stopped suddenly.
- In dogs, stomach or intestinal ulcers, perforation, or bleeding can occur. If your animal stops eating or has a low energy level or you notice a high fever, black tarry stools, or bloody vomit (may look like coffee grounds), contact your veterinarian immediately.
- Side effects (eg, increased panting, appetite, thirst, and need to urinate) are possible, especially when the medication is used long-term, but are less likely to occur than with other medications in this class. Other side effects could include lethargy, muscle weakness, changes in skin and hair/coat, weight gain, and/or pot belly. Contact your veterinarian if these side effects occur.

Chemistry/Synonyms

Budesonide, a nonhalogenated glucocorticoid, occurs as a white to off-white odorless, tasteless powder. It is practically insoluble in water, freely soluble in chloroform, and sparingly soluble in alcohol. The commercially available capsules contain a granulized micronized form of the drug that is enteric coated to protect it from dissolution in gastric juice but that dissolves at pH greater than 5.5. In humans, this pH usually corresponds with the drug reaching the duodenum. After dissolution of the outer coating, budesonide is released from an inner core in a time-dependent manner. The commercially available tablet contains an outer coating that dissolves at or above pH 7.0, followed by a controlled release of budesonide from the inner tablet core.

Budesonide may also be known as S 1320, *Entocord®*, *Entocort EC®*, *Uceris®*, Pulmicort®, and *Rhinocort®*.

Storage/Stability

Budesonide oral capsules should be stored in tight containers at room temperature (20°C-25°C [68°F-77°F]), protected from light and moisture. Exposures to temperatures as low as 15°C (59°F) and as high as 30°C (86°F) are permitted.

Compatibility/Compounding Considerations

If reformulating into smaller capsules, do not alter (damage) the micronized enteric-coated sugar spheres inside the capsules.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Budesonide Extended-Release Capsules: 3 mg and 9 mg (micronized); *Entocort EC®*, *Uceris®*, generic; (Rx)

Budesonide Extended-Release Tablets: 6 mg and 9 mg; *Uceris®*; (Rx)

Budesonide capsules intended for human use may need to be compounded into dosage strengths suitable for dogs and cats, but the enteric-coated sugar spheres found inside the capsule should not be altered or damaged.

Budesonide Inhalation Suspension (for nebulization): 0.25 mg and 0.5 mg in 2 mL ampules; generic; (Rx). The budesonide oral inhaler is a breath-actuated device that is not amenable for typical veterinary use.

Bupivacaine

(byoo-***piv***-a-kane) *Sensorcaine®, Marcaine®*

Local Anesthetic

For information regarding liposomal bupivacaine extended-release formulation, please refer to ***Bupivacaine Liposome****.*

Prescriber Highlights

- ► Local anesthetic with slower onset (20 to 30 minutes) and longer duration of action (3 to 5 hours) than others in its class
- ► Do not convert dosing from any other formulations of bupivacaine to bupivacaine liposome injection suspension or vice versa.
- ► Unintended systemic administration or absorption can lead to severe cardiac and CNS adverse effects, including death.
- ► Adverse effects are unlikely when the correct administration technique is used. Clinicians should be knowledgeable in the diagnosis and management of local anesthetic toxicity, and resources for treating acute emergencies must be readily available.
- ► Patients susceptible to malignant hyperthermia should receive intensified monitoring.

Uses/Indications

Bupivacaine is used in most species to produce local or regional analgesia and anesthesia for surgery and diagnostic or therapeutic procedures. It is also used for caudal and lumbar epidural anesthesia. Local analgesia can have a MAC-sparing effect on inhalant anesthesia, and leads to better postoperative recovery following orthopedic surgery in dogs.[1,2] The duration of analgesia can be extended when bupivacaine is combined with dexmedetomidine for femoral and sciatic nerve blocks in dogs.[3]

Epidural bupivacaine results in reduced intraoperative opioid use[4] and may have a MAC-sparing effect.[5] To provide a longer duration of epidural analgesia, bupivacaine can be combined with buprenorphine.[3]

Additional local anesthetic administration techniques for bupivacaine include intrathecal administration[6] or intraperitoneal spraying[7-10] for incision closure.

Some clinicians prefer a combination of lidocaine (faster onset) and bupivacaine (longer duration) but studies in a variety of species suggest the onset of effect is similar to that of either lidocaine or bupivacaine alone[11-14] and the duration of analgesia is shorter than bupivacaine alone (but longer than lidocaine alone).[11,13,15-18] To achieve a faster onset but longer duration nerve block, use only lidocaine prior to the procedure and repeat the block at the end of the procedure using only bupivacaine.

An extensive description of most common local blocks and epidural/spinal injection in small animals can be found in other reference texts.[19-22]

Pharmacology/Actions

Local anesthetics block sodium ion channels on the nerve cell membrane, thereby altering electrical excitability, depolarization, and action potential propagation. They block the generation and conduction of impulses in motor, sensory, and autonomic nerve fibers around the site of application. Nerve fiber diameter, conduction velocity, and myelination determine loss of nerve function. Clinically, the progressive loss of nerve function occurs in the following order: pain, temperature, touch, proprioception, and skeletal muscle tone. Anesthetic effect is lost in reverse order.

Bupivacaine produces analgesia typically within 20 to 30 minutes after local administration and persists for 3 to 5 hours. Compared to lidocaine, bupivacaine has a slower onset and longer duration of action.

Pharmacokinetics

Local anesthetics are absorbed from their site of administration into the systemic circulation. Systemic absorption increases when administration is repeated in the head and neck region and/or injected into highly vascularized sites.

In dogs, peak plasma concentrations occurred 11 minutes after intra-articular administration and elimination half-life was 1 hour.[23] After epidural use, plasma levels peaked after 5 minutes, and half-life was 3 hours.[24] Intermittent wound infusion of bupivacaine 0.25% solution (2 mg/kg) via wound catheter in dogs resulted in a measurable bupivacaine concentration of 0.25 to 0.35 μg/mL, which is below the known toxic concentration (ie, 2.5 μg/mL).[25]

In cats, peak plasma concentrations have been noted 17 to 30 minutes after administration, with an elimination half-life of 4.8 hours.[26,27]

In humans, peak levels occur ≈15 to 30 minutes after administration. Systemically absorbed drug distributes into all tissues, including the CNS. Protein binding is ≈95%, which may limit but not prevent it from crossing the placenta and being excreted in milk. It is hepatically metabolized and is excreted in the urine, principally as metabolites. Elimination half-life in humans is ≈2.5 hours in adults, and ≈8 hours in neonates.

Epinephrine may be added to bupivacaine formulations at a very low concentration (5 μg/mL) to cause vasoconstriction at the site of administration, thereby reducing the rate of systemic absorption. Commercial bupivacaine products containing epinephrine are available. Epinephrine prolongs the duration of action at the site of administration, as well as minimizing systemic bupivacaine toxicity.

Contraindications/Precautions/Warnings

Bupivacaine is contraindicated in patients with a known hypersensitivity to it or to another amide-type local anesthetic, and for obstetrical paracervical block anesthesia. Epidural use is contraindicated in patients with severe CNS disease. Use with caution in patients with hepatic disease or impaired cardiovascular function. Bupivacaine is more cardiotoxic than other local anesthetic agents and should never be administered IV. When used for IV regional anesthesia (Bier Block) in humans, bupivacaine has been linked to cardiac arrest and death; veterinary significance is unclear.

Epidural injections should be administered incrementally, with aspiration prior to injection. Local anesthetics with preservatives should not be used for epidural or caudal anesthesia.

Bupivacaine products that contain epinephrine should be used with caution, if at all, in patients with cardiovascular disease or hyperthyroidism, or for anesthesia of the digits, ears, nose, or penis. Avoid bupivacaine/epinephrine when nerve integrity or collateral circulation is compromised as it causes intense vasoconstriction and diminished blood flow; ischemic injury could result.

Hyperbaric bupivacaine (bupivacaine solutions with dextrose) produces a different pharmacological effect and is not interchangeable with bupivacaine solution formulated in sterile water. Hyperbaric bupivacaine should not be used for peripheral nerve blocks.

Adverse Effects

Local anesthetics are generally well tolerated when administered correctly. Adverse effects are related to high plasma concentrations, which may result from the dosage or bupivacaine concentration

used, rapid absorption from the injection site, and unintentional intravascular or subarachnoid injection.

Cardiovascular adverse effects include hypotension, bradycardia, AV block, and decreased cardiac output. Either CNS excitation (restlessness, tremors) or depression (drowsiness, loss of consciousness) may occur. Nausea and vomiting are also noted. See ***Overdose/Acute Toxicity.*** Chondrolysis has occurred in humans receiving intra-articular injections, but was considered unlikely to occur in dogs.[28] Intra-articular use in horses induced an anabolic effect in one small study.[29]

Reproductive/Nursing Safety

Bupivacaine crosses the placenta, and the fetal to maternal ratio is ≈0.2 to 0.4. Developmental toxicity was noted in rats and rabbits receiving bupivacaine 40 mg/kg SC and 22 mg/kg SC, respectively, and decreased pup survival was noted in rats. Because safety has not been established in animal species, this drug should only be used when the maternal benefits outweigh the potential fetal risks. An example of when it may be used is a line block of the linea alba prior to cesarean section. Bupivacaine will decrease inhalant anesthesia requirements and thus decrease cardiovascular and respiratory depression effects to the neonates.

Bupivacaine is excreted in human milk in small amounts; significance in veterinary medicine is not known. Use with caution in lactating dams.

Overdose/Acute Toxicity

Toxic blood levels are most likely to occur after unintended intravascular administration. To avoid this, ALWAYS aspirate before injecting the local anesthetic. Toxic effects may occur rapidly and simultaneously. Cardiac conduction and excitability are depressed and may lead to AV block, ventricular arrhythmias, and cardiac arrest; arrhythmias may be refractory to treatment. In addition, myocardial contractility is depressed and peripheral vasodilation occurs, leading to decreased cardiac output and arterial blood pressure. Central nervous system stimulation (restlessness, tremors, and shivering progressing to seizures) may be followed by CNS depression, coma, and respiratory arrest. The mean convulsive dose in cats was 3.8 mg/kg IV and the mean cardiotoxic dose was 18.4 mg/kg IV.[30] In dogs, mean convulsive dose was 4.1 mg/kg IV[31] and the mean cardiotoxic dose was ≈20 mg/kg IV.[32] The LD_{50} in mice is 6 – 8 mg/kg IV.

If signs of overdose are present, management must begin with delivery of oxygen via a patent airway as successful oxygen delivery may prevent convulsions caused by toxicity. Benzodiazepines and barbiturates can be used for seizure management but may cause further CNS depression. Cardiovascular support should be provided and may include IV fluids and vasopressor drugs (eg, dobutamine, norepinephrine). Prolonged resuscitative efforts may be required. Lipid emulsion 20% 1.5 mL/kg IV over 30 minutes can be beneficial.[33,34] See ***Fat Emulsion, Intravenous***.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bupivacaine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Angiotensin-Converting Enzyme Inhibitors (ACEIs; eg, benazepril, enalapril):** Increased risk for bradycardia and hypotension
- **Beta-Adrenergic Antagonists:** (eg, **atenolol, esmolol, propranolol, sotalol**)**:** May increase serum bupivacaine concentrations by reducing bupivacaine clearance

Severe, prolonged hypertension may result when using bupivacaine/epinephrine combination products with the following:

- **Ergot Alkaloids**
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, linezolid, selegiline**)
- **Tricyclic Antidepressants** (**TCAs** ; eg, **amitriptyline, clomipramine**
- **Vasopressors** (eg, **dobutamine**, **norepinephrine**)

Laboratory Interactions

- None noted

Dosages

NOTES:

1. Bupivacaine product concentration, administration volume, site of administration, administration technique (eg, gentle needle insertion, aspiration prior to injection), and underlying patient condition(s) are important interrelated factors that determine bupivacaine's safe and effective use.
2. All dosages are extra-label.

DOGS:

Local anesthesia (tissue infiltration):

1. Using 0.25% or 0.5% bupivacaine solution, 1 – 2 mg/kg[1]
2. Using 0.5% bupivacaine solution, 0.5 mg/kg combined with dexmedetomidine 0.1 µg/kg[3]
3. Using 0.5% bupivacaine solution, mix with equal volume of 2% lidocaine solution to speed onset of effect[15]

Intraperitoneal administration ovariohysterectomy: 3 mg/kg intraperitoneal to linea alba prior to closure.[8,10] 4.4 mg/kg using 0.25% bupivacaine also appears to be effective.[35,36]

Retrobulbar injection: 0.5 mg/kg using 0.5% bupivacaine solution.[37]

NOTE: Peribulbar injection may produce more reliable analgesia.[38]

Epidural:

1. Using 0.5% bupivacaine solution, 1.25 mg/kg[18]
2. Using 0.5% bupivacaine solution, 1 mg/kg combined with morphine 1% preservative-free solution, 0.1 mg/kg[39-41]
3. Using 0.5% bupivacaine solution, 1 mg/kg combined with buprenorphine 4 µg/kg[3]
4. Using 0.5% bupivacaine solution, 1 mg/kg combined with dexmedetomidine 0.05 % solution, 4 µg/kg.[41] Using 0.5% bupivacaine solution, 2 mg/kg combined with dexmedetomidine 7 µg/kg.[42] Note: These doses may increase risk for cranial spread of the local anesthetic, which can impair respiration by blocking intercostal nerves.
5. Using 0.5% bupivacaine solution, 1 – 2 mg/kg; greater efficacy with the higher dosage.[43] If using 0.25% bupivacaine solution, 0.6 mL/kg appears to be the optimal volume for epidural use.[44]

CATS:

Local anesthesia (tissue infiltration): 1.1 mg/kg using 0.5% bupivacaine solution.[45] Most experts consider 1 mg/kg the appropriate dose for cats, but one study safely used 2 mg/kg using 0.5% bupivacaine solution to infiltrate a surgical wound site.[46]

Intraperitoneal administration during ovariohysterectomy (OVH):

1. Using 0.25% bupivacaine solution, 2 mg/kg divided into 3 equal volumes and instilled in the right and left ovarian pedicles, and caudal uterus immediately before OVH using a 3 mL syringe attached to a 22 G IV catheter. Surgery proceeded ≈2 minutes later. [7] Similar results were obtained using bupivacaine 0.25% with epinephrine 2 µg/kg.[47]

2. Using 0.5% bupivacaine solution, 2 mg/kg divided equally into the right and left ovarian suspensory ligaments, uterine body just caudal to bifurcation, and to the subcutaneous tissue between the closed abdominal muscle fascia and subcuticular layers[48]

Retrobulbar injection: 0.7 – 1 mg/kg using 0.5% bupivacaine solution[26,49]

Epidural: Using 0.5% bupivacaine solution, 1.5 – 2.5 mg/kg lumbosacral epidural.[17] Bupivacaine 0.22 mg/kg caudal epidural using 0.5% solution. The addition of preservative-free morphine (0.1 mg/kg) to the epidural modestly (12%) reduced propofol requirements without significantly changing rescue analgesia.[5]

HORSES:

Continuous peripheral nerve block: In an experimental setting using a bupivacaine 0.125% solution, a 3 mL bolus infused through a nerve block catheter, followed by 2 mL/hour infusion over 6 days, suppressed mechanical hoof withdrawal response.[50]

Caudal epidural for perineal analgesia: 0.04 mg/kg bupivacaine using 0.25% solution, or 0.02 mg/kg bupivacaine combined with morphine 0.1 mg/kg OR ketamine 0.5 mg/kg injected into the epidural space. All 3 treatments were effective; bupivacaine plus morphine produced a longer duration of analgesia (5.25 hours vs 3.5 to 4 hours with the other drug combinations).[51]

CATTLE:

Caudal epidural: 0.05 – 0.06 mg/kg using 0.5% bupivacaine solution; analgesia improved with the higher dose.[14]

SHEEP & GOATS:

Local anesthesia (tissue infiltration):

1. 1.25 – 2 mg/kg using 0.5% bupivacaine solution[52-54]
2. 0.2 mL/kg (NOT mg/kg) using 0.5% bupivacaine solution[55]

Perineural administration in forelimbs: 2 mL/animal (NOT mL/kg) using 0.5% bupivacaine solution. A combination block using equal volumes of lidocaine and bupivacaine had similar onset of analgesia but shorter duration than bupivacaine alone.[11]

Lumbar epidural:

1. Bupivacaine 0.5 mg/kg injected into the epidural space[56]
2. In sheep, bupivacaine 0.5 mg/kg injected into the epidural space produced analgesia and fewer cardiovascular or respiratory adverse effects than bupivacaine 0.25 mg/kg combined with either fentanyl 2 µg/kg or methadone 0.3 mg/kg.[57]
3. In goats, using 0.5% bupivacaine solution 0.8 – 1.2 mg/kg combined with methadone 0.22 mg/kg and administered via thoracolumbar epidural resulted in longer duration of analgesia than bupivacaine alone.[58]

SMALL MAMMALS (RABBITS, GUINEA PIGS, CHINCHILLAS, RODENTS):

Local anesthesia (tissue infiltration): 1 mg/kg[59]

Epidural: 1.5 mg/kg using 0.5% bupivacaine into the coccygeal spinal canal of rabbits provided hind limb, perineal, and tail analgesia. Subarachnoid bupivacaine distribution was not observed, but inadvertent vascular entry may occur.[60]

REPTILES, AMPHIBIANS:

Local anesthesia (tissue infiltration): using 0.25% or 0.5% bupivacaine solution, 1 – 2 mg/kg; dilute up to 1:1 to expand volume if needed (diluent not provided, assume sterile water for injection or normal saline—Plumb).[61]

Spinal anesthesia: using 0.5% bupivacaine solution, 1 mg/kg intrathecally at the level of the coccygeal vertebrae of tortoises and turtles; provides regional analgesia for ≈2 hours[62]

Monitoring

- Adequacy of analgesia and anesthesia
- Cardiovascular and respiratory function as well as state of consciousness after each injection

Client Information

- This medication causes temporary loss of feeling. The area where it was injected may not have usual function for several hours.
- This drug should only be used by or on the order of a licensed veterinarian familiar with its use and in a setting where adequate patient monitoring can be performed.

Chemistry/Synonyms

Bupivacaine hydrochloride is an aminoacyl local anesthetic related to mepivacaine and lidocaine, with an amide linkage between the aromatic nucleus and the piperidine group. It occurs as a white crystalline powder that is freely soluble in ethanol and soluble in water. It has a pK_a of 8.1. Solutions are clear and colorless, with a pH 4 to 6.5. Solutions that contain epinephrine have a pH 3.5 to 5.5.

Bupivacaine hydrochloride is also known as AH-2250, LAC-43, Win-11318, bupivakaiinihydrokloridi, *Longocain®*, *Sensorcaine®*, and *Marcaine®*.

Storage/Stability

Bupivacaine HCl should be stored at room temperature, 20°C to 25°C (68°F-77°F). Solutions that contain epinephrine should be protected from light. Bupivacaine stored under field conditions for equine use was found to maintain pH and potency without microbial contamination in a variety of storage conditions and with repeated vial use over 12 months.[63]

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Bupivacaine HCl is **compatible** with D5W and 0.9% sodium chloride solutions and the following drugs (partial list): ampicillin sodium, buprenorphine, epinephrine, fentanyl citrate, hydromorphone, ketamine, lidocaine, morphine sulfate, and penicillin G sodium/potassium. Bupivacaine HCl is reported to be **variably compatible** with sodium bicarbonate, and to be **incompatible** with mepivacaine.

Bupivacaine combinations with epinephrine are commercially available. When preparing this combination in the clinic, the recommended final concentration of epinephrine is 5 µg/mL. To reach this concentration, add 0.1 mg (0.1 mL) of epinephrine (1 mg/mL) to 20 mL of local anesthetic.

Dose Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. See the ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Bupivacaine HCl Solution: 0.25% (2.5 mg/mL) in 10 mL and 30 mL single-dose vials, and 50 mL multidose vials; 0.5% (5 mg/mL) in 10 mL and 30 mL single-dose vials or ampules, and 50 mL multidose vials; 0.75% (7.5 mg/mL) in 10 mL, 20 mL, and 30 mL single-dose vials; *Sensorcaine®*-MPF, *Marcaine®*, generic; (Rx)

Bupivacaine HCl Solution with Epinephrine: bupivacaine 0.25% (2.5 mg/mL) with epinephrine 5 µg/mL (1:200,000) in 10 mL and 30 mL single-dose vials and 50 mL multidose vials; bupivacaine 0.5% (5 mg/mL) with epinephrine 5 µg/mL (1:200,000) in 10 mL and 30 mL single-dose vials and 50 mL multidose vials; bupivacaine 0.75% (7.5 mg/mL) with epinephrine 5 µg/mL (1:200,000) in 30 mL

single-dose vials; *Sensorcaine*®-MPF with epinephrine, *Marcaine*® with epinephrine, generic; (Rx)

Bupivacaine solutions with dextrose (hyperbaric bupivacaine) are not interchangeable with bupivacaine solution formulated in sterile water and should not be used for peripheral nerve blocks.

Bupivacaine Liposome

(byoo-***piv***-ah-kane ***lye***-poh-zoam) *Nocita*®

Local Anesthetic

For information regarding immediate-release bupivacaine, please refer to ***Bupivacaine***

Prescriber Highlights

- ► FDA-approved injectable suspension for postoperative analgesia following cranial cruciate ligament surgery (dogs) and onychectomy (cats)
- ► Do not convert dosing from any other formulations of bupivacaine to bupivacaine liposome injection suspension or vice versa.
- ► May be diluted with a less than or equal volume of 0.9% NaCl or lactated Ringer's solution to obtain a volume sufficient to cover the surgical site. Do NOT dilute with water or other hypotonic solutions.
- ► Potentially effective for 72 hours postsurgery
- ► Adverse effects are unlikely when the correct administration technique is used. Clinicians should be knowledgeable in the diagnosis and management of local anesthetic toxicity, and resources for treating acute emergencies must be readily available.
- ► When used as labeled, very low incidence of adverse effects

Uses/Indications

Bupivacaine liposome injectable suspension is FDA-approved for use in dogs to infiltrate the tissue layers of the surgical site at the time of incision closure (only) to provide local postoperative analgesia for cranial cruciate ligament (CCL) surgery. It is also FDA-approved for use in cats as a peripheral nerve block to provide regional analgesia following onychectomy.

A study has shown that approximately twice as many patients (both dogs and cats) receiving bupivacaine liposome were deemed to have adequate pain control (assessed using established pain scales) compared to those receiving treatment control at all assessed time points up to 72 hours postsurgery.[1] In a pilot field study, 14 of 24 dogs receiving bupivacaine liposome just prior to closure following CCL surgery were considered treatment success (based on established pain scales) at 24 hours compared to 4 of 22 receiving a placebo during the same time period; at 72 hours postsurgery, 9 of 24 dogs were considered treatment success compared to 2 of 22 dogs receiving a placebo.[2]

Although the veterinary-labeled product states that safe use with surgical procedures other than CCL surgery has not been evaluated, the companion product labeled for use in humans (*Exparel*®) is indicated for administration into sites that meet criteria based on size of the surgical site, volume of drug required, and patient factors (eg, to produce postsurgical analgesia).[3]

Pharmacology/Actions

Bupivacaine is an amide local anesthetic. Local anesthetics block the generation and conduction of impulses through all nerve fibers (sensory, motor, and autonomic). These local anesthetics prevent conduction of nerve impulses by decreasing permeability of the nerve cell membrane to sodium ions. This blocking of the sodium channels results in a decreased depolarization rate of the nerve membrane, thus increasing the threshold for electrical excitability and preventing propagation of the action potential.[4]

The liposome form encapsulates the drug, and bupivacaine exerts its effects only after leaving the lipid vesicle. Liposomal bupivacaine releases bupivacaine slowly at the injection site and provides a longer duration of anesthetic action than the standard bupivacaine solution.

Pharmacokinetics

In order to assess systemic uptake of bupivacaine from the liposome encapsulated bupivacaine preparation, bupivacaine liposome 9 mg/kg SC was administered to dogs and cats.[1] Dogs had a median time to maximum serum concentration (T_{max}) of 30 minutes and an elimination half-life of 36.2 hours. Cats had a T_{max} of 10 hours and bupivacaine was measurable for up to 120 hours postinjection.

Intra-articular administration of bupivacaine liposome injectable suspension to horses resulted in sustained bupivacaine concentration in the joint for up to 96 hours.[5] See ***Contraindications/Precautions/Warnings.***

In humans, peak drug concentrations occur 30 minutes to 2 hours after infiltration. The drug is 95% protein bound. Hepatic metabolism is extensive to the metabolite pipecoloxylidide. Bupivacaine AUC is increased 50% in patients with hepatic dysfunction. Bupivacaine is renally eliminated, predominantly as metabolites.[6]

Contraindications/Precautions/Warnings

Do not administer by IV or intra-arterial injection, as adverse cardiovascular (eg, arrhythmias, hypotension, hypertension) or neurologic (eg, tremors, seizures) effects can occur. Although local anesthetic agents have been used intra-articularly, administration by this route is contraindicated due to risk for chondrolysis.[1] Although the veterinary label of bupivacaine liposome does not mention epidural or intrathecal administration, the human label does not recommend use by these routes.

Because they are not bioequivalent, do not convert dosages from any other formulations of bupivacaine to bupivacaine liposome injection suspension and vice versa.

Safe use has not been evaluated in dogs or cats younger than 5 months of age, with cardiac disease, or with hepatic or renal impairment.[1] Because bupivacaine is metabolized by the liver and excreted by the kidneys, use with caution in patients with impaired renal or hepatic function.[6]

Bupivacaine liposome is not indicated for preincisional or preprocedural locoregional anesthetic techniques that require deep and complete sensory block in the area of administration as its ability to achieve effective anesthesia has not been studied.

Wear gloves when handling to prevent accidental exposure.[1]

Bupivacaine is contraindicated for obstetrical paracervical block anesthesia in human patients. Fetal bradycardia and death have been reported.[6]

Adverse Effects

Bupivacaine must exit the liposomes to exert its pharmacologic effect. In a safety study,[7] liposomal bupivacaine demonstrated a favorable safety profile after intravascular administration compared to standard bupivacaine solution.

In preapproval field studies, the following adverse effects were reported in treated dogs (incidence more than 1%): discharge from incision site (3.3%), incisional inflammation (2.4%), vomiting (2.4%), isosthenuria ± proteinuria (1.6%), and increased ALP (1.6%). The placebo treated cohort did not report any of these effects.[1]

In preapproval field studies in cats undergoing onychectomy, the following adverse effects were reported in treated cats (incidence more than 1%): body temperature equal to or more than 39.4°C (103 °F) (6.7%), surgical site infection (3.3%), chewing/licking surgi-

cal site (2.5%), and diarrhea (1.7%).[1]

Adverse effects reported to occur in human patients (incidence more than 10%) include nausea, constipation, and vomiting.[3]

Reproductive/Nursing Safety

The label states that safe use of bupivacaine liposome has not been evaluated in dogs or cats that are intended for breeding or are pregnant or lactating. Bupivacaine, once released from the liposome, can cross the placenta and some animal reproduction studies have demonstrated adverse effects at high dosages. Bupivacaine used for epidural, caudal, or pudendal block anesthesia for human patients during labor and delivery can cause varying degrees of maternal, fetal, and neonatal toxicity.[6] Use with caution in pregnant dogs and cats.

Bupivacaine and its metabolite (pipecoloxylidide) can cross into maternal milk in low concentrations. There does not appear to be information documenting any effects on milk production or harm to nursing offspring; bupivacaine liposome is likely safe to use in nursing mothers.

Overdose/Acute Toxicity

In safety studies, dogs receiving 1.5 to 5 times the labeled dose SC twice weekly all survived the 4-week study. No clinically relevant treatment-related effects on clinical observations, physical examination, body weight, ECG, hematology, serum chemistry, urinalysis, coagulation, or organ weights were detected. When used as labeled, acute toxicity is unlikely unless administered intravascularly. Intravascular administration may result in cardiovascular (eg, dysrhythmias, blood pressure fluctuation) and neurologic (eg, tremors, ataxia, seizures) adverse effects, although one study found that bupivacaine liposome 4.5 mg/kg IV had a favorable safety profile compared to bupivacaine HCl 0.75 mg/kg IV.[7]

In cats receiving up to 3 times the labeled dose (31.8 mg/kg) every 9 days for 3 doses as a right femoral nerve block (suprainguinal approach), 1 cat developed a suppurative, open necrotic wound in the right stifle after the second injection and was euthanized. Right limb impairment occurred in 23 of 24 cats and lasted between 1 to 5 days. Histopathology findings at the injection site included inflammation, mineralization, and myofiber degeneration and necrosis. No clinically relevant treatment-related effects on ECG, hematology, serum chemistry, urinalysis, coagulation, or organ weights were detected.

Management of bupivacaine overdose must begin with delivery of oxygen via a patent airway. Benzodiazepines and barbiturates can be used for seizure management but may cause further CNS depression. Cardiovascular support should be provided and may include IV fluids and vasopressor drugs. Prolonged resuscitative efforts may be required. Lipid emulsion 20% 1.5 mL/kg IV over 30 minutes can be beneficial.[8,9]

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bupivacaine liposome and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antiseptics, Topical** (eg, **chlorhexidine, povidone iodine**): Do not allow contact with topical antiseptics; wait for these agents to dry before administering drug.[1]
- **Bupivacaine, Injectable, And Other Amide Local Anesthetics** (eg, **lidocaine, mepivacaine**): Use with bupivacaine liposome may increase toxic effects. The veterinary label warns, *Do not administer concurrently with bupivacaine HCl, lidocaine, or other amide local anesthetics. A safe interval from time of bupivacaine HCl, lidocaine, or other amide local anesthetic administration to time of Nocita® administration has not been determined.*[1] However, the human bupivacaine liposome label states that other formulations of bupivacaine should not be administered within 96 hours following administration of bupivacaine liposome[3]; the label also states that liposomal bupivacaine may be administered 20 minutes or more after local administration of lidocaine.
- **Hyaluronidase**: May increase local anesthetic toxicity or increase adverse effects

Laboratory Considerations

- None noted

Dosages

NOTES:

1. Do not shake vial. Invert the vial multiple times to re-suspend the particles immediately before withdrawal of the product from the vial.[1]
2. Prior to injection, aspirate to check for negative pressure at the injection site to prevent inadvertent intravascular administration.
3. See ***Compatibility/Compounding Considerations*** prior to diluting or combining bupivacaine liposome with any other drugs.

DOGS:

Single-dose infiltration into the surgical site to provide local postoperative analgesia for cranial cruciate ligament surgery (label dose; FDA-approved): 5.3 mg/kg (0.4 mL/kg) is administered by infiltration injection into the tissue layers at the time of incisional closure. Wear gloves when handling. Administer with a 25-gauge or larger bore needle.

Inject slowly into the tissues using an infiltration injection technique. Do not allow contact with topical antiseptics (eg, povidone iodine, chlorhexidine); wait for these agents to dry before instilling drug. To obtain adequate coverage, infiltrate all of the tissues in each surgical closure layer. Aspirate frequently to prevent intravascular administration. May be administered undiluted or diluted with up to an equal volume (1:1 by volume) of normal (0.9%) sterile saline or lactated Ringer's solution to obtain a volume sufficient to cover the surgical site. Do not dilute with water or other hypotonic solutions. Analgesic effects may persist up to 72 hours.[1]

CATS:

Peripheral nerve block to provide regional postoperative analgesia following onychectomy (label dose; FDA-approved): 5.3 mg/kg (0.4 mL/kg) per forelimb (ie, 10.6 mg/kg per cat) as a 4-point nerve block prior to forelimb onychectomy. Aspirate prior to injecting to prevent intravascular administration. See table below and refer to the product label for administration instructions. Wear gloves when handling. Administer with a 25-gauge or larger bore needle. Do NOT dilute prior to use as nerve block in cats. Analgesic effects may persist up to 72 hours.[1]

Site of 4-point nerve block	% of total forelimb volume	Dose volume (mL/kg)	Instructions
Superficial branch of the radial nerve	35%	0.14	At the center of the limb, on the dorsal aspect at the level of the antebrachiocarpal joint, insert the needle subcutaneously with the bevel up. Advance the needle subcutaneously and inject adjacent to the confluence of the accessory cephalic and cephalic veins.
Dorsal branch of the ulnar nerve	20%	0.08	Palpate a groove between the accessory carpal bone (in the base of the carpal pad) and the styloid process of the ulna. Distal to this groove, insert the needle subcutaneously with the bevel up and advance the needle proximally. Inject once the tip reaches the midpoint of the groove.
Median nerve and superficial branch of the palmar branch of the ulnar nerve	40%	0.16	Insert the needle subcutaneously with the bevel up lateral to the distal tip of the accessory carpal pad and advance the needle medially ⅔ the width of the limb, until the tip is located near the base of the first digit. Inject ⅔ of the volume at this point and the remaining volume while withdrawing the needle. Gently massage for 5 seconds.
Deep branch of the palmar branch of the ulnar nerve	5%	0.02	Orient the needle perpendicular to the long axis of the limb at the level of the accessory carpal bone. Insert the needle subcutaneously and advance the needle laterally until it contacts the medial aspect of the accessory carpal bone. Redirect the needle dorsally by rotating the needle 90°, advance it along the medial side of the accessory carpal bone 2 to 3 mm until it penetrates the flexor retinaculum, and inject.

Incisional block following ovariohysterectomy (extra-label): 5.4 mg/kg diluted to 5 mL with 0.9% NaCl into a syringe with a 22-gauge, 1-inch needle; after linea alba closure 2.5 mL was injected under the rectus sheath in a continuous line on both sides of the incision. After closure of the subcutaneous layer the remaining 2.5 mL was slowly injected at least 5 mm away from the incision such that a continuous line of anesthetic extended around the entire incision. Pain scores remained low for up to 68 hours after surgery, and reduced the need for postoperative robenacoxib use.[10]

Monitoring

- Adequate postsurgical analgesia is indicative of efficacy.
- If there was a significant chance that intravascular administration occurred, monitor for possible toxicity (eg, arrhythmias, changes in blood pressure, CNS excitation).

Client Information

- If your animal is discharged before 72 hours, monitor them for signs associated with pain and infection (eg, discharge, swelling). Be sure to contact your veterinarian if you are concerned about an infection. If an infection occurs, the anesthetic used to control the pain will not work well and it will cause your animal to be more painful.

Chemistry/Synonyms

Bupivacaine is an amide-type local anesthetic structurally related to lidocaine and mepivacaine. Chemically it is 1-butyl-*N*-(2,6-dimethylphenyl)-2-piperidinecarboxamide with a molecular weight of 288.4.

Bupivacaine liposome injectable suspension is a sterile, nonpyrogenic, and preservative-free white to off-white aqueous suspension of multivesicular lipid-based particles containing bupivacaine. Each mL contains 13.3 mg bupivacaine. Inactive ingredients and their nominal concentrations are cholesterol, 4.7 mg/mL; 1,2-dipalmitoyl-sn-glycero-3-phospho-rac-(1-glycerol) (DPPG), 0.9 mg/mL; tricaprylin, 2.0 mg/mL; and 1,2-dierucoylphosphatidylcholine (DEPC), 8.2 mg/mL.

Storage/Stability

Unopened vials should be stored refrigerated between 2°C and 8°C (36°F-46°F). Do not freeze. Unopened bottles may be held at a controlled room temperature of 20°C to 25°C (68°F-77°F) for up to 30 days.

Do not puncture the vial multiple times. Once the vial stopper has been punctured with a sterile needle, draw out the dose into a sterile syringe. Each syringe should be prepared for single patient use only. Discard the vial after all doses are withdrawn. Following withdrawal from the vial into a syringe, *Nocita*® may be stored at a controlled room temperature between 20°C and 25°C (68°F-77°F) for up to 4 hours. After 4 hours, the syringe must be discarded.[1] A study evaluating use of bupivacaine liposome injectable suspension single-dose vials in a multidose fashion (repeated vial entry over 5 days when stored both under refrigeration as well as at room temperature) found no bacterial growth, and free bupivacaine concentration remained stable for 4 days.[11]

According to the human label, bupivacaine liposome should not be administered if the stopper is bulging or if the vial is suspected of having been frozen or exposed to high temperatures.[6]

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

May be administered to dogs undiluted or diluted with up to an equal volume (1:1 by volume) of normal (0.9%) sterile saline or lactated Ringer's solution to obtain a volume sufficient to cover the surgical site. Do not dilute with water or other hypotonic solutions; this will result in disruption of the liposomal particles. Mixing with non-bupivacaine-based local anesthetics, including lidocaine (infiltrated or topical), may cause an immediate release of bupivacaine from the liposomes.[12] The product label states "do not dilute [bupivacaine liposome] prior to use as a nerve block in cats".[1]

The human label product includes similar diluent recommendations but with larger volumes, reflecting the common practice of combining bupivacaine HCL with bupivacaine liposome. This practice does not appear to be needed in veterinary medicine and no studies have been done to assess any possible advantage of such practice. When bupivacaine HCl and bupivacaine liposome are both used in the same patient, it is important to remember that the toxic effects of these products are additive; these drugs should be co-administered with caution, and the patient should be monitored for neurologic and cardiovascular effects related to toxicity.[6]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Bupivacaine Liposome Injectable Suspension 1.3% (13.3 mg/mL) in 10 mL and 20 mL single-use vials; *Nocita*®; (Rx). Approved for use in dogs and cats; NADA #141-461

HUMAN-LABELED PRODUCTS:
Bupivacaine Liposome Injectable Suspension 1.3% (13.3 mg/mL) in 10 mL and 20 mL single-use vials; *Exparel*®; (Rx)[6]

Buprenorphine
(byoo-pre-***nor***-feen) *Buprenex®, Simbadol®, Zorbium®*
Opioid Partial Agonist

Prescriber Highlights
- ► Partial mu-opioid agonist used primarily as an injectable and buccal (ie, oral transmucosal [OTM]) analgesic, especially in cats
- ► Often used as a component of short-term immobilization and anesthetic drug combinations
- ► Buccal/OTM administration is well tolerated and can be effective, but bioavailability is low by this route, as is standard (0.3 mg/mL) buprenorphine administered SC.
- ► Longer onset of action and longer duration of action as compared with most other opioids
- ► Rarely, may cause respiratory depression
- ► Because of tight buprenorphine receptor binding, standard doses of naloxone may not completely reverse drug effects.
- ► DEA Schedule III (C-III) controlled substance

Uses/Indications
Buprenorphine is most often used as an analgesic for mild to moderate pain or in preanesthetic drug combinations in small animals. In most species, buprenorphine provides less analgesia than pure mu-opioid agonists (eg, morphine, hydromorphone) and it is less sedating than most other opioids (particularly butorphanol). For acute pain control, buprenorphine may have the disadvantage of a longer onset of action than other opioids.

In dogs, an isoflurane MAC-sparing effect occurs at IV dosages of 0.01 mg/kg, 0.05 mg/kg, and 0.1 mg/kg[1] but methadone (0.3 mg/kg) provided more effective presurgical analgesia than buprenorphine (0.02 mg/kg) in dogs sedated with acepromazine and medetomidine prior to undergoing ovariohysterectomy (OHE).[2] Use of the feline-labeled *Simbadol*® (0.02 mg/kg IM) prior to surgery in dogs (pretreated with acepromazine and carprofen and undergoing ovariohysterectomy) provided similar postoperative analgesia as standard buprenorphine (0.02 mg/kg IM) but more dogs in the standard buprenorphine group (3/12) required postoperative rescue analgesia (vs 0/12 for *Simbadol*®).[3] Oral transmucosal (OTM) administration can provide effective analgesia (0.02 and 0.12 mg/kg were studied)[4] but bioavailability is low and variable with this route.[5] When used epidurally in combination with bupivacaine for stifle arthroplasty, buprenorphine produced sufficient analgesia for up to 24 hours.[6] Buprenorphine/bupivacaine combination for infraorbital nerve block had an isoflurane-sparing effect and extended the duration of analgesia to 48 to 96 hours.[7]

In cats, one product (*Simbadol*®) is a high-concentration (1.8 mg/mL), long-duration (72 hour) form of buprenorphine that is FDA-approved for SC administration for the control of postoperative pain associated with surgical procedures. A transdermal buprenorphine solution is FDA-approved for the control of postoperative pain. It is applied by veterinary staff in the clinic or hospital 1 to 2 hours prior to surgical procedures and provides analgesia for 4 days.[8]

In one study, when combined with medetomidine (0.002 mg/kg), standard concentration buprenorphine (0.3 mg/mL; 0.002 mg/kg) given IM provided equivalent analgesia to that provided by butorphanol (0.4 mg/kg) or methadone (0.5 mg/kg).[9] Combined with dexmedetomidine (0.001 mg/kg), butorphanol (0.4 mg/kg) provided better sedation and less vomiting than buprenorphine (0.02 mg/kg) when administered IM to cats.[10] With standard buprenorphine, buccal/OTM administration can be a practical, effective method for controlling postoperative pain. However, IV or IM administration of buprenorphine provides better postoperative (OHE) analgesia as compared with SC or buccal/OTM administration, and the cats receiving buprenorphine by the OTM route experienced a high prevalence of treatment failure.[11] Multidose injectable formulations may be less palatable to cats when given by the OTM route than the preservative-free formulation.[12] Combining opioids such as buprenorphine with short-term NSAIDs for postoperative pain control provides better analgesia than buprenorphine alone.[13]

In the UK and Australia, there are licensed buprenorphine products that are labeled for postoperative analgesia in dogs, cats, and horses and potentiation of the sedative effects of centrally acting agents in dogs and horses.

Pharmacology/Actions
Buprenorphine has partial agonist activity at the mu receptor and is a kappa-receptor antagonist. Buprenorphine is considered 30 times more potent than morphine and exhibits many of the same actions as the pure opioid agonists. It produces a dose-related analgesia; however, at higher doses, analgesic effects may plateau. Buprenorphine has a high affinity for, and slow dissociation from, mu receptors in the CNS, which may explain its relatively long duration of action. In dogs, sedative effects are generally seen after 15 minutes, but analgesia may not develop fully until 30 minutes postadministration. Analgesia is unlikely to persist for 12 hours unless pain is mild. A 6- to 8-hour duration of analgesic effect is often reported but analgesia may be as short as 4 hours, with high variability between cats.[13] Multimodal analgesia with frequent pain assessment is recommended. The high-concentration, long duration buprenorphine product lasts 72 hours when given SC to cats.

The cardiovascular effects of buprenorphine may cause a decrease in both blood pressure and cardiac rate. Rarely, human patients may exhibit increases in blood pressure and cardiac rate. Respiratory depression is a possibility and decreased respiratory rates have been noted in horses treated with buprenorphine. GI effects appear to be minimal in cats treated with buprenorphine.

Pharmacokinetics
In cats, buprenorphine is rapidly and completely absorbed when given IM.[14] Peak concentrations after SC injection can vary widely; blood concentrations are low and do not appear to correlate with analgesic effect. Buprenorphine has a volume of distribution at steady-state (VD_{ss}) of ≈3 to 8 L/kg and a clearance of ≈8 to 20 mL/kg per minute. Elimination half-life is ≈6 to 7 hours. When administered by the buccal/OTM route, bioavailability is low and highly variable (≈20% to 30%).[13,15] The human transdermal patch buprenorphine (*Transtec*®; UK) applied to cats has demonstrated widely variable blood concentrations and, without a loading dose, does not appear to provide adequate analgesia. Individual variability in response to buprenorphine administration by all administration routes, especially SC and OTM, has been reported. Some cats may not receive sufficient analgesia from buprenorphine.[13]

In dogs, oral bioavailability is very low (5%), but buprenorphine administered via the buccal/OTM route is ≈35% to 50% absorbed.[5] Elimination half-life ranges from 4 to 9 hours,[16] and wide interpatient variability exists. In a small pilot study, application of topical buprenorphine patches showed that plasma concentrations increased during the first 36 hours, then remained between 0.7 and 1 ng/mL during the study period.[17] In greyhounds, when buprenorphine was administered IV, the volume of distribution, plasma clear-

ance, and terminal half-life were 3.54 L/kg, 10.3 mL/minute/kg, and 3.96 hours, respectively.[18] A pharmacokinetic study in 6 mongrel dogs resulted in a volume of distribution, plasma clearance, and terminal half-life of 4.68 L/kg, 23.3 mL/minute/kg, and 3.97 hours,[19] respectively, when buprenorphine was administered IV, and a terminal half-life of 12.74 hours when the extended-release injection was administered SC.[20]

In horses, the onset of action is ≈15 minutes after IV dosing. Buprenorphine is variably absorbed after IM administration and bioavailability is ≈50% to 80%.[21] Volume of distribution is ≈2.5 to 3 L/kg.[22,23] The peak effect occurs within 30 to 45 minutes and the duration of action may last up to 8 hours. Elimination half-life after an IV or IM dose is ≈3.5 to 6 hours.[22,23] Because acepromazine exhibits a similar onset and duration of action, many equine clinicians favor using acepromazine in combination with buprenorphine. One study found plasma buprenorphine concentrations between 0.34 and 2.45 ng/mL after IV administration of 10 µg/kg.[24] In foals younger than 21 days of age, buprenorphine 0.01 – 0.02 mg/kg IV had a VD_{ss} of 6.5 L/kg; clearance was 56 mL/kg/minute, and elimination half-life was ≈2 hours.[25] The same dosage administered sublingually was only 25% bioavailable, and plasma concentration reached the presumed therapeutic concentration briefly in only one foal; however, physiologic changes did occur, indicating absorption of the drug. The therapeutic concentration could be lower in foals than in other species.

Elimination half-life was 1 to 2.7 hours after IV and SC administration in alpacas, and SC bioavailability was 64%.[26]

The distribution of the drug has not been well studied. Data from work done in rats reflect that buprenorphine concentrates in the liver but is also found in the brain, GI tract, and placenta. It is highly bound (96%) to plasma proteins (not albumin).

In most species, buprenorphine is metabolized in the intestinal wall and liver[27,28] by N-dealkylation likely via CYP3A4 (forming norbuprenorphine, which is active). Buprenorphine and norbuprenorphine also undergo glucuronidation; metabolites are then eliminated by biliary excretion into the feces (≈70%) and urinary excretion (≈27%).

Contraindications/Precautions/Warnings

The drug is contraindicated in patients with a known hypersensitivity to it or other opioids.

Because of the potential for decreased clearance with subsequent exaggerated/prolonged effects, all opioids should be used with caution in patients that have hypothyroidism, impaired hepatic function, or adrenocortical insufficiency (Addison's disease), and in pediatric, geriatric, or severely debilitated patients.

Rarely, patients may develop respiratory depression from buprenorphine; therefore, it should be used cautiously in patients with compromised pulmonary function. Like other opioids, buprenorphine must be used with caution in patients with head trauma, increased CSF pressure, or other CNS dysfunction (eg, coma), as any degree of respiratory depression could result in excessive partial pressure of arterial carbon dioxide with a subsequent increase in intracranial pressure.

Patients with severe hepatic dysfunction may eliminate the drug more slowly than normal patients. Buprenorphine may increase bile duct pressure and should be used cautiously in patients with biliary tract disease[29]; however, this appears to not have any clinical impact. As with all opioids, buprenorphine should also be used with caution in horses that show signs of diminished GI tract motility.

Opioid analgesics are contraindicated in patients stung by scorpions (eg, *Centruroides* spp), as these drugs may potentiate venom effects.[30]

Mild sedation can occur in both dogs and cats, making buprenorphine an important component of a preanesthetic protocol; however, excitement can occur in horses and, less commonly, in cats, as is true of other opioids. Mild postoperative hyperthermia can occur in cats.[28]

Because buprenorphine can cause excitement in horses, when it is used as a preoperative analgesic, an IV sedative should be administered prior to, or in conjunction with, the buprenorphine injection.[22,23]

The standard formulation of buprenorphine by the SC route is not recommended due to poor absorption. Buprenorphine should not be administered via the intrathecal or peridural routes.

The transdermal solution requires ≈30 minutes to dry, and once dried the risk for human buprenorphine exposure following contact of the administration site is limited. Clinic staff should use personal protective equipment (impermeable gloves, eye protection, laboratory coat) when preparing or administering any of the concentrated buprenorphine products.[8]

Adverse Effects

Although rare, respiratory depression appears to be the major adverse effect. Other adverse effects (eg, sedation, nausea, vomiting, bradycardia, excitement [primarily cats and horses]) may be noted but generally occur less frequently as compared with other opioids.

In dogs, as with other opioids, salivation, bradycardia, hypothermia, agitation, dehydration, and miosis have been reported. Tachycardia, vomiting, and high blood pressure rarely occur. Injection site reactions and skin lesions have been noted with the non-FDA-approved extended-release injectable formulation and are most likely due to a reaction to the vehicle.[31] SC administration of high-concentration buprenorphine to dogs resulted in varying degrees of sedation, reduced appetite, panting, whining, and hyperptyalism.[20]

In cats, as with other opioids, mydriasis and behavioral effects (eg, excessive purring, pacing, rubbing, hiding) can be seen. Vomiting, salivation, anorexia, and hyperthermia occur rarely; however, hyperthermia was observed in ≈28% of cats on the day after surgery; constipation and mydriasis also were noted.[32] Vomiting occurred in 55% of cats receiving buprenorphine/dexmedetomidine combination with only 5% vomiting in cats receiving dexmedetomidine/butorphanol.[10] In a study, high doses of standard buprenorphine (0.24, 0.72, and 1.2 mg/kg/day SC) for 9 consecutive days were well tolerated in young cats. Adverse effects included hyperactivity, tachycardia, difficulty in handling, disorientation, agitation, and mydriasis.[33]

In horses, buprenorphine may cause ataxia, excitement, and diminished gut sounds, but colic has not been a major concern. All horses (n = 4) developed constipation after receiving a single SC or IM dose of an experimental sustained-release buprenorphine formulation.[34] Administration with a sedative (eg, acepromazine, detomidine) may help decrease excitement and cardiac and respiratory rates.

In rabbits, SC buprenorphine reduced food and water intake, GI transit, and fecal output.[35,36]

The primary adverse effect seen in humans is sedation, with an incidence of ≈66%.[29] Buprenorphine may cause urine retention or difficulty voiding, particularly with high IV doses or epidural administration.

Reproductive/Nursing Safety

Safe use of veterinary buprenorphine formulations in breeding, pregnant, or lactating animals has not been established. The drug crosses the placenta. Although no controlled studies have been performed in domestic animals or humans, the drug has exhibited no evidence of teratogenicity or causing impaired fertility in laboratory animals. Early fetal death and postimplantation loss have been noted in rats.[27] The *Vetergesic*® 0.3 mg/mL solution for injection for dogs and cats label (Canada) states that the drug is contraindicated preoperatively for cesarean section due to concerns for respiratory depression in offspring.[27]

In rats, maternal milk buprenorphine concentration equaled or exceeded that of plasma[27]; however, maternal milk buprenorphine concentrations are low in humans[37] and no adverse effects were seen in 4-week-old infants nursing from buprenorphine-treated women.[38] There are no data for commonly encountered veterinary species.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The intraperitoneal LD_{50} of buprenorphine has been reported to be 243 mg/kg in rats. The ratio of lethal dose to effective dose is at least 1000:1 in rodents. Because of the apparent high index of safety, life-threatening acute overdoses should be rare in veterinary medicine, but most overdoses will cause clinical signs. Common findings in dogs (in decreasing frequency) include vocalization, ataxia, hypersalivation, hypothermia, and lethargy.

Treatment with naloxone and doxapram has been suggested for cases of acute overdoses causing respiratory or cardiac effects.[27] Secondary to buprenorphine's high affinity for the mu-opioid receptor, high doses and/or repeated doses of naloxone may be required to treat respiratory depression. See ***Naloxone***.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving buprenorphine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed, and additional monitoring performed when appropriate. **NOTE**: Drug interactions may be positive rather than adverse (eg potentiation of local anesthetic effects when combined with buprenorphine).

- **Anesthetics, Local** (eg, **mepivacaine, bupivacaine**): When buprenorphine and the local anesthetic agent are combined in the same syringe and injected perineurally, the anesthetic action may be potentiated.
- **Anticonvulsants** (eg, **phenobarbital, phenytoin**): May decrease plasma buprenorphine concentrations
- **Benzodiazepines** (eg, **diazepam, midazolam**): Case reports of humans developing respiratory/cardiovascular/CNS depression; use combination with caution
- **CNS Depressant Agents** (eg, **anesthetic agents, antihistamines, barbiturates, benzodiazepines, phenothiazines, tranquilizers**): May cause increased CNS or cardiorespiratory depression when used with buprenorphine
- **Desmopressin:** The concurrent use of desmopressin and opioids may increase the risk for hyponatremia.
- **Erythromycin**: Can increase plasma buprenorphine concentrations
- **Halothane**: Reduced hepatic blood flow during anesthesia can increase buprenorphine effects.
- **Ketoconazole, Itraconazole, Fluconazole**: Can increase plasma buprenorphine concentrations
- **Metoclopramide:** Concurrent use of metoclopramide and buprenorphine may increase the risk for CNS depression.
- **Monoamine Oxidase Inhibitors (MAOIs;** eg, **selegiline, amitraz**): Possible additive effects or increased CNS depression; combination is not recommended in humans due to additional risk for serotonin syndrome[29]
- **Naloxone**: Will reduce analgesia but is less effective at reversing buprenorphine effects as compared with other opioids
- **Opioids (Pure Mu-Agonists)** (eg, **fentanyl, hydromorphone**): Buprenorphine may potentially antagonize some analgesic effects but may also reverse some of the sedative and respiratory depressant effects of pure agonists.
- **Pancuronium**: If used with buprenorphine, may cause increased conjunctival changes
- **Phenobarbital:** Concurrent use of phenobarbital and buprenorphine may result in increased risk for CNS depression and/or decreased plasma concentrations of buprenorphine.
- **QT Prolonging Agents** (eg, **cisapride, quinidine, sotalol**)**:** Concurrent use can increase the risk for life-threatening arrhythmias in humans; significance in veterinary patients is unknown.
- **Rifampin**: Potentially decreased plasma buprenorphine concentrations
- **Serotonergic Agents** (eg, **clomipramine, fluoxetine, mirtazapine, trazodone**): Concurrent use may increase the risk for serotonin syndrome.[29]
- **Tramadol:** May increase the risk for serotonin syndrome and respiratory depression[29]

Laboratory Considerations

None noted

Dosages

DOGS:

Analgesia (all extra-label):

a) **General use:** 5 – 30 µg/kg (0.005 – 0.03 mg/kg) IV or IM every 4 to 6 hours; consider extended dosing interval to 8 to 12 hours for treating mild pain. **NOTE**: SC administration of buprenorphine does not provide clinical analgesia due to erratic drug absorption.[39]

b) **Constant rate infusion (CRI):** Following an IV loading dose of 5 – 10 µg/kg (0.005 – 0.01 mg/kg), 2 – 4 µg/kg/hour IV CRI has been suggested. Acceptable analgesia was described in a pharmacokinetic study evaluating a loading dose of 15 µg/kg (0.015 mg/kg) IV administered after recovery from anesthesia, followed by 2.5 µg/kg/hour IV CRI for 6 hours.[40]

c) **Postoperative analgesia**: 10 – 20 µg/kg (0.01 – 0.02 mg/kg) IV or IM.[41,42] For further pain relief, repeat if necessary with 10 µg/kg (0.01 mg/kg) after 3 to 4 hours or 20 µg/kg (0.02 mg/kg) every 5 to 6 hours; exact timing is based on expected duration of the dose administered, degree of pain, and results of pain assessment.

d) **Postoperative analgesia using the feline-labeled buprenorphine product (*Simbadol*®)**: In dogs undergoing ovariohysterectomy, buprenorphine 20 µg/kg (0.02 mg/kg) IV, IM in combination with acepromazine 0.02 mg/kg IM as a premedication followed by carprofen 4.4 mg/kg SC administered after induction of anesthesia provided immediate postoperative analgesia (duration not determined).[39]

e) **Buccal (oral transmucosal; OTM) for postsurgical analgesia**: Based on study results, the authors concluded that 120 µg/kg (0.12 mg/kg) buccally before OHE was an effective analgesic with minimal intraoperative and postoperative adverse effects.[43] Under experimental conditions, 30 µg/kg (0.03 mg/kg) provided antinociceptive effects.[44]

Premedication before surgery or as an anesthetic adjunct (extra-label): **NOTE:** Many potential combinations have been suggested; the following are examples and are not inclusive. For additional information, refer to anesthesia-specific references.

a) In one study, buprenorphine 20 µg/kg (0.02 mg/kg) was

combined in the same syringe with either acepromazine 0.03 mg/kg or dexmedetomidine (dosed by body surface area at 250 μg/m^2) and injected IM prior to induction of anesthesia. IV catheters were placed 30 to 45 minutes after premedication, and general anesthesia was induced with propofol or alfaxalone. Meloxicam 0.2 mg/kg IV was given after induction and before surgery started. General anesthesia was maintained with isoflurane. Both combinations (buprenorphine with either acepromazine or dexmedetomidine) resulted in suitable anesthesia and analgesia for dogs undergoing elective procedures; some animals required additional analgesia within 4 hours of the premedication. Postsurgical analgesic differences were not clinically significant.[45]

b) In another study, the efficacy and cardiorespiratory effects of a combination of dexmedetomidine 15 μg/kg, ketamine 3 mg/kg, and either buprenorphine 40 μg/kg, butorphanol 0.2 mg/kg, or hydromorphone 0.05 mg/kg as a single IM injection (with or without reversal by atipamezole) in dogs undergoing castration was tested. Supplemental isoflurane was used when anesthesia was considered inadequate during surgery. The authors concluded that the most suitable analgesic with this drug combination was buprenorphine and that the use of atipamezole after surgery shortened recovery times.[46]

CATS:

Analgesia:

a) Control of postoperative pain associated with surgical procedures (label dosage; FDA-approved):

i. Using the high-concentration SC injection (*Simbadol®*): 0.24 mg/kg SC once daily for up to 3 days.[28] Administer the first dose ≈1 hour prior to surgery. Do not dispense for administration at home by the pet owner due to the risks associated with the high concentration of *Simbadol®* (1.8 mg/mL) compared with other buprenorphine products.

ii. Using the transdermal solution (*Zorbium®*): The label dosage provides a dosage range of 2.7 – 6.7 mg/kg, and the duration of analgesia is 4 days.[8] Apply to healthy and non-injured skin at the dorsal cervical region; part hair prior to application. Administer in the veterinary clinic or hospital 1 to 2 hours prior to surgical procedure.

- For cats weighing 1.2 to 3 kg (2.6 to 6.6 lb): 0.4 mL (8 mg)
- For cats weighing greater than 3 kg (6.6 lb) and up to 7.5 kg (16.5 lb): 1 mL (20 mg)

b) **General use and postoperative analgesia** (extra-label): 10 – 30 μg/kg (0.01 – 0.03 mg/kg) standard buprenorphine IM, IV, or buccal/OTM every 4 to 8 hours. Dosages at the high end of the dosing range may be required for more severe pain. **NOTE**: If using buccal/OTM, suggest using upper end of dosing range or higher (up to 0.05 mg/kg). Use of high-concentration buprenorphine (*Simbadol®*) 0.12 – 0.24 mg/kg buccal/OTM provided analgesia under experimental conditions with a duration of 8 to 12 hours (not 24 hours as provided by SC administration).[47]

c) **Constant rate infusion** (extra-label)**:** Although not reported in cats, anecdotally the use as an infusion is the same as that used in dogs.

Premedication before surgery or as an anesthetic adjunct (extra-label): **NOTE:** Many potential combinations have been suggested; the following are examples and are not inclusive. For additional information, refer to anesthesia-specific references.

a) 0.01 – 0.03 mg/kg buprenorphine IM either 30 minutes prior to or combined with medetomidine 0.1 mg/kg (or dexmedetomidine 0.05 – 0.08 mg/kg) and ketamine 10 mg/kg and given IM for a brief, light plane of anesthesia. Inhalant may be needed for longer-term anesthesia or moderate-severe pain-level procedures.[48] Atipamezole can be used to reverse the alpha-2 agonist, if desired.

b) In one study, buprenorphine at 20 μg/kg (0.02 mg/kg) was combined in the same syringe with either acepromazine 0.03 mg/kg or dexmedetomidine (dosed by body surface area at 250 μg/m^2) and injected IM. IV catheters were placed 30 to 45 minutes after premedication and general anesthesia induction was done using propofol or alfaxalone. Meloxicam was given IV (0.3 mg/kg) after induction before surgery started. General anesthesia was maintained with isoflurane. Both combinations (buprenorphine with either acepromazine or dexmedetomidine) resulted in suitable anesthesia and analgesia for cats undergoing elective procedures; some animals required additional analgesia within 4 hours of the premedication. Cats given dexmedetomidine were more sedated than when acepromazine was used. Analgesic effect differences postsurgery were not clinically significant.[45]

c) In a study assessing analgesia after OHE, one of the protocols used was: 10 minutes prior to surgery, ketamine 60 mg/m^2 (≈3 mg/kg), midazolam 3 mg/m^2 (≈0.2 mg/kg), medetomidine 600 μg/m^2 (≈30 μg/kg), and buprenorphine 180 μg/m^2 (≈9 μg/kg) were combined and given as a single IM injection in the quadriceps muscles. In addition, either carprofen (4 mg/kg) or meloxicam (0.3 mg/kg) was given SC. All protocols in the study provided adequate analgesia.[49]

HORSES:

Neuroleptanalgesia (all extra-label):

a) 4 – 10 μg/kg (0.004 – 0.01 mg/kg) IV; usually given with a sedative such as acepromazine and/or detomidine.[50–52] IM administration could also be used, but bioavailability may be reduced, and onset of action delayed.

b) **Analgesia**: 10 μg/kg (0.01 mg/kg) IV, given 5 minutes after administration of an IV sedative.[41] A single dose may be repeated if necessary, after no less than 1 to 2 hours. A case report noted 6 μg/kg (0.006 mg/kg) sublingually every 12 hours provided analgesia to a 5-month-old filly with a C1 fracture.[53]

c) **To potentiate sedation**: 5 μg/kg (0.005 mg/kg) IV given 5 minutes after administration of an IV sedative.[41] The dose may be repeated after 10 minutes if necessary.

SHEEP:

Sedation (extra-label): 0.02 mg/kg combined with acepromazine 0.03 mg/kg and given IM provided similar sedation as morphine/acepromazine.[54]

SWINE:

Analgesic (extra-label): 0.04 mg/kg IM once effectively reduced lameness[55] and alleviated castration-related pain behaviors[56] in piglets.

FERRETS:

Analgesic (extra-label): 0.01 – 0.05 mg/kg SC or IM 2 to 3 times daily.[57]Anecdotally can use as a preanesthetic/anesthetic adjunct combined with an alpha-2 agonist and ketamine at the same dosages listed for cats.

RABBITS/GUINEA PIGS:

Analgesic (all extra-label):

a) **Rabbits**:

1. 0.05 mg/kg SC, IM, or IV every 4 to 12 hours; 0.5 mg/kg rectally every 12 hours[58]
2. One study in rabbits found that a compounded buprenorphine extended release (ER) formulation was at least as

effective as commercially available buprenorphine for postoperative analgesia. The ER formulation was prepared using FDA-approved buprenorphine powder and a proprietary polymer matrix. The product was administered at 0.12 mg/kg SC as a single injection and compared with commercially available buprenorphine at 0.02 mg/kg SC every 12 hours.[59]

b) **Guinea pigs**: 0.05 mg/kg SC or IV every 4 to 12 hours [60]

Premedication or anesthetic adjunct in rabbits (all extra-label):

a) **Compromised patients**: 0.05 – 0.1 mg/kg SC[61]

b) Buprenorphine 0.03 – 0.05 mg/kg IM or SC either 30 minutes before or combined with medetomidine 0.25 mg/kg (or dexmedetomidine 0.125 mg/kg) and ketamine 15 mg/kg IM or SC for a brief, light plane of anesthesia. Inhalant may be needed for longer-term anesthesia or moderate-severe pain-level procedures.[62] Atipamezole can be used to reverse the alpha-2 agonist, if desired.

c) **Healthy animals before uncomplicated elective procedures**: buprenorphine 0.02 – 0.06 mg/kg combined with midazolam (0.25 – 0.5 mg/kg) and given IM within 20 minutes of procedure; used with a local or line incisional block using lidocaine and bupivacaine [63]

MICE/RATS:

Analgesic:

a) **Mice:**

i. **Postprocedural pain control** (label dosage, FDA-indexed):

- Using extended-release buprenorphine suspension: 3.25 mg/kg SC as a single injection.[64] If needed, a single repeat dose may be administered 72 hours after the initial dose.
- Using extended-release buprenorphine solution: 1 – 1.5 mg/kg SC[65]

ii. **Using standard buprenorphine** (extra-label): 0.05 – 0.1 mg/kg SC every 12 hours[60]

b) **Rats:**

i. **Postprocedural pain control using extended-release buprenorphine product** (label dosage, FDA-indexed): 0.65 mg/kg SC as a single injection.[64] If needed, a single repeat dose may be administered 72 hours after the initial dose.

ii. **Using standard buprenorphine** (extra-label): 0.01–0.05 mg/kg SC or IV every 8 to 12 hours or 0.1 – 0.25 mg/kg PO every 8 to 12 hours[60]

Monitoring

- Analgesic efficacy (pain scores)
- Respiratory effects (respiratory rate, $ETCO_2$, SpO_2)
- Cardiac effects (heart rate, ECG, blood pressure)
- Body temperature (in cats, due to potential development of hyperthermia)

Client Information

- Buprenorphine is an opioid analgesic often used for short-term pain relief. It is given either by injection or buccally (ie, oral transmucosally [OTM]; squirted into the side of the mouth).
- When giving buccally/OTM to cats, gently squirt or drip just under the tongue or in the cheek pouch for the best effect. The doses are very small for this potent drug, so be sure you are giving the exact amount your veterinarian has prescribed.
- Sedation is the most common side effect.
- Buprenorphine is classified as a schedule III (C-III) controlled drug by the federal Drug Enforcement Agency (DEA) and requires a new written prescription for refills. Use of this medication in animals or humans other than those for whom they are prescribed is illegal.

Chemistry/Synonyms

Buprenorphine is a thebaine derivative and a synthetic partial-opioid agonist. It occurs as a white crystalline powder with a solubility of 17 mg/mL in water and 42 mg/mL in alcohol. The commercially available injectable product (*Buprenex®*) has a pH of 3.5 to 5 and is a sterile solution of the drug dissolved in D_5W. Terms of potency are expressed in terms of buprenorphine. The commercial human product contains 0.324 mg/mL of buprenorphine HCl, which is equivalent to 0.3 mg/mL of buprenorphine. Autoclaving may considerably decrease drug potency.

Buprenorphine HCl may also be known as buprenorphini hydrochloridum, CL-112302, NIH-8805, UM-952; trade names include *Animalgesics®*, BupaqB, *Buprenex®*, *Buprenodale®*, *EthiqaXR®*, *Simbadol®*, Suboxone®, *Subutex®*, and *Temgesic®*, and *Vetergesic®*.

Storage/Stability

Buprenorphine Injection 1.8 mg/mL (*Simbadol®*) should be stored at temperatures up to 25°C (77°F) and protected from light and excessive heat (greater than 40°C [104°F]). The vial has a 56-day in-use shelf-life.

Buprenorphine transdermal solution should be stored at temperatures up to 25°C (77°F) and protected from light.

As a controlled substance, buprenorphine must be stored in an area that is substantially constructed and securely locked in accordance with DEA regulations. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Store buprenorphine extended-release injectable suspension vials (*Ethiqa XR®*) at temperatures between 15°C and 25°C (59°F-77°F) or refrigerated. Do not freeze. Discard 28 days after broaching. Wear gloves when handling. Allow drug to reach room temperature before administration.

Store buprenorphine extended-release injectable solution (*BupreLab-Rat®*) between 15° and 30°C (59°-86°F). Discard 28 days after broaching.

Buprenorphine 0.3 mg/mL injection should be stored at 20°C to 25°C (68°F-77°F) and protected from prolonged exposure to light. Temperatures above 40°C (104°F) or below freezing should be avoided.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Buprenorphine is reported to be **compatible** with the following IV solutions and drugs: acepromazine, atropine, diphenhydramine, D5W, D5W with normal saline, glycopyrrolate, haloperidol, hydroxyzine, lactated Ringer's solution, normal saline, scopolamine, and xylazine. Although no published data could be located to support stability for these combinations, buprenorphine injection has also been mixed in syringes with detomidine, dexmedetomidine, ketamine, medetomidine, and midazolam.

Buprenorphine is reportedly **incompatible** with diazepam and lorazepam.

An in vitro study demonstrated that a 3 mg/mL buprenorphine solution compounded for buccal/OTM use was stable for at least 90 days when stored at room temperature or refrigerated.[66] A buccal/OTM buprenorphine suspension was prepared by dissolving a 2 mg sublingual tablet in 0.6 mL deionized water and adding to 6 mL simple syrup (final concentration, 0.3 mg/mL). The product had a pH of 3.9 and was stable for 21 days at room temperature or refrigerated. A pharmacokinetic study using this formulation showed that peak concentration and AUC were ≈45% and ≈50% lower, respectively,

with the compounded product as compared with the commercial injection (0.3 mg/mL).[67]

Buprenorphine injection (0.3 mg/mL) diluted 1:10 with bacteriostatic saline experienced less than 10% drug loss when stored in glass vials for 180 days either refrigerated or at room temperature. Storage in plastic syringes for 180 days resulted in more than 80% loss at room temperature and 28% loss refrigerated.[68]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Buprenorphine Injection 1.8 mg/mL in 10 mL multidose vials; *Simbadol®*; (Rx; DEA C-III). FDA-approved (NADA #141-434) for use in cats

Buprenorphine Transdermal Solution: 20 mg/mL in 0.4 mL or 1 mL applicator tubes; *Zorbium®*; (Rx; DEA C-III). FDA-approved (NADA #141-547) for use in cats

Buprenorphine Extended-Release Injectable Suspension: 1.3 mg/mL (buprenorphine hydrochloride, equivalent to 1.2 mg/mL buprenorphine) as a lipid-encapsulated formulation in 1.6 and 3 mL multidose vials; *EthiqaXR®*; (Rx; C-III). Not FDA-approved; legally marketed as an FDA-indexed product under MIF 900-014. Extra-label use is prohibited.

Buprenorphine Extended-Release Injectable Solution: 1 mg/mL in 5 mL multidose vials; *BupreLab-Rat*; Rx; C-III). Not FDA-approved; legally marketed as an FDA-indexed product under MIF 900-006. Extra-label use is prohibited.

A compounded sustained-release formulation by ZooPharm has been used in several domestic and wildlife species, such as dogs,[69] cats,[70] rabbits,[59] Göttingen minipigs,[71] sheep,[72,73] elephant seals,[74] and macaques.[75]

HUMAN-LABELED PRODUCTS:

Buprenorphine HCl for Injection: 0.324 mg/mL (equivalent to 0.3 mg/mL buprenorphine); 1 mL amps, vials, and syringes; *Buprenex*, generic; (Rx, C-III)

Buprenorphine HCl Sublingual Tablets: 2 mg and 8 mg (as base); generic; (Rx, DEA C-III)

Buspirone

(byoo-***spye***-rone) *BuSpar®*

Anxiolytic

Prescriber Highlights

- ► Nonbenzodiazepine anxiolytic agent used in dogs and cats.
- ► May take a week or more to be effective; not appropriate for acute treatment of situational anxieties
- ► Use with caution in patients with severe hepatic or renal disease.
- ► Adverse effects are relatively uncommon; cats may exhibit behavior changes.
- ► Many potential drug interactions

Uses/Indications

Buspirone may be effective in treating certain behavior disorders in dogs and cats, principally those that are phobia-related and those associated with social interactions. Buspirone may also be useful for urine spraying,[1] fear-related behavior,[2] or psychogenic alopecia[3] in cats. Approximately 50% of cats show a decrease in urine marking when buspirone is given, and the drug may be more effective in multi-cat households than in single-cat households.[1]

Although no comparative studies have been performed, other drugs (eg, fluoxetine, clomipramine) are likely more effective.

Pharmacology/Actions

Buspirone is an anxioselective agent. Thus, unlike benzodiazepines, buspirone does not possess any anticonvulsant or muscle relaxant activity and little sedative or psychomotor impairment activity. Buspirone does not have significant affinity for benzodiazepine receptors and does not affect GABA binding. It appears to act as a partial agonist at serotonin ($5\text{-}HT_{1A}$) receptors and as an agonist/antagonist of dopamine (D2) receptors in the CNS. In neurons, buspirone slows neuronal serotonin depletion.

Pharmacokinetics

In a limited study done in 6 cats,[4] oral administration of buspirone gave peak concentrations in ≈1.4 hours, but oral bioavailability appeared to be significantly lower than in humans. Transdermal administration of buspirone (PLO-base) did not yield detectable concentrations (ELISA method). However, a study comparing the effects of oral versus transdermal buspirone on urine marking indicated a significant reduction in urine marking frequency for both groups and there was no difference in efficacy between the two groups. This study administered the medication for 35 days and included 17 cats in each group.[5]

In humans, buspirone is rapidly and completely absorbed but a high first-pass effect limits systemic bioavailability to ≈5%. Binding to plasma proteins is very high (95%). In rats, the highest tissue concentrations are found in the lungs, kidneys, and fat. Lower concentrations are found in the brain, heart, skeletal muscle, plasma, and liver. The elimination half-life (in humans) is ≈2 to 4 hours. Buspirone is hepatically metabolized to several metabolites (including the active 1-PP). These metabolites are primarily excreted in the urine.

Contraindications/Precautions/Warnings

Buspirone is contraindicated in patients hypersensitive to it. Clearance of buspirone may be reduced in animals with either significant renal or hepatic disease, therefore increasing the risk for adverse effects. Because buspirone may blunt disinhibitory neural processes, it should be used with caution in aggressive animals. Sedation is possible, although less than with other anxiolytic drugs; use this drug with caution in working or service dogs, as their level of alertness may be affected.

Because buspirone often takes a week or more for effect, it should not be used as the sole therapy for situational anxieties.

Do not confuse BusPIRone and BuPROPion.

Adverse Effects

Buspirone is generally well-tolerated; adverse effects are usually minimal. Bradycardia, GI disturbances (eg, inappetence, vomiting), and stereotypic behaviors (eg, excessive grooming, pacing) are possible. Cats may demonstrate increased affection, which may be the desired effect. In multi-cat households, cats that have previously been extremely timid in the face of repeated aggression from other cats may, after receiving buspirone, become less anxious and more assertive.

In humans, the most likely adverse effect profile seen with buspirone includes dizziness, headache, nausea, anorexia, and restlessness; other neurologic effects (including sedation) may be noted. Rarely, tachycardias and other cardiovascular clinical signs may be present.

Reproductive/Nursing Safety

Although the drug has not been proven safe during pregnancy, doses up to 30 times the labeled human dose in rabbits and rats demonstrated no teratogenic effects.[6] Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Buspirone and its metabolites have been detected in the milk of lactating rats; avoid use during nursing if possible.

Overdose/Acute Toxicity

Limited information is available. Hypertension, increased total peripheral resistance, and increased urinary volume and electrolyte loss occurred in dogs given 0.3 – 3 mg/kg IV.[7] The oral LD_{50} in dogs is 586 mg/kg.[8] Oral overdoses may produce vomiting, dizziness, drowsiness, miosis, and gastric distention. Standard overdose protocols should be followed after ingestion has been determined.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving buspirone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-2-Adrenergic Agonists** (eg, **dexmedetomidine**, **xylazine**): May increase risk for CNS and respiratory depression
- **Alpha-2-Adrenergic Antagonists** (eg, **phenoxybenzamine**, **prazosin, tamsulosin**): May increase risk for hypotension and orthostasis
- **Anesthetic Agents** (eg, **isoflurane, ketamine, propofol**): May increase risk for CNS and respiratory depression
- **Angiotensin Converting Enzyme Inhibitors** (**ACEIs**; eg, **enalapril**): May increase risk for hypotension and orthostasis
- **Angiotensin Receptors Blockers** (eg, **telmisartan**): May increase risk for hypotension and orthostasis
- **Antihistamines** (eg, **cetirizine**, **chlorpheniramine**): May increase risk for CNS and respiratory depression
- **Apomorphine:** May increase risk for CNS depression, somnolence, and dizziness
- **Azole Antifungals** (eg, **fluconazole**, **ketoconazole**): May slow metabolism of buspirone, thus potentially significantly increasing buspirone concentrations
- **Barbiturates** (eg, **methohexital**, **phenobarbital**): May increase risk for CNS and respiratory depression
- **Benzodiazepines** (eg, **alprazolam, midazolam**): May increase risk for CNS depression
- **Bromocriptine:** May increase risk for CNS and respiratory depression and serotonin syndrome
- **Calcium Channel Blockers** (**amlodipine, diltiazem, verapamil**): May increase risk for hypotension and orthostasis. Diltiazem and verapamil may increase buspirone plasma concentrations and adverse effects.
- **Carbamazepine:** May result in decreased buspirone concentrations
- **Cimetidine:** May increase buspirone concentrations
- **Clarithromycin/Erythromycin:** May slow metabolism of buspirone, thus potentially significantly increasing buspirone concentrations
- **Danazol:** May slow metabolism of buspirone, thus potentially significantly increasing buspirone concentrations
- **Diazoxide:** May increase risk for hypotension and orthostasis
- **Digoxin:** Buspirone may displace digoxin from protein binding sites. Clinical significance is uncertain.
- **Diuretics** (eg, **bumetanide**, **furosemide**): May increase risk for hypotension and orthostasis
- **Felbamate**: May increase risk for CNS depression
- **Fenoldopam**: May increase risk for hypotension and orthostasis
- **Flavoxate**: May increase risk for CNS and respiratory depression
- **Gabapentin**: May increase risk for CNS depression
- **Grapefruit Juice** (**powder**): May cause increased buspirone plasma concentrations and adverse effects
- **Glucocorticoids** (eg, **dexamethasone**, **prednis(ol)one**): May increase metabolism of buspirone
- **Ifosfamide:** May increase neurotoxic effects of ifosfamide
- **Levetiracetam:** May increase risk for CNS and respiratory depression
- **Lithium:** May increase risk for serotonin syndrome and CNS and respiratory depression
- **Magnesium Sulfate:** Concurrent use of high doses of magnesium sulfate may increase risk for CNS and respiratory depression.
- **Methylene Blue:** May increase risk for serotonin syndrome
- **Metoclopramide:** May increase risk for CNS and respiratory depression and neuroleptic malignant syndrome
- **Minocycline IV:** May increase CNS depression due to magnesium content of the IV formulation
- **Mirtazapine:** May increase risk for serotonin syndrome
- **Mitotane:** May decrease buspirone concentrations
- **Monoamine Oxidase Inhibitors (MAOIs**; eg, **amitraz, linezolid**, **selegiline**): Concurrent buspirone use, or use within 14 days of discontinuing MAOI, is contraindicated because dangerous hypertension and serotonin syndrome may occur.
- **Muscle Relaxants** (eg, **baclofen**, **methocarbamol**): May increase risk for CNS and respiratory depression
- **Opioids** (eg, **fentanyl, morphine**): May increase risk for severe respiratory depression, coma, and death
- **Phenothiazines** (eg, **acepromazine**, **chlorpromazine**): May increase risk for CNS and respiratory depression
- **Pergolide:** May increase risk for CNS and respiratory depression
- **Phenylbutazone:** May increase rate of buspirone metabolism
- **Pregabalin:** May increase risk for CNS and respiratory depression
- **Procarbazine:** May inhibit metabolism of buspirone, increasing risk for serotonin syndrome and dangerous hypertension
- **Rifampin**: May cause decreased buspirone plasma concentrations
- **Serotonin Antagonists** (eg, **dolasetron**, **ondansetron**): May increase risk for serotonin syndrome
- **Selective Serotonin Reuptake Inhibitors (SSRIs**; eg, **fluoxetine**, **paroxetine**): May increase risk for serotonin syndrome. SSRIs may decrease metabolism of buspirone. Concurrent use may increase psychiatric signs. Dosage reductions may be necessary to minimize adverse effects.
- **Tramadol:** May increase risk for serotonin syndrome and CNS and respiratory depression
- **Trazodone**: Use with buspirone may cause increased ALT and increased risk for serotonin syndrome.
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline**, **clomipramine**): May increase the risk for serotonin syndrome. Dosage reductions may be necessary to minimize adverse effects.

- **Valproic Acid/Divalproex:** May increase risk for CNS and respiratory depression
- **Vasodilators** (eg, **hydralazine**, **nitroglycerin**, **nitroprusside**): May increase risk for hypotension and orthostasis
- **Zonisamide**: May increase risk for CNS and respiratory depression

Dosages

DOGS:

Adjunctive treatment of low-grade anxieties and fears (extra-label): Most recommendations fall into a range of 0.5 – 1 mg/kg PO every 8 to 12 hours, but anecdotal recommendations as high as 2 mg/kg have been noted. Some recommendations have maximum dosage limits of 10 – 15 mg/dog (NOT mg/kg) PO every 8 to 12 hours.

CATS:

Adjunctive treatment of low-grade anxieties and fears, urine spraying, and overgrooming (extra-label): 0.5 – 1 mg/kg PO every 12 hours. Practically, using 5 mg tablets: 2.5 – 7.5 mg/cat (NOT mg/kg) PO every 12 hours[9]

Monitoring

- Efficacy
- Adverse effects

Client Information

- May be given either with food or on an empty stomach. If animal vomits or acts sick after receiving it on an empty stomach, give with food or small treat to see if this helps.
- May take a few weeks for the full benefits of this medication to be noticeable. Best used in conjunction with behavioral therapy.
- This medication has many potential drug interactions. Be sure your veterinarian is aware of all medicines you give your animal, including vitamins, supplements, and herbal therapies.
- If your animal has worn a flea or tick collar in the past two weeks, let your veterinarian know. Do not start new flea/tick products without discussing with your veterinarian first.
- Buspirone is usually well-tolerated by dogs and cats. Cats may show increased friendliness during buspirone treatment.

Chemistry/Synonyms

An arylpiperazine derivative azapirone anxiolytic agent, buspirone HCl differs structurally from the benzodiazepines. It occurs as a white crystalline powder with solubility at 25°C (77°F) of 865 mg/mL in water and ≈20 mg/mL in alcohol.

Buspirone HCl may also be known as MJ-9022; many trade names are available. A common trade name is *BuSpar®*.

Storage/Stability

Buspirone HCl tablets should be stored in air-tight, light-resistant containers at room temperature 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

No specific information noted

Dose Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated buspirone as a class 2 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Buspirone HCl Oral Tablets: 5 mg (4.6 mg as base), 7.5 mg (6.85 mg as base), 10 mg (9.1 mg as base), 15 mg (13.7 mg as base), and 30 mg (27.4 mg as base); generic; (Rx). 5 and 10 mg tablets have a bisecting score, whereas 15 and 30 mg tablets are trisected (allows splitting into ⅓ tablet).

Butorphanol

(byoo-***tor***-fa-nol) *Stadol®, Torbutrol®, Torbugesic®*

Antitussive, Opioid Partial Agonist

Prescriber Highlights

- ► Opioid agonist/antagonist used in a variety of species as an analgesic, premedication, or antitussive; effects are reversible with naloxone.
- ► Moderately effective analgesic for horses; however, more effective options are available for moderate to severe pain in small animal species
- ► Primarily used as a sedative in small animal species as analgesia is mild and of short duration. Provides mild to moderate sedation in ruminants
- ► Contraindicated or should be used with caution in patients with liver disease, hypothyroidism, renal insufficiency, Addison's disease, head trauma, increased intracranial pressure, or other CNS dysfunction (eg, coma) and in geriatric or severely debilitated patients; however, butorphanol has a wide safety margin and effects are reversible, thus it is commonly used in patients with most of these conditions.
- ► Dose should be reduced in dogs with *MDR1 (ABCB-1)* mutation.
- ► Potential adverse effects include ataxia and sedation. Anorexia or diarrhea (rare) may occur in dogs and cats. In horses, reduced intestinal sounds secondary to slowed GI motility; CNS excitement is possible.
- ► DEA Schedule IV (C-IV) controlled substance

Uses/Indications

Butorphanol is FDA-approved for use in dogs to relieve chronic nonproductive cough associated with tracheobronchitis, tracheitis, tonsillitis, laryngitis, and pharyngitis originating from inflammatory conditions of the upper respiratory tract.[1] In cats, butorphanol is labeled for the relief of pain caused by major or minor trauma or pain associated with surgical procedures.[2] It is also used in both dogs and cats as an adjunctive preanesthetic medication or analgesic. As compared with other opioid analgesics, butorphanol is not very effective for treating pain in small animal species as it is less potent and has a short duration of action, necessitating frequent administration. Due to its kappa effects, butorphanol can be an effective reversal agent for the CNS and respiratory depressant effects of mu-opioid agonists (eg, morphine, hydromorphone) without completely reversing the analgesic effects. Because of the short duration (≈50 minutes in dogs[3] and 90 minutes in cats[4]) and mild analgesia but effective sedation, butorphanol is more commonly used as a sedative than an analgesic. Combining butorphanol with an alpha-2 agonist enhances both analgesia and sedation in dogs and cats.

Butorphanol is FDA-approved for use in adult horses and yearlings for relief of pain associated with colic.[5] In horses, combining butorphanol with an alpha-2 agonist (eg, detomidine, xylazine) appears to enhance analgesia and sedation. Buprenorphine provided better postoperative analgesia than butorphanol in horses undergoing elective surgery[6]; however, buprenorphine may be more likely to cause increased locomotor activity and excitement than butorphanol.[7]

Butorphanol has also been used as an analgesic and/or sedative in cattle, camelids, small ruminants, small mammals, and several wild-

life species. Butorphanol use in reptiles is somewhat controversial, and most studies show it has minimal analgesic or anesthetic-sparing activity in many of these species. The same is true for birds.

Pharmacology/Actions

Butorphanol is considered to be, on a weight basis, 4 to 7 times more potent an analgesic (ie, agonist) than morphine, 15 to 30 times more potent than pentazocine, and 30 to 50 times more potent than meperidine; however, a ceiling effect is reached at higher doses, where analgesia is no longer enhanced and may be reduced. Its agonist activity is thought to occur primarily at the kappa- and sigma-opioid receptors as well as in the analgesic receptors in the limbic system (subcortical and spinal levels). Its use as an analgesic in small animals has been less useful as compared with other opioids, primarily because of its short duration of action and ability to alleviate only mild to moderate pain.

The antagonist potency of butorphanol at mu-opioid receptors is considered to be ≈30 times that of pentazocine and 1/40 that of naloxone and will antagonize the effect of true opioid agonists (eg, morphine, meperidine, oxymorphone).

In addition to its analgesic qualities, butorphanol has significant antitussive activity. The drug has 15 to 20 times the oral antitussive activity of codeine or dextromethorphan in dogs. In dogs, butorphanol has been shown to elevate the CNS respiratory center threshold to CO_2, but, unlike pure mu-opioid agonists, it does not depress respiratory center sensitivity. Butorphanol, unlike morphine, apparently does not cause histamine release in dogs. CNS depression may occur in dogs receiving butorphanol, whereas CNS excitation has been noted (usually at high dosages) in horses and dogs.

As with other opioid agonists, butorphanol can cause a decrease in heart rate secondary to increased parasympathetic tone and mild decreases in arterial blood pressure. However, increased heart rates have been noted in horses after IV injection.[8]

The risk for physical dependence appears minimal in veterinary patients.

Pharmacokinetics

In general, butorphanol is absorbed completely in the gut when administered orally, but, because of a high first-pass effect, only ≈1/6 of the administered dose reaches systemic circulation. The drug is completely absorbed following IM administration.

Butorphanol is well-distributed, with the highest concentrations (of the parent compound and metabolites) found in the liver, kidneys, and intestine. Concentrations in the lungs, endocrine tissues, spleen, heart, adipose tissue, and blood cells are also higher than those found in plasma. In humans, ≈80% of the drug is bound to plasma proteins.

Butorphanol is metabolized in the liver, primarily by hydroxylation. Other methods of metabolism include N-dealkylation and conjugation. The metabolites of butorphanol do not exhibit any analgesic activity. These metabolites, and the parent compound, are mainly excreted into the urine (only 5% is excreted unchanged), but 11% to 14% of a dose is excreted into the bile and eliminated with the feces. Terminal half-lives reported in various species include the following: cats, ≈5 to 6 hours (IM/OTM); dogs, 2.6 hours (IM/SC); dairy cattle, 82 minutes[9] and goats, 1.87 hours (IV) and 2.75 hours (IM).

In adult horses, the onset of action after IV administration is ≈3 minutes, with peak analgesic effect at 15 to 30 minutes. The duration of action in horses may be up to 4 hours after a single dose. After a single 0.1 mg/kg IV dose, volume of distribution is ≈1.4 L/kg, clearance is ≈12 mL/minute/kg, and elimination half-life is 6 hours.[8] After SC administration, bioavailability is ≈87% and half-life is ≈5.3 hours.[10] Another study suggested that the half-life in conscious horses is ≈44 minutes with a clearance of 21 mL/kg/minute after a single 0.1 – 0.13 mg/kg IV dose.[11]

Bioavailability after IM injections in adult horses is relatively low (≈37%).[12] In neonatal foals, IM bioavailability is ≈67%, and peak concentrations occurred ≈6 minutes after administration. Terminal half-life was ≈2 hours after IV administration.[13]

In ferrets given a single dose of 0.3 mg/kg SC, peak concentration was reached after 13.3 minutes, and elimination half-life was 91 minutes.[14]

In parrots, butorphanol compounded at 8.3 mg/mL in a sterile 25% poloxamer 407 gel and administered at 12.5 mg/kg SC reached a peak concentration at 1.3 hours and provided analgesia for 4 to 8 hours; however, further studies are required to support clinical use.[15]

Contraindications/Precautions/Warnings

Butorphanol is contraindicated in patients with known hypersensitivity to it. All opioids should potentially be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), or obstructive respiratory disease and in geriatric or severely debilitated patients.

Like other opioids, butorphanol must be used with caution in patients with head trauma, increased intracranial pressure, or other CNS dysfunction (eg, coma). It should be used cautiously with other sedatives or analgesics.

Dogs with MDR1 mutations may develop a more pronounced sedation that persists longer than normal. The Washington State University Veterinary Clinical Pharmacology Lab (http://vcpl.vetmed.wsu.edu) recommends reducing the dosage by 25% in dogs heterozygous for the *MDR1* gene (also known as *ABCB1* gene) mutation and by 30% to 50% in dogs homozygous (mutant/mutant) for the mutation. However, clinically there seems to be a minimal impact and butorphanol effects are reversible so avoidance of butorphanol in these patients is not generally necessary.

Manufacturers state that butorphanol should not be used in animals with a history of liver disease or with severe hepatic or renal dysfunction, and, because of its effects on suppressing cough, "it should not be used in conditions of the lower respiratory tract associated with copious mucous production." The drug should be used cautiously in dogs with heartworm disease, as safety for butorphanol has not been established in these patients.

In turtles and tortoises, butorphanol may not be an effective analgesic and may cause respiratory depression.[16]

Opioid analgesics are contraindicated in patients stung by scorpions (eg, *Centruroides* spp) as they may potentiate venom effects.[17]

Because butorphanol injection is available in different concentrations (see ***Dosage Forms/Regulatory Status***), careful attention should be paid to which concentration is being used when drawing up dosages. Doses should not be ordered in mLs.

Butorphanol is commonly administered with other medications in the same syringe. Due to the negative pressure in the vial, it may become contaminated with other medications. Although one study showed the contamination to be below clinically important levels in 10 mL vials,[18] 50 mL vials may reach significant levels. Caution should be used in critically ill patients when drawing from a previously used vial if the practice of drawing up multiple medications in the same syringe is employed.

Adverse Effects

Adverse effects reported in dogs and cats include sedation, excitement, respiratory depression, ataxia, mydriasis, disorientation, hypersalivation, anorexia, vomiting, or diarrhea (rarely). Sedation with butorphanol and dexmedetomidine can decrease tear production and may require treatment with a tear substitute.[65] Antitussive effect may result in mucus accumulation in the respiratory tract. Although adverse cardiovascular effects are uncommon, bradycardia may occur and can be treated with anticholinergic agents (eg, atropine, glycopyrrolate). Adverse effects are generally less severe than those seen with pure agonists.

Adverse effects in horses may include transient bradycardia, ataxia, and sedation, but restlessness, shivering, and excitement have also been noted. Although reported to have minimal effects on the GI tract, butorphanol has the potential to decrease intestinal motility, and ileus is possible. Horses may exhibit increased heart rates and CNS excitement (eg, tossing and jerking of head, increased ambulation, augmented avoidance response to auditory stimuli), particularly with rapid IV administration of high doses (0.2 mg/kg). Very high doses IV (1 – 2 mg/kg) may lead to the development of nystagmus, salivation, seizures, hyperthermia, and decreased GI motility. It has been suggested that when used for analgesia in horses, butorphanol administered as a continuous rate IV infusion can minimize adverse effects and maximize analgesia as compared with bolus dosing but GI transit time may be delayed.[19] When administered to horses recovering from abdominal surgery for colic, butorphanol CRI slowed GI motility but did not cause signs of colic and resulted in decreased pain-related behavioral scores compared to horses receiving only NSAIDs.[20] However, butorphanol may delay GI transit without affecting somatic nociception as measured by thermal threshold response when it is administered to healthy, nonpainful horses as a CRI in combination with lidocaine, ketamine, or lidocaine/ketamine.[21] Both the presence of pain and the duration of infusion (24 vs 96 hours, respectively) could explain the difference in outcomes.

Reproductive/Nursing Safety

Butorphanol crosses the placenta and neonatal plasma concentrations are approximately equivalent to maternal concentrations. Although no controlled studies have been performed in domestic animals or humans, in laboratory animals the drug has exhibited no evidence of teratogenicity or of causing impaired fertility but has increased the rate of stillbirth and postimplantation losses.[22] Butorphanol is not recommend for use in pregnant bitches or queens or breeding males (feline, equine).[1,2,5]

In humans, butorphanol can be distributed into milk,[23] but not in amounts that would cause concern in nursing offspring.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute life-threatening overdoses with butorphanol are unlikely. The LD_{50} in dogs is reportedly 50 mg/kg.[1] However, because butorphanol injection is available in different dosage strengths (0.5 mg/mL, 2 mg/mL, and 10 mg/mL) for veterinary use, inadvertent overdoses could occur in small animals. It has been suggested that animals exhibiting clinical signs of overdose (eg, CNS effects, cardiovascular changes (including, profound bradycardia, respiratory depression) be treated immediately with IV naloxone. Additional supportive measures (eg, fluids, O_2, vasopressor agents, mechanical ventilation) may be required. Should seizures occur and persist, diazepam may be used for control.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving butorphanol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Alpha-2 Receptor Agonists** (eg, **dexmedetomidine, xylazine**): Concurrent use may increase risk for bradycardia
- **Angiotensin Converting Enzyme Inhibitors** (eg, **benazepril, enalapril**): Concurrent use may increase risk for hypotension and orthostasis.
- **Anticholinergics** (eg, **atropine, glycopyrrolate**): Concurrent use may increase risk for CNS depression, urinary retention, constipation, and ileus.
- **Antidiarrheals:** Concurrent use can lead to severe constipation and ileus.
- **Apomorphine**: Concurrent use may increase risk for CNS depression.
- **Beta-adrenergic Receptor Antagonists** (eg, **atenolol, carvedilol**): Concurrent use may increase risk for hypotension and orthostasis.
- **Bromocriptine**: Concurrent use may increase CNS depression and respiratory depression.
- **Calcium-Channel Blockers** (eg, **amlodipine, diltiazem**): Concurrent use may increase risk for hypotension and orthostasis.
- **Cannabidiol:** Concurrent use may enhance the CNS depressant effect of opioids.
- **Clopidogrel:** Concurrent use of clopidogrel and opioid agonists may result in reduced efficacy of clopidogrel.
- **CNS Depressants** (eg, **anesthetic agents, antihistamines, anticonvulsants, benzodiazepines, phenothiazines, barbiturates, muscle relaxants, tranquilizers, opioids**): May cause increased CNS or respiratory depression when used with butorphanol; dosage may need to be decreased
- **CYP 3A Inhibitors** (eg, **cimetidine, erythromycin, itraconazole**)**:** May decrease metabolism of butorphanol, increasing risk for respiratory depression and apnea
- **Desmopressin**: Concurrent use may increase concentrations and pharmacologic activity of desmopressin, increasing risk for hyponatremia and water intoxication.
- **Diuretics** (eg, **furosemide, hydrochlorothiazide**): Concurrent use may increase risk for hypotension and orthostasis.
- **Fenoldopam**: Concurrent use may increase risk for hypotension and orthostasis.
- **Hydromorphone**: In cats, butorphanol administered 30 minutes after hydromorphone reduced the duration of hydromorphone antinociception.[24]
- **Ifosfamide:** Concurrent use may increase risk for neurotoxic effects of ifosfamide, including sleepiness, confusion, hallucinations, extrapyramidal clinical signs, seizures, psychotic behavior, and coma.
- **Inhalant Anesthetics** (eg, **isoflurane, sevoflurane**): Opioids may decrease MAC anesthetic requirements.
- **Iohexol:** Concurrent use of intrathecal iohexol may increase risk for seizures. Butorphanol should be withheld 48 hours before and 24 hours after intrathecal iohexol if possible.
- **Metoclopramide:** The prokinetic effects of metoclopramide may be decreased and risk for CNS depression may be increased.
- **Minocycline:** Minocycline may enhance the CNS depressant effects of opioids.
- **Monoamine Oxidase Inhibitors** (**MAOIs;** eg, **furazolidone, methylene blue, selegiline, procarbazine**): Concurrent use may increase risk for anxiety, confusion, respiratory depression, hypotension, cyanosis, and coma by an unknown mechanism. A 14-day washout should be observed between discontinuation of furazolidone and initiation of butorphanol.
- **Opioids** (eg, **fentanyl, hydrocodone, morphine**): Butorphanol may potentially antagonize some analgesic effects and will also reverse some of the sedative and respiratory depressant effects of pure agonists. Withdrawal effects may occur in patients receiving

chronic opioid therapy.

- **Pancuronium:** If used with butorphanol, may cause increased conjunctival changes
- **Phenoxybenzamine:** Concurrent use may result in additive hypotension and orthostasis.
- **Polyethylene Glycol:** Concurrent use may increase risk for seizures associated with the use of bowel cleansing preparations.
- **Selective Serotonin Reuptake Inhibitors** (eg, **fluoxetine, sertraline**): Concurrent use may increase risk for CNS or respiratory depression and serotonin syndrome.
- **Tamsulosin:** Concurrent use may increase risk for hypotension and orthostasis.
- **Theophylline**: Could decrease metabolism of butorphanol
- **Tramadol**: Concurrent use may increase risk for seizures, CNS depression, and respiratory depression.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Concurrent use may increase risk for CNS and respiratory depression, constipation, and urinary retention.
- **Vasodilators** (eg, **hydralazine, nitroglycerin**, **nitroprusside**): Concurrent use may result in additive hypotension and orthostasis.

Laboratory Considerations

None noted

Dosages

NOTE: Potency of veterinary-labeled products is expressed as butorphanol base, whereas the human product strength is labeled as the tartrate salt; these formulations are not equal. All dosages are expressed in mg/kg of the base activity. As a rough conversion, 1.5 mg butorphanol tartrate will provide 1 mg butorphanol base.

DOGS:

Antitussive (label dosage; FDA-approved):

a) *Injection*: 0.055 mg/kg SC every 6 to 12 hours; may be increased to 0.11 mg/kg SC every 6 to 12 hours.[25] Treatment should not normally be required for longer than 7 days.

b) *Oral*: 0.55 mg/kg PO every 6 to 12 hours; may increase dose to 1.1 mg/kg PO every 6 to 12 hours.[1,25] Treatment should not normally be required for longer than 7 days.[26]

Analgesic (extra-label):

a) 0.2 – 0.4 mg/kg IV, IM, SC is the most common range chosen, but 0.1 – 0.5 mg/kg IV, IM, SC can also be used. Butorphanol provides only mild to moderate analgesia (potentially better visceral than somatic analgesia but this is controversial); duration of sedative action is 2 to 4 hours, but analgesic action may be less than 1 hour.[3,27]

b) **Constant rate infusion (CRI):** 0.2 mg/kg IV as a loading dose followed by 0.1 – 0.24 mg/kg/hour IV CRI. Dosages as high as 0.4 mg/kg/hour can be used but may cause sedation.

c) **Epidural analgesic**: 0.25 mg/kg diluted with preservative-free saline or local anesthetic (to a total volume of 0.2 mL/kg with a maximum of 6 mL) injected into the lumbosacral epidural space. Onset of action is less than 30 minutes and duration is 2 to 4 hours. This method of delivery has predominantly supraspinal effects.[28]

In combination as an anesthetic or sedative adjunct (extra-label): **NOTE:** There are many potential combinations that have been suggested; the following are examples and are not inclusive. For additional information, refer to other anesthesia-specific references.[29,30]

a) **In combination with acepromazine for dogs undergoing OHE or gastroduodenoscopy**: butorphanol 0.3 – 0.4 mg/kg with acepromazine 0.02 mg/kg IV[31] or in the same syringe and given IM[31–33]

b) **In combination with dexmedetomidine:** butorphanol 0.4 mg/kg IM has been combined with dexmedetomidine at 5 – 10 µg/kg IM for echocardiography. This combination results in sedation, but with decreased heart rate, cardiac output, and the development of valvular regurgitation. Caution should be used when giving this drug combination to dogs with cardiovascular disease.[34] Butorphanol 0.15 mg/kg with dexmedetomidine 0.01 mg/kg IM produced superior antinociceptive effects under experimental conditions.[35]

c) **In combination with dexmedetomidine and ketamine ('doggie magic') to provide anesthesia and pain management:** see ***Dexmedetomidine*** or ***Ketamine***

d) **In combination with medetomidine**: butorphanol 0.4 mg/kg IM can be combined with medetomidine 2.5 µg/kg IM to provide moderate to deep sedation for 20 to 30 minutes; there will be a decrease in heart rate.[36]

e) **In combination with medetomidine and alfaxalone IM:** butorphanol 0.25 – 0.3 mg/kg in combination with medetomidine 2.5 – 5 µg/kg, and (preservative-free) alfaxalone 1 – 2.5 mg/kg IM provided anesthetic effect without severe cardiorespiratory depression[37,38]; however, substantial cardiorespiratory depression was noted when butorphanol 0.1 mg/kg has been combined with medetomidine 10 µg/kg and (preservative-free) alfaxalone 1.5 mg/kg IM to induce anesthesia/analgesia.[39]

f) **In combination with medetomidine and midazolam:**

i. **Dogs requiring light to moderate sedation for short procedures (eg, nail trims, radiographs):** butorphanol 0.2 mg/kg with medetomidine 0.001 – 0.01 mg/kg ± midazolam 0.05 – 0.2 mg/kg; combined and administered IM

ii. **Dogs requiring more sedation**: butorphanol 0.2 mg/kg with medetomidine 0.01 – 0.02 mg/kg and midazolam 0.05 – 0.2 mg/kg; combined and administered IM. Consider adding tiletamine/zolazepam or ketamine at 1 – 2 mg/kg if insufficient sedation from above drug combination. For painful procedures, consider adding buprenorphine at 0.02 – 0.04 mg/kg or substituting butorphanol or buprenorphine with either morphine 0.5 – 1 mg/kg or hydromorphone 0.1 – 0.2 mg/kg.[40]

g) **In combination with midazolam:** butorphanol 0.2 mg/kg IV followed by midazolam 0.1 mg/kg IV was deemed a good option for contrast-enhanced ultrasonography of the duodenum.[41]

h) **In combination with midazolam and alfaxalone IV:** butorphanol 0.2 mg/kg IV followed by midazolam 0.2 mg/kg IV, then administration of alfaxalone 2 mg/kg IV over 1 minute, provides excellent quality of induction and good to excellent recovery with minimal cardiopulmonary effects in healthy dogs. Time from induction to extubation was ≈29 minutes and to standing was ≈36 minutes.[42]

Reversal agent for the sedative and respiratory depressant effects of mu-agonist opioids (extra-label): 0.05 – 0.1 mg/kg IV; the benefit of using butorphanol over naloxone is that butorphanol does not completely reverse analgesic effects.[43]

CATS:

Analgesic:

a) **Relief of pain caused by major or minor trauma, or pain associated with surgical procedures** (label dosage; FDA-approved): 0.4 mg/kg SC. The dose may be repeated up to 4 times daily for up to 2 days.[44]

b) **Relief of pain** (extra-label): 0.1 – 0.5 mg/kg IV, IM, or SC; provides only mild to moderate analgesia (potentially bet-

ter visceral than somatic analgesia but this is controversial). Duration of sedative action is 2 to 4 hours, but analgesic action may be 1 to 2 hours or less.[4,45]

c) **Postoperative CRI** (usually in combination with ketamine; extra-label) for mild to moderate pain: Loading dose of butorphanol 0.1 – 0.2 mg/kg IV, followed by butorphanol 0.1 – 0.2 mg/kg/hour IV CRI. Ketamine may be added for complementary analgesia with a loading dose of 0.1 mg/kg IV followed by ketamine 0.4 mg/kg/hour IV CRI. Opioid and ketamine IV CRI combinations may allow dose reductions for both drugs.[46]

d) **Epidural analgesic** (extra-label): 0.25 mg/kg, diluted with preservative-free saline or local anesthetic (to a total volume of 0.2 mL/kg) and injected into the lumbosacral epidural space. Onset of action is less than 30 minutes with a duration of 2 to 4 hours. This drug delivery combination has predominantly supraspinal effects.[28]

Prevention of dexmedetomidine-induced emesis (extra-label): butorphanol 0.1 – 0.2 mg/kg IM when given concurrently with dexmedetomidine[47]

In combination as an anesthetic or sedative adjunct (extra-label): **NOTE:** There are many potential combinations that have been suggested; the following are examples and are not inclusive. For additional information, refer to other anesthesia-specific references.[29,30]

a) **In combination with ketamine, midazolam, and medetomidine:** In the study assessing analgesia after OHE,[48] one of the protocols used was: Ten minutes prior to surgery, ketamine 60 mg/m^2 (≈3 mg/kg), midazolam 3 mg/m^2 (≈0.2 mg/kg), medetomidine 600 µg/m^2 (≈30 µg/kg), and butorphanol 6 mg/m^2 (≈0.3 mg/kg) were combined and given as a single IM injection in the quadriceps muscles. Additionally, either carprofen (4 mg/kg) or meloxicam (0.3 mg/kg) were given SC. All protocols in the study provided adequate analgesia.

b) **In combination with dexmedetomidine:** Butorphanol 0.4 mg/kg in combination with dexmedetomidine 10 µg/kg IM provided adequate sedation and was superior to dexmedetomidine/buprenorphine combination.[47,49]

c) **In combination with midazolam and ketamine OR dexmedetomidine:** From a small (n = 6) healthy cat crossover study, butorphanol 0.4 mg/kg in combination with midazolam 0.4 mg/kg and ketamine 3 mg/kg IM provided acceptable sedation and minimal cardiovascular changes.[50] Substituting dexmedetomidine 5 µg/kg for ketamine produced excellent sedation and recovery but caused more cardiovascular depression and hematologic changes.

d) **In combination with alfaxalone:**

i. **SC dosing for sedation during short procedures:** In a study in hyperthyroid cats,[51] butorphanol 0.2 mg/kg in combination with (preservative-free) alfaxalone 3 mg/kg drawn up in the same syringe and administered as a single SC injection in the region dorsal to the right hip. Maximum sedation occurred 45 minutes postadministration. Blood pressure, heart rate, and respiratory rate were all significantly decreased. Monitoring blood pressure is recommended. Further studies are required to determine whether the sedative, respiratory, and cardiovascular effects are similar in euthyroid cats.

ii. **IM dosing:**

- Rapid, deep, short duration sedation can be achieved with butorphanol 0.2 mg/kg and (preservative-free) alfaxalone 2 mg/kg IM; recumbency attained within 36 ± 4.4 minutes. Cats had smooth recovery with no adverse effects.[52]
- Another study combined butorphanol 0.4 mg/kg IM with (preservative-free) alfaxalone 2 – 3 mg/kg IM to achieve sedation in cats sufficient to undergo phlebotomy; median recumbency time was 53 minutes, and no adverse effects were noted.[66]
- Butorphanol 0.4 mg/kg and (preservative-free) alfaxalone 2 – 3 mg/kg IM provided sufficient restraint for blood donation.[53]
- In cats undergoing diagnostic imaging or noninvasive procedures, butorphanol 0.2 mg/kg IM with (preservative-free) alfaxalone 5 mg/kg IM yielded better sedation than a lower alfaxalone dose (2 mg/kg IM).[54]
- Butorphanol 0.3 mg/kg with alfaxalone 3 mg/kg combined and injected IM; injection into the supraspinatus muscle produced faster and superior sedation as compared to injection into the quadriceps muscle.[55]

e) **In combination with dexmedetomidine and alfaxalone OR ketamine for anesthetic induction**:

i. Butorphanol 0.3 mg/kg, dexmedetomidine 25 µg/kg, and alfaxalone 2 mg/kg combined and given IM[56]

ii. Butorphanol 0.2 mg/kg and dexmedetomidine 10 µg/kg combined with *either* (preservative-free) alfaxalone 3 mg/kg OR ketamine 5 mg/kg IM produced acceptable anesthesia for short procedures.[57]

iii. A study evaluated efficacy and cardiorespiratory effects of a combination of butorphanol 0.2 mg/kg combined with dexmedetomidine 25 µg/kg and ketamine 3 mg/kg as a single IM injection (with or without reversal by atipamezole) in cats undergoing castration. Cats also received meloxicam 0.2 mg/kg SC immediately prior to the conclusion of surgery.

iv. **Short-term restraint:** butorphanol 0.3 mg/kg with dexmedetomidine 5 µg/kg +/- ketamine 3 mg/kg mixed in the same syringe and administered IM. Duration of sedation is longer when ketamine is added.[58]

v. **'Kitty magic' to provide anesthesia and pain management:** see ***Dexmedetomidine*** or ***Ketamine***

f) **In combination with medetomidine and alfaxalone as injectable anesthesia:** butorphanol 0.2 mg/kg, medetomidine 20 µg/kg, and (preservative-free) alfaxalone 5 mg/kg mixed in the same syringe and administered IM. Analgesia lasted ≈1 hour and recovery took 2 hours.[59]

Reversal agent for sedative and respiratory depressant effects of mu-opioid receptor agonists (eg, fentanyl, hydromorphone, morphine; extra-label): 0.05 – 0.1 mg/kg IV. The benefit of using butorphanol over naloxone is that butorphanol does not completely reverse analgesic effects[43]; however, one study showed that butorphanol administration decreased the duration of hydromorphone analgesic effects in cats.[24]

HORSES (EQUIDS):

Analgesic:

a) **Relief of pain associated with colic in adult horses and yearlings** (label dosage; FDA-approved): 0.1 mg/kg IV every 3 to 4 hours; duration of therapy not to exceed 48 hours[5]

b) **SC administration** (extra-label): 0.1 mg/kg SC. This route of administration provided less marked physiologic and behavioral effects as compared with the same dose given IV.[10]

c) **Constant rate infusion** (**CRI**; extra-label): There is evidence that giving butorphanol via a CRI may provide better analgesia and reduce the potential for adverse effects.[19]

i. **Postceliotomy:** Butorphanol 13 µg/kg/hour IV CRI and

continued for 24 hours; therapy was combined with flunixin 1.1 mg/kg IV every 12 hours; administration started at the end of celiotomy.[20] Although horses treated with this combination had delayed passage of feces following surgery, no horses experienced colic, pain scores were significantly decreased, less weight was lost, and recovery scores were improved. Treated horses were discharged 3 days sooner, on average, than those treated with flunixin alone.[20]

ii. **Sedation**: Sedation with butorphanol 17.8 µg/kg in combination with xylazine 1 mg/kg IV followed by butorphanol 23.7 µg/kg/hour IV CRI may be useful.[60] Horses sedated with the same protocol and receiving butorphanol/xylazine infusions had more ataxia and instances of falling and occasionally inadequate sedation.

iii. **Standing procedures**: butorphanol (loading dose, 18 µg/kg IV; CRI, 25 µg/kg/hour) combined with romifidine (loading dose, 80 µg/kg IV; CRI, 29 µg/kg/hour) for standing dentistry and ophthalmologic procedures.[61]

iv. Butorphanol 0.02 mg/kg combined with dexmedetomidine 3.5 µg/kg and given as an initial IV bolus followed by butorphanol 0.024 mg/kg/hour with dexmedetomidine 3.5 µg/kg/hour IV CRI provided clinically sufficient sedation for 30 minutes.[62]

d) **Foals** (extra-label): Most recommend dosages of ≈0.1 mg/kg IV or IM. One study in pony foals (both neonatal and older) found that 0.1 mg/kg IV, but not 0.05 mg/kg IV, significantly raised the thermal nociceptive threshold[63]; however, a pharmacokinetic study in neonatal foals found that dosages of 0.05 mg/kg IV significantly changed behaviors (increased nursing, sedation).[63] Because elimination half-life in foals is longer than in adults, repeat doses may be considered every 4 to 6 hours, when needed.

Sedative and analgesic in combination with other agents (extra-label): Several protocols have been described using butorphanol in conjunction with an alpha-2 receptor agonist (eg, xylazine, romifidine, detomidine); often, butorphanol is used at a lower dose than labeled (eg, 0.02 – 0.05 mg/kg).

a) Premedicate with xylazine 1 mg/kg IV OR 2 mg/kg IM 5 to 10 minutes (longer for IM route) before induction of anesthesia with ketamine 2 mg/kg IV. Horse must be adequately sedated (head to knees) before giving the ketamine, as ketamine alone can cause muscle rigidity. If adequate sedation does not occur, either: 1) Re-dose xylazine using up to half the original dose. 2) Add butorphanol 0.02 – 0.04 mg/kg IV. Butorphanol can be given with the original xylazine premedication if the horse is suspected to be difficult to tranquilize (eg, high-strung thoroughbreds) or added before the ketamine induction. This drug combination improves induction quality, increases analgesia, and increases recumbency time by ≈5 to 10 minutes. 3) Give diazepam 0.03 mg/kg IV. Mix the diazepam with the ketamine. This combination will improve induction quality when sedation is marginal, improve muscle relaxation during anesthesia, and prolong anesthesia by ≈5 to 10 minutes. 4) Guaifenesin 5% solution administered IV to effect can also be added to increase sedation and muscle relaxation.[64]

b) Butorphanol 0.05 – 0.1 mg/kg in combination with romifidine 0.05 – 0.1 mg/kg IV.[65] Sedation onset and duration were ≈5 minutes and ≈60 minutes, respectively. Analgesia lasted ≈30 minutes.[66]

c) Butorphanol 0.02 mg/kg IV in combination with detomidine 8 µg/kg IV[67]

Intravenous anesthetic protocol (extra-label):

a) **Procedures in standing horses**: butorphanol 0.018 mg/kg and romifidine 0.08 mg/kg IV bolus followed by butorphanol 0.025 mg/kg/hour and romifidine 0.029 mg/kg/hour[61]

b) **Standing laparoscopic ovariectomy:** Butorphanol 0.01 mg/kg IV and medetomidine 5 µg/kg IV bolus; to maintain sedation, bolus doses of butorphanol 0.004 mg/kg IV and medetomidine 1 µg/kg IV were repeated every 15 minutes.[68]

Analgesia and sedation of donkeys (extra label): One study recommended a combination of butorphanol 0.05 mg/kg and *either* detomidine 0.04 mg/kg OR romifidine 0.08 mg/kg IV.[69] These combinations provided safe and effective sedation with complete analgesia in standing donkeys. Another study recommended xylazine 0.5 mg/kg and butorphanol 0.04 mg/kg IV.[70]

CATTLE:

Analgesic (extra-label): When used alone in cattle, butorphanol has been recommended anecdotally at 0.02 – 0.04 mg/kg IV or SC every 4 hours.

Analgesia, sedation/restraint in calves (extra-label): Butorphanol 0.1 mg/kg with xylazine 0.1 mg/kg provided reliable recumbent restraint in healthy Holstein-Friesian calves[71]

Analgesia, sedation/restraint, and disassociation from a noxious procedure in combination as "ketamine stun" (extra-label):

a) **IV administration:** Butorphanol 0.01 – 0.025 mg/kg with xylazine 0.02 – 0.05 mg/kg and ketamine 0.05 – 0.5 mg/kg IV; doses at upper end of these ranges should produce recumbency, while lower doses are expected to produce standing restraint; duration of effect is ≈15 minutes.[72]

b) **IM/SC administration:** Butorphanol 0.02 – 0.1 mg/kg with xylazine 0.02 – 0.05 mg/kg and ketamine 0.04 – 0.1 mg/kg IM or SC; doses at upper end of these ranges should produce recumbency for ≈ 45 minutes, whereas lower doses are expected to produce standing restraint for 60 to 90 minutes. SC administration provides slightly longer duration of effect than IM.[72]

CRI in calves: in isoflurane-anesthetized calves, butorphanol 0.1 mg/kg IV followed by 20 µg/kg/minute IV CRI. Hemodynamic variables were unaffected, and recovery was uneventful.[73]

GOATS:

Premedication (extra-label): A combination of midazolam 0.3 mg/kg and butorphanol 0.1 mg/kg IM has been used to decrease the amount of IV alfaxalone needed for induction of general anesthesia.[74] Cardiorespiratory parameters were within clinically accepted limits.

CAMELIDS:

Analgesic and sedative (extra-label): Most butorphanol dosage recommendations fall between 0.05 – 0.1 mg/kg IM or IV every 4 to 6 hours. Several dose protocols have been suggested for combining butorphanol with other sedative and/or anesthetic agents:

a) As an anesthetic: Butorphanol 0.07 – 0.1 mg/kg with ketamine 0.2 – 0.3 mg/kg and xylazine 0.2 – 0.3 mg/kg combined and given IV OR butorphanol 0.05 – 0.1 mg/kg with ketamine 0.2 – 0.5 mg/kg and xylazine 0.2 – 0.5 mg/kg combined and given IM[75]

b) Procedural pain relief (eg, castrations) when recumbency (up to 30 minutes) is desired: *Alpacas*: Butorphanol 0.046 mg/kg with xylazine 0.46 mg/kg and ketamine 4.6 mg/kg combined and given IM. *Llamas*: Butorphanol 0.037 mg/kg with xylazine 0.37 mg/kg and ketamine 3.7 mg/kg combined and given IM. May administer 50% of original dose of ketamine and xylazine during anesthesia to prolong effect up to 15 minutes. If doing castrations on 3 or more animals sequentially, it is acceptable to make up a bottle of the drug mixture: Add butorphanol 10 mg (1 mL) and xylazine 100 mg (1 mL) to ketamine 1 g (10 mL vial). This mixture is dosed at 1 mL/18 kg (40 lb) for

alpacas and 1 mL per 22 kg (50 lb) for llamas. Handle quietly and allow plenty of time before starting procedure. Expect 20 minutes of surgical time; patient should stand 45 minutes to 1 hour after injection.[75]

c) **Alpacas**: Ketamine 4 mg/kg with xylazine 0.4 mg/kg and butorphanol 0.04 mg/kg combined and given IM resulted in ≈30 minutes of anesthesia time for castrations. Additional anesthesia (⅓ the induction dose) was given at the discretion of the anesthetist.[76]

BIRDS:

Analgesic (extra-label):

a) Butorphanol 1 – 4 mg/kg IM has been suggested in birds, but dose frequencies range from every 2 to 24 hours. Limited pharmacokinetic studies in birds suggest that frequent dosing may be necessary in birds, raising issues of the practicality of using this drug.[77]

b) Butorphanol 2 mg/kg IM every 2 hours was used in broiler chickens undergoing terminal surgical procedures.[78]

Anesthesia/sedation in psittacid species (extra-label):

a) Butorphanol 1 mg/kg IM with midazolam 0.5 mg/kg IM in the pectoral muscle provided good anesthetic premedication prior to isoflurane. The combination improved induction quality and reduced induction time and isoflurane concentration required for anesthetic maintenance without adverse effects on cardiorespiratory parameters.[79]

b) In cockatiels, butorphanol 3 mg/kg combined with midazolam 3 mg/kg and given intranasally provided rapid, deep sedation with no adverse effects.[67]

FERRETS:

Analgesic (extra-label): Because butorphanol appears to have shorter duration of action, buprenorphine is more commonly recommended for use as an analgesic in ferrets, but a butorphanol CRI of 0.1 – 0.2 mg/kg can be useful. Recommended analgesic dosages generally range from 0.1 – 0.4 mg/kg IM, IV, or SC every 2 to 6 hours.

Anesthetic adjunct (extra-label):

a) Butorphanol 0.1 mg/kg, ketamine 5 mg/kg, medetomidine 80 µg/kg. Combine in one syringe and give IM. May need to supplement with isoflurane 0.5% to 1.5% for abdominal surgery[80]

b) Butorphanol 0.2 mg/kg with xylazine 2 mg/kg IM[32]

c) Butorphanol 0.2 mg/kg with tiletamine/zolazepam 1.5 mg/kg and xylazine 1.5 mg/kg IM; may reverse xylazine with yohimbine 0.05 mg/kg IM

RABBITS/RODENTS/SMALL MAMMALS:

Analgesic (extra-label):

a) **Rabbits**: Butorphanol dosage recommendations generally range from 0.1 – 0.5 mg/kg SC, IM, or IV every 2 to 4 hours. An IV CRI dosage of 0.1 – 0.2 mg/kg/hour has also been recommended.[81]

b) **Rabbits:** Intranasal dexmedetomidine 0.1 mg/kg with midazolam 2 mg/kg and butorphanol 0.4 mg/kg produces profound sedation and analgesia lasting 45 minutes, with moderate sedation lasting another 25 minutes. Residual central nervous system impairment lasted up to 100 minutes. Because blood pressure and respiratory rates decrease with this drug combination, oxygen supplementation and careful monitoring are required. Use cautiously in compromised rabbits.[82]

c) **Rodents and Guinea pigs**: 1 – 2 mg/kg SC every 4 hours

d) **Chinchillas**:

i. Butorphanol 0.2 – 2 mg/kg SC every 2 to 4 hours[83]

ii. Butorphanol 0.5 mg/kg with (preservative-free) alfaxalone 5 mg/kg IM resulted in rapid anesthesia but of inconsistent depth and quality.[84]

Monitoring

- Analgesic and/or antitussive efficacy
- Respiratory rate and depth
- Appetite and bowel function
- CNS effects
- Heart rate

Client Information

- Be sure to tell your veterinarian if you notice any significant changes in your animal's behavior, appetite, bowel or urinary habits.
- This medicine is a controlled substance. Keep it in a secure location out of reach of children and animals.
- Butorphanol is classified as a schedule IV controlled drug by the federal Drug Enforcement Agency (DEA). Use of this medication in animals or humans other than those for whom it is prescribed is illegal.

Chemistry/Synonyms

Butorphanol tartrate is a synthetic narcotic agonist-antagonist and a morphinan derivative related structurally to morphine but that exhibits pharmacologic actions similar to other partial agonists (eg, pentazocine, nalbuphine). The compound occurs as a white crystalline powder that is sparingly soluble in water and insoluble in alcohol. It has a bitter taste and a pK_a of 8.6. The commercial injection has a pH of 3 to 5.5. One mg of butorphanol tartrate is equivalent to 0.68 mg of butorphanol base.

Butorphanol tartrate may also be known as levo-BC-2627 (butorphanol), *Alvegesic®*, *Butador®*, *Butomidor®*, *Butordyne®*, *Butorgesic®*, *Dolorex®*, *Equanol®*, *Stadol®*, *Torbutrol®*, *Torbugesic®*, *Torphadine®*, and *Verstadol®*.

Storage/Stability

The injectable product should be stored out of bright light and at controlled room temperature (20°C-25°C [68°F-77°F]), with excursions between 15°C to 30°C (59°F-86°F). The US label states to use contents within 4 months of first puncture. UK/AU/Canadian labels state to discard vial 28 days after first use.

Butorphanol is a controlled substance that should be stored in an area that is substantially constructed and securely locked. Follow applicable local, state, and federal rules regarding disposal of unused or wasted controlled drugs.

Compatibility/Compounding Considerations

Label information from butorphanol products approved in other countries state that butorphanol should not be mixed with any other drug in the same syringe. The injectable butorphanol product is reported to be **compatible** with the following drugs when mixed in the same syringe: acepromazine, atropine, chlorpromazine, diphenhydramine, fentanyl, hydroxyzine, meperidine, metoclopramide, midazolam, morphine, pentazocine, perphenazine, prochlorperazine, promethazine, scopolamine, and xylazine. Although studies confirming compatibility were not located, butorphanol is reportedly also compatible with preservative-free alfaxalone, detomidine, dexmedetomidine, ketamine, and medetomidine.

Butorphanol is reportedly **incompatible** with the following agents: alfaxalone from multi-dose vials (preservatives may form precipitate), dimenhydrinate, and pentobarbital sodium. It is unlikely to be compatible with diazepam.

Butorphanol has been compounded in a 8.3 mg/mL gel using a sterile 25% poloxamer 407 gel. Administration of this product in parrots at 12.5 mg/kg SC reached a peak concentration at 1.3 hours, and provided analgesia for 4 to 8 hours, but further studies are required to support clinical use.[15]

Dosage Forms/Regulatory Status

NOTE: Butorphanol is a class IV controlled substance. The veterinary product (*Torbutrol®*, *Torbugesic®*) strengths are listed as base activity, whereas the human product strength is labeled as the tartrate salt; these formulations are not equal.

VETERINARY-LABELED PRODUCTS:

Butorphanol Tartrate Injection: 2 mg/mL (activity as base) in 10 mL vials. *Torbugesic®-SA*, generic; (Rx, C-IV). FDA-approved for use in cats. NADA #141-047

Butorphanol Tartrate Injection: 10 mg/mL (activity as base) in 10 mL and 50 mL vials; *Torbugesic®*, *Dolorex®*, *Butorphic®*, generic; (Rx, C-IV). FDA-approved for use in horses not intended for food

Butorphanol Tartrate Tablets: 1 mg, 5 mg, and 10 mg (activity as base) tablets; bottles of 100; *Torbutrol®*; (Rx, C-IV). FDA-approved for use in dogs. NADA #103-390. **NOTE: Although this product is still listed in FDA's Green Book of approved animal drugs, it may no longer be commercially available in the United States.**

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Food Animal Residue Avoidance Databank (FARAD) recommends a 5-day meat withdrawal and 3-day milk withdrawal with butorphanol use.[85]

HUMAN-LABELED PRODUCTS:

Butorphanol Tartrate Injection: 1 mg/mL (as tartrate salt; equivalent to 0.68 mg base) in 1 mL vials; 2 mg/mL (as tartrate salt) in 1 mL and 2 mL vials; generic; (Rx, C-IV)

Butorphanol Nasal Spray: 10 mg/mL in 2.5 mL metered dose; generic; (Rx, C-IV)

Butylscopolamine

N-Butylscopolammonium Bromide (NBB) Hyoscine Butylbromide, Butylscopolamine Bromide

(***byoo***-tel-skoe-***pahl***-ah-***meen***) *Buscopan®*

Quaternary Ammonium Antispasmodic and Anticholinergic

Prescriber Highlights

- ► Injectable anticholinergic used in horses
- ► Labeled for treating colic associated with spasmodic colic, flatulent colic, and simple impactions. May be an alternative to atropine or glycopyrrolate for treating bradycardia or acute episodes of severe equine asthma (SEA)
- ► Shorter-acting than atropine; only labeled for a single dose IV. Extra-label IM dosing has a longer duration of action.
- ► Not for use in patients with ileus or when decreased GI motility may be harmful
- ► Adverse effects include transient tachycardia, pupil dilation, decreased secretions, and dry mucous membranes.

Uses/Indications

N-butylscopolammonium bromide (NBB) injection is indicated (per the label) for control of abdominal pain (colic) associated with spasmodic colic, flatulent colic, and simple impactions in horses. As compared with butorphanol, NBB provided superior analgesia for ponies in a balloon model of abdominal pain.[1] It may also be of benefit in horses in combination with oxytocin to treat esophageal obstruction (choke) and as an aid to performing rectal examinations,[2] including colonoscopy. It can be considered an alternative to atropine as a positive chronotropic agent in horses[3] and has demonstrated bronchodilatory effects in horses with severe equine asthma (SEA),[4,5] although it does not improve yield during bronchoalveolar lavage.[6] NBB may be used to facilitate ophthalmic examination.[7]

Pharmacology/Actions

N-butylscopolammonium reduces GI peristalsis and rectal pressure via its anticholinergic actions by competitively inhibiting muscarinic receptors on smooth muscle. It has some bronchodilatory and chronotropic effects in horses. The bronchodilatory effects are observed within 10 minutes of IV administration, and dissipate within 1 hour.[4] NBB has shorter duration of action than atropine. It appears to have brief (15 to 20 minutes) visceral colorectal distention antinociceptive effects in horses.[8]

Pharmacokinetics

Limited information is available for horses. After an IV dose, the drug is eliminated within 48 hours in urine and feces equally. Estimated elimination half-life is ≈6 hours.

Contraindications/Precautions/Warnings

N-butylscopolammonium is labeled as contraindicated in horses with impaction colic associated with ileus or those with glaucoma.

NBB might be useful for equine ileal impactions by reducing intestinal spasm, but further studies are needed to confirm these effects and impaction is still listed as a contraindication.[9]

Because NBB can increase heart rate, use with caution in horses with systemic cardiovascular compromise.[10]

Adverse Effects

Adverse effects include transient tachycardia and hypertension, and a period of ≈20 to 30 minutes of decreased borborygmal sounds after IV dosing. Transient pupil dilation can be noted. Other effects include decreased secretions and dry mucous membranes.

Because this drug can cause increases in heart rate, heart rate cannot be used as a valid pain indicator for 30 minutes after injection.

When used for labeled indications, a lack of response may indicate a more serious problem that may require surgery or more aggressive care.[11]

Reproductive/Nursing Safety

Because no data are available to document safety, the manufacturer does not recommend use in nursing foals or pregnant or lactating mares.

Overdose/Acute Toxicity

Doses up to 10 times (3 mg/kg) the recommended amount were administered to horses as part of preapproval studies.[12] Clinical effects noted included dilated pupils (returned to normal in 4 to 24 hours), tachycardia (returned to normal within 2 hours) and dry mucous membranes (returned to normal in 1 to 2 hours). Gut motility was inhibited but returned to baseline within 4 hours and normal feces were seen within 6 hours. Two of the 4 horses treated at 10 times the recommended dose developed mild signs of colic that resolved without further treatment.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in animals receiving N-butylscopolammonium bromide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate**): May cause additive anticholinergic effects
- **Metoclopramide** (and other drugs that have cholinergic-like actions on the GI tract): These drugs and NBB may counteract one another's actions on GI smooth muscle.
- **Xylazine**: In healthy horses, NBB with xylazine can cause significant hypertension and cardiac tachyarrhythmias; may falsely influence surgical decision-making and prognosis in horses with colic.[10]

Laboratory Considerations
- No specific concerns noted

Dosages
HORSES:

Control of abdominal pain (colic) associated with spasmodic colic, flatulent colic, simple impactions (label dosage; FDA-approved): 0.3 mg/kg (30 mg or 1.5 mL per 100 kg (220 lb) of body weight) slowly IV, one time[12]

Control of abdominal pain (colic) associated with spasmodic colic, flatulent colic, simple impactions (extra-label): 0.3 mg/kg IM[13]

Esophageal obstruction (extra-label): NBB 0.3 mg/kg IV with oxytocin 0.11 – 0.22 units/kg IV once. Oxytocin should be avoided in mares, or dose significantly reduced; do NOT use in pregnant mares.[14]

Monitoring
- Heart rate (**NOTE:** Heart rate cannot be used as indicator for pain for the first 30 minutes after administration.)
- GI motility via gut sounds and feces output

Client Information
- Because an accurate patient assessment must be performed prior to the use of this medication and it requires IV administration and subsequent monitoring, this drug should only be administered by your veterinarian.

Chemistry/Synonyms
N-butylscopolammonium bromide, a derivative of scopolamine, is a synthetic, quaternary ammonium antispasmodic-anticholinergic agent. It occurs as a white crystalline substance that is soluble in water.

N-butylscopolammonium bromide may also be known as butylscopolamine bromide, hyoscine butylbromide, hyoscine N-butylbromide, scopolamini butylbromidum, hyoscini butylbromidum, *Buscopan*®, or *Buscapina*®.

Storage/Stability
The commercially available injection should be stored at or below 25°C (77°F) with excursions permitted up to 30°C (86°F).

Compatibility/Compounding Considerations
No specific information noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

N-butylscopolammonium bromide injection: 20 mg/mL in 50 mL multidose vials; *Buscopan*®; (Rx). NADA #141-228. FDA-approved for use in horses. Do not use in horses intended for human consumption

HUMAN-LABELED PRODUCTS:

None in the United States. There are several products with the trade name *Buscopan*® or *Buscapina*® available in many countries. Refer to actual product labels as ingredients and concentrations may vary.

References
For the complete list of references, see **wiley.com/go/budde/plumb**

Cabergoline
(ka-***ber***-goe-leen) *Dostinex®, Galastop®*

Dopamine Agonist/Prolactin Inhibitor

Prescriber Highlights
- ► Synthetic ergot derivative used for reducing prolactin levels in bitches and queens for medical treatment of pyometra, inducing and synchronizing estrus, inducing abortion, treating pseudopregnancy, mastitis, and pre-surgery for mammary tumors.
- ► Appears to be well tolerated in dogs and cats; vomiting has been reported, but adverse effects are much less than with bromocriptine.
- ► May need to be compounded for accurate dosing in cats and small dogs
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies cabergoline as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
For dogs and cats, cabergoline may be useful for medical treatment of pyometra, inducing and synchronizing estrus, treatment of primary or secondary anestrus, mastitis, pseudopregnancy, as a treatment prior to mammary tumor surgery, and for pregnancy termination in the second half of pregnancy. Cabergoline has also been used for post-spay aggression and anxiety in dogs and cats particularly when the surgery is performed during the luteal phase.

Cabergoline has been used in psittacines (primarily cockatiels) for adjunctive treatment of reproductive-related disorders, particularly persistent egg laying.[1-3]

Pharmacology/Actions
Cabergoline is an ergot alkaloid-derived dopamine (D_2) receptor agonist that exhibits multiple pharmacologic actions. It has a high affinity for dopamine$_2$ (D_2) receptors and a long duration of action. It exerts a direct inhibitory effect on the secretion of prolactin from the anterior pituitary gland. Its effect in inducing estrus is presumably due to its dopamine agonist effects on GnRH secretion rather than its effects on prolactin. When compared to bromocriptine, cabergoline has greater D_2 receptor specificity, longer duration of action, and less tendency to cause vomiting.

Pharmacokinetics
The pharmacokinetics of cabergoline have not been reported for dosages commonly used in dogs or cats. In humans, the drug is absorbed after oral dosing but its absolute bioavailability is not known.[4] Food does not appear to significantly alter absorption. The drug is extensively distributed throughout the body and is moderately bound to plasma proteins (40%). Cabergoline is extensively metabolized in the liver via hydrolysis. Half-life is estimated to be around 60 hours. Duration of pharmacologic action may persist for 48 hours or more. Elimination occurs by fecal (≈60%) and renal (≈22%) routes. Renal dysfunction does not appear to significantly alter elimination characteristics of the drug, but in severe hepatic insufficiency C_{max} and AUC are substantially increased.[4]

Contraindications/Precautions/Warnings
Cabergoline is contraindicated in patients that are hypersensitive to ergot derivatives (eg, bromocriptine)[4] or during pregnancy unless termination of pregnancy is desired. Patients that do not tolerate bromocriptine may not tolerate cabergoline.

In humans, bromocriptine is contraindicated in patients that have uncontrolled hypertension as additive hypertension could occur[4]; use with caution in those with hypertension that are already being treated with antihypertensive medications as syncope may result.[5,6]

It should be used with caution in patients with hepatic disease as the metabolism of the drug may be reduced.[6]

When using to induce estrus, it is recommended to wait at least 4 months after the prior cycle to allow the uterus to recover.

The National Institute for Occupational Safety and Health (NIOSH) classifies cabergoline as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure. Pregnant or nursing women, or women trying to become pregnant should avoid handling the medication due to reproductive risks.

Adverse Effects

Cabergoline is usually well tolerated by animal patients; it may cause lethargy and decreased appetite. Vomiting has been reported (most commonly after first few doses) but may be alleviated by reducing the dose and/or administering with food.[6,7] Dogs receiving cabergoline for more than 14 days may exhibit changes in coat color or texture[8]; this effect is likely reversible with drug withdrawal.

Human patients have reported postural hypotension, dizziness, headache, nausea, and vomiting while receiving cabergoline.[4]

Reproductive/Nursing Safety

This drug can cause spontaneous abortion in pregnant dogs or cats because prolactin is luteotrophic in these species.

Because cabergoline suppresses prolactin, it should not be used in nursing dams. A study in rats detected significant levels of cabergoline and its metabolites in maternal milk.[4]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdose information is not available for dogs or cats and remains limited for humans. It is postulated that cabergoline overdoses in people could cause hypotension, nasal congestion, syncope, or hallucinations.

Standard GI decontamination techniques (eg, emesis induction, activated charcoal) should be employed when applicable; however, emesis may occur spontaneously from the overdose and induction of emesis may not be necessary. Cardiovascular monitoring (eg, blood pressure, heart rate) and supportive care should be provided based on clinical presentation.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving cabergoline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Butyrophenones** (eg, **azaperone**, **haloperidol**)**:** Use of cabergoline with dopamine (D_2) antagonists may reduce the efficacy of both drugs and should be avoided.
- **Hypotensive Drugs** (eg, **amlodipine, enalapril, telmisartan**): Because cabergoline may have hypotensive effects, concomitant use with other hypotensive drugs may cause additive hypotension. Avoid concomitant use.
- **Macrolide Antibiotics** (eg, **clarithromycin**): Cabergoline concentration may be elevated.
- **Metoclopramide**: Use with cabergoline may reduce the efficacy of both drugs and use together should be avoided.
- **Phenothiazines** (eg, **acepromazine, chlorpromazine**): Use of cabergoline with dopamine (D_2) antagonists may reduce the efficacy of both drugs and should be avoided.
- **Reserpine**: May increase prolactin concentrations, and cabergoline doses may need to be increased

Laboratory Considerations

- None

Dosages

Because of the dosage differences in animals versus human patients and the strength of the commercially available product in the US, a compounding pharmacist must usually reformulate this medication (especially in cats and small dogs).

DOGS:

Estrus induction (extra-label):

a) Most commonly recommended: cabergoline 5 µg/kg PO once daily until 2 to 8 days after onset of proestrus or 14 to 42 days of treatment.[9] Proestrus occurs within 6 to 30 days.

b) 0.6 µg/kg PO once daily.[10] Continue treatment until day 2 after the onset of the first signs of proestrus, or until day 42 without signs of proestrus; 81% (22 of 27) of dogs treated at this low dose showed proestrus between days 4 and 48.

Pseudocyesis (pseudopregnancy) |suppression of lactation (extra-label):

a) 5 µg/kg PO once daily for 4 to 6 consecutive days depending on the severity of the clinical condition.[7] If signs do not resolve after a course of treatment, or if they recur, treatment may be repeated.

b) **Adjunctive treatment of pyometra** (extra-label): cabergoline 5 µg/kg PO in combination with cloprostenol 1 µg/kg SC once a day for 7 days with oral antibiotic therapy and supportive hydration. If no response, continue cloprostenol (without cabergoline) and any supportive treatment required for another 7 days.[12-14] See ***Monitoring***.

Abortifacient (extra-label):

a) Between gestation days 35 and 45: cabergoline 5 µg/kg PO once daily for 7 days in food and cloprostenol 1 µg/kg SC (after a tenfold dilution with physiologic saline) on days 1 and 3 given at least 8 hours after food. If pregnancy not terminated by day 8, continue cabergoline (at same dose) until day 12.[15] See ***Monitoring***.

b) Between gestation days 22 and 23: cabergoline 10 µg/kg PO once daily for 10 days[16]

Presurgical treatment mammary tumors (extra-label): 5 µg/kg PO 5 to 7 days prior to surgery aids in the detection of the tumors, decreases postsurgical reactions, and promotes recovery.[17]

CATS:

Abortifacient (extra-label):

a) At 30 days postcoitus, cabergoline 5 µg/kg PO once daily in combination with cloprostenol 5 µg/kg SC every 48 hours for 7 to 13 days was used to induce abortion.[18]

b) Cabergoline 15 µg/kg PO once daily with or without alfaprostol 10 µg/kg SC every other day was effective at terminating pregnancy when treatments were started on days 25 to 42 of pregnancy.[19]

Pseudocyesis (pseudopregnancy) | suppression of lactation (extra-label): 5 µg/kg PO once daily[6,20]

Presurgical treatment mammary tumors (extra-label): 5 µg/kg PO 5 to 7 days prior to surgery aids in the detection of the tumors, decreases postsurgical reactions, and promotes recovery.[17]

BIRDS:

Persistent egg laying in psittacines (extra-label):

a) Initially 10 – 20 µg/kg PO daily[1]; higher dosages were also

used. Treatment is done in combination with removal of males and altered light cycle. Further work needed to determine the dose rate.[2]

b) 10 – 50 µg/kg PO every 12 to 24 hours[3]

Monitoring

- Monitoring for efficacy is dependent on the reason for use.
- Adverse effects (eg, lethargy, hyporexia, vomiting)
- Serum progesterone concentrations can be measured to assess response to cabergoline and client's adherence to therapy

Client Information

- Give this medicine with food to help prevent vomiting.
- Usually well tolerated by dogs and cats
- Because this drug has a higher risk for causing birth defects and affecting pregnancy or nursing, pregnant or nursing women should be very careful not to accidentally take it. Wear disposable gloves when giving doses or handling the drug, and avoid inhaling any dust from split or crushed tablets.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Cabergoline, a synthetic, ergot-derivative, dopamine agonist similar to bromocriptine, occurs as a white powder that is insoluble in water and soluble in ethanol or chloroform. The commercially available tablets also contain the inactive ingredients leucine and lactose.

Cabergoline may also be known as FCE-21336, cabergolina, *Cabaser®*, *Actualene®*, *Sostilar®*, *Dostinex®*, *Finilac®*, *Galastop®*, or *Kelactin®*.

Storage/Stability

The commercially available tablets should be stored at controlled room temperature (20°C-25°C [68°F-77°F]).

The veterinary oral solution (available in EU and UK) should be stored below 25°C and protected from light. Do not refrigerate. Once opened, it should be used within 28 days.

Compatibility/Compounding Considerations

It has been reported that cabergoline is unstable or degrades in aqueous suspensions and if compounded into a liquid that will not be used immediately, should be compounded into a lipid-based product. Aqueous preparations should be used immediately and the remainder discarded. In one report a 10 µg/mL solution was prepared by dissolving one 0.5 mg [500 µg] commercial tablets in 50 mL of warm distilled water; the dose was administered within 15 minutes of preparation and the remaining solution was discarded.[21]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE IN THE UNITED STATES

Cabergoline is available in Europe as a 50 µg/mL oral solution. An injectable product, *Galastop®* Injectable, is available in some countries.

HUMAN-LABELED PRODUCTS:

Cabergoline Oral Tablets: 0.5 mg (500 µg); generic; (Rx)

Caffeine

(***kaf***-een) *Cafcit®*

CNS Stimulant

Prescriber Highlights

- ► May be useful for respiratory acidosis in foals and as an adjunctive treatment for pneumonia in dogs
- ► Use with caution in patients with cardiovascular or seizure disorders, or a history of GI bleeding
- ► Adverse effects include increased locomotor activity, GI effects, increased heart rate, and glucose dysregulation.
- ► Use with caution in patients with cardiac, hepatic, or renal disease, or those at risk for GI bleeding
- ► Tolerance may develop; physical withdrawal symptoms may occur if stopped abruptly.

Uses/Indications

Caffeine may be used in foals with hypercapnia and respiratory acidosis,[1,2] although it appears to be less effective than doxapram. While there is support for a beneficial effect on equine exercise performance,[3] other evidence suggests caffeine has no effect.[4] In dogs, caffeine has been used anecdotally as adjunctive treatment with pneumonia.

In humans, caffeine is used to treat episodes of prolonged apnea in premature infants.

Pharmacology/Actions

Caffeine is a methylxanthine, like theophylline and theobromine; however, it has weaker respiratory, cardiac, and diuretic effects and more potent CNS effects. Caffeine antagonizes phosphodiesterase (via nonselective inhibition, which results in accumulation of cyclic AMP and GMP and increased transmission through these pathways) and adenosine A1 and A2 receptors to cause stimulation of the respiratory center via vagal and vasomotor pathways. This respiratory center stimulation may result in increased tidal volume and diaphragm contractility. Caffeine may also stimulate release of catecholamines, and beta-1 and beta-2-adrenergic effects may cause tachycardia and hypertension, but at high doses, hypotension and reduced peripheral vascular resistance may result. Caffeine can constrict cerebral blood vessels. Increased renal blood flow, combined with reduced proximal tubular sodium reabsorption, produces a mild diuresis. The drug also increases intraocular pressure, skeletal muscle contraction, and parietal cell acid release in the stomach.

Tolerance to caffeine's stimulating effects may occur rapidly.

Pharmacokinetics

In dogs, peak concentrations are reached 1.6 hours after oral administration; elimination half-life is ≈3.2 hours.[5]

In horses, caffeine is variably absorbed after oral administration, with bioavailability between 39% to 100%.[6,7] CNS penetration lags behind blood concentrations.[8] It has an elimination half-life between 10 to 21 hours after IV administration[6,7,9] that may be shortened by exercise.[10] Theophylline is one of many metabolites formed after caffeine administration in horses.[8]

In camelids, elimination half-life was 11 hours in male alpacas and 16 hours in female llamas.[11]

In humans, caffeine is readily absorbed, and peak concentration occurs within 30 to 120 minutes after oral administration. Food does not alter absorption. It is widely distributed, and CNS concentrations approximate plasma concentrations. Protein binding is ≈35%. In adults, caffeine is almost completely metabolized in the liver, including by CYP1A2; metabolites are excreted in the urine. Hepatic metabolism in neonates is immature and results in most of the drug being excreted unchanged in the urine; hepatic metabolism similar

to adults is reached by ≈9 months of age. Elimination half-lives are 3 to 7 hours in adults, but 3 to 4 days in neonates.

Contraindications/Precautions/Warnings

Caffeine is contraindicated in patients hypersensitive to it or any of its components. Use caffeine with caution in patients with cardiovascular or seizure disorders, or a history of GI bleeding. Lower dosages may be required for patients with hepatic or renal disease. Cases of necrotizing enterocolitis occurred in human infants during FDA approval studies, although a causal relationship with caffeine has not been fully established.[12]

Adverse Effects

Excessive CNS stimulation may cause tremors, irritability, and decreased sleep. Increased locomotor activity in horses correlates with blood and CNS caffeine concentrations.[8] Caffeine may increase heart rate and blood pressure and disrupt blood glucose regulation. Nausea, vomiting, and inappetence may also occur. Physical withdrawal signs (eg, restlessness, irritability) may occur if drug administration is stopped abruptly.

Reproductive/Nursing Safety

Caffeine crosses the placenta. Reduced reproductive performance and embryotoxicity occurred in male rats receiving 50 mg/kg SC daily for 4 days.[12] Low rates of cleft palate occurred in pregnant mice implanted with sustained-release caffeine pellets.

Caffeine is found in human breast milk at ≈50% to 75% of plasma concentrations. Moderate intake by breastfeeding women is generally considered safe, although poor sleep may be noted in nursing infants.[13]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Hypokalemia, hyperglycemia, tachycardia, hypertension (possibly followed by hypotension), metabolic acidosis, fever, hypertonia, rhabdomyolysis, and seizures may occur with caffeine overdose.[14] Serious toxicity in humans is associated with serum caffeine concentration greater than 50 micrograms/mL.[12] In human pediatric patients, toxicity may be seen at 35 mg/kg PO; an estimated oral lethal dose in adults is 150 – 200 mg/kg. Caffeine toxicosis has occurred in horses after ingestion of coffee husks used for bedding.[15]

Treatment is mainly supportive based on clinical presentation.[12] GI decontamination with activated charcoal should be considered. Blood pressure, ECG, electrolytes, and acid-base status should be monitored. Treat seizures with benzodiazepines (eg, diazepam, midazolam). Caffeine is dialyzable.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

In humans, caffeine is metabolized by CYP1A2. The following drug interactions either have been reported or are theoretical in humans or animals receiving caffeine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Adrenergic Receptor Agonists** (eg, **albuterol, dobutamine, epinephrine**)**:** Inotropic effects may be enhanced.
- **Cimetidine**: May reduce caffeine metabolism by 50% to 70%
- **Estrogens**: May reduce caffeine metabolism
- **Ciprofloxacin, Enrofloxacin**: May reduce caffeine metabolism
- **Mexiletine**: May reduce caffeine metabolism by 30% to 50%
- **Phenobarbital**: May increase caffeine metabolism
- **Phenylpropanolamine**: May increase plasma caffeine concentrations. Combination increases blood pressure to greater extent than either drug alone.
- **Terbinafine**: May reduce caffeine metabolism
- **Theophylline**: May have additive adverse effects. Premature human neonates metabolize theophylline to caffeine; horses metabolize caffeine to theophylline.[8]

Laboratory Interactions

- Falsely elevated **serum urate** when measured by the Bittner method
- Increases in urine levels of **catecholamines**, **vanillylmandelic** acid and **5-hydroxyindoleacetic acid** may occur.

Dosages

NOTE: Dosages are expressed in terms of caffeine *base*. See ***Chemistry/Synonyms***.

DOGS:

Adjunctive treatment of pneumonia (extra-label):

a) 5 – 10 mg/kg IV every 6 to 8 hours diluted and administered slowly over at least 30 minutes[16]

b) 10 mg/kg PO was used in a single-dose pharmacokinetic study.[5]

HORSES:

Respiratory acidosis and apnea in foals (extra-label): Loading dose: 7.5 – 12 mg/kg PO; maintenance dosage: 2.5 – 5 mg/kg PO every 12 to 24 hours[1,2,17,18]

Improving exercise performance in adult horses (extra-label): 5 mg/kg IV improved short-duration, intense exercise performance in Arabians.[3] A separate study using 2.5 mg/kg IV did not have an effect on any performance variable in physically fit thoroughbreds.[4] See ***Dosage Forms/Regulatory Status***.

Monitoring

- Respiratory character and rate, heart rate and rhythm, blood pressure
- Thoracic radiographs, pulse oximetry, and arterial blood gas as indicated by clinical condition

Client Information

- Caffeine is only administered by veterinary professionals; it may cause increased alertness and disrupt your animal's normal sleep pattern.
- Vomiting, diarrhea, and decreased appetite are possible side effects.

Chemistry/Synonyms

Caffeine is a methylxanthine. Caffeine citrate occurs as a bitter white powder that is freely soluble in water and soluble in alcohol. Caffeine citrate is ≈50% anhydrous caffeine. That is, each 1 mL of 20 mg/mL caffeine citrate solution and injection provides 10 mg caffeine base.

Caffeine citrate is also known as citrated caffeine, *Cafcit*®, and *Peyona*®.

Storage/Stability

Caffeine citrate should be stored at room temperature 20°C to 25°C (68°F-77°F). Caffeine citrate oral solutions and injections do not contain preservatives, and unused portions should be discarded.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Caffeine citrate for injection is reportedly **compatible** with dextrose-containing solutions, as well as the following drugs (partial

list): calcium gluconate, dexamethasone sodium phosphate, diphenhydramine, dobutamine HCl, dopamine HCl, doxapram, fentanyl citrate, heparin, ketamine HCl, lidocaine HCl, morphine sulfate, and potassium chloride. The drug is reportedly **incompatible** with furosemide and pantoprazole.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Caffeine Citrate for Injection: 20 mg/mL in 3 mL vials; *Cafcit®*, generic; (Rx)

Caffeine Citrate Oral Solution: 20 mg/mL in 3 mL vials; generic; (Rx)

Calcitonin

(kal-si-***toe***-nin) *Miacalcin®, Calcimar®*

Osteoclast-Inhibiting Hormone

Prescriber Highlights

- ► Hormone used primarily to control hypercalcemia in dogs and reptiles. Very short duration of action in dogs and can be expensive
- ► Hypersensitivity possible. May cause GI effects
- ► Young animals may be extremely sensitive to effects.
- ► Do not confuse with calcitriol.

Uses/Indications

In small animals and reptiles, calcitonin has been used as adjunctive therapy to control hypercalcemia. It may be of use in the adjunctive treatment of pain that originates from bone. Calcitonin's use in veterinary medicine has been limited by expense, availability, and development of resistance to its effects after several days of treatment.

Pharmacology/Actions

Calcitonin has a multitude of physiologic effects. It principally acts on bone, inhibiting osteoclastic bone resorption. By reducing tubular reabsorption of calcium, phosphate, sodium, magnesium, potassium, and chloride, it promotes their renal excretion. Calcitonin also increases jejunal secretion of water, sodium, potassium, and chloride (not calcium).

Pharmacokinetics

Calcitonin is destroyed in the gut after oral administration and therefore must be administered parenterally. In humans, the onset of effect after IV administration of calcitonin salmon is immediate. After IM or SC administration, onset occurs within 15 minutes, with maximal effects occurring in ≈4 hours. Duration of action is 6 to 12 hours after IM or SC injection. The drug is believed to be rapidly metabolized by the kidneys and in blood and peripheral tissues.

Contraindications/Precautions/Warnings

Calcitonin is contraindicated in animals hypersensitive to it. Patients with a history of hypersensitivity to other related proteins may be at risk. Young animals are reportedly up to 100 times more sensitive to calcitonin than are older animals (adults).[1,2] Hypocalcemia must be corrected prior to use whenever calcitonin is being used for an indication other than hypercalcemia.

Do not confuse calcitriol with calcitonin. Consider writing orders and prescriptions using tall man lettering; calciTONIN and calciTRIOL.

Adverse Effects

There is not a well-documented adverse effect profile for calcitonin in domestic animals; however, anorexia and vomiting have been reported in dogs. Overmedicating with this drug can lead to hypocalcemia. The following effects are documented in humans and potentially could be seen in animals: diarrhea, anorexia, vomiting, swelling and pain at injection site, and redness and peripheral paresthesias. Rarely, allergic reactions may occur. Tachyphylaxis (resistance to drug therapy with time) may occur in some treated dogs.

Reproductive/Nursing Safety

There is little information on the reproductive safety of calcitonin; however, it does not cross the placenta. Very high doses have resulted in decreased birth weight in rabbits, presumably due to the drug's metabolic effects.

Calcitonin has been shown to inhibit lactation in rats. Safe use during nursing has not been established.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Very limited data are available. Nausea and vomiting have been reported after accidental overdose injections. Chronic overdosing can lead to hypocalcemia.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcitonin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Calcium-Containing Products**: May interfere with the efficacy of calcitonin
- **Lithium**: Concurrent use may result in decreased lithium concentrations and loss of lithium efficacy.
- **Pamidronate:** Although pamidronate and calcitonin are used together in human medicine, studies do not show any benefit when these drugs are used together in dogs.[3]
- **Vitamin D Analogues** (eg, **calcitriol, cholecalciferol**): May interfere with the efficacy of calcitonin

Dosages

DOGS:

Vitamin D toxicity, hypercalcemia (extra-label): Calcitonin treatment is not routinely recommended due to expense, frequency of dosing, and limited efficacy. In a recent review of management of hypercalcemia associated with cholecalciferol and vitamin D analogues,[4] the authors stated that the following protocol using calcitonin could be used but, due to inconsistent results, some patients becoming refractory to treatment, and the potential for greater soft tissue mineralization, they prefer substituting pamidronate for calcitonin: 1) Normal saline; twice maintenance; forced diuresis; maintain diuresis until calcium levels have dropped; 2) Furosemide 2.5 – 4.5 mg/kg PO 3 to 4 times a day or 0.5 mg/kg/hour via continuous IV infusion; 3) Either dexamethasone 1 mg/kg SC or IV divided 4 times daily, or prednisone 2 – 3 mg/kg PO twice daily;

4) Calcitonin 4 – 6 units/kg SC 2 to 3 times a day

REPTILES:

Hypercalcemia in green iguanas: 1.5 units/kg SC every 8 hours in combination with fluid therapy for several weeks if necessary[5]

Nutritional secondary hyperparathyroidism (NSHP):

1) If reptile is not hypocalcemic: 50 units/kg IM once weekly for 2 to 3 doses[6]
2) Correct husbandry problems and correct hypocalcemia with calcium and vitamin D. Once calcium level is normal and the animal is on oral calcium supplementation (usually about 7 days after starting therapy), give calcitonin at 50 units/kg IM weekly for 2 to 3 doses. Supportive care can be tapered once the animal becomes stable.[7]

Monitoring

- Serum-ionized (if possible) calcium. Directly measured serum-ionized calcium is a better indicator of calcium status than is total calcium but requires specific collection techniques and analyzers. Refer to your laboratory's guidelines or your analyzer's instructions.
- Phosphorus, BUN, and creatinine
- Hydration status
- Urine sediment for cast formation

Chemistry/Synonyms

Calcitonin is a 32-amino acid polypeptide with a molecular weight of ≈3600. Calcitonin is available commercially as either calcitonin human or calcitonin salmon, both of which are synthetically prepared. The potency of calcitonin salmon is typically expressed in international units (IU) but is expressed as units in this reference. Calcitonin salmon is ≈50 times more potent than calcitonin human on a per-weight basis.

Calcitonin salmon may also be known as calcitonin-salmon, calcitoninum salmonis, salmon calcitonin, SCT-1, or *Calcimar®*; many other trade names are available internationally.

Storage/Stability

Calcitonin salmon for injection should be stored in the refrigerator (2°C-8°C [36°F-46°F]).

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Calcitonin Salmon for Injection: 200 units/mL in 2 mL vials; *Miacalcin®*; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Calcitriol

(kal-si-***trye***-ole) *Rocaltrol®, Calcijex®, Active Vitamin D_3*

Vitamin D Analogue

Prescriber Highlights

- ► Vitamin D analogue that is used in dogs and cats for treatment of hypocalcemia and chronic kidney disease (CKD)
- ► Contraindications include hypercalcemia, hyperphosphatemia. Use cautiously in patients with malabsorption syndromes, calcium oxalate uroliths
- ► Adverse effects including hypercalcemia, hypercalciuria, and hyperphosphatemia are the greatest concern.
- ► Administer on an empty stomach to minimize promotion of calcium absorption and risk for hypercalcemia
- ► Do not confuse with calcitonin

Uses/Indications

Calcitriol is combined with oral calcium therapy for the long-term treatment of hypocalcemia associated with hypoparathyroidism. It has been shown to confer a survival benefit in dogs with CKD,[1] but there is only weak evidence to support calcitriol use in cats.[2] The decision remains unclear on how soon in the course of CKD calcitriol should be employed; it can reportedly improve cats' appetite and general wellbeing. Calcitriol may be a useful adjunctive drug for treating certain neoplasias (eg, mast cell tumors) as it may potentiate some chemotherapy agents.[3] It may also be of benefit in treating some types of refractory dermatopathies (eg, primary idiopathic seborrhea).[4]

Pharmacology/Actions

Calcitriol is a vitamin D analogue. Vitamin D is considered a hormone that, in conjunction with parathormone (PTH) and calcitonin, regulates calcium homeostasis in the body. Active analogues (or metabolites) of vitamin D enhance calcium absorption from the GI tract, promote reabsorption of calcium by the renal tubules, and increase the rate of accretion and resorption of minerals in bone. Unlike other forms of vitamin D, calcitriol does not require renal activation for it to be effective.

Pharmacokinetics

If fat absorption is normal, vitamin D analogues are readily absorbed from the GI tract (small intestine). Bile is required for adequate absorption and patients with steatorrhea or hepatic or biliary disease will have diminished absorption. Calcitriol has an onset of action of 1 to 4 days and a duration of action of less than 2 weeks.[5,6]

Contraindications/Precautions/Warnings

Calcitriol is contraindicated in patients with hypercalcemia, vitamin D toxicity, or abnormal sensitivity to the effects of vitamin D. Withhold treatment if hypercalcemia develops; resume treatment with a lower dosage only after calcium normalizes.[7] It should be used with extreme caution in patients with hyperphosphatemia (many clinicians believe hyperphosphatemia or a combined calcium-phosphorous product of more than 70 is a contraindication to the use of vitamin D analogues). Using calcitriol in patients with hyperphosphatemia can increase risks for tissue mineralization with additional renal tissue damage and dysfunction. Generally, calcium and phosphorus levels should be in the low normal range before beginning treatment, and adequate hydration maintained during therapy.[7]

As calcitriol can promote hypercalciuria, it should be used with caution in animals susceptible to calcium oxalate uroliths.

Monitoring of serum calcium levels is mandatory while using this drug.

Calcitriol absorption may be impaired in patients with malabsorption syndromes, resulting in reduced or unpredictable efficacy.

Do not confuse calcitriol with calcitonin. Consider writing orders and prescriptions using tall man letters: calciTONIN and calciTRIOL.

Adverse Effects

Although hypercalcemia is a known adverse effect, calcitriol administered in low dosages to dogs with CKD infrequently causes hypercalcemia, unless it is used with a calcium-containing phosphorus binder, particularly calcium carbonate. Signs of hypercalcemia include polydipsia, polyuria, and anorexia. Hyperphosphatemia may also occur with calcitriol therapy and patients' serum phosphate levels should be normalized before therapy is begun. Tissue calcification has been demonstrated in dogs with marginally elevated calcitriol concentration after chronic (up to 26 weeks) administration.[7]

Reproductive/Nursing Safety

Calcitriol has proven to be teratogenic in rabbits, but not in rats, when given at doses several times higher than those used therapeutically.[7] Reduced fetal weight, skeletal abnormalities, hypercalcemia in the offspring, and reduced pup survival have been observed. Because safety has not been established in animal species, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Calcitriol is passed into human breast milk. Safe use during lactation has not been established.

Overdose/Acute Toxicity

Overdose can cause hypercalcemia, hypercalciuria, and hyperphosphatemia. Intake of excessive calcium and phosphate may also cause the same effect. Clinical signs may include vomiting, diarrhea, anorexia, and lethargy; azotemia may occur. Hypercalcemia may require several days to up to 1 week to resolve. Acute ingestions should be managed using established protocols for removal or prevention of the drug being absorbed from the GI tract. Orally administered cholestyramine or mineral oil may reduce absorption and enhance fecal elimination.

Hypercalcemia secondary to chronic dosing of the drug should be treated by temporarily discontinuing calcitriol (not dose reduction) and exogenous calcium therapy. If the hypercalcemia is severe, a bisphosphonate (eg, pamidronate), furosemide, calcium-free IV fluids (eg, normal saline), urine acidification, and corticosteroids may be employed.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcitriol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aluminum-containing Phosphorus Binding Agents** (eg, **aluminum hydroxide**)**:** Calcitriol may increase aluminum absorption.
- **Barbiturates** (eg, **phenobarbital**, **primidone**)**:** May induce hepatic enzyme systems and increase the metabolism of vitamin D analogues thus decreasing their activity
- **Calcium Channel Blockers** (eg, **amlodipine**, **diltiazem, verapamil**): Calcitriol-induced hypercalcemia may antagonize the effects of calcium channel blocking agents.
- **Calcium-containing Phosphorus Binding Agents** (eg, **calcium acetate, calcium carbonate**): Use with calcitriol may induce hypercalcemia.
- **Cholestyramine:** May reduce calcitriol absorption; separate administration by several hours.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): Can nullify the effects of vitamin D analogues
- **Digoxin**: Hypercalcemia increases the risk for digoxin toxicity.
- **Magnesium-Containing Products** (eg, **magnesium hydroxide**)**:** Concurrent use may result in hypermagnesemia.
- **Sevelamer**: May reduce calcitriol absorption; separate administration by several hours.
- **Sucralfate**: Calcitriol may increase aluminum absorption.
- **Thiazide Diuretics** (eg, **chlorothiazide, hydrochlorothiazide**): May cause hypercalcemia when given in conjunction with vitamin D analogues

Laboratory Considerations

- **Serum cholesterol** levels may be falsely elevated by vitamin D analogues when using the Zlatkis-Zak reaction for determination.

Dosages

DOGS:

Cases of secondary hyperparathyroidism and slow progression of chronic kidney disease (CKD) (extra-label):

1. Recommended initial dosage: 1.5 – 3.5 ng/kg PO once daily, preferably in the evening on an empty stomach, to minimize calcium absorption and risk for hypercalcemia. Strong evidence supports use of calcitriol in dogs with IRIS CKD Stages 3 and 4.[8] Do not exceed calcitriol dosages of 5 ng/kg per day. If hypercalcemia develops, try giving double the daily dose every other day to reduce GI calcium absorption. Lifelong treatment is required.[9]
2. 2 – 2.5 ng/kg/day PO given on an empty stomach; maximum of 5 ng/kg/day. If hypercalcemia occurs, administer twice the daily dose every other day (eg, 2 ng/kg PO per day becomes 4 ng/kg every other day).[10]

Long-term maintenance of hypocalcemia-associated hypoparathyroidism (extra-label):

1. 30 – 60 ng/kg/day PO on an empty stomach. Combine with oral calcium to reduce vitamin D dose requirements.[11]
2. Initially, 20 – 30 ng/kg/day PO divided in two daily doses for 2 to 4 days.[6] Maintenance dosage 5 – 15 ng/kg/day

Primary idiopathic seborrhea (extra-label): 10 ng/kg PO once daily. Give on an empty stomach[4]

CATS:

Secondary hyperparathyroidism associated with CKD (extra-label):

1. 1.5 – 3.5 ng/kg PO daily given separately from meals[12]
2. 2.5 – 3.5 ng/kg PO once daily[13]

Long-term maintenance of hypocalcemia associated with hypoparathyroidism (extra-label):

1. 30 – 60 ng/kg/day PO. Maximal effect is in 1 to 4 days. Combine with oral calcium to reduce vitamin D dose requirements. Adjust dose by monitoring serum calcium.[11]
2. Initial dose 20 – 30 ng/kg/day PO for 2 to 4 days then decrease to 10 – 20 ng/kg/day PO for long-term management. Maximal effect is in 1 to 4 days. Oral calcium supplementation should also be provided initially but can usually be tapered and discontinued within a week of starting calcitriol. [14]
3. Initially, 20 – 30 ng/kg/day PO divided in 2 daily doses for 2 to 4 days.[6] Maintenance dosage 5 – 15 ng/kg/day

Monitoring

- Monitoring preventive dose: Assess serum calcium on days 7 and 14 after starting calcitriol and then every 6 months. Serum creatinine should be measured every 1 to 3 months. If hypercalcemia

occurs, stop calcitriol for 1 week to determine if the drug is causing the hypercalcemia or if it is due to another cause (eg, too little calcitriol).

- Serum calcium: baseline and at 1 week after starting calcitriol therapy, then every 2 to 4 weeks thereafter. **NOTE**: Directly measured serum ionized calcium (ie, biologically active fraction) is a better indicator of calcium status than total calcium and requires specific collection techniques and analyzers. Refer to your laboratory's or analyzer's instructions. It is recommended to consult a veterinary endocrinology reference for a more thorough discussion of calcium measurement and monitoring.
- Serum phosphorous, magnesium, and creatinine. Baseline and at 1 week after starting calcitriol therapy, then every 2 to 4 weeks thereafter.
- Serum calcium (total) x phosphate product should remain below 70.[5,15]
- Baseline and periodic serum PTH levels: Monitor as above and determine PTH levels at 4 to 6 weeks after starting calcitriol. If PTH remains elevated, increase calcitriol dose by 1 – 2 ng/kg/day, but do not exceed 6.6 ng/kg/day unless also monitoring ionized calcium. If higher daily doses are required (5 – 7 ng/kg/day), a pulsed-dosing strategy may be considered; this is usually ≈20 ng/kg given twice weekly PO at bedtime on an empty stomach.[16]
- Clinical efficacy (eg, improved appetite, activity level, slowed progression of disease)

Client Information

- Best given on an empty stomach; some recommend giving at night.
- Watch for signs of high blood calcium (eg, greater thirst and urination, reduced or lack of appetite) and low blood calcium (eg, muscle tremors, twitching, stiffness, weakness, stiff gait, unsteadiness, behavioral changes, seizures, facial itching). If any of these signs are seen, contact your veterinarian immediately.
- Do not give calcium supplements or antacids (eg, *Tums*®) without your veterinarian's approval.

Chemistry/Synonyms

Calcitriol, a vitamin D analogue, is synthesized for pharmaceutical use. It is a white crystalline compound and is insoluble in water.

Calcitriol may also be known as calcitrolo, calcitriolum, 1,25-dihydroxycholecalciferol, 1-α,25 dihydrocholecalciferol, 1α, 25-Dihydroxyvitamin D_3, or 1,25-DHCC, 1,25-dihidroxyvitamin D_3, Ro 21-5535, U 49562, or *Rocaltrol*®.

Storage/Stability

Protect from light. Store oral calcitriol products in air-tight, light-resistant containers at room temperature 15°C to 30°C (59°F-86°F). The injection should be stored at 20°C to 25°C (68°F-77°F). It does not contain preservatives; any remaining drug should be discarded after opening ampule.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Note: Most doses are expressed in nanograms/kg (ng/kg); to convert µg to ng: 1 µg = 1000 ng, 0.25 µg = 250 ng. Reformulation by a compounding pharmacy may be required to assure accurate dosing, especially in smaller patients.

Calcitriol Oral Capsules: 0.25 and 0.5 µg; *Rocaltrol*®, generic; (Rx)

Calcitriol Oral Solution: 1 µg/mL in 15 mL bottles; *Rocaltrol*®, generic; (Rx)

Calcitriol Injection: 1 µg/mL and 2 µg/mL in 1 mL single-dose amps and vials; generic; (Rx)

Topical calcitriol is also available.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Calcium Acetate

(***kal***-see-um ***ass***-ah-tate) *Calphron*®

Oral Phosphate Binder

Prescriber Highlights

- ► Oral calcium salt used as a phosphorus binding agent in treating hyperphosphatemia associated with chronic kidney disease
- ► Must monitor serum phosphorus and calcium; hypercalcemia is possible but less likely from calcium acetate when compared to other calcium salts (eg, calcium carbonate)

Uses/Indications

Calcium acetate is administered orally to treat hyperphosphatemia in patients with chronic kidney disease. Secondary to its phosphorus binding efficiency and lower concentration of elemental calcium, calcium acetate is considered the most effective of the calcium-based phosphorus-binding agents and has the lowest potential for causing hypercalcemia.

Pharmacology/Actions

When calcium acetate is given with meals, it binds to dietary phosphorus and forms calcium phosphate, an insoluble compound that is eliminated in the feces. Calcium acetate is soluble over a wide pH range and therefore, available for binding phosphorus in the stomach and proximal small intestine. Calcium acetate binds ≈50% more phosphorous than calcium carbonate. Calcium acetate is less likely to cause hypercalcemia than calcium carbonate. Unlike calcium citrate, calcium acetate does not promote aluminum absorption.

Pharmacokinetics

No information was located on the pharmacokinetics of calcium acetate in dogs and cats. In humans, ≈30% is absorbed when given with food.

Contraindications/Precautions/Warnings

This agent should not be used when hypercalcemia is present. Because hypercalcemia can result from administering oral calcium products to animals with chronic kidney disease, adequate monitoring of serum ionized calcium and phosphorus is required.

Use calcium-containing phosphate binders with caution in patients with a serum calcium x phosphorus product greater than 60.

Calcium acetate decreases systemic absorption of dietary phosphorous; patients who are not eating will not benefit from this treatment to lower serum phosphorous levels.

Using calcium-based phosphate binders and calcitriol together is controversial. Some authors state that the combination is contraindicated, whereas others state that intensified monitoring for hypercalcemia is required.

Adverse Effects

Hypercalcemia and extraosseous (soft tissue) calcification are the primary concerns associated with calcium acetate, especially when using high doses long-term. Adequate monitoring is required.

In humans, GI intolerance (nausea) has been reported.

Reproductive/Nursing Safety

No reproductive safety studies were located, and the human label states that it is not known whether the drug causes fetal harm. How-

ever, it would be surprising if calcium acetate caused teratogenic effects.

It would be expected that calcium acetate would be safe to administer during lactation.

Overdose/Acute Toxicity

Acute overdoses could potentially cause hypercalcemia. Patients should be monitored, and their clinical signs treated. If the dose was massive and recent, consider using standard protocols to empty the GI tract.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcium acetate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aspirin**: Concurrent use may result in decreased salicylate effectiveness.
- **Atenolol**: Concurrent use may result in reduced atenolol efficacy.
- **Bisphosphonates, Oral** (eg, **alendronate**): Concurrent oral administration may reduce bisphosphonate absorption. If combination is required, separate doses by at least 2 hours if possible.
- **Calcium Channel Blockers** (eg, **amlodipine**, **diltiazem, verapamil**): Concurrent use may reduce the therapeutic effects of calcium channel blockers.
- **Cefpodoxime**: Concurrent use may result in decreased cefpodoxime efficacy.
- **Ceftriaxone**: Concurrent use may result in formation of ceftriaxone-calcium precipitates. This combination is contraindicated in human neonates.
- **Digoxin**: Calcium acetate is not recommended for use in human patients that are on digoxin therapy, as hypercalcemia may cause serious arrhythmias.
- **Fluoroquinolones** (eg, **enrofloxacin, marbofloxacin**): Oral calcium-containing products can reduce absorption of fluoroquinolones. If combination is required, separate doses by at least 2 hours.
- **Iron**: Concurrent use may result in decreased iron effectiveness.
- **Ketoconazole**: Concurrent use may result in decreased ketoconazole exposure.
- **Levothyroxine**: Oral calcium products may reduce levothyroxine absorption if given at the same time. Separate doses by at least 2 hours if possible.
- **Penicillamine**: Oral calcium-containing products can reduce penicillamine absorption.
- **Phosphates, Oral**: Concurrent use may result in decreased phosphate absorption.
- **Sucralfate**: Concurrent use may result in decreased sucralfate efficacy.
- **Tetracyclines** (eg, **doxycycline, minocycline**): Oral calcium-containing products can reduce absorption of tetracyclines. If combination is required, separate doses by at least 2 hours.
- **Thiazide Diuretics** (eg, **chlorothiazide/hydrochlorothiazide**): Concurrent use may increase risk of hypercalcemia.
- **Trientene**: Oral calcium-containing products can reduce trientene absorption.
- **Vitamin D Analogues** (eg, **calcitriol, cholecalciferol, ergocalciferol**): Concurrent use may increase risk of hypercalcemia.

Laboratory Considerations

- **Hemolyzed blood samples** or **hyperlipidemia:** Can cause falsely elevated total calcium reports
- **Heparin**: Sodium or lithium heparin may bind small amounts of ionized calcium. Heparinized samples are acceptable provided that careful attention is paid to the concentration of heparin in the final sample.
- **Hyperbilirubinemia:** Can cause falsely low total calcium reports
- **Oxalate, citrate, ethylenediaminetetraacetic acid (EDTA)**: These anticoagulants in blood sample collection tubes can bind calcium and cause falsely low total calcium reports.

Dosages

DOGS/CATS:

Hyperphosphatemia associated with chronic kidney disease, in conjunction with a low-phosphorus diet (extra-label): 60 – 90 mg/kg/day PO divided and given with food, mixed with food, or just prior to each meal. Therapy usually begins at the lower end of the recommended dose range and is adjusted upward as needed every 4 to 6 weeks until the therapeutic target is reached. Monitor ionized calcium; hypercalcemia is possible. Decrease dose if serum calcium exceeds normal limits.[1-3]

Hyperphosphatemia associated with chronic kidney disease, in conjunction with a low-phosphorus diet (extra-label): Initially, 30 – 60 mg/kg/day PO in divided doses and mixed with food at each meal. Adjust dose to achieve target phosphorus concentration.[4,5]

Monitoring

- Serum phosphorus (after a 12-hour fast) and ionized calcium: monitor values at 4- to 6-week intervals initially, then once stable, recheck every 3 months.[4,5] Some clinicians recommend more frequent intervals (eg, every 10 to 14 days) initially, particularly in patients at higher risk for hypercalcemia. **NOTE:** Directly measured serum ionized calcium is a better indicator of calcium status than total calcium, but requires specific collection techniques and/or analyzers.[6]

Client Information

- Give this medicine with meals; either just before feeding or mixed into food. Your veterinarian may prescribe additional doses to be administered between meals.
- Contact your veterinarian if your animal develops increased thirst and urinations, vomiting, decreased appetite, or low energy level while receiving this medicine.
- While your animal is taking this medicine, your veterinarian will need to perform periodic blood tests to know how well the medicine is working. Do not miss these important follow-up visits.

Chemistry/Synonyms

Calcium acetate is a white, odorless, hygroscopic powder that is freely soluble in water and slightly soluble in alcohol. Each gram contains ≈254 mg of elemental calcium.

Calcium acetate may also be known as calcii acetas, acetato de calcio, kalcio acetates, kalciumacetat, or kalciumasetaatti, *Calphron®*, *PhosLo®*.

Storage/Stability

The commercially available tablets, capsules, and gelcaps should be stored at room temperature (25°C [77°F]); excursions are permitted to 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Calcium Acetate Oral Tablets: 667 mg (169 mg elemental calcium); *Calphron*®, generic; (Rx)

Calcium Acetate Oral Capsules and Gelcaps: 667 mg (169 mg elemental calcium); generic; (Rx)

Calcium Acetate Oral Solution: 667 mg/5 mL (169 mg elemental calcium); *Phoslyra*®; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Calcium, IV (-Borogluconate, -Chloride, -Gluconate)

(kal-***see***-um)

Essential Cation

Prescriber Highlights

- ► Used IV to treat or prevent severe hypocalcemia, and effects of acute hyperkalemia and hypermagnesemia; SC administration is somewhat controversial.
- ► Contraindications include ventricular fibrillation or hypercalcemia.
- ► Determine dosages carefully as calculations can be confusing.
- ► Must be given slowly IV to avoid adverse effects
- ► Must monitor therapy carefully; frequency of monitoring depends on condition and response to therapy
- ► Many potential drug interactions as well as drug and fluid incompatibilities

Uses/Indications

Parenteral calcium is used to treat confirmed hypocalcemia, calcium channel blocker toxicity, hypermagnesemia, and/or hyperkalemia. Parenteral calcium salts include calcium gluconate, calcium borogluconate, and calcium chloride. Calcium gluconate is generally preferred as it is less irritating to vascular tissues.

Routine administration of IV calcium during CPR is not recommended as administration does not improve the odds of survival. However, it may be considered in cases with moderate to severe hypocalcemia and hyperkalemia.[1]

Pharmacology/Actions

Calcium is an essential element that is required for many functions, including nervous and musculoskeletal system function, cell membrane and capillary permeability, and activation of enzymatic reactions.

Pharmacokinetics

After administration, ionized calcium enters the extracellular fluid and is rapidly incorporated into skeletal tissue. Calcium administration does not necessarily stimulate new bone formation. Approximately 99% of total body calcium is stored in bone. Of circulating calcium, ≈50% is bound to serum proteins or complexed with anions and ≈50% is found in the ionized form. Total serum calcium is dependent on serum protein concentrations. Total serum calcium changes by ≈0.8 mg/dL for every 1.09 g/dL change in serum albumin. Calcium crosses the placenta and is distributed into milk.

Calcium is eliminated primarily (≈80%) in the feces, consisting of both unabsorbed calcium and calcium excreted into the bile and pancreatic fluids. Only small amounts of calcium are excreted in the urine as most cationic calcium is filtered by the glomeruli and reabsorbed by the tubules and ascending loop of Henle. Vitamin D, parathyroid hormone, and thiazide diuretics decrease the amount of calcium excreted by the kidneys. Loop diuretics (eg, furosemide), calcitonin, and somatotropin increase calcium renal excretion.

Contraindications/Precautions/Warnings

Calcium is contraindicated in patients with ventricular fibrillation or hypercalcemia. Parenteral calcium should not be administered to patients with serum calcium levels above normal. Calcium should be used cautiously in patients receiving digitalis glycosides (eg, digoxin) or those with cardiac or renal disease. Due to its acidifying nature, calcium chloride should be used with caution in patients with respiratory failure, respiratory acidosis, or renal disease.

Hypocalcemia may not resolve in some animals until they receive magnesium supplementation.[2,3]

Rapid IV injection of calcium can cause hypotension, cardiac arrhythmias (eg, bradycardia, ST segment elevation, or QT interval shortening), and cardiac arrest. Dilution prior to administration may help promote a safer injection rate, and thus reduce risks associated with rapid injection.

Administration of calcium salts by SC or IM routes has been associated with severe injection site reactions, including tissue necrosis, and is not recommended.[3]

Parenteral treatment using calcium should be considered "High Alert" with dosages double-checked by another person.

Adverse Effects

Hypercalcemia can be associated with calcium therapy, particularly in patients with cardiac or renal disease; animals should be adequately monitored. Calcium chloride may be more irritating to vascular tissue than other parenteral salts and is more likely to cause hypotension. Rapid IV injection of calcium can cause hypotension, cardiac arrhythmias, and cardiac arrest. Calcinosis cutis has been observed in animals receiving diluted 10% calcium gluconate SC; this effect is more prevalent in small dogs or cats and those with concurrent hypophosphatemia.

Venous irritation may occur after IV administration. If calcium salts are accidentally infused perivascularly, stop the infusion. Treatment then may include infiltrating the affected area with normal saline SC, corticosteroids administered SC locally, applying heat to and elevating the area, and infiltrating the affected area with a local anesthetic and hyaluronidase.

Reproductive/Nursing Safety

Although parenteral calcium products have not been proven safe for use during pregnancy, they are often used before, during, and after parturition in cows, ewes, bitches, and queens to treat parturient paresis secondary to hypocalcemia.

In humans, calcium crosses the placenta and is excreted in milk. Calcium salts are considered compatible with pregnancy and lactation.[4]

Overdose/Acute Toxicity

Hypercalcemia can occur with parenteral therapy, oral therapy in combination with vitamin D, or increased parathyroid hormone levels. Treat hypercalcemia by withholding calcium therapy and other calcium elevating drugs (eg, vitamin D analogues). Mild hypercalcemia will usually resolve without further intervention when renal function is adequate. Moderate to marked hypercalcemia should be treated with IV fluid diuresis using normal saline and administering a loop diuretic (eg, furosemide) to increase sodium and calcium excretion. Potassium and magnesium must be monitored and replaced as necessary. ECG should also be monitored during treatment. Corticosteroids (and in humans, calcitonin and hemodialysis) have also been employed in treating hypercalcemia.

Horses with functional kidneys can eliminate large amounts of calcium; hypercalcemia from excessive calcium administration is rare, especially if the horse is receiving fluid therapy.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcium and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Bisphosphonates** (eg, **alendronate, pamidronate, zoledronic acid):** Bisphosphonate use may result in hypocalcemia.
- **Calcitonin:** Calcium administration may interfere with the calcium-lowering effects of calcitonin.
- **Calcium Channel Blockers** (eg, **amlodipine**, **diltiazem, verapamil**): IV calcium may antagonize the effects of calcium channel blocking agents.
- **Digoxin**: Patients on digoxin therapy are more susceptible to developing arrhythmias if receiving IV calcium (especially if given rapidly); use with caution.
- **Dobutamine**: Calcium salts may decrease the therapeutic effects of dobutamine.
- **Loop Diuretics** (eg, **furosemide**): Loop diuretics promote calcium excretion.[5]
- **Magnesium Sulfate**: Parenteral calcium can neutralize the effects of hypermagnesemia or magnesium toxicity secondary to parenteral magnesium sulfate.
- **Neuromuscular Blockers** (eg, **atracurium, pancuronium, vecuronium**): Parenteral calcium may reverse the effects of nondepolarizing neuromuscular blocking agents.
- **Potassium Supplements**: Patients receiving both parenteral calcium and potassium supplementation may have an increased chance of developing cardiac arrhythmias—use cautiously.
- **Thiazide Diuretics** (eg, **chlorothiazide, hydrochlorothiazide**): May cause hypercalcemia and metabolic alkalosis when used in conjunction with large doses of calcium
- **Vitamin D Analogues** (eg, **calcitriol, ergocalciferol**): Concurrent use may increase risk for hypercalcemia. Monitor calcium and phosphate and watch for signs of hypercalcemia.

Laboratory Considerations

- **Hemolyzed blood samples** or **hyperlipidemia:** Can cause falsely elevated total calcium reports
- **Heparinized blood collection tubes**: Sodium or lithium heparin may bind small amounts of ionized calcium. Heparinized samples are acceptable provided that careful attention is paid to the concentration of heparin in the final sample
- **Hyperbilirubinemia:** Can cause falsely lower total calcium levels
- **Oxalate, citrate, ethylenediaminetetraacetic acid (EDTA) blood collection tubes**: These anticoagulants in blood sample collection tubes can bind calcium and cause falsely low total calcium reports.

Dosages

NOTES:

1. **WARNING**: Dosing parenteral calcium can be confusing and potentially dangerous. Depending on the reference, dosages can be listed by mL/kg, mEq/kg, mmol/kg, or mg/kg. These may be for the calcium salt being used OR for elemental calcium. Calcium chloride 10% (100 mg/mL) injection contains ≈3 times more **elemental calcium** per mL than calcium gluconate 10% (100 mg/mL). See ***Contraindications/Precautions/Warnings***.
2. Patient response (ie, improvement of clinical signs) determines the final dose of calcium. Patients must be continually monitored during the infusion. See ***Monitoring.*** Stop infusion immediately if a pronounced change in rate or rhythm is detected.
3. Rapid IV injection of calcium can cause hypotension, cardiac arrhythmias (eg, bradycardia, ST segment elevation, or QT interval shortening), and cardiac arrest. Dilution prior to administration may help promote a safer injection rate, thus reducing risks associated with rapid injection.

Calcium source	Elemental calcium (mg/mL)
Calcium gluconate 10% injection	9.3
Calcium chloride 10% injection	27.3

DOGS/CATS:

Treatment of clinical signs associated with hypocalcemia (ie, tetany, seizures; extra-label): 5 – 15 mg/kg of elemental calcium IV *slowly* over 10 to 30 minutes. This dosage corresponds to*:

a. **Calcium gluconate 10% injection:** 0.54 – 1.61 mL/kg (NOT mg/kg)
b. **Calcium chloride 10% injection:** 0.18 – 0.55 mL/kg (NOT mg/kg)

***NOTE:** If using other concentrations or other salts (eg, calcium borogluconate), the actual volume to inject will vary depending on the concentration of the solution and which salt is being used.

Short-term maintenance after tetany has been corrected using a constant rate infusion (CRI; extra-label)**:** 2.5 – 3.5 mg/kg/hour of elemental calcium IV CRI. Dilute in compatible IV solution (eg, lactated Ringer's, 0.9% sodium chloride; see ***Compatibility/Compatibility Considerations*** for more information). The goal of treatment is to maintain calcium within the normal range, and to wean off parenteral calcium as soon as oral calcium and vitamin D take effect and serum calcium concentration remains stable. Parenteral calcium is preferably given by constant rate infusion (**calcium gluconate** or **calcium chloride**) or subcutaneous administration (**calcium gluconate** only).

Hyperkalemic cardiotoxicity (extra-label): elemental calcium 4.65 – 9.3 mg/kg (0.5 – 1 mL/kg calcium gluconate 10%) IV *slowly* over 10 to 20 minutes. Rapidly corrects arrhythmias but effects are very short (10 to 15 minutes). **NOTE:** IV calcium treatment can antagonize the cardiotoxic effects of potassium but does not reduce potassium concentrations. IV dextrose (0.5 – 1 g/kg body weight with or without regular insulin) can be administered to lower serum K+ concentrations.[6]

Adjunctive therapy for nonobstructive dystocia (extra-label): In most cases, calcium is given *before* oxytocin to improve contraction strength. See ***Oxytocin*** for further information.

a. Elemental calcium 9 mg/kg IV *slowly* infusion (≈ 1 mL/kg calcium gluconate 10%); dogs 20 kg or greater received a total dose of 180 mg elemental calcium (total dose, NOT mg/kg; ≈ 20 mL calcium gluconate 10%)[7]
b. Elemental calcium median dose 3.8 mg/kg (0.41 mL/kg calcium gluconate 10%) IV *slowly*[8]
c. Elemental calcium ≈2 mg/kg (0.2 mL/kg calcium gluconate 10% solution) IV *slowly*[9]

HORSES:

Hypocalcemia (extra-label):

a) **Mild hypocalcemia**: add 50 mL of 23% **calcium borogluconate** per 5 L of lactated Ringer's solution (LRS); administer IV at twice maintenance rate; this is sufficient to restore normocalcemia. Horses with functional kidneys can eliminate large amounts of calcium; hypercalcemia from excessive calcium administration is rare, especially when the horse is receiving fluid therapy.

b) **Severe hypocalcemia**: add 100 – 150 mL of 23% **calcium borogluconate** per 5 L of LRS. In animals with chronic or refractory hypocalcemia, PO supplementation with **calcium carbonate** (limestone) 100 – 300 g/horse/day (NOT g/kg) or dicalcium phosphate 100 – 200 g/horse/day (NOT g/kg) should be considered. Adding vitamin D treatment is questionable and some horses may develop toxicity from hypervitaminosis D; however, low doses of vitamin D might benefit horses with decreased calcium absorption and reabsorption.

c) **Calcium gluconate injection**: 150 – 250 mg/kg IV *slowly* to effect (intraperitoneal route may also be used)[10]

d) **Lactation tetany**: 250 mL per 450 kg (992 lb) body weight of a standard commercially available solution that also contains magnesium and phosphorous IV *slowly* while auscultating heart. If no improvement of clinical signs after 10 minutes, repeat dosing. Intensity in heart sounds should be noted, with only an infrequent extrasystole.[11]

e) **During general anesthesia for colic surgery**: If serum ionized calcium is less than 1.1 mmol/L (2.2 mEq/L or 4.4 mg/dL), administer **calcium gluconate** 10 mg/kg IV *slowly* over 30 to 60 minutes.[12]

CATTLE:

Hypocalcemia (labeled dosage; not FDA approved): 250 – 500 mL IV *slowly*. Some product labels also state that the intraperitoneal route may be used. **NOTE:** There are no known products that are FDA-approved for use in animals. Calcium predates formal FDA approval regulations for its use in animals.

Hypocalcemia (extra-label): **Calcium gluconate** injection: 150 – 250 mg/kg IV *slowly* to effect (intraperitoneal route may also be used)[10]

SHEEP/GOATS:

Hypocalcemia (extra-label):

a) **Calcium borogluconate** 23% is ≈50 – 75 mL/45 kg (100 lb) body weight (NOT mL/kg) IV *slowly*. Slow IV infusion of calcium should show immediate clinical response. May also be given SC.

b) **Sheep**: **Calcium gluconate** 150 – 250 mg/kg IV *slowly* to effect (intraperitoneal route may also be used)[10]

SWINE:

Hypocalcemia (extra-label): **Calcium gluconate** 150 – 250 mg/kg IV *slowly* to effect (intraperitoneal route may also be used)[10]

BIRDS:

Hypocalcemic tetany (extra-label): **Calcium gluconate** 50 – 100 mg/kg IV *slowly* to effect; may be diluted and given IM if a vein cannot be located[13]

Egg-bound birds (extra-label): Initially, **calcium gluconate** 1% solution 0.01 – 0.02 mL/g IM. Provide moist heat (26°C to 29°C [80°F-85°F]) and allow 24 hours for bird to pass egg.[14] **NOTE**: calcium gluconate 1% must be compounded; dilute the 10% solution with a compatible solution.

REPTILES:

Egg binding in combination with oxytocin (extra-label): **Calcium glubionate**: 10 – 50 mg/kg IM and oxytocin 1 – 10 units/kg IM as needed until calcium levels back to normal or egg binding is resolved. Use care when giving multiple injections. Calcium with oxytocin is not as effective in lizards as in other species.[15]

Monitoring

- During IV administration, monitor temperature, pulse, respiratory rate, and continuous monitoring of heart rate and rhythm with an ECG. If bradycardia, shortened QT interval, or ST segment elevation occurs, temporarily stop the calcium infusion.
- Serum ionized calcium every 4 to 6 hours; more frequent monitoring may be required based on response to therapy. Directly measured serum ionized calcium is a better indicator of calcium status than total calcium but requires specific collection techniques and analyzers.[3,16]
- Serum magnesium, phosphorous, and potassium when indicated. Calcium x phosphorus product should be less than 60
- Serum PTH (parathyroid hormone) if indicated
- Renal chemistry panel initially and as needed during therapy

Chemistry

Several different salts of calcium are available in various formulations. Calcium gluceptate and calcium chloride are freely soluble in water; calcium lactate is soluble in water; calcium gluconate and calcium glycerophosphate are sparingly soluble in water, and calcium phosphate and carbonate are insoluble in water. Calcium gluconate for injection has a pH of 6.0 to 8.2 and calcium chloride for injection has a pH of 5.5 to 7.5.

To determine approximate elemental calcium content *per gram* of various calcium salts:

Calcium borogluconate: 90 mg (4.6 mEq; 2.3 mmol)
Calcium chloride: 273 mg (13.6 mEq; 6.8 mmol)
Calcium glubionate: 66 mg (3.29 mEq; 1.64 mmol)
Calcium gluceptate: 82 mg (4.08 mEq; 2.04 mmol)
Calcium gluconate: 93 mg (4.65 mEq; 2.32 mmol)

Storage/Stability

Calcium gluconate, calcium borogluconate, and calcium chloride injectable formulations should be stored at room temperature 20°C to 25°C (68°F-77°F) and protected from freezing.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Calcium chloride for injection is reportedly **compatible** with the following IV solutions and drugs: amikacin sulfate, ascorbic acid, chloramphenicol sodium succinate, dopamine HCl, hydrocortisone sodium succinate, isoproterenol HCl, lidocaine HCl, norepinephrine bitartrate, penicillin G potassium/sodium, pentobarbital sodium, phenobarbital sodium, sodium bicarbonate, verapamil HCl, and vitamin B complex with C.

Calcium chloride for injection **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: fat emulsion 10%, dobutamine HCl, oxytetracycline HCl, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used.

Calcium chloride for injection is reportedly **incompatible** with the following solutions or drugs: amphotericin B and chlorpheniramine maleate.

Calcium gluconate for injection is reportedly **compatible** with the following IV solutions and drugs: sodium chloride 0.9% for injection, lactated Ringer's injection, dextrose 5% to 20%, dextrose-lactated Ringer's injection, dextrose-saline combinations, amikacin sulfate, aminophylline, ascorbic acid injection, chloramphenicol

col sodium succinate, corticotropin, dimenhydrinate, erythromycin gluceptate, heparin sodium, hydrocortisone sodium succinate, lidocaine HCl, norepinephrine bitartrate, penicillin G potassium/sodium, phenobarbital sodium, potassium chloride, tobramycin sulfate, vancomycin HCl, verapamil, and vitamin B complex with C.

Calcium gluconate compatibility information conflicts or is dependent on diluent or concentration factors with the following drugs or solutions: phosphate salts, oxytetracycline HCl, and prochlorperazine edisylate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used.

Calcium gluconate is reportedly **incompatible** with the following solutions or drugs: IV fat emulsion, amphotericin B, ceftriaxone, dobutamine HCl, methylprednisolone sodium succinate, metoclopramide, or fluids containing bicarbonate, or phosphate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: Not necessarily a complete list. Veterinary-labeled products may not be FDA-approved, as they do not appear in the Green Book.

Calcium Gluconate 23% (mg/mL; equivalent to 20.7 mg [1.07 mEq] elemental calcium per mL), in 500 mL bottles; generic; (OTC). Some formulations may contain boric acid (ie, calcium borogluconate). Labeled for use in cattle. No withdrawal times are required.

Products are also available that include calcium, phosphorus, potassium, magnesium and/or dextrose; refer to the individual product's labeling for specific dosage information. Trade names for these products include *Norcalciphos®*, and *Cal-Dextro® Special, #2, C,* and *K*; (Rx).

Oral Products: No products containing only calcium (as a salt) are available commercially with veterinary labeling. There are several products (eg, *Pet-Cal®* and *Osteoform® Improved*) that contain calcium with phosphorous and vitamin D (plus other ingredients in some preparations).

HUMAN-APPROVED PRODUCTS: (NOT A COMPLETE LIST)

Calcium Gluconate Injection 10% (100 mg/mL; equivalent to 9.3 mg [0.465 mEq] elemental calcium per mL), preservative-free in 10 mL and 50 mL single-dose vials and 100 mL pharmacy bulk vials; generic; (Rx)

Calcium Chloride Injection 10% (100 mg/mL; equivalent to 27.3 mg [1.36 mEq] elemental calcium per mL) in 10 mL vials, and syringes; generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Calcium, Oral (-Carbonate, -Gluconate, -Lactate)

(***kal***-see-um)

Oral Phosphate Binder and Antacid (Calcium Carbonate); Calcium Supplement (Calcium Carbonate and Calcium Gluconate)

Prescriber Highlights

- ► Calcium carbonate is used as a phosphorus binding agent for treating hyperphosphatemia associated with chronic kidney disease and as a calcium supplement in animals with chronic hypocalcemia. It could also be used as an oral antacid but is rarely recommended for this purpose in small animals.
- ► Calcium gluconate and calcium lactate are alternative oral calcium supplements.
- ► Serum phosphorus and calcium concentrations must be monitored during therapy.

See also ***Calcium Acetate***

Uses/Indications

Calcium carbonate can be used for oral administration to treat hyperphosphatemia in patients with chronic kidney disease and as a calcium supplement in animals with chronic hypocalcemia. Unlike calcium citrate, calcium carbonate does not promote aluminum absorption. Calcium carbonate could also be used as an oral antacid but is rarely recommended for this purpose in small animals.

Calcium gluconate and calcium lactate are alternatives to calcium carbonate as an oral calcium supplement.

Pharmacology/Actions

When calcium carbonate is given with meals, it binds to dietary phosphorus and forms calcium phosphate, an insoluble compound that is eliminated in the feces. Calcium carbonate is more likely than calcium acetate to cause hypercalcemia because calcium carbonate binds ≈50% as much phosphorous as calcium acetate, making it less effective as a phosphorus binding agent and resulting in higher concentrations of elemental calcium.

Pharmacokinetics

No information was located on the pharmacokinetics of calcium carbonate, calcium gluconate, or calcium lactate in dogs and cats. In humans, calcium carbonate is converted to calcium chloride by gastric acid. Oral calcium absorption is influenced by a variety of factors, including intestinal pH, vitamin D status, and the administered dose. Approximately ≈80% calcium is eliminated in the feces, and ≈20% is renally eliminated.

Contraindications/Precautions/Warnings

Calcium salts should not be used when hypercalcemia is present. Because hypercalcemia can result from administering oral calcium products to animals with kidney disease, monitoring of serum ionized calcium and phosphorus concentrations is required. Because oral calcium reduces dietary phosphorus absorption, treatment will be ineffective in animals that are not eating.

Use calcium-containing phosphate binders with caution in patients with serum calcium-phosphorus product concentrations greater than or equal to 60.

Using calcium-based phosphate binders and calcitriol together is controversial. Some authors state that the combination is contraindicated, whereas others state that intensified monitoring for hypercalcemia is required.

Adverse Effects

Hypercalcemia and extraosseous (soft tissue) calcification are the primary concerns associated with calcium carbonate, especially when using high dosages long-term; adequate monitoring is required.

In humans, nausea and constipation have been reported while taking this drug.

Reproductive/Nursing Safety

In humans, calcium crosses the placenta and is excreted in milk; calcium salts are considered compatible with pregnancy and lactation.[1]

Overdose/Acute Toxicity

Potentially, acute overdoses could cause hypercalcemia in susceptible animals. Patients should be monitored and treated based on clinical signs. If overdose was massive and recent, consider using standard protocols to empty the gut.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral calcium-containing products and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aspirin**: Concurrent use may result in decreased salicylate effectiveness.
- **Azole Antifungals** (eg, **itraconazole**, **ketoconazole,** but *not* **fluconazole):** Concurrent use may result in decreased antifungal exposure.
- **Bisphosphonates, Oral** (eg, **alendronate**): Concurrent oral administration may reduce bisphosphonate absorption.
- **Calcitriol**: If administered with calcium carbonate, may lead to hypercalcemia; if calcitriol is used concomitantly, intensified monitoring for hypercalcemia is mandatory.
- **Cefpodoxime**: Concurrent use may result in decreased cefpodoxime effectiveness.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one**): Calcium may reduce corticosteroid bioavailability.
- **Digoxin**: Calcium carbonate is not recommended for use in human patients that are on digoxin therapy as hypercalcemia may cause serious arrhythmias.
- **Fluoroquinolones** (eg, **enrofloxacin**): Oral calcium-containing products can reduce absorption of fluoroquinolones; if both calcium carbonate and a fluoroquinolone are required, separate doses by at least 2 hours.
- **H_2 Receptor Antagonists** (eg, **famotidine**, **ranitidine**): Reducing stomach acid may lower the phosphorous binding capacity of calcium carbonate.
- **Levothyroxine**: Oral calcium products may reduce levothyroxine absorption if given at the same time. Separate doses by at least 2 hours if possible.
- **Loop Diuretics** (eg, **furosemide**): Loop diuretics promote calcium excretion.[2]
- **Mycophenolate**: Oral calcium-containing products can reduce absorption of mycophenolate.
- **Oral Phosphates**: Concurrent use may result in decreased phosphate absorption.
- **Propranolol**: Concurrent use may result in decreased propranolol bioavailability.
- **Proton Pump Inhibitors** (eg, **omeprazole**): Reducing stomach acid may lower the phosphorous binding capacity of calcium carbonate. Omeprazole reduces dietary calcium digestibility[3]; the effect, if any, on calcium supplementation is unclear.
- **Quinidine**: Oral calcium-containing products can decrease quinidine excretion.
- **Rifampin:** Oral calcium-containing products can reduce absorption of rifampin; if both calcium carbonate and rifampin are required, separate doses by at least 2 hours.
- **Sotalol**: Oral calcium-containing products can reduce sotalol absorption.
- **Sucralfate**: Concurrent use may result in decreased sucralfate efficacy.
- **Tetracyclines** (eg, **doxycycline, minocycline**): Oral calcium-containing products can reduce absorption of tetracyclines; if both calcium carbonate and a tetracycline are required, separate doses by at least 2 hours.
- **Thiazide Diuretics** (eg, **chlorothiazide/hydrochlorothiazide**): Concurrent use may increase risk of hypercalcemia.
- **Verapamil**: Concurrent use may result in reversal of hypotensive effects.

Laboratory Considerations

When using to treat hypocalcemia:

- **Hemolyzed blood samples** or **hyperlipidemia:** Can cause falsely elevate total calcium concentrations
- **Heparinized blood collection tubes**: Sodium or lithium heparin may bind small amounts of ionized calcium. Heparinized samples are acceptable provided that careful attention is paid to the concentration of heparin in the final sample.
- **Hyperbilirubinemia:** Can cause falsely lower total calcium concentrations
- **Oxalate, citrate, ethylenediaminetetraacetic acid (EDTA) blood collection tubes**: These anticoagulants in blood sample collection tubes can bind calcium and cause falsely low total calcium concentrations.

Dosages

DOGS/CATS:

Hyperphosphatemia associated with chronic kidney disease using a low-phosphorus diet (extra-label): Calcium carbonate 30 – 60 mg/kg PO per day *divided* and given with food or just prior to each meal.[4,5] Doses up to 90 – 150 mg/kg/day PO may be needed.[6] Therapy usually begins at the lower end of the recommended dose range and is adjusted upward as needed every 4 to 6 weeks until the serum phosphorus target is reached. Decrease dose if serum calcium exceeds normal limits. See ***Chemistry/Synonyms***.

Calcium supplement for chronic hypocalcemia: Dogs (total dose/dog, NOT mg/kg): ≈1250 mg (toy breeds) – 10 g (giant breeds) of calcium carbonate PO per day. This dosage is equivalent to 0.5 – 4 g/dog (NOT mg/kg) of elemental calcium PO per day. Cats: 1250 mg – 2.5 g/cat (NOT mg/kg) (0.5 – 1 g/cat of elemental calcium) PO per day. See ***Chemistry/Synonyms***.

Monitoring

The IRIS guidelines suggest monitoring serum phosphorus and calcium concentrations every 4 to 6 weeks initially, then, once stable, at 12-week intervals.[4,5] However, some recommend more frequent intervals (ie, initially every 10 to 14 days), particularly in patients at higher risk for hypercalcemia.

- Serum phosphorus (after a 12-hour fast): 2.7 – 4.6 mg/dL is the goal for Stage 2 patients and is ideal for all stages. More realistic goals for Stage 3 and 4 patients are less than 5 mg/dL and less than 6 mg/dL, respectively.
- Serum ionized (if possible) calcium: Directly measured serum ionized calcium is a better indicator of calcium status than total calcium but requires specific collection techniques and analyzers.[7] The IRIS guidelines suggest a goal for total calcium of less than 12 mg/dL in cats.
- Calcium x phosphorus product less than 60

Client Information

- Give medication with meals, either just before the animal eats or mixed into its food.

- Your veterinarian may prescribe additional doses to be administered between meals if additional calcium is required; give only with meals unless your veterinarian instructs you to do otherwise.
- Use of this medication requires ongoing laboratory monitoring.

Chemistry/Synonyms

Calcium carbonate occurs as a fine, white, odorless, microcrystalline powder. It is practically insoluble in water, but water solubility is increased by presence of carbon dioxide or ammonium salts. Calcium carbonate dissolves with effervescence in hydrochloric acid. It is insoluble in alcohol. Calcium carbonate may also be known as calcii carbonas, E170, or precipitate chalk. A common oral dosage form trade name is *Tums*®. One gram of calcium carbonate contains 400 mg of elemental calcium (40%).

Calcium gluconate is a white or almost-white, crystalline or granular powder. It is sparingly soluble in water and freely soluble in boiling water. One gram of calcium gluconate contains 90 mg of elemental calcium (9%).

Calcium lactate is a white or almost-white, crystalline or granular powder. It is soluble in water (freely soluble in boiling water) and slightly soluble in alcohol. It may also be known as calcii lactas. One gram of calcium lactate contains 130 mg of elemental calcium (13%).

When using oral calcium supplements, adjust the dose to give an equivalent amount of elemental calcium as provided by the chosen calcium salt. For example, 1 g of calcium gluconate contains 90 mg of elemental calcium, 1 g of calcium lactate contains 130 mg of elemental calcium, and 1 g of calcium carbonate contains 400 mg of elemental calcium.

Storage/Stability

The commercially available tablets, capsules, and gel caps should be stored at room temperature (25°C [77°F]); excursions are permitted at 15°C to 30°C (59°F-86°F).

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

An oral nutritional supplement (*Epakitin*®) (not FDA-approved) contains calcium carbonate 10% (100 mg/g) and chitosan (8%).

HUMAN-LABELED PRODUCTS:

Calcium Carbonate: Many oral products are available, and all are OTC. Dosage forms include chewable and regular tablets in strengths ranging from 420 mg (168 mg calcium) to 1250 mg (500 mg calcium; common sizes are 500 mg [200 mg calcium] and 750 mg [300 mg calcium]), oral powders (1000 mg/packet [400 mg calcium]), suspensions (1250 mg/5 mL), and capsules (600 mg [240 mg calcium]); generic.

Calcium Gluconate: Generally available as 500 mg (45 mg calcium), 650 mg (58.5 mg calcium), and 1 g (90 mg calcium) oral tablets; all are OTC.

Calcium Lactate Tablets: 325 mg (42.3 mg calcium) and 650 mg (84.5 mg calcium); generic; OTC

Cannabidiol (CBD)

(can-na-bi-***dye***-ole) *Epidiolex*®

Cannabinoid

NOTE: The information presented in this monograph is for products containing only cannabidiol (CBD); extrapolation of this information to "full-spectrum" products will not accurately predict safety or efficacy.

Prescriber Highlights

- ► The use of cannabidiol (CBD) in animals has not been approved by the FDA. State and local laws vary, and practitioners should consult independent legal counsel to determine their compliance obligations with respect to the veterinary use of CBD.
- ► Naturally occurring cannabinoid that has been used to treat canine osteoarthritis and epilepsy
- ► In veterinary species, efficacy for specific conditions and optimal dosages are under investigation.
- ► Contraindications include hypersensitivity to CBD.
- ► Use with caution in patients with hepatic impairment; dosage reduction may be needed
- ► Withdraw gradually when discontinuing its use as an anticonvulsant.
- ► CBD appears to be well tolerated at dosages that have been studied; hypersalivation, diarrhea, emesis, increased liver enzymes, lethargy, and ataxia have been noted.
- ► Products that also contain tetrahydrocannabinol (THC) appear more likely to cause adverse effects; choose products carefully, as formulations may contain varying amounts of CBD as well as other cannabinoids (eg, THC) or impurities.

Uses/Indications

Cannabidiol (CBD) use in veterinary medicine is an area of active investigation. CBD has shown benefit as an analgesic for canine osteoarthritis[1–3] and has reduced seizure frequency in dogs with epilepsy.[4] CBD controlled pruritic behavior in dogs with atopic dermatitis.[5] One study found no difference between CBD and placebo for relieving clinical signs associated with osteoarthritis in dogs.[6] Low-dose CBD (1.4 mg/kg daily PO) lacked efficacy as an anxiolytic in dogs with noise phobia.[7]

Although most studies have focused on CBD, the products used in many studies contained varying amounts of other cannabinoids. The impact of these other cannabinoids on the safety and efficacy of CBD products remains unclear. See ***Chemistry/Synonyms*** for further information.

Pharmacology/Actions

Cannabidiol (CBD) is a lipophilic, nonintoxicating cannabinoid that can bind to CB_2 cannabinoid receptors, which are primarily found in the periphery (ie, immune system) and have little to no psychotropic effects. Activation of these receptors is thought to prevent inflammatory cytokine release.[8,9] CBD also interacts with many (over 65) noncannabinoid receptors,[10] including the serotonin 1A receptor ($5\text{-}HT1_A$), which may help alleviate anxiety, insomnia, pain, and nausea; it also acts on the vanilloid receptor (TRPV1), which assists in perception of pain, inflammation, and body temperature.[11,12] The anticonvulsant effect of CBD in humans is not thought to be due to a direct effect on cannabinoid receptors.[13]

In contrast, tetrahydrocannabinol (THC) is a cannabinoid primarily targeting CB_1 receptors, which modulate calcium and potassium ion influx and appear to inhibit excitatory and inhibitory neurotransmitter release.[14] The CB_1 receptor is found primarily in the CNS and is involved in cognitive function, emotion, movement,

and hunger. THC is considered intoxicating and is responsible for the "high" associated with marijuana use in humans.[8,15]

Alterations in the canine metabolome were observed after 3 weeks of cannabidiol administration to healthy dogs; the physiologic relevance of this finding warrants further investigation.[16]

Pharmacokinetics

Assessment of cannabidiol (CBD) pharmacokinetics is complicated by the lack of standardized CBD formulations.

Absorption of CBD after oral administration appears to be limited by an extensive first-pass effect.[14,17] In dogs, bioavailability after transdermal application to the pinna was ≈9% relative to oral administration.[18] CBD is widely distributed into tissues and is highly lipophilic.[8,19] Elimination half-life of CBD is ≈1 to 4 hours following single doses,[1,20,21] but is ≈14 to 25 hours following 28 days of CBD administration.[22] When CBD was administered IV, half-life varied between 7 and 9 hours.[23,24]

In cats that were given a single dose of a CBD fish oil formulation, peak concentration of 43 ng/mL occurred 1 to 4 hours after administration; AUC was 164 ng/hour/mL and half-life was 1.7 hours.[21]

In horses, orally administered CBD (in oil) was readily absorbed, with peak concentration occurring ≈3 to 5 hours after dosing.[25,26] Peak concentration following pelleted CBD occurred at ≈2.5 hours.[27] Terminal half-life ranged from 8.5 to 15 hours following single or repeated (4 to 6 weeks) administration.[25–27]

In humans, peak CBD concentration is reached ≈2 to 2.5 hours after administration.[13] Administration with food increases absorption, leading to a 4- to 5-fold increase of C_{max} and a 3- to 4-fold increase in AUC. The drug is widely distributed, and protein binding exceeds 94%. CBD is extensively metabolized, primarily in the liver but also in the GI tract, by CYP2C19, CYP3A4, UGT1A7, UGT1A9, and UGT2B7. At least one metabolite (7-OH-CBD) is active. Half-life is ≈60 hours, and elimination occurs via the feces.

Contraindications/Precautions/Warnings

Cannabidiol (CBD) is contraindicated in patients that are hypersensitive to it or to other components of the formulation. Use CBD with caution in patients with hepatic dysfunction; dosage reduction is recommended in humans with hepatic impairment, and it is assumed that this applies to veterinary patients.

When it is used to control seizures, CBD should be discontinued gradually, as rapid withdrawal can increase the risk for seizures.[13]

Adverse Effects

When cannabidiol (CBD) is administered at 4 mg/kg/day PO (the dosage most commonly used in studies), it appears to be well tolerated. Occasional GI effects[6,28] (eg, hypersalivation, diarrhea, emesis) and lethargy may occur, but CBD is without apparent effect on voluntary daily activity in dogs.[22,29] Decreased body weight was noted in one study of healthy dogs, despite food intake being considered adequate.[22] Higher dosages and/or products that also contain tetrahydrocannabinol (THC) appear more likely to cause adverse CNS effects (eg, hyperesthesia, static ataxia) in dogs.[22,30] A case of Stevens-Johnson syndrome has been documented in one dog after receiving a CBD-containing product.[31] Increases (2 times the upper limit of normal) in ALP were noted in healthy dogs and were not associated with adverse effects, and in one study increases in ALP were more common at higher dosage (12 mg/kg/day) as compared with lower dosages (1 – 4 mg/kg/day).[28]

Cats experienced low rates of lethargy and ataxia following administration of CBD-infused oil; emesis and hypersalivation also occurred, but these effects appeared to be due to the medium-chain triglyceride oil in the formulation.[32] One cat was reported to have an increased ALT (3 times the upper limit of normal).[21]

Horses receiving CBD for up to one week showed no adverse GI or behavioral effects, or changes in activity (step count).[25,27] In one study in 12 horses receiving CBD for 6 weeks,[26] 10 horses gained weight (average 18.5 kg), and elevated liver enzymes were noted in 8 horses. Additionally, all horses experienced mild decreases in total calcium, although ionized calcium remained within the reference range. Hypocalcemia and elevated liver enzymes normalized within 10 days of discontinuing CBD.

Reproductive/Nursing Safety

Administration of cannabidiol (CBD) 150 – 250 mg/kg/day to pregnant rats increased embryofetal mortality, decreased growth, delayed sexual maturation, and caused small testes and reduced fertility in male offspring.[13] Administration of CBD to rabbits caused decreased birth weights, and reproductive system changes.

CBD is excreted in human maternal milk following maternal medical or recreational use of cannabis products,[33] and in mouse milk following intraperitoneal injections of CBD.[34] It is unknown if CBD is excreted in maternal milk following oral administration.[13]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Cannabidiol (CBD) products may contain more or less CBD than is stated on the product label.[35] They also may contain varying amounts of tetrahydrocannabinol (THC), which may increase the risk for adverse effects or toxicity. Although the ASCPA has not seen an increase in calls from states that have legalized recreational marijuana, animal clinics in Colorado have reported significant increases in marijuana exposures.[19,36] Because recreational use of marijuana remains illegal in many states, clients may be reluctant to discuss possible exposures to marijuana or treatment with cannabis products, including CBD. For that reason, some clients may need reassurance when taking a history.

Clinical signs of a CBD overdose can include hypersalivation, emesis, lethargy, diarrhea, and ataxia.

Treatment of a significant cannabinoid overdose may consist of GI decontamination (inducing emesis, activated charcoal) for recent ingestion or if a significant amount remains in the stomach, and supportive treatment (eg, IV fluids, antiemetics). Additionally, butorphanol may be used for agitation and a benzodiazepine (eg, diazepam, midazolam) may be administered to control seizures as indicated. IV lipid emulsion may be useful.[8] Anecdotally, most overdoses of cannabinoids do not require intervention; placing the animal in a dark, quiet room can minimize stimulations while the animal is intoxicated.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison control centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

In humans, cannabidiol (CBD) is a substrate of CYP3A4 and CYP2C19; therefore, it may affect concentrations of drugs metabolized by CYP2C19 and CYP1A2. The following drug interactions either have been reported or are theoretical in humans or animals receiving CBD and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amiodarone:** Concurrent use may lead to increased CBD concentration.[13,37,38]
- **Azole Antifungals** (eg, **fluconazole**, **itraconazole, ketoconazole**, **voriconazole**): Increased CBD concentration is possible; there is possible additive hepatotoxicity risk.[13,37,38]

- **Benzodiazepines**: Concurrent use with CBD may lead to increased concentrations of certain benzodiazepines (eg, **alprazolam, diazepam**; not midazolam).[11,13] Concurrent use may increase risk for sedation and respiratory depression.
- **Central Nervous System (CNS) Depressants** (eg, **acepromazine, gabapentin, pregabalin, tramadol, trazodone**): Concurrent use with other CNS depressants increases risk for sedation.[13,38]
- **Chloramphenicol:** Concurrent use may lead to increased CBD concentration.[13,37,38]
- **Cimetidine:** Concurrent use may lead to increased CBD concentration.[13,37,38]
- **Clopidogrel**: CBD may decrease formation of clopidogrel active metabolite. Clopidogrel may increase CBD concentration.[13,37,38]
- **Dexamethasone:** Concurrent use may lead to decreased CBD concentration.[13,38,39]
- **Diltiazem:** Concurrent use may lead to increased CBD concentration.[13,37,38]
- **Fenofibrate**: Increased fenofibrate concentration may occur when used concurrently with CBD.
- **Fluoxetine:** Concurrent use may lead to increased CBD concentration and risk for serotonin syndrome.[13,37,38]
- **Glipizide**: CBD may decrease glipizide metabolism, increasing hypoglycemic effect.
- **Hepatotoxic Drugs** (eg, **lomustine, prednis(ol)one**, **sex-steroid hormones** [eg, **estrogens**, **progestins**]): Concurrent use with valproate and clobazam increased serum liver transaminases.[13] It is suggested to use CBD cautiously with other hepatotoxic drugs.
- **Lidocaine**: Increased lidocaine concentration is possible with concurrent use.
- **Loperamide**: Increased loperamide concentration is possible with concurrent use.
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)** (eg, **carprofen, meloxicam**): Concurrent use with CBD oil for 4 weeks resulted in no apparent adverse effects or significant laboratory value changes in dogs.[1]
- **Opioids** (eg, **fentanyl, methadone, morphine, tramadol**): Increased risk for CNS depression
- **Phenobarbital:** A pharmacokinetic interaction was not observed in healthy dogs, but possible additive risk for CNS depression or hepatotoxicity.[40]
- **Propofol:** CBD use may increase propofol concentration.
- **Proton Pump Inhibitors** (eg, **omeprazole, pantoprazole**): Concurrent use may lead to increased CBD concentration.[13,37,38]
- **Rifampin:** May decrease CBD concentration[13,38,39]
- **Sildenafil**: CBD may increase sildenafil concentrations.
- **Theophylline/Aminophylline:** CBD may increase theophylline concentration.
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, clomipramine**): Concurrent use increased risk for cardiovascular effects (hypotension, tachycardia).[38]
- **Warfarin**: CBD may prolong prothrombin times and increase the risk for bleeding.

Laboratory Considerations

- Cannabidiol may cause a false-positive on **cannabis screening** tests, particularly if the product administered was a full- or mislabeled broad-spectrum product.

Dosages

NOTES:

1. Effective cannabidiol (CBD) dosages remain under investigation and are yet to be fully determined. The dosages listed below represent recommendations from peer-reviewed studies using products that contain *only* CBD and do not accurately reflect dosage recommended for full-spectrum products. Some clinicians recommend starting with lower dosages and slowly escalating to the dosages presented below.
2. In humans, dosage reductions of 50% and 80% are recommended for patients with moderate and severe hepatic impairment, respectively.[13] Until veterinary-specific information becomes available, it is suggested to reduce initial dosages in veterinary patients with hepatic impairment.
3. Be sure to fully understand and comply with local, state, or provincial regulations related to CBD. See ***Dosage Forms/ Regulatory Status***.

DOGS:

Osteoarthritis (extra-label): 2 mg/kg PO, OTM every 12 hours[2]
Epilepsy (extra-label): 2.5 mg/kg PO every 12 hours in addition to current therapy. The authors hypothesize that a higher dosage may be more effective.[4]

Monitoring

- Clinical efficacy
- Liver enzymes (ALP, ALT) and bilirubin at baseline; at 1, 3, and 6 months after initiating therapy and then as clinically indicated during ongoing therapy[13]
- Adverse effects (eg, vomiting, salivation, sedation, ataxia)

Client Information

- Although there is limited information available, it appears cannabidiol (CBD) is well tolerated by dogs and cats.
- Giving CBD with food will increase the amount of medicine that is absorbed, but CBD can be given with or without food. It is important to give CBD the same way each time.
- If your animal vomits or acts sick after receiving the drug on an empty stomach, try giving the next dose with food or a small treat. If vomiting continues, contact your veterinarian.
- Information regarding the use of CBD in animals is continually emerging and other side effects may be discovered. Contact your veterinarian if you notice any unexplained side effects or abnormal behaviors in your animal.
- Do not give your animal a CBD product without first discussing it with your veterinarian. Some products contain ingredients other than CBD that could be harmful to your animal.

Chemistry/Synonyms

Cannabidiol (CBD) is a cannabinoid derived from the *Cannabis sativa L* plant that occurs as a white to pale yellow crystalline solid that is soluble in oils and organic solvents and is insoluble in water. The FDA-approved product (*Epidiolex*®) contains sesame seed oil and 7.9% (w/v) dehydrated alcohol.[13]

Cannabidiol may also be known as CBD or *Epidiolex*®.

Cannabis sativa L contains more than 100 cannabinoids, of which CBD and tetrahydrocannabinol (THC) are the most well-known but others may exert a pharmacologic effect. Hemp is distinguished from marijuana by THC concentration: Although hemp and marijuana can both be from the *Cannabis sativa L* plant, **hemp** contains not more than 0.3% THC (dry weight), whereas **marijuana** contains more than 0.3% THC.[41] That is, hemp and marijuana are varieties or cultivars of the same plant but differ in THC concentration. CBD may only be legally produced from hemp grown under the restrictions established by the 2018 Farm Bill.[41]

Storage/Stability

The product FDA-approved for human use (*Epidiolex*®) should be stored upright at 20°C to 25°C (68°F-77°F), with permitted excursions between 15°C to 30°C (59°F-86°F); keep the cap tightly

closed.[13] Do not freeze. Use product within 12 weeks of opening. Unless otherwise instructed by the manufacturer, store other cannabidiol (CBD) products at room temperature in tightly closed containers.

Compatibility/Compounding Considerations

Many compounded formulations are available. It is recommended to request a certificate of analysis that demonstrates product potency and purity. A 3-fold difference in cannabidiol (CBD) concentration was discovered between batches of commercially supplied CBD in oil.[26]

Dosage Forms/Regulatory Status

Other than the product FDA-approved for human use (*Epidiolex®*), cannabidiol (CBD) products are compounded, and as such, product quality (eg, potency, purity, stability) is not overseen or enforced by the FDA. Considerations for selecting a product include:

1. Choose a product made from hemp, not marijuana. Legally, CBD oil products must be derived from hemp and must contain less than 0.3% tetrahydrocannabinol (THC). Because hemp contains minimal amounts of THC, using a product derived from hemp will limit the amount of THC present. Legally grown hemp is no longer a controlled substance under federal law, but it may be a controlled substance in individual states. See ***Chemistry/Synonyms*** for further information.
2. Request a certificate of analysis (COA). Reputable companies will provide a COA of their products stating CBD, THC, or other cannabinoid content. Some companies will also confirm the absence of other harmful toxins (eg, pesticides, microbes, residual solvents, heavy metals).
3. Using CBD in animals has not been approved by the FDA. State and local laws vary, and practitioners should consult independent legal counsel to determine their compliance obligations with respect to the veterinary use of CBD.

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated CBD as a class 2 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Cannabidiol Solution: 100 mg/mL in 60 mL or 100 mL bottles; *Epidiolex®*; (Rx)

References

Capromorelin

(***kap***-roe-moe-***rel***-in) *Elura®, Entyce®*

Appetite Stimulant

Prescriber Highlights

- FDA-approved to stimulate appetite in dogs, and for management of weight loss in cats with chronic kidney disease
- Ghrelin-receptor agonist that stimulates growth hormone release and causes the feeling of hunger
- Contraindications include hypersensitivity and acromegaly (hypersomatotropism) in cats.
- Use with caution in dogs and cats with hepatic dysfunction, in dogs with renal insufficiency, and in cats with cardiac disease or severe dehydration. Hyperglycemia has occurred in healthy cats given labeled doses of capromorelin; use in diabetic patients has not been evaluated and may not be appropriate.
- Adverse effects include vomiting, hypersalivation, hiding behavior (cats), diarrhea, and polydipsia; some cats have developed hypotension and bradycardia after administration.

Uses/Indications

Capromorelin is labeled for the stimulation of appetite in dogs and for the management of weight loss in cats with chronic kidney disease (CKD).

In preapproval studies, dogs given capromorelin for 4 to 7 days had an ≈60% increase in food consumption and ≈6% weight gain as compared with the baseline.[1] In a clinical field study, 68.6% of dogs receiving capromorelin experienced increased appetite based on owner observation as compared with 44.6% of dogs that received the vehicle control. In the same study, 76% of dogs receiving capromorelin gained weight (1.8% increase) as compared with 44.6% of dogs that received the control (0.1% increase).[2] A post-approval study demonstrated that healthy beagles treated with capromorelin had an average 60% increase in food consumption compared to an 11% decrease in placebo-treated dogs.[3]

In cats with CKD, field studies demonstrated a 3.3% increase in body weight after 2 weeks of treatment, and 5.2% increase after 8 weeks.[4] In healthy laboratory cats receiving capromorelin, food consumption increased by 25% to 45% and body weight increased by 4% to 6.6% as compared with an 11% food consumption increase and 1% decrease in body weight in cats receiving a placebo.[5,6] In a safety study, cats given capromorelin 6 mg/kg PO once daily for 91 days had a nonsignificant increase in food consumption but significant weight gain.[6] Further studies are warranted to establish efficacy.

Pharmacology/Actions

Capromorelin is a ghrelin-receptor agonist that stimulates growth hormone (GH) release and causes release of insulin-like growth factor 1 (IGF1). Serum GH and cortisol increased in healthy dogs given capromorelin for 7 days, and levels returned to baseline 8 hours after administration; the magnitude of GH and cortisol elevations were diminished by days 4 and 7 as compared with day 1. Increased IGF1 levels were sustained throughout the 7-day study period.[7] Sustained elevation of IGF1 was also noted in cats.[8]

Ghrelin appears to regulate cardiac, gastric, and pancreatic function and may result in anxiety. In mice, exogenous ghrelin accelerates gastric emptying and intestinal transit.[9] At the spinal cord level, capromorelin stimulates bladder emptying in mice[10] and colonic motility in rats.[11,12]

In addition to stimulating appetite and the effects described above in rats, ghrelin and ghrelin-receptor agonists have been shown to stimulate bone formation, increase muscle mass, and have anti-inflammatory and immunomodulatory effects.[13]

Pharmacokinetics

In dogs, ≈44% of an oral dose is absorbed[14] and peak levels are reached within 1 hour. Protein binding is ≈50%. Hepatic metabolism is primarily via cytochrome P450 3A4 isozyme (CYP3A4) and CYP3A5. Elimination half-life is ≈1.2 hours. Capromorelin (primarily as metabolites) is excreted in urine (≈37%) and feces (≈62%) within 72 hours of oral administration. Capromorelin does not accumulate with repeated administration.[1,15]

In fasted healthy cats, capromorelin peak concentration is reached within 0.25 to 1 hour after administration.[4] Giving with food delays time to peak concentration (0.5 to 4 hours) and reduces capromorelin peak concentration by ≈50% and exposure (AUC) by ≈40% compared to fasted cats.[4] Half-life in fasted cats is 1.1 hours.

Contraindications/Precautions/Warnings

Capromorelin is contraindicated in patients hypersensitive to it or its components. Avoid use in cats with acromegaly (hypersomatotropism). Caution should be used in dogs and cats with hepatic dysfunction, in dogs with renal insufficiency, and in cats with cardiac disease or severe dehydration. Although the manufacturer recommends using capromorelin with caution in dogs with renal insufficiency, cats with CKD enrolled in a pilot study gained weight and tolerated the drug.[16] Blood glucose may increase for several hours after administration to cats[4,17]; capromorelin use in diabetic or prediabetic cats has not been evaluated and may not be appropriate.

Drug interactions are possible in dogs concurrently treated with CYP3A4 and CYP3A5 inducers and inhibitors, but specific interactions have not been reported to date. See ***Drug Interactions***.

Adverse Effects

Adverse effects reported in dogs during clinical trials included diarrhea, vomiting, polydipsia, hypersalivation, flatulence, nausea, abdominal discomfort, increased gut sounds, and lethargy.[15] Elevated BUN and phosphorus have also been noted.

In cats with CKD (median age 15 years and 67% with Stage 2 CKD) receiving capromorelin 2 mg/kg/day, reported adverse effects included vomiting, hypersalivation, inappetence, hiding behavior, lethargy, anemia, dehydration, progression of CKD stage, diarrhea, upper respiratory infection, UTI, and hyperglycemia. Emesis, increased salivation, lip smacking, and head shaking reportedly occurred immediately after administration and resolved within a few minutes.[4,6,17] Clinical signs of bradycardia and hypotension may occur after administration, reaching peak effect after 1 hour, and resolving within 4 hours[4]; anecdotally, in some instances, hypotension may be profound enough to require fluid resuscitation. Hypotension appears to decrease in magnitude with repeated dosing. In healthy cats, insulin secretion and glycemic control decreased during the first several days of treatment; significance in diabetic patients has not been ascertained.[17]

Reproductive/Nursing Safety

The manufacturer recommends capromorelin not be used in breeding, pregnant, or lactating bitches or queens, as safety studies have not been performed for these animals.[4,15]

Overdose/Acute Toxicity

In safety studies in dogs, capromorelin (7 mg/kg/day and 40 mg/kg/day) was associated with increased salivation, red and swollen paws, increased liver weight, and hepatocellular vacuolation. In dogs receiving capromorelin at 17.5 times the label dose for up to 12 months, the drug was generally well tolerated and resulted in statistically insignificant decreased RBC count, hemoglobin, and hematocrit as compared with a placebo. Dose-related increased cholesterol and alkaline phosphatase were also noted.[7] Increased PR interval was noted on the ECG in dogs receiving either 7 mg/kg/day or 40 mg/kg/day; however, no evidence of cardiac toxicity was noted on physical examination or cardiac histopathology.[1]

Cats receiving capromorelin (6 mg/kg/day PO) for 91 days tolerated treatment well with no significant alterations in clinical pathology.[8] One cat receiving capromorelin 10.5 mg/kg/day as part of a safety study developed hyperglycemia and was euthanized after the onset of diabetic ketoacidosis.[4] Cats receiving capromorelin (up to 60 mg/kg/day PO) for 14 days experienced a greater frequency of emesis, hypersalivation, and lethargy as compared with the control group.[6]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

No drug interactions with capromorelin have been reported. Capromorelin is metabolized by CYP3A4 and CYP3A5 in dogs. In feline field studies, capromorelin was used concurrently with parenteral fluids, methimazole, amlodipine, antibiotics, laxatives, antiparasitics, and antiemetics.[18] The following drug interactions are theoretical in animals receiving capromorelin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed, and additional monitoring performed when appropriate.

- **CYP3A4 Inhibitors** (eg, **amiodarone, cimetidine, diltiazem, erythromycin, itraconazole, ketoconazole**): May reduce capromorelin metabolism in dogs
- **CYP3A4 Inducers** (eg, **phenobarbital**, **rifampin**): May increase capromorelin metabolism in dogs

Laboratory Interactions

- None noted

Dosages

DOGS:

Appetite stimulation (label dosage; FDA-approved): 3 mg/kg PO once daily. **NOTE**: The effectiveness of capromorelin solution has not been evaluated beyond 4 days of treatment.[15]

CATS:

Management of weight loss in cats with chronic kidney disease (label dosage; FDA-approved): 2 mg/kg PO once daily 30 minutes before routine feeding.[4] Readminister the dose if the cat receives only a partial dose, or if the cat vomits within 15 minutes of administration.

Appetite stimulation (extra-label): 1 – 3 mg/kg PO once daily for up to 21 days[5]

Monitoring

- Food and fluid intake
- Body weight
- Adverse effects (eg, vomiting, diarrhea, inappetence, lethargy)
- Additional monitoring as applicable to address underlying condition(s)

Client Information

- Gently shake the bottle prior to withdrawing the appropriate amount of solution using the provided syringe (dog product only). Rinse syringe between treatment doses.
- Store medication out of reach of other pets and children.
- Drooling, vomiting, and head shaking may occur shortly after administration.
- Common side effects in dogs include vomiting and frequent urination. In cats, vomiting, hypersalivation, lack of appetite, hiding behavior, and lethargy have been noted.

- When giving this medicine to cats:
  a) Administer the dose 30 minutes prior to feeding.
  b) Only readminister if a partial dose is received, or if your cat vomits within 15 minutes.

Chemistry/Synonyms
Capromorelin is a growth hormone secretagogue-receptor agonist. The commercial oral solutions contain capromorelin tartrate. No solubility data was located.

Capromorelin is also known as AT-002, RQ-5, CP-424391, *Entyce®*, and *Elura®*.

Storage/Stability
Capromorelin should be stored at or below 30°C (86°F) and kept out of reach of children and pets.

Compatibility/Compounding Considerations
None noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
Capromorelin Flavored Solution: 30 mg/mL in 10 mL, 15 mL, and 30 mL bottles; *Entyce®*; (Rx). FDA-approved for use in dogs. NADA #141-457

Capromorelin Flavored Solution: 20 mg/mL in 15 mL bottles; *Elura®*; (Rx). FDA-approved for use in cats. NADA #141-536

HUMAN-LABELED PRODUCTS: NONE

Carbimazole
(kar-***bi***-ma-zole) *Vidalta®*
Antithyroid

Prescriber Highlights
- ► Prodrug of methimazole; used for treatment of feline hyperthyroidism
- ► Contraindications include hypersensitivity to carbimazole or methimazole and in cats with abnormal red or white blood cell counts, thrombocytopenia, coagulopathies, severe liver disease, diabetes mellitus, or with signs of autoimmune disease. Use with caution in cats with existing renal or hepatic disease.
- ► Most adverse effects occur within the first 3 months of treatment; vomiting, hyporexia, and lethargy are the most frequent. Eosinophilia, leukopenia, and lymphocytosis are usually transient. Rare but serious effects include self-induced excoriations, bleeding, hepatopathy, thrombocytopenia, agranulocytosis, immune-mediated hemolytic anemia, immune-mediated thrombocytopenia, and acquired myasthenia gravis.
- ► Dosing requirements may change with time.
- ► Typically administered PO; give with food. Do not crush or split tablets.
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies methimazole (the active carbimazole metabolite) as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
Carbimazole (a prodrug of methimazole) and methimazole are considered by most clinicians to be the agents of choice for treatment of feline hyperthyroidism and hyperthyroidism-associated clinical signs in cats.[1]

Pharmacology/Actions
Carbimazole is converted almost entirely to methimazole in vivo. Methimazole inhibits thyroid peroxidase and interferes with iodine incorporation into tyrosyl residues of thyroglobulin, thereby inhibiting thyroid hormone synthesis. It also inhibits iodinated tyrosyl residues from coupling to form iodothyronine. Methimazole has no effect on the release or activity of thyroid hormones already formed or in general circulation.

Pharmacokinetics
Carbimazole is rapidly absorbed from the GI tract and rapidly and nearly totally converted to methimazole.[1] Administering carbimazole with food increases bioavailability. Because of differences in molecular weight (carbimazole 5 mg vs methimazole 3 mg), to attain an equivalent serum concentration, the dose of carbimazole for oral administration must be ≈2 times that of methimazole.[2]

In cats, the volume of distribution of methimazole is variable (0.12 – 0.84 L/kg). Methimazole apparently concentrates in thyroid tissue and biologic effects persist beyond measurable blood concentrations. After oral dosing, plasma elimination half-life ranges from 2.3 to 10.2 hours. There is usually a 1- to 3-week lag time between starting the drug and significant reductions in serum T_4. Timed-release formulations of carbimazole can extend methimazole (active metabolite) half-life and allow once-daily dosing. Carbimazole may be amenable for use transdermally with twice-daily dosing in cats to control hyperthyroidism.

In dogs, methimazole has a serum half-life of 8 to 9 hours.

Contraindications/Precautions/Warnings
Carbimazole is contraindicated in patients that are hypersensitive to it or methimazole. It should not be used in patients with concurrent systemic diseases (eg, severe primary liver disease, diabetes mellitus[1]) or with hematologic abnormalities (eg, anemia, neutropenia, lymphopenia, thrombocytopenia), coagulopathies, or autoimmune disease.[1,3] Use with caution in cats with preexisting hepatic disease.

Because carbimazole is a prodrug and is converted into methimazole, cats that have had prior severe reactions to methimazole should not receive carbimazole.[1]

Treatment of hyperthyroid cats with methimazole can unmask underlying renal disease because lowering thyroid hormone levels decreases glomerular filtration rates.[4] As such, a cat's renal parameters should be monitored closely during treatment (see ***Monitoring***).[5] In a study, a significant reduction in serum creatinine was noted after restoration of euthyroidism in cats with iatrogenic hypothyroidism caused by methimazole or carbimazole.[6]

The prevalence of moderate to severe thyroid disease (eg, large thyroid tumors, multifocal disease, intrathoracic thyroid masses) increased with the duration of hyperthyroidism, despite ongoing methimazole use; the authors speculated that this finding may indicate a progressive nature of feline hyperthyroidism that is not stopped by maintaining euthyroidism with methimazole.[7]

The National Institute for Occupational Safety and Health (NIOSH) classifies methimazole (the active carbimazole metabolite) as a hazardous drug representing an occupational hazard to healthcare workers; wash hands after handling and use personal protective equipment (PPE) accordingly to minimize the risk for exposure.[8]

Consider writing part of the drug's name in uppercase letters (tall man designations) on prescriptions/orders to reduce the risk for errors. Do not confuse carbiMAZOLe with carbamazEPINE or CARBOplatin. Additionally, do not write prescriptions for this drug using the abbreviation SID. Many nonveterinary pharmacists are unfamiliar with this abbreviation and could interpret it as another abbreviation (eg, QID).

Adverse Effects
Most adverse effects associated with carbimazole or methimazole use in cats occur within the first 3 months of therapy.[9] In cats receiving carbimazole, vomiting, anorexia, and lethargy occur most frequent-

ly[1,10] (≈10%), are often transient, and can typically be managed with a dosage reduction.[11] Eosinophilia, leukopenia, and/or lymphocytosis may be noted in ≈5% of cats[12]; these hematologic effects are usually also transient and generally do not require drug withdrawal unless the blood dyscrasia is persistent or severe.[1]

Methimazole and carbimazole may also rarely cause self-induced excoriations and hepatopathy, and potentially trigger immune-mediated hemolytic anemia and immune-mediated thrombocytopenia in cats[1,9,13-15]; these more serious effects generally require withdrawal of the drug. In one study, increased antinuclear antibodies (ANA) were noted in ≈22% of all cats receiving methimazole, and in ≈50% of cats receiving methimazole for greater than 6 months, but none of the cats had signs of a lupus-like syndrome.[9] The occurrence of ANA is dose dependent,[16] and although elevated ANA have historically been viewed as an indication for dose reduction, this may not be necessary in the absence of clinical signs or other indications of autoimmune disease.[9] Rarely, cats treated with methimazole or carbimazole have developed acquired myasthenia gravis that requires drug withdrawal.[17,18] One case report indicated that a cat developed hypersensitivity vasculitis after receiving carbimazole.[19]

Potentially, treatment with methimazole or carbimazole could unmask underlying renal dysfunction in some cats.[20] The hyperthyroid state may increase GFR and, by treating the hyperthyroidism, this effect is abolished.

Reproductive/Nursing Safety

Carbimazole has been associated with teratogenic and embryotoxic effects in rats.[1] Do not use carbimazole in pregnant animals as it may also affect offspring thyroid development or function.

Methimazole enters milk and reaches concentrations higher than those found in maternal serum.[1] If treatment with carbimazole is necessary for nursing queens, switch to milk replacer for nursing animals.

Overdose/Acute Toxicity

Acute toxicity that may be seen with overdoses includes those effects listed in ***Adverse Effects***. Agranulocytosis, thrombocytopenia, autoimmune hemolytic anemia, GI bleeding (potentially with hematemesis), hepatitis, and nephritis are perhaps the most serious effects that may be seen.[1] Coat and skin abnormalities (erythema, alopecia) can also occur. Treatment of overdose/toxicity consists of following standard protocols for handling an oral ingestion (eg, empty stomach, administer charcoal if not contraindicated) and to treat supportively and based on clinical signs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving carbimazole or methimazole and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but veterinarians should weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **heparin, rivaroxaban**): Methimazole may potentiate anticoagulant activity.
- **Benzimidazole Antiparasitics** (eg, **albendazole**, **fenbendazole**, **thiabendazole**): Concurrent use with methimazole can reduce hepatic oxidation of benzimidazoles and increase blood levels of the parent drug or its metabolites.[1,16,21-23]
- **Beta-Adrenergic Antagonists** (eg, **atenolol, propranolol**): Beta-blocker dose may need to be decreased once the patient becomes euthyroid.[16]
- **Chloramphenicol:** Combination with carbimazole may increase the risk for myelosuppression
- **Digoxin**: Correction to euthyroidism reduces digoxin clearance,[16] resulting in increased digoxin exposure and risk for toxicity. A reduction in the digoxin dose may be needed when the patient becomes euthyroid.
- **Dipyrone:** Combination with carbimazole may increase the risk for myelosuppression.
- **Iodine 131:** There was no difference in response to radioiodine based on when methimazole was discontinued relative to I^{131} administration.[24]
- **Phenobarbital**: Concurrent use of phenobarbital may reduce the clinical effectiveness of carbimazole.
- **Prednis(ol)one:** A reduction in predniso(lo)ne dose may be needed when the patient becomes euthyroid.
- **Theophylline**: Theophylline dose may need to be reduced once the patient becomes euthyroid.[16]
- **Warfarin**: In humans with hyperthyroidism, the metabolism of vitamin K clotting factors is increased, resulting in increased sensitivity to oral anticoagulants.[25] By reducing the effects of hyperthyroidism, methimazole may decrease clotting factor metabolism, thus reducing the effects of warfarin. However, patients that are euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. Methimazole also has antivitamin K activity, so anticoagulants may be potentiated by methimazole.[16] Recommendation: If methimazole and warfarin are used together, increased monitoring of anticoagulant effect is warranted.

Laboratory Considerations

- Methimazole and carbimazole may affect **serum fructosamine** levels in diabetic cats. Increased serum fructosamine after 6 weeks of treatment has been reported. It has been recommended that serum fructosamine not be used to initially diagnose or assess the adequacy of diabetic control in cats with concurrent hyperthyroidism until hyperthyroidism is controlled for at least 6 weeks.[26]
- **Technetium-99m Pertechnetate:** Carbimazole administration should be discontinued at least 2 weeks prior to thyroid scintigraphy, as it may interfere with accurate detection of ectopic thyroid tissue.[12,27,28]

Dosages

CATS:

Hyperthyroidism:

a) **Immediate-release tablets** (extra-label): Most dosage recommendations are initially 5 mg/cat (NOT mg/kg) PO every 8 to 12 hours.[10,12,15] Once a euthyroid state is established, the dosage amount or frequency is slowly decreased to the lowest effective dose. Most cats will require 2.5 – 5 mg/cat (NOT mg/kg) PO every 12 hours, but some cats can be controlled on once-daily dosing.[12,29]

b) **Sustained-release tablets** (extra-label): 15 mg/cat (NOT mg/kg) PO once daily at the same time each day.[1,30] 10 mg/cat (NOT mg/kg) PO once daily can be considered for cats with moderate hyperthyroidism (TT_4 between 50 and 100 nmol/L; 3.9 – 7.8 µg/dL). Adjust dosage within a range of 10 – 25 mg/cat/day (NOT mg/kg) in 5 mg increments depending on clinical signs and TT_4 (**NOTE**: Tablets cannot be split, so combinations of 10 mg and 15 mg tablets must be used). If cat requires doses less than 10 mg/day, use alternate-day dosing (eg, 10 – 15 mg/cat [NOT mg/kg] every other day), or consider different treatment.

Monitoring

During the first 3 months of therapy (baseline and after every 3 and 6 weeks of treatment or dosage change)[5,16]:

- Physical examination to include body weight, body condition score, heart rate, and fundic examination
- Blood pressure
- CBC (including platelet count)
- Serum chemistry profile
- Serum TT_4: Blood samples can be collected at any time (ie, do not need to be collected at a prescribed time after methimazole treatment).
- Serum fT_4: Note that this assay is not indicated as a sole monitoring parameter for hyperthyroidism.
- Serum TSH: May be useful to evaluate for iatrogenic hypothyroidism
- **NOTE:** Cats receiving higher dosages should be monitored more frequently.

After stabilization (at least 3 months of therapy)[16]:

- Body weight
- Blood pressure
- TT_4 at 3- to 6-month intervals
- Other diagnostic tests as indicated by adverse effects

Client Information

- Give this medicine with food. Do not crush or split tablets.
- For this medication to work, give it exactly as your veterinarian prescribed.
- This medicine will decrease excessive thyroid hormones but does not cure the condition. It may take several weeks before your cat shows improvement.
- While your cat is taking this medicine, your cat will require close monitoring with regular examinations by your veterinarian as well as blood tests. Do not miss these important follow-up visits.
- Treatment is long term, often for the remainder of your cat's life.
- Most side effects (including vomiting, decreased appetite, or low energy level occur in the first 3 months of therapy. If any of these side effects are seen, stop giving this medicine to your cat and contact your veterinarian before restarting this medicine.
- Serious side effects are rare. If your cat develops yellow skin, eyes, or gums (*jaundice*) or becomes intensely itchy, discontinue this medicine and contact your veterinarian immediately.
- Wash your hands with soap and water after handling the medicine (even if gloves are worn) or used litter.
- Pregnant women or women who may become pregnant, nursing mothers, or people with low thyroid hormones should avoid handling carbimazole. If this is not possible, wear disposable gloves while handling this medication and cat litter or bodily fluids (ie, feces, blood, saliva) of treated animals. Do not reuse gloves. Once used, the gloves should be thrown away in the trash.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

A thioimidazole-derivative antithyroid drug, carbimazole occurs as a white to creamy white powder with a characteristic odor. It is slightly soluble in water and soluble in alcohol.

Carbimazole may also be known as carbimazolum, *Basolest®*, *Camazol®*, *Carbimazole®*, *Carbazole®*, *Carbistad®*, *Cazole®*, *Neo Tomizol®*, *NeoMercazole®*, *Neo-Thyreostat®*, *Thyrostat®*, *Tyrazol®*, *Vidalta®*, or *Neo-morphazole®*.

Storage/Stability

Unless otherwise labeled, carbimazole tablets should be stored at room temperature (not above 77°F [25°C]) in tightly closed containers and protected from light.[1] Do not remove desiccants from manufacturer's bottle.

Compatibility/Compounding Considerations

No specific information was noted. Do not crush or break the prolonged-release tablets.[1]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE IN THE UNITED STATES

In some countries: Carbimazole Oral Prolonged-Release Tablets: 10 mg and 15 mg; *Vidalta®*; (POM-V)

HUMAN-LABELED PRODUCTS:

There are no FDA-approved products in the United States; elsewhere it may be available as:

Carbimazole Oral Tablets: 5 mg, 10 mg, 15 mg, and 20 mg. Many trade names available outside the US; (POM)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Carboplatin

(***kar***-boe-pla-tin) *Paraplatin®*

Antineoplastic

Prescriber Highlights

- ► Platinum antineoplastic agent used for a variety of carcinomas and sarcomas. In general, less nephrotoxic and fewer GI adverse effects as compared to cisplatin.
- ► Unlike cisplatin, carboplatin may be used safely in cats.
- ► Contraindicated in patients with a history of hypersensitivity to carboplatin or other platinum agents, and with severe bone marrow depression. Use with caution in patients with hepatic or renal disease, or active infection.
- ► Primary adverse effects include bone marrow suppression (dose-limiting toxicity) and GI upset. Neutrophil nadir in dogs typically occurs around day 14 or 21 after administration.
- ► Embryotoxic, teratogenic
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies carboplatin as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

Carboplatin is a broad-spectrum antineoplastic agent used to treat a variety of neoplastic diseases, including carcinoma (squamous cell carcinoma, ovarian carcinoma, pulmonary carcinoma, nasal carcinoma, anal sac apocrine gland adenocarcinoma,[1] colonic adenocarcinoma, urinary tract carcinoma,[2] hepatocellular carcinoma, and thyroid adenocarcinoma), melanoma,[3] and sarcoma (osteosarcoma[4]).

Unlike cisplatin, systemic carboplatin appears to be safe and well-tolerated in cats.[5,6]

Intracavitary carboplatin may be used to treat carcinomatosis and other malignant effusions.[7] Interventional radiology techniques can be used to facilitate intra-arterial carboplatin administration for the treatment of lower urinary tract carcinoma.[8] Carboplatin may be considered for intralesional use in conditions such as equine sarcoids[9] and to treat adenocarcinoma in birds.[10,11] Carboplatin beads and poloxamer gel have also been used locally. They have been well tolerated in different species (equines, canines, and felines), though efficacy has not been thoroughly established.[12–14]

Carboplatin is a radiation sensitizing agent.[15] Small studies have shown the tolerability of carboplatin in combination with other chemotherapy agents, such as toceranib[16] or 5-fluorouracil[1716,17]; however, further studies are needed to determine the efficacy of these combinations.

Pharmacology/Actions

Carboplatin is an antineoplastic agent. Its chemical reactivity is nonspecific, but the primary cytotoxic effect is thought to be due to intra- and interstrand DNA cross-linking that causes single- and double-stranded DNA breakage, impairs DNA replication, RNA transcription, and protein synthesis, leading to cell death and inhibition of tumor growth.[18]

Acquired resistance to carboplatin has been reported and is thought to be due to several mechanisms.[19]

Pharmacokinetics

After IV administration, carboplatin is well distributed throughout the body and is not protein-bound.[18] The highest concentrations are found in the liver, kidney, skin, and neoplastic tissue. The metabolism and elimination of carboplatin are complex. After degradation into platinum and platinum-complexed compounds, they become highly protein-bound and are slowly eliminated by the kidneys. In dogs, almost ½ of the dose is excreted unchanged in the urine within 24 hours. After 72 hours, ≈70% of the platinum administered is secreted in the urine.

Contraindications/Precautions/Warnings

Carboplatin is contraindicated in patients hypersensitive to it or other platinum-containing compounds (eg, cisplatin). It is also contraindicated in patients with severe bone marrow suppression or significant bleeding. Bone marrow suppression is the dose-limiting toxicity of carboplatin.[18] Bone marrow suppression is dose-dependent, and blood counts should be monitored frequently during treatment. Patients with severe carboplatin-induced myelosuppression should be allowed to recover their blood cell counts before additional therapy.

Caution is advised in patients with active infections and preexisting renal or hepatic disease. The elimination of carboplatin is impaired in cats with renal insufficiency, which increases the risk for myelosuppression.

Do not confuse CARBOplatin with CISplatin. Consider using tall man lettering when writing orders or prescriptions. Carboplatin is considered a high alert medication (medication that requires special safeguards to reduce the risk for errors). Consider instituting practices such as redundant drug dosage and volume checking and special alert labels.[20]

Aluminum can react with carboplatin, causing precipitates and loss of potency. Thus, for the preparation or administration of carboplatin, needles or administration sets containing aluminum parts should NOT be used.[18]

The National Institute for Occupational Safety and Health (NIOSH) classifies carboplatin as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[21]

Adverse Effects

The dose-limiting toxicity of carboplatin in dogs and cats is bone marrow suppression, particularly neutropenia or thrombocytopenia. Bone marrow suppression is dose-dependent, and neutrophil and platelet nadirs most commonly occur on day 14 or day 21 after treatment.[5,22] Bone marrow suppression can also lead to secondary complications, such as infection and bleeding. In dogs, lithium carbonate did not prevent carboplatin-induced thrombocytopenia.[23]

In dogs, myelosuppression associated with carboplatin is related to patient body weight.[24] Dogs weighing less than 15 kg (33 lb) appear to be at a higher risk of developing myelosuppression after treatment with carboplatin. One study found that dogs weighing less than 10 kg (22 lb) were 3.5 times more likely to develop severe (grade 3 or 4) neutropenia and 2.5 times more likely to develop severe (grade 3 or 4) thrombocytopenia than dogs 10 kg (22 lb) or greater. Dogs weighing less than 15 kg (33 lb) were 3 times more likely to develop severe (grade 3 or 4) neutropenia than dogs weighing 15 kg (33 lb) or more.

Other than myelosuppression, most adverse effects in dogs and cats are GI-related and include vomiting, diarrhea, and inappetence.

GI effects usually occur 2 to 5 days after a dose. In general, carboplatin is associated with fewer adverse effects in dogs compared to cisplatin with reduced nephrotoxicity and vomiting.

One case of a dog developing a cutaneous delayed hypersensitivity reaction has been reported.[25] In humans, sterile hemorrhagic cystitis (SHC) is a rare adverse effect. One case of a dog developing SHC has been reported in the veterinary literature.[26] Although carboplatin is classified as an irritant rather than a vesicant, necrosis associated with extravasation and suspected cases of extravasation have been reported in dogs.

Hepatotoxicity (increased serum bilirubin and liver enzymes) is observed in about 15% of humans treated with carboplatin. Other potential adverse effects include nephrotoxicity, neuropathies, and ototoxicity. These adverse effects occur less frequently with carboplatin therapy than with cisplatin therapy. Anaphylactoid reactions have been reported rarely in humans who have received platinum-containing compounds (eg, cisplatin). Some dogs receiving chemotherapy will have minor hair coat changes (eg, shagginess, loss of luster). Breeds with continuously growing hair coats (eg, poodles, terriers, Afghan hounds, or old English sheepdogs) are more likely to experience significant alopecia.

Reproductive/Nursing Safety

For sexually intact patients, verify pregnancy status before administration. Carboplatin is fetotoxic and embryotoxic in rats. The risks of its use during pregnancy should be weighed with its potential benefits.

It is unknown whether carboplatin enters maternal milk. In humans, it is recommended to discontinue nursing if the mother is receiving the drug.

Overdose/Acute Toxicity

The intravenous LD_{50} in dogs and mice is 31.2 mg/kg and 89.36 mg/kg, respectively. Anticipated complications of overdose would be secondary to bone marrow suppression and hepatic toxicity.[18] If overdose is suspected, patients should be monitored for neurotoxicity, ototoxicity, hepatotoxicity, and nephrotoxicity. Treatment is supportive as there is no known antidote.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information on overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving carboplatin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but veterinarians should weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **gentamicin**): Potential for increased risk of nephrotoxicity and ototoxicity
- **Myelosuppressive Agents** (eg, **antineoplastics**, **immunosuppressants**, **iron chelators**): Concurrent use with other bone marrow depressant medication may result in additive myelosuppression; avoid combination when possible.
- **Nephrotoxic Agents** (eg, **aminoglycosides**): Renal effects of nephrotoxic compounds may be potentiated by carboplatin.
- **Radiation Therapy**: Potential for increased hematologic toxicity
- **Tigilanol Tiglate:** The tigilanol tiglate administration proto-

col does not permit concurrent use of other antineoplastic drugs. Avoid combination.

- **Vaccines** (live and inactivated): Myelosuppressive drugs may diminish vaccine efficacy and enhance adverse effects of vaccines.

Laboratory Considerations

- None noted

Dosages

NOTES:

1. Because of the potential toxicity of this drug to patients, veterinary personnel, and clients, and because chemotherapy indications, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[27–31] are strongly recommended.
2. Dosages are commonly listed as mg/m^2. Do not confuse with mg/kg dosages. See ***Appendix*** for a conversion table.
3. Do not confuse CISplatin and CARBOplatin dosages; CISplatin dosages are much lower.

The following is a usual dosage range for carboplatin and should be used only as a general guide (dosage may need adjustment in patients with reduced renal function or bone marrow suppression):

DOGS:

- **Chemotherapeutic agent** (extra-label): 250 – 300 mg/m^2 IV every 3 weeks. For dogs weighing 15 kg or less, consider lower doses, such as 240 mg/m^2 (or 10 mg/kg), due to increased risk of toxicity at typical starting doses.[24] Consider lower doses if using in combination with toceranib (*Palladia®*); one study found the maximum tolerated dose of carboplatin to be 200 mg/m^2 with this combination.[16]

CATS:

- **Chemotherapeutic agent** (extra-label): 240 – 260 mg/m^2 IV every 3 weeks.[5] Lower carboplatin doses of 180 – 200 mg/m^2 have also been reported.[5,6]

Monitoring

- Baseline CBC, serum chemistry profile, and urinalysis
- Frequency of hematologic monitoring depends on the protocol employed. Consultation with a veterinary oncologist is recommended.
- CBC 1, 2, and 3 weeks after the first treatment.
  a) If absolute neutrophil count is less than 1000/µL or platelet count is less than 50,000/µL at weeks 1 or 2, then reduce the next dosage by 10% to 20%. Be sure to recheck the CBC before the following treatment.
  b) If absolute neutrophil count is less than 2000/µL or platelet count is less than 75,000/µL the day of treatment, then delay scheduled treatment until blood cell counts have recovered, then either reduce dose by 10% to 20% or change to an every 4-week dosing interval).
  c) For subsequent treatments, a CBC is needed just before each treatment if the patient is stable and the dosage remains unchanged.
    - Chemistry panel every 3 months initially, then every 6 months once stable
    - Tumor measurement and radiography at least monthly (eg, every 4 to 6 weeks)

Client Information

- Carboplatin is a chemotherapy (cancer) drug. The drug and its byproducts can be hazardous to people and other animals that come in contact with it. The drug and its metabolites will stay in your pet's system for a few days after treatment. Therefore, on the day of and for a few days after treatment, wear disposable gloves to handle all bodily waste (urine, feces), blood, or vomit.
- If possible, keep treated dogs in a separate area of the yard, and use a separate litter box for cats. Clean up all pet waste right away whenever possible. Double bag waste, seal, and throw away in the regular trash. Completely change litter and disinfect litter box a few days after the dose was given.
- If any accidents occur in the house (vomit, urine, feces), absorb as much as possible with paper towels, double bag, and discard in the trash, then clean the area with a diluted bleach solution.
- Carboplatin may be toxic to the gastrointestinal tract and cause vomiting and gastrointestinal upset. Carboplatin may also cause changes in blood cell counts, which may cause an increased risk of bleeding, bruising, infection, lethargy, bloody diarrhea, and shortness of breath. Contact your veterinarian immediately if you notice these signs or if you have any other concerns.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Carboplatin, like cisplatin, is a platinum-containing antineoplastic agent. It is supplied as a clear, odorless aqueous solution with a pH of 5 to 7. It has a solubility of 14 mg/mL in water and insoluble in ethanol, acetone, and dimethylacetamide.

Carboplatin may also be known as cis-Diammine-1,1-cyclobutanedicarboxylato-platinum; carboplatinum; CBDCA; JM-8; or NSC-241240. Many trade names are available.

Storage/Stability

Protect the solution for injection from light and store at 25°C (77°F); excursions permitted from 15°C to 30°C (59°F-86°F). Multidose vials maintain microbial, chemical, and physical stability for up to 14 days following multiple needle entries.[32] After dilution, the manufacturer recommends discarding unused portions after 8 hours.[33] However, other sources suggest discarding after 24 hours.[34]

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used. Consult specialized references or a hospital pharmacist for more specific information.

The commercially available solution can be infused directly (usually over 15 minutes) or further diluted to as low as 0.5 mg/mL. Carboplatin is **compatible** with 5% dextrose in water, 5% dextrose in sodium chloride (0.2%, 0.45%, or 0.9%), and normal saline for dilution. Carboplatin is **incompatible** for Y-site administration with amphotericin B, chlorpromazine, diazepam, lansoprazole, leucovorin calcium, phenytoin, procainamide, and thiopental. It is **compatible** for admixture with cisplatin, etoposide, floxuridine, ifosfamide, and paclitaxel.

Because aluminum can displace platinum from carboplatin, the solution should not be prepared, stored, or administered where aluminum-containing items can come into contact with the solution. Should carboplatin come into contact with aluminum, a black precipitate will form, and the product should not be used.

Carboplatin prepared in a proprietary liquid polymer delivery system steadily released platinum over the 28-day investigation period. The clinical efficacy of the compounded formulation was not assessed, but thrombocytopenia and neutropenia were noted.[35]

Intralesional carboplatin in poloxamer gel was reported in one case as an adjunct to surgery and systemic carboplatin therapy. Car-

boplatin 10 mg/mL injection was mixed with an equal volume of poloxamer 407 gel in a sterile environment ≈15 minutes before use. While efficacy was unclear, no adverse wound healing or myelosuppressive effects were observed as a result of the intralesional dose.[14]

Multiple studies have looked at carboplatin impregnated calcium sulfate hemihydrate beads with variable results. Overall, CSH appears to be an effective carrier for carboplatin in vitro, and beads appear well-tolerated in vivo. However, caution is required regarding its use due to variability in compounded formulations and hazards associated with compounding.[12,36,37]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Carboplatin Injection: 10 mg/mL in 5 mL, 15 mL, 45 mL, 60 mL, and 100 mL multi-dose vials; generic; (Rx)

Carnitine

Levocarnitine

(***kar***-ni-teen) *Carnitor®*

Nutrient

Prescriber Highlights

- ► Nutrient required for normal fat utilization and energy metabolism
- ► May be useful as adjunctive therapy in dogs for cysteine or urate urolithiasis and cardiomyopathies (eg, dilated cardiomyopathy, doxorubicin induced); in cats, as adjunctive therapy for feline hepatic lipidosis
- ► Use only L (levo-) forms.
- ► Preferably give with meals

Uses/Indications

Levocarnitine may be useful as adjunctive therapy for dogs with cysteine or urate urolithiasis and dilated cardiomyopathy (DCM); however, only ≈5% with dilated cardiomyopathy respond to supplementation. It may also protect against doxorubicin-induced cardiomyopathy. It may also be beneficial in the adjunctive treatment of valproic acid toxicity.

In cats, levocarnitine has been recommended as a useful adjunctive therapy in feline hepatic lipidosis by facilitating hepatic lipid metabolism, but its use for this indication is somewhat controversial.

Pharmacology/Actions

Levocarnitine is an endogenous substance; it is required for normal fat utilization and energy metabolism in mammalian species. It serves to facilitate entry of long-chain fatty acids into cellular mitochondria, where they can be used during oxidation for energy production. Cardiac and skeletal muscle are significant sites for levocarnitine storage and activity.

Severe chronic deficiency is generally a result of an inborn genetic defect where levocarnitine utilization is impaired and not the result of dietary insufficiency. Effects seen in levocarnitine deficiency may include hypoglycemia, progressive myasthenia, hepatomegaly, DCM, hepatic coma, neurologic disturbances, encephalopathy, hypotonia, and lethargy.

D-carnitine lacks biologic activity, and competitively inhibits levocarnitine (L-carnitine) function.

Pharmacokinetics

In humans, levocarnitine is rapidly absorbed via the GI tract via passive and active mechanisms with a bioavailability of about 15%.[1,2] Half-life is ≈17 hours. Exogenously administered levocarnitine is eliminated primarily in the urine.

Contraindications/Precautions/Warnings

There are no known contraindications to levocarnitine use.

Products not specifically labeled as "levocarnitine" may contain D-carnitine, and should be avoided (see ***Pharmacology/Actions***).

In humans with severely compromised renal function, chronic administration of large doses of oral levocarnitine may result in accumulation or potentially toxic metabolites; the significance of this finding for veterinary patients is uncertain.[1]

Do not confuse levoCARNitine with levetiracetam.

Adverse Effects

Adverse effect profile is minimal. GI upset (eg, nausea, vomiting, diarrhea) is the most likely effect that may be noted and is usually associated with high doses.[3] Human patients have reported increased body odor while taking supplemental carnitine.

Reproductive/Nursing Safety

Studies done in rats and rabbits have demonstrated no teratogenic effects. It is generally believed that levocarnitine is safe for use in pregnancy though documented safety during pregnancy has not been established. Levocarnitine is distributed in milk.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Levocarnitine is a relatively safe drug; the LD_{50} in rats is 5.4 g/kg IV and in mice is 19.2 g/kg PO. In humans, there are no reports of toxicity following overdose, although diarrhea may occur with large doses.[1]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving levocarnitine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- ■ **Valproic Acid:** Patients receiving valproic acid may require higher dosages of levocarnitine.

Dosages

DOGS:

Myocardial carnitine deficiency associated with dilated cardiomyopathy (extra-label):

a) 100 – 200 mg/kg PO every 8 to 12 hours[3]; response to treatment may require 2 to 4 months

b) Adjunctive treatment of American cocker spaniels with dilated cardiomyopathy: carnitine 1 g with taurine 500 mg PO 2 to 3 times daily[4,5]

Systemic carnitine deficiency (extra-label): 50 – 100 mg/kg PO every 8 hours[3,6,7]

CATS:

Adjunctive therapy for severe hepatic lipidosis (extra-label): 250 – 500 mg/cat (NOT mg/kg) PO per day[8-10]

Monitoring
- Depends on indication for use; examples include:
  a) DCM: resting respiratory rate, echocardiographic measurements to monitor myocardial function, body weight
  b) Hepatic lipidosis: baseline and periodic serum liver chemistry panels, appetite, body weight
- Adverse effects (eg, diarrhea)
- Baseline and periodic plasma carnitine concentrations

Client Information
- This medicine usually causes no side effects but vomiting or diarrhea can occur with larger doses. Giving this medicine with food may help with these side effects.
- If using a powder form of this medicine, mix it into your animal's food as directed by your veterinarian.
- Do NOT use any carnitine product that contains D-carnitine; use only L-carnitine.
- Most dogs that respond to carnitine therapy for dilated cardiomyopathy will require other medication to control their condition.

Chemistry/Synonyms
Levocarnitine (the L-isomer of carnitine) is an amino acid derivative, synthesized in vivo from methionine and lysine. It occurs as a white hygroscopic crystalline powder that is soluble in water and insoluble in acetone.

Carnitine may also be known as vitamin B_T, L-carnitine, or levocarnitinum; many trade names are available.

Storage/Stability
Levocarnitine formulations should be stored at room temperature 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations
No specific information noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:
Levocarnitine Oral Tablets: 330 mg and 500 mg; *Carnitor®*, generic; (Rx and OTC)

Levocarnitine or L-Carnitine Oral Capsules: 250 mg, 300 mg, and 400 mg; generic; (OTC)

Levocarnitine Oral Solution: 100 mg/mL in 118 mL; *Carnitor®*, generic; (Rx – regular and sugar free [saccharin] available)

NOTE: L-carnitine may also be available in bulk powder form or other capsule strengths from local health food stores. Check labels to ensure products do not contain D-Carnitine (see ***Pharmacology/Actions***).

Carprofen

(kar-***pro***-fen) *Rimadyl®, Carprieve®, Carprovet®, Norocarp®, Novox®, quellin®, Rovera®, Vetprofen®*

Nonsteroidal Anti-inflammatory Drug (NSAID)

Prescriber Highlights
- ► NSAID used in a variety of domestic animal species
- ► Contraindications include use in dogs with bleeding disorders (eg, Von Willebrand disease) or dogs with a history of serious reactions to it or other propionic-class NSAIDs.
- ► Caution advised in geriatric patients or those with preexisting chronic diseases (eg, inflammatory bowel disease, renal or hepatic insufficiency) or taking certain medications (eg, corticosteroids, nephrotoxic agents)
- ► Mild GI effects (eg, vomiting, diarrhea, constipation, inappetence) and/or lethargy are the most common adverse effects, but incidence is low (less than 2%).
- ► Rare cause of idiosyncratic hepatic failure; liver enzymes should be monitored

Uses/Indications
Carprofen is labeled for the pain and inflammation associated with osteoarthritis and for control of postoperative pain associated with soft tissue and orthopedic surgeries in dogs.[1] An evaluation of the scientific literature concluded that there is evidence to support the clinical benefit of longer-term (more than 28 days) NSAID use with a low risk for serious adverse effects in dogs with chronic osteoarthritis,[2] although others note that most studies of NSAIDs were conducted in nongeriatric, healthy dogs.[3] Carprofen injection prior to surgery has a sevoflurane minimum alveolar concentration (MAC)-sparing effect.[4] Carprofen has demonstrated a survival benefit in dogs with prostatic carcinoma.[5]

Carprofen may also be of benefit in other species. Outside the United States, carprofen is registered for use in horses, cattle, and cats. Little data exist to support safe use of carprofen beyond short-term administration in cats, and adverse GI effects (eg, vomiting) have been reported in cats given more than a single dose.

Pharmacology/Actions
Like other NSAIDs, carprofen can exhibit analgesic, anti-inflammatory, and antipyretic activity, most likely through inhibition of cyclooxygenase, phospholipase A_2, and prostaglandin synthesis. However, its relatively weak inhibition of prostaglandin synthesis suggests that other mechanisms may also be responsible for carprofen's pharmacologic effects.[6] Carprofen appears to be more sparing of COX-1 in vitro and, in dogs, appears to have fewer COX-1 effects (eg, GI ulceration, platelet inhibition, renal damage) as compared with older non-COX–2 specific agents. The specificity of carprofen's COX-2 effects appears to be species-, dose-, and tissue-dependent. Carprofen use in horses and cats does not appear to be as COX-2 specific as it is when used in dogs.

Pharmacokinetics
When administered orally to dogs, carprofen is rapidly absorbed and has over 90% bioavailability. Peak serum concentrations occur 1 to 3 hours after oral administration. Subcutaneous administration delays the rate of absorption but results in comparable total drug absorption within 12 hours. The drug is highly bound to plasma proteins (99%) and has a low volume of distribution (0.12 to 0.22 L/kg). Carprofen is extensively metabolized in the liver, primarily via glucuronidation and oxidative processes. Approximately 70% to 80% of a dose is eliminated in feces and 10% to 20% is eliminated in urine. Some enterohepatic recycling of the drug occurs.

In dogs, the elimination half-life of carprofen is ≈8 hours, with the S form having a longer half-life than the R form.[1]

In cats, the average half-life of carprofen is 20 hours; however, there is a high degree of interpatient variability (9 to 49 hours). Half-life is not necessarily a good predictor of duration of effect, as the drug's high affinity for tissue proteins may act as a reservoir for the drug in inflamed tissues. However, one study showed that although the terminal half-life was longer in interstitial fluid than in plasma, there was no difference between unbound drug concentrations in inflamed versus control interstitial fluid.[7]

In horses, bioavailability following oral administration is 75% to 100%. Plasma protein binding is high (99%). Following intramuscular injection, half-life ranges from 23 to 43 hours.[8]

In adult cattle, the half-life is ≈30 to 65 hours.[9,10] In calves younger than 10 weeks, the half-life is ≈43 hours.[11]

Contraindications/Precautions/Warnings

In healthy dogs, carprofen has minor effects on bleeding times and platelet aggregation but remains contraindicated in dogs with bleeding disorders (eg, Von Willebrand disease, thrombocytopenia) due to increased risk for impaired hemostasis. Carprofen is also contraindicated in animals with prior serious reactions to it or other propionic-class anti-inflammatory agents (eg, ketoprofen, naproxen, ibuprofen). It should be used with caution in geriatric animals or those with preexisting conditions and diseases (eg, GI ulceration, dehydration, hypoproteinemia, cardiovascular disease, inflammatory bowel disease, renal or hepatic insufficiency). Using parenteral fluids during general anesthesia should be considered to decrease the risk for NSAID-induced perioperative renal injury. Carprofen use inhibited bone healing in healthy dogs that received the drug for 120 days following tibial osteotomy.[12]

The manufacturer states that the safe use of carprofen in dogs younger than 6 weeks has not been established.

Adverse Effects

Adverse effects are uncommon with carprofen use in dogs; mild GI effects (eg, vomiting, diarrhea, constipation, inappetence) and/or lethargy are most common, but incidence is low (less than 2%). Subclinical GI erosions have been demonstrated in dogs receiving carprofen chronically.[13,14] Development of hepatocellular damage and/or renal disease is a rare but serious possibility. Preexisting renal insufficiency, dehydration, and sodium depletion can increase the risk for renal toxicity. Other reported adverse effects include neurologic (eg, ataxia, paresis, paralysis, seizures, vestibular signs, disorientation), behavior (eg, sedation, lethargy, hyperactivity, restlessness, aggression), hematologic (eg, immune-mediated hemolytic anemia and thrombocytopenia, blood-loss anemia, epistaxis), dermatologic (eg, pruritus, alopecia, moist dermatitis, panniculitis, vasculitis, ventral ecchymosis), hypersensitivity (eg, facial swelling, hives, erythema), and serious GI effects (eg, ulceration, pancreatitis). Swelling and warmth at injection sites may be noted.

The reported incidence of hepatopathy is ≈0.05% or less in dogs. Geriatric dogs or dogs with chronic diseases (eg, inflammatory bowel disease, renal or hepatic insufficiency) may be at greater risk for development of hepatotoxicity while receiving this drug, but the effect may be idiosyncratic and unpredictable. Labrador retrievers have been associated with ≈25% of the initially reported cases of hepatic syndrome; however, Labrador retrievers are most commonly treated with this drug, and it is not believed that this breed has a greater chance to develop this hepatic syndrome. Pretreatment patient evaluation, as well as discussion with the owner regarding the potential risks versus benefits of therapy, is advised before therapy is initiated. There are rare case reports of neutrophilic dermatosis (ie, Sweet's syndrome).[15,16]

Carprofen has been used in cats, but, because cats have limited ability to glucuronidate, there is a greater potential for drug accumulation with resultant adverse effects. In particular, cats appear to be more susceptible for development of renal adverse effects from NSAIDs. Prolonged administration of carprofen in cats has also caused adverse GI effects. Development of hepatotoxicity does not appear to be a significant concern with NSAID use in cats, possibly because cats do not form significant amounts of glucuronidated metabolites.

Reproductive/Nursing Safety

The manufacturer states that safe use of carprofen in pregnant dogs, dogs used for breeding purposes, or lactating bitches has not been established. Carprofen (up to 20 mg/kg) has been given to pregnant rats during days 7 to 15 of gestation. Although no teratogenic effects were noted in pups, the drug did delay parturition, and there was an increased number of dead pups at birth.

Carprofen given 1 hour after parturition to first-lactation cows increased milk yield during the 305-day lactation period, increased pregnancy rates, and reduced calving interval and somatic counts.[17]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

In toxicologic studies on dogs, repeated administration of up to 10 times the recommended dose resulted in few adverse effects. Some dogs exhibited hypoalbuminemia, melena, or slight increases in ALT. However, postmarketing surveillance suggests there may have been significant interpatient variability in response to acute or chronic overdoses. According to the ASPCA Animal Poison Control Center (APCC) database, vomiting has been reported after administration of a dose as low as 5.3 mg/kg in dogs and 3.9 mg/kg in cats. Based on reports to the APCC from 2009 to 2013, clinical signs in dogs or cats may include vomiting, lethargy, diarrhea, anorexia, elevated liver enzymes, and azotemia. The APCC level of concern for renal damage is 50 mg/kg in dogs and 8 mg/kg in cats.

This drug is an NSAID, and an overdose can lead to GI and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For toxic doses in which GI effects are expected, the use of GI protectants is warranted. If renal effects are also expected, fluid diuresis is warranted. Therapeutic plasma exchange may be beneficial.[18] IV lipid emulsion therapy was successfully used to manage caprofen toxicity in a cat.[19]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

NOTE: Although the manufacturer does not list any specific drug interactions in the package insert, it cautions against concomitant carprofen use with other ulcerogenic drugs (eg, **corticosteroids**, other **NSAIDs**) unless the animal is closely monitored for adverse effects. Although a multiday washout period may be appropriate when switching from one NSAID to another, there does not appear to be any credible evidence to support this (except with ***Aspirin***).

The following drug interactions have either been reported or are theoretical in humans or animals receiving NSAIDS, including carprofen, and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Anticoagulants** (eg, **coumarin** or **indanedione derivatives, heparin,** or **thrombolytic agents**): NSAID-induced inhibition of platelet aggregation and GI ulceration may be hazardous in animals receiving anticoagulant or thrombolytic therapy.

- **ACE Inhibitors** (eg, **benazepril, enalapril**): ACE inhibitors act through the effects of vasodilatory prostaglandins on renal function, so NSAIDs may decrease their effectiveness; however, one study in dogs receiving tepoxalin (an NSAID) did not show any adverse effects. It is unknown what effects, if any, occur if other NSAIDs and ACE inhibitors are used together in dogs.
- **Aspirin** or **Other NSAIDS**: Concurrent administration with carprofen may increase the risk for toxicity (eg, GI ulceration). Animals receiving aspirin therapy that will be replaced with a COX-2 NSAID should undergo a washout period of 3 to 10 days between stopping aspirin and starting the NSAID.[20]
- **Corticosteroids**: Concomitant administration with NSAIDs may increase the risk for GI adverse effects.
- **Cyclosporine** or **Other Nephrotoxic Medications**: The risk for drug-induced nephrotoxicity may be increased when NSAIDs and other nephrotoxic medications are coadministered, in part because NSAIDs can increase the plasma concentrations of nephrotoxic drugs through inhibition of renal prostaglandin.
- **Dacarbazine; Dactinomycin**: Concurrent use with NSAIDs may increase risk for bleeding.
- **Desmopressin**: Concurrent use may increase risk for water intoxication and/or hyponatremia. Electrolytes and renal function should be monitored.
- **Digoxin**: Carprofen may increase serum concentrations of digoxin; caution is advised in patients with severe cardiac failure.
- **Dinoprost:** NSAIDs may inhibit prostaglandin synthesis.
- **Highly Protein Bound Drugs** (eg, **phenytoin, valproic acid, oral anticoagulants, other anti-inflammatory agents, salicylates, sulfonamides, sulfonylurea antidiabetic agents**): Because carprofen is highly bound to plasma proteins (99%), it could potentially displace other highly bound drugs; increased serum concentrations may occur. Although these interactions are typically not a clinical concern, caution is advised when these drugs are used together. Cefovecin does not significantly affect the pharmacokinetics of the active S(+) enantiomer of carprofen.[21]
- **Insulin** or **Oral Antidiabetic Agents**: The hypoglycemic effects of insulin and antidiabetic agents may be increased by NSAIDs because prostaglandins contribute to regulation of glucose metabolism.
- **Loop Diuretics** (eg, **furosemide**): Carprofen may reduce the diuretic, saluretic, and antihypertensive effects by inhibiting prostaglandin synthesis. Concurrent use of NSAIDs and diuretics may increase the risk for renal insufficiency secondary to decreased renal blood flow. In dogs, glomerular filtration rate has been shown to decrease after 8 days of concurrent use.[22]
- **Methotrexate**: NSAIDs may cause increased and prolonged methotrexate plasma concentrations due to decreased protein binding and/or renal excretion. Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; extreme caution is advised when these drugs are used together, especially during high-dose methotrexate infusion therapy.
- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs), Other**: Concomitant administration with other NSAIDs should be avoided.
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine**): Concurrent use of this drug class may increase antiplatelet effects of NSAIDs.
- **Tricyclic Antidepressants** (eg, **clomipramine**): Concurrent use of this drug class may increase antiplatelet effects of NSAIDs.

Laboratory Considerations

- In dogs, carprofen may slightly lower **Free T_4**, **Total T_4**, and **TSH** concentrations.
- Increases in liver enzyme values, including **ALP, ALT, lactate dehydrogenase (LDH), and other transaminases**, may be detected. Concurrent administration of phenobarbital, rifampin, or other hepatic enzyme-inducing agents may also elevate liver enzymes and interfere with interpretation of these tests.
- Prolonged bleeding times
- Decreased **hematocrit** or **hemoglobin** due to GI bleeding, microbleeding, and/or hemodilution caused by fluid retention
- **Leukocyte and platelet count** may be decreased.
- Serum **potassium** concentrations may be increased.
- NSAIDs may decrease renal function, which will be reflected in renal function tests (eg, increased serum **creatinine** coupled with consistently lowered **urine specific gravity**).

Dosages

DOGS:

Anti-inflammatory and analgesic (label dose): 4.4 mg/kg PO once daily, or divided and given as 2.2 mg/kg PO twice daily. Dose should be rounded down to the nearest half-caplet increment. For postoperative pain, carprofen should be administered at 4.4 mg/kg SC ≈2 hours before the procedure.[1]

CATS:

Anti-inflammatory and analgesic:

Warning: Extreme caution is advised, particularly with continued administration. All dosages listed are extra-label in the United States.

a) 4 mg/kg SC or IV once for treatment of postoperative pain; best given preoperatively at the time of induction of anesthesia[23]

b) 12.5 mg/cat (adult) (NOT mg/kg) PO or SC once weekly[24]

HORSES: (NOTE: ARCI UCGFS CLASS 4 DRUG)

Anti-inflammatory and analgesic (extra-label): 0.7 mg/kg IV once; dose may be repeated every 24 hours up to a total of 5 days.[25]

CATTLE:

Reduce pyrexia or clinical signs in acute infectious respiratory disease and acute mastitis (extra-label in United States): 1.4 mg/kg IV or SC once[26]

SHEEP:

Anti-inflammatory and analgesic agent (extra-label): 8 mg/kg PO once daily (every 24 hours)[27]

FERRETS:

Anti-inflammatory and analgesic (extra-label): 1 – 4 mg/kg SC every 12 to 24 hours; 4 mg/kg PO once daily (every 24 hours)

RABBITS/RODENTS/SMALL MAMMALS:

Anti-inflammatory and analgesic (all are extra-label):

a) **Rabbits**: 2 – 4 mg/kg PO every 12 to 24 hours; 4 mg/kg SC[28]

b) **Rats/mice**: 5 mg/kg SC every 12 to 24 hours[29]

c) **Guinea pigs/chinchillas**: 4 mg/kg SC every 12 to 24 hours[29]

BIRDS:

Anti-inflammatory and analgesic (all are extra-label):

a) 2 mg/kg PO every 8 to 24 hours[30]

b) 1 mg/kg SC; single-dose study demonstrated increased walking ability in lame chickens.[31]

c) 1 – 4 mg/kg IM, IV, PO[32]

REPTILES:

Anti-inflammatory (extra-label): 1 – 4 mg/kg IV, IM, SC, PO every 24 to 72 hours[32]

Monitoring

- Baseline parameters should be established before therapy is started, especially in geriatric dogs, in dogs with chronic diseases, or when prolonged treatment is likely. Physical examination, CBC, serum chemistry profile (including liver and renal parameters), and urinalysis should be evaluated. Liver enzymes should be reassessed 2 to 4 weeks after starting carprofen therapy and at 3- to 6-month intervals. Carprofen should be discontinued if problems arise.
- Clinical efficacy
- Signs of potential adverse effects include: inappetence, diarrhea, vomiting, melena, polyuria, polydipsia, anemia, jaundice, lethargy, behavior changes, ataxia, and seizures.
- Chronic therapy: Clinicians should consider repeating CBC, urinalysis, and serum chemistry profiles as needed.

Client Information

- Read and understand the client information sheet provided with this medication; contact your veterinarian with any questions or concerns.
- May be given with or without food, but food may reduce the chances for stomach problems.
- Most dogs tolerate carprofen well, but rarely some dogs can develop ulcers or serious kidney and liver problems. Watch for changes in bowel movements, behavior or activity level (ie, more or less active than normal), and/or drinking (ie, frequency, amount consumed) or urination (ie, frequency, color, or smell) habits; signs of decreased appetite, vomiting, muscle weakness (eg, stumbling, clumsiness), seizures (ie, convulsions) or aggression; and yellowing of gums, skin, or whites of the eyes (jaundice).
- Store flavored, chewable tablets out of reach of animals and children to avoid accidental ingestion.
- Periodic laboratory tests are recommended to check liver and kidney function. Do not miss these important follow-up visits.

Chemistry/Synonyms

Carprofen, a propionic acid derivative nonsteroidal anti-inflammatory agent, occurs as a white crystalline compound. It is practically insoluble in water and freely soluble in ethanol at room temperature. Carprofen has an S(+) enantiomer and R(-) enantiomer. The commercial product contains a racemic mixture of both. The S(+) enantiomer has greater anti-inflammatory potency than the R(-) form.

Carprofen may also be known as C-5720, Ro-20-5720/000, *Rimadyl®*, *Carprovet®*, *Vetprofen®*, *Zinecarp®*, *Canidryl®*, *Novox®*, *Aventicarp®*, *Rycarfa®*, *Rimifin®*, *Carpox®*, *Prolet®*, *Tergive®*, *Carprodyl®*, or *Norocarp®*.

Storage/Stability

Store the commercially available caplets or chewable tablets at room temperature (15°C-30°C [59°F-86°F]).

Store the commercially available injection (in the United States) in the refrigerator (2°C-8°C [36°F-46°F]). Once broached, store the injection at temperatures up to 25°C (77°F) for 28 days.

Compatibility/Compounding Considerations

Compounded preparation stability: Carprofen oral suspension compounded from commercially available tablets has been published.[33] In adaptation of that work, triturating 1 carprofen 100 mg tablet with 10 mL of *Ora-Plus®* and *qs* ad to 20 mL with *Ora-Sweet®* will yield a 5 mg/mL suspension that retains 90% potency for 21 days stored at both 5°C (41°F) and 25°C (77°F). Compounded preparations of carprofen should be protected from light.

A 1:10 dilution of carprofen injection with sterile water maintained potency for over 28 days when stored at room temperature or refrigerated; no bacterial contamination or endotoxin was detected.[34]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Carprofen Scored Caplets: 25 mg, 75 mg, and 100 mg; *Rimadyl® Caplets*, *Novox®*, *Carprieve®*, *Rovera®*, *Norocarp®*, generic; (Rx). FDA-approved for use in dogs

Carprofen Flavored Tablets: 25 mg, 75 mg, and 100 mg: *Carprovet®*, *Truprofen®*, *Vetprofen®* (Rx). FDA-approved for use in dogs

Carprofen Chewable Tablets: 25 mg, 75 mg, and 100 mg; *quellin®* (soft chewable; scored), *Rimadyl®*, *Carprieve®*, *Novox®*, *Truprofen®*, generic; (Rx). FDA-approved for use in dogs

Carprofen Sterile Injectable Solution: 50 mg/mL in 20 mL multidose vials; *Rimadyl®*; generic; (Rx). FDA-approved for use in dogs

Outside the United States, carprofen injection is labeled for use in dogs, cats, cattle (slaughter withdrawal, 21 days; milk withdrawal, 0 hours), and in horses not intended for human consumption.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS: NONE

Carvedilol

(kar-***ve***-dil-ole) *Coreg®*

Alpha- and Beta-Adrenergic Antagonist

Prescriber Highlights

- ► Nonselective beta-adrenergic blocker with selective alpha1-adrenergic blocking activity that could be useful as adjunctive treatment of congestive heart failure in dogs
- ► Negative inotrope, which may prohibit its use in patients with CHF, as it could cause worsening of their condition
- ► Additional adverse effects that may demonstrate intolerance include lassitude, inappetence, and hypotension.

Uses/Indications

Carvedilol may be useful as adjunctive therapy in the treatment of congestive heart failure (specifically, dilated cardiomyopathy) in dogs. One study[1] performed in a small number of dogs with dilated cardiomyopathy showed that carvedilol dosed at 0.3 mg/kg PO every 12 hours for 3 months did not produce any significant improvements in neurohormonal activation, heart size, or owner-perceived quality of life. The authors stated that dosages greater than 0.3 mg/kg every 12 hours are likely to be required to effect changes in ventricular remodeling and function.

In a retrospective study, 38 dogs (33 were Cavalier King Charles spaniels) with stage B2 (left-sided heart enlargement without CHF) chronic valvular heart disease were treated with carvedilol. The average initial dosages of 0.31 mg/kg PO twice daily and average uptitration target dosages of 1.11 mg/kg PO twice daily were well tolerated.[2] The median survival was 48.5 months. Additional prospective studies to assess efficacy are warranted.

In a study in dogs, carvedilol attenuated the development of systolic dysfunction of pacing-induced dilated cardiomyopathy and inhibited cardiac apoptosis and fibrosis in the heart; however, there was an enlargement of the left ventricle and atrium.[3]

In one study, when carvedilol was combined with conventional therapy (benazepril, digoxin, ±furosemide, ±spironolactone, ±hy-

drochlorothiazide) for acquired chronic mitral valve disease in dogs, it improved the quality of life and the heart disease stage classification.[4] It has also been shown that carvedilol can suppress atrial fibrillation inducibility and oxidative stress of the atrial tissue[5] and autonomic nerve activity and paroxysmal atrial tachycardia.[6]

Pharmacology/Actions

Carvedilol is a nonselective, beta-adrenergic blocker with selective alpha$_1$-adrenergic blocking activity. Although beta-blockers have negative inotropic effects, long-term dosing in humans with dilated cardiomyopathy can be beneficial in reducing morbidity and mortality. Patients in heart failure chronically activate their sympathetic nervous system, thereby leading to tachycardia, activation of the renin-angiotensin-aldosterone system, down-regulation of beta-receptors, induction of myocyte necrosis and myocyte energy substrate, and calcium ion handling. By administering beta-blockers, these negative effects may be reversed or diminished. As carvedilol also inhibits alpha$_1$-adrenergic activity, it can cause vasodilation and reduce afterload. Carvedilol has free radical scavenging and antidysrhythmic effects that could be beneficial in patients with heart failure.

Pharmacokinetics

In dogs, a pilot study[7] showed the bioavailability of carvedilol after oral dosing (standard tablets) averaged about 23% in the 4 dogs studied; however, in 3 of the 4 dogs, the bioavailability ranged from 3% to 10%. The volume of distribution averaged about 1.4 L/kg; the elimination half-life was about 100 minutes. At least 15 different metabolites of carvedilol have been identified after dosing in dogs. The most predominant metabolisms in dogs are hydroxylation of the carbazolyl ring and glucuronidation of the parent compound. No pharmacokinetic data were located for the extended-release oral capsules (*Coreg CR*®) in dogs.

In cats, oral carvedilol has a relatively low mean bioavailability (15.7%) with a wide interpatient variation. Peak concentrations occur about one-hour post oral dose. The elimination half-life is about 4.5 hours.[8]

In humans, carvedilol is rapidly and extensively absorbed, but due to a high first-pass effect, its bioavailability is about 30%. The drug is extensively bound to plasma proteins (98%). It is extensively metabolized, and the R(+) enantiomer is metabolized 2 to 3 times greater than the S(-) form during the first pass. Both the R(+) and S(-) enantiomers have equal potency as nonspecific beta- or alpha-adrenergic blockers. CYP2D6 and CYP2C9 are the P450 isoenzymes most responsible for hepatic metabolism. Some of these metabolites have pharmacologic activity. Metabolites are primarily excreted via the bile and feces. The elimination half-life of carvedilol in humans is about 8 to 9 hours.

Contraindications/Precautions/Warnings

In humans, carvedilol is contraindicated in patients with decompensated heart failure, bronchial asthma, second- or third- degree AV block, sick sinus syndrome (unless artificially paced), severe bradycardia, cardiogenic shock, and hypersensitivity to the drug. Dogs with similar conditions should not receive the drug. Patients with hepatic insufficiency should receive the drug with caution.

Too rapid dose up-titration can cause cardiac decompensation.[9] Do not discontinue carvedilol abruptly; in humans, tapering over 1 to 2 weeks is recommended.

Adverse Effects

Veterinary experience with carvedilol is sparse, and an accurate portrayal of adverse effects in dogs has yet to be elucidated. Too rapid dose escalation can cause decompensation in patients with heart failure; cautious dosage titration is mandatory. Dogs that do not tolerate the medication may show signs of inappetence, lassitude, or hypotension.

In humans, carvedilol use has resulted in hypotension, bradycardia, bronchospasm, hyperglycemia and on rare occasions, caused mild hepatocellular injury.[9]

Reproductive/Nursing Safety

In rats and rabbits, carvedilol increased postimplantation loss.[9]

It is unknown if carvedilol enters maternal milk in dogs, but it does enter milk in rats.[9] Use it with caution in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The acute oral LD$_{50}$ in healthy rats and mice is greater than 8 g/kg.[10] Clinical signs associated with large overdoses of carvedilol include severe hypotension, cardiac insufficiency, bradycardia, cardiogenic shock, and death due to cardiac arrest. Gut-emptying protocols should be considered if ingestion was recent. In humans, bradycardia is treated with atropine. Cardiovascular function is supported with glucagon and sympathomimetics (eg, dobutamine, epinephrine).

Clinical signs associated with an overdose in dogs include lethargy, bradycardia, hypotension, hypertension, and tachycardia; in cats, lethargy and vomiting are the most common clinical signs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving carvedilol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antidiabetic Agents, Oral** (eg, **glipizide, metformin**): Carvedilol may enhance the blood-glucose-lowering effects of antidiabetic agents.
- **Amiodarone**: Concurrent use may result in bradycardia, hypotension, sinus arrest, and AV block.
- **Beta-Adrenergic Receptor Antagonists** (eg, **atenolol, propranolol**): Use with carvedilol may cause additive effects
- **Calcium Channel Blockers** (eg, **amlodipine, diltiazem, verapamil**): Increased risk for hypotension and bradycardia; may precipitate heart failure in patients with pre-existing cardiac conditions
- **Cimetidine**: May decrease metabolism and increase the AUC of carvedilol
- **Clonidine**: Carvedilol may potentiate the cardiovascular effects of clonidine.
- **Cyclosporine**: Carvedilol may increase cyclosporine concentrations.
- **Digoxin**: Carvedilol can increase (in humans) digoxin plasma concentrations by ≈15% and increase the risk for complete heart block.[9]
- **Dobutamine**: Concurrent use may lead to decreased dobutamine efficacy.
- **Doxorubicin**: Concurrent use may result in increased doxorubicin exposure.
- **Epinephrine**: Concurrent use may result in hypertension, bradycardia, and resistance to epinephrine in anaphylaxis.
- **Fluoxetine, Paroxetine:** May increase R(+) carvedilol concentrations and increase alpha$_1$ blocking effects (vasodilation)

- **Hypotensive Agents** (eg, **enalapril, telmisartan**): Concurrent use may increase the risk for hypotension.
- **Insulin**: Carvedilol may enhance the blood-glucose-lowering effects of insulin or other antidiabetic agents.
- **Methimazole**: Concurrent use may alter the metabolism of carvedilol.
- **Nonsteroidal Anti-inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam, robenacoxib**): Concurrent use may lead to decreased antihypertensive effects of carvedilol.
- **Opioids** (eg, **fentanyl, hydrmorphone, methadone**): Increased risk for hypotension and bradycardia. Concurrent use with morphine may lead to increased morphine exposure.
- **Quinidine**: May increase R(+)carvedilol concentrations and increase alpha$_1$ blocking effects that lead to vasodilation.
- **Rifampin**: Can decrease carvedilol plasma concentrations by as much as 70%.[9]
- **Reserpine**: May increase risk for bradycardia and hypotension
- **Vincristine**: Concurrent use may lead to increased vincristine plasma concentrations.
- **Yohimbine**: Concurrent use may lead to decreased carvedilol efficacy.

Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

Dosages

DOGS:

Adjunctive treatment of stage B myxomatous mitral valve disease (extra-label):

a) From a retrospective study: Carvedilol at an initial dose of 0.31 mg/kg (mean) PO twice daily and a target dose of 1.11 mg/kg (mean) PO twice daily is safe and well tolerated in dogs with stage B1 and early stage B2 when an uptitration protocol is used that involves a 50% to 100% increase in dose every 7 to 14 days until the target dose is reached.[11]

b) Initial dose 0.15 – 0.2 mg/kg PO twice daily for 1 week. After evaluating blood pressure and heart rate, the dose can be increased to 0.3 mg/kg PO twice daily. [4,12]

Adjunctive treatment of pseudoephedrine toxicosis (extra-label): From a case report, 0.5 mg/kg PO twice daily [13]

Monitoring

- Adverse effects (eg, lethargy, inappetence, collapse)
- Blood pressure, heart rate
- Resting respiratory rate
- ECG and cardiac function (ie, echocardiography)
- Plasma drug concentrations may be useful.

Client Information

- This medication is best given with food.
- When starting this medicine for your animal, your veterinarian may begin with a low dose and gradually increase the dose over time. It is critical to be aware of the changing doses and not administer more at one time than your veterinarian prescribes. Do not stop the medication without talking with your veterinarian first.
- If the initial doses are too high, it may cause your animal's condition to worsen and show signs of loss of appetite, depression, lack of energy, or weakness. If any of these clinical signs occur, call your veterinarian immediately.
- Do NOT store compounded liquids of carvedilol in the refrigerator.

Chemistry/Synonyms

Carvedilol, a nonselective beta-adrenergic blocker with selective alpha$_1$-adrenergic blocking activity, occurs as a white to off-white crystalline powder that is practically insoluble in water, dilute acids, and gastric or intestinal fluids. It is sparingly soluble in ethanol. The compound exhibits polymorphism and contains both R(+) and S(-) enantiomers. It is a basic lipophilic compound.

Carvedilol may also be known as BM-14190, carvedilolum, *Cardilol®*, *Cardiol®*, *Carloc®*, *Carvil®*, *Carvipress®*, *Coreg®*, *Coritensil®*, *Coropres®*, *Dilatrend®*, *Dilbloc®*, *Dimitone®*, *Divelol®*, *Eucardic®*, *Hybridil®*, *Kredex®*, or *Querto®*.

Storage/Stability

Store carvedilol tablets and extended-release capsules below 30°C (86°F), protected from moisture. Dispense them in tight, light-resistant containers.

Compatibility/Compounding Considerations

Compounded preparation stability: Carvedilol oral suspension compounded from commercially available tablets has been published[14] ; however, HPLC analysis of drug samples in this study gave inconsistent and variable results, indicating a loss of potency at refrigerated temperatures compared with room temperature. Results of this study do not necessarily confirm that carvedilol is stable when prepared as an oral liquid.

Another published[15] compounded oral suspension with documented 90-day stability to accurately dose dogs is to powder 25 mg tablets and add enough de-ionized water to make a paste, allowing the tablet coating to dissolve. Then, suspend the paste in a commercially available simple syrup to a concentration of either 2 mg/mL or 10 mg/mL. Store the medication in amber bottles at temperatures not exceeding 25°C (77˚F) and protect from light for up to 90 days. Shake well before administering.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Carvedilol Oral Tablets: 3.125 mg, 6.25 mg, 12.5 mg, and 25 mg; *Coreg®*, generic; (Rx)

Carvedilol extended-release oral capsules are available; however, no information about use in veterinary species was located for this dosage form.

Caspofungin

(kas-poe-***fun***-jin) *Cancidas®*

Parenteral Antifungal

Prescriber Highlights

- ► Parenteral antifungal that has potential for treating invasive aspergillosis or disseminated candidal infections in companion animals
- ► Very limited clinical experience in veterinary medicine
- ► Must be given slow IV

Uses/Indications

Caspofungin has potential for treating invasive aspergillosis or disseminated candidal infections in companion animals, although limited information on its use in dogs or cats is available.

Pharmacology/Actions

Caspofungin is an echinocandin antifungal agent. These drugs inhibit beta-glucan synthase, thereby blocking the synthesis of beta-(1,3)-D-glucan, a component found in cell walls of filamentous fungi. Beta-(1,3)-D-glucan is not present in mammalian cells.

Caspofungin has activity against *Aspergillus* spp and *Candida* spp and is effective in treating pneumonia caused by *Pneumocystis carinii*. Because it contains very little beta-glucan synthase, *Cryptococcus neoformans* infections are not effectively treated with caspofungin.[1]

An in vitro study found that caspofungin had significant, but only minimal to moderate inhibition of *Pythium insidiosum* and a *Lagenidium* spp.[2]

Pharmacokinetics

In cats given caspofungin 1 mg/kg IV infused over 1 hour, peak concentration was 14.8 µg/mL after the first dose and 19.8 µg/mL at steady state; trough concentration was ≈5 µg/mL. Clearance was 18 mL/kg/minute, and elimination half-life was 14.5 hours.[3]

In humans, the drug is not appreciably absorbed from the gut and must be administered IV. Protein binding (primarily to albumin) is high (97%), and the drug is distributed to tissues over a 36- to 48-hour period. Caspofungin is slowly metabolized via hydrolysis and N-acetylation. It also spontaneously degrades chemically. Caspofungin exhibits polyphasic elimination, but little is excreted or biotransformed during the first 30 hours postadministration. Elimination half-life for the primary phase is about 10 hours; the secondary phase between 40 and 50 hours. Excretion, consisting mostly as metabolites, is via the feces and urine. Only small amounts (1% to 2%) are excreted unchanged into the urine.[4]

Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. Caspofungin is contraindicated in human patients that are hypersensitive to it. Elevated liver enzyme tests, hepatic necrosis, and hepatic failure have been observed in humans; dosage adjustment is recommended in humans with moderate hepatic impairment. No information is available for use in patients with significant hepatic impairment; avoid use.

Adverse Effects

An adverse effect profile for animals has not been determined. Diarrhea and transient fever have been observed in healthy cats given caspofungin.[3]

In humans, caspofungin is generally well tolerated. Nausea and diarrhea have been noted. Histamine-mediated signs have occurred (eg, rash, facial swelling, pruritus) and anaphylaxis has been reported. IV site reactions (eg, pain, redness, phlebitis) and elevated liver enzymes have also been reported.[4]

Reproductive/Nursing Safety

Fertility and reproductive performance were not affected by the IV administration of caspofungin to rats at doses up to 5 mg/kg.[4] Studies in pregnant rats and rabbits demonstrated changes in fetal ossification and increased fetal resorption. The drug should be avoided during the first trimester of pregnancy unless the benefits associated with treating outweigh the risks.

Caspofungin is distributed into milk in rats.[4] Although no data are available, because the drug is not appreciably absorbed from the gut, it would be expected that caspofungin would be safe to administer during lactation.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited information is available. Doses of 210 mg (about 3 times) in humans were well tolerated.[4] Some monkeys receiving 5 – 8 mg/kg (≈4 to 6 times the recommended dose) over 5 weeks developed sites of microscopic subcapsular necrosis on their livers.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving caspofungin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but veterinarians should weigh the potential risks and perform additional monitoring when appropriate.

- **Cyclosporine**: Increased caspofungin plasma concentrations and increased risk for elevated liver enzymes
- **Dexamethasone**: Reduced caspofungin plasma concentrations
- **Rifampin**: Reduced caspofungin plasma concentrations

Laboratory Considerations

- None noted

Dosages

DOGS:

Treatment of *Aspergillus deflectus* (extra-label): From a case report in a dog that had disease progression despite treatment with other antifungals (eg, voriconazole, amphotericin B lipid complex), caspofungin 1 mg/kg IV over 1 hour every 24 hours[5]; the drug was diluted in 250 mL 0.9% sodium chloride. Rapid clinical improvement and resolution of lymphadenomegaly was noted after 6 weeks of treatment, at which time caspofungin was administered 3 times weekly for 2 months, then on 3 consecutive days every 3 weeks for 4 months, then discontinued. One month later, small numbers of *A deflectus* (sensitive to caspofungin) were noted in urine culture. Twice-weekly caspofungin treatment was administered for 2 weeks, and urine culture again was negative. Treatment was continued on 3 consecutive days every 3 weeks. One year later, the dog showed clinical signs of disease recurrence, and enlarged mesenteric lymph nodes revealed fungal hyphae with marked necrosis.

CATS:

- **Sino-orbital aspergillosis** (extra-label):
  a) 1 mg/kg IV once daily for 14 to 22 days.[6,7] The calculated dose was administered in 20 mL 0.9% sodium chloride and infused over 1 hour.[7]
  b) From a pharmacokinetic study, 1 mg/kg IV loading dose followed by 0.75 mg/kg IV every 24 hours yielded the optimal ratio of peak caspofungin concentration to minimum effective concentration (C_{max}:MEC).[3] This dosage was effectively used in 2 cats with sino-orbital aspergillosis; treatment continued for 2 to 3 weeks.[8] Alternatively, 1 mg/kg IV loading dose followed by 1 mg/kg IV every 72 hours yielded a similar C_{max}:MEC.

Monitoring

- Clinical efficacy
- Baseline and periodic CBC, serum electrolytes, liver enzymes, bilirubin
- Clinical signs associated with infusion reactions (eg, pyrexia, blood pressure changes, tachycardia)

Client Information

- This medication is appropriate for inpatient use only.

- Clients should understand the investigational nature and the associated expense of using this drug in veterinary patients.

Chemistry/Synonyms

Caspofungin acetate is a semisynthetic echinocandin compound produced from a fermentation product of *Glarea lozoyensis*. It occurs as a white to off-white powder that is freely soluble in water and slightly soluble in ethanol. The commercially available lyophilized powder for injection also contains acetic acid, sodium hydroxide, mannitol, and sucrose.

Caspofungin may also be known as caspofungina, caspofungine, caspofungini, kaspofungiinia, kaspofungina, L-743873, MK-0991, or *Cancidas*®.

Storage/Stability

The commercially available product should be stored refrigerated 2° to 8°C (36°F-46°F). Refer to the package insert for very specific directions on preparing the solution for IV use. Reconstituted solutions must be further diluted within 1 hour. Caspofungin diluted in saline or lactated Ringer's may be stored for 24 hours at room temperature below 25°C (below 77°F), or 48 hours if refrigerated. Unused portions should be discarded.

Do not use this product if the solution is cloudy or has precipitated.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Caspofungin must be infused slowly diluted in lactated Ringer's or sodium chloride containing solutions. It is not stable in dextrose-containing IV solutions. Do not mix or infuse caspofungin with any other medications.[4]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Caspofungin Acetate Lyophilized Powder for Injection: 50 mg and 70 mg in single-use vials; *Cancidas*®; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Cefaclor

(***sef***-a-klor) *Ceclor*®

Oral Second-Generation Cephalosporin

Prescriber Highlights

- ► More active against some gram-negative bacteria than first-generation cephalosporins (eg, cephalexin, cefadroxil)
- ► It is potentially useful when an oral cephalosporin is desired to treat bacterial infections that are susceptible to cefaclor but resistant to first-generation cephalosporins.
- ► Limited clinical experience in veterinary medicine
- ► Contraindications include hypersensitivity to cefaclor or other cephalosporins.
- ► The most likely adverse effects in small animal species are GI related.

Uses/Indications

Cefaclor may be useful in uncommon situations when an oral cephalosporin is desired to treat infections that are susceptible to cefaclor but resistant to first-generation cephalosporins, such as cephalexin or cefadroxil. However, little information is available on the clinical use of cefaclor in small animals.

The World Health Organization (WHO) has designated cefaclor as a Highly Important antimicrobial for human medicine.[1]

Pharmacology/Actions

Cefaclor, like other cephalosporins, is bactericidal and acts via inhibiting cell wall synthesis. Its spectrum of activity is similar to that of cephalexin, but it has a broader spectrum to include activity against gram-negative bacteria, including strains of *Escherichia coli*, *Klebsiella pneumoniae*, and *Proteus mirabilis* (but not most other *Proteus*). It is ineffective against enterococci, *Enterobacter,* most *Pseudomonas* spp, methicillin-resistant staphylococci, and extended-spectrum beta-lactamase (ESBL)–producing gram-negative bacteria.

Pharmacokinetics

Limited information is available on the pharmacokinetics of cefaclor in dogs, and no information is currently available for cats. In dogs, about 75% of an oral dose is absorbed, but an apparent first-pass effect reduces bioavailability to about 60%.[2] Cefaclor is distributed to many tissues, but concentrations are lower in interstitial fluid than those found in serum. High concentrations are excreted into the urine unchanged. Bile concentrations are higher than those found in serum. Dogs appear to metabolize a greater percentage of cefaclor than do rats, mice, or humans. The elimination half-life is ≈2 hours in dogs.[3] Pharmacokinetic information for the extended-release oral tablets in dogs was not located.

In humans, cefaclor is well absorbed after oral administration; food delays, but does not appreciably alter, the amount of cefaclor absorbed when immediate-release capsules are used. The bioavailability of extended-release tablets is decreased by 23% when taken on an empty stomach and the maximum concentration is decreased by 67% and should therefore be given with food. The drug is widely distributed, crosses the placenta, and enters breast milk.[4] Up to 85% of a dose is excreted unchanged into the urine; elimination half-life is less than 1 hour in patients with normal renal function.

Contraindications/Precautions/Warnings

Cefaclor is contraindicated in humans that are hypersensitive to it and other cephalosporins. Cefaclor must be cautiously used in patients with an allergy to penicillin.[5] Use with caution in patients with severe renal impairment.[6]

Cefaclor can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: CefaCLOR.

Adverse Effects

As use of cefaclor in animals has been limited, a comprehensive adverse effect profile has not been determined. In humans, cefaclor is generally well-tolerated but commonly can cause GI effects (eg, nausea, diarrhea). Hypersensitivity reactions including anaphylaxis are possible; cefaclor appears to cause a higher incidence of serum-sickness-like reactions than other cephalosporins, particularly in children who have received multiple courses of treatment. In humans, it is estimated that up to 15% of patients who are hypersensitive to penicillins will also be hypersensitive to cephalosporins.[5]

Rare adverse effects reported include erythema multiforme, rash, increases in liver function tests, and transient increases in BUN and serum creatinine. High doses or prolonged use of cephalosporins have been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, interstitial nephritis, and tubular necrosis.

Reproductive/Nursing Safety

Cefaclor cross the placenta. Studies performed in pregnant mice and rats (doses up to 12 times the human dose) and ferrets (doses up to 3 times the human dose) demonstrated no overt fetal harm.[6]

Cefaclor enters maternal milk in low concentrations, and alteration to gut microbiome is possible in the nursing offspring with re-

sultant diarrhea. Cefaclor is considered compatible with breastfeeding in humans.[4]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Cefaclor appears quite safe in dogs. Acute oral cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other, more serious effects are possible. See ***Adverse Effects***. Dogs given daily PO doses of 200 mg/kg/day (10 times the normal dosage) for 30 days developed soft stools and occasional emesis.[7] Two dogs in this study group developed transient moderate decreases in hemoglobin. One dog in another study group that was given 400 mg/kg/day (20 times the normal dosage) for 1 year developed a reversible thrombocytopenia.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefaclor and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: The nephrotoxic effects of aminoglycosides may be enhanced by second-generation cephalosporins.
- **Antacids** (**aluminum-, calcium-** or **magnesium- containing**): Reduces the extent of absorption of extended-release cefaclor tablets in humans; separate doses by at least 2 hours
- **Probenecid**: Reduces renal excretion of cefaclor
- **Warfarin**: Rare reports of increased anticoagulant effects when used concomitantly with cefaclor

Laboratory Considerations

- Cefaclor may cause false-positive **urine glucose determinations** when using the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest®*); tests utilizing glucose oxidase (*TesTape®*, *Clinistix®*) are not affected.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cefaclor given in high doses may result in falsely elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.
- Cefaclor may also result in falsely elevated **17-ketosteroid** values in urine.

Dosages

DOGS/CATS:

Susceptible infections (extra-label): 7 – 20 mg/kg PO every 8 hours

Monitoring

- Clinical efficacy
- Patients with renal insufficiency should have periodic renal function monitored.

Client Information

- This medicine works best when given without food. If your animal vomits or develops a lack of appetite while receiving the medicine, it can be administered with food.
- The most common side effects are diarrhea, vomiting, and loss of appetite.
- Be sure to give the medication to your animal as long as your veterinarian has prescribed, even if your animal seems better.
- Cephalosporin antibiotics have an odor that resembles cat urine.

Chemistry/Synonyms

Cefaclor occurs as a white to off-white powder that is slightly soluble in water.

Cefaclor may also be known as cefaclorum, cefaklor, cefkloras, kefakloori, or compound 99638. There are many internationally registered trade names.

Storage/Stability

Store cefaclor capsules, tablets, and powder for suspension in tight containers at room temperature (15°C-30°C [59°F-86°F]). After reconstituting, store the oral suspension in a tight container in the refrigerator. Discard it after 14 days.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefaclor Oral Capsules: 250 mg and 500 mg; generic; (Rx)

Cefaclor Extended-Release Oral Tablets: 500 mg; generic; (Rx)

Cefaclor Powder for Oral Suspension: 125 mg/5 mL (25 mg/mL), 187 mg/5 mL (37.4 mg/mL), 250 mg/5 mL (50 mg/mL), and 375 mg/5 mL (75 mg/mL), generic; (Rx)

Cefadroxil

(sef-a-***drox***-ill) *Duricef®*

First-Generation Cephalosporin

Prescriber Highlights

- ► Oral antibiotic indicated in dogs and cats for bacterial cystitis or skin/soft tissue infections
- ► Usually well-tolerated; adverse GI effects (eg, anorexia, vomiting, diarrhea) may occur
- ► May be administered with or without food; however, administering the drug with food may help prevent GI upset.
- ► Severe renal impairment may require dose adjustment.

Uses/Indications

Cefadroxil is FDA-approved for use in dogs for genitourinary tract infections (cystitis) caused by susceptible strains of *Escherichia coli, Proteus mirabilis,* and *Staphylococcus aureus* and skin and soft tissue infections including cellulitis, pyoderma, dermatitis, wound infections, and abscesses caused by susceptible strains of *S aureus*. In cats, cefadroxil is labeled for treatment of genitourinary tract infections (cystitis) caused by susceptible strains of *Escherichia coli, Proteus mirabilis,* and *Staphylococcus aureus;* and skin and soft tissue infections including abscesses, wound infections, cellulitis, and dermatitis caused by susceptible strains of *Pasteurella multocida, S aureus, Staphylococcus epidermidis, and Streptococcus* spp.

This antibiotic is used primarily for its activity against staphylococci, particularly for pyoderma.[1,2] Because of high urine concentrations, cefadroxil can be an effective drug for treatment of bacterial cystitis caused by most gram-negative pathogens.

The World Health Organization (WHO) has designated first-generation cephalosporins as Highly Important antimicrobials for human medicine.[3] The Office International des Epizooties (OIE) has

designated first-generation cephalosporins as Veterinary Highly Important Antimicrobial (VHIA) agents in veterinary medicine.[4]

Pharmacology/Actions

Cephalosporins are considered time dependent and bactericidal against susceptible bacteria, and they act by inhibiting mucopeptide synthesis in the cell wall, which results in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (eg, carboxypeptidases, transpeptidases, endopeptidases) in the bacterial cytoplasmic membrane that are involved in cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins [PBPs]) help explain the differences in spectrums of activity of these drugs that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, cephalosporins are generally considered to be more effective against actively growing bacteria. For bactericidal activity, cephalosporin levels should exceed bacterial MIC for ≈40% of the dose interval for staphylococcal infections and ≈60% of the dose interval for streptococcal infections.[5]

Although there may be differences in MICs for individual first-generation cephalosporins, their spectrums of activity are similar. First-generation cephalosporins generally possess excellent coverage against most gram-positive pathogens (with the exception of enterococci). They have variable to poor coverage against most gram-negative pathogens. These drugs are active in vitro against streptococci, staphylococci, *Proteus mirabilis,* and some strains of *Escherichia coli*, *Klebsiella* spp, *Actinobacillus* spp, and *Pasteurella* spp. Methicillin-resistant staphylococci are resistant to this class of antibiotics. In vitro susceptibility is generally predictive of the potential for in vivo efficacy. Cefadroxil is inactive against *Enterococcus* spp, *Pseudomonas* spp, *Rickettsia* spp, mycobacteria, *Mycoplasma* spp, fungi, and viruses.

Pharmacokinetics

Cefadroxil is reportedly well-absorbed after oral administration to dogs regardless of feeding state.[6] After an oral dose of 22 mg/kg, peak serum concentrations of ≈18.6 µg/mL occur within 1 to 2 hours of dosing. Only ≈20% of the drug is bound to canine plasma proteins. The drug is excreted into the animal's urine and has a half-life of ≈2 hours. Over 50% of a dose can be recovered unchanged in the urine within 24 hours of dosing.

In cats, the serum half-life has been reported as ≈3 hours.

Oral absorption of cefadroxil suspension in adult horses was characterized as poor and erratic. In a study done in foals, oral bioavailability ranged from 36% to 99.8% (mean, 58.2%); mean elimination half-life was 3.75 hours after oral dosing.[7,8] Oral absorption becomes more rapid as foals age, but bioavailability decreases significantly.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, cephalosporins should be used cautiously in patients that have a documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cefamycins, carbapenems).

Cefadroxil should be used with caution in patients with significant renal impairment; dose adjustment may be required. However, this guidance is likely only necessary for patients with severe renal disease, and there is no guidance for optimal dose and frequency changes in animals with renal disease. In humans with significant renal dysfunction, dosing frequency is decreased.[9]

In general, oral antibiotics such as cefadroxil should not be used for patients with septicemia, shock, or other grave illnesses, as absorption of the medication from the GI tract may be significantly delayed or diminished.

Cefadroxil can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefaDROXil.

Some formulations of cefadroxil may contain sodium benzoate or benzoic acid.

Adverse Effects

Adverse effects with cephalosporins are usually mild and have a relatively low frequency of occurrence. When cephalosporins are given orally, they may cause GI effects (eg, anorexia, vomiting, diarrhea). Administering the drug with a small meal may help alleviate these effects. Because cephalosporins may alter GI microbiota, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or anaphylaxis. The use of cephalosporins in patients that are documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that up to 15% of patients that are hypersensitive to penicillins will also be hypersensitive to cephalosporins.[10] The incidence of cross-reactivity in veterinary patients is unknown.

Although cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity, at clinically used doses in patients with normal renal function, the risks for the occurrence of this adverse effect appear minimal.

High doses or prolonged use of cephalosporins have been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Coombs test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

Reproductive/Nursing Safety

Cephalosporins cross the placenta. Cefadroxil did not demonstrate teratogenicity in laboratory animals,[9] and cefadroxil is considered compatible with human pregnancy.[11]

Cefadroxil is excreted into human breast milk in clinically insignificant amounts[12] and the drug is considered compatible with nursing.[11]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other, more serious effects are possible. See ***Adverse Effects***.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving cefadroxil and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Nephrotoxic Drugs**: Concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (eg, amphotericin B) with cephalosporins is somewhat controversial. Cephalosporins could potentially cause additive nephrotoxicity when used with these drugs, but this interaction has only been well-documented with cephaloridine (no longer marketed). Caution is advised when using these drug combinations.

- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives
- **Vitamin K Antagonists:** Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists (eg, warfarin).

Laboratory Considerations

- Cephalosporins may cause false-positive **urine glucose determinations** when a cupric sulfate solution (Benedict's solution, *Clinitest®*, Fehling's solution) is used. Tests using glucose oxidase (*TesTape®, Clinistix®*) are not affected by cephalosporins.
- When the Jaffe reaction is used to measure **serum or urine creatinine**, high-dose cefadroxil may cause falsely elevated values.
- In humans, particularly in those with azotemia, cephalosporins may cause a false-positive direct **Coombs test.**
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.
- Cephalosporins may falsely decrease serum **albumin** measurements.
- **Cefazolin-surrogate susceptibility** is not a good predictor of cefadroxil susceptibility.[13,14]

Dosages

DOGS:

Susceptible genitourinary or skin/soft tissue infections (label dosage; FDA-approved): **NOTE**: The label specifies treatment duration times for various infections, but these duration times are outdated and and may no longer apply.

- **Skin/soft tissue infections caused by susceptible strains of *Staphylococcus aureus*:** 22 mg/kg PO twice daily (ie, every 12 hours) for a minimum of 3 days[15,16]; continue treatment for at least 48 hours after the dog becomes afebrile or clinical signs resolve. If no improvement is seen after 3 days of treatment, discontinue therapy and re-evaluate the case. Do not treat for more than 30 days.
- **Genitourinary infections (cystitis) caused by susceptible strains of *Escherichia coli, Proteus mirabilis, and S aureus*:** 22 mg/kg PO twice daily (ie, every 12 hours) for a minimum of 7 days[15,16]; continue treatment for at least 48 hours after the dog becomes afebrile or clinical signs resolve. If no improvement is seen after 3 days of treatment, discontinue therapy and re-evaluate the case. Do not treat for more than 30 days.

Superficial pyoderma (extra-label): 22 – 35 mg/kg PO twice daily (ie, every 12 hours) for 28 to 42 days[1,17]

Deep pyoderma (extra-label): Either 20 mg/kg PO twice daily (ie, every 12 hours) or 40 mg/kg PO once daily (ie, every 24 hours) for 21 days[1]

Bacterial cystitis (extra-label): 12 – 25 mg/kg PO every 12 hours for 3 to 5 days.[18] **NOTE**: Chronic urethrocystitis or pyelonephritis are best initially treated with a veterinary-labeled fluoroquinolone or cefpodoxime, pending culture and susceptibility results.[18]

CATS:

Susceptible infections (label dosage; FDA-approved): **NOTE**: The label specifies treatment frequency and duration times for various infections, but these duration times are outdated and may no longer apply.

- **Skin/soft tissue infections caused by susceptible strains of *S aureus*:** 22 mg/kg PO twice daily (ie, every 12 hours) for a minimum of 3 days[15,16]; continue treatment for at least 48 hours after the cat becomes afebrile or clinical signs resolve. If no improvement is seen after 3 days of treatment, discontinue therapy and re-evaluate the case. Do not treat for more than 30 days.
- **Skin/soft tissue infections caused by susceptible strains of *Pasteurella multocida, S aureus, Staphylococcus epidermidis,* and *Streptococcus* spp:** 22 mg/kg PO once daily (ie, every 24 hours)[15,16]; continue treatment for at least 48 hours after the cat becomes afebrile or clinical signs resolve. If no improvement is seen after 3 days of treatment, discontinue therapy and re-evaluate the case. Do not treat for more than 21 days.
- **Genitourinary infections (cystitis) caused by susceptible strains of *E coli, P mirabilis, and S aureus*:** 22 mg/kg PO twice daily (ie, every 12 hours) for a minimum of 7 days[15,16]; continue treatment for at least 48 hours after the cat becomes afebrile or clinical signs resolve. If no improvement is seen after 3 days of treatment, discontinue therapy and re-evaluate the case. Do not treat for more than 30 days.

FERRETS:

Susceptible infections (extra-label): 15 – 20 mg/kg PO twice daily[19]

Monitoring

- Culture and susceptibility testing as indicated by clinical condition
- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is often all that is required.
- Patients with diminished renal function may require intensified monitoring of renal parameters (eg, BUN, creatinine, urinalysis).

Client Information

- This medicine can be given with or without food, but GI side effects (eg, loss of appetite, vomiting, diarrhea) might be prevented if given with food. If your animal vomits or acts sick after receiving this medication on an empty stomach, try administering the next dose with food or a small treat. If vomiting continues, contact your veterinarian.
- The most common side effects are vomiting, diarrhea, and loss of appetite.
- Be sure to give this antibiotic to your pet as long as your veterinarian has prescribed, even if your animal seems better.
- This antibiotic has an odor that resembles cat urine.

Chemistry/Synonyms

A semisynthetic cephalosporin antibiotic, cefadroxil occurs as a white to yellowish-white, crystalline powder that is soluble in water and slightly soluble in alcohol. The commercially available product is available as the monohydrate.

Cefadroxil may also be known as BL-S578, cefadroxilum, cephadroxil, or MJF-11567-3; many trade names are available.

Storage/Stability

Cefadroxil tablets, capsules, and powder for oral suspension should be stored at room temperature (20°C-25°C [68°F-77°F]) with temperature excursions (15°C-30°C [59°F-86°F]) permitted in tight containers. After reconstitution, the oral suspension is stable for 14 days when kept refrigerated (4°C[39°F]).[15]

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Cefadroxil Oral Tablets: 50 mg, 100 mg, 200 mg, and 1000 mg tablets; *Cefa-tabs®*; (Rx). FDA-approved for use in dogs and cats. NADA #119-688. Product is not marketed but remains listed in the FDA Green Book.

Cefadroxil Powder for Oral Suspension: 50 mg/mL in 15 mL and 50 mL bottles; *Cefa-Drops®*; (Rx). FDA-approved for use in dogs and cats. NADA #140-684. Product is not marketed but remains listed in the FDA Green Book.

HUMAN-LABELED PRODUCTS:
Cefadroxil Oral Tablets: 1 g; generic; (Rx)

Cefadroxil Oral Capsules: 500 mg; generic; (Rx)

Cefadroxil Powder for Oral Suspension: 250 mg/5 mL (50 mg/mL) and 500 mg/5 mL (100 mg/mL) in 50 mL, 75 mL (500 mg/5 mL only), and 100 mL; generic; (Rx)

Cefazolin

(sef-***a***-zoe-lin) *Ancef®, Kefzol®, Zolicef®*

First-Generation Cephalosporin

Prescriber Highlights

- ► First-generation parenteral cephalosporin; often used for surgical prophylaxis for gram-positive coverage
- ► May cause hypersensitivity reactions
- ► Can cause pain on IM injection; give IV slowly over 3 to 5 minutes (or more, as needed).

Uses/Indications

Cefazolin is used in several animal species when an injectable first-generation cephalosporin is indicated. Cefazolin is used for surgical prophylaxis, particularly for orthopedic surgery and other procedures in which *Staphylococcus* spp is the most common cause of surgical site infections.

Because cefazolin is a time-dependent antibiotic, where time above minimal inhibitory concentration (MIC) is the critical factor, constant rate IV infusion protocols may be used to maintain serum and tissue concentrations above MIC.

The World Health Organization (WHO) has designated cefazolin as a Highly Important antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) has designated cefazolin as a Veterinary Highly Important Antimicrobial (VHIA) Agent in bovine, caprine, and ovine species.[2]

Pharmacology/Actions

Cephalosporins are considered time dependent and bactericidal against susceptible bacteria, and they act by inhibiting mucopeptide synthesis in the cell wall, which results in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (eg, carboxypeptidases, transpeptidases, endopeptidases) in the bacterial cytoplasmic membrane that are involved in cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins [PBPs]) help explain the differences in spectrums of activity of these drugs that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, cephalosporins are generally considered to be more effective against actively growing bacteria.

Cefazolin is a first-generation cephalosporin that exhibits activity against most gram-positive pathogens (excluding enterococci) and variable to poor coverage against most gram-negative pathogens. Cephalosporins are active in vitro against streptococci, staphylococci, *Proteus mirabilis,* and some strains of *Escherichia coli*, *Klebsiella* spp, *Actinobacillus* spp, and *Pasteurella* spp. With the exception of *Bacteroides fragilis*, most anaerobes are susceptible to first-generation cephalosporins. Bacterial resistance is of increasing concern, particularly with methicillin-resistant staphylococci and extended spectrum beta-lactamase (ESBL) producing Enterobacterales. Cefazolin is inactive against *Enterococcus* spp, *Pseudomonas* spp, *Rickettsia* spp, mycobacteria, *Mycoplasma* spp, fungi, and viruses.

Although the spectrum of activity among first-generation cephalosporins are similar, there may be differences in their individual MICs. Plasma concentrations of less than or equal to 2 µg/mL are believed to be effective for most bacteria not inherently resistant to the drug or those that have acquired resistance. For bactericidal activity, cephalosporin levels should exceed bacterial MIC for at least 40% of the dose interval for staphylococcal infections and ≈60% of the dose interval for streptococcal infections.[3]

Pharmacokinetics

Cefazolin is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum concentrations; it is excreted unchanged by the kidneys into the urine. Elimination half-life may be significantly prolonged in patients with severely diminished renal function.

In dogs, peak concentrations occur ≈30 to 90 minutes after IM administration. The apparent volume of distribution at steady state (Vd_{ss}) is 700 mL/kg, and total body clearance is 10.4 mL/kg/minute. Elimination half-life is ≈45 to 70 minutes.[4,5] In one study of dogs undergoing gonadectomy and receiving 25 mg/kg IV, cefazolin Vd_{ss} and clearance were 400 mL/kg and 150 mL/kg/hour; half-life was 3 hours.[6] Approximately 64% of clearance can be attributed to renal tubular secretion. Cefazolin is ≈16% to 28% bound to plasma proteins in dogs. Penetration into pancreatic tissue is poor. Cefazolin concentration in interstitial fluid remained above 4 µg/mL for 4 hours after a single dose of 22 mg/kg IV was administered to beagles and for 5 hours after 22 mg/kg IV and 22 mg/kg IM (combined, 44 mg/kg) were administered to beagles.[4] Administration of 22 mg/kg IV every 2 hours during surgery was predicted to maintain serum cefazolin concentrations at least 10 times MIC for 3 to 4 hours; 8 mg/kg IV every hour during surgery was also suggested as an option.[5] A concentration of cefazolin (ie, 4 µg/mL) in the surgical wound was maintained for longer than 12 hours by administering cefazolin (20 mg/kg IV) at the beginning of surgery and repeating administration via SC injection 6 hours later.[7]

In cats given a single dose of cefazolin 20 mg/kg IV, peak plasma concentration (initial peak plasma concentration [$Cp_{(0)}$]) was 134.8 µg/mL, Vd_{ss} was 290 mL/kg, and elimination half-life was 1.2 hours. Eighty-four percent of the dose was eliminated within 6 hours after administration. Tissue:plasma concentration ratios ranged from 0.18 to 0.58, and plasma concentration remained above 2 µg/mL for up to 4 hours in all cats.[8]

In horses, the apparent Vd_{ss} is 190 mL/kg; total body clearance is 5.51 mL/kg/minute with a serum elimination half-life of 38 minutes when given IV and 84 minutes after IM injection (gluteal muscles). Bioavailability after IM administration is ≈80%. Cefazolin is about 4% to 8% bound to equine plasma proteins.[9] Probenecid administration is expected to alter the kinetics of cefazolin because of the significant tubular secretion of cefazolin. One study performed in horses[10] did not show any effect from probenecid, but the authors concluded that the dosage of probenecid used in the study may have been subtherapeutic in this species.

In calves, the volume of distribution is 165 mL/kg, with a terminal elimination half-life of 49 to 99 minutes after IM administration.[11]

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, cephalosporins should be used cautiously in patients with a documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cefamycins, carbapenems). Cephalosporin use in small mammals (eg, hamsters, guinea pigs) may cause antibiotic-induced enterocolitis; a 25% mortality rate was reported in guinea pigs that received 100 mg IM every 6 hours for 5 days.

Cefazolin should be used with caution in patients with significant renal impairment; dose adjustment may be required. However, this guidance is likely only necessary for patients with severe renal disease, and there is no guidance for optimal dose and frequency changes in animals with renal disease. In humans with significant renal dysfunction, dosing frequency is decreased.[12]

Cefazolin can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering (ie, ceFAZolin).

Adverse Effects

Adverse effects with cephalosporins are usually mild and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dosage can occur with these agents and can manifest as a rash, fever, eosinophilia, lymphadenopathy, or anaphylaxis. Use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that up to 15% of patients that are hypersensitive to penicillins will also be hypersensitive to cephalosporins.[13] The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site with IM administration, although this effect occurs less with cefazolin than with other related agents. Sterile abscesses or other severe local tissue reactions are possible but are much less common. Thrombophlebitis is also possible after IV administration of this drug class.

Although cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinically used doses in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal.

High doses or prolonged use have been rarely associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Coombs test, interstitial nephritis, and tubular necrosis. These effects, with the exception of tubular necrosis and neurotoxicity, have an immunologic component. Cefazolin may be more likely than other cephalosporins to cause seizures at very high doses. A case of status epilepticus was reported after cefazolin was mistakenly injected into the subarachnoid space of a dog undergoing lumbar myelography[14]; the dog in this case had no previous history of seizures.

Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and, although safety during pregnancy has not been firmly established, there are no documented teratogenic problems associated with these drugs. Cefazolin should only be used when the potential benefits outweigh the risks. In humans, cefazolin is compatible with pregnancy.[15] The pharmacokinetics of cefazolin are changed in pregnant women, resulting in a shorter half-life, a smaller area under the curve (AUC), and an increased clearance and volume of distribution.

Cefazolin is compatible with breastfeeding in humans, although it is distributed into milk and could potentially alter the neonatal gut flora. Cefazolin should be used with caution in nursing dams.

Overdose/Acute Toxicity

Cefazolin LD_{50} in rats and mice is greater than 2000 mg/kg.[16] Cephalosporin overdoses are unlikely to cause significant problems, but other effects are possible (see ***Adverse Effects***). Very high doses given rapidly IV can cause seizures.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with cefazolin either have been reported or are theoretical in humans or animals and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks must be weighed and additional monitoring performed when appropriate.

- **Aminoglycosides and Other Nephrotoxic Drugs**: Concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (eg, **amphotericin B, furosemide**) with cephalosporins is somewhat controversial. Cephalosporins could potentially cause additive nephrotoxicity when used with these drugs, but this interaction has only been well-documented with cephaloridine (no longer marketed). Caution is advised when using these drug combinations.
- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives
- **Vitamin K Antagonists** (eg, **warfarin)**: Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists.

Laboratory Considerations

- Cephalosporins may cause false-positive **urine glucose determinations** when used with cupric sulfate solution (eg, Benedict's solution, Fehling's solution, *Clinitest*®). Tests using glucose oxidase (eg, *Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- When the Jaffe reaction is used to measure **serum or urine creatinine**, high-dose cefazolin may cause falsely elevated values.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.
- In humans, particularly those with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.
- Cephalosporins may falsely decrease serum **albumin** measurements.
- Prothrombin time may be increased.

Dosages

NOTES:

1. If injecting IM, the drug must be injected into a large muscle mass.
2. IV injections should be given slowly (ie, over 3 to 5 minutes).

DOGS/CATS:

Surgical prophylaxis (extra-label): 20 – 22 mg/kg IV slowly 30 to 60 minutes prior to incision and repeated every 90 to 120 minutes until wound closure

Susceptible infections (extra-label):

a) 15 – 35 mg/kg IV (slowly), IM (large muscle), or SC every 6 to 8 hours. A typical dosage is 20 mg/kg every 8 hours.

b) **CRI**: Loading dose of 1.3 mg/kg IV slowly, then 1.2 mg/kg/hour IV[17]

c) **Empirical dosage adjustment for renal insufficiency in cats**: 20 mg/kg every 12 hours IV (slow), IM (large muscle), or SC if CrCL is greater than or equal to 0.15 mL/kg/minute (roughly a serum creatinine up to 5.5 mg/dL); decrease frequency to every 24 hours if CrCL is less than 0.15 mL/kg/minute (roughly a serum creatinine of 8.5 mg/dL or more).[18] **NOTE:** These recommendations have been extrapolated from human data.

HORSES:

Susceptible infections (extra-label): 25 mg/kg IV slowly or IM every 6 to 8 hours

REPTILES:

Susceptible infections in chelonians (extra-label): 22 mg/kg IM once daily (every 24 hours)[19]

Monitoring

- Culture and susceptibility testing as indicated by clinical condition
- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is often all that is required.
- For patients with diminished renal function, consider intensified monitoring of renal parameters (eg, BUN, creatinine, urinalysis).

Chemistry/Synonyms

Commercial cefazolin dosage forms contain cefazolin sodium. Cefazolin sodium, an injectable, semisynthetic cephalosporin antibiotic, occurs as a practically odorless (or with faint odor), white to off-white, crystalline powder or lyophilized solid. It is freely soluble in water and very slightly soluble in alcohol. Each gram of the injection contains 2 mEq of sodium. After reconstitution, the solution for injection has a pH of 4.5 to 6 and a light-yellow to yellow color.

Cefazolin sodium may also be known as 46083, cefazolinum natricum, cephazolin sodium, or SKF-41558; many trade names are available.

Storage/Stability

Cefazolin sodium powder for injection and solutions for injection should be protected from light. The powder for injection should be stored at room temperature (20°C-25°C [68°F-77°F]) but may be exposed to 15°C to 30°C (59°F-86°F) temperatures; temperatures above 40°C (104°F) should be avoided. The frozen solution for injection should be stored at temperatures no higher than -20°C (-4°F). Once thawed (at room temperature or under refrigeration), the solution will be stable for 48 hours at room temperature or 30 days if refrigerated. The solution should not be refrozen.

After reconstitution, the solution will be stable for 24 hours if kept at room temperature or for 10 days if refrigerated (5°C [41°F]). If, after reconstitution, the solution is immediately frozen in the original container, the preparation will be stable for at least 12 weeks when stored at -20°C (-4°F).

Darkening of cefazolin powder or solution may occur but does not affect potency.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, concomitant drugs, and diluent used; clinicians should consult specialized references or a hospital pharmacist for more specific information.

The following solutions are reportedly **compatible** with cefazolin: amino acids 4.25%/dextrose 25%, D_5W in Ringer's, D_5W in lactated Ringer's, D_5W in sodium chloride 0.2% to 0.9%, D_5W, $D_{10}W$, Ringer's injection, lactated Ringer's injection, and normal saline. The following drugs are reportedly **Y-site compatible** with cefazolin: amiodarone in normal saline (incompatible in dextrose), atracurium, calcium gluconate, famotidine, cyclophosphamide, dexmedetomidine, diltiazem, doxorubicin liposome, heparin, hetastarch, regular insulin, lidocaine, magnesium sulfate, midazolam, metronidazole, morphine, propofol, ranitidine, vancomycin (concentration-dependent), vecuronium, verapamil, and vitamin B-complex.

The following drugs or solutions are reportedly **incompatible** or only compatible in specific situations with cefazolin: amikacin, ascorbic acid injection, bleomycin, calcium chloride/gluconate, cimetidine, cisapride, erythromycin gluceptate, lidocaine, oxytetracycline, pentobarbital, polymyxin B, tetracycline, and vitamin B-complex with C injection.

Cefazolin beads prepared by addition to polymethyl methacrylate (PMMA) reduced bead compression strength but not bending strength.[20] Neither the heat of polymerization nor steam sterilization affected cefazolin activity in PMMA beads. Under experimental conditions, antibacterial effect was maintained for 9 days[21] and 30 days,[22] but a combination of cefazolin and amikacin did not maintain the antibacterial effect.[22] Approximately 35% of the total amount of cefazolin incorporated into PMMA beads was eluted over 15 days as compared with 95% of cefazolin in calcium sulfate (ie, plaster of Paris) beads. Freshly prepared cefazolin beads in calcium sulfate eluted more drug than stored beads, but storage conditions (eg, exposure to light, room temperature, refrigeration) over 6 months had little effect on drug elution.[23]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefazolin Sodium Powder for Injection: 500 mg, 1 g, 2 g, 10 g, and 20 g, in vials and piggyback vials; 100 g and 300 g in flex containers; generic; (Rx)

Cefazolin Sodium for Injection (Iso-osmotic IV infusion): 1 g in 4% dextrose and 2 g in 3% dextrose, 50 mL plastic containers, or duplex bags; generic; (Rx)

References

Cefepime

(***sef***-eh-pim) *Maxipime®*

Fourth-Generation Cephalosporin

Prescriber Highlights

- ► Injectable fourth-generation cephalosporin that is more active against some gram-negative and gram-positive bacteria than third-generation cephalosporins
- ► Potentially useful for treating neonatal foals and dogs with serious infections, where more commonly used antimicrobials are not options
- ► Limited clinical experience with this drug in veterinary medicine
- ► Adverse GI effects (eg, diarrhea) are possible. Injection site reactions have occurred following IM injections in dogs.

Uses/Indications

Cefepime is a semi-synthetic fourth-generation cephalosporin with enhanced activity against many gram-negative and gram-positive pathogens. It may be useful in treating severe infections in dogs or foals, particularly when aminoglycosides, fluoroquinolones, or other more commonly used beta-lactam drugs are ineffective or contraindicated. As with other fourth-generation cephalosporins, the use of this critically important human drug in veterinary patients should be limited to patients with culture and susceptibility testing results that indicate its use is necessary.

The World Health Organization (WHO) has designated cefepime as a Critically Important, Highest Priority antimicrobial for human medicine.[1]

Pharmacology/Actions

Cefepime, like other cephalosporins, is usually bactericidal and acts by inhibiting cell wall synthesis. It is classified as a fourth- generation cephalosporin, implying it has increased gram-negative activity (particularly against *Pseudomonas* spp) and better activity against many gram-positive bacteria than would be seen with the third-generation agents. Cefepime has activity against many gram-positive aerobes, including staphylococci, streptococci, and Enterobacteriaceae (eg, *Escherichia coli, Enterobacter* spp). Cefepime has good activity against many gram-negative bacteria and has better activity (than other cephalosporins) against many Enterobacteriaceae, including *Enterobacter* spp, *E coli*, *Proteus* spp, and *Klebsiella* spp. It is

considered an antipseudomonal cephalosporin, with activity against *Pseudomonas* spp being similar to, or slightly less than, that of ceftazidime (a third-generation cephalosporin). It has limited activity against extended-spectrum beta-lactamase (ESBL) producing bacteria.

Cefepime also has activity against certain atypical organisms like *Mycobacterium avium-intracellulare* complex but is not a suitable antibiotic for monotherapy.

Some anaerobes are susceptible to cefepime; however, *Bacteroides* spp is typically resistant.

Cefepime does not readily induce beta-lactamases and is highly resistant to hydrolysis by them. Cefepime is ineffective against enterococci, *Listeria monocytogenes,* and methicillin-resistant staphylococci.

Pharmacokinetics

Cefepime is not absorbed from the GI tract and must be administered parenterally. In dogs, cefepime's volume of distribution at steady state is ≈0.14 L/kg, elimination half-life is about 1.1 hours, and clearance is about 0.13 L/kg/hour.[2]

In neonatal foals, cefepime's volume of distribution at steady state is ≈0.18 L/kg, elimination half-life is about 1.65 hours, and clearance is about 0.08 L/kg/hour.[2]

In calves, the volume of distribution at steady state is ≈0.21 L/kg, elimination half-life is about 2.38 hours, and clearance is about 1.1 mL/minute/kg. Cefepime has a bioavailability of 95.7% following IM administration in this species.[3]

In ewes, the volume of distribution at steady state is ≈0.32 L/kg, and the elimination half-life is about 1.76 hours. Clearance is 2.37 mL/minute/kg. Cefepime has a bioavailability of 86.8% after IM administration.[4]

In humans, the volume of distribution is about 18 L in adults; 20% of the drug is bound to plasma proteins.[5] The elimination half-life is about 2 hours. Approximately 85% of a dose is excreted unchanged into the urine; less than 1% is metabolized.

Contraindications/Precautions/Warnings

No specific information is available regarding contraindications in veterinary patients. Cefepime is contraindicated in human patients that are hypersensitive to it or other cephalosporins. Dosage adjustment is recommended in humans with severe renal impairment.

Cefepime can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefePIME.

Adverse Effects

As use of cefepime in animals has been very limited, a comprehensive adverse effect profile has not been determined.

There are some reports of dogs or foals having loose stools or diarrhea after receiving cefepime.[2] IM injections may be painful (may be alleviated by combining with lidocaine 1% as diluent). Lameness and injection site edema were observed in dogs receiving IM cefepime.[6]

Human patients generally tolerate cefepime well. Injection site inflammation and rashes occur in ≈1% of treated patients.[5] GI effects (eg, dyspepsia, diarrhea) occur in less than 1% of treated patients. Hypersensitivity reactions, including anaphylaxis, are possible. In humans, it is estimated that up to 15% of patients who are hypersensitive to penicillins will also be hypersensitive to cephalosporins.[7] Rarely, patients with renal dysfunction who have received cefepime without any dosage adjustments will develop neurologic effects (see ***Overdose/Acute Toxicity*** section).

Reproductive/Nursing Safety

Studies performed in pregnant mice, rats, and rabbits demonstrated no overt fetal harm.[5]

Cefepime enters maternal milk in low concentrations, and alteration to gut microbiome is possible in the nursing offspring with resultant diarrhea. It is considered compatible with breastfeeding in pregnant women.[8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No specific information was located regarding acute toxicity in veterinary patients. Acute oral cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other, more serious effects are possible. See ***Adverse Effects***.

Humans with impaired renal function receiving inadvertent overdoses have developed encephalopathy, seizures, and neuromuscular excitability.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefepime and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: Potential for increased risk for nephrotoxicity; monitor renal function
- **probenecid**: Probenecid may increase the serum concentration of cephalosporins.
- **vitamin k antagonists** (eg, **warfarin)**: Cephalosporins may increase the concentration of vitamin K antagonists.

Laboratory Considerations

- Cefepime may cause false-positive **urine glucose determinations** when using the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest*®); tests utilizing glucose oxidase (*TesTape*®, *Clinistix*®) are not affected by cephalosporins.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test.**

Dosages

DOGS/CATS:

Susceptible infections (extra-label): Based on pharmacokinetic studies, 40 mg/kg IV over 30 minutes every 6 hours has been recommended for dogs.[2] Anecdotal sources state that it can be given to dogs and cats at 50 mg/kg IM or IV every 8 hours or as a CRI using 1.4 mg/kg IV as a loading dose, followed by 1.1 mg/kg/hour IV CRI.

HORSES:

Susceptible gram-negative infections in foals: 11 mg/kg IV over 30 minutes every 8 hours.[2,9] Its use has been limited primarily to neonates for whom aminoglycoside cannot be used.

Monitoring

- Clinical efficacy
- Patients with renal insufficiency should have periodic renal function monitored.

Client Information

- This medicine should only be given by veterinary professionals.

Chemistry/Synonyms

Cefepime HCl occurs as a white to off-white, non-hygroscopic powder that is freely soluble in water.

Cefepime may also be known as BMY-28142, cefepimi, or cefepima; internationally registered trade names include *Axepime®*, *Biopime®*, *Cefepen®*, *Ceficad®*, *Cemax®*, *Cepim®*, *Cepimix®*, *Forpar®*, *Maxcef®*, *Maxipime®*, and *Maxil®*.

Storage/Stability

Store the powder for injection and *Duplex®* containers between 20°C and 25°C (68°F-77°F), with excursions to 15°C to 30°C (59°F-86°F) allowed by some manufacturers. Protect the powder from light. Some manufacturers store the powder between 2°C and 25°C (46°F-77°F). Refer to package insert for further information.

Generally, the solution is stable for up 24 hours at room temperature and up to 7 days if kept refrigerated.

Store *GALAXY®* containers at or below -20°C (-4°F). Once thawed, the solution is stable for 7 days under refrigeration or 24 hours at room temperature.

Compatibility/Compounding Considerations

It is possible to reconstitute and administer cefepime with several diluents, including normal saline and D_5W. Drugs that may be admixed with cefepime include amikacin (but not gentamicin or tobramycin), ampicillin up to 40 mg/mL, and clindamycin. These admixtures have varying times at which they remain stable. Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefepime Powder for Injection: 500 mg, 1 g, and 2 g in 15 mL and 20 mL vials, ADD-Vantage vials, and 100 mL piggyback bottles; *Maxipime®*, generic; (Rx)

Cefepime Injection Solution: 1 g/50 mL, and 2 g/50 mL single-dose *DUPLEX®* containers with 5% dextrose; generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Cefixime

(sef-***ix***-eem) *Suprax®*

Third-Generation Cephalosporin

Prescriber Highlights

- ► Oral third-generation cephalosporin that may be useful in dogs and cats, but that has a limited spectrum compared to most other third-generation cephalosporins
- ► Contraindications include hypersensitivity to cefixime or other cephalosporins.
- ► May need to adjust dose if the patient has renal disease
- ► Adverse effects primarily include GI distress, but hypersensitivity reactions are possible.

Uses/Indications

Cefixime is a third-generation cephalosporin with broad-spectrum antibacterial properties. Uses for cefixime are limited in veterinary medicine, in large part because of the availability of other approved third-generation cephalosporins. Its use should be reserved for those times when infections are caused by susceptible gram-negative organisms where oral treatment is indicated or when FDA-approved fluoroquinolones are either contraindicated or ineffective. Given the enhanced antibacterial spectrum and similarity in the adverse effects compared to other third-generation cephalosporins (eg, cefpodoxime), there would rarely be an indication for this antibiotic in veterinary patients.

The World Health Organization (WHO) has designated cefixime as a Critically Important, Highest Priority antimicrobial for human medicine.[1]

Pharmacology/Actions

Like other cephalosporins, cefixime inhibits bacterial cell wall synthesis. It is considered bactericidal. Cefixime's primary spectrum of activity is against gram-negative bacteria in the family Enterobacteriaceae, including *Escherichia* spp, *Proteus* spp, and *Klebsiella* spp. It is resistant to penicillinases but is inactivated by extended-spectrum beta-lactamases (EBSLs). Unlike veterinary third-generation cephalosporins, it has limited activity against gram-positive bacteria. Against streptococci, it is efficacious but has a limited effect. Cefixime is not efficacious against *Bordetella* spp, *Campylobacter* spp, *Enterobacter* spp, *Proteus* spp, *Pseudomonas aeruginosa,* and *Enterococcus* spp; it has limited efficacy against anaerobes. Because of the difference in the spectrum of cefixime compared to commonly tested third-generation cephalosporins (eg, ceftiofur, cefpodoxime, cefovecin), specific testing for cefixime susceptibility is required.

Pharmacokinetics

Cefixime is relatively rapidly absorbed after oral administration. Bioavailability in the dog is about 50%. Food may impede the rate, but not the extent, of absorption. The suspension may have a higher bioavailability than tablets. The drug is highly bound to plasma proteins in the dog (about 90%).[2] It is unknown if the drug penetrates into the CSF.

Elimination of cefixime is by both renal and nonrenal means, but serum half-lives are prolonged in patients with decreased renal function. In dogs, the elimination half-life is about 7 hours.[2]

Contraindications/Precautions/Warnings

Cefixime is contraindicated in patients hypersensitive to it or other cephalosporins. Because cefixime is excreted by the kidneys, dosages and/or dosing frequency may need to be adjusted in patients with significantly diminished renal function. Use with caution in patients with seizure disorders and patients allergic to penicillins.

Cefixime can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefIXIME.

Adverse Effects

Cefixime use in animals has been limited, and a comprehensive adverse effect profile has not been determined. Adverse effects in dogs may include GI distress (eg, vomiting) and hypersensitivity reactions (eg, urticaria and pruritus, possibly fever).

In humans, it is estimated that up to 15% of patients who are hypersensitive to penicillins will also be hypersensitive to cephalosporins.[3]

Reproductive/Nursing Safety

Cefixime is has not been shown to be teratogenic but should only be used during pregnancy when indicated.[4] In humans, cefixime is considered compatible with pregnancy.[5] Cefixime is considered compatible with breastfeeding in humans.[5]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems, but other effects are possible. See ***Adverse Effects***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefixime and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives.
- **Salicylates** (eg, **aspirin**): May displace cefixime from plasma protein binding sites; the clinical significance is unclear.
- **Vitamin K Antagonists** (eg, **warfarin**): Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists.

Laboratory Considerations

- Cefixime may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Fehling's solution, Benedict's solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected.
- If using the nitroprusside test for determining **urinary ketones,** cefixime may cause false-positive results.
- May cause a false-positive direct **Coombs test**.
- When using the Jaffe reaction to measure serum or urine creatinine, cefixime in high doses may cause falsely elevated values.

Dosages

DOGS/CATS:

Susceptible infections (extra-label): Dosage recommendations range from 5 mg/kg PO once or twice daily for UTIs, to 10 – 12.5 mg/kg PO twice daily for systemic infections. As other third-generation cephalosporins (eg, cefpodoxime) have a superior antibacterial spectrum, there would rarely be an indication for this antibiotic in veterinary patients.

Monitoring

- Efficacy
- Adverse effects

Client Information

- This medicine works best when given without food. If your animal vomits or develops a lack of appetite while receiving the medicine, try administering with food.
- The most common side effects are diarrhea, vomiting, and loss of appetite.
- Be sure to give the medication to your animal as long as your veterinarian has prescribed, even if your animal seems better.
- Cephalosporin antibiotics have an odor that resembles cat urine.

Chemistry/Synonyms

Cefixime is an oral third-generation semisynthetic cephalosporin antibiotic. It is available commercially as the trihydrate. Cefixime occurs as a white to slightly yellowish-white crystalline powder with a characteristic odor and a pK_a of 3.73. Solubility in water is pH-dependent. At a pH of 3.2, 0.5 mg/mL is soluble and 18 mg/mL at pH 4.2. The oral suspension is strawberry flavored and, after reconstitution, has a pH of 2.5 to 4.2.

Cefixime may also be known as cefiximum, CL-284635, FK-027, FR-17027, and *Suprax*®; many internationally registered trade names are available.

Storage/Stability

Cefixime powder for suspension should be stored at room temperature (20°C-25°C [68°F-77°F]) in tight containers. The reconstituted oral suspension may be stored in the refrigerator or at room temperature and should be discarded after 14 days.

Compatibility/Compounding Considerations

No specific information noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefixime Oral Capsules: 400 mg; *Suprax*®; (Rx)

Cefixime Oral Chewable Tablets: 100 mg and 200 mg; *Suprax*®; (Rx)

Cefixime Powder for Oral Suspension: 100 mg/5 mL (20 mg/mL) in 50 mL, 75 mL, 100 mL; 200 mg/5 mL (40 mg/mL) in 25 mL, 37.5 mL, 50 mL, 75 mL, and 100 mL; 500 mg/5 mL (100 mg/mL) in 10 mL and 20 mL; *Suprax*®; 100 mg/5 mL (20 mg/mL) in 50 mL; 200 mg/5 mL (40 mg/mL) in 50 mL and 75 mL; generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Cefotaxime

(sef-oh-***taks***-eem) *Claforan*®

Third-Generation Cephalosporin

Prescriber Highlights

- ► Third-generation cephalosporin for parenteral use
- ► May cause hypersensitivity reactions, granulocytopenia, or diarrhea
- ► Causes pain on IM injection; give IV over at least 3 to 5 minutes
- ► Extra-label use in food-producing animals is prohibited by the FDA.

Uses/Indications

In the United States, there are no cefotaxime products FDA-approved for veterinary species, but it has been used clinically in several species when an injectable third-generation cephalosporin may be indicated. Uses include treatment of susceptible bone, joint, and CNS infections, surgical prophylaxis, and as empiric therapy for bacterial sepsis.

The World Health Organization has designated cefotaxime as a Critically Important, Highest Priority antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) has designated third-generation cephalosporins as Veterinary Critically Important Antimicrobial (VHIA) agents in veterinary medicine.[2]

Pharmacology/Actions

Cefotaxime is a third-generation injectable cephalosporin agent and, like other cephalosporins, it inhibits bacteria cell wall synthesis. It is bactericidal and time-dependent. Cefotaxime has a relatively wide spectrum of activity against both gram-positive and gram-negative bacteria. Although less active against *Staphylococcus* spp. than the first-generation agents, it still has significant activity against those and other gram-positive cocci, except *Enterococcus* spp. Cefotaxime, like the other third-generation agents, has extended coverage of gram-negative aerobes particularly in the Enterobacterales, including *Klebsiella* spp, *E coli*, and *Salmonella* spp. Many anaerobes are also susceptible to cefotaxime including strains of *Bacteroides fragilis*, *Clostridium* spp, *Fusobacterium* spp, *Peptococcus* spp, and *Peptostreptococcus* spp. Cefotaxime is as effective as penicillins for treating leptospirosis in humans. Like most other third-generation cephalosporins, cefotaxime is ineffective against *Serratia* spp, *Proteus vulgaris, Acinetobacter* spp, *Citrobacter* spp, and *Enterobacter* spp ("SPACE" organisms), as well as *Pseudomonas aeruginosa,* methicillin-resistant staphylococci, and extended spectrum beta-lactamase (ESBL)-producing Enterobacterales.

Because third-generation cephalosporins exhibit specific activities against bacteria, a 30 µg cefotaxime disk should be used when performing Kirby-Bauer disk susceptibility tests for this antibiotic.

Pharmacokinetics

Cefotaxime is not appreciably absorbed after oral administration and must be given parenterally to attain therapeutic serum concentrations. After administration, the drug is widely distributed in body tissues including bone, prostatic fluid (human), aqueous humor, bile,

and ascitic and pleural fluids. Cefotaxime crosses the placenta and activity in amniotic fluid either equals or exceeds that in maternal serum. Cefotaxime distributes into milk in low concentrations. In humans, ≈13% to 40% of the drug is bound to plasma proteins.

Unlike the first-generation cephalosporins (and most second-generation agents), cefotaxime will enter the CSF in therapeutic concentrations (at high dosages) when the patient's meninges are inflamed.

Cefotaxime is partially metabolized by the liver to desacetylcefotaxime which exhibits some antibacterial activity. Desacetylcefotaxime is partially degraded to inactive metabolites by the liver. Cefotaxime and its metabolites are primarily excreted in the urine. Because tubular secretion is involved in the renal excretion of the drug, in several species probenecid has been demonstrated to prolong the serum half-life of cefotaxime.

Pharmacokinetic parameters in certain veterinary species follow: In dogs, the apparent volume of distribution at steady state is 480 mL/kg, and total body clearance is 10.5 mL/minute/kg after IV injection. Serum elimination half-lives of 45 minutes when given IV, 50 minutes after IM injection, and 103 minutes after SC injection have been noted. Bioavailability is about 87% after IM injection and ≈100% after SC injection.[3]

In cats, total body clearance is ≈3 mL/minute/kg after IV injection and the serum elimination half-life is about 1 hour. Bioavailability is about 93% to 98% after IM injection.

In foals, several pharmacokinetic studies have been performed with reported values for volume of distribution ranging from 0.29 L/kg to 4.2 L/kg. Half-life is around 1 hour, and clearance is ≈0.32 L/kg/hour.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients that have a documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cefamycins, carbapenems).

Patients with significant renal impairment may need dosage adjustments.

In humans, rapid administration (less than 1 minute) via central line may cause potentially life-threatening arrhythmias.[4]

Cefotaxime can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man letters: cefoTAXime.

Adverse Effects

Adverse effects with the cephalosporins are usually mild and have a relatively low frequency of occurrence. In humans, the most common adverse effects are pain and inflammation at the injection site, rash, diarrhea, nausea, and vomiting.[5]

Hypersensitivity reactions, unrelated to dosage, can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that up to 15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins.[6] The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site when administered intramuscularly. Sterile abscesses or other severe local tissue reactions are also possible but much less common. Thrombophlebitis is also possible after IV administration of these drugs.

Because the cephalosporins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Coombs test, interstitial nephritis, and tubular necrosis.[7] Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta. No evidence of embryotoxicity or fetotoxicity was observed in pregnant laboratory animals given cefotaxime at doses similar to those used clinically in humans.[4]

Cefotaxime is excreted in milk in small quantities.[4] Alteration of the intestinal biome in the offspring with resultant diarrhea is theoretically possible when using this antibiotic; however, in humans, cefotaxime is considered compatible with breast feeding.[8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems, but other effects are possible (see ***Adverse Effects*** section).

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving cefotaxime and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **gentamicin**): Potential for increased risk of nephrotoxicity—monitor renal function; however, aminoglycosides and cephalosporins may have synergistic or additive actions against some gram-negative bacteria (Enterobacteriaceae).
- **Nephrotoxic Drugs** (eg, **amphotericin B, furosemide**): Concurrent use with cephalosporins could potentially cause additive nephrotoxicity, although this is somewhat controversial. Use together cautiously and monitor renal function closely.
- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives.
- **Vitamin K Antagonists**: Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists (eg, warfarin).

Laboratory Considerations

- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.
- Cephalosporins may cause falsely elevated **17-ketosteroid** values in urine.
- Cefotaxime like most other cephalosporins, may cause a **false-positive urine glucose determination** when using the cupric sulfate solution test (eg, *Clinitest®*, Benedict's solution or Fehling's solution).

Dosages

DOGS/CATS:

Susceptible infections (extra-label):

a) *Intermittent infusion*: Dosage recommendations vary widely, ranging from 20 – 80 mg/kg IV, SC, or IM every 6 to 12 hours. A common anecdotal dosage is 40 – 50 mg/kg IV, SC, or IM every 8 hours. Alternatively, 20 – 40 mg/kg IV, IM, SC every 6 to 12 hours has also been suggested. Use the higher end of the

dosing range when treating meningitis.

b) *Continuous-rate infusion*: initial IV load of 3.2 mg/kg IV followed by 5 mg/kg/hour IV CRI

HORSES:

Susceptible infections (extra-label):

a) **Neonatal foals**: 40 mg/kg IV every 6 hours.[9–11] Alternatively, based on a pharmacokinetic study, foals were given a 40 mg/kg IV bolus followed by a CRI 120 mg/kg/day (5 mg/kg/hour) IV the first day. On subsequent days foals were given a CRI 160 mg/kg/day (6.66 mg/kg/hour) IV.[12]

b) **Foals**: As regional perfusion for adjunctive treatment of septic arthritis: 1 g cefotaxime in 20 mL of saline. Tourniquet above and below joint. Inject antibiotic solution and leave tourniquet in place for 20 minutes.[13]

BIRDS:

Susceptible infections (extra-label):

a) 50 – 100 mg/kg IM or IV every 8 to 12 hours[14]

b) **Ratites** (young birds): 25 mg/kg IM 3 times daily[15]

c) **Bacterial infections, including bacterial hepatitis**: 75 – 100 mg/kg IM or IV every 4 to 8 hours[16,17]

REPTILES:

Susceptible infections (extra-label):

a) 20 – 40 mg/kg IM once daily for 7 to 14 days[18]

b) Chelonians: 20 – 40 mg/kg IM once daily (every 24 hours)[19]

c) Nebulized antibiotic therapy: 100 mg/animal (NOT mg/kg) twice daily[20]

Monitoring

- Efficacy: culture and susceptibility as indicated by underlying condition being treated
- Patients with diminished renal function may require intensified renal monitoring.

Chemistry/Synonyms

A semisynthetic, third-generation aminothiazolyl cephalosporin, cefotaxime sodium occurs as an odorless, white to off-white crystalline powder with a pK_a of 3.4. It is sparingly soluble in water and slightly soluble in alcohol. Potency of cefotaxime sodium is expressed in terms of cefotaxime. One gram of cefotaxime (sodium) contains 2.2 mEq of sodium.

Cefotaxime sodium may also be known as cefotaximum natricum, CTX, HR-756, RU-24756 and *Claforan*®; many other trade names are available internationally.

Storage/Stability

Cefotaxime sodium sterile powder for injection should be stored at 20°C to 25°C (68°F-77°F) and protected from light. Depending on storage conditions, the powder or solutions may darken which may indicate a loss in potency. Cefotaxime is not stable in solutions with pH is greater than 7.5 (sodium bicarbonate). The reconstituted solution is stable for 12 to 24 hours below 22°C (71.6°F) (concentration dependent), 7 to 10 days when stored below 5°C (41°F) in original container and 13 weeks when frozen.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information. All commonly used IV fluids and the following drugs are reportedly **compatible** with cefotaxime: clindamycin, metronidazole, and verapamil.

Do not mix cefotaxime with aminoglycosides.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefotaxime Sodium Powder for Injection: 500 mg, 1 g, 2 g, and 10 g in vials, bottles, infusion bottles and *ADD-Vantage* system vials; *Claforan*®, generic; (Rx)

Cefotetan

(***sef***-oh-tee-tan) *Cefotan*®

Second-Generation Cephalosporin (cephamycin)

Prescriber Highlights

- ► Second-generation parenteral cephalosporin (cephamycin) similar to cefoxitin, with more activity against gram-negative bacteria than first- and other second-generation cephalosporins
- ► Pharmacokinetic profile of cefotetan is better (and it may be more effective against *Escherichia coli* in dogs) than cefoxitin, although cefotetan is rarely used in animals and clinical data are lacking.
- ► Contraindications include hypersensitivity to cefotetan or cephalosporins.
- ► Adverse effects are unlikely; however, cefotetan could increase risk for bruising or bleeding.
- ► If severe renal dysfunction occurs with cefotetan, may need to increase time between doses.

Uses/Indications

Cefotetan is similar to second-generation cephalosporins, with relatively broad-spectrum activity against gram-positive and gram-negative bacteria. It may be a reasonable choice for treating serious infections caused by susceptible bacteria, including *Escherichia coli* or anaerobes. It appears to be well tolerated in small animals and may be given less frequently than cefoxitin. Although extended spectrum beta-lactamase (ESBL)-producing bacteria are often susceptible to cefotetan in vitro, evidence of clinical efficacy is lacking and cephamycins are not recommended.

The World Health Organization (WHO) has designated cefotetan as a Highly Important antimicrobial for human medicine.[1]

Pharmacology/Actions

Cefotetan, like cefoxitin, is a cephamycin antimicrobial and classified with second-generation cephalosporins. It has most of the same properties of second-generation cephalosporins except it is not affected by extended spectrum beta-lactamases (ESBLs) in vitro. It is usually bactericidal and acts by inhibiting mucopeptide synthesis in the bacterial cell wall.

As with second-generation cephalosporins, cefotetan has activity against gram-positive and gram-negative bacteria, with enhanced gram-negative activity compared with first-generation cephalosporins. Cefotetan's in vitro activity against aerobes include *Escherichia coli, Proteus* spp, *Klebsiella* spp, *Salmonella* spp, *Staphylococcus* spp, and *Streptococcus* spp. It also has efficacy against most anaerobes, including *Actinomyces* spp, *Clostridium* spp, *Propionibacterium* spp, and many strains of *Bacteroides* spp. Cefotetan is generally ineffective against *Pseudomonas aeruginosa* and enterococci, as well as methicillin-resistant staphylococci. Because in vitro susceptibility to cefotetan is rarely tested, cefoxitin susceptibility is used for clinical decision making.

Pharmacokinetics

Cefotetan is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum concentrations. The drug is well distributed into most tissues, but it only has limited penetration into the CSF. Cefotetan is primarily excreted unchanged by the kidneys into the urine via both glomerular filtration (primarily) and tubular secretion. Elimination half-lives may be significantly prolonged in patients with severely diminished renal function.

Contraindications/Precautions/Warnings

Cephamycins are contraindicated in patients that have a history of hypersensitivity to them. Because there may be cross-reactivity, use cephamycins cautiously in patients that are documented to be hypersensitive to other beta-lactam antibiotics (eg, penicillins, cephalosporins, or carbapenems). Cefotetan may prolong prothrombin time and increase the risk for bruising or bleeding.

Cefotetan can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefoTEtan.

Adverse Effects

There is little information on the adverse effect profile of this medication in veterinary species, but it appears to be well tolerated. In humans, less than 5% of patients report adverse effects.[2] Because cefotetan contains an N-methylthiotetrazole side chain (like cefoperazone), it may have a greater tendency to cause hematologic effects (eg, hypoprothrombinemia) or disulfiram-like reactions (eg, vomiting) than other parenteral cephalosporins.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients that are documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that up to 15% of patients who are hypersensitive to penicillins will also be hypersensitive to cephalosporins.[3] The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site when they are administered IM. Sterile abscesses or other severe local tissue reactions are also possible but are less common. Thrombophlebitis is also possible after IV administration of these drugs.

Even when they are administered parenterally, cephalosporins may alter the gut microbiome, resulting in antibiotic-associated diarrhea or the proliferation of resistant bacteria in the colon (superinfections).

Although cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinically used doses in patients with normal renal function, the risks for the occurrence of this adverse effect appear minimal. High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Coombs test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

Reproductive/Nursing Safety

Cefotetan did not demonstrate impaired fertility or harm to the fetus when administered to laboratory animals.[2,4] In humans, cefotetan is considered compatible with pregnancy.

Cefotetan enters maternal milk in low concentrations, and alteration to gut microbiome is possible in the nursing offspring with resultant diarrhea. Cefotetan is considered compatible with breastfeeding in humans.[5]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems. In mice, the LD_{50} is 5 to 6.4 grams/kg IV, and in rats it is 6.8 to 8.5 grams/kg IV.[4] Cefotetan is unlikely to cause adverse effects, unless it is massively or chronically overdosed; seizures are possible. Treat these overdoses supportively.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to the ***Appendix***.

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving cefotetan and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alcohol** (eg, **ethylene glycol**): A disulfiram reaction is possible.
- **Aminoglycosides/Nephrotoxic Drugs**: The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (eg, **amphotericin B**) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).
- **Probenecid**: May increase the serum concentration of cephalosporins
- **Vitamin K Antagonists** (eg, **warfarin**): Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists.

Laboratory Considerations

- Cefotetan may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's solution, *Clinitest®*, Fehling's solution). Tests utilizing glucose oxidase (*Tes-Tape®*, *Clinistix®*) are not affected.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cefotetan in high doses may cause falsely elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

Dosages

DOGS/CATS:

Susceptible infections (extra-label):

a) 30 mg/kg IV every 8 hours or 30 mg/kg SC every 12 hours[6]

b) Empirical dosage adjustment for renal insufficiency: If creatinine clearance (CrCl) is 0.15 to 0.4 mL/kg/minute (in cats, roughly a serum creatinine between 4.9 – 5.5 mg/dL [433 – 486 µmol/L]) consider dosing once daily (every 24 hours); if CrCl is less than 0.15 mL/kg/minute (in cats, roughly a serum creatinine of 8.5 mg/dL [751 µmol/L]), consider dosing every 48 hours.[7]

Surgical (GI surgery) prophylaxis (extra-label): 30 mg/kg IV 30 to 60 minutes prior to incision. Intraoperative re-dosing should not be required because of the long half-life of the drug.

Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- Patients with diminished renal function may require intensified renal monitoring and decreased dosage frequency. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Chemistry/Synonyms

A semisynthetic cephamycin similar to cefoxitin, cefotetan disodium occurs as a white to pale yellow, lyophilized powder. It is very soluble in water and alcohol. The injection contains ≈3.5 mEq of sodium per gram of cefotetan and after reconstitution has a pH of 4 to 6.5.

Cefotetan Disodium may also be known as ICI-156834, YM-09330, *Apacef®*, *Apatef®*, *Cefotan®*, *Ceftenon®*, *Cepan®*, *Darvilen®*, or *Yamatetan®*.

Storage/Stability

The sterile powder for injection should be stored at 20°C to 25°C (68°F-77°F) and protected from light. A darkening of the powder with time does not indicate lessened potency. After reconstituting with sterile water for injection, the resultant solution is stable for 24 hours at 25°C (77°F), 96 hours at 5°C (21°F), and 7 days at -20°C (-4°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefotetan Disodium Powder for Solution: 1 g, 2 g, and 10 g in 10 mL and 20 mL vials, and 1 g and 2 g premixed bags (with dextrose); generic; (Rx)

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Cefovecin

(sef-oh-***vee***-sin) *Convenia®*

Third-generation Cephalosporin

Prescriber Highlights

- Long-acting injectable cephalosporin labeled in the United States for treatment of skin infections in dogs and cats. Labeled in the United Kingdom, European Union, and Australia as adjunctive treatment for periodontal disease and UTIs.
- Primary benefit is for patients with owners that have difficulty adhering to an oral dosing regimen or when oral antibiotics are not tolerated or absorbed.
- Cefovecin use should be carefully considered as third-generation cephalosporins are critically important for human medicine.
- Usually well tolerated
- Effectiveness against systemic (non-UTI) *Escherichia* coli or other Enterobacterales (eg *Enterobacter* spp) infections is limited because of high protein binding and the inability to reach adequate drug concentrations for an adequate period of time.

Uses/Indications

In the United States, cefovecin is FDA-approved to treat canine skin infections (secondary superficial pyoderma, abscesses, wounds) caused by susceptible strains of *Staphylococcus intermedius* and *Streptococcus canis* (group G) and feline skin infections (wounds, abscesses) caused by susceptible strains of *Pasteurella multocida*.[1] A review of antibiotic efficacy for the treatment of superficial and deep pyoderma in dogs found a good level of evidence for high efficacy when treating superficial pyoderma and a fair level of evidence for moderate to high efficacy when treating deep pyoderma.[2] Cefovecin's long half-life in dogs and cats allows for a single dose or extended dosing intervals (determined by organism susceptibility and minimum inhibitory concentration [MIC]) for treatment of a variety of other infections.

In other countries, cefovecin is labeled for use in dogs to treat skin and soft tissue infections caused by *S pseudintermedius*, beta-hemolytic streptococci, *Escherichia coli,* and/or *P multocida*[3–5]; for treatment of UTI associated with *E coli* and/or *Proteus* spp,[3,4] and/or *S intermedius*[1 1]; and as an adjunctive treatment for mechanical or surgical periodontal therapy for severe infections of the gingival and periodontal tissues associated with *Porphyromonas* spp and *Prevotella* spp.[3–5] In cats, cefovecin is also labeled for treatment of skin infections caused by *P multocida*, *Fusobacterium* spp, *Bacteroides* spp, *Prevotella oralis*, beta-hemolytic streptococci, and/or *S pseudintermedius*, and treatment of UTIs associated with *E coli.*[3,4] The Working Group of the International Society for Companion Animal Infectious Diseases recommended that cefovecin be used for treating UTIs in dogs and cats *only* when oral treatment is problematic.[6]

A study evaluating treatment of upper respiratory tract infections in cats found that single-dose cefovecin appeared to be less effective than oral amoxicillin/clavulanic acid and oral doxycycline.[7] It has been shown that 2 doses of cefovecin, given 14 days apart, appears to be as effective as 4 weeks of therapy with amoxicillin or doxycycline for the treatment of canine Lyme borreliosis.[8,9]

Cefovecin, in combination with diligent supportive therapies (eg, SC fluid therapy, antiemetics) and monitoring, may be a considered for outpatient treatment of canine parvoviral enteritis when hospitalization is not an option.[10]

The World Health Organization (WHO) has designated cefovecin as a Critically Important, Highest Priority antimicrobial for human medicine.[11] The World Organisation for Animal Health (OIE) classifies third-generation cephalosporins as a Veterinary Critically Important Antimicrobial Agent (VCIA).[12]

Pharmacology/Actions

Cefovecin is a third-generation cephalosporin antibiotic, but it is not as active against gram-negative organisms as other antibiotics of this class (eg, cefotaxime, ceftazidime). Cefovecin's mechanism of action in susceptible bacteria, like other beta-lactams, is to bind to and disrupt the actions of bacterial penicillin-binding proteins (ie, transpeptidase and carboxypeptidase), thereby interfering with bacterial cell wall synthesis and resulting in bactericidal activity.[1]

Cefovecin is not active against *Pseudomonas* spp, methicillin-resistant staphylococci, enterococci, or *Bordetella bronchiseptica*.[3] Extrapolation of results of other third-generation cephalosporins should be avoided because of the reduced activity of cefovecin against gram-negative organisms (eg, susceptibility to cefotaxime does not necessarily indicate susceptibility to cefovecin). Cefovecin's effectiveness against systemic (non-UTI) *Escherichia coli* or other Enterobacterales (eg, *Enterobacter* spp) is limited because the drug's extensive protein binding result in the inability to reach adequate free drug concentrations for an adequate period of time for these organisms.[12]

Cefovecin rapidly cleared spirochetes and reduced antibodies in dogs with experimentally induced Lyme borreliosis.[8]

Pharmacokinetics

Cefovecin is completely absorbed after SC injection in dogs and cats. Peak concentrations occur ≈6 hours after administration in dogs and ≈2 hours after administration in cats. Cefovecin is highly bound to plasma proteins (dogs, 98.5%; cats, 99.8%) that slowly dissociate and give cefovecin a long elimination half-life. Because cefovecin exhibits nonlinear kinetics in dogs and cats, an increased dose does not proportionally increase the plasma concentration. The following additional pharmacokinetic values are listed on the product label:

Pharmacokinetic value	Canine	Feline
Terminal plasma elimination half-life	133 ± 16 hours (5.5 days)	166 ± 18 hours (6.9 days)
Maximum total plasma concentration	121 ± 51 µg/mL	141 ± 12 µg/mL
Volume of distribution (steady-state)	0.122 ± 0.011 L/kg	0.090 ± 0.010 L/kg
Total body clearance	0.76 ± 0.13 mL/hour/kg	0.35 ± 0.40 mL/hour/kg

Elimination of cefovecin is primarily via renal mechanisms; the majority is excreted unchanged in urine, but a small amount is excreted unchanged in bile. Cefovecin may persist in the body for up to 65 days and be excreted in urine at therapeutic concentrations for 14 days in dogs and 21 days in cats.

Several small pharmacokinetic studies have been done in other species. In alpacas, after IV injection, the elimination half-life of cefovecin was ≈10.28 hours, volume of distribution was 85.76 mL/kg, and clearance was 7.07 mL/hour/kg. After SC injection, the elimination half-life was ≈16.87 hours. This study found that cefovecin had lower levels of protein binding in this species (≈79%) than in dogs and cats.[13] One study in healthy horses showed that intra-articular injection of cefovecin in the radiocarpal joint was well tolerated and after a single dose of 240 mg, the maximum plasma concentration of 5.54 µg/mL was achieved at ≈4 hours.[14] The concentration remained above 1 µg/mL in the joint for 28 hours after administration, although therapeutic use is still unclear. Many other studies are available that report the pharmacokinetics of a variety of animal species (eg, sea otters,[15] copper rockfish,[16] Patagonian sea lions,[17] cheetahs,[18] lions,[19] koalas,[20] tigers,[21] mice[22]); an exhaustive listing of this information is beyond the scope of this reference.

Cefovecin's usefulness appears to be limited for certain species. Shorter half-lives and a larger volume of distribution (possibly due to lower protein binding) in birds and reptiles[23] may indicate that cefovecin offers no advantage over current treatments for these species.[24] A short elimination half-life was also found in rhesus monkeys (≈6.6 hours), and cefovecin did not reach a sufficient concentration over the MIC of bacteria found in infected skin wounds.[25]

Hypoproteinemia may alter cefovecin pharmacokinetics; however, there are no studies that support or refute this.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, cephalosporins should be used cautiously in patients with a documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cefamycins, carbapenems). Anaphylaxis has been reported with the use of cefovecin.[1]

Safe use in dogs or cats younger than 4 months, with long-term use, or with IV or IM administration has not been established[1]; in other countries, there is a warning against use in dogs or cats younger than 8 weeks.[3,4] Cefovecin should be used with caution in patients with significant renal impairment; dose adjustment may be required. However, this guidance is likely only necessary for patients with severe renal disease. There is no guidance for optimal dose and frequency changes in animals with renal disease.

Cephalosporin use in small mammals (eg, guinea pigs, rabbits) is not recommended, as it may cause antibiotic-induced enterocolitis.[3,4]

Humans with beta-lactam allergies should exercise caution while handling this product.

Cefovecin can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefoVECin.

Adverse Effects

Cefovecin appears to be well tolerated in dogs and cats. Emesis, diarrhea, anorexia, and injection site reactions are possible. Premarketing (in United States) studies in dogs and cats found no significant increase in adverse effect types or rates when compared with control; however, treated animals did have some changes in laboratory values. Several dogs had mild to moderate increases in liver enzymes (eg, ALT, gamma-glutamyl transferase [GGT]).[26] In 147 treated cats, 4 had mild increases in ALT concentrations, 24 had increases in BUN, and 6 had moderately elevated serum creatinine values.[26]

In the FDA's Cumulative Veterinary Adverse Drug Experience Reports (through April 2013), the most common adverse effects listed in decreasing order of frequency are:

- Dogs: depression/lethargy, anorexia, vomiting
- Cats: anorexia, depression/lethargy, vomiting

Hypersensitivity reactions, anaphylaxis, and death associated with cefovecin are possible and have been reported. The manufacturer also states, *Occasionally, cephalosporins and NSAIDs have been associated with myelotoxicity, thereby creating a toxic neutropenia*. Other hematologic reactions seen with cephalosporins include neutropenia, anemia, hypoprothrombinemia, thrombocytopenia, prolonged prothrombin time (PT) and partial thromboplastin time (PTT), platelet dysfunction, and transient increases in serum aminotransferases (eg, ALT, AST).

In healthy dogs, beta-lactam resistance in fecal *E coli* and the bla(CMY-2) gene were increased after cefovecin treatment as compared with dogs that received a placebo.[27]

Because cefovecin can persist in the body for up to 65 days, adverse effects that require prolonged treatment may occur.

Reproductive/Nursing Safety

The manufacturer states that safe use in breeding or lactating animals has not been determined. Product labeling in the European Union states, *treated animals should not be used for breeding for 12 weeks after the last administration*.[3] However, cephalosporins are generally considered safe for use during pregnancy and lactation and veterinarians and owners can weigh any risks of using the drug versus potential benefits to the dam and offspring.

Overdose/Acute Toxicity

Acute overdoses should be relatively safe. Dogs receiving cefovecin SC up to 180 mg/kg (22.5 times the label dose) showed injection site irritation, vocalization, edema, vomiting, and diarrhea. Edema resolved within 8 to 24 hours.[1] Cats given the same dose (22.5 times the label dose) showed the same signs but had lower mean WBC counts 10 days after treatment as compared with controls, and one cat had a small amount of bilirubinuria on day 10.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

Because cefovecin is highly bound to plasma proteins, it could theoretically displace other highly bound drugs causing a transient increase in serum concentrations of each drug. These interactions are unlikely to be of clinical concern because increased free drug levels will equilibrate through increased clearance. Monitor for adverse effects of each drug when using together. In experimental, in vitro systems, cefovecin has been shown to increase free concentrations of **carprofen, furosemide, doxycycline,** and **ketoconazole**. Other highly protein-bound drugs that could theoretically compete with cefovecin for binding and cause adverse effects include **maropitant, other NSAIDs, propofol, anticonvulsants, cardiac medication, and behavior medication.**[1] However, actual clinical significance has not been established and a recent report concluded that a clinically significant drug interaction is unlikely from the concurrent administration of **carprofen** and cefovecin in dogs.[28]

Laboratory Considerations

- Cephalosporins may cause false positive **urine glucose determinations** when the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest*®) is used; tests using glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- When the Jaffe reaction is used to measure **serum or urine cre-**

atinine, cephalosporins (not ceftazidime or cefotaxime) given in high dosages may cause falsely elevated values.
- Cephalosporins may cause falsely lowered **albumin** levels when certain tests are used to measure albumin.
- In humans, particularly those with azotemia, cephalosporins have caused a false positive direct **Coombs test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

Dosages

DOGS:

Skin infections due to susceptible strains of *Staphylococcus intermedius* or *Streptococcus canis* (group G) (label dosage; FDA-approved): 8 mg/kg SC once.[1] A second injection (same dosage/route) may be administered if response to therapy is not complete after 7 days for *S intermedius* infections and after 14 days for *S canis* (group G) infections. Maximum treatment should not exceed 2 injections.

Susceptible skin and soft tissue infections (extra-label): 8 mg/kg SC once. If required, treatment may be repeated at 14-day intervals, up to 3 additional times.[3,4]

UTIs and severe infections of the gingival and periodontal tissues (extra-label; for indicated organisms, see ***Uses/Indications***): 8 mg/kg SC once [3,4]

Lyme disease (extra-label): 8 mg/kg SC, with a second dose repeated after 14 days was effective in eliminating spirochetes and reducing *Borrelia burgdorferi* antibodies in experimentally induced Lyme borreliosis.[8]

CATS:

Skin infections (eg, wounds, abscesses) caused by susceptible strains of *Pasteurella multocida* (label dosage; FDA-approved): 8 mg/kg SC as a single, one-time SC injection.[1] Therapeutic concentrations are maintained for ≈7 days for *P multocida* infections.

Susceptible skin and soft tissue infections (extra-label): 8 mg/kg SC once. If required, a second treatment may be repeated 14 days after the first injection.[3,4]

UTI and severe infections of the gingival and periodontal tissues (extra-label): 8 mg/kg SC once[3,4,6]

Monitoring

- Culture and susceptibility testing as indicated by clinical condition. Because cefovecin has prolonged excretion, optimal timing of the sampling for posttreatment urine culture is unclear; however, testing 3 weeks after the last dose may be reasonable.[6]
- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is often all that is required.
- Patients with diminished renal function may require intensified monitoring of renal parameters (eg, BUN, creatinine, urinalysis).

Client Information

- This medicine must be injected; it does not work when given by mouth.
- Medication is well tolerated in dogs and cats, but vomiting, diarrhea, or lack of appetite can occur.
- Antibiotic effect is long-lasting after a single injection in dogs and cats, and side effects can occur up to 2 months after an injection.
- If giving this medicine to your animal at home, be sure you understand how to do the injections.
- Store this medicine in the refrigerator, protected from light. Discard any unused medicine after 56 days.

Chemistry/Synonyms

Cefovecin sodium is a third-generation cephalosporin antibacterial agent with a molecular weight of 475.5. Each mL of reconstituted lyophilized powder contains cefovecin sodium equivalent to 80 mg of cefovecin; methylparaben (1.8 mg) and propylparaben (0.2 mg) are added as preservatives, and sodium citrate dihydrate (5.8 mg) and citric acid monohydrate (0.1 mg), sodium hydroxide, or hydrochloric acid are added to adjust pH.

Cefovecin sodium may also be known as UK-287074-02, cefovecina sodica, céfovécine sodique, or natrii cefovecinum. A trade name is *Convenia*®.

Storage/Stability

Store the powder and the reconstituted product protected from light in the original carton and refrigerate at 2°C to 8°C (36°F-46°F); do not freeze. Use the entire contents of the vial within 56 days of reconstitution. Cefovecin is light-sensitive. Although the color of the solution may vary from clear to amber at reconstitution and may darken over time, if the solution is stored as recommended, color does not adversely affect potency.

Compatibility/Compounding Considerations

To deliver the appropriate dose, the vial should be aseptically reconstituted with 10 mL of sterile water for injection. The vial should be shaken then allowed to sit until all material is visually dissolved. The resulting solution contains cefovecin sodium equivalent to 80 mg/mL of cefovecin.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Cefovecin Sodium (lyophilized) 800 mg (of cefovecin) per 10 mL multidose vial (80 mg/mL when reconstituted); *Convenia*®; (Rx). FDA-approved as labeled for use in dogs and cats. NADA #141-285. 320 mg/4 mL vials may be available in other countries.

HUMAN-LABELED PRODUCTS: NONE

Cefoxitin

(se-***fox***-i-tin) *Mefoxin*®

Second-Generation Cephalosporin (Cephamycin)

Prescriber Highlights

- ► Parenteral antimicrobial effective against most gram-positive cocci and gram-negative rods, and against some anaerobes
- ► Potentially causes hypersensitivity reactions, thrombocytopenia, and diarrhea
- ► Causes pain on IM injection; IV injections should be given over 3 to 5 minutes (or longer)
- ► Dosage reductions may be needed for patients with renal insufficiency.

Uses/Indications

Cefoxitin has been used clinically in several species when an injectable second-generation cephalosporin is indicated; however, no cefoxitin products are FDA-approved for veterinary species in the United States. Cefoxitin has been used in treatment protocols for dogs with parvoviral enteritis.[1]

Pharmacology/Actions

Cefoxitin is a cephamycin, not a true cephalosporin; however, it is usually classified as a second-generation antibacterial agent. Cefoxitin has activity against most gram-positive cocci, but activity is less on a per weight basis than with first-generation cephalosporin agents. Cefoxitin has better activity against *Escherichia coli, Klebsiella* spp, *Campylobacter* spp, *Proteus* spp, and other gram-negative bacteria compared to first-generation cephalosporin agents. Extend-

ed spectrum beta-lactamase (ESBL) producing gram-negative bacteria are typically susceptible to cefoxitin in vitro but in vivo response is unpredictable.

Bacterial resistance to cefoxitin is a growing concern. Methicillin-resistant staphylococci and AmpC producing gram-negative bacteria are resistant to cefoxitin. Cefoxitin resistance is commonly used as an in vitro marker for methicillin resistance in *Staphylococcus aureus*. Activity against enterococci and *Pseudomonas* spp is poor.

The World Health Organization has designated cefoxitin as a Highly Important antimicrobial for human medicine.[2]

Pharmacokinetics

In dogs (n = 4) after 30 mg/kg doses (IV, SC), plasma cefoxitin concentrations remained greater than MIC_{90} (*Escherichia coli*) for 4 to 6 hours after an IV dose and ≈8 hours after SC administration.[3]

In cats after 30 mg/kg doses, peak concentrations are similar when given IV or IM, and IM bioavailability is ≈90%. Apparent volume of distribution is 0.32 L/kg, clearance is 0.14 L/hour/kg, and elimination half-life is ≈1.5 hours. No significant accumulation occurs when dosed at 30 mg/kg every 8 or 12 hours, and time of MIC (estimated for cefoxitin) is similar after IV or IM administration: 75% every 8 hours or 50% every 12 hours.[4]

In horses, the apparent volume of distribution at steady state is 120 mL/kg, total body clearance is 4.32 mL/min/kg, and serum elimination half-life is 49 minutes. Bioavailability after IM injection was 77%.[5]

In calves, the volume of distribution is 318 mL/kg, and terminal elimination half-life is 67 minutes after IV dosing and 81 minutes after IM administration. Cefoxitin is ≈50% bound to calf plasma proteins. Probenecid (40 mg/kg) has been demonstrated to significantly prolong elimination half-lives.[6]

In humans, cefoxitin is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum concentrations. Cefoxitin is distributed into pleural and joint fluids.[7] The drug is primarily excreted unchanged by the kidneys into the urine via both tubular secretion and glomerular filtration, and high urinary concentrations are reached. Approximately 2% of a dose is metabolized to descarbamylcefoxitin, which is inactive. Elimination half-life is ≈1 hour but may be significantly prolonged in patients with markedly diminished renal function.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because cross-reactivity may occur, use cephalosporins cautiously in patients with documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cephamycins, carbapenems).

Patients with renal insufficiency may need dosage adjustments.

Cephalosporins in small mammals such as Syrian hamsters and guinea pigs may cause antibiotic-induced enterocolitis.

Cefoxitin can be easily confused with other cephalosporins. Writing part of the drug's name in uppercase on prescriptions/orders may reduce the risk of errors: CefOXitin. Do not confuse cefoxitin with *Cytoxan*® (cyclophosphamide).

Adverse Effects

Adverse effects with cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions, unrelated to dosage, can occur with cephalosporins and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, ≈1% to 15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site when administered IM. Sterile abscesses or other severe local tissue reactions are also possible but are less common. Thrombophlebitis is possible after IV administration of cephalosporins.

Even when administered parenterally, cephalosporins may alter gut microbiota, causing antibiotic-associated diarrhea or proliferation of resistant bacteria in the colon (superinfections).

Although cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinical dosages in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal. High doses or prolonged use in humans has been associated with neurotoxicity (eg, seizures), neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Coombs test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic etiology.

Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta. No teratogenic or fetal toxic effects were observed in studies performed in mice and rats. In humans, cefoxitin is considered compatible with pregnancy.[8]

Cefoxitin can be distributed into human milk in low concentrations. It is unlikely to pose significant risk to nursing offspring but may cause alterations in bowel flora. In humans, cefoxitin is considered compatible with breastfeeding.[8]

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant adverse effects. The IV LD_{50} in mice is 8 g/kg.[7]

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with a 24-hour poison consultation center that specializes in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefoxitin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides**: The concurrent use of parenteral aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should be administered separately.
- **Nephrotoxic Drugs** (eg, **amphotericin B, furosemide, iohexol**): Concurrent use with cefoxitin could cause additive nephrotoxicity.
- **Probenecid**: Probenecid approximately doubled cefoxitin half-life and mean residence time in calves.[6]
- **Vitamin K Antagonists** (eg, **warfarin**): Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists.

Laboratory Considerations

- **Methicillin-resistant staphylococci**: Although cefoxitin resistance is widely used as an indicator of methicillin resistance in *S aureus*, it is a less effective indicator for *Staphylococcus pseudintermedius*. Cefoxitin resistance in *S pseudintermedius* indicates methicillin resistance; however, false negative results can occur.[9]
- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's solution, Fehling's solution, *Clinitest*®). Tests

utilizing glucose oxidase (*Tes-Tape®, Clinistix®*) are not affected by cephalosporins.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (except ceftazidime and cefotaxime) in high dosages may cause falsely elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.
- Cephalosporins may cause falsely elevated **17-ketosteroid** values in urine.

Dosages

DOGS/CATS:

Susceptible infections (extra-label): 30 mg/kg IV or IM every 6 to 8 hours[10,11]

Surgical (GI and orthopedic) prophylaxis (extra-label): 20 – 30 mg/kg IV, IM 30 to 60 minutes prior to incision. May repeat 1 time in 2 to 4 hours

HORSES:

Susceptible infections (extra-label): Foals: 20 mg/kg IV every 4 to 6 hours[12]

Monitoring

- Because cephalosporins are usually associated with minimal toxicity, monitoring for efficacy is typically all that is required.
- Patients with diminished renal function may require intensified renal monitoring.

Chemistry/Synonyms

Cefoxitin sodium, a cephamycin, is a semisynthetic antibiotic that is derived from cephamycin C produced by *Streptomyces lactamdurans*. It occurs as a white to off-white, somewhat hygroscopic powder or granules with a faint but characteristic odor. It is very soluble in water and only slightly soluble in alcohol. Each gram of cefoxitin sodium contains 2.3 mEq of sodium.

Cefoxitin may also be known as MK-306, L-620-388, cefoxitinum, cefoxitina, cefoxitine, *Mefoxin®*, *Mefoxitin®*, *Cefociclin®*, or *Cefoxin®*.

Storage/Stability

Cefoxitin sodium powder for injection should be stored between 2°C and 25°C (36°F-77°F) and should not be exposed to temperatures greater than 50°C (122°F). Once the 1 g and 2 g vials are reconstituted with sterile water for injection, 0.9% sodium chloride or 5% dextrose to 100 mg/mL, the solution is stable for 6 hours at room temperature and for 7 days if refrigerated below 5°C (41°F), while the bulk pharmacy 10 g vials are stable for 4 hours after initial entry. The solution may be diluted further to 50 to 1000 mL, which provides an additional 18 hours of stability at room temperature or an additional 48 hours under refrigeration.

Inactivated dual chamber bags of cefoxitin with dextrose should be stored at 20°C to 25°C (68°F-77°F) with excursions permitted to 15°C to 30°C (59°F-86°F). Do not freeze. Once activated, use the contents within 12 hours if stored at room temperature or within 7 days if stored under refrigeration.

The powder or reconstituted solution may darken but this does not affect the potency of the product.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

All commonly used IV fluids and the following drugs are reportedly **compatible** with cefoxitin: amikacin sulfate, cimetidine HCl, gentamicin sulfate, kanamycin sulfate, mannitol, metronidazole, multivitamin infusion concentrate, sodium bicarbonate, tobramycin sulfate, and vitamin B complex with vitamin C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefoxitin Sodium Powder for Injection: 1 g, 2 g, and 10 g in vials; generic; (Rx)

Cefoxitin Sodium Injection Solution (with dextrose): 1 g and 2 g in 50 mL dual chamber bags; generic; (Rx)

Cefpodoxime

(sef-poe-***docks***-eem) *Simplicef®, Vantin®*

Third-Generation Cephalosporin

Prescriber Highlights

- ► Oral third-generation cephalosporin that may be useful in dogs and cats
- ► Contraindications: Known hypersensitivity to cephalosporins and beta-lactam antibiotics
- ► Adverse effects are primarily GI-related; hypersensitivity is possible.

Uses/Indications

In dogs, cefpodoxime is labeled for the treatment of skin infections caused by susceptible strains of *Staphylococcus pseudintermedius*, *Staphylococcus aureus*, *Streptococcus canis*, *Escherichia coli*, *Proteus mirabilis*, and *Pasteurella multocida*. Although not currently FDA approved for use in cats, cefpodoxime may be useful in this species. Cefpodoxime can be used to treat UTIs in dogs and cats.[1]

The World Health Organization (WHO) has designated cefpodoxime as a Critically Important (Highest Priority) antimicrobial in human medicine.[2]

Pharmacology/Actions

Like other cephalosporins, cefpodoxime binds penicillin-binding proteins, inhibiting bacterial cell wall synthesis and resulting in bacterial cell lysis. It is considered a time-dependent bactericidal antibiotic that is relatively resistant to bacterial beta lactamases.

Cefpodoxime is characterized as a third-generation cephalosporin. Although cefpodoxime has activity against many gram-negative bacteria in the Enterobacteriaceae family, including many *Escherichia* spp, *Proteus* spp, and *Klebsiella* spp, MICs with cefpodoxime are often significantly higher than with other third-generation drugs (eg, cefotaxime, ceftazidime). Against wild-type *Escherichia coli*, cefpodoxime has a MIC that is 8 times greater than cefotaxime's and 4 times greater than ceftazidime's.[3] Cefpodoxime has good activity against methicillin-susceptible staphylococci and many streptococci. Cefpodoxime has no activity against fungi, viruses, or parasites.

Cefpodoxime is not effective against the "SPACE" organisms (ie, *Serratia* spp, *Pseudomonas* spp, *Acinetobacter* spp, *Citrobacter* spp, *Enterobacter* spp), *Enterococcus* spp, anaerobes, or methicillin-resistant staphylococci. An ongoing concern is the development of resistance to third-generation cephalosporins by *E coli* and other gram-negative bacteria, mainly through the production of extended-spectrum beta-lactamases (ESBLs).

Due to potential differences between cefpodoxime and other third-generation cephalosporins, cefpodoxime-specific disks or dilutions should be used to determine susceptibility rather than susceptibility being inferred from other third-generation cephalosporins.

Pharmacokinetics

Cefpodoxime proxetil is not active as an antibiotic. Cefpodoxime is

active after the proxetil ester is cleaved in vivo, which occurs rapidly and almost completely in the intestine. After administration of single oral doses of 5 or 10 mg/kg in dogs, bioavailability is ≈63%, the volume of distribution is 150 mL/kg, peak concentration is ≈16 µg/mL, and time to peak concentration is 2.2 hours. The concentration of a free drug in the skin and SC fluid is 1.7 µg/mL and 3 µg/mL, respectively.[4] The elimination half-life is 4.7 to 5.7 hours.[4–6] High levels of the drug are found in urine, and ≈70% to 95% is excreted unchanged.[4] ≈83% of the drug is bound to plasma proteins.[5] Oral bioavailability between the oral suspension and tablets is equivalent.[6]

In neonatal foals (7 to 14 days old), an oral suspension dose of 10 mg/kg can produce peak levels in ≈1.7 hours and a maximum serum concentration of ≈0.8 µg/mL. The elimination half-life is ≈7 hours. In a study, levels in synovial and peritoneal fluids were similar to those found in the serum, but no drug was detected in CSF.[7] Half-life in 3- to 4-month-old foals and adult horses is 6.2 hours and 3.8 hours, respectively.[7]

In humans, cefpodoxime proxetil is ≈40% to 50% absorbed from the GI tract.[8] Food does not alter the rate but may increase the extent of absorption. Cefpodoxime penetrates most tissue well; it is unknown if it penetrates into CSF. ≈20% to 30% of the drug is bound to plasma or serum proteins. It is eliminated in both the urine and feces. Serum half-life is 2 to 3 hours but may be prolonged in patients with impaired renal function; hepatic dysfunction does not alter elimination half-life.[8]

Contraindications/Precautions/Warnings

Cefpodoxime is contraindicated in patients hypersensitive to it or to other beta-lactam antibiotics (eg, penicillins, other cephalosporins).

Because cefpodoxime is excreted by the kidneys, doses and/or dose frequency may need to be adjusted in patients with significantly diminished renal function. However, there is limited guidance regarding when and how to reduce doses. In humans, cefpodoxime should be used with caution in patients with seizure disorders; this warning is not listed on the veterinary label. It is not known whether this concern applies to veterinary patients receiving cefpodoxime at the label dosage.

Cefpodoxime can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefPODOXime.

Adverse Effects

The most likely adverse effects in dogs include inappetence, diarrhea, vomiting, and lethargy. Hypersensitivity and pemphigus-like drug reactions are rare but possible.

Rarely, blood dyscrasias may be seen following high doses of cephalosporins.

Reproductive/Nursing Safety

Cefpodoxime has not been shown to be teratogenic, but it should be used during pregnancy only when clearly indicated. The safety of cefpodoxime proxetil in dogs used for breeding, pregnant dogs, or lactating bitches has not been demonstrated.[9] In humans, cefpodoxime is considered compatible with pregnancy.[10]

In humans, cefpodoxime enters maternal milk in concentrations up to 16% of that of maternal serum levels.[8] Alteration of the gut microbiota with resultant diarrhea is theoretically possible.[8] Cefpodoxime should be used cautiously in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems, but other effects are possible. See ***Adverse Effects***.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefpodoxime and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides and Other Nephrotoxic Drugs**: The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (eg, **amphotericin B**) with cephalosporins is somewhat controversial. Cephalosporins can cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine, which is no longer marketed. *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides.
- **Antacids** (eg, **aluminum hydroxide**, **magnesium hydroxide**): Drugs that can increase stomach pH may decrease the peak levels and extent of absorption of cefpodoxime.
- **Histamine$_2$ (H_2) Receptor Antagonists** (eg, **famotidine**): H_2 antagonists may decrease peak levels and extent of absorption of cefpodoxime. Oral doses should be separated by at least 2 hours.
- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives
- **Proton-Pump Inhibitors** (**PPIs**; eg, **omeprazole**, **pantoprazole**): Concurrent use with cefpodoxime may reduce serum cefpodoxime concentrations.
- **Vitamin K Antagonists** (eg, **warfarin**): Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists (eg, warfarin).

Laboratory Considerations

- Cefpodoxime may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's solution, *Clinitest®*, Fehling's solution). Tests using glucose oxidase (*TesTape®, Clinistix®*) are not affected by cephalosporins.
- Cefpodoxime may cause false-positive results when the nitroprusside test is used for determining **urinary ketones**.
- Cephalosporins (except ceftazidime and cefotaxime) in high doses may cause falsely elevated values when the Jaffe reaction is used to measure **serum or urine creatinine**.
- In humans, particularly humans with azotemia, cephalosporins have caused a false-positive direct **Coombs test** result.

Dosages

DOGS:

NOTE: Whether this drug should be used as a first- or second-tier drug is of debate, as the broader gram-negative coverage provided by this drug as compared with other antimicrobials commonly used to treat pyoderma is rarely necessary.[11] Supporting antimicrobial stewardship, narrow-spectrum cephalosporins, such as cephalexin, should always be considered prior to considering broad-spectrum cephalosporins, such as cefpodoxime.

Susceptible skin infections (wounds and abscesses) (label dosage; FDA approved): 5 – 10 mg/kg PO once daily for 5 to 7 days

or 2 to 3 days beyond the cessation of clinical signs, up to a maximum of 28 days.[9] Treatment of acute infections should not be continued for more than 3 to 4 days if no response to therapy is seen. May be given with or without food.

Deep pyoderma (extra-label): 5 - 10 mg/kg PO once daily until 1 to 2 weeks after clinical resolution. Extended treatment duration (eg, 8 to 12 weeks) may be required. Higher doses may be needed for bacteria with MICs greater than 0.5 µg/mL.[4]

Bacterial cystitis (extra-label): 5 – 10 mg/kg PO every 24 hours.[1] Urinary excretion data supports cefpodoxime proxetil effectiveness in the treatment of UTIs in dogs, although not as a first-line option.[4]

CATS:

Susceptible skin and soft tissue infections (extra-label): 5 mg/kg PO every 12 hours or 10 mg/kg PO once daily until complete clinical resolution (extrapolated from human dose)[12]

HORSES:

Foals (neonates) with bacterial infections (extra-label): From a pharmacokinetic study, 10 mg/kg PO every 6 to 12 hours.[7] Additional studies are required to confirm clinical efficacy and safety. Safety in adult horses has not been established, and cefpodoxime should be avoided in horses beyond the neonatal period due to the risk for severe colitis seen with other oral beta-lactam antimicrobials.

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Can be given with or without food, but GI side effects might be prevented if the medication is given with food.
- Most common side effects are diarrhea, vomiting, and loss of appetite.
- Be sure to give as long as your veterinarian has prescribed, even if your animal seems better.
- Cephalosporin antibiotics have an odor that resembles cat urine, but this is normal.

Chemistry/Synonyms

Cefpodoxime proxetil, an oral semisynthetic aminothiazolyl third-generation cephalosporin, is a prodrug that is hydrolyzed *in vivo* to cefpodoxime. The esterified form (proxetil) enhances lipid solubility and oral absorption. Potency is expressed in mg of cefpodoxime.

Cefpodoxime proxetil may also be known as CS-807; R-3763, U-76252, U-76253, *Banan®, Biocef®, Cefodox®, Cepodem®, Garia®, Instana®, Kelbium®, Orelox®, Otreon®, Podomexef®, Simplicef®*, or *Vantin®*.

Storage/Stability

Store tablets and unreconstituted powder between 20°C and 25°C (68°F and 77°F) in well-closed containers. After reconstitution, store the oral suspension in the refrigerator between 2°C and 8°C (36°F and 46°F) and discard after 14 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Cefpodoxime Proxetil Tablets: 100 mg and 200 mg; *Simplicef®*, Cefpoderm®, generic; (Rx). FDA approved for use in dogs. NADA #141-232

HUMAN-LABELED PRODUCTS:

Cefpodoxime Proxetil Oral Tablets: 100 mg and 200 mg; *Vantin®*, generic; (Rx)

Cefpodoxime Proxetil Granules for Suspension, Oral: 50 mg/5 mL (10 mg/mL) and 100 mg/5 mL (20 mg/mL) in 50 mL, 75 mL, and 100 mL bottles; *Vantin®*, generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Cefquinome

(sef-***kwi***-nohm) *Cobactan®, Ceffect®*

Fourth-Generation Cephalosporin

Prescriber Highlights

- ► Antibacterial agent used in horses, cattle, and pigs
- ► Appears safe when used according to the label
- ► Not an approved drug in the United States; extra-label use of cephalosporins in major food-producing animals is prohibited by the FDA.

Uses/Indications

Cefquinome is approved in some countries for the treatment of susceptible gram-positive and gram-negative infections in cattle, pigs, and horses.

The following table lists the veterinary species with indications for cefquinome use.

Species	Indication(s)
Horses	Respiratory diseases caused by *Streptococcus equi* subsp *zooepidemicus*
Foals	Severe bacterial infections that carry a high risk for *Escherichia coli* septicemia
Cattle*	Respiratory disease caused by *Pasteurella multocida, Mannheimia haemolytica,* or *Histophilus somni* Digital dermatitis, infectious bulbar necrosis, and acute interdigital necrobacillosis (ie, foot rot) Acute *E coli* mastitis with signs of systemic involvement
Dry dairy cattle*	Subclinical mastitis at the time of drying off and for the prevention of new bacterial infections caused by *Staphylococcus aureus*, *S dysgalactiae*, *S uberis, S agalactiae,* and coagulase-negative staphylococci
Lactating dairy cattle*	Clinical mastitis caused by susceptible bacteria (including *S aureus, S uberis, S dysgalactiae*, and *E coli*)
Calves*	*E coli* septicemia
Pigs*	Bacterial infections of the lungs and respiratory tract caused by *P multocida, Haemophilus parasuis, Actinobacillus pleuropneumoniae, S suis,* and other cefquinome-sensitive organisms Mastitis, metritis, agalactia (MMA) syndrome caused by *E coli, Staphylococcus* spp, *Streptococcus* spp, and other cefquinome-sensitive organisms
Piglets*	Reduction of mortality in cases of meningitis caused by *S suis* Arthritis caused by *Streptococcus* spp, *E coli*, and other cefquinome-sensitive organisms Epidermitis (eg, mild or moderate lesions) caused by *S hyicus*

*In the United States, cefquinome use in food-producing animals is considered extra-label and is therefore prohibited by the FDA.

The World Health Organization (WHO) has designated fourth-generation cephalosporins such as cefquinome as Critically Import-

ant, Highest Priority antimicrobials for human medicine.[1] The Office International des Epizooties (OIE) has designated cefquinome as a Veterinary Critically Important Antimicrobial (VCIA) Agent in bovine, caprine, equine, lagomorph, ovine, and swine species.[2]

Pharmacology/Actions

Cefquinome is a fourth-generation cephalosporin with time-dependent bactericidal activity. Like other cephalosporins, this drug interferes with bacterial cell wall synthesis, which causes the cell to become more susceptible to lysis and results in cell death. Cefquinome is not an antiviral, antifungal, or antiparasitic drug.

Cefquinome penetrates the outer membrane of gram-negative bacteria more readily than other cephalosporins. This drug is not hydrolyzed by plasmid-mediated or AmpC-type cephalosporinases but may be hydrolyzed by some extended-spectrum beta-lactamases (ESBLs). To minimize selection of resistant bacteria strains carrying ESBLs, cefquinome use should be reserved for clinical conditions that have responded poorly to first-line treatment and, whenever possible, cefquinome use should be based on susceptibility testing. Cefquinome is ineffective against methicillin-resistant staphylococci.

Cefquinome has excellent gram-negative activity and retains good activity against gram-positive bacteria. In vitro, cefquinome has antibiotic activity against gram-positive and gram-negative bacteria (including *Staphylococcus* spp, *Streptococcus dysgalactiae, S agalactiae, S uberis, S equi* subsp *zooepidemicus, Clostridium* spp, *Corynebacterium pyogenes, Erysipelothrix rhusiopathiae*, *Actinobacillus* spp, *Bacteroides* spp, *Bacillus* spp, *Citrobacter* spp, *E coli, A pleuropneumoniae, Fusobacterium* spp, *Haemophilus* spp, *Klebsiella* spp, *Mannheimia haemolytica*, *Pasteurella* spp, *Prevotella* spp, *Proteus* spp, *Salmonella* spp, and *Serratia marcescens*).

In Europe, ≈98% of bacterial isolates in cattle and pigs were susceptible to cefquinome, with a minimum inhibitory concentration (MIC) ranging from less than 0.004 µg/mL to 2 µg/mL and a resistance breakpoint of 4 µg/mL.[3]

Pharmacokinetics

In adult horses given cefquinome at 1 mg/kg IM, the drug is completely absorbed, and peak concentration (2.5 µg/mL) occurs 1 hour after administration. Protein binding is minimal. The time above MIC for *Streptococcus equi* subsp *zooepidemicus* is ≈12 hours, and the elimination half-life is 2 hours. In foals, bioavailability is 87% after IM administration. Peak concentration (1.8 µg/mL) occurs within 1 hour of administration, and the elimination half-life is 1.4 hours.[4]

In cattle given cefquinome at 1 mg/kg IM or SC, a peak serum concentration of 2 µg/mL is reached within 90 to 120 minutes. Protein binding is minimal. This drug is excreted unchanged in urine, and the elimination half-life is 2.5 hours.[3] The average cefquinome concentration in milk is 19 µg/mL 12 hours after intramammary administration and ≈2.5 µg/mL after the animal is milked a second time following the last infusion.[5]

In sheep, cefquinome has been shown to accumulate after repeated SC doses given every 24 hours. One study showed statistically significant increases in AUC and maximum concentration between Day 1 and Day 5.[6]

In goats, peak concentration of cefquinome is 2.37 µg/mL and terminal elimination half-life is 4.85 hours. Elimination is prolonged when coadministered with ketoprofen in goats.[7]

In pigs or piglets, a peak serum concentration of 5 µg/mL is reached within 15 to 60 minutes after administration of 2 mg/kg IM. Protein binding is poor, and 12 hours after administration, the drug is able to penetrate into CSF fluid at a concentration similar to plasma. Elimination half-life is ≈9 hours.[3]

Cefquinome is not absorbed after oral administration.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, caution is advised in patients that have a documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cefamycins, carbapenems). Isolated cases of hypersensitivity reactions have been noted in cattle.

In the United States, cefquinome use in food-producing animals is considered extra-label and is therefore prohibited by the FDA.

Cefquinome is renally excreted. Dosage modification may be necessary in patients with reduced or impaired renal function.

It is important not to confuse cefQUINome with other cephalosporins.

Adverse Effects

When used according to label instructions, cefquinome appears to be well tolerated. Local tissue reactions at the injection site have been noted to last 15 to 28 days after administration.[3,4]

Reproductive/Nursing Safety

Cephalosporins cross the placenta. Reproductive toxicity studies in laboratory animals did not show teratogenic or fetotoxic effects. No information is available regarding reproductive toxicity in horses, cattle, or swine. Intramammary suspensions have demonstrated no evidence of reproductive toxicity in cattle.

Safe use of cefquinome, including intramammary infusions, in nursing animals has not been established.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Dosages up to 20 mg/kg/day IV in cattle and 10 mg/kg/day in pigs and piglets have been well tolerated.[3,4]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions with cefquinome have either been reported or are theoretical in animals or humans receiving similar cephalosporins and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate:

- **Aminoglycosides**: Concurrent use may increase the risk for nephrotoxicity.
- **Chloramphenicol**: Concurrent use with some cephalosporins may reduce antibacterial effectiveness; interaction may apply to cefquinome. Combination should be avoided.
- **Probenecid**: Concurrent use can increase cephalosporin exposure; interaction may apply to cefquinome.

Laboratory Considerations

No specific laboratory interactions or considerations were noted for cefquinome. The following class effects are known regarding cephalosporins:

- Except for cefotaxime, cephalosporins may cause false positive **urine glucose determinations** when using cupric sulfate solution (eg, Benedict's solution, *Clinitest*®). Tests using glucose oxidase (eg, *Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- When the Jaffe reaction is used to measure serum or urine creatinine, cephalosporins (not ceftazidime or cefotaxime) given in high dosages may cause falsely elevated values.

- In humans, particularly those with azotemia, cephalosporins have caused a false positive direct **Coombs test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

Dosages

HORSES:

Respiratory disease caused by *Streptococcus equi* subsp *zooepidemicus* (extra-label): 1 mg/kg IV or IM once daily for 5 to 10 consecutive days. Treatment should be stopped 2 days after clinical signs cease. Diagnosis should be re-evaluated if no response to treatment is seen in 3 to 4 days.[1,4]

In foals, severe bacterial infections with a high risk for septicemia caused by *Escherichia coli* (extra-label): 1 mg/kg IV or IM twice daily for 6 to 14 consecutive days. It is recommended to begin treatment with IV doses for 3 days followed with IM injections. Treatment should be stopped 3 days after clinical signs cease. Diagnosis should be re-evaluated if no response to treatment is seen in 3 to 4 days.[4]

NOTE: The following dosages are approved in some countries outside the United States; however, because cefquinome is not FDA-approved, all use is considered extra-label in the United States. FDA prohibition of extra-label use of cephalosporins in major food animal species effectively bans cefquinome use in food-producing animals in the United States.

CATTLE:

Susceptible infections (extra-label use prohibited in United States): 1 mg/kg IM once daily for 2 to 5 consecutive days depending on indication and age. The cervical neck region is the preferred injection site, and subsequent injection sites should be rotated.[3]

SWINE:

Susceptible infections (extra-label use prohibited in United States): 2 mg/kg IM once daily for 2 to 5 consecutive days depending on indication and age. The cervical neck region is the preferred injection site, and subsequent injection sites should be rotated.[3]

Monitoring

- Clinical efficacy
- Adverse effects
- Culture and susceptibility as appropriate

Client Information

- Handle this medicine with caution if you have an allergy to penicillin or cephalosporin antibiotics.
- Clean and disinfect teat and orifice prior to intramammary infusion.
- Follow all withdrawal instructions for production animals.
- In the United States, the FDA prohibits the extra-label use of cephalosporins in food-producing animals.

Chemistry/Synonyms

Cefquinome is structurally related to other beta-lactam antibiotics. Commercial dosage forms contain cefquinome sulfate; 1.19 mg cefquinome sulfate contains 1 mg cefquinome. Cefquinome sulfate occurs as a powder or crystal that can be white, faint/pale yellow, beige, or brown. Cefquinome 2.5% suspension for injection contains ethyl oleate and is light brown. The 7.5% suspension for injection has a white to off-white color. Cefquinome intramammary suspensions contain a paraffin vehicle.

Cefquinome may also be known as *Cobactan®*, *Ceffect®*, *Cefimam®*, or *Cephaguard®*.

Storage/Stability

Store cefquinome products protected from light at a controlled room temperature of 25°C (77°F). Cefquinome 45 mg/mL solution should be refrigerated (2°C-8°C [36°F-46°F]) after reconstitution. Manufacturers of cefquinome for injection state the following discard intervals:

- 25 mg/mL solution: 28 days after first use or 25 vial punctures; store vial in original carton
- 45 mg/mL solution: 10 days after reconstitution (refrigerated) or after 20 punctures of vial stopper
- 75 mg/mL suspension: 28 days after first use

Compatibility/Compounding Considerations

A study tested the stability of cefquinome sulfate after it was diluted to 5 mg/mL and stored in polyvinyl chloride mini bags at 6°C (42.8°F; refrigerated), 22°C (71.6°F; room temperature), and -20°C (-4°F; frozen). Refrigerated cefquinome solutions were stable over the 6 day study interval when diluted with sterile water, 0.9% sodium chloride, 0.9% sodium chloride with glucose, lactated Ringer's solution, and multielectrolytic isotonic fluid and were less stable when stored at room temperature. Frozen solutions were stable for the 30-day study interval.[8]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

NOTE: In the United States, cefquinome use in food-producing animals is considered extra-label and, therefore, is prohibited by the FDA.

Cefquinome Suspension for Injection: 25 mg/mL in 50 mL and 100 mL vials; *Cobactan®*, *Ceffect®*; (POM-V). Available in Europe, United Kingdom, and New Zealand. Withholding periods vary by product and country of origin; it is important to read and follow the label instructions.

Cefquinome Solution for Injection: 45 mg/mL in 30 mL and 100 mL powder vial bundled with solvent vial; *Cobactan®*; (POM-V). Available in Europe and United Kingdom. Not to be used in horses producing milk for human consumption. Withholding periods vary by product and country of origin; it is important to read and follow label instructions.

Cefquinome Suspension for Injection: 75 mg/mL in 50 mL, 100 mL, and 250 mL vials; *Cobactan®*; (POM-V). Available in Europe and United Kingdom. Not to be used in dairy cows producing milk for human consumption or within 2 months prior to first calving in heifers intended to produce milk for human consumption. Withholding periods vary by product and country of origin; it is important to read and follow label instructions.

Cefquinome Intramammary Infusion for Lactating Cows: 75 mg cefquinome in 8 g tubes in cartons of 3, 15, 20, or 24 syringes; *Cephaguard®* Milking Cow, *Cefimam®* LC, *Cobactan®* LC; (POM-V). For the treatment of clinical mastitis in lactating cows. Withholding periods vary by product and country of origin; it is important to read and follow label instructions.

Cefquinome Intramammary Infusion for Dry Cows: 150 mg in 3 g tubes in cartons of 20, 24, or 60 syringes or buckets of 120 syringes. *Cefimam® DC, Cephaguard®* DC; (POM-V). For the treatment of subclinical mastitis at drying off and prevention of new bacterial infections in dairy cows during the dry period; not for treatment of mastitis. If there is erroneous use during lactation, milk will need to be discarded for 35 days. Withholding periods vary by product and country of origin; it is important to read and follow label instructions.

HUMAN-LABELED PRODUCTS: NONE

Ceftazidime

(sef-***taz***-i-deem) *Ceptaz®, Fortaz®, Tazicef®*

Third-Generation Cephalosporin

Prescriber Highlights

- ► Parenteral antibacterial primarily used for serious systemic *Pseudomonas* spp infections in dogs and cats as well as for broad-spectrum antimicrobial coverage in reptiles
- ► Constant rate IV infusion or frequent parenteral administration may be necessary in dogs and cats with serious systemic *Pseudomonas* spp infections.
- ► Use with caution in patients with renal insufficiency; dosing interval may need to be increased.
- ► May cause hypersensitivity reactions, granulocytopenia, thrombocytopenia, diarrhea, and mild azotemia
- ► May cause pain on IM injection; SC injection may be less painful.

Uses/Indications

Ceftazidime is a third-generation cephalosporin with antipseudomonal properties. It is effective against *Pseudomonas* spp, Enterobacteriaceae, and other gram-negative bacteria. Ceftazidime is usually reserved for use in patients with severe infections that cannot be treated with licensed veterinary alternatives and when other antimicrobial agents such as aminoglycosides are not indicated because of their potential toxicity. Ceftazidime is of particular interest in treating gram-negative infections in reptiles because of its long half-life in many species.

The World Health Organization has designated ceftazidime as a Critically Important (Highest Priority) antimicrobial for human medicine.[1]

Pharmacology/Actions

Ceftazidime is a third-generation injectable cephalosporin. It is bactericidal and acts via its inhibition of enzymes responsible for bacterial cell wall synthesis. The third-generation cephalosporins retain much of the gram-positive activity of the first- and second-generation agents but have expanded gram-negative activity. As with the second-generation agents, enough variability exists with individual bacterial sensitivities that susceptibility testing is necessary for most bacteria. Unlike most other third-generation cephalosporins, ceftazidime is considered an anti-pseudomonal cephalosporin, but resistance can be present. Ceftazidime is ineffective against extended-spectrum beta-lactamase (ESBL)–producing bacteria and methicillin-resistant staphylococci, as well as enterococci.

Because susceptibility of various bacteria to the third-generation cephalosporin antibiotics is unique to a given agent, ceftazidime-specific disks or dilutions must be used to determine susceptibility. Resistance of *Pseudomonas* spp to other third-generation cephalosporins does not necessarily indicate resistance to ceftazidime because of the poor anti-pseudomonal activity of most other cephalosporins.

Pharmacokinetics

Ceftazidime is not appreciably absorbed after oral administration. In dogs after SC injection, the terminal half-life of ceftazidime was 0.8 hours; a 30 mg/kg dose resulted in drug concentrations greater than the serum breakpoint for *Pseudomonas aeruginosa* for 4.3 hours. When ceftazidime was administered as a 4.1 mg/kg/hour CRI (after a loading dose of 4.4 mg/kg), mean serum concentration was greater than 165 µg/mL.[2] Another study in dogs reported average terminal elimination half-lives between 1 and 2 hours after IV, IM, or SC dosing.[3]

In cats, ceftazidime is ≈83% bioavailable after IM administration. It has an apparent volume of distribution of 0.18 L/kg and a clearance of 0.19 L/kg/hr. Elimination half-life is ≈0.8 hours (IV) to 1 hour (IM).[4]

In neonatal foals, bioavailability was 90% after IM administration, and median half-life was 2 hours.[5] Synovial ceftazidime concentrations declined rapidly following regional limb perfusion in horses.[6] Clinical use by this route is not recommended because concentration exceeded MIC for only 2 to 6 hours.

Ceftazidime is widely distributed throughout the body, including into bone and CSF, and is primarily excreted unchanged by the kidneys via glomerular filtration. As renal tubular excretion does not play a major role in the drug's excretion, probenecid does not affect elimination kinetics.

Two studies have examined the pharmacokinetics of ceftazidime in lactating animals. One study compared ceftazidime pharmacokinetics between nonlactating and lactating Creole goats. A dose of 10 mg/kg was given IV or IM. The elimination half-life when ceftazidime was given IV was ≈2.3 hours in nonlactating goats and 1.6 hours in lactating goats. The volume of distribution was 200 mL/kg in nonlactating goats and 238 mL/kg in lactating goats. Bioavailability after IM injection was excellent at 96% to 113%. Half-life was similar to half-life after IV injection. The maximum serum concentration was 67.5 µg/mL in lactating goats and 31.9 µg/mL in nonlactating goats. Penetration into the milk was 18% after IV dosing and 14% after IM dosing. No ceftazidime was detected in the milk after 96 hours.[7] A similar study was performed in lactating dromedary camels. The camels were given a 10 mg/kg dose either IV or IM. The half-life was ≈2.85 hours after IV administration and 3.2 hours after IM administration. Bioavailability after IM administration was 93%. The maximum mean serum concentration was 32.43 µg/mL. The volume of distribution was 0.21 L/kg. Penetration into the milk was ≈10.8% for IV dosing and 12.8% for IM dosing.[8] Both sets of authors concluded that systemic ceftazidime may be a useful treatment for mastitis but further clinical studies are needed.

Contraindications/Precautions/Warnings

Ceftazidime is contraindicated in patients that have had allergic reactions to cephalosporins in the past. Because cross-reactivity may occur, use cephalosporins cautiously in patients that have a documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cephamycins, carbapenems).

Ceftazidime is primarily excreted via the kidneys and may accumulate in patients with markedly impaired renal function; use with caution and adjust dose as required. The risk of neurologic toxicity (eg, seizures, myoclonus, encephalopathy) is increased in patients with renal impairment.

Ceftazidime can be easily confused with other cephalosporins. Consider writing part of the drug's name in uppercase letters (tall-man designations) on prescriptions/orders to reduce the risk of errors, for example, cefTAZidime.

Adverse Effects

Because veterinary use of ceftazidime has been limited, a full adverse effect profile has not been determined for veterinary patients. GI effects have been reported in dogs that have received the drug SC. When given IM, pain may be noted at the injection site; in animals, pain on injection could also occur after SC administration.

Hypersensitivity reactions, hemolytic anemia, and GI signs have been reported in humans and may not apply to veterinary patients.

Pseudomembranous colitis (*Clostridium difficile*) may occur in patients receiving this antibiotic. Increased serum liver enzyme (eg, ALT, AST, LDH, GGT) activity have been described in 1% to 8% of human patients given ceftazidime[9]; significance in veterinary medicine is unknown.

Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta. No teratogenic effects were demonstrated in studies in pregnant mice and rats given up to 40 times labeled doses of ceftazidime.[9] In humans, cef-

tazidime is considered compatible with pregnancy.[10]

Because of the drug's low oral absorbability, it is unlikely to be harmful to nursing offspring, but alterations to GI microbiota of nursing animals could occur. In humans, ceftazidime is considered compatible with breastfeeding.[10]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

An acute overdose in patients with normal renal function is unlikely to be of great concern; but in humans with renal insufficiency, overdose of ceftazidime has caused seizures, encephalopathy, coma, neuromuscular excitability, asterixis, and myoclonia.[9] Treatment of signs associated with overdose is primarily based on clinical signs and is supportive. Hemodialysis could be used to enhance elimination. Ceftazidime is cleared significantly during continuous renal replacement therapies (CRRTs).

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ceftazidime and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin**): The concurrent use of parenteral aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides,[11] but they should be administered separately.
- **Nephrotoxic Drugs** (eg, **amphotericin B, furosemide, iohexol**): Concurrent use with ceftazidime may cause additive nephrotoxicity.
- **Chloramphenicol**: May be antagonistic to ceftazidime's effects on gram-negative bacilli; concurrent use is not recommended.
- **Vitamin K Antagonists** (eg, **warfarin**): Cephalosporins may enhance the anticoagulant effect of vitamin K antagonists.

Laboratory Considerations

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's solution, Fehling's solution, *Clinitest®*). Tests utilizing glucose oxidase (*Tes-Tape®*, *Clinistix®*) are not affected by cephalosporins.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.
- **Prothrombin time** may be prolonged.
- When using **Kirby-Bauer disk diffusion** procedures for testing susceptibility, a specific 30 µg ceftazidime disk should be used. An inhibition zone of 18 mm or greater indicates the organism is susceptible, 15 to 17 mm is intermediate, and 14 mm or less is resistant. When using a dilution susceptibility procedure, an organism with a MIC of 8 µg/mL or less is considered susceptible, 16 µg/mL is intermediate, and 32 µg/mL or greater is resistant. With either susceptibility method, infections caused by organisms with intermediate susceptibility may be effectively treated if the infection is limited to tissues in which the drug concentrates, or when a higher-than-normal dose is used.

Dosages

DOGS:

Susceptible *Pseudomonas aeruginosa* infections (extra-label):

1. **Based on a pharmacokinetics/pharmacodynamics (PK/PD) study:** 30 mg/kg IV, IM, SC every 4 hours or given as a continuous IV infusion (CRI) with a loading dose of 4.4 mg/kg and a CRI infusion rate of 4.1 mg/kg/hr. The authors recommended that these regimens be tested in clinical trials of dogs with *P aeruginosa* infections and that ceftazidime should be reserved for those dogs with *P aeruginosa* isolates that are resistant to or develop adverse effects to aminoglycosides and fluoroquinolones.[2]
2. **Based on a PK/PD study:** The authors concluded that ceftazidime administered at 20 mg/kg IV or 25 mg/kg IM, SC every 8 hours should be a useful alternative to aminoglycosides and fluoroquinolones for the empirical treatment of most *P aeruginosa* infections in dogs. However, higher doses may be needed and clinical trials must be conducted to verify these recommendations.[3]

CATS:

Susceptible infections (extra-label): Based on a PK/PD study: 30 mg/kg IM every 8 hours should be effective, but for *Pseudomonas* spp infections, ceftazidime would either need to be dosed much more frequently (every 2 to 4 hours) or as a CRI similar to the dose suggested for dogs (loading dose of 4.4 mg/kg and a CRI infusion rate of 4.1 mg/kg/hour).[4]

HORSES:

Susceptible infections in neonatal foals (extra-label): 25 mg/kg IV or IM every 8 hours. Based on a single-dose pharmacokinetic study in healthy neonatal foals[5]

REPTILES:

Susceptible infections (extra-label): 20 mg/kg IM or SC every 72 hours (every 3 days)[12]

Bacterial infections in snakes, particularly for Enterobacteriaceae or *P aeruginosa* infections (extra-label): 20 mg/kg IM every 72 hours at 30°C (86°F)[13,14]

Chelonians (extra-label): 50 mg/kg IM once daily (every 24 hours)[15]

Wild turtles (extra-label): 20 mg/kg IM as a single dose is predicted to maintain ceftazidime concentration above MIC of most wild-type bacteria.[16]

Monitoring

- Culture and susceptibility as indicated
- Baseline and periodic serum renal and hepatic chemistry panel (eg, BUN, creatinine, ALT, ALP), urinalysis
- For patients with renal insufficiency, monitor for neurotoxicity (eg, seizures, myoclonus)
- Because veterinary use of ceftazidime has been limited, a full adverse effect profile has not been determined for veterinary patients. Pet owners should be encouraged to be in communication about any adverse effects that could be caused by the drug.

Client Information

- Ceftazidime must be injected under the skin (subcutaneously); it is not effective when given by mouth.
- Closely follow storage requirements and discard dates.
- This medicine may cause GI side effects; however, because this

drug is not used commonly in animals, other side effects could occur that are not known. Be sure to contact your veterinarian if you have any concerns about how your animal is responding to this medicine.

- Be sure your animal has access to plenty of fresh water while receiving this medicine.
- Discard used needles and syringes in a puncture-resistant ("sharps") container immediately after use, making sure you do not attempt to disconnect the needle from the syringe or recap the needle. Do not reuse needles or syringes. Your veterinarian or pharmacist will help you obtain these containers as well as disposing them when full, or therapy is complete.

Chemistry/Synonyms

A semisynthetic, third-generation cephalosporin antibiotic, ceftazidime occurs as a white to cream-colored crystalline powder that is slightly soluble in water (5 mg/mL) and insoluble in alcohol, chloroform, and ether. The pH of a 0.5% solution in water is between 3 and 4.

Ceftazidime may also be known as ceftazidimum, GR-20263, LY-139381, *Fortaz®*, *Ceptaz®*, *Tazicef®*, and *Tazidime®*; many trade names are used internationally.

Storage/Stability

Commercially available powders for injection should be stored at 20°C to 25°C (68°F-77°F) and protected from light.

Commercial products contain sodium carbonate (*Fortaz®*, *Tazicef®*), which releases carbon dioxide (effervesces) when reconstituted. Vials are under negative pressure; do not allow pressure to normalize before adding diluent.

Once reconstituted, the solution retains potency for 12 hours at room temperature and 3 days when refrigerated. Some manufacturers state that the solution is stable for 24 hours at room temperature and 7 days when refrigerated. Consult the package insert for further information.

Activated Duplex containers must be used within 12 hours if at room temperature or 3 days if refrigerated.

Once thawed, the premixed frozen solution is stable for 8 hours at room temperature or 3 days under refrigeration. Do not refreeze.

Ceftazidime reconstituted with sterile water to 100 mg/mL and frozen at -20°C (-4°F) in glass vials or plastic syringes retained greater than 90% potency for 91 days; once thawed, the solution may be stored at room temperature for 24 hours or refrigerated for 7 days.[17,18]

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Ceftazidime is **compatible** with the following diluents when being prepared for IM (or SC) injection: sterile or bacteriostatic water for injection, 0.5% or 1% lidocaine. Once reconstituted, ceftazidime is **compatible** with several IV fluids including D5W, 0.9% and 0.45% sodium chloride, Ringer's injection, and lactated Ringer's injection.

Do not use sodium bicarbonate solution for a diluent. Ceftazidime is **compatible** with additives of clindamycin, fluconazole, heparin, and potassium chloride. Ceftazidime is **incompatible** with gentamicin, pantoprazole, ranitidine, and vancomycin.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Ceftazidime Powder for Injection: 500 mg, 1 g, 2 g, and 6 g in 20 mL and 100 mL vials, infusion packs, *ADD-Vantage* vials and piggyback vials; *Fortaz®*, *Tazicef®*, generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Ceftiofur Crystalline Free Acid

(sef-***tee***-oh-fur) *Excede®*

Third-Generation Cephalosporin

Prescriber Highlights

- ► Veterinary-only third-generation cephalosporin labeled for use in horses, cattle, and swine
- ► Oil-based suspension maintains concentrations of ceftiofur and metabolites above MIC for more than 96 hours after a single IM or SC injection.
- ► Administered IM in swine and horses. Administered SC at the posterior aspect of ear in cattle. **Inadvertent intra-arterial injection is likely to result in sudden death.**
- ► Potentially causes hypersensitivity reactions, granulocytopenia, thrombocytopenia, or diarrhea
- ► Shake well prior to use.

Uses/Indications

In horses, ceftiofur CFA is FDA-approved for the treatment of lower respiratory tract infections caused by susceptible strains of *Streptococcus equi* ssp *zooepidemicus*.

In beef and dairy cattle, ceftiofur crystalline free acid (CCFA) is FDA-approved for the treatment of bovine respiratory diseases (BRD, shipping fever, pneumonia) associated with *Mannheimia haemolytica, Pasteurella multocida,* and *Histophilus somni* and for the treatment of foot rot (interdigital necrobacillosis) associated with *Fusobacterium necrophorum* and *Porphyromonas levii.*[1] In beef and nonlactating dairy cattle, CCFA is indicated for the control of respiratory disease in animals at high risk for developing BRD associated with *M haemolytica*, *P multocida*, and *H somni*. Additionally, this antibiotic is indicated for the treatment of acute metritis in lactating dairy cattle (0 to 10 days postpartum) associated with bacterial organisms susceptible to ceftiofur.

In swine, ceftiofur CFA is FDA-approved for the treatment and control of swine respiratory disease (SRD) associated with *Actinobacillus pleuropneumoniae, P multocida, Haemophilus parasuis,* and *Streptococcus suis***.**

The World Health Organization has designated third-generation cephalosporins as Critically Important (Highest Priority) antimicrobials for human medicine.[2] The Office International des Epizooties (OIE) has designated ceftiofur as a Veterinary Critically Important Antimicrobial (VCIA) Agent in avian, bovine, caprine, equine, lagomorph, ovine, and swine species.[3]

Pharmacology/Actions

Ceftiofur is a time-dependent, bactericidal, third-generation cephalosporin antibiotic active against a variety of gram-positive and gram-negative bacteria and anaerobes. Like other cephalosporins, it inhibits bacteria cell wall synthesis. Ceftiofur is not active against *Pseudomonas* spp or enterococci. Acquired resistance is increasingly common, particularly in staphylococci (methicillin-resistant staphylococci) and Enterobacteriaceae (extended spectrum beta-lactamase (ESBL) or extended spectrum cephalosporinase producers).

Ceftiofur is rapidly cleaved into furoic acid and desfuroylceftiofur (active). Desfuroylceftiofur inhibits cell wall synthesis (at stage 3) of susceptible multiplying bacteria and exhibits a spectrum of activity similar to that of cefotaxime, also a third-generation cephalosporin. Parent ceftiofur and the primary metabolite are equally potent and assays to measure microbial sensitivity (plasma and tissue levels) are based on ceftiofur equivalents (CE). The protein binding activity of ceftiofur creates a reservoir effect to maintain active levels at the site of infection.

In cattle, ceftiofur has a broad range of in vitro activity against a variety of pathogens, including *Pasteurella* spp, *Streptococcus* spp,

Staphylococcus spp, *Salmonella* spp, and *E coli*. In dairy cattle with metritis treated with systemic ceftiofur, the effects on postpartum inflammation and fever significantly improved the cure rate, milk yield, and rectal temperature in cows with fever and vaginal discharge or dystocia.[4]

In swine, CCFA at a single IM dose of 5 mg/kg (2.27 mg/lb) provides concentrations of ceftiofur and desfuroylceftiofur-related metabolites in plasma that are multiples above the MIC_{90} for an extended period of time for the SRD label pathogens *Actinobacillus pleuropneumoniae, Pasteurella multocida, Haemophilus parasuis,* and *Streptococcus suis.*

Pharmacokinetics

CCFA is formulated in a caprylic-capric triglyceride acid/cottonseed oil base that allows slow and sustained release from the site of injection to provide prolonged therapeutic concentrations with a single injection.[5,6]

In horses, CCFA at 6.6 mg/kg IM is relatively slowly absorbed and eliminated. After the first dose, the time to peak serum level is ≈22 hours and after a second dose 96 hours after the first, time to peak serum drug levels was ≈16 hours.[7] When given at this dosage, the drug and its active metabolites stay above the determined therapeutic concentration (0.2 µg/mL) for susceptible strains of *Streptococcus equi* subsp *zooepidemicus* for 10 days.

In cattle, SC administration of CCFA—in the middle third of the posterior aspect of the ear of beef and nonlactating dairy cattle or in the posterior aspect of the ear where it attaches to the head of beef, nonlactating dairy, and lactating dairy cattle—provides therapeutic concentrations of ceftiofur and desfuroylceftiofur-related metabolites in plasma above the MIC_{90} for BRD pathogens (*Pasteurella multocida, Mannheimia haemolytica*, and *Histophilus somni*) for generally not less than 150 hours after single administration. Pharmacokinetic studies indicate that base of ear (BOE) administration in dairy cattle is therapeutically equivalent to middle of ear (MOE) administration in beef cattle, with blood levels at therapeutic threshold within 2 hours of administration at both sites using labeled doses.

CCFA 6.6 mg/kg SC in neonatal calves to treat diarrhea (extra-label) provided plasma concentrations above the therapeutic target of 2 µg/mL for at least 3 days following a single dose.[5]

In swine, therapeutic plasma levels for the parent compound and primary metabolite, desfuroylceftiofur, are reached within 1 hour of administration.[8] Plasma levels remained above the MIC for nearly 100% of target SRD pathogens for an average of 8 days.

Approximate half-lives of ceftiofur/desfuroylceftiofur after administration of 6.6 mg/kg SC in a variety of species include alpacas, 45 hours[9]; goats, 37 to 49 hours[10-12]; and elephants, 84 hours.[13] In elephants, a dose of 6.6 mg/kg SC provided adequate plasma concentrations for 7 to 10 days.

In sheep, adequate therapeutic serum concentrations of CCFA for treatment of disease caused by *M haemolytica* and *P multocida* were achieved following SC administration in the right cervical region with a single dose of 6.6 mg/kg. The dosing interval for CCFA in sheep is suggested to be 48 to 72 hours. Adverse systemic reactions were not observed.[14]

A single dose of CCFA (30 mg/kg) administered IM or SC to bearded dragons yielded plasma concentrations of ceftiofur and its metabolites more than 1 µg/mL for more than 288 hours.[6] The author reports the SC route was preferred over the IM route because of less variability in plasma concentrations and greater ease of administration. The author's analysis suggests that a single dose of 30 mg/kg SC may be used to treat infections susceptible to ceftiofur in bearded dragons.

In red-tailed hawks, study results suggest that CCFA could be administered IM in the pectoral region at 10 or 20 mg/kg to treat infections with ceftiofur-susceptible bacteria.[15] Administration resulted in little to no inflammation at the injection site.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Hypersensitivity reactions unrelated to dosage can occur with cephalosporin antibiotics and manifest as rashes, fever, eosinophilia, lymphadenopathy, or anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin class antibiotics is controversial. In humans, it is estimated that 1% to 15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown; however, because there may be cross-reactivity, use cephalosporins cautiously in patients that are documented hypersensitive to other beta-lactam antibiotics (eg, penicillins, cephamycins, carbapenems).

In horses, the manufacturer warns that if acute diarrhea is observed after dosing, additional doses should not be administered and appropriate therapy for diarrhea should be initiated.[7] Ceftiofur use has not been evaluated in horses less than 4 months of age and in breeding, pregnant, or lactating horses. The long-term effects on injection sites have not been evaluated in this species. Additionally, the manufacturer warns that due to the extended exposure in horses, based on the drug's pharmacokinetic properties, adverse reactions may require prolonged monitoring and care, as ≈17 days are needed to eliminate 97% of the dose from the body.

Administer to cattle by the SC route only. Inadvertent intra-arterial injection is likely to result in sudden death.

Ceftiofur can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man letters: cefTIOfur. Do not confuse the three distinct formulations for this drug (HCl, sodium, and CFA).

Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence, but cephalosporins can cause allergic reactions in sensitized patients. Topical exposures to such antimicrobials, including ceftiofur, may elicit mild to severe allergic reactions in some patients. Repeated or prolonged exposure may lead to sensitization.

In horses, CCFA may cause firmness, swelling, sensitivity, and/or edema at the injection site and diarrhea, soft or loose stools, ataxia, muscle tremors, and allergic reactions.[7] When used in an extra-label manner (long-term weekly SC injections), significantly greater swelling occurred at the injection site compared to that observed after single IM administration.[16] Clinical signs consistent with foot pain were noted in healthy horses undergoing a pharmacokinetic study, but causal relationship with ceftiofur was not definitively determined.[7]

Following SC injection in the middle third of the posterior aspect of the ear of cattle, thickening and swelling (characterized by aseptic cellular infiltrate) of the ear may occur.[1] As with other parenteral injections, localized postinjection bacterial infections may result in abscess formation. Attention to hygienic procedures can minimize occurrence. Following SC injections at the posterior aspect of the ear where it attaches to the head (base of the ear), areas of discoloration and signs of inflammation may persist for at least 13 days, potentially resulting in trim loss of edible tissue at slaughter. Injection of volumes greater than 20 mL in the middle third of the ear may result in open draining lesions in a small percentage of cattle.

Reproductive/Nursing Safety

The manufacturer states that the effects of ceftiofur on bovine reproductive performance, pregnancy, and lactation have not been determined,[1] and the safety of ceftiofur has not been demonstrated

for pregnant swine or swine intended for breeding.[8] Ceftiofur use has not been evaluated in breeding, pregnant, or lactating horses.[7] However, cephalosporins as a class are relatively safe for use during pregnancy, and teratogenic or embryotoxic effects would not be anticipated.

Target animal safety studies report administration of a single dose of ceftiofur CFA at the base of the ear in high-producing dairy cattle did not adversely affect milk production compared to untreated controls. Ceftiofur in maternal milk would be unlikely pose significant risk to offspring.

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems other than injection site reactions or GI distress, but other effects are possible (see ***Adverse Effects***). Use of this drug in excess of labeled dosages or via unapproved routes of administration may cause violative residues; contact FARAD (see ***Appendix***) for assistance in determining appropriate withdrawal times in these circumstances.

Equine safety data: Dosages up to 20 mg/kg IM every 4 days for 6 doses given to healthy horses resulted in injection-site reactions (eg, edema, firmness) but no treatment-related GI findings.[7]

Cattle safety data: Results from a 5-day tolerance study in feeder calves indicated that ceftiofur sodium was well-tolerated at 55 mg ceftiofur equivalents/kg (25 times the highest recommended dose) for 5 consecutive days. Ceftiofur administered IM had no adverse systemic effects.[1]

Swine safety data: Results from a 5-day tolerance study in normal feeder pigs indicated that ceftiofur sodium was well-tolerated when administered at 125 mg ceftiofur equivalents/kg (more than 25 times the highest recommended daily dosage) for 5 consecutive days. Ceftiofur administered IM to pigs produced no overt adverse signs of toxicity.[8]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ceftiofur and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin**): The concurrent use of parenteral aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well-documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides,[17] but the drugs should be administered at separate times.
- **Nephrotoxic Drugs** (eg, **amphotericin B, furosemide, iohexol**): Concurrent use with ceftiofur may cause additive nephrotoxicity.
- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives.

Laboratory Considerations

NOTE: Considerations listed below are for cefotaxime, which is structurally similar to ceftiofur; these considerations may apply to ceftiofur.

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's solution, *Clinitest®*). Tests using glucose oxidase (*TesTape®, Clinistix®*) are not affected by cephalosporins.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) at high dosages may cause falsely elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.[18]
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

Dosages

HORSES:

Equine strangles *(Streptococcus equi* subsp *zooepidemicus)* (label dosage; FDA-approved): 6.6 mg/kg IM; repeat in 4 days. A maximum of 20 mL per injection site may be administered.

Susceptible bacterial infection in neonatal foals (extra-label): 13.2 mg/kg SC every 48 hours. **NOTE**: Dosage is based on a pharmacokinetic study in healthy foals.[19]

CATTLE:

Treatment of Bovine Respiratory Disease (BRD) and bovine foot rot (label dosage for beef, nonlactating dairy, and lactating dairy cattle; FDA-approved): 6.6 mg/kg (3 mg/lb) as a single injection SC in the posterior aspect of the ear base where it attaches to the head (1.5 mL sterile suspension per 45.3 kg [100 lb] BW).[1] In beef and nonlactating dairy cattle, it may also be administered as a single SC injection in the middle third of the posterior aspect of the ear at the same dosage. Most animals will respond to treatment within 3 to 5 days. If no improvement is observed, the diagnosis should be re-evaluated.

Control of BRD (label dosage for beef and nonlactating dairy cattle only at high risk of developing BRD; FDA-approved): 6.6 mg/kg (3 mg/lb) as a single injection SC in the middle third of the posterior aspect of the ear OR in the posterior aspect of the ear base where it attaches to the head (1.5 mL sterile suspension per 45.3 kg [100 lb] BW).[1]

Acute metritis in lactating dairy cattle (labeled dosage; FDA-approved): 6.6 mg/kg (3 mg/lb) as a single injection SC in the posterior aspect of the ear base where it attaches to the head (1.5 mL sterile suspension per 45.3 kg [100 lb] BW).[1] Repeat this dose in the opposite ear ≈72 hours following the initial dose.

GOATS:

Susceptible bacterial infection (extra-label): 6.6 mg/kg SC once. **NOTE**: dosage based on a pharmacokinetic study in healthy female goats.[11]

SWINE:

Swine Respiratory Disease (label dosage; FDA-approved): Administer by IM injection in the postauricular region of the neck as a single dosage of 5 mg/kg (1 mL sterile suspension per 20 kg [44 lb] BW).[8] No more than 2 mL should be injected in a single injection site. Pigs heavier than 40 kg (88 lb) will require more than one injection. Most animals will respond to treatment within 3 to 5 days. If no improvement is observed, the diagnosis should be re-evaluated.

RABBITS:

Susceptible bacterial infection (extra-label): 40 mg/kg SC every 24 to 72 hours. **NOTE:** Dosage is based on a single-dose pharmacokinetic study in healthy New Zealand White rabbits.[20]

Monitoring

Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.

Patients with diminished renal function may require intensified renal monitoring. Therapeutic drug monitoring is not typically done.

Client Information

- Be sure you know how to administer this medication safely. **Injection of this form of ceftiofur into a blood vessel can result in sudden death of the animal.**
- This drug must be injected as a shot; it does not work when given by mouth. In cattle, it is injected under the skin (SC) in the ear; in swine, it is given into the muscle in the neck, behind the ear; in horses, it is given into the muscle (IM).
- Antibiotic effect is long-lasting after a single injection under the skin in cattle, pigs, and horses.
- Follow recommended withholding times when using in an animal that will be used for human food.
- Persons with a known hypersensitivity to penicillin or cephalosporins should handle this drug carefully to avoid accidental exposure.

Chemistry/Synonyms

CCFA contains 200 mg/mL of ceftiofur in a caprylic/capric triglyceride and cottonseed oil base. It has a molecular weight of 523.58.

CCFA may also be known as CM-31916, ceftiofuri, or *Excede®*.

Storage/Stability

CCFA cattle and swine products should be stored at a controlled room temperature 20°C to 25°C (68°F-77°F). Shake well before using. Contents should be used within 12 weeks after the first dose is removed.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Ceftiofur Crystalline Free Acid equivalent to 200 mg/mL ceftiofur in 100 mL and 250 mL vials; *Excede®* Sterile Suspension. FDA-approved for use in horses, beef, lactating and nonlactating cattle. Following labeled use as either a single-dose or 2-dose regimen, no milk discard period is required, but a 13-day pre-slaughter withdrawal period is required after the last treatment. Do not use in calves to be processed for veal, or in horses intended for human consumption. A withdrawal period has not been established for this product in preruminating calves. Use of doses in excess of 6.6 mg/kg or administration by unapproved routes (SC injection in the neck or IM injection) may cause violative residues.

Ceftiofur Crystalline Free Acid equivalent to 100 mg/mL ceftiofur in 100 mL vials; *Excede® for Swine*; (Rx). Following labeled use as a single treatment, a 14-day preslaughter withdrawal period is required. Doses in excess of label directions or administration by an unapproved route may result in illegal residues in edible tissues.

In 2012, the FDA prohibited extra-label use of cephalosporin in major food animal species (see ***Extra-Label Drug Use***).

HUMAN-LABELED PRODUCTS: NONE

Ceftiofur HCl

(sef-***tee***-oh-fur) *Excenel® RTU EZ, Cefenil® RTU, Spectramast®*

Third-Generation Cephalosporin

Prescriber Highlights

- ► A veterinary-only third-generation cephalosporin approved as an intramammary infusion for dairy cattle and as an injection (given daily) for swine and cattle
- ► Withdrawal times in cattle vary based on product formulations.
- ► Potentially causes hypersensitivity reactions, granulocytopenia, thrombocytopenia, or diarrhea
- ► IM injection route can cause pain in small animal species.

Uses/Indications

In cattle, ceftiofur HCl is FDA-approved for the treatment of the following bacterial diseases: Bovine respiratory diseases (eg, BRD, shipping fever, pneumonia) associated with *Mannheimia haemolytica, Pasteurella multocida,* and *Histophilus somni*; acute bovine interdigital necrobacillosis (foot rot, pododermatitis) associated with *Fusobacterium necrophorum* and *Bacteroides melaninogenicus*; and acute metritis (0 to 14 days postpartum) associated with bacterial organisms susceptible to ceftiofur.

The intramammary syringe for dry dairy cattle (*Spectramast DC®*) is FDA-approved for the treatment of subclinical mastitis in dairy cattle (at the time of dry off) associated with *Staphylococcus aureus*, *Streptococcus dysgalactiae*, and *Streptococcus uberis*. The intramammary syringe for lactating dairy cattle (*Spectramast LC®*) is labeled for the treatment of clinical mastitis in lactating dairy cattle associated with coagulase-negative staphylococci, *Streptococcus dysgalactiae*, and *Escherichia coli* and the treatment of diagnosed subclinical mastitis associated with coagulase-negative staphylococci and *Streptococcus dysgalactiae*.

In swine, ceftiofur HCl injection is FDA-approved for the treatment and control of swine bacterial respiratory disease associated with *Actinobacillus (Haemophilus) pleuropneumoniae*, *Pasteurella multocida*, *Salmonella choleraesuis,* and *Streptococcus suis*.

The World Health Organization has designated third-generation cephalosporins as Critically Important (Highest Priority) antimicrobials for humans.[1] The Office International des Epizooties (OIE) has designated ceftiofur as a Veterinary Critically Important Antimicrobial (VCIA) Agent in avian, bovine, caprine, equine, lagomorph, ovine, and swine species.[2]

Pharmacology/Actions

Ceftiofur is a third-generation, time-dependent, bactericidal cephalosporin antibiotic that is active against a variety of gram-positive and gram-negative bacteria and that, like other cephalosporins, inhibits bacteria cell wall synthesis.

Ceftiofur is rapidly cleaved into furoic acid and desfuroylceftiofur (active). Desfuroylceftiofur inhibits cell-wall synthesis (at stage 3) of susceptible multiplying bacteria and exhibits a spectrum of activity similar to that of cefotaxime (a third-generation cephalosporin). Parent ceftiofur and the primary metabolite are equally potent and assays to measure microbial sensitivity (plasma and tissue levels) are based on ceftiofur equivalents (CE). The protein-binding activity of ceftiofur creates a reservoir effect to maintain active levels at the site of infection.

In cattle, ceftiofur has a broad range of in vitro activity against a variety of pathogens, including *Pasteurella* spp, *Streptococcus* spp, *Staphylococcus* spp, *Salmonella* spp, and *Escherichia coli*.

In swine, ceftiofur HCl has activity against the pathogens *Actinobacillus pleuropneumoniae, Pasteurella multocida, Haemophilus parasuis,* and *Streptococcus suis* for an extended period of time.

Ceftiofur is ineffective against methicillin-resistant staphylococci, extended-spectrum beta-lactamase–producing gram-negative bacteria, and enterococci.

Pharmacokinetics

In cattle and swine, ceftiofur is rapidly metabolized to desfuroylceftiofur, the primary and active metabolite. In cattle, the peak total ceftiofur concentration (ceftiofur + desfuroylceftiofur) of ≈9.2 µg/mL is reached ≈1.7 hours and 2.25 hour after IM and SC administration, respectively, and elimination half-life is 29 to 33 hours.[3] Total ceftiofur plasma concentration remained above 0.2 µg/mL for ≈41 hours after administration of a single SC or IM dose of 5 mg/kg (**NOTE:** This exceeds the FDA-approved dose).[3]

The elimination kinetics of ceftiofur HCl in milk when used in an extra-label manner to treat coliform mastitis has been studied. Milk samples were tested after two 300 mg doses (6 mL) administered 12 hours apart into the affected mammary quarters. The samples tested at less than the tolerance level for this drug set by FDA by 7 hours after the last intramammary administration. However, the authors noted considerable variability in the time required for samples from individual cows and mammary gland quarters to consistently have drug residues less than the tolerance level and reported that elimination rates of the drug may be related to milk production. Therefore, cows producing smaller volumes of milk may have prolonged withdrawal times.[4]

In lactating dairy cattle, active ceftiofur concentrations were measured after the administration of 1 mg/kg SC in healthy dairy cattle within 24 hours of calving. Drug concentrations were found to exceed MIC in uterine tissues and lochial fluid for common pathogens.[5]

In swine given 5 mg/kg IM, the peak total ceftiofur concentration (ceftiofur + desfuroylceftiofur) of 19.7 µg/mL is reached after ≈1.5 hours, elimination half-life is 20 hours, and total ceftiofur plasma concentration remained above 0.2 µg/mL for 82.5 hours.[3] A study measuring tissue distribution following IM injection of varying doses to swine revealed the highest concentration was detected in the kidneys, followed by the lungs, liver, and muscle tissues.[6]

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Hypersensitivity reactions unrelated to dosage can occur with cephalosporin antibiotics and manifest as rashes, fever, eosinophilia, lymphadenopathy, or anaphylaxis. Use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that 1% to 15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown; however, because there may be cross-reactivity, use cephalosporins cautiously in patients that are documented hypersensitive to other beta-lactam antibiotics (eg, penicillins, cephamycins, carbapenems).

In cattle, after IM or SC administration, areas of discoloration at the site may result in trim loss of edible tissues at slaughter. Discard milk obtained during treatment with intramammary (LC) product.

In swine, areas of discoloration associated with the injection site may result in trim-out of edible tissues at slaughter.

The injectable product should not be given in a vein or artery.

Ceftiofur can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man letters: cefTIOfur. Do not confuse the 3 distinct formulations for this drug (HCl, sodium, and crystalline free acid [CFA]). Branded drug names may not be consistent internationally (eg, in Canada, *Excenel*® contains ceftiofur sodium, whereas in the US, *Excenel*® *RTU EZ* contains ceftiofur HCl).

Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence, but cephalosporins can cause allergic reactions in sensitized individuals. Topical exposures to such antimicrobials, including ceftiofur, may elicit mild to severe allergic reactions in some individuals. Repeated or prolonged exposure may lead to sensitization.

Injection-site reactions (eg, swelling, erythema, firmness) occur in ≈59% in cattle following SC administration but appear to be uncommon (less than 0.4%) with IM administration.[3]

Reproductive/Nursing Safety

The manufacturer states that the effects of ceftiofur on bovine reproductive performance, pregnancy, and lactation have not been determined, and the safety of ceftiofur has not been demonstrated for pregnant swine or swine intended for breeding. However, cephalosporins as a class are relatively safe for use during pregnancy, and teratogenic or embryotoxic effects would not be anticipated.

Ceftiofur in maternal milk would be unlikely pose significant risk to offspring.

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see ***Adverse Effects*** section). Use of this drug in excess of labeled dosages or by unapproved routes of administration may cause violative residues. Contact FARAD (see ***Appendix***) for assistance in determining appropriate withdrawal times in circumstances where the drug has been used at higher-than-labeled dosages.

Cattle safety data: Results from a 5-day tolerance study in feeder calves indicated that ceftiofur sodium (proven to be equivalent to ceftiofur HCl) was well tolerated at 55 mg ceftiofur equivalents/kg (25 times the highest recommended dose) for 5 consecutive days. Ceftiofur administered IM had no adverse systemic effects.[7]

Swine safety data: Results from a 5-day tolerance study in normal feeder pigs indicated that ceftiofur sodium (proven to be equivalent to ceftiofur HCl) was well-tolerated when administered at 125 mg ceftiofur equivalents/kg (more than 25 times the highest recommended daily dosage) for 5 consecutive days. Ceftiofur administered IM to pigs produced no overt adverse signs of toxicity.[7]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ceftiofur and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin**): Concurrent use of parenteral aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well-documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides,[8] but the drugs should be administered at separate times.
- **Nephrotoxic Drugs** (eg, **amphotericin B, furosemide, iohexol**): Concurrent use with ceftiofur may cause additive nephrotoxicity.
- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives.

Laboratory Considerations

NOTE: Considerations listed below are for cefotaxime, which is structurally similar to ceftiofur; these considerations may apply to ceftiofur.

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when cupric sulfate solution (Benedict's solution, *Clinitest®*) is used. Tests using glucose oxidase (*Tes-Tape®, Clinistix®*) are not affected by cephalosporins.
- When the Jaffe reaction is used to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) at high dosages may cause falsely elevated values.
- In humans, particularly those with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.[9]
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

Dosages

CATTLE:

Bovine respiratory disease (BRD) and acute bovine interdigital necrobacillosis (label dosage; FDA-approved): 1.1 – 2.2 mg/kg IM or SC (1 – 2 mL sterile suspension per 45kg [100 lb]) daily for a total of 3 consecutive days.[3,10] Additional treatments may be administered on days 4 and 5 for animals that do not show a satisfactory response. For BRD only: Based on an assessment of the severity of disease, pathogen susceptibility and clinical response, can administer 2.2 mg/kg IM or SC every other day on days 1 and 3 (48-hour interval). Do not inject more than 15 mL per injection site.

Acute postpartum metritis (label dosage; FDA-approved): 2.2 mg/kg IM or SC (2 mL sterile suspension per 45 kg [100 lb]) daily for 5 consecutive days.[3,10] Do not inject more than 15 mL per injection site.

Subclinical mastitis in dairy cattle at time of dry off associated with *Staphylococcal aureus*, *Streptococcus dysgalactiae,* or *Streptococcus uberis* (label dosage; FDA-approved): Infuse one syringe of *Spectramast® DC* into each affected quarter at the time of dry off.[12]

Clinical or diagnosed subclinical mastitis in lactating dairy cattle associated with coagulase-negative staphylococci *Streptococcus dysgalactiae* or *Escherichia coli* (label dosage; FDA-approved): Infuse one syringe of *Spectramast® LC* into each affected quarter.[13] Repeat this treatment in 24 hours. For extended duration therapy, once daily treatment may be repeated for up to 8 consecutive days.

Neonatal salmonellosis (extra-label): Ceftiofur HCl 5 mg/kg IM once daily for 5 days[11]

SWINE:

Swine bacterial respiratory infections (label dosage; FDA-approved): 3 – 5 mg/kg IM (1 mL of sterile suspension per 10 to 16.7 kg [22 to 37 lb] body weight) every 24 hours for a total of 3 consecutive days[3,10]

Monitoring

Because minimal toxicity is associated with use of cephalosporins, monitoring for efficacy is usually all that is required. Patients with diminished renal function may require intensified renal monitoring. Therapeutic drug monitoring is not typically done.

Client Information

For the injectable product:

- Be sure you know how to administer this medication safely.
- This drug must be given as a shot under the skin or into the muscle only; do not give in a vein or artery. It does not work when given by mouth.
- Do not give more than 15 mL at one site.
- May cause discoloration of the skin at the injection site
- Follow recommended drug residue withholding times if you are administering to an animal that will be used for human food.

For the intramammary product:

- Wash teats thoroughly with warm water mixed with a suitable antiseptic and dry thoroughly.
- Milk udder out completely.
- Wipe end of affected teat with provided alcohol pad; use a separate pad for each teat.
- Insert tip of syringe into teat canal and push plunger to dispense entire contents.
- Massage quarter to distribute suspension into the milk cistern.
- Follow recommended drug residue withholding times.

Chemistry/Synonyms

Ceftiofur HCl is a semisynthetic third-generation cephalosporin. Ceftiofur HCl is a weak acid, acid-stable, and water soluble with a molecular weight of 560. The RTU injectable sterile suspension is a ready-to-use formulation that contains ceftiofur hydrochloride equivalent to 50 mg ceftiofur, 5.73 mg aluminum monostearate, 1.03 mg sorbitan monooleate, and medium chain triglycerides. The RTU EZ injectable sterile suspension is a ready-to-use formulation that contains ceftiofur hydrochloride equivalent to 50 mg ceftiofur, 2.50 mg polyoxyethylene sorbitan monooleate (polysorbate 80), 6.5 mg water for injection in a caprylic/capric triglyceride (*Miglyol* 812) suspension. Both *Spectramast®* products are sterile, oil-based suspensions of ceftiofur HCl.

Ceftiofur HCl may also be known as U-64279A, ceftiofuri hydrochloridium, *Cefenil® RTU, Excenel® RTU*, or *Excenel® RTU EZ*.

Storage/Stability

The ready-to-use injectable product should be stored at room temperature (either 20°C to 25°C (68°F-77°F) or less than 30°C (86°F), depending on the product used; consult product label). Shake well before using; protect from freezing. Contents should be used within 42 days after first dose is removed.

The intramammary syringes should be stored at controlled room temperature 20°C to 25°C (68°F-77°F). Protect from light. Store plastets in carton until used.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Ceftiofur HCl Sterile Suspension for injection, 50 mg/mL in 100 mL and 250 mL vials; *Cefenil®* RTU; (Rx). FDA-approved for use in cattle and swine. Slaughter withdrawal = 3 days in cattle; 4 days in swine. There is no required milk discard time.

Ceftiofur HCl Sterile Suspension for injection, 50 mg/mL in 100 mL and 250 mL vials; *Excenel®* RTU EZ; (Rx). FDA-approved for use in cattle (not veal calves) and swine. Slaughter withdrawal = 4 days in cattle (withdrawal period not determined in pre-ruminating calves); 4 days in swine if injected volume is less than/equal to 5 mL, and 6 days if volume is greater than 5 mL but less than or equal to 15 mL. There is no required milk discard time.

Ceftiofur HCl Sterile Suspension for Intramammary Infusion in Dry Cows 500 mg ceftiofur equivalents (as the HCl) per 10 mL syringe (plastets) in packages of 12 or 144 syringes with 70% isopropyl alcohol pads; *Spectramast® DC*; (Rx). Slaughter withdrawal for cattle = 16 days (no slaughter withdrawal required for neonatal calves born from treated cows)

Ceftiofur HCl Sterile Suspension for Intramammary Infusion in

Lactating Cows 125 mg ceftiofur equivalents (as the HCl) per 10 mL syringe (plastets) in packages of 12 or 144 syringes with 70% isopropyl alcohol pads; *Spectramast® LC*; (Rx). Cattle slaughter withdrawal = 2 days; milk discard = 72 hours

In 2012, the FDA prohibited extra-label use of cephalosporin in major food animal species. (See ***Extra-Label Drug Use***)

Ceftiofur Sodium

(sef-***tee***-oh-fur) *Naxcel®, Ceftiflex®*

Third-Generation Cephalosporin

Prescriber Highlights

- ► A veterinary-only third-generation cephalosporin approved for use in dogs, horses, cattle, sheep/goats, swine, and poultry. Also used in an extra-label manner in a variety of other species
- ► Potentially causes hypersensitivity reactions, granulocytopenia, thrombocytopenia, or diarrhea
- ► Causes pain on IM injection in small animals

Uses/Indications

In dogs, ceftiofur is labeled for treatment of canine UTIs associated with *Escherichia coli* and *Proteus mirabilis*.

In horses, ceftiofur is labeled for treatment of respiratory infections associated with *Streptococcus equi* subsp *zooepidemicus*.

In cattle, ceftiofur sodium is FDA-approved for treatment of bovine respiratory disease (BRD; eg, shipping fever, pneumonia) associated with *Mannheimia haemolytica*, *Pasteurella multocida*, and *Histophilus somni*. It is also indicated for treatment of acute bovine interdigital necrobacillosis (eg, foot rot, pododermatitis) associated with *Fusobacterium necrophorum* and *Bacteroides melaninogenicus*.

In swine, ceftiofur is labeled for treatment and control of swine bacterial respiratory disease (eg, swine bacterial pneumonia) associated with *Actinobacillus (Haemophilus) pleuropneumoniae*, *Pasteurella multocida*, *Salmonella choleraesuis*, and *Streptococcus suis*.

In sheep and goats, ceftiofur is labeled for treatment of sheep/caprine respiratory disease (eg, sheep/goat pneumonia) associated with *Mannheimia haemolytica* and *Pasteurella multocida*.

In day-old chicks and poults, ceftiofur is labeled for control of early mortality associated with *Escherichia coli* organisms susceptible to ceftiofur.

Ceftiofur has also been used in an extra-label manner in a variety of veterinary species (see ***Dosages***) to treat infections susceptible to a third-generation cephalosporin.

The World Health Organization (WHO) has designated third-generation cephalosporins as Critically Important, Highest Priority antimicrobials for human medicine.[1] The Office International des Epizooties (OIE) has designated ceftiofur as a Veterinary Critically Important Antimicrobial (VCIA) Agent in avian, bovine, caprine, equine, lagomorph, ovine, and swine species.[2]

Pharmacology/Actions

Ceftiofur is a third-generation cephalosporin and a time-dependent bactericidal antibiotic active against a variety of gram-positive and gram-negative bacteria; like other cephalosporins, it inhibits bacteria cell wall synthesis.

Ceftiofur is rapidly cleaved into furoic acid and desfuroylceftiofur (active). Desfuroylceftiofur inhibits cell wall synthesis (at stage 3) of susceptible multiplying bacteria and exhibits a spectrum of activity similar to that of cefotaxime (ie, a third-generation cephalosporin). Parent ceftiofur and the primary metabolite are equally potent and assays to measure microbial sensitivity (plasma and tissue levels) are based on ceftiofur equivalents (CE). Ceftiofur has a broad range of in vitro activity against a variety of pathogens, including *Pasteurella* spp, *Streptococcus* spp, *Staphylococcus* spp, *Salmonella* spp, and *Escherichia coli*. It is ineffective against methicillin-resistant staphylococci, extended spectrum beta-lactamase-producing gram-negative bacteria, and enterococci.

Pharmacokinetics

In cattle, ceftiofur sodium and HCl have practically equivalent pharmacokinetic parameters. The following pharmacokinetic values for cattle are for the active metabolite desfuroylceftiofur. The volume of distribution in cattle is ≈0.3 L/kg. Peak concentrations are ≈7 µg/mL after IM injection of *Naxcel®*, but areas under the curve and elimination half-lives (≈8-12 hours) for both forms of the drug are practically equal. Peak concentrations occur 30 to 45 minutes after IM dosing. Pharmacokinetic parameters of ceftiofur sodium are similar for either SC or IM injection in cattle.

In dairy goats given ceftiofur 1.1 mg/kg or 2.2 mg/kg IV or IM, 100% bioavailability was demonstrated via the IM route. After 5 daily IM doses of the drug, serum concentrations were found to be dose proportional.[3] Lactating does eliminate the drug more rapidly as compared with nonlactating does.[4]

Ceftiofur sodium given IM to beef cattle, dairy cattle, swine, and sheep is absorbed quickly and metabolized rapidly to desfuroylceftiofur (DFC), which can be further converted to desfuroylceftiofur cysteine disulfide (DCCD), condensed to a dimer, or bound to proteins or other macromolecules. New determinative and confirmatory methods by liquid chromatography-mass spectrometry (LC-MS) have been developed and validated for DCCD in bovine kidney, liver, and muscle to modernize the drug residue monitoring approach.[5]

In horses, 2 g of ceftiofur was administered via regional IV perfusion or systemic IV to determine radiocarpal joint synovial fluid and plasma concentrations.[6] Mean synovial fluid concentrations were higher for the regional IV perfusion than systemic IV administration. The study concluded that regional IV perfusion induced significantly higher intra-articular antibiotic concentrations in the radiocarpal joint as compared with systemic IV administration. In addition, synovial fluid drug concentrations remained above the MIC for common pathogens longer than 24 hours.[6] A separate study evaluating regional IV perfusion found plasma concentration above common bacterial MIC 12 hours after administration and SC tissue concentration above MIC for 24 hours.[7]

In foals, administration of ceftiofur sodium 2.2 mg/kg once daily for 5 days (5 total doses) via nebulization was well-tolerated, and desfuroylceftiofur acetamide concentrations in plasma and pulmonary epithelial lining fluid remained above the MIC required to inhibit the growth of 90% of *Streptococcus equi* subsp *zooepidemicus* for ≈24 hours after administration, suggesting further investigation for treatment of bacterial infections of the lower respiratory tract in horses.[8] Terminal half-life in pregnant pony mares was ≈3 to 4 hours after IM administration.[9]

In dogs, ceftiofur sodium only attains effective concentrations in urine.[10]

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Hypersensitivity reactions unrelated to dosage can occur with cephalosporin antibiotics and manifest as rashes, fever, eosinophilia, lymphadenopathy, or anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin class antibiotics is controversial. In humans, it is estimated that 1% to 15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity

in veterinary patients is unknown; however, because there may be cross-reactivity, use cephalosporins cautiously in patients that are documented to be hypersensitive to other beta-lactam antibiotics (eg, penicillins, cephamycins, carbapenems).

Ceftiofur can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man letters: cefTIOfur. Do not confuse the 3 distinct formulations for this drug (HCl, sodium, and crystalline free acid [CFA]). Branded drugs names may not be consistent internationally (eg, in Canada, *Excenel®* contains ceftiofur sodium; in the US *Excenel® RTU EZ* contains ceftiofur HCl).

Adverse Effects

Adverse effects with cephalosporins are usually not serious and have a relatively low frequency of occurrence, but cephalosporins can cause allergic reactions in sensitized patients. Topical exposures to such antimicrobials, including ceftiofur, may elicit mild to severe allergic reactions in some patients. Repeated or prolonged exposure may lead to sensitization.

Following SC administration of ceftiofur sodium in the neck, small areas of discoloration at the site may persist beyond 5 days, potentially resulting in trim loss of edible tissue at slaughter. Localized postinjection bacterial infections may result in abscess formation in cattle; attention to hygienic procedures can minimize their occurrence.

Reproductive/Nursing Safety

The manufacturer states that the effects of ceftiofur on bovine reproductive performance, pregnancy, and lactation have not been determined, and the safety of ceftiofur has not been demonstrated in pregnant swine or swine intended for breeding. However, cephalosporins as a class are relatively safe for use during pregnancy, and teratogenic or embryotoxic effects would not be anticipated.

Most cephalosporins are excreted in milk in small quantities. The active ceftiofur metabolite was present in colostrum of pony mares at 3% to 33% of maternal serum values.[9] Modification/alteration of GI microbiota with resultant diarrhea in the nursing patient is theoretically possible. When given as labeled, there are no milk withdrawal times necessary for ceftiofur products in dairy cattle.

Overdose/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see ***Adverse Effects***). Use of this drug in excess of labeled dosages or via unapproved routes of administration may cause violative residues; contact FARAD (see ***Appendix***) for assistance in determining appropriate withdrawal times in these circumstances.

No toxicity was noted during safety studies in cattle, swine, sheep, and goats given up to 25 times the highest labeled dosage for each species, in chicks given up to 100 mg/kg SC, and in poults given up to 400 mg/kg SC. Colitis and diarrhea occurred in horses receiving 22 – 55 mg/kg/day IV. Thrombocytopenia and anemia were noted in dogs given 2.2 – 11 mg/kg/day SC for 42 days.[4]

Swine safety data: results from a 5-day tolerance study in normal feeder pigs indicated ceftiofur sodium was well-tolerated when administered at 125 mg ceftiofur equivalents/kg (more than 25 times the highest recommended daily dosage) for 5 consecutive days. Ceftiofur administered IM to pigs produced no overt adverse signs of toxicity.[4]

Cattle safety data: results from a 5-day tolerance study in feeder calves indicated ceftiofur sodium was well-tolerated when administered at 55 mg ceftiofur equivalents/kg (25 times the highest recommended dose) for 5 consecutive days. Ceftiofur administered IM had no adverse systemic effects.[4]

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ceftiofur and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin**): Concurrent use of parenteral aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well-documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides,[11] but the drugs should be administered at separate times.
- **Nephrotoxic Drugs** (eg, **amphotericin B, furosemide, iohexol**): Concurrent use with ceftiofur may cause additive nephrotoxicity.
- **Probenecid**: Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives

Laboratory Considerations

NOTE: Considerations listed below are for cefotaxime, which is structurally similar to ceftiofur; these considerations may apply to ceftiofur.

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's solution, *Clinitest®*). Tests using glucose oxidase (*TesTape®, Clinistix®*) are not affected by cephalosporins.
- When using the Jaffe reaction to measure **serum** or **urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) at high dosages may cause falsely elevated values.
- In humans, particularly those with azotemia, cephalosporins have caused a false-positive direct **Coombs test**.[12]
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

Dosages

DOGS:

UTIs associated with *Escherichia coli* and *Proteus mirabilis* (label dosage; FDA-approved): 2.2 mg/kg SC every 24 hours for 5 to 14 days (0.1 mL reconstituted sterile solution per 2.2 kg [5 lb] body weight)[4]

Susceptible Infections (extra-label):

a) **UTI**: 2 mg/kg SC every 12 to 24 hours[13]

b) **Neonatal septicemia**: 2.5 mg/kg SC every 12 hours for no longer than 5 days; presumptive therapy with vitamin K_1 (0.01 – 1 mg/neonate [NOT mg/kg] SC) may be used in puppies younger than 48 hours.[14,15]

c) 5 mg/kg IV or SC every 12 hours is predicted to treat susceptible bacteria with MIC less than or equal to 4 µg/mL; based on a single-dose pharmacokinetic study[16]

CATS:

Susceptible Infections (extra-label):

a) **UTI**: 2 mg/kg SC every 12 to 24 hours[13]

b) **Neonatal septicemia**: 2.5 mg/kg SC every 12 hours for no longer than 5 days; presumptive therapy with vitamin K_1 (0.01 – 1 mg/neonate [NOT mg/kg] SC) may be used in kittens younger than 48 hours.[14,15]

c) 5 mg/kg IV or SC every 12 hours is predicted to treat susceptible bacteria with MIC less than or equal to 4 µg/mL; based on a single-dose pharmacokinetic study[17]

HORSES:

Respiratory infections associated with *Streptococcus equi* subsp *zooepidemicus* (label dosage; FDA-approved): 2.2 – 4.4 mg/kg IM (2 – 4 mL reconstituted sterile solution per 45 kg [100 lb] body weight) daily; continue for 48 hours after clinical signs have disappeared.[4] A maximum of 10 mL may be administered per injection site. Do not exceed 10 days of treatment.

Susceptible Infections in adults (extra-label): 2.5 – 3.2 mg/kg IV loading dose, followed by 200 – 285.12 µg/kg/hour (3.33 to 4.75 µg/kg/minute) IV CRI[18,19]

Susceptible Infections in foals (extra-label):

a) Based on a pharmacokinetic study, a bolus loading dose of 1.26 mg/kg IV followed immediately by 2.86 µg/kg/minute IV CRI. Daily dose is ≈5.4 mg/kg. This dosage could presumably be used to treat bacteria with an MIC of less than or equal to 4 µg/mL. Once clinical condition improves, dosing can be switched from CRI daily to IM every 12 hours.[20]

b) 2.2 – 5 mg/kg IM every 12 hours[21]

CATTLE:

Bovine respiratory disease (BRD) and acute bovine interdigital necrobacillosis (label dosage; FDA-approved): 1.1 – 2.2 mg/kg IM or SC (1 – 2 mL reconstituted sterile solution per 45 kg [100 lb] body weight) daily for a total of 3 consecutive days.[22] Additional treatments may be given on days 4 and 5 for animals that do not show a satisfactory response (ie, not recovered) after the initial 3 treatments.

SHEEP/GOATS:

Respiratory disease associated with *Mannheimia haemolytica* and *Pasteurella multocida* (label dosage; FDA-approved): 1.1 – 2.2 mg/kg IM (1 – 2 mL reconstituted sterile solution per 45 kg [100 lb] body weight) daily for a total of 3 consecutive days.[4] Additional treatments may be given on days 4 and 5 for animals that do not show a satisfactory response (ie, not recovered) after the initial 3 treatments. When used in lactating does, the high end of the dosage is recommended.

SWINE:

Swine bacterial respiratory infections associated with *Actinobacillus (Haemophilus) pleuropneumoniae, P multocida, Salmonella choleraesuis* and *Streptococcus suis* (label dosage; FDA-approved): 3 – 5 mg/kg IM (1 mL of reconstituted sterile solution per 10 to 16.7 kg [22 to 37 lb] body weight) daily for a total of 3 consecutive days[4]

BIRDS:

Control of early mortality associated with *E coli* (label dosage; FDA-approved):

a) **Day-old turkey poults**: 0.17 – 0.5 mg/poult (NOT mg/kg) SC in the neck region.[4] 1 mL of the 50 mg/mL reconstituted solution will treat ≈100- to 294-day-old poults.

b) **Day-old chicks**: 0.08 – 0.2 mg/chick (NOT mg/kg) SC in the neck region.[4] 1 mL of the 50 mg/mL reconstituted solution will treat ≈250- to 625-day-old chicks. A sterile, 26-gauge needle and syringe or properly cleaned automatic injection machine should be used.

REPTILES:

Susceptible Infections (extra-label):

a) **Chelonians**: 4 mg/kg IM once daily for 2 weeks. Commonly used in respiratory infections[23]

b) For microbes susceptible at more than 2 µg/mL, 5 mg/kg, IM or SC, every 24 hours[24]; based on a pharmacokinetic study in green iguanas

c) **Bacterial pneumonia**: 2.2 mg/kg IM every 24 to 48 hours; keep patient at upper end of ideal temperature range[25]

Monitoring

Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required. Patients with diminished renal function may require intensified renal monitoring. Therapeutic drug monitoring is not typically done.

Client Information

- This drug must be injected; it does not work when given by mouth.
- Pain is possible when this drug is injected in the muscle. If given at home to small animals, it is usually given via injection under the skin (ie, subcutaneously).
- Observe recommended withholding times if injecting an animal that will be used for human food.

Chemistry/Synonyms

Ceftiofur sodium is a semisynthetic third-generation cephalosporin that is a weak acid, acid-stable, and water-soluble.

Ceftiofur sodium may also be known as CM 31-916, U 64279E, ceftiofen sodium, *Excenel®* (not *Excenel® RTU*), *Naxcel®*, *Ceftiflex®*, or *Accent®*.

Storage/Stability

Concentrated ceftiofur sodium powder for reconstitution should be stored at room temperature (20°C-25°C [68°F-77°F]). Protect from light. Color of the cake may vary from off-white to tan, but this does not affect potency.[4]

After reconstitution with bacteriostatic water or sterile water for injection, the solution is stable for up to 7 days when refrigerated at 2°C to 8°C (36°F-46°F) and for 12 hours at room temperature (20°C-25°C [68°F-77°F]).

There is a one-time salvage procedure for the reconstituted product. At the end of day 7 refrigeration or 12-hour room temperature storage following reconstitution, any remaining reconstituted product may be frozen for up to 8 weeks without loss in potency or other chemical properties. To use this salvaged product at any time during the 8-week storage period, hold the vial under warm running water, gently swirling the container to accelerate thawing, or allow the frozen material to thaw at room temperature. Rapid freezing or thawing may result in vial breakage. Any product not used immediately upon thawing should be discarded.[4]

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Ceftiofur Sodium Powder for Injection: 50 mg ceftiofur/mL when reconstituted in 1 g and 4 g vials; *Naxcel®*[4]; *Excenel®* (in Canada), *Ceftiflex®*, generic; (Rx). FDA-approved for various indications in cattle, swine, sheep, goats, horses, dogs, and day-old chicks or turkey poults. Withdrawal times: Cattle: 4-day slaughter withdrawal time is required. No milk discard time is required. Swine: A 4-day slaughter withdrawal time is required. Sheep/Goats: No slaughter withdrawal time or milk discard time is required. Not to be used in horses intended for human consumption.

- In 2012, the FDA prohibited cephalosporin extra-label drug use in major food animal species. (See ***Extra-Label Drug Use***)

HUMAN-LABELED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Ceftriaxone

(sef-try-***ax***-ohn) *Rocephin®*

Third-Generation Cephalosporin

Prescriber Highlights

- ► Injectable antibiotic used to treat serious bacterial infections
- ► Achieves therapeutic concentrations in CNS; long half-life
- ► Adverse effects include hypersensitivity reactions and injection site reactions (eg, skin tightness, induration).
- ► Administer ceftriaxone IV over 30 minutes (or longer). Pain on IM injection is reduced when reconstituted with lidocaine.
- ► **In the United States, extra-label drug use of cephalosporins is restricted in food-producing animals.**

Uses/Indications

Ceftriaxone is used to treat serious infections (particularly against susceptible Enterobacteriaceae) that are not susceptible to other agents or when aminoglycosides are not indicated because of their potential toxicity. Its long half-life, good CNS penetration, and activity against *Borrelia burgdorferi* have also made ceftriaxone a potential choice for treating Lyme borreliosis and other infections in animals. Although ceftriaxone has been reported for the treatment of uncomplicated lower UTI,[1] its use is not recommended for this purpose.[2] In dogs, ceftriaxone's lower protein binding and shorter half-life (when compared with humans) give it no advantage over the other parenteral third-generation cephalosporins. In horses, intraperitoneal ceftriaxone successfully treated cases of septic peritonitis.[3]

The World Health Organization (WHO) classifies third-generation cephalosporins as Critically Important, Highest Priority antimicrobials for human medicine.[4] The Office International des Epizooties (OIE) has designated third-generation cephalosporins as Veterinary Critically Important Antimicrobial (VCIA) agents in avian, bovine, ovine, and swine species.[5]

Pharmacology/Actions

Ceftriaxone is a third-generation injectable cephalosporin agent that is bactericidal and displays time-dependent killing. Third-generation cephalosporins retain the gram-positive activity of the first- and second-generation agents, but have much expanded gram-negative activity. This class of antibiotics is often chosen for their excellent gram-negative coverage and significantly less toxic potential (as compared with the aminoglycosides). As with the second-generation cephalosporins, enough variability exists with individual bacterial sensitivities that susceptibility testing is necessary.

Ceftriaxone is ineffective against methicillin-resistant staphylococci, enterococci, extended-spectrum beta-lactamase (ESBL)-producing Enterobacterales, and AmpC-producing Enterobacterales. It generally has excellent activity against gram-negative bacteria; however, it is not a good choice for *Serratia* spp, *Pseudomonas* spp, some *Proteus* spp, *Citrobacter* spp, and *Enterobacter* spp ("SPICE" organisms).

Pharmacokinetics

In humans, ceftriaxone is not absorbed after oral administration and must be given parenterally. It is widely distributed throughout the body and highly bound (95%-98%) to plasma proteins. Ceftriaxone crosses into the CNS; CSF concentrations are higher when meninges are inflamed. Ceftriaxone is excreted by both renal and biliary mechanisms; elimination half-lives are ≈6 to 11 hours.

In dogs, ceftriaxone bioavailability after IM or SC administration was equal after IV administration, but peak concentrations occur much faster after IM (≈30 minutes) than SC (80 minutes) administration.[6] Peak concentrations are higher with IM administration than with SC, but total area under the curve is similar for both routes. Elimination half-life is longer after SC administration (1.73 hours) than after either IM (1.17 hours) or IV administration (0.88 hours). The authors of the study concluded that once or twice daily IM or SC injections of 50 mg/kg should be adequate to treat most susceptible infections in dogs.

In a study of cats, ceftriaxone was well-absorbed when administered IM and SC.[7] Elimination half-life averaged between 1.5 and 2 hours. Protein binding was not determined.

One study compared healthy cows with endometritic cows.[8] After a single ceftriaxone IV dose, elimination half-life was about 1 hour in healthy cows, clearance was 0.3 L/kg/hour, and volume of distribution was 0.5 L/kg. In endometritic cows, elimination half-life was slightly longer at 1.56 hours, clearance was 0.56 L/kg/hour, and volume of distribution was 1.55 L/kg.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, cephalosporins should be used cautiously in patients that have a documented hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cefamycins, carbapenems).

Human patients that have significant renal insufficiency with concomitant hepatic impairment may need dosage adjustments[9]; the relevance of this finding for veterinary patients is unclear.

Ceftriaxone can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefTRIAXone.

Adverse Effects

Because use of ceftriaxone is limited in veterinary patients, an accurate adverse effect profile has not been determined. Pain at the injection site has been reported.[6,7] In dogs, very high dosages (100 mg/kg per day) of ceftriaxone have caused sludge in the bile.

One case report describes 2 horses that were experimentally infected with *Borrelia burgdorferi* and experienced anaphylactoid reactions (ie, nonimmunologic anaphylaxis) after receiving ceftriaxone treatment.[10] Each horse was supposed to receive 25 mg/kg IV, but both infusions were stopped early because of the reaction. Both horses had previously received penicillin without any problems. It is unclear whether the reactions were due to the drug itself, caused by a reaction between the drug and the infection, or due to massive die-off of the bacteria.

The following adverse effects have been reported in humans and may or may not apply to veterinary patients: hematologic effects, including eosinophilia (6%), thrombocytosis (5%), leukopenia (2%), and, more rarely, anemia, neutropenia, lymphopenia, and thrombocytopenia.[9] Approximately 2% to 4% of humans get diarrhea. Hypersensitivity reactions (usually a rash) have been noted. Increased serum concentrations of liver enzymes, BUN, creatinine, and urine casts have been described in ≈1% to 3% of patients.

Reproductive/Nursing Safety

Cephalosporins cross the placenta. Teratogenic effects were not demonstrated in studies in pregnant mice and rats that received up to 20 times the label doses of ceftriaxone.[9] Ceftriaxone is considered compatible with human pregnancy.[11]

Ceftriaxone enters maternal milk in low concentrations.[12] Ceftriaxone is considered compatible with breastfeeding in humans.[11]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

All beagles receiving ceftriaxone 300 mg/kg/day IV developed soft or mucoid feces and diarrhea; emesis was common.[13] As limited information is available, overdoses should be monitored and treated

supportively based on clinical signs.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving ceftriaxone and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides and other Nephrotoxic Drugs** (eg, **amphotericin B**): Concurrent use of parenteral aminoglycosides or other nephrotoxic drugs with cephalosporins is somewhat controversial. Cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well-documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides.
- **Calcium Salts, Intravenous (IV)**: Concomitant use with calcium-containing solutions has caused fatal calcium/ceftriaxone precipitates in lungs and kidneys of neonatal humans. Do not mix with calcium or administer calcium-containing solutions (eg, lactated Ringers, Hartmann's solution) or products within 48 hours of ceftriaxone administration. There have been no reported interactions between oral calcium products and ceftriaxone.

Laboratory Considerations

- Because bacterial sensitivity to third-generation cephalosporin antibiotics is unique, when Kirby-Bauer disk diffusion procedures are employed for testing susceptibility, a specific ceftriaxone 30 µg disk should be used. A cephalosporin-class disk containing cephalothin should not be used to test for ceftriaxone susceptibility.
- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when cupric sulfate solution (Benedict's solution, Fehling's solution, *Clinitest*®) is used. Tests that use glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- Ceftriaxone in high concentrations (50 µg/mL or greater) may cause falsely elevated **serum creatinine** levels when manual methods of testing are used. Automated methods do not appear to be affected.

Dosages

NOTE: In humans, it is recommended that IV infusions be administered over 30 minutes (60 minutes in neonates) at concentrations between 10 – 40 mg/mL.[9]

DOGS:

Susceptible infections (extra-label): 50 mg/kg IM or SC once or twice daily,[6] based on a pharmacokinetic study

Borreliosis | Lyme disease | *Borrelia burgdorferi* infection (extra-label): 25 mg/kg IV or SC once daily for 14 to 30 days[14]

Infective endocarditis caused by *Streptococcus canis* (extra-label): 20 mg/kg IV twice daily for 2 weeks, followed by long-term treatment with oral antibiotics[15]

CATS:

Susceptible infections (extra-label): 25 mg/kg IM or SC every 12 hours[7], based on a pharmacokinetic study

Borreliosis | Lyme disease | *Borrelia burgdorferi* infection (extra-label): 25 mg/kg IV or SC once daily for 14 to 30 days[14]

HORSES:

Susceptible infections (extra-label): 25 – 50 mg/kg every 12 hours IV or IM[16]

Adjuvant treatment for septic peritonitis (extra-label): 25 mg/kg diluted in 250 mL of warmed 0.9% sodium chloride and administered intraperitoneally once daily until resolution of clinical signs and laboratory parameters.[3] Used in combination with parenteral antimicrobial therapy (eg, gentamicin) and supportive treatment. The study authors recommend reserving intraperitoneal ceftriaxone for aggressive cases or cases that have failed to respond to routine antibiotics.

Monitoring

- Culture and susceptibility testing as indicated by clinical condition
- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- With long-term administration, consider periodic monitoring of CBC, chemistry panel, and urinalysis.

Client Information

- This drug must be injected; it does not work when given by mouth.
- This drug causes pain when administered in the muscle. If the drug is given at home to small animals, it usually is administered by injecting under the skin (subcutaneously).

Chemistry/Synonyms

A third-generation cephalosporin, ceftriaxone sodium occurs as a white to yellowish-orange crystalline powder. It is soluble in water (400 mg/mL at 25°C [77°F]). Potencies of commercial products are expressed in terms of ceftriaxone. One gram of ceftriaxone sodium contains 3.6 mEq of sodium.

Ceftriaxone sodium may also be known as ceftriaxonum natricum, Ro-13-9904, or Ro-13-9904/000; many trade names are available.

Storage/Stability

The sterile powder for reconstitution should be stored between 20°C to 25°C (68°F-77°F) and protected from light.

After reconstituting with sterile water, 0.9% sodium chloride, or D_5W, ceftriaxone solutions (at concentrations of up to 100 mg/mL) are stable for 2 days at room temperature and for 10 days when refrigerated. Solutions of 250 mg/mL are stable for 24 hours at room temperature and 3 days when refrigerated. At concentrations of 10 – 40 mg/mL, solutions frozen at -20°C (-4°F) are stable for 26 weeks. Reconstituted solutions do not need to be protected from normal light; solution color may darken over time.

Solutions reconstituted with 1% lidocaine to a concentration of 100 – 350 mg/mL are stable for 24 hours at room temperature and 3 days when refrigerated.

Compatibility/Compounding Considerations

When ceftriaxone is used IM in humans, it may be reconstituted with lidocaine 1% (10 mg/mL, without epinephrine) to reduce pain on administration.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Ceftriaxone is **compatible** with dextrose 5% and sodium chloride 0.9%. The manufacturer does not recommend admixing any other anti-infective drugs with ceftriaxone sodium, but amikacin and metronidazole are reported to be **compatible**.

Do not mix with calcium or calcium-containing solutions (eg, lactated Ringer's) or administer simultaneously **(Y-site)** with calcium or calcium-containing products (see ***Drug Interactions***) as a

precipitate may form.

Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

NOTE: Extra-label use of cephalosporins in food-producing animals is restricted. Contact the Food Animal Residue Avoidance Databank (FARAD) for guidance in determining withdrawal periods.

HUMAN-LABELED PRODUCTS:

Ceftriaxone Injection Powder for Solution: 250 mg, 500 mg, 1 g, 2 g, 10 g, and 100 g (as base) in vials, single-use duplex containers, and in bulk; generic; (Rx). *Rocephin®* has been discontinued in the United States.

Cefuroxime

Cefuroxime Axetil

Cefuroxime Sodium

(sef-yoor-***oks***-eem) *Ceftin®, Zinacef®*

Second-Generation Cephalosporin

Prescriber Highlights

- ► Oral and parenterally administered second-generation cephalosporin that is more active against some gram-negative bacteria than first-generation (eg, cephalexin, cefazolin) cephalosporins
- ► Potentially useful in small animals when a cephalosporin is desired but there is resistance to first-generation cephalosporins, or when slightly enhanced gram-negative coverage is desired for surgical prophylaxis
- ► Limited clinical experience in veterinary medicine
- ► Adverse effects most commonly seen in small animal species are GI-related

Uses/Indications

Cefuroxime is a semi-synthetic second-generation cephalosporin with enhanced activity against some gram-negative pathogens when compared with the first-generation agents. Cefuroxime is available in both oral and parenteral dosage forms. It may be useful in small animal species when a cephalosporin is desired to treat bacterial infections that are resistant to first-generation cephalosporins, when slightly enhanced gram-negative coverage is desired for surgical prophylaxis, or for the treatment of bacterial meningitis or other CNS infections in which inflamed meninges will allow cefuroxime to penetrate into the CNS. Little information is available regarding the clinical use of cefuroxime in small animal species.

The World Health Organization (WHO) has designated cefuroxime as a Highly Important antimicrobial for human medicine.[1] The Office International des Epizooties (OIE) has designated cefuroxime as a Veterinary Highly Important Antimicrobial (VHIA) Agent in bovine species.[2]

Pharmacology/Actions

Cefuroxime, like other cephalosporins, is a time-dependent bactericidal antibiotic and acts by inhibiting cell wall synthesis. Its spectrum of activity is similar to that of cephalexin, but it is more active against gram-negative bacteria, including strains of *Escherichia coli*, *Klebsiella pneumoniae*, *Salmonella* spp, and *Enterobacter* spp. It is not effective against methicillin-resistant *Staphylococcus* spp, *Pseudomonas* spp, *Serratia* spp, or *Enterococcus* spp and it has little activity against *Bacteroides fragilis*. It is also ineffective against extended-spectrum beta-lactamase (ESBL)–producing bacteria.

Pharmacokinetics

In dogs, cefuroxime is rapidly distributed after IV injection. The volume of distribution is about 0.49 L/kg. The elimination half-life is ≈1.12 hours. When cefuroxime is given at 20 mg/kg IM, the elimination half-life is 1.13 hours, bioavailability is ≈80%, and peak plasma concentration is 23 µg/mL. When given at the same dose SC, the elimination half-life is 1.04 hours, bioavailability is ≈77%, and peak plasma concentration is 15.4 µg/mL. Clearance is 0.34 L/kg/hour for both routes. The authors concluded that cefuroxime given at 20 mg/kg IM or IV every 11 hours, or SC every 12 hours, would be effective for bacteria with an MIC less than or equal to 1 µg/mL, but the interval would need to be shortened to every 8 hours (IM or SC) for bacteria with an MIC less than or equal to 4 µg/mL; however, further pharmacokinetic and pharmacodynamic studies as well as clinical trials are needed.[3]

In goats, after 40 mg/kg is administered, IM bioavailability is high and protein binding is low. Volume of distribution is about 0.46 L/kg. Elimination half-life is about 2.1 hours (IM).

In humans, cefuroxime axetil is well absorbed after oral administration and is rapidly hydrolyzed in the intestinal mucosa and circulation to the parent compound.[4] Bioavailability ranges on average from 37% (fasted) to 52% (with food). Peak serum concentrations occur in about 2 to 3 hours after oral dosing. When the sodium salt is administered IM, peak concentrations occur within 15 minutes to 1 hour. Cefuroxime is widely distributed after absorption, including to the bone, aqueous humor, and joint fluid.[4,5] Therapeutic levels can be attained in the CSF if meninges are inflamed. Binding to human plasma proteins ranges from 35 to 50%. Cefuroxime is primarily excreted unchanged in the urine; elimination half-life in patients with normal renal function is between 1 to 2 hours.

Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. In humans, cefuroxime is contraindicated in patients that are hypersensitive to it or other cephalosporins. Dosage adjustment is recommended in humans with severe renal impairment.

Cefuroxime can be easily confused with other cephalosporins. Consider writing orders and prescriptions using tall man lettering: cefUROXime.

Adverse Effects

As use of cefuroxime in animals has been limited, a comprehensive adverse effect profile has not been determined. A 6-month toxicity study of oral cefuroxime axetil given at dosages ranging from 100 mg/kg/day to 1600 mg/kg/day in beagles demonstrated little adversity associated with cefuroxime.[6] At the highest dosing levels (≈80 times the recommended dose), some vomiting and slight suppression of body weight gain were noted. Minor reductions in neutrophils and red blood cells and prolonged prothrombin times were also seen.

When cefuroxime is used clinically in dogs, GI effects (eg, inappetence, vomiting, diarrhea) would be the most likely expected adverse effects, but incidence rates are not known.

The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that up to 15% of patients that are hypersensitive to penicillins will also be hypersensitive to cephalosporins[7].

Cefuroxime is generally well-tolerated in humans. Injection site inflammation can occur when cefuroxime is used IV. GI effects (eg, nausea, diarrhea) may occur, but are not frequently reported. Eosinophilia and hypersensitivity reactions (including anaphylaxis) are possible. Neurologic effects (eg, hearing loss, seizures), pseudomembranous colitis, serious dermatologic reactions (eg, toxic epidermal necrolysis [TEN], Stevens-Johnson syndrome), hematologic

effects (eg, pancytopenia, thrombocytopenia), and interstitial nephritis have been reported rarely.

Reproductive/Nursing Safety

Studies performed in pregnant mice at dosages of up to 6400 mg/kg and rabbits at 400 mg/kg demonstrated no adverse fetal effects. In humans, cefuroxime is considered compatible with pregnancy.[8]

Cefuroxime enters maternal milk in low concentrations. Although cefuroxime is likely safe for nursing offspring, the potential for adverse effects cannot be ruled out, particularly alterations to gut flora with resultant diarrhea. In humans, cefuroxime is considered compatible with breast feeding.[8]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Beagles receiving daily dosages of up to 1600 mg/kg/day orally tolerated cefuroxime well (see ***Adverse Effects***).[6]

Cerebral irritation with seizures has been reported with large overdoses in humans. Plasma concentrations of cefuroxime can be reduced with hemodialysis or peritoneal dialysis.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving cefuroxime and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **gentamicin**): Potential for increased risk of nephrotoxicity—monitor renal function; however, aminoglycosides and cephalosporins may have synergistic or additive actions against some gram-negative bacteria (Enterobacteriaceae).
- **Antacids, Aluminum-, Calcium-, or Magnesium-Containing**: Antacids may decrease serum levels of oral cefuroxime. Separate doses by 1 to 2 hours.
- **H_2-Receptor Antagonists** (eg, **famotidine, ranitidine**): H_2 antagonists may significantly decrease the absorption of cefuroxime. Concurrent use is not recommended.
- **Nephrotoxic Drugs** (eg, **amphotericin B, furosemide**): Concurrent use with cephalosporins could potentially cause additive nephrotoxicity, although this is somewhat controversial. Use together cautiously and monitor renal function closely.
- **Probenecid**: Reduced renal excretion of cefuroxime.
- **Proton Pump Inhibitors** (eg, **omeprazole, pantoprazole**): Cefuroxime absorption may be significantly decreased. Concurrent use is not recommended.
- **Sodium Bicarbonate**: Cefuroxime absorption may be decreased. Separate doses by 1 to 2 hours.
- **Vitamin K Antagonists**: Cephalosporins may enhance the anticoagulant effects of vitamin K antagonists (eg, warfarin).

Laboratory Considerations

- Cefuroxime may cause false-positive **urine glucose determinations** when using the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest*®); tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs test.**

Dosages

DOGS/CATS:

Susceptible infections (extra-label):

a) Oral: Anecdotally, 10 – 15 mg/kg IV every 8 to 12 hours

b) Parenteral: From a small PK study, 20 mg/kg SC every 12 hours for bacteria with MIC less than or equal to 1 µg/mL OR 20 mg/kg IM or SC every 8 hours for bacteria with MIC less than or equal to 4 µg/mL[3]

Surgical prophylaxis (extra-label): 20 – 50 mg/kg IV slowly (over at least 3 to 5 minutes) ≈30 minutes prior to surgery (often given at induction) and every 1.5 to 3 hours during surgery

GOATS:

Susceptible infections for organisms with MIC less than or equal to 1 µg/mL (extra-label): 40 mg/kg IM every 12 hours based on a pharmacokinetic study[9]

Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- Patients with diminished renal function may require intensified renal monitoring.
- Therapeutic drug monitoring is not routinely done with these agents.

Client Information

- Give this medicine with food.
- Do not crush tablets. This medicine has a bitter taste. Contact your veterinarian if you have trouble medicating your animal.
- The most common side effects are diarrhea, vomiting, and loss of appetite. Contact your veterinarian if your animal develops severe vomiting/diarrhea or rash/itching.
- Be sure to give this medicine to your animal as long as your veterinarian has prescribed, even if your animal seems better.
- Cephalosporin antibiotics have an odor that resembles cat urine, but this is normal.

Chemistry/Synonyms

Cefuroxime axetil occurs as a white or almost white powder that is insoluble in water and slightly soluble in dehydrated alcohol.

Cefuroxime sodium occurs as a white or almost white hygroscopic powder that is freely soluble in water.

Cefuroxime may also be known as CCI-15641, cefuroxim, cefuroxima, cefuroximum, cefuroksiimi, or cefuroksimas; many internationally registered trade names are available.

Storage/Stability

Cefuroxime axetil tablets should be stored in tight containers at room temperature (15°C-30°C [59°F-86°F]); protect from excessive moisture.

The powder for suspension should be stored at 2°C to 30°C [36°F-86°F]. Once reconstituted, it should be kept refrigerated (2°C to 8°C [36°F-46°F]) and any unused suspension should be discarded after 10 days.

The powder for injection should be stored at room temperature (15°C-30°C [59°F-86°F]) and protected from light. The powder may darken, but this does not indicate any loss of potency. When the powder is reconstituted with sterile water to a concentration of 90 mg/mL, the resulting solution is stable for 24 hours at room temperature; 48 hours, if refrigerated. The 7.5 g pharmacy bulk container is stable for 7 days when reconstituted to 95 mg/mL and kept under refrigeration. Any of these containers may be further diluted into a compatible IV solution such as 5% dextrose, 0.9% sodium chloride, or Ringer's, and the resulting solution is stable for 24 hours at room temperature or up to 7 days if refrigerated. The powder for injection

may be reconstituted at up to 90 mg/mL and then immediately frozen in a Viaflex mini-bag containing 50 to 100 mL of 0.9% sodium chloride or 5% dextrose. This solution is stable for up to 6 months when it is stored at -20°C (-4°F). Thaw at room temperature and do not refreeze. Thawed solutions are stable for 24 hours at room temperature or 7 days under refrigeration.

Compatibility/Compounding Considerations

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Cefuroxime is **compatible** with dextrose 5 and 10%, Ringer's injection, lactated Ringer's, and sodium chloride 0.9%. Drugs that are reportedly **compatible** when mixed with cefuroxime for IV use include clindamycin, furosemide, and metronidazole. Drugs that may be given at a Y-site with a cefuroxime infusion running include morphine, hydromorphone, and propofol. Cefuroxime is **incompatible** with aminoglycosides, ciprofloxacin, and ranitidine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cefuroxime Axetil Oral Tablets (film coated): 125 mg, 250 mg, and 500 mg; *Ceftin®*, generic; (Rx)

Cefuroxime Axetil Oral Suspension: 25 mg/mL and 50 mg/mL (125 mg/5 mL and 250 mg/5 mL; as base) when reconstituted in 50 mL and 100 mL; generic; (Rx)

Cefuroxime Sodium for Injection: 750 mg, 1.5 g, 7.5 g, and 225 g (as sodium); *Zinacef®*, generic; (Rx)

Cephalexin

(sef-a-***lex***-in) *Rilexine®, Keflex®*

First-Generation Cephalosporin

Prescriber Highlights

- ► First-generation oral cephalosporin. Some countries may have an injectable form.
- ► May be administered with food (especially if GI upset occurs)
- ► Most likely adverse effects are GI in nature; hypersensitivity reactions are possible

Uses/Indications

Cephalexin is labeled for the treatment of secondary superficial bacterial pyoderma in dogs caused by susceptible strains of *Staphylococcus pseudintermedius.* Cephalexin is also often used extra-label for other bacterial skin infections such as deep pyoderma. Cephalexin has also been used clinically in cats, ferrets, reptiles, and birds, particularly for susceptible staphylococcal infections. Cephalexin is considered a first-tier drug for the treatment of bacterial skin infections.[1,2]

Cephalexin may not be effective in patients with history of lack of response to other cephalosporins, multiple antibiotic use, and multidrug resistance. Before using cephalexin in these cases, antimicrobial culture and susceptibility testing is recommended. Additionally, topical antimicrobial therapy using antibacterial agents and biocides with proven anti-staphylococcal efficacy should be considered prior to systemic antibiotics, including cephalexin, for any surface or superficial pyoderma and wound infections, particularly those that are mild or associated with localized lesions or due to methicillin-resistant infections, to help reduce antibiotic pressure and antimicrobial resistance.[3]

The World Health Organization (WHO) has designated cephalexin as a Highly Important antimicrobial for human medicine.[4] The Office International des Epizooties (OIE) has designated cephalexin as a Veterinary Highly Important Antimicrobial (VHIA) Agent in bovine, caprine, equine, ovine, and swine species.[5]

Pharmacology/Actions

Cephalexin is a first-generation cephalosporin that exhibits activity against bacteria usually covered by this class. First-generation cephalosporins generally possess excellent coverage against most gram-positive pathogens (excluding enterococci); they are active in vitro against streptococci and staphylococci. Because first-generation cephalosporins have variable coverage against most gram-negative pathogens, their usefulness for these bacteria is mainly for treatment of lower UTIs because of the high drug concentrations achieved in urine. With the exception of *Bacteroides fragilis*, most anaerobes are susceptible to the first-generation agents. Resistance is of increasing concern, particularly with methicillin-resistant staphylococci and extended-spectrum beta-lactamase (ESBL) producing Enterobacteriaceae.

Cephalexin is inactive against *Enterococcus* spp, *Pseudomonas* spp, *Rickettsia* spp, mycobacteria, *Mycoplasma* spp, fungi, and viruses.

Cephalosporins are considered time-dependent and bactericidal against susceptible bacteria, and they act by inhibiting mucopeptide synthesis in the cell wall, which results in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (eg, carboxypeptidases, transpeptidases, endopeptidases) in the bacterial cytoplasmic membrane that are involved in cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins [PBPs]) help explain the differences in spectrums of activity of these drugs that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, cephalosporins are generally considered to be more effective against actively growing bacteria. For bactericidal activity, cephalosporin levels should exceed bacterial MIC for at least 40% of the dose interval for staphylococcal infections and ≈60% of the dose interval for streptococcal infections.[6]

Pharmacokinetics

In a study in dogs and cats, peak serum concentrations reached 18.6 µg/mL ≈1.8 hours after a mean oral dose of 12.7 mg/kg in dogs and reached 18.7 µg/mL ≈2.6 hours after an oral dose of 22.9 mg/kg in cats.[7] Elimination half-lives ranged from 1 to 2 hours in both species. Bioavailability after oral administration is ≈90% in dogs and ≈60% in cats.[8,9] A different study found that protein binding of cephalexin in dogs is low (21%) and elimination half-life in interstitial fluid (protein unbound) is ≈3.2 hours, as compared with 4.7 hours in total plasma.[10] The FDA-approved tablets that were administered at 22 mg/kg orally to fasted dogs yielded peak concentrations of 21.7 µg/mL 1.4 hours after administration; when the tablets were given with food, a lower peak concentration (17 µg/mL) was reached more quickly (1.2 hours). Elimination half-lives were 7.3 hours fasted and 8.8 hours given with food. The drug is renally eliminated.

There may be temporal differences in pharmacokinetics depending on the time of day the drug is administered. Six beagles given cephalexin orally at 10:00 and 22:00 had significantly lower peak concentrations (77%) after the 22:00 dose as compared with the 10:00 dose. In addition, the elimination half-life was ≈50% longer with the evening dose as compared with the morning dose. Clinical significance is not clear, as times above an MIC of 0.5 µg/mL were not different.[11]

In horses, oral cephalexin has low bioavailability (≈5%) and a short plasma half-life (≈2 hours), and at dosages of 30 mg/kg PO

every 8 hours, plasma and interstitial concentrations were achieved to only treat gram-positive bacteria with MIC less than 0.5 µg/mL.[12]

An oil-based suspension of the sodium salt is available in several countries for IM or SC injection in animals. In calves, the sodium salt had 74% bioavailability after IM injection and a serum half-life of ≈90 minutes. When 7.5 mg/kg was injected either SC or IM in adult cattle, the 20% suspension had longer durations of time above MIC_{90} for common gram-positive pathogens when injected SC as compared with IM (11 to 14 hours vs 8 to 9 hours).[13] In the United States, extra-label use of cephalosporins in food animals is prohibited by the FDA.

After oral administration in humans, cephalexin is rapidly and completely absorbed, although absorption can be delayed. Food apparently has little impact on absorption.

Contraindications/Precautions/Warnings

Cephalexin is contraindicated in patients with a history of hypersensitivity to it and other cephalosporins. Because there may be cross-reactivity, cephalexin should be used cautiously in patients that are documented hypersensitive to other beta-lactam antibiotics (eg, penicillins, cephamycins, carbapenems). Use of cephalosporins in patients that are documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that 1% to 15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins.[14] The incidence of cross-reactivity in veterinary patients is unknown.

Oral systemic antibiotics should not be administered in patients with septicemia, shock, or other grave illnesses, as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral routes (preferably IV) should be used for these cases. Although cephalexin has been used in some small mammal species, products licensed in the United Kingdom state: *Do not use in rabbits, guinea pigs, hamsters and gerbils, and other small rodents*; potentially serious enterocolitis can result. Similar risks are likely in horses.

In humans, it is recommended to use cephalosporins with caution in those with significantly impaired renal function. Although the relevance of this finding in veterinary patients is unclear, a dosage reduction (eg, prolonged dosing interval) may be considered in patients with marked renal impairment.

Cephalexin can be easily confused with other cephalosporins. Writing orders and prescriptions using tall man letters may help: cephaLEXin.

Adverse Effects

Adverse effects associated with cephalexin are usually not serious and have a relatively low frequency of occurrence.

When given orally, cephalexin may cause GI effects (eg, salivation, vomiting, diarrhea, anorexia). Administration with a small meal may help alleviate these effects. Because cephalexin may also alter the gut microbiome, antibiotic-associated diarrhea or proliferation of resistant bacteria in the colon can occur.

Cephalexin has reportedly caused lethargy, pruritus, salivation, tachypnea, and excitability in dogs, and emesis and fever in cats. Rarely, cephalexin has been implicated in causing serious skin reactions (eg, erythema multiforme, toxic epidermal necrolysis, cutaneous vasculitis, and pemphigus foliaceus) in small animals. Hypersensitivity reactions unrelated to dosage can occur with these agents and can manifest as a rash, fever, eosinophilia, lymphadenopathy, interstitial nephritis, or anaphylaxis. Although apparently uncommon, the true incidence of these effects is not known.

Nephrotoxicity can occur (rare) during therapy with cephalexin, but patients that have renal dysfunction, are receiving other nephrotoxic drugs, or are geriatric may be more susceptible.

High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Coombs test, interstitial nephritis, and tubular necrosis. Longer prothrombin times have also been noted. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use during pregnancy has not been firmly established.[6] There have been no documented teratogenic problems associated with these drugs.

Small amounts of cephalexin may be distributed into maternal milk; it could potentially affect gut flora in neonates. It should be used with caution in nursing patients.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Acute oral cephalosporin overdoses are unlikely to cause significant problems other than GI distress (eg, salivation, vomiting, diarrhea), but other effects are possible. See ***Adverse Effects***. Dogs receiving 110 mg/kg every 8 hours developed sporadic GI effects (eg, salivation, vomiting, diarrhea); increased ALT and decreased total protein were also noted but not considered clinically relevant. The drug is removed by dialysis.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cephalexin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed, and additional monitoring performed when appropriate.

- **Aminoglycosides and Other Nephrotoxic Drugs:** Concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (eg, amphotericin B, furosemide) with cephalosporins is somewhat controversial. Cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). In vitro studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides.
- **Cholestyramine:** Cephalexin absorption may be reduced.
- **Estrogens** (eg, **estriol**)**:** Cephalexin disruption of GI flora may alter enterohepatic recirculation, which may decrease estrogen effectiveness.
- **Metformin:** Metformin levels may be increased.
- **Metoclopramide:** Metoclopramide given IV may increase cephalexin peak concentration and AUC when given prior to oral cephalexin.[15]
- **Omeprazole:** Omeprazole may reduce peak cephalexin concentration and AUC and may delay oral absorption in adult dogs; however, time above MIC was not altered.[16]
- **Probenecid**: May competitively block the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives
- **Warfarin**: May increase risk for bleeding
- **Zinc (oral)**: Cephalexin absorption may be reduced.

Laboratory Considerations

- Most laboratories use cephalothin as the class representative for

testing veterinary isolates for susceptibility to other first-generation cephalosporins, including cephalexin. One study established cephalexin breakpoints of less than or equal to 2 µg/mL (susceptible), 4 µg/mL (intermediate), and more than or equal to 8 µg/mL (resistant) for isolates obtained from dogs, particularly for *Staphylococcus pseudintermedius* isolates, and recommended that cephalothin should not be used for susceptibility testing of cephalexin for veterinary bacterial pathogens, and canine-specific breakpoints should be used for testing susceptibility.[17]

- Cephalexin may cause false positive **urine glucose determinations** when cupric sulfate solution (Benedict's solution, *Clinitest®*) is used. Tests using glucose oxidase (*Tes-Tape®*, *Clinistix®*) are not affected.
- When the Jaffe reaction is used to measure **serum creatinine or urine creatinine**, cephalexin in high dosages may cause falsely elevated values.
- Cephalexin may cause falsely elevated **urine 17-ketosteroid** values.
- In humans, particularly those with azotemia, cephalexin has caused a false positive direct and indirect **Coombs test** result.
- **Prothrombin time** may be increased.
- False elevation of **urine protein** may occur.
- Cephalexin may falsely decrease **albumin** measurements.

Dosages

DOGS:

Susceptible skin infections (label dosage; FDA-approved): 22 mg/kg PO twice daily for 28 days. Appropriate culture and susceptibility tests should be performed before treatment, and antimicrobial therapy should be adjusted accordingly.

Susceptible skin infections (extra-label):

a) 15 – 30 mg/kg PO every 12 hours is often recommended.[1] Some believe that the higher end of the dosage range may be more effective. Good evidence to support treatment duration is lacking, but continuing treatment for 7 days (superficial pyoderma) or 14 days (deep pyoderma) after clinical signs have resolved is commonly recommended.

b) 25 mg/kg PO every 12 hours for up to 3 weeks.[18] Treatment should be reassessed if no improvement is seen after 14 days.

c) 15 – 30 mg/kg PO twice daily.[19] Treat for at least 15 days in cases of superficial infectious dermatitis and at least 28 days in cases of deep infectious dermatitis.

Susceptible UTIs (extra-label):

a) 12 – 25 mg/kg PO every 12 hours[20]

b) 15 – 30 mg/kg PO twice daily for 14 days[19,21]

c) 20 mg/kg PO every 12 hours for 10 days is recommended for sporadic bacterial cystitis[20]

CATS:

Susceptible skin infections (extra-label):

a) 22 – 30 mg/kg PO every 12 hours is often recommended. Good evidence to support treatment duration is lacking, but continuing treatment for 7 days (superficial pyoderma) or 14 days (deep pyoderma) after clinical signs have resolved is commonly recommended.

b) 15 mg/kg PO twice daily for 5 days for wounds and abscesses and 14 days at least in case of pyoderma.[8] The treatment must be continued for 10 days once the lesions have disappeared.

Susceptible UTIs (extra-label):

a) 12 – 25 mg/kg PO every 12 hours[20]

b) 15 mg/kg PO twice daily for 10 to 14 days for lower UTIs due to *E coli* and *Proteus mirabilis*[8,21]

c) 20 mg/kg PO every 12 hours for 10 days is recommended for sporadic bacterial cystitis.[20]

RODENTS & SMALL MAMMALS:

Susceptible infections in guinea pigs (extra-label): 50 mg/kg IM every 24 hours[22] **NOTE**: Use with caution in small mammals. See ***Contraindications/Precautions/Warnings***.

FERRETS:

Susceptible infections (extra-label): 15 – 25 mg/kg PO every 8 to 12 hours[23]

REPTILES:

Susceptible infections (extra-label): 20 – 40 mg/kg PO every 12 to 24 hours[24]

BIRDS:

Susceptible infections (extra-label):

a) 35 – 50 mg/kg PO every 6 hours (using suspension)[25]

b) 40 – 100 mg/kg PO every 6 hours[26]

Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- Culture and susceptibility when indicated (eg, clinical condition does not improve, recurring infection, intracellular bacterial rods seen on cytology, history of multi-drug resistant infection)
- Therapeutic drug monitoring is not routinely done with these agents.

Client Information

- This medicine can be given with or without food, but gastrointestinal side effects might be prevented if given with food.
- Most common side effects are diarrhea, vomiting, and loss of appetite. Contact your veterinarian if your animal develops severe vomiting/diarrhea or rash/itching.
- Be sure to give this drug for as long as your veterinarian has prescribed, even if your animal seems better.
- Cephalosporin antibiotics have an odor that resembles cat urine, but this is normal.

Chemistry/Synonyms

Cephalexin is a semisynthetic oral cephalosporin. As the monohydrate, cephalexin occurs as a bitter-tasting, white to off-white crystalline powder. It is slightly soluble in water and practically insoluble in alcohol.

Cephalexin may also be known as cefalexin, 66873, or cefalexinum; many trade names are available.

Storage/Stability

Cephalexin tablets, chewable tablets, capsules, and powder for oral suspension should be stored at room temperature (15°C-30°C; 59°F-86°F) in tight containers. After reconstitution, the oral suspension is stable for 2 weeks when refrigerated.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Cephalexin Chewable Tablets (scored): 75 mg, 150 mg, 300 mg, and 600 mg; *Rilexine®*; (Rx). Approved for use in dogs. NADA #141-326.

In the UK and other countries, there are other oral dosage forms li-

censed for dogs and cats. Trade names include *Cefaceptin*®, *Ceporex*®, *Cephaforte*®, *Cephorum*®, *Cefaseptin*®, *Kefvet*®, and *Therios*®. Sodium cephalexin 180 mg/mL suspension for injection (*Ceporex*®) also is available in the United Kingdom for use in dogs, cats, and cattle.

HUMAN-LABELED PRODUCTS:

Cephalexin Oral Capsules: 250 mg, 333 mg, 500 mg, and 750 mg; generic; (Rx)

Cephalexin Oral Tablets: 250 mg and 500 mg; generic; (Rx)

Cephalexin Powder for Oral Suspension: 125 mg/5 mL (25 mg/mL) and 250 mg/5 mL (50 mg/mL) after reconstitution in 100 mL and 200 mL; *Keflex*®, generic; (Rx)

Cephapirin

Cephapirin Benzathine

Cephapirin Sodium

(sef-a-***pye***-rin) *ToDAY®, ToMORROW®*

First-Generation Cephalosporin

Prescriber Highlights

- ► First-generation intramammary cephalosporin; also used via intrauterine infusions for endometritis
- ► Drug has potential to cause hypersensitivity reactions
- ► Available as both dry and lactating cow treatments; follow withdrawal times.

Uses/Indications

An intramammary cephapirin sodium product is FDA-approved in the United States for treatment of mastitis in lactating dairy cows, and cephapirin benzathine is FDA-approved in dry cows. In the United States, there are no longer parenterally administered cephapirin products available. An intrauterine suspension is available in some countries.

The lay literature is replete with reports on the extra-label use of the mastitis products to treat thrush or topical wounds in equids; however, this practice is not supported by peer-reviewed scientific literature and the use of antibacterial agents in the absence of a veterinarian's supervision is strongly discouraged.

The World Health Organization (WHO) has designated first-generation cephalosporins as Highly Important antimicrobials for human medicine.[1] The Office International des Epizooties (OIE) has designated cephapirin as a Veterinary Highly Important Antimicrobial (VHIA) Agent in bovine species.[2]

Pharmacology/Actions

Cephapirin is a first-generation cephalosporin that exhibits activity against bacteria usually covered by this class. Although there may be differences in minimum inhibitory concentration (MIC) for individual first-generation cephalosporins, their spectrums of activity are similar. They generally possess excellent coverage against most gram-positive pathogens (excluding enterococci) and variable coverage against most gram-negative pathogens. These drugs are very active in vitro against streptococci and staphylococci. With the exception of *Bacteroides fragilis*, most anaerobes are very susceptible to the first-generation agents. Resistance is of increasing concern, particularly with methicillin-resistant staphylococci and extended-spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae.

Cephalexin is inactive against *Enterococcus* spp, *Rickettsia* spp, mycobacteria, *Mycoplasma* spp, fungi, and viruses.

Cephalosporins are considered time-dependent and bactericidal against susceptible bacteria, and they act by inhibiting mucopeptide synthesis in the cell wall, which results in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (eg, carboxypeptidases, transpeptidases, and endopeptidases) in the bacterial cytoplasmic membrane that are involved in cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins [PBPs]) help explain the differences in spectrums of activity of these drugs that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, cephalosporins are generally considered to be more effective against actively growing bacteria. For bactericidal activity, cephalosporin levels should exceed bacterial MIC for ≈40% of the dose interval for staphylococcal infections and ≈60% of the dose interval for streptococcal infections.

Pharmacokinetics

In cattle, when cephapirin is administered systemically, the apparent volume of distribution has been reported as 0.335 to 0.399 L/kg, total body clearance is 12.66 mL/minute/kg, and serum elimination half-life is ≈64 to 70 minutes.

When cephapirin sodium was administered to healthy (no mastitis) dairy cattle via intramammary infusion, it was rapidly metabolized to the active metabolite desacetylcephaprin in milk.[3] Time above MIC_{90} for common mastitis pathogens and time to reach FDA tolerance concentrations was similar whether the cow was milked 2 or 3 times daily. Additionally, giving the second dose 16 hours later (rather than 12 hours as labeled) to cows that were milked 3 times daily caused no significant effect on withdrawal times or times above MIC. Cows with low daily milk production (less than 25 kg) appeared to absorb more cephapirin systemically and had longer mean residence times than those with high milk production. The authors caution that extended withdrawal times would be prudent in cows with very low milk production and that more studies are required to determine the pharmacokinetics in animals with mastitis.

Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients that are documented to be hypersensitive to other beta-lactam antibiotics (eg, penicillins, cefamycins, or carbapenems).

Adverse Effects

Adverse effects from cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Potentially, hypersensitivity reactions could occur with intramammary infusion. Hypersensitivity reactions unrelated to dosage can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated that up to 15% of patients that are hypersensitive to penicillins will also be hypersensitive to cephalosporins.[4] The incidence of cross-reactivity in veterinary patients is unknown.

Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No clinical effects would be expected but if used at doses or rates

higher than labeled, withdrawal times may be prolonged.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

There are no significant concerns when cephapirin is used via the intramammary or intrauterine routes.

Laboratory Considerations

- No significant concerns when cephapirin is used via the intramammary route or intrauterine routes
- A cephalothin disk is usually used to determine bacterial susceptibility to this antibiotic when using the Kirby-Bauer method.

Dosages

CATTLE:

Mastitis in cows caused by susceptible strains of *Streptococcus agalactiae* and *Staphylococcus aureus* including strains resistant to penicillin (label dosage; FDA-approved):

a) **Lactating cow** (cephapirin *sodium*): Just prior to administration, completely milk out the udder, clean and dry teat area, then disinfect teat tip with an alcohol wipe and allow to dry.[5] Insert tip of syringe into teat canal; push plunger to instill entire contents of one syringe (10 mL; cephapirin 200 mg) into each infected quarter; repeat once only, 12 hours after initial dose. Massage quarter gently and do not milk out for 12 hours.

b) **Dry cow** (cephapirin *benzathine*): Perform treatment at the time of drying off and no later than 30 days prior to calving.[6] Just prior to administration, completely milk out all four quarters, then wash the udder and teats with warm water and a suitable dairy antiseptic; allow to dry. Disinfect the teat tip with an alcohol wipe, using a separate swab for each teat; allow to dry. Insert tip of syringe into teat canal; push plunger to instill entire contents of one syringe (10 mL; cephapirin 300 mg) into each infected quarter. Massage quarter gently.

Subacute and chronic endometritis (at least 14 days after parturition) caused by cephapirin-sensitive bacteria (extra-label): Using the intrauterine suspension, instill syringe contents (cephapirin 500 mg) through the cervix into the lumen of the uterus; depending on response may re-treat in 7 to 14 days if clinical signs persist. May be used one day after insemination. If pyometra is present, pretreatment with a prostaglandin is recommended to cause luteolysis and expel debris from the uterus.[7]

Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.

Client Information

- Follow all label information and milk and slaughter withdrawal times.

Chemistry/Synonyms

A semisynthetic cephalosporin antibiotic, cephapirin sodium occurs as a white to off-white crystalline powder with a faint odor. It is very soluble in water and slightly soluble in alcohol. Each gram of the injection contains 2.36 mEq of sodium. After reconstitution, the solution for injection has a pH of 6.5 to 8.5.

Cephapirin sodium may also be known as BL-P-1322, cefapirin, cefapyrin, cefapirinum natricum, *Metricure*®, *ToDAY*®, or *ToMORROW*®.

Storage/Stability

Cephapirin intramammary syringes should be stored at controlled room temperature (15°C-30°C [59°F-86°F]); avoid excessive heat. Do not freeze.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Cephapirin Sodium Mastitis Tube: cephapirin 200 mg/10 mL tube; *ToDAY*®; (OTC). FDA-approved for use in lactating dairy cattle. Milk withdrawal = 96 hours; slaughter withdrawal = 4 days

Cephapirin Benzathine Mastitis Tube: cephapirin 300 mg/10 mL tube; *ToMORROW*®; (OTC). FDA-approved for use in dry dairy cattle. Milk withdrawal = 72 hours after calving and must not be administered within 30 days of calving; slaughter withdrawal = 42 days.

Cephapirin is excluded from the 2012 FDA/CVM ban on ELDU of cephalosporins in food-producing animals. There are multiple reports from the lay literature on the extra-label use of the mastitis products to treat thrush or topical wounds in equids.

In many countries, including Canada, Australia, and the UK, cephapirin benzathine 500 mg intrauterine infusion syringes are available for treating endometritis in dairy or beef cattle. *Metricure*®; (Rx). Milk and meat withdrawal times may vary with each country; refer to each specific label, but commonly, milk withdrawal = 0 hours and meat withdrawal = 48 hours.

HUMAN-LABELED PRODUCTS: NONE

Cetirizine

(se-***tih***-ra-zeen) *Zyrtec*®

Antihistamine, Second Generation

Prescriber Highlights

- ► Oral, relatively nonsedating antihistamine
- ► No significant anticholinergic or serotonergic effects
- ► Recommended dosages for dogs and cats vary widely
- ► Can potentially cause vomiting, hypersalivation, or somnolence in small animals

Uses/Indications

Cetirizine is an H_1 receptor blocking antihistamine agent that may be useful for the adjunctive treatment of histamine-mediated pruritic and allergic conditions, including respiratory allergies (eg, nasal and ocular discharge, sneezing), urticaria, and insect bite hypersensitivity in dogs and cats. Although antihistamines are commonly used to treat canine atopic dermatitis, cetirizine does not appear effective for the treatment of chronic and acute flares of canine atopic dermatitis.[1–3] Guidelines for atopic dermatitis treatment in dogs state that antihistamines have modest efficacy; cetirizine should be given continuously (ie, daily) as preventive therapy before an acute flare.[3,4] Moreover, one randomized double-blinded crossover study showed that cetirizine was effective in preventing cutaneous allergic reactions in healthy dogs.[5]

An open clinical trial administering cetirizine in cats with allergic skin disease showed pruritus reduction in 41% of cats.[6] A separate randomized double-blind placebo-controlled crossover study investigated cetirizine at 1 mg/kg/day PO for 14 days for the control of pruritus in cats with feline atopic skin syndrome. The study showed there were no statistically significant differences between cetirizine and placebo regarding clinical and pruritus scores.[7]

Cetirizine may also have a role in treating allergic conditions,

including dermatographism[8] and seasonal headshaking[9] in horses. However, one controlled study showed no apparent benefit from a 3-week trial treating insect bite hypersensitivity in horses.[10] Cetirizine appears to reduce the risk for recurrence of eosinophilic keratitis in horses.[11]

Pharmacology/Actions

Cetirizine hydrochloride, a metabolite of hydroxyzine, is a nonsedating antihistamine (ie, it does not cross the blood-brain barrier as compared with first-generation drugs) that selectively inhibits peripheral H_1 receptors. Cetirizine inhibited histamine and anticanine immunoglobulin E (IgE)-mediated skin reactions (wheals) in dogs.[2,12] Cetirizine administered for 6 days at 2 mg/kg/day PO to healthy dogs was effective in preventing immediate- and late-phase cutaneous allergic reactions.[5] It also appears to decrease histamine release from basophils in some species; in cats, cetirizine or cyproheptadine do not reduce eosinophilic airway inflammation (experimentally produced).[13] Cetirizine does not possess significant anticholinergic or antiserotonergic effects. Tolerance to its antihistamine effects is thought not to occur.

Pharmacokinetics

In dogs, peak concentration occurred 4 to 7 hours after oral administration,[2] and elimination half-life was ≈10 hours.[2,12]

In a study of cats receiving an oral dose of 5 mg/cat (NOT mg/kg), protein binding was 88%, volume of distribution was 0.24 L/kg, and clearance was ≈0.3 mL/kg/minute.[14] The terminal elimination half-life was ≈10 hours. The mean plasma concentrations remained above 0.72 µg/mL (a concentration reported to be effective for humans) for 24 hours after administration.

In horses, peak concentration occurred 0.7 hours after oral administration.[15] The terminal elimination half-life was reported to be between 3.5 and 6 hours, with trough plasma concentrations of ≈16 to 18 ng/mL after 0.2 mg/kg PO, and ≈45 ng/mL after 0.4 mg/kg PO.[15–17] Another study showed a longer terminal half-life for cetirizine of 7.13 hours in exercised Thoroughbred horses.[18] Drug accumulation does not appear to occur in horses.[16]

After oral administration to humans, cetirizine peak concentrations occur in ≈1 hour. Food can delay but not affect the extent of absorption. Cetirizine is 93% bound to human plasma proteins, and brain concentrations are ≈10% of those found in plasma. Approximately 80% of the drug is excreted in the urine, primarily as unchanged drug. Terminal elimination half-life is ≈8 hours; antihistaminic effect generally persists for 24 hours after administration. Elimination half-life is ≈12 hours in geriatric adults. Its elimination was shown to be slowed in individuals with liver disease.[19]

Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. In humans, cetirizine is contraindicated in those that are hypersensitive to it or hydroxyzine. Avoidance or dose adjustment is recommended in geriatric humans or in humans with severe renal or hepatic impairment.

The combination product containing pseudoephedrine (eg, *Zyrtec-D*®) is not appropriate for use in dogs or cats. Commercially available liquid formulations may contain propylene glycol, which is toxic to cats; orally disintegrating tablets may contain xylitol, which is toxic to dogs.

Adverse Effects

Cetirizine appears to be well tolerated in dogs and cats. Vomiting or hypersalivation after administration may occur in some dogs.[1] Drowsiness has been reported in small dogs given higher doses.

A pharmacokinetic/pharmacodynamic study performed in a small number of horses yielded no visible adverse effects.

In humans, the primary adverse effects reported have been drowsiness (13%) and dry mouth (5%). Hypersensitivity reactions, increased liver enzymes, hepatitis, and cholestasis have been rarely reported. Additionally, pruritus after discontinuation of cetirizine has been reported in humans.[20]

Reproductive/Nursing Safety

Cetirizine did not impair fertility or reproductive performance in mice or rats. In pregnant mice, rats, and rabbits, doses ≈40 times, 180 times, and 220 times the human dose (respectively)—when compared on an mg/m^2 basis—caused no teratogenic effects. Results from a retrospective study in humans suggested that exposure to cetirizine was not associated with adverse pregnancy outcomes in the fetuses above background rates.[21] One prospective study determined that cetirizine does not appear to be associated with increased teratogenic risk.[22]

In beagles, ≈3% of a dose was excreted into milk. Cetirizine enters human breastmilk, and one study estimated the relative infant dose to be ≈1.8% at 24 hours.[23] In humans, international guidelines recommend cetirizine as an acceptable choice if an antihistamine is required during breastfeeding. Small infrequent doses of cetirizine are likely tolerated during breastfeeding; however, larger doses or long-term use may cause drowsiness and other adverse effects in the infant or reduce milk production, mainly when combined with a sympathomimetic, such as pseudoephedrine, or before lactation is settled.[24]

Because safety has not been established, this drug should only be used when the maternal benefits outweigh the potential fetal risks.

Overdose/Acute Toxicity

Limited information is available. Reported minimum lethal oral doses for mice and rats are 237 mg/kg (95 times the human adult dose on an mg/m^2 basis) and 562 mg/kg (460 times the human adult dose on an mg/m^2 basis), respectively. In cases of overdose, cetirizine may cross into the CNS and cause neurologic signs (eg, hyperactivity, lethargy); it may also cause vomiting, panting, mydriasis, and tachycardia. Cetirizine does not appreciably prolong the QT interval on ECG at high serum levels.

Overdoses of cetirizine products that also contain pseudoephedrine (eg, *Zyrtec-D*®) may be serious.

For patients that have experienced or are suspected of having experienced an overdose, it is strongly encouraged that a 24-hour poison consultation center that specializes in providing veterinary-specific information be consulted. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cetirizine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **CNS DEPRESSANTS** (eg, **acepromazine, benzodiazepines, opioids**): Additive CNS depression or sedation is possible.
- **IVERMECTIN**: The use of ivermectin 12 hours prior to cetirizine significantly increased cetirizine exposure (area under the curve [AUC]) by 60% and elimination half-life by 18% in horses. Administration of ivermectin 90 minutes prior to cetirizine did not produce the same effect. Clinical significance is unknown.[15]
- **P-GLYCOPROTEIN SUBSTRATES** (eg, **cyclosporine**, **digoxin, vincristine**): Cetirizine has been shown to be a p-glycoprotein inhibitor (however, not a metabolite of the CYP450 system)[25]; therefore, avoidance or care should be taken with coadministration of cetirizine with p-glycoprotein substrate drugs.[26]

Laboratory Considerations

- **Intradermal allergy testing (IDT)**: Suppression of IDT results may persist for 1 to 2 weeks after discontinuation of cetirizine; it is recommended that treatment be discontinued at least 2 weeks prior to testing.[27]

Dosages

DOGS:

Pruritus associated with atopic dermatitis (extra-label): 1 – 4 mg/kg PO once daily with or without food.[2,12,27] Cetirizine should be given continuously (ie, daily) as preventive therapy before an acute flare.[3,4] Reduced efficacy was noted in one study[1] at lower dosages (1 mg/kg PO every 24 hours), as well as in dogs with acute[28] or chronic[3] atopic dermatitis.

CATS:

Adjunctive treatment of pruritus (extra-label):

a) Based on an open trial: 5 mg/cat (NOT mg/kg) PO once daily; 41% of cats had pruritus reduced.[29]
b) Anecdotal: 0.5 – 1 mg/kg or 2.5 – 5 mg/cat (NOT mg/kg) PO every 12 to 24 hours

HORSES:

Antihistamine (extra-label): 0.2 – 0.4 mg/kg PO every 12 hours[9,16]; a subsequent study did not support this dose as being efficacious.[10]

Eosinophilic keratitis (extra-label): 0.4 mg/kg PO twice daily[11]

Monitoring

- Clinical efficacy (trial periods to determine an individual antihistamine's efficacy are usually 1 to 2 weeks long)
- Adverse effects (eg, vomiting, somnolence)

Client Information

- Use antihistamines on a regular ongoing basis in animals that respond well. Antihistamines work better when used before an animal has been exposed to an allergen.
- Cetirizine may cause less drowsiness or sleepiness than other antihistamines, but this effect is still possible.
- **Only use products that contain cetirizine as a single active ingredient.** Any other ingredients (eg, pain relievers, decongestants) found in human-label combination products can be toxic to animals.
- Cetirizine may be given with or without food. If your animal vomits or acts sick after receiving the drug on an empty stomach, try giving the next dose with food or a small treat. If vomiting continues, contact your veterinarian.

Chemistry/Synonyms

Cetirizine is a piperazine derivative that occurs as a white to almost white crystalline powder that is freely soluble in water. A 5% solution has a pH of 1.2 to 1.8. Commercial formulations contain cetirizine HCl.

Cetirizine may also be known as UCB-P071, P-071, cetirizina, cetirizini, cetirizin, ceterizino, or *Zyrtec®*; many internationally registered trade names are available.

Storage/Stability

Store cetirizine tablets and syrup at room temperature 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

No specific information has been noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Cetirizine HCl Oral Tablets (film-coated): 5 mg and 10 mg; *Zyrtec®*, generic; (OTC)

Cetirizine HCl Chewable Tablets: 5 mg and 10 mg; *Zyrtec®*; (OTC). Available in fruit flavors.

Cetirizine HCl Oral Syrup or Solution: 1 mg/mL in 118 mL and 473 mL; *Zyrtec®*, generic; (OTC). Available in bubble gum or fruit flavors. May contain propylene glycol

Cetirizine 10 mg is also available in liquid gel caps and orally disintegrating tablet formulations. Combination products are available but are not appropriate for use in small animals. Disintegrating tablets may contain xylitol.

For the complete list of references, see **wiley.com/go/budde/plumb**

Charcoal, Activated

(***char***-kole) *ToxiBan®, Actidose®*

Oral Adsorbent

Prescriber Highlights

- ► Orally administered adsorbent for ingested toxins and drug overdoses; consider consulting with an animal poison control center before use
- ► Some formulations contain a cathartic (eg, sorbitol). Use caution when administering with cathartics; monitor closely for dehydration and electrolyte disturbances (eg, hypernatremia, hyperkalemia).
- ► Contraindications include administration to animals with a reduced gag reflex or at risk for aspiration pneumonia (eg, megaesophagus, CNS depression), decreased peristalsis, hypernatremia, or hyperosmolar states (eg, diabetic ketoacidosis).
- ► Not effective for treatment of inorganic molecules (eg, iron), mineral acid or alkali ingestion
- ► Adverse effects include emesis with rapid administration, dehydration, hypernatremia, constipation, or diarrhea.
- ► Charcoal stains clothing and animal fur.

Uses/Indications

Activated charcoal is administered orally to prevent or reduce systemic absorption of certain drugs or toxins in the GI tract. To enhance elimination of the charcoal-toxin moiety, an osmotic cathartic (eg, sorbitol; combinations are commercially available) is often given with activated charcoal. In humans, the benefit of adding a cathartic remains unproven. There is little need to administer a cathartic if significant diarrhea is already present. One study suggested single-dose activated charcoal alone was equally as effective as activated charcoal with sorbitol (as a cathartic) in reducing the serum concentration of carprofen following overdose in dogs.[1]

In humans, a single dose of activated charcoal is recommended when a potentially toxic amount of a substance (known to be adsorbed by charcoal) has been ingested in the past hour[2]; this same recommendation appears to also apply to veterinary patients.[1]

Pharmacology/Actions

Activated charcoal has a large surface area and adsorbs many chemicals and drugs via ion–ion, hydrogen bonding, dipole, and Van der Waals forces in the upper GI tract, thereby preventing or reducing their absorption. Efficiency of adsorption increases with the molecu-

lar size of the toxin, and poorly water-soluble organic substances are better adsorbed than small, polar, water-soluble organic compounds.

Although activated charcoal also adsorbs various nutrients and enzymes from the gut, there are generally no significant impacts on nutritional needs when used for acute poisonings.

Activated charcoal slurries are most effective in adsorbing most toxins.[3] Charcoal is most effective if given within 1 hour of toxin ingestion and is generally not recommended over 4 hours postingestion unless the exposure involves a drug that is enterohepatically recirculated.[1,2]

Pharmacokinetics

Activated charcoal is not absorbed or metabolized in the gut. Activated charcoal slurries can slow GI transit times; thus, an osmotic cathartic (eg, sorbitol) is often given concurrently to enhance expulsion of the toxin-charcoal moiety. See ***Contraindications/Precautions/Warnings***.

An in vitro study demonstrated that the presence of dog food can reduce the adsorptive capacity of activated charcoal, but the authors concluded the reduction was clinically insignificant.[4]

Contraindications/Precautions/Warnings

Activated charcoal should not be used for mineral acids, salt toxicosis (including paintballs and homemade play dough), hydrocarbons, or caustic alkalis, as it is either ineffective or dangerous (eg, risk for bowel perforation) with these substances. Although activated charcoal is not contraindicated with ethanol, methanol, ethylene glycol, xylitol, caustic alkalis, nitrates, sodium chloride/chlorate, petroleum distillates, mineral acids, heavy metals (eg, lithium), or iron salts, it is ineffective in adsorbing these products and may obscure GI lesions during endoscopy. Administration of activated charcoal (after orogastric lavage) for acute cyanide ingestion may be helpful if administered within 1 hour; however, it is not a replacement for use of cyanide antidotes.[5,6]

Animals with a decreased gag reflex or that are otherwise at risk for aspiration pneumonia (eg, megaesophagus, CNS depression) should not be given activated charcoal without adequate airway protection (ie, endotracheal intubation). Administration of activated charcoal via a nasogastric tube may be appropriate in these situations; however, if clinical signs related to the toxicity are already present, the benefit of activated charcoal treatment may not outweigh the risk for potential complications (eg, aspiration pneumonia) related to its administration. Other potential contraindications to charcoal therapy include a history of decreased peristalsis, recent GI surgery, GI obstruction or ileus, GI perforation, hypernatremia and other hyperosmolar states (eg, acute kidney injury, diabetic ketoacidosis), or imminent GI surgery or endoscopy. The ability of activated charcoal to adsorb toxicants (and therefore, its efficacy) decreases significantly 1 to 2 hours after toxicant ingestion[2]; however, delayed or repeated activated charcoal administration may be effective for agents that are enterohepatically recirculated (eg, caffeine, cannabinoids, phenobarbital, theobromine, theophylline, bromethalin, pyrethrins, marijuana, NSAIDs, organophosphate insecticides, ivermectin, digoxin, antidepressants).[2,7]

If multiple doses of activated charcoal are administered, it has been recommended that only the first dose contain the cathartic to prevent diarrhea, dehydration, and potentially hypernatremia.[8,9] Check the product label to ensure the appropriate product is being used at the appropriate time, as some commercial products contain a combination of activated charcoal and a cathartic in a premixed solution. Contraindications to cathartic use include absent bowel sounds, recent abdominal trauma, recent bowel surgery, intestinal obstruction, intestinal perforation, ingestion of a corrosive substance, volume depletion, hypotension, and electrolyte imbalance.

Although over-the-counter tablets are available to control flatulence and bloating, they are not as effective.[3]

Separate administration of any other orally administered therapeutic agents by at least 2 to 4 hours, as activated charcoal will adsorb the drug while in the GI tract. Administer any needed drugs parenterally when possible.

Endoscopic examination may be difficult after activated charcoal administration.[10] Feces will appear black when it is eliminated, making detection of melena challenging.

Adverse Effects

Rapid GI administration of charcoal can induce emesis. If aspiration occurs after activated charcoal is administered, acute pneumonitis and aspiration pneumonia[10] may result and lead to chronic pneumonitis. Charcoal can cause either constipation or diarrhea; in one study, diarrhea was more likely in dogs receiving repeated charcoal doses.[1] Prolonged constipation may cause release of the toxin from the activated charcoal; monitor stool production. Products containing sorbitol may cause loose stools, vomiting, and abdominal cramping. In humans, most activated charcoal complications are due to aspiration or inadvertent administration in the lungs; this likely also applies to veterinary patients.

Dehydration and hypernatremia may occur after administration of activated charcoal (with sorbitol[11] or without[12]), presumably due to an osmotic effect pulling water into the GI tract. Low sodium fluids (eg, dextrose 5%, 0.45% NaCl/dextrose 2.5%) and warm water enemas can be administered to alleviate the hypernatremic effect.[12] Increased osmolality and serum lactate has also been observed following activated charcoal administration.[13]

Charcoal powder stains, and dry powder is a respiratory irritant that tends to aerosolize across wide areas.

Reproductive/Nursing Safety

Charcoal is unlikely to cause embryo- or fetotoxicity or toxicity to nursing offspring, as it is not absorbed into the systemic circulation. Maternal benefits of activated charcoal treatment are likely to outweigh any potential risks to offspring.

Overdose/Acute Toxicity

The most likely effect from administering too much activated charcoal is induction of emesis with risk for aspiration. Activated charcoal that contains a cathartic (eg, sorbitol) can cause electrolyte abnormalities and dehydration. See ***Adverse Effects*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving charcoal and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acepromazine**: Risk for GI obstruction may be increased by drugs that slow GI motility.
- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate, hyoscyamine, meclizine, oxybutynin**): Risk for GI obstruction may be increased by drugs that slow GI motility.
- **Antidiarrheal Agents** (eg, **diphenoxylate, loperamide**): Risk for GI obstruction may be increased by drugs that slow GI motility.
- **Antihistamine H_1-Receptor Antagonists** (eg, **diphenhydramine, hydroxyzine**): Risk for GI obstruction may be increased by drugs that slow GI motility.
- **Dairy Products**: May reduce the adsorptive capacity of activated charcoal

- **Mineral Oil**: May reduce the adsorptive capacity of activated charcoal
- **Opioids** (eg, **butorphanol, hydrocodone, morphine, tramadol**): Risk for GI obstruction may be increased by drugs that slow GI motility.
- **Orally Administered Drugs**: Separate administration of any other orally administered therapeutic agents by at least 3 hours, as the charcoal will adsorb the drug while in the GI tract. Administer any needed drugs parenterally when possible.
- **Polyethylene Glycol ± Electrolyte Solutions** (eg, *Miralax®*, *GoLytely®*): May reduce the adsorptive capacity of activated charcoal
- **Tricyclic Antidepressants** (**TCA**; eg, **amitriptyline, clomipramine, doxepin**): Risk for GI obstruction may be increased by drugs that slow GI motility.

Laboratory Considerations

- A false-positive **ethylene glycol test** may result from products that contain sorbitol or polyethylene glycol.

Dosages

NOTE: Depending on the toxin exposure, recommendations for using activated charcoal can vary. It is highly recommended to contact an animal poison control center for specific guidance on using activated charcoal in veterinary patients.

DOGS & CATS:

Adjunctive treatment for toxin ingestion (extra-label): 1 – 2 g/kg PO but doses up to 5 g/kg have been described. Charcoal with sorbitol is commonly employed (only with the first dose) to reduce GI transit time. For drugs and toxins that undergo enterohepatic recirculation (eg, caffeine, phenobarbital, theobromine, theophylline, bromethalin, pyrethrins, marijuana, NSAIDs, organophosphate insecticides, ivermectin, digoxin, antidepressants), multiple subsequent doses of activated charcoal WITHOUT sorbitol at 1 – 2 g/kg PO every 4 to 8 hours for 24 to 48 hours is recommended. Dogs and cats with no clinical signs may freely consume the charcoal suspension if administered via syringe. A small amount of food may be added to the solution to enhance palatability.[4] In animals exhibiting clinical signs, administration of activated charcoal suspensions may be done via a nasogastric tube, as it may be better accepted, easier to place (especially in cats), and offer a greater margin of safety; always ensure adequate airway protection.[7,8,14,15]

HORSES:

Adjunctive treatment for toxin ingestion (extra-label):

a) 1 – 2 g/kg PO as a slurry through a stomach tube, with or without a cathartic[16]
b) Up to 750 g/horse (NOT g/kg) PO.[17] Make a slurry by mixing with up to 4 L (depending on animal's size) of warm water, and administer via stomach tube. Leave in stomach for 20 to 30 minutes then give a cathartic to hasten removal of toxicants.

RUMINANTS:

Plant intoxication (extra-label): 1 – 5 g/kg PO.[18] Multidose activated charcoal is beneficial for a number of plant intoxications, including oleander. Administration of a cathartic mixed in the activated charcoal slurry helps to hasten elimination of contents from the GI tract. Commonly used cathartics include sodium sulfate (ie, Glauber's salts), magnesium sulfate (ie, Epsom salt), and sorbitol. Sodium or magnesium sulfate can be administered at 250 – 500 mg/kg PO mixed in the activated charcoal slurry. Sorbitol (70%) can be administered at 3 mL/kg PO and also mixed in the activated charcoal slurry.

General treatment for toxicosis (extra-label): 1 – 3 g/kg PO every 8 – 12 hours[19]

FERRETS:

Adjunctive treatment for toxin ingestion (extra-label): 1 – 3 g/kg PO, usually via syringe or gastric tube. Repeat doses may be indicated if the drug or toxin undergoes enterohepatic recirculation.[20]

Monitoring

- Monitoring for efficacy of charcoal is usually dependent on the toxin/drug's mechanism of action, extent of toxicity, and patient's clinical signs.
- When activated charcoal is given with a cathartic, repeated serum sodium measurements (eg, every 8 to 12 hours) are recommended to address potential hypernatremia before clinical signs (eg, tremors, ataxia, seizures) occur. Serum sodium increases can be seen 6 to 10 hours after cathartic administration.[11]
- Hydration status
- Stool production: prolonged constipation can cause the toxin to be released from activated charcoal.

Client Information

- Activated charcoal should be used under the guidance of a licensed veterinarian. Monitor your animal for at least 4 hours after the drug is given to watch for weakness, unsteadiness, tremors, or convulsions. Contact your veterinarian immediately if these signs occur.
- Charcoal can permanently stain clothing and fur.
- It is expected that your animal's feces will be black when the charcoal is passed.

Chemistry/Synonyms

Activated charcoal occurs as a fine, black, odorless, tasteless powder that is insoluble in water or alcohol. Commercially available activated charcoal products may differ in their adsorptive properties, but 1 g must adsorb 100 mg of strychnine sulfate in 50 mL of water to meet USP standards.

Activated charcoal may also be known as AC, active carbon, activated carbon, carbo activatus, adsorbent charcoal, decolorizing carbon, or medicinal charcoal. There are many trade names available. Activated charcoal with sorbitol may be known as ACS.

Storage/Stability

Store activated charcoal in well-closed glass or metal containers or in the manufacturer's supplied container.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

NOTE: Carefully read label to determine if the product also contains a cathartic; avoid multiple administrations of cathartic-containing combinations.

VETERINARY-LABELED PRODUCTS:

The following products are labeled for veterinary use, but there are no oral activated charcoal products listed as FDA-approved on the FDA's Green Book website.

Activated charcoal 47.5%, kaolin 10%, sorbitol 20% granules (free flowing and wettable) in 453.6 g (1 lb) bottles and 5 kg (11.02 lb) pails; *ToxiBan® Granules*; (OTC). Labeled for use in both large and small animal species

Activated charcoal 10.4%, kaolin 6.25% suspension in 240 mL bottles; *ToxiBan® Suspension*; (OTC). Labeled for use in both large and small animal species

Activated charcoal 10%, kaolin 6.25%, sorbitol 10% suspension in 240 mL bottles; *ToxiBan® Suspension* with *Sorbitol*; (OTC). Labeled for use in small animal species

Activated charcoal 10%, attapulgite 20%, sodium chloride 35 mg/mL,

potassium chloride 35 mg/mL gel/paste in 80 mL and 300 mL; *D-Tox-Besc®*, *Activated Charcoal Gel with Electrolytes®*; (OTC). Labeled for use in small and large animal species

Activated hardwood charcoal and thermally activated attapulgite clay (concentrations not labeled) in an aqueous gel suspension in 8 fl oz bottle, 60 mL tube, and 300 mL tube with easy dose syringe; *UAA® (Universal Animal Antidote) Gel*; (OTC). Labeled for use in dogs and cats and for grain overload in ruminants

HUMAN-LABELED PRODUCTS:

Activated charcoal oral powder: 15 g, 30 g, 40 g, 120 g, 240 g, and UD 30 g; generic; (OTC)

Activated charcoal oral liquid/suspension with sorbitol: 25 g in 120 mL and 50 g in 240 mL; *Actidose® with Sorbitol*, generic; (OTC)

Activated charcoal liquid/suspension without sorbitol: 208 mg/mL to 12.5 g in 60 mL, 15 g in 72 mL, 25 g in 120 mL, and 50 g in 240 mL; *Actidose-Aqua®*, generic; (OTC)

Activated charcoal oral granules: 25 g; *EZ Char®*; (OTC)

Chlorambucil

(klor-***am***-byoo-sil) *Leukeran®*

Antineoplastic, Immunosuppressant

Prescriber Highlights

- ► Nitrogen mustard derivative antineoplastic and immunosuppressant in dogs, cats, and horses
- ► Caution: Pre-existing bone marrow depression or infection
- ► Adverse effects: Primarily myelosuppression and GI toxicity
- ► Known teratogen; National Institute for Occupational Safety and Health (NIOSH) hazardous drug; use appropriate precautions when handling.

Uses/Indications

Chlorambucil may be useful as part of multidrug protocols in a variety of neoplastic diseases, including lymphocytic leukemia, T-cell lymphoma,[1] GI lymphoma,[2,3] multiple myeloma, lymphangiosarcoma,[4] mast cell tumor,[5] cutaneous plasmacytosis, polycythemia vera, macroglobulinemia, and ovarian adenocarcinoma. Chlorambucil may also be used as a solo metronomic agent for some neoplasias (eg, hemangiosarcoma, transitional cell carcinoma).[6,7] It may also be useful as adjunctive therapy for some immune-mediated conditions (eg, inflammatory bowel disease, nonerosive arthritis, immune-mediated hemolytic anemia, immune-mediated skin disease).[8,9]

Pharmacology/Actions

Chlorambucil is an aromatic nitrogen mustard derivative and an alkylating antineoplastic agent. Its chemical reactivity is nonspecific, but the primary cytotoxic effect is due to alkylation of cancer cell DNA strands resulting in cross-linking and cellular apoptosis. Immunosuppressive effects may not be noted until 2 to 4 weeks after starting the drug.

Acquired resistance to chlorambucil has been reported and is thought to be caused by several mechanisms.[10]

Pharmacokinetics

Chlorambucil is rapidly and completely absorbed after oral administration, reaching C_{max} in ≈1 hour. It is highly bound to plasma proteins. Although it is unknown if chlorambucil crosses the blood–brain barrier, neurologic adverse effects have been reported. Chlorambucil is extensively metabolized in the liver primarily to the active metabolite phenylacetic acid mustard. Phenylacetic acid mustard is further metabolized to other metabolites that are excreted in the urine. Terminal half-life is 1.5 hours in humans.

Contraindications/Precautions/Warnings

Chlorambucil is contraindicated in patients with a history of hypersensitivity to it or other alkylating agents. It should be used with caution in patients with pre-existing bone marrow depression, patients susceptible to bone marrow depression (including patients receiving long-standing maximum-tolerated dose chemotherapy), or patients that have an active systemic infection. Because chlorambucil is hepatically metabolized, use with caution in patients with hepatic impairment.

Because chlorambucil is a chemotherapy agent with potential to cause teratogenic effects, proper and safe handling methods are recommended to reduce personal and occupational exposure.[11] The National Institute for Occupational Safety and Health (NIOSH) classifies chlorambucil as a hazardous drug.[12]

Adverse Effects

The most common major adverse effect associated with chlorambucil therapy is myelosuppression (eg, anemia, leukopenia, thrombocytopenia). Myelosuppression may occur gradually, with nadirs occurring within 7 to 14 days of the start of therapy. Recovery generally takes from 7 to 14 days. Severe bone marrow depression, an uncommon adverse effect occurring more often with prolonged (months to years) therapy, can result in pancytopenia that may require months to years for recovery. GI toxicity (eg, vomiting, diarrhea) is more common with higher (20 mg in humans) pulse doses. Hepatotoxicity was noted in 23% of dogs in one study.[5] Alopecia and delayed regrowth of shaven hair have been reported in dogs; breeds with a continuously growing hair coat (eg, poodles, terriers, Afghan hounds, old English sheepdogs) are more likely to experience significant hair loss. Lower-dose metronomic therapy (4 mg/m^2 [NOT mg/kg] once daily) in dogs is associated with a lower incidence of adverse effects. One study that evaluated several metronomic dose schedules found that dogs receiving 6 mg/m^2 (NOT mg/kg) once daily and 8 mg/m^2 (NOT mg/kg) once daily were at higher risk for adverse effects (GI and hematologic) as compared with dogs that received 4 mg/m^2 (NOT mg/kg) once daily. In addition, higher dosages of metronomic chlorambucil did not improve tumor response.[13]

One case report of neurotoxicity (eg, facial twitching, myoclonus, agitation, seizures) in a cat has been reported.[14] In addition, acquired Fanconi syndrome has been reported in 4 cats receiving chlorambucil and corticosteroids. Partial or complete resolution of Fanconi syndrome was seen in 3 of 4 cats within 3 months of discontinuing chlorambucil therapy.[15] In another report, chlorambucil was suspected of causing seizures in a dog.[16]

In humans, skin reactions that may progress to erythema multiforme or toxic epidermal necrolysis have been reported rarely. Bronchopulmonary dysplasia with pulmonary fibrosis, neurotoxicity, uric acid nephropathy, and hepatotoxicity have also been reported. Secondary malignancies may occur.

Reproductive/Nursing Safety

Chlorambucil has been documented to cause teratogenic effects in laboratory animals. Use during pregnancy only when the benefits to the dam outweigh the potential risks. In humans, chlorambucil has caused prolonged or permanent azoospermia in men, amenorrhea in women, and both reversible and irreversible infertility, particularly when given during pre-puberty and puberty.

It is unknown whether chlorambucil enters maternal milk. In humans, it is recommended to discontinue nursing if the mother is receiving the drug.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

The oral LD_{50} of chlorambucil in rats and mice is 76 mg/kg and 80 mg/kg, respectively. Experiences with acute overdoses in humans have been limited, but doses of up to 5 mg/kg resulted in neurologic (seizures) toxicity and pancytopenia (nadirs at 1 to 6 weeks postingestion). All patients recovered without long-term sequelae. Supportive treatment and gut emptying protocols are recommended following an overdose but beware of rapidly changing neurologic status if inducing vomiting. CBC should be monitored for several weeks following an overdose, and blood component therapy may be necessary. Chlorambucil is not dialyzable.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorambucil and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Myelosuppressive Agents** (eg, **antineoplastics**, **immunosuppressants**, **iron chelators**): Concurrent use with other bone marrow depressant medications may result in additive myelosuppression; avoid combination when possible.
- **Vaccines** (live and inactivated)**:** Chlorambucil may diminish vaccine efficacy and enhance adverse effects of vaccines.

Laboratory Considerations

- Chlorambucil may raise **serum uric acid** concentrations. Drugs such as allopurinol may be required to control hyperuricemia in some patients.

Dosages

NOTE: Because of the potential toxicity of this drug to patients, veterinary personnel, and clients, and because chemotherapy indications, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[17-21] are strongly recommended.

WARNINGS:

1. Chlorambucil dosages are commonly based on surface area (mg/m^2). Do not confuse with citations that list dosages in mg/kg. Commercial tablet size (2 mg) may make precise dosing difficult without compounding.
2. **Tablets should not be crushed, split, or formulated into a liquid**, unless adequate environmental, personal, and occupational exposure can be safeguarded.

DOGS:

Immunosuppressive agent (extra-label): Commonly dosed at 1.95 – 4.5 mg/m^2 (NOT mg/kg) once daily. Dosages are generally rounded to the nearest 2 mg. Following remission, chlorambucil has been dosed every other day for maintenance.[8] Use lowest dosage that will control condition. Often used in conjunction with prednisolone

Inflammatory colorectal polyps (extra-label): Consider in dogs with inflammatory colorectal polyps that do not respond well to traditional therapies (based on a retrospective study of 6 dachshunds): average chlorambucil initial dose: 2 mg/m^2 (NOT mg/kg) PO once daily used in combination with ***EITHER*** prednisolone 0.47 mg/kg PO once daily ***OR*** firocoxib 6.2 mg/kg PO daily (average). A positive response was seen in 5 of 6 dogs.[22]

Antineoplastic agent (metronomic) (all are extra-label):

a) **Chronic lymphocytic leukemia**: 3 – 6 mg/m^2 (NOT mg/kg) PO every day for 1 to 2 weeks, then decrease to 3 – 6 mg/m^2 (NOT mg/kg) PO every other day as determined by routine hematologic screening and cancer response.[23] Concurrently with chlorambucil, prednis(ol)one can be used at a dosage of 1 mg/kg PO every day for 1 to 2 weeks, then 0.5 mg/kg PO every other day thereafter.

b) **Mast cell tumor**: 4 – 6 mg/m^2 (NOT mg/kg) PO every 48 hours for 8 weeks. Chlorambucil treatment followed 3 or 4 sessions of lomustine 60 – 90 mg/m^2 (NOT mg/kg) every 21 days.[5]

c) **Lymphoma and other lymphoreticular neoplasia OR as a substitute for cyclophosphamide in the COP or CHOP protocol if sterile hemorrhagic cystitis occurs**: 1.4 mg/kg PO once on the same schedule as cyclophosphamide, in substitute of cyclophosphamide[23]

d) **Metronomic chemotherapeutic agent (eg, hemangiosarcoma, transitional cell carcinoma)** (extra-label): 4 mg/m^2 (NOT mg/kg) PO once daily. For dogs weighing more than 8 kg (17.6 lb), the dose is rounded to the nearest 2 mg; for dogs weighing less than or equal to 8 kg (17.6 lb), the dose is compounded to 4 mg/m^2 (NOT mg/kg).[6,7]

CATS:

Immunosuppressive agent (extra-label): Chlorambucil is generally considered a second-line immunosuppressant (after glucocorticoids) in cats and often used in conjunction with prednisolone. Anecdotal chlorambucil dosing recommendations vary and the commercial tablet size (2 mg) may make precise dosing difficult without compounding. For immune-mediated conditions, chlorambucil is commonly dosed initially at 0.1 – 0.2 mg/kg (≈1.5 – 4 mg/m^2 PO once daily). If using the entire 2 mg tablet, chlorambucil is dosed in a practical manner every 48 hours for cats weighing more than 4 kg (8.8 lb) and every 72 hours for cats weighing less than 4 kg (8.8 lb). Once remission occurs, the dose is reduced or the dosing interval (often every 3 to 4 days) is extended to an interval that still controls the condition.

Low-grade GI lymphoma; **chronic lymphocytic leukemia** (extra-label): Several protocols using chlorambucil with prednisolone have had a relatively high degree of efficacy, including:

a) Chlorambucil 15 mg/m^2 (NOT mg/kg) PO once daily for 4 days repeated every 3 weeks, and prednisolone initially at 3 mg/kg PO once daily[24]

b) Chlorambucil 20 mg/m^2 (NOT mg/kg) (rounded to nearest 2 mg) PO once every 2 weeks and prednisolone 2 mg/kg PO once daily[25]

c) Chlorambucil 2 mg/cat (NOT mg/m^2 or mg/kg) PO every 2 to 3 days (48-72 hours) and prednisolone 5 – 10 mg PO every 12 to 24 hours[26]

HORSES:

Adjunctive therapy in treating lymphoma using the LAP protocol (extra-label): Cytarabine 200 – 300 mg/m^2 (NOT mg/kg) SC or IM once every 1 to 2 weeks; chlorambucil 20 mg/m^2 (NOT mg/kg) PO every 2 weeks (alternating with cytarabine) and prednisone 1.1 – 2.2 mg/kg PO every other day. If this protocol is ineffective (no response seen in 2-4 weeks), add vincristine at 0.5 mg/m^2 (NOT mg/kg) IV once weekly.[27]

FERRETS:

Adjunctive therapy in treating lymphoma (extra-label): As part of a multiagent protocol, 2 mg total dose (NOT mg/kg) PO in weeks 11 and 20 of a 20-week protocol

Monitoring

- Efficacy
- Baseline CBC, serum chemistry profile, urinalysis
- Frequency of hematologic monitoring depends on protocol employed. Consultation with a veterinary oncologist is recommended. Recommendation for patients receiving continuous dosing without breaks is CBC 1 month after starting treatment, then CBC/serum chemistry profile every 2 to 3 months thereafter or earlier if patient is presented for unexpected changes in behaviors (eg, weight loss, fever, reduced activity, and/or appetite). For patients receiving bolus dosing with hiatus between treatment, CBC is recommended 1 week after each treatment. If neutrophils are less than 2500/µL or platelets less than 75,000/µL, stop chlorambucil until patient has recovered, and reduce dose by 10% to 20% or increase dosing interval. Other references recommend CBCs at 0, 1, 2, 4, 8, and 12 weeks and then every 3 to 6 months[28] or, in cats, CBCs at 2 to 3 weeks after starting therapy and every 3 to 6 months thereafter.[29]
- For sexually intact patients, verify pregnancy status prior to administration.

Client Information

- Bone marrow depression can occur. The greatest effects on bone marrow usually occur within a few weeks after treatment. Your veterinarian will do blood tests to watch for bone marrow depression, but if you see bleeding, bruising, or fever (indicating an infection), or if your animal tires easily, contact your veterinarian right away.
- Chlorambucil may be toxic to the gastrointestinal tract and cause vomiting and gastrointestinal upset. Chlorambucil may cause changes in blood cell counts, which may cause increased risk for bleeding, bruising, infection, lethargy, bloody diarrhea, and shortness of breath. Contact your veterinarian immediately if you notice these or any other atypical signs. Contact your veterinarian immediately if you notice abnormal bleeding, bruising, depression, infection, shortness of breath, or bloody diarrhea.
- It is important to follow your veterinarian's orders in administering this medication as prescribed to help minimize the risk for side effects.
- Routine bloodwork is recommended to monitor for changes in blood cell counts and liver and kidney laboratory values while the animal is on this medication. Do not miss these important follow-up visits.
- Handle this drug with caution. Wear gloves when administering medication or cleaning up your animal's waste. Those who are pregnant, attempting to conceive, or nursing should not administer the drug or clean up the animal's waste.
- Hair loss and delayed regrowth of shaven hair have been reported in dogs; breeds with a continuously growing hair coat (eg, poodles, terriers, Afghan hounds, old English sheepdogs) are more likely to experience significant hair loss.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Chlorambucil is a nitrogen mustard derivative antineoplastic agent. It occurs as an off-white, slightly granular powder. It is soluble in diethyl ether or acetone but is considered insoluble in water with a pK_a of 5.75.

Chlorambucil may also be known as CB-1348, NSC-3088, WR-139013, chlorambucilum, chloraminophene, chlorbutinum, *Chloraminophene®*, *Leukeran®*, or *Linfolysin®*.

Storage/Stability

Chlorambucil tablets should be stored in light-resistant, well-closed containers under refrigeration (2˚C -8˚C [36˚F-46˚F]). Tablets can be stored at a maximum of 30°C (86°F) for up to 1 week.

Compatibility/Compounding Considerations

Compounding chlorambucil should only be undertaken in facilities where adequate environmental and personnel exposure can be safeguarded.

Compounded preparation stability: For chlorambucil 2 mg/mL oral suspension, crush 60 2 mg oral tablets completely and suspend in 30 mL of methylcellulose 1%. Dilute with a sufficient amount of syrup for a final total volume of 60 mL. A 2 mg/mL oral suspension retains 90% potency for 7 days at 5°C (41°F).

Suspensions of chlorambucil stored at room temperature rapidly decompose with losses greater than 15% in 1 day. Chlorambucil is rapidly hydrolyzed independently of pH, but minimal hydrolysis occurs at pH 2. Refrigeration slows hydrolysis.

Compounded chlorambucil capsules demonstrated variable potency (71% to 104% of labeled strength), and stability and potency should be considered when prescribing compounded oral chemotherapy.[30]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Chlorambucil Oral Tablets (film-coated): 2 mg; *Leukeran®*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Chloramphenicol

(klor-am-***fen***-i-kole) *Chloromycetin®,Victeon®*

Antibacterial

Prescriber Highlights

- ► Broad-spectrum antibiotic with good tissue penetration, including in the eye, CNS, and prostate
- ► Use in food animals is prohibited by the FDA.
- ► Use should be avoided or pursued with extreme caution in animals with preexisting hematologic disorders or hepatic failure as well as in animals that are pregnant, or that are neonates. Doses may need to be reduced in animals with hepatic or renal insufficiency.
- ► Lower dosages are used in cats, for which there is a greater risk for complications, particularly with long-term use (ie, longer than 14 days).
- ► GI adverse effects are possible; there is also the potential for myelosuppression, especially with high-dose, long-term treatment.
- ► National Institute for Occupational Safety and Health (NIOSH) Hazardous Drug; use appropriate precautions when handling

Uses/Indications

Because of potential adverse effects in animals and human exposure concerns, chloramphenicol should only be used when other antimicrobial agents are not viable options. Chloramphenicol is used in small animal species and horses for the treatment of a variety of bacterial infections, particularly those caused by streptococci, staphylococci, and anaerobes. In dogs, chloramphenicol is indicated for the treatment of bacterial pneumonia, canine respiratory disease complex, as well as ocular infections, otitis media, and UTIs caused by susceptible bacteria. This antibiotic is also potentially useful for

the treatment of methicillin-resistant staphylococcal infections and bacterial prostatitis caused by susceptible bacteria. In cats, it is used for the treatment of haemobartonellosis, chlamydiosis, ocular infections, and UTIs. Chloramphenicol appears relatively safe to use in hindgut-fermenting species (eg, rabbits, guinea pigs, horses).

The World Health Organization (WHO) has designated chloramphenicol as a Highly Important antimicrobial for human medicine.[1]

Pharmacology/Actions

Chloramphenicol usually acts as a time-dependent, bacteriostatic antibiotic, but it can be bactericidal at higher concentrations or against some susceptible organisms. Chloramphenicol acts by binding to the 50S ribosomal subunit of susceptible bacteria, thereby preventing bacterial protein synthesis. Erythromycin, clindamycin, lincomycin, and tylosin also bind to the same bacterial ribosomal subunit, but unlike these other antibiotics, chloramphenicol appears to also have an affinity for mitochondrial ribosomes of rapidly proliferating mammalian cells (eg, bone marrow) that may result in reversible bone marrow suppression.

Chloramphenicol has a wide spectrum of activity against many aerobic and anaerobic gram-positive and gram-negative organisms. Gram-positive aerobic organisms that are generally susceptible to chloramphenicol include many streptococci and staphylococci. Some strains of methicillin-resistant staphylococci are susceptible. Chloramphenicol is also effective against some gram-negative aerobes, including *Neisseria* spp, *Brucella* spp, *Salmonella* spp, *Proteus* spp, *Shigella* spp, and *Haemophilus* spp. Many anaerobic bacteria (eg, *Clostridium* spp, *Bacteroides* spp [including *B fragilis*], *Fusobacterium* spp, *Veillonella* spp) are susceptible to chloramphenicol. Chloramphenicol also has activity against *Nocardia* spp, *Chlamydia* spp, *Mycoplasma* spp, and *Rickettsia* spp. This antibiotic is ineffective for the treatment of viral, fungal, or parasitic infections

Antimicrobial resistance appears to be mediated by enzymatic acetylation and inactivation by chloramphenicol acetyltransferases, efflux pumps, or altered ribosomal binding sites.[2–4]

At present, the Clinical and Laboratory Standards Institute (CLSI) has established a susceptibility breakpoint for most human bacterial pathogens at an MIC target of 8 µg/mL. Some studies show that equine plasma concentrations did not reach the recommended MIC target.[5–7]

Pharmacokinetics

Chloramphenicol is rapidly absorbed after oral administration; peak serum concentrations occur ≈30 minutes after administration. The compounded oral suspension produces significantly lower peak serum concentrations when administered to horses[5] and fasted cats. The palmitate and sodium succinate salts are hydrolyzed to the base in the GI tract and liver.

Chloramphenicol is widely distributed throughout the body, and although the highest concentrations are found in the liver and kidney, the drug attains therapeutic concentrations for some pathogens in most tissues and fluids, including the aqueous and vitreous humor and synovial fluid. CSF concentrations may be up to 50% of those in the serum when meninges are uninflamed and higher when meninges are inflamed. There may be a 4- to 6-hour lag time before CSF peak concentrations occur. Chloramphenicol concentrations in the prostate are ≈50% of those in the serum. Because only a small amount of the drug is excreted unchanged in the urine in dogs, chloramphenicol is not a good option for treatment of lower UTIs. The volume of distribution of chloramphenicol has been reported as 1.6 – 1.8 L/kg in dogs, 2.4 L/kg in cats, and 1.41 L/kg in horses. Chloramphenicol is ≈30% to 60% bound to plasma proteins. A recent study in horses indicated that plasma chloramphenicol concentrations after oral administration of chloramphenicol base (50 mg/kg) were lower than previously reported, resulting in a recommendation to evaluate the MIC of the causative bacterium before using this drug.[7]

The elimination half-life has been reported as 1.1 to 5 hours (average, ≈2.4 hours) in dogs, less than 1 hour in foals and ponies, and 4 to 8 hours in cats. The elimination half-life in birds is highly variable across species, ranging from 26 minutes in pigeons to nearly 5 hours in bald eagles and peafowl.[8]

In most species, chloramphenicol undergoes hepatic metabolism primarily via glucuronidative mechanisms. Parent drug (≈10%) and metabolites (≈90%) are predominantly renally eliminated (ie, only ≈5% to 15% of the drug is excreted unchanged in the urine). Cats have less ability to glucuronidate drugs, so ≈25% of a dose is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

The FDA prohibits use of chloramphenicol in food animals.

Chloramphenicol is contraindicated in those hypersensitive to it. Because of the potential for hematopoietic toxicity, chloramphenicol should be used with extreme caution, if at all, in animals with preexisting hematologic abnormalities, especially preexisting anemia. Chloramphenicol should be used with caution in animals with impaired hepatic or renal function, as drug accumulation can occur; dosage adjustments may be needed in these patients. Chloramphenicol should only be used in animals in hepatic failure when no other effective antibiotics are available and then only with prolonged treatment intervals. Consideration should be given to monitoring WBC and RBC counts in animals in which long-term use (greater than 14 days) is anticipated. See also ***Reproductive/Nursing Safety***.

Use with caution in cats. Dosages for dogs and cats are significantly different.

Chloramphenicol should be used with caution in neonatal animals, particularly in young kittens. In human neonates, circulatory collapse (ie, Gray syndrome) has occurred with chloramphenicol use.[9] This syndrome is probably caused by toxic drug accumulation secondary to an inability to conjugate the drug or excrete the conjugate effectively.

The National Institute for Occupational Safety and Health (NIOSH) classifies chloramphenicol as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[10]

Do not confuse chloramphenicol with chlorambucil, chlorpheniramine, or chlorpromazine.

Adverse Effects

Although chloramphenicol toxicity in humans has been greatly discussed in the literature, it is generally considered to have a low order of toxicity in adult companion animals when administered appropriately. A retrospective review found that in 51 dogs treated with chloramphenicol at recommended doses (≈50 mg/kg) for methicillin-resistant *Staphylococcus pseudintermedius* (MRSP) pyoderma, 53% developed adverse effects that included GI signs (47%), lethargy (14%), shaking (8%), and increased liver enzymes (6%).[11] Anemia, panting, and aggression were reported in individual dogs. GI signs and rear limb weakness were noted in another retrospective review.[12] Peripheral neuropathy (ie, rear limb weakness) anecdotally appears to be more common in large-breed dogs, which may be more likely due to ease of recognition of this clinical sign versus a truly increased incidence. As there is no evidence that peripheral neuropathy is dose-related, treatment of large-breed dogs at the lower end of the dose range should be weighed against consequences of treatment failure.

Development of aplastic anemia (reported in humans) does not appear to be a significant problem for veterinary patients[9]; however, a dose-related bone marrow suppression (reversible) has been seen in all species, primarily with long-term therapy. Early signs of bone marrow toxicity can include vacuolation of many of the early cells

of the myeloid and erythroid series, as well as lymphocytopenia and neutropenia. Thrombocytopenia associated with chloramphenicol use in cats has been reported.

Other possible adverse effects include anorexia, vomiting, diarrhea, and depression. Chloramphenicol in guinea pigs can have a negative effect on the cardiovascular system, as seen by ECG changes (eg, shortened P waves, P-R interval, QRS complex).[13]

Cats tend to be more sensitive to developing adverse effects to chloramphenicol than dogs, but this is likely because the drug's half-life is longer in cats due to poor glucuronidation capacity. Cats given higher-than-label feline dosages for prolonged periods (eg, 50 mg/kg every 12 hours for 2 to 3 weeks) may experience a high incidence of adverse effects, including bone marrow hypoplasia, and should be closely monitored.

Reproductive/Nursing Safety

Chloramphenicol should not be administered to dogs maintained for breeding purposes, as significant disorders in gonad morphology and function have been noted under experimental conditions.[14] Chloramphenicol readily crosses the placenta to achieve concentrations at 75% of maternal blood. The drug may decrease protein synthesis in the fetus, particularly in the bone marrow. It should be given with extreme caution during pregnancy and only when the maternal benefits of therapy clearly outweigh the risks to the fetus.

Because chloramphenicol is found in milk in humans at 50% of serum concentrations, the drug should be given with extreme caution to nursing animals, particularly within the first week of giving birth. Use of an alternative antimicrobial is recommended during nursing.[15]

Overdose/Acute Toxicity

Dosages of 200 mg/kg/day for up to 4 months were tolerated by dogs,[14] but cats show toxicity at 60 mg/kg daily within 14 days.[16]

Because of the potential for serious bone marrow toxicity, large overdoses of oral chloramphenicol should be handled by GI decontamination using standard protocols followed by supportive care based on clinical presentation. For more information on chloramphenicol toxicity, see ***Adverse Effects***.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

Chloramphenicol is a cytochrome P450 CYP2B11 inhibitor in dogs and may possibly inhibit other CYP isoenzymes in dogs and other species. The following drug interactions have either been reported or are theoretical in humans or animals receiving chloramphenicol and may be of significance in veterinary patients. (**NOTE**: Cats may be particularly susceptible to chloramphenicol's effects on the hepatic metabolism of other drugs.)

- **Acetaminophen:** Concurrent use of chloramphenicol and acetaminophen resulted in increased serum concentrations of chloramphenicol in one human study, but subsequent studies have contradicted that result. There are no veterinary data for this interaction.
- **Aminoglycosides** (eg, **amikacin**, **gentamicin, streptomycin**): May cause antibacterial antagonism; clinical significance, if any, is not clear
- **Anti-Anemia Drugs** (eg, **epoetin, folic acid, iron, vitamin B_{12}**): Chloramphenicol may delay hematopoietic response.
- **Aspirin and Other Salicylates** (eg, **bismuth subsalicylate**): Chloramphenicol may delay hepatic metabolism of the salicylate and therefore potentiate toxicity.
- **Beta-Lactam Antibiotics** (eg, **cephalosporins, penicillins**): May cause antibacterial antagonism; clinical significance, if any, is not clear
- **Cimetidine:** May reduce the metabolism of chloramphenicol, increasing the risk for toxicity
- **Cyclophosphamide:** Chloramphenicol may reduce formation of the active cyclophosphamide metabolite and reduce cyclophosphamide efficacy. Additive myelosuppression may occur.
- **Cyclosporine:** May increase the risk for cyclosporine toxicity
- **Dipyrone:** May increase the risk for myelosuppression
- **Glipizide:** Chloramphenicol may decrease sulfonylurea metabolism and increase the risk for hypoglycemia.
- **Ketamine:** Chloramphenicol may prolong effects. Chloramphenicol did not prolong anesthesia in dogs receiving xylazine/ketamine in a study.[17]
- **Levamisole:** Fatalities have been reported after concomitant levamisole and chloramphenicol administration; avoid using these agents together.
- **Lidocaine**: Chloramphenicol may delay hepatic metabolism.
- **Methadone**: Chloramphenicol inhibits hepatic metabolism and increases methadone effects.[18]
- **Midazolam**: Chloramphenicol may prolong effects.
- **Myelosuppressive Drugs** (eg, **azathioprine, interferons, methimazole, toceranib**): May cause additive bone marrow depression
- **Opioids:** Chloramphenicol can significantly inhibit metabolism and prolong opioid effects.
- **Pentobarbital**: Chloramphenicol has been demonstrated to prolong the duration of pentobarbital anesthesia by 120% in dogs and 260% in cats,[19,20] but there was no prolonged duration in guinea pigs.[21]
- **Phenobarbital/Primidone**: Chloramphenicol may inhibit phenobarbital metabolism, and phenobarbital may decrease chloramphenicol concentrations. Interaction does not apply to chloramphenicol ophthalmic ointment.[22,23]
- **Propofol**: Chloramphenicol may prolong anesthesia.
- **Rifampin**: May decrease serum chloramphenicol concentrations
- **Voriconazole**: Chloramphenicol may increase voriconazole concentration.

Laboratory Considerations

- False positive **glucosuria** (glycosuria) has been reported, but the incidence is unknown.

Dosages

NOTE: Because of potential adverse effects in animals and human exposure concerns, chloramphenicol should only be used when other antimicrobial agents are not viable options.

DOGS:

Susceptible GI, pulmonary, and urinary bacterial infections (label dosage; FDA-approved): 55 mg/kg PO every 6 hours[14]

Susceptible infections (extra-label):

a) 25 – 50 mg/kg PO every 6 to 8 hours, continuing for 3 to 5 days after the animal has become free of clinical signs or afebrile[24]

b) 40 – 50 mg/kg PO, IV, SC, IM every 8 hours.[25,26] Dosages up to 60 mg/kg PO every 8 hours may be necessary for some infections. IV doses should be administered over at least 1 minute.

CATS:

Susceptible infections (extra-label): 12.5 – 20 mg/kg every 12 hours PO, IV, IM, or SC.[25] Practically, it is often administered at

50 mg/cat (NOT mg/kg) PO every 12 hours.

HORSES:

NOTE: All are extra-label.

Susceptible infections:

a) **Adult horses**:45 – 60 mg/kg PO every 8 hours; 45 – 60 mg/kg IM, SC, or IV every 6 to 8 hours[27]
b) **Foals**: 20 mg/kg PO or IV every 4 hours[28]
c) **Foals**: Chloramphenicol sodium succinate: 25 – 50 mg/kg IV every 4 to 8 hours; chloramphenicol base or palmitate: 40 – 50 mg/kg PO every 6 to 8 hours[29]
d) **Regional limb perfusion**: 2000 mg diluted to 100 mL perfusion volume with sterile saline.[30]

BIRDS:

Susceptible infections (extra-label):

a) Chloramphenicol sodium succinate: 80 mg/kg IM 2 to 3 times daily, 50 mg/kg IV 3 to 4 times daily
b) Chloramphenicol sodium succinate: 50 mg/kg IM or IV every 8 hours[31]

FERRETS:

Susceptible infections (extra-label): 50 mg/kg PO, SC, IV every 12 hours

RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits** (extra-label): 30 – 50 mg/kg PO, SC, IM, IV every 8 to 24 hours[32]
b) **Hedgehogs** (extra-label): 50 mg/kg PO every 12 hours; 30 – 50 mg/kg SC, IM, IV, or intraosseous (IO) every 12 hours[33]
c) **Chinchillas** (extra-label): 30 – 50 mg/kg PO, SC, IM every 12 hours
d) **Gerbils, guinea pigs, hamsters, mice, rats** (extra-label): 20 – 50 mg/kg (succinate salt) SC every 6 to 12 hours[34]
e) **Pneumonia in guinea pigs** (extra-label): 30 – 50 mg/kg PO every 12 hours[35]

REPTILES:

Susceptible infections (extra-label):

a) For most species using the sodium succinate salt: 20 – 50 mg/kg IM or SC for up to 3 weeks. Chloramphenicol is often a good initial choice until susceptibility results are available.[36]
b) 30 – 50 mg/kg/day IV or IM for 7 to 14 days[37]

Monitoring

- Baseline and periodic (eg, every 1 to 2 weeks) CBC during treatment
- Clinical efficacy
- Culture and susceptibility testing is recommended prior to treatment, as this drug should typically be reserved for treatment of infections in which more commonly used drugs are not appropriate.
- Adverse effects (eg, GI adverse effects, hindlimb weakness)

Client Information

- Wear gloves when handling this medicine and avoid contact with the drug, especially around your mouth, nose, or eyes. Avoid crushing pills.
- For this medication to work, give it exactly as your veterinarian has prescribed. Missing a dose can cause the medicine to not work properly for your animal.
- This medicine is best given with food as it has an extremely bitter taste that can make administration of the tablets difficult.
- The most common side effects are stomach upset, vomiting, and diarrhea. Cats may be more likely to experience serious side effects.
- This medicine is banned for use in animals to be used for food, including egg-laying chickens and dairy animals.
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

Chloramphenicol, originally isolated from *Streptomyces venezuelae*, is now produced synthetically. It occurs as fine, white to grayish, yellow-white, elongated plates or needle-like crystals with a pK_a of 5.5. It is soluble in alcohol and propylene glycol, and ≈2.5 mg are soluble in 1 mL of water at 25°C (77°F).

Chloramphenicol sodium succinate occurs as a white to light yellow powder. It is freely soluble in both water and alcohol.

Chloramphenicol may also be known as chloramphenicolum, chloranfenicol, cloranfenicol, kloramfenikol, or laevomycetinum; *Chloromycetin*® and *Viceton*® are common trade names.

Storage/Stability

Chloramphenicol tablets should be stored in tight containers at or below 25°C (77°F) and in a dry place. The sodium succinate powder for injection should be stored between 20°C and 25°C (68°F-77°F). After reconstituting the sodium succinate injection with sterile water, the solution is stable for 30 days at room temperature or 6 months if frozen. The solution should be discarded if it becomes cloudy.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Reconstitute each chloramphenicol sodium succinate 1g vial with 10 mL sterile water for injection or 5% dextrose solution.

The following drugs and solutions are reportedly **compatible** with chloramphenicol sodium succinate injection: all commonly used IV fluids, amikacin sulfate, aminophylline, amphotericin B lipid complex, ampicillin sodium (in syringe for 1 hour), atropine, buprenorphine, calcium chloride/gluconate, cefazolin, cyclosporine, dexamethasone sodium phosphate, ephedrine, fentanyl, furosemide, heparin, hydrocortisone sodium succinate, hydromorphone, lidocaine, magnesium sulfate, mannitol, methylprednisolone sodium succinate, metoclopramide, metronidazole, morphine, naloxone, norepinephrine, oxytocin, penicillin G potassium/sodium, pentobarbital, phenobarbital, phenylephrine, piperacillin/tazobactam, plasma protein fraction, potassium chloride, ranitidine, sodium bicarbonate, tobramycin, vasopressin, verapamil, and vitamin B-complex with vitamin C.

The following drugs and solutions are reportedly **incompatible** (or compatibility data conflicts) with chloramphenicol sodium succinate injection: amiodarone, ascorbic acid, ceftazidime, chlorpromazine, diazepam, diltiazem, diphenhydramine, dobutamine, dopamine, famotidine, fluconazole, gentamicin, glycopyrrolate, hydroxyzine, midazolam, ondansetron, oxytetracycline, pantoprazole, sulfa-/trimethoprim, and vancomycin.

FDA-approved chloramphenicol tablets dissolved in water with *Karo*® syrup added just prior to administration to horses demonstrated greater bioavailability, higher peak concentration, and area under the curve (AUC) as compared with compounded chloramphenicol paste and suspension.[5] The study also noted that tablets required ≈5.5 hours to dissolve.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Chloramphenicol Oral Tablets: 250 mg, 500 mg, and 1 g; *Viceton*®; (Rx). FDA-approved for use in dogs. NADA #055-059

Chloramphenicol is prohibited by the FDA for use in food animals.

HUMAN-LABELED PRODUCTS:
Chloramphenicol Powder for Injection: 1 gram vials (100 mg/mL as sodium succinate when reconstituted); generic; (Rx). **NOTE**: this product is no longer commercially available.

Chlorothiazide

(klor-oh-***thye***-a-zide) *Diuril®*
Thiazide Diuretic

Prescriber Highlights

- ► Thiazide diuretic used for nephrogenic diabetes insipidus
- ► Contraindications include hypersensitivity to the drug; pregnancy is a relative contraindication.
- ► Use with extreme caution or avoid in cases of severe renal disease, pre-existing electrolyte and/or water balance abnormalities, impaired hepatic function, hyperuricemia, calcium oxalate urolithiasis, systemic lupus erythematosus (SLE), or diabetes mellitus.
- ► Adverse effects include hypokalemia, hypochloremic alkalosis, other electrolyte imbalances, hyperuricemia, and GI effects.
- ► Many drug–drug and laboratory test interactions

Uses/Indications

Thiazides are used for the treatment of systemic hypertension, ascites, hypermagnesemia, and nephrogenic diabetes insipidus (DI); they are also used as adjunctive therapy in patients with central DI.[1-3]

In veterinary medicine, furosemide has largely supplanted the use of thiazides as a general diuretic. If a thiazide diuretic is necessary, hydrochlorothiazide is preferred for use in dogs and cats. Chlorothiazide is also FDA-approved for use in dairy cattle for the treatment of postparturient udder edema,[4] but the veterinary-labeled product is no longer marketed in the United States.

Pharmacology/Actions

Thiazide diuretics act by interfering with the transport of sodium ions across the renal tubular epithelium, possibly by altering the metabolism of tubular cells. The principal site of action is at the cortical diluting segment of the nephron (between the proximal and distal convoluted tubules), which results in enhanced excretion of sodium, chloride, and water. Thiazides also increase the excretion of potassium, magnesium, phosphate, iodide, and bromide and decrease the glomerular filtration rate (GFR). Plasma renin and resulting aldosterone levels are increased, which contributes to the hypokalemic effects of the thiazides. Bicarbonate excretion is increased, but effects on urine pH are usually minimal. Thiazides usually initially have a hypercalciuric effect, but with continued therapy, calcium excretion is significantly decreased. Thiazides can cause or exacerbate hyperglycemia in diabetic patients or induce diabetes mellitus in prediabetic patients.

In nephrogenic diabetes insipidus, the administration of a thiazide diuretic can result in a paradoxical decrease in urine output. The proposed mechanism for this effect is related to sodium reduction. Thiazide diuretics reduce the reabsorption of sodium and chloride in the distal tubule of the nephron. This initially results in sodium loss and extracellular volume contraction, which results in increased reabsorption of sodium and water in the proximal tubule. Less filtrate is presented to the distal nephron and collecting duct and is subsequently excreted as urine.

The antihypertensive effects of thiazides are well-known, and these agents are used extensively in human medicine for treating essential hypertension. The exact mechanism of this effect has not been established.

Pharmacokinetics

The pharmacokinetics of thiazides have not been studied in domestic animals. In humans, chlorothiazide is only 10% to 21% absorbed after oral administration. The onset of diuretic activity occurs in 1 to 2 hours and peaks at about 4 hours. The serum half-life is ≈1 to 2 hours, and the duration of activity is 6 to 12 hours. Chlorothiazide is not metabolized and is eliminated almost entirely as unchanged drug via the urine. Like all thiazides, the antihypertensive effects of chlorothiazide can be delayed by several days.

Contraindications/Precautions/Warnings

Thiazides are contraindicated in patients that are anuric or hypersensitive to any one of these agents. Although many sources state that thiazides are contraindicated in patients that are hypersensitive to sulfonamides, clear evidence for cross-reactivity has not been established in humans or animals.

Thiazides should be used with extreme caution, if at all, in patients with severe renal disease or with preexisting electrolyte or water balance abnormalities, impaired hepatic function (may precipitate hepatic coma), hyperuricemia, systemic lupus erythematosus (SLE), or diabetes mellitus. Patients with conditions that may lead to electrolyte or water balance abnormalities (eg, vomiting, diarrhea) should be monitored carefully. The use of chlorothiazide is not recommended in patients with calcium oxalate urolithiasis, as it has been demonstrated to increase renal calcium excretion, particularly at higher doses[5]; if a thiazide diuretic is required in these patients, hydrochlorothiazide should be used instead.

Adverse Effects

Hypokalemia is one of the most common adverse effects associated with thiazides but rarely causes clinical signs or progresses further; however, monitoring of serum potassium is recommended with chronic therapy.

Hypochloremic metabolic alkalosis (with hypokalemia) may develop, especially if there are other causes of potassium and chloride loss (eg, vomiting, diarrhea, potassium-losing nephropathies) or if the patient has cirrhotic liver disease. Dilutional hyponatremia and hypomagnesemia may also occur. Hyperparathyroid-like effects of hypercalcemia and hypophosphatemia have been reported in humans but have not led to effects, such as nephrolithiasis, bone resorption, or peptic ulceration.

Hyperuricemia can occur but it is usually subclinical.

Other possible adverse effects include vomiting, diarrhea, pancreatitis, hypersensitivity, dermatologic reactions, polyuria, hematologic toxicity, hyperglycemia, hyperlipidemias, and orthostatic hypotension.

Reproductive/Nursing Safety

Thiazides cross the placenta and are contraindicated in pregnant patients that are otherwise healthy and have only mild edema, as newborn human infants have developed thrombocytopenia when their mother received thiazides. Chlorothiazide did not impair fertility in rats that were given doses up to 60 mg/kg/day.

Chlorothiazide enters maternal milk and can reduce milk volume and suppress lactation. Because of the risk for idiosyncratic or hypersensitivity reactions, it is recommended that these drugs not be used in lactating female patients or nursing mothers. In general, either discontinuation of the drug or nursing is recommended in humans.

Overdose/Toxicity

Acute overdose may cause dehydration and electrolyte problems (eg, hyponatremia, hypokalemia), CNS effects (lethargy, coma, seizures), and GI effects (eg, hypermotility, GI distress). Transient increases in BUN have also been reported.

Treatment consists of GI decontamination after recent oral ingestion using standard protocols. Avoid giving concomitant cathartics, as they may exacerbate the fluid and electrolyte imbalances that may ensue. Monitor and treat electrolyte and water balance abnormalities supportively. Monitor respiratory, CNS, and cardiovascular status; treat clinical signs supportively.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorothiazide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Amphotericin B**: Use with thiazides can lead to increased risk for severe hypokalemia.
- **Bromides:** May enhance bromide excretion and reduce seizure control
- **Calcium Salts** (eg, **calcium carbonate, calcium acetate**): Hypercalcemia may be exacerbated if thiazides are concurrently administered with vitamin D or calcium salts.
- **Corticosteroids** (eg, **dexamethasone, prednis(ol)one corticotropin**):Use with thiazides can lead to increased risk for severe hypokalemia.
- **Diazoxide**: Increased risk for hyperglycemia, hyperuricemia, and hypotension may occur.
- **Digoxin**: Thiazide-induced hypokalemia, hypomagnesemia, and/or hypercalcemia may increase the likelihood of digitalis toxicity.
- **Furosemide**: May have additive diuretic and hypokalemic effect
- **Hypoglycemic Agents** (eg, **acarbose, glipizide, insulin, metformin**): Thiazides may cause or exacerbate hyperglycemia in diabetic patients; increase in doses of hypoglycemic agents may be required.
- **Hypotensive Agents** (eg, **amlodipine, enalapril, telmisartan**): May have additive hypotensive effect
- **Lithium**: Thiazides can increase serum lithium concentrations.
- **Methenamine**: Thiazides can alkalinize urine and reduce methenamine effectiveness.
- **Nonsteroidal Anti-inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam, robenacoxib**): Thiazides may increase risk for renal toxicity, and NSAIDs may reduce diuretic actions of thiazides.
- **Nondepolarizing Neuromuscular Blocking Agents** (eg, **atracurium, rocuronium, vecuronium**: Nondepolarizing neuromuscular-blocking agents' response or duration may be increased in patients receiving thiazide diuretics.
- **Probenecid**: Blocks thiazide-induced uric acid retention (used to therapeutic advantage)
- **Quinidine**: Half-life may be prolonged by thiazides (thiazides can alkalinize the urine).
- **Vitamin D** (eg, **cholecalciferol, ergocalciferol**): Hypercalcemia may be exacerbated if thiazides are concurrently administered with vitamin D or its analogues.

Laboratory Considerations

- **Amylase**: Thiazides can increase serum amylase values in subclinical patients and those in the developmental stages of acute pancreatitis (humans).
- **Cortisol**: Thiazides can decrease the renal excretion of cortisol.
- **Estrogen, Urinary**: Thiazides may falsely decrease total urinary estrogen when a spectrophotometric assay is used.
- **Hydroxycorticosteroids:** Thiazides may decrease urinary corticosteroid values by interfering in vitro with the absorbance in the modified Glenn-Nelson technique for urinary 17-hydroxycorticosteroids**.**
- **Parathyroid-Function Tests**: Thiazides may elevate serum calcium; discontinuing thiazides prior to testing is recommended.
- **Phenolsulfonphthalein** (**PSP**): Thiazides can compete for secretion at proximal renal tubules.
- **Pheochromocytoma:** Thiazides may cause false-negative results with **histamine**, **phentolamine,** or **tyramine** tests.
- **Protein-Bound Iodine**: Thiazides may decrease values.
- **Triiodothyronine Resin Uptake Test**: Thiazides may slightly reduce uptake.

Dosages

DOGS/CATS:

Congestive heart failure (CHF) (label dosage; FDA-approved): 11 – 22 mg/kg PO 2 or 3 times daily. Severe conditions may require higher doses.[4]

Some dogs may have an adequate response to intermittent doses (eg, administered for 3 to 5 days per week).[4] **NOTE:** Most clinicians recommend furosemide as a general diuretic for CHF.

Diuresis or treatment for nephrogenic diabetes insipidus (extra-label): 20 – 40 mg/kg PO every 12 hours[6]

Monitoring

- Baseline and periodic serum electrolytes, BUN, creatinine, glucose
- Hydration status
- Blood pressure, if indicated
- CBC, if indicated

Client Information

- When beginning this medicine, your animal may urinate more frequently than normal.
- This medicine may be given with or without food. Provide your animal with access to fresh water at all times and encourage normal food intake.
- Because this drug can change electrolytes (salts) in the blood, your veterinarian will want to do more frequent testing.
- Contact your veterinarian immediately if you notice weakness, collapse, head tilt, lack of urination, or a racing heartbeat.

Chemistry/Synonyms

Chlorothiazide is a thiazide diuretic and occurs as a white to practically white odorless crystalline powder that has a slightly bitter taste.

It is very slightly soluble in water and slightly soluble in alcohol.

Chlorothiazide may also be known as chlorothiazidum, clorotiazida, *Azide®*, *Diuril®*, or *Saluric®*.

Storage/Stability

Store the oral suspension at room temperature (15°C to 30°C [59° to 86°F]) and protected from freezing.[7]

Compatibility/Compounding Considerations

None

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Chlorothiazide Oral Suspension: 50 mg/mL in 237 mL; *Diuril*®; (Rx)

Chlorothiazide Sodium Powder for Injection (lyophilized): 500 mg (0.25 g mannitol) in 20 mL vials; *Diuril*®; (Rx)

References

Chlorpheniramine

(klor-fen-***ir***-a-meen) *Chlor-Trimeton*®

Antihistamine, First Generation

Prescriber Highlights

- ► Used principally for antihistaminic and antipruritic properties; used as adjunctive agent for atopic dermatitis
- ► Contraindications include known hypersensitivity to the drug.
- ► Use with caution in patients with narrow-angle glaucoma, hypertension, GI or urinary obstruction, hyperthyroidism, and cardiovascular disease.
- ► Adverse effects include sedation, anticholinergic effects, and GI effects.
- ► Chlorpheniramine may be found OTC in combination with other drugs that may be toxic to animals (eg, acetaminophen, pseudoephedrine).

Uses/Indications

Chlorpheniramine is a first-generation antihistamine that may be useful in dogs and cats for the adjunctive treatment of histamine-mediated pruritic and allergic conditions (eg, urticaria, insect-bite hypersensitivity). Guidelines for atopic dermatitis treatment in dogs state there is no conclusive evidence regarding the efficacy of oral first-generation antihistamines in the treatment of chronic and acute flares of canine atopic dermatitis, with only highly variable therapeutic efficacy reported anecdotally; chlorpheniramine should be given continuously (ie, daily) as preventive therapy before an acute flare.[1,2]

The response to chlorpheniramine, as with other antihistamines in dogs and cats, is individualized and not predictable. One patient may respond to one formulation but not another. Chlorpheniramine, when combined with hydroxyzine, has potentially shown better results in reducing clinical signs of canine atopic dermatitis in ≈1 of 3 treated dogs,[3] and pruritus improved by more than 25% in 10 of 17 dogs.[4] In pruritic cats, chlorpheniramine has been shown to have an antipruritic effect when combined with oral omega-3 and -6 fatty acid supplements[5]

First-generation antihistamines may also be used as adjunctive therapy for mast cell tumors and to prevent local histamine release during surgical excision of mast cell tumors.

Pharmacology/Actions

H_1-receptor antagonist antihistamines competitively inhibit histamine H_1 receptors; they do not inactivate or prevent the release of histamine but can prevent histamine's action on the cell. In addition to its antihistaminic effects, chlorpheniramine also has varying degrees of anticholinergic, sedative, tranquilizing, antispasmodic, local anesthetic, mild bronchodilator, and antiemetic activities.

Pharmacokinetics

Pharmacokinetic information for chlorpheniramine in small animals is limited. In dogs, chlorpheniramine has an oral bioavailability of 10% to 40% that is considered dose-dependent with extensive drug distribution to the extravascular tissues.[6] The mean distribution half-life was reported to be 12.5 minutes with an elimination half-life of ≈1.7 hours.

In healthy thoroughbred horses, administration of 0.5 mg/kg IV plasma drug disposition was very rapid, with the mean terminal half-life and total body clearance calculated as 2.7 hours and 0.7 L/hour/kg, respectively. The observed maximal inhibition of wheal formation at 0.5 hours after administration of 0.1 and 0.5 mg/kg IV were 37.8% and 60.6%, respectively. Administration of d-chlorpheniramine at 0.5 mg/kg PO resulted in a bioavailability of 38%, with a peak plasma concentration at 1 hour and a maximal inhibition of wheal formation of 39% at 2 hours, suggesting that a larger dose rate and more frequent intervals may be needed to maintain therapeutic concentrations in horses.[7]

In humans, chlorpheniramine is well absorbed after oral administration, but bioavailability is 25% to 60% due to first-pass metabolism. The apparent steady-state volume of distribution is 2 to 12 L/kg, and 33% to 70% is bound to plasma proteins. Chlorpheniramine is metabolized in the liver and practically all the drug (as metabolites and unchanged drug) is excreted in the urine. In human patients with normal renal and hepatic function, the terminal serum half-life of the drug ranges from 13.2 to 43 hours. Half-life is increased with renal dysfunction; children have a decreased half-life.

Contraindications/Precautions/Warnings

Chlorpheniramine is contraindicated in patients that are hypersensitive to it or other antihistamines in its class. Because of its anticholinergic activity, chlorpheniramine should be used with caution in animals with narrow-angle glaucoma, prostatic hypertrophy, pyloroduodenal or bladder neck obstruction, and pulmonary diseases with minimal mucosal secretions. In addition, the drug should be used cautiously in animals with hyperthyroidism, cardiovascular disease, hypertension, or renal dysfunction. Palatability of this drug is also an issue in cats.

Do not confuse chlorPHENiramine with clomiPRAMINE or chlorpromAZINE.

Adverse Effects

The most common adverse effects are CNS depression (eg, lethargy, sedation)[8] and GI effects (eg, constipation, diarrhea, vomiting, anorexia). The sedative effects of antihistamines may adversely affect the performance of working dogs. With continued administration the sedative effects of antihistamines may diminish over time. Anticholinergic effects (eg, dry mouth, urine and fecal retention) are possible. Chlorpheniramine may cause paradoxical excitement in cats.

Reproductive/Nursing Safety

Laboratory animals given 50 to 85 times the human dose (based on weight) experienced no reproductive impairment or fetal harm. The drug is considered compatible with pregnancy.

Chlorpheniramine is excreted into milk; use with caution in dams and nursing neonates.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Overdose of first-generation antihistamines may cause CNS stimulation (eg, hyperexcitability, seizures) or depression (eg, lethargy, coma), anticholinergic effects, respiratory depression, and/or death. A 9-month-old dachshund that ingested 25 mg/kg showed signs of ataxia, tremors, bradycardia, coma, and cardiac arrest and died within 11 hours of ingestion.[9] Another source states not to use dosages greater than 1.1 mg/kg/day in dogs, as sudden death has occurred.[10]

Treatment consists of GI decontamination (if ingestion was oral) using standard protocols. Induce emesis if the patient is alert and CNS status is stable. A saline cathartic and/or activated charcoal may be given after emesis or gastric lavage. Treatment should be performed using supportive therapy based on clinical signs.

For patients that have experienced or are suspected to have expe-

rienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorpheniramine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Acetylcholinesterase Inhibitors** (eg, **neostigmine, pyridostigmine**): Chlorpheniramine may reduce effects of acetylcholinesterase inhibitors.
- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate, oxybutynin**): Additive anticholinergic effects may occur when chlorpheniramine is used concomitantly with other anticholinergic agents.
- **Anticoagulants** (eg, **heparin, warfarin**): May partially counteract the anticoagulation effects of heparin or warfarin
- **CNS Depressant Drugs, Other** (eg, **acepromazine, ketamine, methocarbamol, mirtazapine, phenobarbital, trazodone**): Additive CNS depression may be seen if combining chlorpheniramine with other CNS depressant medications.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **amitraz, amitriptyline, selegiline**): May prolong and exacerbate anticholinergic effects
- **Opioids** (eg, **buprenorphine**, **fentanyl, hydromorphone, methadone, morphine, tramadol**): Additive CNS depression and anticholinergic effects may occur.
- **Potassium Supplements, Oral**: The risk of focal upper GI injury caused by solid oral dosage forms of potassium salts may be increased by agents that reduce GI transit.
- **Prokinetics** (eg, **cisapride, metoclopramide**): Chlorpheniramine may reduce the effects of prokinetic agents.
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine**): Additive CNS depression and anticholinergic effects may occur.

Laboratory Considerations

- **Intradermal allergy testing (IDT)**: Although antihistamines may suppress IDT results, it is recommended that chlorpheniramine be discontinued a minimum of 2 days, but optimally 7 days prior to testing.[11]

Dosages

DOGS:

Adjunctive treatment and prevention of histamine-related pruritic conditions or as a mild sedative (extra-label): Most recommendations range from 0.2 – 0.5 (maximum) mg/kg PO every 8 to 12 hours. Using commercially available oral tablets, this is usually rounded off to the nearest 2 mg, with doses ranging from 2 – 8 mg/dog (NOT mg/kg) 2 to 3 times per day.

CATS:

Adjunctive treatment and prevention of histamine-related pruritic conditions or as a mild sedative (extra-label): Most recommended dosages are 1 – 4 mg/cat (NOT mg/kg) PO 2 to 3 times per day. Commonly administered at 2 mg/cat (NOT mg/kg) twice daily.[5,12] Some cats may be controlled with once-daily administration.

HORSES:

Adjunctive treatment and prevention of histamine-related pruritic conditions such as insect-bite hypersensitivity (extra-label): 0.25 mg/kg PO every 12 hours[13] **NOTE**: A pharmacokinetic study found a single dose of 0.5 mg/kg PO to be less efficacious than other antihistamines.[7]

BIRDS:

Adjunctive treatment (prevention) of histamine-related pruritic conditions or as a mild sedative (extra-label): One 4 mg tablet in one cup (240 mL; 8 oz) of bottled water to be used as drinking water; changed daily[14]

FERRETS:

Adjunctive treatment (prevention) of histamine-related pruritic conditions or as a mild sedative (extra-label): 1 – 2 mg/kg PO 2 to 3 times per day[15]

Monitoring

- Clinical efficacy; trial periods to determine an antihistamine's efficacy are usually 1 to 2 weeks in duration
- Adverse effects

Client Information

- This medicine may be difficult to give to cats, as it has a bitter taste. Acceptance by cats may be improved by dipping the split tablet into tuna juice, butter, or petrolatum, or by placing split tablets into empty gelatin capsules.
- Antihistamines should be used on a regular ongoing basis in animals that respond well to the medicine. Antihistamines work better when used before an animal has been exposed to an allergen.
- Drowsiness/sleepiness can occur with this medication, but this effect will usually lessen with time. Cats sometimes become excited after receiving the drug.
- Dry mouth, decreased gastrointestinal activity (including constipation), and urine retention (less frequent urinations) are possible.
- Use caution with over the counter (OTC) formulations, as other potentially toxic drugs (eg, acetaminophen, pseudoephedrine) may be combined in the product. Be sure to select a product that only contains chlorpheniramine.
- If using a sustained-release product, do not split or crush the tablets. If using a long-acting capsule, you may empty the contents of the capsule over food, but do not allow the beads to dissolve before the animal eats the food.

Chemistry/Synonyms

Chlorpheniramine maleate, a propylamine (alkylamine) antihistaminic agent, occurs as an odorless white crystalline powder with a melting point between 130°C and 135°C (266°F-275°F) and a pK_a of 9.2. One gram is soluble in ≈4 mL of water or 10 mL of alcohol.

Chlorpheniramine maleate may also be known as chlorphenamini maleas, chlorprophenypyridamine, or CAS No 113-92-8; many trade names are available; a commonly known brand is *Chlor-Trimeton®*.

Storage/Stability

All chlorpheniramine products should be stored at room temperature (15°C-30°C [59°F-86°F]) and protected from light. Avoid freezing the oral solution.

Compatibility/Compounding Considerations

Timed-release forms of the drug should not be crushed or allowed to dissolve in liquids.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 4 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Chlorpheniramine Maleate Oral Tablets: 4 mg tablets; (OTC)

Chlorpheniramine Maleate Extended-Release Tablets: 12 mg; (OTC)

Chlorpheniramine Maleate Oral Syrup: 2 mg/5 mL in 118 mL; (OTC)

Chlorpheniramine Maleate Oral Drops: 2 mg/mL in 60 mL; (OTC)

Many combination products are available that combine chlorpheniramine with decongestants, analgesics, and/or antitussives, but these generally should not be used in animals due to the potential for unpredictable adverse effects.

For the complete list of references, see **wiley.com/go/budde/plumb**

Chlorpromazine

(klor-***proe***-ma-zeen) *Thorazine*

Phenothiazine Sedative/Antiemetic

Prescriber Highlights

- ► Prototype phenothiazine used primarily as an antiemetic; may be particularly useful in treating motion sickness in cats
- ► Provides no analgesic effects
- ► Contraindications include hypersensitivity and use in horses; relative contraindications include use in hypovolemic animals, or animals with tetanus or strychinine intoxication.
- ► Use should be avoided or dose-reduced in debilitated animals, especially those with predicted or pre-existing hypotension or hepatic insufficiency; and use with caution in patients with moderate to severe cardiac disease that cannot tolerate reduced blood pressures
- ► Adverse effects may include significant hypotension, cardiac rate abnormalities, or hypo- or hyperthermia; extrapyramidal effects may occur in cats that are given high doses
- ► Inject diluted solution IV slowly
- ► Dogs with the multidrug sensitivity gene (MDR1) mutation (also known as *ABCB1*-1delta) may be overly sensitive to effects and require dose reduction.

Uses/Indications

Clinical use of chlorpromazine has diminished, but it is still occasionally used for its antiemetic and tranquilizing/sedating effects in small animals. Although it was previously the principal phenothiazine used in veterinary medicine, chlorpromazine has been largely supplanted by acepromazine.

Chlorpromazine (or acepromazine) can be useful in patients exhibiting severe anxiety, tachycardia, or hypertension secondary to a toxin or overdose of amphetamine-like attention-deficit disorder (ADD)/attention-deficit/hyperactivity disorder (ADHD) medications, selective serotonin reuptake inhibitors (SSRIs), antidepressants (or other agents that can cause serotonin syndrome), or the paradoxical CNS stimulation that can be seen with overdoses of human sleep aids (eg, eszopiclone, zolpidem).[1] As an antiemetic, chlorpromazine use is limited to normotensive or hypertensive patients, as it causes hypotension. It will inhibit apomorphine-induced emesis in dogs but not in cats. Chlorpromazine will also inhibit the emetic effects of morphine in dogs. It does not inhibit emesis caused by copper sulfate or digitalis glycosides.

Pharmacology/Actions

Chlorpromazine has similar pharmacologic effects as acepromazine but is less potent and has a longer duration of action. For further information, refer to ***Acepromazine***.

Pharmacokinetics

Chlorpromazine is absorbed rapidly after oral administration but undergoes extensive first-pass metabolism in the liver. The drug is also well-absorbed after IM injection, but the onset of action is slower than after IV administration.

Chlorpromazine is distributed throughout the body, and brain concentrations are higher than those in plasma. Approximately 95% of chlorpromazine in plasma is bound to plasma proteins (primarily albumin).

The drug is extensively metabolized, principally in the liver and kidneys, but little specific information is available regarding its excretion in dogs and cats.

Contraindications/Precautions/Warnings

Chlorpromazine is contraindicated in patients that are hypersensitive to it. Use chlorpromazine cautiously and in smaller doses in animals with hepatic dysfunction, cardiac disease, or general debilitation. Because of its hypotensive effects, phenothiazines are relatively contraindicated in patients with hypovolemia or shock and in those with tetanus or strychnine intoxication due to effects on the extrapyramidal system. Because of adverse CNS effects (eg, ataxia, panic reaction), this drug is not recommended for use in horses.

Chlorpromazine has no analgesic effects; animals should be treated with appropriate analgesics to control pain. Animals may require lower doses of general anesthetics when receiving phenothiazines in their premedications.

Phenothiazines should be used cautiously as restraining agents in aggressive dogs; they may make the animal more prone to startle and react to noises or other sensory inputs.

IV injections must be diluted with saline to concentrations of no more than 1 mg/mL and administered slowly. Chlorpromazine causes severe muscle discomfort and swelling when injected IM in rabbits; therefore, chloropromazine should only be administered IV in this species.

Breed-specific concerns include dogs with *MDR1* gene mutation (also known as *ABCB1*-1delta), which may develop a more pronounced sedation that persists longer than expected.[2] The drug is best completely avoided in *MDR1*-mutant dogs because there is no reversal, but if no other option is available, the dose should be reduced by 25% in dogs that are heterozygous and by 30% to 50% in dogs that are homozygous for the *MDR1* gene mutation (mutant/mutant).

Consider writing part of the drug's name in uppercase letters (ie, tall man designations) on prescriptions/orders to reduce the risk for errors. Do not confuse chlorproMAZINE with chlordiazePOXIDE, clomiPRAMINE, prochlorperazine, or promethazine.

Adverse Effects

In addition to the possible effects listed in the ***Acepromazine*** monograph (eg, hypotension, contradictory effects such as CNS stimulation and bradycardia), chlorpromazine may cause extrapyramidal signs (eg, tremors, shivering, rigidity, loss of the righting reflexes) in cats when used at high doses; lethargy, diarrhea, and loss of anal sphincter tone may also be seen.

Horses may develop ataxia, paradoxical excitation, and unpredictable behavior (eg, thrashing). These ataxic periods may cycle with periods of sedation. Because of these adverse effects, chlorpromazine is rarely used in equine medicine.

Reproductive/Nursing Safety

Embryotoxicity and increased neonatal mortality have been demonstrated in rodents. Chlorpromazine is excreted into maternal milk, and safety to nursing offspring cannot be assured.[3]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Most small overdoses cause only somnolence; larger overdoses can cause serious effects including coma, agitation, seizures, arrhythmias, hypotension, tachycardia, and extrapyramidal effects (eg, tremors, shivering, rigidity, loss of the righting reflexes).

Most overdoses can be handled by monitoring the patient and providing supportive care based on presenting signs; oral overdoses should be treated by GI decontamination if possible. IV lipid emulsion therapy may also be helpful.[4] Seizures may be controlled with barbiturates or diazepam. Hypotension should be treated initially with IV fluids; alpha-adrenergic pressor agents (eg, norepinephrine, phenylephrine; *not* epinephrine) can be considered if IV fluid therapy does not maintain adequate blood pressure. **NOTE**: The FDA label states *Epinephrine is contraindicated for treatment of acute hypotension produced by phenothiazine-derivative tranquilizers since further depression of blood pressure can occur.*[5,6] This phenomenon, known as epinephrine reversal, can occur when epinephrine is administered after an alpha-adrenergic antagonist (eg, chlorpromazine). In these situations, the peripheral beta-adrenergic effects of epinephrine will predominate, resulting in relaxation of the vascular smooth musculature and hypotension.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorpromazine or other phenothiazines and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antipyretics** (eg, **acetaminophen, dipyrone, NSAIDs**): Possible increased risk for hypothermia with concurrent use
- **Antacids, Aluminum-, Calcium- or Magnesium-Containing:** May cause reduced GI absorption of oral phenothiazines
- **Antidiarrheal Mixtures** (eg, **kaolin/pectin, bismuth subsalicylate mixtures**): May cause reduced GI absorption of oral phenothiazines
- **Bromocriptine:** Phenothiazines may antagonize effects of bromocriptine and increase risk for dizziness, hypotension, and drowsiness.
- **Buspirone:** Concurrent use may increase the risk for neuroleptic malignant syndrome and serotonin syndrome.
- **Cabergoline:** Concurrent use may decrease the efficacy of both medications. Increased risk for serotonin syndrome and neuroleptic malignant syndrome may occur.
- **Calcium Channel Blockers** (eg, **amlodipine**, **diltiazem, verapamil**): Concurrent use may increase risk for hypotension and orthostasis. Monitor blood pressure, especially at initiation of therapy or with parenteral administrations of phenothiazines. Slow-dose titration is advisable.
- **CNS Depressant Agents** (eg, **barbiturates, cannabidiol, anesthetics**): May cause additive CNS depression if used with phenothiazines
- **Desmopressin:** Concurrent use may increase risk for water intoxication and/or hyponatremia. Electrolytes and renal function should be monitored.
- **Diazoxide:** Concurrent use may increase risk for hypotension and orthostasis. Phenothiazines may increase the risk for hyperglycemic effects from diazoxide.
- **Doxorubicin:** Chlorpromazine may increase levels of doxorubicin.
- **Emetics** (eg, **apomorphine, ropinirole**)**:** May reduce the effectiveness of emetics as well as increase risk for sedation and hypotension
- **Epinephrine/Norepinephrine**: Phenothiazines block alpha-adrenergic receptors, and concomitant epinephrine can lead to unopposed beta activity, causing vasodilation and increased cardiac rate.
- **Laxatives** (eg, **bisacodyl**): Overuse of laxatives may cause electrolyte loss, increasing the risk for cardiovascular adverse effects with chlorpromazine.
- **Loop Diuretics** (eg, **bumetanide, furosemide**): Concurrent use may cause hypomagnesemia and hypokalemia, increasing the risk for cardiac arrhythmias.
- **Metoclopramide**: Concurrent use with metoclopramide may increase risk for extrapyramidal adverse effects (eg, tremor, catalepsy, rigidity, excitement, sweating, seizures).
- **Opioids** (eg, **buprenorphine, fentanyl, morphine**): May enhance the hypotensive effects of the phenothiazines; dosages of chlorpromazine may need to be reduced when used with an opioid.
- **Organophosphate Agents**: Phenothiazines should not be given within one month of these antiparasitic agents, as their effects may be potentiated.
- **Physostigmine**: Toxicity may be enhanced by chlorpromazine.
- **Propranolol**: Increased blood concentrations of both drugs may result if propranolol is administered with phenothiazines.
- **QT Prolonging Agents** (eg, **cisapride, domperidone, erythromycin** and **sotalol**): Concurrent use may increase risk for QTc prolongation and should be avoided.
- **Quinidine**: May cause additive cardiac depression
- **Sucralfate:** May reduce GI absorption of oral phenothiazines
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine, doxepin**): Concurrent use may increase levels of either agent and may increase risk for serotonin syndrome, QT interval prolongation, and anticholinergic intoxication.

Dosages

DOGS/CATS:

Antiemetic or sedative (extra-label): Most recommendations range from 0.2 – 0.5 mg/kg IM or SC every 6 to 8 hours. IV dosage recommendations can vary widely (0.05 – 0.5 mg/kg [dogs] or 0.025 – 0.5 mg/kg [cats] IV every 6 to 8 hours). It is advised when giving the drug IV to start at the lower end of the dosage range and increase dosage as necessary (to effect) while monitoring blood pressure.

CATTLE:

Premedication for cattle undergoing standing procedures (extra-label): 0.2 – 1 mg/kg IM (may cause regurgitation if animal undergoes general anesthesia)[7]

SHEEP/GOATS:

a) **Sedative or premedicant in sheep and goats** (extra-label): 0.55 – 4.4 mg/kg IV or 2.2 – 6.6 mg/kg IM[8]

b) **Goats** (extra-label): 2 – 3.5 mg/kg IV every 5 to 6 hours[9]

SWINE:

Premedication (extra-label): 1 mg/kg IM[7]

Restraint (extra-label): 1.1 mg/kg IM (effects peak in 45 to 60 minutes); prior to barbiturate anesthesia: 2 – 4 mg/kg IM[9]

Monitoring
- Cardiac rate and rhythm and blood pressure (critical); end-tidal carbon dioxide ($ETCO_2$) and pulse oximetry (recommended)
- PCV and total protein, especially in borderline anemic patients and patients with current or expected blood loss
- Degree of sedation/tranquilization
- Body temperature (especially if ambient temperature is very hot or cold)

Client Information
- Causes sedation (sleepiness)
- Sedative or tranquilizing effects (sleepiness) and side effects may last up to 24 hours.
- Keep treated animal in a quiet environment at a comfortable temperature. Avoid getting this medication on hands or clothing; a skin rash (contact dermatitis) may develop.
- This medicine may cause a harmless pinkish to reddish-brown discoloration of your animal's urine. This change is not to be worried about.

Chemistry/Synonyms
Chlorpromazine is a propylamino-phenothiazine derivative and is the prototypic phenothiazine agent. It occurs as a white to slightly creamy white, odorless, bitter-tasting crystalline powder. One g is soluble in 1 mL of water and 1.5 mL of alcohol. The commercially available injection is a solution of chlorpromazine HCl in sterile water at a pH of 3 to 5.

Chlorpromazine HCl may also be known as aminazine or chlorpromazini hydrochloridum; many trade names are available.

Storage/Stability
Protect from light and store at room temperature 15°C to 30°C (59°F-86°F); avoid freezing. Do not store in plastic syringes or IV bags for prolonged periods as the drug may adsorb to plastic.

Chlorpromazine will darken with prolonged exposure to light; do not use solutions that are darkly colored or those in which precipitates have formed. A slight yellowish color will not affect potency or efficacy.

Compatibility/Compounding Considerations
Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

The following products have been reported to be **compatible** when mixed with chlorpromazine HCl injection: all commonly used IV electrolyte solutions, ascorbic acid, atropine sulfate, butorphanol tartrate, diphenhydramine, fentanyl citrate, glycopyrrolate, heparin sodium, hydromorphone HCl, hydroxyzine HCl, lidocaine HCl, meperidine, metoclopramide, metaraminol bitartrate, morphine sulfate, pentazocine lactate, promazine HCl, promethazine, scopolamine HBr, and tetracycline HCl.

Alkaline solutions will cause the drug to oxidize. The following products have been reported as being **incompatible** when mixed with chlorpromazine: aminophylline, amphotericin B, chloramphenicol sodium succinate, chlorothiazide sodium, dimenhydrinate, methohexital sodium, penicillin G potassium, pentobarbital sodium, phenobarbital sodium, and thiopental sodium.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 1 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Chlorpromazine Injection: 25 mg/mL in 1 mL and 2 mL amps; generic; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Chlortetracycline

(klor-te-tra-***sye***-kleen) *Aureomycin®*

Tetracycline Antibiotic

Prescriber Highlights
- ► Tetracycline antibiotic used primarily in water or feed treatments or topically for ophthalmic use
- ► Many bacteria are now resistant; may still be useful to treat *Mycoplasma* spp, *Rickettsia* spp, spirochetes, and *Chlamydia* spp
- ► Contraindications include hypersensitivity to the drug. Use chlortetracycline with extreme caution during pregnancy
- ► Use with caution in patients with liver or renal insufficiency
- ► Adverse effects include GI distress, staining of developing teeth and bones, superinfections, and photosensitivity.

Uses/Indications
There are a variety of FDA-approved chlortetracycline products for use in food animals. This antibiotic may also be useful in treating susceptible infections in cats, birds, and small mammals (excluding guinea pigs).

The World Health Organization (WHO) has designated tetracyclines as Highly Important antimicrobials for human medicine.[1] The Office International des Epizooties (OIE) has designated chlortetracycline as a Veterinary Critically Important Antimicrobial (VCIA) Agent in avian, bovine, caprine, equine, lagomorph, ovine, and swine species.[2]

Pharmacology/Actions
Tetracyclines generally act as bacteriostatic antibiotics inhibiting protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing protein transcription. Tetracyclines are also believed to alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can inhibit protein synthesis in mammalian cells.

As a class, the tetracyclines have activity against most *Mycoplasma* spp, spirochetes (including *Borrelia burgdorferi*), *Chlamydia* spp, and *Rickettsia* spp. The tetracyclines have activity against some gram-positive bacteria, including strains of staphylococci and streptococci, but resistance of these organisms is increasing. Additional gram-positive bacteria that are usually susceptible to tetracyclines include *Actinomyces* spp, *Bacillus anthracis*, *Clostridium perfringens, Clostridium tetani*, and *Listeria monocytogenes*. Tetracyclines usually have in vitro and in vivo activity against the following gram-negative bacteria: *Bordetella* spp, *Brucella* spp, *Bartonella* spp, *Haemophilus* spp, *Pasteurella multocida*, *Shigella* spp, and *Yersinia pestis*. Many or most strains of *Escherichia coli*, *Klebsiella* spp, *Bacteroides* spp, *Enterobacter* spp, *Proteus* spp, and *Pseudomonas aeruginosa* are resistant to the tetracyclines.

Oxytetracycline, chlortetracycline, and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance, and a tetracycline susceptibility disk is often used for in vitro testing for chlortetracycline susceptibility.

Pharmacokinetics
Refer to ***Oxytetracycline*** for general information on the pharmacokinetics of tetracyclines.

Contraindications/Precautions/Warnings

Chlortetracycline is contraindicated in patients that are hypersensitive to it or other tetracyclines. Because tetracyclines can delay fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline, chlortetracycline, and tetracycline are considered more likely to cause these abnormalities than doxycycline or minocycline.

In patients with renal insufficiency or hepatic impairment, chlortetracycline must be used cautiously. Lower than normal dosages are recommended, in addition to enhanced monitoring of renal and hepatic function. Avoid concurrent administration of other nephrotoxic or hepatotoxic drugs.

Because it may cause clostridial enterotoxemia in guinea pigs, chlortetracycline should not be used in this species.

Adverse Effects

Chlortetracycline given to young animals can cause discoloration of bones and teeth to a yellow, brown, or gray color. High dosages or chronic administration may delay bone growth and healing.

In humans, tetracyclines at high levels can exert a catabolic effect that can cause an increase in BUN and/or hepatotoxicity, particularly in patients with preexisting renal dysfunction.[3] As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated.

In ruminants, high oral doses can cause ruminal microflora depression and ruminoreticular stasis.

In small animals, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline very well; signs of colic, fever, hair loss, and depression may be seen. There are reports that long-term tetracycline use may cause urolith formation in dogs.[4]

Horses that are under stress (eg, from surgery, anesthesia, trauma) may exhibit severe diarrhea after receiving tetracyclines (especially with oral administration).

Tetracycline therapy (especially long term) may result in overgrowth (superinfections) of nonsusceptible bacteria or fungi.

Tetracyclines have been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias.

Reproductive/Nursing Safety

Tetracyclines cross the placenta; they are embryotoxic when used early in pregnancy and can retard fetal skeletal growth and permanently discolor teeth.

Tetracyclines are excreted in milk, but because much of the drug will be bound to calcium in milk, it is unlikely to be of significant risk to nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants can cause ruminal microflora depression and ruminoreticular stasis. Rapid IV injection of undiluted propylene-glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

Rapid IV injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (less than 5 minutes), some clinicians recommend pretreating the animal with IV calcium gluconate.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlortetracycline and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Beta-Lactam or Aminoglycoside Antibiotics**: Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides; however, there is some controversy regarding the actual clinical significance of this interaction.
- **Cholestyramine:** May decrease absorption of tetracyclines
- **Digoxin**: Tetracyclines may increase the bioavailability of digoxin in a small percentage of patients (human) and lead to digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.
- **Divalent or Trivalent Cations** (eg, **oral antacids, saline cathartics** or other **orally-administered products containing aluminum (eg, sucralfate), bismuth, calcium, iron, magnesium, or zinc cations**): When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1 to 2 hours before or after the cation-containing products.
- **Lanthanum:** May decrease absorption of tetracyclines
- **Retinoid Acids** (eg, **acitretin, vitamin A**): May increase the potential for the occurrence of intracranial hypertension. Combination is contraindicated.
- **Warfarin**: Tetracyclines may depress plasma prothrombin activity, and anticoagulant dosage adjustment may be needed.

Laboratory Considerations

- Tetracyclines (excluding minocycline) may cause falsely elevated values of **urine catecholamines** when using fluorometric methods of determination.
- Tetracyclines can reportedly cause false positive **urine glucose** results if using the cupric sulfate method of determination (Benedict's reagent, *Clinitest®*), but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false negative results in determining urine glucose when using the glucose oxidase method (*Clinistix®*, *Tes-Tape®*).

Dosages

CATS:

Prevent recurrence of *Mycoplasma* spp or chlamydial conjunctivitis in large catteries where topical therapy is impractical (extra-label): Soluble chlortetracycline powder in food at a dose of 50 mg/cat (NOT mg/kg) daily for 1 month[5]

BIRDS:

All dosages are extra-label. Refer to product labels for FDA-approved dosing rates in poultry and withdrawal times.

a) **Chlamydiosis**: In small birds, add chlortetracycline to food

in a concentration of 0.05%; larger psittacines require 1% chlortetracycline.[6]

b) **Pigeons**: 50 mg/kg PO every 6 to 8 hours; or 1000 – 1500 mg/gallon drinking water; in warm weather, mix fresh every 12 hours. Best used in combination with tylosin for ornithosis complex; calcium inhibits absorption; therefore, grit and layer pellets should be withheld during treatment.[7]

RABBITS/RODENTS/SMALL MAMMALS:

All dosages are extra-label.

a) **Rabbits**: 50 mg/kg PO every 12 to 24 hours[8]
b) **Chinchillas**: 50 mg/kg PO every 12 hours[9]
c) **Hamsters**: 20 mg/kg IM or SC every 12 hours[10]
d) **Mice**: 25 mg/kg SC or IM every 12 hours[10]
e) **Rats**: 6 – 10 mg/kg SC or IM every 12 hours[10]

Monitoring

- Adverse effects
- Clinical efficacy
- Long-term use or in susceptible patients: baseline and periodic renal, hepatic, hematologic evaluations

Client Information

- Avoid giving this drug orally within 1 to 2 hours of feeding milk or other dairy products.
- When this medicine is given orally, it should be administered on an empty stomach 1 to 2 hours before or after consumption of food, milk, other dairy products, and minerals such as calcium or iron. If your animal vomits or acts sick after receiving the medicine on an empty stomach, give it with a small amount of food to see if this helps. If vomiting continues, contact your veterinarian.
- Chlortetracycline may permanently stain teeth and interfere with developing bones in young animals.
- If used in food animals, follow label dosages and withdrawal times.

Chemistry/Synonyms

Chlortetracycline is a tetracycline antibiotic that occurs as yellow odorless crystals. It is slightly soluble in water.

Chlortetracycline may also be known as clortetraciclina, A-377, NRRL-2209, or SF-66; *Aureomycin®* is a common trade name.

Storage/Stability

Chlortetracycline should be stored in tight containers and protected from light.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

There are several feed additive/water mix preparations available containing chlortetracycline. The Type A Medicated Feed Article products require a VFD. There are also combination products containing chlortetracycline and sulfamethazine (*Aureomycin Sulmet®, Aureo S 700®*); chlortetracycline, sulfamethazine, and penicillin G (*Aureomix 500®, Pennclor SP 250®, and 500®*); and chlortetracycline, sulfathiazole, and penicillin G (*Aureozol 500®*); (Rx)

HUMAN-LABELED PRODUCTS: NONE

Cholestyramine

(***ko***-less-***tər***-a-meen) *Questran®, Prevalite®*

Bile-Acid Sequestrant

Prescriber Highlights

- ► May bind drugs that undergo enterohepatic recirculation in dogs and cats and thus may be helpful in the treatment of toxicoses associated with those drugs
- ► Avoid using formulations with xylitol for veterinary patients.
- ► Adverse effects can include constipation, bloating, and decreased appetite.
- ► Not commonly used in veterinary patients

Uses/Indications

Cholestyramine may be used to treat toxicoses of enterohepatically recirculated agents[1] (eg, cholecalciferol,[2,3] amiodarone, digoxin, NSAIDs,[4] vincristine).[5] In a case report of a dog with cyanotoxin (blue-green algae, microcystin) exposure, clinical improvement was noted within 48 hours of cholestyramine administration.[6] Cholestyramine may also be beneficial in patients with diarrhea caused by bile acid malabsorption.[7–9] In addition, cholestyramine reduces cholesterol in dogs.[10]

In small mammals, cholestyramine has been used to manage enterotoxemia caused by penicillin in guinea pigs[11] and clindamycin in rabbits.[12] Cholestyramine also increased survival rate in a rabbit model of brodifacoum poisoning.[13]

In humans, cholestyramine is used as an adjunct to lifestyle changes to reduce total cholesterol and low-density lipoprotein (LDL) concentrations. The drug also reduces pruritus in patients with partial cholestasis, partial biliary obstruction, and/or biliary cirrhosis.[14] Other uses include management of diarrhea, including *Clostridium difficile* enterocolitis, and non-life–threatening cases of cardiac glycoside (eg, digoxin) toxicosis.

Pharmacology/Actions

Cholestyramine is a nonabsorbable resin that binds to anionic bile acids in the small intestines in exchange for cholestyramine's chloride ions to form an insoluble complex that prevents enterohepatic recirculation of bile acids and thus reduces serum bile acid concentrations.[14]

In humans, the resulting excretion of bile acids stimulates the liver to convert cholesterol to bile acids, which leads to decreased serum cholesterol and plasma LDL concentrations. Chloestyramine's maximal effect on bile acid and cholesterol concentrations can be seen after ≈3 weeks of therapy.

Cholestyramine was also shown to bind microcystin-LR in experimental rat models of blue-green algae hepatotoxicity.[15]

Pharmacokinetics

Cholestyramine is not systemically available, as it is not absorbed after oral administration. The insoluble complex formed by cholestyramine and bile acids is excreted in the feces.

Contraindications/Precautions/Warnings

Cholestyramine should not be used in patients that are hypersensitive to it or with GI or complete biliary obstruction or biliary cirrhosis. Cholestyramine may increase triglyceride concentrations and is contraindicated in humans with triglyceride concentrations greater than 300 mg/dL. The drug should be used with caution in patients with renal insufficiency, volume depletion, mild hypertriglyceridemia, and cholelithiasis.[14] Adequate patient hydration status should be ensured prior to initiating therapy. Prolonged use can result in hyperchloremic acidosis. Patients receiving cholestyramine long term may benefit from folic acid and fat-soluble vitamin supplementation (eg, vitamin K).

Adverse Effects

Veterinary use is limited, and little is known regarding the adverse effects of cholestyramine in veterinary patients. In a study of healthy beagles, a 14-day course of cholestyramine was well tolerated but increased fecal output and decreased nutrient digestibility were observed.[16]

Constipation is the most common adverse effect in humans and may lead to fecal impaction. Other adverse effects include bloating, flatulence, steatorrhea, nausea, and anorexia. Impaired absorption of fat-soluble vitamins associated with long-term cholestyramine use may lead to bleeding disorders and osteoporosis.[14] Increased triglyceride concentrations may occur. Cholestyramine is poorly tolerated in humans due to the GI adverse effects, which leads to discontinuation of therapy in ≈70% of patients.[17,18]

Hyperchloremic metabolic acidosis may occur due to liberation of large quantities of chloride anions; this risk appears to be greater with high cholestyramine doses or long-term use, or when the drug is used in patients with low body weights. Altered absorption and/or excretion of other electrolytes (eg, calcium, nitrogen, phosphorus) is also possible.

Reproductive/Nursing Safety

Reproductive safety in veterinary patients is not known.

Because cholestyramine is not absorbed, it does not cross the placenta or enter into breast milk; however, cholestyramine impairs fat-soluble vitamin absorption for the dam, which may have consequences for the offspring (eg, reduced vitamin concentration in milk). Therefore, cholestyramine should be used with caution in pregnant or nursing patients; vitamin supplementation and/or a milk replacer should be considered.

Because safety of cholestyramine has not been established in animals, it should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Because cholestyramine is not absorbed, there is little to no risk for systemic toxicity. Adverse GI effects, including risk for GI obstruction, are the primary concern. Continued GI motility should be ensured, and electrolytes and serum chemistry profiles should be monitored.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Cholestyramine can bind to and decrease the absorption of many orally administered medications. Acidic drugs and drugs that undergo enterohepatic recirculation are particularly susceptible. Other oral drugs should be administered at least 1 hour before or 4 to 6 hours or longer after administering cholestyramine. The following drug interactions include those drugs/drug classes in which absorption has either been reported or is theoretical in humans or animals receiving cholestyramine and may be of significance in veterinary patients; unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate:

- **Acetaminophen**
- **Amiodarone**
- **Digoxin**
- **Estrogens** (eg, **estriol**)
- **Glucocorticoids** (eg, **dexamethasone, hydrocortisone, prednis(ol)one**)
- **Fish Oil supplements**
- **Folic Acid**
- **Gemfibrozil**
- **Glipizide**
- **Iron salts**
- **Isotretinoin**
- **Leflunomide:** Separating administration times will not prevent an interaction.
- **Levothyroxine**
- **Loop Diuretics** (eg, **furosemide, torsemide**)
- **Methotrexate**
- **Metronidazole**
- **Mycophenolate**
- **Nonsteroidal Anti-Inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam, piroxicam**)
- **Phenobarbital**
- **Phosphate Supplements (oral)**
- **Progesterone**
- **Propranolol**
- **Spironolactone:** Concurrent use may increase risk for hyperkalemic metabolic acidosis.
- **Testosterone**
- **Tetracyclines** (eg, **doxycycline, minocycline**)
- **Thiazide Diuretics** (eg, **hydrochlorothiazide**)
- **Ursodiol**
- **Vancomycin (oral):** Combination is contraindicated.
- **Vitamin A**
- **Vitamin D** (eg, **calcitriol, cholecalciferol**)
- **Vitamin E**
- **Vitamin K**: Concomitant cholestyramine may bind to vitamin K and worsen underlying coagulopathy.
- **Warfarin:** Combination may increase or decrease anticoagulant effect of warfarin.

Laboratory Considerations

- None have been noted.

Dosages

DOGS:

Vincristine overdose (extra-label): 100 mg/kg PO every 12 hours for 5 days; concurrent treatments included activated charcoal 13 mL/kg once, sorbitol 3 mL/kg PO for 3 days (frequency not specified), folinic acid 3 mg/m^2 PO every 24 hours for 3 days, antibiotics (**NOTE:** Antibiotic coverage should be appropriate for leukopenic patients), and filgrastim 5 µg/kg SC every 24 hours for 5 days.[5]

Reduction of NSAID exposure (extra-label): 2.5 g/dog (NOT g/kg) diluted in 20 mL of water PO (gavage), followed by 20 mL of water as a rinse administered 3 times daily.[4]

Bile acid diarrhea (extra-label): 2 – 3 g/dog (NOT g/kg) PO twice daily. From a case report of 2 dogs refractory to management of diarrhea, including dietary trials, probiotics, cyclosporine therapy, fecal transplantation, and metronidazole.[19]

Cholecalciferol toxicosis: 0.3 – 1 g/kg, dissolved in liquid and administered orally every 8 hours for 4 days; administer in between activated charcoal doses.[3]

CATS:

Reduction of NSAID exposure (extra-label): From experimental studies, cholestyramine 1 g/cat (NOT mg/kg) PO administered immediately prior to flunixin injection has been shown to significantly reduce volume of distribution and mean residence time.[20]

RABBITS/GUINEA PIGS:

Antibiotic-induced enterotoxaemia (extra-label): 2 g/animal (NOT g/kg) cholestyramine diluted in 20 mL of water and administered orally once daily for 21 days.[12,21] Dose may be divided over 24 hours.

Monitoring

- Clinical efficacy
- Adverse effects
- Prothrombin time with long-term use

Client Information

- The most common side effects are constipation, bloating, abdominal discomfort, flatulence, and loss of appetite.
- Always mix cholestyramine powder with water or other fluids or into high-moisture content foods (eg, applesauce). Do not give dry powder, as intestinal irritation or obstruction may result.
- Give medicine with a meal
- Other drugs should be given at least 1 hour before or at least 4 to 6 hours after giving cholestyramine.

Chemistry/Synonyms

Cholestyramine is the chloride salt of a basic polymeric anion exchange resin. It is hydrophilic but insoluble in water and alcohol. The drug occurs as a white to off-white fine powder, although the appearance of manufactured dose forms varies based on the presence and amounts of inactive ingredients (eg, sweeteners, dyes).

Cholestyramine may also be known as colestyramine, *Cholebar®*, *Olestyr®*, *Prevalite®*, or *Questran®*.

Storage/Stability

Store cholestyramine powder at a controlled room temperature between 20°C and 25°C (68°F-77°F). Excursions are permitted between 15°C and 30°C (59°F-86°F). Protect from moisture until time of use.

Compatibility/Compounding Considerations

Cholestyramine has been applied topically as a 5% to 15% compounded ointment or paste for perianal skin irritation due to fecal exposure[22,23] or following hemorrhoidectomy[24] or ileostomy.[25]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cholestyramine Powder for Suspension: Formulations vary: 4 g cholestyramine in 210 g, 231 g, or 378 g containers or canisters measured with provided scoop to deliver 5 to 9 g total powder weight, or in individual packets, pouches, or sachets containing 5.5 to 9 g total powder weight; *Questran®*, generic; (Rx). Scoops in bulk containers may not be interchanged between products.

Cholestyramine Light Powder for Suspension: 4 g cholestyramine measured with provided scoop to deliver 5.5 g or 5.7 g total powder weight in 202, 210 g, 231 g, or 339 g containers or canisters or in individual pouches or sachets containing 5.5 g or 5.7 g total powder weight; *Questran® Light, Prevalite®*, generic. (Rx). Contains aspartame. Scoops may not be interchanged between products.

Chorionic Gonadotropin

hCG, HCG

(kor-ee-***on***-ic goe-***nad***-oh-troe-pin) *Chorulon®*

Reproductive Hormone

Prescriber Highlights

- ► Human glycoprotein hormone that mimics luteinizing hormone; used for a variety of theriogenology conditions in many species
- ► *For parenteral use only*
- ► Contraindications include androgen-responsive neoplasias and hypersensitivity to the drug.
- ► Adverse effects are rare and include anaphylactic reaction.
- ► The National Institute of Occupational Safety and Health (NIOSH) classifies chorionic gonadotropin as a hazardous drug; use appropriate precautions when handling.

Uses/Indications

The veterinary FDA-approved human chorionic gonadotropin (hCG) product is used parenterally in cows for the treatment of nymphomania (frequent or constant heat) caused by cystic ovaries and as an aid to improve spawning function in male and female brood finfish.[1] It has been used for other purposes in several species; refer to the ***Dosages*** section for more information.

Pharmacology/Actions

Chorionic gonadotropin (CG) mimics the effects of luteinizing hormone (LH). In males, CG stimulates the differentiation of testicular interstitial (Leydig) cells and produces androgens. Hormonal treatment of cryptorchidism with human chorionic gonadotropin (hCG) is controversial in humans and domestic animals.

In females, hCG is primarily used in an extra-label fashion as an ovulation-inducing agent. In bitches, administration of hCG induces estrogen secretion during anestrus and can, therefore, be used to identify spayed bitches with ovarian remnants.[2]

Pharmacokinetics

Human chorionic gonadotropin (hCG) is destroyed in the GI tract after oral administration, so it must be given parenterally. After IM injection, peak plasma concentrations occur in about 6 hours.

hCG is distributed primarily to the ovaries in females and to the testes in males, but some hCG may also be distributed to the proximal tubules in the renal cortex.

hCG is eliminated from the blood in a biphasic manner. The initial elimination half-life in humans is about 11 hours and the terminal half-life is ≈23 hours.

Contraindications/Precautions/Warnings

In humans, chorionic gonadotropin (hCG) is contraindicated in patients with prostatic carcinoma or other androgen-dependent neoplasias, precocious puberty, or those with a previous hypersensitivity reaction to hCG. No labeled contraindications for veterinary patients were noted, but these human contraindications should be used as guidelines.

Antibody production to hCG has been reported after repetitive use; however, despite this effect, pharmacological activity (induction of ovulation) is expected to remain unaltered.

The National Institute for Occupational Safety and Health (NIOSH) classifies hCG as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.

Adverse Effects

Repeated doses of chorionic gonadotropin (hCG) may cause abortion in mares prior to the 35th day of pregnancy, possibly because of

increased estrogen levels.[3] Potentially, hypersensitivity reactions are possible with this agent. Anaphylactic reactions are rare, and several practitioners have anecdotally reported mares showing transient hives and respiratory distress immediately following hCG administration. Problems associated with using *PG 600*® in dogs for estrus induction include unpredictability of response, potential for allergic reactions, and premature luteal failure.[4]

In humans, hCG has caused pain at the injection site, gynecomastia, headache, depression, irritability, restlessness, and edema.

Reproductive/Nursing Safety

In humans, chorionic gonadotropin (hCG) and its metabolites have been found in maternal milk.[5] There are no similar studies with animals reported following administration of hCG.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

No overdose cases have been reported with chorionic gonadotropin.

Drug Interactions

No interactions have apparently been reported with chorionic gonadotropin.

Laboratory Considerations

None

Dosages

NOTE: Unless otherwise noted, dosages refer to the use of chorionic gonadotropin (hCG) (*Chorulon*®).

DOGS:

hCG challenge test to determine if testicular tissue remains in neutered male dogs (extra-label): 44 µg/kg hCG IM and take a 4-hour post sample. **NOTE:** Contact your laboratory for specific recommendations for testing. Various protocols exist including taking a sample for resting testosterone level.

hCG challenge test to identify the presence of ovarian tissue in presumably spayed bitches or those suspected to have ovarian remnants (extra-label): 200 – 500 units/dog (NOT units/kg) IV and take a blood sample before and 90 minutes after the treatment. Submit plasma samples for determination of estradiol concentrations. Highly variable response; results may be inconclusive.

Produce luteinization of a follicular cyst (extra-label): 500 – 1000 units/dog (NOT units/kg) IM; repeat in 48 hours or once daily for 3 days

Improve semen quality in male dogs with oligospermia (extra-label): 500 – 1000 units/dog (NOT units/kg) IM.[6] Semen quality expected to improve transiently between 2 to 4 weeks after treatment.

CATS:

hCG challenge test to determine if testicular tissue remains in neutered male cats (extra-label): Various protocols exist including: Take baseline serum testosterone sample, administer 250 units/cat (NOT units/kg) IM; take second sample 4 hours later. **NOTE:** Contact your laboratory for specific recommendations for testing.

hCG challenge test to identify the presence of ovarian tissue in presumably spayed queens or those suspected to have ovarian remnants (extra-label): 500 units/cat (NOT unit/kg) IM between 1 and 3 days following the onset of estrus behavior and take a blood sample before hCG administration and 7 days later. Submit plasma samples for determination of progesterone concentrations.[7]

Infertility, reduced libido, cryptorchidism in male cats (extra-label): 50 – 100 units/cat (NOT unit/kg) IM; repeat if necessary[8]

Induction of ovulation in female cats (extra-label): 100 – 500 units/cat (NOT unit/kg) IM on day 1 or days 1 and 2 of estrus. Alternatively, 250 units/cat (NOT unit/kg) IM on days 2 and 3 of estrus, coupled with mating 3 times per day at 3-hour intervals for the first 3 days of estrus[9]

HORSES:

Induction of ovulation (extra-label in the United States): 1500 – 3000 units/horse (NOT units/kg) IV to mares in estrus with more than 30 to 35 mm follicle. Ovulation is expected to occur within 48 hours from administration.[10]

hCG challenge test to determine if testicular tissue remains in a gelding (extra-label): Take baseline serum testosterone sample, administer 10,000 units IV; take samples 30 minutes, 1 hour, and 24 hours later.[11,12] **NOTE:** Contact your laboratory for specific recommendations for testing as various protocols exist.

Induction of testicular descent in cryptorchids (less than 2 years of age): 2500 units/horse (NOT units/kg) IM twice weekly for 4 weeks.[13] Four of eight horses responded to therapy.

CATTLE:

Treatment of ovarian cysts (label dosage): The reconstituted contents of one vial (10,000 units; 10 mL) should be administered as a single deep IM injection. Dose may be repeated in 14 days if the animal's behavior or rectal examination of the ovaries indicates the necessity for retreatment.[1]

Induction of ovulation (extra-label): 1500 or 2000 units/cow (NOT units/kg) IM will induce ovulation in cows subjected to estrus synchronization protocols.

SHEEP:

Induction of estrus (extra-label in the United States): 400 – 800 units eCG (*Pregnecol*®, not available in the United States) IM or SC in the anterior half of the neck. (Adapted from product label; *Pregnecol*®)

GOATS:

Induction of estrus (extra-label in the United States): 200 – 600 units eCG (*Pregnecol*®, not available in the United States) IM or SC in the anterior half of the neck. (Adapted from product label; *Pregnecol*®)

SWINE:

Induction of fertile estrus (heat) in healthy prepuberal (noncycling) gilts over 5 ½ months of age and weighing at least 85 kg (187 lb) or in healthy sows at weaning that are experiencing delayed return to estrus (labeled dosage): One dose (5 mL) of reconstituted *PG 600*® injected into the gilt or sow's neck behind the ear. Prepuberal gilts should be injected when they are selected for addition to the breeding herd. Sows should be injected at weaning during periods of delayed return to estrus. (Adapted from product label; *PG 600*®)

BIRDS:

Reduce feather plucking (especially in female birds); (extra-label): 500 – 1000 units/kg IM; dosage is empirical.[14] If no response in 3 days, repeat. If no response after second injection, unlikely to be of benefit at any dose. If reduces feather plucking, will need to repeat after 4 to 6 weeks. Major drawback is that with repeated usage, time between treatments is reduced.

FISH:

Improve spawning function in male and female brood finfish (labeled dosage): Administer IM just ventral to the dorsal fin for 1 to 3 injections.[1] See product label for weight-based dosing based on species of fish.

Chemistry/Synonyms

A gonad-stimulating polypeptide secreted by the human placenta,

chorionic gonadotropin (hCG) is obtained from the urine of pregnant women. It occurs as a white or practically white amorphous lyophilized powder. It is soluble in water and practically insoluble in alcohol. One international unit (called units in this reference) of hCG is equal to 1 USP unit. There are at least 1500 USP units per mg.

This drug may also be known as human chorionic gonadotropin, HCG, hCG, LH 500, CG, chorionic gonadotrophin, dynatropin, gonadotropine chorionique, gonadotrophinum chorionicum, choriogonadotrophin, chorionogonadotropin, pregnancy-urine hormone, PU, equine chorionic gonadotropin, eCG, pregnant mare serum gonadotropin, or PMSG; there are many trade names internationally.

Storage/Stability

Store *Chorulon®* powder for injection at room temperature (15°C-30°C [59°F-86°F]) and protected from light. Store *PG 600®* in the refrigerator (2°C-8°C [36°F-46°F]). After reconstitution, the resultant solution is stable for 30 to 90 days (depending on the product) when stored at 2°C to 15°C (36°F-59°F). The labels for *Chorulon®* and *PG 600®* state to use the vial immediately after reconstituting with the supplied diluent.[1,15] Alternatively, freezing of unused hCG in aliquots can be used to maximize the use of the veterinary preparation that typically contains 10,000 units.[10]

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Chorionic Gonadotropin (hCG) Injection: 10,000 units per 10 mL double vial packs containing 10,000 USP units per vial with bacteriostatic water for injection; single dose 10 mL vials of freeze-dried powder and five 10 mL vials of sterile diluent; *Chorulon®*; (Rx). FDA-approved for use in cows and finfish. In fish intended for human consumption, the total dose administered (all injections combined) should not exceed 25,000 units (25 mL) per fish. No withdrawal time is required when used as labeled.

Chorionic Gonadotropin freeze-dried powder: Single dose 5 mL vials when reconstituted contains pregnant mare serum gonadotropin (equine chorionic gonadotrophin, eCG, PMSG) 400 units and human chorionic gonadotropin (hCG) 200 units; five dose 25 mL vials that when reconstituted contain pregnant mare serum gonadotropin (PMSG) 2000 units and human chorionic gonadotropin (hCG) 1000 units; *PG 600®*; (OTC). FDA-approved for use in swine (prepubertal gilts and sows at weaning); no meat withdrawal time is required when used as labeled.

HUMAN-LABELED PRODUCTS:

Chorionic Gonadotropin (Human) Powder for Injection: 5000 units/vial with 10 mL diluent (to make 500 units/mL); 10,000 units/vial with 10 mL diluent (to make 1000 units/mL); 20,000 units/vial with 10 mL diluent (to make 2000 units/mL) in 10 mL vials; *Novarel®*, *Pregnyl®*, generic; (Rx)

Ciclesonide

(sye-***kles***-oh-nide) *Aservo® EquiHaler®*

Glucocorticoid, Inhaled

Prescriber Highlights

- ► Indicated for management of clinical signs associated with severe equine asthma. May be combined with other asthma treatment modalities
- ► Clinical improvement may be delayed by several days.
- ► Ciclesonide is not a bronchodilator and should not be used for management of acute bronchospasm.
- ► Use with caution in patients with active respiratory infection, chronic nephritis, congestive heart failure, equine pituitary pars intermedia dysfunction (PPID), and when there is higher risk for, or a history of, laminitis.
- ► Common adverse effects include nasal discharge and cough during or after administration; leukocytosis, nasal irritation, and sneezing may also occur but are uncommon.
- ► Drug is delivered via intranasal inhalation into the horse's left nostril; the inhaler device should have a snug fit into the nostril to ensure delivery of a complete dose.
- ► Unlike traditional human inhaler devices, ciclesonide does not require shaking prior to administration, and the device contents are neither pressurized nor contain aerosol propellants.
- ► Be sure to explain proper use of the inhalation device; dispense this drug with the manufacturer's user manual.

Uses/Indications

Ciclesonide is indicated for the management of clinical signs associated with severe equine asthma. It may be used in addition to other treatment strategies (eg, bronchodilators, environmental management).[1] Under experimental conditions, ciclesonide treatment was comparable with oral dexamethasone in reducing measures of experimentally induced airway obstruction in asthmatic horses, but ciclesonide did not reduce serum cortisol.[2] Roughly 85% to 92% of horses accepted the drug's inhaler device.[3] In a study, improvement in clinical score and owner-perceived quality of life were observed in horses that received ciclesonide.[4]

In some regions (eg, UK,[5] EU[6], ciclesonide is approved for summer pasture-associated severe equine asthma.

Pharmacology/Actions

Ciclesonide, a glucocorticoid with potent anti-inflammatory activity, is a prodrug converted into des-ciclesonide by esterases in the respiratory tract.[7] Des-ciclesonide has an affinity 12 times that of dexamethasone for human glucocorticoid receptors, and 120 times greater than the parent drug. Des-ciclesonide demonstrates inhibitory activities against a variety of cell types (eg, mast cells, eosinophils, basophils, lymphocytes, macrophages, neutrophils) as well as against pro-inflammatory mediators (eg, histamine, eicosanoids, leukotrienes, cytokines) involved in the pathophysiology of asthma. Cortisol suppression was not observed at the labeled dosage in the equine species.[5] For a more thorough discussion of glucocorticoid effects, refer to the ***Glucocorticoid*** monograph.

Pharmacokinetics

Ciclesonide is a prodrug rapidly de-esterified to the active component des-ciclesonide, which is detectable within 5 minutes of administration. Des-ciclesonide plasma concentration peaks 30 minutes after administration, and increasing doses result in greater-than-proportional increases in peak concentration. Absolute systemic bioavailability of ciclesonide is 5% to 17%, and apparent systemic bioavailability of des-ciclesonide is 34% to 59%. Peak des-ciclesonide concentration is higher and more variable in lightweight

horses (defined as body weight of 121.5 to 260.5 kg [266 to 574 lb]) compared with average weight horses. Drug accumulation is minimal with the labeled dosage. Ciclesonide volume of distribution is ≈26 L/kg in horses, and protein binding of des-ciclesonide in other species has been found to be ≈98% with less than 1% of the unbound drug found in the systemic circulation.[5,6] Enterohepatic recirculation may occur.[6] Half-life is 2 to 5 hours for ciclesonide and 3 to 6 hours for des-ciclesonide. The drug and metabolite are excreted primarily via the feces.[1,5,6]

Contraindications/Precautions/Warnings

Ciclesonide is contraindicated in patients that are hypersensitive to it.

Clinical improvement is expected to be delayed by several days after initiating therapy.[5] Ciclesonide is not a bronchodilator, and should not be used for management of acute bronchospasm.

Corticosteroids may worsen existing bacterial, viral, or fungal infections, and active respiratory infection should be ruled out prior to ciclesonide use; use with caution, if at all, in patients with active respiratory infection. The drug should be used with caution in horses with chronic nephritis, congestive heart failure, equine pituitary pars intermedia dysfunction (PPID), or in horses at higher risk for, or with a history of, laminitis.

Ensure that the device fits snugly in the patient's *left* nostril, as an incomplete dose may be delivered with a poor fit.

When transferring from systemic steroid therapy to inhaled glucocorticoids, systemic therapy may need to be slowly weaned to avoid acute adrenal insufficiency, and additional glucocorticoid therapy may be required during periods of acute stress, severe asthma attacks occurring during the withdrawal stage, or after transfer to inhaled steroids.

Adverse Effects

Common adverse effects reported[1] with ciclesonide nasal inhalation include cough during or after inhalation and nasal discharge; however, the incidence of these effects (≈17% and ≈10%, respectively) was similar to that reported for placebo inhalation. Adverse effects that might be attributable to ciclesonide include leukocytosis or neutrophilia (6.1%), nasal irritation (eg, soreness, redness, scabs) or bleeding (3% to 6%), sneezing (3%), increased sorbitol dehydrogenase (≈1.5%), and hives (0.6%).[1] The inhalation solution contains ethanol, which could cause ocular irritation if a dose inadvertently comes in contact with the horse's eyes.

According to the United States product label, laminitis developed in 3 horses, 2 of which had a history or prior evidence of laminitis.[1] In a large, placebo-controlled study of severe equine asthma, reported adverse events were minimal, and laminitis was not reported in any horses in the ciclesonide treatment arm (n = 110).[4]

Reproductive/Nursing Safety

Safe use of ciclesonide in pregnant mares has not been established. Ciclesonide was not found to be teratogenic in rats, but doses as low as 5 µg/kg/day SC administered to pregnant rabbits caused decreased body weight and fetal loss, reduced fetal weight, cleft palate, and skeletal abnormalities.[8] Corticosteroids that are administered during the last trimester may induce premature parturition leading to dystocia and fetal death, and therefore ciclesonide should only be used if the benefit to the mare outweighs the potential harm.

Safe use in lactating mares has not been established.

Ciclesonide should only be used in pregnant or lactating mares if the maternal benefit justifies the potential risk to offspring.

Overdosage/Acute Toxicity

Clinical signs in horses receiving up to 3 times the labeled dosage included mucoid and seromucoid nasal discharge, and weight loss (mean estimated weight loss of 24 kg [52.9 lb]).[1,6] Facial asymmetry was observed in 2 horses, one of which resolved during treatment. Cortisol was suppressed in 2 lightweight horses receiving 3 times the label dose. No other pathological changes were identified.

The oral LD_{50} in rats is over 2,000 mg/kg. Inhaled doses up to 5.3 mg/kg/day administered to rats for 2 weeks resulted in reduced food intake and body weight, and reduced organ weights in the spleen, thymus, and adrenal gland. Inhaled doses up to 1.8 mg/kg/day administered to dogs for 4 weeks resulted in reduced body weight and dose-dependent decrease in cortisol concentration as well as adrenal gland atrophy.[6] A reduced cortisol response to ACTH stimulation also was noted.

For patients that have experienced or are suspected to have experienced an overdose, it is strongly encouraged to consult with one of the 24-hour poison consultation centers that specialize in providing information specific for veterinary patients. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

Coadministration of ciclesonide with clenbuterol was tolerated in a small number of horses.[9] The following drug interactions have either been reported or are theoretical in humans or animals receiving ciclesonide and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- Aspirin: May increase risk for GI or renal toxicity
- beta-Blockers (eg, **atenolol, propranolol**): May exacerbate asthma signs
- Corticosteroids (eg, **fludrocortisone, prednis(ol)one**): Concurrent use of inhaled ciclesonide with corticosteroids may increase the risk for GI or renal toxicity.
- Ketoconazole: Concomitant use of ciclesonide with ketoconazole increased des-ciclesonide plasma concentration.[8]
- Nonsteroidal Anti-Inflammatory Drugs (NSAIDs; eg, **phenylbutazone, firocoxib**): Combined use of ciclesonide with NSAIDs may increase the risk for GI or renal toxicity.
- Protein-Bound Drugs (eg, **oral anticoagulants, other anti-inflammatory agents, salicylates, sulfonamides, sulfonylurea antidiabetic agents, valproic acid**): Because ciclesonide is highly bound to plasma proteins (≈98%), it could theoretically displace other highly bound drugs, causing a transient increase in serum levels of each drug. These interactions are unlikely to be of clinical concern because increased free drug levels will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.

Laboratory Considerations

- **Intradermal allergy testing (IDT)**: The effects of inhaled ciclesonide on intradermal allergy testing results are unknown. Systemic glucocorticoids suppress IDT results in horses[10] and inhaled budesonide suppresses IDT results in cats.[11]

Dosages

HORSES:

Severe equine asthma (label dosage; FDA-approved): Initially, 8 actuations (2744 µg ciclesonide)/horse twice daily for 5 days, followed by 12 actuations (4116 µg ciclesonide)/horse once daily for 5 days. **NOTE:** Dosage is independent of body weight. Total treatment duration is 10 days.[1]

Monitoring

- Clinical efficacy
- Adverse effects
- Because this is a new drug with a novel drug delivery system, suspected adverse effects should be reported to the manufacturer.

Client Information

- Dispense the drug with the manufacturer-supplied user manual, which contains very detailed instructions for use of the inhalation device.
- Be sure you understand how to properly activate the device, and how to administer doses. Shaking of the device is not required. Administer doses in a well-ventilated area.
- Ensure the inhaler device fits snugly into the left nostril prior to administering doses. An insecure fit may incompletely deliver doses.
- The device's breath indicator should be seen to curve inward with each inhalation and outward with exhalation. Reposition the device for a more secure fit in the nostril if these movements are not seen. Deliver a dose ("puff") at the *beginning* of an inhalation.
- The device is made to be used with only the left hand (ie, one-handed), while the right hand holds or controls the horse.
- The fill indicator displays the approximate percentage of doses available in the device. The device mechanism will continue to work even if no drug remains in the chamber. Discard after completion of a 10-day treatment course, even if the fill indicator reads above 0%.
- Discuss other equine asthma treatment options (eg, soaking hay, use of airway dilating medication) with your veterinarian.
- Contact your veterinarian if your horse's condition does not improve or worsens.
- Discharging the device will release the medicine into the air and could result in human exposure. It may be appropriate to wear an aerosol-filtering mask during administration. Ask your veterinarian or pharmacist for guidance.
- Not for use in humans. Pregnant women should not administer this product.

Chemistry/Synonyms

Ciclesonide is a nonhalogenated glucocorticoid that occurs as a white to yellow-white powder.[8] It is practically insoluble in water and freely soluble in ethanol. The commercial solution is a clear, colorless to yellow solution that also contains ethanol 0.84% but does not contain propellants.

Ciclesonide may also be known as *Aservo® EquiHaler®* for equine use, or *Alvesco®, Omnaris®, or Zetonna®* for human use.

Storage/Stability

Ciclesonide inhaler is a nonpressurized device. Store at 15°C to 30°C (59°F-86°F); excursions permitted up to 40°C (104°F).[1] Protect from freezing. Use within 12 days of activation. Discard after a 10-day treatment course has finished, even if the fill indicator reads above 0%.[1]

Compatibility/Compounding Considerations

None noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

The Association of Racing Commissioners International (ARCI) has designated other inhaled glucocorticoids (eg, budesonide, fluticasone) as class 4 substances. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

Ciclesonide Inhalation Spray: 343 µg/actuation in a 140-dose prefilled, nonpressurized nasal inhalation device containing ciclesonide 30 mg/mL; *Aservo® EquiHaler®*;(Rx). NADA #141-533. Each device contains enough doses for a 10-day treatment course. **NOTE**: Although human-labeled products containing ciclesonide are available, they are not intended to be used with this device. Do not use in horses intended for human consumption.

HUMAN-LABELED PRODUCTS:

Ciclesonide Metered Aerosol: 80 and 160 µg/actuation in pressurized metered dose inhalers containing 60 actuations; *Alvesco®*;(Rx)

Ciclesonide Metered Nasal Aerosol Solution: 37 µg/actuation; *Zetonna®*; (Rx)

Ciclesonide Metered Nasal Suspension: 50 37 µg/actuation; *Omnaris®*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Cimetidine

(sye-***met***-i-deen) *Tagamet®*

Histamine H_2 Receptor Antagonist

Prescriber Highlights

- ► Prototype H_2-receptor antagonist primarily used to reduce GI acid production. Newer H_2-antagonists (eg, ranitidine, famotidine) and other antacid agents (eg, omeprazole) are preferred due to greater efficacy, longer duration of activity, and/or fewer drug interactions.
- ► Use with caution in geriatric patients or those with hepatic or renal insufficiency
- ► Many drug interactions are possible.

Uses/Indications

Cimetidine use in veterinary and human medicine has been supplanted by newer agents that are more effective, need less frequent dosing, and do not have as many drug-interaction concerns. Cimetidine has also been used in the past as an adjunctive treatment for acetaminophen toxicity in cats; however, cimetidine may increase the risk of methemoglobinemia[1,2] in cats and some consider its use contraindicated.[2] Of note, adjunctive cimetidine use in the management of acetaminophen overdose was not effective in humans[3] and is not recommended.[4]

Historically, cimetidine has been used in veterinary medicine for the treatment and/or prophylaxis of gastric, abomasal, and duodenal ulcers; uremic gastritis; stress-related or drug-induced erosive gastritis; esophagitis; duodenal gastric reflux; and esophageal reflux. It has also been employed to treat hypersecretory conditions associated with gastrinomas and systemic mastocytosis. Cimetidine has also been used investigationally as an immunomodulating agent in dogs.

Cimetidine has been used for the treatment of melanomas in horses,[5] but efficacy is unproven.[6]

Pharmacology/Actions

At the H_2 receptors of the parietal cells, cimetidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, pentagastrin, histamine, or insulin. Gastric emptying time, pancreatic or biliary secretion, and lower esophageal pressures are not altered by cimetidine. By decreasing the amount of gastric acid secretions, cimetidine also decreases pepsin secretion.

Cimetidine has an apparent immunomodulating effect, as it has been demonstrated to reverse suppressor T-cell–mediated immune suppression. It also possesses weak anti-androgenic activity.

Pharmacokinetics

In dogs, the oral bioavailability of cimetidine is reported to be ≈75% to 95%; food can significantly reduce oral bioavailability. Serum half-life is 1.3 to 1.6 hours and volume of distribution is 1.2 L/kg.[7]

In horses, after oral administration, bioavailability is only ≈30%; after IV administration the steady-state volume of distribution is 1.1 L/kg, median plasma clearance is 0.44 L/kg/hour, and half-life is ≈2.2 hours.[8] Separately, a half-life of 7 hours was reported after oral administration.[9]

In humans, cimetidine is rapidly and well absorbed after oral administration, but a small amount is metabolized in the liver before entering the systemic circulation (first-pass effect). The oral bioavailability is 70% to 80%. Food may delay absorption and slightly decrease the amount absorbed, but when given with food, peak concentrations occur when the stomach is not protected by the buffering capabilities of the ingesta. Cimetidine is well distributed in body tissues and only 15% to 20% is bound to plasma proteins. Cimetidine is metabolized in the liver and excreted unchanged by the kidneys. More of the drug is excreted by the kidneys when administered parenterally (75%) than when given orally (48%). The average serum half-life of 2 hours can be prolonged in elderly patients and patients with renal or hepatic disease.

Contraindications/Precautions/Warnings

Cimetidine is contraindicated in patients with known hypersensitivity to the drug.

Cimetidine should be used cautiously in geriatric patients and patients with significantly impaired hepatic or renal function. In humans meeting these criteria, increased risk of CNS effects (confusion) may occur; dosage reductions may be necessary. Acid-suppressing therapy has been associated with increased risk of pneumonia in humans.[10]

Cimetidine inhibits CYP450 microsomal enzymes and may alter the metabolism of other drugs (see ***Drug Interactions*** below).

Adverse Effects

Adverse effects appear to be quite rare in animals at the dosages generally used. Potential adverse effects (documented in humans) include mental confusion, headache (upon discontinuation of the drug), increased liver transaminase activity (ie, increased ALT, AST), pancreatitis, and gynecomastia. Rarely, myalgia, arthralgia, and agranulocytosis may develop; if given rapidly IV, transient cardiac arrhythmias may be seen. Pain at the injection site may occur after IM administration.

Reproductive/Nursing Safety

Cimetidine crosses the placenta. No fetal harm was observed in laboratory animals given up to 40 times the normal human cimetidine dose.[11] In humans it is considered compatible with pregnancy.[12] High doses in humans have been associated with impotence[11]; relevance for veterinary patients is unknown.

Cimetidine is distributed into milk; although safety during nursing is not assured, it is usually considered compatible with nursing in humans.[12]

Overdose/Acute Toxicity

Clinical experience with cimetidine overdose is limited. In laboratory animals, toxic doses have been associated with tachycardia and respiratory failure.[11] The oral LD_{50} in mice is 2550 mg/kg.[13] If these signs occur, consider respiratory support and treatment with beta-adrenergic antagonists (eg, atenolol, propranolol). Peritoneal dialysis does not appreciably enhance the removal of cimetidine from the body.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cimetidine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids** (eg, **aluminum- and/or magnesium-containing agents**): May decrease the absorption of cimetidine; stagger doses (separate by 2 hours if possible).
- **Cefpodoxime, Cefuroxime:** Concurrent use may decrease antibacterial efficacy.
- **Clopidogrel:** Concurrent use may result in decreased clopidogrel efficacy because of lack of metabolism to its active form. However, the clinical effects of this are unclear.[14]
- **Iron Preparations, Oral** (eg, **ferrous sulfate**): Cimetidine may decrease iron absorption.
- **Itraconazole, Ketoconazole:** Cimetidine may decrease the absorption of these drugs; give these medications at least 2 hours before cimetidine.
- **Myelosuppressive Drugs**: Cimetidine may exacerbate leukopenias when used with myelosuppressive agents.
- **Tolazoline**: Concurrent use may result in decreased tolazoline efficacy.

Cimetidine may inhibit the hepatic microsomal enzyme system and thereby reduce the metabolism, prolong serum half-lives, and increase the serum concentrations of several drugs. It may also reduce the hepatic blood flow and reduce the amount of hepatic extraction of drugs that have a high first-pass effect, resulting in increased risk of adverse effects and toxicity. Affected drugs include:

- **Benzodiazepines** (eg, **alprazolam**, **diazepam, midazolam**)
- **Beta-Blockers** (eg, **atenolol, carvedilol, propranolol**)
- **Calcium Channel Blockers** (eg, **diltiazem, verapamil,** *not* **amlodipine**)
- **Carbamazepine**
- **Chloramphenicol**
- **Cisapride**
- **Cyclosporine** (no overall effect was found in dogs,[15] but interaction may apply to other species)
- **Domperidone**
- **Doxepin**
- **Epirubicin** (avoid combination)
- **Fluorouracil**
- **Glipizide/Glyburide**
- **Lidocaine**
- **Loratadine**
- **Metformin**
- **Metronidazole**
- **Mirtazapine**
- **Opioids** (eg, **alfentanil, fentanyl, hydrocodone**)
- **Pentoxifylline**
- **Praziquantel**
- **Procainamide**
- **Quinidine**
- **Sildenafil**
- **Selective Serotonin Reuptake Inhibitors** (**SSRIs**; eg, **fluoxetine**, **sertraline**)
- **Tamsulosin**
- **Theophylline**
- **Terbinafine**
- **Tramadol:** Cimetidine increases tramadol bioavailability.[16]
- **Triamterene**
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline**, **clomipramine**)
- **Warfarin**

Laboratory Considerations

- **Creatinine**: Cimetidine may cause small increases in plasma creatinine concentrations early in therapy; these increases are generally mild, nonprogressive, and have disappeared when therapy is discontinued.
- **Gastric Acid Secretion Tests**: H_2-receptor antagonists may antagonize the effects of histamine and pentagastrin in the evaluation of gastric acid secretion; it is recommended that H_2-receptor antagonists be discontinued at least 24 hours before performing this test.
- **Intradermal allergy testing (IDT):** H_2-receptor antagonists may inhibit histamine responses[17]; based on half-life in dogs, consider discontinuing cimetidine at least 24 hours before performing this test in this species

Dosages

DOGS/CATS:

Esophagitis, gastritis, ulcer disease (extra-label): 5 – 10 mg/kg PO every 6 to 8 hours

HORSES:

Gastroprotectant, reduce stomach acid (extra-label): 300 – 600 mg per foal (NOT mg/kg) PO 3 to 4 times daily

Melanomas, adjunctive treatment (extra-label): 1.6 – 7.5 mg/kg PO once to twice daily.[6,18] Efficacy is questionable at these dosages, and 1 author[18] speculates that higher doses may be needed.

FERRETS:

Stress-induced GI ulcers (extra-label): 5 – 10 mg/kg PO 3 times daily[19]

RABBITS/RODENTS/SMALL MAMMALS:

Rabbits: GI ulceration (extra-label)**:** 5 – 10 mg/kg PO every 8 to 12 hours[20]

Mice, rats, gerbils, hamsters, guinea pigs, chinchillas (extra-label): 5 – 10 mg/kg PO every 6 to 12 hours[21]

Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in clinical signs, endoscopic examination, intragastric pH, blood in feces
- Adverse effects if noted
- If drug interactions are possible, adverse or toxic effects of other drug therapy

Client Information

- Used to reduce stomach acid and to treat or prevent stomach ulcers
- Doses often need to be given 2 to 4 times per day; signs may recur if dosages are missed.
- Cimetidine interacts with many other medications. Do not give your animal new medicines without your veterinarian's approval.
- Cimetidine is available OTC (over the counter; without a prescription), but only give it to your animal if your veterinarian recommends it.

Chemistry/Synonyms

An H_2-receptor antagonist, cimetidine HCl occurs as a white to off-white crystalline powder. It has what is described as an "unpleasant" odor and a pK_a of 6.8. Cimetidine is sparingly soluble in water and soluble in alcohol.

Cimetidine HCl occurs as a white crystalline powder and is very soluble in water and soluble in alcohol. It has a pK_a of 7.11, and the commercial injection has a pH of 3.8 to 6.0.

Cimetidine may also be known as cimetidinum or SKF-92334; many trade names are available.

Storage/Stability

Cimetidine products should be stored protected from light in airtight containers and kept at room temperature, 20°C to 25°C (68°F-77°F).

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Compounded preparation stability: Cimetidine oral suspension has been compounded from commercially available tablets.[22] Triturating twenty-four (24) cimetidine 300 mg tablets with 10 mL of glycerin and a sufficient quantity (up to 120 mL) of simple syrup yields a 60 mg/mL oral suspension that retains greater than 90% potency for 17 days stored at 4°C (39°F). Apply "shake well" and "refrigerate" labels to the compounded product.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE.

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 5 substance. See ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Cimetidine Oral Tablets: 200 mg, 300 mg, 400 mg, and 800 mg; *Tagamet®*, generic; (Rx, OTC)

Cimetidine HCl Oral Solution: 300 mg (as HCl)/5 mL in 240 mL, 480 mL, and UD 5 mL; generic; (Rx)

A parenteral solution was formerly available in the US but has been withdrawn.

For the complete list of references, see **wiley.com/go/budde/plumb**

Ciprofloxacin

(sip-roe-***flox***-a-sin) *Cipro®*

Fluoroquinolone Antibiotic

Prescriber Highlights

- ► Human-label fluoroquinolone antibiotic; in dogs and cats, oral bioavailability can be very low and unpredictable.
- ► Injectable products are formulated for IV administration only.
- ► Contraindicated in animals with a history of hypersensitivity to it or other fluoroquinolones
- ► When possible, avoid use in young, growing animals because of the potential negative impact on cartilage development.
- ► Caution is advised in patients with hepatic or renal insufficiency or dehydration.
- ► Adverse effects include GI distress, CNS stimulation, crystalluria, or hypersensitivity.
- ► Many potential drug interactions
- ► FDA prohibits extra-label use in food animals.

Uses/Indications

Ciprofloxacin is a broad-spectrum antibiotic with good gram-negative coverage. Because of its similar spectrum of activity, ciprofloxacin could be used as an alternative to enrofloxacin when an IV product is desired. It is important to note that ciprofloxacin and enrofloxacin cannot be considered equivalent because of pharmacokinetic differences (see ***Pharmacokinetics***). Because of ciprofloxacin's poor and variable bioavailability, there is little justification for its use in place of fluoroquinolones approved for veterinary use. Further, it has been suggested that human breakpoints for susceptibility should not be applied to isolates from dogs (and presumably cats) because of

ciprofloxacin's poor bioavailability and because a much lower breakpoint should be used.[1]

The World Health Organization (WHO) has designated ciprofloxacin as a Critically Important, Highest Priority antimicrobial in human medicine.[2]

Pharmacology/Actions

Ciprofloxacin is a bactericidal and concentration-dependent antibiotic, with susceptible bacteria cell death occurring within 20 to 30 minutes of exposure. Ciprofloxacin has demonstrated a significant postantibiotic effect in both gram-negative and gram-positive bacteria and is active in both the stationary and growth phases of bacterial replication. Its mechanism of action is not thoroughly understood, but it is believed to act by inhibiting bacterial DNA-gyrase (a type II topoisomerase), thereby preventing DNA supercoiling and DNA synthesis.

Enrofloxacin and ciprofloxacin have similar spectrums of activity. Both agents have good activity against many gram-negative bacilli and cocci, including most species and strains of *Pseudomonas aeruginosa*, *Klebsiella* spp, *Escherichia coli*, *Enterobacter* spp, *Campylobacter* spp, *Shigella* spp, *Salmonella* spp, *Aeromonas* spp, *Haemophilus* spp, *Proteus* spp, *Yersinia* spp, *Serratia* spp, and *Vibrio* spp. Other organisms that are generally susceptible include *Brucella* spp, *Chlamydia trachomatis*, staphylococci (including penicillinase-producing and some methicillin-resistant strains), *Mycoplasma* spp, and *Mycobacterium* spp (except *Mycobacterium avium* subsp *paratuberculosis*, the etiologic agent for Johne's disease). However, acquired resistance is increasingly common in some important pathogens (eg, *Pseudomonas* spp, *Staphylococcus* spp, enterobacteriales [ie, *Escherichia coli*]). Ciprofloxacin has weak activity against streptococci and enterococci and is not recommended in the treatment of these infections; it is ineffective against anaerobes.

It is recommended that human breakpoints for susceptibility should not be applied to isolates from dogs because of ciprofloxacin's poor bioavailability and because a much lower breakpoint should be used. Even with a lower breakpoint, high doses are required. A dosage of 25 mg/kg PO once daily was estimated to have only an 18% chance of attaining a target AUC/MIC of 100 for bacteria with an MIC of 0.25 µg/mL.[1]

Development of resistance to this class of antibiotics is a concern with many bacteria, particularly *E coli,* staphylococci, and *P aeruginosa*. In a study of pigs receiving ciprofloxacin orally, *E coli* MIC increased 16-fold after only 3 days of treatment but decreased after the drug was stopped.[3] Temporary ciprofloxacin exposure to canine *E coli* isolates increased expression of drug efflux pumps, which are mechanisms for drug resistance.[4]

Pharmacokinetics

Ciprofloxacin is the active metabolite of enrofloxacin. Approximately 10% to 40% of circulating enrofloxacin is metabolized to ciprofloxacin in most species. Approximately 15% to 50% of both ciprofloxacin and enrofloxacin are eliminated unchanged in the urine by tubular secretion and glomerular filtration. Enrofloxacin and ciprofloxacin are metabolized to various metabolites that are less active than the parent compounds. These metabolites are eliminated in the urine and feces. Because of the dual means of elimination (ie, renal and hepatic), patients with severely impaired renal function may have slightly prolonged half-lives and higher serum concentrations but may not require dosage adjustment.

In dogs, ciprofloxacin's bioavailability is variable and significantly less than enrofloxacin, likely due to incomplete dissolution of tablets formulated for human use. In one study, after oral tablets (250 mg/dog [NOT mg/kg]) were administered to beagles, bioavailability ranged from 32% to 80% (mean, 58%). Administration of a 10 mg/mL solution given via stomach tube resulted in more uniform and consistent bioavailability (71%).[5] Improved absorption with an oral solution was confirmed in another study.[6] In dogs given a target dose of 25 mg/kg PO, the AUC was 13.6 to 22.5 µg/hour/mL.[1,5,7] Volume of distribution in the same study was 10.7 L/kg and peak plasma concentration was 1.9 µg/mL.[1] Elimination half-life has been reported to be 2.9 to 3.7 hours for IV administration[5,6] and 2.5 to 4.35 hours for PO administration.[1,5]

Oral bioavailability in cats can be very low. A study found that the oral bioavailability average in cats was ≈33%. After IV dosing, volume of distribution (steady-state) was ≈3.9 L/kg; clearance was ≈0.64 L/hour/kg; and elimination half-life averaged ≈4.5 hours.[8]

In a study in healthy mares, oral bioavailability was 10.5%.[9] Studies of the oral bioavailability in ponies have shown that ciprofloxacin is poorly absorbed (2% to 12%),[10] whereas enrofloxacin in foals is apparently well absorbed.[11] Terminal half-life in horses after PO and IV administration was 3.6 hours and 5.8 hours, respectively.[9] Minimal systemic absorption and exposure occurred after intrauterine ciprofloxacin administration to mares in estrus.[12] Following a single intrauterine infusion, resultant intrauterine lumen ciprofloxacin concentration was 148 µg/mL (± 33 µg/mL) and 91 µg/mL (± 51 µg/mL) 24 hours after infusion into healthy mares. Mean intrauterine concentrations 12 hours postinfusion were 10 to 40 times the MIC_{90} for *Klebsiella pneumoniae, Pseudomonas aeruginosa,* and *S equi* subsp *zooepidemicus*; at 24 hours postinfusion the intrauterine concentration was 1.2 to 5 times MIC_{90}. For *Escherichia coli*, ciprofloxacin concentration was 2000 times greater than MIC_{90} at both 12 and 24 hours postinfusion.[12]

In humans, the oral bioavailability of ciprofloxacin has been reported to be between 50% to 85%. The volume of distribution in adults is ≈2 L/kg to 3.5 L/kg, and it is ≈20% to 40% bound to serum proteins. High tissue concentrations are found in the kidneys, gallbladder, liver, and lungs.

Contraindications/Precautions/Warnings

There are potential concerns for cartilage damage in growing animals, although the incidence and highest risk periods are poorly defined. Bubble-like changes in articular cartilage have been noted when the drug was given at 2 to 5 times the recommended doses for 30 days, although clinical signs have only been reported at 5 times the recommended dose.[13] The need for fluoroquinolones must be balanced with the potential risk in dogs younger than 8 months of age. To avoid cartilage damage, treatment for large- and giant-breed dogs may need to wait until 12 to 18 months of age, respectively. Quinolones are also contraindicated in patients hypersensitive to them.

Because ciprofloxacin has occasionally been reported to cause crystalluria, animals should not be allowed to become dehydrated during therapy. In humans, ciprofloxacin has been associated with CNS stimulation and should be used with caution in patients with seizure disorders.[14] Patients with severe renal or hepatic impairment may require dosage adjustments to prevent drug accumulation. Fluoroquinolones increase risk for QTc interval prolongation in humans and should be used with caution in veterinary patients with cardiac disease. In humans, fluoroquinolones may exacerbate muscle weakness in patients with myasthenia gravis.[14]

No reports of retinal toxicity secondary to ciprofloxacin in cats have been located. Although retinal toxicity appears to be less likely than with a high dose of enrofloxacin (ciprofloxacin is less lipophilic than enrofloxacin), use of an alternative fluoroquinolone can be considered.

Adverse Effects

Potential adverse effects include cartilage abnormalities in young, growing animals (see ***Contraindications/Precautions/Warnings***); GI distress (eg, vomiting, anorexia, esophagitis, diarrhea); crystalluria/urolithiasis (dogs); CNS stimulation; and hypersensitivity reactions (dogs).

In a pharmacokinetic study in healthy mares,[9] IV ciprofloxacin caused agitation, excitement, and muscle fasciculation, and all horses experienced diarrhea. After oral administration, diarrhea, colitis, laminitis, and endotoxemia occurred, necessitating humane euthanasia in 3 of the 8 (≈39%) horses.[9] In mares receiving an intrauterine ciprofloxacin infusion, 3 of 10 horses had cytological evidence of intrauterine inflammation.[12]

In humans, systemic fluoroquinolones, including ciprofloxacin, have been associated with disabling and potentially irreversible serious adverse effects, including tendonitis and tendon rupture, peripheral neuropathy, and CNS effects (eg, convulsions, increased intracranial pressure, lowered seizure threshold). In humans, fluoroquinolones may also alter cardiac conduction and cause prolongation of the QTc interval, especially in those with a history of QTc interval prolongation, electrolyte disorders, and cardiac disease.

Reproductive/Nursing Safety

Ciprofloxacin crosses the placenta. Studies in laboratory animals have not demonstrated adverse fetal outcomes; however, because of ciprofloxacin's adverse effects on cartilage, it should be used cautiously in pregnant animals.

Ciprofloxacin is distributed into milk. In lactating cows given a CRI of ciprofloxacin (prohibited in the United States) for 7 days, ≈6% of the ciprofloxacin dose was transferred to milk, and ciprofloxacin concentration in milk was 45 times higher than in plasma. Milk from the cows was fed to calves, but oral absorption was negligible, and the drug did not accumulate in the calf.[15] No adverse effects have been reported in nursing human infants of mothers receiving ciprofloxacin.

Because safety has not been fully established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Little specific information in veterinary patients is available. See ***Enrofloxacin*** for more information.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

In hepatic microsomes from healthy beagles, select fluoroquinolones (ie, ofloxacin, orbifloxacin, ciprofloxacin, enrofloxacin, norfloxacin) were shown to inhibit CYP1A activity, with ciprofloxacin the most likely to have clinically relevant drug interactions.[16] The following drug interactions have either been reported or are theoretical in humans or animals receiving ciprofloxacin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Aluminum-, Calcium-, and Magnesium-Containing Oral Products**: May bind to fluoroquinolones and prevent absorption; doses of these products should be separated from ciprofloxacin by at least 2 hours
- **Antibiotics, Other** (eg, **aminoglycosides, extended spectrum penicillins, third-generation cephalosporins**): Synergism may occur against some bacteria (particularly *Pseudomonas aeruginosa*), but this is unpredictable. Although enrofloxacin and ciprofloxacin have minimal activity against anaerobes, in vitro synergy has been reported when used with clindamycin against strains of *Peptostreptococcus* spp, *Lactobacillus* spp, and *Bacteroides fragilis*.
- **Blood Glucose Lowering Agents** (eg, **insulin, sulfonylureas** [eg, **glipizide, glyburide**]): Fluoroquinolones may enhance hypoglycemic effect of blood glucose lowering agents.
- **Corticosteroids** (eg, **dexamethasone, prednis[ol]one**): Concomitant use with fluoroquinolones may increase the risk for tendonitis and tendon rupture.
- **Cyclosporine** (**systemic**): Fluoroquinolones may exacerbate nephrotoxicity and reduce the metabolism of cyclosporine.
- **Doxorubicin**: Ciprofloxacin may increase doxorubicin exposure in humans. Combination may also increase the risk for QT prolongation.
- **Drugs that Prolong QT Interval** (eg, **azithromycin, chlorpromazine, cisapride, fluconazole, fluoxetine, ketoconazole, methadone, ondansetron, quinidine, sotalol**): Combinations with ciprofloxacin may increase the risk for QTc prolongation; concurrent use of cisapride and ciprofloxacin is contraindicated in humans.
- **Fentanyl**: Ciprofloxacin may increase fentanyl effects.
- **Flunixin**: Enrofloxacin increases the AUC and prolongs the elimination half-life of flunixin in dogs, which could increase flunixin toxicity. Flunixin decreases the C_{max} of enrofloxacin in dogs, which could decrease antibiotic efficacy. Interaction may apply to ciprofloxacin.
- **Iron, Zinc** (**oral**): Concomitant administration may decrease fluoroquinolone absorption; doses should be separated by at least 2 hours.
- **Lanthanum**: Concomitant administration decreases ciprofloxacin absorption by 50% in humans; use of an alternate phosphate binder is recommended.
- **Levothyroxine**: Ciprofloxacin may decrease levothyroxine efficacy.
- **Magnesium** (**parenteral**): May bind to fluoroquinolones and prevent absorption; doses of these products being administered by the same route as ciprofloxacin should be separated by at least 2 hours
- **Methotrexate** (**MTX**): Concomitant administration may increase MTX concentrations and increase the risk for toxicity.
- **Mycophenolate**: Ciprofloxacin may decrease mycophenolic acid exposure.
- **Nitrofurantoin**: May antagonize the antimicrobial activity of fluoroquinolones; concomitant use is not recommended
- **Probenecid**: Blocks renal tubular secretion of ciprofloxacin and may increase ciprofloxacin serum concentrations and elimination half-life. Monitor for increased ciprofloxacin adverse effects (eg, nausea, diarrhea).
- **Sevelamer**: Concomitant administration decreases ciprofloxacin absorption by 50% in humans; administer ciprofloxacin at least 2 hours before or 6 hours after sevelamer.
- **Sildenafil:** Concomitant use with ciprofloxacin may increase sildenafil serum concentrations and adverse effects.[13]
- **Sucralfate**: Concomitant oral administration may inhibit GI absorption of ciprofloxacin; doses of these drugs should be separated by at least 2 hours.[7,13]
- **Theophylline Derivatives** (eg, **aminophylline, theophylline**): Enrofloxacin reduces theophylline metabolism in dogs, increasing theophylline serum concentration by 30% to 50%[17]; interaction likely applies to ciprofloxacin.
- **Warfarin**: Concomitant use may increase anticoagulant effects of warfarin.

Laboratory Considerations

- In some humans, fluoroquinolones have caused increases in **liver**

enzymes, **BUN**, and **creatinine** and decreases in **hematocrit**. The clinical relevance of these mild changes in veterinary patients is unknown.

Dosages

NOTES:

1) Considering improved bioavailability of other approved fluoroquinolones after oral administration, ciprofloxacin is best reserved for use when an IV fluoroquinolone is indicated and a fluoroquinolone approved for veterinary use is not available.
2) Ciprofloxacin IV should be administered slowly to reduce the risk for vein irritation. In humans, IV ciprofloxacin is given as a diluted solution (0.5 – 2 mg/mL) by slow IV infusion over 60 minutes into a large vein.

DOGS:

Susceptible infections (extra-label): 25 mg/kg PO or 20 mg/kg IV slowly once daily. **NOTE**: Because of the drug's variable oral bioavailability in dogs, a dosage of 25 mg/kg PO once daily may not achieve adequate drug exposure for bacteria with an MIC greater than 0.06 µg/mL, despite the human breakpoint (1 µg/mL) often used by laboratories.[1,7]

Bacterial pyoderma (extra-label): 30 mg/kg PO once daily[18]

UTI (extra-label): 30 mg/kg PO once daily[19]

CATS:

Susceptible infections (extra-label): 20 – 25 mg/kg PO or IV slowly once daily

UTI (extra-label): 30 mg/kg PO once daily[19]

HORSES:

Endometritis (extra-label): 600 mg/horse (NOT mg/kg) via intrauterine infusion. **NOTE:** Dosage based on a pharmacokinetic study in healthy mares.[12]

BIRDS:

NOTE: Higher doses administered once daily are considered more clinically appropriate than lower, twice-daily dosages.

Susceptible gram-negative infections (extra-label):

a) 20 – 40 mg/kg PO twice daily using ciprofloxacin 500 mg tablets. Crushed tablets mix into the suspension well but must be shaken before administering.[20]
b) 20 mg/kg PO every 12 hours[21]
c) 10 – 15 mg/kg PO every 12 hours[22]

FERRETS:

NOTE: Higher doses administered once daily are considered more clinically appropriate than lower, twice-daily dosages.

Susceptible infections (extra-label):

a) 10 – 30 mg/kg PO every 24 hours[23]
b) 5 – 15 mg/kg PO twice daily[24]

RABBITS/RODENTS/SMALL MAMMALS:

NOTE: Higher doses administered once daily are considered more clinically appropriate than lower, twice-daily dosages.

a) **Rabbits** (extra-label): 5 – 20 mg/kg PO every 12 to 24 hours[24]
b) **Pasteurellosis in rabbits** (extra-label):
   i. 15 – 20 mg/kg PO twice daily for a minimum of 14 days in mild cases and up to several months in chronic infections[25]
   ii. 20 mg/kg IV, PO once daily based on a pharmacokinetic study.[26]
c) **Chinchillas, gerbils, guinea pigs, hamsters, mice, rats** (extra-label): 5 – 20 mg/kg PO every 12 to 24 hours[24]

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- This medicine should be given without food and on an empty stomach. However, it may be given with a small amount of food or treat if your animal experiences an upset stomach (eg, salivating, refusing to eat, vomiting). Contact your veterinarian if upset stomach persists.
- Do not give this medicine at the same time as other drugs or vitamins that contain calcium, iron, or aluminum, as these can reduce the amount that gets absorbed.
- Ciprofloxacin may cause joint abnormalities if used in young, pregnant, or nursing animals.
- The most common side effects are vomiting, nausea, and diarrhea.

Chemistry/Synonyms

Ciprofloxacin HCl, a fluoroquinolone antibiotic, occurs as a faintly yellowish to yellow crystalline powder. It is slightly soluble in water. Ciprofloxacin is related structurally to the veterinary FDA-approved drug enrofloxacin (enrofloxacin has an additional ethyl group on the piperazinyl ring).

Ciprofloxacin may also be known as ciprofloxacine, ciprofloxacinum, ciprofloxacino, Bay-q-3939, or *Cipro*®.

Storage/Stability

Unless otherwise directed by the manufacturer, ciprofloxacin tablets should be stored in airtight containers at temperatures less than 30°C (86°F). Protect this product from strong UV light. The injection should be stored at 5°C to 25°C (41°F-77°F) and protected from light and freezing.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used. Specialized references or a hospital pharmacist should be consulted for more specific information.

Ciprofloxacin should be diluted to a concentration of 1 to 2 mg/mL in 5% dextrose, 0.9% sodium chloride, or lactated Ringer's solution (LRS) prior to IV administration. Diluted solutions in 5% dextrose, 0.9% sodium chloride, or LRS from 0.5 to 2 mg/mL are stable for up to 14 days at room temperature or in the refrigerator.

The manufacturer recommends administering IV ciprofloxacin alone and temporarily discontinuing other solutions or drugs while ciprofloxacin is being administered; however, other sources state that ciprofloxacin injection is reportedly **compatible** with the following IV solutions and drugs: 5% dextrose, 5% dextrose with 0.22% or 0.45% sodium chloride, Ringer's solution, lactated Ringer's solution (LRS), 0.9% sodium chloride; **Y-site compatible with** amikacin sulfate, amiodarone, aztreonam, calcium gluconate, ceftazidime, cimetidine, clarithromycin, cyclophosphamide, cyclosporine, cytarabine, dexmedetomidine, diltiazem, diphenhydramine, dobutamine, dopamine, fluconazole, gentamicin, hydromorphone, lidocaine, metoclopramide, metronidazole, midazolam, mycophenolate mofetil hydrochloride, ondansetron, oxytocin, potassium chloride (KCl), ranitidine, tobramycin, vancomycin, voriconazole, and vitamin B complex.

Ciprofloxacin injection is reportedly **incompatible** with aminocaproic acid, aminophylline, amphotericin B, ampicillin/sulbactam, azithromycin, cefepime, cefuroxime, clindamycin, dexamethasone sodium phosphate, furosemide, heparin sodium, magnesium sulfate, meropenem, methylprednisolone sodium succinate, pantoprazole, piperacillin/tazobactam, potassium phosphate, propofol, sodium bicarbonate, and sodium phosphate.

The pH of the IV solution in vials ranges from 3.3 to 3.9, and pH of the IV solution in PVC bags ranges from 3.5 to 4.6.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Ciprofloxacin Oral Tablets: 100 mg, 250 mg, 500 mg, 750 mg, and 1000 mg; *Cipro®*, generic; (Rx)

Ciprofloxacin Extended-Release Oral Tablets: 500 mg and 1000 mg; *Cipro XR®*, generic; (Rx)

Ciprofloxacin Solution for Injection: 200 mg and 400 mg in 100 mL and 200 mL, respectively, in 5% dextrose flexible containers (0.2%); *Cipro® I.V.*, generic; (Rx)

In the United States, the FDA has banned extra-label use of ciprofloxacin (and other fluoroquinolones) in food animals.

Cisapride

(***sis***-a-pride)

Promotility Agent

Prescriber Highlights

- ► Oral GI prokinetic agent used in several species for GI stasis, gastroesophageal reflux, and constipation/megacolon (cats)
- ► Not commercially available; must be obtained from a compounding pharmacy
- ► Contraindications include hypersensitivity to the drug and use for patients in which increased GI motility could be harmful (eg, GI perforation, obstruction, hemorrhage).
- ► Unlike in humans, cisapride-induced arrhythmias have not been reported in veterinary patients.
- ► Adverse effects appear to be minimal in veterinary patients; vomiting, diarrhea, and abdominal discomfort can occur.
- ► Many drug interactions are possible.

Uses/Indications

Proposed uses for cisapride in small animal species include treatment of gastroesophageal reflux, reflux esophagitis, and primary gastric motility disorders. It may be used for the prevention of reflux and aspiration pneumonia in dogs during surgery.[1–3] Cisapride has been found to be useful in the treatment of constipation and megacolon in cats. Cisapride has also been proposed to enhance detrusor contractility in dogs with micturition disorders,[4] but it is not commonly used for this purpose. Cisapride has limited efficacy in conditions of esophageal dysmotility.

Pharmacology/Actions

Cisapride is a 5-HT_4-receptor agonist that enhances the release of acetylcholine at the myenteric plexus without stimulating nicotinic or muscarinic receptors or inhibiting acetylcholinesterase activity. Cisapride is also a 5-HT_1- and 5-HT_3-receptor antagonist of the enteric cholinergic neurons; it is a direct 5-HT_2-alpha-receptor agonist on colonic smooth muscle. The drug stimulates smooth muscle contraction (thus increasing lower esophageal peristalsis and sphincter pressure), [1,5] increases gastric contractions,[6] accelerates gastric emptying,[7] and promotes small[8,9] and large[10] intestinal motility. Cisapride blocks dopaminergic receptors to a lesser extent than metoclopramide and does not increase gastric acid secretion. Cisapride stimulates distal esophageal smooth muscle and is considered ineffective for distal esophageal dysmotility in dogs due to the striated muscle of that species' distal esophagus. In horses, cisapride attenuated the gastric hypomotility effects of endotoxin under experimental conditions[7], and it increased GI motility and rate of passage in horses with chronic grass sickness.[11] Cisapride may be preferred to promote colonic activity over metoclopramide, as it does not cause collapse when it is given IV. Cisapride did not increase gastric or intestinal contractility in the bovine abomasal antrum or proximal duodenal smooth muscle preparations.[12]

Pharmacokinetics

In dogs, the oral bioavailability of cisapride has been reported as ≈53%.[13] It is widely distributed into tissues and has a high volume of distribution. Plasma protein binding is 95%. Cisapride is hepatically metabolized to mostly inactive compounds, with ≈25% of an oral dose eliminated in the urine and ≈70% in the feces, and ≈23% of the dose is excreted unchanged in the feces.[14] Half-life in dogs is reported as ≈4 to 10 hours[13]; a study evaluating lower esophageal pressure in dogs after cisapride administration (0.5 mg/kg PO) found that effects were absent after 7 hours.[15]

In cats, the oral bioavailability is variable but averages 30%, and the elimination half-life is ≈5 to 6 hours.[16]

In horses, the oral bioavailability is ≈50%, the volume of distribution is 1.5 L/kg, and clearance is ≈0.5 L/hour/kg.[17] The elimination half-life is ≈2 hours.[17,18] The drug is not appreciably absorbed after rectal administration.[18,19]

In humans, cisapride is rapidly absorbed after oral administration. Bioavailability is 35% to 40%, indicating substantial first-pass metabolism. The drug is ≈98% bound to plasma proteins and well distributed throughout the body. Cisapride is extensively metabolized in the liver, primarily by CYP3A4.[20] The elimination half-life is ≈6 to 12 hours.[21]

Contraindications/Precautions/Warnings

Cisapride is contraindicated in patients in which increased GI motility could be harmful (eg, perforation, obstruction, GI hemorrhage) or in patients that are hypersensitive to the drug. Use it with caution in patients with significant hepatic impairment and in patients with mechanical obstruction, GI perforation, or GI hemorrhage. Correct hypokalemia and hypomagnesemia prior to use; use cisapride with caution in patients that may experience precipitous decreases in plasma potassium (eg, potassium-wasting diuretics, insulin).

In humans, cisapride therapy has resulted in QTc prolongation leading to fatal arrhythmias (eg, torsade de pointes, ventricular tachycardia, ventricular fibrillation) and is contraindicated in patients with QTc prolongation or other conditions (eg, AV block, cardiomyopathy) that predispose to or potentiate QTc prolongation, including drugs that inhibit CYP3A. Significance in veterinary species is unclear; cisapride-induced arrhythmias have not been reported in veterinary patients.

Adverse Effects

Cisapride appears to be safe in small animal species at recommended dosages. Occasionally, vomiting, diarrhea, and abdominal discomfort may be noted. Although no reports have been noted in dogs or cats, prolonged QT intervals or other cardiac arrhythmias are possible.

In humans, the primary adverse effects are GI related with diarrhea and abdominal pain most commonly reported, but the drug was removed from the market due to concerns with QT-interval prolongation.[22]

Reproductive/Nursing Safety

Cisapride at high dosages (greater than 40 mg/kg/day) caused fertility impairment in female rats.[23] At doses 12 to 100 times the maximum recommended dose, cisapride caused embryotoxicity and fetotoxicity in rabbits and rats. Its use during pregnancy should occur only when the benefits outweigh the risks.

Cisapride is excreted in maternal milk; use it with caution in nursing mothers.

Overdose/Acute Toxicity

LD_{50} doses in various laboratory animal species range from 160 to 4000 mg/kg. The reported oral lethal dose in dogs is 640 mg/kg.[24] In

one reported human overdose of 540 mg, the patient developed GI distress and pollakiuria. The most common adverse effects seen in dogs and cats are diarrhea, lethargy, ataxia, hypersalivation, muscle fasciculations, agitation, abnormal behavior, hyperthermia, ataxia and incoordination, and possibly seizures (dogs).[24]

Significant overdoses should be handled using standard gastric decontamination protocols when appropriate; supportive therapy should be initiated when required. Activated charcoal is effective in binding unabsorbed cisapride.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

In humans, cisapride is a substrate of CYP3A4. The following drug interactions have either been reported or are theoretical in humans or animals receiving cisapride and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **atropine**): Use of anticholinergic agents may diminish the effects of cisapride.
- **Benzodiazepines**: Cisapride may enhance the sedative effects of alcohol or benzodiazepines.
- **Cyclosporine**: Cisapride may increase the risk for cyclosporine toxicity.
- **Diuretics, Potassium Wasting** (eg, **furosemide**): Hypokalemia may increase the risk for cardiac arrhythmias.
- **Highly Protein Bound Drugs** (eg, **nonsteroidal anti-inflammatory agents [NSAIDs]**, **oral anticoagulants**, **salicylates**, **sulfonamides**, **sulfonylurea antidiabetic agents, valproic acid**): Because cisapride is highly bound to plasma proteins, it could theoretically displace other highly bound drugs, causing a transient increase in serum concentrations of each drug. These interactions are unlikely to be of clinical concern because increased free drug concentrations will equilibrate through increased clearance. Monitor for adverse effects of each drug when using this combination.
- **Insulin**: Insulin-induced decrease in plasma potassium concentration may increase the risk for cardiac arrhythmias.
- **Opioids** (eg, **fentanyl, morphine**): May diminish the effects of cisapride
- **Oral Drugs With A Narrow Therapeutic Index** (eg, **digoxin, warfarin**): Closer monitoring of serum drug concentrations may be needed when adding or discontinuing cisapride, as cisapride can decrease GI transit times and potentially affect the absorption of other oral drugs.
- **Warfarin**: Cisapride may enhance anticoagulant effects; additional monitoring and anticoagulant dosage adjustments may be required.

As cisapride is metabolized via CYP450 (3A4 in humans), the following medications/foods that can inhibit this enzyme may lead to increased cisapride concentrations and an increased risk for cisapride cardiotoxicity:

- **Amiodarone**
- **Azole Antifungals** (eg, **fluconazole, itraconazole, ketoconazole**)
- **Chloramphenicol**
- **Cimetidine**
- **Fluvoxamine**
- **Grapefruit Juice/Powder**
- **Macrolide Antibiotics** (**except azithromycin**): **NOTE:** Erythromycin did not alter cisapride pharmacodynamics in one study in dogs.
- **Ondansetron**

The following drugs may increase QTc interval, and use with cisapride may increase this risk:

- **Amiodarone**
- **Domperidone**
- **Fluoroquinolones** (eg, **ciprofloxacin, moxifloxacin**)
- **Macrolide Antibiotics** (including **azithromycin**): Dose-related QT prolongation occurred in dogs receiving an erythromycin and cisapride combination, but arrhythmias were not observed.[25]
- **Methadone**
- **Phenothiazines** (eg, **promethazine**, possibly **acepromazine**)
- **Procainamide**
- **Quinidine**
- **Sotalol**
- **Tricyclic Antidepressants** (eg, **amitriptyline, clomipramine, doxepin**)

Dosages

DOGS:

Promotility agent (extra-label): Initially, 0.1 – 0.5 mg/kg PO every 8 to 12 hours; some gastroenterologists recommend administering 30 minutes before feeding. Some sources state that dosages (gradually increased) up to 1 mg/kg PO every 8 hours may be required (if tolerated).[26]

Reduce gastroesophageal reflux and aspiration pneumonia in anesthetized dogs: Cisapride 1 mg/kg IV combined with esomeprazole (1 mg/kg IV) 11.5 hours prior to anesthesia.[2] Alternately, cisapride 1 mg/kg IV infusion (diluted in 100 or 150 mL 0.9% sodium chloride) beginning 90 minutes prior to anesthesia induction. Half of the admixed volume is delivered over the first 60 minutes, and if vital parameters (eg, TPR) are acceptable, the remaining volume is administered over 30 minutes.[3] (**NOTE:** Finding a compounding pharmacy to prepare cisapride for injection can be difficult.)

CATS:

Promotility agent (extra-label):

a) Initially, 2.5 mg/cat (NOT mg/kg) PO twice daily, preferably 15 to 30 minutes before food. Dosages may be titrated upwards, if tolerated, to as high as 7.5 mg/cat (NOT mg/kg) PO 3 times daily in large cats. Cats with hepatic insufficiency may need dosage interval extensions.[27–29]

b) 1 mg/kg PO every 8 hours, or 1.5 mg/kg PO every 12 hours based on a study in 7 healthy cats[16]

c) 2.5 mg/cat (NOT mg/kg) PO every 8 hours in cats less than 5 kg (11 lb); 5 mg/cat (NOT mg/kg) PO every 8 hours in cats greater than 5 kg (11 lb)[26]

HORSES:

Promotility agent in foals with periparturient asphyxia (extra-label): 10 mg/horse (NOT mg/kg) PO every 6 to 8 hours. Adequate time for healing of damaged bowel before using prokinetic agents is essential.[30]

Chronic grass sickness (extra-label): 0.1 mg/kg IM 3 times daily for 7 days, or 0.8 mg/kg PO 3 times daily for 7 days[11]

Promotility agent in adult horses: In a study of 7 clinically healthy male horses, cisapride was administered at a dose of 0.22 mg/kg PO every 8 hours for 2 days.[31] GI transit time, bowel movements per day, and stool weight were significantly improved with cisapride as compared with the control phase (no drug).

RABBITS/RODENTS/SMALL MAMMALS:

Promotility agent (extra-label):

a) **Mice, rats, gerbils, hamsters, guinea pigs, chinchillas**: 0.1 – 0.5 mg/kg PO every 12 hours[32]

b) **Rabbits for GI stasis**: 0.5 mg/kg PO every 6 to 12 hours. With IV or SC fluids, depending on the amount of dehydration, feeding a high-fiber slurry, with or without metoclopramide (0.2 – 1 mg/kg PO, SC every 6 to 8 hours). Begin after first stools were produced or no intestinal obstruction appreciated. It may be synergistic if used with ranitidine (0.5 mg/kg IV every 24 hours).[33,34]

c) **Ileus if GI tract not obstructed in guinea pigs, chinchillas**: 0.5 mg/kg every 8 to 12 hours (*Route not specified; assume PO*)[35]

Monitoring

- Efficacy
- Adverse effects
- ECG in patients with underlying cardiac disease (eg, arrhythmias) or concurrently receiving other potentially pro-arrhythmic drugs

Client Information

- Side effects are not common, but vomiting, diarrhea, and abdominal discomfort can occur.
- This medicine may be given with or without food.
- Give this medicine as directed by your veterinarian.
- Other medications can interact with cisapride, so be sure to tell your veterinarian and pharmacist what medications (including vitamins, supplements, or herbal therapies) you give your animal, including the amount and time you give each.

Chemistry/Synonyms

Cisapride is a substituted piperidinyl benzamide and is structurally but not pharmacologically related to procainamide and metoclopramide. It is available commercially as a monohydrate, but the potency is expressed in terms of the anhydrate.

Cisapride may also be known as cisapridum or R-51619; many trade names are registered.

Storage/Stability

Unless otherwise instructed by the manufacturer, store cisapride tablets in tight, light-resistant containers at room temperature.

Compatibility/Compounding Considerations

Compounded preparation stability: Cisapride oral suspension compounded from commercially available tablets has been published.[36] Triturating twelve (12) cisapride 10 mg tablets with 60 mL of *Ora-Plus®* and add *Ora-Sweet® qs ad* to 120 mL, with pH finally adjusted to 7 with sodium bicarbonate. This yields a 1 mg/mL oral suspension that retains greater than 90% potency for 60 days stored at both 5°C (41°F) and 25°C (77°F). Although cisapride tablets are no longer commercially available, the active pharmaceutical ingredient powder (medicinal grade) may be used to compound suitable oral suspensions of cisapride. Compounded preparations of cisapride should be protected from light. A cisapride 1 mg/mL suspension formulated in a 1:1 combination of simple syrup and methylcellulose 1% was found to be stable for 28 days at room temperature and for 91 days when refrigerated.[37] **NOTE:** Medicinal-grade cisapride should be purchased from FDA-approved pharmacies and must be of USP quality. The USP has an approved monograph with stability information.

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information. Anecdotally, compounded cisapride injection is incompatible when mixed in the same syringe as cefazolin injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

Because of adverse effects in humans, cisapride has been removed from the US market. It may be available from compounding pharmacies.

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Cisplatin

(***sis***-pla-tin) *Platinol®*

Antineoplastic

Prescriber Highlights

- ► Platinum antineoplastic agent used for a variety of carcinomas and sarcomas
- ► **Systemic use is contraindicated in cats.**
- ► Contraindicated in patients with preexisting significant renal impairment or myelosuppression
- ► Drug-related deaths possible
- ► The most common adverse effects include vomiting (pretreat with antiemetic), nephrotoxicity (use forced saline diuresis), ototoxicity, and myelosuppression. Many other adverse effects are possible.
- ► Must be given as slow IV infusion; rapid administration (less than 5 minutes) may increase toxicity
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies cisplatin as a hazardous drug; use appropriate precautions when handling; it is teratogenic, fetotoxic, and may cause azoospermia.

Uses/Indications

The systemic use of cisplatin is presently limited to treatment of dogs with a variety of neoplastic diseases including squamous cell carcinoma, transitional cell carcinoma, ovarian carcinoma, osteosarcoma, nasal carcinoma, and thyroid adenocarcinoma. There is some evidence that efficacy for transitional cell carcinoma can be enhanced with concurrent NSAIDs.[1]

Cisplatin may also be useful for the palliative control of neoplastic pulmonary effusions after intracavitary administration.[2,3]

Intralesional injections of compounded cisplatin suspension in oil or as cisplatin-impregnated beads have been used for intralesional treatment of skin tumors (sarcoids) in horses. Cisplatin also shows some promise as an electrochemotherapy agent for treating incompletely excised mast cell tumors or sarcomas[4] in dogs,[5] sarcoids in horses,[6] incompletely excised injection site sarcomas in cats,[7] (ie, injected into tumor margins, *not* systemically administered), and potentially fibromas in birds.[8]

Cisplatin has also been used successfully as a topical treatment for equine hoof cankers.[9]

Various studies have investigated the use of liposomal cisplatin and cisplatin in hyaluronan nanoparticle carriers; however, current data do not support the use of these formulations.[10–13]

Pharmacology/Actions

Cisplatin is an antineoplastic agent. Its chemical reactivity is nonspecific, but the primary cytotoxic effect is thought to be due to intra- and interstrand DNA cross-linking that causes single- and double-stranded DNA breakage, impairs DNA replication, RNA transcription and protein synthesis, leading to cell death and inhibition of tumor growth.

Acquired resistance to cisplatin has been reported and is thought to be due to several mechanisms.[14]

Pharmacokinetics

After administration, the drug concentrates in the liver, lungs, ovaries, uterus, and kidneys. Cisplatin is highly protein bound (90%) and is renally excreted.

In dogs, cisplatin exhibits a biphasic elimination profile. The initial plasma half-life is short (≈20 to 50 minutes), but the terminal phase is much longer (≈60 to 80 hours). Approximately 80% of a dose can be recovered as free platinum in the urine within 48 hours of cisplatin dosing in dogs.[15]

Contraindications/Precautions/Warnings

Systemic cisplatin use is contraindicated in cats because of severe dose-related primary pulmonary toxicities (dyspnea, hydrothorax, pulmonary edema, mediastinal edema, and death). Death can occur within 2 to 4 days of administration. Cats given intralesional chemotherapy have also developed sarcomas at the injection site.[16] Cisplatin is also contraindicated in patients with significant preexisting renal impairment, myelosuppression, or a history of hypersensitivity to it or other platinum-containing compounds (eg, carboplatin).

Cisplatin-induced nephrotoxicity is dose-related. Ensure adequate hydration before, during, and after administration and monitor renal values. Because of the diuresis required prior to and after dosing, cisplatin should be used with caution in patients with congestive heart failure. Cumulative renal toxicity, ototoxicity, and neurotoxicity have been reported in humans. Ocular toxicity has also been reported in humans with standard doses. Cisplatin should **not** be administered IM or SC due to the risk for tissue irritation.

Cisplatin is classified as a highly emetogenic chemotherapeutic agent; patients should be premedicated with antiemetics.[17]

Owners must understand the importance of immediately reporting any signs associated with toxicity (eg, abnormal bleeding, bruising, abnormal urination, depression, infection, shortness of breath).

Do not confuse CISplatin with CARBOplatin. Consider using tall man lettering when writing orders or prescriptions. Cisplatin is considered a high alert medication (medication that requires special safeguards to reduce the risk for errors). Consider instituting practices such as redundant drug dosage and volume checking and special alert labels. [18]

Aluminum can react with cisplatin, causing precipitates and loss of potency. Thus, for the preparation or administration of cisplatin, needles or administration sets containing aluminum parts should NOT be used.[17]

The National Institute for Occupational Safety and Health (NIOSH) classifies cisplatin as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[19]

Adverse Effects

In dogs, the most frequent adverse effect seen after cisplatin treatment is vomiting, usually occurring within 6 hours after dosing and can persist for 1 to 6 hours. Maropitant, ondansetron, dolasetron, metoclopramide, and butorphanol have all been used successfully as antiemetics when given prior to cisplatin administration.

Nephrotoxicity is the dose-limiting toxicity in humans. Nephrotoxicity is cumulative and dose related. Diuresis and adequate hydration can significantly reduce the incidence and severity of nephrotoxicity in the majority of dogs. Methimazole 40 mg/kg IV has been demonstrated in experimental models to protect against cisplatin-induced nephrotoxicity in dogs.[20,21] Other agents being investigated to reduce cisplatin-induced nephrotoxicity include edaravone[22] and vitamin E/cod liver oil[23]; however, further research is required for these agents.

Ototoxicity (high-frequency permanent hearing loss and tinnitus) has been reported, but incidence in dogs is not known. Coadministration of antioxidants (eg, vitamins A and E, glutathione) has been proposed to help protect against cisplatin-induced ototoxicity. The use of these supplements is somewhat controversial, as theoretically they could also reduce cisplatin's antitumor efficacy.[24] In humans, ototoxicity is cumulative.

Other adverse effects include myelosupppression (thrombocytopenia, granulocytopenia), anorexia, diarrhea (including hemorrhagic diarrhea), seizures, peripheral neuropathies, electrolyte abnormalities (eg, hypokalemia, hypomagnesemia), hyperuricemia, increased liver enzymes, anaphylactic reactions, and death. Some dogs receiving chemotherapy will have minor hair coat changes (eg, shagginess, loss of luster). Breeds with continuously growing hair coats (eg, poodles, terriers, Afghan hounds, or old English sheepdogs) are more likely to experience significant alopecia.

Reproductive/Nursing Safety

For sexually intact patients, verify pregnancy status prior to administration. Cisplatin's safe use in pregnancy has not been established. It is teratogenic and embryotoxic in mice.[25] In human males, the drug may cause azoospermia and impaired spermatogenesis.

Cisplatin is excreted in milk. In humans, it is recommended to discontinue nursing if the mother is receiving this drug.

Overdose/Acute Toxicity

The minimum lethal dose in dogs is reportedly 2.5 mg/kg (≈80 mg/m^2). At this dose, a dog exhibited hematological changes and nephrotoxicity. The IV LD_{50} in mice is 11 mg/kg. In humans, overdoses may result in kidney failure, liver failure, deafness, ocular toxicity, severe myelosuppression, nausea/vomiting, neuritis, and death.[17] Treatment is supportive as there is no known antidote.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cisplatin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **gentamicin**): Potential for increased risk for nephrotoxicity and ototoxicity; if possible, delay aminoglycoside administration by at least 2 weeks after cisplatin.
- **Amphotericin B**: Potential for increased nephrotoxicity
- **Carboplatin**: Human patients previously treated with carboplatin have an increased risk for developing neurotoxicity or ototoxicity after receiving cisplatin.
- **Furosemide** (and other **loop diuretics**): Potential for increased nephrotoxicity and ototoxicity
- **Iohexol**: Potential for increased nephrotoxicity
- **Myelosuppressive Agents** (eg, **antineoplastics**, **immunosuppressants**, **iron chelators**): Concurrent use with other bone marrow depressant medication may result in additive myelosuppression; avoid combination when possible.
- **Nonsteroidal Anti-inflammatory Drugs (NSAIDs**; eg, **carprofen, flunixin, meloxicam**): Potential for increased nephrotoxicity
- **Polymyxin B:** Potential for increased nephrotoxicity and ototoxicity
- **QT Prolonging Agents** (eg, **acepromazine, amiodarone, cisapride, quinidine, sotalol**): Potential increased risk for QT interval prolongation, cardiac arrhythmias, and torsade de pointes
- **Tigilanol Tiglate:** The tigilanol tiglate administration protocol does not permit concurrent use of other antineoplastic drugs. Avoid combination.

- **Vaccines** (live and inactivated): Myelosuppressive drugs may diminish vaccine efficacy and enhance adverse effects of vaccines.
- **Verdinexor:** Concurrent use may increase serum concentration of either drug due to competitive inhibition of glutathione S-transferase. Avoid combination if possible or monitor closely for adverse effects of each drug if combination cannot be avoided.

Laboratory Considerations

- None noted

Dosages

NOTES:

1. Because of the potential toxicity of this drug to patients, veterinary personnel, and clients, and because chemotherapy indications, treatment protocols, and monitoring and safety guidelines often change, the following dosages should only be used as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references[26–30] are strongly recommended.
2. Dosages are commonly listed as mg/m^2. Do not confuse with mg/kg doses. See ***Appendix*** for conversion table.
3. Do not confuse CISplatin and CARBOplatin dosages; CARBOplatin doses are much higher.

DOGS:

Potentially susceptible carcinomas and sarcomas (extra-label): The following is a usual dosage range for cisplatin and should only be used as a general guide: Dogs: 50 – 60 mg/m^2 (NOT mg/kg) IV over 20 minutes to several hours every 3 to 5 weeks.[31–33] Dogs must undergo saline diuresis before *and* after cisplatin therapy to reduce the potential for nephrotoxicity.

Intracavitary administration for palliative control of neoplastic pulmonary effusions (extra-label): Administer 0.9% sodium chloride 10 mL/kg/hour IV for 4 hours prior to treating. Then, administer cisplatin 50 mg/m^2 (NOT mg/kg) diluted in 0.9% sodium chloride to a total volume of 250 mL/m^2).[2,3] Warm diluted cisplatin solution to body temperature. Place a 16 gauge over-the-needle catheter into the pleural space using sterile technique. Remove as much pleural fluid as possible and then slowly infuse diluted cisplatin solution through same catheter. Once infusion is completed, remove catheter. May repeat administration every 3 to 4 weeks as needed to control effusion. On resolution, discontinue therapy after the fourth treatment. Restart if neoplastic effusion recurs.

HORSES:

Intralesional injection of skin tumors (extra-label): Following hazardous drug protocols, add cisplatin powder 10 mg to 1 mL of water and 2 mL of medical-grade sesame oil. Resultant solution contains cisplatin 3.3 mg/mL. Inject cisplatin solution at 1 mg/cm^3 of tumor bed intralesionally with a small gauge needle (22 to 25 gauge) attached to an extension set with luer-lock connections. Inject in multiple planes no more than 0.6 to 1 cm apart. Because the volume of tumor is difficult to measure, the rule of thumb is to discontinue injection when fluid extrudes from the skin surface. Because recurrence at the periphery of the treated area is the primary cause of treatment failure, injection into 1 to 2 cm of normal tissue surrounding the tumor has been recommended. Intralesional injection is generally repeated at 2-week intervals for 4 total treatments.[6,34]

Monitoring

- Baseline CBC, serum electrolytes, serum renal and liver chemistry profiles, and urinalysis
- Repeat tests before each dose and as needed if signs of toxicity develop.
  a) Delay scheduled treatments if absolute neutrophil count is less than 2000/µL, platelet count is less than 100,000/µL, serum creatinine is elevated above normal reference range for the patient, or if electrolyte or acid-base imbalance is present.
- Tumor measurement and radiography at least monthly (eg, every 4 to 6 weeks)[1]
  a) Dogs demonstrating complete or partial remission, or stable disease should continue to receive additional cisplatin therapy.
  b) Dogs that have progressive disease should have cisplatin therapy stopped and receive alternate therapies, if warranted.
- Regular neurologic examinations as indicated by clinical presentation.

Client Information

- Care should be taken to avoid contact with the administration site.
- Cisplatin is a chemotherapy (anticancer) drug. The drug and its byproducts can be hazardous to humans and other animals that come in contact with it. The drug and its metabolites will stay in your pet's system for a few days after treatment. Therefore, on the day of and for a few days after treatment, all bodily waste (urine, feces, soiled litter), blood, or vomit should only be handled while wearing disposable gloves.
- If possible, keep treated dog in a separate area of the yard. Clean up all pet waste right away whenever possible. Double bag waste, seal, and throw away in the regular trash.
- If any accidents occur in the house (vomit, urine, feces), absorb as much as possible with paper towels, double bag, and discard in the trash, then clean area with a diluted bleach solution.
- The most common side effects are vomiting and kidney toxicity.
- Bone marrow suppression can occur. The greatest effects on bone marrow usually occur within a few weeks after treatment. Your veterinarian will do blood tests to watch for this, but if you see bleeding, bruising, fever (indicating an infection), or if your animal becomes tired easily or develops shortness of breath, contact your veterinarian immediately.
- Contact your veterinarian immediately if your pet has any signs associated with toxicity (eg, abnormal bleeding, bruising, urination, depression, infection, shortness of breath).
- This medication is considered to be a hazardous drug as defined by the National Institute for Occupational Safety and Health (NIOSH). Talk with your veterinarian or pharmacist about the use of personal protective equipment when handling this medicine.

Chemistry/Synonyms

An inorganic platinum-containing antineoplastic, cisplatin occurs as white powder. It is soluble in water or saline. The drug is also available commercially as a solution for injection that is odorless and clear. Cisplatin injection (premixed solution) has a pH of 3.7 to 6.

Cisplatin may also be known as cis-Platinum II, cis-DDPCDDP, cis-diamminedichloroplatinum, cisplatina, cisplatinum, cis-platinum, DDP, NSC-119875, Peyrone's salt, or platinum diamminodichloride; many trade names are available.

Storage/Stability

The injection should be protected from light and stored at 20°C to 25°C (68°F-77°F); do not refrigerate, as a precipitate may form. During infusion, the injection should be protected from direct bright sunlight, but does not need to be protected from normal room incandescent or fluorescent lights. The manufacturer recommends that diluted solutions be administered within 24 hours as the solution contains no preservatives. Following initial entry, vials are stable at room temperature for 7 days under fluorescent light and 28 days protected from light.

Compatibility/Compounding Considerations

Compatibility is dependent on factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Cisplatin is **compatible** with 5% dextrose in sodium chloride (0.2%, 0.45%, or 0.9%) and sodium chloride (0.225%, 0.3%, 0.45%, or 0.9%) for dilution. It is also **compatible** in syringes with bleomycin sulfate, cyclophosphamide, fluorouracil, furosemide, heparin sodium, leucovorin calcium, methotrexate, metoclopramide, vinblastine sulfate, and vincristine sulfate.

Cisplatin is **incompatible** with amphotericin B, cefepime, diazepam, regular insulin, lansoprazole, pantoprazole, piperacillin-tazobactam, and 2 in 1 TPN mixtures for y-site administration.

Because aluminum can displace platinum from cisplatin, the solution should not be prepared, stored, or administered where aluminum-containing items can come into contact with the solution. If cisplatin comes into contact with aluminum, a black precipitate will form and the product should not be used.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Cisplatin Injection: 1 mg/mL in 50 mL, 100 mL, and 200 mL multidose vials; *Platinol-AQ®*; generic; (Rx)

Cisplatin lyophilized powder for injection: 10 and 50 mg in vials; *Platinol®*; (Rx)

Cisplatin powder or compounded formulations appropriate for intralesional injection may be available from compounding pharmacies.

Citrate, Potassium

(***si***-trate) *Urocit-K®*

Alkalinizing Agent

Prescriber Highlights

- ► Orally administered precursor to bicarbonate; used to treat hypokalemia and for urinary alkalization and treatment of chronic metabolic acidosis; may be useful in prevention of calcium oxalate urolith formation
- ► Contraindications include severe myocardial damage, acute or chronic kidney failure, active UTI with any type of urolithiasis, hyperkalemia, conditions that predispose to hyperkalemia (ie, hypoadrenocorticism, diabetic ketoacidosis, acute dehydration) and GI ulcers. Potassium citrate tablets are contraindicated in patients with delayed gastric emptying, esophageal disease, or intestinal obstruction.
- ► Most prevalent adverse effect is GI distress, but hyperkalemia, fluid retention, and metabolic alkalosis can also occur. Severe GI adverse effects (eg, GI perforation and ulceration) may also occur especially with the solid forms of potassium citrate.
- ► Adequate serum electrolyte and urine pH monitoring is mandatory.

Uses/Indications

Potassium citrate (*Urocit-K®*) has been used to increase urine pH to make conditions less favorable for the formation of calcium oxalate and uric acid uroliths. Compounds containing potassium (eg, potassium citrate) can also be used for treatment of hypokalemia. As a bicarbonate precursor, potassium citrate may help inhibit the increased activity of osteoclasts and improve bone health in patients with metabolic acidosis.

The optimal dosage and overall efficacy of potassium citrate supplementation on the reduction of calcium oxalate uroliths in veterinary patients have not been fully elucidated.[1] A single study evaluating its use in normal dogs found no difference in relative supersaturation (RSS) of calcium oxalate and failed to demonstrate a significant increase in urinary citrate between control and study groups, although a subset of miniature schnauzers experienced a significant decrease in calcium oxalate RSS and increased urinary citrate excretion. A difference in urinary pH was detected between groups, with the study group having a higher urinary pH for a longer part of the day than the control group.[2]

Potassium citrate may be beneficial for treatment of hypokalemia in patients with Fanconi syndrome but cannot replace sodium bicarbonate in correcting metabolic acidosis. It should be noted that this treatment (ie, Gonto protocol) has not been evaluated in a clinical study but is used extensively in the management of Fanconi syndrome.[3,4]

Alkalization of urine can help restore pH to inhibit new calcium nephrolith formation in humans with distal renal tubular acidosis.

Pharmacology/Actions

Citrate salts are oxidized in the liver to form bicarbonate, thereby acting as systemic and urinary alkalinizing agents. Specifically, metabolism of absorbed citrate produces an alkaline load, increasing urinary pH, and raises urinary citrate by affecting citrate clearance.[5] The citric acid component of multicomponent products is converted only to carbon dioxide and water and has only a temporary effect on systemic acid–base status. Citrate also forms a complex with calcium to decrease urinary concentrations of calcium oxalate. The urinary alkalinizing effects of the citrate increase the solubility of uric acid.

Pharmacokinetics

Absorption and oxidation are nearly complete after oral administration; less than 5% of a citrate dose is excreted unchanged.[6]

Contraindications/Precautions/Warnings

Contraindications for products containing potassium citrate include aluminum toxicity, severe myocardial damage, severe renal impairment, hyperkalemia, acute kidney injury (with azotemia or oliguria), and calcium or struvite uroliths associated with an active UTI. Additional contraindications for potassium citrate include conditions that predispose to hyperkalemia (eg, adrenal insufficiency, acute dehydration, advanced kidney disease, uncontrolled diabetes mellitus). Potassium citrate *tablets* are particularly contraindicated in patients with GI ulceration or with conditions that increase the risk of GI mucosal damage due to prolonged contact with the tablet (eg, delayed gastric emptying conditions, esophageal compression, or intestinal obstruction).

Potassium citrate should be used with caution in patients with impaired potassium excretion (eg, heart failure, chronic renal failure), or in patients with hepatic impairment as they may have decreased ability to metabolize citrate to bicarbonate.

Adverse Effects

The primary adverse effects noted with potassium citrate products are GI in nature (eg, nausea, vomiting, diarrhea). Potassium citrate products have the potential to cause hyperkalemia, especially in animals predisposed to developing hyperkalemia (eg, adrenal insufficiency, acute dehydration, advanced kidney disease, uncontrolled diabetes mellitus). Because patients with hyperkalemia may present subclinically until cardiovascular collapse or muscle paralysis occurs, periodic electrolyte monitoring is recommended when prescribing potassium citrate. See ***Monitoring***.

Oral liquids containing potassium citrate can have a bitter taste, making patient acceptance difficult.

Solid forms of potassium citrate may cause esophageal, gastric or

intestinal ulcers, obstructions, or perforations; this risk may be increased in patients with pre-existing GI disease.

Reproductive/Nursing Safety

As long as dosages do not result in hypernatremia, hyperkalemia, or metabolic alkalosis of the dam, potassium citrate products should not cause fetal harm.

No specific data are available on the safety of citrates during nursing, but no documented adverse effects have been reported.

In humans, potassium citrate is most likely compatible during pregnancy and nursing.[7]

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Signs related to overdose and acute toxicity are generally related to GI distress (eg, diarrhea, nausea, vomiting) and ulceration, metabolic alkalosis, or hyperkalemia. Treatment is based on clinical signs with IV fluids and/or other supportive care (eg, GI mucosal protectants) as needed. Hyperkalemia, hypernatremia, and metabolic alkalosis should be treated if warranted.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving citrates and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aluminum-Containing Phosphate Binders:** Increased risk for aluminum toxicity and systemic alkalosis, particularly in patients with advanced kidney disease
- **Antacids**: Citrate alkalinizers used with antacids (particularly those containing bicarbonate or aluminum salts) may cause systemic alkalosis and aluminum toxicity (aluminum antacids only), particularly in animals with advanced kidney disease. Sodium citrate combined with sodium bicarbonate may cause hypernatremia and, in animals with pre-existing uric acid stones, the development of calcium stones.
- **Anticholinergic Agents** (eg, **aminopentamide, atropine, oxybutynin, tricyclic antidepressants**): Anticholinergic drugs may reduce GI motility and therefore prolong GI transit time, which increases the risk for GI erosions or ulceration from potassium citrate tablets.
- **Antidiarrheal Agents** (eg, **diphenoxylate, loperamide**): Prolonged GI transit time may increase the risk for GI erosions or ulceration from extended-release potassium citrate formulations.
- **Aspirin**: Alkalinized urine can increase the excretion of salicylates.
- **Digoxin**: Hyperkalemia increases the risk for digoxin-induced cardiac toxicity.
- **Fluoroquinolones**: The solubility of ciprofloxacin and enrofloxacin is decreased in an alkaline environment. Patients with alkaline urine should be monitored for signs of crystalluria.
- **Lithium**: Alkalinized urine can decrease excretion of lithium.
- **Methenamine**: Concurrent use with methenamine is not recommended, as it requires an acidic urine for efficacy.
- **Opioids** (eg, **butorphanol**, **morphine**, **tramadol**): May prolong GI transit time, increasing the risk for GI erosions or ulceration from extended-release potassium citrate formulations
- **Phenobarbital**: Alkalinized urine can increase excretion of phenobarbital.[8]
- **Quinidine**: Alkalinized urine can decrease excretion of quinidine.
- **Sympathomimetic Agents** (eg, **amphetamines, ephedrine, pseudoephedrine**): Alkalinized urine can decrease excretion of these drugs and therefore increase the risk for adverse effects.
- **Tetracyclines**: Alkalinized urine can decrease excretion of tetracyclines.

With potassium citrate products, the following agents may lead to increases in serum potassium concentrations (including severe hyperkalemia), particularly in patients with advanced kidney disease:

- **ACE Inhibitors** (eg, **benazepril**, **enalapril, lisinopril**)
- **Angiotensin Receptors Blockers** (**ARBs**; eg, **telmisartan**)
- **Heparin**
- **Nonsteroidal Anti-inflammatory Drugs** (**NSAIDs**; eg, **carprofen, meloxicam**)
- **Potassium-Containing Drugs and Foods**
- **Potassium-Sparing Diuretics** (eg, **spironolactone; triamterene**)

Dosages

NOTE: No prospective studies supporting any dosage protocol were noted.

DOGS:

Adjunctive therapy to inhibit calcium oxalate formation (extra-label): Potassium citrate 50 – 75 mg/kg PO every 12 hours.[2] If urine pH is already greater than 7.5, do not use potassium citrate. Usually used with dietary therapy; some recommend concurrent use of hydrochlorothiazide.

Adjunctive therapy of chronic kidney disease as a potassium supplement and alkalinizing agent (extra-label): Potassium citrate 40 – 60 mg/kg (0.4 – 0.6 mEq/kg) PO every 8 to 12 hours[9]

Fanconi syndrome, as part of the Gonto protocol (extra-label): Dosing based on serum potassium concentrations[4]:

- K+= 1.5 to 2.0 mEq/L: give 15 mEq (1620 mg potassium citrate) PO every 12 hours
- K+= 2.1 to 2.75 mEq/L, give 10 mEq (1080 mg potassium citrate) PO every 12 hours
- K+= 2.76 to 3.75 mEq/L, give 5 mEq (540 mg potassium citrate) PO every 12 hours

CATS:

Adjunctive therapy to inhibit calcium oxalate formation (extra-label): Initial potassium citrate dosage recommendations range from 50 – 75 mg/kg PO every 12 hours. Efficacy is not well-established in cats.

Adjunctive therapy of hypokalemia associated with chronic kidney disease (extra-label): Below are suggested starting dosages. Dose should be adjusted based on serial measurements of serum potassium during treatment.

a) 40 – 60 mg/kg PO daily divided into 2 to 3 doses[9,10]
b) From a retrospective study, 0.04 – 1.34 mEq/kg OR 0.25 – 2.8 mEq/cat (NOT mEq/kg) PO daily[11]
c) 1 – 4 mEq/cat (NOT mEq/kg) PO every 12 hours[12]

Adjunctive therapy of metabolic acidosis associated with chronic kidney disease (extra-label): Start with 40 – 60 mg/kg PO every 8 to 12 hours when renal diet is insufficient to maintain appropriate acid-base status with CKD; may also be used in conjunction with oral sodium bicarbonate.[9] Dose adjustments should be based on serial measurements of acid-base status once therapy has started.

Monitoring

Depending on patient's condition, product chosen, and reason for use:

- Serum potassium, sodium, bicarbonate, and chloride:
  - *Dogs:* Monitor serum potassium and bicarbonate concentrations every 7 to 14 days to establish the final maintenance dosage when used as potassium supplement and urinary alkalinizer. Target serum bicarbonate concentration should be between 18 to 24 mmol/L.[13]
  - *Cats*: Monitor serum potassium and bicarbonate concentrations every 7 to 14 days to establish the final maintenance dosage. Target serum bicarbonate concentration should be between 15 to 24 mmol/L.[14]
- Venous blood gas
- Urinalysis with urine pH
- Serum BUN, creatinine

Client Information

- This medication can be used to prevent the formation of calcium oxalate bladder and kidney stones. In animals with chronic kidney disease, it can be used to increase blood potassium concentrations and prevent acids from accumulating in the body.
- Usually given with or mixed into food. Provide free access to water after each dose.
- Use of this medication requires periodic laboratory monitoring to ensure patient safety and adequate treatment.

Chemistry/Synonyms

Potassium citrate occurs as odorless transparent crystals or a white granular powder with a cooling, saline taste. It is freely soluble in water. There is ≈1 mEq of potassium in every 108 mg of potassium citrate.

Potassium citrate may also be known as citrate of potash or citric acid tripotassium salt monohydrate. Sodium citrate and citric acid solutions may also be known as Shohl's solution.

Storage/Stability

Store potassium citrate products in tight containers at room temperature of 20°C to 25°C (68°F-77°F) unless otherwise recommended by the manufacturer.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Potassium Citrate Tablets: 675 mg (6.25 mEq of potassium); *CitraVet*® (also contains liver flavoring), generic; (OTC). Labeled for dogs and cats, but does not appear to be an FDA-approved product

Potassium Citrate and Fatty Acids Granules: Each 5 g (1 scoop) contains potassium citrate 300 mg (≈2.8 mEq of potassium) and total fatty acids 423 mg; also contains several amino acids—quantities not labeled; *Nutrived*® *Potassium Citrate Granules for Cats and Dogs*; (OTC). Does not appear to be an FDA-approved product

Potassium Citrate and Cranberry Extract Chewable Tablets: Potassium citrate 680 mg (6.25 mEq of potassium) and cranberry extract 113.3 mg; generic; (OTC). Does not appear to be an FDA-approved product

Potassium Citrate, Cranberry Extract, and Fatty Acids Granules: Each 5 g (1 scoop) contains potassium citrate 300 mg (≈2.8 mEq of potassium), cranberry extract 50 mg, and total fatty acids 423 mg; generic; (OTC). Does not appear to be an FDA-approved product

HUMAN-LABELED PRODUCTS:

Potassium Citrate Extended-Release Oral Tablets: 5 mEq (540 mg), 10 mEq (1080 mg), and 15 mEq (1620 mg); *Urocit-K*®, generic; (Rx)

Potassium Citrate/Sodium Citrate Combinations:

Tablets: Potassium citrate 50 mg and sodium citrate 950 mg; *Citrolith*®; (Rx)

Syrup: Potassium citrate 550 mg, sodium citrate 500 mg, and citric acid 334 mg/5 mL (1 mEq of potassium, 1 mEq of sodium per mL; equivalent to 2 mEq of bicarbonate) in 120 mL and 480 mL; *Polycitra*®; (Rx)

Solution: Potassium citrate 550 mg, sodium citrate 500 mg, and citric acid 334 mg /5 mL (1 mEq of potassium, 1 mEq of sodium per mL; equivalent to 2 mEq of bicarbonate) in 120 mL and 480 mL; *Polycitra-LC*®; (Rx)

Potassium citrate 1100 mg and citric acid 334 mg/5 mL (2 mEq of potassium/mL; equivalent to 2 mEq of bicarbonate) in 120 mL and 480 mL; *Polycitra-K*®; (Rx)

Crystals for reconstitution: potassium citrate 3300 mg and citric acid 1002 mg per UD packet (equivalent to 30 mEq of bicarbonate) in single-dose packets; *Polycitra-K*®; (Rx)

Potassium Citrate, Sodium Citrate/Citric Acid Solutions:

Potassium citrate monohydrate 550 mg, sodium citrate dihydrate 500 mg, and citric acid monohydrate 334 mg per 5 mL (1 mEq of potassium and 1 mEq of sodium per mL; equivalent to 2 mEq of bicarbonate) in 60-oz bottles; *Cytra-LC*®; (Rx)

Potassium citrate monohydrate 1100 mg and citric acid monohydrate 334 mg per 5 mL (2 mEq of potassium per mL; equivalent to 2 mEq of bicarbonate) in 473 mL; *Cytra-K*®; (Rx)

Potassium citrate monohydrate 3300 mg and citric acid monohydrate 1002 mg (30 mEq of potassium; equivalent to 30 mEq of bicarbonate) in unit-dose packets; *Citra-K Crystals*; (Rx)

For the complete list of references, see **wiley.com/go/budde/plumb**

Clarithromycin

(klar-***ith***-ro-my-sin) *Biaxin*®

Macrolide Antibiotic

Prescriber Highlights

- ► Macrolide antibiotic that may be useful for treating atypical mycobacterial infections or *Helicobacter* spp infections in dogs, cats, and ferrets and *Rhodococcus equi* infections in foals.
- ► Use with caution in hindgut fermenters (eg, adult horses, rabbits).
- ► Appears to be well tolerated by domestic animals, but common adverse effects include GI upset.
- ► Many potential drug interactions

Uses/Indications

In small animal medicine, clarithromycin is primarily of interest in treating atypical mycobacterial and *Helicobacter* spp infections in cats and ferrets. However, one study used quadruple therapy (amoxicillin, clarithromycin, metronidazole, and a proton pump inhibitor) and demonstrated this drug combination did not eradicate *Helicobacter pylori* in 4/13 treated cats and might only cause transient suppression.[1] A 21-day treatment course is recommended for eliminating *Helicobacter* spp infections in dogs.[2] In equine medicine, clarithromycin may be used to treat *Rhodococcus equi* infections in foals, but drug interactions with rifampin and development of resistance[3] raise questions for its usefulness.

The World Health Organization has designated clarithromycin

as a Critically Important, Highest Priority antimicrobial for human medicine.[4]

Pharmacology/Actions

Similar to other macrolide antibiotics, clarithromycin penetrates susceptible bacterial cell walls and binds to the 50S ribosomal subunit, inhibiting protein synthesis. The macrolide class of antibiotics is usually bacteriostatic but may be bactericidal at high concentrations in susceptible organisms. Clarithromycin's spectrum of activity is similar to that of erythromycin, but it also has activity against several bacteria that are not easily treated with other antibiotics (eg, mycobacteria). The activity against gram-positive aerobic cocci is also similar to that of erythromycin. Clarithromycin is typically not effective against methicillin-resistant staphylococci. It is also ineffective against *Pseudomonas,* Enterobacterales (eg, *Escherichia coli*), and enterococci. Clarithromycin has activity against *Rhodococcus equi*. It has activity against gram-negative aerobic bacteria, including *Haemophilus influenzae, Pasteurella multocida, Legionella pneumophila, Bordetella pertussis,* and *Campylobacter* spp. Clarithromycin has inhibitory activity against a variety of mycobacteria, including *Mycobacterium avium complex* and *Mycobacterium leprae*, and good activity against *Mycoplasma pneumoniae* and *Ureaplasma urealyticum*. Other organisms where clarithromycin may have therapeutic usefulness include *Nocardia* spp, *Toxoplasma gondii, H pylori, Borrelia burgdorferi, Bartonella* spp, and *Cryptosporidium parvum.*

Clarithromycin also has immunomodulatory effects via impacts on cell-mediated immunity, but the clinical implications are not clear. It has been suggested that clarithromycin can have effects against biofilm production by staphylococci. One study showed no impact on *Staphylococcus pseudintermedius*.

Pharmacokinetics

In dogs, clarithromycin bioavailability ranges from 60% to 83%. Higher values are obtained when given to fasted animals.[5] Elimination half-life following oral administration is ≈4.6 to 5.9 hours.

In foals, clarithromycin is apparently well absorbed (≈50% to 60%) after intragastric administration, with peak serum concentrations occurring about 1.6 hours after dosing. The elimination half-life is about 5.4 hours.[6] However, when it is used with chronic rifampin treatment, oral bioavailability can be reduced by 90%.[7]

Clarithromycin is well distributed throughout the body, reaching therapeutic concentrations in body fluids and most tissues, including the eye and prostate.

Contraindications/Precautions/Warnings

Clarithromycin is contraindicated in human patients who are hypersensitive to it or other macrolide antibiotics (eg, erythromycin, azithromycin).

Use clarithromycin cautiously in hindgut fermenters (eg, adult horses, rabbits, guinea pigs), as these species appear to be at increased risk for developing diarrhea and enteritis.

Adverse Effects

Clarithromycin is relatively well tolerated in dogs, cats, ferrets, and foals. Like all orally administered antibiotics, GI disturbances (eg, inappetence, vomiting, diarrhea) are possible. The incidence of diarrhea in foals may be higher than with other macrolides. Pinnal or generalized erythema may be associated with this drug when used in cats. Orange staining of skin is possible. Clarithromycin may cause anhidrosis in foals but to a lesser degree than erythromycin.[8]

Adverse effects in humans include GI adverse effects (primarily nausea, vomiting, abdominal pain, abnormal taste, diarrhea)[9] that, when compared with erythromycin, are milder and occur less frequently. Approximately 4% of treated humans develop transient, mildly elevated BUN levels. Rarely, prolonged QT interval, hepatotoxicity, thrombocytopenia, or hypersensitivity reactions have been reported. Pseudomembranous colitis secondary to *Clostridium difficile* has been reported after clarithromycin use.[9,10]

Reproductive/Nursing Safety

Teratogenic studies in rats and rabbits failed to document any teratogenic effects in some studies; however, at high dosages (yielding plasma concentrations 2 to 17 times those achieved in humans with the maximum recommended dosages) in pregnant rats, rabbits, and monkeys, some teratogenic effects (cleft palate, cardiovascular abnormalities, fetal growth retardation) were noted.[9]

Clarithromycin is excreted into the milk of lactating animals, and concentrations may be higher in milk than in the dam's plasma, but this is unlikely to be of clinical significance.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Generally, overdoses of clarithromycin are usually not serious with only GI effects seen. A dog that ingested clarithromycin 5 g/kg developed nausea, vomiting, and hemorrhage.[11,12] Patients ingesting large overdoses may be given activated charcoal with a cathartic to remove any unabsorbed drug. Forced diuresis, peritoneal dialysis, or hemodialysis do not appear to be effective in removing clarithromycin from the body.

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as poison control centers' contact information, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clarithromycin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticoagulants** (eg, **rivaroxaban, warfarin**): Clarithromycin may potentiate the effects of oral anticoagulant drugs.
- **Colchicine**: Increased risk for colchicine toxicity. In humans with normal renal or hepatic function a reduced colchicine dose is recommended, but concurrent use is contraindicated with renal or hepatic impairment.
- **Cyclosporine**: Clarithromycin can significantly increase oral bioavailability of cyclosporine in cats and dogs and reduce dosage requirements by 30% to 35%.[13,14]
- **Digoxin**: Clarithromycin may increase the serum concentrations of digoxin.
- **Leflunomide**: Increased risk for hepatotoxicity
- **QT Interval Prolongation Drugs** (eg, **amiodarone, cisapride, procainamide, sotalol**): Combinations with clarithromycin may increase the risk for QT prolongation. Concurrent cisapride and clarithromycin are contraindicated in humans.
- **Rifampin**: Can significantly decrease the oral bioavailability of clarithromycin in foals and can negate its efficacy.[7,15]
- **Zidovudine**: Clarithromycin may decrease serum concentrations of zidovudine.

Like erythromycin, clarithromycin can inhibit the metabolism of other drugs that use the CYP3A subfamily of the cytochrome P450 enzyme system, thereby increasing exposure to those agents. Depending on the therapeutic index of the drug(s) involved, therapeutic drug monitoring and/or dosage reduction may be required if the medications must be used together. These drugs include:

- **Azole Antifungals** (eg, **itraconazole, ketoconazole**): May in-

crease concentration of each other, and also increase risk for QT interval prolongation
- **Benzodiazepines** (eg, **alprazolam, diazepam, midazolam**)
- **Bromocriptine, Cabergoline**
- **Buspirone**
- **Calcium Channel Blockers** (**amlodipine, diltiazem**)
- **Cannabidiol**
- **Chemotherapeutic Agents** (**doxorubicin, vinblastine, vincristine**): Clarithromycin may increase the serum concentration of chemotherapy drugs.
- **Corticosteroids** (eg, **dexamethasone**, **methylprednisolone, triamcinolone**)
- **Disopyramide** (also risk for QT interval prolongation)
- **Ketamine**
- **Mitotane** (also may decrease clarithromycin concentration)
- **Opioid Analgesics** (eg, **fentanyl, hydrocodone, methadone, morphine**)
- **Quinidine** (also risk for QT interval prolongation)
- **Sildenafil**
- **Tacrolimus** (**systemic**)
- **Theophylline/Aminophylline**

Laboratory Considerations
- None noted

Dosages

DOGS:

Susceptible infections (extra-label): 5 – 10 mg/kg PO twice daily

Severe or refractory cases of canine leproid granuloma syndrome (extra-label): Clarithromycin 15 – 25 mg/kg total daily dose PO divided every 8 to 12 hours combined with rifampin 10 – 15 mg/kg PO once daily. Treatment is usually continued for 4 to 8 weeks until lesions are substantially reduced in size and ideally have resolved completely.[16]

CATS:

Susceptible infections (extra-label): 7.5 mg/kg PO every 12 hours

Feline leprosy syndrome and other opportunist mycobacteria (extra-label):

NOTE: Combination therapy using two or more antibiotics has been recommended and appears more efficacious than single antibiotic therapy. Prolonged treatment courses are often needed (2 to 14 months) and should be continued for at least 2 months beyond the resolution of the lesions. Several treatment protocols have been suggested (see below). No evidence was located that clearly supports one over the other.

a) Clarithromycin 7.5 – 15 mg/kg PO twice daily in combination with pradofloxacin 3 mg/kg PO once daily and *either* rifampin 10 – 15 mg/kg PO once daily OR clofazimine 4 – 10 mg/kg PO once daily (alternatively, clofazimine can be given at 25 – 50 mg/cat (NOT mg/kg) PO every 24 to 48 hours)[17]

b) Clarithromycin 62.5 mg/cat (NOT mg/kg) PO every 12 hours combined with doxycycline 5 mg/kg PO every 12 hours, or enrofloxacin (or marbofloxacin) 5 mg/kg PO once daily, or clofazimine 8 – 12 mg/kg PO once daily, and/or rifampin 10 – 15 mg/kg PO once daily[18]

***Nocardia* (*N nova*) infections** (extra-label): Combination therapy with amoxicillin 20 mg/kg PO twice daily with clarithromycin 62.5 – 125 mg/cat (NOT mg/kg) PO twice daily and/or doxycycline 5 mg/kg or higher PO twice daily[19]

***H pylori* infections** (extra-label):

a) Using quadruple therapy: Amoxicillin 20 mg/kg PO twice daily, metronidazole 20 mg/kg PO twice daily, clarithromycin 7.5 mg/kg PO twice daily, and omeprazole 0.7 mg/kg every 8 hours for 14 days. Treatment did not eradicate the organism in 4 of 13 cats in the study.[1]

b) Using triple therapy (anecdotal): Amoxicillin 20 mg/kg PO twice daily, clarithromycin 7.5 mg/kg PO twice daily, and metronidazole 10 mg/kg PO twice daily for 14 to 21 days. Further studies are required before clear guidelines can be made. The author recommends a 21-day treatment only for patients with clinical signs associated with infection and that have biopsy-confirmed *Helicobacter* spp infection and gastritis.[20]

HORSES:

***Rhodococcus equi* infection in foals** (extra-label): 7.5 mg/kg PO twice daily in combination with rifampin based on a retrospective study[21]

***Lawsonia intracellularis* (equine proliferative enteropathy [EPE]) infections in foals** (extra-label): Chloramphenicol 50 mg/kg PO every 6 to 8 hours and oxytetracycline 10 mg/kg IV once daily (every 24 hours), followed by doxycycline 10 mg/kg PO every 12 hours or clarithromycin 7.5 mg/kg PO every 12 hours. Treatment length is determined by clinical response, but 3 weeks minimum is recommended.[22]

FERRETS:

***Helicobacter mustelae* infections** (extra-label):

a) Clarithromycin 12.5 mg/kg PO every 12 hours in combination with ranitidine bismuth citrate (**NOTE:** Not currently available in the US but may be available from compounding pharmacies) 24 mg/kg PO every 12 hours for 14 days. Same dosing regimen but given every 8 hours is also published.[23]

b) Clarithromycin 12.5 – 50 mg/kg every 8 to 24 hours with omeprazole at 0.7 mg/kg PO once daily[24]

c) Clarithromycin 12.5 mg/kg PO every 12 hours, along with metronidazole 20 mg/kg PO every 8 hours[25]

Monitoring
- Clinical efficacy
- Adverse effects

Client Information
- This medicine can be given with or without food. Give with food if stomach upset or vomiting occurs.
- May cause stomach and intestinal pain and cramping when given by mouth
- Cats may experience reddening of the skin (especially the ears) while taking this medicine.
- Do not give this medicine to rabbits, gerbils, guinea pigs, hamsters, or adult horses/ponies.
- Many possible drug interactions. Tell your veterinarian and pharmacist what other medications you are giving your animal.
- If using the oral suspension, keep it at room temperature and discard it after 14 days. Do not refrigerate.

Chemistry/Synonyms
Clarithromycin is a semi-synthetic macrolide antibiotic related to erythromycin. It differs from erythromycin by the methylation of position 6 in the lactone ring. Clarithromycin occurs as a white to off-white crystalline powder. It is practically insoluble in water, slightly soluble in ethanol, and soluble in acetone. It is slightly soluble in a phosphate buffer at a pH of 2 to 5.

Clarithromycin may also be known as 6-*O*-methylerythromycin, TE-031, and A-56268. *Biaxin*® is a common trade name.

Storage/Stability
Store tablets in well-closed containers at controlled room temperature (20°C to 25°C [68°F-77°F]) with excursions permitted to 15°C to 30°C (59°F-86°F). Store the granules for reconstitution into an oral

suspension in well-closed containers at 15°C to 30°C (59°F to 86°F). After reconstitution, store the oral suspension at room temperature (do not refrigerate) and discard any unused drug after 14 days.

Compatibility/Compounding Considerations

No specific information was noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS:

Clarithromycin Regular and Film-Coated Oral Tablets: 250 mg and 500 mg; Extended-release Tablets: 500 mg and 1000 mg; *Biaxin®* & *Biaxin XL®*, generic; (Rx).

Clarithromycin Granules for Oral Suspension: 125 mg/5 (25 mg/mL) mL and 250 mg/5 mL (50 mg/mL) in 50 mL and 100 mL; *Biaxin®*, generic; (Rx).

A pre-packaged combination containing lansoprazole, amoxicillin, and clarithromycin for *H pylori* in humans is marketed as *Prevpak®*; (Rx).

References

For the complete list of references, see **wiley.com/go/budde/plumb**

Clemastine

(***klem***-as-teen) *Dayhist®*

First-Generation Antihistamine

Prescriber Highlights

- ► Oral antihistamine with greater anticholinergic activity and fewer sedative effects as compared with other first-generation antihistamines
- ► Poor pharmacokinetic profile for oral administration in dogs and horses
- ► Use with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyloroduodenal obstruction.
- ► Most likely adverse effects in dogs are sedation, paradoxic hyperactivity, and anticholinergic effects (eg, dryness of mucous membranes); in cats, diarrhea

Uses/Indications

Clemastine may be used for relief of clinical signs of histamine$_1$-related allergic conditions. One uncontrolled study investigating the efficacy of clemastine in dogs with atopic dermatitis reported that 29.1% showed good to excellent response[1] however, a retrospective study in dogs with canine atopic dermatitis observed that clemastine had a lower positive response rate compared with other H_1-receptor antihistamines.[2] Guidelines for atopic dermatitis treatment in dogs state that antihistamines have modest efficacy; they should be given continuously (ie, daily) as preventative therapy before an acute flare.[3,4] In allergic cats, one open clinical trial showed that pruritus improved in 50% of the cats when clemastine was administered at 0.68 mg/cat (NOT mg/kg) PO twice daily, as compared with 0.34 mg/cat (NOT mg/kg) PO twice daily for 14 days.[5]

Pharmacology/Actions

Like other H_1-receptor antihistamines, clemastine acts by competing with histamine for H_1-receptor sites on effector cells. They do not block histamine release but can antagonize its effects. Clemastine has greater anticholinergic activity with fewer sedative effects as compared with other first-generation antihistamines.

Pharmacokinetics

In dogs, oral bioavailability is very low (3%). Clemastine has a high volume of distribution (13.4 L/kg; 98% protein bound) and clearance (2.1 L/hr/kg). After IV administration, clemastine completely inhibited wheal formation for 7 hours; elimination half-life was ≈4 hours. Oral administration of 0.5 mg/kg only yielded minor inhibition of wheal formation. The authors of the study concluded that most oral dosage regimens in the literature are likely to give too low a systemic exposure of the drug to allow effective therapy.[6]

In horses, clemastine has poor oral bioavailability (3%-4%), a volume of distribution at steady-state of 3.8 L/kg, a clearance (TBC) of 0.79 L/hour/kg, and a terminal half-life of ≈5.4 hours. The duration of effect after IV administration was ≈5 hours. The authors concluded that the drug is not appropriate for oral administration in horses and must be dosed at least 3 to 4 times a day IV to maintain therapeutic plasma concentrations.[7]

In humans, clemastine has a variable bioavailability (20% to 70%); its distribution is not well characterized, but it does distribute into milk. Metabolic fate has not been clearly determined, but clemastine appears to be extensively metabolized, with metabolites eliminated in the urine. In humans, its duration of action is ≈12 hours.

Contraindications/Precautions/Warnings

Clemastine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyloroduodenal obstruction.

Adverse Effects

The most likely adverse effects seen in dogs receiving clemastine are sedation, paradoxical hyperactivity, and anticholinergic effects (eg, dryness of mucous membranes). Urinary incontinence, dysuria, and stranguria with profound depression was reported in 3/102 dogs treated with clemastine, necessitating discontinuation of treatment in one study.[1] In cats, diarrhea has been noted most commonly; one cat reportedly developed a fixed drug reaction while on this medication.

Reproductive/Nursing Safety

Clemastine has been tested in pregnant lab animals in dosages up to 312 times the label dosage without evidence of harm to fetuses. However, because safety has not been established in other species, its use during pregnancy should be weighed carefully.

Clemastine enters maternal milk and may potentially cause adverse effects in offspring. Use with caution, especially with newborns. Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

There are no specific antidotes available. Significant overdoses should be handled using standard gut emptying protocols, when appropriate, and supportive therapy should be initiated. The adverse effects seen with overdoses are an extension of the drug's side effects; principally CNS depression (although CNS stimulation may be seen), anticholinergic effects (eg, severe drying of mucous membranes, tachycardia, urinary retention, hyperthermia), and possibly hypotension. Physostigmine may be considered to treat serious CNS anticholinergic effects and diazepam employed to treat seizures, if necessary.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving clemastine and may be

of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate**)**:** Additive anticholinergic effects (eg, dry eyes, urinary retention, constipation) possible
- **CNS Depressant Medications** (eg, **anesthetics**, **benzodiazepines, opioids**): Additive CNS depression may be seen if combining clemastine with other CNS depressant medications.
- **Monoamine Oxidase Inhibitors** (**MAOIs**; eg, **furazolidone, amitraz, linezolid, selegiline**): May intensify the anticholinergic effects of clemastine

Laboratory Considerations

Intradermal allergy testing (IDT): IV clemastine can completely inhibit wheal formation in dogs for 7 hours.[8] A 7-day withdrawal prior to IDT is considered optimal; a 2-day withdrawal should be considered the minimum.[9]

Dosages

DOGS:

Antihistamine: Usual dosages are ≈0.05 – 0.1 mg/kg PO every 12 hours[1]; however, 0.5 mg/kg (10 times most published doses) PO in dogs only inhibited histamine-induced wheal formation to a slight degree.[8] Anecdotally, higher dosages, such as 1 mg/kg PO every 12 hours, may be needed to achieve beneficial antipruritic response. Other antihistamines with better bioavailability in dogs may be considered.

CATS:

Antihistamine (extra-label): 0.34 – 0.68 mg/cat (NOT mg/kg) PO twice daily. **NOTE:** Clemastine 0.68 mg/cat (NOT mg/kg) twice daily appears to be more efficacious based on one open label clinical trial.[5]

Monitoring

- Efficacy
- Adverse effects

Client Information

- Antihistamines are used on a regular, ongoing basis in animals that respond to them. They work better if used before exposure to an allergen and prior to allergy flare.
- Drowsiness (sleepiness) can occur with this medication but usually this lessens with time.
- Use caution with over-the-counter formulations as other potentially toxic drugs may be combined in the products. Be sure to only use products that contain clemastine as a single ingredient.
- Cats can develop diarrhea.

Chemistry/Synonyms

Also known as meclastine fumarate or mecloprodin fumarate, clemastine fumarate is an ethanolamine antihistamine. It occurs as an odorless faintly yellow crystalline powder. It is very slightly soluble in water and sparingly soluble in alcohol.

Clemastine fumarate may also be known by the following synonyms and internationally registered trade names: clemastini fumaras or HS-592; a common trade name is *Dayhist®*. *Tavist®* is no longer commercially available.

Storage/Stability

Oral tablets and solution should be stored in tight, light resistant containers at room temperature.

Compatibility/Compounding Considerations

No specific information noted

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 3 substance. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See the ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

Clemastine Fumarate Oral Tablets: 1.34 mg as fumarate (equivalent to 1 mg clemastine), 2.68 mg (equivalent to 2 mg clemastine); *Dayhist®Allergy*, generic; (OTC)

Clemastine Fumarate Oral Syrup: 0.67 mg/5 mL (equivalent to 0.5 mg clemastine) in 120 mL bottles; generic; (OTC)

Clenbuterol

(klen-***byoo***-ter-ol) *Ventipulmin®*

Beta-2-Adrenergic Agonist

Prescriber Highlights

- ► Beta-2-adrenergic agonist used in horses as a short-term bronchodilator for the management of airway obstruction and as a uterine relaxant for dystocia
- ► Extra-label use in food animals is prohibited in the United States.
- ► In pregnant animals, clenbuterol antagonizes the effects of dinoprost (prostaglandin F2 alpha) and oxytocin and can diminish normal uterine contractility.
- ► Acute adverse effects include tachycardia, muscle tremors, sweating, restlessness, and urticaria.
- ► Long-term administration may cause tachyphylaxis and deleterious effects on endocrine, immune, and reproductive functions.

Uses/Indications

Clenbuterol is FDA-approved for use in horses as a bronchodilator in the management of airway obstruction (eg, severe equine asthma [SEA], formerly known as recurrent airway obstruction [RAO]).[1] Clenbuterol has been shown to increase tracheal mucociliary clearance rate, which may be useful in horses to prevent pneumonia that can develop from long-distance travel.[2] It has been used both parenterally and orally as a uterine relaxant in the adjunctive treatment of dystocia.

Clenbuterol has been used as a repartitioning agent in food-producing animals, but its use for this purpose is banned in the United States, as relay toxicity has been documented in humans.[3] It is rarely used in small animal species.

Pharmacology/Actions

Like other beta-2 agonists, clenbuterol is believed to act by stimulating production of cyclic adenosine monophosphate (cAMP) through the activation of adenyl cyclase. Beta-2 agonists produce more smooth muscle relaxation activity (ie, bronchial, vascular, uterine smooth muscle) than beta-1 cardiac effects (positive inotropy, lusitropy, chronotropy). Clenbuterol appears to have secondary modes of action in horses, as it can inhibit the release of proinflammatory cytokines (eg, interleukin 1 beta and tumor necrosis factor alpha) from macrophages, increase mucociliary clearance, and reduce mucus production.[2,4]

Tachyphylaxis has been observed with an increase in tracheal mucociliary clearance rate (TMCR) after 12 days of administration[5] and histamine-induced airway reactivity after 21 days of administra-

tion.[6] Long-term use (greater than 21 days) of clenbuterol has been theorized to desensitize sweat glands in horses, as these glands also contain beta-2 adrenergic receptors. Studies that have tested this theory were not well powered and did not show a desensitization of sweat glands.[6] High-dose clenbuterol (3.2 µg/kg PO twice daily) downregulates genes encoding beta-2-adrenergic receptors.[7] Clenbuterol reduces the number and responsiveness of beta-2 receptors, but concurrent dexamethasone can prevent this effect.[8]

Clenbuterol has anabolic activity in humans and cattle. In horses, it can increase muscle mass,[9] but any performance increases are offset by a negative ergonomic effect. The drug attenuates skeletal muscle changes (eg, heave lines) in horses with severe equine asthma (SEA).[10] Clenbuterol has also been shown to decrease body fat percentage in adult horses.[11]

When clenbuterol was administered IV to healthy horses, aerobic capacity was not improved, insulin levels were increased, and treadmill velocities for defined heart rates were reduced as compared with the control group.[12] Clenbuterol administration does not appear to confer additional benefit to furosemide in healthy horses with exercise-induced pulmonary hemorrhage (EIPH).[13]

Clenbuterol administration at the low end of the labeled dosage (0.8 µg/kg [route of administration unknown] every 12 hours) for 14 days improved cardiac function in horses with SEA.[14] Long-term administration of clenbuterol in horses can cause decreased aerobic performance, which may be due to effects on thermoregulation. Clenbuterol can induce cardiac hypertrophy and infiltration of collagen in cardiac muscle and can suppress cortisol response to exercise. Long-term clenbuterol administration in combination with exercise training can diminish immune function by reducing numbers of monocytes and CD8+ T cells.[15] Anti-inflammatory effects have been demonstrated in horses experimentally challenged with endotoxin.[16,17]

In pregnant mares, clenbuterol can inhibit uterine tone and contractility,[18] but these effects are not considered detrimental. In nonpregnant mares, clenbuterol's effects on uterine contractility may potentially increase risks for mating-induced endometritis. Some studies have shown that clenbuterol can impair reproductive function in stallions.[19]

Pharmacokinetics

In horses, peak plasma concentrations occur ≈2 hours after oral administration, and oral bioavailability is ≈84%.[20] After multiple oral doses, the drug's volume of distribution is ≈1.6 L/kg[20] and the highest concentrations of the drug are found in the liver, lungs, and left ventricle.[21] The manufacturer states that the duration of effect varies from 6 to 8 hours. In a study, average clearance was 94 mL/kg/hour, and half-life was ≈10 to 13 hours after a single dose[20], although another study noted a half-life of ≈46 hours after oral administration of 3.2 µg/kg twice daily.[22] Seventy percent to ninety percent of a dose is excreted by the kidneys. Urinary concentrations of clenbuterol are ≈100 times greater than those found in plasma and can persist at quantifiable levels for 288 hours (12 days) in urine after the last oral dose.[20]

Contraindications/Precautions/Warnings

Clenbuterol is contraindicated in animals that are hypersensitive to it and in horses that are suspected of having cardiovascular impairment. Extra-label use in food animals is prohibited in the United States.

Pregnant women are advised to avoid risk for exposure to clenbuterol.[23]

In human athletes, clenbuterol has been touted as an alternative to anabolic steroids for muscle development and body fat reduction; however, its use for this purpose is prohibited.[24] Those prescribing this medication should be alert for scams to divert clenbuterol for this purpose.

Adverse Effects

Muscle tremors, sweating, restlessness, urticaria, tachycardia, and ataxia may be noted, particularly early in the course of therapy. Creatine kinase elevations have been noted in some horses.

A few studies performed in rats[25] and dogs[26] have shown that clenbuterol causes skeletal and cardiac muscle apoptosis. Studies in horses have not shown this adverse effect.[27] A recent case study in a human documented rhabdomyolysis subsequent to clenbuterol use for muscle-building effects.[28]

One study in adult horses found that a dosage of 0.8 µg/kg PO twice daily for 21 days resulted in significant decreases in body fat with no loss in body weight.[11] Adverse effects such as muscle tremors, tachycardia, and electrolyte abnormalities have been observed in humans after ingestion of animals that have been treated with clenbuterol.

Reproductive/Nursing Safety

Clenbuterol's safety in breeding stallions and brood mares has not been established. Clenbuterol should not be used in pregnant mares near full-term, as it antagonizes the effects of prostaglandin F2 alpha and oxytocin and can diminish normal uterine contractility. Clenbuterol reportedly induces abortion in pregnant animals. Clenbuterol crosses the placenta and is detectable in milk. In countries where clenbuterol is approved for human use, the label states to avoid use during breastfeeding.

Overdose/Acute Toxicity

Clinical signs associated with overdose/acute toxicity are similar its adverse effects.

In a report of 3 horses with clenbuterol toxicosis due to incorrectly compounded clenbuterol products, horses received oral dosages between 10 – 100 µg/kg. Sinus tachycardia, muscle tremors, hyperhidrosis, colic, hyperglycemia, hyperbilirubinemia, azotemia, and elevated liver enzymes and creatine kinase activity were noted.[29] Elevated temperature and agitation/excitation occurred in 2 of the 3 horses. Cardiomyopathy, skeletal and cardiac muscle necrosis, laminitis, and/or rhabdomyolysis led to euthanasia in 2 of the horses.[29]

Depending on dose and species, GI decontamination may be appropriate. Supportive therapy may include fluid and electrolyte management, insulin, and administration of parenteral beta-blockers (eg, propranolol) to control heart rate and rhythm and elevated blood pressure. Benzodiazepines can be used to manage agitation or seizures.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clenbuterol and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but the potential risks should be weighed and additional monitoring performed when appropriate.

- **Anesthetics, Inhalant** (eg, **isoflurane**): Use of clenbuterol with inhalation anesthetics may predispose patients to arrhythmias. In a study, transient hypotension was noted in dogs receiving clenbuterol IV at the time of surgery.[30]
- **Beta Blockers** (eg, **propranolol, sotalol**): May antagonize clenbuterol's effects
- **Digoxin**: Use with digitalis glycosides may increase the risk for cardiac arrhythmias.

- **Dinoprost**: Clenbuterol may antagonize the effects of dinoprost (prostaglandin F2 alpha).[23]
- **Oxytocin**: Clenbuterol may antagonize the effects of oxytocin.[23,31]
- **Sympathomimetic Amines, Other** (eg, **albuterol, phenylpropanolamine**): Concomitant administration with other sympathomimetic amines may enhance the adverse effects of clenbuterol.
- **Theophylline/Aminophylline:** May enhance the adverse effects (eg, tachycardia, CNS stimulation) of clenbuterol
- **Tricyclic antidepressants** (eg, **amitriptyline, clomipramine**): May potentiate the vascular effects of clenbuterol
- **Xylazine**: Clenbuterol may antagonize the uterine contractility effects of xylazine[32]; this effect likely applies to other alpha-2 agonists.

Dosages

HORSES:

Management of airway obstruction (label dosage; FDA-approved): Initially, 0.8 µg/kg PO twice daily for 3 days; if no improvement, dose can be increased to 1.6 µg/kg twice daily for 3 days; if no improvement, dose can be increased to 2.4 µg/kg twice daily for 3 days; if no improvement, dose can be increased to 3.2 µg/kg twice daily for 3 days; if no improvement, therapy should be discontinued. Recommended duration of therapy is 30 days, then it should be withdrawn and therapy should be reevaluated. If signs return, the above stepwise dosage schedule can be reinitiated.[1] **NOTE:** One study of horses with SEA noted increased airway reactivity and reduced bronchodilatory effects after 21 days of administration of clenbuterol. Use clenbuterol no longer than is needed for clinical benefit.[6]

Adjunctive treatment for dystocia emergencies (extra-label): 300 µg/500 kg (1102 lb) mare IV slowly (**NOTE:** Parenteral formulation not available commercially in the United States). The drug's fast onset of action when given IV allows the veterinarian to decide quickly if uterine relaxation will correct the problem. Clenbuterol is particularly useful when repelling the equine fetus to allow manipulation of the head and limbs. May be used in combination with sedatives, analgesics, and tranquilizers. Xylazine or detomidine may inhibit the uterine relaxant effects of clenbuterol.[33]

CATTLE:

Uterine relaxant in cattle (extra-label): 300 µg/cow (NOT µg/kg) slow IV once. May be used during embryo transfer or during the final stages of pregnancy, including labor. **NOTE:** IV formulation not available in the United States. Extra-label use of clenbuterol in food-producing animals is prohibited by the FDA.[23]

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- This medicine is usually used in horses with asthma or airway obstruction to relax muscles and improve breathing.
- Clenbuterol may be used to treat difficult delivery (*dystocia*) emergencies in mares.
- This medicine can be used to prevent labor and thus, it should be used with caution in pregnant animals.
- Seek immediate medical attention if accidental ingestion occurs in humans.
- Extra-label use in food animals in the United States is illegal. Use may also be prohibited in show or racing horses. Check rules and regulations before entering your animal in a competition while this medication is being administered.

Chemistry/Synonyms

Clenbuterol HCl is a substituted phenylaminoethanol beta-2-adrenergic agonist. It is very slightly soluble in water and has a molecular weight of 313.65. The commercial syrup is a colorless solution.

Clenbuterol HCl may also be known as NAB-365, clebuterolum, *Bronchopulmin®, Dilaterol®, Planipart®, Respipulmin®, Spiropent®*, or *Ventipulmin®*.

Storage/Stability

The commercially available syrup should be stored at or below 25°C (77°F); avoid freezing. The manufacturer warns to replace the safety cap on the bottle when not in use.

Clenbuterol injection should be stored below 25°C (77°F) and discarded 28 days after first use.

Compatibility/Compounding Considerations

No specific information is noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Clenbuterol HCl Oral Syrup: 72.5 µg/mL in 100 mL and 330 mL bottles; *Ventipulmin® Syrup*; (Rx). NADA #140-973. Do not use in horses intended for human consumption.

Clenbuterol HCl for Injection: 0.03 mg/mL (30 µg/mL) in 10 mL vials; *Planipart®* (POM-V, CD [Sch 4 pt 2])

Extra-label clenbuterol use in food animals is prohibited by federal United States law.

Association of Racing Commissioners International (ARCI) Uniform Classification Guidelines for Foreign Substances (UCGFS) Class 3 Drug. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS: NONE

For the complete list of references, see **wiley.com/go/budde/plumb**

Clindamycin

(klin-da-***mye***-sin) *Antirobe®, Cleocin®*

Lincosamide Antibiotic

Prescriber Highlights

- ► Used for broad-spectrum coverage against many anaerobes, gram-positive aerobic cocci, and *Toxoplasma* spp
- ► Contraindicated in hindgut fermenters (eg, horses, rodents, ruminants, lagomorphs) and patients that are hypersensitive to lincosamides
- ► Use with caution in patients with liver or renal dysfunction; dose reduction should be considered if the dysfunction is severe.
- ► Potential adverse effects include gastroenteritis, and esophageal injuries if dry pilled.

Uses/Indications

Labeled indications for clindamycin include treatment of skin infections (eg, wounds, abscesses), dental infections, and osteomyelitis (in dogs) caused by coagulase-positive staphylococci (ie, *Staphylococcus aureus*, *Staphylococcus intermedius*), *Streptococcus* spp (in cats), *Bacteroides fragilis*, *Prevotella melaninogenicus*, *Fusobacterium necrophorum*, and *Clostridium perfringens*.[1]

Clindamycin is also used for a variety of protozoal infections, including toxoplasmosis, but high doses may be required to achieve adequate CNS concentrations.

The World Health Organization (WHO) has designated clindamycin as a Highly Important antimicrobial for human medicine.[2] The Office International des Epizooties (OIE) has designated lincosamides as Veterinary Highly Important Antimicrobial (VHIA) Agents in veterinary species.[3]

Pharmacology/Actions

Lincosamide antibiotics may act as bacteriostatic or bactericidal agents, depending on the concentration of the drug at the infection site and the susceptibility of the organism. Lincosamides act by binding to the 50S ribosomal subunit of susceptible bacteria, thereby inhibiting peptide bond formation and protein synthesis of the bacterial cell wall. The lincosamides—lincomycin and clindamycin—share mechanisms of action and have similar spectrums of activity, although lincomycin is usually less active against susceptible organisms. Complete cross-resistance occurs between the 2 drugs, and at least partial cross-resistance occurs between lincosamides and erythromycin.

Most aerobic gram-positive cocci are susceptible to lincosamides. Clindamycin has excellent activity against staphylococci and streptococci. Other organisms that are generally susceptible include *Corynebacterium diphtheriae*, *Nocardia asteroides*, *Erysipelothrix* spp, and *Mycoplasma* spp. Enterococci are inherently resistant. Acquired resistance is a potential problem, particularly among staphylococci. Inducible resistance to clindamycin is common in methicillin-resistant *Staphylococcus aureus* (MRSA) and occurs less commonly in other methicillin-resistant staphylococci.[4–6] Methicillin-resistant staphylococci, particularly methicillin-resistant *Staphylococcus pseudintermedius*, are usually resistant to clindamycin. This resistance cannot be detected with routine testing and can lead to treatment failure. Testing for inducible clindamycin resistance is important in any *Staphylococcus* spp that have been reported as erythromycin-resistant or in cases in which erythromycin susceptibility has not been reported; erythromycin-susceptible staphylococci will not be inducibly resistant.[5,6] Streptococcal resistance is rare.

Most anaerobic bacteria are susceptible to lincosamides. There is a low prevalence of resistance in the *Bacteroides fragilis* group.

Clindamycin has activity against a variety of protozoal organisms, but it may be more suppressive than curative in the treatment of *Toxoplasma gondii* infections. Clindamycin can have a delayed onset of action (1 to 3 days), and drug concentrations may not be high enough to achieve complete efficacy. Clindamycin is not effective against the extracellular tachyzoites associated with these protozoal infections.

Pharmacokinetics

In dogs, oral bioavailability is ≈73%, and the elimination half-life is reportedly 5 hours after oral administration and 10 to 13 hours after SC administration. The volume of distribution is ≈0.9 L/kg. Half-life may be longer with higher dosages. One study in dogs found a mean half-life of ≈4 hours after administration of 5.5 mg/kg PO every 12 hours as compared with 7 to 10 hours after administration of 11 mg/kg PO every 24 hours; overall drug exposure (area under the curve $[AUC]_{0\text{-}24}$/MIC) was higher with the higher, once-daily dose.[7]

In cats, clindamycin half-life after a dose of 11 mg/kg is ≈16 hours (capsules) and 8 hours (liquid). The volume of distribution is ≈1.6 L/kg to 3 L/kg. The highest concentrations are found in the lungs, liver, spleen, jejunum, and colon.

In humans, the drug is rapidly absorbed from the gut, and ≈90% of the total dose is absorbed. Food decreases the rate of absorption but not the extent. Peak serum concentrations are attained ≈45 to 60 minutes after oral administration. After IM administration, peak concentrations are attained ≈1 to 3 hours postinjection.

Clindamycin is distributed in most tissue and fluids. Therapeutic concentrations are achieved in bone, synovial fluid, bile, pleural fluid, peritoneal fluid, skin, and myocardial tissue. Clindamycin also penetrates well into abscesses, scar tissue, and WBCs. CNS concentrations may only reach 40% of those found in serum if meninges are inflamed and use for this indication in humans is not recommended. Clindamycin does not penetrate the eye at concentrations required to treat infections. Clindamycin is ≈93% bound to plasma proteins. The drug crosses the placenta and can be distributed in milk at concentrations equal to those in plasma.

Clindamycin palmitate and clindamycin phosphate are inactive, and hydrolysis in vivo to free (active) clindamycin usually occurs rapidly. Clindamycin is partially metabolized in the liver to both active and inactive metabolites. The unchanged drug and metabolites are excreted in the urine, feces, and bile; however, active drug concentrations in urine are poor (low). Halflives can be prolonged in patients with severe renal or hepatic dysfunction.

Contraindications/Precautions/Warnings

Clindamycin should never be administered undiluted as a bolus.[8] A calculated dose should be administered by IV intermittent infusion over at least 10 to 60 minutes (see ***Dosages***).

Although there have been case reports of parenteral administration of lincosamides to horses, cattle, and sheep, lincosamides are contraindicated in hind-gut fermenters, such as horses, ruminants, rabbits, hamsters, chinchillas, and guinea pigs, as serious GI effects, including death, can occur. Clindamycin is also contraindicated in patients with known hypersensitivity to it or lincomycin.

Clindamycin has been implicated in causing esophagitis and, potentially, esophageal strictures in small animal species.[9] Dry pilling should be avoided when administering this drug.

Patients with severe renal and/or hepatic disease should receive the drug with caution; the manufacturer suggests monitoring serum clindamycin levels in dogs or cats receiving high-dose therapy.[1]

In humans, it has been suggested to use the drug with caution in patients with atopy or a history of GI disease, particularly colitis; the significance of this suggestion for veterinary patients is not known.

Clindamycin use is becoming more scrutinized and restricted in humans due to the risk for severe *Clostridium difficile* infection and *Clostridium difficile*–associated diarrhea (CDAD). Clindamycin in 5% dextrose injection therapy has been associated with severe colitis, which may end up fatal. Though of lesser concern in dogs and cats, it may need to be monitored.

Adverse Effects

Reported adverse effects after oral administration in dogs and cats include gastroenteritis (eg, emesis, loose stool, infrequently bloody diarrhea [dogs]). In a study of healthy cats, administration of a symbiotic (prebiotic and probiotic mixture) 1 hour after administration of oral clindamycin reduced antibiotic-associated GI signs.[10] In rabbits, cholestyramine reduced enterotoxemia caused by IV clindamycin administration.[11]

There have been case reports of esophageal injuries (eg, esophagitis, strictures) in cats when solid dose forms were administered without food or a water bolus. Cats may occasionally show signs of hypersalivation or lip-smacking after oral administration. IM injections reportedly cause pain at the injection site.

In humans, eye pain and contact dermatitis have been reported.

Reproductive/Nursing Safety

Clindamycin crosses the placenta, and cord blood concentrations are ≈46% of those found in maternal serum. Safe use in dogs and cats during pregnancy has not been established, but the drug has not been implicated in causing teratogenic effects.

Clindamycin is distributed in milk; nursing puppies or kittens of

mothers receiving the drug may develop diarrhea; however, in humans, the American Academy of Pediatrics considers clindamycin compatible with breastfeeding.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

There is little information available regarding overdoses of this drug. In dogs, oral dosages of up to 300 mg/kg/day for up to 1 year did not result in toxicity. Dogs receiving 600 mg/kg/day for 6 months developed anorexia, vomiting, and weight loss; erosive gastritis and focal gallbladder necrosis were found on necropsy. Cats that received 110 mg/kg/day for 15 days or 55 mg/kg/day for 42 days displayed little evidence of toxicity.[1] Hyporexia, vomiting, and/or diarrhea occurred in healthy research cats that received oral clindamycin ≈35 mg/kg/day.[12]

For patients that have experienced or are suspected of having experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clindamycin and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides:** Clindamycin has been reported to antagonize the bactericidal activity of aminoglycosides in vitro.
- **CYP3A Inducers** (eg, **phenobarbital, rifampin**): In humans, clindamycin is a substrate of CYP3A isoenzymes, and inducers of this isoenzyme may reduce plasma clindamycin concentration and decrease antimicrobial effectiveness.[13] Veterinary significance is uncertain.
- **CYP3A Inhibitors** (eg, **clarithromycin**, **ketoconazole**): In humans, clindamycin is a substrate of CYP3A isoenzymes and inhibitors of this isoenzyme may increase plasma clindamycin concentration and risk for adverse effects. Veterinary significance is uncertain.
- **Cyclosporine**: Clindamycin has been reported to reduce levels in humans, but this apparently does not occur in dogs.
- **Erythromycin**: In vitro antagonism when used with clindamycin; concomitant use should likely be avoided.
- **Neuromuscular Blocking Agents** (eg, **atracurium, pancuronium**): Clindamycin possesses intrinsic neuromuscular blocking activity and should be used cautiously with other neuromuscular blocking agents.

Laboratory Considerations

- **Slight increases in serum liver enzymes** (AST, ALT, ALP) can occur. Apparently, no clinical significance has been associated with these increases.

Dosages

NOTE: Clindamycin should never be administered IV as an undiluted bolus. The calculated dose should be administered by IV intermittent infusion over at least 10 to 60 minutes at a maximum rate of 30 mg/minute (do not exceed 1200 mg/hour). The final concentration for administration should not exceed 18 mg/mL.

DOGS:

Skin infections (eg, wounds, abscesses) and dental infections (label dosage; FDA-approved): 5.5 – 33 mg/kg PO every 12 hours for a maximum of 28 days.[1] If no response after 3 to 4 days, the drug should be discontinued.

Osteomyelitis (label dosage; FDA-approved): 11 – 33 mg/kg PO every 12 hours for a minimum of 28 days[1]

Pyoderma, superficial (extra-label): 5.5 – 10 mg/kg PO every 12 hours.[14] Fair level of evidence for moderate to high efficacy.[15] Pharmacokinetic studies have suggested 11 mg/kg PO every 24 hours to be at least equal, if not more effective, than 5.5 mg/kg PO every 12 hours.[7,16]

Pyoderma, deep (extra-label): 11 mg/kg PO every 12 to 24 hours for at least 1 week beyond clinical resolution

Systemic infections (eg, sepsis); (extra-label): 10 mg/kg slow IV infusion every 12 hours.[17,18] **NOTE:** Broad-spectrum coverage requires an additional antibiotic (eg, aminoglycoside, fluoroquinolone) for protection against gramnegative organisms.

Surgical prophylaxis for gram-positive aerobes and anaerobic coverage prior to dental procedure (extra-label): 11 – 22 mg/kg PO every 12 to 24 hours for 5 days prior to dental cleaning[19]; however, there is no evidence that this practice minimizes the risk for bacterial translocation from the oral cavity during a dentistry procedure.[20]

Surgical prophylaxis for gram-positive aerobes and anaerobic coverage when beta-lactam antibiotics are contraindicated (extra-label):

a) 5 – 11 mg/kg PO 60 minutes preoperatively[21]
b) 10 mg/kg slow IV infusion to be completed 30 minutes before incision[21]

Susceptible protozoal infections (extra-label):

a) ***Babesia gibsonii:***
   i. Begin therapy with diminazene aceturate 2 mg/kg SC every 48 hours for 3 doses. Once complete, begin (day 8 of a treatment regimen) clindamycin 25 mg/kg PO twice daily for 21 days. This treatment regimen was shown to reduce infection relapse rates.[22]
   ii. In cases of atovaquone resistance, clindamycin 30 mg/kg PO every 12 hours with diminazene aceturate 3.5 mg/kg IM once on the first day of treatment and imidocarb dipropionate 6 mg/kg SC once on the day after diminazene administration; the average duration of treatment was 6 weeks.[23]
   iii. Alternative after atovaquone and azithromycin failed to eliminate infection on PCR test: Clindamycin 25 mg/kg PO twice daily in combination with metronidazole 15 mg/kg PO twice daily and doxycycline 5 mg/kg PO once daily for 30 to 90 days[24]
b) ***Hepatozoon canis*:** Clindamycin 10 mg/kg PO every 8 hours in combination with sulfadiazine/trimethoprim 15 mg/kg PO every 12 hours and pyrimethamine 0.25 mg/kg PO every 24 hours (or ponazuril 10 mg/kg PO every 12 hours) for 14 days.[25]
c) **Other protozoal (eg, *Neospora* spp,[26] *Toxoplasma* spp) infections**: Most recommendations for adjunctive treatment are clindamycin 12.5 mg/kg PO every 12 hours for at least 2 weeks or longer. Additional drugs are often used (eg, sulfadiazine/trimethoprim, pyrimethamine).

CATS:

Skin infections (eg, deep wounds, abscesses) and dental infections (label dosage; FDA-approved): 11 – 33 mg/kg PO every 24 hours.[1] In cases of acute infections, therapy should not continue for more than 3 to 4 days if no clinical response is seen. The maximum labeled treatment period is 14 days.

Systemic infections (eg, sepsis); (extra-label): 10 mg/kg slow IV

infusion every 12 hours.[17,18] Up to 33 mg/kg PO every 12 hours may be considered in refractory infections that are still susceptible to clindamycin. **NOTE:** Broad-spectrum coverage requires an additional antibiotic (eg, aminoglycoside, fluoroquinolone) for protection against gram-negative organisms.

Surgical prophylaxis for gram-positive aerobes and anaerobic coverage when beta-lactam antibiotics are contraindicated (extra-label):

a) 11 mg/kg PO 60 minutes preoperatively[21]

b) 10 mg/kg slow IV infusion to be completed 30 minutes before incision[27]

Toxoplasmosis (extra-label): 10 – 12 mg/kg slow IV infusion every 12 hours until able to tolerate oral administration for a total of 4 weeks.[28] Patients with uveitis should receive topical, oral, or parenteral glucocorticoids to reduce the risk for secondary glaucoma and lens luxations.[29]

BIRDS:

Susceptible infections (extra-label):

a) 25 mg/kg PO every 8 hours[30]

b) For mild spore-forming enteric bacterial infections: 50 mg/kg PO every 12 hours for 5 to 10 days[31]

FERRETS:

Susceptible infections (extra-label): 5 – 10 mg/kg PO every 12 hours[32]

REPTILES:

Susceptible anaerobic infections (extra-label):

a) 5 mg/kg PO every 24 hours[33]

b) Respiratory infections (eg, anaerobes, mycoplasma): 5 mg/kg PO every 24 hours for 14 days[34]

Monitoring

- Clinical efficacy
- Culture and susceptibility testing as warranted by clinical presentation
- Adverse effects, particularly vomiting and severe diarrhea
- Periodic CBC and liver and kidney chemistry profiles if therapy persists for more than 30 days[13]

Client Information

- This medicine is an antibiotic that is used to treat infections of skin, wounds, and bone, but is also useful in the treatment of toxoplasmosis.
- Give this medicine as directed by your veterinarian.
- Do not give this medicine to horses, cattle, sheep, goats, deer, rabbits, mice, rats, hamsters, or guinea pigs, as it may cause fatal diarrhea.
- This medicine may be given with or without food. Do not dry pill, as doing so may cause throat burns. Give a small amount of food or water (slightly over a teaspoonful) after pilling.
- This medicine has a very bitter taste and may require disguising in food to get the animal to take it.
- Be sure to let your veterinarian know if your animal has any severe, prolonged, or bloody vomiting or diarrhea.

Chemistry/Synonyms

Clindamycin, a semisynthetic derivative of lincomycin, is available as hydrochloride hydrate, phosphate ester, and palmitate hydrochloride. The potency of all 3 salts is expressed as milligrams of clindamycin. The hydrochloride occurs as a white to practically white crystalline powder. The phosphate occurs as a white to off-white hygroscopic crystalline powder. The palmitate HCl occurs as a white to off-white amorphous powder. All may have a faint characteristic odor and are freely soluble in water. With the phosphate, ≈400 mg is soluble in 1 mL of water. Clindamycin has a pK_a of 7.45. The commercially available injection has a pH of ≈6 (range, 5.5 to 7).

Clindamycin HCl may also be known as chlorodeoxylincomycin hydrochloride, (7S)-chloro-7-deoxy-lincomycin hydrochloride, clindamycini hydrochloridum, U-28508, or U-25179E; many trade names are available.

Storage/Stability

Clindamycin capsules and the palmitate powder for oral solution should be stored at controlled room temperature 20°C to 25°C (68°F to 77°F). After reconstitution, do not refrigerate the palmitate oral solution (human product), as thickening may occur. It is stable for 2 weeks at room temperature. The veterinary oral solution should be stored at room temperature and has an extended shelf life.

Store clindamycin phosphate injection at controlled room temperature. If refrigerated or frozen, crystals may form, which resolubilize on warming.

Compatibility/Compounding Considerations

Compatibility is dependent on factors, such as pH, concentration, temperature, and diluent used; specialized references or a hospital pharmacist should be consulted for more specific information.

Clindamycin for injection is reportedly **compatible** for at least 24 hours in the following IV infusion solutions: dextrose 5%, dextrose 10%, dextrose combinations with Ringer's solution, lactated Ringer's, and sodium chloride, sodium chloride 0.9%, Normosol R, Ringer's solution, and lactated Ringer's solution.

Clindamycin for injection is reportedly **compatible** with the following drugs: amikacin sulfate, amphotericin B (cholesteryl, lipid complex, and liposomal), aztreonam, buprenorphine, butorphanol, calcium salts, cefazolin sodium, cefoperazone sodium, cefotaxime sodium, ceftazidime sodium, cefuroxime sodium, dobutamine, doxycycline, famotidine, furosemide, gentamicin sulfate, heparin sodium, hydrocortisone sodium succinate, ketamine, lidocaine, methylprednisolone sodium succinate, magnesium sulfate, metoclopramide HCl, metronidazole, morphine sulfate, ondansetron, penicillin G potassium/sodium, piperacillin/tazobactam sodium, potassium chloride, sodium bicarbonate, tobramycin HCl (not in syringes), verapamil HCl, and vitamin-B complex with C.

Drugs that are reportedly **incompatible** with clindamycin include aminophylline, amphotericin B (conventional colloid), ampicillin sodium, ciprofloxacin, diazepam, midazolam, quinidine gluconate, ranitidine HCl, pantoprazole, trimethoprim/sulfamethoxazole, and ceftriaxone sodium.

In a study, clindamycin impregnated in calcium hemihydrate beads failed to elute in a concentration above the MIC for common infecting bacteria.[35]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Clindamycin HCl Oral Capsules: 25 mg, 75 mg, and 150 mg; *Antirobe*®; (Rx). NADA #120-161. FDA-approved for use in dogs

Clindamycin HCl Oral Tablets: 25 mg, 75 mg, and 150 mg; *Clintabs*®; (Rx). NADA #200-316. FDA-approved for use in dogs

Clindamycin HCl Oral Solution: 25 mg/mL in 30 mL bottles; *Antirobe*® *Aquadrops*, *Clinsol*®, generic; (Rx). NADA #135-940. FDA-approved for use in dogs and cats

HUMAN-LABELED PRODUCTS:

Clindamycin HCl Oral Capsules: 75 mg, 150 mg, and 300 mg; *Cleocin*®, generic; (Rx)

Clindamycin Palmitate HCl Granules for Oral Solution: 75 mg/5 mL in 100 mL; *Cleocin*® *Pediatric*, generic; (Rx)

Clindamycin Phosphate Solution Concentrate for Injection: 150 mg/mL in 2 mL, 4 mL, and 6 mL single-dose vials and 2 mL, 4 mL, and 6 mL *ADD-Vantage®* delivery vials; 150 mg, 300 mg, 600 mg, and 900 mg in 50 mL or 60 mL with 5% dextrose flexible bags; *Cleocin®*, generic; (Rx)

Also available in topical and vaginal preparations

Clodronate

Clodronic Acid

(kloe-***dron***-ayte) *OSPHOS®*

Bisphosphonate

Prescriber Highlights

- ► Bisphosphonate approved for clinical signs associated with navicular syndrome in horses
- ► Contraindications include patients with known hypersensitive to it or those with impaired renal function or a history of renal disease.
- ► Do not administer concurrently with NSAIDs (eg, phenylbutazone).
- ► Adverse effects include abdominal pain (colic), discomfort, and agitation.
- ► Given IM; dose is divided into 3 equal injections. Single-use vial; discard unused drug.
- ► May be re-administered every 3 to 6 months if initially effective

Uses/Indications

In horses, clodronate is indicated for the control of clinical signs associated with navicular syndrome.[1] Based on a pre-approval study, 75% of treated horses were deemed a treatment success, defined as an improvement in lameness grade in the primarily affected limb by at least 1 AAEP grade and no worsening of lameness grade in the other forelimb on Day 56 after treatment. Clinical improvement was most evident at 2 months posttreatment; approximately 65% of horses that responded to initial treatment maintained their level of improvement through the 6-month evaluation.

A human-labeled (E.U.) IV form was used in a study to determine the effects of clodronate (4 mg/kg in 150 mL 0.9% NaCl IV infusion 24 hours post vitamin D_3 administration; administration rate not reported) on vitamin D_3-induced hypercalcemia in dogs. The authors concluded that clodronate may be useful within the first 24 hours to treat vitamin D_3-induced hypercalcemia in dogs, but that further studies are necessary to define toxicity and appropriate dosing.[2]

Liposome-encapsulated clodronate (LCP) is preferentially phagocytosed by osteoclasts, macrophages, and dendritic cells, which then undergo apoptosis. Therefore, LCP may be clinically useful for treating certain autoimmune diseases. Research is ongoing to evaluate LCP for the management of immune-mediated hemolytic anemia and malignant histiocytosis in dogs.[3]

Pharmacology/Actions

Clodronate is a bisphosphonate that inhibits bone resorption by binding to calcium phosphate crystals thereby inhibiting their formation and dissolution, and by directly inhibiting osteoclast cell function. Clodronate's mechanism of action for treating navicular disease is not well understood.

Pharmacokinetics

After IM injection in horses, clodronate disodium is rapidly absorbed and cleared from the plasma. Plasma half-life of the parent compound is relatively fast (≈2 to 3 hours). Like other bisphosphonates, a percentage of bioavailable clodronate is taken up by bone and then slowly excreted over a sustained period of time (months to years). The actual residence time in equine bone has not been established.

Contraindications/Precautions/Warnings

Clodronate is contraindicated in animals with a known hypersensitivity to clodronate or clodronic acid, in horses with impaired renal function or with a history of renal disease, or in pregnant or lactating mares.[1] See ***Reproductive/Nursing Safety***. Do not administer concurrently with NSAIDs (eg, phenylbutazone). See ***Drug Interactions***.

Use with caution in horses younger than 4 years of age as the drug has not been evaluated in this age group.[1] Since bisphosphonates can affect bone, they may affect bone growth in young, growing horses.

As a class, bisphosphonates are renally excreted and may be associated with GI and renal toxicity. Use clodronate with caution in patients receiving other potentially nephrotoxic drugs (eg, aminoglycosides).[1] Animals should be well-hydrated prior to and after clodronate administration.

Use with caution in horses with conditions affecting mineral or electrolyte homeostasis (eg, hyperkalemic periodic paralysis, hypocalcemia) as bisphosphonates can affect plasma concentrations of electrolytes (eg, calcium, magnesium, and potassium) immediately posttreatment, with effects lasting up to several hours.[1]

Adverse Effects

In pre-approval field studies, the following adverse reactions in horses were reported: Within 2 hours of injection: discomfort, agitation, pawing, or signs of colic (reported together; incidence rate 9%); lip licking (5.4%); yawning (4.5%); head shaking (2.7%); and injection site swelling (1.8%). One horse (of 111) developed colic that required treatment and another, hives, and pruritus. Other reported adverse effects (partial listing) include renal failure, polydipsia, polyuria, anorexia, lethargy, hypercalcemia, hyperkalemia, hyperactivity, recumbency, and injection site reactions.[1]

Reduced bone turnover and remodeling may lead to increased bone fragility, especially when given at high doses or with long-term use.[1]

Reproductive/Nursing Safety

Bisphosphonates have been shown to cause fetal developmental abnormalities in laboratory animals and uptake into fetal bone may be greater than into maternal bone creating a possible risk for fetal skeletal or other abnormalities.[1]

Although oral bioavailability is likely very low, bisphosphonates may be excreted in milk and absorbed by nursing animals.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Five of 6 horses given single doses of 5 times the labeled dosage (9 mg/kg) IM divided evenly into 5 separate injection sites showed changes in attitude (eg, agitation, nervousness, pawing, circling, and tail twitching) within 6 minutes of the dose. Four of 6 also showed excessive yawning, flehmen, tongue rolling, head shaking, and head bobbing. All horses developed mild to moderate muscle fasciculations between 2 and 30 minutes posttreatment. By 30 minutes posttreatment, 4 of 6 also developed signs of discomfort and possible abdominal pain including full body stretching, repetitive lying down and rising, and kicking at the abdomen. At approximately 1 hour posttreatment, 1 horse exhibited agitation and clinical signs of colic requiring medical therapy. This horse responded to medical therapy and was clinically normal at 7 hours posttreatment. Three of 6 developed

temporary gait abnormalities that included mild to moderate hypermetria, spasticity, or mild ataxia. Four of 6 developed mildly elevated BUN concentrations by 48 hours posttreatment and one had a creatinine concentration slightly above the reference range (2.0 mg/dL; reference range 0.9-1.9 mg/dL) for 12 hours posttreatment.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison control center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix***.

Drug Interactions

The following drug interactions either have been reported or are theoretical in humans or animals receiving clodronate and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Aminoglycosides** (eg, **amikacin, gentamicin**): Potential for additive effects in lowering serum calcium concentrations and increasing risk for nephrotoxicity and should not be given for 72 hours after receiving clodronate.[1,4]
- **Digoxin**: May increase digoxin concentrations; use together with caution.
- **Furosemide (or other loop diuretics)**: Increased risk of hypocalcemia; use together with caution.
- **Nonsteroidal Anti-Inflammatory Drugs** (NSAIDs; eg, **flunixin, phenylbutazone**): Concurrent use may increase the risk for renal insufficiency or failure.[1,4]
- **Tetracyclines** (eg, **oxytetracycline**): As tetracyclines can reduce serum calcium concentrations, they should not be given for 72 hours after administration of clodronate[4]

Laboratory Considerations

- No specific information noted

Dosages

HORSES:

Control of clinical signs associated with navicular syndrome (label dosage; FDA-approved): 1.8 mg/kg IM (up to a maximum dose of 900 mg/ horse; NOT mg/kg).[1] Divide the total volume equally and administer into three separate injection sites. If no response to initial therapy, re-evaluate patient. In horses that initially respond but do not maintain clinical improvement for 6 months, it may be re-administered at 3- to 6-month intervals based on recurrence of clinical signs. In horses that respond initially and maintain clinical improvement for 6 months, re-administer after clinical signs recur. **NOTE:** Anecdotal reports suggest that administering the dose over a 2-day period (eg, half dose on day one and second half of dose on day two) reduces postinjection reactions and nephrotoxicity.

Control of clinical signs associated with navicular syndrome (extra-label): 1.53 mg/kg IM (up to a maximum dose of 765 mg/horse; NOT mg/kg).[4] Divide the total volume equally and administer into 3 separate injection sites.

Monitoring

- Efficacy
- Serum renal chemistry panel to include creatinine, calcium, phosphorous, magnesium, potassium at baseline and prior to each treatment
- Hydration status before and after each treatment
- Water intake and urine output for 3 to 5 days posttreatment
- Baseline and periodic urinalysis
- Adverse effects (eg, signs of colic, agitation, and/or abnormal behavior)

Client Information

- Watch your horse for at least two hours after treatment for agitation, signs of colic, and other abnormal behavior, such as head shaking and lip licking. If your horse seems uncomfortable, nervous, or experiences cramping, hand-walk your horse for 15 minutes. Contact your veterinarian if signs don't resolve or if your horse displays other abnormal signs.
- Be sure your horse has access to plenty of clean, fresh water at all times before and for 3 to 5 days after treatment. Make sure your horse is drinking and urinating adequately. Contact your veterinarian if you notice any changes to your horse's drinking, appetite, or urinations.
- Do not administer other medications to your horse in the days before and after treatment without first discussing with your veterinarian.

Chemistry/Synonyms

Clodronate disodium, a non-amino, chloro-containing bisphosphonate, occurs as a white or almost white, crystalline powder. It is freely soluble in water, practically insoluble in alcohol, and slightly soluble in methyl alcohol. A 5% solution in water has a pH of 3 to 4.5. Sodium hydroxide is used in the equine product to adjust pH. Clodronic acid is also used to describe the active entity in some research or products. 60 mg of clodronate disodium is equivalent to 51 mg of clodronic acid.

Clodronate disodium may also be known as 177501, BM-06.011, ZK-00091106, clodronate sodium, sodium clodronate, dichloromethane diphosphonate, or dichloromethylene diphosphonate disodium.

Storage/Stability

Store at controlled room temperature 25°C (77°F) with excursions between 15°C to 30°C (59°F-86°F) permitted. Discard unused vial contents; single use vial and does not contain a preservative.

Compatibility/Compounding Considerations

Do not mix the IM injection with other medications or solutions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Clodronate Disodium Injection 60 mg/mL, 15 mL/single-use vial; *OSPHOS*®; (Rx). FDA-approved (NADA #141-427) for use in horses not intended for human consumption

Association of Racing Commissioners International (ARCI) Uniform Classification Guidelines for Foreign Substances (UCGFS) Class 3 Drug. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance. See ***Appendix*** for more information.

HUMAN-LABELED PRODUCTS:

None in the United States; both injectable and oral products may be available elsewhere.

Clofazimine

(kloe-***fa***-zi-meen) *Lamprene*®

Antimycobacterial Antibiotic

Prescriber Highlights

- ► Antimycobacterial antibiotic that may be used as part of multi-drug therapy for leprosy-like or *Mycobacterium avium*-related diseases in small animals.
- ► Use in humans has been restricted to minimize the emergence of resistant strains and preserve its efficacy in patients with leprosy. May be difficult for veterinarians to obtain
- ► Clinical experience and documentation supporting its use in veterinary patients are very limited.
- ► Clofazimine stains skin, eyes, bodily fluids, and excreta. It has dose-limiting GI adverse effects.
- ► Availability may be a concern.

Uses/Indications

In small animals, clofazimine is sometimes used as part of multi-drug therapy against non-tuberculous *Mycobacterium* infection, primarily leprosy-like or *M avium* complex (MAC)-related disease states.

In humans, clofazimine is used primarily as part of a multi-drug regimen in the treatment of all forms of leprosy (with rifampin and dapsone) or the treatment of MAC (with at least two of the following agents: clarithromycin or azithromycin, rifampin or rifabutin, and ethambutol).

The World Health Organization (WHO) has designated clofazimine as a Highly Important antimicrobial for human medicine.[1]

Pharmacology/Actions

Clofazimine binds to mycobacterial DNA and inhibits growth. It is considered to be slowly bactericidal against susceptible organisms. Clofazimine has activity against a variety of mycobacteria, including *Mycobacterium leprae, Mycobacterium tuberculosis*, *M avium* complex (MAC), *Mycobacterium bovis*, and *Mycobacterium chelonae*. Clofazimine is ineffective against most other bacteria, fungi, and protozoa. Resistance is thought to occur only rarely; cross-resistance with dapsone or rifampin apparently does not happen. Clofazimine may have some activity against *Leishmania* spp. Clofazimine has anti-inflammatory and immunosuppressive effects, but the mechanisms of action for these effects are not understood. Clofazimine is a red dye that may discolor tissue, skin, and bodily fluids (see ***Adverse Effects***).

Pharmacokinetics

Clofazimine's pharmacokinetics have apparently not been determined in domestic animals. In humans, the microcrystalline form of the drug is variably absorbed after oral administration. Bioavailability ranges from 45% to 70%. Food enhances absorption, but increasing the dosage decreases the percentage absorbed. Clofazimine is highly lipid-soluble and is distributed primarily to lipid tissue and the reticuloendothelial system. Throughout the body, macrophages take up clofazimine. The drug crosses the placenta and is distributed into milk but does not apparently cross into the CNS or CSF. Clofazimine is retained in the body for an extended time; its elimination half-life from tissues is at least 70 days long. Bile excretion may be responsible for most of the drug's excretion, but excretion in sputum, sebum, and sweat may also contribute.

Contraindications/Precautions/Warnings

It is suggested that clofazimine be used with caution in patients with pre-existing GI conditions, such as diarrhea or abdominal pain.

Adverse Effects

There is very limited clinical experience with this medication in domestic animals, and its adverse effect profile is not well documented. Apparently, the skin, eye, and excretion discoloration (described below) also occur in animals. GI effects have been reported. A dog receiving clofazimine and rifampin to treat canine leproid granuloma developed hepatotoxicity. There is a report of one cat treated with clofazimine developing a photosensitization reaction.[2]

In humans, clofazimine is usually well-tolerated, particularly at dosages of 100 mg/day or less. The most troubling adverse effect in many human patients is the dose-related discoloration (pink to brownish-black) of skin, eyes, and body fluids, which occurs in most patients. This discoloration can persist for months to years after clofazimine has been discontinued. GI effects (pain, nausea, vomiting, diarrhea) occur frequently and are dose related. Other adverse effects (CNS, increased liver enzymes, etc.) are reported in less than 1% of patients receiving the drug.

Reproductive/Nursing Safety

In rats, clofazimine impaired fertility, reducing implantation rates and the number of offspring. Large doses (12 to 25 times) demonstrated no teratogenic effects in rats or rabbits, but some effects were noted in mice. The World Health Organization (WHO) states that the drug is safe for use during pregnancy when used as part of one of their treatment protocols for leprosy.

Clofazimine enters maternal milk, and skin discoloration of nursing offspring can occur.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Limited data are available; the LD_{50} for rabbits is 3.3 g/kg and is greater than 5 g/kg in mice, rats, and guinea pigs. Treatment, if required, would include gut emptying and supportive care. Contact an animal poison control center for additional guidance.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as poison control centers' contact information, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clofazimine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Antacids**: May reduce clofazimine concentrations
- **Dapsone**: There is weak evidence that suggests dapsone may reduce the anti-inflammatory effects of clofazimine; the clinical significance is unclear.
- **Isoniazid**: May reduce the clofazimine levels in the skin and increase the amounts in plasma and urine; the clinical significance is unclear.
- **QT Prolonging Agents** (eg, **amiodarone, cisapride, quinidine, sotalol**): May increase risk of QT interval prolongation and serious cardiac arrhythmias

Laboratory Considerations

- None noted

Dosages

DOGS:

***M avium-intracellulare* complex infections, some other non-tuberculous mycobacterial infections (especially rapidly growing *Mycobacterium*), and canine leproid granuloma syndrome** (extra-label): 4 – 8 mg/kg PO once a day for 4 weeks, usually as part of a multi-drug protocol[3]

CATS:

***M avium-intracellulare* complex infections, feline leprosy, other non-tuberculous mycobacterial infections, or feline leprosy** (extra-label): 4 – 10 mg/kg (or 25 – 50 mg/cat [NOT mg/kg]) PO every 24 to 48 hours for 4 weeks, usually as part of a multi-drug protocol

BIRDS:

Avian mycobacteriosis (extra-label): Treatment protocols include: **1**) rifampin 45 mg/kg, ethambutol 30 mg/kg, and clofazimine 6 mg/kg PO once daily; or **2**) ethambutol 20 mg/kg every 12 hours, cycloserine 5 mg/kg every 12 hours, enrofloxacin 15 mg/kg every 12 hours, and clofazimine 1.5 mg/kg PO once daily; (recommended regime for raptors). Regular monitoring of fecal samples is needed; antifungal medication may be required. Surgery for discrete nodules may be curative.[4]

Monitoring

- Efficacy against mycobacterial disease
- Adverse effects (primarily GI, but consider monitoring hepatic function in dogs)

Client Information

- Unless otherwise instructed, give this medication with food.
- This medication may cause your animal's skin to turn color (usually pink, but from red to orange to brown). It may also cause discoloring of tears, urine, feces, and other body fluids to a brownish-black color. This discoloration may persist for many months after therapy is concluded.

Chemistry/Synonyms

Clofazimine is a phenazine dye antimycobacterial agent. It occurs as an odorless or nearly odorless, reddish-brown powder that is highly insoluble in water. In room temperature alcohol, clofazimine's solubility is 1 mg/mL.

Clofazimine may also be known as B-663, G-30320, NSC-141046, Chlofazimine, *Clofozine®*, *Hansepran®*, *Lamcoin®*, *Lamprene®*, or *Lampren®*.

Storage/Stability

Clofazimine oral capsules should be stored in tight containers, protected from moisture at temperatures less than 30°C (86°F).

Compatibility/Compounding Considerations

The commercially available capsules are a micronized form of the drug in a wax matrix base; it may be difficult to obtain an accurate dosage for small animals. It is suggested to contact a compounding pharmacist for advice.

A topical clofazimine formulation, which successfully treated a dog with leproid granuloma, was prepared by incorporating the contents of 40 capsules' contents (crushed inside a plastic bag) into 100 g petroleum ointment. No potency or stability testing was performed on the resulting ointment, but it was found effective when used for a 2-month treatment course.[5]

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: NONE

HUMAN-LABELED PRODUCTS: NONE

In November 2004, clofazimine (*Lamprene®*) became available in the US only on a limited basis. It may be obtained for treating human leprosy cases by contacting the National Hansen's Disease Program (NHDP) of the US Department of Health and Human Services, Health Resources and Services Administration. The NHDP may make clofazimine available for other uses in rare circumstances; contact 800-642-2477 or email HRSANHDPCLINIC@hrsa.gov. Its status for use in veterinary patients is uncertain at the time of writing (2021); approach the FDA Center for Veterinary Medicine (see appendix) for more information.

Clomipramine

(kloe-***mi***-pra-meen) *Clomicalm®*,*Anafranil®*

Tricyclic Antidepressant

Prescriber Highlights

- ► FDA-approved for use in conjunction with behavior modification in dogs with separation anxiety that may manifest as inappropriate barking, destructive behavior, and/or inappropriate elimination
- ► May be used extra-label in cats for urine spraying and in birds for treatment of feather-picking
- ► Use is contraindicated in male breeding dogs and in animals with a history of seizures.
- ► Caution is advised in animals with liver disease, cardiac arrhythmia, increased intraocular pressure, pre-existing liver disease, reduced GI motility, or urinary retention disorders.
- ► Common adverse effects include urine and fecal retention, sedation, vomiting, diarrhea, anticholinergic effects (eg, dry mouth, tachycardia); cats may be more sensitive than dogs.
- ► Use may decrease total triiodothyronine (tT3), total thyroxine (tT4), and free T4 (fT4) concentrations in dogs and cats; baseline thyroid testing should be performed prior to therapy.

Uses/Indications

Clomipramine is a tricyclic antidepressant (TCA) labeled for use in dogs as part of a comprehensive behavioral management program to treat separation anxiety. When used in conjunction with behavior training for separation anxiety, both the time to improvement and the final result were improved as compared with behavioral training alone.[1] Clomipramine may also be used in an extra-label manner for compulsive disorder and noise phobias.[2,3] Clomipramine appeared to be more effective than amitriptyline, but equivalent to fluoxetine and dog-appeasing pheromone, in controlling compulsive behavior in dogs.[4–6] In beagles, short-term use had a modest effect on reducing fear and anxiety related to ground transport.[7] **NOTE:** This drug was not effective in reducing canine aggression toward human family members.[8]

Clomipramine may also be useful in cats, particularly for urine spraying.[9–12] Clomipramine was as effective as fluoxetine in reducing urine marking in one study in cats.[10] The usefulness of clomipramine in cats with psychogenic alopecia is unclear, with efficacy demonstrated in a case series[13] but no benefit observed in a prospective, double-blinded, study.[14]

Clomipramine has been used to treat feather-picking in birds.[15]

Pharmacology/Actions

Although the exact mechanism of action of TCAs is not fully understood, it is believed that their most significant effects result from preventing neurotransmitter reuptake at the neuronal membrane. Clomipramine is predominantly an inhibitor of serotonin (5-HT) reuptake, but it also has effects on norepinephrine and possibly other neurotransmitters. Desmethylclomipramine, clomipramine's active metabolite, primarily inhibits noradrenergic uptake and may be responsible for the majority of the drug's adverse effects (in humans). Clomipramine also binds to histamine-1 (H_1) receptors and antagonizes alpha-1 adrenergic and muscarinic acetylcholine receptors.

Pharmacokinetics

In dogs, an extensive first-pass effect limits clomipramine oral bioavailability (17%). Peak concentration is reached ≈1.5 to 2 hours after a single oral dose and ≈3 to 4 hours with repeated oral adminis-

tration. The presence of food increases clomipramine bioavailability, peak concentration, and area under the curve by ≈20% to 25%. Clomipramine accumulates with repeated oral administration. Volume of distribution is 3.8 L/kg. Clomipramine is rapidly converted in the liver to its active metabolite (ie, desmethylclomipramine). Both the parent drug and the active metabolite are highly bound to plasma proteins (96%). The elimination half-life of clomipramine is ≈6 to 7 hours and of desmethylclomipramine is ≈2 hours. The parent and metabolite are further metabolized by glucuronidation.[1,16–18]

Cats appear to metabolize clomipramine more slowly than dogs,[19] and wide interpatient variability in pharmacokinetic parameters have been shown after single oral doses. Male cats may metabolize clomipramine more slowly than female cats.[19,20] In a limited (6 subject) pharmacokinetic study, oral bioavailability averaged 90%, time to peak concentration was ≈6 hours, and elimination half-life was 12.3 hours.[21]

In humans, the drug is well absorbed from the GI tract, but a substantial first-pass effect reduces its systemic bioavailability to ≈50%. The presence of food in the gut does not significantly alter absorption of the drug. Clomipramine is highly lipophilic and widely distributed throughout the body, with an apparent volume of distribution of 17 L/kg. Both clomipramine and its active metabolite (ie, desmethylclomipramine) cross the blood–brain barrier, and significant concentrations are found in the brain. Clomipramine is metabolized principally in the liver to several metabolites, including desmethylclomipramine, which is active. Approximately ⅔ of these metabolites are eliminated in the urine and the rest in the feces. After a single dose, the elimination half-life of clomipramine averages 32 hours and desmethylclomipramine averages 69 hours, but there is wide interpatient variation.

Contraindications/Precautions/Warnings

Clomipramine is contraindicated in those hypersensitive to it or other TCAs. Concomitant use (or use within 14 days before or after treatment) with monoamine oxidase inhibitors (eg, selegiline or amitraz [including collars]) is contraindicated. Use of clomipramine is also contraindicated in dogs with a history of seizures or concomitantly with drugs that lower the seizure threshold. Epileptiform pathology and sustained generalized discharges occurred in cats given clomipramine.[22] Safety in dogs less than 6 months of age has not been studied.[1]

TCAs should be used cautiously in animals with hyperthyroidism or in those that are receiving thyroid supplementation, as there may be an increased risk for cardiac rhythm abnormalities. Clomipramine impairs synthesis of thyroxine (T4); concentrations of tT3, tT4, and free T4 may be reduced by 16% to 35% in dogs and cats.[23,24]

Because of its anticholinergic effects, use clomipramine with caution in animals with decreased GI motility, urinary retention, cardiovascular disease (especially cardiac rhythm disturbances), narrow angle glaucoma, or increased intraocular pressure.[1,25] Caution should also be used in animals with pre-existing hepatic disease.

If discontinuing clomipramine, the manufacturer recommends tapering the medication to minimize the risk for signs of withdrawal.[1] Clomipramine should be discontinued for as long as clinically feasible prior to elective surgery using general anesthetic agents.

Do not confuse clomiPRAMINE with chlorproMAZINE.

Adverse Effects

The primary adverse effects reported in dogs are anorexia, emesis, diarrhea, dry mouth, elevation of liver enzymes, and sedation/lethargy/depression. Significant ECG abnormalities were not identified in small studies in dogs[26,27] or cats.[23] One case of a dog developing pancreatitis after receiving clomipramine has been published.[28]

Cats have been reported to be more susceptible than dogs to developing adverse effects, including anticholinergic effects (eg, dry mouth, mydriasis, urine retention, constipation), sedation, and diarrhea; this may be the result of slower elimination of the active (desmethyl) metabolite in cats.

Adverse effects reported in birds include ataxia, drowsiness, and regurgitation.

Although therapeutic effects may take several weeks to be seen, adverse effects can occur early in the course of treatment.

Reproductive/Nursing Safety

Clomipramine crosses the placenta. Embryotoxic and fetotoxic effects were noted in mice and rats given clomipramine at dosages up to 20 times the usual maximum human dosage. Data in other domestic species appear to be lacking. The manufacturer warns not to use in breeding male dogs, as studies of high-dose toxicity (12.5 times the maximum label-recommended dose) demonstrated testicular hypoplasia. Long-term administration (8 weeks) in mice resulted in decreased sperm count and motility; these effects were reversed after discontinuing clomipramine.[29]

Clomipramine has been detected in human milk. Use clomipramine with caution in nursing animals or consider using a milk replacer.

Because safety has not been established in animals, this drug should only be used when the maternal benefits outweigh the potential risks to offspring.

Overdose/Acute Toxicity

Clomipramine has a narrow margin of safety; significant clinical signs (eg, ataxia, mydriasis, tremors) can be seen at or slightly above therapeutic range (2 – 3 mg/kg, APCC database). Dogs receiving 20 mg/kg experienced bradycardia and sporadic SA and AV block.[30] Overdoses of tricyclic antidepressants can be life-threatening (ie, arrhythmias, seizures, cardiorespiratory collapse). In dogs, lethal doses are ≈50 – 100 mg/kg/day PO.

Clinical signs seen in dogs with a clomipramine overdose include lethargy/sedation, tachycardia, vomiting, vocalization, and ataxia; common signs seen in cats include mydriasis, lethargy, tachycardia, ataxia, vocalization, and agitation.

Clomipramine oral overdoses should be treated with standard decontamination measures if appropriate for the animal; IV lipid emulsion therapy may be beneficial.

For patients that have experienced or are suspected to have experienced an overdose, consultation with a 24-hour poison consultation center specializing in providing veterinary-specific information is recommended. For general information related to overdose and toxin exposures, as well as contact information for poison control centers, refer to ***Appendix.***

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clomipramine and may be of significance in veterinary patients. Unless otherwise noted, use together is not necessarily contraindicated, but weigh the potential risks and perform additional monitoring when appropriate.

- **Alpha-2-Adrenergic Agonists** (eg, **dexmedetomidine, xylazine**): Increased risk for CNS and respiratory depression and bradycardia. Use cautiously in combination.
- **Amlodipine:** Increased risk for hypotension
- **Anesthetic Agents** (eg, **alfaxalone**, **isoflurane, ketamine, propofol**): Discontinue clomipramine as long as clinically feasible prior to elective surgery with general anesthetic agents.[1,31]
- **Angiotensin Converting Enzyme Inhibitors** (**ACEIs**; eg, **benazepril, enalapril**): Increased risk for hypotension
- **Angiotensin Receptor Blockers** (**ARBs**; eg, **telmisartan**): Increased risk for hypotension
- **Anticholinergic Agents** (eg, **atropine, glycopyrrolate, oxy-**

butynin): Because of the additive anticholinergic effects, use cautiously with clomipramine.

- **Antihistamines** (eg, **cetirizine, chlorpheniramine, diphenhydramine, hydroxyzine**): Concurrent use may increase risk for CNS depression and additive anticholinergic effects. Avoid combination or monitor for sedation, tachycardia, ileus, mydriasis, or constipation.
- **Azole Antifungals** (eg, **itraconazole, ketoconazole**): Concurrent use may increase the risk for QT-interval prolongation.
- **Barbiturates** (eg, **pentobarbital, phenobarbital**): May result in decreased clomipramine efficacy or additive adverse effects.[31] Monitor clomipramine efficacy.
- **Buspirone**: Increased risk for CNS depression and serotonin syndrome
- **Cimetidine**: May inhibit tricyclic antidepressant metabolism and increase the risk for toxicosis
- **CNS Depressants** (eg, **cannabidiol**, **diazepam, methocarbamol, pregabalin**): Because of the additive CNS effects, use cautiously with clomipramine.
- **Cyproheptadine**: May antagonize the serotonergic effects of tricyclic antidepressants
- **Dextromethorphan**: Increased risk for serotonin syndrome
- **Flumazenil**: Flumazenil use in animals suspected of TCA overdose may increase the risk for seizures and arrhythmias.[32]
- **Fluoroquinolones** (eg, **enrofloxacin, marbofloxacin, pradofloxacin**): Concurrent use may increase the risk for QT-interval prolongation.
- **Levothyroxine**: Concurrent use may increase therapeutic and toxic effects of both levothyroxine and clomipramine.
- **Metoclopramide**: Concurrent use may increase the risk for extrapyramidal reactions or neuroleptic malignant syndrome; combination is contraindicated in humans. No data available for veterinary patients. Avoid combination or use conservative doses and monitor carefully.
- **Mirtazapine**: Increased risk for constipation, urinary retention, CNS depression, and serotonin syndrome
- **Monoamine Oxidase Inhibitors** (eg, **amitraz**, **furazolidone, linezolid, methylene blue, procarbazine, selegiline**): Concomitant use (within 14 days) with monoamine oxidase inhibitors is contraindicated (serotonin syndrome).
- **Opioids** (eg, **buprenorphine, butorphanol, fentanyl, meperidine, methadone, morphine**): Concurrent use may result in additive CNS and respiratory depression; rarely, serotonin syndrome has been reported in humans. Monitor closely for adverse effects.
- **Pentazocine**: Increased risk for serotonin syndrome
- **QT Prolonging Agents** (eg, **amiodarone**, **cisapride, procainamide, quinidine, sotalol**): Increased risk for QT-interval prolongation and tricyclic adverse effects
- **Selective Serotonin Reuptake Inhibitor** (**SSRIs**; eg, **fluoxetine**, **paroxetine**, **sertraline**): Concurrent use may increase the risk for serotonin syndrome. In dogs, if switching from treatment with clomipramine to an SSRI, a 3- to 4-day washout period has been recommended.[33]
- **Serotonin Receptor Antagonists** (eg, **dolasetron, ondansetron**): Concurrent use may increase the risk for serotonin syndrome.
- **Sympathomimetic Agents** (eg, **albuterol, ephedrine**, **phenylpropanolamine**): Use in combination with sympathomimetic agents may increase the risk for cardiac effects (eg, arrhythmias, hyperpyrexia, hypertension).
- **Tramadol**: In humans, concurrent use may increase the risk for serotonin syndrome and seizures; veterinary clinical significance is not known, but one source states that tricyclic antidepressants (eg, amitriptyline, clomipramine), should not be administered concurrently with tramadol.[34]
- **Trazodone**: Concurrent use may cause additive CNS depression and may increase the risk for serotonin syndrome in humans.
- **Tricyclic Antidepressants** (**TCAs**; eg, **amitriptyline, doxepin, imipramine**): Concurrent use of two tricyclic antidepressants should be avoided due to increased risk for serotonin syndrome, anticholinergic adverse effects, and cardiac arrhythmias.
- **Yohimbine**: Concurrent use may increase the risk for hypertension.

Laboratory Considerations

- **Metapyrone stimulation test**: The response to metapyrone may be decreased by clomipramine.
- **Blood glucose**: TCAs may alter (ie, increase or decrease) blood glucose concentrations.

Dosages

NOTE: Dosages are generally started at the low end and increased gradually (ie, every 2 weeks) until efficacy is noted or limited by adverse effects. Up to 8 weeks of treatment are required to determine efficacy. Discontinuation of the drug should be done gradually, preferably over several weeks.

DOGS:

Separation anxiety (label dosage; FDA-approved): 2 – 4 mg/kg PO once daily or divided twice daily in conjunction with a comprehensive behavior management program.[1]

Adjunctive treatment of behavioral conditions (extra-label): 1 – 2 mg/kg PO twice daily initially and eventually up to 3 mg/kg PO once to twice daily[35]; up to 4 mg/kg PO twice daily was well tolerated in one study.[3] Dosages are generally started at the low end and increased gradually (ie, every 2 weeks) until efficacy is noted or limited by adverse effects. Up to 8 weeks of treatment are required to determine efficacy.[4] When used for treatment of situational anxiety/phobias, it is recommended by many clinicians that this drug should be used in conjunction with a benzodiazepine (eg, alprazolam) as necessary.[2] When behavioral modification treatment efficacy is established, doses may be reduced in many animals.

CATS:

Adjunctive treatment of behavioral conditions (extra-label): 0.25 – 1 mg/kg PO once daily,[9–11,36] in combination with behavior modification therapy. Practically, 2.5 – 5 mg/cat (NOT mg/kg) PO once daily

BIRDS:

Adjunctive treatment of feather-picking (extra-label): From a study in cockatoos, 3 mg/kg PO every 12 hours.[15] Reported dosages range from 0.5 – 9 mg/kg PO every 12 to 24 hours.[37]

Monitoring

- Clinical efficacy
- Adverse effects
- Baseline CBC, serum chemistry profile, urinalysis, and baseline thyroid testing[23,24] (eg, tT4, thyroid panel) prior to therapy, 1 month after initial therapy, and yearly, thereafter.
- Baseline ECG is recommended prior to therapy. TCAs can widen QRS complexes, prolong PR intervals, and invert or flatten T-waves on ECG; significance in animals is not fully understood.

Client Information

- This medicine works best when used with behavior therapy.
- It may take several weeks to determine if this medicine is working.
- This medicine may be given with or without food; giving with

food may reduce the risk for vomiting.
- The most common side effects are drowsiness/sleepiness, dry mouth, and constipation; be sure your animal has access to fresh, clean water.
- Rare side effects that can be serious include abnormal bleeding, fever, seizures, or very fast or irregular heartbeat. Contact your veterinarian immediately if you see any of these signs.
- An overdose can be very serious. Be sure to keep this medicine out of reach of animals and children.
- Tell your veterinarian if your animal has worn a flea or tick collar in the past 2 weeks. Do not use a new flea and tick collar on your animal without talking to your veterinarian first.
- Do not suddenly stop giving this medicine to your animal. If you want to stop giving the medication before the prescription is completed, first contact your veterinarian. There may be an important reason to continue its use. Clomipramine must be tapered off slowly or your animal may suffer uncomfortable withdrawal signs including vomiting, anxiety, and shaking.

Chemistry/Synonyms
Clomipramine HCl, a dibenzazepine-derivative tricyclic antidepressant, occurs as a white to off-white crystalline powder and is freely soluble in water.

Clomipramine HCl may also be known as chlorimipramine hydrochloride, clomipramini hydrochloridum, G-34586, monochlorimipramine hydrochloride, *Anafranil®*, *Clofranil®*, *Clomav®*, *Clomicalm®*, *Clopram®*, *Clopress®*, *Equinorm®*, *Hydiphen®*, *Maronil®*, *Novo-Clopamine®*, *Placil®*, *Tranquax®*, or *Zoiral®*.

Storage/Stability
The commercially available veterinary tablets should be stored in a dry place at a controlled room temperature (15°C-30°C [59°F-86°F]) in the original closed container. The (human label) capsules should be stored at 20°C-25°C (68°F-77°F) in tight containers and protected from moisture.

Compatibility/Compounding Considerations
No specific information noted

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Clomipramine HCl Oral Tablets: 5 mg, 20 mg, 40 mg, and 80 mg; *Clomicalm®*; generic; (Rx). FDA approved for use in dogs. NADA #141-120

The Association of Racing Commissioners International (ARCI) has designated this drug as a class 2 substance. See the ***Appendix*** for more information. Use of this drug may not be allowed in certain animal competitions. Check rules and regulations before entering in a competition while this medication is being administered. Contact local racing authorities for further guidance.

HUMAN-LABELED PRODUCTS:

Clomipramine Oral Capsules: 25 mg, 50 mg, and 75 mg; *Anafranil®*; generic; (Rx)

Clonazepam
(kloe-***na***-ze-pam) *Klonopin®*

Benzodiazepine

Prescriber Highlights
- ► Benzodiazepine anticonvulsant used primarily as adjunctive therapy for short-term treatment of epilepsy in dogs and for long-term adjunctive treatment of epilepsy in cats; may also be used as an anxiolytic, particularly when a longer-acting benzodiazepine is desired
- ► Contraindicated in patients with hypersensitivity to benzodiazepines, narrow angle glaucoma, or significant liver disease. May exacerbate myasthenia gravis
- ► If using for treatment of seizures, discontinue use gradually.
- ► Sedation and ataxia are the most prevalent adverse effects. Cats may experience hepatic necrosis, but it is believed this is less likely to occur than with diazepam.
- ► Dogs may develop a tolerance to efficacy over a few weeks.
- ► Schedule-IV controlled substance in the United States
- ► The National Institute for Occupational Safety and Health (NIOSH) classifies clonazepam as a hazardous drug; use appropriate precautions when handling.

Uses/Indications
Clonazepam is used primarily as a short-term adjunctive anticonvulsant for the treatment of epilepsy in dogs. It has been considered for long-term adjunctive therapy in dogs not controlled with more standard therapies, but, like diazepam, tolerance tends to develop within a few weeks of treatment. Clonazepam can also be used as an anxiolytic agent or as a muscle relaxant.

Clonazepam has been used as an anxiolytic and in the treatment of epilepsy in cats. The availability of oral dispersible tablets (ODT) in strengths from 0.125 mg may make dosing in cats easier than with other dosage forms.

Pharmacology/Actions
Clonazepam and other benzodiazepines depress CNS subcortical levels (primarily limbic, thalamic, and hypothalamic), thereby producing anxiolytic, sedative, skeletal muscle relaxation, and anticonvulsant effects. The exact mechanism of action is unknown, but postulated mechanisms include antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine-specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

Pharmacokinetics
In dogs, clonazepam's oral bioavailability is variable (ie, 20%-60%), but absorption is rapid. Protein binding is ≈82%, and the drug rapidly crosses into the CNS. Clonazepam exhibits saturation kinetics in dogs, as elimination rates are dose-dependent.

In humans, the drug is well absorbed from the GI tract, crosses the blood–brain barrier and placenta, and is metabolized in the liver to several metabolites that are excreted in the urine. Peak serum levels occur ≈3 hours after oral administration. Half-life ranges from 19 to 40 hours.

Contraindications/Precautions/Warnings
Clonazepam is contraindicated in patients that are hypersensitive to it or other benzodiazepines or have significant liver dysfunction or acute narrow angle glaucoma. Benzodiazepines have been reported to exacerbate myasthenia gravis. Use with caution in patients with renal or hepatic impairment. Clonazepam should be used cautiously in aggressive patients.

Clonazepam orally dispersible tablets (ODT) that contain xylitol (unknown quantity) should be used with caution in dogs.

Tolerance (usually noted after several weeks) to the anticonvulsant effects has been reported in dogs. Dosage adjustment may restore efficacy.

In patients chronically treated with clonazepam at high doses for seizure control, the drug should be tapered off, as status epilepticus may be precipitated; vomiting and diarrhea may also occur during the withdrawal period.

Do not confuse clonazepam with clonidine or other benzodiazepines (eg, clorazepate, lorazepam). Consider writing orders and prescriptions using tall man letters (eg, clonazePAM).

The National Institute for Occupational Safety and Health (NIOSH) classifies clonazepam as a hazardous drug; personal protective equipment (PPE) should be used accordingly to minimize the risk for exposure.[1]

Adverse Effects

There is limited information on the adverse effect profile of this drug in domestic animals. Sedation (or excitement) and ataxia may occur.[2] The effect, if any, of clonazepam on working dogs is unknown.

In cats, clonazepam may cause sedation and ataxia. Acute hepatic necrosis has been documented from oral administration of diazepam in cats[3]; other benzodiazepines (eg, clonazepam) may cause similar adverse effects.

Clonazepam has been reported to cause various adverse effects in humans. Some of the more significant effects include hypotonia, ataxia, sedation, increased salivation, hypersecretion in upper respiratory passages, GI effects (eg, vomiting, constipation, diarrhea), transient elevations of liver enzymes, and hematologic effects (eg, anemia, leukopenia, thrombocytopenia).

Reproductive/Nursing Safety

Clonazepam crosses the placenta. Teratogenic effects (eg, cleft palate, fused sternebrae, limb defects) have been seen in rabbits and rats receiving clinical doses.[4] Neonates may experience signs of withdrawal if the dam has received clonazepam during the later stages of pregnancy.

Clonazepam is excreted into maternal milk. Use with caution in nursing dams.

Overdose/Acute Toxicity

Overdoses commonly cause sedation, depression, and ataxia. Some animals have paradoxical signs (eg, hyperactivity, disorientation, vocalization). Emesis is generally not indicated. With mild to moderate overdoses, animals can often be monitored at home, as long as the animal is rousable and does not show paradoxical signs; animals should be confined and stimulation kept to a minimum. Paradoxical excitation can be treated with a mild sedative (eg diphenhydramine).

Common clinical signs seen in dogs with a clonazepam overdose include ataxia, sedation, agitation, and vomiting; common signs seen in cats include ataxia, sedation, and agitation.
